Results: According to DVHs 111 SBRT plans did not violate any of the dose constraints requested in the Lungtech trial. For 7/100 patients SBRT plans exceeded the Lungtech dose constraint for the proximal bronchial tree of EqD2=74.8Gy to > 0.5cc, one of them additionally for the esophagus of EqD2=64 Gy. 6/7 patients showed an increase in dyspnea, 2 of them died 3 and 9 months after SBRT, one after hemoptysis and subsequent pneumonia, the other after being hospitalized for unclear progressive dyspnea; in both cases association of G5 toxicity to SBRT cannot be excluded.

Conclusion: Despite the lack of detailed specific constraints within the STRIPE trial OAR exposure did not largely differ from current practice in modern SBRT. However, these preliminary results underline the importance of the dose constraints for the main airways within the Lungtech trial and the necessity to continuously review and adjust treatment procedures to upcoming evidence, especially when employing new techniques.

EP-1241

Relationship of dosimetric findings and toxicity following SABR for lung cancer

K. Johnson¹, A. Morenc², T. Sridhar², L. Aznar-Garcia²

¹University Of Leicester, Cancer Studies, Leicester, United Kingdom

²University Hospitals Leicester, Oncology, Leicester, United Kingdom

Purpose or Objective: SABR for primary NSCLC is becoming increasingly popular as evidence is mounting for its equivalent long-term clinical outcomes and good overall tolerability. We review our toxicity against dosimetry and achievement of dose constraints (SABR UK Consortium). We suggest that dosimetric constraints alone cannot be used to prevent SABR related side effects.

Material and Methods: Patients with stage I NSCLC treated with SABR between January 2014 and August 2015 were included in this single centre cohort study. They were planned using relaxed breathing 4D CT then treated using VMAT. Baseline and dosimetric data was retrospectively collected by a clinical oncologist or physicist from the radiotherapy records. Patients were followed up at 4 weeks then at 3 monthly intervals until 1 year. CT scans were performed 3 and 12 months post radiotherapy. Prospective data collection was performed at follow up visits for clinical outcomes and acute and late normal tissue toxicity (scored using CTCAE v 3.0).

Results: 28 patients were included in the study with a median follow up of 10.4 months. 19 patients have attended for post radiotherapy CT scans with 84.2% showing radiological response as per RECIST. All patients were assessed for acute toxicity data, 3.5% (1/28) noted grade 2 reaction. Data on late toxicity was available for 19 patients: 26.3% (5/19) experienced grade 2-3, no grade 4 or 5 reactions were recorded. When adjusted for baseline function (late toxicity score minus baseline score) this fell to 15% (3/19). Other than chest wall (CW) tolerances all dosimetry criteria were met. 10.7% of plans exceeded tolerance to 30cc CW (>30/32) with no recorded episodes of grade 2 CW pain in these patients. 71.4% of plans exceeded dose constraint to 0.01cc CW (>37/39) only 5% (1/20) complained of CW pain. Dosimetric analysis for this patient revealed dose to 30cc of CW was 25.8 Gy (<32), dose to 0.01 cc of CW was 59.1 Gy (<39), volume of PTV and CW overlapping was 0.03 cc and % of PTV-CW overlapping was 0.21%.

Conclusion: We are achieving low rates of moderate or severe toxicity. Despite achieving dose constraints, a small cohort of patients developed toxicity grade 2-3. We hypothesize that these patients could develop radiotherapy

toxicity due to other idiosyncratic factors (genetic polymorphisms, microenvironment). Further studies are currently running to investigate other causative factors.

EP-1242

Stereotactic body radiation therapy for early stage NSCLC: clinical outcomes

A. Iurato¹, A. Carnevale¹, E. Ippolito¹, M. Fiore¹, C. Greco¹, L.E. Trodella¹, A. Di Donato¹, S. Ramella¹, R.M. D'Angelillo¹, L. Trodella¹

¹Policlinico Universitario Campus Biomedico, Radioterapia Oncologica, Roma, Italy

Purpose or Objective: The aim of this study is to evaluate efficacy and toxicity of stereotactic body radiation therapy in early stage medically inoperable non-small lung cancer.

Material and Methods: Data from patients affected by medically inoperable stage I NSCLC treated with stereotactic body radiation therapy (SBRT) were prospectively recorded. Treatments were planned employing 4D-CT. The prescribed dose was modulated according to location of the lesion and tolerance of the surrounding organs at risk: 54 Gy in 3 fractions for peripheral lesions, 60 Gy in 4 fractions for lesions adjacent to the chest wall, 60 Gy in 8 fractions for central lesions. The primary endpoints were local control and toxicity, secondary endpoint was survival. The follow-up examinations were performed with CT and/or PET-CT at 1, 3, 6, 9 and 12 months after treatment and every 6 months subsequently. Acute and late side effects were recorded according to RTOG morbidity Scoring Scale.

Results: From 2009 to 2014, 65 patients were treated. Mean patients' age was 74 years (range 62-86). The lesions had a mean maximum diameter of 20 mm (range 10-36). All but seven patients were staged by PET-CT. 83% of cases lung cancer was histologically proven: 34 cases were adenocarcinoma, 15 squamous cell carcinomas, 5 undifferentiated carcinomas. In the last 11 patients biopsy was not performed because of high risk features for complications and/or patient's refusal. In this last group 81% had a positive PET-CT and lesion growth documented at subsequent CT and just two patients had only lesion growth. Lesion's location were as follow: RUL 25/65 (38%), RML 2/65 (3%), RIL 7/65 (11%), LUL 22/65 (34%) and LIL 9/65 (14%). Median follow-up in 61 evaluable patients was 40 months. Five local failure (8%) were recorded at a mean of 11,5 months from the end of treatment (range 5.3-22). PET-CT SUV was the only parameter predictive for local failure, with a mean value of 14,2 in the recurrence-free group versus 6,1 in the recurrence-free group, respectively; p=0.03. Local control at 1 and 2 years were 89.6% and 86%. Median DFS was 22.2 months and 1y-, 2y- and 3y- DFS were 66%, 47% and 40%, respectively. Lesions' location according to treatment group was related to distant progression, which was significantly higher in peripheral location (p=0.004). Overall survival at 1y-, 2y- and 3y were 97%, 77% and 66%, respectively. Treatment was well tolerated. G1 asymptomatic pulmonary toxicity was observed in 18% of cases (11/61), G2 pulmonary toxicity was recorded in 3% of patients. There were no pulmonary toxicity grade 3-4. No other toxicities were reported.

Conclusion: SBRT is an effective and safe treatment for patients with medically inoperable stage I NSCLC. Local recurrence predictive value of PET-CT SUV could be investigated in bigger series.

EP-1243

A multicentre clinical trial using 3DCRT to reduce toxicity of palliative radiation for lung cancer

R. McDermott¹

¹St Luke's Radiation Oncology Center, Radiation oncology, Dublin, Ireland Republic of

Purpose or Objective: Radiation therapy in the palliation of intra-thoracic symptoms from locally advanced non-small cell lung cancer (NSCLC) is a significant component of workload in most radiotherapy departments. While most trials have

concentrated on optimizing dose schedules, we proposed a study demonstrating that using more technically advanced techniques would result in equivalent symptomatic relief and reduce symptomatic oesophagitis.

Material and Methods: Thirty-five patients with symptomatic locally advanced or metastatic NSCLC were treated using a three-dimensional conformal technique and standardized dose regimens of 39Gy in 13 fractions, 20Gy in 5 fractions or 17Gy in 2 fractions. Treatment plans sought to minimize oesophageal dose and oesophagitis was recorded during and at one month and three months following radiation therapy where applicable. Mean dose to the irradiated oesophagus was calculated for all treatment plans.

Results: At follow-up of one month after therapy for all patients accrued, there were no grade three or higher oesophageal symptoms of oesophagitis or dysphagia reported. Four patients (11.4%) had experienced grade 2 toxicity. All patients in the study derived clinical benefit from the radiation therapy course.

Conclusion: Use of three-dimensional conformal radiation techniques is widely practiced for treating intra-thoracic symptoms in the setting of NSCLC, however no direct study exists proving its superiority in reducing toxicity. This trial is the first of its kind showing that such techniques do provide patients with lower rates of oesophageal toxicity whilst yielding acceptable rates of symptom control. (Sponsored by the All-Ireland Cooperative Oncology Research Group (ICORG). Trial registration number 06-34)

EP-1244

Radiotherapy for loco-regional recurrence of non-small-cell lung cancer after complete resection

K. Terashima¹, M. Inamori², A. Matsunobu³, H. Hirata¹, K. Sakamoto¹, K. Okabayashi⁴, A. Furuya², M. Hirakawa¹

¹Kyushu University Beppu Hospital, Department of radiology, Beppu, Japan

²Fukuoka Higashi Medical Center, Department of radiology, Fukuoka, Japan

³SAGA-HIMAT Foundation, Ion Beam Therapy Center, Tosu, Japan

⁴Fukuoka Higashi Medical Center, Department of Thoracic Surgery, Fukuoka, Japan

Purpose or Objective: Although there is no standard treatment for postoperative recurrence of non-small-cell lung cancer (NSCLC), radiotherapy is occasionally used in the treatment of loco-regional recurrences. The objective of this study is to analyze clinical results of curative intent radiotherapy for loco-regional recurrence of NSCLC after complete surgical resection.

Material and Methods: A total of 38 patients, who had developed loco-regional recurrence after complete resection and received curative intent radiotherapy between 1999 and 2014, were retrospectively analyzed. There were 29 male patients and 9 female patients. The age range was 47-89 years (median 70 years). 25 patients had adenocarcinoma, thirteen patients squamous cell carcinoma. There were 29 patients with regional lymph nodes recurrence, and 10 patients with local recurrence at primary or anastomotic sites with or without lymph nodes recurrence. No patient had distant metastasis at presentation. The clinical endpoints included overall survival, progression-free survival, loco-regional recurrence within the irradiated field, and any other recurrence. The overall survival and local control rate were calculated from the day of radiotherapy completion and estimated by Kaplan-Meier method.

Results: The median total dose of radiotherapy was 60 Gy (range, 50-70 Gy). Thirteen of the 38 patients were treated with concurrent chemotherapy. The median follow-up time after radiotherapy was 30.4 (2.9-151) months. 1-5-year survival rates were 81.2, 69.6, 55.7, 48.5 and 39.6%, respectively. The 5-year progression-free survival, and local control rate were 32.6%, and 67.6%, respectively. Eight

patients have survived more than 5 years. There was no significant difference between patients with lymph nodes recurrence and those with local recurrence in overall survival.

Conclusion: Radiation therapy for loco-regional recurrence after complete resection provides acceptable disease control. Curative intent radiation therapy can be the treatment of choice if no evidence of metastasis is observed.

EP-1245

BED <100Gy and ITV≤20cc predict local relapse after stereotactic radiation therapy for lung cancer

A. Suissa¹, A. Levy¹, F. Belkhir¹, N. Grellier-Adedjouma¹, P. Xu¹, F. Martinetti¹, C. Le Pêcheux¹

¹Gustave Roussy, Radiation Oncology, Villejuif, France

Purpose or Objective: To determine predictive factors of local recurrence (LR) after Stereotactic Body Radiotherapy (SBRT).

Material and Methods: Data were retrospectively analyzed from 136 consecutive patients and 156 lung tumors treated with curative intent SBRT between April 2012 and December 2014 at our institution. Most patients had early lung cancer (76%). SBRT was also included in the treatment strategy for locally advanced (3%) or oligometastatic (21%) patients with an intent to complete response.

Results: The median follow-up was 21.8 months (2.4-70.8 months). The median age at diagnosis was 66,5 years (33-89 years) and median performance status was 0,5 (range 1-3). 54% patients had a smoking history with a median VEMS of 62,2%. Histological confirmation was obtained in 67%: 35% adenocarcinoma, 21% squamous cell carcinoma, 5% undifferentiated NSCLC and 5% other. Molecular markers were known in 27 tumors (17%): negative markers in 10%, KRAS mutation in 6%, other in 2%. Tumor location was central in 28%, peripheral in 48%, and intermediate in 24%. Median SUVmax at diagnosis was 7,1. Median ITV was 31,7 cc (0,56-104,8 cc) and median Biological effective dose (BED) was 123,8 Gy (72-151,2 Gy, $\alpha/\beta=10$). 11 LR occurred resulting in a 2 year LR rate of 8% [CI 95%: 3-14%]; median: not reached; mean time to LR: 38.4 month [CI 95%: 36-39.6]. BED ≤100Gy (HR=5 [CI 95%: 1.1-22]; p=0.03), and Internal Target Volume (ITV) ≥20cc (HR=4.9 [CI 95%: 1.3 -18.5]; p=0.02) were associated with a decreased LR in the multivariate analysis (MVA). Histology (squamous cell carcinoma), central location, and SUVmax of the treated lesion > 8 were not associated with local control in the MVA. Delay from diagnosis to SABR and molecular markers were not correlated with LR results in the univariate analysis. Two years overall survival and progression free survival rates were respectively 74% (IC 95%: 65-83%) and 62% (IC 95%: 52-72%).

Conclusion: BED should carefully be taken into account, particularly in case of tumors that exceed 20 cc

EP-1246

Is there a different dose-effect relation between the tumour and involved lymph nodes in NSCLC?

L. Van den Bosch¹, G. Defraene², S. Peeters¹, C. Dooms³, W. De Wever⁴, C. Deroose⁵, D. De Ruysscher¹

¹University Hospitals Leuven, Radiation Oncology, Leuven, Belgium

²University Hospitals Leuven, Experimental Radiation Oncology, Leuven, Belgium

³University Hospitals Leuven, Respiratory Oncology, Leuven, Belgium

⁴University Hospitals Leuven, Radiology, Leuven, Belgium

⁵University Hospitals Leuven, Nuclear Medicine, Leuven, Belgium

Purpose or Objective: It is unknown whether dose-response for the primary tumor is different from that of the involved lymph nodes (LN). As the recurrence rate is much lower in LN, we hypothesized that involved LN need a lower radiation dose than the primary tumor.

Material and Methods: A retrospective analysis of prospective data was performed on patients with locally advanced NSCLC treated with radiotherapy. Three dose groups were defined based on EQD2,T (A: < 50 Gy, B: 50-55 Gy, C: > 55 Gy). The primary endpoint was involved nodal relapse (INR). An actuarial Kaplan-Meier analysis was performed to evaluate the cumulative proportion of INR and primary tumor progression per dose group.

Results: From 2006 to 2010, 75 consecutive patients were included in this study. Groups A, B and C consisted of 22, 24 and 29 patients respectively. Median follow-up was 7 months. All patient characteristics were well balanced between the 3 dose groups. A total of 142 lymph nodes were included in the analysis (A: 49; B: 36; C: 57). Any relapse (locoregional/distant) occurred in 58 patients (77%). INR was observed in 18% in group A, 8% in group B and 14% in group C. No dose-response relationship was observed in the involved LN ($p=0.35$). Primary tumor progression was seen in 55%, 42% and 28% in group A, B and C respectively. A significant dose-response relationship was observed in the primary tumor ($p=0.02$). Baseline nodal diameter was not associated with INR (HR 1; $p=0.82$).

Conclusion:

The results of this study suggest that LN control can be achieved at lower radiation dose than needed for the primary tumor. Prospective dose de-escalation studies on LN are needed to decrease incidence of severe oesophagitis without compromising local control.

EP-1247

Is CC Chemokine Ligand 18 a biomarker for the prediction of radiation induced lung disease?

E. Gkika¹, S. Adebahr¹, T. Schimek-Jasch¹, A. Brenner¹, T. Brunner¹, A. Prasse², G. Ziesel³, A.L. Grosu¹, U. Nestle¹

¹Uniklinik Freiburg, Radiation Oncology, Freiburg, Germany

²Uniklinik Hannover, Pulmonology department, Hannover, Germany

³Uniklinik Freiburg, Pulmonology department, Freiburg, Germany

Purpose or Objective: The CC Chemokine Ligand 18 (CCL18) is produced by alveolar macrophages in patients with fibrosing lung disease and its concentration is increased in various inflammatory and fibrotic lung diseases. In this study we aimed to analyze the role of CCL18 as a potential

prognostic biomarker for the development of radiation induced lung disease (RILD) after thoracic irradiation.

Material and Methods: Between August 2011 and February 2012, 60 patients were enrolled prospectively in the study. Forty-six patients were treated for lung cancer; thirteen had an esophageal cancer and one a thymoma. Patients were treated either with conventionally fractionated (n=47) or hypo-fractionated (n=13) radiotherapy, 9 patients were treated adjuvant, 3 neoadjuvant, 4 with palliative intent and 44 with a definitive radiochemotherapy. The CCL18 levels in serum were quantified with ELISA (enzyme-linked immunosorbent assay) at predefined time points; before treatment, after 30 Gy, after 60 Gy (for conventional fractionation), at 6 weeks after completion of treatment and 3 months after therapy. These results were then correlated with clinical signs of RILD routinely performed computed tomographies (CTs) at 6 weeks and 3 months after the last treatment.

Results: Twenty three patients developed radiologic signs of RILD but only three of them developed symptoms. The mean CCL18 levels, for the whole group of patients, were before treatment 110 ng/ml (standard deviation, + 53) and at the end of treatment 85 ng/ml (+ 73). During the first (6 weeks after treatment) and second follow-up (3 months after treatment) the mean CCL18 levels were 93 ng/ml (+ 57) and 104 ng/ml (+ 49), respectively. The CCL18 concentrations in serum were not significantly elevated in the group of patients who developed a RILD. The mean CCL18 levels at six weeks and three months after treatment were in the RILD-group 94 ng/ml (+ 62) and 104 ng/ml (+ 61) and in the non-RILD-group 93 ng/ml (+ 54) and 103 ng/ml (+ 39). Patients with elevated CCL18 over the mean had a slightly worse local control ($p=0,047$) and a slightly worse overall survival which didn't reach statistical significance.

Conclusion: These findings do not suggest that the chemokine CCL18 is involved in the development of RILD in patients undergoing radiotherapy for chest tumors.

EP-1248

Lung re-irradiation with stereotactic body radiation therapy (SBRT)

P. Bonome¹, C. Scaringi¹, M. Valeriani¹, V. De Sanctis¹, G. Minniti¹, M.F. Osti¹

¹Azienda Ospedaliera Sant' Andrea, Institute of Radiation Oncology, Rome, Italy

Purpose or Objective: In the present study we have evaluated local control, overall survival (OS) and toxicity of re-irradiation with stereotactic body radiation therapy (SBRT) in patients with recurrent/progressive primary or secondary lung tumors after previous radical radiation therapy or SBRT.

Material and Methods: Between August 2011 and December 2014, 9 patients (6 men and 3 women) received a second course of SBRT in single (23 Gy or 30 Gy) or multiple fractions (15 Gy x 3). The median volume was 19.8 cc (range 3,7 - 46,8 cc). The median interval from previous irradiation was 18 months (range 12 - 47 months). Previous treatment included radical radiation therapy (60 Gy) in 33% of lesions and single-fraction SBRT (23 Gy or 30 Gy) in 67% of lesions.

Results: The median follow-up was 11 months (range 2 - 38 months). The median OS after the second course of SBRT was 12 months (range 3 - 39 months). The 6- and 12-months survival rates were 100% and 88%, respectively. No patient developed grade 2 toxicity. Complete response was observed in 2 patients (22%) and stable disease in 6 patients (66%). One patient died for progressive systemic disease.

Conclusion: Re-irradiation with SBRT for recurrent/progressive primary or secondary lung tumors is a feasible treatment associated with good local control and acceptable toxicity

EP-1249

Neoadjuvant chemoradiation in locally advanced NSCLC: impact of histology and drugs on results.

B. Floreno¹, R.M. D'Angelillo¹, M. Fiore¹, C. Greco¹, E. Molfese¹, C.G. Rinaldi¹, L.E. Trodella¹, A. Iurato¹, L. Trodella¹, S. Ramella¹

¹*Policlinico Universitario Campus Biomedico, Radiotherapy, Roma, Italy*

Purpose or Objective: Locally Advanced Non-Small Cell Lung Cancer (LA-NSCLC) or stage (St) III disease accounts for about 30% of patients with NSCLCs. Treatment strategies include definitive chemoradiation or induction treatment (IT) followed by radical surgery. The main end-points of inductive treatment are resection rate with pneumonectomy rate, and pathological downstaging.

Material and Methods: Pooled data from four consecutive trials published on patients receiving radiochemotherapy from 1992-2007 have been analyzed. The study group comprised 199 patients (87% males, 63±9 mean age, 48% squamous cell carcinoma (SCC), 65% cStIIIA). Patients have been treated with involved field radiotherapy and concurrent carboplatin or cisplatin + 5-FU (old drugs), weekly Gemcitabine only at 300mg/m²(GEM) and Cisplatin at systemic dose plus weekly Gemcitabine at 300mg/m² (P-GEM).

Results: Present series confirms the impact on survival endpoints (OS, DFS, DSS) of surgical resection, pathological downstaging and tumor response. The indication for resection (HR = 2.7 [95%CI: 1.9; 3.7]; p<0.0001), together with response to radiochemotherapy (HR = 2.3 [95%CI: 1.6; 3.3]; p<0.0001) were the strongest predictors of OS. The most significant predictors of DSS were surgery (No resection vs Resection - HR: 2.0 [95%CI:1.3; 2.9], p<0.001), and the presence of response to induction radiochemotherapy (No response vs Partial Response - HR: 2.0 [95%CI:1.2; 3.1], p<0.004). Concurrent compounds influenced pathological downstaging (4% pStage 0 with old drugs vs. 23% with GEM vs. 36% with P-GEM; p=0.01), response rate (79% and 80% of partial response with GEM and P-GEM vs. 68% with old drugs; p= 0.002) and pneumonectomy rate (33% of patients treated with old drugs, 29% of those treated with GEM, and 19% of those treated with P-GEM). Squamous histology influenced response rate (80% vs. 69%; p=0.009) and disease specific survival (median DSS time was 30 months vs. 20 months).

Conclusion: The roles of major survival predictors (particularly, surgery, pathological downstaging) are discussed. The availability of reliable surrogate end-points (e.g.: pathological downstaging) may drive clinical strategy in the short time combining concurrent compounds and tumor histology.

EP-1250

Outcome after stereotactic radiotherapy for brain metastasis of lung cancer: a retrospective study

N. Grellier Adedjouma¹, A. Levy¹, A. Suissa¹, F. Belkhir¹, P. Xu¹, F. Martinetti¹, D. Plancharde², B. Besse², C. Le Pêcheux¹

¹*Institut Gustave Roussy, Radiation Oncology, Villejuif, France*

²*Institut Gustave Roussy, Medical Oncology, Villejuif, France*

Purpose or Objective: The aim of our study was to evaluate the efficacy and safety of brain stereotactic radiotherapy (SBRT), and potential interactions with mutational status/systemic therapies of patients treated in our Institute.

Material and Methods: We conducted a retrospective study of 85 patients (150 lesions) receiving SRT for brain metastases (mets) of lung cancer between 01/2012 and 03/2015.

Results: 90% patients were smokers and the most frequent histology was adenocarcinoma (ADK: 74%). In 99 patients with mutational analysis: 35%, 8%, and 56% had EGFR/ALK, others (KRAS/PI3K), or no mutations, respectively. The median GPA-

DS score was 2.5 (0.5-3.5). The median estimated biologic equivalent dose (BED) was 57.6 Gy (16,7-57,6). 35 patients (41%) had a whole brain radiation therapy (WBRT) prior or after SABR. The median follow-up from SRT was 1.6 years. The 2-year local control (LC) was 54% (95IC: 40-68%). Histology (non-ADK: HR=7.2) and others mutations (KRAS/PI3K: HR=5.8) were associated with lower LC in the multivariate analysis (MVA). The type of systemic treatment, or its delay before BSRT, as well as other variables (history of WBRT, GPA, number of brain mets) did not correlate with LC in the MVA.

Conclusion: In our study, K-Ras mutational status seemed to be associated with poorer local control. The impact of mutational status should be evaluated in a larger set of patients.

EP-1251

Stereotactic Body Radiation Therapy (SBRT) for recurrent lung cancer following prior radiation

J. Wurzer¹, M. Mackowsky²

¹*AtlantCare Cancer Institute, Radiation Oncology, Linwood, USA*

²*New Jersey Health Network, Radiation Oncology, Linwood, USA*

Purpose or Objective: Patients with recurrent lung cancer following prior thoracic radiation therapy have limited therapeutic options. This study analyzes the efficacy and morbidity associated with fractionated stereotactic body radiation therapy (SBRT) in the treatment of locally recurrent lung cancer following prior radiation therapy with or without concurrent chemotherapy or prior surgery.

Material and Methods: 37 patients diagnosed with recurrent local lung cancer recurrence following prior thoracic radiation therapy were treated with stereotactic body radiation therapy between June 2009 and December of 2013 at AtlantCare Cancer Institute. Patients were treated with either robotic-assisted linear accelerator based stereotactic body radiation therapy with 4-D CT simulation and image guidance with cone beam CT or CyberKnife robotic radiosurgery utilizing Synchrony respiratory tracking. SBRT doses included 5400 cGy in 3 fractions and 5000 cGy in 5 fractions depending on normal tissue dose constraints. Patients underwent routine imaging with PET/CT and CT for surveillance.

Results: With a median follow-up of 3 years, the in-field local control was 92%. The actuarial overall survival was 46% with a progression free survival of 27%. Worsened dyspnea was noted in 13% of patients, 5% experienced esophagitis, 5% noted chest wall pain, and 8% experienced clinical pneumonitis. There was no grade 4 or 5 toxicity.

Conclusion: For patients experiencing local recurrence following prior thoracic radiation, robotic SBRT offers both excellent local control and limited toxicity. Despite these favorable results, progressive failure outside of the local therapy field and competing co-morbidities continue to pose a significant challenge.

EP-1252

Oligometastatic NSCLC: long-term results show efficiency of radical approaches in selected patients

A. Bunea¹, D. Schiebahn¹, D. Schanne¹, T. Schimek-Jasch¹, E. Gkika¹, S. Wiesemann², J. Rawluk³, C. Waller³, A.L. Grosu¹, U. Nestle¹

¹*Universitätsklinik Freiburg, Klinik für Strahlenheilkunde, Freiburg, Germany*

²*Universitätsklinik Freiburg, Chirurgische Klinik-Thoraxchirurgie, Freiburg, Germany*

³*Universitätsklinik Freiburg, Medizinische Klinik, Freiburg, Germany*

Purpose or Objective: Basing on the concept of oligometastases, i.e. less than 5 distant metastases, it was previously described that local, radical treatment of the

primary and/or its metastases in patients with non-small-cellular-lung-cancer (NSCLC) can lead to a favourable progression-free- (PFS) and overall-survival- rates (OS). An analysis made for patients treated between 2008 and 2012 at our institution already showed encouraging results. We extended this group of patients to those treated till 2015.

Material and Methods: Between 2008 and 2015 a total of 58 patients at our centre with an initial stage IV NSCLC with a maximum of 4 metastases at time of diagnosis received local radical treatment to all tumor sites. Method of treatment was indicated by the centre's interdisciplinary tumor board review. This retrospective analysis acquired data using our comprehensive cancer centre's patient-databases, that collected the patients' data and by contacting the patients' GP or their oncologists outside our institution.

Results: Between 2012 and 2015 a total of 58 patients (43 men (74%) and 15 women (26%)) where diagnosed with stage IV NSCLC, having less than 5 distant metastases. The median age at the time of diagnosis was 59 (range 48-86 years). The Karnofsky Performance Score (KPS) at a median of 90% (70-100%). The staging was completed by, MRI, CT and/or PET/CT (47 cases; 81%) as well as by histopathological examination. A biopsy was available in all patients. 43 (74%) had an adenocarcinoma, while 15 patients (26%) had a squamous cell carcinoma. Mutation analyses of epidermal growth factor receptor (EGFR) was determined in 26 patients, of which 4 (15%) showed a mutation. The patients underwent either surgery (74%) or radiotherapy (100%) of the primary or its metastases or a combination of both. Main target volumes were the primary, the mediastinum, brain metastases or bone metastases. Total cumulative doses at the site of the primary had a median of 60 Gy (30-68Gy). 45 patients (78%) were systemically treated. Out of these, 16 patients (28%) received a combined radio-chemotherapy with cisplatin, whereas 29 individuals obtained chemotherapy alone (50%) at some point in their history. Radiotherapy was generally well tolerated. One patient had grade three pneumonitis, requiring hospitalisation. Grade one toxicity occurred in four cases. During cytotoxic treatment one patient suffered grade three nausea. Mild to moderate cytopenia occurred in four patients. Median follow-up-time (FU) was 12.3 months, median PFS 6 months (95%, CI: 3.378-6.622%), while mean OS was 20 months, median OS was 15 months (95%, CI: 7.068-16.932%).

Conclusion: In line with literature, our analysis showed that radical treatment of patients with oligometastatic NSCLC may lead to an improvement of PFS and of the OS. Appropriate groups of patients with high KPS might benefit the most. Treatment modalities are generally well tolerated.

EP-1253

Local control and toxicity for centrally located NSCLC: SABR in no fly zone

C. Menichelli¹, G. Pastore², A. Fanelli¹, S. Grespi¹, P. Ferrazza¹, A. Chella³, I. Petrini⁴, F. Casamassima¹

¹Research Institute "Ecomedica", Department of Radiation Oncology, Empoli, Italy

²Research Institute "Ecomedica", Department of Radiation Physics, Empoli, Italy

³AOU Pisana, Cardiothoracic Department, Pisa, Italy

⁴AOU Pisana, Department of Medical Oncology, Pisa, Italy

Purpose or Objective: Only few experiences had investigated the use of SABR for locally advanced NSCLC centrally located. The RTOG 0236 Trial warns about the risks of SBRT in NSCLC located within 2 cm of the bronchial tree, the esophagus, heart and pericardium. The aim of this study is to evaluate the use of hypofractionated ablative radiotherapy in this setting of disease in terms of local control, toxicities and overall survival (OS).

Material and Methods: Between Jun 2011 and March 2015 36 patients (pts) were treated with Hypofractionated Image guided-Volumetric Modulated Arc Therapy (IGRT-VMAT) for centrally located NSCLC stage III-IV or centrally recurrent

NSCLC biopsy-proven. Target was contoured using volumetric mdc enhanced CT and PET/CT scan and OAR according RTOG 0236 Trial criteria. Dose Constraints used were: Single lung V10<20%, Dmax bronchus 38 Gy, Dmax esophagus 35 Gy, Spinal Cord 22.5 Gy, Heart and pericardium 38 Gy. The dose was prescribed to 80% isodose. The VMAT treatment was delivered by 6MV beam modulator Linac with 4 mm MLC and in breath hold using ABC device. Patient set-up and isocenter position was controlled before each fraction by CBCT. Target volume ranged from 21 to 150 cm³ (median 49.5). Median delivered dose was 40 Gy/5fx (median BED 10 of 100 Gy). Toxicities were assessed by CTCAE 4.0 criteria and the response was evaluated 2 months after the end of SBRT and every 4 month successively by CT and PET/CT.

Results: Median follow-up was 18 months (range 3 - 45). 25 pts are still alive (69.5%) and 8 of them have NED. 19/36 (52.8%) of treated lesions show complete response and 10 (27.7%) partial response. Local control was 89% at 12 months and 67% at 18 months. OS was 84% and 73% at 12 and 18 months respectively. Acute toxicity worse than G2 was observed only in 1 pt. Late toxicity G3 was observed in 3 pts (esophageal stenosis in 1 case and broncho-esophageal fistula in 2 pts). Both fistulas occur in the same site of local recurrence

Conclusion: In our experience hypofractionated treatment with ablative dose for NSCLC locate in "no fly zone" is safe if dose constraints for OAR are respected. The two major late toxicities observed occurred in the same site of local recurrence. The treatments with BED 10 values of 100 Gy or more are effective leading to LC rate of 89% and 67% at 12 and 18 month respectively. Although OS is not the primary endpoint of this study, because include also metastatic and recurrent disease, nevertheless shows interesting values (84% at 12 months and 73% at 18 months)

EP-1254

Updated outcomes for patients treated with SABR for lung cancer at the Leeds Cancer Centre

P. Murray¹, K. Spencer¹, P. Dickinson¹, M. Snee¹, P. Jain¹, K. Clarke¹, K. Franks¹

¹St James' Institute of Oncology, Clinical Oncology, Leeds, United Kingdom

Purpose or Objective: To report ongoing longer-term outcomes of a large cohort of patients undergoing SABR for primary stage I lung cancer at the Leeds Cancer Centre.

Material and Methods: Patients were prospectively selected and received SABR for medically inoperable peripheral early stage lung cancer between May 2009 and January 2014. Electronic records were reviewed for baseline characteristics, treatment details and recorded toxicity and outcomes.

Results: 572 patients underwent SABR treatment, with 43 of these patients receiving 2 or more treatments, either concurrently or sequentially. Median follow-up 24 months (IQR 14-35 months, range 0-76 months). Kaplan-Meier (KM) estimated Median Overall Survival (OS) was 33 Months (S.E. 2.43 Months), and estimated 5-year OS 29.5% (S.E. 6%). 128 patients had clinical and radiologically reported recurrence. 26 patients (4.5%) developed local recurrence, 25 (4.3%) developed nodal recurrence, with 77 patients developing distant disease (13.5%). One, two and three-year K-M local control rates were 98.7% (S.E. 0.5%), 95.8% (S.E. 1.0%), and 92.3% (S.E. 1.6%) respectively. 94(21.2%) patients had a radiological report of pneumonitis (G1), 31(6.6%) patients had a clinical diagnosis of pneumonitis recorded (G2) and 2 (0.4%) patients had an episode of Grade 3 pneumonitis. 37 patients had a radiologically reported rib fracture, 14 symptomatic (2.9%) and 23 (4.8%) were asymptomatic (G1-2). There was no other reported toxicity. Cox regression analysis showed that factors significantly associated with survival were poorer performance status (P=0.002) and increasing tumour size (p=0.008). Other factors such as histology, treatment related fibrosis, tumour lobar location,

clinical or radiological pneumonitis did not reach statistical significance ($P < 0.05$).

Conclusion: SABR for primary lung cancer performed at the Leeds Cancer Centre continues to show excellent local control rates, with low toxicity and has comparable overall 5-year survival rates to other published series. Poorer performance status and larger tumour size were associated with a negative effect on overall survival.

EP-1255

SABR and FDG-PET in lung cancer: a SUV cut-off value before treatment to predict local control.

S. Vagge¹, M. Marcenaro², G. Timon², G. Siffredi², R. Corvò²

¹IRCCS San Martino IST, Radiation Oncology, Genova, Italy

²IRCCS San Martino IST, Radiation Oncology, Genoa, Italy

Purpose or Objective: To investigate the prognostic value of [(18)F] fluorodeoxyglucose positron emission tomography (FDG-PET) uptake before stereotactic ablative radiotherapy (SABR) for stage I non-small-cell lung cancer (NSCLC).

Material and Methods: From August 2009 to December 2014, 80 medically inoperable patients with proven Stage I NSCLC or FDG-PET-positive primary lung tumors were analyzed retrospectively. SABR consisted of 48-50 Gy delivered in 4 to 5 fractions, respectively by two or one fraction per week. Maximum standardized uptake value (SUV (max)) of the treated lesion was assessed before SABR. Patients were subsequently followed at regular intervals using computed tomography (CT) and FDG-PET scans. Association between post-SABR SUV (max, at minimum of 12 weeks after treatment) and local control (LC), overall survival (OS) was examined.

Results: Median follow-up time was 20 months (range, 9-55 months). Median lesion size was 20 mm (range, 8-50 mm). Due to statistical evaluations around the median range of SUV (max), a pre SABR SUV (max) 5.0 was selected as a cut-off to analyze LC and OS. The 2-year LC was 61.2% versus 78.7% for higher or equal than 5.0 versus lower than 5.0 SUV (max), yielding an adjusted sub-hazard ratio (SHR) for high pre SABR SUV (max) of 5.3 (95% confidence interval [CI], 1.3-25.5; $p = 0.057$). Two-year OS was 80.6% versus 76.6% respectively (hazard ratio [HR], 1.4; 95%; $p = 0.46$). No differences were observed between fractionation schedules or different tumor volumes.

Conclusion: FDG uptake (SUV (max) ≥ 5.0) before SABR signifies reduces risk of local failure. These results from single institution might stimulate a large accrual from

multicenter prospective analysis, due to controversial results already published.

Electronic Poster: Clinical track: Upper GI (oesophagus, stomach, pancreas, liver)

EP-1256

Stereotactic body radiation therapy for liver metastases using RapidArc technique

E. Del Cerro¹, A.A. Diaz Gavela¹, F. Couñago Lorenzo¹, F. Marcos Jimenez¹, E. Pardo Perez², Y. Molina Lopez²

¹Hospital Quiron Madrid, Radiation Oncology, Pozuelo de Alarcon- Madrid, Spain

²Hospital Quiron Madrid, Radiophysics, Pozuelo de Alarcon- Madrid, Spain

Purpose or Objective: To report our initial experience in stereotactic body radiation therapy (SBRT) delivered using RapidArc (RA) technique with or without flattening filter beam in terms of toxicity and clinical outcomes.

Material and Methods: From September 2013 to September 2015, 16 consecutive patients with 27 metastatic hepatic lesions were treated with SBRT in a TrueBeam unit using RA technique. 6 lesions received a Volumetric Modulated Arc Therapy (VMAT) treatment using 6Mv RA with flattening filter and 21 were treated without flattening filter (flattening filter free beam- FFF) with an energy of 10Mv. GTV was defined using multi-phase CT scans, PET/CT and/or MRI. The lesions were marked with a radiopaque coil to localize them in the verification CBCT (ConeBeamCT) that was performed daily. ITV (internal target volume) was calculated in gated modality with internal coil tracking by 2D imaging. Prescribed doses ranged from 30-60Gy in 3-5 fractions to ITV. The dose was downscaled in cases of not full achievement of dose constraints. 99.5% of the target volume was covered by 100% of the prescription dose. Initially, we followed the constraints proposed by Timmerman: Three fractions constraints for organs at risk were: 700cc of liver free from the 17.1Gy isodose, Dmax < 24Gy for stomach and duodenum, D5cc < 15Gy for duodenum, Dmax < 30Gy for heart, D1.2cc < 11Gy and D0.25Gy < 18Gy for spinal cord. Five fractions constraints for organs at risk were: 700cc of liver free from the 21Gy isodose, Dmax < 32Gy for stomach and duodenum, D5cc < 18Gy for duodenum, Dmax < 38Gy for heart, D1.2cc < 13.5Gy and D0.25Gy < 22.5Gy for spinal cord. Nowadays we are following the constraints proposed by the Spanish Society of Radiation Oncology: Liver: 700cc of liver free from the 15Gy isodose, V21 < 30%, V15 < 20Gy, Mean dose: < 15Gy for three fractions and < 20Gy for five fractions; D5cc < 15Gy for duodenum; V30 < 1cc and V21 < 5cc for heart; Dmax < 18Gy for spinal cord.

Results: Mean age of the patients was 59 years and the mean following time since the end of SBRT was 9.14 months. ITV mean volume was 41.78cc. The most frequent side effect was acute asthenia and we identified two cases of asymptomatic increase in liver enzymes. No patient experienced acute toxicity greater than Grade 2. In relation to the local response, we used RECIST and/or PERCIST criteria to reevaluate the lesions. We found 15 complete and 1 partial responses, 1 progression, 5 stable lesions and 2 pseudo progressions. 2 patients (4 lesions) were lost in the long-term clinical follow up. No differences between both treatment modalities (with or without FF) were found in terms of local control or side effects (either acute or chronic).

Conclusion: SBRT for liver targets delivered by means of RapidArc resulted to be a feasible technique, with few side effects and good rates of local response in metastatic liver targets.

EP-1257

Stereotactic radiotherapy for recurrent pancreatic adenocarcinoma at stump or abdominal lymph nodes

H.H. Wang¹, H.H. Wang¹, M.B. Meng¹, Z.Q. Wu¹, Y.C. Song¹, H.Q. Zhuang¹, D. Qian¹, L.J. Zhao¹, Z.Y. Yuan¹

¹Tianjin Cancer Hospital, Department of Radiation Oncology, Tianjin, China

Purpose or Objective: To evaluate the efficacy and safety of stereotactic radiation therapy (SRT) in the treatment of patients with recurrent pancreatic adenocarcinoma at the stump or abdominal lymph node after surgery.

Material and Methods: Between October 1 2011 and May1 2015, patients with recurrent pancreatic adenocarcinoma at the stump or abdominal lymph nodes after surgery were enrolled and treated with SRT at our hospital. The primary end-point was overall survival after SRT (OS). Secondary end-points were: local control rates (LC), time to symptom alleviation, and toxicity using the Common Terminology Criteria for Adverse Events (CTCAE v4.0).

Results: Twenty-four patients with 24 lesions (17 abdominal lymph nodes and 7 stumps) were treated with SRT. Among these patients, five patients were presented with abdominal lymph node and synchronous metastases in liver and lung. For the entire cohort, the median OS from diagnosis and SRT were 28.93 months and 12.20 months, respectively. The 6-month, 12-month, and 24-month actuarial LC rates were 95.2%, 83.8% and 62.1% respectively. Symptom alleviation was observed in 11 of 14 patients reported symptoms (78.6%) with a median of 8 days (range, 1-14 days) after SRT. Nine patients (37.5%) experienced CTCAE v4.0 Grade 1 to 2 acute toxicities; one patient experienced grade 3 acute toxicity due to thrombocytopenia.

Conclusion: SRT is a safe and efficacious treatment modality for patients with recurrent pancreatic adenocarcinoma at the stump or abdominal lymph nodes after surgery. Further studies are needed before SRT can be recommended routinely.

EP-1258

Concurrent high-dose (60-70 Gy) radiation and chemotherapy for esophageal cancer: long-term results
T. Kondo¹, Y. Shibamoto¹, A. Hayashi¹, A. Miyakawa¹, T. Murai¹, T. Yanagi¹, C. Sugie¹, Y. Ogawa¹
¹Nagoya City University Graduate School of Medical Sciences, Department of Radiology, Nagoya, Japan

Purpose or Objective: Based on the results of the intergroup-0123/RTOG 94-05 trial that demonstrated no benefit of dose escalation over 50.4 Gy in definitive chemoradiotherapy (CRT) for esophageal carcinoma, 50.4 Gy appears to be accepted as a standard dose. Radiobiologically, however, higher radiation doses, if safely delivered, could lead to better local control. We have used combination of standard FP (5-fluorouracil [5-FU] and cisplatin) chemotherapy and radiation with dose 60 Gy in the treatment of non-metastatic esophageal cancer. We report clinical outcome of the treatment protocol.

Material and Methods: Between 2002 and 2014, 86 patients with stage I-III or IV (M1 LYM) esophageal cancer were treated with CRT. Median age of the patients was 68 years (range: 46 to 84); 76 were men and 10 were women. Histology was squamous cell carcinoma in 98%. Patients were divided into 4 groups according to the stage and operability; Group 1: stage I patients (n = 10); Group 2: stage II-III operable patients (n = 20); Group 3: stage II-III (non-T4) inoperable patients (n = 21); and Group 4: stage III-IV (T4/M1 LYM) patients (n = 35). Chemotherapy protocols were either cisplatin (70 mg/m²) plus 5-FU (700 mg/m² x 4 days) administered every 4 weeks or low-dose daily cisplatin (4 mg/m²) and 5-FU (200 mg/m²). Radiation was given by 10-MV X rays with a daily fraction of 1.8-2 Gy. Treatment volume included primary tumor plus regional lymph nodes. A total dose between 60 and 70 Gy was chosen depending on the treatment volume. Median radiation dose was 64 Gy (range: 50-70 Gy; 5 patients could not complete planned treatment). Failure was confirmed by pathology or findings of progressive disease on serial endoscopy and/or imaging studies. Overall survival (OS) and locoregional control (LC)

rates were calculated by the Kaplan-Meier method. Toxicities were evaluated by the Common Terminology Criteria for Adverse Events version 4.0.

Results: For all 86 patients, the 3-year LC and OS rates were 65% and 29%, respectively; they were 100% and 100%, respectively, in Group 1, and 72% and 42%, respectively, in Group 2. The 2-year LC and OS were 53% and 14%, respectively, in Group 3, and 69% and 25%, respectively, in Group 4. Overall response rate was 78% (complete response in 31 and partial response in 36). Grade 3 or higher acute toxicities, mainly hematological, were observed in 37% of the patients and 10% experienced grade 3 or higher late toxicities.

Conclusion: CRT with FP and 60-70 Gy of radiation appears to be tolerable for patients with esophageal cancer. Although outcome of this treatment in inoperable patients is not satisfactory, the 3-year LC of 100% for stage I patients and 76% for stage II-III operable patients appear promising. Further investigation is warranted to clarify the optimal radiation dose in CRT for esophageal cancer.

EP-1259

Clinical significance of lymphocyte count before chemoradiotherapy in resected pancreatic cancer
J. Heo¹, O.K. Noh¹, H.W. Lee², M. Chun¹, Y.T. Oh¹, J. Kim³
¹Ajou University School of Medicine, Radiation Oncology, Suwon, Korea Republic of
²Ajou University School of Medicine, Hemato-oncology, Suwon, Korea Republic of
³Dankook University College of Medicine, Radiation Oncology, Cheonan, Korea Republic of

Purpose or Objective: The objective of this study was to investigate the prognostic value of circulating lymphocyte level at the beginning of postoperative chemoradiotherapy (CRT) in pancreatic adenocarcinoma.

Material and Methods: From 2007 to 2014, 41 patients treated with postoperative CRT were analyzed. The median dose of radiotherapy was 50.4 Gy (range, 45 - 59.4) and chemotherapy was administered after surgery. Absolute lymphocyte counts (ALC) was obtained from complete blood count tests performed prior to CRT. We analyzed blood lymphocyte count as well as clinical parameters to identify prognostic factor

Results: With a median follow-up of 16.9 months, 32 patients had cancer recurrence and 28 died from the disease. The median overall survival (OS) and disease free survival (DFS) were 19.7 months and 9.8 months. The median OS of high postoperative ALC (>2.074 ×10³ / μL) group was significantly longer than that of the lower ALC group (32.0 months versus 17.0 months, p = 0.007). In multivariate analysis, high postoperative ALC was a good prognostic factor for OS. (Hazard Ratio = 0.341, CI, 0.149 - 0.778, p = 0.011). High ALC at the beginning of postoperative CRT was also a prognostic factor for DFS in multivariate analysis (Hazard Ratio = 0.452, CI, 0.215 - 0.946, p = 0.035).

Conclusion: Postoperative ALC is a significant prognostic factor for resected pancreatic cancer patients. Postoperative immune status might help to predict survival outcome and to stratify group that is effective in CRT for resected pancreatic cancer.

EP-1260

Prognostic factors in hepatoma patients treated with radiotherapy for lymph node metastasis

C.W. Wee¹, K. Kim¹, E.K. Chie¹, S.J. Yu², Y.J. Kim², J.H. Yoon²

¹Seoul National University College of Medicine, Department of Radiation Oncology, Seoul, Korea Republic of

²Seoul National University College of Medicine, Department of Internal Medicine, Seoul, Korea Republic of

Purpose or Objective: To investigate prognostic factors for overall survival (OS) in hepatocellular carcinoma (HCC) patients treated with external beam radiotherapy (RT) for lymph node (LN) metastasis.

Material and Methods: Between 2004 and 2015, 105 HCC patients underwent palliative RT for LN metastasis. The median age was 60 years (range, 30-82). Biologically effective radiation doses of 39-75 Gy10 (median, 59.0 Gy10) were delivered. The median follow-up period was 5.7 months.

Results: The median OS was 5.8 months. On univariate analysis, young age, symptoms related to LN metastasis, poor performance status, Child-Pugh class B-C, uncontrolled intrahepatic disease, non-nodal distant metastasis (DM), multi-station LN metastasis, biologically effective dose <60 Gy10, lack of local response to RT, and stable or increased post-RT alpha-fetoprotein levels compared to pre-RT levels were significant prognostic factors predicting poor OS (all $p < 0.05$). On multivariate analysis among pre-RT factors, symptoms related to metastatic LNs (HR, 2.93), Child-Pugh class B-C (HR, 2.77), uncontrolled intrahepatic disease (HR, 2.74), and non-nodal DM (HR, 1.62) were significant prognostic factors for poor OS (all $p < 0.05$). Risk stratification in 4 groups by the number of risk factors had a significant predictive value for OS, with patients having 0, 1, 2, and 3-4 risk factors demonstrating median OS intervals of 18.0, 11.7, 5.7, and 3.0 months, respectively ($p < 0.001$).

Conclusion: Our risk stratification model can be used effectively in assessing the life expectancy of the HCC patient before initiating palliative RT for LN metastasis. Moreover, the presence of symptoms related to LN metastasis was shown to be the most powerful indicator of poor OS.

EP-1261

Impact of sarcopenia on adverse effects in trimodality therapy for esophageal carcinoma

C. Panje¹, L. Höng², G. Henke², T. Ruhstaller³, M. Guckenberger¹, V. Baracos⁴, L. Plasswilm²

¹University Hospital Zürich, Radiation Oncology, Zurich, Switzerland

²Kantonsspital St. Gallen, Radiation Oncology, St. Gallen, Switzerland

³Kantonsspital St. Gallen, Medical Oncology, St. Gallen, Switzerland

⁴University of Alberta, Oncology, Edmonton, Canada

Purpose or Objective: Sarcopenia is a major hallmark of cancer cachexia and associated with increased treatment toxicity and worse overall survival in cancer patients. The aim of the study is to investigate the incidence and course of sarcopenia in patients undergoing curative trimodality therapy for locally advanced esophageal cancer and to correlate skeletal muscle mass with treatment complications during neoadjuvant treatment and surgery.

Material and Methods: A subset of 31 patients treated in a prospective trial for locally advanced esophageal cancer with induction chemotherapy, neoadjuvant chemoradiation and surgical resection were identified at two institutions and

clinical data was analyzed for treatment-related adverse events and consequent additional hospitalizations. Skeletal muscle mass was obtained by a second analysis of staging CTs before, during and after curative trimodality therapy and analyzed based on previously established threshold values for sarcopenia.

Results: Fourteen patients (45%) were characterized as sarcopenic at the initial staging. Unplanned hospitalizations occurred significantly more frequently in sarcopenic patients (71% vs. 29%, $p = 0.03$) with a significantly longer total duration of hospital stay including postoperative stay (median 33.5 vs. 21.3 days, $p < 0.05$). During neoadjuvant therapy with a median duration of 3.5 months, patients showed a statistically significant reduction of skeletal muscle mass of 10.1% ($p < 0.01$) resulting in an increase in the prevalence of sarcopenia from 45% to 74%.

Conclusion: CT-based assessment of sarcopenia demonstrates a significant decline of muscle mass during curative trimodality therapy for locally advanced esophageal cancer and can predict toxicity-related unplanned hospitalization. Based on these findings, CT-based measurement of muscle mass may serve as objective parameter to identify frail patients in need of intensified supportive therapy.

EP-1262

Survival and symptom relief after salvage radio(chemo)therapy for recurrent esophageal cancer

P.G. Kup¹, A. Gitt¹, H. Bühler¹, I.A. Adamietz¹, K. Fakhrian²

¹Marien Hospital Herne- Ruhr-University Bochum, Radiation Oncology, Herne, Germany

²Marienhospital Herne- Ruhr-University Bochum, Radiation Oncology, Herne, Germany

Purpose or Objective: Loco-regional recurrence of esophageal cancer (REC) after initial treatment remains a dominant cause of death. Treatment options for REC are limited. This study was realized to assess the survival and symptom relief after salvage radio(chemo)therapy for recurrent esophageal cancer.

Material and Methods: Data from 259 patients from 3 centers were retrospectively reviewed to screen for eligible patients. 194 patients were excluded because of following criteria: 1) no pathologically confirmed squamous cell carcinoma or adenocarcinoma; 2) distant metastasis; 3) no dose-volume histogram (DVH) data available; 4) salvage resection after REC; 5) Brachytherapy in the initial or current treatment. Between January 1998 to December 2014 sixty-five patients with REC after curative intended treatment (primary RCT or surgical resection with or without neoadjuvant radiochemotherapy) met our inclusion criteria retrospectively. The recurrence was diagnosed by computed tomography (CT) and/or upper gastrointestinal endoscopy. The initial treatment was as follows: surgical resection in 47 patients (72%), neoadjuvant RCT (median 50,4Gy, range 45-50,4Gy) plus surgery in 12 (19%) patients or definitive RCT (median 60Gy, range 50,4-64 Gy) in 6 patients (9%). The median time to recurrence from initial treatment was 16 months (range 3-101 months).

Results: Median follow-up time for surviving patients was 27 months (5-150 months). The 1-year and 2-year survival rates were $58 \pm 6\%$ and $27 \pm 6\%$, respectively. Subjective symptom relief was achieved in 25 of 34 symptomatic patients (74%). The most common toxicities were leukopenia, nausea, vomiting and gastritis. RT Doses ³ 50Gy and ECOG-PS (1-2 vs. 3) associated with better median survival time (MST) and prognosis, respectively ($p=0.003$; $p=0.001$).

Conclusion: Salvage radio(chemo)therapy for recurrent esophageal cancer is a reliable option in patients suffering from REC. In particular therapy of symptoms caused by the tumor can be managed by salvage-RCT. The toxicity is in an acceptable range. Long-term survival is possible in some patients.

EP-1263

Survival and symptom relief after palliative radiotherapy for esophageal cancer

P.G. Kup¹, J. Welsch¹, H. Bühler¹, H. Hermani¹, I.A. Adamietz¹, K. Fakhrian¹

¹Marien Hospital Herne- Ruhr-University Bochum, Radiation Oncology, Herne, Germany

Purpose or Objective: The aim of this study was to assess the 6-months dysphagia-free survival, improvement in swallowing function, complication rate, and overall survival in patients with incurable esophageal cancer treated with palliative radiotherapy.

Material and Methods: We retrospectively reviewed data from 139 patients (median age 72 years) with advanced/recurrent incurable esophageal cancer, who were referred to 3 German radiation oncology centers for palliative radiotherapy between 1994 and 2014. Radiotherapy consisted of external beam radiotherapy (EBRT) with 30 - 40.5 Gy/2.5 - 3 Gy per fraction, brachytherapy alone (BT) with 15 - 25 Gy/5 - 7Gy per fraction/weekly and EBRT + BT (30 - 40.5 Gy plus 10 - 14 Gy with BT) in 65, 46, and 28 patients, respectively. Dysphagia-free survival (Dy-PFS) was defined as the time to worsening of dysphagia for at least one point, a new loco-regional failure or death of any cause.

Results: Median follow-up time was 6 months (range 0.57-6.0 months). Subjective symptom relief was achieved in 72 % of patients with median response duration of 5 months. The 1-year survival rate was 30%. The 6-months Dy-PFS time for the whole group was 73 ± 4%. The 6-months Dy-PFS was 90 ± 4% after EBRT, 92 ± 5% after EBRT + BT and 37 ± 7% after BT, respectively (p<0.001). Five patients lived for more than 2 years, all of them were treated with EBRT ± BT. Ulceration, fistula and stricture developed in 3, 6 and 7 patients, respectively.

Conclusion: Radiotherapy leads to symptom improvement in the majority of patients with advanced incurable esophageal cancer. The present results favor EBRT ± BT over BT alone. Due to the retrospective nature of this study, imbalances in baseline characteristics might have contributed to this finding, and further trials appear necessary.

EP-1264

Patterns of recurrence in stage pT3N0M0 thoracic ESCC patients after two-field esophagectomy

Y.X. Wang¹, L.L. Wang^{1,2}, Z.S. Li¹, M. He³, Q. Yang^{1,4}, J. Li¹, Z. Qi³, S.C. Zhu¹, X.Y. Qiao¹

¹The Fourth Hospital of Hebei Medical University, Department of Radiation Oncology, Shijiazhuang, China

²the People Hospital of Pizhou, Department of Radiation Oncology, Pizhou-Jiangsu Province, China

³The Fourth Hospital of Hebei Medical University, Department of Thoracic Surgery, Shijiazhuang, China

⁴Handan Central Hospital, Department of Radiation Oncology, Handan- Hebei Province, China

Purpose or Objective: To evaluate patterns of recurrence and identify its related factors among patients with Stage pT3N0M0 thoracic esophageal squamous cell carcinoma (ESCC) after two-field esophagectomy.

Material and Methods: 249 patients with Stage pT3N0M0 thoracic ESCC after radical esophagectomy administered in 2008 and 2009 were identified and enrolled into this study. There were 171 men and 78 women; median age was 60 years-old(33 - 78). The distributions of tumor sites were 39 in upper-, 166 in middle- and 44 in lower-thoracic segment. The median lesion length was 5 cm with a range of 2 to 12 cm. Among them, there were 98 patients received with surgery alone, 20 with radiotherapy (RT), 110 with chemotherapy alone (CT), and 21 with radiotherapy and chemotherapy (CRT). Their locoregional recurrence (LR) of tumor and distant metastasis (DM) as the endpoints were analyzed.

Results: The overall recurrence rates was 43.4% (108), LR occurred in 23.7%, DM in 10.4%, and combined recurrence in 9.2%, respectively. For 82 patients with LR, there were 15.9%(13/82) recurred in supraclavicular, 87.8% (72/82) in mediastinum, 9.8% (8/82) in upper abdomen. The rate of LR in upper-mediastinal and supraclavicular was 80%(66/82). The rate of LR were 53.8% in upper-, 33.1% in middle- and 13.6% in low-thoracic ESCC, respectively. Multivariate analysis indicate, site of lesion was the independent factors for total recurrence and LR.

Conclusion: The recurrence rate was very high in pT3N0M0 thoracic ESCC patients, LR was the mainly cause and most of it was occurred in supraclavicular and upper-mediastinum. Site of lesion was the mainly factor effected on LR. PORT should be strongly suggest in upper- and recommend in middle-, but not in low-thoracic ESCC.

EP-1265

Salvage chemoradiation for locoregional recurrences of esophageal cancer after curative treatment

P.M. Jeene¹, E. Versteijne¹, E.D. Geijsen¹, M.I. Van Berge Henegouwen², J.J.G.H.M. Bergmann³, K. Muller⁴, H.W.M. Van Laarhoven⁵, M.C.C.M. Hulshof¹

²Academic Medical Center, Academic Surgery, Amsterdam, The Netherlands

³Academic Medical Center, Academic Gastroenterology, Amsterdam, The Netherlands

⁴Radiotherapiegroep Deventer, radiation oncology, Deventer, The Netherlands

⁵Academic Medical Center, Academic Medical Oncology, Amsterdam, The Netherlands

Purpose or Objective: Locoregional recurrence pattern after curative treatment for patients with esophageal cancer has changed since the introduction of preoperative chemoradiation as standard part of curative treatment. The aim of this study was to determine the outcome of salvage definitive chemoradiation (dCRT) for a locoregional recurrence outside previously irradiated areas.

Material and Methods: We retrospectively reviewed 41 patients treated between January 2005 and December 2014 for locoregional recurrent esophageal cancer outside previously irradiated areas. All patients were treated with external beam radiotherapy (50.4 Gy in 28 fractions) combined with weekly concurrent paclitaxel and carboplatin.

Results: The median follow up period was 30 months (range 1.7-120 months). dCRT was completed according to protocol in 90%. The 1-, 3- and 5-year overall survival rate after treatment for recurrence was 74%, 35% and 30% respectively. The median local recurrence free survival (LRFSS) and overall survival (OS) time was 27 and 22 months respectively. Median OS was 14.4 months for squamous cell carcinoma (SCC) and 22.0 months for adenocarcinoma (AC) (p=0.81). Median survival after salvage dCRT for a lymph node recurrence was 48 months versus 14 months for a recurrence at the anastomosis (p= 0.009). Sixteen patients (39%) developed a locoregional recurrence after salvage dCRT, 8 out of 20 SCC and 8 out of 21 AC patients. Only 2 LR after salvage dCRT were solely outfield. In 8 of the 16 LR patients there were synchronous distant metastasis (43%).

Conclusion: Definitive chemoradiation is an effective treatment for recurrent esophageal cancer outside a previously irradiated area, and should be given with a curative intent. This holds true for recurrences of both squamous cell carcinoma and adenocarcinoma. Lymph node recurrences have a markedly better prognosis than recurrences at the anastomotic site. Locoregional failures after salvage treatment occur almost solely infield, at the site of the first recurrence.

EP-1266

Acute health-related quality of life changes after liver stereotactic ablative radiotherapy

H. Chung¹, J. Helou¹, I. Thibault¹, W. Chu¹, D. Erler¹, K. Chan¹, E. Chow¹, R. Korol¹, M. Davidson¹, L. Zhang¹

¹Odette Cancer Centre - Sunnybrook Health Science, Radiation Oncology, Toronto, Canada

Purpose or Objective: Stereotactic ablative radiotherapy (SABR) for liver metastases is currently accepted as a standard treatment option for patients with liver metastases. Multiple studies have demonstrated high rates of local control and low risk of serious toxicities. However, there is limited prospective patient-reported health-related quality of life data (HRQoL). Herein, we report the acute HRQoL changes in patients treated with SABR for liver metastases.

Material and Methods: A prospective study was performed to measure HRQoL changes in patients treated with SABR to 1-3 hepatic metastases. Doses of 30- 60 Gy in 3-5 fractions were delivered as per institutional policy depending on tumor location, histology and size. Changes in patients' self-reported HRQoL were measured using the European Organisation for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire-Core 15 Palliative (C15) at baseline (T0) and first follow-up (T1: 6 - 8 weeks post-SABR). The C15 consists of 15 questions; 2 multi-item symptom scales along with 5 single item symptom scales and a final overall QoL question. A significant change in HRQoL was defined as [T0 score-T1 score] > 0.5SD, where SD was the standard deviation of baseline values for each scale. For the overall QoL question, a significant change was defined by a 10-point or greater change from baseline.

Results: Fifty patients were included. Median age at treatment was 65 (40-88) years. Median BED10 was 98 Gy. The 4 most common primary sites of cancer were: gastrointestinal (29), breast (9), renal cell (4) and lung (4). All patients were Child-Pugh score A. Nine patients had previous hepatectomies for liver metastases. Thirty-one patients had oligometastatic diseases (5 metastases) and 19 had oligoprogression (5 metastases progressing). Forty-seven patients filled the C15 at T1 (94%). The majority of patients did not report a significant change in any of the C15 scales (table 1). For the overall QoL, 64% of the patients reported no significant change at T1, 24% had deterioration and 13% had an improvement.

C15 Scales	Significant Change from Baseline		
	No Significant Change	Improved	Worsen
Physical Functioning	32 (68.09%)	7 (14.89%)	8 (17.02%)
Emotional Functioning	31 (65.96%)	8 (17.02%)	8 (17.02%)
Overall QOL	16 (34.04%)	6 (12.77%)	25 (53.19%)
Pain	18 (38.30%)	16 (34.04%)	13 (27.66%)
Fatigue	26 (55.32%)	7 (14.89%)	14 (29.79%)
Nausea / Vomiting	38 (80.85%)	3 (6.38%)	6 (12.77%)
Appetite loss	34 (72.34%)	6 (12.77%)	7 (14.89%)
Dyspnoea	33 (70.21%)	8 (17.02%)	6 (12.77%)
Insomnia	22 (46.81%)	18 (38.30%)	7 (14.89%)
Constipation	33 (70.21%)	6 (12.77%)	8 (17.02%)
Specific Q7 Scale	30 (63.83%)	6 (12.77%)	11 (23.40%)

Conclusion: SABR offers a non-invasive option for liver metastases ablation. Acute patient-reported outcomes, as measured by C-15, for patients with liver metastases treated with SABR seem favourable. Longer follow-up is needed.

EP-1267

Induction chemotherapy followed by chemoradiotherapy in locally advanced pancreatic adenocarcinoma

J. Reure¹, J. Doyen¹, A. Falk¹, D. Lam Cham Kee¹, L. Evesque¹, P. Follana¹, E. François¹, K. Benezery¹

¹Centre Antoine Lacassagne, Radiotherapy, Nice, France

Purpose or Objective: Treating locally advanced pancreatic cancer (LAPC) remains a challenging issue. Chemotherapy or chemoradiotherapy alone have not demonstrated their efficacy. A strategy combining chemotherapy and chemoradiotherapy seems promising. Our retrospective analysis aims to evaluate effectiveness and tolerability of induction chemotherapy with Folfirinox followed by chemoradiotherapy in patients with LAPC.

Material and Methods: Nineteen patients treated for LAPC between Mars 2010 and February 2015 were retrospectively identified. These patients with unresectable disease, were initially treated with Folfirinox and then received a chemoradiotherapy with capecitabine or gemcitabine in case of stable disease. Survival was estimated with Kaplan Meier method.

Results: Median number of cycles achieved for Folfirinox was 5. Following chemotherapy, all patients had stable disease and received chemoradiotherapy with capecitabine (53%) or gemcitabine (47%). Majority of patients (63%) received radiotherapy at a dose of 50.4 Gray in 28 fractions. Toxicities are acceptable: three cases of grade 3 nausea / vomiting, three cases of grade 3 asthenia and three cases of grade 3 diarrhea were described during chemotherapy. No grade 3 toxicity was identified during chemoradiotherapy. The median follow-up time was 9 months (1-43 months). Survival rates were 93.8% at six months, 52.7% at 1 year and 21.1% at 2 years. Disease free survival rates were 35.3% at six months, 7.8% at 1 year and 0% at 2 years. Local recurrence free survival rates were 75.3% at six months, 47.3% at 1 year and 31.6 at 2 years. Distant recurrence free survival rates were 34.3% at six months, 18.3% at 1 year and 9.2% at 2 years. At the end of the therapeutic procedure, one patient received surgical resection.

Conclusion: Induction chemotherapy with Folfirinox followed by chemoradiotherapy in locally advanced pancreatic adenocarcinoma seems effective and allows very promising overall and progression free survival rates. Larger studies would be needed to conclusively confirm these observations.

EP-1268

Dosimetric parameters predict toxicity in chemoradiotherapy with nelfinavir for pancreatic cancer

D. Holyoake¹, J. Wilson¹, M. Partridge², T. Brunner³, S. Mukherjee⁴, M. Hawkins¹

¹CRUK/MRC Oxford Institute for Radiation Oncology, Advanced Radiation Oncology Group, Oxford, United Kingdom

²CRUK/MRC Oxford Institute for Radiation Oncology, Radiotherapy Physics Research Group, Oxford, United Kingdom

³University of Freiburg, Department of Radiation Oncology, Freiburg, Germany

⁴Oxford University Hospitals NHS Foundation Trust, Department of Clinical Oncology, Oxford, United Kingdom

Purpose or Objective: Gastrointestinal (GI) toxicity impedes dose escalation in radiotherapy for pancreatic cancer and limits local tumour control. Clinical data on tolerance doses for the organs of the proximal digestive system remain sparse. We analysed patterns of toxicity in patients treated with concomitant chemoradiotherapy (gemcitabine and cisplatin) with nelfinavir (hypoxia modifier) to identify associated dosimetric factors and establish predictive cut-off values to inform radiotherapy planning.

Material and Methods: Dose-volumes and acute toxicity data were analysed for 21 patients treated for locally-advanced pancreatic cancer in a prospective phase II clinical trial (ARCI, EudraCT 2008-006302-42). Radiotherapy comprised 50.4Gy in 28 daily fractions to the tumour and elective lymph nodes followed by a sequential boost to the primary tumour of 9Gy in 5#. Univariate analysis was performed to investigate association of the dose-volume received by stomach and duodenum with RTOG upper GI toxicity symptoms, and of small-bowel with diarrhoea. Receiver Operating Characteristic analysis was used to identify

strongest predictive factors and to derive optimum cut-off values for predicting likelihood of toxicity incidence.

Results: Grade ≥ 2 acute RTOG upper GI toxicity attributed to treatment was seen in 11 patients (52%), grade ≥ 3 in 3 (14%); grade ≥ 2 diarrhoea was recorded in 3 patients (14%), grade ≥ 3 in 2 (10%). In patients who experienced grade ≥ 2 toxicity, stomach V15-55 Gy (absolute volume of stomach receiving 15-55 Gy, in cm³) were significantly larger when compared to those without ($p < 0.05$, Mann-Whitney). Differences in V35 Gy and V40 Gy remained significant after Bonferroni correction ($p < 0.004$) and ROC analysis was performed to identify the most predictive cut-off values: V35 Gy 55.7cm³ and V40 Gy 43.6 cm³ (both sensitivity 0.82, specificity 0.80, Youden index = 0.62). Significant associations were not seen between duodenal dose-volume and acute toxicity, nor between small-bowel dose-volume and incidence of treatment-related diarrhoea.

Figure. Results of Mann-Whitney comparison of stomach dose-volume according to grade ≥ 2 toxicity, showing that V_{35 Gy} & V_{40 Gy} are statistically significant predictors

Conclusion: In concomitant chemoradiotherapy with nelfinavir for pancreatic cancer, stomach dosimetric parameters were associated with clinically important acute radiotherapy toxicity and thresholds were derived for predicting toxicity risk. Stomach V35 Gy and V40 Gy were most strongly predictive of acute grade ≥ 2 side effects.

EP-1269

Dose tolerance of small bowel in patients treated with radiochemotherapy for pancreatic cancer

L. De Filippo¹, G.C. Mattiucci¹, N. Dinapoli¹, M. Boccardi², V. Pollutri¹, M. Bianchi¹, R. Canna¹, S. Chiesa¹, G. Macchia², A. Morganti³, V. Valentini¹

¹Università Cattolica del Sacro Cuore -Policlinico A. Gemelli, Radiotherapy Division, Rome, Italy

²Fondazione di Ricerca e Cura Giovanni Paolo II-Università Cattolica S. Cuore, Department of Radiotherapy, Campobasso, Italy

³Department of Experimental- Diagnostic and Specialty Medicine - DIMES - University of Bologna- S.Orsola-Malpighi Hospital, Radiation Oncology Unit, Bologna, Italy

Purpose or Objective: Tolerance of small bowel is the dose limiting factor in radiation therapy for abdominal neoplasms. Bowel constraints for treatment planning in abdominal radiotherapy derive from scientific publications of pelvic tumors. This study has the aim to evaluate dose tolerance of small bowel detecting acute toxicities in patients with pancreatic cancer treated with radiochemotherapy.

Material and Methods: Patients with pancreatic cancer were treated between 2009 and 2014 with 3D-conformal radiotherapy with a total dose of 5040 cGy and conventional fractionation. Chemotherapy with gemcitabine or fluoropyrimidine was simultaneously administered. Nausea, vomit and loss of weight, as acute upper gastrointestinal (GI) toxicities, were scheduled using RTOG scale. In all patients small bowel loops and bowel sac were contoured using QUANTEC guidelines and DVHs were analyzed for this

structures using R statistical software (<http://www.R-project.org>).

Results: Forty-three patients with a median age of 66 years (range 42-79), 14 resected and 29 unresected, were analyzed. Fourteen (32%) patients reported no upper GI toxicity; on 8 (19%), 12 (28%) and 9 (21%) patients were observed respectively grade 1, 2 and 3 toxicity. No grade 4 toxicity was recorded. Nineteen patients discontinued radiotherapy but all of them completed the treatment. Analyzing V Dose on DVHs by logistic regression, small bowel loops V36 Gy resulted as the parameter which most influenced upper GI G1 or higher Toxicity ($p < 0.05$). Multivariate analysis showed no impact of surgery on upper GI toxicity.

Conclusion: Our preliminary analysis suggests that new constraints for radiochemotherapy in upper GI cancer could be upgraded. Our study has to be confirmed on a larger sample.

EP-1270

SBRT for liver metastases from low grade neuroendocrine tumors

M. Bignardi¹, A. Huscher¹, M. Centurioni¹, M.M. Colangione¹, D. Barbieri¹, M. Galelli², A. Zaniboni³

¹Fondazione Poliambulanza, Radiation Oncology Unit, Brescia, Italy

²Fondazione Poliambulanza, Medical Physics, Brescia, Italy

³Fondazione Poliambulanza, Oncology Department, Brescia, Italy

Purpose or Objective: Specific results of SBRT for liver metastases from rare tumors have been reported scarcely. This applies also to metastases from low grade neuroendocrine tumors (NET), either derived from gastrointestinal organs or from an unknown primary site. Here we report two cases of multiple liver metastases from low grade NET repeatedly treated by means of SBRT, achieving the outcome of long-term local control.

Material and Methods: From March 2011 to September 2015 49 SBRT courses were delivered to 39 patients for liver metastases from different primaries. All courses were given by VMAT with 6 MV photons, image guided by CBCT in every fraction. Since 2013, deep inspiration breath hold was adopted in order to control organ motion. Two patient had metastases from well differentiated neuroendocrine tumors, one from an unknown primary (patient A), the other from a pancreatic primary (patient B). Patient A underwent two SBRT courses, both in 2011, the first one on segment 6 (CTV volume 25 ml, CTV dose 75 Gy, PTV 50 Gy, in 3 fractions), the second one on two adjacent metastases, respectively in segment 7 and 8 (total CTV volume 54 ml, CTV dose 60 Gy, PTV 50 Gy, in 3 fractions). Patient B received three courses, respectively in 2013, 2014 and 2015. The first SBRT was delivered on segment 6 (CTV volume 38 ml, CTV dose 50 Gy, PTV 45 Gy, in 5 fractions), the second on segment 8 (CTV volume 30 ml, CTV dose 50 Gy, PTV 45 Gy, in 5 fractions), the last on segment 4 (CTV volume 44 ml, CTV dose 50 Gy, PTV 45 Gy, in 5 fractions). Patient A was found to be somatostatin receptor-negative, thus he was followed up mainly by serial CT scans; also, his disease status matched well to trends of two biomarkers (chromogranin A and gastrin). Patient B was followed up by alternating CT scans and PET/CT-68Ga-DOTATOC.

Results: At last follow up patient A achieved long-term local control in S6 metastasis (45 months) as well as in S7-8 (42 months), while showing disease progression at a new liver site at 45 months after first SBRT. At last follow up patient B achieved local control in all sites (S6: 30 months; S8: 13 months; S4: 6 months) with a durable partial PET response in S8 and S4 and a complete PET response in S6. Disease progression took place in two bone sites at 30 months after first SBRT, without any concomitant liver progression.

Conclusion: these favorable results in large volume liver metastases from low grade NET, although derived from only two anecdotal cases, give support to the concept that the outcome of SBRT is relatively independent from tumor type, being mainly mediated by an ablative effect. Also they represent a typical example showing how repeat liver SBRT may lead to a significant delay in disease progression although without achieving a definitive cure.

EP-1271

Stereotactic body radiation therapy for malignant tumours of the pancreas

X. Chen¹, E. Sanchez¹, A. Montero¹, O. Hernando², M. Lopez¹, J. Garcia³, J.M. Perez⁴, R. Ciervide¹, J. Valero¹, M. Garcia-Aranda¹, R. Alonso², D. Zucca³, M.A. De la Casa³, B. Alvarez¹, S. Payano¹, J. Marti³, L. Alonso⁴, P. Fernandez-Leton³, C. Rubio¹

¹Hospital Universitario HM Sanchinarro, Radiation Oncology Department, Madrid, Spain

²Hospital Universitario HM Puerta del Sur, Radiation Oncology Department, Madrid, Spain

³Hospital Universitario HM Sanchinarro, Medical Physics Department, Madrid, Spain

⁴Hospital Universitario HM Puerta del Sur, Medical Physics Department, Madrid, Spain

Purpose or Objective: To review stereotactic body radiation therapy (SBRT) safety and local control utility in malignant tumor of the pancreas based in a single center experience since February 2014.

Material and Methods: A systematic review was done. Thirteen patients were treated with SBRT. Eleven patients had a primary pancreatic tumor and two patients had metastatic affection of the pancreas. In those patients with primary pancreatic cancer, four patients were treated with a radical intent, five as a part of a neoadjuvant treatment and four patients with a palliative intent. All of the treated tumors had a diameter bigger than 2 cm. At least 2 fiducials were located into the tumor, guided by endoscopic ultrasound. All the treatments included CT or PET-CT for GTV delineation, intensity-modulated radiation therapy (IMRT) and image-guided radiation therapy (IGRT) with intrafraction control of tumor motion with a Novalis Exactrac Adaptive Gating System. 50 Gy in 10 fractions were prescribed in eleven patient, one patient was treated with 35Gy in 5 fractions and one patient was treated with 40Gy in 10 fraction.

Results: Pancreatic SBRT was very well tolerated in our cohort of patients. No grade 3 or higher toxicity was observed. Only 3 patients developed grade 2 epigastric pain and/or grade 2 nausea/vomiting. The median patient age was 62 years old (range 36 - 86 years) and the median follow-up was 14 months (range 2 - 18 months). Five patients underwent surgery after SBRT. The median overall survival was 14.5 months (range 2.4 - 18.2 months), with 65.3% survival at one year. Median survival time is 15 month (range 12 - 17 months). Median time to local progression has not been reached.

Conclusion: In our experience, gating SBRT for pancreatic tumor is a well-tolerated feasible treatment. Most patients are free from local progression, but overall survival remains poor. Prospective studies are needed to define the role of SBRT for pancreatic tumors.

EP-1272

Stereotactic radiotherapy in pancreatic cancer. Review of two different treatment approaches

E. Gkika¹, S. Kirste¹, S. Adebahr¹, T. Schimek-Jasch¹, R. Wiehle¹, K. Zirlík², U. Wittel³, U. Nestle¹, A.L. Grosu¹, T. Brunner¹

¹Uniklinik Freiburg, Radiation Oncology, Freiburg, Germany

²Uniklinik Freiburg, Medical Oncology, Freiburg, Germany

³Uniklinik Freiburg, Department of Surgery, Freiburg, Germany

Purpose or Objective: Stereotactic body radiotherapy (SBRT) in pancreatic cancer can be limited by its proximity to critical organs at risk (OAR) of the upper abdomen. In this study we evaluate the toxicity and efficacy of two different treatment approaches.

Material and Methods: Patients with recurrent or oligometastatic pancreas cancer were treated with SBRT. The planning target volume (PTV) was created through a 4 mm expansion of the internal target volume (ITV) based on a four dimensional CT (4D-CT). All patients were treated with intensity modulated radiation therapy (IMRT). In some cases we created a sub-volume, in order to reduce the risk of toxicity in critical adjacent OARs without compensating the whole PTV. This sub-volume was defined as a simultaneous integrated protection (SIP) PTV. The SIP consisted of the interface of the PTV with the planning risk volume (PRV) of a specific vulnerable structure at which we prescribed a pre-defined reduced dose.

Results: Between 2009 and 2014, 18 patients with 23 lesions were treated in our institution. Seven patients were treated for a local recurrence, nine were treated for oligometastases (liver, lymph nodes) and two patients were treated for both. Of these lesions 11 were treated with SIP and 12 were treated without SIP. The median follow up was 10.8 months (range 1.2-40.3 months). The freedom from local progression (FFLP) at 6 and 12 months was 90% and 84% respectively. The overall survival (OS) rates at 6 months and 12 months after SBRT were 77% and 54%, respectively. Two patients (11%) experienced grade >3 acute toxicity (mechanical ileus, gastrointestinal bleeding) and 2 patients (11%) experienced a grade > 3 late toxicity (cholangitis, bleeding).

Conclusion: Local control and overall survival after SBRT in this high risk group of patients with pancreatic cancer were excellent despite of dose sacrifice in half of the patients when OARs were close to the PTV, with overall favourable toxicity.

EP-1273

Clinical results of stereotactic ablative radiotherapy in the treatment of liver metastases

M. Fiore¹, P. Trecca¹, L. Trodella¹, C. Rinaldi¹, P. Matteucci¹, S. Silipigni¹, A. Iurato¹, S. Ramella¹, R. D'Angelillo¹, L. Trodella¹

¹Università Campus Biomedico, Department of Radiation Oncology, Roma, Italy

Purpose or Objective: To evaluate the efficacy and feasibility of stereotactic ablative radiotherapy (SABR) in the treatment of liver metastases.

Material and Methods: We retrospectively analyzed patients with 1-2 secondary liver lesions treated with SABR. The total dose prescriptions were 30 Gy, 37.5 Gy and 45 Gy on three consecutive days in 42.8%, 22.8% and 34.4% of patients respectively. The dose was prescribed to the 80% isodose line covering the PTV. The primary endpoints were in field local control and toxicity; the secondary endpoint was survival rates.

Results: Between March 2007 and May 2015, 30 patients (17 males, 13 females) with 36 liver metastases were treated. The mean age was 66 years (range, 40-90 years). Twenty-five patients (83.3%) had a single hepatic lesion and the remaining 5 patients (16.7%) two hepatic lesions. Twenty patients (64.5%) had extrahepatic stable disease. The most frequent sites of primary tumor were colorectal (58%) and breast (20%). The majority of the lesions treated (75.6%) had a diameter of less than 3 cm. With a median follow-up of 21 months (range 2.3-69.8 months) for all patients, "in field" local response rate was 90%. No patient developed a toxicity greater than grade 2 according to CTC scale v4.02 and no radio-induced liver disease (RILD) was recorded. One-year LC and two-year LC were 62% and 39% respectively. One-year and two-year PFS were 46% and 25% (median, 11 months). One-year, two-year and three-year OS were 89%, 69 and 42%

respectively, with a median survival time, calculated from the date of metastasis and last follow-up or death, of 29.8 months.

Conclusion: These data suggest that stereotactic ablative radiotherapy (SABR) is a safe, non-invasive and effective option in the treatment of liver metastases.

EP-1274

Prognostic factors of gastric cancer treated with adjuvant radiochemotherapy

M. Martin Sanchez¹, M.A. Perez Escutia², M.C. Peña Sanchez², D. Lora Pablos³, S. Guardado Gonzalez², S. Pedraza Fernandez², T.C. Chavez Jimenez², A. Moreno Hurtado⁴, M. Casado Jimenez⁵, J.P. Perez-Regadera Gomez²

¹Hospital Ramón Y Cajal, Radiation Oncology, Madrid, Spain

²Hospital 12 De Octubre, Radiation Oncology, Madrid, Spain

³Hospital 12 De Octubre, Investigation, Madrid, Spain

⁴Grupo Imo, Radiation Oncology, Madrid, Spain

⁵Hospital De La Princesa, Radiation Oncology, Madrid, Spain

Purpose or Objective: The aim of this study was to investigate the outcome and prognostic factors for patients with locally advanced gastric cancer (LAGC) treated with adjuvant radiochemotherapy, according Macdonald scheme.

Material and Methods: Between May 2004 and October 2014, a total of 106 patients, 70 men and 36 women, with locally advanced gastric cancer were treated in the University Hospital 12 de Octubre, Spain. The mean age was 57 years. The mean follow-up was 96.48 months. The most common tumor location was antrum (29.25%). The majority of tumors were T3 (52.83%) or T4 (22.64 %) and 86.79 % had nodal metastases, with an average of 8.24 nodes involved. Predominant histological subtype was diffuse (43.4%) and poorly differentiated (grade 3, 50%). Complete resection (R0) was achieved 84.91%, whereas microscopic residual disease (R1) was found in 13.21%. Survival was calculated by Kaplan-Meier and method and differences were assessed by the Log-rank test. Multivariate analysis was used Cox proportional hazards regression model.

Results: A total of 50 (47.16 %) patients relapsed; 16 (15.09%) locoregional, 13 (12.26%) peritoneal, 18 (16.98%) distant metastases and 3 (2.83%) unknown. The overall survival (OS), disease-free survival (DFS), locoregional failure-free survival (LFS) rates to three years were 48.75%, 46.27% and 76.72% and to five years were 32.11%, 38.78%, 69.67% respectively. In univariate analysis, T stage (T1-T2), N negative stage and R0 resection were associated with better survival ($p < 0.05$) for OS and only N negative stage for DFS and LFS. In the multivariate analysis identified only R0 resection as an independent predictor of better survival ($p < 0.05$) for OS and DFS.

Conclusion: In this study, the prognostic factors associated with better survival in patients with LAGC treated with adjuvant radiochemotherapy were: T stage (T1-T2), N negative stage and R0 resection ($p < 0.05$). Complete R0 resection also can be considered as independent prognostic factor of better survival ($p < 0.05$)

EP-1275

Influence of pretreatment blood parameters on the outcome of gastric cancer patients.

A. Namysl-Kaletka¹, J. Wydmanski¹, A. Tukiendorf², E. Wolny-Rokicka³, I. Wzietek¹, D. Gabrys¹

¹Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology- Gliwice Branch- Poland., Radiotherapy Department, Gliwice, Poland

²Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology- Gliwice Branch- Poland., Department of Epidemiology and Silesia Cancer Registry, Gliwice, Poland

³Karol Marcinkowski Regional Hospital, Department of Radiotherapy, Zielona Góra, Poland

Purpose or Objective: Activation of coagulation and fibrinolysis are found among gastric cancer patients. The

ones with non-metastatic gastric cancer are at risk for thrombotic events due to the combined increase in fibrinogen plasma levels and thrombin formation. It could be associated with a higher risk of local invasion and might be important poor predictive and prognostic factor. In our study, we sought the associations between blood parameters and outcome

Material and Methods: The study examined eighty-nine patients with biopsy-proven, operable gastric adenocarcinoma, with no evidence of distant metastases. Pre-operative fibrinogen, PT, APTT and INR levels were measured before surgery. Complete blood count were also collected before initiation of therapy. All patients underwent surgery as a primary treatment. The survival function was computed using Kaplan-Meier method. The overall survival (OS), Disease-free survival (DFS), time to distant metastases (DM) and locoregional control (LRC) were calculated from the date of surgery. Multivariate analyses and characteristic (ROC) have been done.

Results: In Multivariate Cox analysis higher level of WBC was associated with worse local control ($p=0,0024$), and shorter overall survival ($p=0,0035$). Shorter Prothrombin Time was correlated with better overall survival ($p=0,0280$). Higher Fibrinogen level has caused better local control ($p=0,0280$). No other correlation between DFS, LRC, DM and OS and other blood parameters were observed in multivariate analyses.

Conclusion: The level of White Blood Cells, Fibrinogen and Prothrombin Time were found to be useful prognostic factor which influenced overall survival and local control. However, further prospective investigations are necessary to assess the predictive value of those factors.

EP-1276

Stereotactic robotic body radiotherapy for patients with unresectable hepatic oligometastases.

P. Berkovic¹, P. Viet Nguyen¹, A. Gulyban¹, D. Dechambre¹, P. Martinive¹, N. Jansen¹, P.A. Coucke¹

¹C.H.U. - Sart Tilman, Radiotherapy Department, Liège, Belgium

Purpose or Objective: To evaluate the feasibility, efficacy and toxicity of robotic SBRT for the treatment of unresectable hepatic oligometastases.

Material and Methods: Between 09/2010 and 01/2013, 15 consecutive patients (12 female, 3 male, median age at treatment: 70.5, range: 57-85 years) with up to 3 synchronous or metachronous hepatic oligometastases were referred for Cyberknife treatment (Accuray Incorporated, Sunnyvale, CA) at our center. In order to enable tumor tracking, gold fiducial markers were inserted around the lesion 2 weeks prior to each treatment. The treatment was delivered using the Synchrony Respiratory Tracking System to continuously track fiducial position and adjust for respiratory motion during treatment. Treatment planning was performed using the Multiplan TPS (v4.6, Accuray) with Raytracing algorithm, and was retrospectively recalculated using a Monte Carlo dose calculation algorithm (v5.1). The primary endpoint of this study was local control (LC), assessed with either contrast enhanced spiral CT or MRI. Secondary endpoints were liver and distant progression free-survival (liverPFS and DFS), overall survival (OS) and treatment toxicity, evaluated using the Common Terminology Criteria for Adverse Events v4.0. (Institute NC, NIH publication 2009). Statistical analysis was performed using R software (3.1.1, R Development Core Team 2010).

Results: A total of 20 metastatic lesions were treated from primary colorectal (7), breast (7), unknown primary (3), melanoma (2) and stomach (1) cancer. The mean GTV and PTV volumes were 23.8cc (Standard deviation (SD):23) and 74.5cc (SD:45.3) respectively. All treatments were delivered 3x/week in a median three fractions (range: 3-6) to a median dose of 45 Gy (range: 30-45), prescribed to the 80% isodose line. This corresponds to an equivalent 2-Gy dose of 93.75Gy,

when considering a α/β ratio of 10. The mean GTV and PTV D98% and D50% were 41.6Gy (SD:7.7) and 46.5Gy (SD:6.8), 39.3Gy (SD:7) and 46.1Gy (SD:6.6) respectively. Each treatment was delivered by an average of 158 beams. All dose constraint parameters proposed by Timmerman were respected (Semin.Radiat.Oncol.2008). Furthermore, the average difference between the Raytracing and the Monte Carlo algorithm was 0.43% on these values. At a median follow up of 30.9 months (range: 5.7-50.3), the 1 and 2-year LC rates remained stable at 83.5%. The 1 and 2-year liver PFS and the DFS rates were 57.1%, 46.1% and 75.5%, 64.4% respectively. The 2 year OS was 60.6% (Figure 1). No acute grade 2 toxicities were observed. Three patients reported late grade 2 gastro-intestinal toxicities. No late grade 3 nor 4 toxicities were reported.

Conclusion: Robotic SBRT is feasible, safe and very well tolerated for the treatment of hepatic oligometastases. Our outcome results compare favorably from previous published studies of SBRT. It could represent a valid treatment option in the multimodality treatment of unresectable hepatic oligometastases.

EP-1277

Adjuvant chemoradiation for resected gallbladder cancer: single center 25-year experience

C. Solé¹, V. Solé²

¹Instituto de Radiaciones Médicas, Radiotherapy, Santiago, Chile

²Universidad San Sebastian, Medicine School, Santiago, Chile

Purpose or Objective: Patients with locally advanced gallbladder cancer (LAGC) have a dismal prognosis. We investigated outcomes and risk factors for overall survival (OS) in patients treated with radical surgery and adjuvant chemoradiotherapy (CRT).

Material and Methods: A total of 212 patients with LAGC [\geq cT3 59% and/or cN+ 52%) were studied. For survival outcomes potential associations were assessed in univariate and multivariate analyses using the Cox proportional hazards model. We constructed a risk scoring system in which points were assigned to each risk factor by dividing each β coefficient in the final model by the lowest β coefficient and rounding to the nearest integer.

Results: Median follow-up was 46.2 months (2-235). Five-year OS for the entire cohort was 50.2%. In multivariate analysis higher pT stage [HR 1.73, $p = 0.01$], R1 resection [HR 5.06, $p < 0.01$], and number of surgical procedures [HR 1.41, $p = 0.05$] were associated with an increased risk of death. A risk model was generated to determine a prognostic index for individual patients with LAGC.

Conclusion: Overall results after multimodality treatment of LAGC are promising. Classification of risk factors for death has contributed to propose a prognostic index that could allow us to guide risk-adapted tailored treatment

EP-1278

CCRT with or without surgery using Helical Tomotherapy or IMRT for esophageal cancer patients

P.-Y. Hou¹, W. Le-Jung¹, H. Chen-Hsi¹, S. Pei-Wei¹

¹Far Eastern Memorial Hospital, Radiation Oncology, New Taipei City, Taiwan

Purpose or Objective: To retrospectively review the treatment outcome of esophageal cancer in our hospital, and compare the radiotherapy efficacy and toxicity of helical tomotherapy with step-and-shoot Intensity Modulation Radiation Therapy (IMRT).

Material and Methods: Between 2007 and 2012, 108 consecutive patients with locally advanced esophageal cancer, cT2-4N0-3M0-1, received neoadjuvant concurrent chemoradiotherapy (CCRT) followed by esophagectomy or definitive CCRT treatment course respectively. The radiotherapy was delivered with helical tomotherapy in 56 patients, and with conventional IMRT in other 52 patients. We had evaluated outcomes with radiation dose, overall survival rate (OS), disease-free survival rate (DFS), and toxicity of radiation pneumonitis.

Results: The median follow-up duration was 16 months. The median time of overall survival among all patients was 15 months. The treatment modality with neoadjuvant CCRT followed by esophagectomy had favorable OS (47.6% : 10.4%, $p = 0.014$), DFS (42.9% : 23.9%, $p = 0.013$), and local recurrence (33.3% : 50.7%, $p = 0.574$) comparing with definitive CCRT. No significant difference outcome of OS was found between tomotherapy and conventional IMRT. The patients using tomotherapy had less incidence and severity of radiation pneumonitis (only one patient with less than grade 3 radiation pneumonitis in tomotherapy group; 5 patients < grade 3 and 2 patients > grade 3 radiation pneumonitis in conventional IMRT group).

Conclusion: In our study, the treatment outcomes of neoadjuvant CCRT followed by esophagectomy for esophageal cancer are better in OS, DFS, and local control than definitive CCRT. Tomotherapy may reduce lung dose, and probably reduce incidence and severity of radiation pneumonitis when compared with conventional IMRT.

EP-1279

SABR in inoperable liver oligometastatic patients and radioresistant primary tumors.

E. Clerici¹, T. Comito¹, L. Cozzi¹, A. Fogliata¹, A. Tozzi¹, C. Iftode¹, C. Franzese¹, P. Navarra¹, G.R. D'Agostino¹, P. Mancosu¹, F. Lobefalo¹, S. Tomatis¹, M. Scorsetti¹

¹Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

Purpose or Objective: To evaluate the feasibility and efficacy of Stereotactic Ablative Body Radiotherapy (SABR) in the treatment of liver metastases from radioresistant primary tumors.

Material and Methods: Patients with inoperable liver metastases from renal cancers, melanoma and sarcomas, not amenable to other locoregional therapies, treated with SABR were included in this retrospective study. Inclusion criteria were: Karnofsky Performance Status of 70; no evidence of progressive or untreated gross disease outside the liver; maximum tumor diameter less than 6 cm; no more than 3 liver lesions; normal liver volume greater than 1000 cm³; adequate liver function. Dose prescription ranged from 75 to 50.26Gy in 3 consecutive fractions, delivered with RapidArc VMAT, with 10MV FFF photons. Local control was defined according to RECIST criteria. Toxicity was classified according to the Common Toxicity Criteria (CTC) version 3.0.

Results: From April 2010 to October 2015, 20 patients were treated with SABR for a total number of 24 lesions. Median follow-up was 21 (range 6-58) months. In field progression was observed in 1 patient for a total of 2 lesions. One and 2

years actuarial local control (LC) rates were 100% and 88%, respectively. Median overall survival (OS) was 24 months. Actuarial OS rates at 1 and 2 years were 83% and 38%, respectively. Median progression-free survival (PFS) was 7 months. No patients experienced radiation-induced liver disease (RILD) or grade >3 toxicity.

Conclusion: SABR is an effective, safe and non-invasive alternative for the treatment of inoperable liver metastases from radioresistant tumor.

Preoperative short vs. long course chemoradiation with delayed surgery for rectal cancer patients

M.J. Chung¹, W.K. Chung¹, D.W. Kim¹, S.H. Lee², S.K. Jeong³, J.K. Hwang⁴, C.S. Jeong⁵

¹Kyung Hee University Hospital at Gangdong, Department of Radiation Oncology, Gangdong-Gu- Seoul, Korea Republic of

²Kyung Hee University Hospital at Gangdong, Department of Surgery, Gangdong-Gu- Seoul, Korea Republic of

³Yang Hospital-Seoul, Department of Surgery, Seoul, Korea Republic of

⁴Yang Hospital- Namyangju, Department of Surgery, Seoul, Korea Republic of

⁵Hansol Hospital, Department of Surgery, Seoul, Korea Republic of

Purpose or Objective: To compare the clinical outcomes between short course chemoradiotherapy (SCRT) and long course chemoradiotherapy (LCRT) with delayed surgery for locally advanced rectal cancer patients retrospectively.

Material and Methods: Seventy two patients, staged cT3-4N0-2M0, had participated in a multicenter study. With regard to the SCRT arm, a total dose of 25 Gy of radiotherapy was delivered in 5 fractions and chemotherapy was given on days 1-3 and delivered 5-Fluouracil and Leucovorin 400mg/m² by bolus injection on day 1 and 5-Fluouracil 1200mg/m² by continuous infusion on day 2 and 3. And additional two cycles of chemotherapy was administered before the surgery. With regard to the LCRT arm, a total dose of 50.4Gy of radiotherapy was delivered in 28 fractions. Chemotherapy was a bolus injection of 5-Fluouracil and leucovorin for the first and last week of radiotherapy. Surgery was performed during 6 - 8 weeks after completion of the radiotherapy in the both group.

Results: From 2010 to 2015, 19 patients were treated using the SCRT and 53 patients were treated using the LCRT. Median Follow-up was 25.0 months (range, 3.0-58.0 months). The patient characteristics of the both arms were not significantly different. The sphincter saving rate (89.5 %, 94.3%), complete remission (21.1%, 13.2%), downstaging (47.4%, 26.4%), treatment complications including wound dehiscence, bowel adhesion, hematologic toxicities of the SCRT were not inferior results to those of the LCRT. Locoregional recurrence was seen in 1 (5.3%) patients in the SCRT, 1 (1.9%) in the LCRT (p=0.442). Distant metastasis was seen in 1 (5.3%) patients in the SCRT, 12 (22.6%) patients in the LCRT (p=0.162). The 2-year disease free survival, overall survival in the SCRT and LCRT arms were 93.8% and 74.0% (P =0.338), 90.0% and 91.2% (P =0.448), respectively.

Conclusion: The preoperative SCRT was an effective and safe modality. We got comparable clinical outcomes to the LCRT for locally advanced rectal cancer. We get a further study for randomized clinical study to compare between SCRT and LCRT.

EP-1281

DVH relationships in rectal cancer: effects of contouring methods and patient positioning

N. Bennion¹, Y. Lei¹, V. Verma¹, A. Bhirud¹, G. Blessie¹, C. Lin¹

¹UNMC, Radiation Oncology, Omaha, USA

Purpose or Objective: Preoperative chemoradiation for rectal cancer may cause acute bowel toxicity. Efforts to reduce such side effects include tracking bowel DVH relationships and proper patient positioning to minimize the risks. Our aim is to quantify volume and DVH relationship differences between prone and supine positioning as well as compare different contouring methods to account for such changes.

Material and Methods: Nineteen patients undergoing preoperative chemoradiation for rectal cancer were simulated supine and prone for plan comparison. Thirty-eight plans were compared, 19 prone, and 19 supine. Correlating prone and supine plans were constructed with similar target volumes, beam energies and arrangements. A single physician contoured the bowel bag (BB) and individual bowel loops (BL) with the superior border 1 cm above the PTV per RTOG guidelines. If the RTOG recommended boundaries fell short of the 5 Gy isodose line, additional CT slices were contoured on BB and BL structures to the 5 Gy isodose line and labeled as extended contours. Tabular dose-volume histograms were utilized to assess the volume of bowel receiving 5-50 Gy in 5 Gy intervals. Wilcoxon signed rank test as well as Spearman's correlation tested all variables.

Results: The target volumes showed no statistical differences between supine and prone positioning (p = 0.7344, 0.8203, 0.3594). The median reduction in volumes from supine to prone contours for the extended contour BB, extended contour BL, RTOG BB, and RTOG BL was 316 cc, 156 cc, 324 cc, and 115 cc respectively. Wilcoxon signed rank sum test showed significantly reduced volumes at each dose level (5-45 Gy at 5 Gy intervals) in the prone group compared to supine (range p = 0.0039- 0.0391). All combinations of contours (RTOG and extended contours of BB and BL) showed similar statistically significant reductions in volumes receiving each dose (except 50 Gy) in the prone position. All RTOG defined BB and BL volumes required additional contours to account for the entire volume receiving 5 Gy. RTOG contours required a median of 359 cc to the BB (range 209-1375 cc) and 113 cc to BL (range 37-271 cc).

Conclusion: Volume of bowel was less for nearly all dose levels (5 - 45 Gy) if the patient was positioned prone. Bowel loop contours correlated with bowel bag contours; suggesting they can be used interchangeably. BB and BL contoured volumes, by the RTOG definition, consistently fell short of the 5 Gy isodose line where the "extended contours" were a more complete DVH representation.

EP-1282

Does blood glucose level normalisation improve PET-based response prediction in rectal cancer?

I. Joye¹, A. Debucquoy², A. Wolthuis³, A. D'Hoore³, E. Van Cutsem⁴, V. Vandecaveye⁵, X. Sagaert⁶, C. Deroose⁷, K. Haustermans¹

¹KU Leuven/University Hospitals Leuven, Department of Radiation Oncology, Leuven, Belgium

²KU Leuven, Department of Oncology, Leuven, Belgium

³University Hospitals Leuven, Department of Abdominal Surgery, Leuven, Belgium

⁴University Hospitals Leuven, Department of Digestive Oncology, Leuven, Belgium

⁵University Hospitals Leuven, Department of Radiology, Leuven, Belgium

⁶University Hospitals Leuven, Department of Pathology, Leuven, Belgium

⁷University Hospitals Leuven, Department of Nuclear Medicine, Leuven, Belgium

Purpose or Objective: The standard treatment for locally advanced rectal cancer (LARC) is preoperative chemoradiotherapy (CRT) followed by total mesorectal excision (TME). The tumoral response to CRT is highly heterogeneous and about 15-30% of the patients achieve a pathological complete response (pCR). 18F-FDG PET/CT is

promising in response prediction and a reduction in maximal standardized uptake value (SUVmax) has been correlated with therapy response. In a prospective study, we investigated whether PET-based response prediction improves with blood glucose level (BGL) normalization.

Material and Methods: Eighty-five patients with LARC were treated with CRT (45 Gy in 1.8 Gy fractions, 5-FU (225mg/m²) followed by TME after 6-8 weeks. Patients underwent 18F-FDG PET/CT scans at three time points: prior to CRT, after 10-12 fractions and prior to surgery. PET data were normalized to the BGL measured before FDG injection. Three normalization methods were compared: linear correction according to Janssen et al (SUVnormalized=SUVmax*(glycemia/100)), and two corrections suggested by Keramida et al (SUVnormalized = (SUVmax*glycemia)/SUVmeanliver and SUVnormalized = SUVmax*e(0.099*glycemia)). Treatment response was classified as pCR, ypT0-1 and ypT0-2. PET parameters were compared with pathological response using Mann-Whitney U tests. ROC analysis was employed to investigate the performance of the glycemia corrected and uncorrected PET parameters. A p-value ≤0.05 was considered statistically significant.

Results: Thirteen patients achieved pCR while ypT0-1 and ypT0-2 response was observed in 23 and 50 patients respectively. While the value of PET obtained prior to (SUVmaxpre) and during (SUVmaxduring, RI SUVmaxduring) CRT was limited, presurgical scans (SUVmaxpost, RI SUVmaxpost) appeared useful for response prediction (see Table and Figure). The performance of PET-based response assessment increased with a less stringent definition of tumor response. There were no major differences in the predictive performance of PET-based response parameters before and after BGL normalization and between different normalization methods.

Table: Correlation of PET-based parameters with treatment response.

	pCR p-value	ypT0-1 p-value	ypT0-2 p-value
SUVmax_{pre}			
Uncorrected	0.5798	0.0971	0.0207
Linear correction	0.7554	0.3045	0.1407
Correction to SUVmean _{liver}	0.7217	0.5616	0.1541
Exponential correction	0.8637	0.2491	0.0714
SUVmax_{during}			
Uncorrected	0.1861	0.0171	0.0219
Linear correction	0.4282	0.0309	0.1517
Correction to SUVmean _{liver}	0.2213	0.0126	0.0800
Exponential correction	0.2808	0.0183	0.0767
SUVmax_{post}			
Uncorrected	0.0406	0.0003	0.0003
Linear correction	0.0512	0.0005	0.0015
Correction to SUVmean _{liver}	0.0600	0.0014	0.0013
Exponential correction	0.0434	0.0003	0.0008
RI SUVmax_{during}			
Uncorrected	0.5506	0.3507	0.7351
Linear correction	0.4282	0.3394	0.7968
Correction to SUVmean _{liver}	0.3784	0.2988	0.7769
Exponential correction	0.7445	0.4847	0.9141
RI SUVmax_{post}			
Uncorrected	0.0158	0.0004	0.0004
Linear correction	0.0134	0.0002	0.0006
Correction to SUVmean _{liver}	0.0097	0.0004	0.0018
Exponential correction	0.0119	0.0002	0.0006

Figure: Area under the curve (AUC) of response prediction

Conclusion: Especially presurgical 18F-FDG PET/CT is useful for the prediction of the tumoral response to CRT in rectal cancer. Blood glucose level normalization has little effect on the performance of PET-based response prediction and there is no large difference in performance between normalization approaches.

EP-1283

Outcomes and toxicities in advanced anal cancer treated with radical VMAT chemoradiotherapy

E. Jiad¹, D. Woolf¹, N. Pasha¹, S. Ball¹, S. Raouf¹

¹Queen's Hospital, Oncology, London, United Kingdom

Purpose or Objective: To investigate the outcomes of advanced anal carcinoma treated with radical Volumetric Modulated Arc Therapy (VMAT) chemoradiotherapy.

Material and Methods: From January 2013 - March 2015, twenty patients (median age 64; Range 46-83; M:F 4:16) with advanced anal carcinoma (T3-T4 or N1-N3) were treated with radical VMAT chemoradiotherapy at our hospital.

The clinical target volume (CTV) included the anal canal, primary tumour, mesorectum, presacral nodes, interior iliac nodes and inguinal nodes. All Patients were prescribed Mitomycin C (12mg/m² D1; capped at 20mg) and capecitabine (600mg/m² BD D1-14 and D22-35) chemotherapy concurrently with radiotherapy.

Results: All patients had histologically confirmed squamous cell carcinoma. Treatment was completed in all patients. The standard dose prescription was 50.4Gy in 28 fractions for T3 tumours (8 patients). T4 or node positive cancers received either a simultaneous integrated boost of 2.8Gy to a total dose of 53.2 Gy in 28 fractions (9 patients) or up to a further 3 fractions to a maximum total dose of 56Gy (3pts).

At time of analysis (Median follow up 22.3 months) one patient (5%) had a local recurrence and two patients (10%) had developed metastatic disease, all of which are currently being managed with palliative intent.

The only significant toxicities recorded were local skin erythema and desquamation. Additionally one patient (5%) developed secondary myelodysplastic syndrome which was

presumed to be related to his chemotherapy; and died of neutropaenic sepsis.

Conclusion: Our study shows VMAT chemoradiotherapy delivers excellent local control in the treatment of advanced anal cancers. Treatment was well tolerated and all patients completed the prescribed course of radiotherapy. More data is needed and longer term follow-up to confirm clinical outcomes.

EP-1284

Predictive factors of tumour response after neoadjuvant chemoradiation for rectal cancer

F. Lopez Campos¹, A. Hervas¹, C. De la Pinta¹, J.A. Dominguez¹, E. Fernández¹, M. Martín¹

¹Hospital Ramon y Cajal, Clinical Oncology, Madrid, Spain

Purpose or Objective: Neoadjuvant chemoradiation followed by surgery is the standard of care for locally advanced rectal cancer (LARC).

The aim of this study was to identify predictive factors of tumor responsiveness.

Material and Methods: A retrospective study was carried out on a series of 243 patients with histologically proven LARC treated between 2000 and 2014 by preoperative chemoradiation before total mesorectal excision. The radiation dose was 45-50.4Gy with fluoropyrimidine-based chemotherapy regimens. The influence of tumor characteristics and treatment regimen in tumor downstaging and regression grade (TRG) was tested using Mandard scoring system on surgical specimens.

Results: Median age (range 33-85) was 67 years. The predominant cancer stages were stage II (38%) and stage IIIB (56%). Tumor downstaging occurred in 167 patients (69%), including 48 (19.8%) with ypT0 (documented T0 at surgery) and 166 (68.3%) with a satisfactory tumor regression grade, defined as TRG1-3. Identified predictive factors for pathologic complete response (pCR) included a planning target volume receiving 50.4Gy (PTV 50.4) and tumor location: PTV 50.4 ≤ 600cc (p=0.049) and upper rectal tumor location (p=0.004) were associated with higher pCR by univariate analysis. Multivariate analysis revealed a positive association of the TRG1-3 rate with longer intervals from chemoradiation to surgery (p=0.008): 5.4% at ≤5 weeks, 43.4% at 6-8 weeks and 51.2% at ≥9 weeks. Actuarial 3 and 5 years survivals were 95% and 90% for the group as a whole. Among ypT0 cases, the overall survival and relapse-free survival were 97% and 94%, respectively with a median follow-up of 49.4 months, significantly different compared with the remaining group 89% and 74% respectively. There were no treatment-associated fatalities. Thirty-two of the 243 patients (13%) experienced Grade III or IV toxicities (proctitis (8.6%), epithelitis (3.7%) and neutropenia (0.8%) during preoperative treatment.

Conclusion: PTV50.4Gy and tumor location were identified as predictive factors of pCR for LARC treated with preoperative chemoradiation. PTV50.4 ≤ 600cc and upper rectal tumors are more likely to develop complete responses.

Delay in surgery was identified as a favourable predictive factor for TRG1-3, Innovative strategies incorporating further time extension of the surgical interval can be safely explored.

EP-1285

Is watch and wait policy after chemoradiotherapy for rectal cancer detrimental to outcome?

N. Pasha¹, D. Woolf¹, E. Jiad¹, S. Ball¹, S. Raouf¹

¹Queen's Hospital, Clinical Oncology, Romford, United Kingdom

Purpose or Objective: Neo-adjuvant chemoradiotherapy (CRT) is considered a standard approach for locally advanced rectal cancer. In this study we assessed the outcomes of patients who declined surgery following standard CRT in comparison to those who received surgery.

Material and Methods: We evaluated all patients who received CRT for rectal cancer between February 2012 and December 2014 at our centre. All patients received 50.4Gy in 1.8Gy fractions with concurrent capecitabine chemotherapy (825mg/m² BD) daily throughout treatment. 61 patients received surgery (total mesorectal excision), performed 8-12 weeks after completion of CRT (Group A). 12 patients received CRT alone and declined definitive surgery (Group B). These patients were monitored on a watch and wait approach. The primary end point of this study was disease free survival (DFS), with local recurrence being a secondary end point.

Results: Group A comprised of 19/61 (31%) females and 42/61 (69%) male, median age of this group was 66 years. 59/61 (96.7%) patients showed an imaging response (defined as any improvement in disease) following CRT. Group B comprised of 6/12 (50%) male and female, median age of this group was 75 years. 9/12 (75%) patients showed an imaging response following CRT. Group A showed a local recurrence rate of 5/61 (8%) and a distant recurrence rate of 9/61 (15%). Group B showed a recurrence rate of 4/12 (33%), all of which were local recurrences. There was no significant difference in overall recurrence rates between the two groups (t = 0.90; p = 0.37). The disease free survival, using the Kaplan-Meier methodology, for Group A was 88% at one year and 80% at two years. For Group B it was 91% at one year and 66% at two years; the difference between the two groups being non-significant (log rank chi-square 1.35; p=0.245)

Conclusion: This study suggests that a watch and wait approach after CRT is associated with increased risk of local relapse and a shorter disease free survival interval. The difference was not significant which might be due to small numbers in the watch and wait group. We continue to advocate surgery as the standard approach post CRT and await the results of prospective studies evaluating a watch and wait approach, as well as the use of imaging biomarkers to enable better prediction of outcome.

EP-1286

Does dose-escalated neo-adjuvant radiotherapy improve pathological response in rectal cancers?

N. Pasha¹, D. Woolf¹, M. Martinou¹, K. Williams¹, S. Ball¹, S. Raouf¹

¹Queen's Hospital, Clinical Oncology, Romford, United Kingdom

Purpose or Objective: Neoadjuvant chemoradiotherapy (CRT) is considered a standard approach for locally invasive rectal cancer. Several phase 3 studies have shown an improvement in local control with combined radiotherapy and capecitabine / 5-fluorouracil. There is good evidence that increased dose of radiotherapy is associated with both better pathological response and survival in many malignancies, although the data in rectal cancer is less convincing. In this study we assessed the impact of dose-escalated radiotherapy on pathological outcome.

Material and Methods: We evaluated all patients who received chemo-radiotherapy for rectal cancer and subsequently had an anterior resection/ abdominoperineal resection with a total mesorectal excision (TME) between February 2012 and December 2014. Patients received 50.4Gy 1.8Gy fractions, and more recently those who have T3/4 disease with a threatened circumferential margin had a simultaneous integrated boost of the primary tumour to a total dose of 53.2Gy, with concurrent capecitabine chemotherapy (825mg/m² BD) daily throughout treatment. Treatment was initially using 3-D conformal radiotherapy but more recently has been using a VMAT technique with cone beam CT used during treatment. Surgery was performed 8-12 weeks after completion of CRT. The primary end point was pathological response (Dworak score 0-4) of the operative specimen. Scores of 0-2 were considered to be non-pathological responders and scores of 3-4 were considered to be pathological responders.

Results: A total of 73 patients received neoadjuvant chemoradiotherapy. 61 patients were treated with a standard radiotherapy fractionation of 50.4Gy in 28 fractions (Group A) and 12 patients were treated with a dose escalated fractionation to the primary tumour of 53.2Gy in 28 fractions (Group B). The rate of pathological response was 39.3% in Group A and 86.7% with Group B (t=3.55, p<0.001).

Conclusion: This study demonstrates the beneficial effects of dose-escalated radiotherapy and therefore recommend this regime be considered for inclusion in future phase 2 studies.

EP-1287

Radiation-induced rectal toxicity in prostate cancer: a proctoscopy evaluation

⁷Radiation Oncology Center- Sant'Orsola-Malpighi Hospital- University of Bologna, Department of Experimental-Diagnostic and Specialty Medicine - DIMES, Bologna, Italy

Purpose or Objective: Early proctoscopy (1 year) can predict late rectal mucosa changes and therefore can be used as surrogate end-point for late rectal toxicity. The aim of this study was to retrospectively analyze data of patients treated at a single institution, consecutively enrolled in different prospective clinical trials, trying to determine a correlation between treatment parameters and VRS (Vienna Rectoscopy Score) recorded at 1-year proctoscopy.

Material and Methods: Patients with prostate adenocarcinoma treated with curative or adjuvant RT underwent endoscopy one year after RT; 195 patients were included in this analysis. Correlations between VRS > 2 and several treatment parameters were investigated by univariate and multivariate logistic analysis.

Results: Patients treated with an EQD2 dose > 75 Gy, with hypofractionated schedule and radiosurgery boost had a higher incidence of VRS > 2 (p= < 0.001). On the contrary, previous surgery and 3D-conformal radiotherapy (vs IMRT) were associated with a lower incidence of rectal mucosal changes (p=< 0.001; p= 0.003, respectively). At multivariate analysis radiosurgery boost was associated with the highest odd ratios for the risk of developing a VRS > 2 (OR: 4.143; CI: 1.24-13.81; p=0.001). Even surgery showed a significant correlation with VRS > 2 (OR: 0.39; CI: 0.17-9.94; p=0.037, Table 1).

Table 1. Univariate and multivariate logistic regression for VRS score = 2.

Variable	Univariate			Multivariate		
	OR	CI 95%	P	OR	CI 95%	P
Surgery	0.265	0.130-0.539	<0.001	0.397	0.167-0.944	0.037
IMRT/VMAT	2.588	1.356-4.942	0.004	2.097	0.960-4.581	0.063
EQD2 dose > 75 Gy	3.833	1.742-8.437	0.001	-	-	-
Seminal vesicles irradiation	3.801	1.254-11.528	0.018	2.075	0.577-7.463	0.264
Radiosurgery boost	4.250	2.822-24.117	<0.001	4.143	1.243-13.812	0.021

Conclusion: Prolonged patients follow-up is needed to "clinically" confirm the increased rectal toxicity produced by radiosurgery boost.

EP-1288

Sphincter function and dose of radiation in rectal cancer. A Single-Institutional study

F. Arias¹, C. Eito¹, G. Asin¹, I. Mora¹, K. Cambra², F. Mañeru³, B. Ibáñez², L. Arbea⁴, M. Errasti¹, M. Barrado¹, M. Campo¹, I. Yisus¹, J. García-Escobedo¹, C. Torres¹, M. Ciga⁵

¹Complejo Hospitalario de Navarra, Department of Radiotherapy-Oncology, Pamplona, Spain

²Complejo Hospitalario de Navarra, Statistics Department, Pamplona, Spain

³Complejo Hospitalario de Navarra, Department of Physics, Pamplona, Spain

⁴Clinica Universidad de Navarra, Department of Radiotherapy-Oncology, Pamplona, Spain

⁵Complejo Hospitalario de Navarra, Department of Surgery, Pamplona, Spain

Purpose or Objective: The objective of the study is to determine the correlations among the variables of dose and the sphincter function (SF) in patients with locally advanced rectal cancer treated with preoperative capecitabine/radiotherapy followed by Local Anterior Resection(LAR) +TME.

Material and Methods: We have retrospectively reviewed 92 consecutive patients with LARC treated at our center with LAR from 2006 and more than 1 year free from disease. We re-contoured the anal sphincters (AS) of patients with the help of the radiologist. SF was assessed with the Wexner scale (0-20 points, being punctuation inversely proportional to SF). All questionnaires were filled out between January 2010 and December 2012. Dosimetric parameters that have been studied include: V20 V30, V40, V50, mean dose (Dmean), minimum dose (Dmin), D90 (dose received by 90% of the sphincter) and D98 Statistical analysis: the correlations

among the variables of dose and SF were studied by the Spearman correlation coefficient. Differences in SF related to maximum doses to the sphincter were assessed by the Mann-Whitney test.

Results: Mean Wexner score was 5.5 points higher in those patients with V20>0 compared to those for which V20=0 (p=0.008). In a multivariate regression model, results suggest that the effect of V20 on poor anal sphincter control is independent of the effect of distance, with an adjusted OR of 3.42 (1.09, 10.72).

Conclusion: In order to improve the SF, the maximum dose of radiation to the AS should be limited, when possible, to < 20 Gy

²St Luke's Radiation Oncology Network, Radiation Oncology, Dublin, Ireland Republic of

³Beaumont Hospital, Surgery, Dublin, Ireland Republic of

Purpose or Objective: Anal cancer is a relatively rare cancer, making up approximately 0.4% of all new diagnoses of cancer. In 2011, there were 1,175 new cases of anal cancer diagnosed in the UK. The current standard treatment is radical chemoradiotherapy. We conducted a retrospective case series of anal squamous cell carcinoma treated in the regional radiation oncology network between 2008 and 2014 inclusive to examine recent management practice and outcome of anal squamous cell carcinoma.

Material and Methods: Patients were identified from the regional radiation oncology cancer database. Data was collected retrospectively from ARIA® oncology information system and patient charts. Information was collected in relation to demographic details, radiotherapy dose and regimen, chemotherapy regimen, persistence and recurrence of disease, salvage surgery rates, and survival analysis. Statistical analyses were carried out using IBM® SPSS® statistical software version 21.0.

Results: 79 cases of anal squamous cell carcinoma were identified. Mean age at commencement of radiotherapy was 60.2 years (+/-13.2 years). 29 patients were male (36.7%) and 50 (63.3%) were female. 8 (10.1%) patients had documented HIV infection. 74 (93.7%) patients were treated with radical chemoradiotherapy. The most common total radiotherapy dose delivered was 50.4 Gy in 28 fractions (N=58; 73.4%) (see table 1). The majority of patients (N=67; 84.8%) received combination chemotherapy with mitomycin C and 5-FU. 2 (2.5%) patients who received radical treatment had persistent disease following radiotherapy. 5 (6.3%) patients had loco-regional recurrence and 3 (3.8%) patients developed solid organ metastases following complete treatment response at the primary. 4 patients had salvage surgery. Survival was measured from the initiation of radiotherapy treatment using the Kaplan-Meier method. Overall survival was 98%, 90%, 83% and 83% at 1, 2, 3 and 4 years respectively. Disease free survival was 91%, 77%, 74% and 74% at 1, 2, 3 and 4 years respectively (see fig. 1).

Table 1 Total delivered radiotherapy dose and fraction

Radiotherapy Dose (Gy)/Fraction	Number of Patients (%)
50.4/28	58 (73.4)
54/30	11 (13.9)
59.4/33	5 (6.3)
57.6/32	2 (2.5)
60/30	1 (1.3)
54.8/31	1 (1.3)
50/25	1 (1.3)

Fig. 1 Disease free survival shown on Kaplan-Meier curve

Conclusion: Our study found that the majority of patients in our radiation oncology network were treated with chemoradiotherapy in line with international guidelines. In our study, chemoradiotherapy in the treatment of anal squamous cell carcinoma was associated with a high complete response rate and a low treatment failure rate. Treatment and outcomes in our study are consistent with international trial data.

EP-1290

A review of grade 3 bowel toxicity in patients treated with chemoradiotherapy for rectal cancer

J.A. King¹, L. Davidson¹, N. Alam¹, C. Arthur¹, C. McBain¹, A. Mirza¹, M. Saunders¹, V. Misra¹

¹The Christie NHS Foundation Trust, Clinical Oncology, Manchester, United Kingdom

Purpose or Objective: Concurrent chemoradiotherapy (CRT) is the standard treatment for locally advanced rectal cancer to downstage disease prior to definitive surgery. Previous studies report ≥ grade 3 (G3) bowel toxicity of 3 -4%; QUANTEC recommend small bowel V45 <195 cm³ to reduce G3 toxicity. We noted an increase in G3 bowel toxicity in the period Sept - Dec 2014 in our institution and aimed to determine the cause.

Material and Methods: We retrospectively identified patients who received pre-operative long-course CRT for rectal cancer between Sept - Dec 2014 and Jan - April 2014 (control), and reviewed case notes and radiotherapy (XRT) plans. Small bowel V45 was calculated for each patient. G3 toxicity was defined as per the CTCAE grading system for diarrhoea, abdominal pain and vomiting.

Results: Fifty patients were identified: Jan - April cohort (n=28) was compared to Sept - Dec cohort (n=22). Both groups were similar for patient demographics, CRT treatment volumes and doses, patient positioning and XRT delivery technique. Two of 28 patients (9%) in Jan - April cohort had G3 bowel toxicity; both were admitted for symptom control. Six of 22 patients (27%) in Sept - Dec cohort developed G3 bowel toxicity; 5 (23%) required admission. G3 toxicity occurred after a minimum of 16 fractions (range 16-21). All patients had normal bowel function prior to

treatment; 1 had an ileostomy. Two patients (25%) required prolonged admission, 1 was admitted to critical care with neutropenic colitis. Capecitabine was discontinued in 6/8 (75%); 5 (63%) required a break in XRT. Two patients (25%) discontinued XRT altogether. Mean small bowel V45 for patients who did and did not develop G3 toxicity was 38.6 cm³ (range 0 - 178.8) and 113.0 cm³ (38.4 - 222.4) respectively. Two patients had a small bowel V45 >195 cm³, both developed G3 bowel toxicity.

Conclusion: In this series, incidence of G3 bowel toxicity in patients receiving chemoradiotherapy for rectal cancer was not influenced by gender, age, pre-treatment bowel habit or body habitus. PTV size, patient positioning and radiotherapy delivery technique did not alter the risk. Patients who developed G3 toxicity had a larger volume of small bowel receiving ≥ 45 Gy. Based on this, we now routinely calculate dose to small bowel, thus identifying patients who are at higher risk of developing G3 toxicity and review or change the treatment plan, including chemotherapy dose, to mitigate this risk.

EP-1291

Can mucosal criteria estimate response in rectal cancer treated with neoadjuvant chemoradiotherapy?

A. Garant¹, T. Niazi¹, A. Gologan¹, A. Spatz¹, J. Faria¹, N. Morin¹, C. Vasilevsky¹, M. Boutros¹, T. Vuong¹

¹Jewish General Hospital, Radiation Oncology, Montreal, Canada

Purpose or Objective: The past decade in rectal cancer research has raised questions about complete pathological response (pCR) after neoadjuvant therapy. In this context, there has been much hype to identify patients with clinical complete response (cCR) who could eventually be candidates for nonoperative cancer care. So far, experts have published stringent criteria to define cCR, which remain to be validated with surveillance strategies. The purpose of our study is to review pathological mucosal changes after neoadjuvant combined chemoradiation therapy (CRT) for rectal cancer.

Material and Methods: This retrospective review was conducted in a tertiary referral center. Histopathology reports were retrieved for rectal cancer patients treated with neoadjuvant CRT. Exclusion criteria included recurrent rectal cancer, stage IV disease, rectal cancer in the context of IBD or FAP, patient enrollment under clinical trials with chemotherapy or other treatment schemes, and patients who were not operated. The macroscopic mucosal appearance of the specimen was compared with the final pathological staging.

Results: Eighty-eight patients met our inclusion criteria and had complete staging and pathological data with gross mucosal descriptions. These included 59 male and 29 female patients with a median age of 63 years (range 29-83). The staging proportions were: 3.4% stage cI, 15.9% stage cII, and 80.7% stage cIII; 93.2% of patients were cT3/cT4 and 75% were cN+. Clinical CRM was involved in 30 patients. All patients were treated with neoadjuvant CRT consisting of 45 Gy in 25 fractions to the pelvis with a tumour bed boost of 5.4 Gy in 3 fractions using 3D conformal radiotherapy; chemotherapy was 5-FU based. Total mesorectal excision (TME) was performed in all patients. The median time between the last day of radiotherapy and surgery was 58 days (range 32-308). As a result, 15 patients (17.0%) were staged as ypT0N0 (pCR); 12 patients (13.6%) remained CRM+ on surgical pathology evaluation. Eighty-seven patients (98.9%) had residual mucosal abnormalities incompatible with cCR: most changes seen were ulceration and, less often, stenosis. Of the 70 patients with microscopic residual tumor, 7 patients had no macroscopic tumor visualized but an ulcer in its place. There was no statistically significant association between time from CRT to surgery and pCR.

Conclusion: Most patients undergoing neoadjuvant CRT have residual mucosal abnormalities two months after CRT. There

are needs to define criteria for clinical endoscopic evaluation to define cCR.

EP-1292

Association between obesity and local control of rectal cancer after surgery and radiotherapy

Y.S. Choi¹

¹Busan Paik hospital, Radiation Oncology, Busan, Korea Republic of

Purpose or Objective: The association between metabolism and cancer has been recently emphasized. This study aimed to find the prognostic significance of obesity in advanced stage rectal cancer patients treated with surgery and radiotherapy (RT).

Material and Methods: We retrospectively reviewed the medical records of 111 patients who were treated with combined surgery and RT for clinical stage II-III (T3 or N+) rectal cancer between 2008 and 2014. The prognostic significance of obesity (body mass index ≥ 25 kg/m², according to Asian classification) in local control was evaluated.

Results: The median follow-up was 27.3 months (range, 3.3-82.1 months). Twenty-five patients (22.5%) were classified as obese. Treatment failure occurred in 33 patients (29.7%), including local failures in 13 patients (11.7%), regional lymph node failures in 5, and distant metastases in 24. The 3-year local control, recurrence-free survival, and overall survival rates were 88.6%, 72.6%, and 87.3%, respectively. Obesity (n=25) significantly reduced the local control rate ($p=0.049$, 3-year local control 75.8%), especially in women (n=37, $p=0.026$). Segregation of local control was best achieved by body mass index of 25.6 as a cutoff value.

Conclusion: Obese rectal cancer patients showed poor local control after combined surgery and RT. More effective local treatment strategies for obese patients are warranted.

EP-1293

Intensified neo-adjuvant chemoradiotherapy in locally advanced rectal cancer: long-term follow-up

F. De Felice¹, D. Musio¹, A.L. Magnante¹, N. Bulzonetti¹, I. Benevento¹, R. Caiazzo¹, V. Tombolini¹

¹Policlinico Umberto I- "Sapienza" Università di Roma, Radioterapia, Roma, Italy

Purpose or Objective: To report long-term follow-up data and determine the toxicity rate in patients with locally advanced rectal cancer (LARC) treated with intensified neo-adjuvant regimen.

Material and Methods: Patients with histologically proven adenocarcinoma of the rectum, stage III-IV, were included and treated with a tri-modality approach. Baseline patient characteristics are shown in Table 1.

Intensified neo-adjuvant treatment (CRT) consisted of RT total dose of 50.4/54 Gy and concomitant OXP (50 mg/m²/week) and 5-FU (200 mg/m²/ five daily continuous infusion). Surgery was planned 7-9 weeks after the end of CRT. Adjuvant chemotherapy was recommended in those patients with lymph-node metastasis at diagnosis.

Results: One hundred patients (median age 64 years) were eligible, between January 2007 and December 2014. Overall, the 5-years OS and DFS were 76.4% and 74.5%, respectively. Local recurrence was recorded in 9 patients (9%) and 23 patients (23%) presented distant metastasis. CRT was well tolerated, with only 17% grade 3/4 acute toxicity. Twenty-four patients (24%) had a pathologic complete response (pCR) and only 1 patient peri-operative metastasis. The 5-year OS rate was 95.7% for patients with pCR and 70.4% without pCR ($p = 0.0489$). The 5-year DFS were 95.7% and 66.7% for pCR and no-pCR tumor histology, respectively ($p=0.0275$) (Figure1).

Conclusion: Distant metastasis remains the major issue in the management of LARC. This study demonstrated improvement in pCR, as well as the potential to achieve higher survival rates, including DFS. Waiting for randomized phase III trials long-term follow-up data, OXP should be considered as feasible and valid neo-adjuvant treatment option. The low rate of severe toxicity and the effective benefit on pCR and peri-operative metastasis support this concomitant CHT schedule for LARC.

EP-1294

Total mesorectal excision vs. local excision following preoperative RT for "early" cT3 rectal cancer

Y. Shin¹, J.H. Park¹, J.C. Kim², C.S. Yu², T.W. Kim³, J.H. Kim¹
¹University Of Ulsan College Of Medicine, Radiation Oncology, Seoul, Korea Republic Of

²University Of Ulsan College Of Medicine, Surgery, Seoul, Korea Republic Of

³University Of Ulsan College Of Medicine, Oncology, Seoul, Korea Republic Of

Purpose or Objective: To compare the oncologic outcome of total mesorectal excision (TME) to local excision (LE) in "early" clinical T3 rectal cancer patients who received preoperative radiation therapy.

Material and Methods: "Early" clinical T3 patients, who underwent preoperative radiation therapy followed by TME or LE at Asan Medical Center between January 2007 and December 2013 were retrospectively analyzed. "Early" clinical T3 was defined as extramural extension, circumferential resection margin negative and lateral lymph node negative in pretreatment magnetic resonance imaging. A one-to-one propensity case-matched analysis was used with covariates of baseline characteristics. Local recurrence free survival (LRFS), disease free survival (DFS), overall survival (OS) were compared between the matched two groups.

Results: A total of 425 patients were identified; 366 underwent TME and 59 underwent LE. The median follow-up period was 47 months. After propensity score-matching, we obtained 55 matched pairs. There were no significant differences in 3-year LRFS (95.8% vs 94.2%, p=0.927), DFS (85.7% vs 90.8%, p=0.473), OS (96.2% vs 100%, p=0.987) between TME and LE groups.

Conclusion: In "early" clinical T3 rectal cancer, local excision could be a feasible alternative to mesorectal excision after preoperative chemoradiation.

EP-1295

Anal cancer as a second human Papillomavirus-related presentation after cervical dysplasia/neoplasia

A. Yates¹, S. Pendlebury², E. Segelov³
¹Yates Angela, St Vincent's Hospital- Darlinghurst NSW 2010 Australia, Annandale NSW, Australia

²St Vincent's Hospital, Radiation Oncology, Darlinghurst, Australia

³St Vincent's Hospital, Medical Oncology, Darlinghurst, Australia

Purpose or Objective: Cervical intraepithelial neoplasia (CIN) and anal squamous cell carcinoma (SCC) are both causally associated with human papilloma virus infection (HPV). Women who have an HPV infection of the cervix are at a higher risk of HPV infection of the anal canal with the same HPV subtype(1). The incidence of HPV infection and related cancers is increasing in developed nations(2). Until the impact of widespread HPV vaccination is manifest, presentation with multiple HPV related malignancies will become a more common clinical scenario. Our objective was to identify the proportion of women with anal cancer who had a history of CIN or invasive cervical cancer (ICC) and discuss the implications for future practice.

Material and Methods: The medical records and histopathology of all consecutive women treated definitively for anal cancer at our centre between January 2004 and July

2015 were reviewed. A case was defined as a woman reporting a history of CIN or ICC treated with either a cone biopsy or hysterectomy. We extracted treatment details of both the anal cancer and CIN or ICC, demographic and outcome data. Women with a previous abnormal pap smear or low grade cervical dysplasia were not included as a case.

Results: Eight cases (25%) were identified; Stage III (63%), I, II, IV (each 12.5%). The women were HIV negative, aged 36-62 years and diagnosed with HPV positive anal SCC 10-40 years after their initial diagnosis. Of the remaining 24 women, Nine had no prior history, Four had a previous abnormal pap smear, one a partial hysterectomy for unknown reason, two a hysterectomy for benign uterine disease and eight no recorded gynaecological history. Seven women had definitive chemoradiotherapy and one had sequential chemotherapy and radiotherapy (Stage IV). All were alive and disease free at follow up.

Conclusion: One quarter of women with anal SCC had a previous history of CIN or ICC. This may be an underestimate as a gynaecological history was missing in 25% of patients. There are several implications for practice: the importance of specifically elucidating a history of HPV-related disease such as warts, CIN or ICC on history; secondly, to have a high index of suspicion when these women present with bowel symptoms; third, that this represents a high risk group of women who may benefit from participation in anal pap screening programs similar to that being investigated in high risk men.

EP-1296

A correlation between PTV dosimetric criteria and pathological response in rectal cancer patients

A. Franzetti Pellanda¹, P. Urso¹, S. Gianolini², B. De Bari³, G. Ballerini¹, L. Negretti¹, C. Vite¹, N. Corradini¹

¹Clinica Luganese, Department of Radiation Oncology, Lugano, Switzerland

²Medical Software Solutions GmbH, Medical Software Solutions GmbH, Hagendorn, Switzerland

³CHUV, Radiotherapy department, Lausanne, Switzerland

Purpose or Objective: To test the relationship between dosimetric data and pathological response in a series of 52 patients treated with combined pre-operative chemoradiation (CRT) for local advanced rectal cancer..

Material and Methods: We studied 52 consecutive patients treated with pre-operative CRT for locally advanced rectal cancer (T3-4N0M0 or any TN+M0, G1-3). Total dose prescribed was 44 Gy (2 Gy/tx) (Group 1, n = 10) or 45 Gy (1.8 Gy/tx) (Group 2, n = 42), delivered using helical Tomotherapy (HT). A concomitant Capecitabine-based chemotherapy was also delivered. All patients underwent surgery 6 to 8 weeks after the end of CRT. Surgery consisted of low anterior resection (LAR) or abdominoperineal excision (APR), depending on the tumor distance from anal margin. For all patients, we calculated pathological response through difference between TNM clinical staging and TNM pathological staging such as by pathological Dworak tumor regression score (TRG). We tested the relationship between pathological response and planning target volume (PTV) dosimetric criteria in agreement with ICRU 83 and internal guidelines. Selected parameters were: Dmax, Dmin, Dmean, D98, D95, D2, V95, V100, V107, V110 and target volume (cc). Non-parametric statistical analysis (Wilcoxon, U-Mann-Whitney, Kruskal-Wallis tests) was performed using SPSS.21 software (significant level p < 0.05). Planning dosimetric data were extracted from patient archives using VODCA 5.4.0.

Results: Results: A significant reduction in TNM staging was observed post-treatment (p < 0.001 and p < 0.010 for T & N, respectively). Furthermore, 3 patients presented a total remission (5.8%) and 30 remained stable (57.7%). For Group 1, average values and standard deviation of Dmean, Dmin and Dmax (Gy) were 44.5 ± 0.4, 30.4 ± 3.6, and 47.2 ± 0.3, while for Group 2 were 45.1 ± 0.3, 33.1 ± 3.5, and 48.1 ± 0.6. Dose

fractionation was not significant for both TNM and TRG ($p > 0.100$). Among dosimetric parameters, Dmin resulted statistically different depending on the patient T staging variation ($p < 0.005$). Specifically, focusing on the 21 patients with favourable pathological response, significant correlation was found with the T index variation ($\rho_{\text{Spearman}} = -0.667$, $p = 0.001$), with higher Dmin related to patients undergoing total remission. No other dosimetric parameters resulted associated with clinical tumor regression outcomes.

Conclusion: In this series we found a statistically significant correlation between T staging regression and the Dmin to the PTV. Patients with partial or complete pathological response showed a higher Dmin when compared to patients with no change in TNM staging. Further studies are needed to understand if there is any relation between the site of underdosages and the tumor site.

EP-1297

Impact of 18F-FDG-PET/CT in evaluating the response to neoadjuvant chemoradiotherapy in rectal cancer

S. Pedraza Fernández¹, M. Pérez-Escutia¹, D. Sánchez-Fuentes², P. Nenclares¹, S. Ruiz-Solís², M. Peña¹, D. Lora³, J. Pérez-Regadera¹

¹Hospital 12 Octubre, Radiation Oncology, Madrid, Spain

²Hospital 12 Octubre, Nuclear Medicine, Madrid, Spain

³Hospital 12 Octubre, Investigation and Statistics, Madrid, Spain

Purpose or Objective: The standard treatment for locally advanced rectal cancer (LARC) is neoadjuvant chemoradiation (CRT) followed by mesorectal excision. However, surgical specimen histopathology demonstrates a complete pathological response (pCR) in almost 30% of cases. In consequence, these patients (pts) may benefit from conservative management.

The aim of this study is to evaluate the role of 18F-FDG-PET/CT in pts with LARC in the prediction of pCR after treatment with CRT.

Material and Methods: From September 2009 to May 2014, 39 pts (mean age: 62 years, range 40-83) with LARC underwent 18F-FDG-PET/CT for staging and radiotherapy (RT) treatment planning. Tumour location within rectum: superior: 17 (43.85%); middle: 14 (35.89%); inferior: 8 (20.51%). Histology: adenocarcinoma: 37 (94.87%); mucinous adenocarcinoma: 2 (5.13%). Tumour staging: II: 7 (17.95%); III: 31 (79.48%); IV (resected liver metastases disease): 1 (2.56%).

All pts received conformal RT (Nodal PTV: 4500 cGy, Tumor PTV: 5040 cGy) with concurrent Capecitabine, before undergoing either low anterior resection (32pts-82.05%) or abdomino-perineal resection (7pts-17.95%).

The tumour regression grade (TRG) according to Mandard's criteria was assessed by the pathologist. Pts were classified into two groups: responders (TRG 1 and 2) and non-responders (TRG 3 to 5). The TRG was correlated with 18F-FDG-PET/CT parameters (tumour volume, tumour SUVmax and nodal SUVmax).

Results: Following CRT, 7/39 pts (17.94%) showed no evidence of residual tumour in the surgical specimen (pCR). By TRG status, 14 pts (35.9%) were classified as responders and 25 (64.10%) as non-responders. When analyzing 18F-FDG-PET/CT parameters, no significant difference was found between responders and non-responders for: tumour volume (mean: 5.84cm³ vs 6.24 cm³, $p=0.35$); tumour SUVmax (21.95 vs 20.73, $p=0.61$); nodal SUVmax (4.73 vs 7.56, $p=0.12$) or staging (6.71 vs 7.56, $p=0.23$). Histopathological responders had better overall survival compared to non-responders, however this was not statistically significant (617 vs 269 days, $p=0.37$).

Conclusion: In our cohort, 18F-FDG-PET/CT parameters cannot predict the tumour response to CRT. Nevertheless, higher levels of SUVmax and bigger tumour volumes are found in the non-responders group and also worst overall survival. Stronger conclusions should be established in this matter in order to select patients for an organ-preservation safely.

EP-1298

Stereotactic radiotherapy in oligometastatic patients with lung metastasis from colon-rectal cancer

S. Montrone¹, C. Vivaldi², G. Coraggio¹, M. Cantarella¹, B. Manfredi¹, C. Laliscia¹, G. Masi², F. Loupakis², A. Falcone², M.G. Fabrini¹, A. Sainato¹, F. Pasqualetti¹

¹Azienda Ospedaliero Universitaria Pisana, Radiotherapy, Pisa, Italy

²Azienda Ospedaliero Universitaria Pisana, Medical Oncology, Pisa, Italy

Purpose or Objective: The approach to patients with lung metastasis from primary colon-rectal cancer is based on systemic therapy and the role of stereotactic body radiotherapy (SBRT) is still to be investigated. The present work aims to study the impact of SBRT in oligometastatic patients with lung metastasis from colon-rectal cancer.

Material and Methods: From May 2010 to March 2015, 33 consecutive patients (median age 66 years, range 31-88) with lung metastasis from colon-rectal cancer were treated with SBRT. All patients were treated using Image Guided Radiotherapy (IGRT) and stratified according to K-RAS and B-RAF genotype. The systemic progression free survival and local control were the primary and secondary endpoint evaluated respectively.

Results: A total of 56 active lesions were treated. After a median follow-up of 12.6 months, median OS was 10.5 months. The radiotherapy dose delivered and the schedule adopted were 24-27 Gy as a single fraction and 27-42 Gy/3 fractions. Nineteen out of 33 patients were affected by rectal cancer while 14 patients by colon cancer. Median Planning Target Volume value was 21.45 cc (range 6-156). Mean local relapse was recorded in 23 lesions (41.1%) at a median interval of 19.3 months (range 5-37). By the way, 23 out 33 patients (69.7%) experienced systemic progression after a mean time of 12.6 months (1-24) from SBRT. No differences of local or systemic control were observed considering K-RAS and B-RAS genotype. Severe toxicity were not recorded.

Conclusion: The results of this study suggest that SBRT could represent a safe and valid approach to oligometastatic patients with lung metastasis from colon-rectal cancer. However, further studies are needed in order to better characterize patients potentially suitable for SBRT.

EP-1299

Tomotherapy for anal cancer: analysis of toxicity and response in a dual institution experience

P. Bonomo¹, B. Meduri², E. D'Angelo², A. Galardi¹, C. Delli Paoli¹, C. Tata², G. De Marco², I. Desideri¹, F. Bertoni², L. Livi¹

¹University of Florence, Radiation Oncology, Firenze, Italy

²University Hospital of Modena, Radiation Oncology, Modena, Italy

Purpose or Objective: The purpose of our study is to report on the acute toxicity and response to treatment in patients affected by squamous cell anal carcinoma (SCAC) that underwent tomotherapy (TO) at 2 institutions.

Material and Methods: A cohort of 39 patients affected by SCAC and treated with TO between December 2009 and July 2015 was retrospectively analyzed. Concurrent chemotherapy (CT) was always administered except in patients unfit for intensive therapy due to comorbidity and/or with early stage disease (T1-T2N0). The choice of CT regimen was left to the discretion of the treating institution, as well as the IMRT schedule adopted. The dose/fractionation prescribed to PTV1 (high-risk volume), PTV2 (intermediate-risk volume) and PTV3 (low-risk volume) ranged between 66- 50 Gy, 50.4 - 45 Gy and 46.2 - 36 Gy, respectively, at a corresponding dose per fraction range of 2.2 - 1.8 Gy for PTV1, 2 - 1.67 Gy for PTV2, and 1.65 - 1.5 Gy for PTV3, delivered in a range of 25-33 daily fractions. Acute toxicity was scored according to NCI - CTCAE v.4. Response was assessed at 12 weeks after the end of treatment via digital rectal exam and anoscope.

Morphologic and/or metabolic imaging re-assessment was performed between 12 and 26 weeks after treatment. Disease-free survival (DFS) was calculated from the end of treatment to the date of first event of disease recurrence. Overall survival (OS) was calculated from the end of treatment to the date of death from any cause or of last follow-up.

Results: All patients are evaluable for acute toxicity assessment while clinical outcome has been analyzed in 29/37 (79,4%) patients, with a median follow-up of 8 months (range 3-69). Baseline clinical features of the whole cohort are summarized in table 1. Concurrent CT was given in 30 patients (81.1%) and in 23 of them (76.6%) the preferred regimen consisted of 5 - fluoruracil - mitomycin C combination. A sequential IMRT schedule was delivered in 9 patients (24.3%) while 28 (75.7%) underwent IMRT-SIB. In 22 patients (60%) treatment was completed without any interruptions while the median duration of treatment breaks was 7 days (range 1-16) in the remaining group. In terms of acute toxicity, the rate of G3+ diarrhea and dermatitis was 8.1% and 13.5%, respectively. No G3+ GU and hematological toxicities were reported. Complete response was achieved in 21/29 patients (72.4%), partial response/stable disease in 7 (24.1%) and local disease progression in 1 (3%). All patients were alive at last follow-up. The 1-year OS, DFS, and colostomy-free survival were 100%, 85% and 96%, respectively.

Conclusion: In our dual institution experience, concurrent chemo-radiation with TO for SCAC was associated with a favorable acute toxicity profile, in line with published experiences. Considering the prevalence of very advanced loco-regional disease in our cohort, early response assessment is noteworthy, although a longer follow-up is needed to confirm the long-term benefit and to evaluate the incidence of late toxicity.

EP-1300

Preoperative, Adaptive Radiotherapy with Tomotherapy concomitant with chemotherapy in rectal cancer

P. Passoni¹, N. Slim¹, C. Fiorino², C. Gumina¹, M. Ronzoni³, F. De Cobelli⁴, A. Palmisano⁴, V. Ricci³, A. Fasolo³, A. Tamburini⁵, P. De Nardi⁵, S. Di Palo⁵, C. Staudacher⁵, R. Rosati⁵, R. Calandrino², N. Di Muzio¹

¹Ospedale San Raffaele IRCCS, Radiation Oncology, Milan, Italy

²Ospedale San Raffaele IRCCS, Medical Physics, Milan, Italy

³Ospedale San Raffaele IRCCS, Medical Oncology, Milan, Italy

⁴Ospedale San Raffaele IRCCS, Radiology, Milan, Italy

⁵Ospedale San Raffaele IRCCS, Surgery, Milan, Italy

Purpose or Objective: To report the clinical results of six years experience with Adaptive Radiotherapy concomitant with chemotherapy in the preoperative treatment of rectal cancer.

Material and Methods: Patients (pts) with T3/T4N0 or any TN+ rectal adenocarcinoma were enrolled in an observational trial. Chemotherapy consisted of Oxaliplatin 100mg/m² on the days -14, 0, +14, and continuous infusion 5-FU 200mg/m²/day from day -14 to the end of radiotherapy. Concomitant Radiotherapy (RT) started on the day 0, was delivered with Tomotherapy, and consisted of 41.4 Gy in 18 fractions (frs) (2.3 Gy/fr) to the PTV defined as CTV, the tumor and regional lymph-nodes contoured on the initial simulation CT and MRI, with a margin of 0.5 cm. Simulation CT and MRI were repeated after two cycles of chemotherapy and 9 frs of RT for the planning of the adaptive RT phase:

PTVadapt was generated by adding a margin of 5 mm to the residual tumour visible on the intermediate MRI images (GTVadapt). A simultaneous integrated boost of 3.0 Gy/fr was delivered to PTVadapt on the last 6 frs of RT until a total dose of 45.6 Gy in 18 frs.

Results: From September 2009 to September 2015, 56 pts completed the preoperative treatment. Toxicity. No G4 toxicity occurred. G3 toxicity was only gastrointestinal: diarrhoea in 9/56 pts (16%), and proctitis in 3/56 (5%). Diarrhoea started before the adaptive RT phase in all the cases. Treatment feasibility. Two pts interrupted radiotherapy after 7 and 13 fractions, respectively, the remaining pts (54/56=96%) completed the treatment; the median duration of RT was 25 days (22-36 days). 47/56 pts (84%) and 45/56 pts (80%) received the full dose of oxaliplatin and 5-FU, respectively: 18% of pts received moderately reduced doses (60%-90%), and only two pts (2%) received less than 60% of the planned dose. Responses. Two pts achieved clinical complete response (cCR) and refused surgery, 1 pt was lost, 1 pt had early distant progression. Fifty-two pts underwent surgery (49 R0, 3 R1). Fifteen pts (29%) had pathological complete response (pCR); 24/52 (46%) had Tumor Regression Grade 3 response: 14/52 (27%) and 6/52 (12%) had 0%, and 6 -10% residual viable cells, respectively. Regarding the two patients with cCR who refused surgery, 1 pt is still in cCR after 69 months, 1 pt had local relapse and underwent transanal resection 1 year after the preoperative treatment.

Conclusion: This study confirms that adaptive Radiotherapy with Tomotherapy concomitant with oxaliplatin based chemotherapy in the preoperative treatment of rectal cancer is feasible, has an acceptable G3 toxicity rate and a very encouraging tumour response rate. A further dose escalation to the PTVadapt could be feasible and could increase the pCR and/or cCR rates.

EP-1301

Neoadjuvant treatment intensification in cT4NXM0 rectal cancer: long-term outcome analysis.

F. Calvo¹, E. Sagarra², J. Garcia-Sabrido², E. Del Valle², M. Rodriguez², E. Alvarado Vasquez², C. Sole¹, M. Gomez-Espi³, M. Lozano³, R. Obregon²

¹Hospital General Universitario Gregorio Marañon, Oncology, Madrid, Spain

²Hospital General Universitario Gregorio Marañon, Surgery, Madrid, Spain

³Hospital General Universitario Gregorio Marañon, Radiation Oncology, Madrid, Spain

Purpose or Objective: To evaluate the contribution of components for intense multimodal local treatment to the most adverse loco-regional staging scenario of M0 rectal cancer.

Material and Methods: From 1/00 to 12/13, 95 cT4NXM0 patients were treated with radical intent. 54 completed preoperative intensified chemo-radiation (all had post-resection intraoperative electron pelvic boost, IOERT). Adjuvant systemic chemotherapy was recommended considering individualized risk features. Incomplete and complete pre and intra-operative treatment cohorts were comparable in characteristics: male (44/55%); age >70 (44/33%); PS 0 (46/62%); inferior segment (42/41%); grade 2 (67/62%); cN+ (75/83%).

Results: With a median follow-up time of 62 months overall, disease-free (DFS) and loco-regional relapse-free survival were superior in the cohort of complete intensification (75% vs 51%, p=0.009; 67% vs 54%, p=0.03; 77% vs 71%, p=0.01), respectively. IOERT significantly improved presacral control rates. Multivariate analysis indicated that uninvolved surgical margin and intense tumour regression grade assessed response, were protective for DFS.

Conclusion: Multimodal preoperative approach contributed to remarkable cancer-control outcomes and survival in cT4M0

rectal patients, if components of therapy are feasible to be maximized (including free surgical margins) and an intense pathological disease response is described.

EP-1302

The utility of Squamous Cell Carcinoma SCCAg as a marker for treatment response or relapse

L. Pietrzak¹, K. Bujko¹

¹The Maria Skłodowska-Curie Memorial Cancer Center, Radiotherapy, Warsaw, Poland

Purpose or Objective: The utility of SCCAg as a marker for treatment response or relapse is unknown in anal cancer.

Material and Methods: This is a retrospective analysis of 28 patients in whom SCCAg serum level was increased prior to treatment (mean 6,4 ng/ml, range 1,6-19,6 ng/ml). In all patients, measurement of SCCAg was performed at baseline, after completion of chemoradiation and at each visit during follow-up (median 35 months, range 7-81). All patients were treated radically.

Results: In 27 (96%) patients SCCAg level decreased to normal level after treatment. One remaining patient had persistent unresectable tumor confirmed by pathology and persistent high SCCAg level. Only one of 27 patients with normalization of SCCAg after chemoradiation had persistent ulceration in the anal canal and persistent enlarged inguinal lymph node. This patient underwent abdominoperineal resection with inguinal lymphadenectomy. On pathological examination only a few cancer cells were found in the inguinal nodes and the primary tumour site was free of cancer. In six patients, increase of SCCAg was observed during follow-up. In one of these 6 patients, locoregional recurrence was also detected clinically at the same time. In 4 patients, the diagnostic examinations performed because of elevated SCCAg revealed locoregional recurrence (n=2) or distant metastases (n=2). In one remaining patient the diagnostic examinations were negative; distant metastases were detected 5 months thereafter. The remaining 20 patients had both: sustained clinical complete regression and normal SCCAg level.

Conclusion: This study suggests utility of SCCAg in the monitoring of response to chemoradiation and in the detection of recurrence

EP-1303

Radiotherapy dose-escalation in rectal cancer: preliminary results of a pooled analysis.

M. Lupattelli¹, V. Picardi², F. Navarra³, M.A. Gambacorta⁴, M. Osti⁵, G. Macchia², E. Palazzari⁶, A.M. Podlesko⁶, A. Re⁴, L. Nicosia⁵, A. De Paoli³

³CRO Aviano, Radiotherapy, Aviano, Italy

⁴UCSC Rome, Radiotherapy, Rome, Italy

⁵S. Andrea Hospital, Radiotherapy, Rome, Italy

⁶Perugia University Santa Maria della Misericordia Hospital, Radiotherapy, Perugia, Italy

Purpose or Objective: Preoperative radiotherapy (RT), alone or in combination with chemotherapy (CT) is the standard of care in patients (pts) with locally advanced rectal cancer (LARC). Nevertheless in those tumors in which the down-sizing and down-staging are necessary, (cT3 MRF - / + N0 of lower rectum or cT3-4 MRF + / N0-2) preoperative chemoradiotherapy (CT-RT) is recommended. There is a correlation between RT dose and response and the tumor regression grade (TRG) represents an independent prognostic factor. The aim of the study is to analyze the role of RT dose intensification in the preoperative treatment of LARC in terms of feasibility, toxicity and pathological response grade.

Material and Methods: We have retrospectively analyzed 69 pts with histological diagnosis of LARC (stage II-III) treated in five Italian Radiotherapy centres. The treatment programme included: intensity-modulated radiotherapy (IMRT) delivered

to total mesorectum and pelvic lymphatic drainage with simultaneous integrated boost (SIB) to the tumor bed and adjacent mesorectum. Fluoropyrimidine-based CT was administered. The acute toxicity was evaluated according to CTCAE 4.0 scale.

Results: Pts characteristics: median age 63.5yy (range 29-84), median tumor distance-IAS 50 mm (range 0-100), median tumor size 50 mm (range 25-120), MRF involvement 24 pts, Stage IIA 7 pts - III 62 pts. All of the pts completed the RT; 45 Gy were delivered to total mesorectum and lymphatic drainage with median SIB dose of 55 Gy (range 52.5-57.5). Forty-nine (71%) pts received concomitant CT with capecitabine alone and 17 (25%) capecitabine plus oxaliplatin. Globally, 16/69 (23%) pts did not complete CT for haematological (5) or, gastrointestinal toxicities (5) and other causes (6). Fourteen (20%), 33 (48%) and 23 (33%) pts experienced grade 1-2 haematological, gastrointestinal and genitourinary toxicity, respectively. Two out of 69 (3%) pts developed grade 3 haematological toxicity and 9/69 (13%) grade 3 gastrointestinal toxicity. Forty-three pts underwent surgery (LAR 28, APR 10, local excision 5 pts) but definitive histology is not yet available in 7 pts. Twenty-six pts are waiting for surgery. The tumor downstaging was documented in 29/36 (80.5%) pts. Forty-four rate (16/36) of surgical cases achieved pathologic complete response.

Conclusion: Despite the limitations related to the heterogeneity of the treatment delivery (SIB dose and concomitant CT), the RT dose-escalation in the preoperative treatment of LARC seems feasible, well tolerated and effective in terms of tumor downstaging and pathological complete response. Nevertheless, this results need to be confirmed on a larger cohort.

Image guided intensity modulated radiotherapy for anal cancer: a multi institutional study

B. De Bari¹, L. Lestrade², A. Franzetti Pellanda³, R. Jumeau¹, M. Kountouri¹, O. Matzinger⁴, N. Corradini⁵, M. Biggiogero³, G. Ballerini³, J. Bourhis¹, R. Miralbell², M. Ozsahin¹, T. Zilli²

¹Centre Hospitalier Universitaire Vaudois, Department of Radiation Oncology, Lausanne Vaud, Switzerland

²Hopitaux Universitaires de Genève, Department of Radiation Oncology, Genève, Switzerland

³Clinica luganese, Department of Radiation Oncology, Lugano, Switzerland

⁴Riviera-Chablais Hospital, Department of Radiation Oncology, Vevey, Switzerland

⁵Clinica luganese, Medical Physics, Lugano, Switzerland

Purpose or Objective: To report the results of a retrospective pooled analysis of anal carcinoma (AC) patients treated with IMRT, VMAT, helical tomotherapy (HT) and daily image-guided RT (IGRT) in 3 Swiss radiotherapy centers.

Material and Methods: Local control (LC) and grade 3 or more toxicity rate (CTCAE v.4.0) were the primary endpoints. Overall (OS), disease-free (DFS), distant metastasis-free (DMFS) and colostomy-free survival (CFS) were also studied. Volumes were defined as follows: CTV1 : Anal canal, mesorectal, pelvic, and inguinal nodes. CTV2 : anal tumor and clinically positive nodes. Planning target volumes were obtained by adding 5-mm margin to the CTV (PTV1 and PTV2, respectively). PTV1 received 36 Gy (1.8 Gy/fraction) delivered with IMRT (n = 44), VMAT (n = 16) or HT (n = 100), while PTV2 received a sequential boost up to a total dose of 59.4-60 Gy (1.8-2 Gy/fr), delivered with IMRT (n = 16), VMAT (n = 18) , HT (n = 59) or 3D-conformal RT (CRT, n = 67).

Results: From 03.2006 to 04.2015, 160 patients were treated; 30, 68, 60 and 2 patients presented stage I, II, III, and IV, respectively. Median age was 62 years (range: 35-89). A planned gap was used in 130 patients. Median gap duration was 10 days (range, 5-24). Concomitant chemotherapy (CTX) was delivered in 149 patients, mainly using mitomycine C combined with fluoropyrimidines (i.v. or oral, n = 139). Median follow-up was 45 months (range: 3-97). Four-year LC,

OS, DFS, DMFS and CFS rates were 83.6%, 82.3%, 82.7%, 93.4% and 88%, respectively. Time to progression for relapsing patients was 29 months (range: 1-78). A total of 24 patients presented a recurrence (local only in 14, locoregional in 1, locoregional and distant in 1, local and distant in 3, regional only in 2, and distant only in 3 patients). Fourteen patients underwent a colostomy because of local recurrence (n = 12) or pretreatment anal sphincter dysfunction (n = 2). Grade 3 acute toxicity was observed in 30 patients (18.4%), usually as erythema (23/30) or diarrhoea (10/30). No late G3 cutaneous toxicity was recorded. At the time of analysis, 150 patients presented more than 6 months of follow-up and were considered evaluable for late toxicity. Data about late toxicity were not available for 6 patients, followed in other Institutions. Looking at the final 144 patients, 3 of them patients presented a late G3 gastrointestinal toxicity (anal incontinence). No G4 acute or late toxicity was recorded. No significant differences were observed in terms of local control or acute G3 toxicity between IMRT and 3D-CRT boost techniques.

Conclusion: A total dose of 59.4/60 Gy to the anal tumor and involved nodes, including 36 Gy to the elective nodal regions , is effective and safe when delivered using modern IMRT techniques and daily IGRT. Thus, VMAT or HT and concurrent CTX are the standard of care in our institutions.

EP-1305

Impact of time from neoadjuvant treatment and surgery in rectal cancer: a monoinstitutional report

L. Belgioia¹, A. Bacigalupo¹, I. Chiola¹, G. Blandino¹, G. Lamanna¹, S. Vagge¹, S. Scabini², E. Romairone², R. Murialdo³, A. Ballestrero³, R. Corvò¹

¹IRCCS AOU San Martino-IST, Radiation Oncology, Genoa, Italy

²IRCCS AOU San Martino-IST, Surgery Department, Genoa, Italy

³IRCCS AOU San Martino-IST, Medical Oncology, Genoa, Italy

Purpose or Objective: The aim of the study was to analyze if time from neo-adjuvant chemoradiotherapy (CRT) to radical surgery influences oncologic outcomes in locally advanced rectal cancer.

Material and Methods: We performed a retrospective analysis of 132 consecutive patients with rectal cancer treated at our Institute from March 2006 to March 2013 who underwent to neoadjuvant therapy followed by radical resection. Of these, 12 patients were excluded as lost at follow up, 3 patients for peritoneal carcinosis detection at surgery time and 3 patients refused surgery after neoadjuvant treatment. The remaining patients were analyzed and divided into two groups according to time to surgery (group A ≤ 8 weeks and group B > 8 weeks) after completion of CRT

Results: A total of 114 patients underwent total mesorectal excision (TME) after neoadjuvant treatment for stage II and III rectal cancer between 0 and 15 cm from anal verge. There were 51 (45%) patients in group A (interval ≤ 8 weeks) and 63 (55%) in group B (interval > 8 weeks). Median time from chemo-radiotherapy and surgery was 7 weeks (range 1-8) and 12 weeks (range 9-17), respectively, in group A and B. In group B there was a major number of patients with no involvement of circumferential resection margin (CRM), 60 vs 48, and a higher number of major pathologic response (pT0 - pT1), 19 vs 9. Disease free survival (DFS) at 5 years was 85.7% vs 75.9% and overall survival (OS) at 5 years was 83.7% vs 92% in group A vs group B.

Conclusion: In our analysis we did not reach statistical significance difference as regards DFS and OS in the two groups of patients; however we observed a favorable trend in the group of patients that underwent to surgery after 8 weeks from neoadjuvant treatment in terms of pathological response and free radial margin.

EP-1306

Helical Tomotherapy with daily image guided radiotherapy for neoadjuvant treatment of rectal cancer

B. De Bari¹, A. Franzetti Pellanda², A. Saidi¹, G. Ballerini², M. Biggioero², L. Negretti², A. Durham¹, J. Bourhis¹, M. Ozsahin¹
¹Centre Hospitalier Universitaire Vaudois, Department of Radiation Oncology, Lausanne Vaud, Switzerland
²Clinica luganese, Department of Radiation Oncology, Lugano, Switzerland

Purpose or Objective: Intensity modulated radiotherapy (IMRT), including helical Tomotherapy (HT), has been only recently introduced in the treatment of locally advanced rectal cancer (LARC) patients. We retrospectively assessed acute toxicity and efficacy of concomitant chemoradiotherapy (CRT) delivered with HT and daily image-guided RT (IGRT) for non metastatic LARC patients in 2 Swiss institutions.

Material and Methods: We analyzed acute grade 3+ toxicity (CTC-AE v.4.0) and local control (LC) rates. Late toxicity 3+, Overall (OS), disease-free (DFS), and colostomy-free survival (CFS) were also studied and reported. Tumor Regression Rate (TRG) after CRT was scored using the Mandard score. Volumes were defined as follows: CTV1: rectum + mesorectum + internal iliac nodes + presacral nodes + obturator nodes. In one of the 2 institution, a CTV2 was also defined: rectal GTV + corresponding mesorectum (with a 2-cm margin in the cranio-caudal direction) + nodal GTV (if N+ patients). Planning target volumes were obtained by adding 5-mm margin to the CTV (PTV1 and PTV2, respectively). PTV1 received 44-45 Gy (1.8-2 Gy/fraction), while PTV2 received a simultaneous integrated boost up to a total dose of 50 Gy (2 Gy/fr).

Results: From 01.2010 to 01.2015, 118 patients were treated; 35, 9, 61, 12 and 1 patients presented a stage II, IIIA, IIIB, IIIC and IVa, respectively. Median age was 65 years (range, 32-85). All patients received concomitant CTX with fluoropyrimidine (i.v. or oral). After a median time of 53 days (range, 1-142), all patients received a radical surgery. Mean follow-up was 21 months (range: 1-62). No Grade 3 acute toxicity was observed. Acute grade 1-2 toxicity was observed in 22% of patients. Three-years LC, OS, DFS, and CFS rates were 95.2%, 82.4%, 83% and 69%, respectively. Median time to any progression for relapsing patients was 23 months (range: 5-66). At the time of analysis, 108 patients presented more than 4 months of followup and were considered evaluable for late toxicity. Data about late toxicity were not available for 48 patients, followed in other Institutions after RT-CT. Looking at the final 60 patients, only 2 of them patients presented a late G3 gastrointestinal toxicity (anal incontinence). Looking at 3-year LC, at univariate analysis, patients operated in the 66 days after the end of the treatment (98.8% vs 83.6%, Log-rank test: $p = 0.022$) and those without endovascular invasion at final pathology (98.6% vs 83.3%, $p = 0.022$) presented better LC rates. Concomitant boost did not improve 3-year LC, but increased the rate of TRG1 and TRG1-2 patients (Pearson's chi-squared test: $p = 0.002$ and $p = 0.04$, respectively).

Conclusion: CRT delivered using HT and daily IGRT is safe and effective in the treatment of LARC patients. Longer followup time and prospective series are needed to confirm our results. Concomitant boost increase the rate of complete or nearly complete pathological response. The impact of TRG on the LC could probably assessed on after a longer followup time.

EP-1307

Chemoradiation in anal cancer with using VMAT: toxicity and early outcome.

D. Russo¹, E. Donno¹, A. Papaleo¹, E. Cavaleri¹, C. Capomolla², D. De Luca², G. Di Paola¹, F.P. Ricci¹, M. Santantonio¹

¹Vito Fazzi Hospital ASL LE, Radioterapia, Lecce, Italy

²Vito Fazzi Hospital ASL LE, Fisica Sanitaria, Lecce, Italy

Purpose or Objective: To evaluate safety and feasibility of SIB-IMRT with VMAT combined with chemotherapy as exclusive treatment in patients with anal cancer. Early response is a secondary endpoint.

Material and Methods: From November 2010 to June 2015, 16 consecutive patients with histological diagnosis of anal squamous cells carcinoma underwent to chemoradiation in our center. Patients' characteristics are described in Table 1. Radiation schedule consisted of 52-58 Gy in 2-Gy daily fractions to High Risk Volume (HR), 49.95-54 Gy to Intermediate Risk Volume (IR) and 45-48 Gy to Low Risk Volume. Daily dose fraction was around 1.65 and 1.75 for LR and IR respectively. One patient received a radiation boost up to 66 Gy after 60 days from the end of chemoradiation due to a poor objective response. HR, IR and LR delineation was performed according to AIRO guidelines published in 2012 and reviewed in 2014. Organs at Risk (OAR) were: bladder, bilateral femoral heads and small bowel. All treatment plans were obtained with VMAT technique. SIB was calculate by Oncentra Inverse Planning System. In the first 3 patients was performed a split course radiation schedule to reduce toxicity risk. Target objectives were minimum coverage by 95% isodose and maximum dose of 107% within the volume. OARs' constraints were those suggested by AIRO guidelines (femoral heads: V52<10%; small bowel V45< 195cc; bladder: V60<50%). Median follow-up was 13 months (3-55). Concomitant chemotherapy is described in table 1.

Patient characteristics	
Age	Range 45-83
Sex	F: 12
	M: 4
Stage (TNM)	I: 1
	II: 5
	IIIA: 4
	IIIB: 6
Concomitant Chemotherapy	Mytomycin/5 FU: 4
Schedule	Mytomycin/Xeloda: 6
	CDDP/ 5 FU: 2
	SFU: 2
	Xeloda: 2

Table 1: Description of patients' characteristics and concomitant chemotherapy schedules.

Acute Toxicity, according to RTOG criteria, was weekly recorded during radiotherapy course and monthly in the first three months of follow-up.

Results: Target coverage and organ at risk sparing were optimal in all plans (fig1).

Fig 1: Example of treatment plan. Prescription doses were 54 Gy to HR, 49.95 Gy to IR and 45.9 Gy to LR. Treatment was delivered in 27 fractions.

During chemoradiation none of patients developed G3 Gastroenteric toxicity (6 G1; 7 G2) and Genitourinary side effects were extremely rare (1 G1; 1 G2). Skin toxicity was the most important adverse event registered (8 G2; 4 G3). All chemotherapy schedule were well tolerated such the

incidence of hematologic toxicity was low (1 G1; 1G2). Early response evaluated by instrumental re-staging after 3 months from the end of treatment was encouraging, since 8 patients achieved complete response and 8 a partial response. Among the 6 patients with at least 2 years of follow up, 3 patient developed a progression disease (1 local relapse an 2 distant metastasis) and 1 patient died of disease after 3 years from treatment. The patient who underwent to radiation boost after chemoradiation developed anal stenosis which required a permanent colostomy.

Conclusion: SIB with VMAT combined with chemotherapy is quite feasible in anal cancer treatment. It easily allows different dose delivering to target at different risk of disease involvement. Split course schedule has not be more used because of acceptable acute toxicity profile, which was confirmed in conventional fractionation. A larger patient number and a longer follow-up are required to confirm our data.

EP-1308

Effect of prone and supine positions on setup and organ-at-risk sparing using VMAT for rectal cancer

A. Kim¹, A. Karotki¹, J. Foster², K. Yip², J. Presutti², S. Wong³, W. Chu³

¹Sunnybrook Health Sciences Centre University of Toronto, Medical Physics, Toronto, Canada

²Sunnybrook Health Sciences Centre University of Toronto, Radiation Therapy, Toronto, Canada

³Sunnybrook Health Sciences Centre University of Toronto, Radiation Oncology, Toronto, Canada

Purpose or Objective: Radiation treatment for rectal cancer is usually given in the prone position on a belly board with the aim to move the small bowel away from the treatment volume. In practice, this position is sometimes difficult to set up reproducibly and is poorly tolerated for some patients. With the increasing conformality and accuracy of using VMAT and cone beam CT (CBCT), we asked if there was any dosimetric advantage of treating rectal patients prone—it may be that patients can be better treated in the supine orientation. The two aims of this study are 1) to investigate setup reproducibility of rectal cancer patients treated in the prone and supine positions, and 2) to compare dose-volume histogram (DVH) metrics for the bladder and small bowel for both treatment positions.

Material and Methods: Eighteen consecutive patients with rectal cancer who received neoadjuvant chemoradiation were selected for this study. 9 were treated supine and 9 in the prone position. Patients were prescribed a total dose of 50.4 Gy in 1.8 Gy daily fractions according to institutional protocol and were planned with a VMAT posterior half arc. To determine setup reproducibility, weekly CBCTs were acquired and matched to bone. The CBCT-determined translational and rotational shifts were recorded. Clinically relevant dose-volume histogram values were generated for the small bowel and bladder.

Results: The CBCT-determined rotational setup error ranges for the prone position in pitch, roll, and yaw were [-3.6° 4.7°], [-4.2° 3.2°], and [-1.4° 1.1°] respectively. For the supine position the corresponding ranges were [-4.8° 2.0°], [-2.4° 1.3°], and [-1.0° 3.2°]. 7 patients exhibited >±3° rotational errors in the prone versus only 2 in the supine position, indicating better setup reproducibility in the supine position. Translational errors were generally <±1 cm in all directions for both positions. The small bowel V45 and mean dose for prone was 7.3±9.9% and 16.9±6.8 Gy (± values represent standard deviations) respectively; for supine the values were 6.8±7.6% and 19.6±6.4 Gy. The bladder V30 and mean dose for prone were 64.4±14.3% and 36.8±4.1 Gy respectively; for supine, these values were 68.7±18.5% and 37.3±4.1Gy.

Conclusion: There may be increased rotational instability in the prone position, but no apparent dosimetric advantage for small bowel sparing was observed. Rectal cancer patients

who undergo neoadjuvant radiation using VMAT and CBCT may not need to be treated prone on a belly board.

EP-1309

Predictive value of FDG-PET in rectal cancer: correlation with tumour characteristics and response.

³University Hospital Maggiore della Carità, Biostatistica ed Epidemiologia Clinica, Novara, Italy

⁴Università del "Piemonte Orientale", Dipartimento di Medicina Traslazionale, Novara, Italy

Purpose or Objective: The present study analyses the correlation of pre-treatment (18)F-fluorodeoxyglucose Positron Emission Tomography/Computed Tomography (FDG-PET/CT) standardized uptake value (SUV) and total lesion glycolysis (TLG) with tumour characteristics and clinical response in a series of rectal cancer patients treated with neoadjuvant chemo-radiotherapy.

Material and Methods: Fifty-six patients were included in the present analysis. Pre-treatment PET maximum SUV (SUVmax), mean SUV and TLG of primary tumour were calculated for each patient. The total dose of pelvic radiotherapy was 45-50.4 Gy, 1.8 Gy/fraction. Chemotherapy was delivered with capecitabina or 5-fluorouracil. Six to eight weeks after RT-CT, 44 patients (78.6%) had anterior rectal resection and 12 patients (21.4%) had abdominal pelvic resection (Miles). Tumor Regression Grade (TRG) (Mandard, 1994) was defined on surgical specimen. Complete regression (TRG1) was observed in 10/56 (17.9%). The correlation between PET/CT results and histopathological data and tumour response was analyzed.

Results: At the level of the primary tumour, SUVmax ranged from 4.17 and 54.06 (mean 22.46, median 18.96), SUV mean ranged from 6.22 and 32.64 (mean 13.42, median 11.09) and TLG ranged from 7.96 and 3158.23 (mean 350.21, median 183.55).

SUVmax (p=0.05) and TLG (p=0.002) significantly correlated with T-stage. Median SUVmax was significantly higher (p = 0.05) for lesions with partial response (PR, 46/56, 82.1%) than for lesions with complete response (CR, 34/54, 17.9%). Median TLG was significantly higher (p=0.034) for lesions with partial response (PR, 45/54, 83.3%) than for lesions with complete response (CR, 9/54, 16.7%).

SUVmean was not significantly correlated with T-stage (p=0.074). Median SUVmean was higher for lesions with partial response (PR, 45/54, 83.3%) than for lesions with complete response (CR, 9/54, 16.7%) but without statistical significance (p =0.18).

Conclusion: Our data suggest that pre-treatment FDG-PET/CT SUVmax and TLG are strongly associated with tumour primary tumour stage. Furthermore they correlate with prediction of tumour response after neoadjuvant treatment.

⁴Hospital Universitario Marques De Valdecilla, Medical Oncology, Santander, Spain

⁵Hospital Universitario Marques De Valdecilla, Patology, Santander, Spain

⁶Hospital Universitario Marques De Valdecilla, Gynecology, Santander, Spain

Purpose or Objective: To evaluate pathological response and clinical outcomes in women with locally advanced cervical cancer treated with radiochemotherapy and surgery in a tertiary hospital.

Material and Methods: In this retrospective analysis we have included 59 patients with cervical cancer (FIGO stages IB2-IVA) who were treated between December 2004 and July 2015 with concurrent chemoradiation therapy (CCRT) followed by surgery. The patients were treated with pelvic external beam radiotherapy at 46-50,4 Gy, 1,8-2 Gy/day.

Based on CT or PET CT if aortic nodes were demonstrated, extended external beam radiotherapy was performed. We boosted nodes or parametria if they were affected (60-68 Gy, 2 Gy/day). After four weeks of treatment, patients received brachytherapy from 15 to 26 Gy in 3-6 fractions with 2D planification or 3D planification ($n=28$), with a total tumour dose between 85 and 90 Gy. Concurrent chemotherapy with weekly platinum and in some cases oral fluoropyrimidine was administered. Overall treatment time did not exceed 8 weeks. All patients completed surgery between 4-15 weeks after CCRT.

Results: The median age was 52 years (range 30 and 77). Squamous cell carcinoma was the most common subtype (81%). All patients received hysterectomy. 7 patients (12%) underwent lymphadenectomy. In global, 32 patients (54%) had a complete response, 20 (34%) a partial response and 7 (12%) patients had residual microscopic disease in the pathologic analysis. With a median follow up of 53 months (range from 2 to 128 months) overall survival was 85% and disease free survival 81%

Conclusion: Our results show that CCRT followed by surgery gets excellent outcomes with acceptable toxicity and may reduce local recurrences. Besides it enables assessment of the pathological response.

EP-1312

Measurement of GTV delineation uncertainty for centrally recurrent gynaecological cancers

D. Bernstein¹, M. Llewelyn¹, A. Taylor¹, S. Nill¹, U. Oelfke¹

¹Royal Marsden Hospital Trust & Institute of Cancer Research, Department of Medical Physics, London, United Kingdom

Purpose or Objective: To quantify the magnitude of clinician uncertainty in GTV delineation for patients with recurrent gynaecological cancers.

Material and Methods: GTV delineation uncertainty was retrospectively investigated in patients previously treated in our institution for centrally recurrent gynaecological cancer. In order to record clinician delineation uncertainty, clinicians were asked to draw 3 outlines per GTV; an inner GTV (GTV_I) corresponding to the innermost boundary the GTV is likely to have, an outer GTV (GTV_O) corresponding to the outermost boundary the GTV is likely to have and a clinical GTV (GTV_C) outlined in accordance with local treatment protocols. For GTV_C, each observer submitted a confidence score from 1 to 5, with 1 being no confidence in drawn and 5 complete confidence. For each patient, the 3 GTV's were delineated on a co-registered CT-MR, using a local rigid soft tissue registration, as well as on MR images only in order to identify how the co-registered CT information affects the decision process. Paired T Tests (p) were used to test for significance and Pearson correlation coefficient (r) for correlations.

Results: To date, 18 recurrences from 17 patients were investigated by a single observer. For all 17 MR only contours and for 15 out of the 17 CT-MR contours, the GTV_O and GTV_C were identical. GTV_C ranged from 6.3 to 192.9cm³ for CT-MR contours and from 5.5 to 180.1cm³ for the MR only contours, with a mean \pm standard deviation of 53.3 \pm 44.7cm³ and 39.3 \pm 40.4cm³ respectively. The reduction in GTV_I relative to GTV_C was 19.6 \pm 12.4cm³ ($p<0.01$) for CT-MR contours and 13.3 \pm 9.8cm³ ($p<0.01$) for MR only contours. For GTV_C, MR only contours were consistently smaller than CT-MR contours by 14.0 \pm 11.4cm³ ($p<0.01$). For GTV_I, MR only contours were smaller for 13 out of the 17 cases, with differences of 7.9 \pm 7.7cm³ ($p<0.01$). The 3D difference in the centre of mass (COM) between GTV_O and GTV_C was 2 \pm 2mm for the CT-MR contours and 2 \pm 1mm for the MR only contours. Scoring of GTV_C was significantly lower ($p<0.01$) for CT-MR contours relative to MR only contours, with scores of 2.8 \pm 0.6 and 3.6 \pm 0.7 respectively.

Conclusion: Uncertainty exists in defining the boundary of the GTV for this patient cohort resulting in uncertainty in

both the volume and centre of the GTV. The process of using co-registering MR-CT images increases the uncertainty and leads to larger volumes when compared to GTV delineation using MR only. Data from additional observers will help quantify the magnitude of GTV delineation uncertainties. The limitation of having outlines from a single non-expert observer will be addressed in the final publication.

⁸Bellaria Hospital, Radiotherapy Department, Bologna, Italy

Purpose or Objective: To evaluate long-term clinical results after intensity modulated radiotherapy technique (IMRT) on vaginal vault in post-operative low-risk endometrial cancer patients.

Material and Methods: Patients enrolled in two sequential trials (June 2006-October 2014) were analysed. A radiopaque methacrylate vaginal applicator was placed in the vagina. Patients were planned in supine position and immobilized using a vacuum cushion. Each patient was instructed to follow a protocol of controlled bladder filling and rectal emptying. Three radiopaque markers (1 mm diameter) fixed on the applicator allowed to improve visualization on portals imaging. Radiotherapy was delivered on the upper two thirds of the residual vagina (CTV), daily identified by the radiopaque markers. A 5 mm isotropic margin was added to the CTV in order to define the planning target volume (PTV). A 7 beams step and shoot IMRT technique was used by means of Plato Sunrise and Ergo++ treatment planning systems. 25Gy/5Gy per fraction in the first trial and 30Gy/6Gy in the second one were the doses delivered to PTV. Toxicity was scored by the CTC-AE v.3.0 scale.

Results: 23 patients (median age 63 years, range 49-88; stage IA: 69.6%, IB: 21.7%, II: 8.7%; grading G1: 3; G2: 17; G3: 3) were included in this analysis. Seven patients received 25Gy/5Gy and 16 received 30 Gy/6Gy per fraction. Proctitis and dysuria were the most common toxicities. Twelve patients (52.2%) developed late mild toxicity (G2: 1 rectal bleeding and 1 atrophic skin with plaque lesions). The most common late toxicity was G1 vulvar telangiectasia (26%), while 3 patients developed G1 vaginal stenosis (Table 1).

Table 1: Toxicity (CTC-AE Scale v.3.0)

Acute Toxicity				
Type	N° pt (%)	N°pt (%)	N° pt (%)	N° pt (%)
	Grade 1	Grade 2	Grade 3	Grade 4
Skin reaction	5(21.7)	2 (8.6)	0 (0)	0 (0)
Proctitis	11(47.8)	3 (13.0)	0 (0)	0 (0)
Dysuria	8(34.7)	4 (17.3)	0 (0)	0 (0)
Mucosal inflammation	2 (8.6)	2 (8.6)	0 (0)	0 (0)
Late Toxicity				
Type	N° pt (%)	N°pt (%)	N° pt (%)	N° pt (%)
	Grade 1	Grade 2	Grade 3	Grade 4
Skin reaction	1(4.3)	1(4.3)	0 (0)	0 (0)
Proctitis/Rectal bleeding	2 (8.6)	1(4.3)	0 (0)	0 (0)
Dysuria	3 (13.0)	0(0)	0 (0)	0 (0)
Atrophic mucosae	1 (4.3)	0(0)	0 (0)	0 (0)
Vulvar telangiectasia	6 (26.0)	0(0)	0 (0)	0 (0)
Vaginal Stenosis	3(13.0)	0(0)	0 (0)	0 (0)

With a median follow-up of 52 months (range 4-103) no vaginal recurrence was observed (5-year local control: 100%), while 4 patients developed pelvic or distance relapse (5-year disease-free survival: 86.4%). Five-year overall survival was 100%.

Conclusion: Endovaginal brachytherapy studies reported 0-5.2% late severe toxicity. Most toxicities were vaginal and urethral stenosis or rectal vaginal fistula, not observed in our study. In conclusion postoperative IMRT on vaginal vault showed promising clinical long-term results.

¹²CHA Bundang Medical Center- CHA University, Department of Radiation Oncology, Seongnam, Korea Republic of

Purpose or Objective: The current study aims to evaluate the outcomes in patients treated with radical radiotherapy for cervical cancer who received external beam radiotherapy (EBRT) boost in place of intracavitary brachytherapy (ICBT).

Material and Methods: We performed a multicenter retrospective study on the patients with cervical cancer treated with external beam boost as a substitution of ICBT during the period of January 2005 through October 2012 in 11 participating radiation oncology centers in Korea. Treatment outcome, prognostic factor, and toxicity were evaluated.

Results: Seventy-five patients were identified. The median age of the patients was 58 years (range, 33-92 years). The clinical stages were I in 6, II in 34, III in 18, and IVA in 17 patients. Concurrent chemotherapy was performed to 64 patients (85.3%). Radiation doses were median 46 Gy (range, 40-54 Gy) for whole pelvis and 24 Gy (range, 9-35 Gy) for tumor boost. Three-dimensional radiotherapy (in 24 patients) or intensity-modulated radiotherapy (in 51 patients) was used for tumor boost. On images taken 3-6 months after radiotherapy, 46 patients showed complete response (CR), 24 had partial response, and 2 were found to have progressive disease. The median follow-up time was 33 months. Disease progression was found in 30 patients (40.0%). Among these patients, 21 (28.0%) showed local progression with a median time to progression of 29 months (range, 3-101 months). The 5-year local progression-free survival (LPFS) rate was 70.0%. On uni- and multivariate analyses, treatment response at 3-6

months after radiotherapy was a significant factor for LPFS. Patients with CR had higher LPFS rate than the patients without CR (88.6% vs. 30.8%, at 5-year, $p < 0.01$). Grade 3 toxicity was found in 8 patients (5 hematologic, 2 urinary, and 1 skeletal) and grade 5 bowel toxicity was found in 1 patient.

Conclusion: In radical radiotherapy for cervical cancer, EBRT can be an option for tumor boost in cases where ICBT cannot be performed. Tumor response at 3-6 months after radiotherapy was a significant prognostic factor for local control.

EP-1315

Abdominopelvic Radiotherapy for advanced endometrial cancer after surgery and chemotherapy: results

V. Rodriguez Gonzalez¹, J. Perez-Regadera², D. Lora³, A. Campos², C. Chavez², B. Gil², R. Prados², M. Colmenero²

¹Rodriguez Gonzalez Virginia, Radiation Oncology, Madrid, Spain

²Hospital Doce de Octubre, Radiation Oncology, Madrid, Spain

³Hospital Doce de Octubre, Epidemiology, Madrid, Spain

Purpose or Objective: Patients with advanced endometrial cancer are a very heterogeneous group of patients in which the prognosis is influenced by the number of extrauterine locations, abdominal and nodal spread, type of surgery, tumor residue and histology.

Material and Methods: We studied 47 patients treated with SQTWAPI. The FIGO staging was IIIA in 6 patients, IIIC in 22 and IVB in 16. The mean follow-up for disease-free survival (DFS) was 32 months. In 26 patients were found 3 extrauterine locations ($\leq 3LE$) and in 21 $> 3LE$. Abdominal spread was present in 26 and was not in 21, negative lymph node spread in 11 (G-), positive in 33 (G+) and unknown in 3 (G?). Combination of abdominal dissemination and lymph node spread (AG) was observed in 19 patients, only abdominal in 7 (SA), single nodal in 17 (SG) and no abdominal or nodal in 4 (NAG). In 23 ovarian surgery was performed and in 24 it was suboptimal. In 8 patients remained tumor residue and 39 did not remain. 19 patients had endometrioid histology and 28 had a different one. Histological grade 1-2 in 11 and G3 in 36.

Results: The 5-year DFS was respectively $3LE$ patients was 69% vs 30% in $> 3LE$ ($p = 0.0445$). With abdominal spread 73% vs 35% without ($p = 0.05$). Group (G-) 90%, group (G+) 47% and Group (G?) 0%, ($p = 0.0062$). No residue 54% vs 34% ($p = 0.11$). Group (AG) 22%, group (SG) 65%, group (SA) 85%, Group (NAG) 100% ($p = 0.0185$). With ovarian protocol surgery 42% and without it 62% ($p = 0.23$).

Conclusion: The number of extrauterine locations, lymph node spread, abdominal dissemination and the combination of both influenced the SLE.

EP-1316

Value of imaging modalities in predicting pelvic lymph node metastases for uterine cervical cancer

W.K. Jung¹, K.J. Lee¹, J.H. Lee¹, Y.J. Kim¹, J.Y. Kim¹, H.J. Yoon², B.C. Kang³, S.C. Kim⁴, H.S. Moon⁴, W. Ju⁴, Y.H. Kim⁴, K.R. Park¹

²Ewha Womans University, Nuclear Medicine, Seoul, Korea Republic of

³Ewha Womans University, Radiology, Seoul, Korea Republic of

⁴Ewha Womans University, Obstetrics and Gynecology, Seoul, Korea Republic of

Purpose or Objective: The only imaging modalities without pathological confirmation are used to assess lymph node (LN) metastases and to perform radiation therapy (RT) planning for patients with uterine cervical cancer treated with concomitant chemoradiotherapy (CCRT) or RT alone. The aim of this study was to evaluate the accuracy of computed

tomography (CT), magnetic resonance imaging (MRI) and positron emission tomography-computed tomography (PET/CT) in predicting pelvic LN metastases.

Material and Methods: From January 2009 to March 2015, one hundred fifty six patients with International Federation of Obstetrics and Gynecology (FIGO) Stage IA1-IIIB uterine cervical cancer who underwent radical hysterectomy and pelvic lymphadenectomy, and CT, MRI and PET/CT before surgery were included in this study. The Criteria for LN metastases were a LN diameter of 1cm or more at CT and MRI and a focally increased FDG uptake greater than SUVmax 3.0 at PET/CT. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy for pelvic LN metastases were estimated on the basis of imaging and postsurgical pathological findings. Chi square test and McNemar's test was used to compare the sensitivity and specificity of imaging modalities for the detection of metastatic pelvic LN. A $P \leq 0.05$ was considered statistically significant.

Results: Among 156 patients, 35 (22%) had pelvic LN metastasis on postsurgical pathological findings. There was no pelvic LN metastasis for stage IA. The rates of pelvic LN metastasis on pathological findings for stage IB, IIA and IIB were 19%, 45%, 67%, respectively. The sensitivity, specificity, PPV, NPV and accuracy for detection of pelvic LN metastases were 48%, 87%, 39%, 91% and 81% for CT; 28%, 97%, 59%, 89% and 87% for MRI; and 43%, 90%, 43%, 90% and 83% for PET/CT, respectively. The sensitivity was highest for PET/CT, the specificity, highest for MRI and the accuracy, highest for MRI. The difference between single and multiple metastases on image studies to predict LN metastasis was not statistically significant ($P = 0.271$).

Conclusion: CT, MRI and PET/CT showed low sensitivity and high specificity. The accuracies (greater than 80%) of the three imaging modalities were acceptable for RT planning for patients treated with CCRT or RT alone. More efforts are necessary to improve sensitivity in predicting pelvic LN metastases.

⁵Ain Touta Hospital, Surgery, Batna, Algeria

⁶Scientific research laboratory of molecular biology and genetics- Faculty of Medicine- University Constantine 3., Medical oncology-, Constantine, Algeria

Purpose or Objective: The outcomes among patients with endometrial cancer (EC) are generally favorable. However, certain risk factors, such as age, comorbidities, FIGO stage, histology type, myometrial infiltration and histology grade, may influence survival and prognosis. The aim of this study was to analyze the impact of prognostic factors on disease-free survival (DFS) and overall survival (OS) in patients treated with adjuvant radiotherapy.

Material and Methods: We reviewed the records of patients diagnosed with EC and received adjuvant radiation therapy. The period of recruitment was from January 2001 to December 2014. This included epidemiological, clinical and treatment characteristics. Statistical analyses, survival curves were generated using the Kaplan-Meier technique, and differences were tested with the log-rank test. Multivariate

analysis of prognostic factors was performed using the Cox proportional hazards model and logistic regression analysis.

Results: 155 eligible patients had their data analyzed for this work. The median age was 58.7 years (range 31-86). 55 patients suffered from coexisting comorbidities. All patients underwent surgery; a total abdominal hysterectomy plus bilateral salpingo-oophorectomy in 92.2%. Lymphadenectomy was realized in only 23 patients. They were classified according to FIGO stage on (91 I, 24 II, 29 III, 10 IVA). Myometrial invasion was > 50 % in 80%. Type1 endometrial carcinoma represents the most common type (134 patients). Histologic low-grade (G1-2) was found in 77.4%. 154 patients received radiotherapy; in 79 cases external beam Radiation therapy (EBRT) was associated with vaginal brachytherapy (VB). After median follow up of 72 months (2 -144 months) loco-regional recurrence occurred in 10 patients (5.1%) and metastasis in 12 patients (7.7%), the 5-year overall survival (OS) and the Disease Free Survival (DFS) was 88,4%, and 76,1% respectively. DFS was highly significant for: histologic type 1vs 2 (p=0.005), histology grade 1-2 vs 3 (p= 0.03) and stage I-II vs III-IV (p= 0.04), The addition of VB to EBRT revealed statistically significant effect on DFS (p= 0.02).

Conclusion: In our study, tumor's histology type, grad, and FIGO stage are the important prognostic factors and should be considered when making treatment decisions. Delivery of adjuvant EBRT+VB seems to be a significant independent predictor for improved survival and pelvic control. Further studies on larger cohorts are necessary for the validation of those results.

EP-1318

Presence of lymph nodes and survival in cancer cervix: audit from tertiary care hospital in India

S. Singh¹, J. Lamin¹, D. Kapoor², A. Rani², N. Rastogi¹, S. Kumar¹

¹Sanjay Gandhi Postgraduate Institute of Medical Sciences, Dept of Radiotherapy A-Block- SGPGIMS, Lucknow UP, India

²Sanjay Gandhi Postgraduate Institute of Medical Sciences, Dept of Gynecology- General Hospital- SGPGIMS, Lucknow UP, India

Purpose or Objective: The present study was done to evaluate the impact of lymph node on survival outcome of cancer cervix treated by chemo-radiotherapy in a tertiary care hospital in a northern part of India

Material and Methods: Between Jan 2008- Dec 2011, 300 cervical cancer patients were registered. Medical records were retrieved and documented for various host and treatment related parameters and outcomes. Local disease free survival (LDFS) and overall survival (OS) was calculated from time of registration and computed by Kaplan-Meier method. Death due to any cause or loss to follow-up was considered as an event for survival analysis i.e. assuming the worst case scenario.

Results: Of 300 patients, 72 (24%) did not report after first consultation while 64 (21%) were referred for brachytherapy from outside medical facilities. For present analysis, 164 (55%) patients who received treatment with either radical or palliative intent in our department were studied. Of 164 cases, 76%, 15% and 9% presented as de novo cervical cancer, post-operative and stump carcinoma respectively. The median age (range) at presentation was 52years (26-90), 75% were postmenopausal. MRI was preferred pre staging imaging modality in half followed by ultrasound .FIGO stage I-IV was 17%, 37%, 30% and 16% respectively with more than half having bulky disease and a third presenting with regional lymph nodes and 10% had para-aortic lymph nodes seen on imaging at presentation. 93% patients were treated with radical while 7% with palliative intent. Two thirds received concurrent platin based chemoradiotherapy. Brachytherapy was taken by 80% cases. Patients were kept on clinical follow up and imaging was done as and when required.

At the time of analysis 38% are disease free and alive, 21 % dead while 40 % were lost to follow-up with or without

disease. At median follow up of 24 months (0-90), LDFS for stage I, II, III and IV was NR (not reached), NR, 17 and 0 months, p=0.000 while median OS was NR, NR, 17 and 8, p=0.000 respectively. The median OS stage-wise with or without lymph node presence was - Stage I 27m vs. NR; Stage II 46m vs.NR; Stage III 14m vs. 17m and Stage IV 9m vs 2m; p=0.000 respectively. Those receiving chemotherapy in presence of lymph nodes had a better survival outcome median 21m vs 5m p=0.001.

Conclusion: Cervical cancer presented in bulky advanced stages with regional and metastatic spread at time of presentation. The presence of lymph node decreased survival in all stages. The addition of chemotherapy improved survival outcome.

EP-1319

Clinicopathological characteristics of patients with synchronous ovarian and endometrial cancers

S. Chaudry¹, T. Sadaf¹, S. Butt¹, A.A. Syed², N. Siddique³, A. Jamshed¹, A. Kazmi³

¹Shaukat khanum Memorial Cancer Hospital, Radiation Oncology, Lahore, Pakistan

²Shaukat khanum Memorial Cancer Hospital, Surgical Oncology, Lahore, Pakistan

³Shaukat khanum Memorial Cancer Hospital, Medical Oncology, Lahore, Pakistan

Purpose or Objective: Synchronous primary endometrial and ovarian cancers are infrequent. The objective of this study is to evaluate clinicopathological characteristics and treatment outcomes of synchronous endometrial and ovarian cancer treated in our institution.

Material and Methods: The clinicopathological characteristics of 12 patients with synchronous ovarian and endometrial cancer treated at SKMCH from July 2005 to July 2015 were reviewed retrospectively. Their medical records and pathology reports were reviewed in depth from hospital database. The histologic determination was followed by the World Health Organization Committee classification, and cancer stage was based on FIGO.

Results: The median age at the time of diagnosis was 50 years (Range23-66).The incidence of synchronous primary endometrial and ovarian cancers was 2.01 % in patients with endometrial cancer. A total of 7 patients were menopausal (58%), 8 patients were nulliparous (66%) the median BMI was 29 kg/m² (range, 20-38). The most common presenting symptom was abnormal uterine bleeding. According to FIGO stage 10 cases of endometrial were I /II (88%) and 2 cases were stage III (16%). Of the ovarian cancers, 9 cases were stage I/II 83.3% and 2 cases were stage III (16.7%). Endometrioid cancer was the main pathological type in uterine carcinoma (86%) followed by serous carcinoma (14%) and similarly for ovarian cancer endometrioid was the most common pathology 67 % followed by serous/clear cell 16% and mucinous 16.7%. Most endometrial and ovarian primaries in our series were grade I and II tumors, 83% and 66% respectively.

8 patients (66%) had similar histology in both primaries while 4 patients (44%) had different histology. All patients underwent surgical intervention. Only one patient did not receive any postoperative adjuvant therapy. 10 patients received platinum-based adjuvant chemotherapy and six patients received adjuvant radiotherapy

Conclusion: Synchronous primary endometrial and ovarian cancers are infrequent and distinct set of patients. Abnormal PV bleed was the most common symptom which helped in early detection. Majority of the patients belong to concordant endometrioid histology, low grade, had younger age and High BMI. Treatment should be tailored to the stage, histology, and grade of the individual tumors.

EP-1320

Postoperative radiotherapy results of serous endometrial carcinoma: 34 cases during 2003-2014

K. Holub¹, A. Roviroso², G. Osés¹, L. Castilla¹, J. Mansilla³, R. Llorente¹, K. Cortes¹, J. Garcia¹, S. Garrido¹, A. Huguet¹, C. Castro¹, J. Sola¹, J. Ordi⁴, J. Pahisa⁵, A. Biete¹

¹Hospital Clínic i Universitari, Radiation Oncology Dpt, Barcelona, Spain

²Hospital Clínic i Provincial, Radiation Oncology Dpt, Barcelona, Spain

³Hospital Rebagliati, Radiation Oncology Dpt, Lima, Peru

⁴Hospital Clínic i Universitari, Pathology Dpt, Barcelona, Spain

⁵Hospital Clínic i Universitari, Gynecological cancer Unit, Barcelona, Spain

Purpose or Objective: To evaluate post-operative treatment results of serous endometrial carcinoma (SEC) comparing two histological subtypes (with and without an endometrioid component) and its impact on overall survival (OS), local control, distant relapses in patients treated from 2003-2014.

Material and Methods: Thirty-four patients (p) with SEC were treated with post-operative radiotherapy at our centre. All the patients were divided into two groups according to the histological subtype: 21p with pure SEC in Group 1, 13p with mixed SEC with endometrioid cells in Group 2. All patients were staged using 2009-FIGO classification. Group 1: 10-IA, 5-IB, 1-IIIa, 4-IIIC1, 1-IIIC2. Group 2: 2-IA, 7-IB, 2-IIIa, 1-IIIB, 1-IIIC1. Pathology. Group 1: Grade (G): G2- in 5p, G-3 in 16p. Group 2: Grade: G1 in 1p, G2- in 3p, G-3 in 9 p. Myometrial invasion was presented in 10p in Group 1 and 3p in Group 2. Median tumour size was 3.6cm in Group 1 and 3.9cm in Group 2. Vascular and lymphatic space invasion was presented in 5p (23.8%) in Group 1 and in 6p (46.2%) in Group 2. Radiotherapy: all p received high-dose-rate brachytherapy (1-3 fractions of 4-7 Gy), and 17/21p in Group 1 and 12/13p in Group 2 received external beam irradiation (mean dose of 45.2Gy in Group 1 and 44.6 Gy in Group 2, after 3D planning and 4-field technique tailored to surgical results). Chemotherapy: 4-6 cycles of carboplatin + paclitaxel in 8/21 pts in Group 1 and 6/13 pts in Group 2.

Results: Mean age: 68.7 years (57-81) in Group 1, 70.3 years (63-83) in Group 2. Mean follow-up (months): in Group 1: 57 (7.8-153), in Group 2: 63 (12-117.8). Relapses: No vaginal relapses were developed; only 3/34p (8.8%) presented loco-regional relapse (2p in Group 1 and 1p in Group 2); 8/34 p (23.5%) had distant metastasis (3/21 in Group 1 and 5/13 in Group 2) and 13/34p (38.2%) had died at the time of the last control. The mean OS (months) was 58.9 (range 22.9-138.8) in Group 1 and 37.1 (range 12-84.8) in Group 2. The mean survival time to metastasis (months) was 38.4 (range 8.2-70.7) in Group 1 and 19.6 (range 9.5-53) in Group 2. The mean survival time to loco-regional relapse (months) was 27.5 (10.9-16.6) in Group 1 (2p) and 13 in Group 2 (only 1p).

Conclusion: At the time of the last control 61.8%p were alive. The main cause of relapse was distant metastases followed by loco-regional relapse with no patient showing vaginal relapse. The mean OS was substantially longer in patients with the pure SEC subtype (58.9 vs. 37.1 months) as was the mean survival time to metastasis (38.4 vs. 19.6 months) possibly due to the higher number of IA stage patients. Comparisons of two histological subgroups are scarce in the literature.

EP-1321

Postoperative treatment results of clear-cell endometrial carcinoma: 20 cases from 2005 to 2014

G. Osés¹, K. Holub¹, A. Roviroso², L. Castilla¹, J. Mansilla³, R. Llorente¹, K. Cortes¹, J. Ordi⁴, J. Pahisa⁵, M. Arenas⁶, S. Sabater⁷, A. Biete¹

¹Hospital Clínic i Universitari, Radiation Oncology Dpt, Barcelona, Spain

²Hospital Clínic i Universitari, Radiation Oncology Dpt, Barcelona, Spain

³Hospital Rebagliati, Radiation Oncology Dpt, Lima, Peru

⁴Hospital Clínic i Universitari, Pathology Dpt, Barcelona, Spain

⁵Hospital Clínic i Universitari, Gynecological Cancer Unit, Barcelona, Spain

⁶Hospital sant Joan de Reus- Tarragona, Radiation Oncology Dpt., Reus, Spain

⁷Hospital General de Albacete, Radiation Oncology Dpt., Albacete, Spain

Purpose or Objective: To evaluate treatment results in the post-operative treatment of Clear-cell endometrial carcinoma (CCEC) related to overall survival (OS), local control and distant relapses from 2005 to 2014

Material and Methods: Twenty patients (pts) with CCEC were treated at our centre with post-operative radiotherapy. All patients were staged after surgery using the 2009-FIGO classification: 6-IA, 4-IB, 2-II, 1-IIIa, 4-IIIC1, 2-IIIC2, 1-IVA. Pathology. Grade (G): G-1 in 2pts, G2- in 5pts, G-3 in 13pts. Myometrial invasion was observed in 40% of pts. Median tumour size was 3.6cm (range 1.2-6.5cm). Vascular and lymphatic space invasion was presented in 25% of pts. Histological subtypes: clear cell in 11 pts (55%), clear cell mixed with endometrioid in 9 pts (45%). Radiotherapy: all pts received high-dose-rate brachytherapy (1-3 fractions of 7-4 Gy) and 18/20 pts received external beam irradiation (mean dose of 45 Gy (44-46Gy) after 3D planning and 4-field technique tailored to surgical results). Chemotherapy: 4-6 cycles of carboplatin + paclitaxel in 8 pts (40%).

Results: The mean age: 67 years (51-79). Mean follow-up: 4.34 years (range 0.96-9.75 years). Relapses: No pts developed vaginal relapse; 6/20 pts (33%) presented loco-regional relapse, 4/20 (20%) pts had distant metastasis (two with pelvic relapse 2/20 (10%); all 6 pts with relapse died (33%). The mean OS of 33.6 months (range 16.3-74.4 months). The mean survival to metastasis was 38.4 months (range 8.2-70.7 months) and 20.64 months (8.2-32months) to loco-regional relapse. No patient was lost to follow-up.

Conclusion: At the time of the last control 70% of patients (14/20) were alive and without relapse. The main cause of relapse was loco-regional followed by distant metastases, with no patients showing vaginal relapse. The results of this study seem to be similar to those reported in the literature.

EP-1322

Effects of upfront radiotherapy on isolated para-aortic lymph node metastasis in cervical cancer

J.H. Kim¹, K.Y. Eom², I.A. Kim², H.G. Wu¹, H.J. Kim¹

¹Seoul National University Hospital, Department of Radiation Oncology, Seoul, Korea Republic of

²Seoul National University Bundang Hospital, Department of Radiation Oncology, Bundang, Korea Republic of

Purpose or Objective: To evaluate the clinical features and treatment outcomes of isolated para-aortic lymph node (PALN) recurrence in cervical cancer patients, and analyze prognostic factors for overall survival

Material and Methods: Between 1992 and 2014, 1302 cervical cancer patients received radiotherapy at two institutions, Seoul National University Hospital and Seoul National University Bundang Hospital. Of these, 29 had isolated PALN recurrence. The median age at recurrence was 62 years (range, 34-81 years). Twenty-seven of 29 patients received salvage treatment: 16 received sequential or concurrent chemoradiotherapy, 6 radiotherapy to the para-aortic region, 4 chemotherapy alone, and 1 chemotherapy followed by salvage operation.

Results: The median follow-up duration after salvage treatment was 17.4 months (range, 1.1-139.2 months). Treatment failure after salvage treatment occurred in 10 of 27 patients. The 5-year progression-free and overall survival rates of all patients were 25.1% and 30.5%, respectively. Disease-free interval \geq 24 months and upfront radiotherapy (or chemoradiotherapy) were good prognostic factors for

overall survival in multivariate analysis. As to progression-free survival, disease-free interval, PALN size, and upfront radiotherapy (or chemoradiotherapy) were significant prognostic factors in multivariate analysis. Acute grade 3 gastrointestinal and hematologic toxicities developed in 3 patients.

Conclusion: For isolated PALN recurrence of cervical cancer, upfront radiotherapy (or chemoradiotherapy) should be considered as a salvage treatment, especially in patients with long disease-free interval.

EP-1323

Clinical audit of cervical cancer records from Kidwai Memorial Institute of Oncology, South India

S. Palled¹, U.K. Annasagara Srivinas², N. Thimmiah², V. Raghu³, T. Chitradurga Abdul Razack², N. Srinath², V. Chandraraj², S. Goyal², L. Vishwanath², G. Hosahalli Boriah², S. Poojr², G. G Venkata², J. Kunigal Puttaswamy²

¹Kidwai Memorial Institute Of Oncology, Radiation Oncology, Bangalore- Karnataka, India

²Kidwai Memorial Institute Of Oncology, Radiation Oncology, Bangalore, India

³Kidwai Memorial Institute Of Oncology, Medical Biostatistics, Bangalore, India

Purpose or Objective: To present the long term outcomes and results of the clinical audit of cervical cancer cases treated at our cancer centre in the year 2010.

Material and Methods: A clinical audit of case records of cervical cancer treated at our centre in the year 2010 was analysed. Out of the 306 patients evaluated for Cervical Cancer, case records for demographics, treatment methodology, long term toxicity and survival data was analysed using the SPSS. The variables were compared using the Chi-square test, the survival by Log-Rank test.

Results: Out of a total of 306 patients with a median age group of 50 years (range-30-80) evaluated for various symptoms pertaining to cervical cancer, 204 underwent concurrent chemoradiation and 102 patients received only radiation alone. In the total cohort, FIGO stage grouping was stage II in 36% (n=111), stage III in 56% (n=172) and stage IVA in the remaining. Radiation was delivered to a dose of 75Gy to point A, external beam radiotherapy (dose of 45-50Gy) being delivered predominantly on the Telecobalt and followed with low dose rate brachytherapy. Cisplatin based concurrent chemotherapy was delivered as weekly at a dose of 40 mg/sqm in 76% of the patients, while in the rest it was delivered as three-weekly regimen. In the weekly chemotherapy arm, 70% of them received atleast 4 cycles. Median overall treatment time (OTT) was 8.4 weeks (40-95 days). At a median follow up of 36 months, 5 year overall survival in the entire cohort was 30%. The OS in the concurrent chemo radiation arm was better (34% Vs. 29%, p=0.036). The OS in the two chemotherapy arms did not show a difference (log rank, p=0.46). The survival difference between the two stage groups demonstrated a superior outcome in patients with stage II (40% vs 32%, p=<0.05). Multivariate analysis showed stage, type of chemotherapy and overall treatment (OTT) time were significant for OS. Acute hematologic, GI, GU and skin toxicity was higher in chemoradiation arm. Difference in long term toxicity between the two treatment arms was not statistically significant.

Conclusion: Our clinical audit of cervical cancer cases treated at our cancer centre, although demonstrates slight inferior survival outcome compared to available literature, might be accounted for the lower Point A dose, longer overall treatment time, and suboptimal chemotherapy dose. These factors have been taken care in our current clinical practice.

EP-1324

High risk early stage endometrial cancer: lymphadenectomy with brachytherapy as alternative to EBRT

R.L. Fabiano¹, M. Molinaro², M. Santoro², E. Mazzei², R. Molè², A. Destito², D. Pingitore², C. Bianco³

¹Magna Graecia University, Radiotherapy, marina di strongoli, Italy

²Ciaccio Hospital, Radiotherapy, Catanzaro, Italy

³Magna Graecia University, Radiotherapy, Catanzaro, Italy

Purpose or Objective: Endometrial cancer (EC) is the most common gynecologic malignancy in developed countries, affecting 40,000 women/year. Recent studies have shown the therapeutic benefit of pelvic lymphnode dissection in order to determine the extent of disease and establish adjuvant therapies. Several trials have also shown that adjuvant radiotherapy(RT) in early stage EC reduces the risk of local recurrence without improving overall survival (OS). However the role of both lymphnode dissection and adjuvant RT in high risk early stage EC is not clearly defined. The aim of our retrospective study is to evaluate the validity of linfadenectomy with intravaginal brachiterapy (IVRT) as therapeutic option in high risk early stage EC, compare it with adjuvant external beam radiotherapy (EBRT) and determine which one determine the best results in terms of Recurrence Free Survival (RFS) and OS.

Material and Methods: Were evaluated 85 patients with EC treated between January 2007 and January 2012 with 36 months of follow-up. Of these, 47 had low risk early stage (G1 with myometrial infiltration less than 50% or G2 with myometrial infiltration less than one third) treated with bilateral hysterolpingovariectomy without any adjuvant therapy; 38 were patients with high risk early stage (G1 with more than 50% of myometrial invasion, G2 with more than one third of myometrial infiltration and G3) treated with bilateral hysterolpingo-oophorectomy and then submitted to pelvic lymphadenectomy (n. 22 pts) plus IVRT or EBRT (n. 16 pts) based on age, comorbidities, tumor grade, histotype, tumor size, presence of lymphovascular invasion space, depth or myometrial infiltration.

Results: The recurrence rate was respectively of 4% (n.2 pts) among the low risk patients with a RFS of 96% and of 19% (n.11 pts) among the high risk patients with a RFS of 81%. Considering the high risk group, the 45% of recurrence (n.5pts) occurred among patients treated with EBRT and the 55%(n.6pts) among those who received lymphadenectomy with IVRT. The mortality rate was respectively 0% (n.0 pts) among patients treated with EBRT and 0% (n.0 pts) among those who received lymphadenectomy with IVRT.

Conclusion: Our study shows that in high risk early stage EC there is no significant difference in terms of RFS among patients who received pelvic lymphadenectomy with IVRT and those which had been treated with EBRT. There was also no statistically significant difference for OS between the two groups.

EP-1325

Phase I/II study of weekly cisplatin plus paclitaxel and radiotherapy for primary cervical cancer

L. Zhu¹, W. Jiang¹, S. Tian¹, A. Qu¹, H. Wang¹, X. Li¹, A. Liao¹, Y. Jiang¹, J. Wang¹

¹Peking University Third Hosiptal, Radiation Oncology, Beijing, China

Purpose or Objective: To determine the maximum tolerated dose (MTD) and effectiveness of weekly PTX plus DDP concurrent with whole pelvic irradiation in Chinese women with locally advanced cervical cancer.

Material and Methods: Between November 2008 and March 2015, a total of 36 patients with primarycervical cancer cervical cancer, FIGO stage IB1 to IIB, confirmed by histology, negative para-aortic lymph nodes were enrolled into this phase I / II trial. Chemotherapy agents were

administered in escalating doses to cohorts of three patients at each dose level. Phase II was then assessed at the selected maximum tolerated dose (MTD). The patients were monitored for acute toxicity using the Common Toxicity Criteria, version 3.0 and late toxicity using the RTOG/EORTC. Between November 2008 and March 2015, a total of 36 patients with primary carcinoma of the cervix, FIGO stage IB1 to IIIB, confirmed by histology, negative para-aortic lymph nodes were enrolled into this phase I / II trial. Chemotherapy agents were administered in escalating doses to cohorts of three patients at each dose level. Phase II was then assessed at the selected maximum tolerated dose (MTD). The patients were monitored for acute toxicity using the Common Toxicity Criteria, version 3.0 and late toxicity using the RTOG/EORTC.

Results: Of the 36 patients, 18 enrolled on phase I study. The MTD was confirmed to be paclitaxel 40mg/m² and cisplatin 40mg/m² administered weekly for six cycles with 3D conformal external beam radiotherapy. There were additional 18 evaluable patients for the phase II analysis, yielding a total of 21 patients at the MTD. 3° (9/21) hematologic, principally neutropenia, occurs late cycles. All patients finished 5-6 cycles chemotherapy and radiotherapy in 7 weeks. The median follow-up was 24 months (5-58). At 4 months, 18 CR (1 pCR), 3 PR. At 24 months local control rate was 90.4% (19/21) . 18/21 patients (85.7%) are still survive (1 was loss of follow-up). 2 of 2 recurrent or metastasis patients have died. Late toxicities did not appear during follow-up.

Conclusion: Combination PTX and DDP administered concurrently with pelvic EBRT can be safely administered at the MTD of DDP 40 mg/m² and PTX 40 mg/m² weekly for six cycles in Chinese women. Primary result showed a good clinical outcome. We need continue follow-up. Further development to determine if the combination will help yield a survival benefit.

EP-1326

The role of PET CT in the IMRT of cervical cancer: the experience of the Institute of Candiolo

G. Cattari¹, S. Squintu¹, E. Delmastro¹, E. Garibaldi¹, S. Bresciani², P. Scapoli³, S. Cauda³, C. Bracco², T. Varetto³, P. Gabriele¹

¹FPO-IRCCS CANDIOLO, Radiotherapy, Torino, Italy

²FPO-IRCCS CANDIOLO, Medical Physics, Torino, Italy

³FPO-IRCCS CANDIOLO, Nuclear Medicine, Torino, Italy

Purpose or Objective: This paper evaluates the impact of FDG CT-PET in the treatment of cervical cancer by volumetric radiation and chemotherapy.

Material and Methods: From June 2010 to October 2015, 38 patients (pts) with cervical cancer were treated by radiotherapy, 21 with curatively (4 recurrences) and 17 with postoperatively (5 with positive margins). The mean age was 58 years (range 32-88). The histology was: squamous cell carcinoma (26 pts), adenocarcinoma (9 pts), adenosquamous carcinoma (3 pts). The grading was: G3 in 14 pts, G2 in 23 pts, G1 in 1 pt. The FIGO stage was: IB1 in 7 pts, IB2 in 3 pts, IIA1 in 5 pts, IIA2 in 2 pts, IIB in 13 pts, IIIA in 2 pts, IIIB in 2 pts, IIIB2 in 1 pt, IIIC2 in 1 pt and IVA in 2 pts. 24 pts received concurrent chemotherapy (CHT), 3 neoadjuvant CHT and 1 neoadjuvant and concomitant CHT. 3 pts were treated with IMRT by LINAC, 34 pts with image-guided IMRT-SB-IGRT using Helical Tomotherapy; 1 patient received exclusive High Dose Rate (HDR) brachytherapy. Tumor doses were ranged from 54 to 70.4 Gy in 30-32 fractions (fr); dose to the pelvis were from 50.4 to 54 Gy / 25-30 fr. In 5 pts was treated lumbar-aortic chain (51 Gy/30 fr); 14 pts received a boost on PET positive lymph nodes with dose range from 54 to 66 Gy/30 fr). 24 pts were treated with HDR boost with dose/fraction of 6-15 Gy in 1-3 frs.

Results: 37 pts received a PET-CT to staging and planning (Philips GEMINI TF), 33 of these had a PET-CT evaluation post RT. PET -CT changed the previous stage of disease in 6/37

cases (16%). 33 pts received also Magnetic Resonance (MRI) to staging, of these 10 showed positive lymph-nodes, conversely PET CT showed positive nodes in 20 pts (20%). 26 pts underwent a PET CT after RT: 18 pts showed a complete response (CR), 7 a partial response (PR), 1 pt a local persistence of lesion and a distance progression disease (PD). The time from end of treatment to PET evaluation was variable from 1 to 15 months (mean 4.3 months). About 6 pts with PR, 3 showed CR at the following PET-CT (8,12 and 14 months), 1 local stable disease (SD) and distance metastases and 2 showed local and distance PD.

Conclusion: FDG-PET changed tumor stage in 6/37 cases (16%) allowing a dose escalation on lymph-nodes detected and finally showed to be a sensitive and reliable method in the evaluation of radio-chemotherapy treatment response. The optimal timing of execution remains to be defined by further studies.

Clinical outcomes of dose escalation using simultaneous integrated boost in cervical cancer

R. Verges Capdevila¹, A. Varo², M. Mañas¹, A. Giraldo¹, J. Giralt³

¹Hospital Universitario Vall d'Hebron, Radiation Oncology, Barcelona, Spain

²Hospital Universitari Vall d'Hebron, Medical Physics, Barcelona, Spain

³Hospital Universitari Vall d'Hebron, Radiation Oncology, Barcelona, Spain

Purpose or Objective: To evaluate the toxicity and outcome of dose escalated radiotherapy using a simultaneous integrated boost (SIB) technique in patients with locally advanced cervical cancer at primary diagnosis or at nodal recurrence.

Material and Methods: Sixteen patients with FIGO Stage IB2-IIIB N1 were treated with intensity modulated radiation therapy utilizing a SIB technique for gross disease in the para-aortic and/or pelvic nodal regions (8/16) or for microscopic disease after laparoscopic pelvic and para-aortic lymphadenectomy (8/16). Women were treated to 50.4 Gy in 1.8 Gy fractions to the tumor region and the pelvic and / or para-aortic lymph node areas, and a simultaneous boost with 59.36 Gy in 2.12 Gy fractions to the boost region. The boost volume was defined as 18FDG-PET/CT positive lymph nodes. Pulse-dose-rate brachytherapy was performed in eleven of sixteen and concurrent chemotherapy consisted of weekly cisplatin 40 mg/m² in twelve patients. Acute and late toxicity, local control in the treated volumes, distant metastases and disease-free survival were assessed.

Results: With a median follow-up of 22 months (range 3 -40), rates of acute > grade 2 gastro-intestinal (GI), genitourinary (GU), and hematologic toxicities were 19%, 0%, and 30%, respectively. There were no grade 4 acute toxicities. One patient developed a small bowel obstruction requiring surgical intervention at 16 months. The 2-year actuarial rate of grade ≥3 GI toxicity was 6%. There were no grade 3 or 4 late GU or hematologic toxicities. All patients achieved complete remission in areas treated with high doses with SIB. Two patients presented a local recurrence at 6 and 30 months of follow-up. Three cases of sixteen (19%) relapsed in this area when you analyzed with 18FDG-PET/CT, that resulted positive, but not present disease in the pathologic anatomy of the salvage lymphadenectomy in two of them. On the other hand, two of sixteen patients (12.5%) presented systemic disease (lung metastases) at 27 and 35 months of follow-up, for each patient respectively. And one patient presented a second neoplasm in urinary tract ten months after the initial treatment of the cervix neoplasm. The 2-year actuarial disease-free survival was 62.5% but noting that only one patient presented recurrence in the area of the SIB (6.25%).

Conclusion: Dose escalated radiotherapy for node positive locally advanced cervical cancer at primary diagnosis or at nodal recurrence using a SIB results in acceptable rates of acute and late toxicity. And although our small size population, the present results contribute that the SIB technique is a good treatment for the patients with nodal regional disease.

EP-1328

Phase I study of weekly PTX/DDP, and postoperative radiotherapy for early cervical cancer in Chinese

L. Zhu¹, W. Jiang¹, S. Tian¹, A. Qu¹, H. Wang¹, X. Li¹, J. Wang¹
¹Peking University Third Hospital, Radiation Oncology, Beijing, China

Purpose or Objective: To determine the maximum tolerated dose (MTD) and dose-limiting toxicity (DLT) of weekly PTX and DDP concurrent postoperative radiotherapy in Chinese women with high- and intermediate-risk early cervical cancer.

Material and Methods: Women with high risks postoperative cervical carcinoma, negative para-aortic nodes, KPS \geq 60 were eligible. Pelvis RT (6/10MV-X, 3D-CRT, DT40Gy/20f, parametrial boost 10-20Gy/5-10f) was followed by 2-4f brachytherapy applications (192Ir, 5Gy/f). Concurrent weekly chemotherapy was started at DDP 20mg/m²/W and PTX 10mg/m²/W, and escalated in three-patient cohorts according to 3+3 methods. Serious Adverse Event (SAE) was defined as grade 4 hematologic toxicity (excluding anemia) within 30 days of treatment, or grade 3/4 non-hematologic toxicity (excluding alopecia, nausea/anorexia, vomiting).

Table 1. Chemotherapy Dose Level Schema

DDP mg/m ² /W	PTX mg/m ² /W			
	10	20	30	40
20	DL1	DL2		
25		DL3	DL4	
30			DL5	
35			DL6	
40				DL7

Results: 25 patients were enrolled and treated over seven doses levels until dose-limiting toxicity (DLT) was reached. Median age was 48 years (range, 34-66). All of patients finished RT in 6 weeks. Grade 3/4 non-hematologic toxicities were diarrhea and observed in two patients (4 cycles, DLT) at level VII. 3/4 hematologic, principally neutropenia, and occurs late cycles. One grade IV WBC and NEUT was observed at dose level VI but not seen in three additional patients. No one was delayed treatment time by concurrent chemotherapy. The 1st patient finished 3 cycles due to 2° diarrhea at level I; 1 patient for 5 cycles at level III; 4 patients finished 6 cycles at level VII. Median follow-up is 56 months. 2 recurrent or metastasis patients have died. 1 patient has died of acute pneumonia (30.5 months). Late toxicities did not appear during follow-up.

Conclusion: Combination PTX and DDP administered concurrently with pelvic EBRT can be safely administered at the MTD of DDP 35 mg/m² and PTX 30 mg/m² weekly for six cycles in Chinese women with postoperative cervical cancer.

EP-1329

Vaginal and pelvic recurrences of endometrial carcinoma with BT HDR alone or in combination with EBRT

⁶A.O.U. "Città della Salute e della Scienza di Torino", Surgical Sciences- Gynecologic Oncology, Torino, Italy

Purpose or Objective: In order to verify the results in a population of patients (pts) staged with CT and MR and treated with HDR BT and modern EBRT techniques, we review our experience in the treatment of vaginal or pelvic recurrences of endometrial adenocarcinoma.

Material and Methods: April 1997-October 2012 181 pts. 161 (89%) endometrioid, 12 adenosquamous and 8 clear cell. 30% G1, 42% G2, 25% G3, 10% G unknown. Median age 70 years (range 41-83). First line treatment: surgery alone 134 pts, surgery plus EBRT 27 pts, surgery plus CTH 18 pts and EBRT alone 2 pts. TAH&BSO 145 (80%) pts (36 with pelvic lymph-node sampling), Piver II and pelvic lymphadenectomy 36 pts. Median time to relapse 27 months (range 3-221). 126 pts had vaginal recurrences (66 limited to the dome and 60 with extension to the mid and/or lower third). 45 had a pelvic mass (31 centropelvic, 14 lateral wall); 10 pts had a vaginal recurrence with synchronous extra pelvic disease (6 lung mts and 4 LA nodes). 27 pts had prior adjuvant EBRT after surgery: dose range 32.4-57 Gy; no pts had received VBT. VBT: we use vaginal, shielded cylinders, Miami applicator and vaginal ovoid; interstitial BT in addition to VBT in 11 patients with sub urethral infiltration. HDR BT alone in 68 pts and in combination with EBRT in 113 pts. EBRT doses: range 30.6-50.4 Gy. VBT HDR doses: range 15-25 Gy when used in combination with EBRT and 30-44 Gy when used alone; fraction size: range 4-6 Gy. Interstitial BT: 2-2.5 Gy fr, 2 frs/day, total dose 20-25 Gy. Prescriptions for VBT were at depths ranging between 5 and 10 mm, according with the lesion size.

Results: Clinical CR 170 pts (94%). Median f-up 102 months (range 32-168). 38 pts DOD (14 lung mts, 8 with peritoneal mts without local failure and 16 with local failure, peritoneal and/or lung mts); 18 AWD and 125 (69%) NED. 27 local recurrences: median time to relapse 20 months (range 5-36); we retreat, 12 of these, with further VBT HDR and five achieved a new CR. Late complication: 98 pts (54%) G0, 45 pts vaginal stenosis and/or severe mucosal dystrophy, 18 mild proctitis (G1), 5 severe proctitis (G2), 2 (G3) small bowel fistula that required surgery; 12 urine incontinence. Two developed a severe necrosis of the mucosa of the inferior third of the vagina that resolved after medical therapy.

Conclusion: Treatment of local recurrences of endometrial adenocarcinoma in a population of pts staged with CT and MR and treated with HDR BT and modern EBRT is effective and safe; severe complications are rare even in pre-irradiated pts.

EP-1330

Single center experience with definitive radiotherapy for vaginal cancer

H. Westerveld¹, J.J. Den Haan¹, E.C.M. Rodenburg¹, J. Wiersma¹, G.G. Kenter², B.R. Pieters¹, L.J.A. Stalpers¹

¹Academic Medical Center, Radiation Oncology, Amsterdam, The Netherlands

²Academic Medical Center, Obstetrics and Gynaecology, Amsterdam, The Netherlands

Purpose or Objective: Vaginal cancer is the most rare gynecological malignancy. Consequently, few dose effect data are available. The main objective of our retrospective study was to analyze the outcome of all patients treated at our department with definitive (chemo-)radiotherapy for primary vaginal cancer, with a focus on local failure.

Material and Methods: Thirty-four patients were included in a period from 1994 until 2013. Patients' charts were reviewed to obtain patients', treatment and tumor characteristics. DVH parameters were analyzed after reconstruction of the original brachytherapy plan plus delineation of intermediate risk CTV (CTVIR) and organs at risk. The target volume at time of BT was the GTVres and was defined by the treating doctor based on clinical examination and CT scan. The CTVIR was defined by the tumor extension at time of diagnosis. Survival rates were calculated using the Kaplan-Meier method. Morbidity was scored by CTCAE v3.0.

Results: Nine (26%) patients had FIGO stages I; 13 (38%) II; 5 (15%) III and 7 (21%) IVA. Median age at diagnosis was 68 years (33-91). Median follow-up was 37 months (3-224). Thirty-two patients received whole pelvic external beam radiotherapy (EBRT) to a median dose of 46 Gy (45-50.4 Gy), followed by BT in 31 patients; two patients received BT alone. The median D90 and D98 of the GTVres were 68 Gy and 67 Gy respectively, with a median V100 of 88%. The median D90 and D98 of the CTVIR were 65 Gy and 61 Gy respectively, with a median V100 of 62%. Complete remission at 3 months was achieved in all but one patient. Overall survival (OS) rates at 2- and 5-years were respectively 76% and 41%. Eight (24%) patients had any grade ≥ 3 toxicity. Local recurrences were seen in seven (21%) patients of whom three had an isolated local recurrence. Patients' and treatment characteristics of this group are shown in Table 1. Although the coverage of the GTVres seemed adequate, in retrospect it was often disputable if the tumor at BT was fully covered due to poor visibility of the tumor on CT scan.

Figure 1

Table 1

Table 1. Patient tumour and treatment characteristics of 7 patients with local recurrences.								
LN: lymph node, LI: Local failure, SCC: squamous cell carcinoma, AC: adenocarcinoma, CT: chemotherapy								
	Year of diagnose	Age	Histology	FIGO stage	LN	Location	Treatment	Applicator
Local failure #1	2005	56	SCC	IVa	yes	entire length of the vagina, bladder	EBRT+BT+chemo	Interstitial needles
Local failure #2	2004	73	SCC	IVa	yes	invasion entire length of the vagina	EBRT+EBRT boost+chemo	No BT
Local failure #3	2005	82	SCC	II	no	entire length of the vagina	EBRT+BT	Intra-uterine tandem + interstitial needles mould
Local failure #4	2008	59	SCC	II	no	upper and middle third of the vagina	EBRT+BT+chemo	Interstitial needles
Local failure #5	2009	34	AC	I	no	lower third of the vagina	Surgery+BT	Interstitial needles
Local failure #6	2009	81	SCC	I	no	lower third of the vagina	EBRT+BT	Multichannel-cylinder
Local failure #7	2011	63	SCC	III	yes	lower and middle third of the vagina	Excision LI, EBRT+EBRT boost+BT+chemo	Multichannel-cylinder

Conclusion: The combination of EBRT and BT with or without concomitant chemotherapy provides reasonable outcomes in terms of tumor control and toxicity. However, there is still room for improvement. This study was too small to illustrate clear dose-effect relationships. In general, the prescribed dose on target at time of BT (GTVres) seemed low. In

addition, coverage of the CTVIR was poor, which can however be explained by the fact that until recently our target at BT was exclusively based on GTVres. Finally, the use of MRI at time of BT seems necessary to better define the target.

EP-1331

Cancer of uterine cervix: PET-CT, IMRT and HDR.
 M. Garcia-Aranda¹, X. CHEN¹, A. Montero¹, J. Valero¹, R. Alonso², D. Zucca³, R. Ciervide¹, M. Lopez¹, B. Alvarez¹, S. Payano¹, E. Sanchez¹, O. Hernandez², C. Rubio¹
¹Hospital universitario HM Sanchinarro, Radiation Oncology Department, Madrid, Spain
²Hospital universitario HM Puerta del Sur, Radiation Oncology Department, Madrid, Spain
³Hospital universitario HM Sanchinarro, Medical Physics Department, Madrid, Spain

Purpose or Objective: To evaluate the treatment results, and complication rates in patients with locally advanced cervical cancer after external beam radiotherapy (EBRT) and high-dose rate (HDR) brachytherapy with dose escalation.

Material and Methods: All patients with locally advanced cervical cancer (FIGO: IB 7 patients, II 10 patients, III 7 patients, IV 4 patients) treated with radical radiotherapy in our center from 2007 to October 2015 were reviewed. Twenty eight patients were treated with EBRT using intensity-modulated radiation therapy (IMRT) technique following by HDR brachytherapy +/- chemotherapy. Planification included CT (50%) or PET-CT (50%) for GTV delineation. The most common prescription was 50.4 Gy (1.8Gy per fraction) for pelvic lymph nodes +/- paraaortic lymph node with concomitant boost up to 60, 48 Gy (2,16Gy per fraction) for macroscopic nodal disease and parametrium affectation. HDR brachytherapy was applied using tandem (25 Gy in 5 fractions) in most patients. Toxicity was assessed according to RTOG-EORTC criteria. All statistical analysis was performed using SPSS vs 22.0.

Results: There was no grade 3 acute toxicity associated with EBRT. Only one case of grade 4 acute toxicity was observed after HDR gynecological brachytherapy. The median age was 51 years (range 39 - 81). The median of follow up was 30 months (range 4 - 85). The actuarial progression-free survival was 77% at 36 months. Median time to local progression has not been reached. The median overall survival was 30 (range 4-85) month.

Conclusion: Radical radiotherapy +/- chemotherapy is still a standard treatment in locally advanced uterine cervical cancer with good local control and global survival. Dose escalation is possible using PET-CT and IMRT which allow better conformation and better tolerance.

EP-1332

Clinical results of Nimotuzumab Plus DDP and concurrent radiotherapy for primary cervix cancer
 L. Zhu¹, S. Tian¹, A. Qu¹, H. Wang¹, X. Li¹, Y. Jiang¹, H. Sun¹, L. Lin¹, J. Wang¹
¹Peking University Third Hospital, Radiation Oncology, Beijing, China

Purpose or Objective: To determine clinical efficacy and toxicity of weekly nimotuzumab plus cisplatin concurrent with intensity-modulated radiotherapy in Chinese women with locally advanced cervical cancer.

Material and Methods: Between December 2013 and July 2015, a total of 27 patients with primary carcinoma of the cervix, FIGO stage IB1 to IVa, squamous cell carcinomas confirmed by histology were enrolled into this study. 26 patients received intensity modulated radiotherapy and 5 - 6 fractions HDR brachytherapy, 1 patient received intensity modulated radiotherapy followed by surgery because she had rectum carcinoma at the same time. Chemotherapy scheme was 200 mg nimotuzumab and 40 mg/m2 cisplatin weekly for six cycles. 2 patients (ages: 78 - 79) received only 200 mg nimotuzumab weekly for six cycles. The patients were

monitored for acute toxicity using the Common Toxicity Criteria, version 3.0 and late toxicity using the RTOG/EORTC.

Results: 3° (9/27) hematologic toxicity, principally neutropenia (9/27) and thrombocytopenia (2/27), occurs late cycles. No grade 4 toxicity occurred. 2 patients (ages: 78-79) finished 200 mg nimotuzumab weekly for six cycles with 1° hematologic. Others finished 5 - 6 cycles chemotherapy. All of patients finished radiotherapy in 7 -8 weeks. The median follow-up was 9.5 months (3 - 22). At 4 months, 24 patients had attained complete response (23 CR, 1 pCR), 3 patients had achieved partial response (PR). 2 of 3 patients who had PR appeared local recurrent at 8 months and 9 months respectively. Local control rates were 92.6 % (25/27) . All of patients are still survive. 1 patient had haemorrhagic radiation proctitis at 7 months.

Conclusion: Combination nimotuzumab 200 mg and DDP 40 mg/m² weekly for six cycles concurrently with intensity-modulated radiotherapy can be safely administered in Chinese women. Primary result showed a good clinical outcome. We need continue follow-up. Further development to determine if the combination will help yield a survival benefit.

Electronic Poster: Clinical track: Prostate

EP-1333

PSA kinetics after hypofractionated stereotactic body radiotherapy for localised prostate cancer

H. Kim¹, J.H. Phark¹, W.C. Kim¹

¹Inha University Hospital, Radiation Oncology, Incheon, Korea Republic of

Purpose or Objective: stereotactic body radiotherapy (SBRT) has emerged as an effective treatment for localized prostate cancer. However, prostate-specific antigen (PSA) kinetics after SBRT has not been well characterized. The objective of the current study is to analyze the rate of PSA decline and PSA nadir following hypofractionated SBRT in low- and intermediate-risk prostate cancer.

Material and Methods: From 2008 to 2014, thirty-six patients newly diagnosed, low- and intermediate-risk (NCCN definition) prostate cancer were treated with SBRT using Cyberknife. Total dose of 36.25 Gy in 5 fractions of 7.25 Gy were administered. No one received androgen deprivation therapy (ADT). PSA nadir and rate of change in PSA (slope) were calculated and compared.

Results: With a median follow-up of 52 months (range, 13-71), the median rates of decline of PSA were -0.359, -0.199 and -0.127 ng/mL/month, respectively, for durations of 1, 2 and 3 years after radiotherapy, respectively. The decline of PSA was maximal in the first year and continuously decreased for durations of 2 and 3 year. The median PSA nadir was 0.27 ng/mL after a median 33 months. 5-year biochemical failure (BCF)-free survival was 100% for low- and intermediate-risk patients.

Conclusion: In this report of low- and intermediate-risk prostate cancer, continuous decrease of PSA level for duration 1, 2 and 3 year following SBRT using Cyberknife resulted in lower PSA nadir. Also, SBRT led to long-term favorable BCF-free survival in low- and intermediate-risk prostate cancer.

EP-1334

PSA kinetics following SBRT versus conventionally fractionated EBRT for localised prostate cancer

H. Kim¹, J.H. Phark¹, W.C. Kim¹

¹Inha University Hospital, Radiation Oncology, Incheon, Korea Republic of

Purpose or Objective: Hypofractionated stereotactic body radiotherapy (SBRT) has emerged as an effective treatment for localized prostate cancer. However, prostate specific

antigen (PSA) kinetics after SBRT has not been well characterized. The purpose of this study was to compare the PSA kinetics between SBRT using Cyberknife and conventionally fractionated external beam radiotherapy (CF-EBRT) in low- and intermediate-risk prostate cancer.

Material and Methods: A total of sixty-nine patients with low-and intermediate-risk prostate cancer were enrolled. 34 patients were treated with SBRT (36.25Gy in 5 fractions) using Cyberknife and 35 patients treated with CF-EBRT (45 Gy whole pelvis EBRT and boost of 25.2-30.6 Gy in 1.8 Gy fractions). PSA nadir and rate of PSA decline in PSA (slope) were calculated and compared.

Results: With a median follow-up of 53.6 months (range, 14-74), the median PSA nadir and median slope for SBRT were 0.23 ng/mL and -0.430, -0.199, -0.127 and -0.094 ng/mL/month, respectively, for durations of 1, 2, 3 and 4 years following radiotherapy. Similarly, for CF-EBRT, the median PSA nadir and median slopes were 0.37 ng/mL and -0.529, -0.138, -0.109 and -0.056 ng/mL/month, respectively. The slope of CF-EBRT was significantly different with a greater median rate of change for 1 year post radiotherapy than that of SBRT (p=0.018). Contrastively, the slopes of SBRT for duration for 2, 3 and 4 year tended to be continuously greater than that of CF-EBRT (p=0.028, p=0.058 and p=0.128, respectively). The significantly lower PSA nadir was observed in SBRT (median nadir 0.23 ng/mL) compared with CF-EBRT (median nadir 0.37ng/mL) (p=0.011). 5-year biochemical failure (BCF) free survival were 100% for SBRT and 80.8% for CF-EBRT (p=0.031).

Conclusion: Patients treated with SBRT using Cyberknife experienced a lower PSA nadir and tended to be continuously greater rate of decline of PSA for duration 2, 3 and 4 years than CF-EBRT. The improved PSA kinetics of SBRT over CF-EBRT led to favorable BCF-free survival. Further studies with more patients and longer follow-up duration are required.

EP-1335

Prostate cancer hypofractionation: impact of prostate gland dimension in genitourinary toxicity

S. Fersino¹, N. Giaj Levra¹, R. Mazzola¹, A. Fiorentino¹, F. Ricchetti¹, R. Ruggieri¹, F. Alongi¹

¹Ospedale Sacro Cuore Don Calabria, Radiation Oncology, Negrar - Verona, Italy

Purpose or Objective: to analyze predictors of genitourinary (GU) toxicity in a cohort of prostate cancer (PC) patients treated with moderate hypofractionation and simultaneous integrated boost (SIB) using volumetric modulated arc therapy (VMAT) technique.

Material and Methods: Clinical and dosimetric data were prospectively collected and retrospectively analyzed. Patients were stratified into low (43%), intermediate (30%) and high-risk (27%) groups. Target volumes (expanded to define the planning volumes (PTV)) were clinical target volume (CTV) 1: prostate; CTV2: CTV1 + seminal vesicles; CTV3: CTV2 + pelvic nodes. Low-risk patients received 73.5 Gy to PTV1; intermediate-risk 73.5 Gy to PTV1 and 60 Gy to PTV2; high-risk 73.5 Gy to PTV1, 60 Gy to PTV2, and 54 Gy to PTV3. All treatments were in 30 fractions. Androgen deprivation therapy (ADT) was prescribed upfront in intermediate and high risk patients. Rectal and GU toxicities were scored according to Common Terminology Criteria for Adverse Events v4.0 scoring system.

Results: From January 2012, 60 patients with localized PC were recruited in an internal protocol of moderate hypofractionation SIB schedule using VMAT technique with definitive intent. The median follow-up was 24 months (range 10 - 36 months). GU acute toxicity was recorded as follow: G0 = 16/60 (27%), G1 = 18/60 (30%); G2= 26/60 (43%); no case of toxicity ≥ G3 was registered. GU late toxicity was recorded as follow: G0 = 20/60 (34%); G1 = 29/60 (48%); G2 = 11/56 (19%); no case of toxicity ≥ G3 was registered. The risk

of acute G2 GU toxicity was about 3 times if the prostate volume is ≥ 80 cc (p-value 0.004; 95% CI: 1.05 - 9.5). In the adjusted prediction model using the logistic regression, the probability of acute G2 GU toxicity was about 60% with the same prostate volume cut-off (p-value 0.001; 95% CI: 0.13 - 0.46), with an attitude to develop a moderate toxicity in the first 3 weeks from the beginning of treatment. In the late setting, a trend to significance ($p=0.076$) to develop an acute GU toxicity $\geq G1$ was found for bladder V60 Gy $\geq 15\%$.

Conclusion: In moderate hypofractionation in 30 fractions for prostate cancer, a prostate gland volume greater than 80 cc resulted as predictor of moderate acute GU toxicity.

EP-1336

Hypofractionated salvage radiotherapy after radical prostatectomy

P. Bulychkin¹, S. Tkachev¹, A. Mikhailova²

¹Federal State Budgetary Institution "N. N. Blokhin Russian Cancer Research Center" the Ministry of Health of the Russian Federation, radiation oncology, Moscow, Russian Federation

²Federal State Budgetary Institution "N. N. Blokhin Russian Cancer Research Center" the Ministry of Health of the Russian Federation, medical physics, Moscow, Russian Federation

Purpose or Objective: We have created and implemented in our department a new scheme of hypofractionated salvage volume modulated arc therapy with simultaneous integrated boost for patients with recurrence of prostate cancer (PCa) after radical prostatectomy (RP). The aims of our research are to evaluate toxicities and biochemical response rate.

Material and Methods: Patients with recurrence of PCa after RP have been treated by hypofractionated (HF) salvage radiotherapy (SRT). Characteristics of HF radiotherapy were as follows: the prescribed dose to the regional lymphatic nodes was 46.8 Gy of 1.8 Gy per fraction, to the prostate bed - 61.1 Gy of 2.35 Gy per fraction in case of biochemical recurrence (BR) and if region of clinical recurrence (CR) was identified - 65 Gy of 2.5 Gy each, in 26 fractions with pretreatment imaging; VMAT (two arcs: CW (185°-175°), CCW (175°-185°) technology with SIB was used. Toxicities were scored using RTOG/EORTC Radiation Toxicity Grading.

Results: 41 patients were treated by the HF SRT. Median follow-up was 22 months (10 - 30). Biochemical control rate - 37 (90.2%) patients, locoregional control rate - 41 (100 %) patients. No grade 3 or greater acute toxicities were observed.

Conclusion: We would like to suggest a new scheme of HF SRT with SIB in 26 fractions for patients with recurrence of PCa after RP. The toxicities and early biochemical response rates were comparable with conventional fractionation SRT.

EP-1337

PSA Kinetics: HDR prostate brachytherapy boost in combination with external beam radiotherapy

S. Rodda¹, F. Sun¹, A. Henry¹, K. Franks¹, D. Bottomley¹

¹St.James Oncology Institute, Clinical Oncology, Leeds, United Kingdom

Purpose or Objective: The Aim of this study is to evaluate PSA kinetics in men with intermediate and high risk prostate cancer treated with HDR brachytherapy boost in combination with external beam radiotherapy (EBRT) and short term androgen deprivation therapy (ADT).

Material and Methods: Data from 134 consecutive patients treated with HDR brachytherapy boost in combination with external beam radiotherapy was extracted from a prospectively maintained database. All the patients had a minimum follow up of 4 years. Patients who were on androgen deprivation therapy for over 12 months were excluded from the analysis. After exclusion we had 95 evaluable patients. All patients received either 17 Gy in 2

fractions or 15 Gy in single fraction of HDR brachytherapy boost followed by external beam radiotherapy 37.5 Gy in 15 fractions. 70% of patients received Androgen deprivation therapy (ADT) for less than or equal to 6 months, 15% received for 6- 12 months, and 15% received no hormones. 3- 6 months of ADT was given neoadjuvantly. Date of HDR boost was considered as time=0. Benign PSA bounce was defined as PSA rise of >0.2 ng/ml followed by subsequent decline to pre bounce level.

Results: Median follow-up was 4.3 years. At the time of median follow up the median PSA was 0.19. PSA bounce was seen in 32.6% (n=31). Magnitude of PSA bounce was <1 ng/ml in 55% (n=17), 1-2ng/ml in 13% (n=4), >2 ng/ml in 32% (N=10). In 16 out of 17 patients with a PSA bounce of <1 ng/ml was due to a benign bounce. 50% of patients with a PSA bounce between 1-2ng/ml had a benign bounce and the remaining 50% developed biochemical failure. In 9 out of 10 patients who had a PSA bounce of >2 ng/ml subsequently developed a biochemical failure. Most common time for benign PSA bounce was between 6 and 18 months.

Change in PSA over time

Conclusion: PSA bounce is a common phenomenon which occurs in about a third of men who were treated with short term ADT in combination with HDR boost and EBRT. Benign PSA bounce tends to have a smaller magnitude of rise in PSA <1 ng/ml. However patients who developed biochemical failure had PSA bounce of larger magnitude >2 ng/ml. Investigators at the time of submission of the abstract are examining variables which predict PSA bounce.

EP-1338

Delay Haematuria after prostatic radiotherapy: do it mean always radiation cystitis?

S. Rodríguez Villalba¹, M. Santos Ortega¹, M. Depiaggio¹, A. Fuster², P. Torrus², J. Martinez², J. Canovas², L. De la Torre², J. Moreno², J. Richart¹, A. Otal¹, J. Perez Calatayud¹

¹Clinica Benidorm, Radiotherapy Department, Benidorm, Spain

²Hospital Marina Baixa, Urology Department, Villajoyosa-Alicante, Spain

Purpose or Objective: A retrospective analysis in 368 consecutive organ confined prostate cancer (PC) patients has been made for evaluating the rates of haematuria, etiology and onset time. All these patients have been treated from September 2001 to December 2013 with different multimodality radical radiotherapy approaches: Intensity Guided Modulated radiotherapy (IGRT), Low dose rate brachytherapy (LDR BT) exclusively, LDR BT plus External radiotherapy (EBRT) or High dose rate Brachytherapy (HDR-BT) plus EBRT.

Material and Methods: Median age of the whole group was 70,5 years (range 60-81y). Median PSA at diagnostic of the prostate cancer was 9.3 ng/ml (range 4,67-95 ng/ml). Median Gleason 6 (range 2-10). 20 patients (41,47%) had received IGRT radiotherapy treatment, 4 patients (8%) LDR BT, 10 patients (21%) LDR plus EBRT and 14 patients (30%) HDR-BT plus EBRT. In 17 patients (35,4%) the complete pelvis (L5-S1)

was irradiated receiving 50,4 Gy. The comorbidities associated were: 21% diabetes, 62,5% High blood pressure, 40% cardiac pathology and 33 % were with anticoagulant treatment. All our haematuria patients have been handled following the next algorithm: Blood Test (Including platelets and liver parameters) and Urine Culture. If both are negative: Ultrasound (Kidney, urether and bladder). If haematuria goes on: Cystoscopy.

Results: With a median follow-up of 52.5 months (range 5-122 m), 48 patients (13%) have had haematuria. As etiological factors we have been found: Urine Infection 12 p (25%. Time 32 months (12-70 m), Bladder cancer 10 p (21%. Four of them a recurrence of a previous treated bladder tumour. Time: 32 months (3-120 m), RADIATION CYSTITIS 10 p (21%. Time: 13 months (6 - 38 m), Lithiasis 4 p (8%. Time: 25.5 months (26-30 m), Local progression of Prostate cancer 1 p (2%). Time: 72 months), Autolimited haematuria (Culture and image studies negatives. It does not repeat.): 9 p (19%. Time: 58 months (25-80 m) and Fatal haematuria (Exitus. Not known etiology): 2 p (4%. Time: 78 and 84 months).

Conclusion: In our experience, haematuria is a frequent pathology in patients treated with radiotherapy of prostate cancer. The etiology of it spreading in similar proportions, across the different causes founded. The time of it presentation is important for the diagnostic. In the mind of the specialist must be different causes of it, NOT ONLY radiotherapy Cystitis taking in account that if it is due to radiotherapy it appears mainly, in the first two years after radiotherapy treatment.

EP-1339

Influence of leaf thickness on prostate VMAT about dosimetric-volumetric and delivering parameters

H. Nagano¹, H. Yokoyama¹, H. Hashimoto¹, M. Watanabe¹, M. Nakanishi¹, Y. Kishida¹, T. Ogawa¹, T. Kawasaki¹, M. Katou², T. Shimo², K. Ishizuka¹

¹Shonan Fujisawa Tokushukai Hospital, Radiation Oncology Department, Fujisawa, Japan

²Tokyo West Tokushukai Hospital, Radiation Oncology Department, Tokyo, Japan

Purpose or Objective: Volumetric modulated arc therapy (VMAT), a complex treatment strategy for intensity-modulated radiation therapy, has been established clinically. While 5 mm thick MLC (L50) is a usual for VMAT, we have been using 2.5 mm thick MLC (L25) from 2012 to treat the prostate cancer. So we compared dosimetric, volumetric and dose delivering parameters between L25 and L50.

Material and Methods: Twenty four cases were selected from our database. Those patients were treated for the prostate carcinoma in the feet-first prone position. Gantry angle range was 182 deg. to 178 deg. and collimation angle was set 0 deg. SmartArc system of Pinnacle3 was used with 6MVX physical data of Novalis Tx (L25) and 6MVX Siemens® ARTISTE physical data loaded on Varian Clinac-21 Ex (the base machine of Novalis) virtually (L50). The same consolidations for optimization were used. For example, Min Dose, D95 and Max Dose of PTV were 76 Gy, 80 Gy and 84 Gy, respectively. Rectal V40 was set to 20%. Wilcoxon rank sum test was applied to D98, D95, D50 and D02 of PTV, rectal V40, irradiation time and MU. To analyze relationships between these values and ROV grouped by L25 or L50, linear regression model was employed with analysis of covariance for the regression coefficients.

Results: Mean values of D98, D95, D50 and D02, V40, Time and MU were 75.8 Gy, 77.5 Gy, 81.2 Gy, 84.2 Gy, 20.3%, 82.7 sec and 646.6 for L25, and were 75.6 Gy, 77.3 Gy, 81.0 Gy, 83.8 Gy, 19.6 %, 149.9 sec and 741.6 for L50, respectively. Only those mean values of D02, V40 and Time were significantly different between L25 and L50 by Wilcoxon test (Table).

Table p values of statistical analyses

Variables	Wilcoxon rank sum test (L25/L50)	Analysis of covariance for the regression coefficients		
		ROV	L25/L50	ROV*L25/L50
D98	NC	<0.001	NC	NC
D95	NC	<0.01	NC	NC

D02	<0.01	NC	<0.01	NC
V40	<0.05	<0.05	<0.05	NC
Time	<0.001	<0.01	<0.001	<0.05
MU	NC	<0.001	<0.05	NC

D98, D95, V40, Time and MU depended on ROV significantly. Slopes of valuables grouped by L25 and L50 were very similar in the all except Time and MU (Table and Figure).

Conclusion: L25 and L50 plans were very similar from the dosimetric point of view (difference of D02 was significant but very small in value; 0.4Gy, L25>L50). From the volumetric (V40) point of view, difference was small (0.7%, L25>L50) but significant. In terms of dose delivery (Time), differences were remarkable and largely depend on the ROV especially in the cases of L50. We may use L50 with the expense of treatment time compared to L25.

EP-1340

Nomograms predicting the probabilities of having indications for adjuvant prostatic radiotherapy

M. Ma¹, X. Gao¹, Z. Zhou², B. Zhao¹

¹Peking University First Hospital, Radiation Oncology, Beijing, China

²Hebei Cancer Hospital, Radiation Oncology, Shijiazhuang, China

Purpose or Objective: For patients with clinically localized prostate cancer with high probabilities to undergo adjuvant radiotherapy after radical prostatectomy(RP), radical radiotherapy may be a proper treatment option for saving time and medical costs. Our purpose is to develop nomograms combining PSA level, clinical T stage, and biopsy Gleason Score to predict probabilities of having indications for adjuvant radiotherapy including extraprostatic extension, positive margin, Gleason Score 8-10 and to provide data for individualizing initial treatment options.

Material and Methods: We analyzed 214 men treated with RP between August 2013 and August 2015 at our hospital. Average age was 66 years. Men who enrolled in this study had a preoperative PSA level assessed before or at least 4 weeks after prostate biopsy, biopsy Gleason Score, pelvic MRI and clinical T stage (TNM 2009 classification). Men were excluded for preoperative treatment with neoadjuvant hormonal therapy, or transurethral resection of the prostate because of potential influence on pathologic stage or PSA level. Preoperative predictors included PSA level, clinical T stage (T2a/b, T2c, T3a, T3b), and biopsy Gleason score (5-6, 3+4=7, 4+3=7, 8-10). These predictors were used in multivariable logistic regression analysis based nomograms to estimate the probabilities of extraprostatic extension, positive margin, Gleason Score 8-10 after RP, respectively. The predictive accuracy and discriminative ability of the

nomogram were determined by concordance index(C-index) and calibration curve.

Results: 47% of the patients had extraprostatic extension, 36% had positive margin, and 20% had Gleason Score 8-10. Nomograms were developed for the predicted probabilities of having the indications of adjuvant radiation therapy(Fig1ABC). The calibration curve for probabilities showed good agreement between prediction by nomogram and actual observation (Fig 1DEF). The C-index of the nomograms for predicting extraprostatic extension disease, positive margin, and Gleason Score 8-10 were 0.799, 0.746, 0.879, respectively. The risk of having one of the indications of adjuvant radiation therapy increased with increases in predictors except for T stage for predicting Gleason Score 8-10($p=0.25$).

Fig.1 nomograms and calibration curves

Conclusion: We produced nomograms that may accurately predict the probabilities of having indications for adjuvant radiation therapy after RP in men with localized prostate cancer, which may contribute to properly selecting initial treatment option.

EP-1341

Single-nucleotide polymorphisms associated with toxicity to radiotherapy in prostate cancer patients

G. Spagnoletti¹, P. Frisani¹, M. Natalicchio², M. Enfasi¹, G. Cocco¹, G. Nardella¹, G. Plotino¹, G. Bove¹

¹Az. Osp.-universitaria Ospedali Riuniti, Struttura Complessa di Radioterapia, Foggia, Italy

²Az. Osp.-universitaria Ospedali Riuniti, II Laboratorio Analisi, Foggia, Italy

Purpose or Objective: Together with surgery, radiotherapy (RT) is a cornerstone in the treatment of prostate cancer. Despite similar prognostic factors, a wide inter-patient variability was observed in tumour response and side effects. Many studies have been made to understand molecular behaviour of tumours exposed to ionizing radiation. It has been hypothesized that single-nucleotide polymorphisms (SNPs) impact response and adverse reactions for patients (pts) receiving RT. We focused on the analysis of some candidate SNPs in pts treated with RT for prostate cancer.

Material and Methods: Between January and September 2014, 66 pts with prostate cancer underwent RT with radical or adjuvant intent. RT was delivered using 4-6 coplanar 10-18 MV beams at a dose of 70-80 Gy (2.5-2 Gy/fraction). At baseline and weekly during treatment, acute gastrointestinal (GI) and genitourinary (GU) toxicities were scored by a fixed questionnaire. The RTOG toxicity scale served as a basis, but additional symptoms were evaluated as well. Genotyping was performed from whole blood samples at the beginning of RT. DNA was purified with the QIAamp DNA Mini Kit. Assays of samples were performed using the "Radiotherapy response"

kit (Diotech Pharmacogenetics, Italy). Pyrosequencing analysis was carried on the PyroMark Q96 ID (Biotage, Sweden). Status of candidate SNPs (GSTP1 A313G, RAD51 G135C, XRCC1 G28152A, XRCC3 A4541G and XRCC3 C18067T) was unknown to interviewers and participants.

Results: Treatments were delivered successfully without any interruption. Grade 1, Grade 2 and Grade 3 GI toxicities were observed in 33%, 12% and 3% of the pts, respectively, during the whole period. Grade 1, Grade 2 and Grade 3 GU toxicities were seen in 50%, 32% and 15% of the pts. Eight items of GI toxicity and six items of GU toxicity were used to calculate, for each patient, his own toxicity score. Time of onset of side effects was taken into account too. Using R statistical program, no significant relation was found between total toxicity or precocity of side effects and the mutational status of our 5 candidate loci, except for GSTP1 and toxicity. Kruskal-Wallis test demonstrated that GSTP1 status (wild-type, heterozygous and mutant) is a strong predictor of GI effects, especially diarrhea ($p=0.01$), frequency of stools ($p=0.01$), incontinence ($p=0.01$) and rectal blood loss ($p=0.02$).

Conclusion: Overall, RT is a well tolerated therapy for prostate cancer. Five SNPs were analyzed in four genes of relevance for RT. GSTP1 showed to be the most important SNP regarding GI toxicity to RT in pts treated for prostate cancer. Other examined SNPs did not prove to play a significant role in this particular subset of pts. Our findings require validation in larger replication studies and open to future clinical trials. One of the next steps will be evaluate if GSTP1 is associated with response to RT too. This would permit personalization and optimization of RT for each prostate cancer patient.

EP-1342

F-18Fluorocholine-PET/CT guide salvage therapy in biochemical failure of prostate cancer

M. Barrado¹, A. Sola¹, P. Navarrete¹, E. Villafranca¹, M. Rico¹, M. Errasti¹, M. Campo¹, I. Visus¹, S. Flamarique¹, M. Rodriguez², E. Martinez¹

¹Complejo Hospitalario de Navarra, Oncología Radioterápica, Pamplona, Spain

²Clinica Universitaria de Navarra, Medicina Nuclear, Pamplona, Spain

Purpose or Objective: To describe the F-18Fluorocholine PET/CT (cPET/TC) activity after biochemical failure in localized prostate cancer. To analyze the response to cPET/TC-guided salvage therapy.

Material and Methods: N: 80 patients(p) with cPET/TC between 2006-2012, 64p at time of biochemical failure.

At diagnosis 15p T1 (18.5%), 37p T2 (46.4%), 23p T3 (28.8%) and 5p T4 (6.3%). N0 (87.5%). Gleason score: 6: 30p (37.6%), 7: 27p (33.8%), ≥ 8: 20p (25.1%), missing: 3p (3.8%). Baseline median PSA 9.0 ng/ml. [0.9-114.5]

Initial treatment: 45p (56.4%) prostatectomy, 13p (16.3%) radiotherapy and hormones 2.5 years, 11p (13.8%) radiotherapy and hormones 6 months, 7p (8.8%) radiotherapy alone and 4p (5%) had hormones alone.

cPET/TC -guided salvage treatments were: 23 radiotherapy (36%), 2 brachytherapy (3.1%), 8 radiotherapy and hormones (12.5%), 29 hormones (45.3%), 1 chemotherapy (1.6%) and 1 radical prostatectomy (1.6%).

Results: Median time from diagnosis to cPET/TC failure: 44.03 months [2.37-126.83]. Median PSA values were 1.69 ng/ml [0.1-70.6].

cPET/TC local failure(LF) occurred in 39p (60.9%), nodal failure(NF) in 15p (23.4%) and metastatic failure(MF) in 10p (15.6%).

With a median follow up of 55 m after rescue treatment, 15p (23.4%) had biochemical failure again. At 5 years biochemical relapse free survival (BRFS) was 65%. Overall survival 5y: 91% (median: 119 months).

BRFS was 59% without LF vs 83% with LF ($p=0.26$)

BRFS was 75% without NF vs 30% with NF ($p=0.065$)

BRFS was 77% without MF vs 17% with MF (p 0.001)
BRFS was: PSA 0.2-1: 83%; 1.1-2: 66%; 2.1-10: 39%; >10.1: 37%. p: 0.02

Conclusion: cPET/TAC detect initial local and regional relapses that can be treated with local radiotherapy with or without hormonal therapy with good results.

EP-1343

PET-CT-related treatment changes in high risk and recurrent prostate cancer

A. Müller¹, D. Zips¹, D. Wegener¹, G. Reischl², K. Nikolaou³, C. La Fougère⁴, C. Pfannenbergl³

¹University Hospital Tübingen- Eberhard Karls University, Radiation Oncology, Tübingen, Germany

²University Hospital Tübingen- Eberhard Karls University, Department of Radiology- Preclinical Imaging and Radiopharmacy, Tübingen, Germany

³University Hospital Tübingen- Eberhard Karls University, Department of Radiology- Diagnostic and Interventional Radiology, Tübingen, Germany

⁴University Hospital Tübingen- Eberhard Karls University, Department of Radiology- Nuclear Medicine, Tübingen, Germany

Purpose or Objective: To prospectively evaluate the impact of Choline/ PSMA PET-CT imaging on management of patients with prostate cancer (PC).

Material and Methods: Fifty patients with high risk or recurrent PC received a 11Choline and/or a 68Ga-PSMA-PET-CT before radiation treatment planning within a prospective register study. Main subgroups were identified and only patients with a conventional staging before PET-CT were evaluated to compare treatment management decisions before and after PET-CT with regard to treatment intent, target volume (TV) definition, radiation dose and duration of androgen deprivation therapy (ADT).

Results: The three main subgroups fulfilling the mentioned conditions above were high risk (HR, n=17), recurrence after prostatectomy (R, n=12) and R plus salvage radiotherapy (RSR, n=7). In HRPC, TNM-changes (n=12/17) led to treatment changes (n=14) including TV-changes (n=12). In R, TNM-changes (n=8/12) resulted in treatment changes (n=8) including TV-changes (n=7). In the group after RSR, TNM-changes (n=6/7) resulted in treatment changes (n=6).

Management was changed in 82% (HRPC), 66%(R) and 85%(RSR). Of these groups (n=36) only two patients were initially stratified as M1. PET-CT led to downstaging (M0) or diagnosed only oligometastatic disease enabling curative treatment in both patients. However, in 12 patients initially planned for curative treatment detection of N1-disease (n=3/9) or newly diagnosed M1-disease (n=9/11) shifted treatment allocation to palliative therapy.

Taken together, curative treatment could be offered to initially diagnosed M1-patients (n=2). Since patients with RSR were usually in the palliative situation, PET-CT enabled in further 28% (2/7) of patients disease localization and curative treatment. However, of initially curatively planned patients (27/29) with R or HRPC, PET-CT facilitated to avoid overtreatment in ~30% (8/27) of patients due to early visualization of incurable disease. Main limitation is the absence of histological verification.

Conclusion: PET-CT had a pronounced impact on decision making and management in this group of patients with high-risk or recurrent prostate cancer. Therefore we suggest that PET-CT should be considered in the work-up in specific clinical situations.

EP-1344

Influence of surgical margins on the biochemical and radiological characteristics of the recurrence

L.G. Sapienza^{1,2}, J.D. Panichella¹, R.C. Camargo¹, A. Ernani¹, J.P. Dos Reis Junior¹, G.A. Pavan¹, H.A. Salmon¹

¹Clinicas Oncológicas Integradas COI-RJ, Radiation Oncology, Rio de Janeiro, Brazil

²A. C. Camargo Cancer Center, Radiation Oncology, São Paulo, Brazil

Purpose or Objective: To evaluate the possible impact of positive margins (PM) after surgery for prostate cancer on: I) biochemical parameters of recurrence (immediate failure rate and the time to development of biochemical recurrence) and II) the incidence of macroscopic disease at magnetic resonance image (MRI) realized before salvage radiation therapy (SRT).

Material and Methods: Data from 101 prostate cancer patients treated between 2012-13 was analyzed. Fifty (49.5 %) had MRI before SRT. PSA failure was defined as a value greater than 0.2 ng/ml after 6 weeks after prostatectomy. Cases with PSA >0.2 at the first measure 6 weeks after the surgery were categorized (no vs yes) and considered separately for the analysis of immediate failure. Categorical analysis were done using chi-square test. The time to the development of biochemical recurrence was presented in Kaplan Meier and log-Rank test was used to compare PM vs negative margins (MN) group. Mann-Whitney-Wilcoxon test was used to compare the PSA means between groups (PM vs NM / macroscopic recurrence present vs absent). The statistical analysis was done using SPSS V.20.

Results: The basic characteristics of this population were: age 66.8 years (median), initial PSA 8.0 ng/ml (median), 52.6% pT2 and 34.7% pT3. The proportions of each pathological risk group were 7%, 42% and 51% (low-risk, intermediate risk, high-risk) and 43,6% had PM (n=44). Those with PM had an increased chance of immediate PSA failure (p=0.004) and an earlier development of biochemical recurrence (23.4 months vs 49 months, p = 0.001). The mean PSA of the recurrence was 1.4 (+/- 1.7) ng/ml vs 2.6 ng/ml (+/- 6.1) (p = 0.839), for NM and PM respectively. Patients with macroscopic recurrence had a greater pre-SRT PSA: 3.5 (+/- 1.7) vs 0.8 (+/- 0.7) ng/ml. The incidence of biochemical recurrence with prostatic nodule in the MRI was not influenced by margin status (p=0.108) and marginally not influenced by pathological status (low or intermediate risk vs high risk) (p=0.062).

Conclusion: PM patients have had an earlier development of biochemical recurrence but our series did not find a significant impact of margin status on the incidence of nodule on prostatic bed. A possible delay in the detection of the recurrence in margin negative patients should be evaluated in next studies.

EP-1345

SBRT in low- and intermediate-risk prostate cancer: results of a phase II study

G. D'Agostino¹, E. Villa¹, C. Franzese¹, R. Liardo¹, G. Reggiori¹, P. Navarra¹, C. Iftode¹, F. De Rose¹, D. Franceschini¹, A. Tozzi¹, T. Comito¹, A. Ascolese¹, S. Tomatis¹, M. Scorsetti¹

¹Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

Purpose or Objective: Recent evidences has fostered the emergence of Stereotactic Body Radiation Therapy (SBRT) as a promising treatment modality for the management of localized prostate cancer. In fact, given the low alpha/beta ratio of prostate cancer, the delivery of very high radiation doses in few fractions, may even improve the therapeutic ratio in the treatment of this disease. This phase II study was aimed to evaluate the efficacy and toxicity of SBRT in a series of patients with low or intermediate risk prostate cancer.

Material and Methods: Biopsy confirmed prostate cancer patients were enrolled in this phase II trial, provided that they had the following characteristics: iPSA < 20 ng/ml, Gleason Score < 7, IPSS < 7. The treatment schedule was 35 Gy in 5 fractions, delivered every other day with VMAT technology in FFF modality. Toxicity was recorded according

to CT-CAE criteria v3.0. Biochemical failure was calculated according to the Phoenix definition.

Results: Between December 2011 and March 2015, 90 patients were enrolled (53 low risk, 37 intermediate risk). The median age was 71 years (range 48 - 82 y). The median Gleason Score was 6 (range 6-7) and the median initial PSA was 6.9 ng/ml (range 2.7 - 17.0). Acute toxicity was mild, with 32.2 patients presenting a G1 urinary toxicity and 31.1% of patients presenting a G2 urinary toxicity, mainly represented by urgency, dysuria and stranguria. A rectal G1 toxicity was found in a 15.5% of patients, while a rectal G2-toxicity was recorded in 6.6% of patients. Regarding late toxicity, a G1 proctitis was recorded in 11.1% of patients and a G1 urinary (urgency, cystitis) in 38.8%; only 2 events of G2 urinary toxicity were observed (transient urethral stenosis, resolved by a 24-hour catheterization). At a median follow up of 27 months (range 6 - 62 months) only two intermediate risk patients experienced a biochemical failure (22 and 24 months after radiotherapy, respectively). PET Choline revealed a nodal recurrence in one patient who underwent a further stereotactic radiotherapy and is now free of disease. In the other patient a local recurrence was diagnosed, associated to bone progression (rib), therefore the patient started ADT. Compliance to treatment was good, as reported by the EPIC questionnaires, which revealed a slight worsening in the urinary domains during treatment, with a return to baseline three months after treatment.

Conclusion: Stereotactic Body Radiotherapy seems to be a valid therapeutic option in low and intermediate risk prostate cancer patients, warranting an adequate control of disease, with mild toxicity profiles and good patient-reported quality of life perception.

EP-1346

Intraoperative radioterapy (IORT) in the multimodality treatment of locally advanced prostate cancer

M. Krenkli¹, D. Beldi¹, G. Apicella¹, G. Marchioro², C. Pisani¹, E. Ferrara¹, C. Perotti¹, G. Loi³, A. Volpe², C. Terrone²

¹University of Piemonte Orientale, Radiotherapy, Novara, Italy

²University of Piemonte Orientale, Urology, Novara, Italy

³University of Piemonte Orientale, Medical Physics, Novara, Italy

Purpose or Objective: The treatment for locally advanced prostate cancer is still a controversial issue and multimodality treatment can lead to treatment optimization. The aim of this study is to describe technical and clinical aspects of intra-operative radiotherapy (IORT) in patients with locally advanced prostate cancer.

Material and Methods: Between September 2005 and September 2015, a total of 110 patients were enrolled. The statistical analysis was performed in 95 patients with follow up > 12 months. Inclusion criteria were: patients age < 76 years, KPS > 90, initial PSA (iPSA) > 10 ng/ml, clinical staging > cT2c according with TNM, probability of organ-confined disease < 25% according to MSKCC nomogram. Median age was 66.9 years (range 51-83), median iPSA was 14.6 ng/ml (range 2.0-80) and median Gleason Score (GS) was 8 (range 4-10). After surgical exposure of the prostate, IORT was delivered by a dedicated linear accelerator (Mobetron, Intraop, Sunnysvale, CA) with 30° beveled collimator, using an electron beam of 9 or 12 MeV to a total dose of 12 Gy. IORT was followed by radical prostatectomy and regional lymph node dissection. Rectal dose was measured "in vivo" by radio-chromic films placed on a rectal probe. All cases with pathological staging pT3a, positive margins (R1) or metastatic lymph nodes (N1) received postoperative external beam radiotherapy (EBRT), delivered to surgical bed with 3D conformal technique or intensity modulated radiation therapy to a total dose of 46-50 Gy (2Gy/fraction). Patients with pT3 or pT4 disease and/or N1 received adjuvant hormonal therapy.

Results: IORT procedure lasted in average 30 minutes (range 15-50). No major intra- or post-operative complication occurred. Median dose to the anterior rectal wall was 4.32 Gy (range 0.06-11.3). Pathological stage was: 30 pT2, 60 pT3, 5 pT4. 55/95 (57.9%) patients were R1 and 27/95 (28.4%) patients were N1. Median post operative PSA was 0.06 ng/ml (range 0-4). Post-operative radiotherapy was delivered to 73/95 patients (76.8%) with pathological staging pT3a or R1. Hormone therapy was prescribed to 61/95 patients (64.2%). Acute toxicity was: 16 G2 (9 GU; 7 GI), 2 G3 (1 GU; 1 GI). Late toxicity was: 11 G2 (5 GU, 6 GI), 4 G3 (2 GU; 2 GI). No G4 acute or late toxicity was observed. Four patients died of prostate cancer. With a median follow-up of 61.5 months (range 12-108), 26/95 patients experienced biochemical failure. Overall biochemical free survival (BFS) was 50% at 5 years. 5 years BFS was 78% and 42 % in high and very high risk classes according to NCCN classification. No evidence of failure in the prostate surgical bed was observed.

Conclusion: IORT during radical prostatectomy is a feasible procedure and allows to deliver safely post-operative EBRT to surgical bed without a significant increase of toxicity. With a median follow-up of 61.5 months, biochemical control seems to be optimal in particular for high risk patients.

EP-1347

Could "radical" RT be a reasonable choice in bone oligometastatic prostate cancer patients?

C.L. Deantoni¹, C. Cozzarini¹, A. Fodor¹, B. Noris Chiorda¹, P. Mangili², M. Picchio³, E. Incerti³, I. Dell'Oca¹, P. Passoni¹, C. Fiorino², R. Calandrino², N. Di Muzio¹

¹IRCCS San Raffaele Scientific Institute, Radiotherapy, Milano, Italy

²IRCCS San Raffaele Scientific Institute, Medical Physics, Milano, Italy

³IRCCS San Raffaele Scientific Institute, Nuclear Medicine, Milano, Italy

Purpose or Objective: To evaluate toxicity, clinical outcome and predictive response factors in patients with prostate cancer (PCa) oligometastatic (<2 lesions) to the bone at diagnosis, simultaneously treated with curative radiotherapy (RT) to primary tumor/prostatic bed (PB) and bone metastases.

Material and Methods: From February 2009, 33 patients with oligometastatic PCa (OPC), 18 of whom previously treated with radical prostatectomy and pelvic lymphadenectomy, underwent RT at "radical" dose to bone metastases (median 2-Gy equivalent dose, EQD2, >40 Gy, for $\alpha/\beta=2,2$), to the pelvic \pm lombo-aortic nodes (51,8 Gy for $\alpha/\beta=1,5$), and to the PB (median EQD2 72,4 Gy) or the prostate (median EQD2 88 Gy) within the same RT course in association with androgen deprivation therapy (ADT). To evaluate the possible role of adding a local treatment (radical dose RT to all sites of disease) to ADT, the biochemical relapse-free survival (bRFS), clinical failure-free survival (CFFS) and freedom from distant progression (FFDP, when the disease occurred in a different site from that treated) were considered, starting from the first day of RT.

Results: After a median follow-up of 20.2 months, 3 patients died, 1 were lost to follow-up, 2 showed in-field and 7 out-of-field progression, 3 have ended ADT and are still free from any progression. Acute toxicity was very mild with no Grade >2 events, and only 2 serious late events, 1 G3 and 1 G4 late urinary toxicity, only in the hypofractionated postoperative cohort. With respect to bone irradiation, no Grade toxicity were reported. Median bRFS, CFFS and FFDP were 15,8 months, 16,9 months and 17,2 months, respectively. When considering FFDP, the most significant clinical endpoint to evaluate the role of RT in this subset of patients, the most predictive factors were: PSA at diagnosis (iPSA>24,2 ng/ml, most-informative cut-off, AUC 77%, p=0,008) (HR=4.2, p=0,05), 2 vs 1 metastasis (HR=2.87, p=0,1), and no previous prostatectomy (HR=3,19, p=0,08), while no role emerged for the site of metastases (pelvic or not). When stratifying

patients by the presence of 0-1 or 2-3 risk factor, the 2-year actuarial FFDP was 100% and 49% respectively ($p=0,01$, Fig 1).

Conclusion: Although with a small cohort and a limited follow-up, these results seem to suggest that radical dose RT to all localization of disease is a valid approach in osseous OPC patients in association with ADT, also considering the low toxicity profile. Our predictive model aiming at identifying which patients may benefit of this kind of treatment seems to show that the ideal candidate could be a previously operated patient, with a $iPSA \leq 24,2$ ng/ml and with only one bone metastasis.

¹¹Policlinico Universitario "A. Gemelli"- Catholic University of Sacred Heart, Department of Radiotherapy, Roma, Italy

Purpose or Objective: Late rectal toxicity (LRT) is one of the main limitations of external radiotherapy (RT) for prostate cancer (PC). Purpose of this study was to evaluate the impact of various parameters on LRT, in a large cohort of patients undergoing radical or adjuvant RT in a series of clinical trials.

Material and Methods: 597 patients were selected (median age: 70 years; range: 43-88; NCCN risk class: 59 low, 199 intermediate, 339 high). Impact on grade ≥ 2 (RTOG) LRT of a series of parameters was analysed: previous radical prostatectomy, RT technique, type and duration of any adjuvant hormone therapy, RT dose and fractionation, acute rectal toxicity. LRT free survival curves were estimated

according to the Kaplan Meier method. Univariate analysis was performed using log-rank test. Multivariate analysis was performed using "Cox's proportional hazard models".

Results: Table 1 shows the results of the analysis. Overall, grade > 2 LRT free survivals was respectively 89.5% and 84.9% at 2 and 5 years. At univariate analysis only acute rectal toxicity was significantly related to LRT ($p < 0.001$) while there was a negative trend in patients receiving adjuvant hormone therapy, especially with LH-RH analogues. Multivariate analysis confirmed only the correlation between acute rectal toxicity and LRT ($p: 0.006$).

Table 1: Grade ≥ 2 late rectal toxicity free survival (%)

		Patients	2-year	5-year	Univariate analysis (log-rank), p:	Multivariate analysis (Cox), p:
Previous R.P.	no	403	88.6	81.1	0.175	
	yes	194	91.6	91.6		
Technique	3D	155	91.1	87.3	0.878	
	IMRT	418	88.4	80.1		
	VMAT	23	95.0	n.v.		
A.O.T. type	no	49	100.0	87.5	0.065	0.991
	LH-RH analogue	287	86.8	83.7		
	Bicalutamide	239	90.8	86.5		
A.O.T. duration	no	49	100.0	87.5	0.539	
	6 months	250	86.6	85.3		
	24 months	298	90.5	85.5		
Dose	≤ 70 Gy	378	90.0	90.0	0.303	
	> 70 Gy	219	88.7	83.1		
	ENI	no	75	85.7		
yes	522	90.5	89.9			
Fractionation	≤ 2 Gy/fr.	227	89.0	83.6	0.413	
	> 2 Gy/fr.	370	89.7	89.7		
	G ≥ 2	571	90.3	85.6		
Acute toxicity	G ≥ 2	30	50.6	50.6	< 0.001	0.006
	G < 2	567	90.3	85.6		

R.P: radical prostatectomy; A.O.T.: adjuvant hormone therapy; ENI: elective nodal irradiation.

Conclusion: The results of this analysis showed no correlation between treatment parameters and LRT. This unexpected result is likely to be related to the use of modulated RT techniques in the majority of patients and to the distribution of the analysed parameters. For example, patients who have previously undergone radical prostatectomy, or treated with a hypofractionated regimen, generally received a lower total dose. The close correlation between acute and late toxicity seems to confirm the existence of a "consequential late toxicity" in radiation-induced damage to the rectum. This seems to suggest the utility of close endoscopic monitoring in the follow-up of patients with severe acute rectal toxicity.

EP-1349

Long term results of a phase I-II study of moderate hypofractionated IGRT in prostate cancer

N. Di Muzio¹, A. Fodor¹, B. Noris Chiorda¹, S. Broggi², P. Mangili², R. Valdagni³, I. Dell'Oca¹, M. Pasetti¹, C. Deantonio¹, A. Chiara¹, G. Berardi¹, A. Briganti¹, R. Calandrino², C. Cozzarini¹, C. Fiorino²

¹San Raffaele Scientific Institute, Department of Radiotherapy, Milan, Italy

²San Raffaele Scientific Institute, Medical Physics, Milan, Italy

³Fondazione IRCCS Istituto Nazionale dei Tumori, Radiotherapy, Milan, Italy

⁴San Raffaele Scientific Institute, Department of Urology, Milan, Italy

Purpose or Objective: To report long term clinical outcomes in prostate cancer patients (pts) treated with IGRT Moderate Hypofractionated Simultaneous integrated boost (SIB) by Tomotherapy in a phase I-II study.

Material and Methods: Between 2005 and 2011, 211pts were treated with IGRT Moderate Hypofractionated SIB in a phase I-II study. A subgroup of 128 pts (55 low-risk [LR], 33 intermediate-risk [IR] and 40 high-risk [HR]) with 5 years minimum follow up were considered for this analysis. IR and HR pts received 51,8 Gy on pelvic lymph-nodes (LN) and concomitant SIB to prostate up to 74,2Gy in 28 fr; LR pts were treated to the prostate to 71,4Gy in 28fr. Androgen deprivation (AD) was delivered to 27% LR/57% IR/87% HR pts for a median time of 12.5, 13.7 and 15,5 months (m) respectively. Biochemical relapse free (bRFS) survival (Phoenix definition), cancer-specific (CCS) and overall survival (OS) actuarial curves were assessed. Selected clinical/dosimetry variables were tested as potential predictors of GI/GU toxicity and of BCR/CCS/OS (Cox test).

Results: Median follow and median age were 75 m (range: 60-99) and 74 y (57-84) respectively, while median Gleason score(GS) was 6 (3-10):GS<7: 75; GS=7: 39; GS>7: 13 ; missing:2. 73 pts were staged as T1, 46 as T2: 6 as T3; and for 3 pts the stage was unclear (Tx). The median initial Psa (iPsa) was 7.8 (1.2-826). The 75-m bRFS was 92.5% (LR: 94.2%; IR: 96.9%; HR: 84.5%); OS was 94.6% (LR:95.9%; IR: 95.8%; HR: 91.1%) and CSS was 97.4% (LR: 100%;IR:94.5%;HR: 97.1%). AD and class risk were not correlated with bRFS/OS/CSS. The incidence of G3 toxicity was around 6% with drastically reduction of the prevalence at the last follow-up for both \geq G2 and \geq G3 toxicities indicating that symptoms were recovered in most patients.

Conclusion: The combination of pelvic LN irradiation and high dose to the prostate, (EQD2=88Gy) delivered with daily image-guided, intensity-modulated, moderate hypofractionation resulted in an excellent 75-m outcome, even in IR/HR patients. This encouraging result seems to be without correlation with AD considering the long time elapsed between the end of the AD and the last follow up of pts. The toxicity profile was acceptable

EP-1350

Postoperative radiation therapy following radical prostatectomy

J.A. Dominguez Rullan¹, A. Hervás¹, T. Muñoz¹, F. López¹, C. Vallejo¹, D. Candini¹, C. De la Pinta¹, D. Ordoñez¹, M. Martín¹, S. Sancho¹

¹Hospital Ramón y Cajal, Radiation Oncology, Madrid, Spain

Purpose or Objective: To compare clinical results of adjuvant and salvage radiotherapy after radical prostatectomy for prostate cancer and to determinate prognostic factors of biochemical relapse free survival (BRFS).

Material and Methods: 302 patients were treated at our institution over a 12-year period. Overall survival and biochemical-relapse free survival were analyzed using Kaplan-Meier and multivariate Cox regression analysis was used to assess differences between groups.

Results: Mean age at diagnosis was 65 years (42-80). All patients underwent radical prostatectomy combined with pelvic lymphadenectomy in 47.1% of cases. Neoadjuvant androgen deprivation before surgery was given to 36.5% . Mean pre-RT PSA of 0.46ng/ml (0-12.8 ng/ml). Adjuvant RT (ART) was performed in 113 patients and salvage RT (SRT) in 183 (9 for local recurrence) and mean dosis to surgical bed was 70 Gy (60-76 Gy). The distribution of patients by pT stage was pT2a/b (30.3%), pT2c (35%), pT3 (29%) and pT4 (2.3%). Upgrade in Gleason Score between transrectal biopsy and prostatectomy was experienced by 46.7% of patients. Positive surgical margins were reported in 56.5% of cases. Mean follow-up was 58.85 months (1-153 months). Overall survival at 5 and 10 years was 98.1% and 94.3%, respectively and BRFS at 5 and 10 years was 76.5% vs. 61.8%, respectively. The timing of RT (ART vs. SRT) and pre-RT PSA <0.5 ng/ml were significant predictors of longer BRFS.

GLEASON SCORE		PROSTATECTOMY					
		5	6	7	8	9	10
BIOPSY	5	1	1	0	0	0	0
	6	0	37	61	3	0	0
	7	1	5	57	16	13	1
	8	0	1	4	5	5	0
	9	0	0	0	0	2	0

Conclusion: Postoperative radiation therapy provides excellent long-term overall survival results with an acceptable BRFS with pre-RT PSA <0.5 ng/ml and adjuvant radiotherapy as predictors of better outcomes.

EP-1351

Developing a prostate decision aid tool considering patients and clinicians decisional needs

A.J. Berlanga¹, B.G.L. Vanneste¹, E. Bloemen¹, D. Rijnkels¹, P. Lambin¹

¹MAASTRO Clinic, GROW School for Oncology and Developmental Biology- Maastricht University Medical Centre, Maastricht, The Netherlands

Purpose or Objective: To facilitate shared decision making, we aim to develop a decision aid tool that helps prostate cancer patients to understand the benefits and side-effects of the treatments offered by their clinicians.

The tool should follow the International Patient Decision Aid Standard, and therefore patient's and doctor's views on decisional needs must be considered. The tool should have a new slant on existing tools: it should personalize the information, guide patients to identify their preferences, and help doctors to understand patients' preferences.

Material and Methods: Patients and clinicians were interviewed to assess their decisional needs. A prototypical tool was developed. Its clarity and acceptability was evaluated by the technology acceptance questionnaire (5-Likert scale).

Results: Prostate cancer patients already treated (N=16) mentioned the need of visual and free of medical jargon information about prostate cancer, treatments, side-effects, and treatment experience. Medical specialists (N=8; radiation oncologists, urologists, nurses) mentioned the need of information about basic anatomy, contraindications, hospital specific figures, and psychological support. Results about comprehensibility of the prototypical tool showed that most the patients fully agree (69%) or agree (31%) that the prototypical tool provides clear information about treatments, their side-effects, the differences between treatments, and eases comparison. Likewise, most of the patients fully agree (69%) or agree (31%) on using the tool if it would become available, and will recommend it to others (67% fully agree; 33% agree).

After considering the views of patients and medical specialists, the result is an alpha version of a web-decision aid tool for prostate cancer patients (<http://www.treatmentchoice.info>). The tool personalizes information for each patient. It assists patients to decide what their preferences regarding quality of life and treatment experience are, and to think how important are the side-effects for them. It provides a printed report of patients' preferences to be using during consultation. Fig below gives an impression.

Conclusion: The alpha version of the tool is a first step towards its implementation in the clinical practice. The tool will be tested further by patients, to investigate whether it (a) influences the quality of the decision; (b) can be used without support. The tool is available in Dutch, English and Italian. Future efforts include the development of decision tools for other primary tumors.

EP-1352
 Early clinical experience from MRI-only based radiotherapy of localised prostate cancer
 M. Tenhunen¹, J. Korhonen¹, M. Kapanen², T. Seppälä¹, J. Collan¹, K. Saarilahti¹, H. Visapää¹
¹Helsinki University Central Hospital, Cancer Centre, Helsinki, Finland
²Tampere University Central Hospital, Department of Oncology, Tampere, Finland

Purpose or Objective: The increased use of magnetic resonance imaging (MRI) for radiotherapy (RT) target delineation has encouraged method development to enable the entire RT treatment planning workflow based on MRI only. Earlier we have presented a procedure for MRI only based treatment planning replacing planning CT in all phases of RT including simulation, target volume definition, dose calculation based on a pseudo-CT image set generated from MRI, and image guidance where comparison between MR or pseudo-CT reference set and MV/kV planar images or cone-beam CT is performed. The method has been applied clinically for RT planning of localized prostate cancer since November, 2012. Here we present our early clinical experience.

Material and Methods: We have followed n = 125 patients treated with MRI only procedure with serum prostate-specific antigen (PSA) at the beginning (baseline) and end of the RT course. As a reference, similar group of patients has been chosen where RT were planned with similar irradiation technique, margins, dosage (prostate 76 Gy in 2 Gy fractions, seminal vesicles 66 Gy in 2 Gy fractions) and image guidance method (gold seeds + daily kV/MV imaging), but where CT planning image set has been used as a primary data set in treatment planning and IGRT, and MRI images were registered to CT for target delineation. For the reference group, equal number of patients with additional antiandrogen therapy (n = 100) or RT only (n = 25) were chosen.

Results: Mean PSA values for all the patient subgroups are presented in Table 1. The two methods show equal early response in PSA. No difference in early toxicity was noticed between the MRI only and CT+MRI groups.

Patient group	PSA baseline (ng/ml)	PSA at the end of RT (ng/ml)
MRI based planning, monotherapy 76 Gy, n = 25	8.1	5.1
CT based planning, monotherapy 76 Gy, n = 25	8.5	5.9
MRI based planning, hormone + RT 76 Gy, n = 100	1.2	0.2
CT based planning, hormone + RT 76 Gy, n = 100	1.3	0.3

Conclusion: MRI only based RT treatment planning gave expected and equivalent results after RT compared with CT (MRI registered) based treatment planning procedure. Longer follow-up is needed to confirm the clinical equivalence related both to tumour response and normal tissue toxicity.

EP-1353
 Phase I/II study of hypofractionated Tomotherapy with CT-MRI planning for prostate cancer
 A. Spera¹, M. Mannino², G. Mortellaro¹, V. Figlia³, G. Caminiti¹, G. Iacoviello⁴, N. Luca³, F. Cuccia³, R. Mazzola³, G. Ferrera¹
¹Ospedale A.R.N.A.S-Civico, U.O. Radioterapia Oncologica, Palermo, Italy
²University of Sussex, Genome Damage and Stability Centre, Brighton, United Kingdom
³Università degli Studi di Palermo, Scuola di Specializzazione Radioterapia, Palermo, Italy
⁴Ospedale A.R.N.A.S-Civico, U.O. Fisica Sanitaria, Palermo, Italy

Purpose or Objective: On the basis of radiobiological studies suggesting a low α/β ratio for prostate adenocarcinoma, hypofractionation has been proposed to improve outcome in localized prostate cancer. STIP trial is a single center prospective phase I/II trial, with the aim of investigating feasibility and safety of moderate hypofractionation in low and intermediate risk (LR and IR) prostate cancer with Helical Tomotherapy (HT). We report early results in the first twelve recruited patients.

Material and Methods: Inclusion criteria are: histologically confirmed adenocarcinoma, age ≥ 18 and ≤ 85 years, LR and IR according to NCCN, performance status (Karnofsky) ≥ 60 , no clinical or radiological sign of metastasis, International Prostate Symptom Score (IPSS) ≤ 19 , no previous cancer history. The addition of short-term Androgen Deprivation Therapy to radiation is prescribed for IR patients and performed for 6 months. CT/MR simulation and all treatment sessions were performed with empty rectum and comfortably full bladder. Clinical target volume (CTV) 1 comprised the prostate gland in 11 LR patients, CTV2 also included the seminal vesicles in one IR patient. Planning target volumes (PTV) 1 and 2 were defined, respectively, as CTV1 and 2 plus a 0.5 cm margin. Total doses of 60 Gy and 54 Gy were delivered, in 20 fractions, to PTV1 and 2, respectively. To compare CTVs and PTVs obtained with CT and MRI, these volumes were contoured on CT scans and then on the merged image sets. Before each fraction, daily megavoltage tomography (MCVT) was performed to reduce interfraction uncertainties.

Results: Median follow-up was 12 months (range 3-20 months). Mean dose to PTV1 was 60.15 Gy (range 59.98-60.27), mean dose to PTV2 was 54.65 Gy. According to CTCAE 3.0 scale, acute G1 and G2 gastrointestinal toxicity occurred in 3 (25%) and 1 (8%) patients, respectively; no patients experienced G3 toxicity. G1 genitourinary toxicity occurred in 6 (50%) patients and no G2 or higher grade side effects were observed. According to the Expanded Prostate Cancer Index Composite (EPIC) questionnaire, urinary function declined 3 months post-treatment but it was similar to baseline at 12 months; bowel related quality of life remained stable during follow-up. IPSS remained similar to baseline for all patients. The contoured volume analysis showed that CTV and PTV based on MRI were always lower than CT based volumes (mean 38.07-87.10 vs 50.84-106). No patients experienced biochemical failure during follow-up.

Conclusion: Our preliminary data support the safety of a 20-fraction hypofractionated schedule delivered with HT in patients with localized prostate cancer.

EP-1354
 Meta analysis of carbon ion therapy prostatic cancer
 Q. Zhang¹, J. Tian¹, X. Wang¹
¹Gansu Cancer Hospital, Department of Radiotherapy, Lanzhou, China

Purpose or Objective: Carbon ion is characterized by unique physical and biological properties which is expected to be suitable to treat localized prostate cancer. In order to assess validate the feasibility and efficacy of carbon-ion radiotherapy for prostatic cancer, we synthesize and

compare available evidence of carbon ion therapy prostatic cancer by meta analysis.

Material and Methods: PubMed, Embase, The Cochrane Library, Web of Science, the Chinese Biomedical Literature Database were systemically searched from 1980 to May 2015 by heavy ion, carbon ion, carbon and $^{12}C^{6+}$, to collect clinical study of carbon-ion radiotherapy for prostatic cancer. Two reviews independently screened citation extracted basic information of local control rate, overall survival rate and phase of clinical study, the related data were analyzed by Stata 12.0.

Results: Three phase II clinical trials, four phase I/II clinical trials and one retrospective study were included, which included 1307 patients. The meta analysis showed 3-, 4-, 5-, and 8-year overall survival rates were 0.934 (95%CI: 0.901, 0.968), 0.909 (95%CI: 0.866, 0.951), 0.872 (95%CI: 0.844, 0.899) and 0.839 (95%CI: 0.793, 0.884) and the 4-, 5-year local control rate were 0.989 (95%CI: 0.973, 1.004) and 0.99 (95%CI: 0.969, 1.01), respectively (Figure 1).

Conclusion: Carbon ion therapy is suitable and tolerable for the treatment of prostate cancer, in the future, more evidence is required before carbon ion therapy can become internationally the standard treatment for prostate cancer patients.

EP-1355

Combined and modulated adjuvant therapy in prostate carcinoma: a phase I-II trial

M. Nuzzo¹, V. Frascino², A.R. Alitto², G. Mattiucci², B. Fionda², M. Vernaleone², F. Catucci², P. Bassi³, G. Macchia¹, F. Deodato¹, G. Siepe⁴, M. Ntreta⁴, A.G. Morganti⁴, S. Cammelli⁴, A. Arcelli⁴, F. Bertini⁴, E. Ippolito⁵, G. Frezza⁶, G. Mantini², V. Valentini²

³Policlinico Universitario "A. Gemelli" - Università Cattolica del Sacro Cuore, Department of Urology, Roma, Italy

⁴Radiation Oncology Center - S.Orsola-Malpighi Hospital - University of Bologna, Department of Experimental-Diagnostic and Specialty Medicine - DIMES, Bologna, Italy

⁵Campus Biomedico University, Radiotherapy Unit, Roma, Italy

⁶Bellaria Hospital, Radiotherapy Department, Bologna, Italy

Purpose or Objective: EORTC trial 22911 showed 75% 5-year biochemical disease-free survival (BDFS) in patients with prostate carcinoma (PCa) treated with radical prostatectomy (RP) followed by postoperative radiotherapy (RT). Aim of this study was to improve this outcome by using a combined-intensified-modulated-adjuvant (CIMA) treatment, based on RT and adjuvant hormone therapy (AHT).

Material and Methods: The study hypothesis was that CIMA treatment may improve 5-year BDFS from 75% to 90%. The study was planned based on Simon's phase II design. We needed to study 100 experimental subjects to be able to reject the null hypothesis that the success rates for standard and experimental treatments are equal with probability

(power) 0.8. The Type I error probability associated with this test of this null hypothesis is 0.05. We used an uncorrected chi-squared statistic to evaluate this null hypothesis. Some over-recruitment was planned to allow for a continuous drop-out process of up to 20% during the follow-up period. Enrolled patients were < 80 years old, with histological diagnosis of PCa, without known metastases, stage pT2-4 N0-1, not previously treated and with ECOG performance status of 0-2. All patients had at least one of these pathologic features: capsular perforation, positive surgical margins, seminal vesicle invasion. Standard dose to the tumor bed was 64.8 Gy. According to the pathological stage patients received a higher dose (70.2 Gy; 85.4%) and/or prophylactic irradiation of pelvic lymph nodes (57.7%) and/or adjuvant hormonal therapy (69.1%).

Results: One-hundred-twenty-three patients were enrolled in the study and completed the planned CIMA treatment. Median preoperative and postoperative PSA were 8.8 and 0.06 ng/dL, respectively. Proportion of patients with pathologically involved nodes and positive resection margin was 14.6% and 58.5%, respectively. Median follow-up was 67 months (interquartile range: 48.0-98.0 months). Actuarial 5-year BDFS was 92.9%. Actuarial 5-year local control and metastasis-free survival were 99% and 96%, respectively. Actuarial 5-year overall survival was 95%.

Conclusion: CIMA therapy, compared to studies based on standard adjuvant radiotherapy, resulted in an improved 5-year BDFS, although patients with nodal metastatic disease and detectable postoperative PSA were enrolled in the study. A prolonged follow-up will be needed to confirm this improvement even in terms of disease-free survival and overall survival.

EP-1356

Postoperative radiotherapy in pT3a R1-resected prostate cancer patients

N.S. Hegemann¹, S. Morcinek¹, C. Belka¹, U. Ganswindt¹

¹Klinikum der Universität München, Department of Radiation Oncology, München, Germany

Purpose or Objective: Despite 3 large randomized studies on adjuvant radiotherapy (RT) proving a significantly improved biochemical recurrence free survival in patients (pts) with advanced prostate cancer (PCA), there is still an dispute regarding the need for adjuvant RT in those pts. The risk of recurrence in these advanced stages may reach 30% to 60%. Nevertheless many of those pts are not referred to adjuvant RT. We therefore performed a retrospective analysis of 94 pts with pT3a pN0/cN0 R1-resected PCA in order to investigate the natural history of the disease and the benefit of adjuvant or salvage RT.

Material and Methods: We included 94 pts with pT3a pN0/cN0 R1-resected PCA that had undergone prostatectomy no later than 2009. In 91 pts lymphadenectomy was performed with an average of 10 removed lymph nodes. Gleason-Score was mainly 7a in 33, 7b in 24 and 8 in 19 pts. Statistical analysis was performed using a Cox proportional hazard model and Kaplan Meier survival analysis. Median follow up was 80 months.

Results: 71 pts had a PSA <0.07ng/ml after surgery. 35 of them experienced a biochemical relapse (Group 1). In 30 pts this occurred within the first 80 months. 28 of the pts with biochemical relapse received early salvage RT. PSA before salvage RT was in median 0.24ng/ml and after RT in 23 pts <0.07ng/ml. 36 pts were PSA negative after surgery and did not have any PSA relapse (Group 2). Nevertheless 14 of these pts received an additive RT treatment within the first 15 months after surgery. At the last date of contact all 36 pts were still PSA negative. 23 pts were PSA positive after surgery (Group 3). 18 pts received an early salvage RT with a PSA in median of 0.4ng/ml (0.12-4.58). After RT PSA was 0.28ng/ml (0.0-4.58). 5 pts in Group 1, 1 patient in Group 2 and 9 pts in Group 3 received androgen deprivation therapy (ADT) after radiotherapy until the last date of contact.

Conclusion: In total 60 of 94 pts (63.8%) with homogeneously pT3a pN0/cN0 R1 resected PCA received radiotherapy highlighting the need of adjuvant/salvage treatment in those pts. The efficacy of radiotherapy is documented by the fact that the median PSA of all irradiated pts at 80 months of follow up was 0.01ng/ml (0.0 - 204.9). This may be blurred by the influence of ADT (15 pts). However, even our small retrospective cohort demonstrates a biochemical recurrence rate of originally postoperatively PSA negative pts of 49.2%. Furthermore, 65.7% of these pts could be rendered at least temporarily PSA-free by postoperative radiation.

EP-1357

Moderately hypofractionated IGRT / IMRT-SIB in prostate carcinoma: toxicity and QoL in 300 patients

M. Ntreta¹, G. Siepe¹, A. Galuppi¹, S. Cammelli¹, M. Nuzzo², G. Macchia², F. Deodato², S. Cilla³, G. Mantini⁴, A. Farioli⁵, A. Arcelli¹, F. Bertini¹, M. Pieri¹, L. Ronchi¹, G. Martorana⁶, A.G. Morganti¹, G. Frezza⁷

⁶S.Orsola- Malpighi Hospital- University of Bologna, Department of Urology - Department of Medical and Surgical Sciences-DIMEC, Bologna, Italy

⁷Ospedale Bellaria, Radiotherapy Department, Bologna, Italy

Purpose or Objective: Aim of this study was to evaluate the safety, in terms of acute and late toxicity and QoL in patients (pts) with prostate carcinoma (PCa) treated with moderately hypofractionated IGRT/IMRT-SIB using fiducial markers.

Material and Methods: Three-hundred consecutive PCa pts were treated with daily on-line IGRT based on 2D (6MV) orthogonal images. Low risk pts received 62.1 Gy in 23 fractions to PTV1 (prostate). Intermediate risk pts with probability < 15% of lymph nodes involvement (Roach's equation) received 67.5 Gy and 56.25 Gy in 25 fractions to PTV1 and PTV2 (seminal vesicles). In high risk patients with probability > 15% of lymph nodes involvement, pelvic lymph nodes (PTV3) received 50 Gy. Acute and late toxicities were prospectively recorded using RTOG-EORTC scale and AUA score. Survival curves were calculated using the Kaplan-Meier method. Androgen suppressive therapy was prescribed based on risk categories.

Results: GI and GU G \geq 3 acute toxicity were 0.7 % and 2.0 %, respectively. With a median follow-up of 30 months (range: 12-72), late GI ad GU toxicity were recorded in 4 and 18 pts, respectively. Based on IPSS score, no pts reported severe urinary symptoms, and 7.7% of pts reported moderate symptoms only. In terms of QoL, 91.3% declared to be "pleased", 5.7% "mostly satisfied" and 1.3% "mixed" (1.7% not evaluable).

Conclusion: Our experience confirms the safety of moderate hypofractionation delivered with IGRT/IMRT-SIB and a moderate impact on QoL in pts with PCa. Prolonged follow-up is needed to evaluate the results in terms of patients outcome.

EP-1358

Prospective evaluation of PSA kinetics during salvage radiotherapy as a predictor for outcome

A. Gunnlaugsson¹, E. Kjellen¹, R. Blom¹, O. Bratt², G. Ahlgren³, P. Nilsson¹

¹Skåne University Hospital and Lund University, Department of Oncology and Radiation Physics, Lund, Sweden

²Cambridge University Hospitals NHS Foundation Trust, Department of Urology, Cambridge, United Kingdom

³Skåne University Hospital and Lund University, Department of Urology, Lund, Sweden

Purpose or Objective: The aims of this prospective observational trial was to study early PSA kinetics by weekly PSA measurements during salvage radiotherapy (RT) for patients with recurrent prostate cancer in order to develop a predictive model for treatment outcome.

Material and Methods: This prospective study included patients with a biochemical recurrence after prostatectomy referred for curative salvage RT. No previous or present anti-hormonal treatment was allowed. All patients were prescribed 70 Gy in 35 fractions to the prostate bed. PSA was measured at baseline and then weekly during RT. A PSA follow-up was scheduled at 3, 6, 12, 18 and 24 months after RT and yearly thereafter. Treatment response was defined as PSA <0.1 ng/ml at these time points (PSA_RESP_3/6/12/18/24). Bivariate analyses of the association between response and clinical factors as well as PSA during RT were performed. Here we report the results for end-point PSA_RESP_6.

Results: Since Sept 2012, 151 patients have reached six months follow-up after RT. PSA_RESP_6 was achieved in 89 (59%) of the cases. Significant predictive clinical factors were proportion of positive biopsies, Gleason score, lymph node extirpation and surgical borders. However PSA during therapy was the single strongest predictive factor for PSA_RESP_6 with a ROC AUC up to 0.92 (95% CI 0.86 - 0.95).

Conclusion: We propose that PSA monitored during salvage RT can be used as a predictive factor for treatment outcome and subsequently for personalized patient management.

EP-1359

A randomized trial comparing bladder volume consistency during EBRT in postoperative prostate cancer

K. Braide¹, J. Kindblom¹, U. Lindencrona²

¹Göteborg University Sahlgrenska University Hospital, Department of Oncology, Göteborg, Sweden

²Göteborg University Sahlgrenska University Hospital, Department of Physics and Biomedical Engineering, Göteborg, Sweden

Purpose or Objective: There are different guide lines about delineating the post-operative prostatic fossa before EBRT. They all recommend that the patients should have a half full or comfortably filled bladder at the planning CT and at each fraction in order to ensure a consistent bladder volume throughout the whole treatment course. The aim of this study was to compare bladder volume variations between 1) a specific bladder filling protocol and 2) a simple instruction to the patients to keep a comfortably filled bladder before each treatment fraction.

Material and Methods: Twenty-nine patients (median 65 y) with PSA-relapse planned for salvage radiation therapy were randomised in two groups, with different preparation instructions:

1. Drinking 300 ml and emptying the bladder one hour before planning CT and treatment fractions. (13 patients)
2. A comfortably filled bladder before planning CT and treatment fractions. A pre-treatment drinking volume according to patient's preference. (16 patients)

Treatment was prescribed to 70 Gy/35/2. As a complement to positioning to bony anatomy a CBCT was performed once a week to calculate the bladder volumes.

Results:

Figure 1. An example of a patient with large variation in bladder filling between planning CT (thin light green) and CBCT before a treatment fraction (thick light green). The planning-CT and CBCT are matched to bony anatomy. (Red =CTV, blue=PTV, dark green= rectum)

The bladder volumes varied widely both within each patient (see example in Fig. 1), between patients in the same group and between the groups.

The individual patient mean bladder volume varied from 79±23 to 269±90 ml in group 1 and between 64±19 to 309±110 ml in group 2.

Furthermore, there was no difference in the group mean bladder volume between the groups, 138±82 ml in group 1 and 150±92 ml in group 2 (p-value 0,59).

Conclusion: The findings indicate that the use of a strict bladder protocol is not superior to a comfortably filled bladder-regime to ensure a consistent bladder volume throughout the whole treatment course. The conclusion would be to let the patient prepare according to his own preference with a comfortably filled bladder. This could result in an easier patient setup due to a more relaxed patient. The impact of the wide variations in bladder volume on toxicity and dose distribution is further to be determined.

⁴Copenhagen University Hospital, Department of Oncology, Copenhagen, Denmark

⁵Herlev Hospital, Department of Oncology, Copenhagen, Denmark

⁶Aalborg University Hospital, Department of Oncology, Aalborg, Denmark

⁷Aarhus University Hospital, Department of Oncology, Aarhus, Denmark

Purpose or Objective: To compare patient-reported outcomes (PROs) with physician-assessed outcomes (PAOs) on gastrointestinal (GI) dysfunction pre- and post-radiotherapy (RT) for locally advanced prostate cancer.

Material and Methods: Adverse GI effects were assessed in 80 subjects treated with intensity-modulated RT for locally advanced prostate cancer (78 Gy/56 Gy in 39 fractions to the prostate/pelvic lymph nodes) in 2011-2012. A study-specific PRO and CTCAE.v.3-based PAOs were completed pre- and

post-RT (end, 3, 6, 12, and 24 m). This study focuses on the 18 (PROs) and 8 (PAOs) potentially RT-induced GI symptoms. Symptomatic subjects were considered as having PRO>Grade 1 and PAO>Grade 0 symptom severity. Relative risk ratios (RR) with related 95% confidence intervals (95%CI), and p-values (two-sided 5% significance level) were calculated for each symptom and follow-up time post-RT, with pre-RT symptom severity as the reference.

Results: Across all follow-up times, significant RRs were observed for in total 4/18 (RR: 2-25; p<0.001-0.02) PROs and 1/8 (RR: 2; p=0.0001-0.02) PAO (Table). Defecation urgency and Obstruction yielded the tightest 95%CI among the PROs, and Flatulence among the PAOs. The RR indicated that the PROs acknowledged both acute (12 symptoms) and late (3m: 5; 6m: 4; 12m: 7; 24m: 9 symptoms) RT-induced effects, and that the PAOs typically focused on acute rather than late effects (7 vs. 1-3 symptoms).

Table: Prevalence (%), relative risk ratio (RR), and 95% CI (p<0.05) at each follow-up time for each PRO (upper) and PAO (lower) symptom.

GI domain	PRO	End of RT N=79		3m post-RT N=79		6m post-RT N=82		12m post-RT N=77		24m post-RT N=74	
		%	RR 95%CI	%	RR 95%CI	%	RR 95%CI	%	RR 95%CI	%	RR 95%CI

	Re-defecate<1h after last defecation	53	4 2-7	32	2 1-4						
	Forcing toilet visit	58	5 3-9	42	3 2-7	35	3 2-6	44	4 2-7	39	3 2-6
Fecal leakage	Liquid stools	25	3 1-8					25	3 1-7	20	3 1-6
	Solid stools										
	Protective pads use	15	24 2-400					12	19 1-310	12	19 1-320
	Nocturnal bowel movements	24	9 2-38								
Obstruction	Soiling underwear							47	2 1-6	51	2 1-3
	Incomplete evacuation	44	4 2-9	30	3 1-6	21	2 1-5	29	3 1-6	34	3 2-7
	Difficulty passing stools	13	20 1-340								
Pain	Strain/defecation	27	2 1-5							27	2 1-5
	@Defecation	22	6 2-18								
Stool content	Anal/rectal	25	3 1-6								
	Mucous	33	25 4-180	15	11 2-85	21	16 2-120	16	12 2-88	16	12 2-91
	Blood									11	8 1-63
	PAO	%	RR 95%CI	%	RR 95%CI	%	RR 95%CI	%	RR 95%CI	%	RR 95%CI
Fecal leakage	Diarhea	49	6 3-14	22	3 1-7						
	Incontinence	14	11 1-81	11	9 1-66			12	9 1-68		
Flatulence	Flatulence	59	2 2-4	48	2 1-3	51	2 1-3	49	2 1-3	45	2 1-3
	Pain	14	4 1-12								
Proctitis	Abdominal	18	5 1-15								
	Bloating	19	7 2-31								
	Rectal										
	Proctitis	13	5 1-22			13	5 1-21				

Conclusion: This study indicates that the number of symptoms and temporal patterns of RT-induced GI dysfunction in locally advanced prostate cancer depend on the applied assessment method. Physician-assessed outcomes according to CTCAE.v.3 captured acute effects, and in particular flatulence, whilst patient-reported outcomes captured both acute and late effects mainly related to defecation urgency and obstruction.

⁶Candiolo Cancer Centre FPO-IRCCS, Laboratory Analysis, Candiolo Turin, Italy

⁷Candiolo Cancer Centre FPO-IRCCS, Medical Physic Units, Candiolo Turin, Italy

Purpose or Objective: The aim of this paper is to analyze, in prostate cancer patients treated with external beam radiotherapy (EBRT), the prognostic factors and their impact on the outcome in terms of Cancer Specific Overall Survival (CSOS), Biochemical Disease Free Survival (BDFS) and Clinical Disease Free Survival (CDFFS).

Material and Methods: From October 1999 and March 2012 we treated by EBRT, 1080 prostate cancer patients. The mean age was 69.2 years. Pretreatment staging examinations were: digital rectal examination (DRE), pretreatment PSA (iPSA), abdominal ultrasound, abdominal CT scan and bone scan. The 87% of patients were classified as < cT2, 87% had a

Gleason Score (GS) < 7; the mean of iPSA was 18 ng/mL; the rate of clinical positive nodes was 1%. The ADT was prescribed to 69% of patients in neoadjuvant setting, 65% in concomitant setting and 34% in adjuvant setting. The mean follow-up was 81 months.

Results: The prognostic factors resulted statistically significant for all groups of patients at both, univariate and multivariate analysis, were the GS and the iPSA. In intermediate and high/very-high risk patients at multivariate analysis the prognostic factors for CSOS were: GS (p=0.001), positive lymph nodes on CT scan (p=0.05) and rectal preparation during the treatment (p=0.005); for the BDFS were: GS (p=0.008), patient risk classification (p=0.037), positive lymph nodes on CT scan (p=0.004), iPSA (p=0.001) and rectal/bladder preparation during the radiation treatment (p=0.001); for the CDFS were: number of positive core on biopsy (p=0.003), GS (p=0.0003), positive lymph nodes on CT scan (p=0.015), iPSA (p=0.0056) and RT dose (p=0.001). In high/very-high risk patient group at multivariate analysis the prognostic factors for CSOS were: biopsic Gleason Score, clinical/radiological stage, RT dose; for BDFS were: biopsic Gleason Score, adjuvant ADT, clinical/radiological stage, iPSA and RT dose>77.7 Gy; for CDFS were: biopsic Gleason Score, clinical/radiological stage, iPSA and RT dose>77.7 Gy.

Conclusion: Our results confirm several prognostic factors already described by literature, adding a new prognostic factor represented by the rectal/bladder preparation, generally known for its effect on toxicity but not yet on outcome. We believe that in the future a new nomogram should include also some therapeutic variables (as RT dose, RT technique and ADT), to help clinicians in decision-making.

EP-1362

Hypofractionated Simultaneous Integrated Boost IMRT in high risk prostate cancer - A novel approach

S. Sashidharan¹, K. Beena¹, P. Chelakkot G¹, R. Madhavan¹, D. Menon¹, D. Makun¹

¹Amrita Institute Of Medical Sciences, Radiation Oncology, Kerala, India

Purpose or Objective: We aim to evaluate the biochemical failure free survival (BFFS) and morbidity in high risk prostate cancer patients treated with long term androgen deprivation therapy (ADT) and hypofractionated Simultaneous Integrated Boost (SIB) IMRT. Recent advances in techniques enable us to deliver a higher dose of radiation to the prostate with limited dose to the adjacent rectum and bladder. Earlier studies have estimated prostate cancer to have low α/B of 1.5. Thus hypofractionated schedules in theory should confer better local control and cancer specific survival (CSS). Due to the long natural history of prostate cancer it becomes imperative to reduce rectal and bladder morbidity. Also BFFS has shown to be a predictor of CSS. Most of the studies with whole pelvic RT and long term ADT have used conventional fractionation schedules. Data on the benefit of hypofractionated SIB IMRT with long term ADT is limited.

Material and Methods: Retrospective analysis of 100 high risk prostate cancer patients treated between 2010-2012. All patients received SIB IMRT with 70Gy in 28 fractions to the prostate and seminal vesicles (if involved) and 50.4 Gy in 28 fractions to the pelvic nodal stations with neoadjuvant hormonal therapy for a duration of 3-6 months prior to radiation and adjuvant hormonal therapy for a duration of 24-36 months. They were followed up with serial PSA values and clinical examination. Biochemical failure was defined as serum PSA >nadir + 2 (ASTRO Phoenix definition). Acute rectal and bladder toxicity was scored with the RTOG toxicity criteria. Chronic rectal toxicity (proctitis) and chronic bladder toxicity (cystitis) were assessed using the CTCAE 4.0. Patients without biochemical failure were censored at last follow-up/last PSA check or death. BFFS was calculated by the Kaplan-Meier method.

Results: At a median follow up of 45 months (20-87 months), there were 13 cases of biochemical failure (13%). 5 year BFFS was 78.6%. There was no Grade 3 or 4 acute rectal or bladder toxicity. Chronic toxicity has been listed in the table below. Urethral stricture developed in 7 patients, of whom 6 had prior TURP showing significant correlation (6/15, p<0.001).

	Grade 2	Grade 3	Grade 4
Proctitis	12	2	0
Cystitis	7	0	0

Conclusion: This study therefore concludes that long term ADT and SIB IMRT provides a feasible alternative to conventional radiation therapy with good biochemical control and acceptable toxicity. Longer follow up of these patients would provide data on cancer specific survival and late morbidity.

EP-1363

Salvage SBRT in isolated nodal oligo recurrence from prostate cancer: UPMC San Pietro FBF experience

M.C. Barba¹, F. Aquilanti¹, F. Bianciardi², B. Nardiello¹, G. Raza², R. El Gawhary², A. Rinaldi¹, C. D'Ambrosio², P. Gentile²
¹UPMC S. Pietro Fatebenefratelli, Radiotherapy, Roma, Italy
²Ospedale S. Pietro Fatebenefratelli, Radiotherapy, Roma, Italy

Purpose or Objective: A status of disease with a limited number of distant lesions and a controlled primitive tumor is recently defined as oligo-recurrence: this group of patients is more favorable than the other with a high number of metastases and, in prostate cancer, often is represented by a single node. The objective of this retrospective study was to evaluate the acute and late toxicity rates, in salvage stereotactic body radiation therapy (SBRT) as a treatment modality in nodes oligo-recurrence, from prostate cancer.

Material and Methods: Between February 2013 and March 2015, 21 patients, for a total of 29 isolated lymph nodes from prostate cancer, were treated with SBRT, delivered with Truebeam Stx (Varian®), at UPMC San Pietro FBF radiotherapy center of Rome. The median age at primitive diagnoses was 65 (range 50-74) years. For the primary treatment, radical prostatectomy and postoperative irradiation, exclusive radiotherapy or prostatectomy was performed in 12 (57%) patients, 7 patients (33%) and 2 patients (10%), respectively. Median previous RT dose was 72 Gy/35 fractions. Median PSA at the time of recurrence was 2.04ng/ml. All patients with arising PSA underwent a [11C] choline-positron emission tomography before SBRT, in order to exclude other sites of disease. The SBRT dose varied from 27 to 30 Gy, in 1-5 daily fractions, according to the previous RT treatment for the primitive lesion or a close organ at risk. A daily cone-beam CT and X-ray (BRAINLAB ExacTrac®) scans were acquired before each treatment session, for every

patient. Acute and late toxicity were analyzed, according to CTCAE toxicity scale (v. 4.0).

Results: The median follow-up was 14.5 months. Most of patients received 30 Gy, in 3 fractions, on alternative days: all the patients completed the prescribed SBRT treatment. Fifteen patients (71%) received androgen deprivation therapy concomitant to SBRT. SBRT was well tolerated: only 1 patient experienced G2 acute rectal toxicity but we didn't observe any severe acute or late toxicity (\geq G3). Despite the short follow up, local control was 100%, distant control was 79% (6/21). All these recurrences were nodal and all out of SBRT field: in 2 of these 6 patients a new SBRT course was delivered (30 Gy in 3 fractions) while in the other hormonal therapy was proposed. At the moment of analysis, all patients were alive.

Conclusion: Our experience shows that SBRT for isolated nodal relapse from prostate cancer is a safe treatment, offering a low toxicity profile and an excellent tumor local control. More data and a longer follow up are needed.

EP-1364

Role of choline PET/CT in Cyberknife treatment planning for recurrent prostate cancer following EBRT

I. Bossi Zanetti¹, A. Bergantini¹, A.S. Martinotti¹, I. Redaelli¹, P. Bonfanti¹, M. Invernizzi¹, A. Vai¹, L.C. Bianchi¹, G. Beltramo¹

¹Centro Diagnostico Italiano, Cyberknife, Milano, Italy

Purpose or Objective: Most studies demonstrate that local salvage therapy after EBRT may provide long-term local control in appropriately selected pts, although toxicity is often significant. In these pts, PET/CT with [11C]choline may accurately detect the presence of recurrence. We investigated the role of [11C]choline PET/CT for target volume selection and delineation in pts with recurrent prostate cancer following EBRT for a salvage tailored Cyberknife Stereotactic Hypofractionated Radiotherapy (SBRT) treatment.

Material and Methods: From December 2012 to April 2015, 22 pts with initial disease category defined as low(2), intermediate(6) high (14), in accordance with NCCN 2008 guidelines, median age of 74 years (range 62-89) and an history of locally-recurrent prostate cancer following EBRT were referred to our Department for salvage Cyberknife SBRT. The diagnosis of a clinically evident recurrence of prostate cancer was based on biochemical progression and imaging studies. Median iPSA was 22,7 ng/ml (4,9-88 ng/ml), EBRT doses ranged from 74 to 79.2 Gy (median 76Gy) and the median interval time between relapse diagnosis and salvage Cyberknife treatment was 60 months (range 19-139). The median pre-reirradiation PSA was 4,64 ng/ml (range 2,23-13,04 ng/ml). CT scan and MRI with T1-T2 sequences were performed and [11C]choline PET/CT images were fused for prostate target volume delineation. 5 pts received 3 fractions of 10 Gy (total dose 30 Gy), 17 pts received 3 fractions of 12 Gy (total dose 36 Gy) delivered to the PET positive prostate node (median volume of 14,3 cc-range 5,75-65,04) in the respect of organ at risk constrains.

Results: The treatment was well tolerated with no RTOG grade 3 acute or late toxicity. With a median follow up of 17 months (range 6-35) we observed the following results: no in field recurrence, with a local control of 100%. In 4 pts, respectively at 11, 14, 16 and 22 months after treatment (median time 15 Months), a [11C]choline PET/CT detect a local recurrence with the evidence of a new positive prostate node outside the irradiated field requiring a second Cyberknife salvage treatment.

Conclusion: Advances in modern imaging show promises in the management of prostate cancer at the different stage (diagnosis, treatment planning and follow up). According to available literature [11C]choline PET/CT is not clinically recommendable to plan target volume, nevertheless, our promising data suggest a potential role of [11C]choline

PET/CT as an image guide tool for the focal irradiation of prostate cancer relapse.

EP-1365

Dosimetric predictors for rectal toxicity with two hypofractionated schedules for prostate cancer

T. Zilli¹, M. Kountouri¹, M. Rouzad¹, A. Dubouloz¹, D. Linero², S. Jorcano², L. Escudé², R. Miralbell³

¹Hôpital Cantonal Univ. Genève, Radiation Oncology, Geneva, Switzerland

²Teknon Oncologic Institute, Radiation Oncology, Barcelona, Spain

³Hôpital Cantonal Univ. Genève and Teknon Oncologic Institute, Radiation Oncology, Geneva and Barcelona, Switzerland

Purpose or Objective: To analyze the dosimetric impact on long term gastro-intestinal (GI) toxicity of two sequential dose escalation regimens of twice weekly 4 Gy/fractions hypofractionated intensity-modulated radiotherapy (IMRT) delivered within a protracted overall treatment time of 6.5 and 7 weeks, respectively.

Material and Methods: Clinical and dosimetric data on 96 prostate cancer patients with cT1c-T3a disease and nodal involvement risk \leq 20% (Roach index) treated twice-weekly to the prostate +/- seminal vesicles with two sequential dose-escalated IMRT schedules of 56 Gy (14 x 4 Gy, n=28) from 2003 to 2007 and 60 Gy (15 x 4 Gy, n=68) from 2006 to 2010 were analyzed. The corresponding NTD2Gy for an α/β ratio of 1.5 and 3 Gy were 88 and 78 Gy for the 56 Gy group, and 94 and 84 Gy for the 60 Gy group, respectively. The planning target volume (PTV) consisted of an anisotropic expansion of 10 mm around the prostate, except 6-mm posteriorly. Patient repositioning was made with bone-matching on portal images or body markers registration. GI toxicities were scored using the CTCAE v3.0 grading scale.

Results: Among the 96 analyzed patients, the 5-year grade \geq 2 late GI toxicity-free survival was similar in patients treated with 56 Gy compared to those treated with 60 Gy (92.6 \pm 5.1% vs. 85.0 \pm 5.1%, p=0.533). Mean volumes of rectum receiving more than 50 Gy (V50Gy, equivalent to V70Gy NTD2Gy, $\alpha/\beta=3$ Gy) and 54 Gy (V54Gy, equivalent to V75Gy NTD2Gy) were 15.8% vs. 20.9% (p=0.001) and 4.2% vs. 13.8% (p=0.0001) for the 56 and 60 Gy groups, respectively. A V50Gy19% (median 19.2%, range 4.4%-37.8%) was achieved in 67.9% and 38.2% of the patients treated with 56 and 60 Gy, respectively. A V50Gy >19% correlated with a 5-year grade \geq 2 late-GI toxicity-free survival of 80.8 \pm 6.3%, significantly worse than patients with a V50Gy \leq 19Gy (95.3 \pm 3.2%, p=0.031).

Conclusion: Independently from the dose prescription, a V50Gy \leq 19% may result in a better long term rectal toxicity profile in patients treated with a hypofractionated IMRT schedule of 56 or 60 Gy in 4 Gy fractions. As for normofractionated schedules the QUANTEC dose constraint V70Gy<20% for the rectum seems to be a strong predictive factor of late GI toxicity for hypofractionated regimens as well.

EP-1366

Hypofractionated prostate EBRT with simultaneously integrated boost: mono-institutional report

J. Hermesse¹, X. Werenne¹, J. Vanderick¹, F. Lakosi¹, A. Gulyban¹, P. Coucke¹

¹C.H.U. - Sart Tilman, Radiation therapy, Liège, Belgium

Purpose or Objective: To report early outcome of hypofractionated radiotherapy for prostate cancer patients using a simultaneous integrated boost strategy (SIB) focusing on acute genitourinary (GU) and acute and late gastrointestinal toxicity (GI).

Material and Methods: Between 01/2012 and 06/2014 ninety-seven low (n=13) -, intermediate (n=22) - and high-risk (n=45)- prostate cancer patients were treated with hypofractionated radiotherapy using VMAT/IMRT and SIB. It

consisted of 65.75 Gy to the prostate gland+seminal vesicles (2.63 Gy/fx) and 45 Gy to the pelvic nodes (1.8 Gy daily) when needed, delivered in 25 fractions. All patients underwent daily image guidance with cone-beam computed tomography. Sixty-six percent of the patients received implanted gold markers (64/97). Acute and late gastrointestinal- and genitourinary toxicity was recorded according to the Common Terminology Criteria for Adverse Events 4.0. Chi-square test and univariate regression analysis were used to determine correlation of categorical and continuous data at the $p < 0.05$ significance level.

Results: During a median follow-up of 23 (range: 4-44) months, 7/97 biochemical failures (7%) were observed. The frequency of Gr. 2 acute gastrointestinal (GI) and genitourinary (GU) toxicities were 8% (8/97) and 45% (44/97) including 6% Gr. 3 bladder urgency and nycturia (6/97). Late \geq Gr. 2 GI toxicities of 14 % (13/97) were mainly rectal bleeding and chronic proctitis. Correlation was found between lymph node irradiation ($p=0.008$) and late rectal toxicities, while for other patient characteristics including the presence of gold markers ($p=0.097$) or smoking ($p=0.99$) did not appear to affect such adverse event. Univariate regression analysis was used to determine correlation of categorical and continuous data at the $p < 0.05$ significance level.

Conclusion: Our experiences suggest that moderate hypofractionation with SIB technique is safe with moderate acute side effects. Longer follow-up and higher number of patients is warranted to confirm these results in long term. 8) and late rectal toxicities, while for other patient characteristics including the presence of gold markers ($p=0.097$) or smoking ($p=0.99$) did not appear to affect such adverse event. Univariate regression analysis was used to determine correlation of categorical and continuous data at the $p < 0.05$ significance level.

EP-1367

IMRT from 70 Gy to 80 Gy in prostate cancer: clinical and dosimetric predictors of late toxicity

M. Jolneroski¹, J. Salleron², V. Beckendorf¹, D. Peiffert¹, A.S. Baumann¹, V. Bernier-Chastagner¹, V. Marchesi³, S. Huger³, G. Vogin¹, C. Chira¹

¹Institut de Cancérologie de Lorraine, Radiation Oncology, Vandoeuvre les Nancy, France

²Institut de Cancérologie de Lorraine, Biostatistics, Vandoeuvre les Nancy, France

³Institut de Cancérologie de Lorraine, Physics, Vandoeuvre les Nancy, France

Purpose or Objective: Evaluate grade ≥ 2 overall late rectal and bladder toxicity in patients (pts) with localized prostate cancer (CaP) treated by IMRT. Identify predictors of radiation-induced toxicity and analyze biochemical progression free survival (bPFS).

Material and Methods: A total of 276 pts were treated between 2000 and 2010 with 70Gy (10.8%), 74 Gy (63.9%) and 80 Gy (25.3%), using static 5-field IMRT without pelvic irradiation. Short or long-course deprivation (ADT) was prescribed in 25.4 % and 20.7%, respectively. The toxicity was described using the Common Terminology Criteria for Adverse Events (CTCAE) v4.0 scale. Cox regression models addressed tumor (T stage, Gleason score, PSA) and patient characteristics (age, diabetes, previous abdominal or pelvic surgery, transurethral prostate resection, anticoagulation treatment, hypertension, coronary insufficiency and International Prostate Symptom Score-IPSS) as well as dosimetric predictors of late grade ≥ 2 overall toxicity.

An analysis of dosimetry data was only performed in the 74-Gy arm. Our institutional HDV constraints for rectal wall (maximal dose ≤ 74 Gy, V68Gy $< 25\%$, V45Gy $< 45\%$) and bladder wall (maximal dose ≤ 74 Gy; V50Gy $< 40\%$, V65Gy $< 25\%$) were tested as potential predictors for late toxicity.

Biochemical progression free survival was analyzed only in pts without ADT.

Results: The median follow-up was 53.1 months (range, 6-150). There was no grade ≥ 4 toxicity. The use of ADT was not found to be predictive. The 5-year rectal and bladder toxicity-free survival was 93.8 % (95% CI, 89.8%-96.2%) and 75.2 % (95% CI, 68.7%-80.5%) respectively.

In multivariate analysis (MVA) only the dose (80Gy vs 74 Gy and 70Gy) increased the risk of overall rectal toxicity (hazard ratio [HR]=2.96; 1.07- 8.20). The non-compliance to our constraints on rectal wall was not a significant predictor of rectal toxicity.

IPSS at baseline ≥ 8 (hazard ratio [HR]=2.60;1.47 -4.62), delivered maximum dose (Dmax) ≥ 74 Gy (HR=2.09;1.04 -4.17) and dose delivered $\geq 2\%$ of bladder (D2%) ≥ 73 Gy (HR=3.33;1.37-8.07) were found to be predictors of bladder toxicity.

The 5-year bPFS was 81.0% (74.5%; 86.0%). D'Amico low (HR=0.09; 0.01- 0.69) and intermediate risk group (HR=0.49; 0.28-0.88) as well as PSA nadir ≥ 0.2 ng/ml (HR =1.79; 1.01 - 3.21) were predictive of biochemical relapse.

Conclusion: The rate of late rectal toxicity increased with higher doses, while Dmax ≥ 74 Gy, D2% ≥ 73 Gy and baseline IPSS ≥ 8 increased bladder toxicity.

EP-1368

A novel decision support method to estimate the value of a rectum spacer: 'Virtual Rectum Spacer'

S. Van der Meer¹, B.G.L. Vanneste¹, W. Van Elmpt¹, C. Schubert², M. Pinkawa², P. Lambin¹

¹MAASTRO clinic, Department of Radiation Oncology- GROW - School for Oncology and Developmental Biology- Maastricht University Medical Center, Maastricht, The Netherlands

²University Hospital RWTH Aachen, Department of Radiation Oncology, Aachen, Germany

Purpose or Objective: A relative new method to decrease the risk of rectal complications during prostate radiotherapy treatments consists of the implantation of a device, an absorbable hydrogel or saline filled balloon, between the prostate and the anterior rectum wall: so called rectum spacers (RS). Nevertheless the implantation of a RS is relatively expensive and invasive. Therefore a decision support system to identify beforehand whether a specific patient will benefit from a RS and whether it will be cost efficient would be very beneficial. We have developed a novel method to predict the CT images with a 'virtual' RS through non-rigid deformations based on a CT scan without RS to be integrated into a decision support system.

Material and Methods: A patient dataset consisting of 16 prostate cancer patients with CT imaging prior and 3-5 days after a gel RS implantation (SpaceOAR™ System, Augmenix Inc.) was used. The median inserted gel volume was 10.5 cc. Gel contours of the first 8 patients were used as a training set to derive the spatial deformation model of the RS. The contours of the RS were registered rigidly according to their centre and an average deformation map was created. The overlapping volumes of RS of different patients having a probability of > 3 contour corresponded with a volume of 10 cc, and was used to derive the deformation model of the RS. From this model, a deformation field was calculated that mimics the expansion of the RS between the prostate and the rectum. The CT images of the remaining 8 patients were used to validate the virtual RS model, for this the distance between the rectum and the prostate was compared for the virtual RS and the actual RS.

Results: An example of the virtual RS is shown in the figure where the contours of the real RS and virtual RS show a good overlap (DICE = 0.63). The average minimum distances between the prostate and rectum of all 8 patients in the validation set increased with 3.7 ± 2.4 (1SD) mm when the virtual RS was applied. For the real RS the average increase in minimum distance was 5.4 ± 2.7 mm. The mean distances between the prostate and rectum without RS was 15.8 ± 3.2 mm, with the virtual RS this was 19.5 ± 3.3 mm comparable to the real RS 22.0 ± 4.3 mm.

Figure: For one patient the CTs with and without RS are shown in combination with the CT containing the virtual spacer. The contours on the right show the overlap of the real and virtual spacer contours.

Conclusion: We have developed a novel method to simulate a model based virtual RS that is a useful tool to identify patients with a potentially high benefit of a RS implantation. The volume of the virtual RS can be estimated through the use of different deformation fields. In future, a dose comparison study is necessary to extend into a full decision support system using the virtual RS approach.

³University Hospital Padova, Radiation Oncology, Padova, Italy

⁴University Hospital Udine, Medical Physics, Udine, Italy

⁵University Hospital Udine, Urology, Udine, Italy

Purpose or Objective: The escalation dose in the treatment of prostate cancer with external beam radiation therapy has proved the winning way in the biochemical control of the tumor. But the dose escalation to the whole prostate gland, which is considered as clinical target volume in external beam radiotherapy, is limited by the tolerance of the surrounding tissue. We have compared the toxicity profiles between patients treated with moderate hypofractionated 3-dimensional conformal radiotherapy (3D-CRT) collated with volumetric-modulated arc therapy (VMAT), both with image-guided radiotherapy (IGRT) by implanted fiducial markers in prostate gland (FMs).

Material and Methods: Between 2009 and 2011, 41 patients with prostate cancer were treated with 3DCRT-IG to a dose of 70 Gy 2.5 Gy/fr with daily online correction of the target position based on MV/MV. This group of patients was compared with a similar cohort of 39 patients who were treated between 2012 and 2014 with VMAT-IG to the same prescription dose with daily online correction of the target position based on MV/KV imaging. The clinical characteristics of these two patient populations are shown in Table 1.

Radiation Therapy Oncology Group/European Organization for Research and Treatment of Cancer late morbidity RTOG/EORTC scores were used for acute and late effects. The median follow-up time was 3 years (range, 1-6 years). The rectal and bladder dose parameters were also included in the statistical analysis.

Table 1 Patient characteristics

Patient demographics	3DCRT-IG (n = 41)		IMRT-IG (n = 39)	
	n	%	n	%
Pretreatment PSA (ng/mL)				
< 10	30	73	32	82
10-20	11	24	4	10
>10	0		3	8
Total Gleason Score				
<7	13	31	11	28
7	28	69	21	54
>7	0		7	18
T stage				
T1o-T2a	28	68	25	64
T2b	7	17	10	26
>T2b	6	15	4	10
Age				
< 70	15	37	11	28
>70	26	62	28	72
NCCN risk				
Low	0		8	21
Intermediate	41	100	22	56
High	0		9	23
Neoadjuvant ADT				
Yes	37	90	32	82
No	4	10	7	18

ADT = androgen deprivation therapy;
NCCN = National Comprehensive Cancer Network;
PSA = prostate-specific antigen.

Results: The rectal acute and late toxicity was low for both treatment groups and no significant reduction was observed for VMAT-IG patients compared with the 3DCRT-IG patients ($P = 0.33$). The likelihood acute genitourinary toxicity for the VMAT-IG and 3DCRT-IG cohorts were 14.5% and 18.0%, respectively ($p = 0.61$). Only for acute genitourinary toxicity, the analyses showed a trend better but non significant result on behalf of VMAT-IG ($P=0.09$). Finally, no significant correlation was observed between the dose parameters and genito-urinary and rectal late toxicity. The PSA relapse-free survival in according to Phoenix criteria (nadir plus 2 ng/ml) for 3D-CRT and VMAT were similar (98% vs. 96%; $p = 0.34$).

Conclusion: Moderate hypofractionated IGRT is associated with a lower rate of genito-urinary and rectal toxicity for both treatment 3D-CRT and VMAT. These data suggest that, the placement of fiducial markers and daily online correction of target positioning may represent the preferred mode of external-beam radiotherapy delivery for the patients treated by definitive radiotherapy.

²University of Milan, University of Milan, Milano, Italy

³European Institute of Oncology, Medical Physics, Milano, Italy

⁴European Institute of Oncology, Urology, Milano, Italy

⁵European Institute of Oncology, Medical Imaging and Radiation Sciences, Milano, Italy

Purpose or Objective: To evaluate the outcome of stereotactic body Vero® linac- or Cyberknife®-based radiotherapy (SBRT) for oligometastatic lymph node recurrent prostate cancer.

Material and Methods: Between 05/2012 and 09/2015 117 patients were treated (180 lymph nodes). Median age, initial PSA (iPSA), pre-SRT PSA and Gleason score (GS) were 70.3 years, 10.3 ng/mL, 4.4 ng/mL and 7, respectively. Any previous treatment was allowed. In all but 4 patients, [11C]choline-positron emission tomography/computer tomography was performed. SBRT consisted in re-irradiation and first radiotherapy for 29 (16%) and 151 (84%) lesions, respectively. Median dose was 24 Gy/3 fractions. Cyberknife-SBRT or Vero linac-SBRT was applied in 20 (11%) and 160 (89%) lymph nodes, respectively. In 56 (48%) patients androgen deprivation was added to SBRT (median duration 13.9 months), some patients were heavily pre-treated and castration-resistant. Biochemical failure was defined as post-SBRT PSA increase over pre-SBRT value. Toxicity was evaluated using Radiation Therapy Oncology Group/European Organization for Research and Treatment of Cancer (RTOG/EORTC) criteria.

Results: All patients completed planned SBRT. The median follow-up was 19.7 months. Acute toxicity included urinary (7 G1 events) and rectal complications (2 G1 events). Late toxicity included only urinary complications (2, 2, and 2 G1, G2, and G4 events, respectively). Both G4 events were temporary and were observed in pts receiving re-RT, with no dose to bladder from SBRT. Complete or partial biochemical response was observed in 68(68%) out of 100 evaluable patients. PSA stabilization was seen for 7(7%) patients and in 24(24%) cases PSA progression was reported. Clinical progression during follow up was observed in 65(65%) patients after a median time of 9 months (range: 1 - 33.1 months) from SBRT. In-field progression was observed in 13(13%) cases. 31(31%) patients had distant metastases and 34(34%) showed regional lymph node progression. All events of clinical failure were preceded by biochemical progression. At the time of the analysis (October 2015), 17(14.5%) patients are alive with no evidence of disease, 79(67.5%) are alive with clinically evident disease, 4(3.5%) died of disease and 17(14.5%) are not evaluable (due to short follow-up).

Conclusion: Our series including 117 unselected pts showed that Vero Linac- or Cyberknife-based SBRT is feasible for oligometastatic lymph node recurrent prostate cancer offering excellent in-field tumor control and low toxicity profile. Further investigation is warranted in order to identify the patients that benefit most from this treatment modality. The optimal combination with androgen deprivation or other systemic treatments should also be defined.

EP-1371

Role of 11C choline PET/CT in the management of prostate cancer patients with biochemical relapse

⁴Nuclear Medicine Unit - S.Orsola-Malpighi Hospital - University of Bologna, Department of Experimental-Diagnostic and Specialty Medicine - DIMES, Bologna, Italy

⁵Ospedale Bellaria, Radiotherapy Department, Bologna, Italy

Purpose or Objective: The aim of our retrospective study was to analyze the role of [(11)C]choline-Positron Emission Tomography/Computed Tomography (cho-PET/CT) in the management of patients (pts) with biochemical failure after curative surgery in patients with prostate cancer.

Material and Methods: We reviewed all patients referred to our department with biochemical failure and without evidence of recurrence on standard imaging (pelvic MRI + total body CT-scan) after curative surgery for prostate cancer. All patients underwent cho-PET/CT scans between 2010 and 2014.

Results: Thirty-four patients fulfilled the inclusion criteria and were included in this study. Previous surgical procedure was: radical prostatectomy (19 pts), radical prostatectomy with pelvic lymph node dissection (8 pts) and radical prostatectomy with lymph node sampling (9 pts). Thirty-six scan cho-PET/CT studies were performed on 34 patients. Median PSA level before cho-PET/CT was 1.7 ng/mL (range 0.2 to 7.6). Cho-PET/CT showed 21 uptakes in prostate bed, 4 in prostate bed and pelvic lymph nodes, 1 in prostate bed and paraaortic lymph nodes, 5 in pelvic lymph nodes, 1 in retroperitoneal lymph nodes (4 exams were negative). Eleven pts underwent salvage radiotherapy, 21 pts salvage radiotherapy and androgen deprivation therapy and 1 patient androgen deprivation therapy only. With a median follow-up of 15 months, 27 showed complete biochemical response to salvage therapy (PSA <0.04 ng/ml), and are still free from biochemical recurrence. Two pts showed biochemical failure, 3 developed lymph node recurrence and 2 patients developed bone metastases.

Conclusion: Cho-PET/CT was able to detect macroscopic disease in prostate cancer pts with biochemical failure after surgery allowing individualized salvage treatment.

EP-1372

Salvage image-guided stereotactic re-irradiation of local recurrence in prostate cancer

G. Timon¹, D. Zerini¹, C. Fodor¹, F. Bazzani¹, A. Maucieri², S. Ronchi², D.P. Rojas², S. Volpe², A. Vavassori¹, F. Cattani³, C. Garibaldi³, S. Comi³, R. Cambria³, O. De Cobelli⁴, R. Orecchia², B.A. Jereczek-Fossa¹

¹IEO - European Institute of Oncology, Radiotherapy division, Milano, Italy

²University of Milan, Health Science department, Milano, Italy

³IEO - European Institute of Oncology, Medical Physics division, Milano, Italy

⁴IEO - European Institute of Oncology, Urology division, Milano, Italy

Purpose or Objective: To retrospectively evaluate external beam re-irradiation (re-EBRT) delivered to either the prostate or prostatic bed for local recurrence after radical or adjuvant/salvage radiotherapy.

Material and Methods: Between February 2008 and March 2015, 59 patients received re-EBRT. Median age was 63.8 years (range 47.1-81.7) and median PSA at the time of relapse was 20.2 ng/ml (range 4.4-110). All patients had clinical and/or radiological local relapse in the prostate or prostatic bed and no distant metastasis at the time of re-EBRT. A concomitant hormonal treatment was administered to 18 patients. Re-EBRT was delivered with image-guided stereotactic technology including Rapid Arc®, VERO® and Cyberknife® to a total dose of 15-32 Gy in 3-6 fractions. Toxicity was evaluated using RTOG/EORTC Criteria. Biochemical control was assessed according to Phoenix definition.

Results: Only one patient experienced an acute GI event >G3, while two patients had late ≥G3 urinary toxicity.

At a mean and median follow-up of 24.1 and 19.8 months respectively (range 2-65.5), 27 patients (45%) show no evidence of disease, 26 (44%) are alive with biochemical or clinical disease and 2 have been lost at clinical follow-up. 4

patients (7%) died: 2 of disease progression and 2 of other causes. Mean and median time-to-progression are 12.1 and 9.8 months respectively (range 2-53).

Conclusion: Re-EBRT using stereotactic approach is a feasible option for local prostate cancer recurrence, achieving tumour control in 45% of the patients and an acceptable progression-free interval. Toxicity of re-EBRT appeared to be very low. Future studies are needed to identify those patients who would benefit the most from this treatment.

EP-1373

Hypofractionated radiotherapy and androgen deprivation in intermediate risk prostate cancer

S. Bracci¹, M.F. Osti¹, L. Agolli¹, L. Bertaccini¹, V. De Sanctis¹, M. Valeriani¹

¹Azienda Ospedaliera Sant' Andrea, Department of Radiation Oncology, Rome, Italy

Purpose or Objective: to evaluate the outcomes in intermediate risk prostate cancer treated with hypofractionated radiotherapy (HyRT)

Material and Methods: Between March 2007 and March 2015, 145 patients affected by intermediate risk (T2b-T2c prostate cancer or Gleason Score equal to 7 or pre-treatment PSA value ranging from 10 to 20 ng/mL) prostate cancer were treated with HyRT. The median age at diagnosis was 74 years (range 53-88). A pre-treatment CT scan with 2.5 mm slices was obtained. MRI was used to better delineate the Clinical Target Volume (CTV) when available. The CTV1 included the prostate plus seminal vesicles (SSV) and the CTV2 the prostate alone. Planning Target Volumes (PTV1 and PTV2, respectively) were generated with 8 mm margin in all directions except posteriorly where a 6 mm expansion was adopted in the first 36 patients. A 5 mm expansion in all direction was used in the other patients as daily kv Cone Beam CT was used to verify the patient position because of an implementation of the linear accelerator. A 3D-CRT and a 15 MV photons linear accelerator was used to deliver the treatment. The PTV1 received 43.8 Gy in 12 fractions and the PTV2 received 54.75 Gy in 15 fractions, three times a week in order to avoid an excess of acute toxicity. Neoadjuvant, concomitant and adjuvant ADT was administered for a total of 9 months and was started 3 months before RT.

Results: After a median follow-up of 52.4 months (range 7 to 95 months), 11 patients (7.6%) died, of whom 9 for intercurrent disease and 2 (1.3%) for PCa. The 5-year OS was 90.1% (95%CI 84.2-97.6%) and the 5-year CSS was 98.6% (95%CI 95.4-100%). Fourteen patients (9.7%) developed biochemical recurrence after a median follow up of 30.5 months (95% CI 28.5 to 32.5 months). Of these patients, thirteen (9.0%) had also a clinical detectable disease while the remaining patient presented only biochemical recurrence. The 5y-bRFS was 88.8% (95%CI 82.8-95.4%). Among the 13 patients with clinical recurrence, 7 (53.8%) had local recurrence, 2 (15.4%) developed distant metastases, and 4 (30.8%) had both local recurrence and distant metastases. Acute genito-urinary (GU) toxicity of grade 1 occurred in 74 patients (51.0%), grade 2 in 15 patients (10.3%) and grade 3 in 2 patients (1.3%). Acute gastrointestinal (GI) toxicity of grade 1 were observed in 27 patients (18.6%), grade 2 in 12 patients (8.2%). None developed acute GI toxicity of grade 3 or 4. Late GU toxicity occurred as follows: grade 1 in 51 patients (35.2%), grade 2 in 12 patients (8.2%), grade 3 in 2 patients (1.3%). Late GI toxicity of grade 1 was observed in 18 patients (12.4%), grade 2 in 6 patients (4.1%) and grade 3 in 1 patient (0.7%).

Conclusion: The hypofractionated schedule used is well tolerated with a low rate of acute and late grade gastrointestinal and genitourinary toxicities. Hypofractionation is useful to obtain high rate of tumor control but a longer follow-up is needed for definitive conclusion.

EP-1374

Contouring guideline optimisation for prostate pts undergoing carbon ions/photons combined treatment

T. Giandini¹, M. Carrara², E. Pignoli², N. Bedini³, S. Morlino³, D. Bosetti³, B. Avuzzi³, S. Villa³, A. Hasegawa¹, S. Russo⁴, B. Vischioni⁵, M. Ciocca⁴, F. Valvo⁵, B. Jereczek-Fossa¹, D. Ciardo¹, D. Zerini¹, S. Colangione¹, C. Fodor¹, F. Cattani¹, R. Valdagni³, R. Orecchia¹

¹European Institute of Oncology, Radiotherapy Division, Milan, Italy

²Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics, Milan, Italy

³Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology 1, Milan, Italy

⁴Fondazione CNAO, Medical Physics Unit, Pavia, Italy

⁵Fondazione CNAO, Clinical Radiotherapy Unit, Pavia, Italy

Purpose or Objective: In the context of the multi-institutional research project "Carbon ions boost followed by pelvic photon intensity modulated radiotherapy for high risk prostate cancer", Contouring Guidelines (CG) for target volumes and Organs At Risk (OARs) were commonly defined based on National/International standards and local experiences. Intra- and inter-institutional variability was evaluated within a contouring dummy-run and a graphical tool was developed to assist the Radiation Oncologists (ROs) in the standardization of the contouring.

Material and Methods: CT and MR images of 5 prostate patients were randomly chosen. Seven ROs belonging to the three Institutes involved in the project were assigned to independently contour targets (prostate (GTV-P), seminal vesicles (CTV-VS) and pelvic lymph nodes (CTV-N) and OARs (rectum (R), bladder (B), femoral heads (FH), small bowel (SB), penile bulb (PB) and anal canal (AC)). The registration between CT and MR images was only used to contour GTV-P and PB. The contours were compared by means of the DICE Index (defined as $2 \cdot (A \cap B) / (A + B)$, where A e B are the volumes in comparison), as provided by the commercial software VODCA (MSS, v.5.4.0). For each structure, the Global DICE Index (GDI) was calculated as the average value for all the ROs and the patients and then compared with the DICE Index of the individual ROs: an individual DICE Index lower than the corresponding GDI (or lower than a threshold value of 0.9 for GDI > 0.9) was recorded as "disagreement" and reported in a graphical tool (Figure 1) that qualitatively shows intra- and inter-institutional variability.

Results: The resulting GDI are reported in Table 1. A visual analysis of the contours on the CT images showed that the poor quality GDI for CTV-VS and AC were due both to a not strict application of the CG by the ROs of the different Institutes and to the small volume of those structures. The other results were instead attributable to random variation in the contouring. The graphical tool clearly showed that inter-institutional variability was predominant compared to intra-institutional variability both for targets and OARs. Nevertheless, some disagreement was found even between ROs of the same Institute.

Table 1 – Mean values and standard deviations of the Global DICE Index for the contoured structures

Structures	Global DICE Index
Prostate	0,87 ± 0,02
Seminal Vesicles	0,49 ± 0,06
Pelvic Lymph Nodes	0,75 ± 0,01
Rectum	0,80 ± 0,02
Bladder	0,959 ± 0,003
Femoral Heads	0,936 ± 0,005
Small Bowel	0,78 ± 0,10
Penil Bulb	0,71 ± 0,02
Anal Canal	0,52 ± 0,06

FIGURE 1 – Graphical tool showing the disagreements between ROs belonging to Institute A (A1,A2,A3), B (B1,B2) and C (C1,C2), for target volumes (a) and OARs (b).

Dark grey cells show intra-Institutional variability, whereas the other cells show inter-Institutional variability

Conclusion: The dummy-run showed that the most significant deviations were obtained when ROs did not precisely apply the CG. Such systematic deviations in the contouring could have a dosimetric impact both for target coverage and OAR sparing, especially for particle therapy. The ROs were provided with the developed graphical tool in order to easily identify their deviations and take corrective actions. The graphical tool could also be useful for the optimization of the contouring strategies within individual Institutes. This work was partially funded by Associazione Italiana per la Ricerca sul Cancro AIRC (grant N-14300)

EP-1375

Adjuvant androgen deprivation therapy and postoperative radiotherapy in prostate cancer: our data

G. Lazzari¹, A. Terlizzi², G. Della Vittoria Scarpati¹, R. Marchese¹, M. Soloperto¹, A. Nikolaou¹, G. Silvano¹

¹Azienda Ospedaliera SS. Annunziata Presidio Osped, Radiology, Taranto, Italy

²Azienda Ospedaliera SS. Annunziata Presidio Osped, Physic Department, Taranto, Italy

Purpose or Objective: To evaluate the role of adjuvant androgen deprivation therapy (ADT) in combination with postoperative radiotherapy (PORT) on biochemical-relapse-free-survival (b-NED) and metastatic-progression-free-survival (mts-NED) in high risk prostate cancer patients (pts).

Material and Methods: Between 2004 and 2012 370 high risk prostate cancer pts received PORT : 120 pts had stage pT3a pN0, 150 pts pT3b pN0 , 100 pts pT2c/pT3 R1 and post surgical PSA > 0.2 ng/ml detected in 50 pts. Mean age was 72 years (55-78 yrs). PORT on pelvis and surgical bed was delivered in 150 pts while 220 pts were treated on surgical bed . Dose to pelvis was 45-50 Gy, while dose on surgical bed was 66- 72 Gy. ADT was administered in 250 pts and consisted of LH-RH analog in monotherapy (70 pts), BAT (60 pts) and bicalutamide 150 mg (120 pts). Timing of ADT ranged six months to 3 years. ADT was administered during and after PORT with a median of 35 months. Kaplan-Mayer b-Ned and mts-Ned survivals , X-square (p< 0.05) and paired t-test for univariate and multivariate analyses (p< 0.001) were calculated.

Results: Three - hundred were evaluable at 64 months with a median of 5 years. Two groups were identified: ADT (210 pts) and no ADT (90 pts). One-hundred and twenty pts (120) relapsed: 40 pts in the no ADT group (5 with a biochemical relapse and 35 pts with a metastatic relapse) and 70 pts in the ADT group (20 pts with a biochemical relapse and 50 pts with a metastatic). The 5- year biochemical relapse free survival was 80% for ADT group and 78% for no ADT group (p = 0.34); the 5-year metastatic progression free survival for ADT group was 82 % vs 65% (p< 0.05)for no ADT group. In the

ADT group, radiotherapy dose <70 Gy and PSA >0.2 ng/ml were independent factors related to high risk of biochemical-relapse while metastatic-relapse-free-survival was influenced by primary component 5 of the Gleason Score (GS) , no use of LH-RH analog and time of ADT<2aa . In the no ADT group, PSA > 0.2 ng/ml, radiotherapy dose <70 Gy and R1 disease, were factors influencing the biochemical relapse, while metastatic relapse was influenced by a value of 5 in the Gleason Score.

Conclusion: The role of ADT in adjuvant setting prostate cancer is still unclear; our results suggest a benefit of ADT in metastatic-progression-free-survival, especially in case of primary component 5 in the GS , post-operative PSA >0, BAT<2 years.

EP-1376

Long term patient reported urinary function following external beam radiotherapy for prostate cancer

S. Chin¹, A. Hayden¹, V. Gebiski¹, S. Cross¹, S. Turner¹

¹Westmead Hospital, Crown Princess Mary Cancer Centre Westmead, Westmead, Australia

Purpose or Objective: This study reports long-term patient reported urinary function, toxicity and related quality of life (QoL) after external beam radiotherapy for localized prostate cancer.

Material and Methods: 574 men underwent definitive 3D conformal radiotherapy to 74Gy ± androgen deprivation therapy between 2000 and 2009 with a median follow-up of 42 months. Patients were evaluated at baseline and post treatment using the International Prostate Symptom Score (IPSS) and RTOG CTC.

Results: For patients with mild (48%), moderate (40%) and severe (12%) baseline total IPSS, median IPSS at baseline was 3,12, and 24. Median IPSS was 4, 9, and 12 at 6 months and 3, 9 and 14 at 48 months respectively. Late grade 2 genitourinary toxicity incidence was 7%, 20% and 33% and late grade 3 genitourinary toxicity was 1%, 2% and 1% respectively. At 48 months, 80%, 49% and 16% of patient with baseline mild, moderate and severe IPSS respectively demonstrated stable IPSS, 5%, 39% and 72% reported improving IPSS ≥5, and 14%, 12% and 6% had a worsening IPSS ≥5. 82% of patients with mild baseline IPSS had mild IPSS scores. 95% of patients with moderate baseline IPSS had mild or moderate IPSS scores, with 43% improving to mild IPSS scores. 75% of patients with severe baseline IPSS scores had improved to mild (28%) or moderate (47%) IPSS scores. 68% of the cohort reported good baseline urinary QoL (score 0-2), with 89% of these patients maintaining good urinary QoL at 48 months. 71% of patients with poor baseline urinary QoL (score 3-6) had improved to good urinary QoL.

Conclusion: The majority of men undergoing definitive radiotherapy for prostate cancer report stable or improving late urinary symptom burden and urinary quality of life, even with severe urinary symptoms or poor urinary quality of life at baseline.

EP-1377

Consistency of cone beam CT-derived bladder volume and inflow during localized prostate cancer IMRT

C.J. HO¹, C.K. McGarry², J.Y. Sun³, C.A. Lyons⁴, R.B. King⁴, S. Jain⁵, A.R. Hounsell⁴, J.M. O'Sullivan⁵

¹Queen's University Belfast, School of Medicine- Dentistry and Biomedical Sciences, Belfast, United Kingdom

²Belfast City Hospital, Medical Physics, Belfast, United Kingdom

³Norwich university hospital, Radiology, Norfolk, United Kingdom

⁴Centre for Cancer Research and Cell Biology, Advanced Radiotherapy, Belfast, United Kingdom

⁵The Northern Ireland Cancer Centre Belfast City Hospital, Radiotherapy, Belfast, United Kingdom

Purpose or Objective: Consistency of bladder volume (BV) during radiotherapy (RT) planning and treatment is important in maintaining the position of the prostate and the surrounding organs at risk, thus minimising RT-related tissue toxicity. This retrospective study evaluated the effectiveness of bladder-filling instructions in achieving a consistent and reproducible bladder volume at the time of planning CT and during the course of radical RT for prostate cancer. This study also assessed the rate of bladder filling (inflow) during the course of RT.

Material and Methods: 28 men with localized prostate cancer were instructed to void their bladder and then drink 500 ml of water before proceeding to RT planning scan 45 minutes later. This bladder filling process was repeated daily before each RT session. BV was assessed during planning CT and at four chronological phases of RT (fractions 1-9, 10-19, 20-29 and 30-37) via cone beam CT (CBCT). Each patient had between four to ten CBCTs taken during his RT sessions and the average BV at each phase was calculated. Inflow was assessed using delineated BV post-treatment in 20 patients. Inflow was calculated by taking the difference in BV between pre-RT CBCT and post-RT CBCT and dividing by the time between the scans. All patients were treated with 74 Gy in 37 fractions via intensity modulated radiotherapy (IMRT).

Results: The mean BV for all treatments (mean= 223.62 ml, range= 57.18- 871.85 ml, SD= 138.08 ml) was significantly lower ($p=0.007$) than the mean BV at the time of planning (mean= 318.88ml, range= 93.96 - 821.37 ml, SD= 165.10 ml). During RT, 68%, 50% and 38% of pre-treatment BV had >50ml, >100ml and >150 ml difference respectively when compared with their volume at the time of planning. When assessing the BV at different treatment time points, the mean BV for RT fractions 1-9 (239.31ml) was 25% lower than the mean planning volume ($p= 0.025$). The mean BV for RT sessions 30-37 (203.65 ml) was 36% lower than the mean planning volume ($p<0.001$).

Inflow over 128 fractions was significantly correlated ($r=0.558$, $p<0.0001$) with pre-RT BV. The mean inflow did not differ significantly over the course of RT. The mean inflow of RT sessions 1-9 (3.86 ml/min, SD= 2.50 ml/min) was not significantly higher ($p=0.24$) than that of RT sessions 30-37 (3.29 ml/min, SD=2.46 ml/min).

Figure 1: Mean bladder volume measured at planning CT and during radiotherapy fractions, with error bars indicating one standard deviation (SD).

	Planning	1 to 9	10 to 19	20 to 29	30 to 37
Mean bladder volume (ml)	318.88	239.31	222.31	203.93	203.65
SD (ml)	165.10	156.87	118.35	122.78	105.51
% volume difference to planning bladder volumes	0	-24.95	-30.28	-36.05	-36.14
Mean Inflow (ml/min)	-	3.86	4.00	4.02	3.29
SD (ml/min)	-	2.50	2.54	2.95	2.46

Table 1: Table summarizing the bladder volume (mean, SD and % volume differences to planning) and inflow (mean and SD) at planning and during radiotherapy.

Conclusion: A difference in BV was found between planning and during the course of radiotherapy. The mean BV decreased most during the first two weeks of radiotherapy. The large decrease in BV at the early phase of RT suggests a systematic difference in bladder filling at the time of planning compared with treatment. This process has been reviewed and a further analysis will be performed. Inflow from pre- and post-CBCT scans was found to be correlated with pre-RT BV. Inflow information may help to reduce bladder filling variations during treatment.

EP-1378

Should pelvic radiotherapy be tailored to early patient-reported gastrointestinal toxicity?

M. Reis Ferreira¹, S. Gulliford², K. Thomas³, L. Truelove⁴, H. McNair⁵, D.P. Dearnaley¹

⁴Institute of Cancer Research, Bob Champion Unit, London, United Kingdom

⁵Royal Marsden NHS Trust, Radiotherapy, London, United Kingdom

Purpose or Objective: Whole-pelvic radiotherapy (WPRT) is a cornerstone of the treatment of high-risk prostate cancer. However, late gastrointestinal (GI) toxicity is the major dose-limiting factor in this treatment. There are concerns that dose escalation and aggressive treatment regimens may result in increased acute toxicity, which may modulate long-term side-effects of radiotherapy, a phenomenon known as consequential late effects. The purpose of this work was to evaluate if late GI side-effects are related to acute toxicity using long-term patient-reported outcomes (PRO) of a previously unreported large, prospective phase I/II trial of IMRT for whole-pelvic treatment of prostate cancer.

Material and Methods: 496 patients were recruited between August 2001 and September 2013. Treatment consisted of

WPRT with intensity modulation techniques and long-term androgen-deprivation therapy. Strict radiotherapy dose-volume constraints were used for treatment planning to minimize the risk of serious toxicity.

PRO data (UCLA-Prostate Cancer Index scale) was available for 450 patients. Patients with less than 2 year follow-up data and any patients without acute (10 week after RT initiation) data were excluded, giving 251 patients for analysis. Median follow-up was 5 years. Only bowel habit outcomes were included for this analysis (questions 17 to 21). Data from patients with positive toxicity scores at baseline was excluded on an endpoint-by-endpoint basis.

We separated patients according to acute toxicity into two groups using question-specific toxicity grade cut-offs which differed between each PRO question. We then assessed if the group with acute toxicity had more toxicity in the late setting by calculating the odds-ratios (OR); we also computed p-values using Fisher's exact test. seline was excluded on an endpoint-by-endpoint basis.

Results: We found that patients with positive self-reported acute GI toxicity at 10 weeks have an increased risk of developing serious late GI problems, while patients without toxicity are more likely to be free of chronic toxicity (table 1). as excluded on an endpoint-by-endpoint basis.

UCLA-PCI bowel habit item Grade cut-off	OR	95% CI	p-value
Rectal urgency More than once a week or higher	2.0	1.1 - 3.6	0.0163
Loose stools Half the time or higher	4.6	2.7 - 8.1	<0.0001
Bowel distress Moderate/Severe	3.8	2.1 - 7.1	<0.0001
Crampy abdominal pain Several times a week or higher	6.9	3.5 - 14.1	<0.0001
Bowel problem Moderate/Severe	6.0	3.2 - 12.1	<0.0001

Table 1: Odds ratios for late patient-reported gastrointestinal toxicity according to early toxicity.
Equal cut-off points were used for early and late outcomes.

Conclusion: Patients with moderate to severe acute bowel toxicity are at increased risk of serious late GI problems which impact quality of life, potentially reflecting a consequential late effect. Tailoring treatment with the modification of treatment planning according to early clinical outcomes may prove to be necessary to tackle this problem.

EP-1379

SBRT in the treatment of bone metastases in hormone refractory prostate cancer

S. Grespi¹, C. Menichelli¹, A. Fanelli¹, P. Ferrazza¹, G. Pastore¹, F. Casamassima¹

¹Ecomedica, Radiotherapy, Firenze, Italy

Purpose or Objective: Evaluate the utility of SBRT in terms of local control (LC), global survival (OS), compliance to the treatment and toxicity in patient with oligometastatic and hormone refractory prostate cancer, limited to the skeletal structures.

Material and Methods: 46 patients with bone metastases from prostate cancer, were treated with SBRT between January 2009 and August 2015. At diagnosis 15/46 patients presented bone metastases. Bone lesions irradiate were 131 (range 1-4). Median age was 68 years (range 54-85). Median PSA pre-treatment was 168,1 ng/ml (range 0,23 -1.470). Patients received a median dose of 30 Gy (range 8-40 Gy) in 3 fractions (range 1 -5). The treatment was delivery by LINAC 6 MeV (Elekta Synergy-S) using technical IGRT-VMAT. All patients received some form of androgen-deprivation therapy (ADT) after completing SBRT. 18/46 patients was submitted systemic chemotherapy treatment.

Results: Median follow-up was 22 months (range 1-78). LC was 100% and OS 50,2% at 5 years. 22/46 patients were died for progression disease, 24/46 patient were still alive, of these 14 were disease free and 10 were in progression disease. The first post-SBRT PSA was lower than pre-treatment levels in 30 patients (65,2%) and continued to decline or remain undetectable in 23 patients (50%) at follow-up of 6 months. Median PSA post-treatment was 32,4

(range 0,29-196). No severe acute or late toxicity of grade >2 was observed.

Conclusion: SBRT is a safe and effective treatment for prostate cancer metastases, presenting excellent LC and an acceptable toxicity profile in selected patient with hormone refractory disease. More importantly, half the patient achieving reductions in serum PSA values.

EP-1380

Primary focal prostate radiotherapy: do all patients really need whole-prostate irradiation?

B.A. Jereczek-Fossa^{1,2}, D. Ciardo¹, G. Petralia³, M. Bellomi^{2,3}, O. De Cobelli^{2,4}, R. Orecchia^{1,2}

¹European Institute of Oncology, Department of Radiation Oncology, Milan, Italy

²University of Milan, Department of Oncology and Hematology, Milan, Italy

³European Institute of Oncology, Department of Radiology, Milan, Italy

⁴European Institute of Oncology, Department of Urology, Milan, Italy

Purpose or Objective: Primary focal therapy has been explored for 20 years now, and more than 2000 patients have been treated so far with several techniques but only limited data have been published on the primary focal radiotherapy (FRT). From the technical point of view, primary FRT can be performed through either focal brachytherapy or external beam radiotherapy. The majority of series include both low-dose-rate (LDR) and high-dose-rate (HDR) brachytherapy, and only recently the feasibility of primary FRT by external beam irradiation has been reported. The current review aims to assess the available evidence for primary FRT performed either by the means of brachytherapy or external beam radiotherapy.

Material and Methods: Inclusion criteria were: Medline search for full paper in English language on primary FRT for early prostate cancer including review articles, planning studies or patient series (clinical outcome available) published before May 31, 2015.

Results: Twenty-two papers have been found: 11 review articles, 4 planning studies and 7 patient series. Eleven review articles were dedicated to all types of focal therapy including FRT and 2 to FRT only. All planning studies were performed on cohort of 5-10 patients and included brachytherapy both HDR (24 patients overall), and LDR (9 patients). All studies underline the significant organs-at-risk dose reduction as well as the higher sensitivity to systematic set-up error as target volume decreases from whole-gland to hemi-gland and to ultra-focal target. Patient series included together 715 patients (range 8-318, 99% treated with brachytherapy). Median follow-up period was 33.6 months (range 2-61 months). Promising tumour control was highlighted in low-risk cancer. In intermediate-risk tumours, FRT might be suboptimal (see Table 1). Moreover, some reports on consensus criteria are already available in literature.

First author, Journal (year)	Population (risk factor)	Technique	N. Pts	Dose prescription	Median follow-up	Toxicity & Outcome
D'Amico, LINCOP (1998)	- T1cN0M0; - PSA < 10 ng/ml; - Biopsy Gleason score ≤ 3+4; - MRI stage T2 disease	MR-guided ¹²⁵ I implant	9	Min. dose to peripheral zone = 160 Gy.	2 months	Minimal acute morbidity.
Albert, Cancer (2003)	MRI-guided BRT: - T1c; - PSA < 10 ng/ml; - Biopsy Gleason score ≤ 3+4; - MRI T2 disease; MRI-guided BRT + EBRT: either PSA > 10-13 or ≥ 50% positive biopsies or MRI evidence of extracapsularity.	MRi-guided BRT or MRi-guided BRT + EBRT	201	MRI-guided BRT: min. dose to peripheral zone = 160 Gy. MRI-guided BRT + EBRT: min. dose to peripheral zone = 77 Gy; 45 Gy with 3D-CRT	2.8 years	Monotherapy vs. combined modality therapy: Rectal bleeding: G1 80% vs. 85% (Pvalue ns), G2 18% vs. 22% (Pvalue ns), G3 8% vs. 30% (Pvalue = 0.0001). Erectile dysfunction: 32-93%. Bladder/urethral dysfunction: no late events after 6 months. Cystitis in 2 patients after combined-modality therapy.
D'Amico, Urology (2003)	- T1c; - PSA < 10 ng/ml; - Biopsy Gleason score ≤ 3+4; - No perineural invasion on biopsy.	Prostatectomy vs. MR-guided BRT	322 vs. 196	< 100% of the PD to anterior base and zone anterior to urethra; > 100% of the PD to peripheral zone	4.2 years vs. 3.95 years	5-year estimate of PSA control: 93% vs. 95% (ns) after RP or brachytherapy, respectively.
Vainshtein, Radiation Oncology (2012)	- Gleason score ≤ 6; - PSA ≤ 10; - T1c-T2a; - Excluded if on androgen deprivation therapy	Standard EBRT (5-IMRT) vs. urethral sparing IMRT (US-IMRT)	16	75.85 Gy in 41 fractions	56 months	No differences in EPIC urinary domain HRQOL summary or subset scores. No differences in the bowel, sexual, hormonal, or satisfaction domain scores. Mean PSA nadir 1.5 vs. 0.78 ng/ml (p=0.05) in US-IMRT vs. 5-IMRT. 2-year PSA failure rate: 25% in US-IMRT, 0% in 5-IMRT.
Barret, European Urology (2012)	- T2a or less - PSA < 10 ng/ml; - Gleason sum ≤ 6; - Unilateral disease; - Fewer than 3 positive biopsies.	¹²⁵ I-BRT (12 pts), HIFU (21 pts), VTP (23 pts), cryotherapy (50 pts)	106	145 Gy	9 months	13% treatment-related complications: 2 G3b. Median IIEF-5 = 14, median IPSS = 6.
Cosset, Brachytherapy (2015)	- life expectancy superior to 10 years - T1c or T2a - PSA < 10 ng/ml - Gleason score ≤ 7 (3+4) - Unilateral disease - No individual biopsy core with more than 50% involvement Total of prostate volume < 60 cc - IPSS ≤ 15	¹²⁵ I-BRT	21	145 Gy	28 months	Mean IPSS: 5.4, 11.8, 6.6, 6.1 @ baseline, 2-6-12 mo. No rectal toxicity at 6 and 12 mo. Mean IIEF: 20.1, 18.6, 19.1, 19.8 @ baseline, 2-6-12 mo. Mean PSA: 6.9, 5.3, 3.2, 2.6 ng/ml @ baseline, 2-6-12 mo. Negative biopsies in 5 pts, a Gleason 6 (3+3) lesion <1mm in one patient contralaterally.
Nguyen, The Journal of Urology (2013)	- T1c - PSA < 15 ng/ml - Biopsy Gleason score ≤ 3 + 4	Monotherapy with MRI-guided ¹²⁵ I, BRT or MRI-guided ¹²⁵ I-BRT + EBRT (61 pts)	318	Monotherapy: prescribed dose = 127 Gy. MRI-guided ¹²⁵ I, BRT + EBRT: 45 Gy in 1.8 Gy/fr to prostate and seminal vesicles, followed by a BRT boost to 90 Gy.	61 months	Using nadir +2 with PSA >0.75ng/ml per year, PSA failure-free survival 91.0% at 5 years and 66.2% at 8 years. For intermediate risk cases: failure-free survival 73.0% at 5 years and 66.4% at 8 years. Distant metastases developed in 1 patient.

Conclusion: Despite the numerous publications on focal therapy in prostate cancer, primary FRT is largely unexplored. Radiotherapy appears to be particularly suitable as a focal approach, since it has an established biological basis, known tumoricidal activity, possibility of dose differentiation, large availability of high-precision dose delivery techniques, limited or no invasiveness and familiarity to radiation oncologists and urologists. However, when applied as primary FRT, its use remains investigational since numerous questions remain unmet: consensus on the initial diagnostic tools, the optimization of technical parameters for therapy delivery, follow-up exams and scheduling, tumour control and toxicity profile, response evaluation and failure definition, salvage therapy and cost-benefit.

EP-1381

ADC of prostate tumour and normal tissue during radiotherapy after neoadjuvant hormone therapy

L. Kershaw¹, A. McPartlin², A. Choudhury², M. Van Herk³

¹The Christie NHS Foundation Trust, CMPE, Manchester, United Kingdom

²The Christie NHS Foundation Trust, Oncology, Manchester, United Kingdom

³University of Manchester, Institute of Cancer Sciences, Manchester, United Kingdom

Purpose or Objective: Changes in prostate and tumour ADC values during radiotherapy (RT) may aid prediction of response to treatment. Intermediate and high risk patients are likely to receive neoadjuvant hormone therapy (NA-HT) prior to RT, causing reduction in prostate and tumour volume and changes in ADC values. It is unclear how this affects further ADC changes during subsequent treatment. We assessed ADC values in prostate tumour and normal tissue during RT after NA-HT.

Material and Methods: Fifteen patients with \geq T2b disease who were due to receive RT (60 Gy in 20 fractions) were recruited after 3 months of NA-HT. Patients underwent three 1.5 T MRI examinations: post NA-HT (one week prior to RT), at the end of the third week of treatment, and eight weeks after RT completion. The imaging protocol included T2 weighted and diffusion weighted imaging, acquired using the cardiac coil (EPI with TR/TE 8000/70 ms, b = 100, 400, 800

s/mm²). ADC maps were processed offline (ADCmap for Osirix). Normal central gland (CG), peripheral zone (PZ) and tumour were outlined on T2w images by a radiologist expert in prostate MRI, with pre-NA-HT imaging (T2w and DWI) available in 12 patients to aid identification. If disease was not clearly visible, clinical findings and biopsy results were used to aid delineation. CG, PZ and tumour regions were transferred to the ADC maps and median values extracted along with interquartile ranges. A Mann-Whitney U test was used to analyse differences between tumour and normal tissue regions at the three time points.

Results: 13 patients completed all scans, 2 patients missed 1 and 2 scans respectively. After NA-HT, there was a significant difference between median tumour and PZ (p=0.009) and tumour and CG (p=0.002) (median values plotted in figure 1). At the other time points, there was no difference between tumour and normal tissue ADCs.

Conclusion: The ADC values display a similar pattern to that seen in previous studies for patients receiving RT alone. The difference between tumour and normal tissue was smaller at baseline than has been seen in other work without NA-HT. This may be due to a reduction in normal tissue ADC during induction therapy, whilst tumour ADC values could have increased due to tumour shrinkage. Variation in imaging protocol for ADC measurement compared to previous studies may also play a role. The reduced magnitude of changes in tumour ADC seen during RT after NA-HT may make its use as a predictive tool for treatment response more challenging in this group of patients.

EP-1382

PET/CT and MRI guided salvage radiotherapy after prostatectomy for prostate cancer

S. Kirste¹, J. Bons¹, N. Volegova-Neher¹, C. Zamboglou¹, K. Henne¹, W. Schultze-Seemann², H.C. Rischke³, A.L. Grosu¹

¹Universitätsklinik Freiburg, Radiooncology, Freiburg, Germany

²Universitätsklinik Freiburg, Urology, Freiburg, Germany

³Universitätsklinik Freiburg, Nuclear Medicine, Freiburg, Germany

Purpose or Objective: At the time of a biochemical recurrence after prostatectomy it is important to distinguish patients who have a local recurrence from patients with distant metastasis. PET/CT and MRI are important imaging modalities that can be used in this scenario. The purpose of this study was to investigate the outcomes and toxicities of patients in a large single-institution cohort treated with salvage radiotherapy (sRT) and dose escalation up to 72 Gy. Boost planning was based on MRI or PET/CT.

Material and Methods: From 2008 to 2012 290 patients who received sRT were included into the analysis. Patients with a PSA > 1 ng/ml or a PSA doubling time > 3 months received a Choline PET/CT before the start of radiotherapy. Additionally, in most patients MRI of the pelvis was conducted. If there was a macroscopic tumor recurrence, defined as local recurrence in the prostate bed in MRI or PET tracer uptake, radiation therapy to the prostatic bed was

complemented by a boost to local recurrence to a total dose of 72 Gy. In case of no macroscopic tumor recurrence the total dose was 66.6 Gy.

Results: MRI was performed in 233 patients and PET/CT was performed in 169 patients. A local recurrence in the prostate bed could be detected in 123 patients with a median volume of 0.5 ml (range, 0.03 - 125.00 ml). The median follow-up time after RT was 49.4 months (range, 7.3 - 86.1 months). A total of 85 patients experienced a biochemical failure with a median time of 19.8 months (range, 1.9 - 76.1 months) after sRT. Median PSA level at the time of recurrence was 0.91 ng/ml (range, 0.01 - 2224.00 ng/ml). The median BRFS after radiation therapy was 73 months. The estimated 3- and 5-year bRFS was 72% and 55%, respectively. On multivariate analysis, Gleason Score (hazard ratio, 6.946; $p = 0.006$) and pre-RT PSA level (hazard ratio, 2.265; $p = 0.022$) were statistically significant predictors for bRFS. bRFS was similar in patients with a macroscopic recurrence in either MRI or PET/CT compared to patients without a macroscopic recurrence. 5-year overall survival was 91% and 5-year cancer-specific survival was 96%. Grade 3 gastrointestinal toxicity was observed in 4 patients and 3 patients showed grade 3 genitourinary toxicities. No grade 4 gastrointestinal or genitourinary side effects were reported.

Conclusion: Gleason score and pre-RT PSA were important predictors for bRFS. The dose in salvage radiotherapy should be increased to 72 Gy to prevent an early recurrence after sRT in patients with a macroscopic recurrence. A higher total dose of up to 72 Gy was well tolerated in this cohort of patients.

EP-1383

PSA kinetics in prostate cancer patients after SBRT radiotherapy using CyberKnife.

M. Konkol¹, A. Galuba¹, P. Milecki¹, A. Skrobal², A. Jodda², M. Adamczyk², J. Litoborska²

¹Greater Poland Cancer Centre, Oddział Radioterapii I i Radiotherapy Dept., Poznan, Poland

²Greater Poland Cancer Centre, Department of Medical Physics, Poznan, Poland

Purpose or Objective: The aim of the study was to assess the kinetics of the Prostate-Specific Antigen (PSA) in prostate cancer patients after stereotactic body radiotherapy using CyberKnife System.

Material and Methods: 44 localized prostate adenocarcinoma patients (33 low and 11 intermediate risk) without hormonal therapy, were irradiated using the CyberKnife Radiosurgical System. The prescription dose was 36,25 Gy in five fractions. During the 1-year follow-up all the patients had at least six PSA measurements - before the treatment (1-2 months before RT), during RT (after the 4th fraction) and 1, 3, 6, 12 months after RT.

Results: The mean initial PSA value among the patients was 6,25 ng/ml (range from 3,02 to 17,46 ng/ml). During the treatment we observe the PSA increase - the mean value was 11,89 ng/ml (4,13-30,68ng/ml, 155% of the initial PSA in average). In every case we noticed the PSA nadir 12 months after the treatment with a mean value of 1,50 ng/ml (0,10-4,56 ng/ml). The mean slope of the PSA was 0,56 ng/ml/month (median 0,46 ng/ml/month). No biochemical failure was observed.

Conclusion: The PSA kinetics after treatment can reflect the biological effect of radiation on prostate cancer and potentially correlate with a clinical outcome. Especially the lower value of PSA nadir (<0,5 ng/ml) is considered to associate with an increased freedom from biochemical failure. The interpretation of PSA slope is more controversial however some studies indicates a correlation with clinical outcome. Our results are similar to other SBRT studies and significantly better than in conventionally-fractionated technics. The rapid decline in PSA is particularly worth to be

underlined. The further follow-up will probably confirm the expected good clinical outcome.

EP-1384

Acute toxicity hypofractionated-IMRT vs standard radiotherapy in prostate cancer: comparative study

J. Valero Albarran¹, R. Guimaraes Domingos da Silva², S. Payano¹, A. Montero¹, E. Sánchez¹, X. Chen¹, O. Hernando¹, M. García Aranda¹, R. Ciervide¹, M. Lopez¹, M. Rubio¹

¹Hospital University HM Sanchinarro, Radiation Oncology, Madrid, Spain

²Institute National of Cancer, Oncology Radiation, Rio of Janeiro, Brazil

Purpose or Objective: To describe and compare acute toxicity rate in three different radiotherapy (RT) protocols for prostate cancer (PC): hypofractionated radiotherapy intensity modulated and image-guided radiation therapy (Hypo-IMRT-IGRT) group A: 21 fractions/3Gy and group B: 28 fractions/2.5Gy) and three-dimensional conformal radiotherapy standard fractionation (3DCRT) group C: 39 fractions/2Gy.

Material and Methods: Patients with the diagnosis of PC treated with RT between January 1st 2011 to June 30th 2015 were included. Hypo-IMRT-IGRT were performed using internal marker and ExacTrac-X-Ray-system. In 3DCRT group not employed internal marker. Acute genitourinary (AGUT) and acute gastrointestinal toxicity (AGIT) were assessed according to RTOG-EORTC criteria. A p value<0.05 was considered significant. Results were expressed as median (IQR). Categorical and continuous variables were compared with X2 and kruskal-Wallis ran sum test respectively. All statistical analysis was performed using R package. The institutional review board approved this study.

Results: 242 consecutive patients were retrospectively analyzed (group A: 39, group B: 128 and group C: 74). No baseline characteristic differences were found (age, PSA, TNM, PTV total, bladder and rectal volume). Maximal bladder doses and V60 rectal were different within the three groups ($p < 0.01$). AGUT (n): in group A was grade 0: 18; grade 1: 9, grade 2: 12; group B grade 0: 35; grade 1: 86; grade 2: 7; and group C grade 0: 23; grade 1: 38; grade 2: 13 ($p < 0.01$). AGIT was in group A grade 0: 38; grade 1: 1; grade 2: 0; group B grade 0: 121; grade 1: 7; grade 2: 0; and group C grade 0: 65; grade 1: 6; grade 2: 3 ($p = 0.07$) Table 1. Comparative AGUT between A+B vs. C did not differ. AGIT in A+B group was less frequent than C group ($p = 0.017$). AGUT from group A was different from group B ($p < 0.01$). AGIT from A group was not different from B group ($p = 0.75$). There were no events > grade 3 reported in any group.

GRADE n (%)	0	1	2	p
AGUT				<0.01
Group A	18(46)	9(23)	12(31)	
Group B	35(27)	86(67)	7(5)	
Group C	23(31)	38(51)	38(51)	
AGIT				0.07
Group A	38(97)	1(3)	0(0)	
Group B	121(95)	7(5)	0(0)	
Group C	65(88)	6(8)	3(4)	

Conclusion: Hypo-IMRT-IGRT was associated to lower AGIT rate than 3DCRT. Hypo-IMRT-IGRT 21 fractions/3Gy was inferior to Hypo-IMRT-IGRT 28 fractions in terms of AGUT.

EP-1385

A comparative study between radical RT and radical prostatectomy in locally advanced prostate cancer

P. Gupta¹, N. Rastogi¹, K. Sharmad², K. Das¹, R. Kapoor², A. Mandhani², S. Kumar¹

¹Sanjay Gandhi Postgraduate Institute of Medical Sciences, Department of Radiation Oncology, Lucknow UP, India

²Sanjay Gandhi Postgraduate Institute of Medical Sciences, Department of Urology, Lucknow UP, India

Purpose or Objective: For the locally advanced prostate cancers (LAPC) dose escalated external beam Radiotherapy (dEBRT) with androgen deprivation therapy (ADT) for 2-3 years is the current standard of care. The role of radical prostatectomy (RP) for high-risk prostate cancer is still debated. Better outcomes with RP as compared to dEBRT especially <69 years of age has been reported. However there is no data available from India to compare dEBRT and RP. We did a retrospective study to compare dEBRT or RP in patients with LAPC.

Material and Methods: Medical records of 77 high risk LAPC treated between 2008-2013 were analysed. All biopsy proven adenocarcinoma of prostate with high risk category (PSA>20ng/ml or Gleason score (GS) >7 or T2c-T4) were included. Patients either underwent dEBRT with image guided RT (IGRT) (group 1) or RP (group 2) along with ADT for 2-3 years. Group 1 and 2 had 37 and 40 patients respectively. The primary end points of the study were biochemical relapse free survival (bRFS), bladder and rectal toxicity, urinary incontinence (UI) and secondary end point was cancer specific survival (CSS).

Results: Median age and median pre-treatment PSA in 2 groups were comparable (66 and 65years) and (22 and 23 ng/ml) respectively. Radiologically T3/T4 lesions were present in 65% and 68% and nodal metastasis was seen in 22% and 30% respectively. Median GS was 8 and 7. Positive surgical margins was seen in 70% in group 2. dEBRT dose was 76Gy with conventional fractionation using IGRT using fiducial marker matching. With a median follow up of 3 years, 5-year bRFS was 78% and 72%. (p=0.12). Median bRFS was not reached in group 1 and in group 2, it was 79 months. Post treatment UI was seen in 0 and 6(15%)(p=0.03). Radiation Therapy Oncology Group (RTOG) grade III-IV bladder toxicity (hematuria and bladder neck contracture requiring incision) was seen in 2(6%) and 7(18%) respectively and rectal toxicity in 2(6%) and peroperative rectal injury occurred in 2(5%) in group 2. Five year CSS was 65% and 87% respectively (p=0.086). Median CSS was not reached in any group. Six (16%) and 7(18%) patients were lost to follow up. Distant metastasis was seen in 8(22%) and 1(3%) (p=0.14).

Conclusion: UI is the complication associated with RP. Dose escalated IGRT for LAPC is no different from RP in terms of bRFS however there was a trend towards better CSS and distant DFS. Further long term follow up is needed to assess the effect on distant disease free survival and CSS.

Electronic Poster: Clinical track: Urology-non-prostate

Adjuvant pelvic radiotherapy for pathological high-risk muscle-invasive bladder cancer

P. Sargos¹, I. Latorzeff², A. Fléchon³, G. Roubaud⁴, V. Brouste⁵, R. Gaston⁶, T. Piéchaud⁶, M. Orré¹

¹Institut Bergonié, Radiotherapy, Bordeaux, France

²Clinique Pasteur, Radiotherapy, Toulouse, France

³Centre Léon Bérard, Radiotherapy, Lyon, France

⁴Institut Bergonié, Medical Oncology, Bordeaux, France

⁵Institut Bergonié, Epidemiology and Clinical Research Unit, Bordeaux, France

⁶Clinique Saint Augustin, Surgery, Bordeaux, France

Purpose or Objective: Radical cystectomy (RC) and pelvic lymph-node dissection (PLND) are standard procedures in the management of non-metastatic muscle invasive bladder cancer (MIBC). Loco-regional recurrence (LRR) is a common early event associated with a poor prognosis. The aim of this study is to evaluate adjuvant radiotherapy (RT) for pathological high-risk MIBC.

Material and Methods: We retrospectively reviewed data from patients treated by RC from 3 institutions. Inclusion

criteria were MIBC, histologically proven urothelial carcinoma treated by RC and adjuvant RT. Patients with conservative surgery were excluded. LRR free-survival, overall survival (OS) and metastasis-free survival (MFS) were evaluated. Acute toxicities were recorded according to CTCAE V4.0 scale.

Results: Between January 2000 and December 2013, 57 patients with a median age of 66 years (45-84) were included. Post-operative pathological staging was pT2, pT3 and pT4 in 16%, 44%, and 39%, respectively. PLND revealed 28% of pN0, 26% of pN1 and 42% of pN2. For 2 patients, no PLND was performed. Median number of lymph-nodes retrieved was 10 (2-33). Forty-eight patients (84%) received platin-based chemotherapy, 7 in neo-adjuvant and 41 in adjuvant setting. For RT, clinical target volume 1 (CTV 1) encompasses pelvic lymph nodes for all patients. CTV 1 also included cystectomy bed for 37 patients (65%). Median dose for CTV 1 was 45 Gy (4-50). Dose complement of 16 Gy (5-22) corresponding to CTV 2 was achieved in 53 of cases, depending on pathological features. Intensity Modulated RT was performed in one third of patients. With a median follow-up of 40.4 months, LRR occurred in 8 patients (14%) that appeared concomitantly with metastasis in two-third of cases. Three-year loco-regional free survival, MFS and OS were 45% (IC 95% 0.30-0.60), 39% (IC 95%, 0.25-0.52) and 49% (IC 95%, 0.33-0.63), respectively. Acute grade≥3 toxicities were observed in 5 patients (9%). One patient died with intestinal fistula in septic context. No survival or toxicity predictive factor was identified.

Conclusion: Adjuvant radiotherapy for pathological high-risk MIBC is safe and may have oncological benefits. Thus, new prospective trials evaluating this approach with modern RT techniques should be undertaken.

EP-1387

Outcomes after recurrent bladder cancer and (chemo)radiotherapy post TUR-B vs cystectomy

S. Knippen¹, C. Kelling¹, M. Henke¹, A. Grosu¹, T. Brunner¹

¹Universitätsklinik Freiburg, Department of Radiation Oncology, Freiburg, Germany

Purpose or Objective: To analyze patients treated for recurrent urothelial cancer with radiation therapy with or without concomitant chemotherapy after surgical intervention that was treated from 2000 to 2012 at our centre.

Material and Methods: Our inclusion strategy was to first identify patients treated for the relevant ICD-10 codes. A number of 270 patients matched the ICD-10 criteria (see CONSORT diagram). In a second step, patients that were treated at other sites than the pelvis, treated for distant metastasis, patients suffering from renal cell cancer and cancer of the renal pelvis were excluded. In a third step patients treated with radiation doses that are typical for palliation (<45Gy) were excluded from the analysis. After this, a number of 57 patients remained at the database for further analyses. All patients were treated for recurrent urothelial cancer of the bladder, of the ureter or of the urethra. All patients were treated using 3D conformal radiation therapy. Mean prescribed dose was 54.22Gy (range 45-72Gy). Mean time from first diagnosis to radio(chemo)therapy was 22.9 months (range one week to 276 months). In 24 cases (42.1 %) a concomitant chemoradiotherapy was applied.

Results: Mean survival from the beginning of radiation treatment was 39.2 months (CI 95 % 24.7 - 53.69 months; median survival 14 months CI 95% 6.8 -21.1). Tumor stage at the time of surgical intervention did not show an impact on overall survival (p=0.96). Patients were divided into three subgroups, depending on the surgical intervention prior to radiation therapy: most patients were treated by TUR(n=38) before the indication to radiation therapy was made, 13 patients had a TUR followed by cystectomy in their further history and in 6 patients early cystectomy was the first type

of treatment. Patients treated with TUR-B followed by radiotherapy were significantly older compared to patients with cystectomy before radiotherapy and were less likely to receive chemotherapy. There was no significant difference for the length of the interval between first treatment and radiotherapy for the three groups. Despite of this, type of surgical procedure before radiotherapy did not show an impact on overall survival ($p = 0.86$).

Conclusion: In our study we found equal survival of patients treated with (chemo)radiotherapy after TUR-B only compared to patients with cystectomy prior to radiotherapy. Younger age and more concomitant chemotherapy of the latter group was not able to prolong survival.

EP-1388

Primary penile cancer: role of adjuvant RT for extracapsular extension in lymph nodes

P. Johnstone¹, G. Diorio², R. Djajadiningrat³, M. Catanzaro⁴, D. Ye⁵, Y. Zhu⁵, N. Nicola⁴, S. Horenblas³, P. Spiess²

¹Moffitt Cancer Center, Radiation Oncology, Tampa, USA

²Moffitt Cancer Center, Urology, Tampa, USA

³Netherlands Cancer Institute-Antoni van Leeuwenhoek Hospital, Urology, Amsterdam, The Netherlands

⁴Fondazione IRCCS Istituto Nazionale Tumori, Urology, Milano, Italy

⁵Fudan University Shanghai Cancer Center, Urology, Shanghai, China

Purpose or Objective: In cancers of the head and neck (HNCa), lymph node (LN) status is a critical prognostic factor. Further, the presence of extracapsular extension (ECE) has been shown prospectively to be a criterion for the addition of chemotherapy to postoperative radiation therapy. Limited data exist regarding ECE in inguinal or pelvic LNs from primary penile cancer (PeCa).

Material and Methods: We retrospectively analyzed outcomes of patients with PeCa and pathologically confirmed LN across four international tertiary referral centers. Clinical and demographic characteristics were compared of outcomes (local control and overall survival) by ECE status and between those who had received adjuvant RT or not.

Results: Records of 93 patients were available. Median age at time of LND was 65.3 years (range 35.9-90.2 years). Median follow up was 9.4 months (IQR: 5.3-19.4). The median number of involved ILNs was 4 (range 1-12), and median PLNs positive was 2 (range 1-21). 72% of patients had ECE in the

inguinal area and 49% had ECE in the pelvis. Infield failure occurred in 26/87 sites with ECE and 8/64 sites without ECE ($p = 0.015$). In the presence of ECE, patients receiving RT experienced infield failure in 17/50 cases and in 10/38 patients not receiving RT ($P=NS$). Absent ECE, patients failed infield in 5/40 cases after RT and 3/24 cases without RT ($p=NS$). RT was not associated with improved OS ($p=0.073$) or recurrence ($p=0.492$) on multivariate analysis. Chemotherapy was significant on multivariate analysis for recurrence ($p = 0.009$) but not survival ($p=0.334$).

Conclusion: ECE is associated with increased likelihood of local recurrence in PeCa patients. Contrary to the experience in HNCa, adjuvant RT has no impact on local control. Prospective studies are needed to validate this unusual finding and further develop the timing and roles of RT and chemotherapy for PeCa patients with advanced disease.

EP-1389

Stereotactic radiotherapy for oligometastatic patients with renal cell carcinoma

A. Ceconi^{1,2}, G. Piperno³, A. Ferrari³, E. Rondi⁴, S. Vigorito⁴, D. Zerini³, F. Cattani⁴, F. Nolè⁵, O. De Cobelli^{2,6}, B.A. Jerezek-Fossa^{2,3}, R. Orecchia^{1,2}

¹European Institute of Oncology, Scientific Direction, Milan, Italy

²University of Milan, University of Milan, Milan, Italy

³European Institute of Oncology, Radiotherapy, Milan, Italy

⁴European Institute of Oncology, Medical Physics, Milan, Italy

⁵European Institute of Oncology, Division of urogenital tumours medical treatment, Milan, Italy

⁶European Institute of Oncology, Division of urologic surgery, Milan, Italy

Purpose or Objective: the aim of this study was the evaluation of local control (LC) and toxicity in oligometastatic patients with renal cell carcinoma (RCC) who had undergone stereotactic radiotherapy (SRT) with CyberKnife (Accuray, Sunnyvale, CA) or Vero™ (BrainLab) for cranial and extracranial metastases.

Material and Methods: between January 2012 and September 2015, 23 patients (30 lesions) with metastases of RCC were treated with SRT alone to the new site of disease (if limited disease) or to residual disease during the maximal response in systemic therapy. Disease control was evaluated with serial imaging. Toxicity was recorder according to the Common Toxicity Criteria version 4.0.

Results: after a median follow-up of 10 months (range 0 - 36 months) 20 patients were alive. Ten patients received SRT alone and 13 patients received that during the maximal response of systemic therapy. The median equivalent of the dose (EQD2) was 50.6 Gy delivered with a median of 2.7 fractions (range 1-5) and the median biological equivalent dose (BED) was 51 Gy assuming $\alpha/\beta = 10$ for tumour. Six patients are lost in follow-up. Clinical and radiological response was thus evaluated in 17 patients and the their LC was 100% (57.1% of patients received SRT alone and the others patients are still undergoing systemic treatment. 27.7% of patients had more than 12 months follow-up and the LC was again 100%). Progression of disease in the other sites was observed in all cases. No toxicity was observed.

Conclusion: SRT is a feasible approach that offer an excellent LC with low toxicity profile in the treatment management of oligometastatic patients with RCC with or without the association of systemic therapy. Further investigation is warranted to identify the patients who would probably benefit from this approach.

EP-1390

Cystoman in the prevention of acute radio-induced urinary toxicity in irradiated pelvic region

E. D'ippolito¹, A. Rese¹, F. Piccolo¹, A. Romano¹, L. Faraci¹, P. Romanelli¹, F. Pastore¹, E. Toska¹, V. De Chiara¹, L. Ghidelli¹, R. Telesco¹, R. Solla^{1,2}, A. Farella¹, M. Conson^{1,2}, R. Liuzzi^{1,2}, R. Pacelli^{1,2}

¹University of Naples "Federico II", Department of Biomedical Sciences Advanced, Naples, Italy

²C.N.R., Institute of Biostructures and Bioimaging, Naples, Italy

Purpose or Objective: Acute urinary unwished effects of pelvic irradiation may impact on quality of life of patients undergoing radiation therapy on the pelvis. Neoplasms such endometrial, cervical, rectal, and anal cancer requires irradiation of relevant pelvic volumes. In this study we tested Cystoman, a dietary integrator of D-mannosium, cranberry and vitamin C, as prophylactic therapy for the development of acute urinary side effects.

Material and Methods: Fifty five patients undergoing pelvic irradiation were randomly assigned to take 2 tablets/day of Cystomann or not from the beginning of radiation therapy. Radiation therapy consisted of 45 - 50.4 Gy on the pelvis given by 1.8 Gy daily fractions with 3D conformal radiation therapy. The patients were weekly checked for urinary symptoms. Urine culture was performed before and after the treatment.

Results: Between November 2014 and September 2015, 55 consecutive patients were enrolled in the study. Median age was 65 year, 11 were affected by cervical cancer, 9 endometrial, 31 rectal, and 4 anal cancer. Twenty two patients were treated preoperatively and 33 postoperatively. Urinary toxicity appeared at the second week in 3/28 patients in Cystoman group and 11/27 in the control group (p=0,02). However by the end of the treatment 8/28 and 13/27 patients had urinary toxicity in the Cystoman and control group, respectively (p=0.1).

Conclusion: Our study suggests that Cystomann delays the radio-induced acute urinary toxicity presentation and could ameliorate the toxicity profile of the pelvic irradiation.

EP-1391

Total skin irradiation using helical tomotherapy: a novel experience and report of three cases

K. Okuma¹, A. Haga¹, T. Imae¹, R. Takenaka¹, M. Sugaya², K. Nakagawa¹

¹University of Tokyo Hospital, Radiology, Tokyo, Japan

²University of Tokyo Hospital, Dermatology, Tokyo, Japan

Purpose or Objective: Description of three cases of total skin irradiation for cutaneous T-cell lymphoma using helical TomoTherapy (Accuray, Sunnyvale, CA).

Material and Methods: In 2015, three patients with refractory T-cell lymphoma underwent total skin irradiation using invers-planned helical tomotherapy. The first case was a 25-year-old man diagnosed as mycosis fungoides with multiple tumors occurring on the extremities, face, and trunk. The second case was a 73-year-old woman diagnosed as primary cutaneous gamma delta T-cell lymphoma. She had received 24 Gy of irradiation in 12 fractions with total skin electron beam irradiation technique 10 years ago, and some parts of her skin were irradiated with 24 Gy in 12 fractions with local electron beam irradiation within 3 years. The third case was a 52-year-old man diagnosed as mycosis fungoides. No bolus was added around the body. Because of the long length of treatment of the body in TomoTherapy, treatments were delivered to three parts of the body (trunk, head and neck, and legs). Irradiation was not performed in two or three parts on the same day. Each plan was generated with a prescription dose of 10 Gy in 10 fractions. The planning target volume (PTV) was the body surface with 5mm margins of internal and external lesions of the skin. The third patient had several swelling lymph nodes, so the PTV was the body surface and swelled lymph nodes with their margins.

Results: TomoTherapy technique was created that enabled delivery of the prescription dose to PTV with a relatively sharp drop-off of dose at depth. The calculated mean doses for the organs at risk were 1.96, 2.08, 2.12, 2.19, and 2.27 Gy for the lung, heart, liver, kidneys, and bones, respectively. Using the couch-indexed Vac-Lok cushion and head mask, inter- and intra-fractional patients motions were minimized. All three patients experienced edemas of fingers and toes, and lost much of their hair. Myelosuppression occurred in two of the three patients. Because of grade 4 myelosuppression, the second patient who was treated total skin electron beam irradiation 10 years ago, was treated with blood transfusion during the treatment. All tumors were reduced during and after the treatment.

Conclusion: Using the TomoTherapy technique in total skin irradiation, we were able to achieve good coverage of the PTV and good sparing of organs at risk, including the bones. This treatment method, including the prescription dose and treatment duration, will be needed further research.

EP-1392

The abscopal effect: efficacy of radiotherapy in patients on progression after ipilimumab 3 mg/kg

A.M. Grimaldi¹, P.A. Ascierto¹, E. Simeone¹, D. Giannarelli², S. Falivene³, V. Borzillo³, F. Giugliano³, F. Sandomenico⁴, A. Petrillo⁴, M. Curvietto¹, A. Esposito¹, M. Paone¹, M. Palla¹, G. Palmieri⁵, C. Caraco¹, G. Ciliberto⁶, N. Mozzillo¹, P. Muto³

¹Istituto Nazionale Tumori Fondazione Pascale, Melanoma-Cancer Immunotherapy and Innovative Therapy Unit, Naples, Italy

²Regina Elena National Cancer Institute, Statistical Unit, Rome, Italy

³Istituto Nazionale Tumori Fondazione Pascale, Radiotherapy, Naples, Italy

⁴Istituto Nazionale Tumori Fondazione Pascale, Radiology, Naples, Italy

⁵National Research Council, research, Sassari, Italy

⁶Istituto Nazionale Tumori Fondazione Pascale, Scientific Direction, Naples, Italy

Purpose or Objective: After more than 30 years, Ipilimumab was the first agent which showed a survival benefit for the treatment of metastatic melanoma. However, only about the 20% of patients have a long-term survival benefit. The combination of ipilimumab with other therapies might improve its efficacy. Abscopal effect refers to a regression of metastatic lesions distant from the primary site of radiotherapy (RT). This systemic response is observed in patients who received ipilimumab. Here we reported the outcomes from patients treated in the ipilimumab Italian expanded access program (EAP) who received RT after ipilimumab progression.

Material and Methods: Patients with advanced melanoma who had received RT after ipilimumab progression were eligible for analysis. Radiotherapy was available upon physician request for patients who failed ipilimumab therapy and for whom no other therapeutic options were available.

Results: 21 out of 95 patients treated with ipilimumab in the Italian EAP were eligible for the analysis. The median age was of 58 years (range 21-77); the progression free survival (PFS) from ipilimumab treatment was 4 months (range 3-6), while the time from the end of treatment with ipilimumab and RT was of 5 months (range 4-8). RT was performed on brain in 13 patients: 8 were treated with whole-brain RT and 5 patients with stereotactic RT. Other RT treatment included bone, metastatic distant lymph nodes, sub-cutaneous metastasis, spinal cord metastasis. The median doses was 30 Gy (range 30-50). A local response to RT was detected in 13 patients while 8 patients did not show any local regression. The abscopal response has been detected in 11/21 patients: in details, we observed 9 abscopal partial response, 2 abscopal stable disease, and 10 progression. The median of occurrence of the abscopal response was of 1 month (range 1-4). The median overall survival (OS) for all the 21 patients was of 13 months (range 6-26). The median OS for patients

with and without abscopal responses was respectively of 22.4 months (range 2,5-50,3) and 8,3 months (range 7,6-9,0). 11 out of 13 patients with local response showed an abscopal effect.

Conclusion: The RT after ipilimumab treatment may be an option for further potentiate its effect. Local response to RT might be predictive for the abscopal response and outcome. Further studies are warranted in this field to better understand and define the role of RT in combination or sequencing with ipilimumab treatment.

EP-1393

Radiological responses of melanoma brain metastases to radiosurgery and patient prognosis

I. Zubatkina¹, P. Ivanov¹, D. Tumarova¹, G. Andreev¹

¹International Institute of Biological Systems, Radiosurgery, Saint-Petersburg, Russian Federation

Purpose or Objective: The aim of this study was to analyze differences in radiological responses of melanoma brain metastases after Gamma Knife radiosurgery and their correlation with patient survival.

Material and Methods: We retrospectively analyzed 78 patients treated with Gamma Knife radiosurgery for melanoma brain metastases between 2009 and 2015 in the Radiosurgical centre (Saint-Petersburg, Russia) and subjected to follow-up MRI examinations. Patients receiving BRAF inhibitor therapy or ipilimumab were not included in the study. The study group consisted of 39 men and 39 women with a mean age of 52 years. The median KPS was 80 %. According to RPA, 14 patients were in Class I, 61 patients in Class II, and 3 patients in Class III. Most of the patients presented with multiple brain metastases (87 %). Radiosurgery was performed with Gamma Knife 4C and Perfection units; the mean dose delivered to the tumor margin was 20 Gy at 50 % isodose. After treatment, the patients underwent control MRI examination with standard protocols (2 mm T2 and 1 mm T1 with double contrast enhancement) at 8 weeks and at regular 3-month intervals thereafter. MR images were analyzed with Gamma Plan software. Volumetric measurements of metastases on pre- and post-treatment images were performed in order to determine different types of radiological response. We divided the patients into groups according to the type of radiological response and compared Kaplan-Meier survival curves in these groups with the long-rank test.

Results: We found that patients with melanoma brain metastases had different radiological reactions to Gamma Knife radiosurgery. We distinguished several types of radiation response: sustained decrease in tumor volume, prolonged stabilization of tumor volume, transient increase in tumor volume due to intratumoral bleeding with subsequent decrease in tumor size, transient increase in tumor volume due to radiation-induced necrosis followed by tumor shrinkage. Statistical analysis revealed that a rapid decrease in tumor volume was associated with poor prognosis. Median overall survival of this group of patients was about two times less compared with patients whose radiation response developed slowly after the first 2 months of radiosurgery ($p < 0.0001$). Stratification to RPA classes revealed that patients with a rapid response have poorer survival prognosis than those with a slow response in the corresponding RPA classes.

Conclusion: Melanoma brain metastases showed different radiological responses to radiosurgery. Rapid shrinkage of brain metastases is associated with poor survival, which may indicate more aggressive biological behavior of this tumor subtype. Different radiation sensitivity of melanoma brain metastases to Gamma Knife radiosurgery may be associated with molecular characteristics of cell subpopulations, which determine biological tumor behavior and affect patient prognosis.

EP-1394

Radiotherapy for adult T-cell leukemia-lymphoma: a single institutional experience

K. Tomura¹, T. Ohguri¹, M. Sakagami¹, K. Yahara¹, H. Imada², Y. Korogi¹

¹University of Occupational and Environmental Health, Radiology, Kitakyushu, Japan

²Tobata Kyoritsu Hospital, Cancer Therapy Center, Kitakyushu, Japan

Purpose or Objective: Adult T-cell leukemia-lymphoma (ATLL) is a rare disease and a peripheral T-cell malignancy associated with human T-cell lymphotropic virus type 1 (HTLV-1) infection. ATLL treatment is based on subclassification, and intensive multidrug chemotherapy regimens are often used for aggressive subtypes. However, disease progression occurs in most of patients. There are only a few reports for the radiotherapy in patients with ATLL. Therefore, the role of radiotherapy for ATLL is not well investigated even for the palliation. The purpose of this study was to evaluate the efficacy and toxicity for the radiotherapy in patients with ATLL.

Material and Methods: Between April 1983 to October 2013, 44 patients with 205 ATLL tumor lesions were treated with radiotherapy at our institution. Sites of tumor lesions were as follows; 184 lesions were in the skin, 13 lesions in the lymph nodes, 6 lesions in the central nerves system, and 2 lesions in the bone. Acute type on ATLL subtypes was seen in 8 patients, chronic type in 7 patients, lymphoma type in 10 patients, smoldering type in 15 patients and others in 4 patients. Median total dose of radiotherapy was 29Gy (range, 2-60Gy), and the median fractionated dose was 3Gy (range, 1-7Gy). For the skin tumor lesions, 45Gy in 15 fractions was selected in 33 lesions, 30Gy in 10 fractions in 38 lesions, 28Gy in 4 fractions in 21 lesions and 20Gy in 5 fractions in 19 lesions and others in 73 lesions. Only 4 of 44 patients were treated with total skin irradiation, and the remaining 40 patients received conventional radiotherapy for local tumor. Efficacy and toxicity of the radiotherapy for ATLL were retrospectively evaluated, and the predictors of a long-term survival were analyzed.

Results: The median follow-up period was 206 days. Objective tumor response rates were 98%. Four of 6 tumor lesions with stable disease or progressive disease on objective tumor response were associated with aggressive subtypes or tumor sites of the central nerves system. In-field recurrence after radiotherapy was recognized in 3 (2%) lesions. Two-year and 5-year overall survival rates were 76% and 44%, respectively. Median overall survival time in patients with indolent subtypes (chronic or smoldering type) of ATLL was 23 months, while that in patients with aggressive subtypes (acute or lymphoma type) was 6 months, and the difference was significant. Acute toxicities of Grade 2 dermatitis were seen in 3 patients. Acute toxicity of Grades 3-5 was not observed. Late toxicity of \geq Grade 2 was also not recognized.

Conclusion: Radiotherapy for ATLL was mainly used for the skin lesion and well tolerated, and could achieve excellent local tumor control without inducing severe toxicity. Radiotherapy should be selected to improve the quality of life, and be incorporated into combined modality therapy for ATLL.

EP-1395

Choroidal melanoma: is radiosurgery more efficient?

L. Larrea¹, E. Lopez¹, P. Antonini¹, V. Gonzalez¹, M. Baños², J. Bea², M. Garcia², T. Sanchez-Minguet³, J. Tomas³

¹Hospital NISA Virgen del Consuelo, Radiation Oncology Department, Valencia, Spain

²Hospital NISA Virgen del Consuelo, Physics Department, Valencia, Spain

³Hospital NISA Virgen del Consuelo, Ophthalmology Department, Valencia, Spain

Purpose or Objective: To evaluate local control, enucleation-free survival, toxicity and cost-effectiveness in patients with choroidal melanoma treated with linac-based stereotactic radiosurgery (SRS). GammaKnife® radiosurgery has report very good results for this melanoma treatment.

Material and Methods: Between 2003-2014, 6 patients with choroidal melanoma were treated at NISA Virgen del Consuelo Hospital in Valencia, Spain. Mean age was 59 years (range 43-79). Three were men and three women. Metastatic disease was ruled out in all cases. Two patients had small tumors, two medium sized lesions and two had large lesions according to Collaborative Ocular Melanoma Study Classification. Mean tumor volume was 0,49 cm³ (range 0,17-0,93). Three tumors were localized in the right eye. Visual field previous to treatment was normal in 5 cases and one patient presented complete hemianopsia of the affected eye. Central vision was preserved in all cases. The procedure was made under sedation and retrobulbar blockage, the eye muscles were fixed to Leksell G-Frame with silk sutures. Magnetic resonance (MRI) and computed tomography (CT) were used to contour lesion. CTV minimal marginal dose is 30 Gy, encompassed the 80 % isodose line in 4 patients and the 60% and 55% isodose lines in the other cases. All were treated with 6 MV linac, one isocenter and cone-collimation. Global cost of this method is around 8.000 € (range 7.000-12.000). It is an ambulatory procedure with a total duration of 3 hours or less.

Results: Median follow-up is 19 months (range 1-69). Follow up includes MRI and ophthalmoscopy every 6 months. Complete response in one patient, maximal partial response ($\geq 50\%$) in three patients, partial response ($\leq 50\%$) in other patient and it's too early for response evaluation (less than 6 weeks) in the last one. For lens and optic nerve, the dose constraints were 4 and 18 Gy, respectively. Up to date, no patient has local or distance progression. Enucleation has not been necessary in any patients. Five years after treatment one patient presented retinal scarring in irradiated area. Glaucoma start 9 month after SRS in one patient with previous cataract surgery. No other toxicities were observed.

Conclusion: In our experience, linac SRS is effective eye and vision-sparing method to treat patients with a minimally invasive, safe and cost-efficient alternative to brachytherapy and enucleation in choroidal melanoma with high local control rates and low incidence of toxicities.

EP-1396

Radiosurgery/Stereotacticradiotherapy with Cyberknife and immunotherapy in melanoma brain metastases
 V. Borzillo¹, R. Di Franco¹, S. Falivene¹, G. Totaro¹, V. Ravo¹, P.A. Ascierio², A.M. Grimaldi², F. Cammarota¹, P. Muto¹
¹Istituto Nazionale Tumori Fondazione Pascale, U.O.C Radioterapia, Napoli, Italy
²Istituto Nazionale Tumori Fondazione Pascale, Struttura Complessa Oncologia Medica Melanoma Immunoterapia Oncologica e Terapie Innovative, Napoli, Italy

Purpose or Objective: The immunotherapy improves survival in patients (pts) with metastatic melanoma, but there is insufficient data on the efficacy in pts with brain metastases. SRS and SRT allow greater local control in pts with melanoma brain metastases, with not significant impact on prognosis. Our analysis evaluated survival and local control in pts treated with SRT/SRS with Cyberknife® system and Immunotherapy.

Material and Methods: From November 2012 to September 2015 we treated 47 pts (26 M and 21 F) with melanoma brain metastases. The median age was 59 years (28-81y). 28 pts received immunotherapy pre (pre-RT), concomitant and post radiation treatment (post-RT). 26 pts received Ipilimumab: 14 pts pre-RT, 5 pts concomitant-RT, 7 pts post-RT; 2 pts received Nivolumab: 1 pt pre-RT and 1 pt concomitant-RT; 11 pts received Pembrolizumab: 3 pts pre-RT, 4 pts concomitant RT, 4 pts post-RT. we treated 91 lesions of average size 13.5 mm (2-36). Based on the number of lesions, size and

location, 69 lesions were treated with SRS (10-24Gy), 22 with SRT (18-24Gy/2-3-5 fractions). We evaluated the local response according to RECIST criteria (complete response CR: disappearance of the lesion; partial response PR: at least a 30% decrease in the diameter of lesion; progression disease PD: increase in the diameter of the lesion > 20%; stable disease SD: everyone else). We assessed overall survival, local control (LC) as the sum of CR, PR and SD, and the impact on LC of the association Radiotherapy (RT) and immunotherapy.

Results: 41 pts were evaluable for follow-up (FU). The 6-month survival was 58%. 11 patients died and 11 pts received Whole Brain RT for progression disease. At two months FU, of the 39 pts evaluable (24 treated with RT and immunotherapy), 85% had LC; at four months FU, of 29 pts evaluable (20 treated with RT and immunotherapy), 81% had LC; at six months FU, the 24 pts evaluable (15 treated with RT and Immunotherapy) 100% had LC.

Conclusion: Our analysis seems to confirm the literature data in terms of overall survival. The results showed a good disease local control in pts treated with SRT/SRS and immunotherapy, demonstrating a potential role of immunotherapy in the treatment of melanoma brain metastases. the recruitment of a greater number of pts, a longer follow-up and new prospective studies of combination RT and immunotherapy are needed to demonstrate the immunotherapy role in the treatment of melanoma brain metastases.

EP-1397

Patterns of failure in patients treated with adjuvant radiotherapy post lymphadenectomy for melanoma
 L. Keenan^{1,2}, S. O'Sullivan¹, A. Glynn¹, M. Higgins³, S. Brennan^{1,2}
¹St Luke's Hospital, Radiation Oncology, Dublin, Ireland Republic of
²St James's Hospital, Radiation Oncology, Dublin, Ireland Republic of
³Cork University Hospital, Radiation Oncology, Cork, Ireland Republic of

Purpose or Objective: Adjuvant radiotherapy is proven to prevent lymph-node field relapse after therapeutic lymphadenectomy for melanoma, but does not improve overall survival. Risk factors for lymph-node field recurrence include presence of extracapsular extension, number and size of lymph nodes at dissection. This study reports patterns of failure in patients treated with adjuvant radiotherapy post lymphadenectomy for melanoma.

Material and Methods: This retrospective study included all patients in three institutions treated with adjuvant radiotherapy post lymphadenectomy for melanoma between June 2012 and March 2015. Patients who received radiotherapy were those with high risk of lymph node field recurrence, as per the findings of Burmeister et al in 2012. Patients received radiotherapy to the head & neck (55%), groin (30%) and axilla (15%). All were staged with PET or CT. Both IMRT (50%) and 3D conformal (50%) techniques were used.

Results: 20 patients were treated during this period (see table). Median follow up was 16 months (range 6.7 - 32 months). There were no lymph node field recurrences. Local recurrence rate was 10%. Distant recurrence rate was 35%, all occurring within 4 months from completion of radiotherapy. Distant recurrence rate was 53.8% in patients with extracapsular extension. All patients with local or distant relapse had extracapsular extension. 71% of patients with distant recurrence had PET staging. 8% of patients experienced grade 3 radiotherapy toxicity.

Age	Primary RT region	Adjuvant RT region	No of positive nodes	of ECE	Site of recurrence	Time to recurrence post RT	to Mortality post recurrence
64	Neck	Neck	6/61	No	-	-	-
57	Unknown	Neck	1/29	Yes	-	-	-
81	Cheek	Neck	2/31	Yes	Distant	4 months	RIP at 4 months
43	Leg	Groin	9/25	No	-	-	-
41	Back	Axilla	3/16	No	-	-	-
19	Neck	Neck	1/35	Yes	Distant	1 month	Alive at 25months
79	Eyelid	Neck	1/58	Yes	Local Distant	+ 3.5 months	Alive at 22months
69	Auricular	Neck	4/50	Yes	-	-	-
68	Unknown	Neck	1/64	Yes	-	-	-
65	Cheek	Neck	1/24	No	-	-	-
75	Unknown	Neck	4/45	Yes	Distant	4 months	RIP at 1 month
73	Neck	Neck	0	No	-	-	-
62	Leg	Groin	5/10	No	-	-	-
70	Leg	Groin	13/33	No	-	-	-
57	Foot	Groin	3/8	Yes	Local Distant	+ 0 months + 2.8 months	+ RIP at 10months
80	Cheek	Neck	38/42	Yes	Distant	1 month	RIP at 7months
48	Unknown	Axilla	13/33	Yes	-	-	-
57	Hand	Axilla	13/33	Yes	Distant	2 months	Alive at 8months
63	Leg	Groin	2/25	Yes	-	-	-
37	Leg	Groin	1/9	Yes	-	-	-

Conclusion: Radiotherapy was well tolerated and effective as no patient developed lymph node field relapse. However patients are at risk of early local and distant relapse, especially those with extranodal extension. Consideration should be given to the use of routine PET CT for high risk patients.

Electronic Poster: Clinical track: Sarcoma

²Institut Bergonié, Surgery, Bordeaux, France

³Institut Universitaire du Cancer Toulouse Oncopole, Radiotherapy, Toulouse, France

⁴Institut Bergonié, Clinical and Epidemiology Research Unit, Bordeaux, France

⁵Institut de Cancérologie de l'Ouest, Radiotherapy, Nantes, France

⁶Institut Bergonié, Physics Unit, Bordeaux, France

⁷Institut Bergonié, Medical Oncology, Bordeaux, France

Purpose or Objective: Surgery is the cornerstone in the management of sarcomas. The aim of this study was to evaluate intensity-modulated radiotherapy (RT) with tomotherapy followed by surgery in terms of acute gastro-intestinal (GI) toxicities, especially regarding the high-level of prescribed dose (54 Gy/30 fractions/6weeks).

Material and Methods: From April 2009 to September 2013, 48 patients were included in a prospective multicenter study. Feasibility of tomotherapy, acute toxicities and local control at 3 years were the principal and secondary objectives. Inclusion criteria were operable, biopsy-proven, retroperitoneal liposarcoma. Patients with non-operable tumors validated after multi-disciplinary team evaluation, other histology or metastatic disease were excluded. Clinical Target Volume (CTV) and mains organs at risk (contralateral kidney, duodenum, bowel bag) were systematically delineated with the surgeon. Dose constraints to the bowel bag were defined as V45 Gy<33% and V30 Gy<50%. Surgery

was planned 4 to 8 weeks after RT. Clinical visits were performed weekly during RT, before surgery, and 2 and 6 months after surgery. Toxicity was recorded according to CTCAE V4.0 scale.

Results: For acute GI toxicity, 46/48 patients were evaluable. All patients completed the radio surgical schedule without dose reduction. Mean age was 62 years (36-82). All patients were OMS2 except one (OMS=3). Mean CTV was 2954 cc (920-4989). Mean small bowel and duodenal volumes were 2725 (1355-4090) and 73 cc (33-113), respectively. Monobloc exeresis was systematically achieved and all patients underwent homolateral nephrectomy. Twenty-nine patients underwent bowel resection, including large bowel (28/29), small bowel(4/29) and duodenum (1/29). Mean weight loss during RT was 5,4 kg (about 8% of mean body weight) and 8,9 kg at the first visit after surgery. At 2 months, grade 3 toxicities included duodenal stenosis (1/46), intestinal fistula (1/46) and enterocolitis (1/46) and grade 4 toxicity included GI fistula (1/46). At 6 months, no GI toxicities were observed. Three patients died within 6 months after surgery, 2 of which were related to treatment: one respiratory disorder 6 days after surgery and 1 duodenal perforation with necrosis and infection 4 months after surgery.

Conclusion: For patients with retroperitoneal liposarcoma, preoperative 54 Gy RT appears feasible. Due to the low rate of severe complications, no statistic correlations with dose in digestive structure were performed.

EP-1399

Safety of concurrent adjuvant radiotherapy and chemotherapy for locally advanced soft tissue sarcoma
D. Greto¹, I. Giacomelli¹, M. Loi¹, C. Muntoni¹, R. Grassi¹, A. Mancuso¹, C. Ciabatti¹, R. Capanna², D. Campanacci², G. Beltrami², G. Scoccianti², A. Franchi³, L. Livi¹

²Azienda Ospedaliero Universitaria Careggi, Orthopaedic Oncology, Firenze, Italy

³Azienda Ospedaliero Universitaria Careggi, Surgery and Translational Medicine, Firenze, Italy

Purpose or Objective: The standard treatment of high grade soft tissue sarcoma (STS) is surgery followed by adjuvant radiotherapy (RT); chemotherapy (CT) can be an option in selected patients due to reported benefit in terms of disease free survival. The association of RT with CT might increase tissue reactions with the consequent risk of unplanned treatment interruptions resulting in an increased risk of treatment failure. This retrospective study analyze the safety and feasibility, respectively in terms of additional toxicity and compliance, of concurrent chemoradiotherapy (CIRT) in adjuvant treatment of STS.

Material and Methods: Data of 84 STS patients treated with surgery and adjuvant RT from June 1994 to November 2014 at the University of Florence, were retrospectively collected. Anthracycline-based CT was performed in high risk patients. Acute and late local toxicity of RT treatment were assessed respectively by Common Terminology Criteria for Adverse Events (CTCAE) 4.0 and RTOG/EORTC criteria for the Late Radiation Toxicity. CT-related hematological Toxicity was assessed by CTCAE 4.0.

Results: Twenty-four (28.6%) patients received CIRT. Mean follow-up was 5.6 years (range 0.4-18.8). At the time of our analysis 8 (9,5%) patients had a local relapse, 17 (19,8%) developed distant metastases, and 14 (16,7%) died of metastatic disease. Local Recurrence Free Survival (LRFS), Distant Relapse Free Survival (DRFS) and Overall Survival (OS) were respectively 83.4%, 70% and 69.5%. Grade ≥3 leucopenia occurred in 6 CIRT patients, resulting in early interruption of the CT treatment in 3 cases. Skin acute toxicity was developed in 59 (70,2%) of patients ; G3 skin toxicity occurred in 19 (22,6%) cases and determined treatment interruption in 15 (17,9%) patients with a mean treatment

delay of 10 days (range 4-20 days). No wound complication occurred. Grade 1-2 fibrosis, joint stiffness and limb edema occurred in respectively 27 (32.1%), 9 (10.7%) and 18 (21.4%) patients. Age > 60 years was the only predictor of LR at multivariate analysis (HR: 5.26; 95% CI: 1.11-25.05; p=0.037) and correlated with impaired DRFS (86.1% vs 39.9%; p=0.006). No statistical significant parameters influencing OS. No correlation was found between CTRT and acute local toxicity (p= 0.75), and in any case the association determined a definitive interruption of the treatment. There was no difference in acute (p=0.25) and late toxicity (p=0.78) incidence in the IMRT and 3DCRT group.

Conclusion: Concurrent CTRT is a well tolerated treatment option with no additional toxicity compared to exclusive RT or sequential CTRT, resulting in adequate compliance to treatment. Combined postoperative CTRT could reduce the gap between surgery and RT in high risk patients eligible for CT. Further studies are needed to assess the optimal timing and sequence of adjuvant therapies.

EP-1400

Combined modality management of myxofibrosarcomas: a single-institution experience

D. Greto¹, M. Loi¹, C. Ciabatti¹, A. Mancuso¹, C. Muntoni¹, R. Grassi¹, I. Giacomelli¹, R. Capanna², D. Campanacci², G. Beltrami², G. Scoccianti², A. Franchi³, L. Livi¹

¹Azienda Ospedaliero Universitaria Careggi, Radiotherapy, Firenze, Italy

²Azienda Ospedaliero Universitaria Careggi, Orthopaedic Oncology, Firenze, Italy

³Azienda Ospedaliero Universitaria Careggi, Surgery and Translational Medicine, Firenze, Italy

Purpose or Objective: Myxofibrosarcomas are a historically heterogeneous group of tumors that exhibit a propensity for local recurrence. The objectives of this study were to analyze the prognostic factors and outcomes of patients with MFS treated.

Material and Methods: We retrospectively reviewed the records of 41 patients with pathologically confirmed MFS, who underwent surgery and radiotherapy from November 1995 to June 2014. Clinicopathologic features, treatments, and patient outcomes were reviewed.

Results: Forty one patients were identified, of whom 19 were men (46 %) and 22 were female (54%). The median age was 66 years (35-89). Mean follow-up was 3.9 years (0.3-13.9). Stage I and II disease was present respectively in 21 (51.2%) and 20 (48.8%) patients. Most patients (73%) had a high histological grade disease. Primary tumor was located at the extremities in 36 cases (88%) and at the trunk in 5 (12%); 21/41 (51%) were superficial lesions. Surgery was performed in our center on 33 (80%) patients while 8 (20%) patients underwent reoperation after prior surgery in a non-referring center; 31 (75%) had a radical surgery while 10 (25%) had a marginal resection. Four patients received Anthracycline-based adjuvant chemotherapy.

Radiotherapy was delivered to all 41 patients, as pre-operative treatment in 3 cases (7%, median dose: 50Gy) and as adjuvant treatment in 38 patients (93%, median dose 60Gy). Twenty-two patients underwent radiotherapy within 90 days since surgery. At a median follow-up of 3.9 years, there were 8 (20%) local recurrence (LR), 11 (27%) distant metastatic (DM) relapse and 10 (25%) deaths. A significant difference on Local recurrence - Free survival (DFS-LR) emerged in favour of post-operative radiotherapy compared to neoadjuvant radiotherapy (0% vs 72.8%, p=0.0001). Multivariate analysis confirmed pre-operative radiotherapy as a major predictor of LR (HR=18.6; 95% CI 3.7-93.7; p=0.0001). Tumor site was correlated with distant metastasis free-survival (DFS-DM), showing higher incidence of metastatic recurrence for deep lesion compared to superficial lesion (72.1% vs 32.4 % p=0.034), as confirmed by Cox univariate analysis (HR 3.8; 95% IC 1.01-14.36; p=0.049). LR occurrence was the only predictor of impaired overall survival, as

confirmed by Cox regression univariate analysis (HR 4.44; 95% CI 1.28-15.45; p=0.019).

Conclusion: In our series adjuvant radiotherapy yielded superior local control compared to neoadjuvant irradiation. Deep localization was correlated with an increased risk to develop distant metastasis; local recurrence was a major predictor of OS. Improvement in local treatment is required to increase local control of disease in order to prevent both recurrence and metastatic dissemination.

⁷German Cancer Research Center, Molecular Radiation Oncology, Heidelberg, Germany

⁸University of Heidelberg, Radiation Oncology, Heidelberg, Germany

⁹University of Heidelberg, Pathology, Heidelberg, Germany

Purpose or Objective: To report our long-term results with surgery, IOERT and EBRT in recurrent soft-tissue sarcomas of the extremities.

Material and Methods: We performed a retrospective analysis of 41 patients suffering from recurrent soft-tissue sarcoma of the extremities, who received IOERT, surgery and EBRT at our institution after prior resection without additional radiation. 11 patients (27%) had more than one prior resection. Median age was 60 years (28-89) and 49% were male. Median tumor size at recurrence was 5 cm and 69% of the tumors were located in the lower limb. Stage in recurrent situation (UICC 7th) was as follows: Ia:2%, Ib:7%, IIa:39%, IIb:10%, III:32%, IV:10%. The majority of patients showed high grade lesions (FNCLCC G1:10%, G2:20%, G3:71%), predominantly liposarcomas (32%) and MFH (29%). Gross total resection was achieved in all patients with free margins in 51% and microscopically positive margins in 49%. IOERT was applied to the tumor bed with a median dose of 15 Gy, using electron energies of 6-8 MeV and a median cone size of 8 cm. IOERT was preceded (10%) or followed (90%) by EBRT with a median dose of 45 Gy. 20% of the patients also received pre- and/or postoperative chemotherapy.

Results: The median follow up was 73 months (9-231) for the entire cohort and 93 months (16-231) in survivors. 9 patients (22%) showed local failures, resulting in estimated 5-year and 10-year local control rates of were 74% and 68%, respectively. 15 patients (37%) showed distant failures, transferring into estimated 5-year and 10-year distant control rates of 62% and 55%, respectively. Overall treatment failure was observed in 23 patients (56%), of whom 7 failed locally only, 15 distant only and 1 combined, resulting in 5- and 10-year estimated FTF rates of 44% and 32%, respectively. 15 patients have deceased, transferring into estimated 5- and 10-year overall survival rates of 74% and 60%, respectively. Severe postoperative complications were observed in 14% of the patients, mainly as wound complications. Severe late toxicity was found in 19% of the patients. Preserved limb function without impairment in activities of daily living was achieved in 81% of the patients.

Conclusion: Combination of surgery, IOERT and EBRT resulted in good local control and overall survival in recurrent soft tissue sarcomas of the extremities, although the results are worse than reported for primary situation. Given the high

rate of failures, evaluation of treatment intensification by systemic components maybe warranted in patients with recurrent soft-tissue sarcomas.

EP-1402

Surgery, IOERT and EBRT in upper extremity sarcomas: long term results

F. Roeder^{1,2}, B. Lehner³, I. Alldinger⁴, L. Saleh-Ebrahimi^{2,5}, G. Egerer⁶, P. Huber^{1,7}, G. Mechtersheimer⁸, J. Debus^{5,7}, M. Uhl⁷

⁷University of Heidelberg, Radiation Oncology, Heidelberg, Germany

⁸University of Heidelberg, Pathology, Heidelberg, Germany

Purpose or Objective: To report our long-term results with surgery, IOERT and postoperative EBRT in patients with soft-tissue sarcomas of the upper extremity.

Material and Methods: We performed a retrospective analysis of 37 patients suffering from soft-tissue sarcomas of the upper extremity, who received surgery, IOERT and postoperative EBRT at our institution. Median age was 61 years (28-83) and median tumor size was 6 cm (1-15). 26 patients (70%) presented in primary situation. Stage at presentation (UICC 7th) was as follows: IIa:43%, IIb:8%, III:43%, IV:5%. All patients suffered from high grade lesions (FNCLCC G2: 27%, G3:73%), predominantly MFH (51%). Gross total excision was achieved in all patients with free margins in 51% and microscopically positive margins in 49%. IOERT was applied to the tumor bed with a median dose of 15 Gy, using electron energies of 6-8 MeV and a median cone size of 8 cm. All patients received postoperative EBRT with a median dose of 45 Gy. 30% of the patients also received pre- and/or postoperative chemotherapy.

Results: The median follow up was 78 months (6-231) for the entire cohort and 94 months (6-231) in survivors. Local failures were observed in 6 patients (16%), resulting in estimated 5-year and 10-year local control rates of 80%. 9 patients (24%) showed distant failures, transferring into estimated 5-year and 10-year distant control rates of 71%. Overall treatment failure was observed in 14 patients (38%), of whom 5 failed locally only, 8 distant only and 1 combined, resulting in 5- and 10-year estimated FTF rates of 55%. 11 patients have deceased, transferring into estimated 5- and 10-year overall survival rates of 82% and 70%, respectively. Severe postoperative complications were rare (3%). Severe late toxicity was found in 11% of the patients. Preserved limb function without impairment in activities of daily living was achieved in 79% of the patients.

Conclusion: Combination of surgery, IOERT and postoperative EBRT resulted in good local control and overall survival given the high rate of microscopically positive resections in this unfavourable patient cohort. Severe postoperative complications were rare compared to other sites.

EP-1403

Radiation of cardiac and large vessel sarcoma

M. Wygoda¹, L. Appelbaum², O. Shapira³, A. Meirovitz⁴, A. Wygoda⁴

¹Hadassah - Hebrew University Medical Center, Oncology - Radiotherapy Unit, Ein-Kerem Jerusalem, Israel

²Hadassah - Hebrew University Medical Center, Oncology - Radiotherapy Unit, Ein Kerem- Jerusalem, Israel

³Hadassah - Hebrew University Medical Center, Cardiothoracic Surgery, Ein-Kerem Jerusalem, Israel

⁴Hadassah - Hebrew University Medical Center, Oncology Radiotherapy Unit, Ein-Kerem Jerusalem, Israel

Purpose or Objective: Cardiac and large vessel sarcomas are extremely rare neoplasms exhibiting aggressive behavior. Surgery is the most widely accepted treatment modality, but local recurrence and metastatic spread are common. The role of radiation ("definitive" or adjuvant) and chemotherapy is poorly-defined. In particular sparse data exists on the benefit of radiotherapy, and on the dose and technique required to achieve maximal benefit, with minimal toxicity.

Material and Methods: Five patients with primary cardiac and great vessel sarcomas, diagnosed between 2010 and 2013, were identified in our radiation oncology department database.

We present here their clinical characteristics, dosimetric data, and outcomes.

Results: All Patients analyzed had high grade sarcoma with various histologic subtypes and without metastatic spread. Sites of origin were left atrium (2), SVC, pulmonary artery and descending thoracic aorta. Four patients had positive margins after curative-intent surgery, while one was considered inoperable. Surgery included reconstruction with a graft in three cases (PTFE / Gore-Tex) and heart autotransplantation technique in one. One patient received neoadjuvant and adjuvant chemotherapy. All patients received fractionated radiotherapy utilizing IMRT with Simultaneous Integrated Boost (SIB) to a maximal dose of 60-65Gy, except for one who received 54 Gy utilizing a 3D technique. Mean PTV was 419.23 (range: 163.99cm³-631.95cm³). All patients completed the full course of treatment. Acute toxicity consisted mainly of fatigue and mild dysphagia, while long term events were significant for NSTEMI in one patient (with local recurrence), and mild-moderate pleural and pericardial effusions in another patient. With a median follow-up of 25 months (range: 24-31), 4/5 pts remain loco-regionally controlled (including the patient treated with definitive radiotherapy) and one had local recurrence (the patient who received 54Gy). One patient remains NED, three others developed metastatic disease, and one died of his local recurrent disease.

Conclusion: Based on our experience, radiotherapy to a dose of 60-65Gy using IMRT/SIB can achieve very good local control in the adjuvant and possibly definitive setting in cardiac and large vessels HG sarcomas. This schedule is feasible and generally well tolerated.

EP-1404

Early results of proton beam therapy in sarcomas at the West German Proton Therapy Center Essen

S. Frisch¹, M. Christiaens², F. Guntrum², S. Bauer³, C. Blase⁴, G. Fleischhack⁵, C. Bäumer¹, D. Geismar², B. Timmermann²

¹West German Proton Therapy Center Essen, University Hospital Essen, Essen, Germany

²West German Proton Therapy Center Essen, Clinic for Particle Therapy / University Hospital Essen, Essen, Germany

³Sarcoma Center / West German Cancer Center, University Hospital Essen, Essen, Germany

⁴AnästhesieNetz Rhein-Ruhr ARR, West German Proton Therapy Center Essen, Bochum, Germany

⁵Paediatrics III, University Hospital Essen, Essen, Germany

Purpose or Objective: Proton beam therapy (PT) is an attractive tool in multimodality cancer care and of increasing interest especially for tumors in close proximity to critical structures or in particular sensitive tissues. First clinical results of patients with sarcomatous tumors treated at the West German Proton Therapy Center Essen (WPE) with regard to early toxicity are presented.

Material and Methods: Between May 2013 and Oct 2015, 101 patients (aged 0.9-84.6 y (median 13.8 y); 56% male) with sarcomas were prospectively enrolled in the registry studies "KiProReg" and "ProReg" at WPE. Histologies were rhabdomyosarcoma (n=38), chordoma/chondrosarcoma (n=28), EWING sarcoma (n=10), synovial sarcoma (n=4), osteosarcoma (n=3), malignant rhabdoid tumors (n=3), and miscellaneous (n=15). In 79% of the cohort, residual disease

was still present when starting PT after incomplete resection or biopsy only. Treatment sites were head and neck/base of skull (n=59), pelvis (n=19), spinal/paraspinal area (n=23). The median PT dose administered was 55.8 Gy (45.0 - 74.0 Gy) with a median number of 31 fractions (range 25-41). Mixed beam technique was delivered in 2 patients only. In 53.5% of the patients (48 children, 6 adults) concomitant chemotherapy was applied. Treatment related side-effects were classified according to CTCAE V4.0 grading system and were assessed weekly during PT and in all follow-up visits.

Results: Median follow-up after first diagnosis was 10.6 months (range 3.3 months to 10.5 years). During PT no or only mild to moderate (grade 1 to 2) additional acute side-effects were documented in the majority of patients (n=79); predominantly erythema, alopecia, mucositis, fatigue, pain, and hematotoxicities when compared to baseline. In 28 children, additional grade 3 side-effects occurred during PT; aplasia (n=10; all receiving concomitant chemotherapy), mucositis (n=7; all receiving concomitant chemotherapy), general disorder (n=5), nausea, skin ulceration, headache, diplopia, anorexia, and arthralgia (each n=1). Additional grade 4 side-effects during PT were only seen in one patient for blood/bone marrow (n=1) while receiving concomitant chemotherapy. So far, nine patients failed due to systemic (n=6) or local (n=3) recurrence or progression. Five of these patients died due to disease.

In 73 patients, information on early-late effects after at least 3 months is available. In this group one new grade 3 side effect (fatigue) revealed and one new hematotoxicity was documented while receiving concomitant chemotherapy. No grade 4 or 5 toxicity was observed.

Conclusion: Current prospective and standardized data in sarcomatous tumor patients from WPE registry suggest good feasibility of the treatment even when high doses are administered at critical sites and sensitive tissues. However, longer FU is needed to understand the clinical benefit both in terms of late side effects and local control.

EP-1405

Chemoradiation with pegulated Liposomal Doxorubicin and Cisplatin for patients with Uterine Sarcomas

C. Varveris¹, A. Varveris¹, A. Spanakis¹, J. Stratakis², M. Mazonakis²

¹University Hospital of Heraklion, Radiotherapy, Heraklion, Greece

²University of Crete, Medical Physics, Heraklion, Greece

Purpose or Objective: Uterine Sarcomas represent 3-7% of Uterine Carcinomas. Stage, Grade, Histology and Lymph Nodes are important prognostic factors. Non metastatic patients had reduced local-regional failure (LRF) with radiotherapy. We evaluated 23 patients treated with 3D-Conformal Irradiation (3D-CRT), Brachytherapy (BT), and Chemotherapy.

Material and Methods: 23 PATIENTS WITH Stage I - III (FIGO 2009) were analysed after TAH/BSO and peritoneal washings sampling. 15 patients with Malignant Mullerian Tumors (MMT), 2 Leiomyosarcomas (LMS), 1 grade 3 Stromal Sarcoma received adjuvant concurrent chemoradiation (CCRT). 5 patients (3 MMT and 2 LMS) were treated for local relapse (Pelvic and/or Nodal involvement). 3D-CRT was given with a 18MV Linac (59.40Gy in 1.8Gy/Fr, 5d/w). All patients received 1 MDR intracavitary insertion with 15Gy at the surface of the applicator. Concomitant Caelyx (12mg/m²) and CDDP (25mg/m²) were given the 1st and 4th day of each week respectively for a total of 6.6 weeks. In addition, Caelyx (20mg total) or CDDP (50mg total) were given simultaneously with MDR Brachytherapy depending on the hematologic toxicity of each patient. The above drugs were used as adjuvant treatment in every case for 4-6 Cycles after CCRT completion.

Results: patients were deemed eligible for the study. The median age was 66 years. For the adjuvant treatment, 13(72%) and 5(27%) patients were Stage I and II respectively.

There have been 3/18(17%) locoregional relapses combined with lung metastases in 2 of them (LMS patients who died at 24 and 26 months). Of the 5 patients with documented LRFs 2 patients died at 24 and 31 months with disease progression. Overall 16/18(88%) with stage I/II and 3/5(60%) with stage III are alive and disease free at a median follow up of 3 years (range 2-8 years). Leucopenia and CCRT enteritis/colitis were the most commonly reported toxicities.

Conclusion: CCRT given for Uterine Sarcoma patients as adjuvant treatment or at LRF is a tolerable and effective treatment which needs verification in large phase II/III trials.

EP-1406

Cardiac sarcomas: update of an evolving multidisciplinary approach with focus on radiation therapy

A. De Paoli¹, C. Lestuzzi², F. Santini³, G. Boz¹, R. Innocente¹, F. Navarria¹, G. Miolo⁴, S. Scalone⁴, V. Canzonieri⁵, A. Buonadonna⁴

¹Centro di Riferimento Oncologico, Radiation Oncology, Aviano, Italy

²Centro di Riferimento Oncologico, Cardiology, Aviano, Italy

³University, Cardiosurgery, Genova, Italy

⁴Centro di Riferimento Oncologico, Medical Oncology, Aviano, Italy

⁵Centro di Riferimento Oncologico, Pathology, Aviano, Italy

Purpose or Objective: Primary cardiac sarcomas are extremely rare and unfavourable malignancies. Surgery, although technically challenging, remains the mainstay of treatment. Only few data are available on the use of chemotherapy (CT) and radiotherapy (RT) for advanced disease. Basing on experiences with combined surgery, RT and CT in extremities sarcomas, we explored the feasibility of this multimodality approach in cardiac sarcomas. An update on tolerance and safety of treatment with focus on RT program is reported.

Material and Methods: A retrospective analysis of a consecutive series of patients (pts) with unresectable disease referred to our Institute is reported. After oncologic-cardiologic evaluation, anthracyclin-based CT was considered, followed by RT. IMRT-IGRT (Helical Tomotherapy) was used for more accurate tumor-conformal treatment while sparing the no-tumor-bearing surrounding heart tissue and to reduce the risk of radiation-induced heart disease (RIHD). Echocardiography was used in the treatment planning for organ motion and target-volume margin definition. Full-dose RT with 45 Gy/25 frs with SIB up to 54 Gy was planned. Individualised dose constraints to left and right ventricles were included.

Results: Between June 1998 and March 2013, 17 consecutive pts (M/F: 11/6, median age: 53yrs (25-72) with M0 cardiac sarcoma were referred to our Institute. Tumor location was right atrium in 8 pts, left atrium in 6, left ventricle in 2, pulmonary artery in 1pt; most common histologic type was angiosarcoma (62%). 8 pts had unresectable disease and 9 had complete resection. 12 pts received 4 cycles of full-dose epirubicin 120mg/m² and Ifosfamide 9g/m² and G-CSF; 2 pts 3 cycles of weekly Taxol 80 mg/m². All pts underwent RT, median dose 54Gy (45-59.4Gy). Only 1 pt had moderate acute pericarditis and 2 had late toxicity (mild ejection fraction reduction). 3 pts with major response to CT-RT underwent successful complete surgical resection. At a median follow-up of 40 months (12-137), 9pts are alive and 6 are disease-free.

Conclusion: In our experience, RT for cardiac sarcomas appeared to be feasible, also when combined with CT and surgery. Technological advances in RT planning and delivery and further insight into RT cardiac tolerance are crucial in minimizing the risk of RIHD. Further experience is needed to confirm these encouraging results.

EP-1407

Surgical spacer for sacral chordoma carbon ion treatment at CNAO

B. Vischioni¹, M. Fiore¹, P. Fossati¹, V. Vitolo¹, A. Iannalfi¹, E. Ciurlia¹, M. Bonora¹, D. Panizza², M. Ciocca², L. Cobianchi³, A. Peloso³, T. Dominioni³, D. Bugada³, P. Dionigi³, F. Valvo¹, R. Orecchia¹

¹Fondazione CNAO, Radiation Oncology, Pavia, Italy

²Fondazione CNAO, Medical Physics Unit, Pavia, Italy

³IRCCS Policlinico san Matteo, Surgery 1, Pavia, Italy

Purpose or Objective: Since the beginning of clinical activity in 2011, approximately 600 patients has been treated with hadrons in CNAO (National Center for Oncological Hadrontherapy), among which 42 were sacral chordoma undergoing carbon ion radiotherapy (CIRT) with a radical intent. The aim of the current study is to analyze the feasibility of the insertion of a newly customized spacer prior CIRT in sacral chordoma patients, in terms of procedure validation and patient tolerance, in selected cases where the sacral chordoma is contiguous to the rectum or the bowel loops in order to safely escalate the dose to the tumor target.

Material and Methods: Since 2014, 6 consecutive sacral chordoma patients (3 males and 3 females) eligible for active scanning beam delivery CIRT at CNAO (prescribed dose 70.4 GyE in 16 fractions), were enrolled for spacer placement at IRCCS Policlinico San Matteo - Dept. of General Surgery. For each patient silicone spacer was shaped according to intraoperative findings from a 10x10 cm silicone sheet with a width of 1 mm (Distrex, Padua, Italy). Prior to the surgery and clinical use, a variety of measurements was performed to evaluate the physical stability of the spacer during and after irradiation, as well as its main properties when exposed to carbon ion beams. During CIRT, at the end and each 3 months afterwards, patients were followed up for acute and late CIRT toxicity with clinical visit and high field magnetic resonance (MRI).

Results: Three patients underwent laparotomic and 3-laparoscopic spacer placement. A representative CIRT plan recalculation performed on one of the enrolled patient CT performed before spacer insertion showed that during CIRT the presence of the spacer keeps digestive tract far away from the irradiated area, thus the radiation field is unaffected by rectum filling or intestine movement. Patient enrolled in the study did not show any gastrointestinal toxicity during CIRT or at follow up. Patient imaging during follow up did not show anatomic variations.

Conclusion: Silicone spacer placement is a valuable tool for safe dose escalation in sacral chordoma patients undergoing CIRT.

EP-1408

Adjuvant concurrent chemoradiotherapy in soft tissue sarcomas of the limbs: an effective strategy.

A. Ducassou¹, T. Valentin², T. Filleron³, M. Delannes¹, G. Ferron⁴, S. Le Guellec⁵, P. Rochaix⁵, B. Boulet⁶, C. Chevreau²

¹Institut Claudius Regaud - IUCT-Oncopôle, Radiotherapy, Toulouse, France

³Institut Claudius Regaud - IUCT-Oncopôle, Biostatistics, Toulouse, France

⁴Institut Claudius Regaud - IUCT-Oncopôle, Surgery, Toulouse, France

⁵Institut Claudius Regaud - IUCT-Oncopôle, Pathology, Toulouse, France

⁶Institut Claudius Regaud - IUCT-Oncopôle, Radiology, Toulouse, France

Purpose or Objective: To determine the efficacy and the morbidity of the post-operative concurrent chemoradiotherapy in patients with advanced localized soft tissue sarcomas (STS) of the limbs: results of a retrospective analysis.

Material and Methods: From 1991 to 2012, 68 patients with primary high grade STS of the limb were treated in our institution with an adjuvant concurrent chemoradiotherapy, following limb sparing surgery. The median age was 47.5 years (range, 19 to 74). The most common location was the thigh (56%). The resection was complete (R0) and marginal (R1) in 46 (68%), and 22 (32%), respectively. The median tumor size was 6 cm (range, 8 to 20cm), deep in 83% of cases, and grade was 2 (FNCLCC) in 28 patients (42%) and 3 in 38 (58%), 2 missing. Adjuvant radiotherapy was delivered by brachytherapy (BRT) plus external radiotherapy (EBRT) in 26 patients (38%) and by EBRT alone in 42 (62%). The median dose of BRT and EBRT were respectively 20Gy (range 12 to 30Gy) and 60Gy (range, 45 to 70). The median time between surgery and EBRT was 48 days (range, 20 to 140). Concurrent chemotherapy (CT) was a combination of doxorubicin (60 mg/m² total dose (TD) and ifosfamide (7,5 g/m² TD), with a median number of 4 cycles (range, 1-4).

Results: With a median follow-up of 105 months (CI95% 89-125), the 5-year disease-free survival and overall survival rates were 67%(CI95 53.9-77) and 81%(CI95 68-89); 25 relapses were observed (6 local, 18 distant, and 1 local and distant). A severe (grade 3-4) hematologic toxicity was observed in 32% of cases, mainly leucopenia; 13 patients (20%) experienced a dose reduction of CT. Severe non hematologic complications occurred in 15 patients (22%), mainly acute cutaneous toxicity (14 patients, 21%). Six patients (10%) experienced an EBRT interruption. Severe wound complications were very rare (2 abscesses), without secondary operation for wound care. In univariate analysis, median EBRT dose was a prognostic factor for hematologic severe complications, the median dose being 64Gy in patients with grade 3-4 toxicities vs 56Gy in patients with grade 1-2 toxicities; p=0.01. Tumor location was a prognostic factor for grade 3-4 wound complications and acute dermatitis. Indeed, 50% of complications were grade 3-4 (5/10) when tumor was located in upper limb, vs 17% in inferior limb (10/58); (p=0.035). No correlation between age, sexe, tumor size, and toxicity was found.

Conclusion: Adjuvant concurrent chemoradiotherapy is efficient, feasible and well-tolerated in soft tissue sarcomas of the limbs.

EP-1409

Neuropathic pain a secondary-effect in Classic Kaposi Sarcoma patients treated with radiotherapy

I. Nieto¹, A. Gonzalez¹, V. Ochagavia¹

¹MEDTEC, Department of Radiation Oncology- OncoRay¹ Centre for Radiation Research in Oncology, Vigo Pontevedra, Spain

Purpose or Objective: Kaposi sarcoma (KS) is a vascular tumor that can affect the skin and the mucosa of the digestive, respiratory and urinary tracts, as well as the lymphatic system. It is associated to human herpes virus 8 (HHV-8). There are three principal variants: Classic KS which affects older people (Mediterranean and Jewish Ashkenazi); Endemic KS which mainly affects African children, is a fulminant lymphadenopathic disease, and HIV-associated KS which affects homosexual men. Patients with Classic KS have skin macules on the legs that enlarge and coalesce into plaques and nodules. Radiotherapy is an effective treatment for localized lesions.

Material and Methods: We retrospectively analyzed patients with classic KS treated in our department between 2004 and 2014. Until 2012, all our patients were treated with a 3 Gy per fraction, 30 Gy total dose treatment schedule. After this date most of our patients were treated with a 2 Gy per fraction, 40 Gy total dose treatment schedule. All patients were treated with the same technique: two parallel-opposed 6 Mv photon fields on both legs submerged into water, in order to homogenize the dose on the entire surface, and as a bolus effect. We observed that some patients treated with 3 Gy per fraction schedule, had neuropathic pain in both legs,

after the end of the radiation treatment, which required the use of high dose-opioid and gabaergic pain relievers, chronically. In fact, this was the main factor to consider in our study. Local control was analyzed too.

Results: Eight patients were treated with 3 Gy /fraction, four of them suffered neuropathic pain in radiation field that required chronic drug treatment. (RR 50%). None of the five patients treated with the 2 Gy per fraction technique had neuropathic pain in legs.

Conclusion: Our preliminary results indicate that the 2 Gy per fraction treatment avoids the onset of neuropathic pain after the radiation treatment. Although the patient recruitment was low, we can affirm that both radiation techniques were very useful in the classic KS local control. The 2 Gy per fraction treatment was not associated to neuropathic pain, compared with the hypofractionated radiation treatment.

EP-1410

BBRT in the treatment of metastases from soft tissue sarcoma (STS): Single-institution Experience
C.H. Canova¹, A. Levy¹, F. Martinetti¹, F.G. Riet¹, C. Le Pechoux¹

¹*Institut Gustave Roussy, Department of Radiation Oncology, Villejuif, France*

Purpose or Objective: To evaluate the results of stereotactic ablative radiotherapy (SABR) in selected metastatic sarcomas patients

Material and Methods: Outcomes of 21 consecutive metastatic STS patients (32 consecutive lesions) receiving SABR between 2012 and 2015 at our center were retrospectively analyzed.

Results: Most patients (85%) had a performance status of 0-1 and the median age at treatment was 62.4 years. Metastases treated were localized in lung (37,5%), brain (37,5%), liver (9,5%), soft-tissue (12,5%) and pancreas (3%). The median size of the treated lesion was 2.1 cm. The median biologic equivalent dose delivered was 120 Gy (range, 52.7-213.8 Gy) delivered in a median number of 5 fractions (range, 1-13). The majority of patients received systemic agents prior SABR (16/21). With a median follow-up of 18 months, the 2 years local control rate was 86% (CI 95%: 51-100%; median: not reached), with four progressive lesions. Only one patient experienced a grade 3 toxicity consisting of an ear bleeding. Two years overall survival and progression free survival rates were respectively 72% (CI 95%: 47-96%) and 39% (CI 95%: 15-63%).

Conclusion: SABR in metastatic sarcoma seems to be an effective tool in local control that might be used as an alternative to other local treatments in highly selected patients.

Evaluating the utility of 18F-DOPA-PET imaging for neurosurgical planning of pediatric gliomas

A. Arnett¹, Y. Zhang¹, M. Seaberg¹, D. Pafundi¹, D. Brinkmann¹, C. Giannini², N. Wetjen³, D. Daniels³, A. NageswaraRao⁴, N. Laack¹

¹*Mayo Clinic, Radiation Oncology, Rochester, USA*

²*Mayo Clinic, Pathology, Rochester, USA*

³*Mayo Clinic, Neurosurgery, Rochester, USA*

⁴*Mayo Clinic, Pediatric Oncology, Rochester, USA*

Purpose or Objective: MRI characteristics and extent of disease in glioma is important for surgical planning. However, MRI may not adequately guide biopsy location in non-enhancing tumors. Furthermore, post-radiation changes are difficult to differentiate from progressive tumor. We previously demonstrated the PET tracer 3,4-dihydroxy-6-

[18F]fluoro-l-phenylalanine(FDOPA) has a sensitivity for gliomas and may improve neurosurgical planning in adults. This study evaluates the utility of FDOPA-PET/CT imaging in biopsy and resection planning in pediatric patients.

Material and Methods: MR/CT and FDOPA-PET/CT images were obtained in 5 patients with primary or recurrent malignant gliomas. Regions of interest were defined based on areas of MRI contrast enhancement (CE) and FDOPA uptake to include both concordant (MRI-CE and high-FDOPA) and discordant (MRI-non-CE and high-FDOPA, MRI-CE and low FDOPA) regions. Ratios of maximum tumor SUV (SUVmax) normalized to mean SUV (SUVmean) of normal brain tissue (T/N) were determined using the SUVmax from each biopsy coordinate and the SUVmean from contralateral normal brain tissue.

Results: The FDOPA-PET images guided biopsy site selection in four patients. One patient with contrast enhancement in an eloquent location near a region of prior radiotherapy did not undergo biopsy after FDOPA-PET failed to show increased uptake. Average tumor SUVmax was 2.135 (range 2.92-1.27), and the T/N average T/N ratio was 1.6 (range 1.92-1.18). Biopsies within the region of highest uptake were performed in 3 patients and were consistent with Grade III or Grade IV, despite lack of contrast enhancement 1 patient. In one patient, SUVmax was in an eloquent region of thalamus and was deemed an unsafe location for biopsy. Biopsy from an adjacent region revealed infiltrating glioma, non-diagnostic for grade. Regions of increased FDOPA uptake extended beyond those identified with MRI in two patients.

Conclusion: FDOPA-PET imaging appears to have utility in guiding biopsy region selection and may assist with identifying regions of higher-grade disease in pediatric patients with astrocytomas.

EP-1412

Respiration-induced organ motion in children during image-guided radiation therapy

S. Huijskens¹, I.W.E.M. Van Dijk¹, M.A.J. De Jong¹, J. Visser¹, R. Dávila Fajardo¹, C.R.N. Rasch¹, T. Alderliesten¹, A. Bel¹

¹*Academic Medical Center, Radiation Oncology, Amsterdam, The Netherlands*

Purpose or Objective: Respiration-induced organ motion is one of the main contributors to intrafractional motion, limiting the maximum achievable accuracy in radiation therapy (RT). Knowledge on respiration-induced organ motion in children during RT is extremely scarce and urgently needed for better definitions of abdominal and thoracic safety margins. It also allows to assess whether developments and introduction of child-friendly breathing exercises and/or coaching during the treatment course could have an added value to control and minimize respiration-induced organ motion. Therefore, the aim of this study is to investigate how respiration influences the diaphragmatic motion, as indicative of organ motion in the abdomen and thorax, during image guided RT (IGRT) in children and to find possible relationships with age and height. In addition, we investigated trends in the respiration-induced diaphragmatic motion during the treatment course.

Material and Methods: This retrospective study consisted of 15 patients with a mean age of 10.6 years (range 2.2-16.9 years) and a mean height of 140 cm (range 90-167 cm), treated at our institute between 2006 and 2015, for whom for setup correction routinely acquired evaluable images of the thorax were available. This amounted to a total of 15 reference CT (refCT) scans and 86 Cone Beam CT (CBCT) scans. CBCTs were reconstructed for the inhale and exhale respiratory phases and registered to the refCT using Elekta XVI software. First, the vertebrae were aligned. Subsequently, the diaphragm was manually aligned in craniocaudal (CC) direction only. The result yields the mean peak-to-peak (PP) motion (i.e., magnitude of motion) of the diaphragm in the CC direction, derived from registration outcomes of the inhale and exhale CBCTs to the refCT.

Possible time trends were investigated by analyzing the derived PP motion from daily CBCTs as a function of treatment day. The reproducibility of the PP motion was measured as the standard deviation (SD) over the mean PP motion per patient. We used a linear regression model to analyse the relationship between these outcomes and age and height.

Results: Over all patients, PP motion was on average 8.6 mm (range 4-15 mm) and varied largely within and between patients. Time trends differed between patients. PP motion correlated with age and height ($p < 0.05$). PP motion increased by 0.42 mm for every yearly increase in patients' age and for every 1 cm increase in height the PP motion increased 0.07 mm (Figure 1). The SD ranged from 1-3.7 mm and correlated with age and height ($p < 0.05$) (Figure 1).

Figure 1. Scatterplots with regression lines describing relationships between mean PP motion and reproducibility of the PP motion (SD) with age (left column) and height (right column) ($p < 0.05$ was considered as statistically significant).

Conclusion: Respiration-induced diaphragmatic motion in children during IGRT is correlated with age and height, however irregular breathing patterns were found. PP motion was variable throughout the treatment. Therefore, introducing child-friendly breathing exercises and/or coaching techniques may be beneficial to minimize PP motion and to enhance its reproducibility.

EP-1413

Second neoplasms in survivors of childhood acute lymphoblastic leukemia treated with radiotherapy

W.S. Looi¹, J.W.J.C. Koh², F.K.C. Chin¹, Y.H.J. Teh¹, A.M. Tan³

¹National Cancer Centre Singapore, Radiation Oncology, Singapore, Singapore

²National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore

³KK Women's and Children's Hospital, Haematology/Oncology Service, Singapore, Singapore

Purpose or Objective: Second malignant neoplasms (SMNs) are a concern in survivors of childhood cancer. Chemotherapy forms the mainstay of treatment for acute lymphoblastic leukaemia (ALL), but radiotherapy has a role in certain situations. As both chemotherapy and radiotherapy can be carcinogenic, patients treated with both modalities may be at a higher risk of SMNs. This study aims to investigate the incidence of SMNs in patients treated with both chemotherapy and radiotherapy at KK Women's and Children's Hospital, Singapore.

Material and Methods: We performed a retrospective review of ALL patients treated in the largest maternal and children's hospital in Singapore. Children aged 16 years and below diagnosed with ALL from 1993 to 2014 were identified in the Childhood Cancer Registry. Manual and electronic medical records were reviewed for information on demographics, management and SMNs.

Results: A total of 64 patients treated with both chemotherapy and radiotherapy were identified. Seventeen (26.6%) were female and 47 (73.4%) were male. The median follow-up was 9.2 years (range, 1.1-22.0 years). The median

age at diagnosis was 5.3 years (range, 0.3-14.6 years). The median age at which radiotherapy was given was 6.6 years (range, 2.9-15.4 years).

SMNs were noted in 3 of 64 (4.7%) patients. Two of 3 patients had a SMN within the radiation field (both cranial). The histological diagnoses were basal cell carcinoma and cerebral PNET. The remaining patient had an ovarian immature teratoma outside the radiation field. The median latency period was 9.4 years (range, 8.3-13.3 years) from date of diagnosis to development of SMN. The estimated 10-year cumulative incidence was 4.3%, 95% CI [0.01, 0.13] using a competing risks analysis.

Radiotherapy data was available in 63 patients. Fifty-one of 63 (81.0%) received cranial irradiation, of which 3 (5.9%) also received spinal irradiation. Total body irradiation was performed in 20 of 63 (31.7%), and testicular irradiation in 17 of 63 (27.0%) patients. The orbit was targeted in 3 of 63 (4.8%) patients.

Conclusion: Long term survivors of ALL treated with both chemotherapy and radiotherapy may have a significant risk of second malignant neoplasms, which may occur years after the initial diagnosis.

EP-1414

Using a DVH registry standardizes IMRT-CSI planning and reduces V20 in non-target tissues

M. Létourneau¹, J. Kildea², W. Parker², A. Joseph², C. Freeman³

¹CHU de Québec, Department of Radiation Oncology, Quebec, Canada

²McGill University Health Centre, Department of Medical Physics, Montréal, Canada

³McGill University Health Centre, Department of Radiation Oncology, Montreal, Canada

Purpose or Objective: An intensity-modulated radiation therapy technique for craniospinal irradiation (IMRT-CSI) delivered on the Tomotherapy unit has been used at our centre since 2008. Defining and prioritizing dose constraints to target and organs at risk (OAR) are time-consuming. To facilitate and standardize the planning process, we developed a dose-volume histogram (DVH) registry and tested its usefulness with two cohorts of patients treated to different doses of CSI.

Material and Methods: The registry consists of a back-end MySQL database and front-end webpages that are served via a web-server internal to the clinic. Approved plans are added to the DVH registry via a filter that standardizes the names of the OARs. Dose constraints for planning are established based on previous aggregate data and planners graphically compare DVH data for a new treatment plan with existing aggregate data without submitting the new data to the registry. We evaluated two cohorts of IMRT-CSI patients: (1) CSI dose 36 Gy in 20 fractions and (2) CSI dose 23.4 Gy in 13 fractions and compared the findings with an earlier cohort of patients that were planned before we started using the registry.

Results: Eighteen patients, age 3 to 17 years, were included in the registry. Eleven were treated to a dose of 36 Gy in 20 fractions and seven to a dose of 23.4 Gy in 13 fractions. Most (56%) had medulloblastoma. Significantly smaller variations were achieved for OAR for patients treated at 36 Gy using the DVH registry compared with patients in the earlier cohort, making the registry a very useful tool for the treating team. V20 were lower for all OARs except the trachea.

Conclusion: The results confirm that the DVH registry standardizes the planning process of IMRT-CSI patients. We will use constraints obtained from the 7 patients treated at 23.4 Gy to start planning new cases and evaluate the benefit of our DVH registry for this regimen.

EP-1415

Cranial irradiation and sleep disorders in children with brain tumour: a case-control study

C. Pilotto¹, E. Coassin², E. Passone¹, M. Robazza¹, S. Birri³, E. Bidoli³, A. Nocerino¹, M. Mascarin²

¹AOU Santa Maria della Misericordia, Clinica Pediatrica, Udine, Italy

²Centro di Riferimento Oncologico, SOS di Radioterapia Pediatrica, Aviano, Italy

³Centro di Riferimento Oncologico, SOS Epidemiologia e biostatistica, Aviano, Italy

Purpose or Objective: Brain tumours as many other neurological diseases may cause sleep problems interfering with the delicate mechanisms of sleep regulation. The presence of a disturbed sleep may have material daily performance effects. In growing subjects this aspect may determine emotional and behavioral problems. The prevalence of sleep disorders (SD) in children with brain tumours is unknown. The main aim of this study is to compare the prevalence of SD in children affected by brain tumours and treated with radiotherapy to the prevalence of SD in children treated only surgically.

Material and Methods: A retrospective case-control study was performed from October 2014 to April 2015 in a Pediatric Department and in a Pediatric Radiotherapy Centre. "Cases" included patients 2 to 16 years old with a diagnosis of CNS tumour at least 3 months after treatment conclusion (surgery and radiotherapy and/or chemotherapy). "Controls" were children 2 to 16 years old with CNS tumours treated only surgically. Children's sleep quality was assessed with a questionnaire administered to parents (Child's Sleep Habits Questionnaire, CSHQ). The sleep was considered disturbed if at least one of the following events was present: sleep delay, sleep duration, sleep-related anxiety, night waking, parasomnias and respiratory disorders. The risk of SD was estimated by the Odds Ratio (OR) and their 95% confidence intervals (95% CI) through logistic regression models.

Results: We enrolled 14 cases and 14 controls, for a total of 28 subjects. 9 out of 14 children in "case" group were treated with surgery, radiotherapy and chemotherapy. Our results highlighted a prevalence of SD of 57.4% among cases and 42.9% in controls. A statistically significant difference between the two groups (OR= 1.78 CI: 0.40-7.94) was not reached.

Conclusion: Cranial irradiation is required to treat many brain tumours in children. Some studies involving only children with midline tumours show that high-dose cranial irradiation in midline site in childhood is associated to objective and subjective changes in the sleep-wake rhythm in adulthood. Our study failed to show a statistically significant difference in SD between the two groups, but there is evidence of a greater prevalence among children treated with radiotherapy. Limitations of the study include the small number of patients involved and the lack of irradiation details, as dose and site. We expect that a relationship between cranial irradiation and SD will be statistically confirmed increasing the number of involved patients. We hope to better define the relationship with irradiation dose and site, as brain tumour position and consequent irradiation may have a role on SD development.

EP-1416

Analysis of childhood brain tumours treated with radiosurgery/stereotactic fractionated radiotherapy

J. Paiva¹, T. Santana¹, V. Zaccariotti¹, J. Arruda¹, L. Oliveira¹, V. Araújo¹, L. Goulart¹

¹Hospital Araújo Jorge, Radiation Therapy, Goiânia, Brazil

Purpose or Objective: The aim of the study is to evaluate data from radiosurgery (RS) and fractionated stereotactic radiotherapy (FSRT) performed in patients from 0 to 14 years of age in Hospital Araújo Jorge, Goiânia, Goiás, Brazil, treated between 2000 to 2013.

Material and Methods: The authors retrospectively assessed medical reports of 65 patients from 0 to 14 years of age with diagnosis of brain tumours and who underwent RS/FSRT from 2000 to 2013. The analysis concerns age at diagnosis, primary location of the tumor, size of the tumor, risk assessment, and employment of either RS or FSRT.

Results: From the 65 records, 42 were included in the analysis for having all the information desired. Of those patients, 46.3% were male and 69.0% were diagnosed with malignant tumors. 29.3% of the patients were between 0 to 6 years, 31.7% between 7 to 10 years, and 39.0% between 11 to 14 years of age. The most frequent histopathological diagnoses were medulloblastoma (19.0%), arteriovenous malformation (14.3%), and glioma (11.9%). As for the treatment, 78.5% underwent to FSRT and 21.5% underwent to RS. The median total radiation dose prescribed dose was 54Gy for the FSRT and 18Gy for the RS. The most frequent prescription dose curves were 90% and 95%, respectively, whilst the conformity index for the RS varied from 1.23 to 2.04. It resulted in 42.9% of the patients having partial response to the performed treatment and 78.6% not having distant disease progression. The overall survival was 58.1 months for patients from 0 to 6 years, 69.3 months for those from 7 to 10 years, and 90.2 months for those in the 11 to 15 years range (p=.0037).

Conclusion: The results show a 13 years experience on treating pediatric tumors with RS/FSRT of that single institution. High precision conformal stereotactic techniques with RS/FSRT employing conservative margins than conventional radiotherapy in childhood tumors appears to be safe based on our experience. Long term prospective trials are required to test their real potential in sustaining local control and minimising treatment related acute and late morbidity.

EP-1417

ANDANTE: second cancers from neutrons following proton therapy: preliminary epidemiological results

K. Perstorfer¹, L. Walsh¹

¹Bundesamt für Strahlenschutz Federal Office for Radiation Protection, AG-SG 1.3, Neuherberg, Germany

Purpose or Objective: Survivors of childhood cancer generally have an increased risk of developing secondary cancers associated with the treatment for the first primary cancer. Proton therapy represents a highly effective treatment technique for some types of childhood cancers but scattered radiation from secondary neutrons is an unwanted by-product.

Material and Methods: The ANDANTE project investigates the relative risk of neutrons compared to photons for tumorigenesis, as a function of dose and energy. The approach is multidisciplinary, including physical measurements and modeling, molecular biology, radiobiology and epidemiology. Based on stem cells irradiated in vitro with either photons or neutrons, a corresponding predicted model of the relative risk of cancer induction from photons or neutrons following pediatric radiotherapy is developed and tested on clinical data, leading to a proposal for a prospective epidemiological study to validate the relative risk of neutrons on the tumorigenesis in humans. The progress on the epidemiological aspects of this current work is reported here.

Results: In order to validate the dose-risk model developed earlier in the project, a feasibility study with clinical data from the Loma Linda University Medical Centre (LLUMC) was performed. A cohort of 242 patients was constituted in August 2013. Those patients were treated between 1991 and 2013, diagnosed with arteriovenous malformation (AVM) (n=108) or low grade astrocytoma (n=134) before the ages of 30 years, and were followed up later. All variables for statistical analyses are available but data extraction has not been finished yet. Results of this feasibility study will provide a basis for the development of the prospective

epidemiological study, and will be used to test the validity of a predictive risk model based on values of neutron RBE which will be derived from the physics task in the ANDANTE project. Based on the experience from the feasibility study at LLUMC, a proposal for a prospective epidemiological study using pediatric proton therapy data collected from multiple proton centers world-wide is prepared. For this purpose, published results of epidemiological studies on second malignant neoplasms (SMN) after radiotherapy in childhood are reviewed. Up to now, 57 papers were identified from 2001 until present with the objective to estimate the magnitude of the effect of radiation exposure on the occurrence of SMN. Furthermore, European proton therapy centers were contacted in order to assess the feasibility of creating a prospective database on pediatric patients. Five out of thirteen proton therapy centers already replied, showing great interest in preliminary participation in discussion on forming a future prospective study.

Conclusion: This will be essential for investigating the far reaching goal to enhance our understanding of the link between radiation exposure to proton therapy and the risk of SMNs.

EP-1418

Proton therapy in paediatric oncology - An Irish perspective

K. Lee^{1,2}, C. O'Sullivan^{1,2}, M. Capra²

¹St Luke's Radiation Oncology Network, Radiation Oncology, Dublin, Ireland Republic of

²Our Lady's Children's Hospital Crumlin, Paediatric Oncology, Dublin, Ireland Republic of

Purpose or Objective: To: (1) produce a descriptive study of Irish children referred abroad for proton therapy (PT), and (2) to discuss the case for PT in general.

Material and Methods: A retrospective review of all children referred for PT before October 2015 was performed. Information was gathered regarding general demographics, diagnosis, tumour grade, other treatments, the PT referral timeline, relapse where relevant, side effects attributable to PT, current status and cost of treatment to the Irish state. Additionally, a review of the relevant literature was performed.

Results: Sixteen children treated in Ireland have been referred abroad for PT to date, with numbers increasing yearly. The largest number referred was in the 0-4 year old group. At initial diagnosis the median age was 5.0 years. Four patients were referred for treatment of rhabdomyosarcoma, 3 for craniopharyngioma, 6 for intracranial ependymoma and 1 each for treatment of meningioma, germinoma and ATRT. The average cost per child has been approximately €52,000. Two patients suffered relapse of their disease - 1 has proven fatal and the other is alive with disease. Four patients have encountered PT-related adverse effects. The time from referral to treatment has improved from 11 to 6 weeks approx.

Conclusion: Despite the fact that >100,000 patients worldwide have been treated with PT, the current level of published evidence to support superiority over conventional treatment remains low. Planning studies have clearly demonstrated superior conformality and reduced risk to normal tissues. It is debated that randomised control trials in this area would be inconsistent with the principle of *clinical equipoise*. In contrast, there is a call for level 1 evidence to justify such drastic changes in patient care, particularly in the light of recent reports of unexpected toxicities. If PT were more widely available, the question remains in which clinical situations would it be likely to show substantial clinical and cost benefit? As no firm conclusions can be derived from the literature, the answer is somewhat speculative. In time, careful evaluation, follow-up and clinical trials will likely support the argument for the preferential use of proton therapy in children. Our challenge remains: how best to use it in the meantime?

EP-1419

Proton irradiation in childhood and adolescence at RINECKER Proton Therapy Center (RPTC)

R. Richter¹, M. Herbst¹, A. Haidenberger², M. Walser¹, I. Teichert-von Lüttichau³, A. Wawer³, K. Beutel³, S. Burdach³, B. Bachtary¹

¹Rinecker Proton Therapy Center, Radiation Oncology, Munich, Germany

²Hospital Agatharied, Radiation Oncology, Hausham, Germany

³Children's Hospital of Munich Schwabing/ Technical University of Munich, Paediatric Haematology and Oncology, Munich, Germany

Purpose or Objective: In the multimodal treatment concept for pediatric tumors the implementation of radiotherapy with protons gains more and more importance due to their outstanding radiobiological, physical and technical characteristics. In particular the fact, that about 60% of the irradiated volume of conventional radiotherapy are not burdened by proton therapy, results in a considerable reduced incidence of side effects with lowering the negative impact on growth and development and a lower rate of secondary malignancies. The German Society for Radiation Oncology (DEGRO) clearly recommends preferably proton therapy in the treatment of pediatric patients.

Material and Methods: Analysis of children and adolescents undergoing proton radiation therapy since start of the RPTC 2009 (time period from Jun 2009 to Sep 2015). A highly complex three-dimensional electromagnetic proton beam control system (spot scanning) can apply the tumor dose only to the planned target volume and spares surrounding healthy tissue without significant neutron exposure to the whole body. There is a wide range of free variety of dose intensity to each spot.

Results: From 06/2009 to 07/2015 a total of 82 patients were previously treated at the RPTC in 88 cases. The mean age at start of irradiation was arithmetically 7.9 years (min. 11mo.; max. 17y. 7mo.). These were mostly rhabdomyosarcomas (RMS; n = 26 [29.5%]), of which 10 were alveolar and 16 were embryonal RMS. In the field of central nervous system, 14 patients with low grade gliomas [16%], 11 high grade gliomas [12.5%], 10 ependymomas [11%] and 2 medulloblastomas were treated. From 12 cases with rare tumor types, 8 were also localized in the CNS. 6 patients had chordoma and chondrosarcoma, 5 Ewing tumors and 2 rare types of soft tissue sarcomas.

Conclusion: At the field of pediatric oncology radiotherapy with protons using spot scanning technology is certainly feasible and a highly effective treatment method with significantly lower toxicity of normal tissue. There is a close cooperation with the Children's Hospital of the Municipal Hospital Munich/ Hospital of Munich Technical University for the integration of multimodal therapy studies or to treat in analogy with rule-based case discussions in interdisciplinary tumor conferences.

EP-1420

Cyberknife® radiotherapy for recurrent or oligometastatic tumours in children and adolescents

S. Gaito¹, F. Saran¹, H. Taylor¹, E. Wells¹, S. Mowat¹, H. Burland¹, C. Jones¹, L. Welsh¹, H. Mandeville¹

¹The Royal Marsden Hospital, Department of Radiotherapy, London, United Kingdom

Purpose or Objective: Despite the increasing availability of stereotactic ablative body radiotherapy (SABR) and stereotactic radiosurgery (SRS) there remains a lack of evidence regarding their indications and role in the treatment of recurrent & oligo-metastatic tumours in children, teenagers & young adults (TYA).

Material and Methods: A retrospective review of paediatric and TYA patients (age ≤24 years) treated with SRS or SABR at The Royal Marsden Hospital from 2010 to 2015 was

performed. Data collected included: tumour type, technique, dose, number of fractions, prescription isodose, acute and late toxicity (CTCAE v4.0), local control (LC) and progression free survival (PFS).

Results: 12 patients were identified: 8 males and 4 females; median age 14.5 years [5-20 years]. Cranial SRS was delivered to 9 sites in 7 patients, and extracranial SABR was delivered to 8 sites in 5 patients. All patients had a Lansky/ Karnofsky score ≥ 70 . All SABR and SRS treatments were performed using the Cyberknife® platform; 8 treatments prescribed as a single fraction (median dose 19 [18-24] Gy), 4 treatments were given in 3 fractions (median dose 28.5 [27-42]Gy) and 5 treatments in 5 fractions (median dose 30 [30-35]Gy). The median prescribing isodose was 79% [70-81%]. For 5 patients SRS was delivered post surgical resection with no macroscopical residual disease at the time of treatment. The treatment for 9 (75%) patients was to previously irradiated sites. After a median follow up of 14.5 [0.9-36.2] months 9 pts (75%) were alive, 2 died from disease progression and 1 died from unclear cause. MRI response assessment was performed at a mean time of 6 [3-17] weeks; 1 patient had a complete response, 10 had stable disease (83 %); 1 was not assessed due to a rapid clinical deterioration. LC was 100 % and 85.7% at 1 and 2 years respectively. PFS was 82.5% at 1 year and 61.9 % at 2 years. 3 reirradiated patients reported symptomatic grade 3 radionecrosis, requiring medical therapy.

Conclusion: In this cohort, SABR and SRS with Cyberknife® have proven feasible in the subset of paediatric & TYA patients with recurrent or oligo-metastatic tumours. It achieved good local control even in pre-irradiated patients. However optimal patient selection for such a treatment approach remains as yet to be determined via an international consensus.

EP-1421

Radiotherapy for pediatric patients from 2006 to 2015 in a large health care region

E. Waldeland¹, T. Hellebust², H. Magelssen³, P. Brandal³

¹Oslo University Hospital, Academic Physics, Oslo, Norway

²Oslo University Hospital, Dep. of Medical Physics, Oslo, Norway

³Oslo University Hospital, Dep. of Oncology, Oslo, Norway

Purpose or Objective: Particle therapy is not available in our country yet, however, quite a few patients are sent abroad for such therapy. In the largest health trust, covering a population of 2.9 million, 25-40 pediatric patients (< 18 years) are treated with radiotherapy (RT) yearly. We wanted to analyze this group of patient with respect to RT technique and diagnosis.

Material and Methods: All pediatric patients treated between January 2006 and June 2015 were identified and included. The treatment techniques were categorized as follows: total body irradiation (TBI), whole CNS RT, IMRT/VMAT, stereotactic RT (SRT), 3D conformal RT (CRT), kV RT and extracorporeal irradiation (ExCRT). Additionally, the pediatric patients referred for proton RT abroad were registered.

Results: 302 pediatric patients were treated with RT in the period. The mean age at treatment were 11.3 ± 4.6 years. 69 patients (25%) had brain tumors, whereas 50 (18%) and 43 (16%) patients were diagnosed with lymphoma and leukemia, respectively.

The figure gives the distribution of the treatment techniques through the whole period (upper panel), showing that more than 50 % of the patients have been treated with CRT. The lower panel in the figure shows the distribution in 2006 (left) and 2014 (right), indicating that the proportion of patients receiving CRT has decreased from 50 to 38 %. However, the number of patients only reduced from 18 in 2006 to 15 in 2014. The number of patients treated with advanced techniques (IMRT/VMAT, SRT) did not change significantly. On the other hand, 20 % of the patients were referred for

proton RT abroad in 2014, while no one received such treatment in 2006. The number of patients where the whole CNS were treated reduced from 8 (25%) in 2006 to 3 (8%) in 2014.

In the whole period 31 patients (10%) were treated with TBI and the number of patients per year did not change significantly from 2006 to 2014.

Conclusion: An official agreement was established with proton centers abroad in 2013. The reduction in whole CNS treatment throughout the period is due to this agreement. Except TBI, kV RT and ExCRT, all the other techniques should be replaced with proton RT when such treatment becomes available.

Electronic Poster: Clinical track: Palliation

EP-1422

Contemporary management of bone metastases from breast cancer: Who is getting long course RT?

C. Nieder¹, B. Mannsäker¹, A. Pawinski¹, E. Haukland¹

¹Nordlandssykehuset HF, Dept. of Oncology and Palliative Medicine, Bodø, Norway

Purpose or Objective: The Norwegian Breast Cancer Group provides national guidelines regarding systemic therapy for metastatic breast cancer. While our center adheres to these recommendations, use of palliative radiotherapy (PRT) for bone metastases is less standardized. Despite general recommendations for short course PRT for uncomplicated metastases, many physicians prefer 10 fractions (long course, LC). Our aim was to analyze factors associated with prescription of ≥ 10 fractions.

Material and Methods: This retrospective study included 118 female patients (all received systemic therapy including bone-targeting agents in accordance with national guidelines).

Results: Median age was 61 years, and median survival 13 months. Long-course PRT was prescribed in 60% of patients, while 21% had PRT with 8 Gy single fraction to at least one target. Reirradiation rate was numerically higher after 8 Gy (9%, compared to 5% after LC PRT and 6% after 4 Gy x5, not significant). Patients with favorable baseline characteristics were significantly more likely to receive LC PRT. These characteristics included absence of lung metastases and/or

pleural metastases/effusion, normal serum hemoglobin, CRP, LDH and albumin (surrogate markers of disease extent), early PRT within 6 months from diagnosis of metastases, age <65 years, and good performance status (ECOG PS). Biological subtype (Her2 and hormone receptors), comorbidity and reirradiation to a previously treated volume did not correlate with fractionation. Rate of LC PRT remained unchanged over time. In line with imbalances in prognostic factors, survival was significantly longer after LC PRT in univariate analysis. However, after correcting imbalances in multivariate analysis no survival difference was found. Prognosis was influenced by biological subtype (worse for triple negative status), extraskelatal disease extent, presence of anemia and abnormal CRP. Even patients with PS3 had median survival of 3 months, which indicates that they live long enough to experience clinical benefit after PRT.

Conclusion: The likelihood of receiving LC PRT was significantly higher in younger patients, those with good PS, limited disease extent, and shorter time interval after diagnosis of metastatic disease. Educating physicians about these factors might contribute to optimal resource utilization. The limited need for reirradiation after single fraction PRT might encourage physicians to prescribe this convenient regimen, which is also suitable for PS3 patients.

EP-1423

Hypofractionated radiotherapy for complicated bone metastases in patients with poor performance

M. Silva¹, G. Marta^{2,3}, F. Lisboa⁴, G. Watte⁵, F. Trippa⁶, E. Maranzano⁶, N. Motta⁴, E. Chow⁷

¹Hospital Universitário de Santa Maria, Radiation Oncology, Santa Maria, Brazil

²Instituto do Câncer do Estado de São Paulo, Radiation Oncology, São Paulo, Brazil

³Hospital Sírio Libanês, Radiation Oncology, São Paulo, Brazil

⁴Universidade Federal de Ciências da Saúde de Porto Alegre, Radiation Oncology, Porto Alegre, Brazil

⁵Liverpool Heart and Chest Hospital NHS Foundation Trust, Department of Radiology, Liverpool, United Kingdom

⁶"S. Maria" Hospital, Department of Radiation Oncology, Terni, Italy

⁷Sunnybrook Odette Cancer Centre, Radiation Oncology, Toronto, Canada

Purpose or Objective: To evaluate the efficacy of hypofractionated radiotherapy (16 Gy in 2 fractions one week apart) in pain relief in patients with complicated bone metastases and poor performance status.

Material and Methods: This was a phase 2 multicenter study of patients with complicated bone metastases and Karnofsky performance status from 30 to 60 who underwent 2 fractions of radiotherapy with 8 Gy each one week apart. Pain response and quality of life (QOL) were measured using the International Consensus on Palliative Radiotherapy Endpoints and EORTC QOL Pal 15 and BM 22 questionnaires. Complete response was defined as a pain score of 0 at treated site with no concomitant increase in daily oral morphine equivalent (OMED). Partial response was defined as pain reduction of 2 or more on a scale of 0 to 10 scales without analgesic increase, or analgesic reduction of 25% or more from baseline without an increase in pain. Pain progression as an increase in pain score of 2 or more above baseline with stable OMED, or an increase of 25% or more in OMED compared with baseline with the pain score stable or 1 point above baseline, and others were indeterminate. The study was registered on clinicaltrials.gov (NCT02376322)

Results: Thirty patients were enrolled from 4 centres in Brazil, Italy and Canada during July 2014 to September 2015. There were 14 male and 16 female patients. The median age was 58 years old (range 26 - 79). Twenty-two (73%) had extraosseous soft tissue component, 4 neuropathic pain, 2 post-surgical intervention, and 2 impending fracture in weight bearing bone. The most common primary cancer sites were breast (n = 7) and lung/prostate (n = 4 each). The most commonly irradiated areas were lumbosacral spine (n = 10),

pelvis/hips (n = 8), thoracic spine (n = 7), cervical spine (n = 3), and superficial bones (n = 2). The median pre-treatment worst pain score was 8 (range 1 to 10) and the median daily OMED was 40 mg (range 0 to 360). The median follow up was 3.7 months (range 0.3 to 9.6). At 2 months, 20 patients were alive (66%). Eleven (55%) had complete or partial response, 4 (20%) progressive disease and 5 (25%) indeterminate response. A statistically significant improvement (p < 0.0001) was seen in the painful sites and physical functioning for the BM22 while the other items in BM 22 and C15-PAL remained stable. No patient suffered from spinal cord compression or pathologic fracture, and re-irradiation was not required.

Conclusion: The 2 fractions of radiotherapy with 8 Gy each one week apart appears to be well tolerated without serious side effects in patients with complicated bone metastases and poor performance status. QOL remained stable. The efficacy was similar in patients with uncomplicated bone metastases treated with hypofractionated radiotherapy.

EP-1424

Palliative short-course radiotherapy in rectal cancer: a phase II study.

²S. Orsola-Malpighi Hospital - University of Bologna, Radiation Oncology Center - Department of Experimental - Diagnostic and Specialty Medicine - DIMES, Bologna, Italy

³S. Orsola-Malpighi Hospital - University of Bologna, Department of Medical and Surgical Sciences - DIMEC, Bologna, Italy

⁴Fondazione di Ricerca e Cura "Giovanni Paolo II" - Catholic University of Sacred Heart, Medical Physics Unit, Campobasso, Italy

⁵Policlinico Universitario "A. Gemelli" - Catholic University of Sacred Heart, Department of Radiotherapy, Roma, Italy

⁶United Hospital Limited, Department of Radiation Oncology, Gulshan - Dhaka, Bangladesh

⁷Assiut University, Faculty of Medicine, Assiut, Egypt

Purpose or Objective: The aim of this phase II study was to evaluate the symptomatic response rate of short course radiation therapy (SCRT) in patients with advanced rectal cancer not amenable for curative treatment and with obstructive symptoms.

Material and Methods: Patients unfit for surgical resection due to synchronous metastases, age and/or comorbidities, were eligible. The sample size was calculated based on the two-stage design by Simon. SCRT was delivered with an isocentric four-field box technique (total dose: 25 Gy; 5 Gy per fraction in 5 days). No chemotherapy was allowed during SCRT. Clinical outcome measures were symptomatic response rate, toxicity, colostomy-free survival and overall survival.

Results: From October 2003 to November 2012, 18 patients (4 females and 14 males; mean age 77.5 years) were enrolled. The median follow up was 57 months (range: 23-132 months). Symptomatic response was: 5.5% no change, 66.7% partial response, 27.8% complete response. No patients stopped treatment for gastrointestinal or genitourinary toxicities: 27.8% patients had grade 1-2 toxicity and 16.7% had grade 3 toxicity; only 1 patient had haematological grade 2 toxicity. One and 2-year colostomy-free survival were 100% and 71.4% (median: 30 months), respectively. Reduction/resolution of pain and bleeding was 87.5% and 100%, respectively. One and 2-year actuarial overall survival were 66.3% and 53% (median: 25 months), respectively.

Conclusion: In this phase II study based on SCRT in patients with symptomatic rectal cancer not eligible for curative treatment an improvement of initial symptoms with

acceptable incidence of side effects was recorded. Furthermore, it was possible to avoid colostomy in a significant proportion of patients.

EP-1425

Phase I study on hypofractionated accelerated radiotherapy for bone metastases from prostate cancer
G. Torre¹, G. Macchia¹, M. Nuzzo¹, F. Deodato¹, F. Labropoulos¹, V. Picardi¹, S. Cammelli², J. Cappuccini², A. Guido², M. Ntreta², G. Siepe², A. Arcelli², G. Compagnone³, R. Schiavina⁴, G. Martorana⁴, A.G. Morganti²

¹Fondazione di Ricerca e Cura "Giovanni Paolo II" - Catholic University of Sacred Heart, Radiation Oncology Unit, Campobasso, Italy

²S. Orsola-Malpighi Hospital- University of Bologna, Radiation Oncology Center- Department of Experimental- Diagnostic and Specialty Medicine - DIMES, Bologna, Italy

³S. Orsola-Malpighi Hospital- University of Bologna, Medical Physic Unit, Bologna, Italy

⁴S. Orsola-Malpighi Hospital- University of Bologna, Department of Urology, Bologna, Italy

Purpose or Objective: To define the Maximum Tolerated Dose (MTD) of Middle Half Body (MHB) Radiotherapy (RT) delivered with a conformal 3D technique and twice daily fractionation in prostate cancer (PC) multiple bone metastases.

Material and Methods: A phase I trial was designed with two level of dose: 13 Gy (3.25Gy per fraction) and 15 Gy (3.75 Gy per fraction). Eligibility criteria were: histological confirmed PC, symptomatic and or impending for fracture multiple bone metastases, ECOG performance status 0-4, expected survival >3 months, and adequate bone marrow function. Radiotherapy was delivered using a 3D conformal technique twice daily in 2 sequential days, with at least 8 hours interval between fractions. Cohort of 6-12 patients were recruited in order to define the MTD (any acute toxicity > grade 3 of RTOG scale). Pain and quality of life were recorded using analogue-visual scales (VAS and CLAS). Clinical target volume was defined as pelvic bones, involved femurs + lumbar spine. Planning target volume was defined as the CTV + 1 cm.

Results: From June 2010 to November 2014, 22 patients (median age 73 years; range 58-86) were enrolled. In Figure 1 treatment volumes are described.

At diagnosis, all patients (100%) reported pain. Clinical pain remission (complete or partial) was observed in 95% of patients. Six patients (27.3%) had a complete symptoms resolution and 15 (68.2%) had a partial symptom control. Pain worsening after radiation treatment was recorded only in 1 patient. On the basis of analogue-visual scales a significant decrease of pain was recorded (mean VAS pre RT versus post RT: 4.6 versus 3,0; $p=0.034$; mean pain score pre RT versus post RT: 3.1 versus 1,9; $p=0.069$; mean drug score pre RT versus post RT: 3.9 versus 2,5; $p=0.088$). Skin and gastrointestinal acute toxicities were only grade 1-2. With a median follow up of 6 months (range 1-26) no late toxicity was recorded.

Conclusion: An accelerated MHB RT treatment with twice daily fraction on bone metastases from PC was well tolerated up to 15 Gy. A phase II study is ongoing to confirm efficacy on pain control and quality of life.

EP-1426

Analysis of treatment response and survival of patients with superior vena cava syndrome (SVCS)

L.G. Sapienza^{1,2}, A. Aiza¹, B.B. Da Silva¹, R. Fogaroli¹, D.G. Castro¹, M.J.L. Gomes³, A.C. Pellizzon¹

¹A. C. Camargo Cancer Center, Radiation Oncology, São Paulo, Brazil

²Clínicas Oncológicas Integradas COI-RJ, Radiation Oncology, Rio de Janeiro, Brazil

³Hospital Federal dos Servidores do Estado do Rio de Janeiro HFSE-RJ, Radiation Oncology, Rio de Janeiro, Brazil

Purpose or Objective: To evaluate the factors associated with treatment response (relieve of SVCS) and overall survival.

Material and Methods: Thirty one patients with SVCS between 2012-2015 were analyzed. The end points were: overall survival and SVCS resolution. SVCS resolution was determined as the absence of symptoms related to the compression of superior vena cava. The variables tested were: sex (male vs female), age (<50 years vs > 50 years), primary site (lung vs others), KPS (<70 vs \geq 70), previous palliative RT (no vs yes), BED Gy10 dose (<25 vs \geq 25), more than 1 year of the initial diagnosis (no vs yes), tumor size (<10 cm vs \geq 10 cm), and number of previous chemotherapy (CT) lines (0 or 1 vs 2 or more), presence of: bone mets (no vs yes), central nervous system (SNC) mets (no vs yes), lung mets (no vs yes), liver mets (no vs yes), lymph node mets (no vs yes) and SVCS resolution (no vs yes).

Results: The mean follow-up time of the patients alive was 376 days (median 241 days). The 6-months and 1-year OS survival were 31.5 % and 18 %, respectively. Factors influencing positively the survival in univariate analysis were: KPS \geq 70 ($p=0.001$), 0 or 1 previous CT lines ($p=0.012$), diagnosis <1y ($p=0.007$), no bone mets ($p=0.010$), no lung mets ($p=0.011$), no liver mets ($p=0.031$) and SVCS resolution ($p<0.001$). In multivariate analysis only SVCS resolution ($p=0.005$) remained significant and no lung metastasis was marginally related ($p=0.060$). The overall SVCS resolution rate was 84% (12/25 cases). Nineteen patient were treated with radiotherapy (RT), four patient with chemotherapy and 2 patients with RT + CT. Six cases receive no treatment (3 because of extremely low KPS and 3 because of the risks of re-irradiation) and were excluded from the efficacy and multifactorial analysis. None of the variables tested influenced the treatment response rate.

Conclusion: Treatment response rate was more than 80 % and it was the strongest factor associated with overall survival. This fact encourages the indication of treatment even in patients with low performance status or previous cervico-thoracic radiotherapy, after a risk-benefit analysis.

EP-1427

Vertebral compression fracture of spinal metastasis from colorectal cancer after radiotherapy

J. Lee¹, W.J. Rhee¹, K.C. Keum¹, W.S. Koom¹

¹Yonsei University College of Medicine, Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: The aim of this analysis was to determine the risk of vertebral compression fracture (VCF) following spine radiotherapy (RT) specific to colorectal cancer (CRC) spinal metastases, and to determine clinical predictors

Material and Methods: We retrospectively reviewed 267 spinal segments (176 metastatic and 91 non-metastatic vertebrae) in 66 patients, which were irradiated for pain palliation between 2007 and 2014. The primary endpoint was development of a VCF following RT, either a de novo VCF or

progression of a baseline VCF. Each metastatic spinal segment was also evaluated according to the six Spinal Instability Neoplastic Score (SINS) criteria (location, pain, bone lesion type, spinal alignment, posterolateral element involvement, bone lesion type, presence of a baseline fracture) to evaluate the predictive significance.

Results: The median spine RT total dose, dose per fraction, and number of fractions was 30 Gy (range, 8-60 Gy), 3 Gy (range, 1.2-18 Gy), and 10 fraction (range, 1-25), respectively. The median follow-up for the entire cohort was 10 months. Nine percent (23/267) had been previously irradiated, 8% (20/267) had a baseline VCF, and 47% (83/176) were lytic tumor. In all spinal segments, 33 VCF (33/267, 12%) were observed following RT, including 21 de novo fractures and 11 progressive fractures, and the median time to VCF was 4 months. The 1-year fracture free probability (FFP) was 85%. Multivariate analysis identified sex ($p = 0.005$), metastatic involvement ($p = 0.012$), prior RT ($p = 0.006$), and baseline VCF ($p < 0.001$) as predictors of VCF. Among 176 metastatic spinal segments, we observed 32 fractures (32/176, 18%) with 1-year FFP of 78.1%. Multivariate analysis showed that the risk of VCF in metastatic spine segments was statistically significant in patients with SINS class II/III with or without pre-existing baseline VCF ($p < 0.001$) and prior RT ($p < 0.001$).

Conclusion: The risk of VCF is higher in women patients with a baseline VCF and prior RT. Additionally, in metastatic spine segments, the risk of VCF is significant in patients with SINS class II/III with or without pre-existing baseline VCF and prior RT. SINS criteria can be used as an option for predicting VCF risk before performing RT specific to spinal metastases from CRC.

EP-1428

Routine Whole Body MRI of bone metastases may reduce the incidence of spinal cord compression

L. Bhattacharya¹, D.K. Woolf¹, A. Makepeace¹, M. Kosmin¹, A. Makris¹, P. Hoskin¹, A. Padhani¹

¹Mount Vernon Cancer Centre, Clinical Oncology, Northwood, United Kingdom

Purpose or Objective: Metastatic spinal cord compression (MSCC) is a common oncological emergency resulting in significant morbidity and detrimental functional outcome. Population studies suggest an incidence of 3-7% in men with metastatic castrate resistant prostate cancer. In our centre, therapy monitoring of established bone disease in breast and prostate cancer is undertaken with whole body MRI scanning (WB-MRI). WB-MRI includes a dedicated spinal examination and diffusion weighted sequences that can aid in earlier detection of disease progression or response to treatment. The aim of this cross-sectional hypothesis generating study was to identify if routine WB-MRI reduces the rates of symptomatic MSCC in metastatic breast and prostate cancer patients.

Material and Methods: Patients with metastatic breast and prostate cancer who underwent ≥ 2 WB -MRI scans between 2010-2014 were identified and cross-referenced with patients receiving emergency radiotherapy for symptomatic MSCC. The number of breast & prostate cancer patients, who had ≥ 2 WB-MRI scans and received emergency radiotherapy for MSCC were recorded.

Results: 63 patients with breast cancer and 89 patients with prostate cancer received emergency radiotherapy for MSCC between 2010-2014. Of the 365 patients with breast cancer who had ≥ 2 WB -MRI scans, only 1 (0.3%) patient underwent emergency radiotherapy for MSCC. 102 patients with metastatic prostate cancer had ≥ 2 WB -MRI scans of which 2 (2.0%) had emergency radiotherapy for MSCC.

Conclusion: Rates of symptomatic MSCC in this series of patients undergoing regular WB-MRI scans for therapy monitoring of bone disease are low.

Routine WB-MRI may aid in the early detection of disease progression in the bones, allowing earlier change in systemic therapy or the use of prophylactic radiotherapy particularly for incipient cord compression. This data generates the hypothesis that WB-MRI may prevent progression of bone disease and development of symptomatic MSCC. This has the caveats that the population studied was selected and in particular had relatively stable disease that permitted the routine use of WB-MRI. It is possible that the morphological spinal MRI examination component, rather than the diffusion weighted sequences, may provide much of the utility of the WB-MRI examination. Further prospective studies are required to confirm our findings.

¹²Delta Medical Center, Radiation Oncology Department, Dhaka, Bangladesh

¹³Fondazione Seragnoli, Hospice Bentivoglio, Bentivoglio, Italy

Purpose or Objective: To assess the effectiveness of a Short-course Accelerated RadiatiON therapy (SHARON) in the palliative treatment of patients with advanced primary or metastatic H&N tumors.

Material and Methods: A phase II clinical trial was planned based on optimal two-stage Simon's design. Eligibility criteria included patients with an Eastern Cooperative Oncology Group performance status of ≤ 3 . Twenty-three patients were treated with H&N radiotherapy at 20 Gy (5 Gy per fraction) in 2 days with a twice daily fractionation. The primary endpoint was the assessment of efficacy in terms of symptoms relief.

Results: Characteristics of the enrolled patients were: male/female: 9/14; median age: 83 years (range: 40-98). Eastern Cooperative Oncology Group performance status was < 3 in 11 patients (47.8%). Grade 1-2 acute skin (60.9%) and mucositis (39.1%) toxicities were recorded. Only one patient (4.3%) experienced grade 3 acute mucositis. With a median follow-up time of 4 months (range, 1-32 months) 3 skin grade 1 and 2 skin grade 2 late toxicities have been observed. Of the 23 symptomatic patients, 21 showed an improvement or resolution of baseline symptoms (overall palliative response rate: 91.3%). Three-month overall survival was 89.7% (median survival time: N.R.). Median survival without symptoms

progression was 5.0 months (95%CI: 1.8-8.1). In 22 patients with pain, a significant reduction of this symptom was recorded in terms of VAS (mean baseline VAS vs mean VAS at follow-up: 4.6 versus 3.1, $p < 0.001$).

Conclusion: Short-course accelerated H&N radiotherapy (20 Gy in twice daily fractions for 2 consecutive days) is tolerated and effective in terms of symptom relief. A phase III comparison against a standard palliative regimen (30 Gy in 10 fractions) has been planned in this patient population.

Purpose or Objective: To assess the effectiveness of a Short-course Accelerated Radiation therapy (SHARON) in the palliative treatment of patients with primary or secondary thoracic neoplasms, symptomatic, and not susceptible of surgery or radical radiotherapy.

Material and Methods: A phase II clinical trial was planned based on optimal two-stage Simon's design. Eligibility criteria included patients with an Eastern Cooperative Oncology Group (ECOG) performance status ≤ 2 and an expected survival > 3 months. Twenty-five patients were treated with radiotherapy (total dose: 20 Gy, 5 Gy per fraction) in 2 days with twice daily fractionation. The primary endpoint was to evaluate symptoms response rate.

Results: Characteristics of the 25 enrolled patients were: male/female: 18/7; median age: 73 years (range: 46-93). ECOG performance status was ≤ 2 in 24 patients (96%). Two G1 skin (8%), 7 G1 haematological (28%) and 4 G1 pulmonary (16%) toxicities were recorded. No patient experienced ≥ 2 acute toxicities. With a median follow-up time of 6 months (range, 1 to 16 months), of the 25 symptomatic patients, 24 showed an improvement or resolution of baseline symptoms (overall palliative response rate: 96%). Three months overall survival was 87.5% (median survival time: 6 months; 95% CI 5.3-6.6 mo). Median survival without symptoms progression was 3 months (95% CI:2.2-3.7mo). In 24 patients with pain, a

significant reduction of this symptom was recorded in terms of VAS (5.0 vs 2.9, $p = 0.02$).

Conclusion: Short-course accelerated thorax radiotherapy (20 Gy in twice daily fractions, 2 consecutive days) is tolerated and effective in terms of symptom relief. A phase III comparison against a standard palliative regimen (30 Gy in 10 fractions) has been planned in this patient population.

EP-1431

SBRT for patients with spine metastases using LINAC

Y. Mironova¹, D. Bentsion¹, S. Bayankin¹

¹Regional Oncology Clinic, Radiotherapy, Ekaterinburg, Russian Federation

Purpose or Objective: Modern technologies of radiotherapy (SBRT, SABR) are utilized to treat patients with solitary spine metastases. Clinical studies have shown the efficacy of image-guided SBRT for pain control, local tumor control, as well as improvement of the life's quality for these patients. In our clinic we have been using this method since 2013 for primary and re-irradiation treatment.

Material and Methods: We have treated 32 pts (20 primary, 12 reirradiation), 44 lesions. Eligible criteria were ECOG 1-2, spine metastases confirmed by MRI, the number of lesions were less than 3, adequate control of the primary tumor. Mean age 55.8 y.o. (47-72); gender distribution: 12 men and 20 women. Option of the radiation dose and limit critical organs were installed according to the recommendations Elekta Spine Radiosurgery Research Consortium (ESRRC) and RTOG 0631. The prescribed dose was 12-24 Gy in 1-3 fr. For re-irradiation we have used the recommendations of Nieder et al. (2006): BED of each course - 98Gy, total BED -135.5Gy, the interval between two treatments was more than 6 months. In these cases the prescribed dose was 20Gy in 5 fr. The procedure was performed by VMAT on a linear accelerator Elekta Synergy S, equipped with a 4-mm MLC, image-guided system (Elekta XVI), 6D robotic positioning system table (HexaPod). Overall duration of procedures was 20-45 min. The follow-up was every 3 months from treatment time. It was assessed the pain intensity on a 10-point VAS, analgesics, performed MRI control.

Results: Toxicity of SBRT was assessed by using CTC AE (v.4.0). Nausea gr.1 was observed in 3 (9.4%) pts, vomiting gr.1 - 1 (3.1%) pt. Toxicity gr.3-4 has not been observed. There were no cases of therapy interruption due to poor tolerability. Hematological toxicity during follow-up period was not revealed. In average of the period of 3 weeks all patients showed relief of pain syndrome with moderate (4-6 points) to the minimum (1-3 points). The overall response to treatment (decrease of pain syndrome, local tumor control by MRI) was 90.6%, including a complete pain relief - 8 (25%) pts, stabilization - 21 (65.6%), lack of response to the treatment - 3 (9.4%). One patient had a pathological compression fracture of the vertebra at 4 months after irradiation, which required surgical intervention (installation of the fixing system). According to one patient's MRI after 3 month of treatment, we have revealed soft tissue component of tumor (MRI).

Conclusion: SBRT was well tolerated. We did not observe any clinically significant toxicity. Reduction of the overall treatment time was comfortable for patients and increase capacity of LINAC. Further research is necessary to evaluate the efficacy and toxicity of the treatment and the development of criteria for the selection of patients.

EP-1432

Predicting pain response after conventional radiotherapy in 1018 patients with bone metastases

J.M. Van der Velden¹, H.M. Verkooijen¹, A.L. Versteeg², A.S. Gerlich³, J.J. Verlaan², L. Zhang³, M. Tsao³, C. Danjoux³, E. Barnes³, M. Van Vulpen¹, E. Chow³

¹University Medical Center Utrecht, Radiation Oncology, Utrecht, The Netherlands

²University Medical Center Utrecht, Orthopedic Surgery, Utrecht, The Netherlands

³Sunnybrook Odette Cancer Centre, Radiation Oncology, Toronto, Canada

Purpose or Objective: Many patients with advanced cancer develop bone metastases, with pain as a common, devastating consequence. Adequate treatment is important to maintain quality of life. Radiotherapy is the standard treatment for patients with painful bone metastases. Meta-analyses of radiotherapy trials have consistently shown a pain response rate of approximately 60% implying that many patients are treated insufficiently. It would be worthwhile to identify patients who will not respond to radiotherapy as these patients might be candidates for other treatments. Furthermore, better understanding and identification of the patients who do not respond to radiation, might help in the development of innovative treatments as alternative or addition to standard (radiation) treatment options. We studied the relationship between patient and treatment characteristics and pain response in patients with metastatic bone disease, with the aim to construct a prediction model to guide individualized treatment decision-making.

Material and Methods: We analyzed all prospectively collected data on pain response from a palliative radiotherapy clinic in an academic hospital. Patients were considered responders if they reported a decrease in pain score of at least 2 points with stable analgesic use within 3 months after treatment. A multivariable logistic regression model was developed with age, gender, primary tumor, Karnofsky performance status (KPS), painful localization, presence of visceral metastases, previous systemic treatment, analgesic use at baseline, and baseline pain score. For variable selection, we started with the full model and applied backward stepwise selection with a selection criterion of $p < 0.20$. Performance of the model was quantified using the c-statistic and corrected for optimism. A worst case scenario (assuming no response in patients who were lost to follow up) was added as sensitivity analysis.

Results: A total of 1018 patients treated between January 1999 and November 2007 were included. Outcome was recorded in 588 (58%) patients, of which 394 (67%) reported a response. Primary tumor, KPS, baseline pain score, and analgesic use were predictive for response with a corrected c-statistic of 0.59 (Table). Assuming non-response in the 430 patients without follow up (worst case scenario), there was still an association between response and primary tumor, KPS, and baseline pain score.

Conclusion: Primary tumor, performance status, baseline pain score, and analgesic use are associated with pain response in patients with bone metastases. However, combining these factors in a prediction model showed poor discrimination limiting its use in clinical practice. Response rates after radiotherapy are moderate, and its prediction is difficult, which shows the need for development of innovative treatments for patients with bone metastases.

EP-1433

Comparison of single fraction versus long course RT treating bone metastasis with cobalt machines

O. Spahiu¹, G. Bardhi¹, E. Kozma¹, E. Hafizi¹, E. Karauli¹, F. Pupuleku Kraja¹, A. Sallaku¹

¹"Mother Theresa" University Hospital Center, Department of Radiotherapy- Oncology Service, Tirana, Albania

Purpose or Objective: To present the observed comparative advantages of the single fraction versus long course radiation therapy in the palliative treatment of bone metastasis, in the conditions of technological resources limited to one national center equipped with only cobalt machines. Purpose: To present the observed comparative advantages of the single fraction versus long course radiation therapy in the palliative treatment of bone metastasis, in the conditions of technological resources limited to one national center equipped with only cobalt machines.

Material and Methods: The Radiation Therapy of Mother Theresa University Hospital Center, the unique public center providing RT in the country, performed a study comparing single dose of 8 Gy/1fr. versus 20 Gy/5fr. and 30Gy/10fr. enrolling 110 patients during a time period of five years (2007 - 2012). Factors for the treatment choice between available options were age, pain level, effect of narcotics and need for assistance as well as time and cost effectiveness. Pain relief was assessed based on the patient perception expressed during the follow up visits, 2 weeks, 4 weeks and 12 weeks after the treatment and subsequently every 12 weeks for a period of 48 weeks. Qualitative data from the follow up visits were classified in a scale of 10 points.

Results: The complete pain relief was attained for 90 patients or 81.8% out of 110 patients, subject to this study. From this number, 33 patients were treated with single shot, 31 with 20 Gy/5 fraction and 46 with 30Gy/10fr. The percentage of patients benefiting partial pain relief varied from 17.4 to 19.5 which indicate also similar results from the available treatment regimes. Therefore, it wasn't evidenced significant difference between the treatment options as regard to the patients achieving complete or partial pain relief. Further, the toxicity level scored 2-3 grade for all the treatment regimes used. In addition, the patients demonstrated similar median survival from 8 to 10 months for the three options.

Conclusion: The findings of the study indicate that single fraction 800cGy/1fr is a treatment option with similar effects with the multiple fractions 20Gy/5fr and 30Gy/10fr. It can be used as more time and cost effective standard treatment especially for patients presenting higher level of pain and more in need for assistance including elder and those more distant from the treatment centers.

¹³Fondazione Seragnoli, Hospice Bentivoglio, Bologna, Italy

Purpose or Objective: To assess the efficacy of a Short-course Accelerated RadiatiON therapy (SHARON) regimen in the palliative treatment of complicated bone metastases.

Material and Methods: A phase II clinical trial was planned based on optimal two-stage Simon's design. Eligibility criteria included patients with an Eastern Cooperative Oncology Group (ECOG) performance status ≤ 2 . The primary endpoint was to evaluate the symptoms response rate produced by a radiotherapy regimen based on the delivery of 4 radiotherapy fractions (5 Gy per fraction) with a twice daily fractionation in two consecutive days.

Results: Twenty-nine patients were enrolled in this trial. Characteristics of the patients were: male/female: 16/13; median age: 66 years (range: 46-87). ECOG performance status was ≤ 2 in 25 patients (86.2%). With a median follow-up time of 5.0 months (range, 1 to 36 months), 9 G1-2 gastrointestinal (31%), 2 G1 haematological (6.8%) and 6 G1 skin (20.7%) toxicities were recorded. Only 1 patient (3.4%) experienced G3 acute gastro-intestinal toxicity. Of 29 symptomatic patients, 27 showed an improvement or resolution of baseline symptoms (overall palliative response rate: 92.6%). Three-month overall survival was 92.2% (median survival time: not reached). In 25 patients with pain, a significant reduction of this symptom was recorded in terms of Drug Score (mean baseline Drug Score vs mean Drug Score at follow-up: 5.3 vs 4.0; $p=0.04$).

Conclusion: Short-course accelerated radiotherapy on complicated bone metastases (20 Gy in twice daily fractions for 2 consecutive days) is tolerated and effective in terms of symptom relief. A phase III comparison against a standard palliative regimen (30 Gy in 10 fractions) has been planned in this patient population.

EP-1435

Radium-223 in castration resistant prostate cancer with bone metastases: preliminary clinical results

⁴S.Orsola -Malpighi Hospital- University of Bologna, Department of Medical Physics, Bologna, Italy

⁵Ospedale Bellaria, Radiotherapy Department, Bologna, Italy

Purpose or Objective: More than 90% of patients with metastatic castration resistant prostate cancer (CRPC) have radiologic evidence of bone metastases. Radium-223 dichloride therapy showed improved overall survival, quality of life and symptom control in patients with symptomatic bone metastases. Aim of the present study is to evaluate clinical course of patients treated in our centre including biochemical and imaging response.

Material and Methods: Since November 2014 we started the treatment of symptomatic bone metastatic CRPC patients with Radium-223 dichloride (50kBq/kg, every 4 weeks). Before and after every administration the following parameter were recorded: PSA and alkaline phosphatase (ALP) values, pain numerical rating scale (NRS), performance status (ECOG scale), analgesic therapy and side effects (graded according to the CTCAE v. 4 classification). A whole body scintigraphy was performed before and one month after the treatment.

Results: Twenty patients (total: 70 administrations) were treated. All patients showed increased PSA value and reduced ALP values. Performance status, evaluated with ECOG scale, was improved in all patients. Pain control was excellent, with reduction of NRS and analgesic therapies in all patients. Most patients showed only G1 toxicity: anaemia (15 pts), fatigue (3 pts), diarrhea (1 pt), nausea (1 pt), and pain flare-up (6 pts).

Eight patients completed the 6 planned cycles of therapy. Six patients discontinued treatment due to adverse events: anaemia (2 pts), pathological fracture of the femur (1 pt), severe bleeding (2 pts) and complications in uncontrolled diabetes (1 pt). The other patients are still under treatment. Whole body scintigraphy performed one month after the end of the treatment demonstrated in all patients a reduced intensity and number of uptake areas without correlation with PSA values.

Conclusion: Treatment with Radium 223 in patients with CRPC and symptomatic bone metastases was tolerated in the majority of patients. High response rates in terms of symptom control and QoL improvement were recorded.

EP-1436

The superior vena cava syndrome (SVCS): role of the radiotherapy

M.S. Mariaquila Santoro¹, M.L. Marianna Lacaria¹, M.A.M. Maria Angela Molinaro¹, L.R.F. Lucia Rachele Fabiano¹, A.D. Anna Destito¹, N.C. Natascia Costantino¹, V.M. Vita Margheriti¹, D.P. Domenicantonio Pingitore¹

¹Hospita Pugliese-Ciaccio, Department of Hemato-Oncology-Operative Unity of Radiotherapy and Radiobiology, 88100 Catanzaro, Italy

Purpose or Objective: To determine the results of 55 patients with Superior Vena Cava Syndrome (SVCS) treated with radiotherapy.

Material and Methods: Between September 2009 and September 2014, 55 patients with SVCS were treated at Operative Unity of Radiotherapy and Radiobiology, "Hospital Pugliese-Ciaccio", Catanzaro. Of these 21 were women and 34 men, with a median age at diagnosis of 61 years (range 33-77 years). The most predominant symptoms were face or neck swelling (85%), upper swelling extremity (73%), dyspnea (70%), cough (62%), neck and vein distension (45%). Radiotherapy (RT) has been the only treatment in 6 of 11 patients in which the rapidly progressive symptoms has not allowed to submit to a histologic diagnosis. For the patients which the histo-pathological diagnosis was known and for those in which to effect it, the treatment has included both the chemotherapy and the radiotherapy. The fractionation schedule usually has included initial fractions of 300-400 cGy (2-4 fractions) followed by conventional fractionation of 180-200 cGy. The RT total dose delivered is varied by 2000 cGy to 5000 cGy

Results: With regard radiotherapy delivered, in 5 (9%) of the 55 patient essays we have observed a complete regression of the SVCS, while in 27 (49%) the response has been partial, stability of illness has been underlined in 15 (27%) patients and disease progression in 8 (15%) patients.

Conclusion: In summary, in the SVCS the clinical symptoms often requires an urgent intervention. Survival depend on the status of patient's disease and on the histologic type of the tumor. Radiotherapy is effective in the treatment of the initial SVCS and in the patients that relapsed or with recurrent illness. The radiotherapy produces a good control of the symptoms. There is no necessity of ample fractions in the initial treatment. In the reirradiation, the radiotherapy on mediastinum is one of the most greater components of the palliation. Moreover, in presence laryngeal stridor the radiotherapy can be administered before the histological diagnosis is available.

EP-1437

Radiofrequency, Cementoplasty and Radiotherapy: combined strategy in patients with bone metastases

A. Daidone¹, F. Verderame², A. Toscano³, C. Rinaldi⁴, S. Montalbano⁵, T. Angileri²

¹U.O. Radioterapia Oncologica Villa Santa Teresa, Radioterapia Oncologica, Bagheria, Italy

²U.O. Diagnostica per Immagini Villa Santa Teresa, Diagnostica Per immagini, Bagheria, Italy

³Istituto Ortopedico Rizzoli, Ortopedia, Bagheria, Italy

⁴*U.O. Fisica Medica Villa Santa Teresa, Radioterapia Oncologica, Bagheria, Italy*

⁵*Servizio di Anestesia, Diagnostica per immagini e Radioterapia, Bagheria, Italy*

Purpose or Objective: To evaluate the feasibility and effectiveness of combining radiofrequency (RF), cementoplasty (CP) and Radiotherapy (RT) for pain treatment of bone metastasis (mts) in oligo-metastatic patients (pts).

Material and Methods: From April 2015 to September 2015 twelve pts. (9 men, 3 women; median age 64 years) with 12 injuries to bones (vertebral column n = 9; femur, n = 1; sacrum, n = 2) were treated. Diagnosis of bone mts and then its treatment should be based on the combination of different elements: clinical evaluation, CT, MRI and nuclear medicine patterns. The mini-invasive treatment of oligo-metastatic pts aims pain relief that improving the quality of life; treat biomechanical stability of the spine; and an antineoplastic effect - cytoreductive. RF ablation was performed with the pts under sedation a CT - guidance, and was followed by cement injection. Pain relief was valuated with visual analogue scale (VAS) score. After 10 days on average, the patient was subjected to Stereotactic-RT or Volumetric Modulated Arc Therapy (VMAT) technique and a total dose of 20-30 Gy.

Results: Technical success and pain relief was archived in all pts. Pain rating with the VAS decrease from a mean of 9 to a mean of 4, and after 3 month was detected a mayor decrease (2,5). We recorded an overall improvement in the quality of life measured with a suitable test There was no particular toxicity. At present no patient died for progression of disease. The evolution of the disease will be evaluated with the use of MRI.

Conclusion: Our data showing the importance of a multi-disciplinary approach oligo-metastatic patients. RF with CP and RT carried out by experts is effective for pain relief and functional recovery in patients with painful bone metastases and can significantly improve quality of life.

EP-1438

Radiosurgery to the resection cavity of brain metastasis: Long term efficacy

A. Leysalle¹, J. Doyen¹, K. Benezery¹, F. Almairac², D. Fontaine², V. Bourg³, J. Darcourt⁴, P.Y. Bondiau¹

¹*Antoine Lacassagne Center, Radiotherapy, Nice, France*

²*CHU Pasteur, Neuro Surgery, Nice, France*

³*CHU Pasteur, Neurology, Nice, France*

⁴*Antoine Lacassagne Center, Nuclear Medecine, Nice, France*

Purpose or Objective: Few phase II trials have been performed to analyse the efficacy of post-operative stereotactic ablative radiotherapy (SABR) for brain metastases. The aim of the present study was to analyse outcome of this strategy in another cohort.

Material and Methods: Between September 2011 and February 2015 a total of 49 patients (49 lesions) were treated and available for analysis. Eligibility criteria included histologically confirmed malignancy with 1 intra parenchymal brain metastase, age ≥18 years, Karnofsky performance status (KPS) ≥70 and controlled extracranial disease. Fourty-two patients have been treated with a single fraction of 18 Gy, and 7 patients with 5 fractions of 5-7 Gy (median dose of 31 Gy) if tumor size was more than 3 cm. SABR treatment was prescribed to the 80% isodose. Survival was evaluated with the Kaplan Meier method.

Results: The median follow-up was 14 months (range, 2-45). SABR to the surgical bed was performed 41 days (13-105) after surgery. Overall, there were 8 local failures (LF) resulting in a 6 months, 1- and 2-year local control rates of 97.9%, 86%, and 74.9%, respectively. The 1- and 2-year overall survival rates were 62.6% and 39%. The 6 months, 1- and 2-year encephalic control rates were 72.9%, 56.7%, and 34.6%, respectively. The Biological Effective Dose, histology,

and time interval between surgery and SABR did not correlate with LF in univariate analysis ($p > 0.05$, Log-Rank). Tumor maximal diameter >3 cm was associated with an increased rate of LF in comparison with smaller tumors (one-year rate LF of 30% vs 7.1%, $p=0.02$, Log-Rank). Seventy percent of patients died because of extra cranial disease progression while 30 % of patient because of intracranial disease progression. For 14 patients with multiple recurrent brain metastases, the whole brain radiotherapy was performed 294 days (126-812) after SABR.

Conclusion: In this cohort postoperative SABR was associated with high rates of local control and encephalic tumor control, especially for brain metastases <3 cm.

EP-1439

Percutaneous pedicle screw fixation for the treatment of unstable spinal metastases

J.J. Verlaan¹, A.L. Versteeg¹, P. De Baat², T. Jiya³, C.H. Diekerhof⁴, G. Van Solinge⁵, F.C. Oner¹

¹*University Medical Center Utrecht, Orthopedics, Utrecht, The Netherlands*

²*Catharina Hospital, Orthopedics, Eindhoven, The Netherlands*

³*VU University Medical Center, Orthopedics, Amsterdam, The Netherlands*

⁴*St. Elisabeth Hospital, Orthopedics, Tilburg, The Netherlands*

⁵*Isala Clinics, Orthopedics, Zwolle, The Netherlands*

Purpose or Objective: Unstable spinal metastases require surgical stabilization often followed by radiotherapy for local tumor control. However, surgical stabilization and radiotherapy are not very compatible treatment modalities. A frequent complication of surgical stabilization after irradiation is disturbed wound healing which can have a devastating impact on quality of life. Advancements in surgical techniques has led to the development of less invasive surgical (LIS) procedures. LIS procedures aim to achieve similar clinical outcomes, as compared with open procedures, but with less approach related morbidity. Additionally, improved wound healing after LIS procedures may allow earlier administration of adjuvant treatments. However, little is known concerning the complications after LIS procedures for the treatment of spinal metastases. Therefore the aim of this study was to determine the incidence and characteristics of complications after percutaneous pedicle screw fixation (PPSF) for the treatment of unstable spinal metastases.

Material and Methods: An ambispective multicentre cohort study of patients who underwent PPSF between 2009 and 2014 for the treatment of unstable spinal metastases was performed. Data regarding demographics, tumor histology, surgical treatment, neurological status, complications and survival were systematically collected.

Results: A total of 101 patients were identified, 45 males and 56 females with a mean age of 60.3 years (± 11.2). The most common primary tumors (in hierarchical order) were breast cancer (25%), multiple myeloma (25%), lung cancer (13%) and renal cell carcinoma (10%). Ninety-three per cent of the patients were neurologically intact at the time of surgery. The median operating time was 122 minutes (range 55 - 325) with a median blood loss of 100 ml (N=41). The overall median survival was 11.0 months (range 0-70 months) with 79 (78%) patients being alive three months postoperative. Eighty-seven per cent of the patients was ambulatory within three days postoperative. A total of 30 complications occurred in 18 patients. Non-surgical adverse events (9%) were most commonly encountered. Wound complications occurred in 4 patients, including 2 deep wound infections with one requiring surgical debridement. Prolonged operating was associated with increased risk of post-operative complications ($P=0.041$). No relation between the administration of pre- or postoperative radiotherapy and the occurrence of complications could be determined.

Conclusion: A complication rate of 18% was found after less invasive surgery for the treatment of spinal metastases. Promising clinical outcomes were demonstrated in terms of minimal blood loss, high rates of early post-operative ambulation and few wound complications, which may allow earlier administration of adjuvant oncological treatments.

EP-1440

Tokuhashi Scoring and Karnofsky Scale: correlated with prognosis in spinal cord compression?

D. Esteban¹, J.P. Marin¹, I. Prieto¹, A. Idoate¹, W. Vasquez¹, A.M. Pérez Casas¹

¹Hospital Universitario Fundación Jiménez Díaz, Oncología Radioterápica, Madrid, Spain

Purpose or Objective: Functional evaluation is crucial in the approach of patients, and the most commonly used functional evaluation tool in cancer patients has been the Karnofsky Scale (KS). A KPS of less than 50% suggests a high mortality risk within 6 months. The Tokuhashi scoring system (TS) is a survival prediction in patients with spinal metastasis. For patients with total TS of 8 or less points, TS predicts a survival of 6 months or less. This study aims to compare KPS and TS for life expectancy in palliative patients with spinal cord compression.

Material and Methods: A sample of 79 patients with cord compression diagnosed from 2007 to 2014 was obtained by consecutive sampling, and KPS and TS were calculated for each patient. The analysis was performed retrospectively, with survival data registered until October 2014. Percentage of patients with KPS 50% and TS ≤ 8 are shown and compared with the survival percentage.

Results: With an average follow up of 4 months (range 0-45), 52.5% of the sample showed KPS ≤ 50% and 80.8% TS ≤ 8. At dead line, 10.3 % continued walking, 2.6 % needed wheelchair, 48.7 % died and 38.5 % were lost in follow up. For patients with follow up, 90% with TS ≤ 8 lived less than 6 months and 90% of patients with KPS ≤ 50% lived less than 6 months.

Conclusion: Both prognostic scoring systems show similar survival rates in groups KPS ≤ 50% and TS ≤ 8, adding evidence to the Tokuhashi scale as a predictor of survival.

Electronic Poster: Clinical track: Elderly

EP-1441

IMRT in elderly woman with breast cancer: are comorbidities related to toxicity?

A. Fiorentino¹, R. Mazzola¹, N. Gaj Levra¹, S. Fersino¹, R. Francesco¹, R. Ruggieri¹, S. Naccarato¹, F. Alongi¹

¹Sacro Cuore Don Calabria Hospital, Radiation Oncology Department, Negrar, Italy

Purpose or Objective: To investigate the feasibility, the tolerability and the impact of comorbidity assessment on the compliance of adjuvant Intensity Modulated Radiation Therapy (IMRT) and simultaneous integrated boost (SIB) in elderly patients with a diagnosis of breast cancer after breast-conserving surgery (BCS).

Material and Methods: Between 09/2011 to 02/2014, 40 consecutive women with a diagnosis of early stage breast cancer were treated with SIB-IMRT after BCS in our Institution. Inclusion criteria were: age ≥ 70 years, pT1 -2 disease, pN0-1, no neoadjuvant chemotherapy, non-metastatic disease. A dose prescription of 50 Gy in 25 fractions was prescribed to the whole breast (PTVbreast) and an additional dose of radiation on the tumour bed was prescribed (PTVboost). A dose prescription of 60 Gy in 25 fractions to PTVboost was used in patients with negative margins after surgery, whereas if the margins were close (< 1 mm) or positive (without a new surgical resection) a dose of 64 Gy was prescribed. Charlson Comorbidity Index (CCI) was used for comorbidity scoring. All patients were followed with

periodic clinical evaluation. Acute and late toxicity were scored using the EORTC/ROG radiation morbidity score system. Both patient and physician recorded cosmetic outcome evaluation with a subjective judgment scale at the time of scheduled follow-up.

Results: Median follow-up was 36 months. At the time of the analysis, OS and LC rates were 100%. All patients completed the SIB-IMRT without interruptions. Acute skin toxicity was recorded as follow: grade 0 in 5 patients (12.5%), grade 1 in 25 cases (62.5%), grade 2 in 10 patients (25%). Regarding late adverse events, skin toxicity was registered as follow: grade 0 in 27 patients (67.5%), grade 1 in 13 cases (32.5%). No toxicity ≥ grade 2 was registered. At statistical analysis, the presence of comorbidities and the breast volume > 700cc were related to skin grade 2 acute toxicity (p=0.01, p=0.04). In terms of cosmetic results, 98% and 2% of patients considered the result as good /excellent and as fair after RT, respectively. No patients had a poor cosmetic outcome.

Conclusion: These data support the feasibility and safety of SIB-IMRT in elderly patients with a diagnosis of breast cancer following BCS with acceptable acute and late treatment-related toxicity. Moreover, the absence of comorbidity reduced the risk of acute radiation side effects.

Oligometastatic colorectal cancer in elderly patients: role of stereotactic body radiation therapy

D. Franceschini¹, E. Clerici¹, L. Cozzi¹, A. Tozzi¹, C. Iftode¹, C. Franzese¹, T. Comito¹, F. De Rose¹, P. Navarria¹, G.R. D'Agostino¹, E. Villa¹, L. Rocco Luca¹, A.M. Ascolese¹, F. Zucconi¹, M. Scorsetti¹

¹Humanitas, Radiotherapy And Radiosurgery, Rozzano, Italy

Purpose or Objective: To report about clinical outcome of stereotactic body radiation therapy (SBRT) in the treatment of oligometastatic disease in elderly patients affected by colorectal cancer.

Material and Methods: Patients with 1-4 inoperable metastases were treated with SBRT. Dose prescription ranged from 40 to 75Gy in 3-8 fractions. SBRT was delivered using the volumetric modulated arc therapy technique with flattening filter-free photon beams. The primary end points were in-field local control (LC) and toxicity. Secondary end points were overall survival (OS).

Results: 52 patients with 57 total metastases were treated. Mean age was 79.85 years (range 73.57-88.56). 47 patients (90.4%) had a single lesion; the remaining had 2 lesions. 34 lesions (59.6%) were located in the liver, 18 (31.6%) in the lungs and the remaining 5 (8.8%) were nodal or adrenal metastases. Local response was observed for 35 lesions (61.4%), with 19 complete responses and 16 partial responses, while local progression in 18 lesions (31.6%); stable disease was recorded in 4 cases (7%). Actuarial 1, 2 and 3 year LC was 92%, 78 % and 71%. At time of analysis, with a mean follow up of 2.2 years (range 0.2-4.9), 38 patients (73.1%) were still alive, while 14 (26.9%) died (11 patients died for disease progression). Actuarial 1, 2 and 3 year OS were 98%, 89% and 61.1% respectively. Treatment-related Grade 2 toxicity was observed in two patients (3.8%); Grade 1 toxicity in five patients (9.6%) and no toxicity was observed in 86.6% of the cases. No G3-4 toxicity was recorded.

Conclusion: SBRT is a safe and effective therapeutic option for the treatment of oligometastatic disease in the elderly affected by colorectal cancer with acceptable rates of LC and low treatment related toxicity. The use of SBRT for oligometastatic disease in the elderly can be considered as a valuable approach, particularly for patients with fragile status or refusing other approaches.

EP-1443

Radical hypofractionated VMAT-RA for stage III NSCLC in the elderly: feasibility and toxicity.

A.M. Ascolese¹, D. Franceschini¹, F. De rose¹, L. Cozzi¹, P. Navarria¹, A. Tozzi¹, C. Iftode¹, E. Villa¹, C. Franzese¹, T. Comito¹, G. D'agostino¹, S. Tomatis¹, L. Liardo¹, M. Scorsetti¹
¹Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

Purpose or Objective: Purpose: To analyze feasibility and toxicity of radical hypofractionated RT schedules in elderly patients with NSCLC

Material and Methods: Material and methods: Elderly patients (≥70 years old) affected by stage III inoperable NSCLC were treated in our institution with radical IMRT (VMAT RA) according to moderately hypofractionated schedules: 56 Gy/20 fractions or 55 Gy/22 fractions or 50 Gy/20 fractions depending on dose constraints of adjacent organs at risk. Patients underwent simulation CT in supine position, immobilized with a thermoplastic mask. PET CT was performed for simulation and coregistered with CT. Primary end point of this analysis were acute and late toxicities, secondary end points were local control and overall survival.

Results: Results: 41 patients, treated between January 2013 and April 2015, were included in this analysis. Mean age was 78.59 years (range 70-86). 22 patients were staged IIIA, 19 patients IIIB. All but one patients had pathological nodal involvement (N1:5, N2: 24, N3: 11). Most of patients were unsuitable for chemotherapy for comorbidities and poor general conditions. 15 patients received chemotherapy before RT, concomitant RT-CHT was not allowed. Acute G1-2 toxicity was recorded in 25 patients(61), mostly esophagitis, dyspnea and dry cough. Late toxicity was recorded in 13 patients, the most reported side effects were pneumonitis and dyspnea. No G3 or G4 acute or late toxicity were recorded. A complete response was obtained in two patients, 26 showed a partial response, while progressive disease was recorded in 2 cases. At time of analysis, with a mean follow up of 9.89 months (range 1.08-25.43), 17 patients died for disease progression, one patient died for other causes, 8 patients were alive with distant metastases and 15 were alive without distant progression. Actuarial OS at 1 and 2 years were 51.3% and 35.1% respectively. Mean estimated OS was 15.12 months (range 12.02-18.22). Actuarial local control at 1 and 2 years were 72%. 10 patients experienced local progression. Mean estimated LC was 12.4 months (range 9.6-15.1).

Conclusion: Conclusion: Radical hypofractionated IMRT (VMAT RA) is a valid treatment for locally advanced inoperable NSCLC in elderly frail patients. Our study shows that this approach is safe and feasible also in a fragile elder population. Survival data are satisfactory.

¹³Fondazione Seragnoli, Hospice Bentivoglio, Bologna, Italy

Purpose or Objective: To assess the efficacy and safety of a Short-course Accelerated Radiation therapy (SHARON) regimen in the palliative treatment of locally advanced or metastatic cancers in elderly patients.

Material and Methods: Eligibility criteria of this analysis (pooled analysis of 3 phase II studies) were: patients with histologically confirmed solid cancers, age ≥80 years, patients with an expected survival > 3 months and Eastern Cooperative Oncology Group (ECOG) performance status of ≤3. The primary endpoint was to evaluate the symptoms response rate produced by a radiotherapy regimen based on the delivery of 4 radiotherapy fractions (5 Gy per fraction) with a twice daily fractionation in two consecutive days

Results: Twenty-four patients were included in this analysis. Characteristics of the patients were: male/female: 17/7; median age: 87.0 years (range: 80-98). ECOG performance status was < 3 in 16 patients (66.7%). Six patients (25.0%) had locally advanced thoracic cancers, 13 patients (54.2%) had advanced primary or metastatic H&N tumors and 5 patients (20.8%) had complicated bone metastases. With a median follow-up time of 5.0 months (range, 1 to 8 months), eleven G1-G2 acute skin (45.9%) and G1-2 mucositis (12.5%) toxicities were recorded. One patient (4.2%) experienced G1 acute gastro-intestinal toxicity and only 1 patient (4.2%) experienced G3 acute mucositis. Of 24 symptomatic patients, 19 showed an improvement or resolution of baseline symptoms (overall palliative response rate: 79.2%). Three-months overall survival was 89.7% (median survival time: 7.0 months; 95%CI 5.4-8.6 mo). Median survival without symptoms progression was 5.0 months (95%CI: 2.5-7.5 mo). In 23 patients with pain, a significant reduction of this symptom was recorded in terms of VAS (mean baseline VAS vs mean VAS after treatment: 3.9 versus 1.7, p=0.001).

Conclusion: Short-course accelerated radiotherapy in locally advanced or metastatic cancers is effective in terms of symptom relief and well tolerated even in older patients.

EP-1445

The role of radiotherapy in the conservative treatment in bladder cancer elderly patients

M.S. Mariaquila Santoro¹, M.A.M. Maria Angela Molinaro², A.P. Armando Pingitore², L.R.F. Lucia Rachele Fabiano², A.C. Angelo Chirillo², L.P. Luigi Perrone², E.M. Elvira Mazzei², A.S. Angela Saccomanno², R.M. Rosa Molè², A.D. Anna Destito², M.L. Marianna Lacaria¹, D.P. Domenicantonio Pingitore¹

²Hospital Pugliese-Ciaccio- Via Pio X- 88100 Catanzaro, Department of Hemato-Oncology- - Operative Unity of Radiotherapy and Radiobiology-, Catanzaro, Italy

Purpose or Objective: The optimal treatment of bladder cancer has been a subject of continuous controversy. In North America, as well as in Europe, the radical cystectomy as the standard option for invasive bladder cancer. In the western countries the elderly ones constitute the part of the population in more rapid growth and, insofar, the group to

taller risk to develop a cancer. The elderly patients, because of the presence of concomitant pathologies, they set to the clinician particular problems and limitations in the therapeutic planning. Several groups have reported the value of combination of conservative surgery and radiochemotherapy or radical radiotherapy alone in patients affected by bladder cancer. In this study we have retrospectively analyzed the prognostic factors influencing survival and relapse free-survival after radiotherapy following transurethral resection (TURB) for bladder cancer.

Material and Methods: Between May 2013 and December 2014, 33 patients with bladder cancer have been treated at the Operative Unity of Radiotherapy and Radiobiology, Hospital of Catanzaro. Of these, 19 patients were treated with radiotherapy alone (RT) and nine with platin based radio-chemotherapy (RCT) after TURB. Overall survival (OS) and Relapse-Free Survival (RFS) were analyzed with the Kaplan and Meyer methods. Comparisons were made using the log-rank test. In the analysis, we proposed the following prognostic factors as affecting the development of relapse after initial treatment: Univariate analysis was performed for age, grade, R-status after initial TURB, T-category relevant to the endpoints initial response, survival and bladder preservation.

Results: Median age was 78 years (range 66-90 years), while the median follow-up is 15 months (range 5-42 months). All patients were treated with three-dimensional conformal therapy (3D-CRT). The total dose of radiotherapy ranged 5040 cGy to 6000 cGy. Complete remissions were achieved at 57% after RT and TURB. Toxicity was acceptable. Further significant prognostic factors were pT-category and R-status. For all patients survival was 31% after 2 years and 25% at 4 years, while the relapse-free survival rates were 19% and 15% at 2 and 4 years, respectively. In the univariate analysis the only significant factor for survival and relapse-free survival and bladder preservation was the R-status after initial TURB

Conclusion: In conclusion, treatment of bladder cancer by TURB and RT alone is an alternative to primary cystectomy, for the elderly patients. Initial TURB is recommended to be as radical as possible.

EP-1446

Multifraction radiotherapy for painful bone metastases in elderly patients: 20 Gy versus 8 Gy
F.M. Giugliano¹, L. Iadanza², R. Di Franco³, D. Borrelli¹, A. Pepe⁴, F. Francomacaro¹, P. Muto³

¹Emicenter, Radioterapia, Casavatore NA, Italy

²INT "Fondazione G. Pascale", Fisica Medica, Napoli, Italy

³INT "Fondazione G. Pascale", Radioterapia, Napoli, Italy

⁴Studio di Radiologia Prof V. Muto, Radioterapia, Napoli, Italy

Purpose or Objective: to compare 2 multifraction radiotherapy (RT)schedules in the palliation of painful bone metastases in elderly patients, assessed at baseline with the Cumulative Illness Rating Scale for Geriatrics (CIRS-G).

Material and Methods: 132 elderly patients were analyzed. Seventy-seven patients received a single 8Gy in single fraction and 55 received 20 Gy in 5 fractions. The choice of the treatment schedule was related to comorbidity, disability, target size and compliance. Pain intensity was measured with Numeral Rating Scale (NRS: 0 = no pain; 10 = high pain). Complete response was defined a pain reduction > 3 of three points, partial response as a pain reduction ≥ 2 (2 \leq pain reduction ≤ 3), no response was defined by pain score < 2. Pain evaluation was recorded at baseline and at 1-4-8 weeks after completing RT.

Results: overall response: 90.3% in 8 Gy arm (49.8% complete and 40.5% partial), 94.6% in 20 Gy arm (44.6% complete and 50%partial). No high grade toxicity were reported. The relief of pain was attained faster with single fraction (p-value ~ 0.2). We observed maximum response of pain control after 8 weeks and no significant differences were noted between

two groups. The re-treatment rate was 17.6% vs 11.1% respectively.

Conclusion: no significant differences between the two arms in terms of pain response, pain control and toxicity. Our experience showed that not influenced by age, but in the elderly, life expectancy, comorbidities evaluated with the CIRS-G, and compliance, are crucial in selecting of shorter treatment.

EP-1447

Lung stereotactic body radiation for oligometastasis treatment in the elderly

L. Larrea¹, E. López¹, P. Antonini¹, V. González¹, M. Baños¹, J. Bea¹

¹Hospital NISA Virgen del Consuelo, Radiation Oncology Department, Valencia, Spain

Purpose or Objective: To evaluate stereotactic body radiation therapy (SBRT) for oligometastatic lung tumors in patients 75 years old or older.

Material and Methods: Between 2002 and 2015, 24 elderly patients with 34 lung metastases were treated using SBRT at our institution. SBRT procedure involved: Slow-scan computed tomography (CT) simulation with immobilization devices, contouring the target volume in 3 sets of CTs, superimposing the volumes in the planning system to represent the internal target volume and dose calculation using heterogeneity correction. Radiation delivery with multiple static planar or non-coplanar beams and arc therapy assured conformal dose distribution and steep fall-off of the radiation. The prescribed dose was 3 fractions of 15 Gy each (90%) given in 6-10 days or a single 30-Gy fraction (10%), with at least 95 % of the ITV covered by the 95% isodose line. Dosimetric constraints were set for surrounding organs at risk. Repeated cone-beam CT were used to verify daily positioning. Toxicity and radiologic response were assessed in follow-up, using standardized criteria (RTOG and RECIST) and analyzed retrospectively. Survival rates and toxicities were calculated by the Kaplan-Meier method.

Results: Median patient age was 79 years (75-85). The origin of the metastases was: non-small cell lung cancer (53 %), colorectal adenocarcinoma (24 %), urotelial tumors (8.5 %), thyroid carcinoma (8.5 %), endometrial adenocarcinoma (3%) and parotid tumor (3%). All patients had good performance status at the moment of treatment (ECOG PS 0-1). Fifty-six percent of all patients also received systemic treatment before or after SBRT. Mean tumor volume was 10.7 cm³ (0.5-106). The only acute toxicity reported was rib pain, grade 2, in 1 patient. No grade > 3 acute or any chronic toxicities were identified. The median follow-up was 11 months (1-60). The 6, 12 and 18 month overall survivals were 97, 88 and 85 %. Local control in the irradiated volume is 97 %, the only failure occurring in a patient who also had distal progression from colon adenocarcinoma.

Conclusion: SBRT is an excellent treatment option for lung oligometastasis in elderly patients. Our encouraging results are in line with those reported in recent literature for younger patients.

EP-1448

Outcomes and tolerance of larynx preservation treatment in the older population

M. Keys¹, S. Brennan¹, O. McArdle¹, I. Fraser¹, N. El Beltagi¹

¹St. Lukes Radiation Oncology Network, Radiation Oncology, Dublin 6, Ireland Republic of

Purpose or Objective: Some recent data has questioned the impact of larynx preservation strategy on overall survival. The median age of patients in most major larynx preservation trials was 55-60 years with little representation of the older age group. The aim of this study is to review the tolerance and outcomes of larynx preservation treatment in the older population (≥ 65).

Material and Methods: Data was obtained from the St. Luke's Radiation Oncology Network patient registry. Patients with stage III & IV non-metastatic laryngeal cancer who were fit for radical intervention and offered larynx preservation treatment were identified between 2008-2014. Those who were aged ≥ 65 years at the time of treatment were included in this study.

Results: A total of 68 patients were identified who met the selection criteria. The majority of patients were male (88%) and between 65-74 years, with a median age of 70. Of the patients identified 6% of patients were changed from radical to palliative intent and received a radiation dose of 40Gy. Currently, 45% of patients are still alive with 10% having required salvage surgery in the form of total laryngectomy post treatment for local recurrence. Of those studied, 60% of patients received radiotherapy only and 40% received combined chemoradiation. Patients who had combined modality treatment had significant toxicity from chemotherapy related to myelosuppression and febrile neutropenia. Among those who received chemotherapy 51% did not complete the prescribed chemotherapy course secondary to toxicity. There were 17 patients (25%) who required enteral feeding via a gastrostomy tube and 2 requiring NG feeding during their treatment course.

Conclusion: Patients who are 65 years or greater seem to tolerate combined chemoradiation poorly. The appropriate selection of patients suitable for larynx preservation treatment in this age group is vital in achieving comparable survival and outcomes to the published major trials.

EP-1449

Personalizing cancer care in elder early-breast-cancer patients after conservative surgery

M.D. De las Peñas-Cabrera¹, P.M. Samper Ots¹, E. Amaya Escobar¹, M. Hernández Miguel¹, A. Seguro Fernández², R. García Marcos², G. Ruíz Galán², A.B. Cuesta Cuesta³, M. De Matías Martínez³, S. Hoyos Simón⁴, M.R. Noguero Meseguer³

¹Hospital Rey Juan Carlos, Radiation Oncology, Mostoles - Madrid, Spain

²Hospital Rey Juan Carlos, Radiophysicist, Mostoles - Madrid, Spain

³Hospital Rey Juan Carlos, Oncology Gynecology, Mostoles - Madrid, Spain

⁴Hospital Rey Juan Carlos, Oncology, Mostoles - Madrid, Spain

Purpose or Objective: To evaluate the use of a new algorithm for making decisions in elderly early breast cancer patients after tumorectomy plus hormone therapy.

Material and Methods: This is a prospective preliminary study stating in June 2014. According to the recommendation of the "Innovation and Best Practices" of the "IDC-Salud health group", a new algorithm to manage elderly (> 70 years) patients with early breast cancer after conservative surgery was designed. This procedure considered the results of the CALGB 9343 randomized trial for counseling patients about the convenience or not to use radiotherapy. Inclusion criteria included patients older than 70 years, early breast cancer (T \leq 2cm, clinical N0), treated by tumorectomy. In order to decide whether or not to indicate external radiotherapy, the new algorithm took into account the following parameter: life expectation estimated by a specialist in Geriatric Oncology using primarily patients' age and the Charlson Comorbidity Index Score. Decision was against to indicate radiotherapy in women fulfilling the following conditions: life expectation 5 years. Those patients were managed according to both the Canadian nomogram (www.tuftsmedicalcenter.org/ibtr/) which calculates the 10-years local recurrence risk; and the MD Anderson nomogram (www3.mdanderson.org/app/medcalc/bc_nomogram5/index.cfm?pagename=opcs), which calculates the risk of mastectomy at both 5 and 10 years in elderly patients. The criteria to decide whether or not indicate radiation therapy in these patients was based on the calculated reduction in

the rate of either local recurrence or mastectomy as follows: $\leq 5\%$ radiotherapy was not indicated; reduction between 5-10% individualize case, reduction $\geq 10\%$ radiotherapy should be always indicated. All patients signed a consent form to participate in the study and to assume the risks of local recurrence and/or further mastectomy.

Results: Since June 2014, 191 women with breast cancer were attended. 14 for them, (7.3%) were older than 70 years. From them seven fulfill the inclusion criteria (3.6%) and were eligible for the study. They all accepted to be included in the study. Data related to decision making are shown in Table 1 and 2.

After a detailed discussion explaining in depth that the benefits of the treatment was below $\pm 5\%$ and the potential risks and side effects, 37.5% (3/7) declined to be treated being surprisingly those who potentially could be more benefited from this therapy as they were at higher risk of recurrence.

Conclusion: Patients fulfilling the criteria represent a low proportion of breast cancer patients. This preliminary study suggests that cultural and psychological aspects should be taken into account when counseling elderly patients with breast cancer in early stages.

Electronic Poster: Clinical track: Health services research / health economics

EP-1450

Incremental radiotherapy treatment complexity: the effect on daily patient treatment times

A. Munshi¹, T. Ganesh¹, B. Mohanti¹

¹Fortis Memorial Research institute, Radiation Oncology, Haryana, India

Purpose or Objective: Modern day radiation oncologists have multiple options of treatment techniques including 3 D conformal radiotherapy (3 D CRT), Intensity modulated radiotherapy (IMRT) (Step shoot and dynamic) and volumetric modulated arc therapy (VMAT). This study assessed the effect of incremental treatment complexity on patient treatment times and the treatment times for first day and subsequent day treatments.

Material and Methods: From Nov 2014 to Feb 2015, data of all the patients treated in our department with all techniques (3D CRT, IMRT, and VMAT) was analyzed using the Mosaic system. Treatment time as computed by Mosaic is the difference between the time at which the patient record is opened in Mosaic Sequencer for treatment and the time at which the activity is captured after all treatment fields are completed. Treatment time on the first day and subsequent days for each technique was separately analyzed. Data was analyzed using SPSS software.

Results: All timings were recorded in minutes. *First day treatment sessions:* For 18 first day sessions of 3 D CRT, the average treatment time was 30.37 (SD ± 11.57). For 81 first day VMAT treatments the average time was 29.49 (SD ± 35.27) while the corresponding time for 5 dynamic and step/shoot IMRT sessions was 13.81 (SD ± 7.72). *Subsequent daily treatments:* For 240 sessions of daily treatments of 3D CRT, the average treatment time was 15.53 (SD ± 12.31). For 2412 daily treatment VMAT sessions, the average treatment time was 15.82 (SD ± 15.37). For combined dynamic (117 sessions) and step/shoot IMRT (33 sessions), the average treatment time was 19.62 (SD ± 5.77). Overall daily treatment times were similar for VMAT as compared to 3 DCRT (p > 0.05). The difference in treatment times for first day treatment versus subsequent first day treatment were statistically significant for 3D CRT as well as VMAT. (p < 0.05)

Conclusion: More complex radiotherapy techniques like VMAT require nearly same treatment times compared to 3 D conformal techniques on a daily basis. However, first day treatment times for all treatment techniques are significantly

more than their corresponding subsequent daily treatment times. Radiation oncologists need to be cognizant of these issues in everyday management of their patients.

EP-1451

Workflow Management: Impact on the ergonomics of a Radiotherapy department in a developing country

R. Miriyala¹, P. Thakur¹, A.O. Singh¹, A. Gupta¹, B.S. Yadav¹, N. Kumar¹, R. Rattan¹, S. Ghoshal¹

¹Post Graduate Institute of Medical Education and Research, Radiotherapy, Chandigarh, India

Purpose or Objective: Integration of multiple technical aspects like treatment prescription, planning, delivery and quality assurance is paramount for smooth and efficient functioning of any radiotherapy department. In the developing world, bearing 60% of global cancer burden, efficient management of available resources assumes even greater importance. Workflow management software is a tool available for effective resource management in radiotherapy. The purpose of this audit is to evaluate the impact of implementation of workflow management on the organisational ergonomics of our department.

Material and Methods: Workflow management software (Aria v 11.0™) has been in use in our department since October 2014. Prior to that, on-paper documentation was the predominant mode of communication between physicians and physicists for all forms of conformal treatment planning. Case records of patients who were treated with conformal radiation in the two month period prior to and after the implementation of workflow management were retrospectively evaluated. Proportion of cases for which treatment was started on the day of appointment was taken as a surrogate for work efficiency, which was the primary end point in this study. Other variables, like time available for target delineation (Td), treatment planning (Tp) and plan evaluation (Te) were analysed for different conformal techniques as secondary end points.

Results: Of the 343 cases analysed, 190 were treated before implementation of workflow management (group 1), while 153 were treated after that (group 2). The mean gap between planning CT scans and date of treatment (overall planning time, $T_o = T_d + T_p + T_e$) was 5.25 days for group 1 and 6.53 days for group 2 ($p=0.104$).

Among 3D-CRT plans, 29% were not started on the day of appointment in group 1, while 20% were not started on time in group 2 ($p= 0.13$). However, mean time available for planning and evaluation ($T_p + T_e$) increased from 1.3 days in group 1 to 2.8 days in group 2 ($p<0.01$), without significant increase in overall planning time (T_o).

In group 1, 71% of IMRT plans were not started on time, while only 27.2% were not started on time in group 2 ($p<0.0001$). Overall planning time (T_o) for IMRT decreased from a mean of 9.4 days to 5.9 days, after workflow management ($p=0.013$), without significant compromise in the time available for planning and evaluation ($T_p + T_e$).

On multivariate analysis, workflow management was an independent factor determining work efficiency ($p=0.04$) irrespective of the diagnosis, physician or physicist.

Conclusion: Implementation of workflow management resulted in significant improvement in work efficiency, as evidenced by an increase in proportion of cases started on time; this improvement was more substantial for IMRT planning. Time available for planning and evaluation also significantly increased with workflow management. Such improvements in work efficiency are essential for resource management in developing countries.

EP-1452

The impact of individual surgeons on the likelihood of mastectomy in breast cancer

I. Boero¹, A. Paravati¹, R. Matsuno¹, E. Gillespie¹, J. Einck¹, L. Mell¹, J. Murphy¹

¹University of California San Diego, Radiation Medicine and Applied Sciences, San Diego, USA

Purpose or Objective: Substantial variations exist in the use of mastectomy and breast-conserving surgery (BCS or lumpectomy) to treat invasive cancer. No recent analysis has queried the broader role of individual surgeons play in the decision making process for BCS or mastectomy. The goal of this study was to evaluate the impact of individual surgeons on surgical procedures for definitive treatment of breast cancer in a large cohort of Medicare beneficiaries.

Material and Methods: 36,068 women with non-metastatic breast cancer undergoing primary surgery (either BCS or mastectomy) were identified from Surveillance, Epidemiology, and End Results-Medicare linked database from 2000 to 2009. Medicare claims were used to determine surgery type and provider. Health service area stratified, multi-level, multivariable logistic models clustered by surgeon were used to determine the impact of surgeons on the likelihood of mastectomy while controlling for a patient's clinical and demographic covariates.

Results: 8,327 women were treated with mastectomy. 20.9% of the variation in the likelihood of mastectomy was due to the individual surgeon; 18.8% of this variation in surgery was due to a patient's clinical and demographic status. The median odds ratio, which allows for a direct comparison between the effect of the cluster variable (surgeon) and the odds ratio (OR) of fixed covariates, was 2.43. The only variables with a greater impact than surgeon were regional lymph node surgery (OR 3.0, 95% confidence interval [CI]: 2.79, 3.23) and primary tumor size 2-5 centimeters (OR 2.79, 95% CI: 2.62, 2.97).

Conclusion: Surgeons have a substantial impact on a woman's likelihood of mastectomy for the treatment of invasive breast cancer. Further research should clarify the role of the patient in the decision making process.

EP-1453

Analysis on research and cooperation status of heavy ion

J. Tian¹, Q. Zhang¹, X. Wang¹, H. Zhang²

¹Gansu Cancer Hospital, Department of Radiotherapy, Lanzhou, China

²Chinese Academy of Science, Institute of Modern Physics, Lanzhou, China

Purpose or Objective: To analyze the status of research on heavy ion using the social network analysis methods and analytical methods bibliometric methods.

Material and Methods: We searched PubMed database by ("heavy ion radiotherapies"[Title/Abstract] OR "heavy ion radiotherapy"[Title/Abstract] OR "heavy ion therapy"[Title/Abstract] OR "heavy ion radiation therapies"[Title/Abstract] OR "heavy ion radiation therapy"[Title/Abstract] OR "carbon ion radiotherapies"[Title/Abstract] OR "carbon ion radiotherapy"[Title/Abstract] OR "carbon ion therapy"[Title/Abstract] OR "carbon ion therapies"[Title/Abstract] OR "carbon ion radiation therapies"[Title/Abstract] OR "carbon ion radiation therapy"[Title/Abstract] OR "Heavy Ion Radiotherapy"[Mesh]) OR ((("hellion ion"[Title/Abstract] OR "helenium ion"[Title/Abstract] OR "carbon ion"[Title/Abstract] OR "carbon ions"[Title/Abstract]) AND (Radiotherapy[Title/Abstract] OR radiotherapies[Title/Abstract] OR "radiation therapy"[Title/Abstract] OR "radiation therapies" [Title/Abstract] OR ("radiotherapy" [Subheading] OR "Radiotherapy"[Mesh])), to collect all relevant research on heavy ion. The related software was used to extract the information of author, country, year of publication, publication year, MeSH terms and journal name. SPSS17.0 was used to analyze the frequency and percentage. NetDraw software was used to draw the social network plot.

Results: 907 studies were retrieved, The number of studies on heavy ion were increased from 1975 to 2014, the author

mainly came from Japan, Germany and China, the number of research on carbon ions were more than the number of research on neon ion and helium ion (Figure 1); the published paper focused on the clinical research on the effectiveness of heavy ion for cancer, at the same time, heavy ions of animal, tumor cells and equipment design were also concerned, 30 kinds of tumor were researched. Cooperation degree of different researchers is not enough (Figure 1).

Conclusion: The number of research on heavy ion are increased, but there is an imbalance in regional development, the research topic focused on the clinical research and basic research topics, at the same time, the equipment and design of heavy ion are concerned.

EP-1454

Analysis on research status of proton

X. Wang¹, J. Tian¹, Q. Zhang¹

¹Gansu Cancer Hospital, Department of Radiotherapy, Lanzhou, China

Purpose or Objective: To analyze the status of research on proton using the social network analysis methods and analytical methods bibliometric methods.

Material and Methods: We searched PubMed and EMBASE database by “proton OR proton radiation OR proton beam therapy OR proton beam radiotherapy OR proton irradiation”, to collect all relevant research on proton. The related software was used to extract the information of author, country, year of publication, publication year, MeSH terms and journal name. SPSS17.0 was used to analyze the frequency and percentage. NetDraw software was used to draw the social network plot.

Results: 2637 studies were retrieved, The number of studies on proton from one study in 1975 to 556 studies in 2014. Figure showed the research in the global distribution. As for different parts of the tumor, mainly for urinary reproductive system tumor (n=349), soft tissue tumor (n=37), skin tumor (n=100), the reticular endothelial cell tumor (n=85), respiratory system tumor (n=232), pelvic tumors (n=10), nervous system tumors (n=531), thoracic and the chest tumor (n=15), the lymphatic system (n=85), the motor system tumor (n=150), the hematopoietic system tumor (n=14), head and neck cancer (n=269), digestive system tumors (n=318), cardiovascular system tumor (n=18), breast tumor (n=211), and abdominal tumor (n=12). As for benign tumors, mainly for epidermoid tumor, epidermoid cyst, ventricle meningioma, cystadenoma, dyeing neoplasia, choroid plexus papilloma, chondroma, cartilage tumor, cavernous hemangioma, inverted papilloma of the mammary gland, mammary gland fibroma and breast fibroadenoma, adenoma and acoustic neuroma. As for type of study, conference abstract (48.24%), conference paper (1.93%), study (38.36%), review (7.61%), letter (1.22%) and comments (1.22%), editor's note (0.59%), short-term observation (1%), and conference review (1%).

Conclusion: the number of studies on proton are increased, but the research in the global distribution is imbalance, many studies focus on the nervous system tumor, urogenital system tumor and digestive system tumor. About 50% published papers were conference abstract/paper.

EP-1455

Impact of the implementation of the radiotherapy workflow optimization software RT-Flow

F. Crop¹, J. Alquier², T. Lacornerie¹, Y. Grondin², X. Mirabel³, S. Besson², E. Lartigau³

¹Centre Oscar Lambret, Physics Department, Lille, France

²Surgiquil Institute, Clinical Applications, Grenoble, France

³Centre Oscar Lambret, Radiotherapy, Lille, France

Purpose or Objective: Workflow in radiotherapy involves a lot of different actors and different steps. Subsequently, the management of agendas, schedules and prioritization becomes difficult in a busy department. This results in delays and (first) sessions being delayed or cancelled without being able to be replaced. RT-Flow is a workflow optimization and visualization application (web based), supporting different workflows and clinical prioritization schemes. Our department works with both conventional retro scheduling and industry-based ConWip (management of a Constant Work-In-Progress rather than agendas) workflow [1].

Material and Methods: RT-Flow was implemented in 2014 (3 tomo's, 2 clinacs and 1 cyberknife). All evaluations were performed by year-to-year comparison: between 01/08 of 2013, 2014 and 2015 (+2500 patients/year). All numbers have been normalized to worked days, excluding breakdowns, holidays and maintenances for fair comparison. Productivity gain was evaluated for the following parameters: machine occupancy and number of first treatment sessions being delayed. Time between CT and prescription finalization has been evaluated before and after implementation of RT-Flow.

Results: Total machine utilization (fractions per worked day, excluding maintenances and failures) rose with >2% in saturated machine conditions. The number of delayed first sessions (all 6 machines combined, all reasons confounded) was halved from 23.6/month to 12.2/month. This was an indirect gain of productivity, as the time slot was most of the time not recovered from late delays. For the specific ConWIP organized Cyberknife, machine utilization raised with 6% (on top of the earlier 30% increase due to the ConWIP organization [1]). This increase was due to the better specific workflow and occupation management by RT-Flow, but also due to a slight change in case mix (3% less liver treatments for example). Mean time between CT and prescription

finalization was reduced by respectively 0.7 and 0.9 days for the conventional and ConWIP (no patient appointment) workflows. The implementation of RT-Flow reduced greatly the delays of MDs generally having prior long delays.

Conclusion: Implementation of the workflow optimization software RT-Flow has reduced the delays and improved productivity, whilst giving users better control over work and better prioritization for patients. Both conventional workflow and ConWIP workflows but also personnel stress levels have proven to be improved. Future work will focus on population TCP optimization and booking curves.

[1] Crop, F., Lacornerie, T., Mirabel, X. & Lartigau, E. Workflow optimization for robotic stereotactic radiotherapy treatments: Application of Constant Work In Progress workflow. *Oper. Res. Heal. Care* 6, 18-22 (2015).

EP-1456

What is the cost of reducing cardiac morbidities when treating breast cancers with radiotherapy?

M. Arunsingh¹, A. Mahato¹, A. Sadhukan¹, R. Achari¹, I. Mallick¹, R.K. Shrimali¹, S. Chatterjee¹
¹Tata Medical Centre, Department of Radiation Oncology, Kolkata, India

Purpose or Objective: There is no threshold limit for radiation induced cardiac toxicity, making it especially relevant for cardiac sparing radiation delivery in adjuvant breast radiotherapy. Deep inspiratory breath hold (DIBH) technique is one method for reducing the heart dose, however, it is resource intensive. This study analyses the cost of cardiac sparing using DIBH and its associated benefits.

Material and Methods: DIBH technique using Varian RPM, was used to deliver radiotherapy for 50 consecutive patients of left sided breast cancer. The time required in minutes and the number of personnel involved during each step of the planning and the treatment (40Gy in 15 fractions) were recorded. Weighted person hours (WPH) for each step were calculated and all the steps were summed up to arrive at the WPH for each patient. Radiographers, medical physicists and radiation oncologists were given a weightage of 1, 2 and 3 respectively for calculating the WPH. The data was analysed to see if experience reduces the time required. We also calculated the average WPH required for reducing the heart dose by 1 Gy.

Results: The mean age was 51 years. 14 patients were known hypertensive on medications while none of them were known ischemic heart disease patients. Three were suffering from COPD. Twenty nine patients had breast conservation surgery while the remaining 21 patients underwent mastectomy. The mean WPH was 21.49 for the entire cohort. The average mean heart dose (MHD) in the free breathing (FB) technique was 380.96cGy and 160.61cGy in the DIBH technique (p =0.002). Average WPH required for the DIBH planning process was 13.09 and 8.39 for delivery. Patients were divided into 2 cohorts, of 20 and 30 respectively, to assess if practice allowed reduction in DIBH WPH and this showed a decreasing trend of the WPH in the second cohort (22.2 vs 21.0, p=0.36). The average WPH required to reduce the MHD by 2.2 Gy was 22.54 WPH. The average person hours of the oncologist required to reduce the MHD by 2.2 Gy was 0.39 hours, while that of medical physicists and radiographers were 2.89 and 15.9 hours respectively.

	Radiographer	Medical Physicist	Radiation Oncologist
Average Person Hours required for a patient treated by DIBH technique	15.9 person hours	2.89 person hours	0.39 person hours
Formulas			
Weighted Person Hours = (Weightage x Person involved x Time in Minutes)/60 Person Hours = (Person involved x Time in Minutes)/60			

Conclusion: Although a resource intensive procedure, with practice the time required reduces with experience. On an average 10.25 WPH is required to reduce the MHD by 1 Gy, with 0.18 person hours of the oncologist versus 1.31 person

hours of physicist and 7.23 person hours of radiographers time.

EP-1457

Delineation of radiation treatment volumes: a regional network based on the software Radiotherap-e

P. Franco¹, F. Arcadipane¹, J. Di Muzio¹, U. Ricardi¹
¹Ospedale Molinette University of Turin A.O.U. San Giovanni Battista di Torino, Department of Oncology - Radiation Oncology, Torino, Italy

Purpose or Objective: Modern radiotherapy is able to provide highly precise and focused dose delivery with simultaneous target volume coverage and normal tissue avoidance. Proper selection and accurate definition of treatment volumes is of paramount importance. Anatom-e (Anatom-e Informations System Ltd, Houston, Tx) is a new platform able to drive, simplify, accelerate and standardize the contouring process in different oncological scenarios. Radiotherap-e is an online upgraded version providing the possibility to create an online network to share, discuss, control and optimize clinical cases, radiological images, radiotherapy contours and treatment approaches. We worked on the implementation of the aforementioned software in the Oncological Regional Network of Piedmont, Italy.

Material and Methods: Four pilot centers within the Oncological Regional Network of Piedmont, Italy were connected with the online Radiotherap-e platform. Challenging clinical cases (head and neck, lung, esophageal and rectal cancers) were exchanged within the system (Figure 1). Treatment choices and volume delineation strategies were analyzed and compared before and after the use of the software.

Results: The use of a unified distribution platform was able to eliminate compatibility issues based on different equipment or different treatment planning systems from site to site. Creation of consensus guidelines and common approaches took about 4 hours. Variation of treatment policies and contouring approaches due to platform use is under evaluation.

Conclusion: The online software Radiotherap-e provided a common platform to share clinical, radiological and radiotherapeutic informations and allowed standardization and optimization of contouring strategies within a regional oncological network.

EP-1458

CBCT-Based On-site Simulation, Planning, and Delivery (OSPD) for whole brain radiotherapy

A. Pompos¹, A. Le¹, R. Timmerman¹, S. Jiang¹, H. Choy¹
¹University of Texas Southwestern Medical Center, Radiation Oncology, Dallas, USA

Purpose or Objective: To demonstrate the feasibility of a CBCT-based on-site simulation, planning, and delivery (OSPD) for whole brain radiotherapy, in which all steps from imaging, planning to treatment delivery are performed at the treatment unit in one appointment time slot. This work serves as the proof of concept for future OSPD single fraction radiation therapy.

Material and Methods: An integrated on-site imaging, planning and delivery workflow was developed and tested for whole brain radiotherapy. An automated two-opposed-oblique-beam plan is created by utilizing the treatment planning system scripting and simple field-in-field IMRT. The IMRT plan is designed with maximum 8 control points to cover the target volume consisting of the brain to C1/C2 of the spinal cord, with dose homogeneity criteria from -5% to +7% of the prescription dose. Due to inaccuracy of reconstructed Hounsfield unit numbers in CBCT images, the dose distribution is calculated with non-heterogeneity correction introducing only clinically insignificant dose discrepancy. A coherent and synchronized workflow was designed for a team of attending physician, physicist, therapists, and dosimetrist to work closely with the ability to quickly modify, approve, and implement the treatment.

Results: Thirty-one patients have been treated with this OSPD treatment, without compromising the plan quality compared to our regular clinically used parallel opposed 2D plans. The average time for these procedures are 48.02 ±11.55 minutes from the time patient entered the treatment room until s/he exited, and 35.09 ±10.35 minutes from starting CBCT until last beam delivered. This time duration is comparable to the net time when individual tasks are summed up during our regular CT-based whole brain planning and delivery.

Workflow Steps	Time (min) $\bar{x} \pm \sigma$
Preparation/Setup	4.25 ± 2.29
Mask	5.11 ± 2.28
CBCT	2.76 ± 2.59
Contouring	5.89 ± 1.24
IMRT planning	2.28 ± 1.23
MD approval (include re-planning)	5.90 ± 7.86
Plan import, documents & films	12.18 ± 6.34
Plan Import to OIS	5.25 ± 4.49
Documentation	4.27 ± 2.95
Port filming	5.89 ± 2.79
Final plan & films checks	3.56 ± 1.80
Beam Delivery	2.54 ± 0.36
Exiting	3.56 ± 1.98
Total (patient enters and exits)	48.02 ± 11.55
Total (CBCT to last beam delivered)	35.09 ± 10.53

Conclusion: The OSPD whole brain treatment has been tested to be clinically feasible. The next step is to further improve the efficiency and to streamline the workflow. Other disease sites will be also tested with this new technology.

EP-1459

Testing the self-sufficiency of the Radiotherapy Department of Ospedali Riuniti Marche Nord
 F. Maurizi¹, C. Blasi¹, G. Moroni¹, M. Mazza¹, A. Bavasso¹, F. Bunkheila¹
¹A.O. Ospedali Riuniti Marche Nord, U.O.C. Radioterapia, Pesaro, Italy

Purpose or Objective: For reasons of logistics in Italy, many public radiotherapy (RT) department deliver treatments to wide geographical areas. It is important that RT capacity is in the right place and that patients (pts) don't have to travel too far for their treatments. The aim of this study is to analyse the mobility for RT involving the RT Department of Ospedali Riuniti Marche Nord (AORMN) naturally devoted to satisfy RT needs of cancer pts living in Pesaro-Urbino (PU) province.

Material and Methods: The Nomogramma di Gandy (NdiG) is a high-level tool which measures the degree to which an area or region is self-sufficient in the delivery of a specified public service. NdiG has been used to diagrammatic represent cancer pts flows for RT at AORMN. District and local datasets were used to obtain the number of local pts being treated by AORMN (Rr), the number of local pts irradiated by other RT Departments (E, "Exported" from an area), and the ones coming from outside that AORMN treated (I, "Imported" into an area). The three data enable to calculate two key indicators: X = The Percentage of Cancer pts Irradiated who were Residents = $(Rr \times 100) / (Rr + I)$ Y = The Percentage of Residents Irradiated Locally = $(Rr \times 100) / (Rr + E)$, useful to determine the Catchment Population for AORMN = Resident Population $\times (Y/X)$.

Results: Between January and December 2013, 646 cancer pts living in PU district and 20 not resident pts were treated by AORMN, while 24 patients residing in PU area received RT by neighbouring RT centres. So during 2013, AORMN coordinates were as follows: X =96,99%, Y=96,42% and Y/X =0,99 (figure 1). Further analysing datasets, 35% of "Imported" pts received IMRT for Head and Neck cancers while the 67% of "Exported" pts underwent Stereotactic Radiation Therapy (SRT) not yet implemented at AORMN (50% stereotactic body radiation therapy and 17% stereotactic radiosurgery for brain metastasis).

Conclusion: AORMN RT Service shows a great deal of self-sufficiency, having values of both X and Y >90%. The degree to which people access their local RT services is important for planning and developing services themselves, thus the use of NdiG to compare access across many geographical areas or across many time periods could be a useful method for planning and commissioning RT centres at a local or regional level. The analysis of patients' flow pattern at AORMN suggests that the implementation of SRT could be useful to further reduce the number of PU users who should travel for RT.

EP-1460

Knowledge, attitudes and decision-making preferences of men considering clinical trial participation
 P. Sundaresan¹, S. Tesson², B. Ager², P. Butow², I. Juraskova², D. Costa², A. Kneebone³, H. Woo⁴, M. Pearce⁵, S. Turner¹
¹Crown Princess Mary Cancer Center- Westmead, Radiation Oncology, Sydney- NSW, Australia
²The University of Sydney, Psycho-Oncology Co-operative Research Group PoCoG, Sydney, Australia
³The University of Sydney, Sydney Medical School, Sydney, Australia
⁴The University of Sydney, Sydney Adventist Hospital Clinical School, Sydney, Australia
⁵Auckland Hospital, Radiation Oncology, Auckland, New Zealand

Purpose or Objective: Only 5-10% of cancer patients eligible for randomized clinical trials (RCT) actually participate. The RAVES RCT (Trans-Tasman Radiation Oncology Group 08.03), compares adjuvant radiotherapy with early salvage radiotherapy for men with high risk features after prostatectomy. We aimed to determine attitudes and knowledge of potential participants regarding RAVES and RCTs, and examine decision-making preferences and decisional-conflict in men deciding on RAVES participation.

Material and Methods: Knowledge, attitudes, decisional conflict and preferences regarding participation in RAVES were measured. Predictors of trial and RAVES knowledge were also determined.

Results: 110 men (median age = 63) eligible for RAVES were recruited through urologists (n=90) and radiation oncologists (n=20). Men preferred collaborative (34%) or semi-active (34%) decision-making roles. Most considered RAVES to be worthwhile (85%), important (81%), 'a good thing' (80%), beneficial (73%) and viewed participation as wise (76%), but over half (51%) had high decisional conflict regarding participation. Objective measures of knowledge regarding RCTs and RAVES were low.

Conclusion: Amongst men considering management after prostatectomy, knowledge of RAVES was poor. Despite positive attitudes towards RCTs and RAVES, there was high decisional-conflict surrounding participation. The utility of decisional support materials to increase RCT knowledge and decrease decisional-conflict is under investigation.

EP-1461

Virtual imaging for patient information on radiotherapy planning and delivery

J. Sulé-Suso¹, S. Finney¹, J. Bisson¹, S. Hammersley¹, S. Jassal¹, C. Knight¹, C. Ellis¹, S. Sargeant², K. Lam³, J. Belcher³, D. Collins³, R. Bhana¹, F. Adab¹, C. O'Donovan¹, A. Moloney¹

¹University Hospital North Midlands, Oncology Department, Stoke-on-Trent, United Kingdom

²Bond University, Faculty of Health Sciences and Medicine, Robina, Australia

³Keele University, School of Computing and Mathematics, Keele, United Kingdom

Purpose or Objective: To assess whether both patients and their relatives would welcome further information on a one-to-one basis on RT planning and delivery using the virtual reality (VR) system VERT.

Material and Methods: One hundred and fifty patients with a variety of solid malignancies receiving radical RT were included in the study (90 prostate tumours, 52 breast tumours, 4 rectal tumours, 3 lung tumours and 1 thymoma). The study was approved by the local ethics committee. For each study patient, their planning CT Scan images and RT plan were uploaded onto the VERT system using the Digital Imaging and Communication in Medicine (DICOM) standard. Patients and relatives were shown using VERT (Figure 1) and on a one-to-one basis with an oncologist or a radiographer, a standard room where RT is given, a linear accelerator, and how RT is planned and delivered using their own planning CT Scans. Emphasis was put on the area to be treated and the organs around it. At the end of the exercise, patients were asked to fill in a questionnaire to assess their expectations. Radiotherapy was performed using 10 or 6 MV photons delivered from a Varian 2100IX linear accelerator. Treatment planning was performed on the 'Eclipse' system using CT scans.

Results:

The analysis of patients' expectations during the whole process of RT planning and delivery showed that 83.0% (95%CI 76.99% to 89.01%) of patients had a moderate or high need to better understand using 3D imaging how RT is planned, and 83.3% (CI 77.33% to 89.27%) of patients had a moderate or high need to understand using 3D imaging how RT is delivered. Furthermore, 80.6% (CI 74.27% to 86.93%) of patients had a moderate or high need to see the area to be treated using their own CT Scans uploaded onto the VERT 3D system. All respondents cited greater understanding as a positive outcome of the exercise. Patients welcomed this information as it helped them to reduce their fears about RT. Relatives felt also more involved in the treatment of their loved one.

Conclusion: Providing this information using 3D imaging systems rather than 2D helped patients and relatives to better understand the complexity of RT planning and delivery, and reduced their anxieties. The results obtained in this pilot study show that VR aids could become an important tool for delivering information on RT to both patients and relatives, hence, improving patients' experience and satisfaction. Further work is needed to assess whether such approaches improve patients' compliance with treatment and whether it could ultimately impact on treatment outcome.

EP-1462

Effects of education using Youtube about radiotherapy process for cancer patients

J. Heo¹, M. Chun¹, Y.T. Oh¹, O.K. Noh¹, J. Kim²

¹Ajou University School of Medicine, Radiation Oncology, Suwon, Korea Republic of

²Dankook University College of Medicine, Radiation Oncology, Cheonan, Korea Republic of

Purpose or Objective: The patient's understanding about radiotherapy process is necessary for safe and accurate delivery of radiation. We developed an education video about radiotherapy process. The purpose of this study was to evaluate the effectiveness of the education contents using YouTube.

Material and Methods: An eleven minutes video was developed instructing whole radiotherapy process including consultation, simulation, radiotherapy treatment planning, verification and irradiation. After consultation for radiotherapy, each patient was required to see the video posted on YouTube through provided lab-top or tablet PC in our clinic. The questionnaire about patient satisfaction with the video and knowledge of radiotherapy was carried out by interviewing after watching video. Also, set up error was measured at the first week of verification process.

Results: In clinic setting, twenty patients who visited to radiation oncology clinic and watched video were enrolled in the study. Of 20 participants, 11 (55%) rated the video as

'recommended' and 15 (75%) responded that the video was 'helpful to understand radiation treatment'. After watching the video, average set up error at the first verification process was significantly decreased compared to the historical values of 124 patients (1.6 mm versus 2.2 mm, $p = 0.03$). In web, two thousand two hundred people globally viewed YouTube videos about radiotherapy.

Conclusion: Implementation of education video instructing the radiotherapy process helped to increase patient safety. Education based on YouTube could be an effective method for cancer patients.

EP-1463

Stereotactic body radiation therapy (SBRT). Outcomes and toxicities

A.A. Diaz Gavela¹, E. Del Cerro Peñalver¹, F. Marcos Jimenez¹, F. Couñago Lorenzo¹, J. Castro Novais²

¹Hospital Quiron Madrid, Radiation Oncology, Pozuelo de Alarcon- Madrid, Spain

²Hospital Quiron Madrid, Radiophysics, Pozuelo de Alarcon- Madrid, Spain

Purpose or Objective: Stereotactic body radiotherapy (SBRT) is evolving into a standard of care in cancer management and consists in giving high doses of radiation to tumor deposits in extracranial locations. The objective of our study is to show our results in terms of toxicity and local response after implementing the technique in our department.

Material and Methods: Between May 2012 to August 2015, 120 patients (170 lesions) with body metastases or primaries of varying histologies were treated with SBRT. We evaluated acute (<3months) and late (>3months) toxicities as well as the response of the treated lesions. 26 patients were treated with a linac-based 3D conformal SBRT planning and 2 lesions with static IMRT. The other 142 lesions received a Volumetric Modulated Arc Therapy (VMAT) treatment using RA (Rapid Arc), 83 with flattening filter and 59 were treated without flattening filter (flattening filter free beam- FFF).

Results: The mean age of patients was 60 years (26-87) and the median follow-up was 8 months (1-33). The most common histology was non-small cell lung cancer and the most frequent localizations of the treated lesions were bone (31.7%), lung (both metastases and primary, 22.2%), liver (17.1%) and lymph node metastases (14.7%); other localizations: 14.3%. Administered dose and fractionation varied significantly depending on the size and location of each lesion and its anatomic relationship with adjacent organs at risk, ranging from one to ten fractions and 8 to 60Gy. The median volume of the PTV was 42.50cc (0.89-259.08cc). In relation to the local response, we found 74.7% of complete or significant responses, 15.8% of minor responses or stability, 2.4% progressions and 7.1% pseudoprogessions. Acutely, the most frequent toxicities were fatigue and bone flair. There were no grade 4 toxicities and we identified only one grade 3 acute asthenia. Chronically, the most frequent side effect was bone pain (3.3%).

Conclusion: Our series confirms excellent local control with a low rate of side effects when treating extracranial metastases with SBRT. Longer follow-up is necessary to assess whether the local response is maintained over time and to identify the factors related to SBRT treatment that may influence overall survival.

EP-1464

Protontherapy or photodynamic therapy in the treatment of circumscribed choroidal haemangiomas

J. Thariat¹, C. Maschi², C. Franceschetti², S. Baillif², G. Angellier¹, M. Peyrichon¹, J. Herault¹, J. Caujolle²

¹Centre Antoine Lacassagne, Department of Radiation Oncology, Nice, France

²Hospital Pasteur 2 - Nice Teaching Hospital, Ophthalmology, Nice, France

Purpose or Objective: To compare the results of low dose protontherapy and photodynamic therapy (PDT) for the treatment of circumscribed choroidal haemangiomas (CCH).

Material and Methods: 48 patients (48 eyes) eyes with CCH were referred, treated between 1994 and 2014 and followed in our clinic. A historical series of 20 patients treated with protontherapy since 1994 was compared to 28 patients treated with photodynamic therapy since 2006. Tumor and functional outcomes were compared. Chi-squared or Fisher's tests were used to establish differences between discontinuous variables. Student t-test or the Mann-Whitney U test was used to compare continuous variables. The Spearman test was utilized for correlations.

Results: Groups were comparable for patient (age, gender) and disease (size, baseline complications and visual acuity) characteristics but neither macular location (16/20 for protontherapy, 9/28 for PDT, $p 0.02$) nor initial thickness (higher in the protontherapy group, $p 0.02$). Mean follow-up was 35 months (48 for protontherapy, 24 for PDT $p 0.001$). There was a higher rate of retreatment for relapse and complications with PDT than protontherapy ($p 0.044$ and 0.006 , respectively). There was a non-significantly higher gain in visual acuity with protontherapy than PDT. There was a mean 67% and 32% thickness decrease with protons and PDT ($p 0.002$).

Conclusion: Considering that protontherapy is more invasive due to clip placement and uses ionizing radiations, it cannot be advocated as a first hand option. However, initially promising results with PDT are challenged by protontherapy and the current series suggest that protontherapy should be proposed after first failure to PDT. Prospective trials are warranted to compare the two options as first treatment.

EP-1465

Early dupuytren's: superficial radiotherapy offers long-term resolution without hand surgery

J.P. Glees¹

¹Cancer Centre London- Parkside Hospital, Radiotherapy Department, London, United Kingdom

Purpose or Objective: First independent Audit to show that giving superficial radiotherapy (100KV Photons) is effective. Majority of cases (94%) did not require subsequent hand surgery.

Material and Methods: During the period 2010 to 2015, over 150 patients were treated by one Radiotherapist using the European treatment protocol of 10 treatments given over a 2 to 3 month period (5 fractions over 1 to 2 weeks followed by 2-month gap and then, the 5 treatments are repeated. Total applied dose of 30Gy). Each patient's disease is photographed before and after treatment, the palpable disease having been marked on the hands and feet in order to clearly show benefit achieved.

Results: Independent Audit of a detailed questionnaire sent to patients showed 94% were satisfied with results up to 4 years post treatment. Satisfaction composed of regression of disease in hands and feet and/or no further progression of the disease.

Conclusion: Superficial radiotherapy is a highly effective and inexpensive treatment of Dupuytren's, provided that patients are referred during the early stages of the disease. Patients are able to continue normal use of hands (and feet) throughout the treatment, so their daily lives are not altered. General Practitioners, hand surgeons and affected patients should be made aware of the good results achieved by radiotherapy, without significant morbidity.

EP-1466

Radiotherapy combined with steroids for Graves' ophthalmopathy: role of magnetic resonance imaging

T. Suwa¹, Y. Negoro¹, T. Fuji¹, T. Iburu²

¹Tenri Hospital, Radiology, Tenri, Japan

²Tenri Hospital, Endocrinology, Tenri, Japan

Purpose or Objective: To review our outcomes for patients in the active inflammatory phase of moderate-to-severe Graves' ophthalmopathy (GO) treated with combined systemic pulsed corticosteroids plus irradiation and demonstrate the role of magnetic resonance imaging (MRI) as a prognostic factor.

Material and Methods: From our database of 35 patients treated with radiotherapy for the active inflammatory phase of GO in our hospital from January 2005 to December 2013, 5 patients were excluded from the analysis because they had a short follow-up, were not treated with pulsed corticosteroids because of liver failure, or had no eye muscle impairment at diagnosis. In the remaining 30 patients in the active inflammatory phase of moderate-to-severe GO treated with combined pulsed corticosteroids plus irradiation, we assessed eye muscle impairment using the SPECS system before and 6 months after the start of treatment. A total dose of 20 Gy in 10 fractions was delivered to the bilateral retrobulbar volume. Intravenous 1 g of corticosteroids daily for 3 successive days was repeated weekly up to 3 weeks. The thickness ratio (TR) of the enlarged eye muscle to the optic nerve and the signal intensity ratio (SIR) of the eye muscle to the cerebral white matter were evaluated as the mean of three cross sections of coronal short-time inversion recovery (STIR) sequence MRI to investigate whether these factors could predict the reversibility of eye muscle impairment.

Results: This study included 10 men and 20 women with median age of 55.5 (range, 37-71) years. The thyroid function at the time of irradiation was euthyroid in 26 patients, hyperthyroid in 2, and hypothyroid in 2. Median duration of eye symptoms from onset to the initiation of radiotherapy was 4 months (range, 1.4-22.1 months). Six months after radiotherapy, there was a significant improvement in eye muscle impairment ($p < 0.001$); complete regression was observed in 10 patients (33%), partial regression in 5 (17%), no change in 14 (47%), and progressive disease in 1 (3%). The median TR was 4.1 (range, 0.4-16.4), and the median SIR was 2.45 (range, 1.7-4.1). There was a trend toward greater, but not significant, improvement in patients with a low TR (<4.2) or high SIR (>2.5) before treatment.

Conclusion: Orbital irradiation combined with pulsed corticosteroids was an effective treatment for the active inflammatory phase of moderate-to-severe GO, especially in patients with a low TR or high SIR on MRI before treatment. A low TR or high SIR may predict the treatment outcome.

EP-1467

Second neoplasms after radiotherapy treatment: a population-based study

M. Arenas Prat¹, L. Castellà¹, R. Botella¹, G. Fliquete¹, M. Arquez¹, M. Carulla², A. Rovirosa³, A. Besora⁴, S. Sabater⁵

¹Hospital Universitari Sant Joan de Reus, Radiation Oncology, Reus, Spain

²Fundació Lliga per a la Investigació i Prevenció del Càncer FUNCA, Tarragona Cancer Registry, Reus, Spain

³Hospital Clínic, Radiation Oncology, Barcelona, Spain

⁴Institut d'Investigacions Sanitàries Pere Virgili, Statistics Unit, Reus, Spain

⁵Complejo Hospitalario Universitario Albacete, Radiation Oncology, Albacete, Spain

Purpose or Objective: The radiotherapy treatment can produce a possible new second primary cancer, but metachronous malignancies can also appear without any relationship with radiotherapy treatment. We have studied the risk of developing a potential radiotherapy induced second cancer.

Material and Methods: We analyse the new second cancers after a radiotherapy treatment for a primary cancer in a population-based study in a province of Spain from 2000 to 2011.

Results: The number of patients (pts) with cancer treated with radiotherapy during this period was 14131, 2989 were breast cancer, 2197 were prostate cancer and 1220 pts were rectal cancer. Three hundred and thirteen (2.2%) patients developed a second cancer after a primary cancer treated with radiotherapy. In relation to the primary cancer, the most frequent were prostate cancer (70 pts, 22.4%), the second breast cancer (43 pts, 13.7%), the third colorectal cancer (40 pts, 12.8%), the fourth skin cancer (36 pts, 11.5%) and the fifth larynx (24 pts). The others were bladder (20 pts), oropharynx (7), endometrial cancer (6), etc. The most frequent of second cancer location was lung cancer (63 cases, 20.1%), the second colorectal cancer (43 cases, 13.7%), the third larynx and oral cavity and pharynx (40 cases, 12.8%), breast (34, 10.9%), prostate (28, 8.9%), bladder (19.6%). The location more frequent after a prostate cancer irradiation is lung (20 pts) and colorectal (17 pts, 9 rectal and 8 colon) and bladder (8). The location more frequent in after a breast cancer irradiation is another breast cancer (21 pts). Colorectal 40 pts: 9 second colorectal, 8 lung cancer. Non-melanoma skin cancer 36 pts: 8 second non-melanoma skin cancer, 6 rectal cancer and 4 lung cancer. Larynx 24 pts: 7 lung cancer, 4 prostate cancers.

Conclusion: The percentage of pts treated with radiotherapy who developed a second cancer after 11 years is 2.2% in our series. It's difficult to know the real probability for developing a second cancer associated with radiotherapy. The higher percentage of primary tumour with second cancer was rectal cancer (40/1220, 3.27%), the second was prostate cancer (70/2197, 3.18%), the third was breast cancer 43/2989, 1.43%). We'll present the results about the location of second cancer, the time between the primary and the second cancer, and some characteristics about the radiotherapy treatment (total dose and other dosimetric characteristics).

EP-1468

Prospective audit showing improved patient-assessed skin toxicity with use of betamethasone cream

S.C. Erridge¹, M. McCabe¹, M.K. Porter¹, P. Simpson¹, A.L. Stillie¹

¹Edinburgh Cancer Centre- Western General Hospital- Clinical Oncology, Edinburgh, United Kingdom

Purpose or Objective: For many years Edinburgh Cancer Centre's radiotherapy skin care policy recommended aqueous cream and, if required, 1% hydrocortisone. However, it was increasingly appreciated that better alternatives existed so in 2015, a review of the literature was performed, and a new skincare policy developed based on:

- 1) Low Risk (treatment only if symptoms),
- 2) Medium Risk (Diprobase moisturising cream),
- 3) High Risk of developing radiation dermatitis (Diprobase & betamethasone valerate 0.1% applied once daily from 1st fraction till 14 days after treatment). The High Risk group included patients with breast, head and neck, anal, or pelvic cancers when body mass index >35 kg/m².

As concerns were raised about the increased cost and potential extent of the clinical benefit, a prospective audit was conducted.

Material and Methods: For one month prior to the change of policy (cohort 1, C1), all patients in High Risk group completed a questionnaire at the end of their course of radiotherapy, scoring (categorical 0-10) their skin reaction for redness, itch, discomfort and pain, and asking what creams and analgesia they were using, and if the reaction disturbed their sleep. The audit was repeated for cohort 2 (C2) four months after the policy changed and the two groups compared using Chi-squared based and ANOVA.

Results: C1 = 109 patients (84 with breast cancer, 13 H&N, 12 pelvis), C2= 104 (87B, 12H&N, 5P). In C1 27% used a cream and in C2 96% used a cream (p<0.001). In C2 88/104 complied with policy using the prescribed betamethasone.

Compared to C1, for C2 the mean score was lower for itch (1.3 (0.8-1.8) v 2.8 (2.2-3.4) p<0.001) and discomfort (2.2 (1.7-2.7) v 3.1 (2.6-3.7) (p=0.021), and when betamethasone was used (comparing the 88 from C2 with 125 from C1 or C2) the mean score was lower for itch (0.9 (0.5-1.4) v 2.9 (2.3-3.4) p<0.001), discomfort (2.0 (1.4-2.5) v 3.2(2.6-3.7) p<0.003), and for pain (1.4 (0.9-1.9) v 2.2 (1.7-2.7) p=0.03). With the use of betamethasone, the frequency of a score of >5 was lower for redness (15% with v 34% without) p=0.002), itch (7% v 25%, p =0.001), discomfort (9% v 22%, p=0.015), but not for pain (9% v 14%, p=0.29). However, sleep disturbance was less common (7% v 21%, p=0.006), as was the use of analgesia (7% v 19%, p=0.015).

Conclusion: The introduction of routine use of prophylactic betamethasone cream for patients with a high risk of radiation skin reaction resulted in a significant reduction in redness, itch, discomfort, sleep disturbance, and on use of analgesia

EP-1469

Survey on the use of complementary and alternative medicine in a German radiooncology department

S. Lettner¹, K.A. Kessel^{1,2}, S.E. Combs^{1,2}

¹Technische Universität München TUM, Department of Radiation Oncology, München, Germany

²Institute of Innovative Radiotherapy iRT, Helmholtz Zentrum München, München, Germany

Purpose or Objective: The use of complementary and alternative medicine (CAM) continuously gains importance, even though objective data are mostly missing - also in radiation oncology. However, in previous trials methods such as acupuncture showed significant advantages compared to standard therapies. Hence, the aim of this study is to evaluate the most frequently used methods, their significance and potential effect during radiotherapy (RT), as well as the general acceptance amongst cancer patients.

Material and Methods: A detailed questionnaire was developed consisting of 18 questions based on the categorical classification released by the National Centre for Complementary and Alternative Medicine (NCCAM). From January to September 2015, the survey was conducted with all patients undergoing RT at the department of Radiation Oncology, Technische Universität München (TUM), Klinikum rechts der Isar, Munich. Participation was voluntary and pseudonymous.

Results: Of 571 patients, 289 answered the questionnaire (50.6%), with 44.6% females and 38.4% males participating in the study, and a mean age of 60 years. Of these, 66.1% (191/289) received RT only, 20.4% (59/289) had a combined radio-chemotherapy (RCT). Of all participants, 25.9% (75/289) used CAM parallel to RT. Before RT, a total of 40.8% (118/289) had already used complementary medicine. The current most frequently applied methods were vitamins, dietary supplements, homeopathy and physical therapy, whereas in the past before RT also acupuncture and osteopathy had been regularly used. The majority (72.6%, 210/289) declined the use of any complementary treatment. Of these 210 patients, 73.3% (154/210) stated that CAM treatment was not offered to them. Only 20.4% (59/289) of all participants had discussed adding complementary treatments to their current therapy with their consulting physician. The most common reasons for CAM use were intended by the patients to improve the immune system (47%, 136/289), to reduce side effects (43.2%, 125/289), and to not miss an opportunity (37.3%, 108/289). Assuming their health insurance would not compensate the costs for CAM during RT, 52.5% (152/289) of the patients would pay for their treatment. A treatment integrated in the individual therapy concept, such as regular acupuncture, would be used by 62.9% (182/289) of RT patients. In order to gain more

information about the changes in attitude towards complementary medicine, we also handed out the questionnaire a second time after RT during the first follow-up visit (n=10). This is an ongoing part of the evaluation. However, it becomes apparent that in retrospect the use of CAM increased.

Conclusion: In comparison to other studies, usage of CAM parallel to RT is considered to be low. The acceptance amongst patients is present, however more information, in terms of personal consultations with physicians, brochures or online information, could encourage a holistic therapy.

EP-1470

Intralesional injection of triamcinolone acetonide in treatment of Radiation Induced Fibrosis

A.M. Maklad¹, H.A.M. Assaf², E.E.D.A. Nada³, A. A. Badran⁴

¹Faculty of medicine- Sohag University, Lecturer of Clinical Oncology and Nuclear medicine department, Sohag, Egypt

²Faculty of Medicine- Sohag University, Assistant professor of Dermatology-Venereology and Andrology, Sohag, Egypt

³Faculty of Medicine- Sohag University, Professor of Dermatology- Venereology and Andrology Department, Sohag, Egypt

⁴Sohag University, Master degree Dermatology-Venereology and Andrology Faculty of Medicine, Sohag, Egypt

Purpose or Objective: On the basis of successful intralesional steroid injection for dermatologic scars treatment such as keloids and burn scars, we planned to evaluate intralesional triamcinolone acetonide injection in treatment of RIF as there is no data available for its use for this indication

Material and Methods: 30 patients with RIF of different sites (19 cases breast, 4 cases neck, 3 back, 2 face and 2 lower limbs) at least 6 months after end of radiation were included in our study. They were treated by intralesional Triamcinolone acetonide injection. Injections were carried out by dermojet at 1 cm interval. Injections were repeated every 2 weeks for 3months. Assessment was done according to RTOG grading before treatment and repeated during and 3 months after end of treatment.

Results: We documented over all response rates of 80%, marked and complete improvement of RIF 43.33%, 30% showed one grade improvement, 6.67% had two grades improvement, while 20% of patients didn't respond (P-value <0.001). Pain score was significantly improved (p value <0.001), 44% of the included patients had complete improvement of pain, 36% had mild residual pain and 20% of patients expressed moderate residual pain. No significant adverse events were observed. The results were significantly better with younger age group (P-value=0.021), smaller BMI (p-value=0.007), patients who received lower radiation doses (P value =0.03), smaller number of radiotherapy treatment sessions (P-value=0.05), smaller radiation field sizes (P value=0.001), and patients with shorter duration of RIF (P value <0.001).

Conclusion: Intralesional triamcinolone acetonide injection can be considered as an effective in treatment of RIF. It can be considered as a promising effective, safe, less costly therapeutic option in treatment of RIF. To the best of our knowledge, no previous data are available about the use of intralesional injection of triamcinolone acetonide for treatment of RIF.

Key words: Radiation, fibrosis, intralesional.

EP-1471

The effect of radiotherapy on Ledderhose disease

J.G.H. Van Nes¹, J.A. Langendijk¹, R.J.H.M. Steenbakkers¹

¹University Medical Centre Groningen, Radiotherapy, Groningen, The Netherlands

Purpose or Objective: The only treatment option for Ledderhose disease seems radiotherapy as surgery is associated with a high chance of recurrence and morbidity.

Therefore, we investigated the effect of radiotherapy on Ledderhose disease.

Material and Methods: Between 2008 and 2014, 37 patients (56 feet) with Ledderhose disease were treated with radiotherapy at our department (figure 1). Radiation treatment consisted of 30 Gy given in 10 fractions (orthovolt 200 kV or electrons 6-10 MeV). After the first 5 fractions, a 8-10 week split was included. After this split, the remaining 5 fractions were given. Progressive disease (PD) was defined as progression of complaints. Stable disease (SD) was defined as no improvement or progression of complaints. Partial response (PR) was defined as improvement or no complaints, but still nodules were present. Complete response (CR) was defined as no complaints and no nodules present.

Results: All patients completed the planned treatment. The mean follow-up time was 25 months (range 3 to 46 months). Mean age of patients was 53 years, 46% were men, 54% were women. In 51% of patients (n=19), both feet were affected. After the radiotherapy, a minority of the patients complained of rash or dry skin, which resolved spontaneously. Of the 56 feet treated, 5% had PD, 23% had SD, 64% had PR and 7% had CR. No radiation induced malignancies were seen. Of the two patients with PD, one patient had previous surgery for Ledderhose disease and the other patient had PD disease after an initial PR.

Conclusion: Radiotherapy is an effective treatment for Ledderhose disease. However, the National Health Care Institute of the Netherlands does not support radiotherapy for Ledderhose disease as no randomized controlled trial have investigated the efficacy of radiotherapy. Therefore, we will present a double blind randomized multicentre phase three study to confirm the current results prospectively.

EP-1472

Role of SBRT with VMAT-FFF for abdomino-pelvic lymph node metastases in oligometastatic patients

C. Franzese¹, L. Cozzi¹, E. Clerici¹, T. Comito¹, F. De Rose¹, G. D'Agostino¹, A. Tozzi¹, C. Iftode¹, A. Ascolese¹, D. Franceschini¹, P. Navarria¹, L. Liardo¹, L. Paganini¹, M. Scorsetti¹

¹Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

Purpose or Objective: Nowadays stereotactic body radiotherapy (SBRT) is considered a safe and effective approach for several sites of metastatic disease. So far, few published data exist on local control rates of radiotherapy in the context of isolated or limited lymph node metastases. We analyzed the dosimetric and clinical results of oligometastatic patients treated with SBRT for isolated lymph node metastases in abdomen and/or pelvis.

Material and Methods: In the analysis we included patients with a maximum of 3 lymph node sites of disease with diameter less than 5 cm, located in the abdomen or pelvis. Radiotherapy was administered with Volumetric Modulated Arc Therapy Rapid-Arc (VMAT-RA) and flattening filter-free (FFF) beams; prescribed dose was 45 Gy in 6 fractions of 7.5 Gy each. We analyzed dosimetric data and correlated them with acute toxicity (CTCAE 3.0), local and distant control of disease, progression free survival and overall survival.

Results: From January 2006 to May 2015, we treated 97 patients with lymph node metastases, of which 26 were lost at follow-up. We analyzed then 71 patients with a total of 79 treated lesions, with a mean follow-up of 1.44 years (range 0.14 - 6.21 years). At reevaluation, complete response was achieved in 39 (49.3%) lesions and partial response in 28 (35.4%) lesions. Stable disease was demonstrated in 10 (12.6%) cases while only 2 (2.5%) lesions showed progression of disease. The overall clinical benefit rate was 97.5% (77/79 lesions). Acute toxicity was mild: 10 (14%) patients reported G1 toxicity (notably nausea and fatigue); 2 (2.8%) patients reported G2 toxicity (nausea and diarrhea). No Grade 3 and 4 toxicities were reported. In-field progression of disease during follow-up was demonstrated in 18 sites (22.7%) with a median time of 10.7 months. Out-field lymph node progression was demonstrated in 22 (27.8%) cases while distant metastases occurred in 25 (31.6%) cases. Local control rate and overall survival rate at 1 year were 83% and 93%, respectively.

Conclusion: In consideration of our dosimetric and clinical results, SBRT with VMAT-RA and FFF beams can be considered a safe and effective approach in oligometastatic patients with abdomino-pelvic isolated lymph node metastases. Although this can be considered an initial experience, these results may be potentially significant for preserving quality of life of patients and delaying further systemic treatments.

EP-1473

The clinical study on oligometastases from different tumors treated with carbon ions

X. Wang¹, Q. Zhang¹, H. Zhang², L. Gao¹, J. Ran¹, Q. Li¹, R. Liu¹, S. Wei¹, H. Luo¹, X. Wei¹, Z. Liu¹, L. Xu¹

¹Gansu Cancer Hospital, Department of Radiotherapy, Lanzhou, China

²Chinese Academy of Sciences, Institute of Modern Physics, Lanzhou, China

Purpose or Objective: The purpose of this study was to evaluate the efficacy and feasibility of carbon ion

radiotherapy(CIRT) for Oligo-metastatic tumors located different organ from various cancer.

Material and Methods: From December 2009 to June 2013, 17 patients joined into the clinical study as volunteers. The patients were not surgical candidates for medical reasons or patient refusal. The Oligometastases located in lung, brain and liver respectively from various cancer were treated with CIRT. The heavy ion beams energy was 230-350 MeV/u and RBE value was 2.5. A median dose of 60 GyE (range, 20-66 GyE) was delivered to the planning target volume (PTV) in 4-12 fractions with a median daily dose of 5 GyE (range, 4.68-5.5 GyE). Short-term effect was evaluated by tumor change in three months after treatment with *RESIST criteria* and adverse reactions were determined by criteria of acute radiation injury from Radiation Therapy Oncology Group. Treatment outcome was analyzed in terms of local control rate(LCR), survival rate.

Results: In total, 17 patients (7 lung Oligometastases, 3 liver Oligometastases and 7 brain Oligometastases) with 17 Oligometastatic lesions were treated with CIRT. Until December 2014, median follow-up period was 18 months(2-40ms). Objective response rate was 94.1% to evaluate short-term effect (3CR, 10PR, 3NC, 1PD). The 1-year LCR and overall survival of the treated patients were 93.3% and 51.0%. Only 1 lung Oligometastases patients relapsed in 7 months after treatment. 1-year Survival rate were 47.6%, 66.7%, 75% respectively in brain, lung and liver Oligometastases. Survival rate and LCR were not significantly correlated with Oligometastases location. All treatment-related complications were acute skin reaction and self-limited, without any grade 4-5 toxicity.

Conclusion: Compared with Conventional radiotherapy, CIRT has short treatment time, high Biological effect advantages. CIRT may be one of effective, the least invasive and safe approach to patients with Oligometastases.

EP-1474

The preliminarily results of carbon ion radiotherapy in 60 patients

X. Wang¹, Q. Zhang¹, H. Zhang², L. Gao¹, J. Ran¹, Q. Li², R. Liu¹, S. Wei¹, H. Luo¹, X. Wei¹, Z. Liu¹, S. Sun¹, L. Xu¹

¹Gansu Cancer Hospital, Department of Radiotherapy, Lanzhou, China

²Chinese Academy of Sciences, Institute of Modern Physics, Lanzhou, China

Purpose or Objective: This study summarizes the experience with carbon ion radiation therapy (RT) at the Heavy Ion Research Facility in Lanzhou since 2009.

Material and Methods: From December 2009 to June 2013, 60 patients joined into the clinical study as volunteers. 14 patients with brain tumor [cerebral glioma(n=6), metastatic brain tumor (n=8)], 8 patients with head and neck tumor, 15 patients with chest tumor [primary lung cancer (n=8), metastatic mediastinal carcinoma(n=1), metastatic lung cancer(n=6)], 13 patients with abdominal carcinoma [primary liver cancer(n=4), pancreatic cancer(n=1), abdominal soft tissue malignant tumor (n=3), metastatic liver cancer(n=4), abdominal lymph node metastasis carcinoma(n=1)], 5 patients with pelvic tumor [rectal cancer(n=1), anal cancer (n=1), ovarian carcinoma(n=1), chordoma(n=1), soft tissue tumor(n=1)], 5 patients with limbs tumor [skin cancer(n=2), soft tissue malignant tumor(n=3)] were treated with carbon ions beams. The beams energy was 230-350 MeV/u and RBE value was 2.5. A median dose of 60 GyE (range, 20-66 GyE) was delivered to the planning target volume (PTV) in 4-12 fractions with a median daily dose of 5 GyE (range, 4.68-5.5 GyE). Short-term effect was evaluated by tumor change in three months after treatment with *RESIST criteria* and adverse reactions were determined by criteria of acute radiation injury from Radiation Therapy Oncology Group.

Treatment outcome was analyzed in terms of local control rate (LCR), survival rate.

Results: Until December 2014, median follow-up period was 18 months (2-40ms). Objective response rate was 98.3% to evaluate short-term effect (9CR, 37PR, 13NC, 1PD). The 1-year LCR and overall survival of the treated patients were 80.2% and 62.8%. The local control and overall survival rates were not correlated with tumor location and pathological types, the main cause of death was distant metastasis. All treatment related complications were 1-2 grade acute skin reaction (incidence rate = 66.7%) and self-limited, without any grade 4-5 toxicity.

Conclusion: Carbon ion therapy is safe with respect to toxicity, offers high tumor local control rates and significantly shorten the treatment time. But this study has limitations: a group of cancer patients in advanced stage and short survival and follow up time, small sample size and high heterogeneity because of tumor location, clinical stage and pathological type. More homogeneous prospective data, large multicentric and randomized trials are needed to evaluate the efficacy of heavy ion tumor therapy.

EP-1475

Radiotherapy for primary orbital tumors - patterns of care and treatment outcomes

Y. Lim¹, I.H. Kim¹

¹Seoul National University Hospital, Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: Although radiation therapy (RT) is widely used in orbital tumors, the clinical use of ophthalmic RT has not been established in the lack of prospective data. This study evaluated the single institution's patterns of care and treatment outcomes of RT in non-metastatic primary tumors and inflammatory diseases in the eye and orbit.

Material and Methods: We retrospectively reviewed a total of 138 patients and 147 treatments of primary orbital malignancies or inflammatory conditions from January 2000 to December 2013. The aims of RT consisted of definitive (n=121), postoperative (n=16), palliative (n=6), and salvage (n=4) treatment. Retrobulbar (34%) and conjunctival (22%) area were the common subsites of treatment. The median external beam RT dose was 30.6 Gy (range, 10.0-66.6) with a daily fraction size ranging from 1.7 to 4.0 Gy. Three-dimensional conformal and intensity-modulated techniques were delivered in 67 (46%) and 5 (3%) treatments, respectively.

Results: Forty-eight (35%) patients had benign inflammatory diseases including thyroid-associated ophthalmopathy (n=24), inflammatory pseudotumor (n=13), and choroidal neovascular membranes (n=11). In 90 (65%) patients with malignant tumors, 13 (9%) patients were children diagnosed with retinoblastoma (n=7), optic glioma (n=4), optic meningioma (n=1), and ocular teratoid medulloepithelioma (n=1). The other 77 (56%) patients were adult with the 5-year overall survival rate of 78.3%. Among the non-pediatric patients, mucosa-associated lymphoid tissue (MALT) lymphoma (n=36) was the most frequent disease entity, and the others also included optic meningioma (n=6), melanoma (n=5), and adenoid cystic carcinoma (n=5). In a total of 81 adult malignant tumors, complete and partial responses were observed in 67 (83%) tumors, and the patients' 5-year relapse-free survival was 60.8%. In the 42 treatments of TAO and inflammatory pseudotumor, inflammatory symptoms were improved in 57%. There were 58 (39%) events of acute toxicities, and grade 1-2 ocular discomfort (n=18) and nausea (n=9) were frequent. Among the 24 (16%) events of late toxicities, 10 (42%) and 2 (8%) events of radiation-induced cataract and retinopathy were observed, respectively. Grade ≥3 toxicities were not reported.

Conclusion: In current practices, the ophthalmic RT achieved an excellent treatment response and tumor control with tolerable short-term and long-term toxicities. Further

analysis with more advanced RT technique is needed to assess the future role of RT in orbital tumors.

EP-1476

General fatigue during the period of radiotherapy; clinical usefulness of Japanese herbal medicine.

N. Yoshikawa¹, H. Yoshioka¹, K. Yoshida¹, T. Shimbo¹, Y. Uesugi¹, Y. Narumi¹

¹*Osaka Medical College, Radiology, Takatsuki, Japan*

Purpose or Objective: Breast cancer patients receiving post-operative radiotherapy (RT) experience adverse effects and general fatigue is one of them. Although it is often not severe enough to interrupt the course of RT, it negatively affects quality of life. Some Japanese herbal medicines such as TJ-41 (Hochu-ekki-to) are effective for fatigue and are often used in daily practice. The purpose of this study is to assess radiation-induced fatigue (RIF) in detail and investigate the effect of Japanese herbal medicine.

Material and Methods: Breast cancer patients who received post-operative RT and agreed to answer a patient self-reporting questionnaire (FACIT-F; Functional Assessment of Chronic Illness Therapy) were eligible for this study. We excluded patients who were receiving chemotherapy concurrently. RIF was defined as fatigue which occurred during the period of radiotherapy and there were no causes for the fatigue other than the radiotherapy. The FACIT-F questionnaire was answered before RT, at one week after the beginning of RT, at the end of RT and one month after the end of RT. We prescribed TJ-41 to the RIF patients during the radiotherapy. We defined as responders the patients who experienced improvements in RIF and hoped for further prescription.

Results: Fifty-two patients were enrolled for this study. RIF was observed in 24 (46 %) patients. On univariate analysis, the statistically significant predictor of RIF was the score of FACIT-F before RT. TJ-41 was administered to 9 patients and 8 of them (89 %) were responders.

Conclusion: RIF was common in breast cancer patients receiving post-operative RT and TJ-41 was effective for the RIF patients and improved their quality of life. However, these results may lack objectivity and the study was conducted with no placebo group. Improvement in objectivity of the assessment and a comparative study will be needed.

EP-1477

Radiotherapy-Hyperthermia: outcome/toxicity in the superficial recurrent/metastatic tumors

E. Garibaldi¹, A. Di Dia², E. Delmastro¹, G. Belli¹, M. Gatti¹, G. Cattari¹, A. Salatino¹, S. Squintu¹, M. Poli², A. Miranti², P. Gabriele¹

¹*Istituto di Candiolo- IRCCS, Department of Radiotherapy and Radiation Oncology, Candiolo, Italy*

²*Istituto di Candiolo-IRCCS, Medical Physics, Candiolo, Italy*

Purpose or Objective: Hyperthermia is a powerful radiosensitizer for treatment of superficial tumors. Several trials showed an advantage of combining radiotherapy with hyperthermia in terms of both local tumor control and overall survival. The purpose of this study is to evaluate both efficacy and toxicity of radiotherapy-hyperthermia (RT-HT) in the treatment of superficial recurrent and metastatic tumors in patients previously or not previously irradiated.

Material and Methods: In our Institution twenty-three patients (mean age 71,4 years; range: 51-88) with histologically confirmed superficial recurrent/metastatic tumors were enrolled: 11 breast carcinoma, 6 head&neck cancer, 2 malignant melanoma, 2 sarcomas, 1 uterine adenocarcinoma and 1 hepatocarcinoma. Patients underwent radiotherapy treatment using 3D-conformal radiotherapy (8/23) or Helical Tomotherapy (15/23). External beam radiotherapy was delivered in 6-27 fractions of 1.8-5 Gy for a total dose of 20-57.5 Gy (mean external dose: 41 Gy). Prescribed dose was established taken into account, of the

previous radiation doses, in previously irradiated patients, Karnofsky performance status and patient compliance. Hyperthermia treatment was performed with an electromagnetic superficial applicator operating at the frequency of 434 MHz. HT session was delivered once/twice weekly during the period of external radiotherapy, 1-2 hours after radiotherapy, to a mean total of 5 treatments [range: 1-9 sessions]. Thermocouples were used to evaluate temperature distribution map. Average, maximum and minimum temperature parameters were recorded during hyperthermia treatment. The treatment goal was to reach 40- 42°C in > 90% (T90) of measured points for a duration of 60 minutes. Acute and late toxicity was evaluated according to the CTCAE criteria. Local control was assessed after the end of the treatment on the basis of the RECIST Criteria.

Results: During hyperthermia treatment the median temperature reached was 40.5 °C [range: 39 - 42.9°C]. During the radiotherapy in association with hyperthermia 2 pts (10%) had G3 toxicity and one of these interrupted the treatment. One pt had acute cutaneous toxicity ≥ G3 at 1 month. No pts had toxicity G2 at 3 and 6 months. No toxicity was observed at 12 months. The mean follow-up was 10 months (range 3-22 months). Four pts (17%) had a complete response (CR), 11 pts (48%) had a partial response (PR), 7 pts (30%) had a stable disease, (SD) and only 1 pt (4%) had progression disease (PD) and subsequently died. The Local control rate was 95%. Univariate analysis showed that Tmean, Tmax, Tmin, T90 parameters were not associated with local control rate.

Conclusion: Radio-hyperthermia can result in an effective approach, particularly in previously irradiated patients or in radio-resistant tumors. Our results show that Radio-Hyperthermia is an useful combined treatment with a good local control rate and a very high patient compliance.

EP-1478

Low Dose Radiation therapy of degenerative painful osteoarthritis

S. Payano¹, A. Montero Luis¹, O. Hernando Requejo¹, J. Valero Albarrañ¹, M. Lopez Gonzalez¹, R. Ciervide Jurio¹, E. Sanchez Saugar¹, X. Chen¹, C. Rubio Rodriguez¹

¹*Hospital Universitario Madrid Sanchinarro - Grupo Hospital de Madrid, Oncología Radioterápica, Madrid, Spain*

Purpose or Objective: The purpose of this study is to evaluate the decrease in pain of patients treated with low-dose radiation therapy in osteoarthritis.

Material and Methods: From April 2015 to September 2015, 11 patients (10 female and 1 men) were treated with low dose radiotherapy for pain control. All patients were refractory to conventional therapy prior to irradiation.

13 joints (6 bursitis and 7 arthrosis): 4 trochanteritis, 5 knees, 1 left thumb rhizarthrosis, 2 metacarpophalangeal joint and 1 right epicondylitis were treated.

The median age was 69 years (range 46-89) with a median follow-up period of 3 months (range 0-6). Painful status was measured by visual analogue scale (VAS), with a median pre-treatment value of VAS= 7(range 4-9).

The radiotherapy dose of 6 Gy was delivered in 6 alternate days fractions of 1 Gy per fraction. In those patient with no pain relive post-treatment with VAS of or above 6 a second course of radiotherapy was proposed.

The second RT series started 8 weeks after the first RT series.

Results: The analysis was performed before the treatment and at the last follow-up. With a median VAS = 5 (range 0-8) 7 patients achieved pain relief, 3 patients underwent a second course of radiotherapy with identical dose, and 1 patient showed no change in pain. Daily requirements of analgesic were removed or reduced in 5 patients, subjective pain perception of response to irradiation evaluated at time of last visit regarding pre-treatment status was considered as "better" by 73% of patient. No patients presented acute or late complications attribute to radiation therapy.

Conclusion: RT is highly effective for refractory degenerative joint diseases. Prognostic factors for outcome can be established. Due to minimal side effects and low costs, RT represents an excellent treatment compared to conventional methods of treatment and surgery in the chronic disease. This study confirms by objective criteria the anti-inflammatory efficacy of low dose RT

EP-1479

Integration of a minituarized linear accelerator in an 20 year IOERT expert institution

E. Alvarado Vasquez¹, M. Gomez-Espi¹, A. Alvarez¹, A. Calin¹, M. Muñoz¹, J. Blanco¹, F. Serrano¹, C. Gonzalez-San Segundo¹, C. Martinez¹, M. Santos¹, L. Guerrero¹, A. Davo¹, I. Sierra¹, R. Ayala², R. Sendon², M. Lopez-Bote², M. Lozano¹, F. Calvo³

¹Hospital General Universitario Gregorio Marañon, Radiation Oncology, Madrid, Spain

²Hospital General Universitario Gregorio Marañon, Medical Dosimetry and Radioprotection, Madrid, Spain

³Hospital General Universitario Gregorio Marañon, Oncology, Madrid, Spain

Purpose or Objective: Hospital General Universitario Gregorio Marañon has a long-standing tradition of IOERT (Intraoperative electron Radiation Therapy), with over 1600 procedures in its 20 year history. Since december 2013, a minituarized linear accelerator (LIAC) started to operate in our center. We describe the 22 months technical and clinical experience with LIAC in our consolidated IOERT program.

Material and Methods: A review of technical and surgical parameters of IOERT procedures using LIAC was performed from December 2013 to October 2015,

Results: From december 2013 to october 2015, 222 procedures in 185 patients were performed (200 procedures with LIAC, 22 transported to a fixed lineal accelerator). Cancer types treated were 64 oligorecurrences / oligometastases, 34 breast cancers, 44 rectal cancers, 42 sarcomas, 6 pancreatic adenocarcinomas, 4 esophageal neoplasms and 6 other cancer types. The treated anatomic sites included 100 cases in pelvis, 40 in abdomen, 25 in limbs, 34 in breast and 1 in thorax. Relevant operational data included 39 days with more than 2 procedures in the same working day (22% of total days). Six different applicator sizes were selected (range 4-10) with 4 beveled ends (range 0-45). Selected energies ranged from 6 to 12.

Conclusion: LIAC is a versatile technology able to be incorporated to expert IORT institutions promoting efficient action with operative benefits in terms of availability of IOERT components for cancer patients.

EP-1480

A comprehensive analysis of immuno- and immunoradiotherapy trial design developments from 2000-2014

S. Raby¹, C. Connell², T. Janowitz²

¹The Christie, Oncology, Manchester, United Kingdom

²Addenbrooke's Hospital, Oncology, Cambridge, United Kingdom

Purpose or Objective: There has been a rapid growth in the number of immuno- and immunoradiotherapy trials over the last few decades. Long term durable responses occur, but only in a subset of patients. As yet no accurate method of identifying those patients most likely to benefit has been identified. The factors behind non-response are unclear but may include 1) inherent characteristics of the tumour, 2) factors influencing immunogenicity such as tumour burden and previous treatments and 3) clinical trial design. By performing a cross sectional analysis of registered clinical trials investigating agents thought to stimulate T-cells we aimed to detect trends in these factors. In particular we aimed to assess the extent to which trials sought to develop and identify novel biomarkers of response to immunotherapy.

Material and Methods: A pubmed literature search was conducted to establish a list of known T cell checkpoints, co-stimulatory receptors, ligands, and the antibodies targeting these. These search terms were entered into clinical trials.gov on October 11, 2014. Study details were downloaded as datasets for review by two independent assessors.

Results: We identified a total of 350 trials of immunomodulatory antibodies targeting PD-1, CTLA4, PD-L1, PD-L2, LAG3, B7-H3, CD137, OX40, CD27 and GITR. A longitudinal analysis by trial registration date shows a steady increase in the number of trials using immunostimulatory antibodies. As some cancer types are thought to be more immunogenic, we looked at the spread of trials by cancer type. Unsurprisingly, melanoma trials represent the largest proportion, but there has been a shift towards testing immunostimulatory antibodies in cancers that are considered less immunogenic with a significant increase in trials in NSCLC when comparing trials registered between 2000 and 2007 and those registered between 2008 and 2014. Only 39% of trials measured a dynamic immune endpoint as a specified outcome. T and B cell number or function were the most common markers analysed. However there was a significant increase in the measurement of PD-L1 expression in recent years.

Conclusion: This analysis provides comprehensive data on the rapid growth of immunotherapy trials and highlights that despite the multiplicity and variability of potential dynamic biomarkers available, there has been a poor uptake. Whilst the future of immunotherapy is not in doubt, biomarkers are essential to understand the considerable lack of response and help guide further trial efforts.

EP-1481

Toxicity of concomitant application of radiotherapy with „new targeted therapies“

M.S. Geier¹, E. Bräutigam¹, B. Aschacher¹, H. Rumpold², H. Geinitz¹

¹Krankenhaus der Barmherzigen Schwestern - Linz, Radiation Oncology, Linz, Austria

²Krankenhaus der Barmherzigen Schwestern - Linz, Oncology, Linz, Austria

Purpose or Objective: New targeted therapies (nTTs) are increasingly used in virtually every type of cancer. On the other hand radiation therapy (RT) is frequently applied in the curative and palliative setting of cancer treatment, confronting clinicians more and more with the problem, whether a previously initiated nTT-therapy could be continued during RT. The aim of this systematic literature analysis was to evaluate the toxicity of concomitant application of RT with nTTs in a qualitative descriptive manner.

Material and Methods: Clinical studies comprising concomitant application of RT with EGFR-, VEGFR-, HDAC-, proteasom-, BRAF-, m-Tor- or immune-checkpoint-inhibitors were eligible. Using fixed search terms 215 publications were identified including more than 6000 patients. Forty-eight studies analyzed combinations of nTTs with ZNS-RT including 1164 patients, 45 with head and neck-RT including 2390 patients, 59 with thoracic RT including 1647 patients, 33 with abdominal RT and 30 with pelvic RT including 492 and 1008 patients respectively.

Results: In most cases combined application produced no additional toxicity or a slight increase of the already known toxicity profile. Scarcely, however, combination of RT with nTTs resulted in serious side effects. These toxicities comprised tracheo-bronchial fistulas or GI-bleeding for combinations of thoracic or abdominal/pelvic RT with VEGF-receptor-inhibitors, recall phenomena in combination of RT with tyrosinkinase inhibitors e.g. erlotinib and severe mucositis, dermatitis or paraplegia (case report) when combining RT with ipilimumab. For the majority of these

serious side effects no predictive risk factors could be isolated.

Conclusion: The currently available data seems to be not adequate to give a general recommendation, on whether RT could be combined with nTTs in clinical routine. If application is carried out on an individual basis it should be done under close clinical surveillance. Multicentric observational studies are needed to address this clinical relevant problem.

EP-1482

Improving accuracy of radiochromic film dosimetry system using control film piece

S. Devic¹, S. Aldelaijan², F. Alzorkany², N. Tomic¹, J. Seuntjens¹, F. DeBlois¹, B. Mofrah²

¹McGill University, Oncology, Montreal, Canada

²King Faisal Specialist Hospital & Research Centre, Department of Biomedical Physics, Riyadh, Saudi Arabia

Purpose or Objective: Over the years, radiochromic film became a reference dosimetry system of choice for two-dimensional dose distribution measurements with acceptable accuracy and uncertainty in both clinical and research applications. Nonetheless, response of the film might be influenced by factors other than irradiation (humidity, extreme temperature and/or exposure to UV light) that could lead to decreased measurement accuracy. We investigate the use of a control film piece, which should compensate for the film response changes other than radiation.

Material and Methods: Response of EBT3 film was measured in terms of net transmittance calculated using green channel from 48-bit RGB image of film pieces scanned with Epson Expression 10000 XL flatbed scanner. We established a calibration curve for the radiochromic film dosimetry system in a dose range up to 20 Gy. Then, we irradiated "control" film pieces to several known doses from 0.05, to 1 Gy, as well as five film pieces of the same size to "unknown" doses of 2, 5, 10, 15 and 20 Gy. Impact of correcting measured ("unknown") doses using "control" film pieces were investigated in terms of both gain in the accuracy and at the same time loss of uncertainty of such determined dose. Depending on a dose range, two approaches of incorporating control film piece were investigated. In a signal based method, response of the control film piece is subtracted from the measuring film piece and the final change in response is converted into the dose using calibration curve. In a dose based method, both readings of measuring and control film pieces are converted to dose using the same calibration curve followed by subtracting the control film piece "equivalent" dose from the dose obtained with measuring film piece.

Results: Figure 1 summarizes results of our investigation into trade-off between gain in accuracy and loss in uncertainty when the control film piece is used, and we found that both are dependent on dose level measured. For dose values above 10 Gy, the increase in accuracy of 3% results in uncertainty loss of 5% by using dose corrected approach, where the measured film response corresponded to 2% of the dose response registered with measuring film piece. At lower doses and signals of the order of 5% (measured by control film piece) we observed an increase in accuracy of 10% with a loss of uncertainty lower than 1% by using the corrected signal approach.

Figure 1: Trade-off using control film piece: percent uncertainty loss and percent accuracy gain for signal corrected (top-left) and dose corrected (top-right) approach as a fraction of measured doses for various dose measurement levels; absolute error for signal corrected (bottom-left) and dose corrected (bottom-right) approach. Lines represent guide for the eye.

Conclusion: Use of the control (un-irradiated) film piece for dose measurements in reference radiochromic film dosimetry is highly recommended. At lower doses, the signal based method should be used, while at higher doses the dose correction method seems to be more appropriate. However, final incorporation of the signal registered by the control film piece into dose measurement analysis should be a judgment call of the user based on a tradeoff between deemed accuracy and acceptable uncertainty for a given dose measurement.

EP-1483

Reference dosimetry of FFF MV photon beams: a correction for intra-Farmer ion chamber dose gradients

R. Ruggieri¹, S. Naccarato¹, P. Stavrev¹, N. Stavreva¹, S. Pasetto¹, I. Salamone², F. Alongi¹

¹U.O. Radioterapia, Ospedale 'Sacro cuore - don Calabria', Negrar, Italy

²U.O. Radiologia, A.O.U. 'G. Martino', Messina, Italy

Purpose or Objective: To estimate and correct the systematic bias which results from the intra-chamber dose gradients when a Farmer ionization chamber is used for reference dosimetry (TRS 398, IAEA 2000) in flattening-filter-free (FFF) MV photon beams.

Material and Methods: An intra-chamber dose gradient correction factor (K_{icdg}) of the charge reading of a Farmer ionization chamber, when used for reference dosimetry (TRS 398, IAEA 2000) in flattening-filter-free (FFF) MV photon beams, is proposed. This is achieved through a user intercomparison of the Farmer ionization chamber with a small volume ($\sim 0.1 \text{ cm}^3$) ionization chamber, and by estimating the inaccuracies of this intercomparison. Further, the factor K_{icdg} is theoretically developed in terms of the corrections for both volume averaging effect (P_{vol}) and charged particle fluence perturbation (P_{fl}). The factor P_{vol} is then estimated as the ratio of the active length (L) of the Farmer ionization chamber ($L = 24 \text{ mm}$) over the integral, computed on L , of a high-resolution FFF transverse dose profile (Figure 1). Once K_{icdg} and P_{vol} are known, P_{fl} is finally deduced.

Results: The estimated overall standard uncertainties on the absorbed dose to water determination in reference conditions, for 6 MV and 10 MV FFF beams, were 1.5 % for the small volume ionization chamber (30013™, PTW), and 1.4 % for the K_{icdg} -corrected Farmer ionization chamber (30013™, PTW). In the latter case, the added uncertainty from the measure of K_{icdg} was balanced by the higher long-term stability of the Farmer ionization chamber. From four distinct dosimetry sessions on a TrueBeam™ (Varian Inc.) linac, mean (sd) values for K_{icdg} equal to 1.0024 (0.0003) for 6 MV-FFF and 1.0056 (0.0003) for 10 MV-FFF, were estimated. Similarly, P_{vol} equal to 1.0030 (0.0001) for 6 MV-FFF, and to 1.0064 (0.0004) for 10 MV-FFF, respectively, were measured.

Finally, P_{fl} equal to 1.0021 (0.0004) for 6 MV-FFF, and to 1.0033 (0.0005) for 10 MV-FFF, respectively, were computed. Figure 1. Average transverse dose profiles of the (10x10) cm² field, for 6 MV (gray) and 10 MV (black) FFF photon beams from a TrueBeam™ (Varian Inc.) linac, scanned, along $L = 24$ mm with 0.5 mm step, by a shielded p-diode (T60016™, PTW) at 10 cm of depth in water with SSD= 90 cm. ($\pm 1sd$)-error bars (<0.1 %) refer to four sessions of measurements spanning about six months.

Conclusion: The factor K_{icdg} , which can be approximated by P_{vol} within 0.1 %, corrects for a dose error up to -0.6 % in reference dosimetry of the 10 MV-FFF photon beam when a Farmer ionization chamber is used.

EP-1484

The dosimetric property of TLD2000 thermoluminescent dosimeter

R. Yang¹

¹Yang Ruijie, Radiation Oncology, Beijing, China

Purpose or Objective: To study the dosimetric properties of TLD2000 thermoluminescent dosimeter (TLD), including repeatability, linearity of dose response, energy response and dose rate effect.

Material and Methods: 1300 TLD2000 TLDs were read out after exposure to a dose of 1 mGy of 65 keV x-ray, then were sorted out to have the same sensitivity within $\pm 3.0\%$. TLDs were irradiated to a dose of 120 MU using 6 MV x-ray, then irradiated to the same dose after 24 h. TLDs were irradiated with two I-125 seeds with the same activity for 24 h, and the interval time was 24 h, to study the repeatability of TLDs for 6 MV x-ray and I-125 seed. TLDs were irradiated to different doses using Cs-137 (662 keV γ -ray), I-125 seed and 6 MV x-ray, to study the dose response of the TLDs. TLDs were irradiated to a dose of 1 mGy using Cs-137, 48 keV, 65 keV, 83 keV, 118 keV and 250 keV x-rays, to study the energy response of the TLDs. TLDs were irradiated to a dose of 120 MU using 6 MV x-ray with different dose rates of 37 MU/min, 75 MU/min, 150 MU/min, 300 MU/min and 600 MU/min; TLDs were irradiated to the same dose using three 125I seeds with different activities of 0.739 mCi, 0.675 mCi and 0.559 mCi, and the irradiated time were 24 h, 26h 17 min and 31 h 48 min, respectively, to study the dose rate effect of TLDs for 6 MV x-ray and 125I seed.

Results: 350 TLD2000 TLDs were selected with the sensitivity within $\pm 3.0\%$. The maximum deviations of the repeatability were 2.7% and 4.0% for 6 MV x-ray and I-125 seed, respectively. The dose response of TLDs for Cs-137 and I-125 seed were linear. For 6 MV x-ray, the linear response range were 0.74 Gy-10.0 Gy, beyond 10.0 Gy the dose response became supralinear but proportional to the absorbed dose to TLD. The energy response for 48 keV, 65 keV, 83 keV, 118 keV and 250 keV x-rays, relative to the energy response of Cs-137, were 1.25, 1.08, 0.99, 0.91 and 0.96, respectively. There were no dose rate effects in the dose rate range of 37 MU/min to 600 MU/min for 6 MV x-ray and 0.66 cGy/h to 0.87 cGy/h for I-125 seed.

Conclusion: TLD2000 TLD has good repeatability and linear dose response for Cs-137, I-125 seed and 6 MV x-ray without dose rate effect, but the dose response is energy dependent.

EP-1485

Characterization and performance of the MR compatible Delta4 patient QA system in a hybrid MRI-Linac

W. De Vries¹, R. Van Rooij², E. Seravalli¹, D. Nystrom³, S.J. Woodings¹, J.W.H. Wolthaus¹, B.W. Raaymakers¹

¹UMC Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands

²UMC Utrecht, Department of Radiology and Nuclear Medicine, Utrecht, The Netherlands

³Scandidos AB, R&D, Uppsala, Sweden

Purpose or Objective: At our institute a prototype of a MRI-Linac (MRL) has been installed combining imaging (MRI, Philips) with treatment (Linac, Elekta). However before starting patient treatments, extensive machine quality assurance (QA) must be investigated including QA of treatment-plans. Standard electronic equipment is not MR-safe so patient-specific QA systems have had to be re-designed, and the performance of a new system in a 1.5 T magnetic field must be tested. The purpose of this study was to examine and characterize the performance of the newly developed MR-compatible Delta4 phantom in a transverse 1.5 T magnetic field.

Material and Methods: A prototype MR-compatible version of the Delta4 QA phantom (ScandiDos AB) was used in these measurements. To characterize this QA-system, the short-term reproducibility, dose linearity, field size dependence, dose rate dependence, dose-per-pulse dependence and angular dependence were evaluated on a conventional linac (B0=0, Elekta, 6MV Flattened (FF) and 6MV Flattening Filter Free(FFF) beam, SAD of 100 cm) and the MR-linac (B0 = 1.5 T, Elekta 6 MV FFF beam, SAD of 142.7 cm). All measurements were normalized to the readings of an ionization chamber. The performance of the MR-compatible Delta4 was also compared to that of a commercially-available clinical version in use in our department.

Results: The maximum differences between the clinical and the MR-compatible Delta4 measurements on a conventional linac are represented in the table below:

	FF-beam (B ₀ =0)	FFF-beam (B ₀ =0)
Short term reproducibility	0.05%	0.21%
Dose linearity	0.59%	0.64%
Fieldsize dependency	0.36%	0.38%
Dose rate dependency	0.25%	0.36%
Dose-per-pulse dependency	0.43%	0.47%
Angular dependency	---	0.89 %

Measurements are currently being performed on the 1.5 T research-prototype MRL. Analysis of the preliminary data show similar behavior to the measurements performed without magnetic field. Final results will be presented.

Conclusion: The characteristics and performance of the MR-compatible Delta4 have been investigated. There are no significant differences found between the clinical phantom and the MR-compatible phantom. The preliminary results at the MR-linac are consistent with those from the clinical linac.

EP-1486

Evaluation of detectors response for small field output factor measurement using Gafchromic film

G. Rucka¹, B. Patrice¹, N. Asquier¹, J.C. Mouttet¹

¹Croix Rouge Française, Radiothérapie, Toulon, France

Purpose or Objective: Most irradiation technics require dose computing from TPS. Calculation accuracy highly depends on the measurements used for beam modeling. Depending on their characteristics, available detectors may be best suited for specific field sizes when measuring Output Factors (OF). Recent studies compare several active with passive detectors and MonteCarlo calculation. The goal of our study is to

evaluate the response of several active detectors exposed to 6 MV X-ray beams of different sizes, down to 1x1 cm², while considering EBT3 Gafchromic films as reference.

Material and Methods: Eight EBT3 films were irradiated with field sizes ranging from 1x1 to 10x10 cm². Measurements were done in a homemade RW3 solid water phantom. Multichannel film dosimetry was used for film opacity-to-dose conversion. All films (including background) were irradiated and scanned simultaneously using the efficient protocol described by D. Lewis *et al.* Among available active detectors, two ionization chambers and two diodes were studied. Measurements were carried out in a water phantom. OF measurements were also done by placing both chambers in the solid water phantom, in the same condition as the films. Results were compared to measurements done in water in order to verify scattering components correspondence for all field sizes. This allows active detectors irradiated in water to be compared to the films in RW3 slabs.

Results:

OF obtained with the ionization chambers placed in the water and solid water phantom are identical for field sizes smaller than 15x15cm². As described in H. Benmakhouf publication, active detector response for each field size was normalized with respect to the reference data. Figure 1 shows results. Concerning ionization chambers, the influence of partial volume averaging is similar to the published results. The three major effects mentioned for the diodes also appear in our results: the charged particles equilibrium between detector material and water, the over-response of the unshielded diode in broad beams and the partial volume averaging.

Conclusion: Our study confirms that partial volume averaging is not the only undesirable effect for OF measurement. Thus, the detector having the best spatial resolution is not systematically the best suited for small fields OF measurements.

EP-1487

Dosimetric properties of a new formula PRESAGE with tin metal catalyst

D. Khezerloo¹, H.A. Nedaei², A. Takavar², A. Zirak³, N. Banaie⁴

¹Tabriz university of Medicine, Radiology, Tabriz, Iran Islamic Republic of

²Tehran university of Medicine, Medical Physics, Tehran, Iran Islamic Republic of

³Laser and Optics Research School, Optics and Photonics, Tehran, Iran Islamic Republic of

⁴Azad university- science and research branch, Radiation Research, Tehran, Iran Islamic Republic of

Purpose or Objective: Metal compounds in the fabrication of new radiochromic polymer gel dosimeters based on polyurethane resin act as catalyst to accelerate the polymerization of the dosimeter precursors. Tin-base catalyst is one of the widely used catalysts in polyurethane technology. The main purpose of this study is an evaluation

of effect of tin-metal catalyst in new formula of PRESAGE response and radiological properties of it.

Material and Methods: A very little amount of dibutyltin dillaurate (0.07 wt%) was used as catalyst in the fabrication of the new PRESAGE which components were: 93.93 wt% polyurethane, 5 wt% tetrachloride and 1 wt% Leucomalachite green. Radiochromic response and post-irradiation response of new PRESAGE were determined. Radiological characteristics of new PRESAGE such as mass density, electron density, mass attenuation coefficient and mass stopping power in different photon energies were assessed and compared with water and a commercial PRESAGE® radiochromic.

Results: Absorption peak of new PRESAGE with metal was seen unchanged. Sensitivity of new PRESAGE was relatively two times higher than commercial PRESAGE® and stability of new PRESAGE after one hour was seen constant. Mass attenuation coefficient in energy less than 0.1 MeV was 10% more than water, whereas the mass stopping power difference was only 2%.

Conclusion: Tin catalyst with very low weight fraction can be used in fabrication of radiochromic polymer gel in order to fabricate a gel with high sensitivity and stability as well as good radiological properties in the megavoltage photon beam.

EP-1488

Estimation of the RBEs of two miniature x-ray devices, I-125, Ir-192 and Co-60 BT-sources

T. Schneider¹, M.U. Bug¹, H. Rabus¹

¹Phys. Techn. Bundesanstalt PTB, AG 6.63 Biological Effectiveness of Ionizing Radiation, Braunschweig, Germany

Purpose or Objective: Today over 300 miniaturized x-ray devices (MXD) from the companies Carl Zeiss Meditec AG (Intrabeam®) and Xoft (Axxent®) are applied in clinics worldwide for radiation therapy treatment (RTT) of breast cancer. Both devices emit an x-radiation field where the energy distribution is given by a continuous Bremsstrahlung-spectrum with a maximum energy of 50 keV and characteristic fluorescence lines induced by the material of the electron target and the materials in the pathway of the emitted photons. Low-energy x-rays are known to have a higher relative biological effectiveness (RBE) than higher energy photons such as the gamma rays from Ir-192 and Co-60. In this work the RBEs of the MXDs and of I-125, Ir-192 and Co-60 BT-sources at several points within a hemispherical water-phantom are estimated by calculational techniques based on both micro- and nanodosimetry.

Material and Methods: Spectra of both devices were obtained by measurements with an HPGe-Detector and applying the sophisticated data evaluation procedures already presented at the 2nd ESTRO-Forum. For the photon transport-calculations the respective source is located 4 cm below the spherical surface and spectra are calculated at several points along the axis through the centre of the hemisphere. The first approach is based on a comprehensive biological study of the α -dic variation by E. Schmid (GSF, Munich) in the photon energy range from 1 keV to 1.3 MeV. The yield coefficient α -dic represents the linear or α -component of the yields of dicentric chromosomes and is considered to be strongly correlated with the RBE. A strong dependence of α -dic on the photon energy was thereby revealed with a maximum of RBE = 8 at 7 keV in comparison with Co-60. Based on this experimental data microdosimetric calculations were performed to obtain an energy dependent function α -dic(E) (D. Harder, W. Friedland et al). The RBE for a given source in a given point is obtained by a convolution of the respective spectrum with α -dic(E). For the second approach each of the calculated spectra is taken as a starting point for simulations with Geant4-DNA to obtain the track structure of the ionising radiation. The track structure is characterised by the frequency distribution of the ionisation

cluster size (ICS), which is the number of ionisations produced by a single particle within a specified volume.

Results: In the figure the RBE-values for the two MXD is presented as a function of the distance from the source. For both sources the RBE decrease with increasing distance from the source. From the shape of the calculated spectra this can be explained by beam hardening effects.

Conclusion: The determined RBE-values of 2.8 and higher can be traced back directly to the experimental data of E. Schmid as in the whole photon energy range from 4 - 50 keV the RBE was found to be higher than 2.6. This finding is in contrast to literature in which an enhanced RBE by 40 - 50% is reported and will be discussed taking the track structure into account.

EP-1489

On the development of a primary standard for validating internal radiation dose assessment methods

I. Billas¹, D.R. Shipley¹, S. Galer¹, G. Bass¹, T. Sander¹, V. Smyth¹

¹National Physical Laboratory, Radiation Dosimetry, Middlesex, United Kingdom

Purpose or Objective: Molecular radiation therapy (MRT) has a long history of treating cancer by delivering a dose of radiation from a radioactively labelled pharmaceutical that is taken up by the tumour. At present the methods for determining the radiation dose to tissue are not traceable to any standards of absorbed dose. The determination of the internal absorbed dose from an administered radionuclide (RN) relies on Monte Carlo (MC) calculations based on nuclear data (emission probabilities and energies). The validation of these methods with experimental measurements is necessary to achieve the required traceability of the measurement of absorbed dose within the patient. The goal of this work is to develop a suitable method for measuring the absorbed dose from a RN solution that can serve as a primary standard. Comparison between measurements and calculations of absorbed dose in the same geometry will allow the validation of the MC dose calculation methods.

Material and Methods: A modified extrapolation chamber (EC) was used for measuring the dose from a Y-90 RN solution. An EC is a suitable dosimeter as it has a thin entrance window allowing beta particle measurement and is capable of measuring low currents with small uncertainties. The volume of the chamber can be varied by changing the distance between the front and back faces. A phantom developed in-house was used to position the EC as closely as possible to the surface of the solution. The performance of the EC was characterised and a full uncertainty budget was obtained. The ionisation current was measured for different chamber volumes of the EC and a product of correction factors was applied to obtain the true current. MC simulations were performed to relate absorbed dose in the volume of the chamber to absorbed dose at the centre of the RN solution. This allows a direct comparison of the calculated and measured absorbed dose of Y-90 RN solution. The Y-90

source emission spectra published by MIRD and RADAR were used to directly determine the calculated absorbed doses at the centre of the RN solution.

Results: The overall standard uncertainty in the measurement of absorbed dose at the centre of a Y-90 solution with the EC was determined to be in the range $\pm 1.3\%$ to $\pm 1.6\%$ ($k = 1$). The calculated Y-90 absorbed dose from published MIRD and RADAR data agreed with measurement to within 1.6% and 1.5% respectively.

Conclusion: These results demonstrate the feasibility of using an EC for performing primary standard absorbed dose measurements of an unsealed radioactive solution. Internal radiation dose assessment methods based on RADAR and MIRD data for Y-90 have been validated with experimental absorbed dose measurements and they agree within one standard uncertainty. Future work will include a repeat of Y-90 measurements in order to further validate the present results and to extend the measurements to other RNs used for MRT.

EP-1490

Angular independent silicon detector for quality assurance in Small Field Radiotherapy

S. Alhujaili¹, M. Petasecca¹, A. Rosenfeld¹

¹University of Wollongong, Centre for Medical Radiation Physics, Wollongong, Australia

Purpose or Objective: Stereotactic Radiosurgery modalities (SRS) allowing conformal dose distributions and adopting hypo-fractionation regimes require accurate Quality Assurance (QA) to avoid plan or operator mistakes. The QA of small field, multidirectional photon beams requires radiation dosimeters that have small sensitive volume, angular independent and operating in real time. The CMRP in collaboration with Advacam Ltd. has developed EDINA, an innovative silicon diode based probe, to meet the QA requirements of SRS.

Material and Methods: The edgeless single diodes are manufactured using both n-type and p-type silicon substrates with 0.5 mm and 0.1 mm thicknesses. By using an ion implantation technique, four different configurations of top and peripheral p-n junctions are created. The Edgeless diodes' samples are also fabricated with two different sizes (0.5x0.5 mm² and 1x1 mm²) and embedded in Kapton tails with 0.5 mm thickness, 3mm width and 30 cm length using CMRP Drop-In Assembling technology, providing the dosimetry probe EDINA easy connected to electrometer. A full dosimetric characterisation of the radiation probes have been carried out. Output factor and angular dependence are measured by the edgeless detectors and compared with EBT3 film under reference irradiation conditions. The dose rate and PDD measurements of EDINA have been performed in a solid water phantom whereas the angular dependence test was carried out in a cylindrical PMMA phantom, rotatable with accuracy of 0.25 degree.

Results: The PDDs measured with EDINA on 6MV photon fields from 1.5 to 25 cm depth demonstrated an agreement with ion chambers within $\pm 2\%$. The dose rate dependence in a range of 0.9×10^{-5} - 2.7×10^{-4} Gy/pulse was less than -7% and +300% for EDINA with diodes fabricated on p-type and n-type substrates, respectively. Diodes fabricated on p-type and n-type substrates demonstrated degradation of the response with accumulated dose of 40 kGy within 5% and 30%, respectively.

The output factor measurements performed by EDINA utilizing smallest size diodes (0.5x0.5 mm²) show an agreement with film within 2% for square radiation field sizes ranging from 0.5 to 10 cm (Fig.1a). The angular response of EDINA utilizing thin 0.1mm thick smallest size p-type diodes (NP_100 and PP_100) varies within 2% (Fig.1b) between 0 and 180 degree and independent from accumulated dose.

Fig.1: a) Output factor measured at 10 cm depth for a 6MV beam energy; b) angular dependence for p-type edgeless detectors with different top-peripheral junction configuration.

Conclusion: A radiation QA probe EDINA for small field dosimetry using new fabrication technology of silicon diodes and packaging has been developed. The EDINA has isotropic response, and well matching to EBT output field factor response making it suitable for small field dosimetry and quality assurance for SRS.

EP-1491

Energy response of radiophotoluminescent glass dosimeter for non-reference condition

S. Hashimoto¹, T. Okano¹, T. Furuya¹, S. Klto¹, K. Karasawa¹
¹Tokyo Metropolitan Cancer and Infectious diseases Center Komagome Hospital, Radiation Oncology, Tokyo, Japan

Purpose or Objective: When an absorbed dose to water is determined using radiophotoluminescent glass dosimeter (RGD), it is necessary to convert the radiophotoluminescent quantity into a water absorbed dose with calibration factor. Generally, dose calibration is performed at reference condition (on the central axis at a depth of 10 cm for a 10 cm×10 cm field). Although, patient specific dose measurement is performed at non-reference condition, RGD response may be changed because RGD has energy dependence. In this study, we evaluated the variation of RGD response for non-reference condition measurement using Monte Carlo (MC) simulation.

Material and Methods: To analyze the energy response of RGD for non-reference condition beam, absorbed dose ratio of water to RGD and mean mass energy absorption coefficient of water to RGD ($(\mu\text{en}/\rho)_{\text{w,RGD}}$) was simulated using EGSnrc code. The irradiation conditions for the MC simulations were set to 5 cm×5 cm, 10 cm×10 cm and 20 cm×20 cm field for 10 MV photon beam. RGD was set to the central axis at 10 cm depth in water phantom. For 20 cm×20 cm field, 20 cm off axis position were calculated, respectively. The photon beams source for the MC simulation, radiation transport in the accelerator was modeled using the BEAMnrc Monte Carlo code. The accelerator geometry and materials were obtained from the manufacturer's data for the Clinac21EX.

Results: The dose ratio was from 1.168 to 1.149 for 5 cm×5 cm to 20 cm×20 cm, respectively. $(\mu\text{en}/\rho)_{\text{w,RGD}}$ was 1.079 and 1.075 for field sizes of 5 cm × 5 cm and 20 cm × 20 cm, respectively. When the field size became large, scattered low energy photon increase. Mass energy absorbed coefficient of RGD is very high for low energy photon. Therefore, the RGD response became increase with increase field size. In the 20 cm off axis position for 20 cm×20 cm field, energy response showed more variation. The dose ratio and $(\mu\text{en}/\rho)_{\text{w,RGD}}$ was 0.962 and 0.937, respectively. In out of field locations, the spectra contained more low-energy photons.

Conclusion: In this study, we evaluate the variation of RGD response for non-reference condition measurement. As a results, RGD response was affected by the low energy photon. This response change should be considered when the non-reference condition measurement is performed using RGD.

³Tehran University Of Medical Sciences-Imam Khomeini Hospital, Cancer institute, Tehran, Iran Islamic Republic of

⁴Payambaran Hospital, Imaging Center, Tehran, Iran Islamic Republic of

Purpose or Objective: In this study a series of basic dosimetric properties of a low density (LD) gel dosimeter are studied. The dose response is investigated regarding to temporal stability, detectable dose range, sensitivity, dose-rate and energy dependence as well as lung tissue equivalence.

Material and Methods: The LD gel is made by mixing the polymer gel with expanded polystyrene spheres. Methacrylic acid is used as a monomer and tetrakis-hydroxy-methyl-phosphonium chloride (THPC) as an oxygen scavenger (MAGAT polymer gel dosimeter). The temporal stability of LD gel is monitored for a period of a month. Energy dependence is studied at two energies; 1.25 MeV and 6 MV photon beam which are produced by ⁶⁰Co and Linac machines. investigation of dose rate dependence is performed in the low, medium, and high absorbed region. Also reproducibility of dose response is studied in three sets of LD gel with identical preparation, irradiation and imaging procedure in three different days. Moreover the linearity and sensitivity is investigated up to dose of 20 Gy.

Results: The response of the gel indicates, the dose response curve attained stability during the measured time. The results also show that the dose response is reproducible. The gel response is found linear over the measured dose with $r^2=0.981$ and sensitivity of 0.814 S-1Gy⁻¹. In the measured range, the dose response of the NIPAM gel is independent of beam energy within less than ± 0.02 and the dose rate had no effect on the gel response. LD gel is nearly lung tissue equivalent with average mass density of 0.35 to 0.42 g/cm³ and average relative electron density of 0.41.

Conclusion: MAGAT LD gel dosimeter appears to be a promising dosimeter in all aspects of dosimetric properties evaluated in this study. In addition, its high linearity together with no dose rate dependence in different level of dose make it a suitable dosimeter to measure 3D-dose distributions inside a non-homogeneous media such as lung tissue.

EP-1493

Modelling the energy dependence of Cherenkov light correction in plastic scintillation detectors

A. Dimitriadis^{1,2,3}, L. Archambault⁴, C. Clark^{2,3}, H. Bouchard³

¹University of Surrey, Faculty of Engineering and Physical Sciences, Surrey, United Kingdom

²Royal Surrey County Hospital, Department of Medical Physics, Guildford, United Kingdom

³National Physical Laboratory, Acoustics and Ionising Radiation, Teddington, United Kingdom

⁴Université Laval, Department of Physics- Engineering and Optics, Québec, Canada

Purpose or Objective: Plastic scintillation detectors (PSD) are highly valuable for a variety of dosimetry applications, since their atomic composition and volume size produce small perturbation effects. A commercial PSD provided by Standard Imaging Inc (Exradin W1) is available and its Cherenkov light correction is based on the method proposed by Guillot et al. However, recent studies showed that the Cherenkov light ratio (CLR) is energy dependent, which could compromise its performance in clinical photon beams. The goal of this work is to investigate a theoretical model to characterize the

energy dependence of the CLR and evaluate its effect on photon beam measurements.

Material and Methods: The electron energy cut-off at which Cherenkov light is produced varies with the wavelength-dependent refractive index. Based on this rationale, the theoretical CLR, describing the relative amount of blue to green light, is formalised analytically using the Cherenkov emission distribution and the detection efficiency functions of the blue and green channels. As the analytic expression depends on the electron spectrum, Monte Carlo simulations of several photon beam qualities are performed to evaluate the spectrum. This allows predicting the theoretical CLR as a function of the TPR₂₀₁₀ quality index (QI), which includes cobalt-60 and megavoltage (MV) beams. Experiments are performed to evaluate CLR over a wide range of QI in cobalt-60 and clinical MV beams.

Results: Comparison between experiments and theory show that the model reproduces the behaviour of the CLR energy dependence. However, the model under predicts the magnitude of the effect. For clinical MV beams, the variation of the theoretical CLR is about 0.5% while it is found to be about 1.8% with experiments. For cobalt-60 beam, the theoretical CLR is found to be about 1.005 of the value at the reference QI while the experiment reports a value of 1.017. Discrepancies between experiments suggest that other effects play a role in the energy dependence. More specifically, the model implicitly assumes isotropic Cherenkov emission, while the angular distribution of the light varies with the electron kinetic energy and the optical fibre only guides light emitted at a specific angular range. Further improvements modelling Cherenkov light transport explicitly should confirm these hypotheses.

Conclusion: The theoretical model proposed in this work is promising to evaluate the energy dependence of the Cherenkov correction in commercial PSD. Potential applications of this work could allow determining the energy dependence of PSD measurements using the CLR technique in small photon fields.

EP-1494

Absolute dosimetry with EBT3 Gafchromic films in a pulsed electron beam at high dose-rate

M. Jaccard¹, K. Petersson¹, T. Buchillier¹, C. Bailat¹, J.F. Germond¹, R. Moeckli¹, J. Bourhis², M.C. Vozenin², F. Bochud¹

¹CHUV - Institute of Radiation Physics IRA, Radiology, Lausanne, Switzerland

²CHUV, Radio-oncology, Lausanne, Switzerland

Purpose or Objective: Animal studies have shown that irradiation by a pulsed electron beam with high dose-rate allows for tumour control while sparing normal tissues. Dosimetry of clinical high dose-rate pulsed beam is challenging because of dose-rate dependence and saturation effects. The aim of this study was to assess the suitability of Gafchromic EBT3 films for performing absolute dose measurements in the electron beam of a prototype linac capable of mean dose-rate (Dm) ranging from 0.07 to 1000 Gy/s, dose-rate in pulse (Dp) up to 106 Gy/s, and energy between 4 and 6 MeV. To this purpose, we evaluated the overall uncertainties of film dosimetry as well as the energy and dose-rate dependence of their response.

Material and Methods: Our dosimetry system is composed of EBT3 Gafchromic films (Ashland Inc., Wayne, NJ, USA) in combination with a flatbed scanner. All sources of uncertainties in film dosimetry (dispersion of pixel values, film inhomogeneity, reproducibility, scanner variability) were carefully evaluated using a conventional clinical linac. Energy dependence was also investigated by acquiring and comparing calibration curves at three different energies (4, 8 and 12 MeV), for doses between 25 cGy and 30 Gy. Dose-rate dependence was studied with the prototype linac for Dm ranging from 0.07 Gy/s to 1000 Gy/s and Dp between 103 and 106 Gy/s. The determination of dose-rate dependence was performed by comparing doses from the films to three independently calibrated dosimeters, namely thermoluminescent dosimeter (TLD), alanine pellets and a chemical dosimeter based on methyl viologen (MV). Furthermore, we studied the correlation between the dose measured by the films and the total charge of electrons measured at the exit of the machine.

Results: We showed that, sticking to a fixed protocol of film processing, a total uncertainty below 4% (k=2) can be obtained in the dose range between 3.5 and 16 Gy. Results also demonstrated that EBT3 films did not display any significant energy dependence for electron energies between 4 and 12 MeV and doses between 25 cGy and 30 Gy since differences between calibration curves were all within uncertainties. In addition, we obtained excellent consistency between films, TLD, alanine and MV over the entire dose-rate range showing the absence of dose-rate dependency. This aspect was further corroborated by the fact that the dose per pulse as measured by films was proportional to the electron charge contained in the pulse.

Conclusion: Our study shows that the use of EBT3 Gafchromic films can be extended to absolute dosimetry in pulsed electron beams with very high dose-rate (Dm up to 1000 Gy/s and Dp up to 106 Gy/s) and energies between 4 and 12 MeV. The measurements results are associated with an overall uncertainty below 4% and are dose-rate and energy independent.

EP-1495

Evaluation of measurement dose uncertainty of Gafchromic EBT3 because of local inhomogeneity

E. Sukhikh¹, L. Sukhikh², E. Malikov³, P. Filatov⁴

¹Tomsk Regional Oncology Center, Radiobiology, Tomsk, Russian Federation

²National Research Tomsk Polytechnic University, Applied Physics, Tomsk, Russian Federation

³National Research Tomsk Polytechnic University, Laboratory No 42, Tomsk, Russian Federation

⁴Meshalkin Research Institute of Circulation Pathology, Radiobiology, Novosibirsk, Russian Federation

Purpose or Objective: Operation of any dosimeter assumes knowledge of the expected uncertainty that could be caused by different factors. The possible sources of uncertainty for Gafchromic EBT3 film were investigated (Phys. Med. v. 29(6), (2013) p. 599) where it was shown that the error amounted 0.55% neglecting local inhomogeneity of the film. The homogeneity of Gafchromic EBT2 film was investigated (Med. Phys. v. 37(4), (2010) p. 1753) and it was shown that inhomogeneity of absorbed dose amounted 6%. The purpose of current work is to calibrate Gafchromic EBT3 films using 10 MV photon beam, 6 MeV and 10 MeV electron beams and to estimate value of the measured absorbed dose uncertainty caused by the local inhomogeneity of the film.

Material and Methods: The calibration of Gafchromic EBT3 film was carried out using 10 MV photon beam and 10 MeV electron beam of Elekta Axesse linac, and also at 6 MeV electron beam using compact betatron for intraoperative therapy. In the case of Elekta Axesse the Farmer FC65-P cylindrical chamber and DOSE-1 electrometer were used. In the case of betatron we used the plane-parallel chamber PTW 23342 (Markus) and Unidose-E electrometer. The pieces of Gafchromic EBT3 film were irradiated by different doses

up to 40 Gy resulted in calibration curves. Due to the fact that the films were irradiated by the uniform field it was possible to estimate local inhomogeneity. The obtained calibration curve allowed to calculate dose from the net optical density of the irradiated films. Using standard error propagation techniques it was possible to estimate calculated dose uncertainty.

Results: The experimentally obtained dependences of reference dose on the film net optical density were fitted by the expression $D = a \text{ NetOD} + b \text{ NetOD}^n$ (a, b, n are the free fit parameters). The comparison of calibration curves for different sources showed that the ones for 10 MeV electron beam and 10 MV photon beam coincide in the range (0.86-1.06) for the red channel and in the range (0.94-1.04) for the green channel depending on the value of net optical density. In the case of electron beams of different energies the coincidence is better for both channels. The values of obtained dose uncertainties lay within 5.5% for 6 MeV electron beam, 5% for 10 MeV electron beam and 7% for 10 MV photon beam (0.95 confidence interval).

Conclusion: The present work shows that homogeneity of the new generation of Gafchromic EBT3 film is better than previous generation one according to the measured dose uncertainty.

EP-1496

Small field correction factors for the IBA Razor

P.Z.Y. Liu¹, G. Reggiori², F. Lobefalo², P. Mancosu², S. Tomatis², D.R. McKenzie¹, N. Suchowska³

¹The University of Sydney, School of Physics, Sydney, Australia

²Istituto Clinico Humanitas, Humanitas Cancer Center, Milan, Italy

³Chris O'Brien Lifehouse, Radiation Oncology, Camperdown-Sydney, Australia

Purpose or Objective: A new p-type unshielded silicon diode, the Razor, has been introduced by IBA as a replacement for the IBA SFD diode. Both diodes are customised for measurements in small radiation fields, having a silicon chip of only 0.6 mm in diameter. The aim of this work is to characterize the response of the Razor in small fields and to evaluate small field correction factors if required (Alfonso et al 2008).

Material and Methods: Relative output ratios were measured in 6 MV and 10 MV X-ray beams, with and without a flattening filter, generated by three Varian linacs: the TrueBeam STX, the EDGE and the Novalis. The output ratio was measured with the IBA Razor and the air core scintillation dosimeter (Lambert et al 2009) at a depth of 50 mm in water. The air core scintillation dosimeter, previously shown to provide accurate relative output ratios in small fields (Ralston et al 2012), consists of a cylindrical BC-400 plastic scintillator 1 mm in length and diameter (volume 0.8mm³). Correction factors for the Razor were calculated for MLC fields (5 and 10 mm in width) and stereotactic cones (4, 7.5 and 10 mm in diameter) using the air core scintillation dosimeter as a reference.

Results: The relative output factors measured for MLC fields on the Varian Truebeam STX are shown in Figure 1. The Razor exhibited an over-response that increases as the field size decreases, consistent with the reported behaviour of unshielded silicon diodes. For MLC fields, the over-response ranged from 2.9% to 5.2% for 5 mm fields and from 0.1% to 2.5% for 10 mm fields. For stereotactic cones, the average over-response was 8.3% for the 4 mm cone, 2.9% for the 7.5 mm cone and 1.4% for the 10 mm cone. Correction factors for specific field sizes were within 1% across the three different linac types. The beam energy and the presence of a flattening filter had a substantial effect.

Conclusion: The new IBA Razor exhibits an over-response at small fields, which is consistent with the behaviour of other silicon diodes. Alfonso small field correction factors were experimentally determined using the air core scintillation dosimeter. The presence of a flattening filter was found to be an important feature of the beam that influenced the correction factor.

EP-1497

High resolution air-vented ionization chamber array for QA of VMAT and stereotactic treatments

M. Togni^{1,2,3}, D. Menichelli¹, C. Vogel¹, J.C. Celi¹, J.J. Wilkens^{2,3}, J. McGlade⁴, R. Mooij⁴, A. Olszanski⁴, T. Solberg⁴

¹IBA Dosimetry GmbH, Physics and Innovation Department, Schwarzenbruck, Germany

²Technische Universität München, Klinikum rechts der Isar, Department of Radiation Oncology

³Technische Universität München, Physik Department, Munich, Germany

⁴Perelman Center for Advanced Medicine, Radiation Oncology Department, Philadelphia, USA

Purpose or Objective: To characterize the 2D implementation of a new ionization chamber technology with high spatial resolution and charge collection efficiency for quality assurance in complex MV X-ray radiotherapy techniques such as VMAT and stereotactic treatments.

Material and Methods: The prototype device (Figure 1) consists of an array of air vented ionization chambers, with 1024 detector elements regularly arranged in a 32 x 32 matrix. The chamber center to center spacing is 4 mm, resulting in an active area of 12.4 cm x 12.4 cm. Dosimetric characterization as well as a comparative evaluation of treatment plans for a variety of clinical localizations and techniques has been performed in a plastic phantom. A CT scan of the device within the phantom was acquired and imported in the Varian Eclipse treatment planning system (TPS) in order to compare the planned and measured dose distributions. Irradiation was performed on two different accelerators: a Varian True Beam and a Cyberknife G4 equipped with an iris collimator (both at UPENN, Dept. of Radiation Oncology, Philadelphia). The characterization has been performed for VMAT, IMRT and stereotactic treatment plans with different beam qualities and dose rates. Other reference detectors used for comparison included radiochromic film (RCF) and a commercial array based on diode technology.

Figure 1. The array prototype inserted in a RW3 phantom adapter.

Results: Response reproducibility, short term stability and linearity with dose are those typical of ionization chamber based detectors. Maximum deviation of approximately 1.5% in sensitivity was observed in the range 0.1 - 2.5 mGy/pulse. For all different clinical evaluations, the array was found to be in very good agreement with the reference detectors. Dose distributions with steep gradients are very well defined due to the 4 mm spatial resolution and to the limited effect of volume averaging. Additionally, good agreement was observed between the expected dose from TPS and the measurements. Moreover, the detector insensitivity on dose per pulse in conjunction with the low energy dependence typical of ionization chambers lead to high performance even when therapy beams feature extremely modulated dose rates.

Conclusion: After an extensive clinical investigation the ion chamber array technology under investigation has been proven to be valuable for patient plan quality assurance, especially when highly modulated fields are used, including unflattened beams.

EP-1498

LET dependence of the PTW-60019 microDiamond detector response in particle beams

S. Rossomme¹, A. Delor², J. Hopfgartner³, J. Denis², S. Vynckier², H. Palmans⁴

¹Université Catholique de Louvain- Institute of Experimental & Clinical Research, Molecular Imaging- Radiotherapy & Oncology, Brussels, Belgium

²Cliniques Universitaires Saint-Luc, Radiotherapy and Oncology Department, Brussels, Belgium

³EBG MedAustron GmbH, Wiener Neustadt, Austria

⁴National Physical Laboratory, Acoustics and Ionising Radiation Division, Teddington, United Kingdom

Purpose or Objective: This work describes investigations that were carried out to assess the effect of the linear energy transfer (LET) on the response of a new synthetic single crystal diamond detector. The investigations were performed comparing the response of a PTW-60019 microDiamond detector (μD) to the response of ionization chambers (IC).

Material and Methods: Two experimental sessions were performed in mono-energetic particle beams. Using a μD with its axis parallel to the beam axis, its response was compared to the response of a Roos type IC in a 60 MeV proton beam and a Markus IC in a 62 MeV/n carbon ion beam. For both experimental sessions, the beam was monitored using an IC placed in front of the detector under investigation. As recommended by IAEA TRS-398, the response of the IC was corrected for temperature, pressure, polarity and ion recombination effects. The latter was studied during experimental sessions, using two IC positioned face to face,

under the same experimental conditions as for the comparison with the μD . The experimental procedure for the determination of the recombination effects consisted of changing the voltage applied to the IC under investigations and studying the saturation curve. The determination of the recombination effect was performed at different depths. No correction was applied to the response of the μD .

Results: In the proton beam, two different values for the ion recombination correction factor (k_s) were used to correct the response of the Roos IC: $k_s = 1.0035$ in the plateau region, and $k_s = 1.004$ in the Bragg Peak region. In carbon ion beam, k_s varies from 1.01 at the entrance of the plateau and it increases slightly in the plateau region and strongly in the Bragg Peak region due to the increase of the LET, to reach 1.06 in the distal edge region.

For both beams, comparison between the responses of both detectors shows a good agreement in the plateau region. In proton beam, considering the uncertainties, no significant difference between both detectors is observed in the Bragg Peak region. The combined relative standard uncertainty of the results is estimated to 0.28% in the plateau region and 14% in the distal edge region. These values are dominated by the uncertainty of range determination. In the carbon ion beam, an under response of the μD of 20% is observed in the Bragg Peak region. The combined relative standard uncertainty of the results is estimated to 2.3% in the plateau region and 12% in the distal edge region. These values are dominated by the uncertainty of alignment in the non-uniform beam and the uncertainty of range determination.

Conclusion: Results were obtained for one particular detector only. However, confirmed by other publications, we can conclude that the LET-independent response in clinical proton beams is a characteristic of the PTW-60019 μD . This conclusion has to be investigated in more details for the carbon ion beams, for which our study show that the detector should not be assumed to be LET independent.

EP-1499

GEANT4 Monte-carlo simulations for the luminescence properties of Gd₂O₃:Eu scintillator

G.S. Cho¹, S.H. Choi^{1,2}, S.S. Lee^{1,3}, Y.H. Ji^{1,2,3}, S. Park¹, H. Jung^{1,3}, M.S. Kim^{1,2,3}, H.J. Yoo², K.B. Kim^{1,2,3}

¹Korea Institute of Radiological and Medical Science, Research center for Radiotherapy, Seoul, Korea Republic of

²Korea Institute of Radiological and Medical Science, Department of Radiation Oncology, Seoul, Korea Republic of

³University of Science and Technology, Radiological &Medico-Oncological Sciences, Daejeon, Korea Republic of

Purpose or Objective: In an indirect radiation detector modeling using Monte-carlo methods, a scintillator modeling that has same luminescence properties with a measured data is firstly performed. Therefore, in this study, we compared the measured and calculated properties of scintillator and we tried to verify an effectiveness of GEANT4 code for the scintillator modeling.

Material and Methods:

1) synthesis of scintillator

In this study, to measure the luminescence properties, we synthesized Gd₂O₃:Eu used as a radiation conversion material using low-temperature solution combustion method. The properties of the synthesized scintillator were obtained by measuring photoluminescence spectrum and the decay time using a PL spectrometer. For the measurement of photoluminescence spectrum, 254nm UV light generated from a xenon(optical photon) lamp was used to excite the phosphor; then, the emitted light was obtained through a monochromator and PMT.

2) Monte-carlo simulations

In this study, GEANT4 code was used for the scintillator modeling. To reduce error rate, we use 70kVp energy spectrum and an optical and scintillator physics process were used. An energy range of the scintillator were defined based on measured data. For an effective simulation, we only

scored optical photon correspond to each energy band and MPI parallel computing was used.

Results: The measured a photoluminescence peak value of the Gd₂O₃:Eu was 611nm, which was identical with literature value. In case of the calculated value using GEANT4 monte-carlo code, an intensity(counting) of the photoluminescence peak value was 2 times higher, but the peak value also was identical with measured the peak value and overall trend of the photoluminescence spectrum was correspond to the measured data. A result of the decay time showed that the measured value was 1.2 times higher than that of the calculated value despite the higher intensity, but the measured and calculated value was well matched in low intensity.

Conclusion: In this study, we performed Gd₂O₃:Eu modeling using GEANT4 and compared measured and calculated the properties of the scintillator. Through the results, we demonstrate the effectiveness of the GEANT4 code for the scintillator modeling and it was used as valuable data for the indirect radiation detector modeling using GEANT4. However, the properties of the scintillator were various according to the ratio of the body material and activator. Therefore, GEANT4 can reflect the ratio of the body material and activator and it considered as future works.

⁶National Cancer Center Hospital, Department of Oncology, Department of Radiation Oncology, Japan

⁷Kyoto University, Graduate school of Medicine, Kyoto, Japan

⁸Keen Medical Physics Co. Ltd., Department of Medical Physics Research, Kanagawa, Japan

Purpose or Objective: We have made innovative proton therapy achieved by imaging technique of positron emitter nuclei generated in the patient body on target nuclear fragmentation reaction and development of a beam ON-LINE PET system (BOLPs). It was found that between the proton delivery dose to the tumor and the activity of positron emitter nuclei generated from the target nuclear fragmentation reaction in tumor have correlation. The purpose of this study is to research and develop a tumor response observation system with delivered dose in particle therapy.

Material and Methods: The specification and design of tumor response observation system for dose-volume delivery guided particle therapy (TROS-DGPT) were performed. And in the TROS -DGPT, a spec of detection head for measurement of various gamma rays emitted from nuclear fragment reaction and nuclear excitation reaction was evaluated.

Results: It was important to measure efficiently the various gamma rays emitted from the patient body by the nuclear reaction with particle beam radiation. Therefore, the high detection efficiency and measurement time resolution were required for development of the TROS -DGPT. The TROS -DGPT was made the specification and the design with both the PET function and Compton Camera function for gamma ray detection head. Results of vibration, impact and

temperature tests for developed GSO detector module were good.

GSO detector module

- Vibration test: 5G, 7.5G, 10~500 Hz, 1 Oct/min, 10 cycle, XYZ Axis
- Impact test: 30G, 75G, 11 ms, 3 Shocks/Direction, 5 Directions, 10~500 Hz
- temperature test: -40 °C ~ +70 °C, 3 h keep condition, 10cycle

Before vibration

5G vibration

7.5G vibration

Conclusion: The specification and the design of the TROS -DGPT were decided for an innovative particle therapy. We will research and develop for completion of this system 3 years later.

New material for high resolution dosimetry using radiation induced changes in fluorescence response

N.H. Sanders¹, M.R. Bernal¹, L.R. Lindvold¹

¹Risoe National Laboratory, DTU Nutech, Roskilde, Denmark

Purpose or Objective: We are developing a new radiation-sensitive polymer material for radiation therapy dosimetry with high spatial resolution for use in 3D solid state dosimetry. The key methods of this project are to determine the radiation dose by measuring its fluorescence, instead of the absorbance which is a more established method[1][2], and to dissolve the radiochromic dye in a rigid polymer matrix. Measuring the fluorescence enables higher spatial resolution and sensitivity, and the polymer matrix prevents degradation and diffusion of the exposed dye over time. In this study we have established that this material shows a linear relationship between the absorbed dose and the fluorescence response.

[1] W.L. McLaughlin, A. Miller, S. Fidan, K. Pejtersen. Radiat. Phys. Chem. 10 (1977) 119-127.

[2] Niroomand-Rad et al. Radiochromic film dosimetry. AAPM Report No. 63 (1998).

Material and Methods: The key elements of this radiochromic material are a solid polymer matrix with additives and a triphenylmethane leuco dye. Thin films of the material were irradiated multiple times with a Co-60 source, and the absorbance and fluorescence responses were measured initially and after each irradiation session. The fluorescence was excited by a 532 nm YAG laser, and was measured with an Ocean Optics QE6500 spectrometer.

Results: The fluorescence response increased linearly with the absorbed dose from 0 to 200 Gy. The absorbance also increased linearly, indicating that the fluorescent dye is the only chemical in the material with a significant absorption in the relevant wavelength range. The dye absorbs from 500 nm to 575 nm and the fluorescence response is in the range from 565 nm to 650 nm.

Conclusion: We have established that the material exhibits a linear relationship between fluorescence response and radiation dose. The fluorescence response is strong enough to be used at low doses. Measurements on individual samples are highly reproducible, but the variance between different samples is still too high to be used at clinically relevant doses. We expect that this variance can be reduced through improvements to the sample preparation. The fluorescence response of the radiochromic dye is highly dependent on the composition of the polymer matrix, since a different study[3] using the same dye observed a decrease in fluorescence with increasing dose. The factors affecting the fluorescence of the dye and hence its dosimetric properties are still being investigated, but in this work we have shown that dosimetry measurements are possible with this novel material. With improvements this could become a precise quantitative 3D dosimeter that is inexpensive, quick, and easy to use.

EP-1502

Effects on dosimetric measurements due to difference in calibration and dosimetry protocols followed

W. Muhammad¹, A. Hussain², Asadullah³

¹Pakistan Institute of Nuclear Science and Technology, Health Physics Division HPD-, Islamabad, Pakistan

²Aga Khan University Hospital, Department of Oncology, Karachi, Pakistan

³Pakistan Institute of Nuclear Science and Technology, Health Physics Division HPD, Islamabad, Pakistan

Purpose or Objective: Radiation dosimetry plays a vital role in external beam radiotherapy. For precise and accurate dose delivery, the dosimetry system should be calibrated properly, following the recommendations of standard dosimetry protocols e.g. TG-51 or TRS-398. Nonetheless, the dosimetry protocol followed by calibration laboratory is often different from the protocols in practice at various clinics. The study is designed to investigate the effects added in dosimetry measurements due to such situations.

Material and Methods: In this study, the dosimetry were performed for a Co-60 teletherapy unit and a high-energy Varian linear accelerator (CLINAC) with 6 and 15 MV-photon and 6, 9, 12 and 15 MeV-electron beams, following the recommendations and reference conditions of AAPM TG- 51 and IAEA TRS-398 dosimetry protocols. A PTW water phantom (T41014) with a cylindrical chamber (PTW-30001) connected to an electrometer (PTW UNIDOS E) was used for the absolute dosimetry of Co-60 unit. Similarly, dosimetry systems consisting of a farmer type ionization chamber (IBA-FC65-G) and a plane-parallel chamber (IBA PPC-05), connected to an electrometer (PTW UNIDOS E) in a Wellhofer water phantom was used for absolute dosimetry of two photon beams and four electron beams dosimetry respectively. Each chamber type combined with PTW UNIDOS E was calibrated in a Co-60 radiation beam at Secondary Standard Dosimetry Laboratory (SSDL) PINSTECH, Pakistan, following the IAEA TRS-398 protocol.

Results: The measured ratios of absorbed doses to water Dw (TG-51/TRS-398) were 0.999 and 0.997 for 6 and 15 MV photon beam respectively whereas the ratios were 1.013, 1.009, 1.003 and 1.000 for 6, 9, 12 and 15 MeV electron beams, respectively as shown in Figure 1 (a & b). The difference arises between the two protocols mainly due to beam quality (KQ) and ion recombination correction factor

(Table 1).

Figure 1: (a) Ratio of the absorbed doses at Z_{max} of Co-60, 6 MV and 15 MV photons by using two protocols (TG-51 / TRS-398). (b) Ratio of the absorbed doses at Z_{max} of 6, 9, 12, 15 MeV Electron beam by using two Protocols (TG-51 / TRS-398).

Table 1: Comparison of the Absorbed Doses at Z_{max}, beam quality factor (K_Q) and ion recombination correction factor, (P_{ion}) values of AAPM TG-51 and IAEA TRS-398 Protocols.

Type of Beam	Energy	AAPM TG-51				IAEA TRS-398					
		%dd(10%)	P _{ion}	K _Q	D _w (Z _{max})	TPR ₂₀₀	P _{ion}	K _Q	D _w (Z _{max})		
Photon	6MV	66.7	1.00714	0.991	0.9970	0.668	1.00714	0.992	0.99748		
	15MV	77.63	1.01135	0.970	0.9967142	0.762	1.01109	0.973	0.999535		
	Co-60	NA	1.0	1.0	1.6489	NA	1.0	1.0	1.6489		
Electron	6 MeV	2.15	1.19	1.024	0.937	1.034418	1.68	2.15	1.024	0.973	1.013106
	9 MeV	3.459	1.975	1.00503	0.921	1.0056445	1.99	3.42	1.00455	0.913	0.99643
	12 MeV	4.910	2.846	1.013277	0.908	1.005852	2.44	4.83	1.011099	0.905	1.002825
	15 MeV	6.237	3.642	1.013251	0.8983	0.998504	2.8	6.12	1.013277	0.898	0.997916

Conclusion: In conclusion TRS-398 gives relatively high doses than TG-51 and the percentage difference increases as the energy increases for photon beams. While in case of electron beams TG-51 calculates relatively high doses than TRS-398 and percentage difference decreases as the energy increases. Since the chambers are calibrated according to the recommendations of IAEA TRS-398 Dosimetry protocol, all the medical centres are requested to follow the IAEA TRS-398 Dosimetry protocols.

EP-1503

Small field output correction factors for 6-X and 6-X FFF beams: GAMOS Monte-Carlo study

D. Akcay¹, R. Kandemir², O. Azaklioglu²

¹Dokuz Eylul University Medical Faculty, Radiation Oncology, Izmir, Turkey

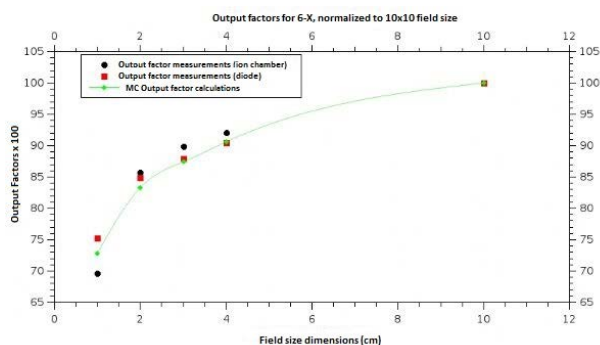

²Dokuz Eylul University Institute of Health Sciences, Medical Physics, Izmir, Turkey

Purpose or Objective: Our purpose was to calculate detector specific small field output correction factors with GAMOS Monte Carlo (MC) for 6-X and 6-X flattening filter free (FFF). In this study MC simulations and water phantom measurements were used to obtain correction factors.

Material and Methods: A formalism of Alfonso et al for correction of output factor measurements was used in the current study. Absorbed dose to water was calculated with MC using 2x2x2 mm³ voxel at 5 cm depth of water phantom. "Range cut" and "Kill particles at BIG X/Y" options were used to optimize simulation in GAMOS MC. Results were obtained below 2% statistical noise. Fields sizes varied from 4x4 to 1x1

cm². Also water phantom measurements were taken at same field sizes at source phantom distance 95 cm with diode(photon) and PinPoint ion chamber to use in formalism. Varian TrueBeam STx LINAC was used for the purpose.

Results: For diode detector, correction factors were 0.993 and 1.000 for 3x3, 4x4 cm² at 6-X respectively and correction factors of 0.999 and 1.000 were found for 6-X FFF. For smaller field sizes, obtained correction factors were below 0.98 for both energies. For ion chamber at the smallest field size, the respective correction factors were 1.046 and 1.079 for 6-X and 6-X FFF. At 2x2 cm², it was 0.971 and 0.967 for 6-X and 6-X FFF respectively. However, with increase of field size, the value of correction factors for ion chamber became close to 1.0.

Output Correction Factors for diode and ion chamber at 6-X energy

Detector Model	1x1	2x2	3x3	4x4	10x10
TM60016 – Diode(photon)	0.968	0.980	0.993	1.000	1.000
TM31014 - PinPoint Ion Chamber	1.046	0.971	0.972	0.983	1.000

Conclusion: For ion chamber, at 1x1 and 2x2 field sizes, correction factors were up to 3% more or less than of optimum value of 1.0. Our MC calculations showed that Pinpoint detector required output correction factor for field sizes below 3x3 cm². For diode detector this requirement was for field sizes below 2x2 cm².

EP-1504

Evaluation of transmission detector model using Monte Carlo simulation of VMAT delivery

D. Johnson¹, D. Thwaites², V. Cosgrove¹, S. Weston¹

¹Leeds Teaching Hospitals NHS Trust, Medical Physics, Leeds, United Kingdom

²University of Sydney, Medical Physics, Sydney, Australia

Purpose or Objective: The Device for Advanced Verification of IMRT Deliveries (DAVID) is a novel, transparent transmission detector. It is designed for in-vivo verification by measuring the radiation fluence from the linac head during treatment. In order to investigate its properties and sensitivity to standard errors it was desirable to build an accurate Monte Carlo model of the device. In this study a working Monte-Carlo model of the detector was built and verified by comparing simulation and measured signals from simple square fields as well as complex IMRT and VMAT fields.

Material and Methods: All results were collected on an Synergy linear accelerator (Elekta AB, Stockholm, Sweden) equipped with an MLCi2 collimator. All treatment plans have been delivered as clinical treatments in the department and were generated by the Monaco 3.3 TPS (Elekta AB, Stockholm, Sweden). The Monte Carlo simulation of the linac and DAVID used BEAMnrc and DOSXYZnrc.

The DAVID is a transmission style detector, specific to the linac (MLC) model. As the MLCi2 collimator has an 80 leaf (40 leaf pairs) MLC; the DAVID used in this work had 40 wires. These collection wires are held in a 2mm thick vented air gap that is encased by two polymethyl methacrylate (PMMA) plates, each 4mm thick. On the inside of the PMMA a thin

layer of aluminium is been evaporated on to the inner surfaces; this layer is thin enough so that the device remains optically transparent, but thick enough to maintain a potential of 400V between the plates and the collection wires. Ionisation charge in the air gap, as a consequence of primary and scattered radiation, migrates towards the collection wires under the influence of the potential, each wire having a collection area of 0.03 cm² per centimeter of length.

It was shown that the collection wires had a negligible effect on the dose deposited in the collection volume allowing the DAVID to be modeled as two 4mm slabs of Perspex separated by a 2mm air gap.

Results: The DAVID signal measured on the linac was shown to be repeatable and stable. All simulated results were shown to agree with measured results to within 3% of the maximum signal

Conclusion: The Monte Carlo model of the DAVID works well for both simple and complex deliveries. The model will provide a useful tool for investigating the sensitivity of the DAVID to linac faults. These can easily be simulated for a variety of cases in the Monte Carlo model.

EP-1505

Comparison of two unshielded diodes for commissioning of Cyberknife

E. Gershkevitch¹, G. Boka²

¹North-Estonian Regional Hospital Cancer Center Radiotherapy, Radiotherapy, Tallinn, Estonia

²Riga East University Hospital- Clinic of Therapeutic Radiology and Medical Physics, Clinical Medical Physics and Dosimetry, Riga, Latvia

Purpose or Objective: The aim of this study was to evaluate the suitability of two recently launched unshielded diodes for commissioning of CyberKnife (Accuray Inc., Sunnyvale, CA) system.

Material and Methods: IBA Razor (IBA dosimetry GmbH, Schwarzenbruck) and PTW SRS 60018 (PTW Freiburg, Freiburg) diodes were used to commission CyberKnife M6 unit. TPR/PDD, OCR and output factors for 12 stereotactic cones (range 5-60mm) were measured with both detectors using PTW MP3-M water tank. The measurement results were compared between each other and with the composite data from the manufacturer.

Results: Output factors measured with both diodes agreed within 1% to the manufacturer supplied uncorrected data for all cones except 5 mm. For 5 mm cone differences of up to 2.3% were observed. Output factors for 5 mm cone were also compared with published Monte Carlo data and correction factors for PTW SRS 60018 and IBA Razor diodes are 0.95 and 0.94, respectively were noted. The difference is being larger for IBA Razor diode. For all other cones the correction for IBA

Razor diode is being smaller than for PTW SRS 60018 diode. PDDs agreed well for both diodes for the measured cones. The tale of the profile for 60 mm cone at 30 cm depth is being overestimated by approximately 10% for both detectors compared to the profiles measured with PTW 31010 ionization chamber. The dose per pulse dependence for IBA Razor diode is larger than for PTW SRS 60018 diode.

Conclusion: Both detectors are suitable for commissioning of Cyberknife M6 system. Correction factor required for 5 mm cone for IBA Razor diode is larger than for it predecessor - IBA SFD diode (as based on published data). Both detectors require correction factors in order to account for the overestimation of the signal. Because of lower sensitivity the time required to collect the same quality data with IBA Razor diode is about 3 times greater than for PTW SRS 60018.

EP-1506
Investigation of PTW's "microDiamond" detector for dosimetry in small animal radiotherapy research
S. Kampfer^{1,2}, J.J. Wilkens^{1,2}
¹Klinikum Rechts der Isar- TU München, Department of Radiation Oncology, München, Germany
²TU München, Physik Department, München, Germany

Purpose or Objective: The recently presented single crystal diamond detector (SCDD) from PTW (PTW-Freiburg, Germany) called microDiamond (μ D, type TM60019) is especially meant to be used in small field dosimetry. As irradiation experiments of small animals in preclinical settings often use small fields this μ D detector could potentially be the right device in this special field of interest.

Material and Methods: Two different kinds of measurements were performed: a) horizontal and vertical beam profiles, and b) depth dose curves. Both types of measurements were done in solid water slabs for two field sizes: 5x5 mm² and 10x10 mm². Measurement a) was done in 2 cm depth with the detector in the isocenter. The orientation of the detector was perpendicular to the beam axis and in terms of rotation in a suitable position to prevent effects due to unequal sensitivity. Measurement b) was performed with a fixed SSD of 304 mm and in depths in the range from 0 to 51 mm. The detector's axis was parallel to the beam axis during this measurement. To enable the comparison of our measured depth dose, the μ D detector was calibrated for our distinct setup against a standard ionization chamber in a large field. We compared the results of the μ D detector to film measurements with radiochromic films (Gafchromic EBT3, Ashland, USA).

Results: The results of the beam profile measurements with the μ D detector of the 10x10 mm² field are 10.10 mm in horizontal and 10.16 mm in vertical direction for the field width at half maximum (FWHM). For the 5x5 mm² field the μ D results are 5.08 mm in both directions. The measured depth dose curve shows values from 4.05 Gy/min in a depth of 1 mm and 3.71 Gy/min in 5 mm down to 1.14 Gy/min in 51 mm. In comparison, the field size measurements with the film resulted in 10.16 mm (5.19 mm) for horizontal and 10.20 mm (5.20 mm) for vertical direction for the 10x10 mm² (5x5 mm²) field. This means a very good agreement in the 10x10 mm² field (difference less than 0.1 mm or 1%). In the 5x5 mm² field, the differences between film and μ D is 0.11 mm and 0.12 mm (less than 2.4%). Depth dose curve measurements show also very good agreement of the two methods. In a depth of 5.3 mm the film measurements produced 3.68 Gy/min, in 51.4 mm depth 1.16 Gy/min (maximum deviation of about 2 %).

Conclusion: We showed measurements with the μ D detector of two very important variables of radiation fields and their comparison to reference measurements with radiochromic film. As the discrepancy between both methods is very small, these findings justify the usage of the described μ D detector for quality assurance measurements in preclinical research, especially for the SARRP.

EP-1507
Which detector for small photon field measurements?
M. Casati¹, A. Compagnucci¹, C. Arilli¹, L. Marrazzo¹, G. Simontacchi², D. Greto², S. Pallotta¹, C. Talamonti¹
¹University of Florence, Azienda Ospedaliero Universitaria Firenze - SOD Fisica Medica, Florence, Italy
²University of Florence, Azienda Ospedaliero Universitaria Firenze - SOD Radioterapia, Florence, Italy

Purpose or Objective: Dosimetry in small fields is an open issue, due to several sources of errors, reported in literature. The purpose of this work is to compare the response of different detectors for the measurements of output factors (OF), profiles and percentage depth dose (PDD) curves for Elekta Synergy S BM 6MVRX beams and field sizes from standard (10.4cmx10.4cm) down to 0.8cmx0.8cm.

Material and Methods: We tested the detectors reported in the first table.

tested detectors	volume (mm ³)	diameter (mm)	thickness (mm)	😊	☹️	μ/ρ (cm ² /g)	ρ (g/cm ³)
Single crystal diamond detector (SCDD)	0.004	2.2	0.001	small thickness, mass energy absorption coefficient similar to water	2mm diameter active area \Rightarrow volume averaging effects \Rightarrow under response, high density \Rightarrow overresponse in small fields	😊	3.3
Exradin W1 plastic scintillator	2.4	1	3	very good water equiv.	instable, not user friendly	😊	1.05
Iba Razor diode	0.01	0.6	0.02	small active volume	overresponse to low energy	☹️	-2.5
Exradin D1V diode	0.05	1.1	0.05	small active volume	overresponse to low energy	☹️	-2.3
Exradin A26 ion chamber	15	3.3			volume averaging effects	😊	
Exradin A15L ion chamber	57				volume averaging effects	😊	
Film gafchromic EBT3			0.28	good water equiv. And spatial resolution	noise	😊	

No corrections were made for the difference between detectors and water (fluence perturbation and non water-equivalence) neither for volume averaging effects.

Results: OF were referred to 3.2cm field and deviations calculated respect to W1 as reference detector, both for its smaller dimensions and its better water equivalence.

field size (cm)	diamond		scintillator		diodes			ion chambers		film
	SCDD	W1	Razor	D1V	A15L	A26	A26	A26	gafchromic	
10,40	-0,5%	0,0%	3,8%	2,3%	-0,4%	-0,1%	-0,1%	-0,1%	-0,1%	
7,20	0,6%	0,0%	3,3%	1,9%	0,9%	0,9%	0,9%	0,9%	0,9%	
5,60		0,0%	0,9%	1,0%					-0,3%	
4,80	0,4%	0,0%	1,3%	0,7%	0,2%	0,5%	0,5%	0,5%	0,6%	
4,00		0,0%	0,6%	1,2%					0,4%	
3,20	0,0%	0,0%	0,0%	0,0%	0,0%	0,0%	0,0%	0,0%	0,0%	
2,40	-0,1%	0,0%	-0,7%	0,0%	-0,6%	-0,4%	-0,4%	-0,4%	-0,5%	
1,60	-0,1%	0,0%	-1,4%	-0,7%	-2,0%	-1,3%	-1,3%	-1,3%	0,6%	
0,80	0,6%	0,0%	-1,1%	-0,9%	-14,3%	-8,0%	-8,0%	-8,0%	-3,5%	

For large fields all detectors agree within 1% except for diodes, which show an over response for large fields, due to low energy scattered radiation. SCDD is in agreement with W1 within 0.6% for all field sizes, also down to 0.8cm, maybe for compensation effects between the over response due to high density and the under response due to volume averaging effects. For 1.6cm and 0.8cm, ion chambers show an under

response up to 14% A1SL and 8% A26 (volume averaging effects), D1V diode is in agreement with W1 within 1%, while Razor diode shows a more pronounced under response presumably due to the enclosure, given its smaller dimensions respect to D1V. Film shows a deviation of -3.5% for 0.8cm field, due to the sampling area, limited inferiorly by noise.

As for PDDs, A26 can be trusted as reference detector for 10.4cm field (no volume averaging effects). Razor diode shows an over response up to 3% at 20cm depth respect to A26 (low energy scattered radiation). Also W1 shows an over response, up to 4% at 20cm depth, respect to A26.

For field sizes under 2cm, volume averaging effects should be considered, especially for ionization chambers, in function of depth. PDD at large depth could in some case be overestimated if large volume effects occur. In this case W1 could be taken as reference, for its small active area and water equivalence. Razor shows a slight over response (within 1%), probably due to low energy scattered radiation, while A26 shows an over response, maybe due to volume averaging effects, up to 3%.

Profiles obtained with Synergy S BM have a minimum penumbra of some mm, so are well represented by all detectors with diameter of the active area inferior or equal to 1mm.

Conclusion: For small field sizes (< 3cm) it is still not possible to identify a reference detector, with an optimal behaviour. For 6MVRX beams by SynergyS BM and field sizes down to 1cmx1cm, SCDD seems to offer the best compromise, since compensation between opposite effects (volume averaging and density) occurs, which allows to avoid corrections. For smaller fields, steeper penumbras or better accuracy, corrections for the above mentioned effects should be applied and detector should be used perpendicular to beam axis for penumbra sampling.

EP-1508

Multicenter study of FFF beams with a new stereotactic diode: can be defined a universal OF curve?

E. Cagni¹, S. Russo², A. Botti¹, S. Bresciani³, V. Bruzzaniti⁴, D. Fedele⁵, M. Iori¹, S. Naccarato⁶, B. Nardiello⁷, L. Orsinger¹, G. Reggiori⁸, A. Rinaldi⁷, R. Ruggieri⁶, M. Stasi³, L. Strigari⁴, M. Zani⁵, P. Mancosu⁸

⁶Ospedale Sacro Cuore Don Calabria, Radiotherapy, Negar VR, Italy

⁷UPMC San Pietro, Medical Physics, Roma, Italy

⁸Humanitas Research Hospital, Medical Physics, Rozzano MI, Italy

Purpose or Objective: The use of flattening filter free (FFF) beams are increasing in stereotactic body radiation therapy (SBRT) due to the reduction in delivery time. Small radiation fields (<30mm) are typically involved in SBRT procedures. In small fields, the measurements of the output factor is subject to large uncertainties, impacting in the effective delivered dose to the patient. Dose output ratios (DORs), defined as the ratio of detector readings without correction factor (Alfonso et al., Med Phys 2008), were evaluated in several different centers and an eventual mathematical description of the DORs curve was investigated.

Material and Methods: A couple of new unshielded stereotactic diodes (Razor, IBA) was tested under 7 different TrueBeams using high dose rate (2400 MU/min) 10MV FFF beams. Small fields ranging from 6 to 50 mm were analyzed in terms of profiles and central axis point measurements. DORs were normalized to 30 mm field and were calculated as a function of nominal (NFS) and effective (EFS) field size. From DORs acquired using Razor1 (4 centers), a theoretical equation was extrapolated by means of a double exponential

fit. The 3 centers with Razor2 were used to test the mathematical relationship.

Results: Penumbra, field width (defined as FWHM) and EFS analysis over the 7 Truebeams were reported in Table 1. The EFS were systematically smaller than NFS ($p < 0.01$) for all field size range, with mean difference of 0.9 ± 0.5 mm. The DORs fits using the NFS and EFS had, respectively, $R^2 = 0.993$ and $R^2 > 0.999$ (Figure 1). The test mean deviations from predicted DORs, using NFS and EFS fits, were 2.9% and 0.7%, respectively, for field size ranging between 6 and 20 mm. The maximum deviations were 6.1% (6mm field size) for NFS and <2% for EFS.

Table 1. Penumbra, field width and EFS analysis in term of mean, standard deviation and relative percentage errors for all 7 Truebeams.

NFS (mm)		Penumbra width (mm)		FWHM (mm)		EFS (mm)

	Relative Error (%)					

Figure 1. Razor1 DORs plotted as a function of NFS (A) and EFS (B) with relative mathematical curve.

Conclusion: EFS measurements were confirmed to be mandatory when comparing DORs over different centers. A "gold standard" curve was tested and found suitable for DORs calculation using the new Razor diode for TrueBeam 10 MV FFF beams.

EP-1509

Small fields Output Factor measurement using several multidetectors arrays

D. Radomiak¹, S. Adamczyk¹

¹Greater Poland Cancer Centre, Medical Physics, Poznan, Poland

Purpose or Objective: The aim of this study was to determine and compare small fields Output Factor (OF) measure with different types of multidetector arrays. OF measurements were performed on a CyberKnife® System.

Material and Methods: OF were measured using multidetector arrays: PTW OCTAVIUS Detector 1500, PTW OCTAVIUS Detector 1000 SRS and SunNuclear SRS Profiler.

The type of detector in each of the array is different. OCTAVIUS Detector 1500 consists of 1405 plane-parallel vented ionization chamber, OCTAVIUS Detector 1000 SRS consists of 977 liquid-filled ionization chambers and SunNuclear SRS Profiler contains 125 silicon diode detectors. The OF values measured in the present study were compared with measured values of unshielded PTW Diode Type E 60017. The measurements were done on the same CyberKnife® System. Set of beam specific correction factors has been calculated by means of Monte Carlo simulations which were obtained by Francescon (2012). Correction factors have been applied for OF values measured by PTW 60017. Values of correction factors were reported for each collimation system. CyberKnife® System uses a 6 MV flattening filter free beam with a high dose-rate of 1000 MU min⁻¹. The machine specific reference field size is defined at the 60 mm diameter field produced by a Fixed collimator 80 cm from the source. Beams were collimated by Fix collimator and Iris Variable Aperture Collimator. The Iris Collimator reproduced the same set of 12 field sizes from 5 mm diameter to 60 mm diameter as well as a Fix collimator. Disparity in physical design of two collimators cause deviations in OF measurements (e.g. -4.89% at 5 mm field size for fix collimators versus -6.95% for Iris). The source-surface distance was set to 78.5 cm and the effective point of measurement used for each detector was set at 1.5 cm depth from the surface of the phantom.

Results: As it was predicted, large deviations in OF measurement are observed. For the smallest field size 5 mm the values of OF varies are more that 4% between arrays and PTW 60017. The largest differences from -3% for 25 mm field size, to -56% for 5 mm were reported for OCTAVIUS Detector 1500, where the vented ionization chamber exhibits the averaging volume effect, due to significant active volume. For field size greater than 40 mm all arrays OF deviate from PTW 60017 by less than 1%. For liquid-filled array in both collimation systems, an excellent agreement was observed (less than 2%) for field size greater than 5 mm diameter.

Conclusion: It has been shown that every type of used active detector behave differently. As it was predicted, for small fields both liquid filled and vented ionization chambers underestimate OF values when silicon diodes overestimate them. It has been proven that liquid-filled multidetector array may be a precise dosimetric tool for OF measurement. A beam specific correction factors for arrays hasn't been published yet.

EP-1510

Monte-Carlo determination of output correction factors for four detectors in small MV photon beams

G. Valdes Santurio^{1,2}, R. Alfonso Laguardia³

¹INOR, Institute of Oncology and Radiobiology, La Habana, Cuba

²Technical University of Denmark, Center for Nuclear Technologies, Roskilde, Denmark

³InSTEC, Higher Institute of Technologies and Applied Sciences, La Habana, Cuba

Purpose or Objective: The purpose of this study was the determination by Monte Carlo (MC) of detector-specific output correction factors $k(Q_{clin}, Q_{ref}, f_{clin}, f_{ref})$ for four radiation detectors in small MLC-conformed square fields of a 6 MV photon beam.

Material and Methods: Two solid-state detectors, PTW - 60017 (Unshielded-Diode) and the PTW - 60019 (microDiamond), and two ionization chambers, PTW-31010 (Semiflex) and the PTW-31016 (Pinpoint) were simulated. Monte Carlo EGSnrc code was used for simulations and its module EGS_Chamber was applied to represent the detectors geometries and to calculate their dose responses for these non-standards configurations. With the obtained data the overall correction factor $k(Q_{clin}, Q_{ref}, f_{clin}, f_{ref})$ was calculated according to the Alfonso's formalism, as the ratio of relative response or so called "output factors" for each detector and the "ideal" relative dose factor, obtained at

several square small fields. The statistical type-A uncertainties in MC simulations were lower than 0.5 %.

Results: For the output factors the experimental data showed a good agreement with the simulations for the two solid-state detectors, in which the relative deviation between them was less than 1% for all field sizes. For the ionization chambers, the simulations and the experimental data showed good agreement for the square field sizes larger than 2x2cm² for the smallest field sizes was up to 11% for the Semiflex chamber. Of all detectors studied, the responses of the solid-state ones were more similar to the "ideal" detector. As was expected, solid-state detectors tended to under-respond for larger field sizes and to over-respond for the smaller ones. For ionization chambers the behavior was different, they tended to under-respond at the smaller field sizes. These results are consistent with published results using other MC codes, such as Penelope.

Conclusion: The study confirms the accuracy of the MC method in correcting detector measurements in small field dosimetry and it demonstrates the possibility of determining the $k(Q_{clin}, Q_{ref}, f_{clin}, f_{ref})$ factors in these conditions. Solid-state detectors found to be more adequate for determining the absorbed dose in relative dosimetry.

EP-1511

Gamma analysis: testing scanners and software tools

B. Almady¹, P. Wesolowska¹, T. Santos¹, J. Izweska¹

¹International Atomic Energy Agency, Nuclear Sciences and Applications, Vienna, Austria

Purpose or Objective: New methodologies for national audit groups are under development within the co-ordinated research project (CRP) on "Development of Quality Audits for Advanced Technology in Radiotherapy Dose Delivery". Film dosimetry is used to check the relative dose distribution in an anthropomorphic head and shoulders phantom through end-to-end tests of IMRT and VMAT dose delivery. As the film dosimetry depends much on hardware and software used, a comparison of the effects of different scanners and software tools on the resulting gamma pass rate was done.

Material and Methods: A set of films irradiated in a head and shoulders phantom (CIRS) with different IMRT techniques were evaluated with 3 software tools (Ashland FilmQA Pro, PTW Verisoft, Radiochromic.com) and 3 scanners (EPSON 11000XL, EPSON 4990 and EPSON 750 Pro). Gamma analysis was performed on the films using the following set of parameters: 3% dose difference (DD), 3 mm distance-to-agreement (DTA) and 20% dose threshold. Both global and local gamma values were calculated.

Results: A range of gamma results were obtained with FilmQA Pro for a set of films scanned with three scanners above. For individual films the maximum differences in gamma pass rates are given. For the global gamma setting the gamma pass rates from 96.2% to 99.6% were obtained and for the local gamma setting, the corresponding results ranged from 91.5% to 97.6%. Overall, the differences in the gamma pass rates were up to 3.4% and 6.1% for the global gamma and the local gamma settings, respectively. Different software tools used in analyzing the same film (scanned by the EPSON 11000XL) also affect the gamma pass value; the results range from 95.9% to 98.3% for the global gamma setting and from 95.1% to 98.2% for the local gamma setting. Overall, the differences between the gamma values calculated by different software tools were up to 3.4% for the global gamma and up to 3.1% for the local gamma settings.

Conclusion: The results of this study show that different scanners and software tools can result in differences in the gamma passing rate. In particular, the use of different scanners can generate significant differences. Comparing gamma analysis results of different national audit groups may not be straightforward due to the differences in hardware/software used for film analysis. Careful attention

should be paid to the use of scanner/software parameters by these groups.

EP-1512

Influence of the incident electron beam energy on the primary dose component for FFF beams

W. Lechner^{1,2}, D. Georg^{1,2}, H. Palmans^{3,4}, P. Kuess^{1,2}

¹Medical University of Vienna, Department of Radiation Oncology- Division Medical Physics, Vienna, Austria

²Medical University of Vienna, Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

³EBG MedAustron, Medical Physics, Wiener Neustadt, Austria

⁴National Physical Laboratory, Radiation Dosimetry, Teddington, United Kingdom

Purpose or Objective: Recently, flattening filter free (FFF) photon beams were introduced into clinical routine and more and more centers take advantage of this kind of beam delivery. For commercial C-arm LINACS, two approaches are currently followed to set the incident electron energy on the target for FFF beams, which in turn have an impact on the comparison with FF beams of the same nominal energy. Either the electron energies of FFF and flattened (FF) beams are identical or the electron energy of the FFF beam is increased to match the percentage depth dose curve (PDD) of the FF beam (in reference geometry). This study focuses on the primary dose components of FFF beams for both kinds of settings, studied on the same LINAC.

Material and Methods: All measurements were performed using VersaHD LINAC (Elekta, Crawley, UK) beams with nominal energies of 6MV and 10MV for both FF and FFF. In clinical mode the energy of the FFF (FFFE1) beams is set to match %dd(10)x of the FF beams. To mimic the second FFF beam delivery method, the incident electron beam of the FFF beam (henceforth FFFE2) was set to the same energy as for the FF beam. Besides the determination of TPR_{20,10} and %dd(10)x, half value layer (HVL) measurements were conducted in narrow beam geometry with an in-house developed measuring device with polystyrene tubes of different lengths. Additionally, the dual beam quality specifier as proposed by Ceberg et al. was determined and compared to published values [1,2]. This beam quality specifier consists of two components, the mean (μ) and the variation coefficient (cv) of the linear attenuation coefficient in water.

Results: All results are summarized in Table 1. For 6 MV FFFE1 beams, all investigated beam quality specifiers were very similar compared to those of the FF beams, while for 10 MV FFFE1 beams only %dd(10)x and HVL values were comparable (differences below 1.5%). TPR_{20,10}, %dd(10)x and HVL values of the FFFE2 beams were substantially lower compared to those of the FF and FFFE1 beams. Figure 1 depicts cv as a function of μ for the beams in this work as well as published data. The dual beam quality specifier of the 6 MV FF and FFFE1 energy are equal within the measurement uncertainty and are comparable to published data of a machine with the same TPR_{20,10} and %dd(10)x. In contrast to that, μ and cv of the 10 MV FFFE1 beam were substantially higher compared to the 10 MV FF beam. The 6 and 10 MV FFFE2 energies were characterized by higher μ values, while having cv values similar as those of the FF beams.

Table 1: Beam quality specifiers and HVL.

Nominal beam energy	TPR _{20,10}	%dd(10)x	HVL [mm Polystyrene]	μ [cm ⁻¹]	C _v
6 MV FF	0.678±0.001	67.5±0.1	155±2	0.0485±0.0005	0.37±0.01
6 MV FFFE ₁	0.673±0.001	67.3±0.1	157±1	0.0486±0.0001	0.367±0.001
6 MV FFFE ₂	0.656±0.001	65.8±0.1	148±3	0.0523±0.0004	0.363±0.006
10 MV FF	0.730±0.001	72.7±0.1	189±3	0.0396±0.0006	0.38±0.02
10 MV FFF ₁	0.719±0.001	72.8±0.1	186±2	0.0424±0.0003	0.432±0.004
10 MV FFF ₂	0.697±0.001	68.4±0.1	169±3	0.0454±0.0001	0.389±0.001

Fig 1 Comparison of dual beam quality specifiers determined in this work with published data. Abbr.: C...CyberKnife, E...Elekta, S...Siemens, T...TomoTherapy, V...Varian

Conclusion: PDD-matched FF and FFF beams were observed to have similar HVL values of both beam energies, indicating similarity of their primary dose components. Using the dual beam quality specifier revealed that this might only be true for 6 MV beams. The dual beam quality specifier has been proven to be useful for a more comprehensive characterization of photon beams.

Polymer gels enable volumetric dosimetry of dose distributions from an MR-guided linac

Y. Roed^{1,2}, J. Wang², L. Pinsky¹, G. Ibbott²

¹University of Houston, Physics, Houston, USA

²MD Anderson Cancer Center, Radiation Physics, Houston, USA

Purpose or Objective: Magnetic resonance-guided radiation therapy (MRgRT) benefits from performing treatment response assessments not only at the end of the overall treatment but also during the treatment itself allowing for more normal tissue sparing and better tumor conformality. This was a qualitative study to assess the potential value of polymer gels to measure volumetric dose distributions delivered by an MRgRT unit while using the magnetic resonance (MR) component for readout.

Material and Methods: Polymer gels in custom-designed glass cylinders of 5 cm diameter and 4 cm height were provided by MGS Research Inc (Madison, CT). The design included a 10 cm long filling port to prevent oxygen contamination of the sensitive dosimetric volume. Two dosimeters were positioned in air on the couch of a 1.5 T MR combined with a 6 MV linac. The penumbra of two opposing field edges of a 10x10 cm² radiation field bisected each dosimeter volume; one dosimeter was centered in the penumbra at the superior left field edge and the second one was centered at the inferior right field edge.

Coronal images of the dosimeters were acquired prior to irradiation, immediately after exposure to 22 Gy without changing the position of the dosimeters and 20 hours post-irradiation. A T2 spin echo sequence was used with a relaxation time (TR) of 1000 ms and five echo times (TEs) of 20 ms, 40 ms, 60 ms, 80 ms, and 100 ms. Spin-spin relaxation rate (R2) maps were generated and line profiles across the penumbra were analyzed. R2 has previously been shown to be proportional to absorbed dose.

Results: Near the end of the filling port the gel demonstrated a region of oxygen-contaminated gel as oxygen had diffused through the cap on the filling port. A distinct demarcation of the radiation field inside the sensitive volume was visible as early as 5 minutes after irradiation. R2 values 5 minutes after irradiation in the exposed areas of the dosimeters were about 85% of those seen 20 hours later.

At 5 minutes after irradiation, the line profiles on the R2 map across the penumbra region showed the fall-off of the radiation field in both dosimeters while the penumbra region on the right field edge appeared steeper compared to the slope of the penumbra region on the left. The R2 color maps indicated a narrower transition from outside to fully inside the radiation field on the right compared to the transition on the left.

20 hours after irradiation the polymerization of the gel was presumably completed. The overall signal was both higher on the R2 gray scale maps and more pronounced on the R2 color maps. The line profiles across the penumbra regions exhibited a similar trend for both field edges compared to the profiles at 5 minutes post-irradiation. Over the time frame tested, the dosimeter appears stable.

Conclusion: These preliminary qualitative results indicate that polymer gels offer a promising means of measuring relative volumetric dose distributions with the MR component of the MR-Linac.

EP-1514

γTools: a new multipurpose phantom for end-to-end tests in Gamma Knife SRS treatments

S. Calusi¹, L. Noferini², M. Casati³, L. Marrasso³, C. Arilli³, A. Compagnucci³, C. Talamonti^{1,3}, S. Scocianti⁴, D. Greto⁴, L. Bordi⁵, L. Livi^{1,4}, S. Pallotta^{1,3}

¹University of Florence, Department of Clinical And Experimental Biomedical Sciences "Mario Serio", Florence, Italy

²AOU Careggi, Health Physics Unit, Florence, Italy

³AOU Careggi, Medical Physics Unit, Florence, Italy

⁴AOU Careggi, Radiotherapy Unit, Florence, Italy

⁵AOU Careggi, Neurosurgery Unit, Florence, Italy

Purpose or Objective: γTools is a phantom designed and manufactured to measure both geometrical and dosimetric accuracy of stereotactic radiosurgery treatments performed with Gamma Knife. In this work we present this new phantom and results of experiments aimed to test its reliability.

Material and Methods: *Phantom:* The phantom (figure) consists of two PMMA cylinders, screwed one above the other, that can be filled with an image deformation module and a dose plan verification module. A tool fixed to the big cylinder permits to fix the phantom to the stereotactic head frame. The image deformation module is composed by 1660 spheres (0,7mm diameter, 1 cm pitch) filled with water and obtained by overlaying ad hoc manufactured PMMA disks. The declared accuracy of the manufactured grid was 0,01 mm. The dose plan verification module is made by PMMA disks that

can host inserts with targets and inhomogeneities. Four holes on two inserts are used to mark a gaf-chromic film, sandwiched between the two inserts, in a reference point visible in MR and/or CT images. Distortions on MR images are evaluated using a software module, developed in MatLab (Mathworks) environment, which automatically identifies the 3D distribution of control points and performs a rigid registration with the theoretical grid. Dose plan verification is made comparing planned doses and dose distributions measured by gaf-chromic films with FilmQA Pro software (Ashland).

γTools assembled for image deformation mapping (top left) and for dose plan verification (bottom left); disks forming a 3D matrix of spheres (top right); disks with cavities and inserts for planned dose verification (bottom right).

Tests: The image deformation module was tested assessing the accuracy of the manufactured grid of spheres with CT studies (0,18 mmx0,18 mmx0,8 mm voxel size) of the phantom. The measured and theoretical points grid were registered and the residual shifts, along x, y and z between the registered and theoretical point positions were evaluated. The points grid was disassembled and reassembled (rotating each foil 90°) and another CT study was acquired. The accuracy of the dose plan verification module depends on the reproducibility of inserts position inside the phantom. CT acquisitions of the phantom inserts (0,09 mmx0,09 mmx0,8 mm voxel size) were performed assembling and disassembling repeatedly the inserts along coronal and sagittal planes and evaluating the differences of the reference point positions in the acquired images.

Results: *Image deformation module:* For both 0° and 90° configurations the residual shifts (Δx , Δy , Δz) between the registered and theoretical point positions along x, y and z directions, together with the residual distances (R) were evaluated. The maximum, mean and standard deviations of the absolute values of the shifts along x, y, z and R are reported in the table. *Dose plan verification module:* In the same table the deviations of the reference point positions along x, y, z together with the residual distances R for both the sagittal and coronal insert configurations are reported.

Image deformation module					
		$ \Delta x $ [mm]	$ \Delta y $ [mm]	$ \Delta z $ [mm]	R [mm]
0°	mean±σ	0.05±0.04	0.05±0.04	0.12±0.10	0.16±0.09
	Max	0.39	0.36	0.42	0.48
90°	mean±σ	0.05±0.04	±0.04	0.017±0.14	0.19±0.13
	Max	0.31	0.29	0.56	0.58
Dose plan verification module					
		$ \Delta x $ [mm]	$ \Delta y $ [mm]	$ \Delta z $ [mm]	R [mm]
	sagittal	0.13	0.13	0.05	0.19
	coronal	0.09	0.09	0.09	0.16

Conclusion: The tests performed demonstrate that the proposed phantom is suitable to assess both the geometrical and dosimetric accuracy of Gamma Knife SRS treatments.

EP-1515

Difference in dose to water for photon beams with and without the presence of a magnetic field.

J. Wolthaus¹, B. Van Asselen¹, S. Woodings¹, S. Hackett¹, L. Van Zijp¹, B. Raaymakers¹

¹UMC Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands

Purpose or Objective: In MRI guided radiotherapy (e.g. MR-linac), radiation is delivered in presence of a magnetic field. Therefore, the dose deposition is different since the path of the secondary electrons is changed due to the Lorentz force. Especially at air-tissue interfaces this causes changes in dose distribution. An example is the change in reading of a ionization chamber in a magnetic field. Besides, since the electrons are bend, the net effect is that electrons will travel less in forward direction, as a result the local dose deposition will change slightly even in an area with homogenous density. How to account for these changes in the various codes of practice for reference dosimetry is yet under debate. The purpose of this abstract is to quantify the change in dose-to-water (for a fixed setup) when applying a magnetic field.

Material and Methods: The Monte Carlo (MC) dose engine from Monaco TPS (Elekta) was used to estimate the change in dose-to-water. Validation of this MC code against other established MC codes has been performed by other research groups. For different square field sizes (from 5 to 30 cm) the dose deposition of a 6MV photon beam of an Elekta Agility linac is calculated in a water phantom of 50x50x40 cm³ (SAD = 100 cm, SSD = 90 cm). Calculations were performed with and without a transversal 1.5T magnetic field for the same number of MU. MC variance was 0.1%. Difference in dose was calculated by means of the percentage difference in depth dose in a volumetric region below dose maximum and above phantom bottom (5<depth<35 cm) and around the central axis. A histogram of the percentage differences was calculated for all field sizes. Subsequently, a Gaussian function is fitted to the peak region of the histogram (central part) to reduce the binning effects.

Results: In figure (a) an example of a depth dose curve (and close up) with and without magnetic field is shown for field size 10x10 cm². Figure (b) shows the percentage difference for all square field sizes (9 sample point per field size). The mean percentage difference for all field sizes ranges between -0.4% and 0.55%.

These results show, within the MC variance, that a tendency is visible over the different field sizes. This may be caused by the change in phantom scatter for different field sizes. However, the MC variation causes large variation in the ratio. For small field sizes (<5x5 cm²) penumbra effects will come into play and are for that reason disregarded. The effect of beam hardening is neglected in this work.

Conclusion: A difference in dose-to-water can be estimated as -0.45% for a 10x10 cm² field, which is related to the fact that the electrons travel less in forward direction. Note that this dose difference can also be expressed as a shift in PDD (in the order of a mm). Depending on the used code of practice for reference dosimetry, this difference needs to be taken into account when applying correction factors for magnetic field effects.

EP-1516

Evaluating a versatile new-generation anthropomorphic phantom for SBRT and thoracic IMRT/VMAT

K. Poels¹, A. Nulens¹, R. De Roover², W. Crijns¹, S. Petilion¹, N. Hermand¹, M. De Brabandere¹, S. Michiels¹, G. Defraene¹, K. Haustermans¹, Verelllen.D.³, T. Depuydt¹

¹Universitair Ziekenhuis Leuven, Department of Radiation Oncology, Leuven, Belgium

²Katholieke Universiteit Leuven, Department of Oncology-Experimental Radiation Oncology, Leuven, Belgium

³Universitair Ziekenhuis Brussel, Department of Radiotherapy, Brussels, Belgium

Purpose or Objective: Time-efficient dose delivery by volumetric modulated arc therapy (VMAT) for stereotactic body radiation therapy (SBRT) is gaining more and more interest in radiation oncology. The combination of VMAT with potentially-lethal SBRT doses in heterogeneous tissue circumstances has led to an emerging use of anthropomorphic phantoms for quality assurance (QA) of both therapeutic target dose coverage and organ-at-risk (OAR) sparing. In this study, the first evaluation worldwide of a new-generation anthropomorphic phantom (E2E SBRT phantom model 036A CIRS INC., Norfolk, VA) was conducted for dose delivery of spine and lung SBRT using VMAT.

Material and Methods: The phantom mimics the thorax anatomy with lung-tissue surrounded by rib structures and vertebrae, allowing appropriate image-guidance with a subsequent anthropomorphic dose evaluation. The phantom was customized to fit an Exradin A15L (Standard Imaging, Middleton, WI) ionization chamber (IC) in the tumor centroid and in the peripheral lung. Also TLD or alanine pellets cutouts are foreseen in the phantom. In thoracic and pelvic part of the phantom, both an axial and coronal plane are available for comparing calculated and measured film dose in the target area. A lung insert with a kidney-shaped tumor was specifically developed to verify VMAT lung SBRT with film and IC. The kidney-shaped lung tumor also allowed for a dose film evaluation of the isodose levels along both the medial concave and lateral convex border of the tumor. External markings on the insert allowed to simulate the influence of a rotational tumor offset (step size 1°) with respect to the planning CT.

Results: To already illustrate the potential of the phantom, initial QA results obtained from the new phantom for a spine SBRT and a lung lesion with VMAT SBRT were visualized in Figure 1A and 1B. Overall, a good agreement was found between dose calculation of the treatment planning system and respectively film (>88%) (absolute dose) and IC (<3%) measurements. The difference in agreement score for an OAR close to respectively the concave or convex border of the tumor was similar (see Figure 1B). With 2 and 5 mm PTV margins for respectively spine and lung SBRT, up to 1° and 3° rotation of the phantom insert led to an adequate target coverage.

Figure 1: (A) shows the evaluation of spine SBRT with VMAT in (a) the coronal plane of the pelvis part and (b) the axial plane in the thorax part and (c) the plane of IC point of measurement for point dose verification in the vertebrae and spinal canal and (B) shows the coronal dose plan and verification results for the new kidney-shaped tumor volume of E&E CIRS (model 036A) for the situation of (1) no OAR (2) an OAR on the concave side and (3) an OAR on the convex side of the tumor.

Conclusion: A novel, next-generation anthropomorphic phantom allows a versatile SBRT QA, by assessing high dose target coverage and simultaneous OAR dose or peripheral lung dose in an end-to-end testing setup hereby including inter-fraction rotations. The phantom will be the basis of a multi-center peer-to-peer institutional audit of thoracic IMRT/VMAT and SBRT.

Characterization of a new stereotactic diode under flattening filter free beams down to small fields

G. Reggiori¹, P. Mancosu¹, A. Stravato¹, F. Lobefalo¹, L. Paganini¹, F. Zucconi¹, V. Palumbo¹, N. Suchowerska², S. Tomatis¹, M. Scorsetti³

¹Humanitas Research Hospital, Medical Physics Service of the Department of Radiation Oncology, Rozzano Milan, Italy

²School of Physics- The University of Sydney, Department of Radiation Oncology, Camperdown, Australia

³Humanitas Research Hospital, Department of Radiation Oncology, Rozzano Milan, Italy

Purpose or Objective: Stereotactic radiotherapy requires detectors capable of determining the delivered dose with high accuracy. The aim of this study is to characterize the performance of a new unshielded silicon diode prototype, the IBA Razor, for dose measurements in small radiation therapy photon beams in flattening filter free (FFF) mode

Material and Methods: The performance of the newly commercialized stereotactic diode was evaluated relative to that of the previously available SFD diode and the PFD detectors, both from IBA. The Razor is made with an n-type implant in p-type silicon. The active volume is 0.6mm in diameter and 20µm in length. The detector response stability in measured dose, dose rate and dose per pulse were evaluated. Dark current as function of the received dose was also evaluated. The detector response in square fields, in the range from 0.8 to 5.0 cm, was evaluated by means of percentage depth dose curves (PDDs), axial beam profiles and output factors.

Results: The short term stability of the Razor was found to be much improved relative to the SFD, exhibiting a variation of less than ±0.1% for a dose of 1.2 kGy delivered in a single-session. Dose linearity showed a deviation of less than ±1% in the 0.05-30 Gy range and a dose rate dependence of less than ±0.5% in the 4-24 Gy/min range. The dose per pulse dependence, evaluated in the 0.08-0.21 cGy/pulse range, was found to be within ±0.8%. A larger dark current with increase in dose was observed for the Razor with values of 0.0025pA/Gy compared to the 0.0002pA/Gy for the SFD. This characteristic is attributed to an increased concentration of the recombination centers and can be practically solved by resetting the background before every acquisition.

The measured PDDs agreed to within 1% with those obtained using the PFD detector. The profile analysis showed good results as long as a background correction was applied before each profile acquisition: penumbra differences were below

±0.3 mm relative to PFD, with a slight overestimation of the tails (<1%), due to the absence of the shielding. When background correction was not applied regularly, larger differences were observed in the low dose penumbra region and in the profile tails, probably due to the higher dark current. Output factors were in good agreement with those measured by the PFD detector to within 1% for fields up to 5x5 cm², for larger fields the absence of the shielding in the stereotactic detector led to differences >2%.

Conclusion: The new IBA Razor unshielded diode replaces the IBA SFD, with the additional advantages of improved stability (up to 1.2 kGy) compared to the reference stereotactic diode. The Razor has the same high spatial resolution and performance in small radiation fields. These features make the Razor diode detector a good candidate for radiation therapy and in small field dosimetry to support advanced radiation therapy techniques.

Figure 1 The dark current plotted as a function of the dose to the Razor and the SFD diodes.

Figure 2 Output Ratios for the three detectors for 10 MV FFF beam. Considered field sizes were 0.6, 0.8, 1, 2, 3 and 5 cm². Volume averaging corrections were applied.

Evaluation of dynamic delivery quality assurance process for internal target based RapidArc

J.Y. Song¹, J.U. Jeong¹, M.S. Yoon¹, T.K. Nam¹, S.J. Ahn¹, W.K. Chung¹

¹Chonnam National University Medical School, Radiation Oncology, Hwasun, Korea Republic of

Purpose or Objective: In this study, a delivery quality assurance (DQA) method was designed to overcome the limitations of the conventional DQA process in the static condition for internal target volume (ITV)-based VMAT. The dynamic DQA measurement device was designed with a moving phantom that can simulate variable target motions. The dose distribution in the real volume of the target and OARs were reconstructed with the measurement data under the dynamic condition. Then, to evaluate the designed DQA method, the dose-volume histogram (DVH) data of the real target and OARs were compared with the DVHs calculated in the ITV-based VMAT plan.

Material and Methods: The dynamic DQA measurement device was designed with a moving phantom that can simulate variable target motions. The dose distribution in the real volume of the target and organ-at-risk (OAR)s were reconstructed using 3DVH with the ArcCHECK measurement data under the dynamic condition. A total of 10 ITV-based RapidArc plans for liver-cancer patients were analyzed with

the designed dynamic DQA process. Appropriate method was applied to correct the effect of moving phantom structures in the dose calculation, and DVH data of the real volume of target and OARs were created with the recalculated dose by the 3DVH program.

Results: We confirmed the valid dose coverage of a real target volume in the ITV-based RapidArc. The variable difference of the DVH of the OARs showed that dose variation can occur differently according to the location, shape, size and motion range of the target.

Figure : Total calculated DVH data through dynamic DQA process. Solid line: DVH in the real volume of target and OAR, Dashed line: DVH calculated in the ITV-based RapidArc plan

Conclusion: The conventional DQA method in a static status for the ITV-based RapidArc, without a gating system, can only verify the mechanical and dosimetric accuracy of the treatment machine. An additional DQA method should be devised for evaluating the dosimetric characteristics in the real volume of the target and OARs under respiratory organ motion. The dynamic dose measurement using the moving phantom, which can simulate respiratory organ motions, and techniques employing the measured data to calculate the dose delivered to patients were devised in this study, and proper dose analysis was possible in the real volume of the target and OARs under the moving condition. The devised DQA process appears to be helpful for evaluating the real dosimetric effect of the target and OARs in the ITV-based RapidArc treatment.

EP-1519

Automatic detection of MLC position errors using an EPID based picket fence test

D. Christophides¹, A. Davies², M. Fleckney²

¹St James' Institute of Oncology, Radiotherapy Physics, Leeds, United Kingdom

²Kent Oncology Center, Radiotherapy Physics, Maidstone, United Kingdom

Purpose or Objective: The correct calibration of multi-leaf collimator (MLC) leaves is essential in the accurate delivery of radiotherapy treatments, particularly IMRT. In this study EPID picket fence test images are analysed to investigate the

possibility to automatically detect intentional errors greater or equal to 0.5mm from baseline MLC errors.

Material and Methods: Picket fence tests were delivered as part of weekly Linac QA in RapidArc mode on Varian iX and 2100CD Linacs equipped with the aS1000 and aS500 EPID respectively. In each QA session a picket fence test was delivered with intentional errors of 0.5mm and 1.0mm; additionally a baseline test was delivered without any intentional errors. A total of 96 picket fence tests were retrospectively analysed covering a period of 6 months.

Using Python v2.7.10 for Windows, an algorithm was implemented to quantify the errors in the MLC positions. Briefly the steps of the algorithm were: 1) Image range calibration, 2) Collimator rotation correction, 3) Isocentre position determination, 4) Derivation of relative leaf positions, 5) Calculation of MLC error from median value at each picket fence field position, and 6) Addition of the errors of opposing leaves at each field position to calculate the combined error (CEr) for each leaf-pair.

The mean and median were calculated from the CEr values of each leaf-pair across the different picket fence field positions. The distribution of the mean and median values calculated was compared between baseline and the intentional MLC errors. Furthermore the normal distribution probability density function was fitted onto all of the baseline CEr data. The mean and standard deviation of the fit were obtained. The t-test and Kolmogorov-Smirnov (KS) statistical tests were used to compare each sample of CEr values obtained from each leaf-pair to the corresponding normal baseline distribution of each Linac examined.

Results: For the Varian iX Linac equipped with the aS1000 EPID the distribution of values of the mean CEr for intentional errors varied between 0.43-1.18mm whereas for the baseline the mean CEr values were between 0.00-0.25mm (Fig. 1). This result showed that the mean CEr can be used to automatically detect MLC errors greater or equal to 0.5mm by setting the detection threshold between 0.25mm and 0.43mm.

Fig. 1. Cumulative probability distributions of the mean CEr calculated for both baseline and intentional picket fence field errors. Note that there is no overlap in the values between the baseline and intentional mean CEr.

The p-values of the t-tests performed on the data from the Varian 2100CD Linac for the baseline CEr varied between 1.18E-7 and 1.00, whereas for the intentional CEr the p-values were between 0.00 and 5.07E-05. This overlap between the p-values resulted in a false-positive rate of 4.3% if the p-value of 5.07E-5 was to be used as the CEr detection threshold. Table 1 summarizes all the results from the statistical analysis.

Table 1
Results of the statistical analysis for the comparison between baseline and intentional CEr.

	Baseline CEr	Intentional CEr	CEr detection threshold	False Positive Rate
Linac: iX aS1000				
Mean	[0.00, 0.25] mm	[0.43, 1.18] mm	0.34	0%
Median	[0.00, 0.26] mm	[0.40, 1.09] mm	0.33	0%
t-test (p-values)	[2.01 x 10 ⁻⁰⁸ , 1.00]	[0.00, 1.04 x 10 ⁻⁰³]	1.04 x 10 ⁻⁰³	8.2%
KS-test (p-values)	[8.14 x 10 ⁻⁰⁶ , 1.00]	[0.00, 3.55 x 10 ⁻⁰⁹]	1.70 x 10 ⁻⁰⁷	0%
Linac: 2100CD aS500				
Mean	[0.00, 0.30] mm	[0.44, 1.21] mm	0.37	0%
Median	[0.00, 0.35] mm	[0.44, 1.16] mm	0.40	0%
t-test (p-values)	[1.18 x 10 ⁻⁰⁷ , 1.00]	[0.00, 5.07 x 10 ⁻⁹]	5.07 x 10 ⁻⁰⁵	4.3%
KS-test (p-values)	[4.25 x 10 ⁻⁰⁷ , 1.00]	[0.00, 3.15 x 10 ⁻¹¹]	3.66 x 10 ⁻⁰⁹	0%

[A, B]: indicates that the range of values is between A and B

Conclusion: The analysis proposed can be used to perform automatic detection of MLC errors ≥ 0.5 mm based on individual Linac performance characteristics. Automatic detection of MLC errors has potential in reducing costs and downtime in external beam radiotherapy.

EP-1520

Uncertainties in film measurements of dose area product
T. Wright¹, J. Lye², D. Butler¹, A. Stevenson³, J. Livingstone³, J. Crosbie⁴

¹ARPANSA, Radiotherapy Section, Yallambie, Australia

²ARPANSA, Australian Clinical Dosimetry Service, Yallambie, Australia

³Australian Synchrotron, Imaging and Medical Beamline, Clayton, Australia

⁴RMIT University, School of Applied Sciences, Melbourne, Australia

Purpose or Objective: To assess the feasibility of using radiochromic film to aid the calorimetric determination of the dose-area product (DAP) in small fields by determining the uncertainty in film DAP measurements.

Material and Methods: Dose measurements in small fields can be problematic. DAP methods with a detector much larger than the radiation field provide an alternative to conventional central-axis (CAX) dose measurements. DAP is the integrated dose over the area of the detector (Equ. 1) with units of Gy.cm². In order to convert the measured DAP to the CAX dose the equivalent area of the beam is required. This is the area of an equivalent field with no penumbra (i.e. a step function profile).

$$DAP = \iint D(r) dr$$

(1)

Out of field doses can contribute considerably to the total dose when the detector is integrating over an area much larger than the field size. Film exposures with centimetre-sized fields were performed on the Imaging and Medical Beamline (IMBL) at the Australian Synchrotron using HD-V2 radiochromic film. Films were scanned using an Epson V700 flatbed scanner. The equivalent beam area was calculated by two methods: by normalising the 2D optical density data to unity and either (a) integrating over the area of the detector, or (b) integrating horizontal and vertical profiles and calculating an area by the product of width and height.

Uncertainties have been assessed for scan repeatability, scanner corrections, scanning conditions of calibration films, selection of normalisation value and the dynamic range of the film.

Results: The most important contribution to the uncertainty in DAP measurements is the calculation of the beam area. In the IMBL beam dose rates are typically 50 - 3000 Gy/s depending on distance from the source. High dose film such as HD-V2 is necessary to measure the large doses, however the dynamic range of the film is not suited to low dose measurements.

Preliminary measurements suggest an uncertainty of 1% to 1.5% in the background dose (relative to CAX dose) can be expected. For a 10x10 mm² field measured with a detector 40 mm in diameter, a 1% uncertainty in background dose will result in a 12% uncertainty in DAP measurement. This is likely to be the limiting factor for DAP film measurements.

Scan repeatability, scanner light intensity variation in the horizontal plane, scanner resolution and air gap between film and scanner window all introduce small uncertainties. These can be reduced by using systematic scanning techniques and averaging over multiple scans.

Conclusion: Determination of the out of field dose was found to be the dominant uncertainty in film DAP measurements. Further work is required to determine if a two-film approach can improve the uncertainty. The desired accuracy of <5% will require additional steps to reduce the uncertainty in the out of field dose.

EP-1521

Comparative study of three pre-treatment verification methods: Portal Dosimetry, Delta4 and Epiqa

J. Maroote¹, A. Derdouri¹, A. Coutte²

¹Centre Hospitalier Universitaire, Unité de Radiophysique, Amiens, France

²Centre Hospitalier Universitaire, Unité de Radiothérapie, Amiens, France

Purpose or Objective: Pre-treatment evaluation of RapidArc plans with three different methods: Portal Dosimetry, Delta4 and Epiqa and comparative study.

Material and Methods: RapidArc plans are calculated by Eclipse V.10 AAA algorithm and treatments are delivered by Varian Clinac iX and 2100 accelerators. The pretreatment verification methods are Portal Dosimetry by Varian, 3D detector Delta4 by ScandiDos and the software Epiqa by EPIidos.

Results: The comparative study is carried out on 100 patients. The acceptance criteria used for gamma analysis are: local, dose difference from 3% to 4% and distance-to-agreement from 3mm to 4mm.

For Head & Neck treatments, the average value of Gamma Agreement Index (GAI) given by Portal Dosimetry is 98,17% with standard deviation of 1,41%, Delta4 gives 97,77% with standard deviation of 1,52% and Epiqa 97,54% with standard deviation of 1,60%.

For Pelvis treatments, the average value of Gamma Agreement Index (GAI) given by Portal Dosimetry is 98,09% with standard deviation of 1,54%, Delta4 gives 98,19% with standard deviation of 1,30% and Epiqa 97,83% with standard deviation of 1,84%.

For Encephalon treatments, the average value of Gamma Agreement Index (GAI) given by Portal Dosimetry is 98,31% with standard deviation of 1,49%, Delta4 gives 98,04% with standard deviation of 1,56% and Epiqa 99,01% with standard deviation of 1,38%.

For Thorax & Abdomen treatments, the average value of Gamma Agreement Index (GAI) given by Portal Dosimetry is 97,57% with standard deviation of 1,77%, Delta4 gives 97,92% with standard deviation of 1,41% and Epiqa 97,96% with standard deviation of 1,58%.

Then, intentional errors were introduced in 3 plans in order to evaluate the capacity of each method to detect these errors. It was errors in terms of Monitor Units (MU) and

collimator angle. The results are based on the value of GAI: when the value is lower than 95%, the error is detected. Introduced errors are smaller and smaller in order to characterize error detection limits of each method.

For Portal Dosimetry, it is possible to detect errors of collimator angle up to 4° and errors of Monitor Units up to 3%. For Delta4, it is possible to detect errors of collimator angle up to 2° and errors of Monitor Units up to 2%. For Epiqa, it is possible to detect errors of collimator angle up to 2° and errors of Monitor Units up to 3%.

Conclusion: In spite of their differences, the three pre-treatment verification methods are able to detect different sort of errors in dose distributions. The comparative study gives us concordant results. Therefore, these data suggest the possibility of using only one routinely and complete the analysis with one of the other in case of problems.

EP-1522

Evaluation of usefulness of patient dose analysis system using MLC log file

C.K. Min¹, W.C. Kim¹, E.S. Kim¹, S.G. Yeo¹, E. Jwa¹, S.H. Choi², K.B. Kim², K.H. Cho¹, S. Lee³

¹SoonChunHyang Univ. Hospital, Radiation Oncology, Cheonan Chungnam, Korea Republic of

²Korea Institute of Radiological and Medical Sciences, Radiation Oncology, Seoul, Korea Republic of

³Korea University Hospital, Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: In this study, we compared patient therapy planning evaluation system, applying MLC log file, with quality assurance system using the fluence map obtained from measurement, in order to assess usefulness of patient dose analysis system.

Material and Methods: To map out IMRT treatment planning, we used 4 targets and organ contours (multiple targets, virtual prostate, virtual head & neck, C type), along with IMRT phantom as presented in AAPM TG-119 Report. The treatment planning was implemented via Eclipse treatment planning system using 7 radiation field at an interval of 50° from 0o for both multiple targets and virtual prostate on one hand and using 9 radiation fields at an interval of 40° from 0o for both virtual head & neck and C type on the other hand. For dose limitation conditions for PTV and critical structure, we adopted the objectives specified in TG 119 Report. In relation to dose evaluation, point dose was evaluated by using CC13 chamber. The gamma index was analyzed for allowable limit of 3%/3mm by using MobiusFx system, a dose analysis software using MLC log file, in tandem with 2D array detector and Compass software that evaluates dose based on fluence map.

Results: Dose distribution was calculated using treatment planning and Mobius system for 4 targets and then compared through three-dimensional gamma index based on the setting criteria for allowable limit of 3%/3mm. The results showed the pass rate of 99.5% in multiple targets, 100.0% in prostate, 99.5% in head & neck, and 99.8% in C type. Based on results of analysis of gamma index for dose distribution, which was performed on the basis of dose distribution calculated by MobiusFX system and MLC log file actually investigated, the pass rate was found to be 100.0% in multiple targets, 100.0% in prostate, 99.7% in head & neck, and 99.5% in C type. Meanwhile, gamma index was analyzed based on dose distribution under treatment planning for 4 targets and dose distribution measured through Compass system, and the results indicated that the pass rate was 99.9% in multiple targets, 99.6% in prostate, 99.2% in head & neck, and 98.8% in C type. In addition, the results of point dose evaluation, performed based on point dose under treatment planning using CC13 chamber and point dose actually measured, showed that difference in pass rate was 1.2% in multiple targets, 1.5% in prostate, 1.3% in head & neck, and 0.4% in C TYPE.

Conclusion: This study may provide useful basis for ensuring quality assurance for each patient by using the MLC log analysis system during special treatments in clinical applications.

EP-1523

Validation of the dosimetric algorithm Acuros XB and the impact of its usage in SBRT treatments

T. Younes^{1,2,3}, L. Vieilleveigne^{1,2,3}

¹Cancer University Institute of Toulouse Oncopole, Engineering And Medical Physics, Toulouse, France

²University Toulouse III- Paul sabatier, UMR1037 CRCT, Toulouse, France

³Inserm, UMR1037 CRCT, Toulouse, France

Purpose or Objective: The aim of this study was to assess the accuracy of the dosimetric algorithm based on the resolution of Boltzmann equation: "Acuros XB" (AXB) implemented in Eclipse (Varian) TPS. The methodology recommended by the IAEA-TECDOC-1583 was followed to evaluate AXB. AXB was also tested for clinical extra cranial stereotactic treatment cases. Moreover AXB with the two absorbed dose reporting options, dose-to-medium (Dm) and dose-to-water (Dw), was compared against the Analytical Anisotropic Algorithm (AAA).

Material and Methods: The IAEA-TECDOC-1583 presents eight different fields configurations in heterogeneous media. All plans were created on a CIRS thorax phantom model 002LFC including different tissue equivalent inserts (water, bone and lung). Measurements were performed with a PinPoint ionization chamber (type 31016, PTW) on Novalis TrueBeam STx accelerator for 6MV and 10MV photons with and without flattening filter (6FF, 6FFF, 10FF, 10FFF). Furthermore, target absorbed dose difference between AXB (Dm and Dw) and AAA were compared using same monitor units for 17 patients with non-small-cell lung cancer (NSCLC) or bone metastases cancer who underwent SBRT.

Results: AXB Dm calculations showed an excellent agreement with measurements for the eight configurations of the IAEA-TECDOC-1583. All the results fulfilled the agreement criterion given in the IAEA-TECDOC-1583. The biggest difference between measured and calculated absorbed dose with AXB (Dm and Dw) in lung was less than 0.6% for all photon energies. Unlike, in the lung region, AAA showed deviations that didn't met the agreement criterion. Maximum deviations were 4.4%, 3.35%, 2.27% and 1.6% for respectively 6FF, 10FF, 6FFF and 10FFF photon energies. Although the Dm and Dw was almost the same in most tissues for all the energies, comparing them in bony structure didn't give similar results. When choosing Dw in the bone region some results didn't fulfilled the agreement criterion, unlike Dm where excellent agreement were found between calculated and measured absorbed dose. For the planning target volume (PTV) in the NSCLC patients, AXB Dm and Dw calculations showed similar results while compared to the AAA calculations, where the average differences were less than 2% for minimum, mean and maximum absorbed doses. For bone metastases cancer patients, comparing the PTV doses between AXB Dm and AXB Dw didn't show similar results. The averaged deviations between AXB Dm and AAA were 1.7%, 0.1% and 2.2% whereas deviations between AXB Dw and AAA were 0.1%, 4.2% and 0.7%, respectively for minimum, maximum and mean absorbed doses.

Conclusion: The results of the IAEA-TECDOC-1583 and of clinical cases showed that the AXB algorithm is more accurate than AAA in the lung region for 6FF, 10FF, 6FFF and 10FFF photons. As for bone metastasis the use of AXB Dm was recommended.

EP-1524

The effect of the table top modeling on calculations and measurements for the Delta4 phantom

L. Paelinck¹, B. Vanderstraeten¹, R. Srivastava¹, L. Olteanu¹, C. De Wagter¹

¹University Hospital Ghent, Radiotherapy, Ghent, Belgium

Purpose or Objective: The purpose of this study was to investigate the effect of the modeling of the treatment table top on the agreement between calculations and measurements on the Delta4 phantom (Scandidos). Also, the effect of the most suitable way to determine the daily correction factor was investigated.

Material and Methods: Two of our linear accelerators are equipped with the standard Elekta iBeam evo carbon fiber table top. In our treatment planning system, Pinnacle v9.0 (Philips), the table top is modeled as a slab with dimensions equal to the width and height of the table top and with a density of 0.25 g/cm³.

We extended the axial dimensions of the artificial CT-image set of the Delta4 phantom provided by Scandidos from 25 x 25 cm² to 50 x 50 cm² by a home-made program written in java. This allows us to place the table top model below the phantom at the real distance, ie 7 cm. 15 IMRT plans for breast cancer were recalculated twice, once on the CT-images of the Delta4 phantom provided by Scandidos and a second time on the extended CT-images with the table top model included. All plans consist of 5 to 6 beams (87 in total) from which 1 to 2 beams go through the table (23 in total). The plans were exported to the Delta4 software and measured. In case no table top model was included in the calculations, a daily correction factor based on the average of 4 beams (gantry angles of 0°, 90°, 180° and 270°) was applied. When the table top model was included, a daily correction factor based on 1 beam (gantry angle of 0°) was applied. A gamma criterion of 3%/3mm was used. Statistical analysis was done by paired t-tests. A p-value < 0.05 was considered as statistically significant.

Results: Without the use of daily correction factors, the mean pass rate for the overall treatment plans was respectively 90.7% (±6.9 SD) and 95.2% (±3.0 SD) without and with the table top model applied. This difference is significant with p = 0.01. In the first group 4 out of 15 pass rates were > 95%, whereas in the second group this is 9 out of 15. With the use of the proper daily correction factors, this increases to respectively 98.6% (±1.2 SD) and 99.1% (±0.9 SD). This difference is also significant with p = 0.04. In both groups, all pass rates were > 95%.

For individual beams going through the table top, the mean pass rate was respectively 90.8% (±9.9 SD) and 99.0% (±1.9 SD) without and with the table top model applied and without the use of daily correction factors (p = 0.0001). In the first group 10 out of 23 pass rates were > 95%, whereas in the second group this is 22 out of 23. With the use of the proper daily correction factors, this increases to respectively 99.0% (±1.6 SD) and 99.9% (±0.4 SD) (p = 0.01). In the first group 22 out of 23 pass rates were > 95% and in the second group all pass rates were > 95%.

Conclusion: The table top modeling results in a better agreement between measurements and calculations, both for total plans and individual beams. This agreement improves when proper correction factors are applied.

EP-1525

Clinical results of an EPID-based in-vivo dosimetry for prostate cancer treated by VMAT

M.D. Falco¹, S. Giancaterino¹, A. De Nicola¹, F. Perrotti¹, S. Menna², A. Fidanzio², A. Piermattei², D. Genovesi¹

¹Ospedale Clinicizzato S.S. Annunziata, of Radiation Oncology "G. D'Annunzio"- University of Chieti, Chieti, Italy

²Istituto di Fisica e Unità Operativa di Fisica Sanitaria, Università Cattolica del S. Cuore, Rome, Italy

Purpose or Objective: In-vivo dose verification is the last step of a quality assurance procedure to ensure that the dose delivered during treatment is in agreement with the prescribed one. This work reports the in-vivo dosimetry (IVD) results obtained by the SOFTDISO software (Best Medical Italy) during VMAT prostate cancer treatments.

Material and Methods: SOFTDISO is based on a method developed by a cooperation between INFN and UCSC. It

reconstructs in quasi-real time (a few seconds at the end of the fraction therapy) (i) the dose at the isocenter (Diso) in the patient from the transit signal acquired by the EPID and (ii) the comparison between EPID images obtained during the fractions of the therapy. In particular for each beam and fraction, the R ratios between the dose reconstructed at the isocenter point, Diso, in single-arc (179-181°) VMAT plans for prostate targets and the dose calculated by the TPS, Diso, TPS (generally about 2 Gy for fraction) obtained by Oncentra Masterplan, were computed. The acceptance criteria was: 0.95 ≤ R ≤ 1.05. Moreover the γ-analysis (2%-2mm) between portal images supplied useful index about the beam delivery reproducibility with the P_γ < 1 > 95% and γ mean < 0.4. 15 patients with prostate cancer were treated with 6 MV photon beam delivered by an Elekta Synergy Agility (Elekta, Crawley). Our protocol required, for each patient, the IVD in the first three treatment sessions after a CBCT based set-up correction and the IVD test once weekly afterwards for the rest of the treatment course when the CBCT scan was not acquired.

Results: The IVD procedure supplied 105 tests and the average R was equal to 1.003 ± 0.028 (1SD), in a range between 0.949 and 1.058. The global R value for each single patient was well-within the 5% tolerance level. The γ-analysis between EPID images supplied P_γ < 1 > 97% in 80% of the tests. 20% of the tests supplied 93% ≤ P_γ < 1 > 95% due to small setup variations as verified by the CBCT required at the end of the fraction therapy.

Conclusion: The IVD results supported the protocol about the CBCT carried out in the first three treatment sessions of the VMAT prostate cancer treatment. The facility of the real time test supplied by SOFTDISO allows a CBCT scan requirement after the daily-fraction that supplies IVD off tolerance level. The authors intend to apply this procedure to estimate protocols about the use of the CBCT scans for other pathologies as the head-neck tumors where heavy dose variations due to morphological changes can occur during the therapy.

EP-1526

SPAN STYLE *In vivo* dosimetry with n-type Isorad semiconductor diodes during pelvic treatment

L. Rutonjski¹, B. Petrovic¹, M. Baucal¹, M. Teodorovic¹, O. Cudic¹, B. Basaric¹

¹Institute of Oncology Vojvodina Radiotherapy, Department of Medical Physics, Sremska Kamenica, Serbia

Purpose or Objective: The study was aimed to check radiotherapy treatment accuracy and definition of action levels during implementation of in vivo dosimetry for treatment pelvic cancer patients as a part of quality assurance program.

Material and Methods: Calibration and corrections factors for in vivo entrance dose measurements for n-type Isorad semiconductor diodes for photon energy of 15 MV were determined as per recommendations published by *European Society for Radiotherapy and Oncology* (ESTRO) Booklet No.5. The pelvic cancer patients for in vivo measurements have been divided into groups, according to radiation technique used, in order to investigate and detect the groups for which the uncertainty was larger or for which a systematic error occurred. Initial tolerance/action levels for all groups were set at level of 5%.

Results: In this study, entrance dose measurements were performed for total 185 treatment fields, of 95 pelvic cancer patients over one year period. In 6 (6%) out of 95 patients, in vivo measurements exceeded the tolerances. The mean value and the standard deviation for different groups were: Rectum and gynecology (four field box): 0.6% ± 3.07% (1SD), Prostate (five fields with wedges): +1.0% ± 2.22% (1SD). All pelvic measurements: +0.77% ± 2.79% (1SD). Larger standard deviation was shown for four field box cases because two large errors were noticed. After the corrections, in vivo dosimetry was repeated in both cases and the results were within the

tolerance levels and mean value and standard deviation four field box cases were $+0.68\% \pm 2.43\%$ (1SD).

Conclusion: It was noticed that standard deviation for both patient groups was similar and that initial tolerance/action levels for pelvic cases were substantial. Also, the five fields technique with wedges showed good results due to uniform directional response around diode axis. Within one year after implementation, in vivo dosimetry has revealed and prevented 6 cases of inaccurate treatment. In our experience, systematic in vivo dosimetry proved to be a very useful tool for quality assurance of a patient plan and treatment, both in detecting systematic errors and for estimating the accuracy of radiotherapy treatment delivery.

EP-1527

A phantom for brachytherapy treatment planning systems verification with the ArcCHECK® device

K. Chelminski¹, P. Sobotka², B. Buczek², E. Gruszczyńska¹, W. Bulski¹

¹The Maria Skłodowska-Curie Memorial Cancer Center, Department of Medical Physics, Warsaw, Poland

²Warsaw University of Technology, Faculty of Physics, Warsaw, Poland

Purpose or Objective: Brachytherapy HDR treatments are performed according to the plans calculated with the computerized treatment planning systems. The source positions and dwell times are established to produce required dose distributions. However, in general, the treatment plans are not verified. A phantom for such dose distribution verification is proposed to be used with the ArcCHECK system.

Material and Methods: The ArcCHECK detector array and the SNC Patient software were designed by Sun Nuclear to verify dose distributions in the IMRT and VMAT external beam therapy. It is a cylindrical tissue-equivalent phantom, containing 3D detector array, consisting of 1386 SunPoint diodes. The detectors are located helically along the cylinder with the external diameter of 21 cm. We believe that the ArcCHECK phantom could also be used to verify the brachytherapy dose calculations. For this purpose a special additional part of PMMA, a Brachyplug, was designed and manufactured. The Brachyplug is a special cylinder installed inside the ArcCHECK in which it is possible to place dosimetric films or ionization chambers. The phantom has a number of through holes, where the HDR catheters can be placed into which the Ir-192 stepping source may enter. A special brachytherapy plan was created using the Ocentra MasterPlan planning system with 4 source positions in order to create evenly distributed dose over the detectors of the ArcCHECK array. In order to check the amount of dose which could be absorbed by the electronics of the ArcCHECK system the doses at the relevant distance were measured with the PTW dosimeter and a Farmer type 30013 ionization chamber placed in PTW RW3 plate phantom under the Brachyplug. The measurements were carried out with and without a shield, a 8 cm thick Wood alloy plug, designed in order to protect the electronic control unit of the ArcCHECK from irradiation. After that the dose distribution for the planned source positions was measured with ArcCHECK device with 8 cm thick Wood alloy plug and Brachyplug placed inside the ArcCHECK cylinder.

Results: Measurements of irradiation according to the prepared plan indicate that when the ArcCHECK detectors obtain the dose of 1 Gy the total dose which could reach the ArcCHECK electronics is 12.7 cGy. Such dose is acceptable and similar to the dose in a case of teletherapy. The ArcCHECK allowed for detecting and displaying in the SNC Patient software the HDR brachytherapy irradiation distributions.

Conclusion: The ArcCHECK device may be potentially used for pretreatment verification of dose distributions in brachytherapy. This would require the development of proper energy calibration procedure for the ArcCHECK detectors and

the SNC Patient software update. The Brachyplug phantom will be used for further research on verification of clinical treatment plans in brachytherapy.

EP-1528

Evaluation of the performance of the Integral Quality Monitor (IQM)

B. Perrin¹, J.A. Beck¹, R. Speakman¹, G. Budgett¹

¹Christie Hospital NHS Trust, CMPE, Manchester, United Kingdom

Purpose or Objective: The IQM is an innovative wedge shaped transmission ion chamber which is mounted below the front face of a Linac head. It monitors the total radiation fluence coming from the treatment head (see figure). It is currently undergoing Beta-testing to monitor and verify the delivery of individual treatment fields in real-time. Its potential as a tool for Linac quality control measurements is also being investigated.

Material and Methods: Over an 11 month period a series of QC and clinical prescriptions were delivered multiple times to the IQM mounted on an Elekta VersaHD Linac, to evaluate its sensitivity to potential clinical errors and its long-term reliability and reproducibility.

IQM mounted on Linac, with schematic of detector design

Results: The device proved reliable over the testing period. Its stability and reproducibility are shown in the table. Measurements showed that MLC/Jaw mis-calibrations of 2mm could be identified, as could 2% errors in MU. A change of energy from 6MV to 10MV gave a difference in IQM signal of 6% for conformal and 'step and shoot' IMRT, and of 2-4% for VMAT deliveries. Seventeen similar VMAT head and neck plans each demonstrated a unique IQM signal vs control point pattern, potentially allowing an incorrect plan, or 'plan of the day' to be identified after only 40 degrees of the arc. The IQM was able to identify clinically significant flatness, symmetry and output errors on the Linac.

Modality	Beam Description	Standard Deviation
Static field	10x10cm @6MV	0.7%
Static field	4x4cm @6MV	1.0%
Conformal Arc	10x10cm @6MV	0.8%
IMRT	Step & Shoot @6MV &10MV	0.7%
Simple VMAT	Prostate VMAT @10MV	0.8%
Complex VMAT	Head and Neck VMAT @6MV	1.1%

Variation in IQM signal over 11 months for different modalities

Conclusion: Although the IQM is still under development it can identify a number of clinically significant potential errors in treatment delivery. It is easy to use 'on set' and has proved stable and reliable. It has the potential for use as a

monitor for quality assurance purposes. The ability of the IQM to detect additional error modes needs further investigation.

EP-1529

A real-time monitor system for QA and VMAT: sensitivity analysis in clinical practice

G. Guidi^{1,2}, N. Maffei^{1,2}, G.M. Mistretta¹, P. Ceroni¹, A. Ciarmatori^{1,2}, L. Morini¹, A. Bernabei¹, P. Giacobazzi³, T. Costi¹

¹Az.Ospedaliero-Universitaria di Modena, Medical Physics, Modena, Italy

²University of Bologna, Physics and Astronomy, Bologna, Italy

³Az.Ospedaliero-Universitaria di Modena, Radiation Oncology, Modena, Italy

Purpose or Objective: The iQM® monitor system was tested to provide a method for treatment field verification using an independent monitor system mounted below the gantry. Real-time monitoring allows delivery errors to be detected during treatment, including record & verify mismatch, calibration errors or malfunctions in multi-leaf collimator (MLC), increasing patient safety.

Material and Methods: The iQM® system consists of a large area ion-chamber with a spatial gradient. The ionization chamber and the data acquisition software system were interfaced to an Elekta Synergy accelerator. During 6 months of VMAT quality assurance (QA) sessions, more than 70 sessions of measurements were carried out to validate the repeatability of the detector as a dedicated QA instrument. To evaluate efficiency in clinical practice, a dummy plan and a Head and Neck (H&N) VMAT plan were delivered and investigated using the system. The dummy plan was composed of 18 segments (17 segments 4x4 cm² and 1 segment 10x10 cm²) and was delivered more than 100 times with constant 50 MU per segments. The VMAT plan was composed of 140 control points delivered by an arc, with low gantry speed, high MU and low dose rate. The sensitivity was then tested by introducing specific dosimetric increases of MU (1%,2%,3%,4%,5%,10% and 20%) in the H&N plan (VMATError Plan). Rotational analysis and validation were investigated; correlation with gantry and collimator angles was quantified using SPSS ANOVA analysis.

Results: The dummy plan delivered in standard condition (gantry and collimator angles=0°) revealed a mean variation in signal counts of 0.7±1.0% compared with the commissioning day. Independence of the detector with gantry position were investigated (gantry angle: 0°-90°-180°-270° and collimator angle: 0°-45°-135°-225°-315°). No statistical difference (significance = 1) was detected for all segments, confirming the high quality of the instrument for daily QA. In the H&N plan, a decrease in measured counts was observed in the particular range of gantry angles from 120° through 240°. Statistical analysis showed a mean dose discrepancy of 2.8±1.0% between planned and measured errors from the original plan. For the VMATError Plan, the system is capable of detecting the error introduced with an agreement of 0.2±0.5% (R2=0.99). No correlation related to collimator angle and delivered MU was detected.

Figure 1 Correlation of MU detected vs. MU delivered with ad-hoc errors (1%,2%,3%,4%,5%,10%,20%)

Gantry angle (°)	MU error						
	1%	2%	3%	4%	5%	10%	20%

320	2,0%	3,4%	3,6%	4,5%	6,4%	12,0%	21,2%
340	2,0%	2,4%	4,6%	5,1%	6,8%	11,7%	22,4%

Table 1. Detected MU errors vs. Gantry angle

Conclusion: The system was shown to be stable for daily QA and could add many advantages to the patients' safety during treatment. Taking into account all the treatment factors, the detector provides punctual and cumulative output for each beam segment, which is compared in real time to each segment's expected value. The robustness of the measurement results suggests that the system could recognize errors or inadequate MU during the delivery. The significant signal deviation seen at particular gantry rotations could be investigated in order to improve the results obtained.

EP-1530

Machine performance check tool data analysis

P. Gago¹, J. Olasolo¹, C. Eito¹, M. Aylas¹, P. Ensunza¹

¹Clinica IMQ Zorrotzaurre, Radiation Therapy, Bilbao, Spain

Purpose or Objective: Machine Performance Check (MPC) is a tool provided with Varian TrueBeam linear accelerators to verify, prior to treatment, that critical functions of the system are within the established tolerances. An evaluation carried out by Clivio et al. compared the results of the checks they made using the MPC application and their independent measurements. The purpose of this analysis is to compare the result obtained with the MPC tool at our institution with those acquired in the mentioned study.

Material and Methods: In order to perform the MPC checks, the IsoCal phantom has to be mounted to the couch top using an appropriate holder. The system acquires a series of MV and kV images and analyses them in order to obtain values for different parameters. Two distinct types of checks can be carried out with MPC: beam constancy checks and geometry checks. With the first ones beam output, uniformity and center shift can be evaluated. Geometry checks give us information about isocenter's size, imaging devices positioning, gantry, MLC, collimator, jaws and couch positioning. We analyzed the data obtained over 15 weeks of measurements in a TrueBeamSTx 2.0 with a Millenium HD120MLC and a DMI imager. Beam checks were done for all

the available photon energies in our TrueBeam: 6MV, 15MV, 6MV FFF and 10MV FFF. Geometrical checks were measured only for the 6MV beam.

Results: In all our measurements we found that the results were within the established tolerances. The value of the isocenter's size is, in our case, 0.27 mm, very close to that obtained by Clivio et al. for the same energy, 0.34 mm. The values of the 6MV beam center shift, MV imager projection offset and absolute gantry positioning are the same that the ones obtained in the mentioned study: 0.04 mm, 0.17 mm and -0.09° respectively. For that same energy the offset of the collimator rotation is, in our case, 0.15°, while the one reported in the study is 0.17°, and the kV imager projection offset, 0.24 mm versus 0.32 mm. The output change in our TrueBeam varies from -0.58% for the 10MV FFF beam to -0.50% for the 6MV beam. In the study these values range from 0.06% for their 15 MV beam to 0.24% for their 6MV FFF beam.

Conclusion: Our TrueBeam MPC results were compared with those obtained by Clivio et al. at their institution. They show great agreement with those reported in their study. We have established MPC tool measurements as part of our routine daily QA.

EP-1531
 Comprehensive commissioning and QA of the new version upgrade of treatment planning system
 J. Peng¹, D. McDonald¹, N. Koch¹, M. Ashenafi¹, C. Mart¹, J. Dise¹, M. Fugal¹, K. Vanek¹
¹Medical University of South Carolina, Radiation Oncology, Charleston, USA

Purpose or Objective: To evaluate the dosimetric and optimization algorithm accuracy of a newly released version 13.5 of the Eclipse treatment planning system (TPS) prior to upgrade, utilizing the recently published AAPM Medical Physics Practice Guideline (MPPG), "Commissioning and QA of treatment planning dose calculations".

Material and Method: Eclipse V13.5 includes many novel features, such as contouring tool enhancements, streamlined 4D CT contouring, new physical materials for the AcurosXB (AXB) dose algorithm, and faster optimization engines. MPPG phantom tests were performed to validate both static and dynamic beams in both homo- and hetero- generous material. Additionally, 54 patient plans were re-calculated in V13.5 with the same beam parameters, monitor units, and dose algorithms in order to examine algorithm difference. A dose-difference plan was created by subtracting the dose calculated in V13.5 from V11 and evaluated in 3D dose display. Those re-calculated patient plans included a variety of treatment sites, energies, and techniques. However, the new Photon Optimizer (PO) algorithm was developed in V13.5 to replace the previous Dose Volume Optimizer (DVO) in IMRT and Progressive Resolution Optimizer (PRO) in VMAT. In order to compare the PO and DVO/PRO optimizers, 25 IMRT/VMAT clinical plans were re-optimized with PO using the same objectives, prescriptions, and number of iterations. The plan quality and optimization time were examined.

Results: Dose differences for all clinical cases and MPPG phantom tests in-field and in homogeneous areas, were within 1% and 3% for photon and electron plans, respectively. Although the beam models were not re-commissioned in V13.5, the dosimetric leaf gap (DLG) value was modified and the new physical material was added in AXB; as a result the dose differences correspond to differences in the dose algorithms. Therefore, at field edges and heterogeneity interfaces, maximum dose differences increased to 3% and 6% for photons and electrons, respectively. Dose calculated using AXB was found to be 3% less at the lung interface and inside the lung in V13.5 compared to dose calculated in V11, but no dose difference calculated using AAA was seen. PO could optimize plans 20-30% faster than DVO/PRO. For most cases, no significant difference in plan quality was noted. However, lung SBRT cases with PO showed a reduction in MUs and slightly improved dose conformity.

Table 1: The mean and maximum dose difference of the same dose algorithms between V11 and V13.5 in 3D (photon and electron), VMAT, SBRT and SRS cases.

Figure 1. The comparison of optimization algorithms between PO (V13.5) and DVO/PRO (V11) in IMRT, VMAT, Lung SBRT and Spine SRS cases. The square dots present DVO/PRO algorithms in V11 and triangle dots show PO algorithms in V13.5

Conclusion: Commissioning and QA of new TPS version is essential prior to clinical release. The tests suggested by MPPG provide an excellent framework for this work, particularly when combined with additional clinical cases. Dose differences noted were chiefly located at beam edges, possibly due to modified DLG values, and in heterogeneous materials and interfaces using AXB, potentially due to differences in material specification. The PO improved optimization efficiency in all cases and MU economy and dose conformity in some SBRTs, with no reduction in plan quality.

EP-1532
 Reliability of the Machine Performance Check application for TrueBeam STx Linac
 V. Mhatre¹, P. Patwe¹, P. Dandekar¹
¹Sir HN RF Hospital, Radiation Oncology, Mumbai, India

Purpose or Objective: Machine Performance Check (MPC) is an application to verify geometry and beam performances of Truebeam STx , through automated checks . In this study,MPC tests were analysed using all photon beam energies of our Truebeam STx, comparing whenever possible with external independent checks.

Material and Methods: The Machine Performance Check (MPC) is a new Truebeam STx major mode, designed to evaluate the machines geometric performance. Data acquisition comprises a series of 39 images acquired with IsoCal Phantom & with particular MLC pattern settings. MPC performs geometric and dosimetric checks. The geometric checks intend to test the treatment isocenter size and its coincidence with imaging devices, the positioning accuracy of the imaging systems, collimator, gantry, jaws, MLC leaves & the couch position. The dosimetric checks refer to a reference MV image and give the beam output, uniformity and center change relative to the reference.MPC data were acquired during one month on different consecutive days. For most of the MPC checks, an independent control has been performed at the same time of the acquisition of the MPC to evaluate the agreement of the two methods. For the independent checks, phantoms and detectors available & used routinely in the department were used.The Daily QA3 was used to check the beam constancy.The first acquisition, acquired at the same time as the MPC baseline, was used as reference. Also weekly output was performed as per TRS 398 protocol on water phantom using FC 65 chamber to compared with the MPC and Daily QA3 output.

Results: Treatment isocenter was between 0.39 ± 0.02 mm with MPC, compared to 0.5 ± 0.01 mm for 6 MV with the Winston-Lutz test. Coincidence of kV and MV imaging isocenters was within 0.26 ± 0.05 and 0.25 ± 0.06 mm, respectively (0.5 ± 0.1 mm with external tests). Positioning accuracy of MLC was within 0.5 mm; accuracy of jaws was 0.12 ± 0.02 , 0.14 ± 0.03 , -0.77 ± 0.08 , 0.11 ± 0.04 mm for X1, X2, Y1, Y2 jaws, respectively, with MPC. Dosimetric tests: the output stability relative to the baseline for 6 MV .10MV and 15 MV was $0.46 \pm 0.09\%$, $0.45 \pm 0.08\%$, $0.3 \pm 0.07\%$ for MPC compare with $0.82 \pm 0.3\%$, $0.33 \pm 0.2\%$, $0.52 \pm 0.33\%$ with the independent measurement.

Conclusion: MPC is a useful tool for QA of Truebeam STx systems and its automation makes it highly efficient for testing both geometric and dosimetric aspects of the machine. Overall, the ability of the MPC to monitor linac output stability was comparable to that of ionization chamber-based measurements.

EP-1533
Sensitivity of ArcCheck system to setup error using Perfect Pitch 6D couch
V. Mhatre¹, P. Patwe¹, P. Dandekar¹
¹Sir HN RF Hospital, Radiation Oncology, Mumbai, India

Purpose or Objective: The purpose of this study is to evaluate the sensitivity of ArcCheck 3D diode array to setup error for patient-specific quality assurance (QA) of

volumetric-modulated arc therapy (VMAT). Translational setup errors of $\pm 1, 2 \& 3$ mm in the RL, SI & AP directions & rotational setup errors of $\pm 0.5^\circ, 1^\circ \& 1.5^\circ$ in the pitch, roll & yaw directions were set up in ArcCheck for 6 patients.The pass rate of γ analysis was computed by comparing the calculated & measured dose distributions using 3%/3 mm, criteria.

Material and Methods: Six VMAT plans for various sites were selected for this study. The VMAT plans were designed using Eclipse v13 treatment planning system.The ArcCheck Dosimetry system consists of 1386 diodes,embedded in the cylindrical wall of the phantom with 10 mm spacing. All tests were carried out using an Truebeam STx accelerator with a high definition MLC . CBCTs were acquired for all the set up. Registration between the reference CT and CBCT was carried out automatically using an inbuilt rigid registration method.The ArcCheck phantom was translated in the right-left (RL), anterior-posterior (AP), and superior-inferior (SI) directions by $\pm 1,2\&3$ mm respectively and rotated in the pitch, roll, and yaw directions by $\pm 0.5^\circ, 1^\circ \& 1.5^\circ$ using the 6D treatment couch. To validate the accuracy of perfect pitch couch for rotation, smart tool digital level was placed on couch to confirm the rotation introduced in phantom. Each patient plan were separately delivered on the phantom for dose verification in total, 37 measurements (1 without positional error, 18 with translational errors, & 18 with rotational errors) were performed for each patient.The pass rate of γ analysis was computed by comparing the calculated and measured dose distributions using 3%/3 mm, criteria respectively.

Results: When the translational setup errors are $\pm 1, 2 \& 3$ mm, respectively, the pass rates of γ analysis with the 3%/3 mm criteria decreased by a maximum of 1.7%, 8.4%, and 11.0% in RL direction; 2.5%, 7.4%, and 12% in the SI direction & 2.0%, 7.5%, and 10.5% in the AP direction. When the rotational setup errors were $\pm 0.5^\circ, 1^\circ \& 1.5^\circ$, respectively, the pass rates of γ analysis with the 3%/3 mm criteria decreased by a maximum of 3.5% ,5% & 12% in the pitch direction; 3.2% ,6% & 15.2% in the roll direction,3.5%,8% & 18% in the yaw direction.

Impact of Setup Error on Gamma Analysis for 3%/3mm Criteria in RL Direction

Conclusion: In this study, ArcCheck diode array showed high sensitivity to rotational setup errors. ArcCheck 3D diode array is capable of detecting an setup error in order of 1 mm/0.5° .

EP-1534
Dosimetric impact of the QFix kVue Calypso couch top and the electromagnetic array with photon beams
J. Molinier¹, N. Aillères¹, L. Bedos¹, A. Morel¹, S. Simeon¹, D. Azria¹, P. Fenoglio¹

¹Centre Val d'Aurelle - Paul Lamarque, Radiation Oncology, Montpellier, France

Purpose or Objective: The Calypso 4D Localization System consists in an electromagnetic detection of implanted Beacon transponders in order to continuously track their moves. The use of this system requires a specific couch top and the introduction in the treatment beam of an electromagnetic array. The purpose of this study is to quantify the dosimetric impact of the new material introduction in photon beams.

Material and Methods: At first, the QFix kVue Calypso couch top and the array attenuation was evaluated by comparing the dose measurements with Eclipse TPS dose prediction for 2 energies (6MV FF and 6MV FFF) and 2 rail configurations (rails in and rails out). Dose measurements at the isocenter were performed with a cylindrical water-equivalent phantom, a 0.125cc ionization chamber, a 10*10cm² field size at 39 gantry angles. The beams between 315 and 45° allowed analyzing the electromagnetic array attenuation. The beams between 90 and 270° were used for couch attenuation. Secondly, the dosimetric impact was analyzed on 20 RapidArc treatment plans of prostate (10 with 6MV FF and 10 with 6MV FFF). Dose distributions were recalculated in the cylindrical phantom and the dose prediction at the isocenter was compared to the dose measurement with the 0.125cc ionization chamber using 2 configurations: classical treatment (with kVue IGRT couch top and rails out) and treatment with Calypso (QFix kVue Calypso couch top, rails out and the electromagnetic array).

Results:

In the configuration of rails out, the mean attenuation of the couch was 2.91% for X6 and 3.45% for X6FFF with a maximum of 12.02% and 13.19% for X6 and X6FFF, respectively. In the configuration of rails in, the mean attenuation was 3.25% for X6 and 3.90% for X6FFF with a maximum of 9.79% and 11.14% for X6 and X6FFF, respectively. Besides, the mean attenuation of the array was 1.15% and 1.67% for X6 and X6FFF, respectively. As regards the impact of global Calypso system on RapidArc treatment plans, the mean deviation with a classical treatment was -0.61% [-0.8%; -0.3%] for X6, and -0.31% [-0.86; 0.43] for X6FFF.

Conclusion: For the fixed beams, the attenuation is not negligible when a beam crosses directly a support rail in particular. The errors in dose calculation can be more of 10%. However, for RapidArc treatments with X6 and X6FFF, the dosimetric impact of the QFix kVue Calypso and the array is not significant.

EP-1535

Electron Skin Irradiation: refinement of an abutting field technique

G. Pittomvils¹, E. Bogaert¹, T. Boterberg¹, M. Van Eijkeren¹, C. De Wagter¹, Y. Lievens¹

¹Ghent University Hospital, Radiotherapy, Ghent, Belgium

Purpose or Objective: Skin electron irradiation is a treatment modality for mycosis fungoides. An overlapping and/or abutting field technique with the patient lying on a stretcher is used with at least two oblique 40x40 cm²; 4 MeV-overlapping fields at 25/335 gantry angles at SSD=170 cm both about 12 cm lateral of patient mid-line. If two fields fail

to cover the entire affected skin additional abutting oblique fields are added in cranio-caudal direction. Using 3 pairs of fields, the entire anterior (or posterior) body is covered. During commissioning of a new Elekta Synergy accelerator special attention was given in the search of an optimal angle incidence and field matching.

Material and Methods: A linear array (PTW LA-48) positioned in a polystyrene phantom is used to evaluate longitudinal and lateral dose profiles at 1 and 4 mm depth. Two different angles of incidence ($\pm 25^\circ$ and $\pm 30^\circ$) and three different abutment gaps (0-32-64 mm; common multipliers of the 8 mm interdetector distance of the LA-48) are evaluated. Prescription dose point is corresponding to the dose value at 4 mm depth of the central axis dose of the most cranial beam pair. Treatment length is defined as the distance between the most cranial and most caudal 90% dose point. Beam spread is calculated over the entire treatment length, beam flatness (1) over 0.9 times the treatment length.

(1) Podgorsak p.196

Results: Both gantry angle pairs show a remarkable flat summed dose profile over the entire range of the LA-48 (3.0-3.2% for $\pm 25^\circ$; 2.3.-2.4% for $\pm 30^\circ$). As expected maximal dose levels are decreasing with increasing obliqueness resulting in more depth-related dose homogeneity. Cranio-caudal measurements show a radiation field increase of 1.5-2 cm (50% field dose boundary) compared to the light field. The initial 6 field light field abutment method results in dose spreads of 3.5% and 5.6% (4-1 mm depth) and dose flatness of 4.7% and 6.1%. Introducing 32 mm gaps improves dose data to 2.5% and 2.8% in spread and to 3.3% and 3.8% in flatness. 64 mm gaps result in a spread of 4.3% and 3.6% and a flatness of 7.5% and 6.0% (fig. 1). The corresponding treatment length increases from 168 cm (no gaps) to 178 cm (32 mm gaps) and to 187 mm (64 mm gaps).

Conclusion: The general conclusion is that for mycosis fungoides treatments, using oblique fields with dedicated abutment in cranio-caudal direction the general accepted overall dose homogeneity of $\pm 10\%$ is more than met on a flat surface equivalent to the size of a human body using 6 oblique fields.

EP-1536

Uncertainties in dose calculations for radiation treatment of breast cancer after mastectomy

R. Chakarova¹, A. Lindberg², M. Gustafsson³, D. Lundstedt⁴

¹Göteborg University Sahlgrenska University Hospital, Department of Medical Physics and Biomedical Engineering, Göteborg, Sweden

²Sahlgrenska University Hospital, Department of Medical Physics and Biomedical Engineering, Gothenburg, Sweden

³Sahlgrenska University Hospital-, Department of Medical Physics and Biomedical Engineering, Gothenburg, Sweden

⁴Sahlgrenska Academy- Sahlgrenska University Hospital, Department of Oncology- Institute of Clinical Sciences, Gothenburg, Sweden

Purpose or Objective: To study dose distributions in chest wall with thickness around or less than 15 mm and to evaluate the accuracy of Eclipse and Oncentra treatment planning algorithms in phantom and patient geometries.

Material and Methods: Measurements by thermo luminescent dosimeters and gafchromic film are performed on a cylindrical phantom with air cavity representing the lung. Tangential 6 MV open beam is applied on the phantom and dose profiles from the surface toward the geometrical center

of the phantom are obtained at beam axis entrance and exit, as well as laterally. Dose distributions for two patients are calculated for clinical plans involving 6 MV and 15 MV photon beams and field-in-field techniques. Three volumes are studied, namely, PTV (516 cm³) and CTVT (10 cm³) for patient one, and PTVT (117 cm³) for patient two. Calculations in the case of phantom and patient geometries are performed by Eclipse AAA and Acuros XB algorithms and by Oncentra CC algorithm. Corresponding Monte Carlo dose calculations are carried out using EGSnrc/BEAMnrc software. Estimates like D98% (dose to 98% of the volume) and V95% (the volume receiving 95% of the dose) are used when comparing the dose distributions. The accuracy of the different algorithms when including a bolus is investigated.

Results: Measurements in the phantom case show a negligible dose decrease at the phantom-in-air interface but more than 10% dose decrease at this interface laterally or at beam exit. Large uncertainties in calculated data are detected in the interface regions, namely up to 4 mm depth from the phantom-air interface and 2 mm depth from the phantom-in-air interface. In the patient cases, deviations less than 3% are observed for PTV and CTVT for the dosimetry parameters D98% D2% and V105% obtained by the different algorithms and the Monte Carlo method. For PTVT, the largest deviations are between AAA and Monte Carlo data, for example, 3.6% for D98% and 9.2% for V105%. The results are explained by the fact that PTV is large and eventual uncertainties at the boundary has smaller effect on the dose volume histograms. CTVT is small, however, the distance from the CTVT contour to the surface and to the lung interface is 4 mm or more at each slice. In the third case, a large partial volume of PTVT is located near the lung interface where the dose uncertainties are large. Furthermore, it has been found, that the algorithms reflect properly the dose changes due to bolus except for AAA, where the dose volume histograms for CTVT obtained with and without bolus can't be distinguished.

Conclusion: Partial volume located near the lung interface has major effect on target coverage. The measured dose decrease and the uncertainties of the treatment planning algorithms near interfaces should be taken into account when establishing guidelines for target delineation and coverage for patients with thin chest wall.

EP-1537

Developing an in vivo dosimetry system for TomoTherapy® using the CT detector array

H. Dhiraj¹, S. Thomas¹, S. McGowan¹

¹Cambridge University Addenbrookes Hospital, Radiotherapy - Medical Physics, Cambridge, United Kingdom

Purpose or Objective: The Hi-Art Helical TomoTherapy unit is a linear accelerator equipped with an on-board CT detector array. It delivers radiation in a helical fashion with daily CT imaging for image guidance and beam monitoring. *In vivo* dosimetry is a recommended part of treatment with the potential of improving patient safety. Conventional approaches of *in vivo* dosimetry cannot be implemented for TomoTherapy due to the rotational nature of the system and thus transit dosimetry is required. This study has investigated the use of the detector sinogram in performing transit dosimetry by modelling how the primary photons are influenced by scatter geometry for a static and helical field. The aim has been to produce a semi-empirical model of the exit detector signal and investigate factors that influence the signal at the imaging panel of a TomoTherapy unit.

Material and Methods: The detector signal profile (detector sinogram) is extracted for the DICOM data for each procedure. It contains the response at each detector channel and for each projection. The exit detector response for an open field is measured in-air with a moving couch for a static and helical delivery. The exit detector sinogram for an in-air measurement has been used as an input into a signal reconstruction model of the exit detector sinogram when a scattering medium is positioned on the couch. A simple ray-

tracing model has been produced using narrow beam conditions for the attenuation of the beam in a cylindrical, uniform phantom (Tomo® Cheese Phantom). The model relies on TPR data previously determined in the department as shown in Thomas *et al.*, (2012).

Results: The simulated sinogram agrees with the measured sinogram for both the static and helical deliveries within $\pm 10\%$ in the central region of the phantom. At the edge of the phantom this increases to $\pm 15\%$ due to set-up issues.

Figure 1 shows a single projection (7 degrees) taken from the sinogram data for the measured and modeled exit detector sinograms.

Conclusion: At this stage of development, the model shows promise in use as an independent check tool. However, second order corrections, such as scatter, should be incorporated if the model is to be clinically used. Further work is also required to reduce set-up errors, i.e. by imaging the phantom prior to measurement.

EP-1538

How well does Compass compare to film for prostate VMAT patient-specific QC?

D. Nash¹, M. Huggins², J. Kearton¹, A.L. Palmer³

¹Queen Alexandra Hospital, Medical Physics, Portsmouth, United Kingdom

²University of Surrey, Department of Physics, Guildford, United Kingdom

³Queen Alexandra Hospital- Portsmouth- UK, Medical Physics, and Department of Physics- University of Surrey- Guildford-UK., United Kingdom

Purpose or Objective: Compass© (IBA, Schwarzenbruck, Germany) is a 3D pre-treatment plan verification system. The linac fluence is measured with an ion chamber array (MatriXX (IBA)). Then via a detector fluence model and collapsed cone algorithm [1], the dose is calculated on the patient's planning CT. It has been demonstrated that Compass can validate VMAT plans (73-99% gamma passing rate at 3%/3mm [2]) although it does introduce some dose blurring [3]. However, occasional failures do occur in plan verification using Compass (i.e. a significant variation on a DVH parameter or reduced gamma pass rate). The purpose of this work was to understand whether failures were due to genuine errors (such as treatment delivery or calculation) or due to the limitations and uncertainties of the Compass methodology. To achieve this, EBT3 film was used as best estimate of the true delivered dose distribution for prostate VMAT plans.

Material and Methods: Six fields which were characteristic of segments from previously failed plans were measured with EBT3 film using advanced triple-channel dosimetry techniques (via FilmQAPro). These were then compared against Compass and the TPS (Pinnacle 9.8) doses using profile and 2D global gamma analysis. Twelve film

measurements were then acquired for 3 clinical prostate patients with Compass and film (one of which had failed Compass QC, likely due to narrow segments) in a solid water phantom and compared.

Results: Profile analysis of the characteristic fields showed that for narrow but long fields on axis, the agreement between Compass and film was within 3%, slightly inferior to the TPS and film comparison at 2%. The worst case was 5% for a 1 x 10 cm off-axis field and 4% for irregular fields. The clinical films demonstrated that Compass accurately modelled dose distribution with 11/12 films achieving at least 95% gamma passing at 3%/3mm with an average of 97.8 ± 2.1 % (sd). The failed film achieved 93.6% passing. This was from the failed clinical plan - this is more likely due to the blurring induced by narrow segments than inaccurate delivery. Figure 1 shows (a) an isodose and (b) a profile taken across the film. All films passed when compared against the TPS (average gamma 98.3 ± 1.3 %).

Figure 1. Representative film showing (a) an isodose and (b) a profile (dashed line on (a)) showing the Compass (thick) and film (thin) where 100% = 3.48 Gy.

Conclusion: By comparison with film measurements, it has been shown that Compass is able to reproduce the dose distribution of clinical VMAT prostate plans, and is sufficiently accurate to detect any clinically relevant errors. However, users should be aware that the resolution of the Compass reconstruction algorithm is limited when narrow segments are predominant.

Proposal for DVH oriented acceptance criteria for VMAT prostate patient specific QA

M. Polsoni¹, F. Rosica¹, F. Bartolucci¹, C. Fidanza¹, G. Orlandi¹

¹AUSL 4 Teramo, Department of Medical Physics, Teramo, Italy

Purpose or Objective: New hybrid systems for patient specific pre-treatment QA are suited for 3D gamma (GA) and DVH reconstructed analysis (DA). For 2D evaluations, a 3%/3mm agreement for 90-95% points is considered to be the

state of art. Recent studies highlighted poor correlation between gamma passing rates and DVH clinical goals variations on PTV and OARs, so it could improve the situation to consider available DVH analysis tools. The aim of this work is to test the robustness and sensitivity of VMAT prostate patient specific DVH based acceptance criteria (AC) for QA using the COMPASS (Iba-Dosimetry) system in combination with the RayStation (Ray Search Laboratories) TPS.

Material and Methods: For thirty prostate dual-arc VMAT plans, the most relevant DVH indices (DI) were considered for the PTV: D98, D95, D50, D1 and Dmean. Clinical doses were computed with both, COMPASS and RayStation, which share the same calculation algorithm. Plans were delivered with a VARIAN Trilogy equipped with a Millenium 120 MLC and measured with COMPASS. RayStation vs COMPASS reconstructed doses were analyzed in terms of DI differences. The AC rely on calculating mean values (m) and standard deviations (std) of DI differences and assigning for each DI difference a confidence interval equal to $1.5 \cdot \text{std}$. To assess the AC robustness in terms of system sensitivity the TG119 prostate case was optimized using a VMAT single arc technique. Three different types of errors were introduced individually in the RT-plan to mimic linac delivery inaccuracies: a) MU number modification (MU-error) from -3% to +4%, b) gantry angle shift (g-error) from 0° to 3° and c) widening of both leaf banks (w-error) from 0 to 2 mm. Modified plans were delivered and beforehand defined DI were calculated.

Results: For RayStation vs COMPASS computed doses analysis DI differences < 0.4% have been found. In the TG119 plan PTV DI differences showed a linear trend respectively with MU-errors (see figure) and g-errors. The proposed DVH based criteria detected MU-errors below -1.8% or above 1.3% and w-errors > 1.5mm. The criteria led to the detecting of g-errors > 3°.

Conclusion: The defined criteria show high predictive capability and robustness to detect MU and w-errors on the PTV. On the other hand g-errors are not easy to detect mainly because of the central position of the prostate.

EP-1540

EBT3 films for proton therapy plan QA using a multichannel approach

L. Marrazzo¹, S. Lorentini², M. Schwarz², S. Pallotta³

¹Careggi University Hospital, Medical Physics Unit, Firenze, Italy

²Trento Hospital, Proton Therapy Department, Trento, Italy

³University of Florence, Department of Biomedical-Experimental and Clinical Sciences 'Mario Serio', Florence, Italy

Purpose or Objective: Due to the excellent spatial resolution, Gafchromic® EBT film (Ashland Inc., Wayne, NJ) are potentially attractive as a 2D dosimeter for dose verification in proton therapy. Multichannel dosimetry (MCD) was recently proposed for film calibration, showing improved accuracy if compared to single channel dosimetry (SCD), since it allows for the separation of the dose-dependent part of the film image from non dose-dependent contributions. The aim of this study was to test MCD vs SCD for patient plans QA in proton therapy.

Material and Methods: We performed irradiations with different levels of complexity in both homogeneous and anthropomorphic (heterogeneous) phantom. Homogeneous phantom: measurements with EBT3 film and MatriXX (Iba Dosimetry, Schwarzenbruck, Germany) were carried-out in solid water slabs delivering 1) a homogeneous 'box-like' dose distribution (range 12cm, modulation 6cm, width 5x6cm², measured at 9cm depth) and 2) a clinical field measured at 6cm depth. Anthropomorphic phantom (Proton Therapy Dosimetry Head - CIRS 731-HN): films were placed on sagittal planes and phantom was irradiated with 1) a homogeneous box-like field, 2) a single clinical field and 3) a three beam clinical plan (two lateral non-coplanar and one anterior oblique). Each film was scanned together with two reference films, one non-irradiated and one exposed to a dose around 80% of the maximum expected dose. The reference films provide data for correcting the dose-response function for the conditions applying to the particular scan, thus reducing the inter-scan variability; this option can be selected in the FilmQA™ Pro software used for the analysis. Films were scanned with an Epson Expression 10000XL. Measured data were compared with those extracted by the TPS (XiO, Elekta).

Results: Table 1 shows the results of the gamma analysis for both SCD and MCD. An average reduction of about 16% and 10% was observed for the 2%/2mm and 3%/3mm gamma parameters, respectively, when moving from MCD to SCD. The standard deviations reported in the table indicate a larger variability among the results for SCD compared to MCD, thus suggesting that MCD is also effective in reducing inter-film variability. Comparing the fields delivered in homogeneous vs anthropomorphic phantom, an average deterioration by 3% (MCD) is observed in gamma passing rates in presence of heterogeneities.

			γ passing rate (%)		
			2%/2mm	3%/3mm	
Homog. phantom	Homogeneous box field	MCD	74,0	88,6	
		SCD	67,7	82,6	
	Clinical field	MCD	74,8	93,0	
		SCD	49,3	73,5	
Anthropomorphic phantom	Homogeneous box field	MCD	72,0	86,1	
		SCD	37,7	68,1	
	Clinical field	MCD	68,2	92,1	
		SCD	42,7	74,5	
	Full plan	Central plane	MCD	71,7	91,5
			SCD	71,7	90,8
		Intermediate plane	MCD	78,0	95,5
			SCD	71,2	93,6
Lateral plane		MCD	69,2	92,5	
		SCD	55,8	83,0	
Mean±1SD		MCD	73±3	91±3	
		SCD	57±14	81±9	

Table 1. Comparison between the multichannel and single channel dosimetry in terms of gamma passing rates (local approach, 10% threshold).

In figure 1, a comparison between the two methods in terms of gamma maps, isodose distributions and profiles is shown.

Figure 1. Gamma maps, isodose distributions and profiles for the SCD (a) and MCD (b) methods (single clinical field delivered on anthropomorphic phantom).

Conclusion: In general, the MC optimization strongly improves the gamma passing rates when comparing measured and calculated dose maps. The proposed method appears to be suitable also for patient dose verification in proton therapy.

EP-1541

Effects of leaf position accuracy of robotic radiotherapy system on dose distribution

J. Suzuki¹, H. Takahashi², M. Tomida², K. Hamajima², Y. Ohhashi², T. OKUDA²

¹Toyota Memorial Hospital, Radiotherapy Quality Management Group, Toyota, Japan

²Toyota Memorial Hospital, Radiology, Toyota, Japan

Purpose or Objective: Recent technological developments in robotic radiotherapy systems have enabled delivery of a large number of non-isocentric, non-coplanar beams using the InCise™ multi leaf collimator (MLC) system. However, the effect of gravity may result in leaf positional errors. We investigate the leaf position accuracy of Cyberknife M6 and evaluate the effects of leaf position accuracy on the dose distribution.

Material and Methods: The leaf position accuracy of Cyberknife M6 was tested at the home position and at eleven positions that may affect the MLC position accuracy through the gravity effect. The position accuracy was analyzed by the Bayouth test with an EBT2 film. Further, the dose distribution for a prostate cancer patient treatment plan when using the MLC was evaluated. Film dosimetry is performed for evaluating the dose distribution. Parameters from the patient

plan are applied to a phantom, and the film is exposed in three orientations. The dose distributions from the film measurements were compared with the planned dose distributions from the treatment planning system. This analysis was performed using the Gamma index method.

Results: The leaf position error was observed with respect to the gravity effect. The maximum leaf position error was 0.42 mm at a Sauce axis distance of 800 mm. All leaf position errors were within the tolerance level of leaf position accuracy recommend by vendors. In the evaluation of the dose distribution, all passing rates of the gamma index method were greater than 90% in criterion of 2%/2 mm and threshold of 30% of the maximum dose.

Conclusion: The leaf position accuracy of Cyberknife M6 can achieve clinically acceptable levels in every position that is affected by the gravity effect.

EP-1542

Comparison between Elekta Oncentra 4.3 and Monaco 5.0 3DCRT dose calculation algorithms

M.G. Brambilla¹, C. Cadioli¹, A.F. Monti¹, C. Carbonini¹, M.B. Ferrari¹, D. Zanni¹, G. Alberta², A. Torresin¹

¹Ospedale Niguarda Ca' Granda, Medical Physics, Milan, Italy
²Elekta S.p.A., Technical Support, Agrate Brianza, Italy

Purpose or Objective: Accurate dose tests have to be performed before using a TPS in clinical practice. Measured and calculated dose distributions must be compared in various irradiation conditions. This process needs a huge amount of time for both calculation and analysis. In this work, we evaluated the differences between 3DCRT calculated dose distributions in the migration between two TPSs produced by the same company.

Material and Methods: In our Hospital, the migration from Oncentra ver. 4.3 (Elekta, SWE) to Monaco ver. 5.0 (Elekta, SWE) was carried out. The 3DCRT dose calculation algorithm (CCC) is the same for the two systems. The kernels for 3 different photon energies produced by a Synergy (Elekta,UK) equipped with an 80 leaves MLC were processed and installed on the Monaco console by Elekta. Some parameters (beam source size and MLC interleaf leakage), were automatically created during the kernel generation. The same Oncentra parameters were previously optimized by the user during the commissioning. In this work, we verified whether significant differences exist in the implemented beam models in the two TPSs and in their use for dose calculations. The dose distributions calculated by the systems were analyzed in terms of depth doses, profiles at various depths and absolute dose. The results were compared to the corresponding measurements according to ESTRO booklet 7 criteria. For relative data, the reference analysis parameter was the gamma index confidence limit, that is the absolute value of gamma index average plus 1.5 times its standard deviation. The dose deviation and the distance to agreement values in global and local gamma index test were changed according to the irradiation geometry complexity (from 2%-2mm to 4%-3mm) and a maximum dose threshold of 7-10% was used. A specific analysis software provided by Elekta Support was used for the comparisons. For absolute doses, the reference analysis parameter was the percentage difference between measured and calculated values (acceptance criteria from 2% to 3% depending on complexity).

Results: Because of the great amount of data, a concise picture of the results is not possible. However no significant differences between Oncentra and Monaco calculated doses were found, except for negligible variations in field shape (around 0.5 mm) probably due to a small difference in source size used in the two TPSs. Yet, new kernel processing was required in order to optimize Monaco behaviour in profile tails.

Conclusion: The migration between the two systems did not show significant differences in 3DCRT calculated dose distributions. Then, if an Oncentra accurate commissioning is

present, a reduced number of comparison tests, involving each implemented energy and radiation unit, could be used with Monaco. Our results refer to Oncentra ver. 4.3 and the present considerations should not be adopted for previous versions without any specific check.

EP-1543

Feasibility of MLC dosimetric leaf gap measurement using OCTAVIUS 4D system

H. Geng¹, W.W. Lam², Y. Bin², K.Y. Cheung², S.K. Yu²

¹Hong Kong Sanatorium & Hospital, Medical Physics & Research Department, Happy Valley, Hong Kong SAR China

²Hong Kong Sanatorium & Hospital, Medical Physics & Research Department, Hong Kong, Hong Kong SAR China

Purpose or Objective: The dosimetric leaf gap (DLG) is an important parameter defined in the Eclipse treatment planning system (TPS) to account for the partial transmission through rounded leaf ends of Varian multileaf collimators (MLC). The DLG is determined by comparing the agreement between calculated and measured dose distributions of Intensity-modulated radiotherapy (IMRT) plan. The IMRT plan dose distribution is typically measured using ionization chamber and radiographic film. Radiographic film dosimetry gives excellent spatial resolution and is widely used for dose distribution measurement; however, it shows energy dependence and limited dose range. Also, developing the film is time consuming. OCTAVIUS 4D system consists of a 2D ionization chamber array and its associated 4D phantom. The chamber array has uniform energy response and relatively wide dose range. Previous investigators have proved that the sampling frequency of this ionization chamber array is appropriate for IMRT dose distribution verification. The 3D dose distribution could be reconstructed immediately after measurement. In this study the feasibility of determining DLG using OCTAVIUS 4D system was investigated.

Material and Methods: A standard 9-fields head and neck IMRT plan was generated in Eclipse TPS using 6MV photon beam. The optimized photon fluence was converted into final dose distributions by applying different DLG values ranging from 1.8 to 2.2. Those IMRT plans were copied and applied to both OCTAVIUS 4D and a cylinder solid water phantom. The optimal DLG was determined independently using these two dosimetry system by comparing the agreement between calculated and measured dose distributions. A point dose was measured using ionization chamber (A1SL, Standard imaging, USA) inserted into the solid water phantom and the 2D dose distribution was measured using radiographic film (EDR2, Kodak, USA) sandwiched in the phantom. The measured point doses were compared with the calculated ones and 2%/2mm criteria were selected for gamma analysis of film comparison. For OCTAVIUS 4D system, 3D dose distributions were measured and reconstructed using OCTAVIUS 4D system. The measured dose distributions were compared with calculated ones using 2%/2mm 3D gamma analysis criteria. The optimal DLG measured using OCTAVIUS 4D was compared with that determined using ionization chamber and film system.

Results: The point dose measurement and the gamma analysis of both film and OCTAVIUS 4D systems were listed in Table 1. The maximum gamma analysis passing rate in OCTAVIUS 4D measurement agreed with the results in EDR2 film analysis and both suggested that 2.0 is the optimal DLG value.

DLG	Percent difference in point dose measurement using A1SL ionization chamber	Passing rate in EDR2 Film comparison (2%/2mm gamma analysis criteria)	Passing rate in OCTAVIUS 4D system measurement (2%/2mm gamma analysis criteria)
1.8	1.72%	80.5%	89.5%
1.9	1.05%	83.1%	92.3%
2.0	0.66%	84.8%	93.2%
2.1	-0.10%	82.2%	93.0%
2.2	-0.54%	79.9%	91.8%

Table 1. The point dose measurement and the gamma analysis of both EDR2 film and OCTAVIUS 4D systems

Conclusion: In this study, the DLG determined using OCTAVIUS 4D system is in good agreement with ionization chamber and film measurement. OCTAVIUS 4D system may be an alternative of film dosimetry and provide an effective and efficient way to determine the MLC DLG value.

EP-1544

Dose conformation evaluation of volumetric modulated arc therapy for cranial radiosurgery

C. Ferrer¹, C. Huertas¹, A. Castaño², A. Colmenar², A. Mañas², A. Serrada¹

¹H.U. La Paz, Radiofísica y Protección Radiológica, Madrid, Spain

²H.U. La Paz, Oncología Radioterápica, Madrid, Spain

Purpose or Objective: To evaluate the quality and dose conformity of a volumetric modulated arc therapy (VMAT) cranial radiosurgery treatment plan using different parameters, as well as the accuracy of the dose calculation.

Material and Methods: Four patients were prescribed to 18Gy, planned with Elekta Monaco treatment planning system (v. 3.30.01), and optimized using biological and physical based cost functions for VMAT treatment on an Elekta Synergy linear accelerator equipped with a 160-leaf Agility MLC. 5 to 9 non coplanar arcs were used, for cranial lesions of different sizes (Target volume, 4 cc- 8 cc). Treatment isocenter was placed at the target volume center. The evaluation was performed using the RTOG Conformation Index (CI), the target coverage (TC), the Paddick's conformity index (Clp), the homogeneity index (HI), volume of healthy brain tissue receiving a dose of 10 Gy or more (V10), and the dose to organs at risk (OAR). The accuracy of the dose calculation was verified measuring the dose distribution with Gafchromic Film EBT3, inside the IBA Scanditronix I'mRT phantom, and read using FilmQA Pro software. Absolute dose measurements were made with a CC13 Scanditronix-Wellhofer ionization chamber located at the treatment isocenter. Also the 4D detector array ArcCHECK (Sun Nuclear Corporation) was used for 2 patients. Van Dyk's criterion, dose percentage difference and distance to agreement (DTA) 3%-3mm, was employed.

Results: Median CI, Clp and HI for all patients were 0.93, 0.82 and 1.16 respectively, with median TC of 88%. V10 was kept below 10cc for all cases. OARs were spared within tolerances. Conformity and received doses to OAR depend on the type and location of the target, and in one case all indices were significantly lower in order to comply with the V10 tolerance. Best results were obtained with 5 -6 non coplanar arcs arrangement. Dose distribution measured with Gafchromic Film EBT3 gave passing rates above 90% and absolute percent differences between measured and calculated dose with the ionization chamber were lower than 2% for all patients. ArcCHECK results showed a passing rate greater than 95% for the two patients.

Conclusion: With Monaco treatment planning system, in combination with a 160-leaf Agility MLC, it is possible to achieve highly conformal dose distributions for cranial radiosurgery VMAT plans, and target volumes larger than 4cc, with low doses to healthy tissue, even with highly irregular lesions. For the plan evaluation, the combination of TC with CI and Clp showed to be more helpful than the CI itself alone.

EP-1545

Dosimetric impact of target separation in craniocaudal direction with TomoDirect Dynamic Jaw

C.W. Kong¹, W.W. Lam¹, W.K.R. Wong¹, S.G. Lo¹, T.L. Chiu¹, S.K. Yu¹

¹Hong Kong Sanatorium & Hospital, Medical Physics & Research Department, Happy Valley, Hong Kong SAR China

Purpose or Objective: TomoDirect is a non-rotational treatment option for Tomotherapy in which the treatment field is delivered at different discrete gantry angles with MLC modulation and couch translational movement. With the introduction of Dynamic Jaw Technique (Available for jaw

setting 5 cm and 2.5 cm) there is a potential improvement in the radiation dose fall-off at the cranio-caudal edges of a target, thus enhancing the effectiveness of dose reduction between the targets in the treatment with multiple metastases. In this study the effectiveness of dose reduction using Dynamic Jaw Technique was investigated for different target separations using different jaw settings, pitch factors and modulation factors.

Material and Methods: Two identical cylindrical targets of 6 cm length and 3 cm diameter aligning along superior-inferior (SI) direction with different separation ranging from 4.5 cm to 2 cm in 0.5 cm decrements were created on a water phantom image. TomoDirect planning was done on the planning CT images using Dynamic Jaw Technique with different jaw setting. Dose prescription was 2 Gy per fraction to 95% volume of both targets. Gantry angles 0°, 120° and 240° were used. Different plans were created with the modulation factor varying from 1.5 to 3 in 0.5 increments and the pitch factor ranging from 0.1 (default value) to 0.05 of the jaw width in 0.01 decrements. Same test plans were created using Fixed Jaw Technique for jaw width 5 cm, 2.5 cm and 1 cm for comparison. All plans were delivered and EDR2 film was used to measure the dose distribution on the coronal plane to verify the planning calculation.

Results: Measured dose distributions were in good agreement with the planning calculation for all plans as the gamma passing rate were higher than 90% with 2% in dose difference and 2 mm in DTA. The impact of reducing pitch value and increasing modulation factor were marginal on the dose fall-off between the targets for all plans. From figure 1, dose reduction effect between targets was greatly enhanced with different separations when Dynamic Jaw Technique was applied for jaw setting 5 cm and 2.5 cm. For target separation as small as 3 cm such dose reduction effect using 2.5 cm Dynamic Jaw Technique was comparable to 1 cm Fixed Jaw Technique.

Figure 1. Isodose distribution on the region between targets with different separation using different technique in TomoDirect.

Conclusion: In Dynamic Jaw Technique, Jaw setting is the critical factor for dose reduction between the targets. For target separation not less than 3 cm Dynamic Jaw Technique with 2.5 cm should be used as the dose reduction effect is comparable with 1 cm Fixed Jaw Technique with shorter treatment time.

Monte Carlo simulation of the Elekta VersaHD linac

E. Borzov¹, A. Nevelsky², S. Daniel², R. Bar-Deroma²¹Rambam Health Care Campus, Oncology, Tirat Karmel, Israel²Rambam Health Care Campus, Oncology, Haifa, Israel

Purpose or Objective: The Elekta VersaHD linac is characterized by the new 160 leaves Agility MLC and the ability to work in Flattening Filter Free (FFF) mode. The objective of this work was to create an accurate Monte Carlo (MC) model of this linac for 6MV and 6MV FFF beams. The Elekta VersaHD linac is characterized by the new 160 leaves Agility MLC and the ability to work in Flattening Filter Free (FFF) mode. The objective of this work was to create an accurate Monte Carlo (MC) model of this linac for 6MV and 6MV FFF beams.

Material and Methods: The BEAMnrc code was used to create detailed models of the linac head for the 6MV and 6MV FFF beams based on the manufacturer data supplied by Elekta. MC simulation with the BEAMnrc code generated the phase-space file using DBS and BCSE variance reduction techniques. This file was used in the DOSXYZnrc code to calculate PDDs, profiles and output factors in a water phantom at SSD= 90 cm. Results from the simulations were compared against measurements performed during commissioning of the linac using an PTW water phantom, a PTW SemiFlex ion chamber and a Scanditronix stereotactic diode. Field sizes from 1x1 cm to 20x20 cm were taken into consideration. The following parameters of the MLC and of the incident electron beam had to be determined to provide the best fit between the measured and calculated data: leaf bank rotation (LBROT) angle, leaf spacing at isocenter, the incident beam spectrum (mean energy and FWHM, under assumption of Gaussian distribution), width (FWHM) and angular divergence. The incident beam spectrum was defined by matching PDDs, the beam width was determined by matching the penumbra in in-plane and cross-plane directions. The angular spread was adjusted by matching the profiles of 20x20cm² field. LBROT angle and leaf spacing were obtained by matching the interleaf measured and calculated values. Output factors (relative to a 10x10 cm² field) were calculated under assumption of negligible backscatter from the MLC to the ion chamber.

Results: Calculated and measured PDDs for all field sizes agreed within 1%/1mm. Lateral profiles in both (in-plane and cross-plane) directions agreed within 2%/1mm for all field sizes. Output factors agreed with 3%. For the 6MV beam, the mean energy and FWHM of the incident electron beam were 6.5MeV and 0.5MeV respectively. For the beam width, FWHM in the in-plane direction was 0.15cm and in the cross-plane direction 0.25cm. For the 6MV FFF beam the mean energy and FWHM of the incident electron beam were 7.4MeV and 0.5MeV. FWHM in the in-plane direction was 0.10cm and in the cross-plane direction 0.20cm. The mean angular spread was 1.1 degree for both beams. LBROT angle was 0.01radian. The leaf spacing at isocenter was 0.5cm.

Conclusion: An accurate MC model for the Elekta VersaHD linac was created to be used with the BEAMnrc code. This model will be employed for our future work of the Agility MLC characterization and modeling of stereotactic cones.

EP-1548

Optimisation of the initial parameters and efficiency in Monte Carlo simulation for Cyberknife

M.J. Lin¹, T.C. Chao², T.C. Chang¹, C.C. Lee², H.L. Chao³, A.C. Shiau²¹Chang Gung Medical Hospital, Department of Radiation Oncology, Taoyuan, Taiwan²Chang Gung University, Graduate Institute of Medical Imaging And Radiological Science, Taoyuan, Taiwan³Tri-service General Hospital, Department of Radiation Oncology, Taipei, Taiwan

Purpose or Objective: To optimize the initial parameters and calculation efficiency in Monte Carlo simulation for Cyberknife G3 system.

Material and Methods: BEAM09 Monte Carlo codes were used for this study. The BEAMnrc code was used to simulate the treatment head and generate the phase space files. The DOSXYZnrc code was used to calculate the depth dose curves (percentage depth dose, PDD), lateral profiles and the output factors. Mean incident electron energy and the radial intensity (FWHM) were used to determine of initial electron parameters. For the calculation of dose in the region of interest, the use of smaller voxel size may increase the calculation time; conversely, the adaption of larger voxel size may cause a higher partial volume effect. This study aims to investigate the optimal voxel size for dose calculation in a water phantom to achieve a reasonable simulation efficiency and an acceptable accuracy. The K_a method was used for the optimization by comparing the differences between diode measurement data and MC simulations in PDDs and profiles. Disagreement between simulation and measurement were evaluated through the dose differences of PDDs from depths of 1.5 to 20 cm, and the lateral profiles of 80% field width. The DTA (distance to agreement) at lateral positions of 20% to 80% dose profiles of penumbra region were also used for the comparisons.

Results: For the efficiency of dose calculation, by setting the voxel size equal to one tenth of field width would produce a optimal simulation efficiency and an acceptable accuracy. For the optimization of initial parameters, the optimal mean incident electron energy is 7.1 MeV and the FWHM(R) is 2.4 mm. According to these parameters, the dose differences of the PDDs is about 1% from depths of 1.5 to 20 cm, and the dose differences for lateral profiles within 80% field width is also within 1.5%, and the disagreements of DTA were less than 0.5 mm. The discrepancies of output factor were 2.8-5% for the three smallest cones, which were possibly caused by the effect of electron scattering at the metallic parts of the detector shielding.

Conclusion: For Monte Carlo simulations of LINAC and dose calculations it is important to accurately determine the initial electron beam. These parameters, mean energy and FWHM of incidence electron, have been determined by matching the calculated dose with the measured dose through a trial and error process. This study also applied some methods to increase simulation efficiency which could be the reference of future research.

EP-1549

Dosimetric evaluation of VMAT planning for Elekta Agility using Eclipse planning system

V. Prokic¹, F. Röhner², S. Spiessens³¹University of Applied Sciences, Mathematics and Technic, Remagen, Germany²The University Medical Center Freiburg, Department of Radiation Oncology, Freiburg, Germany³Varian, Medical Systems, Palo Alto, USA

Purpose or Objective: VMAT planning for Elekta linear accelerators with newest MLC-Agility is supported with the following treatment planning systems: Pinnacle3 (Philips, Fitchburg WI, USA), Oncentra Masterplan (Elekta), RayStation (RaySearch Laboratories AB, Stockholm, Sweden) and Monaco (Elekta). The newest release of Eclipse TPS V13.5 (Varian Medical Systems, Palo Alto, CA, USA) includes an algorithm for Elekta Agility VMAT planning. The purpose of this study was to assess dosimetric validation of the new VMAT optimization algorithm implemented in the treatment planning system Eclipse TPS V13.5 for the latest Elekta MLC-Agility. Testing was performed by creating and dosimetrically verifying VMAT plans for different anatomical sites.

Material and Methods: The Agility multileaf collimator (Elekta AB, Stockholm, Sweden) has 160 leaves of projected width 0.5 cm at the isocenter, with maximum leaf speed 3.5 cm/s and dynamical leaf guides. Ten patients with different carcinoma sites previously treated were selected for this study: head and neck, lung, prostate, anal and cervix carcinoma. Selection was made in order to cover common tumor sites and also to have broad spectrum of complexity. VMAT plans were optimized using the new Photon Optimizer algorithm (PO 13.5.35) implemented in the Eclipse TPS V13.5. The plan quality was evaluated by homogeneity, conformity and target coverage. All plans are re-calculated for Octavius phantom with 729xdr Detector (PTW, Freiburg) and irradiated. Comparison of measured and calculated dose distributions was done in VeriSoft 6.0 Software (PTW, Freiburg) using 2D Gamma-index and "Difference in percent of normalization value of reference matrix"-method.

Results: All VMAT plans met clinical objectives, providing high conformal dose distributions. The comparison of the 3D dose distribution measured by PTW Octavius 729 2D-Array passed both used criteria. 2D Gamma-Value (3% local dose, 3mm distance to agreement) analysis for all plans gave results gamma index=1, with 100% passing points. The other comparison method, resulted in more of 95% passing points for all investigated plans.

Conclusion: This study showed excellent dosimetric validation of VMAT plans made for Elekta Agility using newest Eclipse 13.5 version of the Varian planning system. It is also shown that MLC of Elekta Agility allows treating most complex target volumes in VMAT technique.

EP-1550

Dosimetric comparison of the two dose reporting modes of Acuros XB and AAA for lung SBRT

A.W. Mampuya¹, M. Nakamura¹, Y. Hirose², T. Ishigaki³, T. Mizowaki¹, M. Hiraoka¹

¹Kyoto University- Graduate School of Medicine, Department of Radiation oncology and Image-applied therapy, Kyoto, Japan

²Osaka Red Cross Hospital, Division of Radiology, Osaka, Japan

³Osaka Red Cross Hospital, Department of Radiation oncology, Osaka, Japan

Purpose or Objective: The purpose of this study is to measure the difference in dose-volumetric data between the analytical anisotropic algorithms (AAA) and the two dose reporting modes of the Acuros XB, namely, the dose to water (AXB_Dw) and dose to medium (AXB_Dm).

Material and Methods: Dose volumetric data for 37 lung lesions treated with Stereotactic Body Radiation Therapy (SBRT) were generated using the AXB_Dm in Eclipse Treatment Planning System (TPS) for Varian Clinac iX or TrueBeam and then recalculated with the AXB_Dw and AAA using the same monitor units and identical beam setup. The internal target volume (ITV) was delineated using the averaged image from the 4DCT and the PTV was obtained by adding 5mm margin to the ITV. A dose of 50Gy in 4 fractions was prescribed to the IC and the D95%. The following dose-volumetric parameters were evaluated; D2%, D50%, D95% and D98% for the ITV and the PTV. Two-sided, paired Student's t tests were used to test for statistical significance (p<0.05).

Results: Table I summarized the dose-volumetric data results under the IC and the D95 prescription for all the 37 lesions. Under the IC prescription, the maximum mean difference, observed in the ITVD50% between the AXB_Dm and the AAA was only 1.7 points, although statistically significant (p<0.05). The difference in the PTV D98% was not statistically significant between the three algorithms. With the D95 prescription. The maximum mean difference, observed in the ITVD50% between the AXB_Dm and the AAA was 3.3 points, (p<0.05). The difference in the PTV D98% and D2% was not statistically significant between the AXB_Dm and AXB_Dw. The PTV D95% didn't differ between the three algorithms.

Table I. Dose volumetric data calculated with AXB_Dm, AXB_Dw and AAA. Data are shown as means \pm standard deviation.

PTV	IC			D95		
	AXB_Dm	AXB_Dw	AAA	AXB_Dm	AXB_Dw	AAA
D2*	101.7 \pm 2.2	101.0 \pm 2.1	100.6 \pm 1.7	133.4 \pm 7.7	133.1 \pm 7.6	131.6 \pm 6.5
D50*	95.4 \pm 4	94.8 \pm 3.5	93.9 \pm 3.2	120.4 \pm 4.3	120.3 \pm 4.3	118.4 \pm 4.3
D95 [†]	86.9 \pm 6.2	86.5 \pm 6	86.2 \pm 5.5	100.1 \pm 0	100.1 \pm 0	100.1 \pm 0
D98 [‡]	84.6 \pm 7	84.2 \pm 6.8	84.2 \pm 6.5	93.8 \pm 2.4	93.8 \pm 2.4	94.2 \pm 2.6
ITV	IC			D95		
D2 [§]	102.1 \pm 1.9	101.1 \pm 1.6	101.1 \pm 1.3	134.3 \pm 8.2	133.9 \pm 8.2	132.1 \pm 7.1
D50 [¶]	98.6 \pm 2.2	97.7 \pm 1.8	96.9 \pm 1.9	128.3 \pm 7.4	127.6 \pm 7.3	125.6 \pm 6.4
D95 ^{**}	94.0 \pm 3.4	93.3 \pm 3.3	92.4 \pm 3.2	118.5 \pm 12.5	118.2 \pm 12.5	115.9 \pm 12.1
D98 ^{††}	92.7 \pm 5	92 \pm 5	91.2 \pm 4.8	116 \pm 15	115.8 \pm 14.9	113.6 \pm 14.8

Abbreviations: AXB_Dm= Acuros XB dose-to-medium reporting mode; AXB_Dw= Acuros XB dose-to-water reporting mode; AAA= Analytical anisotropic algorithm; PTV= Planning target volume; ITV= Internal target volume; IC= Isocenter prescription dose; D95= Prescription covering 95% of the target volume.

*A significant difference was found between AXB_Dm and AAA, AXB_Dm and AXB_Dw and AAA and AXB_Dw

†A significant difference was found between AXB_Dm and AAA, AXB_Dm and AXB_Dw and AAA and AXB_Dw only under the D95 prescription.

‡A significant difference was found between AXB_Dm and AAA and AAA and AXB_Dw under the D95 prescription.

§A significant difference was found between AXB_Dm and AAA, AXB_Dm and AXB_Dw under the IC prescription

¶A significant difference was found between AXB_Dm and AAA, AXB_Dm and AXB_Dw and AAA and AXB_Dw under the IC prescription and AXB_Dw and AAA and AXB_Dw under the D95 prescription.

Conclusion: Although statistically significant, the dosimetric difference between the three algorithms are within acceptable range with the maximum difference being 3.3 points between the AXB-Dm and AXB_Dw.

EP-1551 Benchmarking Monte Carlo for proton radiosurgery

P. Trnkova¹, J. Shin¹, J. Schuemann¹, H. Kooy¹, J. Daartz¹

¹Mass. General Hospital, Department of Radiation Oncology, Boston- MA, USA

Purpose or Objective: Small proton fields that are used in proton radiosurgery (PSRS) are defined by the loss of electronic and nuclear equilibrium along the central axis as a consequence of electronic and nuclear interactions. The Bragg peak is degraded which can lead to underestimation of range if the treatment planning system (TPS) does not correctly model nuclear and MCS effects. Monte Carlo simulation is the gold standard for dose calculations. The aim of this project was to benchmark Monte Carlo simulation for PSRS against measurements and compare it to the TPS.

Material and Methods: A fixed beamline for passive scattering PSRS was modeled with TOPAS, a platform for Monte Carlo simulations. Depth dose profiles of pristine Bragg peaks with ranges of 6, 10 and 15 cm as well as SOBPs for the same ranges and respective modulations widths of 2 and 4 cm for 6cm, 2.5 and 4.5 cm for 10 cm and 4.5 and 8 cm for 15 cm were calculated with TOPAS. The simulations were compared to annual QA measurements with a multilayer ionization chamber (MLIC) and to the XiO (Electa, Sweden) TPS. The field size in all cases was 6 cm in diameter. Two scoring volumes were used, a 1 cm and a 4 cm radius cylinder with 0.1 cm binning in beam direction.

Results: The measured and calculated Bragg peaks and SOBPs were in good agreement. The absolute difference between measured and calculated ranges and modulation widths were 0.7 mm (0.1 - 1.5 mm) and 0.6 mm (0.3 - 1.1 mm), respectively. The absolute differences between calculated and XiO ranges and modulation widths were 0.7 mm (0.4 - 0.9 mm) and 0.2 mm (0.1 - 0.4 mm), respectively. The differences in the diameter of the scoring volume mainly influenced the build-up area. Figure 1 presents an example of a SOBP (range 15 cm, modulation 4.5 cm) comparing the three methods (a), and calculated with different scoring diameters (b). The pristine Bragg peak for the range of 15 cm is shown in Figure 1c.

Conclusion: Precise characterization of depth dose curves is very important in PSRS when the field size is small and the number of fractions is limited not allowing wash out of any dosimetric uncertainty. The Monte Carlo simulation of PSRS beamline was successfully benchmarked against measurements. This implementation will enable exploration of even smaller volumes and execution of treatment planning studies for PSRS.

The work was sponsored by Swiss National Fund (SNF project number P300P3_158522).

EP-1552

Phantom measurements and simulated dose distributions in pelvic Intra-Operative Radiation Therapy

F. Costa¹, A. Esposito², P. Limede², C.C. Rosa³, S. Sarmento⁴, O. Sousa⁵

- ¹IPO PORTO, Investigation Center CI-IPOP, Porto, Portugal
- ²INESC TEC, Center for Applied Photonics, Porto, Portugal
- ³Universidade do Porto, Physics and Astronomy Department of Science Faculty, Porto, Portugal
- ⁴IPO Porto, Medical Physics Service and Investigation Center CI-IPOP, Porto, Portugal
- ⁵IPO PORTO, Radiotherapy Service, Porto, Portugal

Purpose or Objective: Rectal cancer is the second most frequent tumour site treated with intra-operative electron radiation therapy (IOERT) in Europe, after breast cancer [1]. Unlike breast, the pelvic irradiation surface is usually irregular and/or concave, and bevelled applicators are frequently used. A previous study in phantoms has shown that the shape of the irradiation surface can alter the IOERT dose distribution, with possibly important consequences for the interpretation of in vivo measurements [2]. The aim of this work is to study pelvic IOERT dose distributions, by simulating clinical irradiation conditions using phantoms and computational models.

Material and Methods: A phantom was created in-house using a sacral bone model covered with 3mm thick radiotherapy bolus, as shown in Figure 1A. To simulate in vivo measurements, small pieces of Gafchromic EBT3 film (1.5x1.5cm²) were placed on this phantom, and irradiated with a 9MeV electron beam from a Varian 2100 CD conventional linear accelerator (LINAC), adapted for IOERT with a hard docking system of cylindrical applicators. The 7cm applicator with a 45° bevel (7B45) was used to irradiate the phantom. A numerical model of this IOERT system had been previously implemented using BEAMnrc, an EGSnrc based Monte Carlo code, and validated by comparison with water tank measurements. This computational model was used to calculate the IOERT dose distributions resulting from a few irradiation surfaces, with varying curvatures, to compare with the measurements performed with the phantom.

Figure 1 A. Sacral bone model covered with 3mm bolus, 3 film pieces, and the 7B45 IOERT applicator; B. Film locations on the phantom (red arrows) and film positions relative to a flat surface (R1, R2, R3); the green square (R) marks the reference point for surface dose on a flat surface; C. Dose distribution calculated with Monte Carlo simulation model, for irradiation of a curved surface.

Results: The surface doses measured with the films placed on the surface of the phantom (Film 1, 2, 3) were compared with the expected surface dose at the centre of the applicator (location R in Figure 1B) in reference conditions (flat irradiation surface). The percentage differences found are presented in Table 1. The variation introduced by the bevelled applicator along the applicator surface, in reference conditions, is also shown for comparison. The differences between the measured values and those expected for a flat surface (at locations R1, R2, R3 of Figure 1B), are in good agreement with the simulated results of curved surfaces with tissue inside the applicator, where a hotspot appears laterally (see Figure 1C).

	3 irradiations			Location (R1, R2,R3) relative to R	Diff_flat (%)
	Diff (%)	Diff (%)	Diff (%)		
Film 1	+16%	+19%	+18%	-1.3cm	1%
Film 2	+5%	+5%	+5%	+0.5cm	0%
Film 3	-5%	-3%	-4%	+2.7cm	-3%

Table 1. Diff: difference between the dose measured with films and the expected dose, D_{exp}, at the location R (see figure 1) in reference conditions (flat surface); Diff_{flat}: expected dose variation in a flat surface (due to the bevelled applicator), for comparison.

Conclusion: The results presented highlight the influence of curved and irregular surfaces on pelvic IOERT dose distributions, and the importance of taking the irradiated surface geometry into consideration when interpreting results of in vivo measurements.

³Fondazione CNAO, Clinical Radiotherapy Unit, Pavia, Italy

⁴Istituto Ortopedico Rizzoli, Department of Oncologic and Degenerative Spine Surgery, Bologna, Italy

⁵Fondazione CNAO, Clinical Directorate, Pavia, Italy

Purpose or Objective: Surgical implant fixation is a common technique in case of spinal and paraspinal tumors, usually considered good candidates for particle therapy (PT). Traditional orthopedic metal implants significantly differ from normal tissues in terms of density and composition, leading to substantial perturbation effects on radiation beams. Recently a Carbon Fibers Reinforced (CFR)-PEEK stabilization device completely metal free has become available (CarboFix Orthopedics). This device is supposed to be more suitable for PT where treatment accuracy can be highly compromised by uncertainties in particles range. The aim of this study was to investigate and compare uncertainties related to the use of titanium and CFR-PEEK screws in terms of image quality, reconstruction artifacts, contouring and dose calculation accuracy, for both proton and carbon ion beams.

Material and Methods: Two vertebral body models, hosting two different types of orthopedic implants (a titanium and a CFR-PEEK implant), were positioned inside a water phantom to simulate real patients configuration. A CT scan was acquired according to our clinical protocols to evaluate induced HU artifacts and their impact on contouring uncertainties. Titanium and CFR-PEEK water equivalent path lengths (WEPL) were measured and implemented in our treatment planning systems (TPS). Implants and artifacts were contoured for proper material density assignment in the TPS HU to WEPL calibration curve. Plans were optimized for both proton and carbon ions, with and without HU correction, to evaluate the impact of CT artefacts and contouring uncertainties on dosimetric calculation accuracy, in comparison with MC simulations. Two patient cases, previously treated in our center were analyzed in terms of target and OAR dose deviation due to wrong material assignment, with respect to the clinically approved plan.

Results: CFR-PEEK implants did not cause appreciable HU artifacts on CT images compared to titanium ones. Significant differences in dose distribution between TPS and MC simulations in high-Z region were observed, while a good agreement was found for CFR-PEEK screws. Inaccurate material assignment did not significantly vary the clinical case 3D dose distribution for CFR-PEEK implants (<1%). Titanium screws made difficult to correctly contour both targets and OARs. Moreover, local dose deviations up to 20% can be found when HU uncertainties are not correctly managed. Besides efforts made towards a robust optimization with respect to potential beam perturbation, dose delivered to healthy tissues positioned behind targets along the implant trajectory can be substantially altered.

Conclusion: CFR-PEEK stabilization devices are more suitable than commonly-used titanium devices for PT of patients with orthopedic implants, leading to less image alteration and consequently reduced contouring uncertainties together with a significantly higher dosimetric treatment planning accuracy.

EP-1554

Retrospective dosimetric comparison of TG43 and a commercially MBDCA for image-based plesiotherapy

A. Pereira¹, S.P. Sara Pinto¹, T.V. Teresa Viterbo¹

¹Instituto Português de Oncologia do Porto Dr. Francisco Gentil Porto, Medical Physics Dept, Porto, Portugal

Purpose or Objective: To compare dosimetry plans using a commercially model based dose calculation algorithm (MBDCA) following TG186 recommendations, and the conventional TG43 method in an 192Ir high dose rate (HDR) brachytherapy (BT) procedure for the treatment of skin lesions.

Material and Methods: Plesiotherapy treatment was performed in three patients with lesions localized in the pre auricular region (patient 1), the nasal dorsum (patient 2) and the nasal tip (patient 3). The lesions (PTV) were marked with radiopaque markers. Patients were immobilized with a thermoplastic mask. A bolus slab of 2 mm thickness and plastic catheters were applied over the mask, and the whole set was fixed with two bolus slabs. All dosimetries plans were based on a CT with 1,25mm slices thickness and the dose was delivered with a micro-Selectron afterloader. Treatment plans were performed using both the TG43 and TG186 dose calculation methods of the Oncentra Brachy v4.5 treatment planning system (TPS). Analysis included dose to the OARs (lens, ocular globe and optic nerves) and to the prescription points (3 mm tissue depth). The TG186 results were obtained using the standard accuracy level option of model-based algorithm (Oncentra Brachy-Advanced Collapsed cone Engine (ACE), Elekta), resulting in calculation times between 7 - 10 min.

Results: In all cases, TG 43 overestimated the doses in the prescription points and in the OARs, in the range of 3.0% and 6.2%, respectively (Figure 1).

Conclusion: Although differences were found between the dosimetric plans obtained with the TG43 and model based dose calculation algorithm following TG186 recommendations, they are minor in terms of prescription dose points for skin lesions, since a 5% difference is within clinical tolerances in brachytherapy.

EP-1555

On the RapidArc tests by Ling 2008: towards flexibility and troubleshoot with a new family of plans

G. Nicolini¹, E. Vanetti¹, A. Clivio¹, S. Presilla¹

¹Ente Ospedaliero Cantonale, Servizio di Fisica Medica, Bellinzona, Switzerland

Purpose or Objective: At the introduction of RapidArc (RA) technique, the paper by Ling et al 2008 has constituted a reference, proposing RA commissioning machine quality assurance (QA) tests. Thanks to the free availability, many centers have implemented these tests in their periodic QA. Recently, tests identified as T2 (variation of dose rate DR and

gantry speed GS) and T3 (variation of MLC Speed MLCs) were updated. Even so, we decided to redraw completely T2 and T3, in the respect of the effective main concept. A family of new plans was generated to guarantee flexibility in the QA procedure and to support the user in a possible troubleshooting.

Material and Methods: Firstly, a historical review of commissioning tests results on 3 different Varian linacs (Clinac iX, Unique, TrueBeam) was collected, for both old (2008: vs1) and new (2015: vs2) Varian test versions; original tests were extended to 10MV, 6FFF and 10FFF beams for TrueBeam. Data were collected monthly through portal vision (PV) images, for respectively 81, 21, and 42 entries for vs1. At the same, delivery parameters were extracted from actual patients plans (3911plans, 6833arcs) and stratified according to the types of treatment. From our experience, we felt the needs to have a more flexible instrument tuned on our clinical practice, able to support us in a possible troubleshooting. A family of new T2 and T3 plans was generated. In addition to the traditional analysis of the images, a direct comparison with the open reference field is proposed to define a more reliable baseline for the monitoring of each strip trend.

Results: First version of the test T2 and T3, have presented during time differences respect reference value >2% (always <3%), for Clinac iX and Unique, while TrueBeam data were always <2%. The first T2 band presents a systematically higher value respect the others, explainable with some weakness in the test itself. Vs2 of T2 and T3, showed an agreement well below 2% for all the three linacs, but still with a systematic higher value for the T2 first delivered strip. The delineation of the new package of RT-plans started from the tune of number and width of the strips; the best compromise was found with 5 strip of 2.8 cm. Now T2 and T3 are fully compatible and can be superimposed, running also a T3 with the same DR-GS variation presents in T2. From this main plan version of T2 and T3, the new family of rt-plans allows to perform tests changing arc direction or/and MLC direction, while an additional basic editing of the dicom files allows to vary the main delivery parameters, in addition to order of the delivered combinations, arc range, MU/deg, etc, as independently as possible.

Conclusion: The new package of RT-plans is proposed in the fully respect of the original idea by Ling, with the intent to offer a more effective tool adjustable to single centre characters. Of particular interested is the extension to FFF beams, which are widely used in stereotactic regimes.

EP-1556

VMAT in nasopharyngeal tumor: clinical implications after a change in the dose calculation algorithm

S. Cilla¹, A. Ianaro¹, F. Deodato², G. Macchia², C. Digesù², M. Ferro², V. Picardi², M. Nuzzo², F. Labropoulos², P. Viola¹, M. Craus¹, A. Piermattei³, V. Valentini⁴, A.G. Morganti⁵

¹Fondazione di Ricerca e Cura Giovanni Paolo II- Università Cattolica del S. Cuore, Medical Physics Unit, Campobasso, Italy

²Fondazione di Ricerca e Cura Giovanni Paolo II- Università Cattolica del S. Cuore, Radiation Oncology Unit, Campobasso, Italy

³Policiinico Universitario A. Gemelli - Università Cattolica del S. Cuore, Medical Physics Unit, Roma, Italy

⁴Policiinico Universitario A. Gemelli - Università Cattolica del S. Cuore, Radiation Oncology Unit, Roma, Italy

⁵DIMES Università di Bologna - Ospedale S.Orsola Malpighi, Radiation Oncology Unit, Bologna, Italy

Purpose or Objective: To assess the clinical implications of the Collapsed Cone algorithm implemented in the Masterplan Oncentra treatment-planning system in VMAT treatments of nasopharyngeal tumors (NPC).

Material and Methods: Ten plans initially produced for patients with nasopharyngeal tumors with Pencil Beam Convolution (PBC) algorithm were retrospectively

recalculated using the Collapsed Cone Convolution (CCC) algorithm. Clinical target volumes were considered as primary tumor, lymph nodes with high-risk of occult metastases and low-risk nodal regions. Corresponding planning target volumes (PTVs) were obtained by adding a 4-mm margin. Radiotherapy was prescribed according to SIB technique with all PTVs irradiated simultaneously over 30 daily fractions. Doses of 70.5 Gy (2.35 Gy/fraction), 60.0 Gy (2.0 Gy/fraction) and 55.5 Gy (1.85 Gy/fraction) were prescribed to the PTV70.5, PTV60.0, and PTV55.5, respectively. All SIB-VMAT plans were optimized using the "dual-arc" feature with 6MV photon energy. The differences in dose distribution for all PTVs and organ-at-risk were assessed using different metrics (D95%=dose to 95% of PTV, D98%=near-minimum, Dmean=mean dose, V95%=volume receiving at least 95% of prescribed dose, D2%=near-maximum dose). The PTV70.5 was also separated into components in tissue (PTVtiss) and air (PTVair). Collapsed Cone plans were also renormalized (CCC_r) in order to obtain the same target coverage in terms of D95% of PBC calculation.

Results: PBC algorithm overestimated dose to PTVs for all considered metrics. The averaged Dmean and D95% to PTV70.5 calculated by CCC decreased by 1.8% (range:0.9%-2.8%) and 3.1% (range:1.5%-5.3%), respectively (1.5% and 2.8% lower for PTVtiss, and 5.5% and 8.6% lower for PTVair). Averaged D98% to PTV70.5 decreased by 3.4% (2.4% in tissue and 9.4% in air). Averaged V95% decreased from 96.0% to 90.2% (from 96.1% to 91.2% for PTVtiss, and from 96.0% to 70.9% for PTVair). The magnitude of dose differences are strongly correlated with the amount of air cavities in PTV70.5. A similar trend was observed for PTV60 and PTV55.5. Maximum doses to spine and brainstem PRVs were found to be approximately 1 Gy lower with CCC. The Dmean to pharyngeal constrictors muscles was found 4.7% higher with PBC. No differences were observed for parotids and mandible. PBC slightly underestimated the doses to eyes and lens (but ≤ 0.5 Gy). When the dose calculation were performed in water, the two algorithms provided differences in dose distributions <0.5%.

Conclusion: The CCC algorithm should be used in preference to PBC in VMAT treatments of nasopharyngeal tumors. A key question remains open: should the prescription dose be adjusted to the actually delivered dose, more accurately predicted by CCC algorithm? If radiation oncologists wanted to keep the PBC original dose prescription and the same accepting criteria for target coverage when switching from PBC to CCC, up to 5% more radiation doses would be given.

EP-1557

Development of dose calculation algorithm in homogeneous phantom through the transit dose
 S. Jeong¹, M. Yoon¹, D.W. Kim², W.K. Chung², M. Chung²
¹Korea University, Bio-Convergence Engineering, SEOUL, Korea Republic of
²Kyung Hee University Hospital at Gangdong, Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: To verify the accuracy of planned dose distribution for patient treatment, patient dose quality assurance using the solid water equivalent phantom is usually performed. This method, however, is not the method of verifying the absorbed dose in real patient. In this study, as a previous process of developing dose calculation algorithm in human, we measured the transit dose using the radio-photoluminescence glass rod detector to develop dose calculation algorithm in homogeneous phantom.

Material and Methods: We measured the transit dose at 150cm from source of linear accelerator to calculate the dose in the homogeneous phantom. The homogeneous phantom (10cm, 20cm, 30cm thickness) was located nearby the isocenter. We can calculate the dose at the bottom of phantom using the measured transit dose, inverse square law value and scatter factor. Scatter factor in this algorithm is ratio of scatter at the bottom of phantom and scatter at the measurement point of transit dose. To develop dose calculation algorithm in homogeneous phantom, we measured the field size dependence of transit dose and bottom dose to calculate the scatter factor, the relative dose response to correct the change of field size and location of isocenter. We evaluated the algorithm of 6MV X-ray beam in 10cm x 10cm field, 200MU.

Results: The measurement results of the relative dose response for isocenter location change are increased when the SSD decreases. The measured scatter factor was about 1.35 in all cases. We could calculate the dose in the phantom using the transit dose, inverse square law, scatter factor and percentage depth dose data. We evaluated the accuracy of developed phantom-dose calculation algorithm. The accuracies of 10cm, 20cm and 30cm phantom were 0.54%, 1.03% and -1.65%, respectively.

Conclusion: We developed the phantom-dose calculation algorithm using the transit dose, inverse square law, scatter factor and PDD data. This result would be used in the development of dose calculation algorithm in the inhomogeneous phantom and real patient.

EP-1558

Comparison between softwares employed in analysis of star shot patterns
 J.A. Vera Sánchez¹, C. Ruiz Morales², A. Gonzalez Lopez³
¹Hospital Universitari Sant Joan de Reus, física mèdica, Reus, Spain
²Hospital IMED- Elche, Radioterapia, Elche, Spain
³Hospital Clínico Universitario Virgen de la Arrixaca, Radioprotección, Murcia, Spain

Purpose or Objective: In linacs QA there are several tests that produce a star shot pattern by exposing a radiographic or radiochromic film. Isocenter size and distance from lasers or crosshair projection to radiation isocenter are some of the parameters obtained by exposing a radiochromic film with a star shot pattern of the rotation of the gantry, table or collimator. The "Twinkle" test was proposed to verify the correct delivery of dose during gantry rotation and it is a

common QA test for linacs that deliver VMAT treatments and that also produces a star shot pattern. In this study we compare two in-house software to analyze the parameters of the star shot patterns.

Material and Methods: Digital images of star shot patterns of table, collimator and gantry rotation and Twinkle tests were obtained exposing several radiochromic films EBT3 and RT-QA. In all cases a external reference was marked onto the films. Throughout the whole process -irradiation, scanning and analysis- a reference direction was held. The digital images were analyzed with two different softwares. The STAR ANALYZE software (SA), implemented with MATLAB, applies Canny algorithm to find the edges of the arms and then, the Hough transform is used to locate these edges and its equations. The second in-house software, FILM CHECK (FC) traces concentric search on the image of the star shot pattern to locate the center axes of the beams. From the characterization of these central axes, by minimax procedure position and radiation isocenter size are obtained.

Results: In the star shot patterns of gantry, table and collimator rotations, the maximum deviation between both algorithms in the isocenter size was lower than 0.5mm, and the maximum deviation in the distance between radiation isocenter and the external reference was lower than 1mm. In the Twinkle tests, the maximum deviation in the thickness of the arms of the star shot was lower than 0.3mm and the maximum deviation in the radii angle was lower than 1°.

Conclusion: The two algorithms shows a very good agreement for the analyzed parameters, despite uncertainty in the localization of the external reference system located in the radiochromic films that affects the parameters related with this external reference system. The Hough transform and the Canny edge detection algorithm are a valid tool for quality control of the linac, although, for the correct determination of sizes and distances we recommend depth knowledge and careful use of the particular parameters involved in both algorithms.

The Australian Clinical Dosimetry Service: The findings from a national auditing service
 I.M. Williams¹, J.E. Lye¹, A.D.C. Alves¹, M.K. Shaw¹, S. Keehan¹, J. Kenny¹, J.O. Lehmann¹, L. Dunn¹, T.K. Kron²
¹ARPANSA, Australian Clinical Dosimetry Service, Victoria, Australia
²Peter MacCallum Cancer Centre, Physical Sciences, Melbourne, Australia

Purpose or Objective: The Australian Clinical Dosimetry Service, (ACDS) was initially funded as a pilot program operating over 2011-2014 to enable the Australian Government to determine whether this design of an independent audit program was suitable for Australia. The pilot program was independently reviewed and interim funding was provided for a further two years. During this time the ACDS would increase the frequency of the developed suite of audits and develop a business plan, encompassing a user-paying structure, which would guarantee longevity for the dosimetry program. A summary of the audit outcomes and key findings to date will be presented along with a discussion about why the ACDS has been successful.

Material and Methods: The ACDS, recognised existing auditing practices, dovetailed the Level I Ionizing Radiation Oncology Centre: Houston audits with the International Atomic Energy Agency, IAEA, publications. The resulting three level audit structure resulted in a mutually supportive audit suite in which successive audits focussed on a more complex part of the clinical planning procedure. The ACDS has developed internal quality control procedures for all measurements to ensure the rigor of all audit outcomes. Critically, the ACDS has actively engaged with the professions, public and jurisdictions which has generated a positive response to the on-going success of the program.

Results: The ACDS achieved or exceeded all the initial pilot requirements. More than the required number of audits at each level were performed over the initial three years. The audit outcomes will be presented detailing the impact the ACDS audits, and resulting recommendations, have had on radiotherapy practice. The paper will also present on how the staff within the ACDS engaged with the professional clinical workforce and provided a successful and functioning audit service. The paper will attempt to identify these social successes and how these were achieved. This will provide details to assist and advise those seeking to design or modify national or regional auditing programs. Finally the paper reviews the potential future for the ACDS.

Conclusion: The raw number of audits indicate that the ACDS met the pilot program's initial auditing requirements. Understanding the reasons for the ACDS' success are also important for ensuring an on-going service or informing and assisting others to establish auditing services. Within the ACDS, success has been highly dependent on: attracting quality staff who can respond with agility to changing situations, a high level of communication with the professional community, and a high level of engagement by the community.

The Australian Clinical Dosimetry Service is a joint initiative between the Department of Health and Ageing and the Australian Radiation Protection and Nuclear Safety Agency

EP-1560

Is EBT-XD film suitable for linac and Gamma Knife radiosurgery dosimetry verification and audit?

A. Nisbet¹, A. Dimitriadis¹, A.L. Palmer², C.H. Clark¹

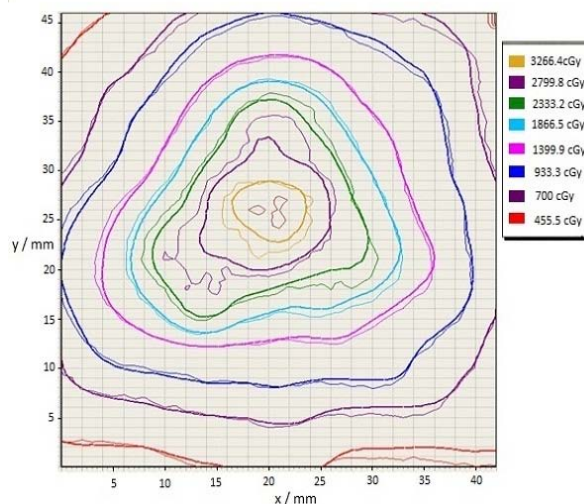

¹St. Luke's Cancer Centre Royal Surrey County Hosp, Medical Physics, Guildford, United Kingdom

²Portsmouth Hospitals NHS Trust, Medical Physics Department, Portsmouth, United Kingdom

Purpose or Objective: The validation of radiotherapy treatments by dosimetric measurement is essential for the introduction of new techniques, pre-treatment verification and dosimetry audit. Film dosimetry has the advantage of high spatial resolution, low energy dependence and water equivalence. A new film (EBT-XD) has been assessed for its suitability for dosimetry of stereotactic radiosurgery (SRS) applications.

Material and Methods: Calibration curves for red, green and blue channels were created in the range of 0-4000 cGy for EBT-XD and its predecessor EBT3. Ten film pieces were irradiated in a nominal 6MV linac. The film was scanned using an EPSON Expression 11000XL scanner and the analysis was performed in FilmQA Pro software (Ashland ISP Inc, NJ, USA). Film dosimetry uncertainties were assessed for typical SRS fields, including lateral scanner effect at high doses. Both EBT-XD and EBT3 films were used in-phantom for treatment dose verification of typical Linac based and Gamma Knife (GK) stereotactic radiosurgery within the STE2EV anthropomorphic phantom (CIRS, VA, USA). The dosimetry methodology for a forthcoming UK dosimetry audit of SRS treatment was utilised.

Results: EBT-XD film has lower optical density than EBT-3 throughout the dose range tested. EBT-XD was more suitable for high-dose applications because of a lower lateral scanner uncertainty. For the width of the film sizes that will be used in the SRS audit (50 mm) and the typical doses measured, the lateral scanner effect was estimated to be of the range of 0.5% for EBT-XD and 3% for EBT-3. Higher agreement between TPS and film dose distributions was seen for EBT-XD using both single and triple channel dosimetry at 2% (local normalization), 1 mm gamma index analysis criteria, with the recommended triple channel used for EBT-XD having a 95.5% passing rate, compared to conventional single channel EBT3 having only 89.1%. Single channel EBT-XD had 89.7% passing rates and triple channel EBT-3 38.9%. An example is shown in figure 1, of EBT-XD showing a 98.3% gamma passing rate for a GK radiosurgery plan at 3% (local), 1.5 mm criteria

Conclusion: We have evaluated the use of a new film, EBT-XD, for SRS dosimetry verification and demonstrated its suitability for a forthcoming audit of radiosurgery services in the UK. EBT-XD is less susceptible to lateral scanner effects and shows better agreement to TPS dose distributions than EBT-3 in linac-based radiosurgery dose verifications. EBT-XD also showed excellent agreement with TPS dose distributions in GK radiosurgery.

EP-1561

Online control point resolved VMAT QA using the integral quality monitor and log files

M. Pasler¹, M. Obenland¹, J. Christ¹, Y. Jaout¹, H. Wirtz¹, M. Bjoernsgard², J. Lutterbach², F. Wittkamper³, D. Georg⁴

¹Gemeinschaftspraxis f. Strahlentherapie Singen-Friedrichshafen, Medical Physics, Singen, Germany

²Gemeinschaftspraxis f. Strahlentherapie Singen-Friedrichshafen, Radiation Oncology, Singen, Germany

³The Netherlands Cancer Institute, Medical Physics, Amsterdam, The Netherlands

⁴Medical University Vienna, Department of Radiotherapy and Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

Purpose or Objective: To systematically assess VMAT delivery accuracy using dynamic benchmark test plans.

Material and Methods: Three VMAT benchmark plans were generated for an Elekta Synergy linac (MLCi2) using iComCAT. These plans consist of square field shapes with varying field size and a full gantry rotation (fig.1a). First, 19 control-points (19cp) were composed to vary dose rate, MLC positions, jaw and gantry speed to push dynamic parameters to their limit. Next the number of control-points was increased (i.e. 37cp and 73cp) by linear interpolation so that MLC, jaw and gantry motion were identical to the 19cp plan, but with tighter regulation of dynamic components. MLC and jaw errors were quantified by analyzing the linac's log files. For dosimetric measurements, a 2D ionchamber array placed in a full scatter phantom (729 & Octavius, PTW) and the integral quality monitor (iQM, iRT) were used. The iQM contains a large area ionchamber and an inclinometer for real-time VMAT verification. Evaluation was performed on the level of cumulated delivery and control-point resolved to investigate the effect of increasing number of control-points.

Results: Slight variations in delivery were observed for the three plans from log-file analysis, overall revealing very accurate linac control in rotational mode. The mean MLC error was almost identical for the three plans (0.2±0.2mm). Relative dosimetric evaluation by means of plan reproducibility resulted in $\gamma_{\text{mean}}=0.4\pm0.1$ (19cp), $\gamma_{\text{mean}}=0.2\pm0.0$ (37cp) and $\gamma_{\text{mean}}=0.1\pm0.0$ (73cp) for the local γ 1%/1mm criterion, respectively. Increased γ -values were found for inter-plan comparison:

$\gamma_{\text{mean}}(19\text{vs}37\text{cp})=0.7\pm 0.1$, $\gamma_{\text{mean}}(19\text{vs}73\text{cp})=0.6\pm 0.1$ and $\gamma_{\text{mean}}(37\text{vs}73\text{cp})=0.6\pm 0.1$. The cumulated iQM signal coincided with 2D ionchamber array measurements and demonstrated accurate reproducibility for all three plans (figure 1b). The control-point resolved analysis (fig.1c) consistently indicated large deviations between 19cp, 37cp and 73cp plans due to an imprecise data sampling synchronization of the preclinical version of the detector. The symmetry of the test plan could not be reflected by the iQM system, especially regarding the 19cp plan.

Conclusion: Increasing the number of control-points changed VMAT delivery accuracy marginally. For clinical treatment plans this effect might not be noticeable. Observation of the cumulative iQM signal coincided well with dosimetric measurements. The VMAT benchmark plan proved to be a prospective tool for visualizing and understanding linac and detector limitations.

EP-1562

VMAT pre-treatment verification using Octavius 4D system: from simple to more complex plans

H. Aslian², M. Severgnini¹, F. Cupardo¹, R. Vidimari¹, M. De Denaro¹

¹AOU "Ospedali Riuniti di Trieste", Medical Physics, Trieste, Italy

²International Center for Theoretical Physics and Trieste University, Medical Physics, Trieste, Italy

Purpose or Objective: Plan verification in complex treatment delivery techniques such as IMRT and VMAT is imperative. Although some studies have been conducted on pre-treatment VMAT quality assurance using PTW Octavius 4D systems, more works are needed to focus on complex VMAT plans including steep gradient regions. The aim of this study

is to evaluate dose delivery of different VMAT plans such as Head and Neck (SIB: Simultaneously Integrated Boost), lung (SBRT: Stereotactic Body Radiation Therapy) and prostate (Hypo-fractionated intensity modulated arc therapy) with the Octavius 4D system.

Material and Methods: Fifteen head and neck, lung and prostate VMAT plans for fifteen patients (5 patients for each case) were created and their respective QA plans were calculated. All plans were optimized and calculated using Monaco (version 5.0) treatment planning system, which is a Monte Carlo-based treatment planning system. The 2D-array seven29, which consists of 729 vented plane-parallel ionization chambers arranged in a 27 x 27 matrix with the spatial resolution of 10mm, embedded in Octavius 4D cylindrical phantom was used to measure the dose distribution and the measurements were done with an Elekta Synergy linear accelerator equipped with an Agility 160 MLC system. In order to reconstruct and analyze the measured 3D dose from each plan, the PTW VeriSoft patient plan verification software was used and a volumetric 3D gamma index analysis for both 3%/3mm and 2%/2mm criteria was performed to compare and evaluate the measured and calculated doses. In addition, in order to improve the spatial resolution in cranial caudal direction due to 1 cm gap across the chambers the second measure was done by shifting the array 5 mm (via couch shift) in caudal direction and merging the matrices with the "merge" function available in PTW VeriSoft.

Results: The mean pass rate of volumetric 3D gamma index for all prostate cases was superior to 97% with 3%/3mm and 92% with 2%/2mm criteria. However, the mean passing rate for lungs was lower than prostate and ranged from 93.7 to 96.3 (3%/3mm) and from 90 to 94.1 (2%/2mm). Expectedly, the mean value of global gamma index for head and neck cases could not be better than 91.5% (ranged from 88.4 to 96.3) and 87.3% (ranged from 82.3 to 89) for the 3%/3mm and 2%/2mm criteria respectively. Also, merged measurements could increase the mean passing rate from 1% up to 3.5% in some complex cases (Fig. 1).

Fig. 1: The images (Left side) represent the failed points of a sample; The images (Right side) depict the average volumetric gamma index for prostates, lungs and HN cases in

which the outer pie-charts show the results with 3%/3mm and the inner pie-charts illustrate results with 2%/2mm.

Conclusion: The results showed that Octavius 4D phantom, with 2D-Array seven29, can be an adequate verification system both for simple and more complex cases. Additionally, the merge capability of the VeriSoft software, which can increase spatial resolution, is a useful tool for more complex VMAT plans.

EP-1563

Study of the characteristic of enhanced dynamic wedged depth dose profiles in non-homogenous media

A. Hussain¹, A. Zaman², M.B. Kakakhel²

¹Aga Khan University Hospital, Department of Oncology, Karachi, Pakistan

²PIEAS, Department of physics and applied mathematics, Islamabad, Pakistan

Purpose or Objective: The aim of this study is to utilize the EGSnrc based Monte Carlo code in order to assess the EclipseTM (AAA) calculated dose estimation at the Water-Lung (WL) interfaces when irradiated by 6 MV photon beams at 15°, 30°, 45° and 60° wedge angles and multiple field sizes of 5 × 5 cm², 10 × 10 cm² and 20 × 20 cm².

Material and Methods: EGSnrc sub codes are used for Monte Carlo dose simulation. BEAMnrc is used to simulate the linear accelerator head, whereas DOSXYZnrc is employed to perform phantom dose estimation. For simulating dynamic wedges the BEAMnrc component module DYNJAWS was employed. Phantom geometry includes a 10 cm layer of lung (ρ=0.250 g/cc) sandwiched between 5 cm and 10 cm water layers. Doses were calculated in exactly the same geometry and same density distribution by Monte Carlo and AAA algorithm. The overall dimension of the phantom was 30 cm × 30 cm × 25 cm. A 5 mm grid size (voxel width) along depth was used for calculating PDDs. The nominal source to surface distance (SSD) of 100 cm was used in both setups.

Results: The dose perturbation effect was found to be field size dependent. It increases with decreasing field size. No clear dependence for the wedge angles was observed. No dose deviation between AAA and EGSnrc was observed at the water→tissue interface. However a lower dose in the lung was estimated by AAA. Whereas at the lung→tissue junction a highest dose discrepancy was observed by AAA, estimating higher dose towards the water layer.

Conclusion: We have demonstrated the limitation of AAA in dose calculation at the water-tissue-water interfaces for four wedge angles. There was no significant wedge angle dependence on the dose perturbation. However an increase in perturbation was observed with decreasing field sizes for all angles.

EP-1564

Impact of dose calculation algorithm on SBRT and normofractionated lung radiotherapy in breath hold

M. Josipovic^{1,2}, G. Persson¹, J. Rydhög^{1,2}, J. Bangsgaard¹, L. Specht^{1,3}, M. Aznar^{1,2}

¹Rigshospitalet, Dept. of Oncology- Section for Radiotherapy, Copenhagen, Denmark

²University of Copenhagen, Niels Bohr Institute, Copenhagen, Denmark

³University of Copenhagen, Faculty of Medical Sciences, Copenhagen, Denmark

Purpose or Objective: Modern dose calculation algorithms only model absence of lateral charged particle equilibrium to a limited extent. The resulting uncertainties are largest in strongly heterogeneous regions, such as the thorax, and will potentially increase in deep inspiration breath hold (DIBH) due to decreased lung tissue density.

Material and Methods: Ten patients with stage I and ten with stage III lung cancer were included. For all patients, a plan in free breathing (FB, based on midventilation) and in DIBH were made with the clinically used Anisotropic Analytical Algorithm (AAA). Stage I disease was treated stereotactically (SBRT) using 3D conformal technique (9-10 fields), 45 Gy in 3 fractions, prescribed to 95% isodose covering 95% of PTV and aiming for 140% dose in the isocenter. Stage III disease was treated with VMAT (2 arcs), 66 Gy in 33 fractions, prescribed to mean PTV dose. 6 MV energy was used for all plans. Calculation grid size was 1 mm for stage I and 2.5 mm for stage III. Plans were recalculated in more advanced Acuros with same MU as in AAA.

Plans were compared for target coverage (GTV, CTV, PTV), estimated from mean dose, near minimum (D98) and near maximum doses (D2), as defined in ICRU 83, and for SBRT also for the fraction of PTV covered by prescription dose (V45). Organs at risk parameter for stage I was fraction of lung receiving more than 13 Gy (V13), and for stage III, mean lung dose, lung V5, V20 and V40 and also mean heart dose and heart V50.

Results: In DIBH, lung density decreased by median 6% (47.6 HU) reduction for stage I and 12% (88.5 HU) for stage III.

In stage III, AAA overestimated mean target doses for FB and DIBH GTV and DIBH CTV (by median <0.8 Gy; p<0.05 Wilcoxon signed-rank test) and had no impact on D2. AAA overestimated D98 by median -1 Gy for GTV and CTV (p<0.05), and more for PTV (by 1.5 Gy and 2.1 Gy, in FB and DIBH respectively; p<0.01).

In stage I, AAA had similar effect on GTV as in stage III. However, differences between the two algorithms were substantial for PTV and more pronounced in DIBH: AAA overestimated all PTV parameters (p<0.01), with largest impact on V45 (up to 41.4% in FB and 66.3% in DIBH), while mean dose and D98 were overestimated by 2.0 Gy and 2.3 Gy in FB and 3.1 Gy and 4.0 Gy in DIBH. These clinically relevant differences may be a combination of small targets and large dose gradients in the SBRT treated volume.

Lung and heart dose parameters decreased in DIBH compared to FB, but were similar for both algorithms and both disease stages (median differences ±0.3% for volumetric parameters and ±0.2 Gy for mean doses). More details on actual dosimetric parameters are presented in the table.

Table – Selected dosimetric parameters on target coverage and dose to organs at risk for AAA and Acuros, for free breathing and deep inspiration breath hold. Data is presented as median (range).

stage III	FB			DIBH		
Target coverage	mean dose [Gy]	D ₉₅ [Gy]	D ₂ [Gy]	mean dose [Gy]	D ₉₅ [Gy]	D ₂ [Gy]
GTV AAA	66.2 (65.9-66.4)	64.3 (63.9-64.7)	68.0 (67.5-68.6)	66.3 (66.0-66.5)	64.3 (64.1-64.9)	68.0 (67.6-69.0)
Acuros	65.6 (65.1-66.4)	63.5 (62.5-64.4)	68.1 (67.3-68.9)	65.5 (65.0-66.2)	63.3 (62.9-64.3)	68.0 (67.2-68.6)
CTV AAA	66.3 (66.1-66.5)	64.3 (63.9-64.7)	68.2 (67.7-68.8)	66.3 (65.6-66.5)	64.3 (64.2-64.8)	68.2 (67.8-69.0)
Acuros	65.6 (65.1-66.4)	63.4 (62.7-64.3)	68.4 (67.8-69.5)	65.7 (65.4-66.4)	63.3 (60.7-64.3)	68.4 (67.8-69.1)
PTV AAA	66.0 (66.0-66.0)	62.6 (61.8-63.7)	68.3 (67.8-68.8)	66.0 (66.0-66.0)	62.6 (61.7-63.6)	68.2 (68.0-69.1)
Acuros	65.4 (65.2-66.7)	61.6 (59.7-63.5)	68.4 (67.9-69.7)	65.4 (64.5-66.0)	60.6 (55.7-62.6)	68.4 (68.0-69.0)
Dose to OAR	MLD [Gy]	V₂₀ [%]	MHD [Gy]	MLD [Gy]	V₂₀ [%]	MHD [Gy]
AAA	16.9 (12.3-20.1)	27.8 (18.6-39.1)	13.5 (5.3-20.3)	13.2 (12.0-19.2)	21.2 (15.9-33.1)	8.9 (4.0-21.2)
Acuros	16.9 (12.3-20.2)	28.1 (18.4-39.7)	13.3 (5.2-20.0)	13.2 (12.0-19.2)	21.5 (16.0-33.4)	8.7 (4.0-20.9)

stage I	FB			DIBH		
Target coverage	mean dose [Gy]	D ₉₅ [Gy]	V ₄₅ [%]	mean dose [Gy]	D ₉₅ [Gy]	V ₄₅ [%]
GTV AAA	57.6 (52.8-61.7)	54.0 (49.7-58.7)		59.6 (53.5-64.7)	55.1 (49.4-62.5)	
Acuros	58.1 (52.7-61.7)	53.2 (49.2-57.2)		57.6 (52.9-65.2)	51.6 (46.1-61.3)	
PTV AAA	51.8 (49.9-54.4)	40.6 (40.0-41.6)	89.7 (86.3-90.7)	52.2 (50.5-53.7)	40.8 (39.5-41.3)	89.2 (87.6-98.7)
Acuros	49.8 (45.2-52.7)	38.3 (34.2-40.4)	82.1 (46.5-90.7)	49.0 (40.6-53.1)	36.8 (30.6-40.4)	70.0 (21.2-84.9)

Abbreviations: FB – free breathing, DIBH – deep inspiration breath hold, OAR – organs at risk, MLD – mean lung dose, MHD – mean heart dose

Conclusion: In VMAT of stage III lung cancer, AAA precision is adequate even in DIBH. In SBRT of stage I lung cancer, AAA overestimates target coverage, especially in DIBH. However, changing to the more correct Acuros for stage I SBRT may potentially facilitate a change in clinically prescribed dose.

Influence of dose specification on prostate VMAT patient-specific QA results

F. Clemente Gutierrez¹, C. Perez Vara¹, M. Clavo Herranz², C. Lopez Carrizosa², J. Saez Garrido², C. Ibañez Villoslada², M. Couselo Paniagua², J. Zapatero Ortuño², M. Martín de Miguel², M. Domínguez Morcillo², V. Jerviz Guía², A. Calapaqui Teran², M. Guijarro Verdu², J. Navarro²

¹Hospital Central de la Defensa Gómez Ulla, Medical Physics, Madrid, Spain

²Hospital Central de la Defensa Gómez Ulla, Radiation Oncology, Madrid, Spain

Purpose or Objective: Monte Carlo-based treatment planning systems (TPS) are becoming as standard in radiation therapy, performing and reporting calculations in terms of the absorbed dose to medium (Dm). In addition, patient-specific QA techniques for IMRT and VMAT treatments have recently evolved from traditional dose distribution comparisons between calculations and measurements to 3D dose calculation and reconstruction on patient anatomy, enabling DVH-based comparisons. In order to perform previous calculations, commercial solutions have introduced collapsed cone algorithms, based in dose engines that report calculations in terms of the absorbed dose to water (Dw). Differences between Dm and Dw can lead to significant discrepancies in DVH comparisons. This study reports the discrepancies between Dm and Dw calculations applied to patient-specific prostate VMAT treatments.

Material and Methods: VMAT treatments were delivered with a 6 MV Synergy (Elekta) machine. Plans were generated with Monaco 3.1 (Elekta). 3D dose calculations were performed with two systems: Mobius3D (Mobius Medical Systems) (M3D) and COMPASS (IBA Dosimetry) (CC). In addition, the second one is capable of reconstructing the dose from measurements (CR). Forty prostate treatments were analyzed, taking 10 from each usual staging (high-, intermediate- and low-risk) and 10 prostate bed treatments after prostatectomy. Parameters analyzed for PTVs were taken from ICRU-83 recommendations. Normal tissue parameters were evaluated

using QUANTEC constraints for rectum, bladder and femoral heads.

Results: Mean differences for PTVs parameters with Dm calculations were -0.61%±0.71%, -0.04%±1.49% and 0.08%±1.52% for CC, CR and M3D, respectively. For PTVs parameters with Dm calculations discrepancies were -0.22%±0.50%, 0.36%±1.27% and 0.47%±1.28%. Mean differences for normal tissue and CC, CR and M3D comparisons, respectively, were: 0.38%±0.74%, 2.94%±1.31% and 2.12%±1.31% for Dm, and 0.38%±0.54%, 2.94%±1.20% and 2.12%±1.40% for Dw in rectum; 0.16%±1.06%, -1.00%±1.11% and 0.16%±1.45% for Dm, and 0.10%±0.58%, -1.06%±0.78% and 0.10%±1.12% for Dw in bladder; -1.42%±0.83%, -1.03%±2.04% and -1.57%±1.77% for Dm, and 0.28%±2.01%, 0.88%±2.45% and -0.07%±2.62% for Dw in femoral heads.

Conclusion: Results were slightly better for Dw in femoral heads than Dm calculations. Remaining data were similar for both Dm and Dw. According AAPM TG-105, QA comparisons should be performed with the same criterion (Dw).

EP-1566

Influence of inner materials of rectal balloon on TPS calculation accuracy and dose distribution

J. Koo¹

¹Korea University, Department of Bio-Convergence Engineering, SEOUL, Korea Republic of

Purpose or Objective: If rectal balloon were not used in rectum cancer treatment, there is a lack of reproducibility of rectum shape on each treatment and irregularly inserted air inside the rectum cause inhomogeneity of density with surrounding tissue, which could be resulted in uncertainty of dose delivery. In this research, we estimated the accuracy of TPS(Treatment Planning System) dose calculation and actual dose, and compared dose distribution when homogeneity of rectum and surrounding tissue increases as inner materials of rectal balloon changes.

Material and Methods: Cylindrical PMMA RPLGD phantom was used to measure dose at rectal wall and Air, water and PMMA were used as inner balloon materials. Total 12 plans(prostate and rectum cancer 3D-CRT(3 Dimensional Conformal Radiation Therapy) and IMRT(Intensity Modulated Radiation Therapy) plans with air, water, and PMMA balloons) were made using Varian Eclipse ver.8.9 to estimate influence of rectal balloon material on dose distribution. Each 16 glass dosimeters were located at rectum wall so that the point doses were compared with TPS.

Results: As Homogeneity increase, Dose distribution was improved. As CT HU value of inner balloon material increase from 0(air) to 1000(water) and 1120(PMMA), Homogeneity Index(HI) and Conformity Index(CI) were increased about 20% and 5%, respectively. And considerable difference, between TPS and RPLGD reading, was measured with air balloon when water and PMMA balloons had less variation.

Conclusion: It was shown that the dose distribution and the accuracy of TPS were better when the density of the balloon material was similar to the density of surrounding tissue. Especially when air is inserted into rectum, there is a possibility of difference between actual dose and TPS calculation. Thus, it is needed to look forward to find a method to increase treatment accuracy using tissue-equivalent inner balloon materials.

EP-1567

Investigation of dose buildup region from electron beam by of polymer films and ionization chamber

E. Sukhikh¹, A. Lysakov², E. Malikov³, L. Sukhikh²

¹Tomsk Regional Oncology Center, Radiobiology, Tomsk, Russian Federation

²National Research Tomsk Polytechnic University, Applied Physics, Tomsk, Russian Federation

³National Research Tomsk Polytechnic University, Laboratory No42, Tomsk, Russian Federation

Purpose or Objective: The use of the film when it is parallel to the beam axis allows to obtain depth distribution of the dose in water during "single shot" of the accelerator. This method could be useful for characterization of the electron beams of intraoperative accelerators due to the fact that for this modality one needs precise knowledge of the dose depth curve starting from the phantom surface. The use of ionization chamber is routine technique but the spatial resolution of the measured curve is worse. The purpose of this work is to compare depth dose curves obtained using Gafchromic EBT3 film and ionization chamber during experimental investigation and Monte-Carlo simulation.

Material and Methods: The experimental comparison of the depth dose curves was carried out using 6 MeV and 9 MeV electron beams of Elekta Synergy accelerator and 6 MeV electron beam generated by compact betatron for intraoperative therapy. The dose distributions were measured by ionization chambers in the water and by Gafchromic EBT3 films in solid phantoms. The film was situated in different geometries, namely along beam axis and across it. The simulation of the process was carried out using PCLab software that allows simulation of the beam interaction with the matter. The first geometry was absorbed dose distribution in pure water that was assumed to be an ideal case. The second geometry assumed film situated along beam axis. The third geometry simulated ionization chamber depth scan. The simulation was carried out for different beam energies assuming monoenergetic beams. In the case of water and film in water it was possible to simulate directly value of dose in water or in the film sensitive layer. In the case of ionization chamber the value of energy lost in the air volume was "measured" as a quantity proportional to dose in water.

Results: Results of the simulation and measurement show that the dose depth distributions obtained for water, film and ionization chamber coincides well at depths deeper than maximum dose. In the case of depths from the surface up to maximum the dose "measured" by ionization chamber is larger than the dose "measured" by the film and simulated in pure water. The experimental investigation of the depth dose distribution also shows that ionization chamber overestimates dose values at small depths.

Conclusion: Simulation and measurement results show that depth dose distribution from electron beam in water measured by radiochromic film is more precise at small depths than the one measured by ionization chamber.

EP-1568

A Monte Carlo based modelling of a dedicated mobile IOERT accelerator

M. Ghorbanpour Besheli^{1,2}, O. Fielitz^{1,2}, W. Budach¹, I. Simiantonakis^{1,2}

¹University Hospital, Department for Radiotherapy and Radiation Oncology, Dusseldorf, Germany

²Heinrich-Heine University, Faculty of Physics/Medical Physics, Dusseldorf, Germany

Purpose or Objective: Intraoperative Electron Radiation Therapy (IOERT) refers to the delivery of single high dose radiation directly to the tumour bed or residual tumour soon after surgery excision. In this study, a Monte Carlo code was employed to simulate the NOVAC7 electron beams, which is a powerful tool for the simulation of clinical radiation beams and for obtaining detailed knowledge of the characteristics of therapy beams from linear accelerators. The simulation makes it possible to evaluate and calculate all dosimetric relevant necessities such as stopping power ratios, photon contamination and scatter contribution with high accuracy.

Material and Methods: The radiation head simulation of NOVAC7 was performed with the EGSnrc user code BEAMnrc. The definite information about the head geometry was given by the manufacturer. Relative absorbed dose measurements, i.e. percentage depth doses (PDDs) and off-axis profiles (OAPs), were carried out using radiochromic films (Gafchromic EBT2, International Specialty Products, Wayne/USA) in a small water phantom type T41023 (PTW-Freiburg, Freiburg/Germany). Specifically measured PDDs and OARs were used to obtain electron energy spectra for different energies (3, 5, 7 and 9 MeV) and applicators (30, 40, 50, 60, 70, 80 and 100 mm). For achieving the measured R50 the most probable energy of Gaussian distribution was varied iteratively in small steps (0.05MeV) around the appropriate nominal energies until a matching of the calculated and measured values of R50 was obtained.

Results: Table 1 shows the parameterised data of the PDDs. Calculated Rmax, R80, R50 and Rp are compared with the measured values. For all nominal energies the calculated PDDs agreed within $\pm 2\%$ or ± 1 mm with those measured and local percentage dose and distance to agreement are below the required thresholds. The values of the most probable energy and the mean energy of the initial electron beams used as input into the Monte Carlo simulation are reported in table 2 for 100 mm applicator. The results were subsequent evaluated for other applicators. The electron source, incident on the titanium window, was modelled as an isotropic point source with a primary Gaussian distribution on z axis. The difference between the mean energy, and the most probable energy, is due to the presence of a low-energy tail in the energy spectrum, which is typical for this type of accelerators.

Table 1: Parameterised data for the PDD comparison between Monte Carlo calculation and film dosimetry at 100 mm field size.

E (MeV)	R _{max} (mm)		R ₈₀ (mm)		R ₅₀ (mm)		R _p (mm)	
	meas.	cal.	meas.	cal.	meas.	cal.	meas.	cal.
3	0.50	0.55	0.95	0.96	1.24	1.25	1.35	1.36
5	0.70	0.80	1.32	1.31	1.71	1.70	1.94	1.93
7	1.10	1.15	2.00	2.00	2.50	2.50	2.95	2.95
9	1.40	1.50	2.50	2.60	3.20	3.20	3.83	3.88

Conclusion: This investigation has been performed on a dedicated IOERT mobile linac (nominal electron energies: 3, 5, 7 and 9 MeV). The virtual model was achieved using the EGSnrc Monte Carlo system. The procedure was found to be effective and could lead to the development of a tool to assist the medical physicist during the NOVAC7 commissioning where the amount of dosimetric measurement is time-consuming.

EP-1569

Dose deposition kernel measurements with radiochromic films

A. González-López¹, C. Ruiz-Morales², J.A. Vera-Sánchez³

¹Hospital Universitario Virgen de la Arrixaca, Radioprotección, El Palmar Murcia, Spain

²IMED Hospitales, Oncología Radioterápica, Elche Alicante, Spain

³Hospital Sant Joan de Reus, Protección Radiológica y Física Médica, Reus Tarragona, Spain

Purpose or Objective: In this work we carried out a series of measurements of a small field to investigate the shape of the dose deposition kernel of a radiotherapy beam. Starting with 2D dose distributions measured with radiochromic films a deconvolution process is followed to obtain the dose deposition kernels.

Material and Methods: Radiochromic films Gafchromic EBT2 were used to measure 6 MV beams from a Varian Clinac 2100 linear accelerator. The nominal field size of the beams was 0.5 cm x 0.5 cm (at isocenter), and the films were placed in a PMMA phantom at 100 cm source to film distance. The dose delivered to the film was 300 cGy. The films were read 6 hours after irradiation with a Microtek ScanMaker 9800XL flatbed scanner. In order to minimize the inhomogeneity variations of the film-digitizer system a procedure, as described in [1] was followed. The procedure uses a number of film cut-outs, taken from one sheet of an RC film, to produce a number of measurements of the same field. After reading the films, the resulting images are registered and averaged. It's worth noting that the film pieces used for the calibration of the film-digitizer response are taken from the same sheet of RC film that the pieces used for dosimetric purposes [1]. In this way, the inter-digitization variability is drastically reduced. Deconvolution of measured dose distributions was carried out by minimizing its Euclidean distance to a calculated dose distribution. The calculated dose distribution was obtained as the convolution of a rectangular aperture with a parameterized kernel,

$$K(r) = k(r) * e^{-p_1 r^2} + p_2$$

where $k(r)$ is the pencil beam dose deposition kernel [2] as calculated by Nyholm [3], p_1 describes the radiation source fluence and p_2 takes the collimators transmission into account. The optimization algorithm acts on both parameters p_1 and p_2 through an iterative process.

Results: The figure shows the dose deposition kernel obtained after deconvolution.

Conclusion: We have determined the dose deposition kernel for a particular set-up: a small field size, 6 MV photon energy and a depth close to d_{max} . The results obtained show a large lateral spread of the dose, which is responsible for the lack of lateral electronic equilibrium near the edges of the radiation field, and also imposes a constrain in the spatial resolution that portal image systems can reach.

EP-1570

Determination of stopping power ratios and output factors of intraoperative electron beams

M. Ghorbanpour Besheli^{1,2}, C. Matuscheck¹, W. Budach¹, I. Simiantonakis^{1,2}

¹University Hospital, Department of Radiotherapy and Radiation Oncology, Dusseldorf, Germany

²Heinrich-Heine University, Department for Radiotherapy and Radiation Oncology, Duesseldorf, Germany

Purpose or Objective: Treatment fields of dedicated Intraoperative Electron Radiation Therapy (IOERT) linacs like NOVAC7 (SIT, Vicenza/Italy) are generated by collimators consisting of PMMA cylindrical applicators. The dosimetry of these electron beams is required to be done under non-reference condition. Therefore, it is necessary that the output factors (OFs) and the mass collision stopping-power ratios to be examined carefully. The aim of this paper was to calculate the sw_{air} (Spencer-Attix stopping power ratios of water-to-air) and OF values for electron beams produced by NOVAC7 using a Monte Carlo based model.

Material and Methods: The simulation of the radiation head was performed by BEAMnrc Monte Carlo code. For achieving the measured $R50$ the most probable energy of Gaussian distribution was varied iteratively in small steps (0.05MeV) around the appropriate nominal energies until a matching of the calculated and measured values of $R50$ was obtained. Based on this Model, the OF values were calculated. To compare the calculated OF values with experimental data, absorbed dose measurements were performed by a PTW 31014 pin-point ion chamber (PTW-Freiburg, Freiburg/Germany). The phase-space files (files that contain all histories related data e.g. energy, direction, etc.) obtained for the IOERT beams were also used as source inputs for the EGSnrc/SPRZRnc code to calculate the sw_{air} values.

Results: The calculated and measured OFs agreed well within the combined uncertainty. The relative differences between calculated and measured OFs (see table 1) were up to 3% but agreed better than 1.8% in average. On the other hand this factor increased when decreasing the applicator diameter which is completely dissimilar to other clinical linacs. At smaller field sizes the increased number of scattered events might lead to larger OF values. Considering our results presented previously and the combined uncertainty of $\pm 2\%$ in SPR determination, a good agreement was found with TRS-398 dosimetry protocol on the water surface and at z_{ref} . The minor discrepancies between Monte Carlo calculation and TRS-398 results are due to the fact that the $SPR_{w,air}$ values are calculated for a dedicated IOERT linac while the Monte Carlo generated values in TRS-398 are based on a variety of linac types.

Table 1. Monte Carlo calculated and measured relative output factors (ROFs) for 7 and 9 MeV nominal electron beams for intraoperative radiation therapy. Output factor measurement was performed by a pin-point ion chamber.

Nominal Energy	Applicator Diameter (cm)	ROF		Difference (%)
		Calculated	Measured	
7 MeV	4	1.468	1.440	+1.9
	5	1.414	1.385	+2.1
	6	1.347	1.309	+2.9
	7	1.216	1.222	-0.50
	8	1.145	1.141	+0.35
9 MeV	4	1.609	1.567	+2.68
	5	1.519	1.520	-0.07
	6	1.416	1.380	+2.61
	7	1.261	1.241	+1.61
	8	1.178	1.150	+2.43

Conclusion: The results considering the OFs support the accuracy of the Monte Carlo model achieved. On the other hand, the deviation between the sw_{air} values calculated in this work and those determined using TRS-398 dosimetry protocol changed with the measurement depth in water. It is worth noticing that, one should be aware of such differences working under non-reference condition although they are not significant.

EP-1571

Electron dosimetric characteristics of a dedicated linear accelerator for IOERT

M. Ghorbanpour Besheli^{1,2}, W. Budach¹, I. Simiantonakis^{1,2}

¹University Hospital, Department of Radiotherapy and Radiation Oncology, Duesseldorf, Germany

²Heinrich-Heine University, Faculty of Physics/Medical Physics, Duesseldorf, Germany

Purpose or Objective: Treatment planning systems for IORT (intraoperative radiation therapy) are able to predict the absorbed dose in the patient only when their algorithm precisely considered the dosimetric characteristics of electrons like energy fluence, angular distribution, etc. Hence, the main objective of the present work was to study the contribution of direct (electron component without interaction with the collimator) and scattered electrons to the energy fluence distribution, fluence and mean energy of total electrons.

Material and Methods: Different electron energies of 3, 5 (low energies), 7 and 9 MeV (high energies) at cylindrical field size of 40, 50 and 100 mm of a dedicated mobile IOERT linac NOVAC7 (SIT, Vicenza/Italy) were investigated. For analysis, the phase-space file generated by Monte Carlo code BEAMnrc including the LATCH variable, for specific energy and applicator, was used by the BEAMDP Monte Carlo user code. The LATCH variable is a 32-bit variable to track the history of particles. On the other hand, BEAMDP was used to obtain energy spectra, fluence and mean energy of the direct and scattered electrons at the phantom surface for different applicator diameters.

Results: It was in general observed that the energy fluence distribution of electrons did not change significantly with decreased applicator diameter. Furthermore, it was shown that the contribution of the direct and the scattered electrons on the total fluence changed depending on the applied energy moving from central axis toward the applicator wall. With respect to the fluence of direct electrons the contribution of the scattered component was much lower on the beam axis but increased significantly near the field edge. This is mainly due to the huge increase of interaction events occurred inside the therapeutic beam between electrons and applicator wall. It was also found that, the mean energy of scattered electrons increased intensely decreasing the applicator diameter up to about 28%. Due to the increased number of scattered electrons (higher fluence) and the larger energies of scattered component in the energy spectrum, the mean energy value of scattered electrons increased.

Conclusion: Significant results regarding the behavior of different electron components were found. It was shown that the fluence and mean energy of different electron components increase at larger energies and smaller applicators especially in the vicinity of the applicator wall. This could be useful to interpret dosimetric difficulties encountered working with such IOERT linacs. Furthermore, it is expected that the results discussed here support for accurate patient dose calculation in an IOERT treatment planning system. Moreover, these results can be employed to chamber simulation regarding the determination of perturbation correction factor.

EP-1572

Effective target spot size and grid size for acuros algorithm on penumbra and delivered dose

M.E. Erturk¹, S. Gurdalli¹

¹MNT Sağlık Hizmetleri, Medical Physics, Istanbul, Turkey

Purpose or Objective: Purpose of the study is to analyze how penumbra and the delivered dose vary with the effective target spot size and grid size.

Material and Methods: Acuros beam model was configured for Varian TrueBeam 6 MV. 'Beam Data' section of 'Beam Configuration' of Eclipse 11 treatment planning system (TPS)

was used at configuration of Acuros with different spot sizes (0, 1, 2 mm). Beam Analysis section was utilized to evaluate profiles of 4 fields (2x2, 3x3, 10x10 and 15x15 cm) at 5 depths (1.5, 5, 10, 20, 30) with 4 grid sizes (1.0, 1.5, 2.0, 2.5 mm). To perform analysis, penumbra of 80 profiles were calculated and compared with the measured profiles. A virtual water phantom and the same fields were prepared at TPS to calculate output factors at two different setups. The first has a Source Surface Distance (SSD) of 100 cm and depth is 1.5 cm. The second one's the depth is 5 cm while SSD is 95 cm. Profiles were measured at SSD of 100 cm with Edge detector while output factors measured with PTW pinpoint detector. Average of 4 fields of each spot size and grid size in units of percent was used to analyze the overall performance of the variables.

Results: All of the errors at each output are less than 1 %. Minimum average error in the first case was found to be 0.29 % when the grid size of 1 mm and the spot size of 2 mm were used. Furthermore, maximum average error was 0.51 % when the grid size of 2.5 mm and the spot size of 2 mm were used. In the second case, maximum average error was 0.31 % when the grid size of 2.5 mm and the spot size of 0 mm. Minimum average error was calculated to be 0.05 % when the spot size of 2 mm and the grid size of 2.5 mm were used. Noting that the profiles of 15x15 field cannot be calculated at 1 mm grid size due to the TPS' hardware requirements. Error in penumbra reaches as high as 6.6 mm. Maximum average penumbra error is nearly 2 mm. Change of average errors of the profiles and the maximum errors of each grid with the target spot size is given in table.

Conclusion: It is understood from the results that the output factors and the profiles can be analyzed separately as the variation of the outputs with the grid size and the spot size is negligible. Moreover, it is observed that penumbra of fields at different depths varies with the spot size and the grid size. Therefore, medical physicists have to take into account during the commissioning of the algorithm. The method defined in this study is quite precise, sensitive, easy and effective to analyze the spot size and the grid size.

EP-1573

Validation of a dedicated Intra-operative radiotherapy TPS: an innovative tool for image-guided IORT

A. Ciccotelli^{1,2}, S. Carpino², M. D'Andrea², G. Iaccarino², A. Soriani², G. Felici¹, M. Benassi³, L. Strigari²

¹S.I.T. - Sordina IORT Technologies S.p.A., R&D Dept, Aprilia LT, Italy

²National Cancer Institute Regina Elena, Laboratory of Medical Physics and Expert Systems, Rome, Italy

³IRCCS Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori IRST, Physics Department, Meldola FC, Italy

Purpose or Objective: The Image Guided Intra-operative Radiotherapy (IGIORT) is a new methodology based on the planning optimization using intra-operative target images acquired after surgery. The dedicated Treatment Planning System (TPS) CSRAD+ has been developed in order to plan intra-operative radiotherapy treatments for patients with malignant diseases as clinically appropriate, using a dedicated mobile accelerator and an imaging device. The CSRAD+ performs IORT dose distribution calculation relying on pre-treatment and intra-operative DICOM_RT images. The aim of this work is to validate the dosimetric output and the performances of CSRAD+ before its introduction in clinical practice.

Material and Methods: The home-made CSRAD+ allows to calculate the dose distributions of a IORT dedicated mobile linac for each energy, applicator diameter and bevel angle in water using a cartesian grid with a 2 mm resolution, using Monte Carlo data stored in a database as look-up tables. Two dose calculation algorithms have been implemented both with and without inhomogeneity corrections. The DICOM images of the representative phantom test cases were acquired using a dedicated CT Scan. The calibration curves were loaded in both the CSRAD+ and in the EGSphant module

(OMEGA-BEAMnrc). The Monte Carlo Simulation was performed using DOSXYZnrc MC code. Gafchromic EBT 3 was used in the test phantoms in order to measure the planar dose distribution and to determine isodoses. Phantom test cases were designed to validate the accuracy of the implemented dose calculation algorithms. An independent tool for data analysis has been implemented with Matlab®.

Results: The test cases were reproduced experimentally and the reference measurements were performed with the LIAC mobile IORT accelerator. The proposed test cases have shown a good agreement between measured and calculated dose distributions (at the surface, at the build-up depth and in clinically relevant points corresponding to the isodoses of 90% and 80%) in all the experimental setups containing both horizontal and lateral inhomogeneities, as reported in the figure for the homogeneous phantom test case.

Comparison between Monte Carlo (a), Gaf Chromic films (b) and TPS (c) dose distributions: 10 MeV electron beam in an homogeneous phantom at four different depths

Conclusion: The developed tool allows independent validation of algorithms implemented within CSRAD+ and MC for absolute dose calculations. The method can test patient-like geometries and more complicated setups.

EP-1574

EpiDream: "All-in-One" model for EPID based quality controls

C. Boutry¹, G. Delpon², J. Fontaine², P. Dudouet¹, D. Franck³
¹Groupe Oncorad Garonne, Service de Radiothérapie, Montauban, France
²Institut de Cancérologie de l'Ouest, Département de Physique Médicale, Nantes, France
³Groupe Oncorad Garonne, Service de Radiothérapie, Toulouse, France

Purpose or Objective: Linac or pre-treatment quality control applications are now commonly based on electronic portal imaging device (EPID) acquisitions due to the high spatial resolution and the ease of use of this detector. Several commercial solutions are available depending on the application. Indeed, commercial algorithms assume the EPID grey level is related to the absorbed dose delivered by the treatment beam. This hypothesis leads to the introduction of correction factors depending on geometric and beam conditions. Consequently, those algorithms are dedicated to a specific application. The goal of our work was then to develop an algorithm able to convert an EPID image into an absorbed dose to water matrix from a single model by energy beam. The study compared our algorithm EpiDream to EpiDose (Sun Nuclear), a commercial solution for EPID dosimetry.

Material and Methods: Two 6MV beams produced by two Clinac (Varian) equipped with AS1000 EPID were included in this study. EpiDream model was based on a set of homogeneous calibration acquisitions to establish a relation between the grey level and the absorbed dose to water for each acquisition frame at a reference depth and a specific arm-backscatter correction. The algorithm yielded to dose to

water matrices for all type of fields used in routine (homogeneous fluence, IMRT and VMAT) at 5cm depth in water. EpiDose models were generated for IMRT and VMAT pre-treatment quality controls, applying first the RT Plan to the acquired image to compute the EPID based dose matrix. EpiDream and EpiDose models were compared for 14 VMAT and 19 IMRT (Eclipse V10) pre-treatment quality controls using gamma pass rates (3%, 3mm). Moreover, the robustness of both algorithms was evaluated first, using gamma pass rates (2%, 2mm) for homogeneous fluence beams and second, using a fake RT Plan to convert EPID images into absorbed dose.

Results: For the modulated plans, the g-comparison led to a very good agreement between both EPID based dose matrices. The success rate was respectively $98.5 \pm 2.4\%$ and $98.0 \pm 1.7\%$ for VMAT and IMRT fields. Using the same models, the homogeneous beams comparison showed large discrepancies, with a low gamma pass rate ($86.6 \pm 2.1\%$). However, EpiDream presented a good agreement with Eclipse RT Dose matrices ($97.1 \pm 1.2\%$). So, unlike EpiDose, EpiDream can be used for many controls with a single model. In addition, as EpiDose converted the image into dose using some data extracted from the RT Plan, a fake RTplan led to a large error in the dose matrix. EpiDream algorithm, only based on the acquired image provided correct dose matrix. Discrepancies between both models were high with a gamma pass rate equal to $89.7 \pm 5.7\%$.

Conclusion: The EpiDream solution allows us to perform the quality control tests for machine and patient in a single application. The independence of the model with the irradiation conditions, except beam energy, ensures computing more consistent absorbed dose matrices compared to other algorithms.

EP-1575

The effect of dental implants on dose distributions calculated by AXB in head and neck IMRT cases

H.M. Hung¹
¹Princess Margaret Hospital, Department of Oncology, Hong Kong, Hong Kong SAR China

Purpose or Objective: Acuros XB (AXB) has been implemented and available commercially for clinical use for several years. Different authors have reviewed the algorithm and demonstrated that AXB shows superior performance in dose estimation accuracy. In some cases, patients may be implanted with high density materials, AXB solves the deterministic solution of linear Boltzmann transport equation, in which the Hounsfield unit and the type of material must be input in order to calculate the dose distribution. However, there are only a few studies to evaluate the effect of high density material on dose distribution by AXB, and clinical data is still lacking. Moreover, most of the clinicians may not know the material of the dental implants. The universal assignment of material for permanent high density dental implants may contribute an uncertainty to the dose calculation. Thereupon the current study aims to investigate the impact of dental implants on dose distributions calculated by AXB in Head and Neck (H&N) IMRT cases and hence provide clinical suggestion to unknown dental material assumption for planning.

Material and Methods: Three materials were evaluated, namely: titanium alloy, zirconia and stainless steel. 50 patients with dental implants and treated with H&N IMRT were evenly divided into two groups according to the location of implants. AXB was used to recalculate the dose distribution, originally computed using Analytic Anisotropic Algorithm (AAA). The dosimetric data among material models were compared statistically. In addition, the dose distribution calculated by AXB were verified with measurements of parallel plate ionization chamber, radiochromic films and Gamma analysis.

Results: There were no sig. differences ($P > 0.05$) among material models in the Planning Target Volume (PTV)

coverage and the conformity due to the dental implant for nasopharyngeal cancer (NPC) group (implant outside the PTV). However, for the Non-NPC group (implant inside the PTV), a large discrepancy was obtained in all PTV parameters. There were statistically significant differences ($P < 0.05$) in PTVmax, PTVmean, Conformation Number and volume covered with 70Gy (V70Gy) among models. A large portion of PTV was underdosed. For the stainless steel, the V70Gy is below 70%, which is 25% poorer when compared with AAA plans. In the phantom study, ionization chamber and film measurements supported the dose perturbations by AXB. Using a 3% and 3mm criteria Gamma analysis, passing rate was between 95.0% and 99.7% demonstrating that AXB was in agreement with measurements in different models.

Conclusion: The effect of high density dental material in H&N IMRT cases highly depends on the location of the PTV. For the case with implant outside the PTV, the impact is independent of the type of material and zirconia is recommended for material assumption. However, for the cases with implant inside the PTV, assumption of material should not be made without proper investigation.

EP-1576

Evaluation of transit in vivo dosimetry using portal imaging in VMAT treatment plans

E. Combettes¹, J. Molinier¹, N. Ailleres¹, L. Bedos¹, A. Morel¹, S. Simeon¹, D. Azria¹, P. Fenoglio¹

¹Institut régional du Cancer de Montpellier- ICM - Val d'Aurelle, Radiotherapy, Montpellier, France

Purpose or Objective: To assess the performance of the EPIgray[®] software in the field of transit in vivo dosimetry using portal imaging in Volumetric Modulated Arc Therapy (VMAT) treatment plans.

Material and Methods: MV images acquired in cine mode using portal imaging were used by EPIgray[®] to reconstruct the delivery dose. These reconstructed doses were compared to the calculated doses obtained by the TPS. The reproducibility of the response was evaluated first on phantom and on patient with a prostate VMAT treatment plan and also on patient with a more complex head and neck plan. The dose deviation, with checkpoints defined in the PTV and the organ at risks, was our main criteria to verify the reproducibility of the response. The dose tolerance was set of $\pm 5\%$. The relevance and performance of the points automatically generated (AUTO VX) by the software on PTV have been tested and compared with points generated by the user. Then, data from 101 patient's cases treated by VMAT plans (various locations) were retrospectively analyzed taking into account only the dose deviation of the automatic control point AUTO VX.

Results: The dose deviation from the VMAT treatment plan (phantom and patient) measurements ranged of 0.26 % to 1.50 %, respectively. The dosimetric study on head and neck treatment showed a variable dose deviation range 0.87% and 2.5% depending on level of dose. Automatic points and points created by the user have similar results. The point AUTO VX is representative of results of all points. Results from patient's cases were $1.31 \pm 1.62\%$ for the prostate and $-4.79 \pm 3.87\%$ (AUTO V1) and $-5.54 \pm 3.74\%$ (AUTO V2) for the head and neck VMAT treatment plans. The first clinical results give 46 % patient's cases out-of tolerance. The relative difference in the overall results was $-4.68 \pm 3.50\%$.

Conclusion: EPIgray[®] gives reproducible results on phantom and for treatments such as prostate VMAT treatment plans. The software seems to be less efficient with more complex VMAT treatment plans such as head and neck cases. This study allowed us to consider a tolerance to own each tumor site.

EP-1577

A robust method to minimize geometric table rotational errors in stereotactic radiotherapy

J. Geuze¹, J. Kaas¹, T.A. Van de Water¹, A.M. Van Mourik¹, F. Wittkämper¹

¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiotherapy, Amsterdam, The Netherlands

Purpose or Objective: In stereotactic radiotherapy of intracranial lesions typically non-coplanar techniques are used. However, if the table rotation axis does not coincide with the linac's MV isocentre, the non-coplanar arc introduces a geometric shift of the patient. We present a method to measure the table rotational error for the Elekta[®] Precise table and correct for this error by moving the table assembly.

Material and Methods: The table rotation axis is measured with respect to the linac's MV isocentre. To determine the MV isocentre position, first an EPID-based Winston-Lutz measurement is performed. Subsequently, without moving the ball bearing (BB), EPID images at gantry angle α are acquired at different table angles (-90° , -45° , 0° , 45° and 90°). For each image, the position of the field and BB is determined by an automated fitting procedure.

The table rotational error is calculated by applying two corrections to the measured positions. 1) To correct for the difference between the field centre from gantry 0 and the MV isocentre, all BB positions are shifted by this calculated difference. 2) The BB position at table angle 0 is translated to the MV isocentre, and for the other BB positions the same translation vector is rotated by the table angle. The final corrected positions represent the geometric shift of the BB due to table rotation as if it was placed exactly at the MV isocentre. The largest geometric shift is defined as the table rotational error. This error indicates the possible geometric shift of the patient caused by table rotation when applying a non-coplanar arc.

In order to minimize the table rotational error, the entire table assembly must be shifted. The required shift equals the difference between the table rotation axis and the MV isocentre. This difference is determined from a semicircle which is fitted to the corrected BB positions for the different table angles. To accurately adjust the ~ 800 kg table assembly, a digital indicator with an accuracy of 0.01 mm and a crowbar are used.

The stability of the adjusted table assembly was ensured by performing a monthly measurement of the table rotational error.

Results: Six Elekta[®] Precise tables were successfully corrected (see figure 1). After adjustment, the table rotation axis coincided with the MV isocentre to within on average 0.3 ± 0.1 mm (max. 0.6 mm). This resulted in an average table rotational error, i.e. maximal possible geometric shift, of 0.5 ± 0.2 mm (max. 1.0 mm). Monthly measurements showed that the table rotational error of all six tables were stable with a standard deviation of 0.1 mm.

Figure 1 Table rotational error of six tables.

Conclusion: We present a robust method to accurately measure and correct the table rotational error. This makes it possible to coincide the table rotation axis with the linac's MV isocentre within on average 0.3 mm. The stability after adjustment shows that the method is useful and effective. This method improves the delivery accuracy of non-coplanar stereotactic radiotherapy.

EP-1578

Evaluation of an Integral Quality Monitor device for monitoring real-time delivery

G. Miori¹, A. Martignano², L. Menegotti², A. Valentini²

¹University of Rome Tor Vergata, School of Medical Physics, Roma, Italy

²Azienda Provinciale per i Servizi Sanitari, Department of Medical Physics, Trento, Italy

Purpose or Objective: Radiotherapy treatments are getting more and more complex, dealing with the continuous development of new technologies. Therefore, it is of increasing importance monitoring delivered beams to identify errors. The use of a linac-head integral quality monitor (IQM, iRT Systems GmbH) for real-time beam delivering control was evaluated. This study analyzed the effect of IQM attenuation on delivered beams and the ability of IQM in detecting errors in VMAT treatments.

Material and Methods: Beam attenuation was calculated at 4 different beam size (from 5x5 to 20x20 cm²) by the IC Profiler (Sun Nuclear Corp.) at 6 MV and 10 MV beam energies in both X and Y directions. The IQM capability in recognizing errors was performed introducing deviations in 4 H&N clinical VMAT plans: 3, 5 and 10 % errors on total delivered MU's and 3, 5 and 10 mm MLC's shifts. The cumulative IQM checksum value was measured and the percentage difference was calculated with respect to the non-modified plan. At the same time we obtained dose distribution maps through the PTW 2D array inserted in a rotating QA phantom (RT-smartIMRT, dose.point GmbH). The phantom was chosen for its geometrical characteristics similar to IQM in signal recollection. The local gamma pass rates (2%/2mm) were compared to the original plan values. Non-modified plans were delivered twice in two different times to take into account LINAC variations.

Results: Beam attenuations were normalized to the central chamber of IC Profiler. It gives average attenuation values of 6.56 % ± 0.03 % and 5.27 % ± 0.12% for 6 MV and 10 MV beams, respectively. The percentage of dose difference with respect to the central chamber value was assessed to be < 0.4 % for the 6 MV beam and < 0.1 % for the 10 MV beam excluding beam penumbra regions. The results for modified VMAT plans are summarized in Figure 1. Figure 1a and 1b shows the gamma pass rates and the IQM signal percentage differences for MU's variations, respectively. Figure 1c and 1d illustrates the results for MLC shifts. Both methods detect specifically MLC shift errors, while MU's variations were better identified by IQM. IQM shows a linear response with dose while gamma analysis seems to have difficulty in identifying 3% and 5% MU's variations. In our opinion the reason for this is that the RT-smartIMRT recollect a 2D dose map as if the entire plan were delivered at a fixed gantry angle. Further comparisons to gamma analysis should be evaluated with a different kind of phantom.

Figure 1

Conclusion: IQM beam attenuation can be considered to be homogenous in both X and Y directions and the machine-specific percentage of beam attenuation could be used to rescale treatment plan dose for clinically IQM use. The IQM shows outstanding features in detecting real-time errors and for time-saving QA's, although the characterization of IQM responses to single segment errors and the definition of a machine-specific alarm threshold still have to be analyzed.

EP-1579

Room scatter effects in Total Skin Electron Therapy: a Monte Carlo study

A. Nevelsky¹, E. Borzov¹, S. Daniel¹, R. Bar-Deroma¹

¹Rambam Health Care Campus- Faculty of Medicine- Technion, Oncology, Haifa, Israel

Purpose or Objective: Total Skin Electron Irradiation (TSEI) is a complex technique which involves the use of large electron fields. Electrons scattered from the treatment room floor and ceiling might contribute to skin dose and distort dose distribution, especially when dual-field approach is used. The purpose of this work is to study effects of scattered electrons on the dosimetry of TSEI by Monte Carlo (MC) simulations.

Material and Methods: 6 MeV and 9 MeV beams from Elekta Precise linac operated in High-Dose-Rate (HDR) mode are used for TSEI treatments. The EGSnrc code package was used for MC simulation. First, the incident electron beam parameters (energy spectrum, FWHM) were adjusted to match the measured data (PDD and profile) for both energies at SSD=100 cm for 40x40 open field. These parameters were then used to calculate vertical dose profile at 1mm depth at the treatment distance of 400 cm. Floor was modeled within BEAMnrc using JAWS module. LATCH variable was used to track electrons history and calculate dose profile with and without electrons scattered from the floor. Dose profiles were normalized to the maximum dose from one horizontal field (gantry angle 90 degrees) at 1 mm depth. Influence of dual field angle and floor material on the contribution of floor scatter was investigated. Spectrum of the scattered electrons was calculated. Measurements of dose profile were performed in order to verify MC calculations.

Results: Vertical profile total dose, dose without floor scatter and the floor scatter contribution is shown in Figure 1. Floor scatter contribution is more than 20% near the floor and decreases to about 10% and 5% at the distance 50cm and 100cm from the floor, respectively. No dependence on the beam energy or dual-field angle was found. The scatter depends on the floor material (at 20 cm from the floor, scatter contribution was about 18%, 15% and 12% for concrete, PVC and water, respectively). Spectrum of the scattered electrons has distribution which is almost uniform between few hundred KeV to 4 MeV and then decreases linearly to 6 MeV. Dose verification measurements for the total dose were in good agreement (less than 3%) with the MC calculations.

Figure 1. Vertical dose profiles

Conclusion: For the TSEI technique, dose contribution due to the electrons scattered from the treatment room floor and ceiling may be clinically significant and should be taken into account during treatment design and commissioning phases. MC calculations can be used for this task.

EP-1580

CyberKnife multi-site small beam dosimetry with a new plastic scintillator detector

S. Russo¹, L. Masi², A. Bergantin³, E. De Martin⁴, R. Doro², C. Frassanito⁵, M.L. Fumagalli⁴, A.S. Martinotti³, E. Rondi⁶, S. Vigorito⁶, P. Mancosu⁷

¹Azienda Sanitaria Firenze, S.C. Fisica Sanitaria, Firenze, Italy

²IFCA, Radiotherapy, Firenze, Italy

³C.D.I., Radiotherapy, Milano, Italy

⁴Istituto Besta, Radiotherapy, Milano, Italy

⁵C.B.H. Città di Bari Hospital, Radiotherapy, Bari, Italy

⁶I. E. O., Radiotherapy, Milano, Italy

⁷Humanitas Research Hospital, Medical Physics Unit of Radiation Oncology Dept, Milano, Italy

Purpose or Objective: Accurate dosimetry of small photon fields is clinically crucial, yet remains difficult to achieve. Water-equivalent detectors with small dimension compared to the beam size can be considered ideal. The aim of this work was to evaluate the suitability of a plastic scintillator detector (PSD) (Exradin W1, Standard Imaging SI) for relative small beams dosimetry over different CyberKnife systems.

Material and Methods: Five CyberKnife centers were involved in the study. Small beam dosimetry was performed with W1 PSD oriented vertically (parallel to the beam axis) within a water tank. Cerenkov Light Ratio (CLR) according to the method of Morin (Med. Phys 2013) using the two-channel SuperMax electrometer (Standard Imaging) was calculated to take into account the Cerenkov effect. Since this electrometer has not been integrated with the scanning water-tank, separate positioning and dosimetric systems were used. Output factors (OF) for cones diameters ranging from 5 to 60 mm were measured. Setup conditions were: 80 cm source to detector distance and 1.5 cm depth in water (SSD=78.5cm). Inline and crossline profiles for 5 mm circular field were also acquired at 10 cm depth in water and 80 cm source to detector distance. Same measurements were repeated by each center with the PTW60017 silicon diode. Monte Carlo correction factors reported in literature for PTW-60017 silicon diode (Francescon et al. PMB 2012, Francescon et al. Med. Phys. 2014) were applied to detector readings for OF and dose profile evaluation.

Results: W1 PSD OF measurements averaged over all centers were lower than silicon diode MC corrected values for all field sizes, with differences within 1.7% (see table 1). Comparing OF measured by W1 PSD to MC corrected PTW-

60017 diode data for each center, relative differences <2% for 60-12.5 mm fixed cones were obtained. Differences < 3.2% for 10 mm and 7.5 mm cones, and up to 4.6% for 5 mm cones in one center were detected.

Field Size (mm)	5	7.5	10	12.5	15	20	30	40	60
W1 PSD	0.665 (0.014)	0.816 (0.007)	0.870 (0.005)	0.913 (0.005)	0.939 (0.004)	0.965 (0.003)	0.982 (0.003)	0.987 (0.003)	1.000
MC corrected	0.675 (0.014)	0.830 (0.008)	0.880 (0.007)	0.919 (0.004)	0.943 (0.002)	0.966 (0.003)	0.982 (0.002)	0.988 (0.004)	1.000
PTW 60017									

Table 1. OF mean values and SD over the five CyberKnife centers for W1 scintillator and MC corrected diode measurements.

Dose profile measured by W1 resulted wider than MC corrected silicon diode ones for each center: (see figure 1 for 5 mm collimator of CyberKnife Unit n°1). W1 PSD profile tails were always above diode corrected values for each center.

Figure 1. CyberKnife Unit n°1 mean profile measured by W1 PSD and silicon diode for 5 mm field size.

Conclusion: The agreement between Exradin W1 PSD and MC corrected silicon diode results is promising for the use of W1 PSD in small field dosimetry. However, the application of CLR correction remains a critical point in the measurement procedure and further research is needed to determine the most accurate method for CLR determination.

EP-1581

PTW Starcheck 2D array for Quality Control in IOERT: an evaluation of accuracy and dose consumption

M. Severgnini¹, H. Aslian², M. De Denaro¹

¹AOU "Ospedali Riuniti di Trieste", Medical Physics, Trieste, Italy

²International Center for Theoretical Physics and Trieste University, Medical Physics, Trieste, Italy

Purpose or Objective: In this study, a PTW Starcheck device, which is an easy handle measurement equipment, is used to check the possibility of executing periodical QC in IOERT.

Material and Methods: The dosimetric properties of the new Starcheck device (T10043, PTW) have been studied for 6, 9 and 12 MeV electron beams by IOERT accelerator, the MOBETRON (IntraOp, Inc. Santa, CA.). The Starcheck, consists of 527 vented ionization chambers with small volume (0.053cc) along the principal and diagonal axes. The matrix cover an area of 26 x 26 cm with the spatial resolution of 3mm. The main beam parameters are measured at the depth of maximum dose at mentioned energies and different flat base collimator sizes (4, 5, 6, 7 and 10cm) in comparison with measures conducted with ionization chamber (Advanced Markus, PTW TW34045) and electron diode (PTW TW60012) in water phantom (PTW MP3-S) and also with EBT3 gafchromic film (International Speciality Products, Wayne NJ) in water

equivalent slab phantom (PTW RW3). The Starcheck data acquisitions were done with the Multicheck software with only 100-200 MU and data analysis was handled by the MEPHYSTO software. Reference profiles measured in water were compared with profiles obtained with 2D array and Gafchromic films using the 2%/2mm gamma-index criterion. Output factor measurements were carried out for the central chamber of the array using its absolute dose value, and the results compared with the reference values.

Results: Comparison between dose profiles obtained with Starcheck 2-Array, chamber, diode and Gafchromic film showed a good agreement and they satisfied gamma analysis (2%/2mm) for almost all the nominal energies and collimators. The high spatial resolution of Starcheck allows accurate evaluation of penumbra, symmetry, flatness and field size and the results showed dosimetric differences less than 1%, 1mm for all the energies in the reference collimator (10 cm). The absolute dose difference at the Zref (IAEA398) between central chamber of 2D-array and Advanced Markus was in the order of 1% for 6 and 9 MeV and was almost 1.5% for 9 MeV. Furthermore, the difference between output factor obtained with the 2D-array and other dosimeters was in the order of 2% for all collimators in different energies except for the smallest collimator (4cm) where the output factor deviated more than 3% from the other results. However, the results for beveled collimators were not acceptable due to angular response variation of chambers.

Fig.1. Starcheck 2D array (a), data analyze with Multicheck software (b), crossplane profiles comparison: Starcheck and diode (c), Starcheck and EBT3 (d)

Conclusion: The high spatial resolution, very small detector size and specific arrangement of this 2D array can be really suitable for dosimetry in IOERT. Additionally, it can reduce setup time and dose consumption more than 30% for frequently QC procedure.

EP-1582

Retrospective study of IORT sarcoma treatment using an innovative dedicated TPS

A. Soriani¹, A. Ciccotelli², S. Carpino¹, M. Petrongari³, M. D'Andrea¹, G. Iaccarino¹, G. Felici², M. Benassi⁴, P. Pinnarò³, C. Giordano³, G. Sanguineti³, R. Biagini⁵, L. Strigari¹

¹Regina Elena Cancer Institute, Laboratory of Medical Physics and Expert Systems, Roma, Italy

²S.I.T.-Sordina IORT Technologies S.p.A., R&D Dept, Aprilia LT, Italy

³Regina Elena Cancer Institute, Radiation Oncology Dept., Roma, Italy

⁴Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori IRST, Medical Physics Dept, Meldola FC, Italy

⁵Regina Elena Cancer Institute, Orthopaedic Surgery Dept., Roma, Italy

Purpose or Objective: The IORT dedicated Treatment planning system (CSRAD+), already validated on simple geometries, has been used to perform calculation on patient-like geometries and to compare the measured and the calculated dose distribution in a clinical configuration. In this study, sarcoma cancer patients have been considered. In sarcoma IORT treatments, the air gap between target and applicator and the extended dimensions are critical parameters that must be fully taken into account. The TPS and MC calculations are mandatory for documenting the dose delivery in order to potentially improve the treatment technique and to better evaluate dose effect correlation.

Material and Methods: Twenty six patients with sarcoma cancer have been treated using NOVAC 7 with an energy from 7 to 9 MeV, an applicator diameter from 40 to 100 mm, delivering a dose from 10 to 16 Gy. In vivo dosimetric data collected during IORT using Gaf films, have been used as the gold standard for testing the accuracy of the algorithms implemented in the TPS. CT images of five representative patients have been used to reproduce the surgery room scenario, using the collected data and taking into account tissue removal during the surgery procedure. Then, the CT images were imported in the TPS and used in order to perform an accurate dose calculation. The dose distribution have been compared with the in vivo dosimetry in order to perform a sensitivity analysis.

Results: The TPS algorithms including the inhomogeneity correction have been investigated considering the clinical scenarios. The algorithm including the inhomogeneity correction allows the best agreement between the in-vivo dosimetry results and calculated dose, for mobile IORT accelerator. CSRAD+ permits to make a virtual docking, to delineate the target ROI, and to evaluate the dose distribution and the dose volume histogram. The sensitivity analysis revealed potential setup uncertainties (up to 80%) due to the manually performed alignment procedure in the surgical room and inaccuracy on target thickness when blood and air are present during the docking.

Conclusion: The developed CSRAD+ shows a good agreement with experimental data and could replace the time consuming MC absolute dose calculation, becoming a potential on-line aid for physician and physicist in the surgical room. The CSRAD+ could represent a training tool for

IORT staff and could provide a provisional plan that includes also DVH and MU calculation.

EP-1583

An automated Monte Carlo plan verification system for spot-scanning proton therapy

J. Richardson¹, A. Aitkenhead¹, T. Lomax², S. Safai², F. Albertini², R. Mackay¹

¹The Christie NHS Foundation Trust, Christie Medical Physics and Engineering, Manchester, United Kingdom

²Paul Scherrer Institute, Center for Proton Therapy, Villigen, Switzerland

Purpose or Objective: Monte Carlo (MC) recalculation of spot-scanning proton therapy treatment plans can provide an independent verification of monitor units required for delivery, and reduce the time treatment rooms need to be reserved for patient specific QA. We describe the development of such a MC verification system for a clinical facility.

Material and Methods: Realistic clinical beam models were developed by matching simulations (using GATE/GEANT4) to measurements made in a clinical beamline. They consist of a tuned physics list, a lookup table relating each of the 115 nominal beam energies to a tuned spot energy (mean and standard deviation) and phase space parameters which allow spot sizes to be properly modeled for any combination of energy and nozzle extension. For all beam energies simulations accurately reproduce both integral depth dose profiles (>97% of data-points pass a local gamma analysis at 2%/2mm) and lateral profiles measured in air and in solid water (with a 0.2 mm maximum difference). The model was further validated against a series of simple test plans which were optimized in the clinical Treatment Planning System (TPS) to produce uniform dose volumes at various depths in water. The automated MC system can process, simulate and analyse treatment plans without user input once it receives the TPS files.

Results:

The system was tested for a three field (11k spot) base of skull treatment plan computed in a patient CT dataset. Simulations were split into 40 calculations over a 10 quad-core CPU cluster, requiring <30 minutes to achieve dosimetric uncertainties (within the 90% isodose volume) of <1%. The figure demonstrates the broad agreement between the TPS (left) and the MC simulation (right). The local gamma pass rate between the two (bottom) is 97% at 4%/4mm (green voxels pass, red / blue voxels fail). This should be interpreted in the context of this being a highly inhomogeneous target site: Differences occurred only in heterogeneous regions where the TPS's analytical dose

calculation would be expected to model dose deposition less accurately than MC systems. For example, the MC simulations predict a lower dose around the sinus air cavities than the TPS.

Conclusion: We have demonstrated that the MC verification system can accurately reproduce the dose distribution predicted by a clinical TPS. Further validation work is ongoing using a variety of plans and phantom measurements. Once clinically commissioned, the system can be used as an independent dose checker, reducing on-set verification time.

EP-1584

Experimental validation of Tomotherapy to VMAT plan conversion using RayStation Fallback Planning

L. Bartolucci¹, O. Jordi-Ollero¹, M. Robilliard¹, S. Caneva-Losa¹

¹Institut Curie, Radiotherapy, Paris, France

Purpose or Objective: To establish the workflow & methodology and to perform an experimental validation of treatment plan conversion from Tomotherapy HD machine (Accuray) using dynamic jaws to a True Beam (Varian) Linac. For this purpose, the RayStation (RS) TPS using fallback planning (RFP) is currently tested. An end-to-end set of phantom configurations of increasing complexity are presented. The ultimate goal is to validate this process in order to minimize the impact of machine downtime on patient treatments.

Material and Methods: Four phantom based treatment plans were generated in the Tomotherapy Planning Station. These plans were mimicked with RFP for the TrueBeam using X6-FFF dual-arc VMAT. The first three cases planned on the Cheese Phantom (Std. Imaging) consisted of 1 to 4 target dose levels and 3 OARs, using heterogeneous inserts for the last one. The 4th case was an integrated boost H&N treatment with 3 target dose levels planned on an anthropomorphic phantom (H&N, IBA). Original Helical Tomotherapy (HT) and RS fallback plans were delivered respectively on each machine. Ion chamber (A1SL, Std. Imaging) and Gafchromic EBT3 (ISP) films were used to measure absolute and planar doses. First, for both machines beam delivery vs. treatment plan was evaluated as a baseline for absolute dose, gamma (γ) passing rate (criteria 3%/3mm) and overall uncertainties. Secondly, in order to ensure that the difference between the two calculated dose distributions (TPS_TOMO / TPS_RAYSTATION) matched the differences between the two measured film dose distributions (Film_TOMO / Film_RAYSTATION), a γ difference (5%/5mm) was performed.

Figure 1 - Principle of the method implemented to validate plan conversion. (A) Helical Tomotherapy TPS dose distributions calculated on the Cheese Phantom is delivered on the Tomotherapy and measured with ion chamber and film. Gamma evaluation (3%/3mm) is performed using FilmQA Pro. (B) same as (A) but mimicked with the RayStation TPS Fallback Planning and delivered on the TrueBeam. (C) Gamma-index evaluation (5%/5mm) for both film measurements (γ_1). Gamma-index (5%/5mm) for both TPS dose distributions (γ_2). The average γ difference ($\gamma_1 - \gamma_2$) is performed between them.

Results: First, gamma evaluation was (99.1 \pm 0.6)% for HT and (99.5 \pm 0.4)% for RS fallback plans while absolute dose differences between calculations and ion chamber measurements were respectively 0.9% for HT and -0.7% for RS on average for all end-to-end tests. Secondly, average γ difference between calculated doses TPS_TOMO /

TPS_RAYSTATION and measured planar doses Film_TOMO / Film_RAYSTATION was $(0.3 \pm 0.2)\%$.

4 cases	γ evaluation (3%/3mm) TPS vs. Film		Absolute dose difference TPS vs. Ion Chamber		(C) Average γ difference (5%/5mm) TPS _{TOMO} /TPS _{RS} vs. Film _{TOMO} /Film _{RS}
	(A) Tomotherapy	(B) RayStation	(A) Tomotherapy	(B) RayStation	
Average	99.1%	99.5%	0.9%	-0.7%	0.3%
SD	0.6%	0.4%			0.2%

Table 1 - Gamma evaluation, absolute dose difference and average γ difference for all end-to-end tests.

Conclusion: Raystation fallback planning is an advanced feature that allows switching patient plans between alternative treatment machines and techniques. This could be useful to reduce impact of machine downtime on patient treatments. However, this process could introduce potential risks as distinct TPS and beam deliveries are involved. The results presented here show that a difference between calculated HT and mimicked RS fallback plans match the measured differences found throughout the end-to-end tests. Results based on a 5%/5mm tolerance show that we can expect at most 0.3% agreement from the difference between original and fallback plans displayed by the RS TPS. Further work will involve the study of clinical plans on various tumors sites.

PRIMO software as a tool for Monte Carlo treatment quality control in IMRT: a preliminary study

V. Pita^{1,2}, A. Esposito², A. Dias³, J. Lencart³, J. Santos³

¹Faculty of Science- University of Lisbon, Institute of Biophysics and Biomedical Engineering, Lisbon, Portugal

²IPO PORTO, Investigation Center CI-IPOP, Porto, Portugal

³IPO PORTO, Medical Physics Service and Investigation Center CI-IPOP, Porto, Portugal

Purpose or Objective: Monte Carlo (MC) approach is considered the gold standard method to perform absorbed dose calculations in external radiotherapy[1], because it provides the most detailed and complete description of radiation fields and particle transport in tissues. Several codes are available and recently a new MC Penelope based code and graphic platform named PRIMO was developed [2]. PRIMO has a user-friendly approach, a suitable and competitive characteristic for clinical activity. Nevertheless, advanced features such as IMRT are not introduced yet. This work is a preliminary study for the PRIMO software as a tool for MC based quality control of IMRT treatment.

Material and Methods: The simulated beam parameters of a Varian CLINAC 2300 were adjusted based on measurements in a water tank for 6 MeV energy and 10x10 cm² field. The water tank was divided in 81x81x155 voxels with dimensions of 2x2x2 mm³. The Gamma Function (GF) was used for agreement assessment and a phase-space was obtained above the MLC. A solid water phantom with a PTW OCTAVIUS® 729 2D ionization chamber array inserted was imaged by a CT scan and used in PRIMO. A dynamic IMRT plan was calculated by the Eclipse™ TPS and irradiated. The LINAC DynaLog files were analysed and the dynamic delivery was divided into series of static fields in PRIMO. MATLAB was used to analyse the PRIMO output and to create images of dose distributions at specific locations. The simulated dose at the ion chamber matrix position in the phantom was compared with the matrix measurement using the 2D GF through the PTW Verisoft program.

Results: The best agreement for the beam parameters of the LINAC numerical model was obtained with initial electron energy of 5.9 ± 0.2 MeV and beam divergence of 1.5° . The gamma function analysis (2%, 2mm) showed that 97% of the points was lower than 1, confirming the good agreement with the experimental data. For the IMRT plan, the measured and simulated dose distributions at the ion chamber matrix (fig 1A-B) show good agreement, as the gamma points lower than 1 were 96% (fig 1C).

Fig 1A: Dose distribution for the dynamic IMRT treatment, measured with ionization chamber array, placed at 100 cm distance from the LINAC head under 5cm of water equivalent.

Fig 1B: Dose distribution at the matrix for the simulated dynamic plan.

Fig 1C: Agreement between the two distribution as assessed by the gamma function (2%, 2mm)

Conclusion: This preliminary study shows that an IMRT plan was successfully simulated through PRIMO with acceptable concordance with the experimental results. Even though further studies on more complex treatments are still required, the results confirm PRIMO as a promising tool for IMRT simulation in clinical environment.

Characterization of a new EPID-based system for in-vivo dosimetry in VMAT treatments

S. Bresciani¹, M. Poli¹, A. Miranti¹, A. Maggio¹, A. Di Dia¹, C. Bracco¹, M. Stasi¹

¹Candiolo Cancer Institute-FPO- IRCCS, Medical Physics, Candiolo TO, Italy

Purpose or Objective: The aim of this paper is to evaluate the EPID detector sensitivity and specificity for in vivo dosimetry of VMAT treatments to identify dosimetric and geometric errors and anatomical variations.

Material and Methods: Measurements were performed by using TrueBeam STx accelerator equipped with EPID aSi1000 (Varian, Palo Alto, CA) and PerFraction (PF) software (Sun Nuclear Corporation, Melbourne, FL). PF is a commercial EPID-based dosimetry software, which allows performing transit dosimetry, to provide an independent daily verification of the treatment. Performance of the EPID detector and of the PF software on anthropomorphic phantom was studied, simulating 17 perturbations of the reference VMAT plan. Systematic variations in dose values (1%-5% output variation), shifts (2,5-11 mm in anterior direction), anatomical variations (adding bolus over phantom), and MLC positioning (locked leaf position for different arc extensions) were applied. The difference in local and global gamma pass rate (%GP) between the no-error and error-simulated measurements with 1%/1mm, 2%/2 mm and 3%/3 mm tolerances was calculated. The clinical impact of these errors was also analyzed through the calculation of the difference between the reference DVH and the perturbed DVH (%DE). We defined as clinically meaningful a variation higher than 3% between calculated and perturbed doses. A value of %GP equal to 95% and 90% and %DE equal to 3% were used as thresholds to calculate sensitivity and specificity.

Results: Repeatability and reproducibility of no-error measurements were excellent with %GP=100% for all gamma

methods. 1%/1mm and local normalization is able to detect all type of errors (1%/1mm with global normalization is not able to detect the systematic shift of 2,5 mm), but it could overestimates some errors that have not clinical impact. In the table, we reported the results of sensitivity and specificity of PF to detect clinically relevant errors.

			Sensitivity	Specificity
%GP>95%	3%/3mm	γ -local	0,5	0,7
		γ -global	0,4	0,7
	2%/2mm	γ -local	0,5	0,6
		γ -global	0,5	0,6
	1%/1mm	γ -local	1	0,2
		γ -global	0,9	0,3
%GP>90%	3%/3mm	γ -local	0,1	1
		γ -global	0	1
	2%/2mm	γ -local	0,3	0,9
		γ -global	0,2	1
	1%/1mm	γ -local	0,7	0,5
		γ -global	0,7	0,5

Conclusion: EPID device and PF software can be confidently used in clinical routine to detect dosimetric, geometrical and anatomical discrepancies. The possibility of this in vivo evaluation and the potentiality of this new system have a very positive impact on improving daily patient QA .

EP-1587

Sensitivity and specificity of gamma index method for Tomotherapy plans.

M. Stasi¹, S. Bresciani¹, A. Miranti¹, M. Poli¹, A. Di Dia¹, A. Maggio¹, E. Delmastro², P. Gabriele²

¹Candiolo Cancer Institute-FPO- IRCCS, Medical Physics, Candiolo TO, Italy

²Candiolo Cancer Institute-FPO- IRCCS, Radiotherapy, Candiolo TO, Italy

Purpose or Objective: The aim of this work is to evaluate the perturbed DVHs generated from Tomotherapy dose distributions according to the dose discrepancies detected with pre-treatment measurements. Through perturbed DVHs data, sensitivity and specificity of gamma passing rate (%GP) were calculated to evaluate if Gamma Index (GI) metric correctly differentiates the high dose error plans from low dose error plans. In the literature GI was found to be a poor predictor of dosimetric accuracy with planar and volumetric dosimeters for IMRT and VMAT techniques, we evaluate if this lack of prediction of GI method is valid also for Tomotherapy plans.

Material and Methods: 12 patients for prostate cancer (P), and 12 for head and neck (HN) cancer, were enrolled in the study. All the treatments were delivered using the Helical Tomotherapy Hi-ART system (Accuray, Inc., Sunnyvale, CA). Pre-treatment QA measurements were performed by using the diode array ArcCHECKTM and perturbed DVHs were obtained with the 3DVH software (both by Sun Nuclear Corporation, Melbourne, FL). Measured and calculated dose distributions were compared using the global and local GI method with 2%/2 mm, and 3%/3 mm criteria. Low-dose thresholds (TH) of 10% and 30% were applied and analyzed. Percentage dose differences between DVHs, obtained by TPS and by 3DVH were calculated. A %GP equal to 95% and a mean absolute DVH 3% dose error were used as thresholds to calculate sensitivity and specificity. In order to quantify the sensitivity and specificity of GI method, we calculated the number of false negative (high Tomotherapy QA passing rates indicate large errors in anatomy dose metrics), true positive (low Tomotherapy QA passing rates do imply large errors in anatomy dose metrics), true negative (high Tomotherapy QA passing rates did imply small errors in anatomy dose metrics) and false positive (low Tomotherapy QA passing rates did imply small errors in anatomy dose metrics).

Results: We found the higher sensitivity (0.55) for global normalization with 3%/3mm and TH=30% and the higher specificity (0.67) with 3%/3mm for global normalization, both for TH 10% and 30%. Instead we obtained the poorer

sensitivity (0) with 2%/2mm, local normalization, and TH=10% because the threshold of 95% is too high for 2%/2mm and local normalization. We observed the poorer specificity (0.39) for 3%/3mm, local normalization, both for TH=10% and 30%. For global normalization, 3%/3mm sensitivity and specificity were always higher than those of 2%/2mm criterion.

Conclusion: The low sensitivity and specificity values of GI method, for all the applied criteria, show that the gamma index metric have disputable predictive power for per-patient Tomotherapy QA.

EP-1588

A methodology for deriving clinically indicative gamma index acceptance criteria

M. Hussein¹, A. Nisbet¹, C.H. Clark¹

¹Royal Surrey County Hospital, Medical Physics, Guildford, United Kingdom

Purpose or Objective: The gamma index (γ) is a common method for comparing measured and predicted dose distributions. The percentage of points passing with $\gamma < 1$ (Γ) is the most frequently reported analysis metric. However, the use of Γ has been reported to have weak correlation against clinically relevant metrics and the result also varies depending on the Quality Assurance (QA) system configuration and software used. Other metrics could be extracted from the γ map but have not been rigorously evaluated in the literature to address appropriate acceptance values. This study has developed a methodology to evaluate the suitability of the mean, median, maximum, or near-maximum γ metrics (γ_{mean} , γ_{median} , γ_{max} , $\gamma_{1\%}$) and their acceptance criteria.

Material and Methods: Investigations were performed using simulated data with deliberate changes created in a virtual phantom test. The changes included: dose deviations of -5% to 5% in 1% steps; and MLC offsets of 1-5mm in 1mm steps. An in-house Matlab-based software was used to perform γ analysis to extract different metrics. The primary PTV mean (PTVmean) and organ at risk maximum (OARmax) dose deviations were extracted from the changed plans. The γ metrics were correlated against PTVmean and OARmax for global γ passing criteria of 3%/2mm (20% threshold relative to a point in high dose low gradient). Acceptance criteria needed to predict a dose deviation $> \pm 3\%$, for 3%/2mm, were assessed using Receiver Operator Characteristic (ROC) analysis and assuming 100% sensitivity. The area under the ROC curve (AUC) was assessed for each γ metric to assess statistical reliability. Since the γ calculation can give varying results between different QA systems, the robustness of the proposed methodology was tested by varying γ passing criteria as well calculating in 2D planes and 3D volumes.

Results: The γ_{mean} , γ_{median} and $\gamma_{1\%}$ metrics had the strongest Pearson correlation coefficient (ρ) against the PTVmean ($\rho > 0.95$, $p < 0.01$); (Fig. 1). The Γ had a weaker correlation of $\rho = -0.76$. These metrics had ROC AUC > 0.9 ($p < 0.01$) showing statistically strong accuracy for predicting a PTVmean deviation $> \pm 3\%$ for 3%/2mm. Optimal acceptance criteria for achieving 100% sensitivity are shown in Table 1. The γ_{max} had the best correlation against OARmax ($\rho > 0.8$, $p < 0.01$) and the AUC was > 0.9 and showed that points with $\gamma > 1.1$ may be associated with a $> 3\%$ increase in the OARmax. Correlations between different γ passing criteria were statistically strong at > 0.95 ($p < 0.01$) as were correlations between 2D & 3D γ calculations, indicating the robustness of the methodology to the variability in γ calculation that could be caused by QA system configuration and software implementation.

Figure 1 3%/2mm global 3D volume γ metrics against (a) PTV mean absolute dose deviation and (b) OAR maximum dose deviation. The passing rate (points passing with $\gamma < 1$) given as a percentage is plotted against the left y-axis and the γ_{mean} , γ_{median} , $\gamma_{1\%}$ and γ_{max} metrics are plotted against the right y-axis.

Table 1 Optimal criterion for the gamma index metrics to predict a $\pm 3\%$ dose deviation in the PTV mean dose and OAR maximum dose based on the simulation study. In all cases, sensitivity was 100%.

y metric	DVH metric			
	PTV2 mean		OAR max	
	Acceptance criterion	AUC & [Specificity]	Optimal criterion	AUC & [Specificity]
Passing rate	$\geq 99.9\%$	0.95 (p<0.01) [73.3%]	100%	0.84 (p<0.01) [62.5%]
γ_{mean}	<0.38	0.96 (p<0.01) [80%]	<0.02	0.71 (p<0.04) [12.5%]
γ_{median}	<0.35	0.97 (p<0.01) [80%]	0.00	0.72 (p=0.03) [12.5%]
γ_{max}	<0.90	0.64 (p=0.22) [33.3]	<1.10	0.94 (p<0.01) [75%]
$\gamma_{1\%}$	<0.85	0.96 (p<0.01) [80%]	<0.19	0.75 (p=0.01) [12.5%]

Conclusion: The γ_{mean} , γ_{median} and $\gamma_{1\%}$ metrics have potential to be used as parameters to predict PTV dose deviations and had better correlation than the passing rate. However for OAR dose deviations, the γ_{max} showed the strongest correlation with DVH deviations. This methodology is robust the variability in γ calculation.

EP-1589

Experimental validation of Tomotherapy TPS in build-up and superficial zones for a H&N plan

M. Zani¹, C. Talamonti^{1,2}, M. Bucciolini¹, M. Marinelli³, G. Verona-Rinati³, P. Bonomo², L. Livi^{1,2}, S. Pallotta^{1,2}

¹University of Florence, Clinical and Experimental Biomedical Sciences "Mario Serio" Department, Florence, Italy

²A.O.U. Careggi, Radiotherapy Department, Florence, Italy

³University of Tor Vergata, INFN-Industrial Engineering Department, Rome, Italy

Purpose or Objective: Aim of this study is the evaluation of build-up and superficial doses for a Head&Neck treatment, delivered by Helical Tomotherapy (HT). Measurements were carried out by two different dosimeters (radiochromic films and a synthetic single crystal diamond detector) and compared with TPS data. Build-up dose profiles and superficial dose points were estimated. The reliability of the TPS in these critical regions was assessed, giving an insight into a subject on which quite contradictory results are reported in the literature.

Material and Methods: A home modified Anderson Rando phantom was employed to house the detectors. As shown in figure (a), two slices of the phantom neck were removed and replaced with a PMMA artificial neck, with a hole inside to mimic the trachea. This allowed to measure dose profiles and superficial dose points with geometrical and scattering conditions similar to the ones taking place when a real patient is treated. Gafchromic EBT3 films (Ashland Inc.,

Wayne, NJ) were sandwiched inside the neck in order to measure dose profiles and attached to the neck surface for superficial dose point assessment. PTW-Freiburg microDiamond (mD) was positioned inside drilled holes at different known distances respect to the phantom surface.

Results: In figure (b) one of the measured dose profiles by EBT3 and mD is reported, along the Antero-Posterior direction, in the range 0-30 mm (distance from the phantom surface). TPS data are also shown, as black dots, with an associated error of ± 0.9 mm, half of the lateral dimension of the calculation pixel (fine grid). The prescribed dose is reached within approximately 4 mm from the phantom surface and it does not show any significant variation going further inside the neck, in particular at the PMMA/air interface, in correspondence of the trachea starting point. A 1D threshold criterion of 3%/mm was adopted in order to discriminate between high and low gradient zones. Dose differences (DD) measured by mD are within 2.5% respect to TPS, in the low gradient region, while a maximum distance-to-agreement (DTA) of 0.9 mm is found for the same device, in the high gradient region. EBT3 profile shows a more noisy behavior, with a maximum DD of 3.8% in the low gradient portion of the profile, while DTA is less than 1 mm in the high gradient zone. The superficial dose measurement by EBT3 film is characterized by a DTA of 0.5 mm and a DD of 5.2%.

Conclusion: Build-up dose profiles measured by the two dosimeters show the same behavior and are in agreement with TPS data; deviations are well within the reference tolerance level. The investigation carried out in this work offers the possibility of studying the TPS behavior not only in terms of dose difference, as carried out for *in vivo* measurements, but also taking into account a "spatial displacement", to be compared with patient (and/or dosimeter) positioning uncertainties.

EP-1590

Verification of small-field VMAT plans using a 2D detector array in a rotational phantom

A. Swinnen¹, M. Ollers¹, E. Roijen¹, S. Nijsten¹, F. Verhaegen¹

¹MAASTRO clinic, Radiotherapy, Maastricht, The Netherlands

Purpose or Objective: To evaluate experimentally the accuracy of the dose calculation algorithm AcurosXB in small-field highly modulated Volumetric Modulated Arc Therapy (VMAT).

Material and Methods: The Octavius 1000SRS detector array inserted in the rotational Octavius4D phantom (PTW) was used, consisting of 977 liquid-filled ion chambers covering an area of 11x11cm². The detector size (2.3x2.3x0.5mm³) and the center-to-center distance of the detectors (2.5mm in the inner 5.5x5.5cm² area) are important parameters for correct spatial measurement of complex dose distributions with steep dose gradients. Clinical treatment plans (n=28), characterized by small treatment volumes, 6 and 10MV photon beams, and fraction doses between 2.75-30 Gy, were projected on the phantom CT data set and recalculated in the Eclipse TPS v11 (Varian Medical Systems) using AcurosXB with a calculation grid size of 2.5mm and 1mm (field sizes <3x3cm²). All measurements were done on a Varian TrueBeamSTx linac. The irradiation technique used was

VMAT, but in a few cases also dynamic conformal arc for the smallest treatment field sizes. The effect of disabling jaw tracking, thereby fixating the collimator jaws at 3x3cm² and applying the MLC to shape the smallest apertures was investigated for static fields between 3x3cm² and 0.5x0.5cm², and for 7 stereotactic patients with small brain metastases. To evaluate the dosimetric agreement between measured and calculated dose, a local gamma evaluation criterion of 2%/2mm was used.

Results: Regarding the clinical VMAT plans, the mean and SD of the volumetric gamma evaluation scores with 10%, 50%, 80% and 95% cut-off dose values are (96±6.9)%, (95.2±6.8)%, (86.7±14.8)% and (56.3±42.3)% respectively. In figure 1, a trend can be observed between relative dose differences and the field size area of 28 VMAT treatments going from very small to medium sized fields. The deviation between 1000SRS readings for static fields 3x3, 2x2, 1x1 and 0.5x0.5cm² collimated with MLC and jaws fixed at 3x3cm² and with collimator jaws only is on average respectively, 0.3%, 0.8%, 6.7%, 5.4% (6 MV) and 0.2%, 1.3%, 11.3%, 20.1% (10MV). The effect of disabling jaw tracking for 7 stereotactic patients with treatment techniques VMAT as well as dynamic conformal arc is shown in table 1: the smaller the target, the higher the improvement in agreement between measured and calculated doses when jaws are fixed at 3x3cm².

Figure 1: Plot of the relative dose differences as a function of field size area defined by collimator jaws for VMAT treatment plans. (D_{max} is referring to the maximum dose in the 3D volume)

Patient	Technique	2% 2mm Threshold					measured D _{max} (Gy)	TPS D _{max} (Gy)	measured D _{max} - TPS D _{max} / TPS D _{max} (%)	Field size (cm ²)

7	Dyn.Conf.Arc	100.0%	100.0%	100.0%	100.0%	100.0%	8.853	8.859	0.7%	1.9x1.9/2.4x2.5
	VMAT	100.0%	100.0%	100.0%	100.0%	100.0%	8.306	8.691	4.5%	3x3/3x3
	Dyn.Conf.Arc	100.0%	100.0%	100.0%	100.0%	100.0%	8.866	8.700	1.8%	3x3/3x3

Table 1: Gamma agreement scores and comparison of measured versus calculated maximum doses for 7 stereotactic brain metastases patients calculated with grid size 1mm and with jaw tracking on (in white rows) against fixed collimator jaws at 3x3cm² (in tinted rows) for both treatment techniques dynamic conformal arc and VMAT. The patients are ordered in such a way that the smallest field area belongs to patient 1 and the largest to patient 7.

Conclusion: Doses calculated for stereotactic VMAT plans show an acceptable agreement against measurements with the 1000SRS in the Octavius4D system. Except for very small highly modulated VMAT fields, larger discrepancies are obtained. Fixating the jaws at 3x3cm² and using the MLC with high positional accuracy to shape the smallest apertures in contrast to jaw tracking is currently found to be the preferred and most accurate treatment technique.

EP-1591

Investigation on backscattered dose of absorber plates for IORT application

M.N. Pirpir^{1,2}, M. Ghorbanpour Besheli^{2,3}, O. Fielitz^{1,2}, H. Ozcan^{1,2}, I. Simiantonakis^{1,2}

¹University Hospital, Department of Radiotherapy and Radiation Oncology, Duesseldorf, Germany

²Heinrich-Heine University, Faculty of Physics/Medical Physics, Duesseldorf, Germany

³University Hospital, Department of Radiotherapy and Radiation Oncology, Duesseldorf, Germany

Purpose or Objective: In intraoperative electron radiation therapy (IOERT) a high single dose is applied to the tumor bed directly after resection of the malignancy. During an IOERT clinical application special shielding materials are used under the tumor bed in order to reduce the absorbed dose on critical organs behind the tumor like rib, heart and lung. Such absorbers produce backscattered dose. The objective of the present study was to investigate the backscattered dose of the absorber shielding plates. This could help us to comprehend the effect of the clinical application of such absorbers.

Material and Methods: The electron beams generated by a dedicated mobile IOERT accelerator NOVAC7 (SIT, Vicenza/Italy) were employed. The electron beams with different energies of 5 and 9 MeV together with 40 and 50 mm applicators which are most clinically used were utilised. These shielding plates are made up of a special steel alloy (AISI 316L). The backscattered dose was measured by radiochromic films, Gafchromic EBT3 (Ashland, Wayne/USA). All films were irradiated with 5 Gy at 100% isodose level.

Results: Some important aspects of results are explained below.

40mm applicator: At the first film slice, increasing the energy from 5 to 9 MeV resulted to a significantly higher backscattered dose. At 5 MeV the backscattered dose was 0.29 Gy, compared to the dose resulted for the film slice without the shielding. The corresponding values were 0.63 Gy for 9 MeV. This increase might be because of the increased energy of the backscattered electrons at higher energy beams (9 MeV) which causes higher dose delivery at the same depth, compared to low energy beams (5 MeV). Moving toward the surface of the phantom the backscattered dose decreased significantly (-11%). This occurs due to decrease of energy and fluence of backscattered electrons when they move toward the phantom surface. 50mm applicator: At larger field size of 50 mm, the backscattered dose increased remarkably, compared to the 40 mm applicator. In comparison with the dose absorbed to the film slice without the shielding, the backscattered dose increased 1.5 and 1.3 Gy for 5 and 9 MeV, respectively. The reason is that at larger field size the energy fluence of scattered electrons might be higher than the 40 mm applicator and this led to a higher dose delivery at the same depth, compared to 40 mm field size.

Table: It is shown the absolute dose differences between the measurement with and without absorber plate on the film slices

Dose differences with 9 MeV electron beams in Gy	50mm 0°	50mm 45°	40mm 0°	40mm 45°
	4 mm above the absorber surface	0.794	0.636	0.194
3 mm above the absorber surface	1.02	0.764	0.268	0.094
2 mm above the absorber surface	1.309	1.009	0.625	0.351
Dose differences with 5 MeV electron beams in Gy				
4 mm above the absorber surface	0.247	0.2	-0.083	0.025
3 mm above the absorber surface	0.691	0.314	0.125	0.034
2 mm above the absorber surface	1.478	0.613	0.29	0.197
under the absorber plate	-0.49	-0.937	-0.328	-1.096

Conclusion: It was concluded that the backscattered dose of steel alloy is significant at higher energies. Furthermore increasing the applicator diameter from 40 to 50 mm increased the backscattered dose more than twice. The results of this study helped us for a better comprehension of backscattered dose of absorber shielding used in clinical practice.

EP-1592

Automatic detection algorithm for MLC position using a single EPID image in a daily QA program

P. Colleoni¹, A. Gambirasio², C. Bianchi¹, M. Fortunato¹, S. Andreoli¹

¹A.O. Papa Giovanni XXIII, Fisica Sanitaria, Bergamo, Italy

²Università degli Studi di Milano, Scuola Specializzazione Fisica Sanitaria, Milano, Italy

Purpose or Objective: We developed a robust and efficient algorithm for automatic detection of MLC (Multi Leaf Collimator) leaves position based on a single EPID (Electronic Portal Image Detector) static image acquisition. Within this framework, assessment of other important parameters such as collimator rotation angle and jaws position is possible as well. The algorithm works on a single image acquired with few MUs and allows a quantitative monitoring of MLC and collimator position accuracy and reproducibility, during a daily QA program.

Material and Methods: Images were acquired on linear accelerators (Varian Medical Systems, Palo Alto, CA) equipped with Millennium 120 MLC and with aS1000 flat panel detector with an active area 40x30 cm² (1024x768 pixels). All images were acquired in integrated modality with less than 10 MU. In-house code for images analysis has been developed using MATLAB® (MathWorks, Natick, MA) as platform. The algorithm for MLC position detection includes two main steps: the local edge detection, based on Canny method, and the edge linking tool to identify edge section belonging to each leaf tip. From these edge portions, leaves positions is evaluated and compared to the expected ones. Collimator angle is extracted using the FFT (Fast Fourier Transform) of the acquired image.

Results: In order to assess the reliability of the algorithm, different configurations were considered: MLC leaves opened asymmetrically to form a four-sides shape, different collimator rotation angles and jaws position. Images obtained from configurations with intentionally introduced errors were also analyzed. Results showed that this algorithm is able to successfully evaluate leaves position within 1 mm accuracy and collimator angle within 1 degree accuracy. The analysis process takes only few seconds.

Conclusion: We developed a fast and accurate algorithm to extract from a single EPID image parameters such as MLC leaves position and collimator rotation angle. This fast

procedure is able to highlight errors related to different kind of parameters. These characteristics make this method suitable for a daily QA program. Further development of this work can be the use of this procedure to check MLC leaves position during VMAT plan delivering for a patient-specific QA program.

EP-1593

Plan specific pitch on Tomotherapy-plans effect on gamma pass rate for patient QA measured on Delta4

A. Haraldsson¹, A. Hauer Karlsson¹, L. Ambolt¹, P. Engström¹

¹Skåne University Hospital, Radiation physics, Lund, Sweden

Purpose or Objective: The purpose of this study was to analyze if the change from standard pitch to individually optimized plan specific pitch values on our Tomotherapy plans had effect on the measured gamma pass rate for our patient QA. Tomotherapy is helically delivered with a pneumatic MLC where each leaf is either closed or open. Pitch on Tomotherapy is the overlap each rotation has with the previous at isocenter; or rather, the couch distance traveled per gantry rotation, and is dependent of collimator width. Our hypothesis is that the change from fixed pitch values, 0.215, 0.287 and 0.43 for field width of 1.05, 2.5 and 5.02 cm respectively, to values calculated individually based on fraction dose, targets position relative to isocenter and field width, will increase the gamma pass rate due to less stress on the mlc.

Material and Methods: At our clinic, all patients undergoing Tomotherapy are planned individually and approved plans are measured on the Tomotherapy with a Delta4, prior to treatment. Gamma pass/fail criteria is 90% at DTA: 2mm and DD: 3% when planned dose distribution is compared with measured. Recently, we started using individually optimized plan specific pitch values. These values are calculated using a program, based on the works of Chen M, Chen Y, Chen Q, et al. Med. Phys. (2011). The ripple effect, which is peak to trough dose relative to average in longitudinal direction is caused by pitch when the target is not at isocenter. This puts stress on the mlc during delivery when the optimizing software tries to compensate the non-optimal overlap with mlc movement. A too low pitch also puts unnecessary stress on the mlc when the gantry rotations are low and thus increases the fraction of mlc movement that are close to mlc latency time, 20ms. A more careful selection of pitch should reduce the ripple effects and use an optimal gantry rotation period, around 20s, that in effect puts less stress on the mlc-pneumatics. We analysed the difference in results of our measurements before and after we started using individually optimized plan specific pitch values.

Results: Our measurements are approximately truncated normally distributed, and with higher gamma pass rate on average after the introduction of plan specific pitch values (M=97.4%, SD=2.08), then with fixed values as used previously (M=95.1%, SD=3.67). As presented in table 1, we have an increase in pass rate over 90%, 95% and 100%. After the introduction of plan specific pitch values, we have no reported plans with gamma pass rate under 90%.

TABLE 1: MEASURED GAMMA PASS RATE BEFORE AND AFTER INTRODUCTION OF PLAN SPECIFIC PITCH VALUES. DTA=2MM DD=3%.

	pre PSPV		post PSPV	
	Value	CI ₉₅	Value	CI ₉₅
NUMBER OF PLANS MEASURED	581		92	
FRACTION 100% PASSRATE	0.04	.05-.02	0.13	.21-.06
FRACTION < 90% PASSRATE	0.07	.09-.05	0.00	.01-.00
FRACTION >95% PASSRATE	0.66	.70-.62	0.82	.90-.73

Conclusion: An introduction of plan specific pitch values increases the pass rate of the patient QA when measured with Delta4.

EP-1594

On-line analysis of 4D treatment deliveries for scanned proton and carbon ion beams

S. Giordanengo¹, V. Monaco², A. Attili¹, A. Vignati¹, M. Varasteh Anvar², M. Donetti³, F. Marchetto¹, F. Mas Milian⁴, M. Ciocca³, G. Russo⁵, R. Sacchi², R. Cirio²

¹Istituto Nazionale di Fisica Nucleare INFN, Section of Torino, Torino, Italy

²University of Torino and INFN of Torino, Physics, Torino, Italy

³Centro Nazionale di Adroterapia Oncologica CNAO, Physics, Pavia, Italy

⁴Universidade Estadual de Santa Cruz, CNPq Fellow, Bahia, Brazil

⁵I-See s.r.l., Torino, Italy

Purpose or Objective: A tool for fast dose distributions analysis in hadrontherapy is presented, which integrates on GPU a Fast Forward Planning (F-FP), a Fast Image Registration algorithm (F-IR), a Fast Gamma-Index (F-GI) and Fast DVH computations. The tool will be interfaced with the dose delivery system (DDS) of a synchrotron-based facility to investigate the feasibility to quantify, spill by spill, the effects of organ movements on dose distributions during 4D treatment deliveries.

Material and Methods: The F-FP was built by porting to CUDA the PlanKIT TPS, developed by INFN and IBA for proton and carbon scanned beams. The feature of choosing, among the 4DCT volumes, the CT volume corresponding to a specific respiratory phase (CT-phase) was added. To evaluate target movements, the 4DCT images are pre-processed (using C++ algorithms) to obtain the deformation vector fields. The F-IR uses the latter to map the dose calculated on a CT-phase to the CT volume used to plan the treatment (CT-reference). The F-FP runs twice to calculate in parallel the planned dose (on the CT-reference), and the delivered dose (on the CT-phase mapped on the CT-reference by the F-IR). Finally, the comparison between the two dose distributions is performed through fast F-GI and DVH computations to quantify the dose deformation due to intra-fraction anatomical changes.

The NVIDIA Tesla K40c in a Workstation (WS) HP Z820 (2xIntel XeE5-2670v2) was used. The WS will be interfaced with a clinical DDS and an optical tracking system (OTS) to test the operations on-line. The tool will receive in real-time the measured beam parameters through a direct and transparent connection with the DDS using FPGA boards.

Results will be promptly shown in the local control room.

Results: A preliminary version of the F-FP has been tested for physical and biological doses for protons and carbon ions, showing total execution times within 1 s, and negligible absolute differences ($<10^{-4}$ Gy) compared with PlanKIT results. The F-GI and DVHs computation times are of the order of few ms, while the F-IR will be within 1 s. The times for data transfer are negligible.

The overall system operations and the execution times are summarized in Fig 1.

Fig. 1

Conclusion: A GPU-based tool for dose distributions analysis in hadrontherapy has been developed and will be interfaced with clinical DDS and OTS. The preliminary results suggest its possible use to on-line quantify the effects of target movements during 4D treatment deliveries with scanned proton and carbon ion beams.

EP-1595

Impact of different dose calculation algorithms on aperture-based complexity metric evaluations

A. Bäck¹, A. Larsson¹, J. Götstedt², A.K. Hauer¹

¹Sahlgrenska University Hospital, Therapeutic Radiation Physics, Göteborg, Sweden

²University of Gothenburg, Radiation Physics, Göteborg, Sweden

Purpose or Objective: The objective is to evaluate the impact of different dose calculation algorithms on the correlation between aperture-based complexity metric scores and field complexity, i.e. difference between calculated and delivered dose.

IMRT/VMAT treatment fields composed of small MLC sub-openings cause discrepancies between planned and delivered dose and are considered complex. Aperture-based complexity metrics have been suggested to quantify this complexity. The correlation between such metric scores and complexity, determined by comparisons of calculations and measurements, were evaluated for static MLC openings representing control points in an IMRT/VMAT treatment plan (Götstedt et al Med Phys 2015; 42: 3911). Different dose calculation algorithms have different built-in limitations that affect the deviations between calculations and measurements and thereby the correlation.

Material and Methods: The dose calculation algorithms studied were the pencil beam convolution (PBC), the analytical anisotropic algorithm (AAA) and the Acuros XB (AXB) in Eclipse treatment planning system (TPS) and the collapsed cone (CC) in Oncentra TPS. The study focus on the complexity metrics, *converted aperture metric* and *edge area metric*, described by Götstedt et al. The same 30 MLC openings of various complexity divided in series of five to describe similar patterns with increasing complexity created by Götstedt et al were used also in this study. The MLC openings were measured with Gafchromic® EBT3 film in solid water on three repeated occasions and compared to different calculations by evaluating the 3% and 5% dose difference (dd) pass rate.

Results: Examples of the correlation between the *edge area metric* and 5% dd pass rate for the 30 MLC openings are shown in the figure for AAA and AXB. The error bars show the standard deviation of the three measurements.

The linear correlations, expressed in Pearson's r-values, between the dd evaluations and the metric scores for the different calculation algorithms are summarized in the table.

	converted aperture metric		edge area metric	
	3% dd pass rate	5% dd pass rate	3% dd pass rate	5% dd pass rate
PBC	-0.93	-0.89	-0.95	-0.94
AAA	-0.85	-0.80	-0.90	-0.84
CC	-0.85	-0.73	-0.91	-0.85
AXB	-0.70	-0.52	-0.81	-0.71

The highest and lowest r-values were seen for the PBC- and the AXB-calculations, respectively. The r-values for the AAA- and the CC-calculations were similar. The *converted aperture*

metric show a somewhat larger influence of the calculation algorithm used compared to the *edge area metric*.

Conclusion: Different dose calculation algorithms can influence on the correlation between aperture-based complexity metric scores and complexity of the treatment field. The impact is different for different metrics.

EP-1596

Intraoperative radiotherapy with electrons in breast cancer patients with cardiac devices.

R. Luraschi¹, R. Lazzari², V. Galimberti³, A. Bazani¹, E. Rondi¹, M. Leonardi², G. Corso³, N. Colombo⁴, B. Jereczek-Fossa^{2,5}, F. Cattani¹

¹European Institute of Oncology, Physics Department, Milan, Italy

²European Institute of Oncology, Radiation Oncology Division, Milan, Italy

³European Institute of Oncology, Molecular Senology Unit, Milan, Italy

⁴European Institute of Oncology, Cardiology Unit, Milan, Italy

⁵University of Milan, University of Milan, Milan, Italy

Purpose or Objective: To evaluate the feasibility and the safety of delivering intraoperative radiotherapy (ELIOT) to the tumor bed in breast cancer patients with cardiac implantable electrical devices as part of breast conservative treatment. Cardiac devices, as pacemakers or defibrillators, can suffer from malfunctions as a result of exposure to ionizing radiation. Scattered radiation can be harmful as direct radiation as well. Measurements of absorbed dose during ELIOT in the subclavicular region supposed to house cardiac implantable electrical devices were carried out in healthy patients without heart disease. The aim of the study is to verify that the intraoperative dose does not exceed the recommended maximum dose of 2 Gy.

Material and Methods: The present analysis was performed on 18 out of 25 patients considered for the study. After signing the informed consent, all patients underwent breast conserving surgery. After tumor removal and before delivering ELIOT to the tumor bed, two catheters, each of them containing 8 thermoluminescent dosimeters (TLDs), were placed. The first catheter, the internal one, was attached to the thoracic shielding (an aluminum-lead disk of 7-8 cm in diameter) and became an integral part of it. The shielding was located beneath the reconstructed breast parenchyma of the tumor bed, to minimize the dose to underlying tissues and its tip was positioned in the subclavicular region, where cardiac devices are supposed to be. The second catheter, the external one, was placed on the skin, parallel to the first one, next to the applicator (4-5 cm of diameter, flat or 15° beveled). The TLD reading showed the absorbed dose due to the scattered dose correlated to the distance from the applicator.

Results: Given a prescribed dose of 21 Gy at 90% isodose, the external TLDs on the skin read a mean dose of 0.32 Gy (range, 0.10 - 0.55 Gy), measured starting 1.5 cm from the applicator wall up to 10.5 cm. By evaluating the doses measured by TLDs in the internal catheter, the minimum distance considered safe for cardiac devices was found to be 2.5 cm from the applicator wall. In fact, at that distance, the cumulative scatter radiation dose was lower than 2 Gy. Comparing the data from the two catheters, higher doses were measured in the internal catheter compared to the external one. Therefore, the main source of scattered dose was the patient herself rather than the mobile accelerator.

Conclusion: Final results are not available yet, as the study is ongoing. However, on the basis of analyzed data, ELIOT seems to be safe for patients using cardiac devices as long as the minimum distance of 2.5 cm is kept between the cardiac device edge and the applicator wall. No correlation with tumor site and electron energy was observed. When clinically indicated, ELIOT might be a valid alternative to external irradiation, which is conditioned by the low threshold dose for cardiac devices, as recommended by current guidelines.

EP-1597

Investigation of in-air output ratios in FFF beams

M. Dalaryd^{1,2}, T. Knöös^{1,2}, C. Ceberg²

¹Skåne University Hospital, Radiation Physics, Lund, Sweden

²Lund University, Medical Radiation Physics- Clinical Sciences, Lund, Sweden

Purpose or Objective: The in-air output ratio (S_c), describes how the photon fluence per monitor unit varies with beam collimator settings. In this study, the contribution from different accelerator head components to the total S_c was investigated for fields generated with and without a flattening filter in the beam line.

Material and Methods: Using the EGSnrc-package, a Monte Carlo model of the accelerator head of an Elekta Synergy linac has been built and verified with measured lateral and depth-dose profiles. Four different energy/filter combinations were simulated, one conventional 6 MV beam with a flattening filter (FF), two flattening filter-free (FFF) beams where the flattening filter was replaced by a 2 mm thick iron plate and the incident electron energy was kept the same as for the FF beam or increased to produce a similar depth-dose curve as the FF beam, and one untuned beam without any filter in the beam line. S_c was calculated as the ratio of primary collision water kerma (K_p) for any collimator setting to a reference collimator setting ($10 \times 10 \text{ cm}^2$) for the same number of monitor units as defined in Zhu *et al.* (Med Phys 36 5261-91, 2009). K_p was derived from a photon spectra scored in air in a circular region with a radius of 0.5 cm centred on the central axis 100 cm from the target for collimator settings ranging from $3 \times 3 \text{ cm}^2$ to $40 \times 40 \text{ cm}^2$. The contributions from different parts of the accelerator were evaluated using the LATCH variable. The calculated S_c was compared to measurements performed with a farmer ion chamber with a 2.5 mm brass build-up cap.

Results: Calculated S_c were within 0.4 % of measured values for both FF and the energy matched FFF beam. Unscattered photons, i.e. photons only interacting in the target, were, as expected, found to be invariant relative to the reference field and accounted for 98 % and 92 % of the total S_c for the conventional FF beam, for the $3 \times 3 \text{ cm}^2$ and $40 \times 40 \text{ cm}^2$ fields, respectively. For the FFF beams this proportion was increased to 99 % and 96 % for the untuned beam and to 99 % and 97 % for both the tuned FFF and the beam without metal plate (Fig 1). For the FF beam, photons having interacted in the flattening filter are the major contributors to the variation in S_c for fields larger than $10 \times 10 \text{ cm}^2$, while for smaller fields the contribution from photons interacting in the primary collimator have an equal or slightly larger impact. However, for the FFF beams, photons interacting in the primary collimator are the largest contributors to S_c for all field sizes and the difference in contribution from the metal plate (if any) and secondary collimators are within the uncertainty of the calculated values.

Conclusion: In-air output ratios were successfully calculated as the ratio of Kp for beams with and without a flattening filter. For FF beams the flattening filter and primary collimator was the largest contributors, while for beams with 2 mm Fe or no filter in the beams line the primary collimator accounts major part of the variation of Sc.

EP-1598

Initial validation of a commercial algorithm for volume dose reconstruction with ionization chamber

J. Garcia-Miguel¹, C. Camacho¹, J. Saez¹, C. Quilis¹, A. Herrerros¹

¹Hospital Clinic, Oncologia Radioteràpica, Barcelona, Spain

Purpose or Objective: We report on our initial experience with the commissioning for fixed-field IMRT of the dose reconstruction algorithm on a phantom with measurements from a helical diode detector array (ArcCheck (AC) from Sun Nuclear (SNC)).

Material and Methods: We designed a set of tests to check on the performance of the dose reconstruction software, 3DVH, which reconstructs the dose inside the AC device from the entrance/exit diode measurements. Dose was measured with and without a small volume ionization chamber (0.125 cc semi-flex by PTW). Dose in the position of the ionization chamber was estimated with the help of 3DVH. TPS calculated dose and reconstructed dose were compared to the ionization chamber dose.

Linearity was assessed by irradiating 10x10 cm² open fields with different isocenter doses: 0.4, 1, 1.6, 2.2 Gy. The electron density override on the CT for the AC was validated with a 2%-2mm gamma analysis on the open fields. Then a set of sliding window gaps (6, 10 and 14 mm) was irradiated with a number of MU matched to obtain 1 and 1.6 Gy at the isocenter plane. The mock cases from TG-119 were transferred to the AC CT for inverse optimization. Finally 16 clinical HN cases were also irradiated. In the mock and HN cases dose was measured in a high dose-low gradient point of the volume.

Results: The dose calculated with 3DVH for the 10x10-cm open fields was lower than the dose measured with the ionization chamber by 1.32% on average. Dose linearity was confirmed and the gamma passing rates were better than 95% for 2%/2mm criteria for all cases which confirmed our electron density override on the AC.

The ratio between the dose delivered with each sweeping gap and a 10x10cm² field with the same planned dose was calculated. The value of this relationship obtained from the doses reconstructed with 3DVH was 5% larger than expected, while the value calculated with Eclipse TPS and with the ionization chamber were 0.999 and 1.001, respectively.

For the TG-119 cases we obtained that the reconstructed dose is 0.28% higher on average than the measured dose. The biggest discrepancy between reconstructed and measured dose was for the MultiTarget case, with a reconstructed dose 1.42% higher than the ionization chamber measurement. The mock H&N case was the best of them, with an error of 0.29% between reconstructed and measured dose. The average on the reconstructed dose with 3DVH for the 16 clinical patients was 0.78% lower than the camera, being 0.07% the smallest error and 2.91% the largest one.

Conclusion: Reconstructed doses over the AC phantom with 3DVH software are in good agreement with measurements for open fields and also for mock cases and clinical patients. However, differences between calculated and measured doses for simple sweeping gaps are inexplicable large and require further investigation.

EP-1599

How far can we go? Reliability of gamma evaluation in IMRT plans.

M. Gizynska^{1,2}, E. Fujak¹, A. Walewska¹

¹The Maria Skłodowska-Curie Memorial Cancer Center, Medical Physics Department, Warsaw, Poland

²University of Warsaw, Faculty of Physics, Warsaw, Poland

Purpose or Objective: The Intensity-Modulated Radiation Therapy (IMRT) is a widely used treatment for many cancer sites. Independent verification in this kind of treatment is recommended and some countries require it. There are many different ways of pre-treatment verification e.g. point dose measurement, 2D or 3D dose verification and various methods of interpreting the verification result. One of the most popular way is gamma evaluation [Depuydt, 2002]. The aim of this study was to identify the relationship between simulated MLC errors and gamma evaluation result. We compared RTdose for error-induced plans with original plan, both calculated in specified phantom used for verification. Such comparison enabled us to obtain result of gamma analysis influenced only by known MLC error, ceteris paribus.

Material and Methods: Verification Plans for ten patients for each of three cancer sites (brain, prostate, head and neck) were prepared. For every case original and modified MLC has been used. Two types of MLC errors were tested: open/close error in which both MLC banks moved in opposite direction and shift error with both MLC banks moved in the same direction. Magnitude of these errors were 0.5, 1.0, 2.0, 3.0 mm. The MLC errors were simulated for all control points, on both banks of active MLC leaves only. The dynamic leaf gap and other MLC physical constraints were taken into consideration. For each plan dose distribution was calculated in Eclipse (AAA v. 10.0.28) for phantom geometry and original gantry angles. Afterwards gamma evaluation was performed with the Verisoft software (PTW, v. 6.1). We investigated results for gamma 3mm/3%, 2mm/2%, 1mm/1% for local and maximum dose difference. The suppressed dose value was set to 10% for 3D gamma evaluation.

Results: For head and neck plans MLC open/close errors, equal or larger than 1mm, weren't detected only for gamma 3mm/3% max dose and passing rate 95%. For brain and prostate plans 2mm open/close errors can be detected with gamma 3mm/3% local and 2mm/2% max dose. For all investigated cancer treatment sites shift errors are hard to detect (1 mm only with passing rate 95% gamma 1mm/1%). For detailed results see Figure. We assume that difference between treatment sites is related to the leaf open/close error (gap width error) as was reported by LoSasso [1998] and plan modulation.

Conclusion: MLC errors may be a reason of unacceptable result of pre-treatment verification. Selection of gamma passing rate and criteria should be preceded with analysis of MLC error which can be detected by used verification method. In the case of Octavius 4D we recommend using 3mm/3% local dose for 3D gamma evaluation in previously mentioned cancer sites. Other cancer sites should be also investigated and tested. Next step should be checking the

influence of dose resolution (re-sampling of the simulated dose distribution to the detector resolution) on gamma result. Clinical relevance of such MLC errors should be also investigated.

EP-1600

VMAT lung SBRT: 3D evaluation in pretreatment patient QA and in vivo dose verification

E. Villaggi¹

¹AUSL Piacenza, Fisica Sanitaria, Piacenza, Italy

Purpose or Objective: SBRT requires patient specific-QA with high spatial resolution, stability and dynamic range. EPID dosimetry has been proofed to be efficient to give accurate results for both conventional and special treatments. In this work, a commercial QA software is used for a lung SBRT clinical case to obtain 3D dosimetry from fluences measured by EPID gantry angle-resolved data acquisition. The purpose is obtain information on actual delivered dose to the tumor volume and surrounding critical structures in terms of clinical dosimetric parameters which are meaningful for both physicians and physicists.

Material and Methods: VMAT SBRT lung treatment is planned by Varian Eclipse treatment planning system using ACUROS algorithm. Treatment is delivered using a Varian2100CD linear accelerator's 6 MV x-ray beam. Fluences are acquired on a Varian aSi1000 EPID. Dosimetry Check (Math Resolutions LLC) is a commercial QA software performing 3D treatment plan verification: the necessary measurements for the exit image kernel for SBRT includes EPID images of various field sizes (minimum field size: 1x1 cmxcm). Fluence maps acquired on the EPID during pre-treatment QA and patient treatment are separately applied to the patient's CT. Agreement between planned and delivered dose distributions for patient-specific SBRT quality assurance is assessed for a lung case utilizing the gamma index method ad dose volume histogram (DVH)-base metrics. The stereotactic approach requires a tight margin: the distance to agreement criterion is set to 1mm. The dose difference is set to 3% if a homogeneous phantom is used and 5% for calculations on a heterogeneous CT set.

Results: Results include 3D gamma evaluation and dose volume histogram (DVH). Volumetric, planar, and point dose comparison between measured and computed dose distribution agreed favorably indicating the validity of technique used for VMAT SBRT QA. Gamma pass rate in axial, coronal and sagittal plane through the isocenter is respectively 93,4%, 86,3% and 95,1% for pretreatment QA; 92,8%, 82,6% and 76% for in vivo QA. 3D values are 89,4% and 90%. Significant clinical structure values from DVH are shown in Table 1.

Table 1. Target and OAR DVH parameters for a lung case (54 Gy in 3 fractions)

Parameter	Treatment Planning	pre-treatment measurement	in vivo measurement
PTV- D98 (Gy)	52,90	49,50 (-6,4%)	52,25 (-1,2%)
PTV- D2 (Gy)	56,05	55,95 (-0,2%)	60,65 (+8,2%)
PTV- D50 (Gy)	54,75	55,85 (+2,0%)	57,25 (+4,6%)
PTV- Dmean (Gy)	54,64	55,85 (+2,2%)	57,10 (+4,5%)
Spinal Cord - D2 (Gy)	9,2	9,4 (+2,2%)	10,0 (+8,7%)
Spinal Cord - D1 (Gy)	9,6	9,7 (+1%)	10,3 (+7,3%)
Esophagus - V18Gy (cc)	0	0	0,06
Omolateral Lung V12Gy (%)	24,9	25,5 (+2,4%)	28,3 (+13,6%)

Conclusion: An efficient procedure of verifying VMAT lung SBRT plans with high accuracy has been obtained. Results from a clinical case are presented in terms of doses to the anatomical structures and in terms of gamma evaluation. Dosimetry Check system employes a pencil beam algorithm in order to calculate dose from fluence measurements taken with the EPID. It can be assumed that some dose differences will arise from the pencil beam algorithm used in Dosimetry Check and the more sophisticated algorithms used in TPS. Differences may depend on the level of heterogeneity of the

anatomical site. Further research is needed to assess these differences.

EP-1601

Dosimetric consequences of using two common energy matching techniques in Monte Carlo

L. Shields¹, B. McClean²

¹University College Dublin/ St.Luke's Radiation Oncology Network, School of Physics/ Medical Physics, Dublin, Ireland Republic of

²St.Luke's Radiation Oncology Network, Medical Physics, Dublin, Ireland Republic of

Purpose or Objective: The aim of this abstract was to report the observed differences between measured and Monte Carlo (MC) calculated dose distributions when using common incident electron energy matching techniques.

Material and Methods: PDDs and profiles on a 6MV Elekta Precise linac were acquired in a PTW MP3 watertank with a semiflex chamber (0.125cm³) at 90cm SSD. A MC model of the linac was created in BEAMnrc. Phase Space files were scored at 90cm from the target at a plane perpendicular to the direction of the beam. The phase space files were used as an input into DOSXYZnrc to calculate dose in a water phantom (60x60x30cm², 90cm SSD, voxel size=0.3x0.3x0.3cm³). The incident electron beam was set to have a Gaussian distribution with a FWHM in the GT and AB directions of 1.92 and 2.42 mm respectively. The energy spectrum of the incident electron beam had a FWHM of 0.5MeV and an energy window of ±0.6MeV. The mean energy of the incident electron beam was determined in two ways:

Method 1:

The mean energy of the electron beam was varied until the calculated CAX PDD matched the measured for a 10x10cm² photon field (between 5-25 cm). 40x40cm² dose profiles (90cm SSD, 10cm deep) were subsequently calculated and compared to measurement. Method 2:

The mean energy of the electron beam was varied until the calculated 40x40cm² dose profiles matched the measured profiles to within 0.5% (within 80% field width). A 10x10cm² CAX PDD (90cm SSD) was subsequently calculated and compared to measurement.

Results:

Results - 1:

The agreement between calculated and measured 10x10cm² CAX PDD was best (between 5-25cm) for an incident electron beam mean energy of 6.65MeV. The resultant 40x40cm² profiles at 90cm SSD, 10cm deep, revealed a reduction in the dose horns of 4% in comparison to the measured profile (Figure 1).

Results - 2:

The agreement between calculated and measured 40x40cm² profiles at 90cm SSD, 10cm deep was best for an incident electron beam with a mean energy of 6.2MeV. The resultant CAX 10x10cm² PDD revealed an agreement to within 1% (between 5-25cm) of the measured PDD.

Comparison of 40x40cm² profiles (90cm SSD, 10cm deep)

Figure 1. Comparison of profiles for the mean electron energy determined using both methods

Conclusion: The MC model of the linac revealed that CAX 10x10cm² PDDs are not very sensitive to changes in the mean energy of the incident electron beam. However 40x40cm² profiles reveal a high sensitivity to changes in the mean energy of the incident electron beam. The use of 10x10cm² CAX PDDs to match the mean energy of the incident electron beam can result in undesired differences between measured and calculated 40x40cm² profiles. However using 40x40cm² profiles to match the mean energy of the incident electron beam can provide an overall better match to measurement of both PDDs and profiles.

EP-1602

Redefinition of the Electron beam treatment parameters for IORT applications

A. Krechetov¹, D. Goer¹

¹Intraop Medical Corp, Research and Development, Sunnyvale, USA

Purpose or Objective: The large number of conventional electron accelerators on the market (we estimate it around 5000) far exceeds the small, but growing number of mobile IORT linacs suitable for unshielded operating rooms. In this paper we discuss the technical aspects of the treatment beams produced by such small mobile IORT linacs. Beam parameter characterization for such machines need to be redefined in order to better reflect mobile IORT applications and provide basis for future technological development in the industry

Material and Methods: Using currently accepted industry standards, we compared the following electron treatment parameters of conventional and IORT linacs.

Treatment field size and shape
Penetration depth
Surface dose
Beam Penumbra and Flatness
Treatment on angular surface

Parameter	Conventional	Mobile
Treatment field size and shape	Standard field size is 10cm + and is constrained by the collimator and cutouts on the distal end of the applicator to form the treatment area.	Size of the field is less than 10 cm, often 4-6 cm diameter. Usually circular, but some oblong applicators are available
Treatment on angular surface	Soft bolus placed on the patient surface can compensate for inhomogeneous distribution of sloping surfaces	All IORT applicators have bevel ends of 0°, 15°, 30° and sometimes 45° to match anatomic planes. The larger the bevel, the greater the dose inhomogeneity across the field.
Penetration depth	Quantized with about 1 cm step (3 MeV equivalent)	Quantized with about 1 cm step (3 MeV equivalent)
Surface dose	There are attempts to reduce surface dose to spare the skin	Surface dose should be as close to 100% as possible to provide optimal treatment
Flatness	Beam is generally quite flat	Beam is generally less flat. Standard flatness definitions are often non-applicable
Penumbra of the beam	Treating at a 5 cm distance. Due to very good flatness inside the treatment area, penumbra of the beam only affects exposure of the healthy tissue outside the treatment field.	Treating in contact with the tissue. Metal applicators provide almost 100% protection of the tissue outside the applicator, and penumbra now affects cold spots inside the applicator

Table 1. Comparison of the critical beam characteristics for conventional linacs and mobile IORT linacs

Results: The following key beam parameters are either not controlled at all for IORT, or controlled in a way that is not very clear and effective. Flatness of the beam: Not well defined. For the applicators 6 cm and below current flatness definition produces no sensible beam characterization.

Penumbra: Not well defined. For beam sizes under 6 cm, the 1 cm wide penumbra might lead to as much as 30% of the treatment volume being either underexposed, or “not properly accounted for”

PDD drop off and Surface dose: Not controlled. PDD curve can change significantly as a function of field size and energy spectrum. An ideal monoenergetic beam has parameters which are not desirable in most IORT treatments.

Effective treatment volume: Not defined or controlled. Very critical parameter. Ratio of the treatment volume with delivered dose above treatment threshold (e.g. 90%) to the

nominal treatment volume can be as low as 30% if cold spots are not properly accounted for.

Beveled applicator characteristics. Not defined or controlled. Procedures for testing of beveled applicators are very vaguely defined, and what definitions do exist are not very useful.

Conclusion: In order to properly redefine critical IORT beam parameters we present newly defined parameters such as controlled Flatness, PDD drop off, Surface dose and Effective treatment volume. When defined and controlled, these parameters will allow engineering teams to optimize the parameters of the treatment devices and provide the superior beam characteristics to improve treatment results. We also propose unified beveled and oblong applicator measurement protocol to summarize the knowledge currently present in the field.

EP-1603

Improved performance of the Varian TrueBeam Portal Dosimetry system for large fields

G. Beyer¹, P. Houston², L. Goodyear³, P. Davies³, J. McLellan²

¹Medical Physics Services Int'l Ltd, Medical Physics, Cork, Ireland Republic of

²Aberdeen Royal Infirmary, Radiotherapy Physics, Aberdeen, United Kingdom

³North Middlesex University Hospital, Radiotherapy Physics, London, United Kingdom

Purpose or Objective: The performance of the Portal Dosimetry (PD) used for pre-treatment verification is affected by the beam profile correction used in the MV imager dosimetry calibration. This study evaluates a simple method to improve the performance of the TrueBeam PD system.

Material and Methods: A 40x40 cm² diagonal profile measured at dmax is used as part of the imager calibration for the Portal Dosimetry software (PDIP). An over-response of the measured dose to predicted dose as the distance increases away from the central axis has been reported. Previous publications relating to the IDU20 panel have shown that manually modifying each point of the diagonal profile or applying software corrections can improve this off-axis effect. This method can be time consuming. A solution for the IDU20 panel with the Clinac model is available as part of the Varian Pre-Configured PDIP Package that utilizes an improved beam profile correction but is not currently available for the TrueBeam. The diagonal profile at d5 cm is almost identical with the profile at dmax up to about 10 cm and deviates downward as the distance increases. Using this profile for the calibration process could improve the off-axis areas of mismatch. The response of measured doses with predicted PDIP doses were evaluated in Varian TrueBeams equipped with either the IDU20 or the new DMI MV imaging panel. The PDIP algorithm was configured for use at 100 cm SDD following the manufacturer's guidelines. Plans were created to compare the predicted with measured dose obtained by calibrating the imager at dmax and at d5 cm for 6X and 10X. Open fields and complex fluence patterns were compared to those predicted by the PDIP to evaluate the

effect of the diagonal profile calibration in the dose measurements.

Results: Measurements of open fields showed an over-response (>3%) between measured and predicted doses at distances beyond 5 cm from CAX for IDU20 and beyond 10 cm from CAX for DMI calibrated with dmax profiles. Profile analysis for a 30x30 cm² field IDU20 panel calibrated using the d5 diagonal profile showed an improved match (<3%) up to X=12 and Y=8 cm for 6X and up to X=13 and Y=9 cm for 10X. The improvement for the DMI panel was up to 15 cm and 14 cm for 6X and 10X, respectively, in both X and Y (Fig. 1)

(a)

(b)

The backscatter from the IDU20 panel is not corrected with this method and resulted in an increased discrepancy in the Y direction. For the DMI panel, which has reduced backscatter, the calibration with the d5 profile yielded an excellent match between predicted to measured dose. Furthermore, for the DMI panel, the open fields gamma analysis improved by up to 5.3% for 6X and 15.2% for 10X. The test fluence patterns resulted in an improvement of up to 7.5% for 6X and 6.6% for 10X (Table 1).

Gamma analysis open fields (3%-3mm, 5% thresh.)				
Fluence field Imager (X x Y)	Diagonal d=dmax		Diagonal d=5 cm	
	6X	10X	6X	10X
Open 3 x 3	100.0%	100.0%	100%	100.0%
Open 5 x 5	100.0%	100.0%	100%	100.0%
Open 10 x 10	100.0%	100.0%	100%	100.0%
Open 15 x 15	100.0%	98.5%	100%	98.9%
Open 20 x 20	100.0%	97.2%	100%	98.0%
Open 30 x 30	94.7%	83.2%	100%	98.4%
Aida (25x12)	100.0%	100.0%	100.0%	100.0%
Chair (12x20)	99.9%	99.8%	99.9%	100.0%
Open (30x20)	100.0%	95.8%	100.0%	100.0%
Gradient (18x26)	100.0%	97.9%	100.0%	100.0%
Steps (30x16)	99.9%	94.4%	100.0%	98.3%
Steps (40x16)	88.1%	84.4%	95.6%	91.0%

Conclusion: The calibration of the imager panel using a diagonal profile at depth of d5 cm instead of the recommended depth of dmax resulted in an improved match between measured and predicted images for larger fields without affecting the results for smaller fields.

EP-1604

Evaluation of safety by skin dosimetry in Intraoperative Radiotherapy for breast cancer patients

J.H. Jung¹

¹Gangnam Severance Hospital Yonsei University Health system, Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: We investigated the safety of Intrabeam™ system, X-ray unit for intraoperative RadioTherapy (IORT) by measuring surface dose using Optically Stimulated Luminescent Dosimeter(OSLD).

Material and Methods: 30 patients were selected, who were in breast cancer patients and had an operation of breast conserving surgery (BCS). At the inner surface of tumor bed, 20 Gy were described, and 5 Gy at 1cm depth from the inner surface. Along the the size of tumor bed which could be decided after resection of tumor, the size of applicator were determined. Usual treatment time were from 18 to 40 minutes. For the measurement of surface doses, OSLD were placed at superior (U1,2), inferior(D1,2), lateral(L1,2) and medial(M1,2) directions from the center of applicator. Each direction, two OSLD were placed at 0.5 cm and 1.5 cm from the center. Mean, maximum, and minimum doses were analyzed to be compared.

Results: Mean values were U1 2.23±0.80 Gy, U2 1.54±0.53 Gy, D1 1.73±0.63 Gy, D2 1.25±0.45 Gy, L1 1.95±0.82 Gy, L2 1.38±0.42 Gy, M1 2.03±0.70 Gy, and M2 1.51±0.58 Gy. Maximum values were 4.34 Gy at U1, and Minimum values were 0.45 Gy at M2. 13.3 % of patient (4pts out of 30) were reported that surface dose were over 4 Gy.

Conclusion: The fact that skin dose of all patients were less than 5 Gy based on OSLD measurement showed the safety of Intrabeam™ system. In the relatively small breast volume, the tendency that surface dose was increased had been shown, which was analyzed by the data of patients who irradiated over 4 Gy at skin surface. Therefore, for appropriate indication for IORT, it is suggested that breast volume as well as the size and position of tumor should be carefully considered.

EP-1605

Dose from kV cone beam CT to lens, breast and gonads for children using different standard protocols

M.S. Assenholt¹, R. Hansen¹, J. Hansen¹

¹Aarhus University Hospital, Cancer Department, Aarhus N, Denmark

Purpose or Objective: With daily image guided kV cone-beam computed tomography (kVCBCT), dose to organs near the target can exceed 1 Gy during a treatment with 30 fractions. Treatment with proton radiation reduces the dose outside the tumor, and reducing the dose from kVCBCT gets even more relevant. Reducing the dose from kVCBCTs can be done by shrinking the area that receive kVCBCT or lower the dose used for the uptake of kVCBCT. Prior study showed that the mAs used for kVCBCT can be greatly reduced without reducing the image quality (B. Loutfi-Krauss, 2015). This study have measured and compared the dose to organs at risk in children using different kVCBCT protocols.

Material and Methods: The dose from kVCBCTs in the Varian TrueBeam™ accelerator were measured with thermoluminescence detectors (TLD), for lens, breast and gonads on CIRS anthropomorphic children phantoms age 1, 5 and 10 years.

The kVCBCTs where performed with three different standard protocols: Head 1, Head 2, Thorax and Pelvis. In table 1 the settings for the different protocols can be seen.

Protocol	kV	mAs	CTDIw [mGy]	FOV [cm]	Length [cm]	kV source skan range
Head1	100	146,4	2.8	26,2	17,7	90°->290°
Head2	100	146,4	2.8	26,2	17,7	340°->180°
Thorax	125	264	3.5	46,5	16,1	360°
Pelvis	125	1056	13.9	46,5	16,1	360°

In figure 1 the difference in image quality can be seen going from 133 mAs (optimized protocol) to 1064 mAs (standard pelvic protocol).

Results: For a scan in the head region going from Head1 to Head2 protocol reduced the mean dose to lens. For the 1 year old child the dose is reduced from 6,6mGy to 1,7mGy. For the 5 years old child from 6,6mGy to 1,4mGy. For the 10 years old child from 6,6mGy to 1,4mGy. For a scan in the Pelvis region changing the protocol from Thorax to Pelvis increased the dose to the Breast from 0,2 to 0,7mGy and Gonads from 13,6 to 57,8mGy for a 5 years old child. For a 10 years old child the breast dose is increased from 0,1 to 0,4 mGy and gonads from 11,8 to 46,0 mGy. With daily image guidance kVCBCT is performed up to 30 times. For the five year old child it is an extra dose to the gonads of $30 \times 44,2 \text{ mGy} = 1,3\text{Gy}$ changing the protocol from thorax to pelvis.

As seen on figure 1 the image quality drops going from pelvis to thorax protocol in the pelvic areas, but the opportunity for bone match is just as good with the thorax protocol.

Conclusion: It matters what protocol is used for the kVCBCT uptake. It is possible to reduce the dose remarkably when choosing the most optimized protocol.

Changing the scan range for head to avoid the lens reduce the lens dose with 471%. Another area where the scan range could be of great interest is the thorax region for girls. The radiation sensitive breast tissue can be spared if an appropriate scan range is chosen.

The image quality drops when mAs is reduced. But be aware of the purpose of the image. Often it is not necessary to see the soft tissue, since a bone match is performed. Being able to evaluate on bones does not require a high image quality. The next step is to define new dose reduced protocols for kVCBCT for each age group 1, 5 and 10 years, and the work will be finished before ESTRO 2016.

EP-1606

Second cancer risk after RT for rectal cancer: 3DCRT vs VMAT using different fractionation schemes

D. Zwahlen¹, L. Bischoff², G. Gruber³, U. Schneider²

¹Kantonsspital Graubünden, Department of Radiation Oncology, Chur, Switzerland

²University of Zurich, Faculty of Science, Zurich, Switzerland

³Klinik Hirslanden, Institute for Radiotherapy, Zurich, Switzerland

Purpose or Objective: To investigate if VMAT shows any disadvantage in terms of reduction of second cancer risk (SCR) compared to 3DCRT using different high dose fractionation schemes in patients treated with RT for rectal cancer (RC)

Material and Methods: 25 patients with stage I-III RC and pre- or postoperative RT were included in this ethics-approved retrospective study. Planning CT data prior to RT were used. CTV for rectal cancer was delineated using RTOG contouring atlas. Organs at risk (OAR) (ICRP 2007) contoured on each CT data set were bladder, colon, sigmoid, bone,

gonads, uterus, skin, small intestine, muscle, anus. PTV=CTV+5 mm. 3-field technique 6/15 MV 3DCRT and 6 MV VMAT plans were created (Eclipse, v.10, AAA-algorithm). Doses prescribed were 25x1.8 Gy and 5x5 Gy, respectively. Carcinogenesis model to estimate SCR emphasizes cell kinetics of radiation-induced cancer by mutational processes was used, integrating cell sterilization processes described by the LC model and repopulation effects. Model parameters were obtained by fits to epidemiological, cancer specific carcinogenesis data for carcinoma and sarcoma induction. From DVHs of structures of interest SCR in relation to organ equivalent dose (OED) was calculated. OED was converted to excess absolute risk for a western population for each organ as well as for all organs together. Resulting lifetime SCR from specific radiotherapy treatment was determined by lifetime attributable risk (LAR) by an integration of excess absolute risk from age at RT to lifetime expectancy (90 years)

Results: Mean LAR was highest for organs adjacent or close to PTV. Total LAR for VMAT and 3DCRT was 2.4-3.0% and 2.0-2.7%, respectively. For 5x5 Gy LAR was 1.4-1.9% for VMAT and 1.2-1.6% for 3DCRT and half as high as using 25x1.8 Gy. Median percentage LAR difference for OAR was significantly higher for VMAT irrespective of fractionation, and highest for bladder and colon. Individual differences in LAR ranged from 0.2-15.9% for 25x1.8 Gy and 0.1-9.6% for 5x5 Gy. Size and shape of PTV influenced SCR, and was highest for age 40 years. For a patient with additional lifetime of 60 years, LAR was 10% for 25x1.8 Gy and 6% for 5x5Gy. No difference was detected using VMAT or 3DCRT

Conclusion: For bladder and colon LAR is lower using 3DCRT, however difference is small. Compared to epidemiological data (Birgisson J Clin Oncol 2005) SCR is smaller when using a hypofractionated schedule treating RC. Total SCR is 2% at normal life expectancy. Risk is highest for young patients

EP-1607

CT imaging doses in radiotherapy - A single centre audit

K. Armoogum¹, G. Cornish¹, S. Evans¹

¹Derby Hospitals NHS Trust, Department of Radiotherapy, Derby, United Kingdom

Purpose or Objective: There is a growing awareness of dose delivered to parts the body outside the target volume during external beam radiotherapy. This concomitant dose could arise from external linac head leakage and scatter, scattered therapy dose outside the target volume, as well as non-therapeutic doses from imaging for planning and delivery, such as CT planning scans. Total concomitant dose has increased steadily with the introduction of more imaging procedures to the treatment process and the drive for better images quality. Much of this exposure is only loosely monitored and it could be the case that the cumulative concomitant dose has a negative biological effect even within the context of radiotherapy [1]. To quantify the dose contributed by CT planning scans, a retrospective dose audit was carried out on a TOSHIBA AQUILION LB multislice CT scanner at Derby Teaching Hospitals in July 2015.

Material and Methods: A cohort of 200 patients were identified, twenty each from ten of the most frequently used CT scanning protocols who were scanned in the 12 months immediately prior to the dose audit. Patients undergoing CT planning scans were initially identified in the Mosaic Oncology Information System (Elekta, Crawley, UK) and subsequently interrogated via the PACSWeb system, (Centricity Enterprise Web V3.0, GE Healthcare, Barrington, IL). Data harvested from PACSWeb included: Number of slices, slice thickness, CTDIVOL, DLP, Patient sex, Patient Age, total scan time, transverse width and AP width. Mean Effective Dose (E) was derived from values of DLP for each examination using appropriately normalised coefficients. As yet, there are no published UK national guidelines for planning CT scans. However, to put the results of this audit into context we have compared local DLP and CTDivol to similar values published for a previous UK national (diagnostic CT) dose audit [2]. The following relationships were

reported: CSA vs Age, CTDIvol vs CSA, DLP vs CSA, CTDIvol by Patient, DLP by Patient.

Results: The mean scan length, DLP, CTDIvol and Effective Dose by Protocol were found for each protocol. The most significant result was that the DLP values from the Head & Neck protocol were tightly clustered but higher than one would normally expect. The mean DLP was a factor of 4 greater than the head and neck reference level reported in the previous UK national (diagnostic CT) dose audit.

Conclusion: The results from this CT dose audit can be used as local Radiotherapy Imaging Reference Levels (RIRL). They will be able to guide protocol optimisation, allow comparison with other similarly equipped radiotherapy departments and participation in regional and national audits. The higher than expected DLP values for the Head & Neck protocol highlighted here has prompted a reassessment of the scanning parameters and may lead to protocol optimisation.

EP-1608

Radiation safety shielding for high dose rates from flattening filter free treatment modalities

S. Sawchuk¹, C. Lewis¹

¹London Regional Cancer Centre - Victoria Hospital, Physics and Engineering, London- Ontario, Canada

Purpose or Objective: Radiation safety for softer flattening filter free (FFF) treatment beams when operating at their very high dose rates should be considered over that of their flattening filter (FF) counterparts. Existing shielding is usually adequate when replacing treatment units utilizing beams of FF only with FFF-beams of the same nominal energy(1). However, depending upon the existing shielding composition and thickness, workload, and occupancy factors, the instantaneous dose rate (IDR) may present a radiation safety concern.

Material and Methods: A generalized analysis is presented with regards to replacing a unit which has only FF-beams to one with FFF-beams in a pre-existing bunker. Extra focus is placed on the situation that radiation levels around the treatment bunker are already at the radiation safety threshold for the unit being replaced. This threshold condition varies with the radiation safety regulations of the land. For example, the Canadian Nuclear Safety Commission (CNSC) imposes a condition that the IDR be less than 25 μ Sv/h to deem an area uncontrolled(3). The United States National Regulatory Council (US NRC) regulates the time averaged dose rate (TADR) to be less than 20 μ Sv in any one hour(2).

Results: It is demonstrated that in switching to FFF-beam treatment units that protection using existing shielding is maintained for annual and weekly equivalent dose protection levels. However, it is possible for the CNSC IDR condition to be exceeded at the highest dose rates for FFF-beams. Thus shielding modification should be considered along with the ALARA principle(4). An analysis of the latter point is presented in general and by example from such a treatment unit replacement at the London Regional Cancer Program. The US NRC regulation is not as stringent as the Canadian condition and is almost impossible to exceed if the conditions

before replacement were met. The analysis of this result is presented in general.

Conclusion: Care must be taken when considering the replacement of radiation treatment units with FF-beams to those with FFF-beams with respect to radiation protection. Radiation protection from the existing shielding is maintained for annual and weekly protection levels. However, IDR may present a radiation safety concern depending upon radiation safety regulations in the country of its location. In Canada, the possibility exists that this threshold can be exceeded. The US NRC condition is almost impossible to exceed.

EP-1609

CBCT and planar imaging dose for prostate and head-&-neck patients using 3 different imaging systems

Y. Dzierma¹, K. Bell¹, E. Ames¹, F. Nuesken¹, N. Licht¹, C. Rube¹

¹Universitätsklinikum des Saarlandes, Department of Radiation Oncology, Homburg/Saar, Germany

Purpose or Objective: In image-guided radiotherapy, imaging dose varies greatly with the imaging technique. We here present imaging doses from planar and cone-beam CT (CBCT) imaging for three different on-board imaging techniques: the treatment beam line (TBL, 6 MV), a dedicated imaging beam line termed kView of nominally 1 MV (IBL), and a kilovoltage system (kVision) at 70-121 kV photon energy. We consider two collectives of patients with common IGRT indications: head-and-neck and prostate cancer.

Material and Methods: In this study, we retrospectively analyzed imaging dose of 54 patients with head-and-neck cancer and 53 with prostate cancer treated in 2013. For all patients, the number of verification images (CBCT and axes) was determined, separately for the three systems (more than 1000 images). The dose for each verification image was calculated in the Philips Pinnacle treatment planning system on a 2 mm grid using the collapsed cone algorithm. We evaluated the dose maximum and dose to the organs at risk, considering the total imaging dose, and for the techniques (6 MV, IBL, kV, planar vs. CBCT) separately.

Results: The calculated imaging doses are given in Table 1. Both the TBL and IBL modality entail considerable imaging dose, even for orthogonal axes. The maximum dose value for each image, averaged over all prostate patients, was 14.8 cGy (6 MV CBCT)/ 2.8 cGy (19 %; 6 MV axes)/ 10.5 cGy (71 %; IBL CBCT)/ 2.1 cGy (14 %; IBL axes)/ 3.8 cGy (26 %; kV CBCT), where percentage values refer to the 6 MV CBCT dose. As can be seen, kV CBCT still amounts to 26 % the imaging dose from MV CBCT, and about twice the dose from IBL axes. Averaged over the collective of head-and-neck cancer patients, the maximum imaging dose was 8.4 cGy (6 MV CBCT)/ 2.6 cGy (31 %; 6 MV axes)/ 6.2 cGy (74 %; IBL CBCT)/ 2.3 cGy (27 %; IBL axes)/ 0.9 cGy (11 %; kV CBCT). Here, the dose reduction from axial images was not as pronounced because less monitor units were used for MV CBCT. kV CBCT reduced the dose further because of low mAs values chosen by the auto-exposure mechanism.

Maximum imaging dose and dose to organs at risk (average over all patients, standard deviation in braces, in cGy), for selected organs at risk. On average, CBCT were taken for prostate cases using 16 MU for 6 MV and 15 MU for 1 MV. The average mAs-value for kV-CBCT was 778 mAs (between 441 mAs and 1132 mAs). For head-and-neck cancer, CBCT were taken using 7 MU for 6 MV and 6 MU for 1 MV; the average mAs-value for kV-CBCT was 118 mAs (between 99 mAs and 177 mAs).

	6 MV CBCT	6 MV planar	1 MV CBCT	1 MV planar	kV CBCT

In our clinical setting, images were acquired at every second or third treatment fraction, resulting in a total median dose from imaging of 34.6 cGy for head-and-neck, and 70.6 cGy for prostate cancer patients. The relative frequency of the techniques and the contributions of the different techniques to the total imaging dose is shown in Figure 1.

Conclusion: The contribution of planar images to the imaging dose is smaller than the dose due to megavoltage CBCT, but not negligible in the clinical routine due to the larger number of planar images. The kV imaging modality has very small overall contribution to the imaging dose, which mainly arises from 6 MV and IBL (the latter being more frequently employed and therefore more prominent in the dose contribution).

EP-1610

A practical approach to assess cumulative dose of CBCT using standard CT dosimetry system

A. Abuhaimed¹, C. J Martin², M. Sankaralingam¹, K. Oommen¹, D. J Gentle³

¹Beatson West of Scotland Cancer Centre, Radiotherapy Physics, Glasgow, United Kingdom

²University of Glasgow, Department of Clinical Physics, Glasgow, United Kingdom

³Garthnavel Royal Hospital, Health Physics, Glasgow, United Kingdom

Purpose or Objective: In recent years, dosimetry in cone beam computed tomography (CBCT) has become an issue as the standard dose index used for CT dosimetry (CTDI100) fails to provide a satisfactory estimation of dose for CBCT scans. AAPM TG-111 proposed replacements of the CTDI100 with a measurement of a cumulative dose to address the problem. The cumulative dose for CBCT scans $f(0)$ is a point dose measured using a small ionization chamber in the middle of a

cylindrical PMMA, polyethylene, or water phantom of length ≥ 450 mm to achieve scatter equilibrium. Although this method overcomes the limitations of CTDI100, the use of longer phantoms is impractical in the clinical environment. A practical approach based on using the standard CT dosimetry system was introduced to assess $f(0)$.

Material and Methods: A function called $Gx(W)100$ was introduced in this study. It was defined as the ratio of $f(0)$ to a dose index $f100(150)$, which was proposed for CBCT dosimetry and equals the cumulative dose averaged over the length of a standard 100 mm CT pencil ionization chamber and measured within standard 150 mm long PMMA CTDI phantoms. Monte Carlo BEAMnrc and DOSXYZnrc codes have been used to simulate the On-Board Imager (OBI) system, and to calculate $f100(150)$ and $f(0)$. Standard 150 mm CTDI phantoms were simulated to calculate $f100(150)$, whereas infinitely long PMMA, polyethylene, and water phantoms were used for $f(0)$. The phantoms were in different diameters to represent head and body of an adult patient, a body polyethylene phantom being equivalent to the ICRU-AAPM phantom. $f100(150)$ and $f(0)$ were measured at the centre and periphery of the phantoms using beams of width 40-500 mm and beam qualities of 80-140 kV. $Gx(W)100$ was evaluated under different conditions with $f100(150)$ and $f(0)$ calculated with the same beam width (W) and at the same position (centre or periphery).

Results: Under the different conditions, $Gx(W)100$ showed a weak dependency on tube voltage over the range 80-140 kV. $Gx(W)100$, however, was influenced by diameter and composition of the phantom. Therefore, a set of $Gx(W)100$ functions based on the diameter and composition was developed to assess $f(0)$ in a given long phantom from $f100(150)$ measurements obtained within the short phantoms. $Gx(W)100$ provides a practical approach to avoid the use of long phantoms, which are impractical in the clinical environment, and hence simplify the AAPM method. Since the CT dosimetry system used for $f100(150)$ is available worldwide, this approach could help to maintain the standard equipment. The $Gx(W)100$ functions used in this study have been applied to a CT scanner, and showed a weak dependency on the scanner type. This gave an indication that $Gx(W)100$ may be comparatively independent of the type of imaging system.

Conclusion: $Gx(W)100$ function was proposed in this study, and was relatively independent of tube voltage and may be independent on the scanner type. $Gx(W)100$ allows measurement of $f(0)$ using the AAPM method with standard CT dosimetry equipment.

³Korea Institute of Radiological and Medical Sciences, Department of Radiation Oncology, Seoul, Korea Republic of

⁴Inje University Ilsan Paik Hospital, Department of Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: The CBCT (Cone-beam CT) is an image guided system verifying the precise location of tumor before the radiation treatment such as IMRT (Intensity-modulated radiotherapy) and SBRT (Stereotactic body radiotherapy) for accurate radiotherapy. However, the frequent use of CBCT scanning can induce the secondary tumor due to increase of radiation exposure to patients. With the CBCT scanning, treatment volume can be verified locally by changing the CBCT scan range. In this study, we evaluated regional organ dose according to CBCT scan range with Monte Carlo simulation.

Material and Methods: We modeled the CBCT system which built-in Varian Clinac iX with full-fan and half-fan filter by using the Monte Carlo code(MCNPX 2.7.0). By acquiring the measured data with EBT3 films for PDD(percent-depth dose) and beam profile for open, full-fan and half-fan filter in static mode, we verified that simulated data was coincided with measured data for spectrum. The assessment of absorbed dose of each organ during the CBCT scanning was performed with ORNL(Oak Ridge National Laboratory)-male-MIRD(Medical Internal Radiation Dose) phantom. In this study, we set the scan range adapted for the CBCT scan conditions and then the absorbed dose of each organ was evaluated applying a half-fan filter. In that time, the CBCT scan range was changed by modulating the Y jaw from 16 cm to 8 cm at intervals of 2 cm and we verified the difference of absorbed dose of each organ according to CBCT scan range.

Results: For CBCT scan in thorax, the absorbed dose of heart and lung were reduced for 46.6-32.1 mGy and 75-47.4 mGy, respectively, and the other side lung was reduced for 31.7-19.1 mGy. As the scan range was decreased at intervals of 2 cm, the absorbed dose in lung was reduced up to 10%. In the case of heart, the absorbed dose was reduced drastically. For prostate, absorbed dose of bladder, sigmoid colon and testes showed dose reduction for 61.4-41.7 mGy, 50.4-38.8 mGy and 81.1-45.4 mGy, respectively. In the case of penis, the absorbed dose was reduced from 81.1 to 45.4 mGy.

Conclusion: We evaluated the change of organ dose according to CBCT scan range with Monte Carlo code MCNPX and male-MIRD phantom. In the result, we verified the organ dose can be different about 30-40% according to changes of CBCT scan range. We thought this study can be used in optimization for radiation exposure to patients, usefully.

EP-1612

Optimizing breast imaging dose in CBCT using patient specific acquisition parameter

S. Deshpande¹, D. Dhote², K. Thakur³, M. Kumar⁴, R. Kumar⁴, A. Pawar³, A. Sutar¹, S. Naidu¹, V. Kannan¹

¹P.D. Hinduja National Hospital, Oncology, Mumbai, India

²Brijalal Biyani Mahavidyalaya, Department of Eletronics, Amravati, India

³Holy Spirit Hospital, Department of Radiation Oncology, Mumbai, India

⁴Bhabha Atomic Research Center, RPAD, Mumbai, India

Purpose or Objective: Defining patient specific Cone beam computed tomography (CBCT) acquisition parameter to optimize breast imaging dose

Material and Methods: Since last few years, in-room volumetric imaging systems which include MV computed tomography (CT) and MV or kV cone-beam computed tomography (CBCT) are being used for greater soft tissue definition and improved target localization. This technology helps in escalating target dose while decreasing normal tissue doses. This improves the therapeutic ratio of radiotherapy. Intense IGRT protocols are adopted to reduce the PTV margin and to understand changes happening during course of treatment. Additional imaging dose due to intense IGRT protocol is concern for deterministic and non-deterministic radiobiology effect. In this study we measure imaging dose to breast in thorax region from Varian on board imaging CBCT Three OSL dosimeters were placed on the contra lateral breast. One dosimeter was placed at centre and other two dosimeters were placed 5 cm apart from centrally placed dosimeter. Low dose thorax imaging protocol was used for all measurements. All CBCT acquisitions were performed with fixed geometry for all measurements. CBCT images were acquired with half-fan cone with bow tie filtration, source-detector distance of 150 cm, 0.25 cm slice thickness, transversal field-of view (FOV) of 25 cm, and a scan length of 18 cm giving a longitudinal FOV of approximately 17.5 cm. Scans were performed with 200 degree rotation of gantry. To get a reasonable signal, dosimeters were irradiated during five consecutive treatment fractions for the CBCT imaging protocols. For some patients CBCT images were acquired

using modified low dose thorax protocol also. In modified Low dose thorax protocol tube current was reduced from 20mA to 10 mA. Dose to contra lateral breast was measured in same three positions

Results: The absorbed dose per fraction using the CBCT for standard low-dose thorax protocol was 9 ± 0.30 mSv; for the "Modified Low dose thorax" protocol it was 4.8 ± 0.21 mSv; it can be seen that the "Modified Low dose thorax" protocol results in a reduction of 51% in absorbed dose compared to the standard low-dose thorax protocol. It was also noticed that, by changing acquisition parameters quality of both scans were comparable.

Conclusion: It is important to have patient specific acquisition protocol rather than vendor supplied protocol so that imaging dose can be optimized.

EP-1613

Comparison of peripheral doses associated to SBRT, VMAT, IMRT, FFF and 3D-CRT plans for lung cancer

⁶Universitat Autònoma de Barcelona, Departamento de Física, Barcelona, Spain

⁷Universidad de Sevilla, Departamento de Fisiología Médica y Biofísica, Sevilla, Spain

Purpose or Objective: Out-of-field doses during radiotherapy treatments (RT) are associated with an increased risk of second malignant neoplasms in cancer survivors. The purpose of this work is to evaluate the impact, in terms of peripheral dose (PD), that new techniques for lung cancer such as stereotactic body radiotherapy (SBRT), modulated beams (IMRT and VMAT) and FFF would have in comparison to more traditional plans (3DCRT).

Material and Methods: Self-developed models [1,2] were used for neutron and photon peripheral dose (NPD and PPD, respectively) estimation to 12 organs, associated to lung treatments delivered using 3 linacs: Siemens Primus (6&15 MV), Elekta Synergy (6 MV) and Varian TrueBeam (6,10&15 MV; FFF mode available for the first two). Facilities were previously characterized in terms of neutron production [3] and photon leakage.

17 plans were generated for a lung cancer case (60 cGy to 100%). Different PTVs were used for conventional and stereotactic treatments (factor of 20 between both volumes). Results were compared to values from the literature [4] where PD studies were done but by terms of direct measurements of only photon component for few external points.

Results: Figure (a) shows estimated NPD and PPD to some selected organs for SBRT treatments in 6 and 10 MV, including FF and FFF modes. Figure (b) shows average PPD to the same representative out-of-field organs (mSv) for 4 studied techniques, considering all the linacs and plans.

As an example, differences in PPD and NPD, for 3D-CRT and IMRT in low and high energies, are shown in the table. Taking into account leakage, field size and MU, an average increase in PPD values of 8.6% and 12.6% has been obtained for Varian and Elekta linacs with respect to Siemens, when considering for the here studied 3D-CRT treatment in 6 MV. However, a decrease in 19% was noticed when using FFF mode.

Organ	3D-CRT			IMRT		
	6 MV	6&15 MV	Neutron	6 MV	6&15 MV	Neutron
Thyroid	96.35	108.85	3.18	114.00	113.90	5.12
Red Marr.	62.35	71.30	8.98	73.45	74.75	9.24
Colon	60.10	72.85	0.95	69.15	77.40	0.93
Bladder	48.00	60.85	5.08	54.35	65.25	5.04
Liver	122.00	134.50	3.32	145.50	140.00	3.49
Bone	68.75	81.55	5.05	79.85	85.95	5.86
Skin	90.35	103.05	16.96	106.50	107.75	23.13
Remainder	83.30	93.30	2.56	99.00	97.45	3.42

Values in mSv

Conclusion: Lower PD in SBRT cases could be due to the smaller size of ITV vs. conventional PTV. Our results are in agreement with previous clinical studies [4]. Additionally, we have quantified the advantage of reduced PD when using FFF mode. However, this study only considers PD while ignoring the impact of radiobiological effect due to the dose per fraction.

The slight differences found between techniques (3D-CRT, IMRT and VMAT) are due to the simple case chosen (in terms of target geometry). Nevertheless, the tendency shows higher values for VMAT and IMRT. Thus, further studies are desirable to extrapolate these results to complex cases. Neutron contributes in a small percentage to global PD, this becomes especially relevant if 15 MV represents only a part of the total treatment.

EP-1614

Comprehensive validation of a Monte Carlo kV-CBCT model using OSL and spectral measurements
 H. Chesneau¹, D. Lazaro¹, J. Plagnard¹, C. Lafond², O. Henry², V. Blideanu¹

¹CEA LIST, LIST, Gif sur Yvette, France
²Centre Eugène Marquis, Medical Physics, Rennes, France

Purpose or Objective: The use of Cone-Beam computed Tomography (CBCT) is progressively increasing in radiotherapy treatments, but additional doses induced are not well quantified and could amplify the risk for patients to develop a second cancer. There is a need, expressed by the medical physics community, to develop tools to estimate, report and potentially help reducing CBCT doses. We hence developed a Monte Carlo (MC) model for the XVI kV-CBCT system. The dosimetric and geometric accuracy of the simulated beams was evaluated by comparisons with measurements in a water tank, and x-ray energy spectra acquisitions. Before clinical use, the model requires an evaluation in anthropomorphic phantoms in which were inserted OSL NanoDots (Landauer). The purpose of the present study is to develop an accurate dosimetric protocol

taking into account for OSL energy dependence in keV energy range.

Material and Methods: A MC model of the XVI was developed using the PENELP code. The dosimetric and geometrical evaluation of the beam MC models was performed by comparing simulations with lateral and depth-dose profiles measured using a PTW Farmer-type chamber, and on-axis energy spectra measured with a CdTe detector. These comparisons were performed at 120, 100 and 80 kVp, and for different filtration/collimation couples. For OSL measurements, the first step was to perform, in different beam qualities, in-air cross-calibrations with a PTW Farmer-type chamber. At this energy range, OSL exhibit strong energy dependence, so the signal needs to be corrected for the spectral variations between calibration and measurement conditions. Thus, to ensure accurate dose measurements, a correction method was developed using calculated spectra. The dosimetric protocol was validated by performing dose profiles with OSL inserted in a PMMA tube submerged in water. Preliminary comparisons with XVI model were made with acquisitions in a home-made heterogeneous phantom consisting of a water tank equipped with PMMA, bone and lung equivalent inserts.

Results: Experimental and simulated lateral and depth-dose profiles, and energy spectra, are in excellent agreement (Fig 1A). These results validate that the MC model accurately reproduces the dosimetric and geometric properties of the XVI beams. The uncorrected OSL profiles in the PMMA tube over-estimate by 15 % the calculated doses. However, energy corrected measurements are matching the simulations and the differences not exceed 7.5 % (Fig 1B and 1C). Table 1 presents doses measured at different points in the heterogeneous phantom and discrepancies not exceed 11.3 %.

Location in the phantom	Simulated doses (mGy)	OSL measurements (mGy)	Differences (%)
Lung (1)	23.5 +/- 0.3	25.6 +/- 2.1	9.0
Lung (2)	25.6 +/- 0.3	28.8 +/- 2.3	11.3
PMMA (1)	18.7 +/- 0.3	18.5 +/- 1.5	1.1
PMMA (2)	20.1 +/- 0.3	19.8 +/- 1.6	1.2
PMMA (3)	17.3 +/- 0.2	15.7 +/- 1.2	10.2

Table 1. Comparisons between OSL measurements in the heterogeneous phantom and simulations for a 360° CBCT acquisition at 120 kVp with a M20 type collimator.

Conclusion: The dosimetric protocol developed for OSL allows accurate measurements of imaging doses, and will be then used to validate the dose calculation tool in pre-clinical conditions. Preliminary results obtained in the home-made phantom highlight the accuracy of XVI MC model. Further validations are on-going in anthropomorphic phantoms.

EP-1615

Decreasing cone beam CT scan's doses and duration for breast cancer

T. Bora¹, I.F. Durmus¹, M.V. Ertekin¹, E.M. Fayda², S. Tokdemir Ozturk³
¹Yeni Yuzyil University Medicine Faculty Gaziosmanpasa Hospital, Radiation Oncology, Istanbul, Turkey
²Istanbul University, Oncology, Istanbul, Turkey

³Gebze Technical University, Physics, Kocaeli, Turkey

Purpose or Objective: to evaluate an automatic registration of partial cone beam CT scan's and full cone beam CT scan's position errors, durations and doses for Breast Cancer

Material and Methods: Before the IMRT treatment's of breast cancer patients using Versa HD, five breast cancer patients were scanned in the same position with partial cone beam CT and a full cone beam CT in sequence. The patient position errors were determined using automatic registration methods in both cases. The full cone beam CT parameters corresponded to the default VolumeView "Chest M20" preset in XVI 4.5; 360 degree, 180 deg/min velocity, 120 kV, 660 frames, 1056mAs and nominal scan dose of 22mGy. Partial cone beam CT parameters were set by us, we choosed S20 filter instead of M20 filter and for right breast; gantry angle was CW direction from 180° to 10°, for left breast; gantry angle was CW direction from 300° to 130°, 180deg/min velocity, 100 kV, 366 frames, 585.6mAs. Both cone beam CT scans were performed in sequence for five patients and position errors in 3 diemensions recorded using automatic registration method with for rotational bone value registration, gray value registration and rotational gray value registration.

Results: We compared partial cone beam CT scan's position errors with full cone beam CT scan's position errors. Firstly, we found an average difference of 1,46mm in lateral direction, 1.80mm in longitudinal direction and 1.96mm in vertical direction difference for bone value rotational automatic registration. Secondly, we determined an average 1,24mm in lateral direction, 1,36mm in longitudinal direction, 1,30mm in vertical direction difference for gray value rotational automatic registration. Thirdly, we determined an average 1,56mm in lateral direction, 1,88mm in longitudinal direction, 1,52mm in vertical direction difference for gray value automatic registration.

Conclusion: Most probably these differences are resulting from time difference between two cone beam CT scans and also it could be related with patient's breathing phase during scanning. Although the partial cone beam CT scan's image quality were worde than with full cone beam CT scan the automatic registration parameter's difference were below 2,0mm in 3 dimensions. When we measured radiation at the isocentre point using cylindrical ion chamber wih 30 cm x 30 cm solid phantom for both cone beam CT techniques, radiation dose decreased % 55±5 with partial cone beam CT scan. Additionally, Cone beam CT scan's duration decreased %40 with partial cone beam CT scan.

Secondary cancer induction of VMAT technique in breast irradiation: organ equivalent dose estimation

G. Guidi^{1,2}, N. Maffei^{1,2}, F. Itta², E. D'angelo³, B. Meduri³, P. Ceroni¹, G. Mistretta¹, A. Ciarmatori^{1,2}, G. Gottardi¹, P. Giacobazzi³, T. Costi¹

¹Az.Ospedaliero-Universitaria di Modena, Medical Physics, Modena, Italy

²University of Bologna, Physics and Astronomy, Bologna, Italy

³Az.Ospedaliero-Universitaria di Modena, Radiation Oncology, Modena, Italy

Purpose or Objective: Secondary cancer induction is a severe effect of Radiation Therapy (RT) treatments. Volumetric Arc Therapy (VMAT) techniques delivery dose distribution with a significant area and organs involved of low dose. We have evaluated, from the dosimetric data of patients treated using VMAT practice, the risk for contralateral breast and lung secondary tumor, estimating the Organ Equivalent Dose (OED).

Material and Methods: 30 patients, treated with VMAT techniques for breast cancer, were analyzed using the dose distribution. Based on the anatomical side of treatment (right and left side), the cohort was divided in two groups of treatment. We have calculated the OED of ipsilateral and

contralateral organs, relatively to the breast and lung tissues. Using the bell shaped model formula, we obtained the OED from the dose volume histogram (DVH) of each organ. Using a MATLAB® toolbox (DVH analyzer), the estimation of the OED values for contralateral and ipsilateral organ was assessed.

Results: The results, summarized in Figure1 and Table1, showed a mean ODE of +2,09±0,32Gy for contralateral lung, +1,94±0,32Gy for ipsilateral lung and +2,55±0,61Gy for contralateral breast. An ANOVA analysis showed that the side of treatment (left or right) was irrelevant for OED estimation (sign.≈1), confirming the independence by the VMAT techniques applied. The study confirmed that contralateral organs are the major tissue involved in risk of the secondary cancer risk, in particular for the contralateral breast. The OED showed, per patients' treated group, a variability of [2,1÷3,1] Gy for the right side and [2,2÷3,8] Gy for the left side. The OED for lung and contralateral lung had less variability in case of treatment. According with the radio sensitivity of the breast tissue, a special attention should be applied during the optimization and treatment to avoid possible variability in induced cancer risks.

Figure 1 OED vs. irradiated organs

	Contralateral lung	Ipsilateral lung	Contralateral breast
OED (Gy) All patients	2,09 ± 0,32	1,94 ± 0,32	2,55 ± 0,61
OED (Gy) Left side	2,15 ± 0,33	2,00 ± 0,42	2,49 ± 0,51
OED (Gy) Right side	2,03 ± 0,30	2,04 ± 0,16	2,61 ± 0,72

Table 1 OED vs. irradiated organs

Conclusion: The ODE data and bell shaped model, obtained from the DVH curves, can be used for the prediction of radiation secondary cancer induction. The OED values obtained showed the low risk of secondary cancer induction of the VMAT techniques compared with other literature data. Most uncertainties still remain related the time patterns of cancer induction and the specific dependencies to the organs rates. For RT plan optimization these factors are irrelevant; therefore, to endorse the safety distribution obtained by VMAT techniques, mathematical models obtained by the DVH and OED should be investigated with epidemiological absolute risk data of large patients' database.

EP-1617

Pre-treatment and in vivo fetal dosimetry in brain radiotherapy treatment during pregnancy

M. Valenti¹, M. Parisotto¹, C. Ardito¹, M. Puschi¹, S. Costantini², M. Cardinali², S. Maggi¹

¹Azienda Ospedaliero Universitaria Ospedali Riuniti, Medical Physics, Ancona, Italy

²Azienda Ospedaliero Universitaria Ospedali Riuniti, Radiotherapy, Ancona, Italy

Purpose or Objective: Radiotherapy treatment of pregnant women is a relevant problem in term of fetus radioprotection. A preliminary dosimetric evaluation of fetal dose could influence clinical decision of patient irradiation and, once the treatment has been approved, an accurate dose evaluation is important to estimate fetal radiation exposure risks. Fetal dose irradiation risks are described in AAPM report n.50 [1] and ICRP 84 [2] where is proposed a fetal dose limit of 10 cGy. In this work we describe dosimetric measurements related to a brain treatment for a pregnant woman in term of: preliminary measurements for optimal plan parameters assessment, pre-treatment in phantom dose measurements of approved plan and in vivo dosimetry to confirm pre-treatment evaluation.

Material and Methods: Treatment has been performed with 3DCRT on a Clinac 21 EX with dose of 60Gy in 30 sessions. At the time of dose evaluation patient was in 22° week of pregnancy. Distance from umbilicus to lower field edge is 53cm. Preliminary and pre-treatment measurements have been performed with both farmer ionization chamber in Rando phantom modified adding a water phantom and with TLD 100 in Rando phantom with bolus. Use of bolus over Rando phantom reproduces in a better way patient shape and dimension. During all treatment we perform daily in vivo TLD dosimetry. In preliminary measurement session we evaluate relation between fetal dose and: field dimension, collimator rotation, presence of MLC, use of enhanced dynamic wedge (EDW) and thickness of lead shielding. We also study change of dose with distance from radiation field edge and with measurement depth.

Results: About treatment parameters we observed an important dose reduction using 90° collimator rotation and using MLC [4]. Fetal dose increase with EDW is acceptable only for small angles. The more relevant parameters related to dose increase are distance from field edge and field dimension. These are anatomy related parameters and cannot be optimized. Considering measured value of fetal unshielded dose (in the range of 1-2 cGy) we decide to use 8mm thickness lead shielding [3]. In preliminary phase we observed a little increase in dose with depth as reported in [5]. Result of pre-treatment and in vivo measurement is reported in table 1.

Conclusion: Treatment parameters like collimator rotation, MLC or EDW strongly influence fetal dose. This aspect must be considered in patient plan preparation. Pre treatment dosimetry is important to estimate fetal clinical irradiation risk and to evaluate the need and thickness of lead shielding. In vivo dosimetry is always important to confirm pre treatment dose evaluation. Differences between pre treatment and in vivo dosimetry should be attributed to differences in patient and phantom shape, dimension and internal structure. In our case we can give a precautionary estimation of fetal dose of 1.6 cGy, a value below 10cGy limit proposed by [1,2]

EP-1618

IGRT Cone Beam CT : a method to evaluate patient dose
 F.R. Giglioli¹, O. Rampado¹, V. Rossetti¹, M. Lai¹, C. Fiandra²,
 R. Ropolo¹, R. Ragona²
¹A.O.U. Città della Salute e della Scienza di Torino, Physics Department, Torino, Italy
²University of Torino, Radiation Oncology Department, Torino, Italy

Purpose or Objective: to calculate organ doses for several protocols of a radiotherapy cone beam equipment using the PCXMC software, validated comparing doses with TLDs. Furthermore a set of coefficients to provide an estimation of organ doses was assessed for patients of different genders and sizes.

Material and Methods: The system in use was an Elekta CBCT (XVI) and the protocols analysed were four: head, pelvis, chest and chest4D with different parameters. The first part of the study investigated the opportunity to use PCXMC, a software based on Montecarlo simulation generally employed for projective radiology, for calculating organ doses. This commercial software allows the user to specify patient age and size, radiation beam geometrical setup, beam energy, filtration; a dosimetric indicator (entrance skin dose or DAP) is required to calculate final organ and effective doses. A new version of the software introduces the possibility to simulate rotational beams, subdividing the exposure in single contributions at different angles and performing the total doses calculation in a batch way. The software was adapted to better simulate the modulated filtration of this particular CBCT considering different filtered beam contributions. A set of 50 TLDs (Harshaw - TLD 100) was selected, irradiated and analysed, for each protocol, to compare measurements with PCXMC results. The influence of patient size on organ dose was evaluated varying heights, weights and genders. Three levels of height and weight corresponding respectively to the 5th, 50th and 95th percentile of US males and females adult population were considered. The organ doses were normalized to the PCXMC standard adult phantom doses and the calculated ratios were plotted versus the equivalent diameter of each patient size.

Results: The differences between PCXMC and TLDs doses are shown in table I for different protocols;

Protocol	Organ	PCXMC	TLD	diff%
Head and neck S20	Oral mucosa	0.89	0.82	8
	Salivary	0.93	0.95	-3
	Respiratory airways	0.84	1.01	-16
Simmetry S20 F0	Lungs	8.9	7.94	12
	Heart	10.1	10.18	-1
	Breasts	15.6	15.98	-2
Chest M20 F0	Lungs	21.7	19.1	14
	Heart	20.4	20.2	1
	Breasts	21.3	19.2	11
Pelvis M20 F1	Ovaries	19.7	22.3	-12
	Colon	16.4	18.21	-10
	Prostate	16.0	13.52	18
	Bladder	22.5	21.45	5

Table I Comparison of organ doses in mGy evaluated by TLD measurements in Rando phantom and by the PCXMC software.

The respiratory airways and the prostate show a difference over 15%, probably as a consequence of their position at the boundaries of the beam, with a critical match of exposure geometry for actual and virtual anthropomorphic phantoms. Regarding simulations with patients of different heights, weights and genders a variability in a range $\pm 40\%$ for pelvic region and $\pm 30\%$ for chest was observed; specifically, for the same acquisition protocol, organ doses for a slim patient could be much higher than the organ dose of an overweight patient. Fig 1 shows, as an example, dose correction factors versus equivalent diameters for breast with different protocols and relative fits.

Fig 1 correction factor vs patient equivalent diameter

Conclusion: Our results confirm the validity of PCXMC with rotational module also for particular geometrical conditions; patient dose can be evaluated based on patient equivalent diameter.

EP-1619

Ovaries and uterus Equivalent dose to in patients treated for Hodgkin Lymphoma with mediastinal RT

L. Spiazzi¹, M. Buglione^{2,3}, F. Trevisan², L. Baushi², N. Pasinetti³, R. Avitabile¹, F. Corrado¹, A. Polonini¹, R. Moretti¹, S.M. Magrini^{2,3}

¹Spedali Civili di Brescia, Department of Medical Physics, Brescia, Italy

²Brescia University, Radiation Oncology Unit, Brescia, Italy

³Spedali Civili di Brescia, Radiation Oncology Unit, Brescia, Italy

Purpose or Objective: Hodgkin's lymphoma (HL) is one of the most curable types of cancer. Most HL patients are young (average age of 32 years); long-term side effects of the treatment are becoming increasingly important. Infertility after treatment could have a high psychosocial burden for young patients. More, HL is one of the most common malignancies diagnosed during pregnancy. The aim of the present study is to measure dose to ovaries and uterus, during supra-diaphragmatic radiotherapy performed with different techniques (3DRT, IMRT, VMAT and helical IMRT-Tomotherapy®).

Material and Methods: Dose measurements were performed using the plans of four different female patients, in reproductive age. The patients have been treated with chemotherapy and mediastinum irradiation (isocenter dose 30 Gy). An adult anthropomorphic Alderson Rando phantom (*Rando phantom*) was utilized for woman simulation. For each patient the *Rando phantom* TC-scan was matched with the PET/CT. Doing it, an approximate patient specific isocenter position on the *Rando phantom* and a relative position of ovaries and uterus in terms of phantom slices were identified. Treatment planning images and diagnostic whole body PET/CT were fused by means of Velocity AI 3.0®. Calcium fluoride thermoluminescent dosimeters, TLD-100, were used for dose measurements, 5 TLDs were used for every measurement. Patient's treatment was simulated in 4 different techniques: 3DRT, IMRT, VMAT and helical IMRT-Tomotherapy®. To compare the results paired T student test was used.

Results: The equivalent doses to left ovary, right ovary and uterus, were respectively 16 mSV (range 5-19), 10 mSV (range 8-14) and 9 mSV (range 7-12) with 3DRT techniques; 15 mSV (range 7-23), 11.5 mSV (range 6-17) and 13 mSV (range 6-18) with VMAT; 14 mSV (range 6-23), 14 mSV (range 5-22) and 13 mSV (range 9-20) with IMRT and 54,5 mSV (range 44-70), 50mSV (range 40-72) and 56 mSV (range 33-67) with helical Tomotherapy®. Helical Tomotherapy® doses were significantly higher than the other three ($p < 10^{-8}$ for all three tests). IMRT results were significantly higher than VMAT and 3D ($p = 0,023$ and $0,004$ respectively). VMAT and 3D results are not statistically different one from each other ($p = 0,42$).

Conclusion: All the techniques give a dose to ovary and uterus well below 100 mSv. This is the dose considered safe in terms of deterministic effects on embryo or foetus and with a relatively low risk of stochastic effect. Helical Tomotherapy® and IMRT give higher gonads dose as compared to other techniques. The implications of these data may be relevant also for patients in the very early stages of their pregnancy.

EP-1620

Accuracy of cone beam computed tomography while decreasing dose to patient

A. Aasa¹, M. Vardja¹, K. Kepler²

¹Tartu University Hospital, Department of Radiotherapy and Radiation Oncology, Tartu, Estonia

²Institute of Physics, Training Centre of Medical Physics and Biomedical Engineering, Tartu, Estonia

Purpose or Objective: The main interest was to decrease the localization CBCT scan dose in lung area since the dose deposited by CBCT contributes fully in increasing low dose volume in lung which is arguably the main indicator of radiotherapy induced pneumonitis and fibrosis. Several scanning protocols with decreasing dose were investigated to confirm that the localization accuracy is not reduced.

Material and Methods: In this work it was investigated how do physical scanning parameters - voltage, current and time - affect the automatic image registration of the localization CBCT using XVI 4.5 system from Elekta. A Cathphan 504 phantom was used for image quality measurements and an anthropomorphic phantom PBU-50 was used to verify localization accuracy. 21 scanning protocols with decreasing dose and two different automatic registration algorithms (Grey value and Bone) were analysed in lung area. Deliberate shifts with different size and direction were introduced. Image quality of acquired scans was analysed using modular transfer function (MTF), uniformity and low contrast visibility. Relative scan dose was measured with centered Farmer chamber.

Results: It was found that CBCT system is rather insensitive to the size (max 20 mm) and direction of the deliberate shift of the phantom. Precision of the correction shifts were within 0,5 mm that is in the limit of estimated uncertainty. It was observed that the MTF was insensitive to physical scanning parameters and much more dependant on image reconstruction protocol parameters. Uniformity improved and low contrast visibility decreased while lowering dose of scanning protocol. The CBCT system under investigation showed excellent precision for positioning the phantom even while dose of scanning protocol was reduced -90%. On the other hand - low contrast visibility decreased and would most likely limit the amount of dose reduction to acceptable level that is still to be determined.

Conclusion: This work showed that CBCT is a very accurate localization method even in conditions where scanning dose was decreased to -10% of initial dose. It is necessary to further assess the suitability of new low dose protocols qualitatively to develop acceptable clinical scanning protocols as well as to investigate possibility to improve reconstruction protocols.

EP-1621

Automated extraction and management of radiotherapy imaging dose data

A. Reilly¹

¹Western Health and Social Care Trust, Medical Physics, Londonderry, United Kingdom

Purpose or Objective: To construct a data warehouse of radiotherapy imaging performance data by automatically extracting CT and CBCT acquisition and dose information from the hospital PACS and ARIA oncology management

system (OMS), thus allowing individual patient dose records to be monitored and radiotherapy imaging dose reference levels (DRLs) to be developed.

Material and Methods: DICOM query/retrieve is used to index and fetch CT dose report objects known to the PACS. Protocol information, patient details, CTDI and DLP are extracted. A script runs against the OMS and extracts CBCT activity information, including exposure settings and scan length. All information is converted into a standard format and stored in a data warehouse structured to make data exploration straightforward using readily available reporting and data mining tools. Data can be plotted and tabulated as a function of scanner, linac, operator, day of week, etc. Authorised operators can drill down to the patient, study and series level to understand the pre-treatment and linac imaging performed on individual patients and review the overall imaging dose record. Data can also be presented anonymised or pseudonymised for research, development and audit purposes.

Results: Table 1 shows data volumes and extract timings for a large centre (8 linacs with CBCT). The processing burden to update the data warehouse on a nightly basis is negligible.

Modality	Scanners / Linacs	Time Period	Number of Patients	Number Of Scans	Bulk Extraction Time
CT	3	Jan 2013 – Feb 2015	12,890	20,697	6 hours
CBCT	8	Jan 2013 – Feb 2015	1,898	21,256	5 mins

Table 1: Data volume and data extraction timing details.

Radiotherapy pre-treatment exposures were consistent with the equivalent diagnostic investigations and both were in line with local and national DRLs. There was clear evidence that when more advanced and automated linac imaging equipment is available more CBCTs are acquired (linacs VT1 and VT3 in Figure 1). Optimisation strategies can be studied by reviewing dose information alongside image quality and clinical decision making (see Figure 2, where dose differs between linacs and was deliberately increased when imaging a large patient).

Figure 1: Number of scans per linac as a function of time. Period from September to December 2014 has been selected.

Figure 2: Linac imaging dose record for large patient (pseudonymised). Dose differences between same protocol on different linacs can be observed, along with move to higher dose protocol to boost image quality.

It was found that ARIA does not always correctly record CBCT exposure information, although if linac imaging is protocol driven there is a unique relationship between recorded values and protocol selected. Also, body site information may be coded differently between CT scanners. Data warehouse mapping tables were employed to identify the actual CBCT protocols utilised and standardise site descriptions.

Conclusion: An automated data warehouse empowers professionals who are not IT experts to ask clinically relevant questions of a rich data source of imaging performance and dose information.

Cyberknife® M6TM: peripheral dose evaluation in brain treatments

N. Delaby¹, J. Bellec¹, J. Bouvier¹, F. Jouyaux¹, M. Perdrieux¹, J. Castelli^{1,2,3}, I. Lecouillard¹, V. Blot¹, J.P. Manens^{1,2,3}, C. Lafond^{1,2,3}

¹Centre Eugene Marquis, Brittany, Rennes, France

²Université de Rennes-1- LTSI, Brittany, Rennes, France

³Inserm U1099, Brittany, Rennes, France

Purpose or Objective: Radiosurgery (SRS) and stereotactic radiotherapy (SRT) are known to deliver very high doses per fraction. The corresponding peripheral dose can be a limiting parameter which potentially generates late toxicities. The purpose of this study was to evaluate peripheral dose delivered to healthy tissues such as thyroid and gonads for brain SRS/SRT treatments performed with a Cyberknife® M6TM system.

Material and Methods: Measurements were performed on a Cyberknife® M6TM (Accuray) equipped with fixed and IrisTM collimator systems. Doses were measured with GR200A (LiF:Mg, Cu, P) thermoluminescent dosimeters (TLD). Each TLD was individually calibrated in a 6 MV beam. TLD readings were performed with a PCL3 automatic reader (FIMEL). Firstly, in-vitro measurements were carried out in an anthropomorphic phantom (CIRS ATOM 701-c) for different typical brain treatment plans using different beam apertures (5 mm to 60 mm). Peripheral doses were measured at 24 points distributed from thyroid to gonads on the median line of the phantom (between 15 cm and 82.5 cm from the PTV center). Secondly, in-vivo measurements were performed on 30 patients, in 4 points representative of thyroid, breast, umbilicus and gonads. The number of monitor units (MU) used for treatment plans ranged from 5499 MU to 28900 MU with a mean value of 13737 MU, delivered in 1 to 3 fractions. Results were compared with peripheral dose published for previous Cyberknife® versions. Treatment plans were calculated with Multiplan v5.1.2 (Accuray). Peripheral dose were reported in cGy as percentage of the number of delivered Monitor Units (% of MU).

Results: Peripheral dose varied according to collimator size: 0.043 % of MU at 15 cm for a 5 mm collimator aperture and 0.235 % of MU at 15 cm for a 60 mm collimator aperture. For an intermediate collimator aperture (20 mm), peripheral doses were between 0.062 % of MU at 15 cm and 0.036 % of MU at 40 cm for fixed collimator system and between 0.040 % of MU at 15 cm and 0.029 % of MU at 40 cm for IrisTM collimator system. Table 1 compares our in-vivo measurements with peripheral dose published in the literature on several Cyberknife® models [1,2].

Table 1: Comparison between peripheral dose values measured for 5 Cyberknife versions in brain treatment

Device	Peripheral dose (expressed in cGy as percentage of the number of delivered Monitor Units (% of MU))				
	Cyberknife G4 preshielding	Cyberknife G4 postshielding	Cyberknife VSI preshielding	Cyberknife VSI postshielding	Cyberknife M6
Study		[1]	[2]	[2]	Our results
Dose measurement methods		In vivo (10 patients)	In vivo (21 patients)	In vitro	In vivo (31 patients)
Distance range from PTV and localization	[10,24] cm for Thyroid	0.220	0.170	0.160	0.066
	[28,44] cm for Thorax	-	0.050	0.108	0.048
	[60,89] cm for Pelvis	0.060	0.050	0.045	0.036

Conclusion: Peripheral dose for the Cyberknife® M6TM version is lower than previous Cyberknife® versions. Nevertheless, for a brain treatment the dose can reach 10 cGy in the thyroid and can exceed 7 cGy in gonads; it should be evaluated for every localization. Peripheral dose will depend on number of monitor units, beam aperture size and collimator system. These parameters should be optimized during treatment planning to limit peripheral dose as lower as possible.

EP-1623

Correlation of organ doses and IEC and AAPM methods for cone beam computed tomography (CBCT)

A. Abuhaimeed¹, C.J. Martin², M. Sankaralingam¹, M. Metwaly¹, D.J. Gentle³

¹Beatson West of Scotland Cancer Centre, Radiotherapy Physics, Glasgow, United Kingdom

²University of Glasgow, Department of Clinical Physics, Glasgow, United Kingdom

³Gartnavel Royal Hospital, Health Physics, Glasgow, United Kingdom

Purpose or Objective: Several dosimetric methods were proposed to overcome limitations of the standard dose index used for CT dosimetry (CTDI100) with cone beam computed tomography (CBCT). Two of these methods were proposed by IEC and AAPM. The aim of this project was to investigate the correlation between organ doses (ODs) resulting from head, thorax, and pelvic CBCT scans and the IEC and AAPM methods.

Material and Methods: The IEC method (CTDIIEC) is based on measuring CTDI100 using a reference beam and the application of a correction factor based on free-in-air CTDI measurements, while the AAPM method $f(0)$ is based on measuring cumulative dose using a small ionization chamber at the middle of an infinitely long phantom 450 mm.

CTDIIEC was evaluated within CTDI head and body phantoms, whereas $f(0)$ was assessed within 450 mm long CTDI phantoms. CTDIIEC and $f(0)$ were measured at the centre and periphery of the phantoms using head, thorax, and pelvic scanning protocols used in the clinic. ODs were evaluated in terms of absorbed dose to organs and tissues using Monte Carlo simulations on the ICRP-110 adult male and female reference computational phantoms. BEAMnrc and DOSXYZnrc user codes were utilized to simulate On-Board Imager (OBI) system mounted on a TrueBeam linac and to assess ODs using the same scanning protocols used for CTDIIEC and $f(0)$. The correlation was studied as the difference between weighed values (2/3 periphery:1/3 centre) of CTDIIEC,w and $f(0)$ w and ODs. The correlation was investigated for organs, which have higher weights of effective dose.

Results: For head scan, CTDIIEC,w were smaller than doses to bone marrow, brain, and salivary gland by 4-55% for male and by 16-84% for female. $f(0)$ w was also smaller than doses to bone marrow and salivary gland by 7-26% and 49-50% for male and female, respectively, but was larger than brain dose by 15% and 5%, respectively. For thorax scan, doses to bone marrow, lung, breast, and oesophagus were underestimated by CTDIIEC,w and $f(0)$ w by 61-100% and 35-58% for male and by 108-161% and 64-106% for female, respectively. However, CTDIIEC,w and $f(0)$ w overestimated doses to stomach and thyroid by 10-34% and 29-45% for male and by 13-28% and 31-43% for female, respectively. For pelvic scan, CTDIIEC,w and $f(0)$ w were smaller than doses to bone marrow and urinary bladder by 91-173% and 51-116%, respectively, but were larger than colon and gonads doses by 30-78% and 44-82%, respectively, for male. For female, however, doses to all the

organs were underestimated by CTDIIEC,w and $f(0)$ w by 76-204% and 40-141%, respectively.

Conclusion: The correlations between CTDIIEC,w and $f(0)$ w and ODs were comparable to the majority of organs. In general, however, $f(0)$ w gave a better estimation for ODs compared to CTDIIEC,w for the scanning protocols studied.

EP-1624

Influence of organ motion on radiation-induced secondary cancer for VMAT and IMPT of prostate cancer

C. Stokkevåg¹, G. Engeseth¹, L. Hysing¹, K. Ytre-Hauge², L. Muren³

¹Haukeland University Hospital, Department of Oncology and Medical Physics, Bergen, Norway

²University of Bergen, Department of Physics and Technology, Bergen, Norway

³Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark

Purpose or Objective: An elevated risk of radiation-induced secondary cancer (SC) in directly irradiated tissues such as the bladder and rectum has been observed in prostate cancer patients following radiotherapy (RT). There are considerable fluctuations in SC risk due to inter-patient anatomy variations, indicating the relevance of also including the effects of internal organ motion for individual patients. Both the bladder and rectum are highly mobile structures and the aim of this study was therefore to investigate the influence of organ motion on SC risk.

Material and Methods: Simultaneously integrated boost treatment plans were generated on the planning CT (pCT) scans of eight prostate patients, using volumetric modulated arc therapy (VMAT) and intensity-modulated proton therapy (IMPT). Both VMAT and IMPT plans were prescribed to deliver 67.5 Gy to the prostate and 60 Gy to the seminal vesicles over 25 fractions, using fiducial marker based image guidance. Each patient had 8-9 repeat CT (rCT) scans throughout the course of treatment on which the bladder and rectum were re-contoured and the originally planned dose distribution re-calculated. Relative risk (RR) of radiation-induced cancer were calculated from the planned and re-calculated dose distributions by using the organ equivalent dose concept adapted to dose-response models reflecting varying degrees of cell sterilisation: a linear model, a linear-plateau model and a bell-shaped competition model.

Results: Using the competition model, the RRs of bladder cancer based on the pCTs ranged from 0.4 to 3.4, while a considerably wider range was found when including all rCTs (from 0.2 to 6.7). Similar trends were seen for the RR for rectal cancer with the competition model and also for both bladder and rectal cancer using the linear model (Fig 1). Overall, the ranges were narrower with the linear model compared to competition model (Fig 1). For 4/8 patients for the bladder and 1/8 patients for the rectum, the estimated risks according to the competition model were consistently lower for IMPT compared to VMAT. Using the linear model the corresponding fractions were 6/8 and 7/8 patients. The remaining patients had rCTs with variations in RR, favouring either VMAT or IMPT, except one of the patients with all rCTs in favour of VMAT for rectal cancer using the competition model. In particular for the competition model, the RRs according to the pCT were often found at the upper or lower side of the RR across rCTs and two cases for bladder cancer and three cases for rectal cancer had RR <1 when addressed with the pCT but a median RR >1 across the rCT.

Figure 1. Relative Risks of radiation-induced bladder and rectal cancer VMAT/IMPT for patients A-H. Median of repeat CTs (range), planning CTs and Median of all planning CTs (range)

Conclusion: The choice of model contributes to SC risk fluctuating in favour of either IMPT or VMAT. Large variations were seen across rCTs, indicating that day-to-day variations in anatomy lead to fluctuations in SC risk estimates that are at least of the same magnitude as the inter-patient variations. Organ motion effects should therefore also be accounted for in SC risk estimates.

EP-1625

A dosimetric analysis of semi-automated knowledge-based VMAT planning for rectal cancer patients

F. Jiang¹, Y. Zhang¹, H. Yue¹, S. Li¹, Q. Hu¹, Y. Zhang², H. Wu¹
¹Peking University Cancer Hospital & Institute, Department of Radiotherapy, Beijing, China
²Peking University Health Science Center, School of Foundational Education, Beijing, China

Purpose or Objective: To compare the dosimetric features of the semi-automated knowledge-based vs. conventional experience-based VMAT planning for pre-operative rectal cancer patients treated with simultaneous-integrated-boosting (SIB) radiotherapy.

Material and Methods: Created by experts following consistent contouring and planning protocols, clinically approved SIB VMAT plans for 150 patients were selected, 80 which were added to the library of Varian RapidPlan to train the DVH estimation model. The other 70 plans were duplicated whose MLC sequences were re-optimized using the model-generated DVH objectives. All plans were normalized to PTV95% ≥ 41.8 Gy and PGTV95% ≥ 50.6 Gy before comparing: dose coverage of GTV and CTV; homogeneity index (HI), conformal index (CI), hotspot volume receiving over 107% of prescription (V107%_PGTV), mean dose and dose to 50% volume of femoral head (Dmean_FH and D50%_FH) and urinary bladder (Dmean_UB and D50%_UB) respectively. Average DVHs of 70 patients were plotted. The normally and non-normally distributed data sets were analyzed using paired samples t-test and Wilcoxon signed ranks test respectively, setting P<0.05 as significant.

Results: Identified as potential outlier or influential data points, the plans of 4 FH and 11 UB were reviewed yet abnormality was excluded. The DVH's and geometry-based expected dose's principal component average fit were 0.999126 and 0.999481 for FH, 0.999585 and 0.999429 for UB respectively. More under-dosed GTV and CTV were found in original than the RapidPlan group, but all V100% were over 99% hence were clinically negligible. Difference of CI was

insignificant (P=0.051 and P=0.900 for PGTV and PTV respectively), yet RapidPlan improved HI of PGTV and PTV significantly (Mean ± 1SD = 0.05 ± 0.006 for PGTV, and 0.255 ± 0.008 for PTV) relative to the original plans (0.06 ± 0.008 for PGTV and 0.263 ± 0.011 for PTV). Positive V107%_PGTV were observed in 18 original plans, which was significantly higher than the RapidPlan group (none). Table 1 shows RapidPlan significantly reduced the D50%_FH, Dmean_FH, D50%_UB and Dmean_UB respectively. The mean DVH of the 70 testing plans (Figure 1) indicates on the basis of comparable target dose coverage, superior dose falloff and organ sparing were achieved by RapidPlan group.

Table 1. Statistics of dose metrics (Gy) of femoral head (FH) and urinary bladder (UB)

		Mean	SD	95% Confidence Interval		P
				Lower	Upper	
D _{50%} FH	Original	15.52	2.17	15.00	16.03	<0.001
	RapidPlan	13.99	1.16	13.71	14.26	
D _{mean} FH	Original	16.59	2.07	16.10	17.08	<0.001
	RapidPlan	15.30	0.70	15.14	15.47	
D _{50%} UB	Original	28.17	3.07	27.44	28.90	<0.001
	RapidPlan	23.24	2.13	22.74	23.75	
D _{mean} UB	Original	29.34	2.34	28.78	29.89	<0.001
	RapidPlan	25.40	1.36	25.08	25.73	

Abbreviations: SD = standard deviation; D_{50%} = dose to the 50% volume of the structure;

D_{mean} = mean dose; FH = femoral head, and UB = urinary bladder.

Figure 1. Average DVHs of the 70 testing plans

Conclusion: Knowledge-based radiotherapy significantly enhanced the consistency of the plan quality by improving the target dose homogeneity, hotspot control and normal tissue sparing. The semi-automated process also reduced the planning time.

EP-1626

4D Energy-based minimisation in lung cancer

I. Mihaylov¹
¹University of Miami- Sylvester Comprehensive Cancer Center, Suite 1500, Miami- Florida, USA

Purpose or Objective: According to published guidelines if tumor motion exceeds 0.5 cm, motion management should be utilized in planning and delivery for NSCLC. Dose-volume-based (Dvh) optimization is the most commonly used treatment planning approach in NSCLC IMRT. Energy-based inverse optimization is a novel IMRT planning framework, which is a rival to Dvh optimization. The purpose of this work is to compare Dvh and Energy IMRT planning for time resolved (4D) in NSCLC.

Material and Methods: Sixteen lung cases were studied. In each case, the target range of motion was over 0.5 cm. For each patient five breathing phases were reconstructed from the pre-planning 4D CT. All anatomical structures were outlined on a reference breathing phase and contours were propagated to the other breathing phases. For each phase inverse optimization was performed with Dvh and Energy based objective functions for the organs at risk (OARs), while target objectives were dose based. Each plan utilized seven

equally spaced beams with total of 35 segments. Step-and-shoot IMRT with minimum segment area of 5x5 cm and minimum of 10 monitor units per segment was used in each plan. Dvh and Energy plans were normalized such that 95% of the propagated PTV for each phase received the prescription dose. Once prescription was achieved, the doses to OARs, such as spinal cord, heart, esophagus, and healthy lungs were iteratively lowered until standard deviation of the dose across the PTV in each plan became less than 4%. After generating Dvh and Energy plans for each breathing phase, deformable dose accumulation to the reference breathing phase for each optimization scheme was performed. The resulting 4D Dvh and Energy plans were compared on the basis of dose indices (DIs), such as DPTV95% (dose to 95% of the PTV), DCord1%, Desophagus50%, Dheart33%, DLungs20%, DLungs30%, and volume indices (VIs) such as VLungs2000 cGy, and VLungs3000 cGy. The differences among the DIs and the VIs were subjected to a two-tailed paired *t*-test to determine the statistically significant dose differences ($p < 0.05$). In addition, total deposited energy in the irradiated volume was assessed.

Results: The table summarizes statistically significant differences over all quantities. On average the DIs and the VIs from the 4D Energy optimization are lower than the indices obtained with the 4D Dvh optimization. The total energy deposited in the entire irradiated volume outside of the target was lower for all Energy optimized 4D plans with statistically significant difference of 13% as compared to the 4D Dvh plans.

Conclusion: In this work time-resolved treatment planning optimization schemes in NSCLC were investigated. The results reveal that 4D Energy based optimization outperforms 4D Dvh based optimization in terms of OAR sparing. For comparable target coverage 4D Energy based plans resulted in statistically significant lower OAR doses ranging from 14% to almost 50%.

EP-1627

Knowledge-based IMRT optimisation using a model trained with VMAT plans of other setup orientations
 Y. Zhang¹, F. Jiang¹, S. Li¹, H. Yue¹, Q. Hu¹, H. Wu¹
¹Key Laboratory of Carcinogenesis and Translational Research Ministry of Education/Beijing- Peking University Cancer Hospital & Institute, Department of Radiotherapy, Beijing, China

Purpose or Objective: Knowledge-based (KB) optimization reduces planning time and quality dependence on humans, yet requires specialty and efforts to develop DVH estimation models. This work applied a model configured with supine VMAT plans to IMRT optimization (supine & prone) to check the feasibility and dosimetric performance.

Material and Methods: Based on Varian RapidPlan, a VMAT model was trained and statistically validated using 81 supine rectal cancer plans of 1 full arc to cover 95% of PGTV and PTV with 50.6 and 41.8 Gy respectively in 22 fractions. Without changing any geometric and beam settings (5 fields were almost symmetric but not strictly), the dynamic MLC sequences of 30 clinical IMRT plans (10 supine and 20 prone) were reoptimized using the model. Volume dose of the original plans were recalculated using the same algorithm as KB plans to avoid bias. All plans were normalized to consistent target prescriptions before comparing: 1. homogeneity index of PGTV (HI_PGTV) and PTV (HI_PTV); 2. conformity index of PGTV (CI_PGTV) and PTV (CI_PTV); 3. volume% exceeding 107% of PGTV prescription (V107%, V54.14Gy); 4. Global maximum dose (Dmax) and PGTV near maximum dose (D2%); 5. mean dose and dose to 50% of the femoral head and urinary bladder (Dmean_FH and

Dmean_UB; D50%_FH and D50%_UB). To compare normally distributed data, paired T test (original vs. KB re-planning) and independent T-tests (supine vs. prone setups) were conducted respectively, otherwise Shapiro-Wilk test and Mann-Whitney U test were performed accordingly.

Results: KB IMRT plans of either setups can be optimized successfully by the supine VMAT model. Under comparable target dose coverage, explicitly better dose falloff in CTV and PTV (between V45-49Gy), and much lower dose to the bladder and femoral head were observed in KB group (figure 1: mean DVHs of 30 patients). As shown in table 1, the normal organ sparing of KB was significantly superior than the original plans, however, the HI_PGTV, HI_PTV, CI_PTV, and Dmax were undermined slightly as trade-off (P<0.05). As a possible explanation, hotspots were usually segmented and suppressed specifically during manual optimization, yet was missing by KB process. V107% also appeared in KB group only (1 supine: V107%=0.03%; 5 prone: V107%=0.01, 0.08, 0.10, 1.15 and 1.76% respectively), although the difference of D2% was not significant (P=0.102). Supine VMAT model was not favourable to patients of same setup (P>0.05), however significantly higher D50% and mean dose to femoral head were observed in supine group for both original and KB plans: indicating the difference may be more attributable to setup orientations or field geometry than to KB model.

Figure 1. Mean DVHs of the 30 patients: comparing the dosimetric difference of the original and knowledge-based planning.

Abbreviations: HI=homogeneity index; CI=conformity index; D_{max}=global maximum dose; D_{50%}=near maximum dose; SD=standard deviation; 95%CI=95% confidence interval; D_{2%}=dose to the 2% volume of the structure; D_{mean}=mean dose; FH=femoral head, and UB=urinary bladder. Dose unit (Gy).

Conclusion: DVH estimation model configured with VMAT plans can be efficiently applied to KB optimization of IMRT plans, including patients of different setup orientations. KB IMRT reduces dose to normal organs, but the concomitant hotspots should be further processed after the automated planning.

Single-click automatic radiotherapy treatment planning for breast, prostate and vertebrae
 R. De Graaf¹, J. Trinks¹, A. Duijn¹, J. Kneijens¹, D. Eekhout¹, R. Harmsen¹, A. Olszewska¹, G. Retel¹, G. Wortel¹, S. V. d. Sanden¹, M. Buijter¹, C. Van Vliet-Vroegindewij¹, E. Damen¹

¹The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: Labour-intensive procedures, such as adaptive radiotherapy and the upcoming new modalities protons and MR linac, result in an increased workload in the treatment planning department. We therefore started the FAST-planning project, a Framework for Automatic Segmentation and Treatment planning. The purpose of this project is to produce single-click automated treatment planning for the majority of tumour sites.

Material and Methods: Easy configuration of treatment protocols was achieved by isolating medical planning protocol relations from software: in-house developed XPP document format (eXtensible Planning Protocol) allows for a complete planning protocol definition in a single document (XML). In FAST planning, the patient ID, dicom identifiers and the selected planning protocol are combined, and an Autoplan document (XML) is composed.

In the framework, each module accepts Autoplan documents and coordinates actions accordingly; e.g. automatic localization of the patient record, import of DICOM objects with delineated target volumes, auto-segmentation of OARs, creation of additional ROIs, creation of advanced beam-sets (VMAT, IMRT), optimization and finally the creation of a report (optionally uploaded to R&V MOSAIQ). The software is written in Python and makes use of Pinnacle3 scripting and transfer protocols DICOM and XML over HTTP. Schemas are used for validation of all XML documents.

Results: The following workflow is automated: after the physician delineated the target, a single mouse-click initiates RT plan generation on our remote treatment planning system Pinnacle3. Subsequently a preview report of the generated plan is sent to R&V system MOSAIQ (Fig. 1). The created RT plan is fully optimized and ready for inspection by the dosimetrist. FAST-planning has been implemented into our clinic for Breast, Prostate, and Vertebral metastases.

Nine Prostate protocols (VMAT) are in place for a variety of dose-levels (51, 64.6 and 77Gy) and target definitions (boost/no-boost and inclusion of seminal vesicles). For Breast, 8 IMRT plans (variation in beam-setup and OAR margins) are created; the dosimetrist and physician can select the best plan based on target coverage and dosimetric trade-offs. For vertebral metastases, 2 plans (conformal beam-sets PA and APPA) are created and screenshots in PDF are sent to R&V MOSAIQ for plan evaluation and selection by the physician.

Conclusion: We have introduced fully automated RT planning for treatment plans Breast (in 20min), Prostate (in 20min) and palliative Vertebrae (in 7min). The automation of these treatment sites has reduced the dosimetrist's planning time considerably (up to 2 hours per RT plan), while maintaining the same plan quality. The FAST framework is generic and allows for easy RT planning protocol configuration for the EBRT techniques VMAT, IMRT and conformal fields. The workflow automation currently covers approx. 20% of our patient throughput, i.e. 1250 RT planning sessions/year.

Single-click from Delineated Target to Full RT Plan

A novel method for electron beam geometry optimisation
T. Felefly¹, C. El Khoury¹, F. Azoury¹, N. Farah¹, J. Barouky¹, R. Sayah¹, N. Khater¹, D. Nehme Nasr¹, E. Nasr¹

¹Hôtel Dieu de France - Saint Joseph University, Radiation Oncology, Beirut, Lebanon

Purpose or Objective: A normal beam incidence optimizes dose distribution in electron radiotherapy. Historically, electron beam direction is chosen clinically with aid of Computed Tomography (CT) data, but commonly without couch rotation. This work describes a novel method for optimizing electron beam incident angle by varying both gantry and couch angles.

Material and Methods: The treated skin surface could be represented using triangle mesh modeling, the vertices being chosen as points on the treated body contour, and their 3D coordinates obtained from the CT dataset. The optimal beam direction would be parallel to the vector sum of all normal vectors to the defined triangles. For each triangle, the normal vector can be obtained by the cross product of two vectors formed by the triangle vertices. Gantry and couch rotation angles of the electron field could then be derived from the vector sum using simple trigonometric formulation. A computer code based on these formulas was developed. The inputs required are the vertices 3D coordinates, the output being the calculated gantry and couch rotation angles. Ideally, using a larger number of vertices, and consequently a larger number of triangles, increases the similarity between the mesh representation and the real skin surface. For practical reasons, two software versions were generated: one using four vertices selected on the treatment planning system such that they are located on the periphery of the treated skin, and the other using nine points selected on the periphery and evenly distributed within the treated skin. Results were compared for fifteen treatment plans and evaluated clinically in the treatment room and dosimetrically using the Eclipse Monte-Carlo electron algorithm.

Results: The two software versions yielded similar results, the root-mean-square deviation being 1.28° for couch rotation angles and 1.9° for gantry angles. When assessed clinically on patients, the derived beam direction appeared fairly normal to the treated skin surface for all cases. A better dose distribution was obtained using the software particularly for cases with large calculated couch rotation angles.

Conclusion: This software tool is an alternative to the historically used method, is more objective and accurate, may provide a better dose distribution, and is reasonably practical using the four vertices based calculation.

Purpose or Objective: Treatment planning for volumetric modulated arc therapy (VMAT) is complex, as the result is highly dependent on the selected optimization objectives. The Auto-Planning module in Pinnacle³ 9.10 (Philips Healthcare, Fitchburg, WI, USA) aims at offering efficient automated planning that directly uses clinical goals for iterative optimization, pushes beyond these goals if possible, and delivers consistent plan quality. In this study, we compared the performance of two Auto-Planning techniques with our original clinical approach of manually optimized prostate cancer VMAT plans.

Material and Methods: Techniques were evaluated for 23 prostate cancer patients (all treated using a rectal balloon), 18 of which underwent primary irradiation with a prescription dose (PD) of 70 Gy in 28 fractions. PTV (planning target volume) for these cases ranged from prostate only to prostate plus entire seminal vesicles. Five patients received salvage treatment with 65 Gy in 26 fractions.

Two Auto-Planning techniques (AP1, AP2) were compared with the manually optimized clinical plan (MP) to evaluate plan quality, focusing on PTV coverage and OAR (organ at risk) sparing. AP1 contained clinical goals for rectal wall, anal wall, bladder and femoral heads (dose-volume relationship and mean dose goals). AP2 used the same technique, excluding the femoral heads, in order to focus on bladder, rectal and anal wall (which are more prone to toxicity), and including a goal to minimize dose on tissue outside PTV and OARs.

Monitor units (MUs) for all plans were scaled to achieve a V95% ≥ 99% for the PTV. One 10 MV VMAT arc (95 to 265° counterclockwise) and two portal imaging beams (for online position verification, 5 MU each) were used.

Results: Table 1 presents the results of the comparison. Both AP techniques show a significant increase in PTV mean dose and number of MU when compared to MP, while PTV max dose is not significantly different. With respect to OARs, Auto-Planning significantly spares all considered structures. AP2 indeed sacrifices sparing of femoral heads for more sparing of bladder, rectal and anal wall. See Figure 1 for an example of dose distributions and DVHs (dose volume histograms).

We selected AP2 as our Auto-Planning technique for clinical use. For 10 subsequently treated patients, AP2 resulted in an approved plan on the first Auto-Planning run for all 8 patients undergoing primary irradiation. The 2 salvage patients needed extra goals for the femoral heads.

Delta-4 measurements for 20 patients treated with AP2 showed a mean gamma pass rate of 98.4 ± 1.4 %, while EBT3 film QA on a subset of 10 patients resulted in a mean gamma pass rate of 97.4 ± 1.2 % (evaluated for 3%/3mm).

Conclusion: Besides its efficiency and consistency, Auto-Planning offers similar PTV coverage as the original clinical plans, combined with better sparing of bladder, rectal and anal wall. Thus, the module widens the therapeutic window and is now used as our clinical standard for prostate cancer VMAT planning.

Structure	Criterion	MP	AP1	AP2
PTV	mean dose (% of PD)	100.1 ± 1.2	101.1 ± 0.5*	101.2 ± 0.8*

EP-1631

mARC treatment planning in non-dedicated systems: two conversion approaches using IMRT and SmartArc

Y. Dzierma¹, N. Licht¹, I. Norton², F. Nuesken¹, C. Rube¹

¹Universitätsklinikum des Saarlandes, Department of Radiation Oncology, Homburg/Saar, Germany

²Philips Healthcare, Philips Radiation Oncology Systems, Zürich, Switzerland

Purpose or Objective: The modulated arc (mARC) technique is Siemens analogue to volumetric modulated arc therapy (VMAT), with a different underlying principle and technical implementation. While this presents the only available rotational technique for existing Siemens users, only few treatment planning systems (TPS) are capable of mARC planning. In particular, the widespread Philips Pinnacle TPS does not support mARC. The purpose of this work is to present two solutions for mARC plan creation starting from either IMRT or SmartArc plans.

Material and Methods: In the first approach, the user creates a step-and-shoot IMRT plan with any number of beams ordered either clockwise or counter-clockwise, and one segment per beam. If desired, a few beams with more than one segment can be included. This plan is then exported as RT-Dose and an in-house software is used to modify the file in such a way that it is interpreted by the linac as an mARC plan. For this aim, each single-segment beam is converted into an arclet of a user-specified length (usually 4°). The calculated dose distribution of the IMRT plan corresponds to the mARC treatment, because mARC dose is usually

calculated under the assumption of stationary arclet delivery.

The second method is a dedicated solution for mARC planning in Philips Pinnacle (V9.2 or higher) without the detour of an external software. In this approach, a SmartArc (VMAT) plan is created in the TPS with 8° final spacing of optimization points. Then a Pinnacle script is applied which duplicates and shifts the optimization points in such a way to separate phases of beam on and of MLC movement. This resulting plan is still treated like a SmartArc plan in the TPS, but irradiated as mARC at the linac.

We present the proof-of-principle and dosimetric verification using the PTW Octavius rotation unit with 2D-array.

Results: A number of plans were created for prostate and head-and-neck cancer. All converted plans could be irradiated without problems. 3D dose distributions agree with the calculated dose distributions (mARC and approximated stationary field plan) within the gamma criteria for IMRT verification (over 90 % of the points passing the criteria of 3 % deviation in local dose, 3 mm distance to agreement, for all dose values above 10 % of the maximum, example in Figure).

	1 st approach: IMRT to mARC	2 nd approach: SmartArc to mARC
Starting plan:	IMRT plan	SmartArc plan
<i>Specifications:</i>	<ul style="list-style-type: none"> Beams ordered (either clockwise or counter-clockwise) Number of segments ≈ number of beams Collimator angle constant Same beam energy 	<ul style="list-style-type: none"> Final spacing of optimization points = 8° (set by script) Only works in Philips Pinnacle with SmartArc
<i>Workflow:</i>	<ul style="list-style-type: none"> Export plan as RTPlan Run conversion script (linux-based) correct cross-sum check import in Mosaic and send to machine for treatment 	<ul style="list-style-type: none"> run script in Philips Pinnacle re-calculate dose distribution export plan for treatment
<i>User choices:</i>	<ul style="list-style-type: none"> if #segments = #beams, this will become an mARC plan if a beam holds more than 1 segment, this will become a hybrid field any number of beams with any spacing any arclet length 	<ul style="list-style-type: none"> any number of rotations
<i>Limitations:</i>	<ul style="list-style-type: none"> generally just one rotation, more rotations require manual separation of beams into several plans 	<ul style="list-style-type: none"> always creates arclets of 4° length spaced 8° apart
<i>Dosimetric accuracy:</i>	As good as for a dedicated mARC planning system	
<i>Treatment stability:</i>	As good as for a dedicated mARC planning system	

Conclusion: Both solutions offer the possibility of mARC planning inside a non-dedicated TPS. If Philips Pinnacle with SmartArc is available, plan creation is straightforward and

can be performed inside the TPS. Otherwise, a special format of IMRT plan is required, which is externally modified before treatment. In both cases, good dosimetric accuracy is achieved, making this a viable solution for the creation of mARC treatment plans inside any treatment planning system.

EP-1632

Spinal SBRT: improving plan quality using an existing database and a geometric parameter

L. Masi¹, R. Doro¹, I. Bonucci², S. Cipressi², V. Di Cataldo², I. Peruzzi¹, L. Livi³

¹IFCA, Medical Physics, Firenze, Italy

²IFCA, Radiation Therapy, Firenze, Italy

³Azienda Ospedaliera Universitaria Careggi, Radiation Therapy, Firenze, Italy

Purpose or Objective: The achievable PTV coverage of spinal SBRT treatment plans depends on the spatial relationship between cord and target. PTV coverage is often sacrificed to fulfill the cord constraints and there are no objective criteria to determine whether an optimal coverage has been achieved. This may lead to suboptimal plan quality and to dependence on the planner's experience. A method to predict the achievable PTV coverage is proposed, which is based on an existing database and on a geometric parameter related to the cord-target 3D distance.

Material and Methods: A clinical database of 70 spine SBRT plans, 41 first treatment and 29 retreatment cases, delivered by the Cyberknife either in 3 fractions or in one fraction is used. TG101 cord constraints or stricter limits for reirradiation were applied. The 3D distance of cord to target was quantified by the expansion-intersection volume (EIV) [M.Descovich (2013)] adapted to spine and calculated as the intersection of the CTV and the cord, both expanded by 5 mm. Plans were classified into 3 groups according to the ratio of the prescribed dose to the cord maximum dose (PD/cordDmax): 1) 1.1-1.65; 2) 1.66-1.9; 3) 1.91-2.9. For each group the correlation between EIV and the PTV coverage was studied, analyzing the linear regression between EIV and the uncovered target volume (PTVout). As validation EIV was calculated for 20 new cases, the expected PTVout value computed by the regression equation and the plans optimized aiming to obtain the predicted coverage respecting the OAR constraints.

Results: EIV values ranged from 0.3 to 18 cc indicating a representative sample of the possible anatomical configurations. Average PTV coverage was 91.2% (range 81.5-98.6%). A significant (p < 0.01) positive correlation (Pearson's r > 0.67) was observed between EIV and the uncovered PTV (PTVout) over the 3 groups, confirming that for larger EIV, lower coverages are expected. The slope of the 3 respective regression lines increased from 0.67 to 0.8 for increasing PD/cordDmax. For 16 out of the 20 new plans PTV coverage was higher than the predicted value, i.e. PTVout was below the regression line (fig.1) fulfilling the optimization purpose.

Uncovered PTV vs. EIV group 2

Conclusion: This study confirms that EIV is a good parameter to represent the cord-target 3D distance in spinal SBRT. The analysis accounted for the interplay between anatomical characteristics and required dose gradient. The results

obtained by the new optimized plans confirm that the EIV method can guide optimization and improve plan quality.

EP-1633

Optimal dose prescription in Linac-based SBRT using VMAT: a "Pareto fronts" approach

S. Cilla¹, A. Ianiro¹, F. Deodato², M. Gabriella², C. Digesù², P. Viola¹, M. Craus¹, M. Ferro², V. Picardi², M. Nuzzo², F. Labropoulos², V. Valentini³, A.G. Morganti⁴

¹Fondazione di Ricerca e Cura Giovanni Paolo II- Università Cattolica del S. Cuore, Medical Physics Unit, Campobasso, Italy

²Fondazione di Ricerca e Cura Giovanni Paolo II- Università Cattolica del S. Cuore, Radiation Oncology Unit, Campobasso, Italy

³Policlinico Universitario A. Gemelli- Università Cattolica del S. Cuore- Roma, Radiation Oncology Department, Roma, Italy

⁴DIMES Università di Bologna - Ospedale s.Orsola Malpighi, Radiation Oncology Department, Bologna, Italy

Purpose or Objective: Pareto fronts are a powerful mathematical strategy to formalize the trade-off between a given set of mutually contradicting objectives. We use this strategy to determine the optimal block margin and prescription isodose for both optimal target coverage and normal tissue sparing for VMAT treatments in extracranial stereotactic radiotherapy.

Material and Methods: Three spherical-shaped targets of different dimensions (20cc, 55cc and 101cc) were selected from our clinical database. GTV included macroscopic disease defined on CT. PTV was defined based on internal margin and setup margin. Healthy liver was considered whole liver minus GTV. A single fraction dose of 26 Gy was prescribed (PD=Prescription Dose). VMAT plans were generated with Ergo++ (Elekta) using a 10MV single arc. Pareto fronts based on (i) different MLC block margin around PTV (ranging from +4mm to -2mm with 1 mm step) and (ii) different prescription isodose line (IDS) ranging from 50% to 100% of PD were produced. For each block margin, the greatest IDS fulfilling the two criteria: 95% of PTV volume reached 100% of PD and 90% of PTV reached 99% of PD was considered as that providing the optimal clinical plan for target coverage. The liver mean dose, V7Gy and V12Gy were used together with the PTV coverage (1-V100) to generate the fronts. The ratio of the prescription isodose surface volume to PTV volume (conformity index CI), gradient index (GI=V50/V100), the ratio of normal tissue volume receiving 50% of prescription dose and PTV volume (NTV50/PTV), homogeneity index (HI=D2%/PD) and healthy liver irradiation in terms of mean dose, V7Gy and V12Gy were calculated to compare different plans

Results: A total of about 450 plans (150 per lesion) were calculated for all block margins and isodose lines. Pareto fronts generated for one of the lesions are plotted in figure 1a,b. For all block margins, PTV coverage is deteriorated with the decrease of liver Dmean, V7Gy and V12Gy. The front for 1mm MLC margin is situated below and on the left of the other fronts for all the three different target sizes. Figure 1c,d show the GI plotted against the prescribed isodose lines and the HI index for the optimal clinical plans. In all cases GI shows a U-shaped behavior with minimum values at 1mm for all metrics. The location of these minimal points was found independent of tumor dimensions. Minimal GI values were found at HI values approximately equal to 1.3. Figure 1e and 1f show the CI and the NTV50/PTV versus HI. With 1mm MLC margin the optimal prescription isodose line was found 77-82% for the three different lesions.

Figure 1: (a) Pareto fronts obtained for liver mean doses vs target coverage for all block margin. Each dot represents a single plan; (b) Pareto fronts obtained for liver mean dose and isodose lines prescriptions. Bold red line connects plans with same optimal dose coverage for different block margins (i.e. the clinical optimal plans obtained with the greatest IDS fulfilling the two criteria: 95% of PTV volume reached 100% of PD and 90% of PTV reached 99% of PD); (c) gradient index vs isodose line prescription for the clinical optimal plans, (d) gradient index vs homogeneity index for the clinical optimal plans, (e) conformity index vs homogeneity index for the clinical optimal plans, and (f) normal tissue volume receiving 50% of PD for the clinical optimal plans. In figure (c) to (f) numbers represent the block margins.

Conclusion: Pareto fronts provide a rigorous strategy to choice clinical optimal plans in SBRT treatments. Our evaluation shows that a 1mm MLC block margin provides the best results with regard healthy liver tissue irradiation and steepness of dose fallout. This choice provided optimal SBRT plans at dose prescription to 77%-82% isodose line for all target dimensions.

EP-1634

Treatment of extremity soft tissue sarcoma using protons - robustness of single and matching fields

B. Knäusl^{1,2}, L. Ulbrich¹, D. Georg¹, G. Kragl², K. Dieckmann¹, M. Stock², P. Georg²

¹Medical University of Vienna, Department of Radiation Oncology and Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

²EBG MedAustron GmbH, Medical Department, Wiener Neustadt, Austria

Purpose or Objective: Extremity soft tissue sarcomas (ESTS) are treated with combined surgery and radiotherapy, involving large volumes of healthy tissue. This increases late toxicity, which has a negative impact on quality of life. Due to the conformal dose distribution of protons a reduction of healthy tissue exposure can be expected. The clinical benefit in preventing long term toxicity can be fully exploited only if the reproducibility and stability of treatment delivery can be guaranteed. The aim of our study was to show the feasibility and robustness of actively scanned proton therapy with single and matched fields.

Material and Methods: In 8 postoperative ESTS patients CTV was defined as GTV radially expanded by 1.5cm and longitudinally by 4cm. For PTV the CTV was expanded isotropically by 1cm [1]. The dose prescription was 60Gy (RBE) to D50% of the PTV (2Gy (RBE)/fraction). For treatment planning the software Raystation v4.7 (Raysearch Laboratories, Sweden) was used. 4/8 patients with PTVs longer than 18cm (maximal available field length) required field matching. Robust optimization is the method of choice in Raystation when two fields with different isocenters are

put together. The robustness was assessed by applying Hounsfield unit (HU) perturbations of 3.5% and isocenter shifts of 5mm. Single beam optimisation (SBO) using a horizontal beam line was used when possible. PTV constraints were $D2\% < 107\%$, $D98\% > 90\%$ and $V95\% > 95\%$ (ICRU). Limits to organs-at-risk (OAR) were the dose-surface area for the skin $A60Gy$ (RBE) $< 20cm^2$ [2], maximum dose to the bones DRBE, $2\% < 60$ Gy (RBE), maximum dose to the nerves and vessels DRBE, $2\% < 70$ Gy (RBE).

[1] Haas et al 2012 IJROBP 84: 572-580

[2] Sugahara et al 2012 RadiotherOncol 105: 226-231

Results: Patients with field lengths $< 18cm$ (PTV volumes: 164-659 cm³) could be treated with SBO using 2 horizontal beams and table rotation. In the nominal plan, PTVV95% ranged from 96.3-98.9%. SkinA60Gy (RBE) was $10\pm 7.5cm^2$. Treatment plans were robust against HU perturbations and 5mm shifts in sup-inf and right-left direction with V95 never dropping below 93%. D2% and D98% of the PTV and OAR doses never exceeded the limits. Shifts of 5mm in ant-post direction caused severe underdosage in the PTV down to V95% of 68%. Robust optimisation in ant-post direction could increase these values up to 91%.

For larger PTVs (420 cm³-2240cm³) field lengths ranged from 25-34 cm. The length of the field overlapping region essentially influenced the robustness of the treatment plans. Isocenter shifts of 5mm to each other or apart resulted in a PTVD2% change of 7% for an overlap $> 6cm$ increasing up to 15% for $\leq 6cm$ (Figure 1).

Figure 1

a) nominal plan with one matching boarder of a representative patient with a field overlap $> 6cm$ with the respective line doses ; b) caudal field; c) cranial field
d) + e) isocenters of the two matching fields shifted by 1 cm to each other and apart with the corresponding DVH curves (solid: nominal plan; dotted: isocenters shifted to each other; dashed: isocenters shifted apart)

Conclusion: Robust treatment plans could be achieved for ESTS patients employing a horizontal beam line only. Before clinical implementation, dosimetric monitoring of skin doses should be performed to verify the calculated values. If field matching is needed a maximal overlap of the matching fields should be guaranteed to avoid hot or cold spots in the overlapping area.

EP-1635

Volumetric modulated arc therapy optimization including dynamic collimator rotation

M.K. Fix¹, D. Frei¹, W. Volken¹, D. Terribilini¹, P. Manser¹

¹Division of Medical Radiation Physics and Department of Radiation Oncology Inselspital, Bern University Hospital, and University of Bern, Switzerland

Purpose or Objective: During the last couple of years, volumetric modulated arc therapy (VMAT) is a treatment modality of increasing interest in radiation oncology. Thereby VMAT utilizes dynamic gantry rotation, dynamic MLC and varying dose rate. However, in addition the collimator angle could be changed dynamically, thus, increasing the degrees of freedom for the optimization, which might lead to improved dose distributions. This work investigates the feasibility of VMAT optimization including a dynamic collimator rotation.

Material and Methods: In this work a $20 \times 20 \times 20$ cm³ homogeneous water phantom with a cigar shaped target volume and a close-by spherical shaped critical structure was used. By means of the Eclipse Research Scripting a predefined collimator rotation was included to a partial arc in a not yet optimized treatment plan. For this purpose a different collimator angle was assigned for each dicom control point. Thereby the collimator rotation takes into account the physical limitations for the dose delivery. This treatment plan was then imported into the treatment planning system Eclipse using the Eclipse Research Scripting interface. Then the VMAT optimization was performed applying the PRO3 optimization algorithm in a research version of Eclipse. For the dose calculation of the optimized treatment plan the Swiss Monte Carlo Plan (SMCP) was used [1]. Similarly, a dose distribution was determined using a static collimator angle as typically applied in conventional VMAT applications. The resulting DVHs for the target and the critical structure were compared for the treatment plans.

Results: The optimization of a VMAT treatment plan with a dynamically rotating collimator was successfully performed. The comparison of the DVHs for the target volume showed a slight improvement of the coverage as well as the dose homogeneity for the treatment plan using dynamic collimator rotation compared to the plan applying a fixed collimator angle. Additionally, the dose to the critical structure could be reduced when using the dynamic collimator rotation instead of a fixed collimator angle.

Conclusion: The usage of a dynamic collimator rotation for VMAT is feasible and has the potential to improve the dose distribution for the target while reducing the dose to critical structures. This work was supported by Varian Medical Systems.

Clinical validation of Automated Planning process in rectal cancer IMRT treatment

N. Dinapoli¹, G. Chiloio¹, G. Mattiucci¹, L. Azario², M. Gambacorta¹, E. Placidi², S. Teodoli², L. Boldrini¹, C. Valentini³, M. Balducci¹, V. Valentini¹

¹Università Cattolica del Sacro Cuore -Policlinico A. Gemelli, Radiation Oncology Department, Rome, Italy

²Università Cattolica del Sacro Cuore -Policlinico A. Gemelli, Physics Institute, Rome, Italy

³Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden, Radiation Oncology Department, Dresden, Germany

Purpose or Objective: Several studies suggest that IMRT can reduce toxicity in rectal cancer patients. A preconfigured plan model might improve daily clinical activity outcomes. Aim of this study was the evaluation of the performances of RapidPlan®Varian Medical System, a commercial model-

based optimization engine, in locally advanced rectal cancer (LARC) IMRT plans in terms of planning target volume (PTV) coverage and Organs at Risk (OaRs) sparing.

Material and Methods: Between January 2014 and March 2014, 60 previously irradiated patients with LARC were retrospectively recruited: 40 IMRT plans were selected to configure the Dose Volume Histogram (DVH) model and to train it. The remaining 20 were firstly manually optimized by 2 medical physicists and then used to validate the model as benchmark plans (BP). OaRs constrains followed Quantec guidelines. Three model based on different PTV objectives have been generated: DVH model 95-105%, DVH model 98-105% and DVH model 98-103% where more than 95%, 98% and 98% of the PTV received more than 95% of the prescription dose and less than 5%, 5% and 3% of the PTV received more than 105% of the prescription dose, respectively. The performances of automated plans (one series for each model) vs BP were statistically compared using Wilcoxon signed-rank test, for PTV V95 and V105, hot spot out of PTV (HToPTV), bladder mean dose (BmD) and maximum dose (BMD), bowel mean dose (BomD) and V45 (BV45). Two expert radiotherapists (observer1 and observer2) clinically validated in double blind the IMRT plans.

Results: A statistical significant improvement was observed for the following dosimetric parameters: HToPTV (for DVH model 98-105 and DVH model 98-103 plans, $p=0.002$ and $p=0.005$, respectively); BmD (DVH model 95-105 and DVH model 98-105 plans, $p=0.01$ and $p=0.03$, respectively). A statistically significant disadvantage in terms of BMD was observed for DVH model 98-103 and DVH model 98-105 ($p=0.02$ and $p=0.05$, respectively). No statistical differences were recorded in term of BV45 and BomD and PTV V95 and V105. (TABLE 1) At a clinical validation, the two observers most frequently chose the test plans optimized from DVH model 98-103% (34 times versus 26 times of the BP).

	DVH model 95-105 vs BP (p value)	DVH model 98-105 vs BP (p value)	DVH model 98-103 vs BP (p value)
Bladder mean dose	0.01	0.03	0.13
Bladder maximum dose	0.35	0.02	0.05
Bowel mean dose	0.65	0.81	0.84
Bowel V45	0.75	0.70	0.90
Hot spot out of PTV	0.13	0.002	0.005

Conclusion: The results of this study show dosimetric and clinical improvements of IMRT plans optimized by knowledge-based planning models compared to BP. The data suggest and encourage the application of this engine into daily clinical practice.

EP-1637

Dose plan assessment of coplanar and non-coplanar beam angle optimization algorithms

T. Ventura¹, H. Rocha², B.C. Ferreira³, L. Khouri⁴, J. Dias², M.C. Lopes¹

¹Instituto Português de Oncologia Coimbra - Francisco Gentil-EPE, Medical Physics Department, Coimbra, Portugal

²INESC, INESC Coimbra, Coimbra, Portugal

³Polytechnic Institute of Porto, School for Allied Health Technologies, Porto, Portugal

⁴Instituto Português de Oncologia Coimbra - Francisco Gentil-EPE, Radiotherapy Department, Coimbra, Portugal

Purpose or Objective: To assess the performance of coplanar and non-coplanar beam angular optimization for two different algorithms integrated in a fully automated multicriterial plan generation system for nasopharyngeal tumour cases.

Material and Methods: A retrospective study including data of 40 nasopharyngeal cases was performed. In each plan, the primary tumour, up to 3 adenopathies, and ipsilateral and contralateral lymph nodes were irradiated with doses of 70 Gy, 59.4 Gy and/or 54 Gy delivered in 33 fractions, respectively. A 'wish-list' based on hard constraints and prioritized objectives for the target volumes and the organs at risk was tailored according to the local clinical practice. Seven coplanar equidistant angles (E7) were used in the standard plan. For each patient, this IMRT plan was compared to coplanar and non-coplanar IMRT plans with 5, 7 and 9 beam angles, optimized with a multicriterial beam angle optimization algorithm (A5, A7, A9), and an in-house derivative-free optimization algorithm (B5, B7, B9). Dose distribution quality for each plan was assessed through DVH analysis and a dose metrics weighted sum approach.

Results: Globally all generated plans presented a good dose distribution. On average, similar results have been obtained for both coplanar beam angle optimization algorithms. For non-coplanar beams, the best results were obtained with algorithm B. When compared with B coplanar cases, on average, slightly better results were achieved with non-coplanar plans for all number of beams (B5, B7 and B9). For algorithm A, on average, no relevant improvement was obtained with the non-coplanar optimization compared with the coplanar plans or the E7 plans. Despite these average results, in particular clinical cases, appreciable differences concerning organ sparing could be found. Up to 9 Gy difference in parotid sparing was achieved both with B9 and A9 coplanar plans when compared with E7 plans. This maximum dose sparing rose to 22 Gy when non-coplanar beams were considered. For the spinal cord, a maximum dose difference of 6 Gy was found between A9 and B9 both for coplanar and non-coplanar beam geometries. In the chiasm, B9 gave up to 5 Gy less than A9 in coplanar beams but this dose sparing for B9 rose to 35Gy for the non-coplanar geometry. For ears B5 non-coplanar plans achieved a better performance than A9 coplanar plans in 66% of the cases. For this structure, up to 15 Gy differences were found between B5 non-coplanar and A9 coplanar plans.

Conclusion: Using a dose metric weight sum approach two beam angle optimization algorithms were compared in a faster and systematic way. On average, both algorithms performed well for the tested clinical cases. However, the different beam angle optimization strategies intrinsic to each of the algorithms revealed to favour algorithm B for non-coplanar beam geometries while for coplanar beams no relevant differences were found between algorithms A and B.

EP-1638

Multicriteria optimisation for whole-pelvic VMAT planning in prostate patients

M. Buschmann^{1,2}, Y. Seppenwoolde^{1,2}, D. Georg^{1,2}

¹Medical University of Vienna, Department of Radiation Oncology, Wien, Austria

²Medical University of Vienna, Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Wien, Austria

Purpose or Objective: A Multicriteria Optimization (MCO) algorithm for VMAT planning that can generate Pareto-optimal plans was recently implemented in the RayStation TPS. The user can generate a plan database with a defined number of Pareto-optimal plans and can explore tradeoffs between different objectives in real time. This study investigates MCO for semi-automated VMAT planning for irradiation of prostate including pelvic lymph nodes.

Material and Methods: CT datasets of ten patients with high risk prostate cancer were used for this study. For each patient, a two stage VMAT plan (6 MV Elekta Agility linac) was generated, consisting of a stage 1 plan delivering 50.4 Gy to the lymph nodes (PTV-LN) and 56 Gy to the prostate (PTV-P) in a simultaneous integrated boost (SIB) in 28 fractions with a dual arc and a stage 2 plan delivering 22 Gy to the PTV-P in 11 fractions with a partial arc. The separation of the

plan into two stages was performed for radiobiological reasons. Planning goals were $D_{98} > 95\%$ and $D_{max} < 110\%$ for the PTVs with maximum OAR sparing. The plans were analyzed for planning time efficiency (hands-on time of the planner and total planning time) and the sum of stage 1 and stage 2 was tested against our clinical DVH constraints for OARs.

Results: A list of objectives and constraints was generated for MCO planning. The number of plans created for the MCO database was set to 33 (3n) and 18 (2n) for the stage 1 plan and the stage 2 plan, respectively, where n corresponds to the number of objectives. The best-suited plan was selected and was segmented to a deliverable VMAT plan in the next optimization step, which minimizes the error in DVHs between pre-optimized and final doses. Some fluence-based dose distributions of the stage 1 plan turned out to be infeasible to segment and recreate, which made additional user interactions (up to 2) necessary to get acceptable plans. The segmentation of the deliverable plan was a critical step that degraded the quality of the Pareto-optimal plan. The 3D information of the pre-optimized dose distribution was lost, which resulted in hotspots of $>110\%$ in the low dose PTV-LN in the SIB plan. The average hands-on times were 156 sec and 83 sec and the average total planning times were 1 h 27 min and 9 min for stage 1 and stage 2, respectively. Clinical dose constraints for the summed plans were all met.

Table: List of constraints and objectives for the generation of the plan databases for both plan stages in MCO planning

Stage 1 plan SIB	
Objectives	Constraints
Rectum: Max EUD 0 Gy (A=2)	PTV-Prostate: Max Dose 56 Gy x 1.1
Bladder: Max EUD 0 Gy (A=2)	PTV-Prostate: Min Dose 56 Gy x 0.95
Bowel: Max EUD 0 Gy (A=2)	PTV-Prostate: Min DVH 56 Gy to 90%
Femoral Heads: Max EUD 0 Gy (A=2)	PTV-Lymph nodes: Min Dose 50.4 Gy x 0.95
External: Max Dose 45 Gy	PTV-Lymph nodes: Min DVH 50.4 Gy to 90%
External: Fall-Off 50.4 Gy to 0 Gy in 1 cm	External: Max Dose 56 Gy x 1.1
PTV-Prostate: Uniform Dose 56 Gy	
PTV-Prostate: Min Dose 56 Gy	
PTV-Lymph nodes: Uniform Dose 50.4 Gy	
PTV-Lymph nodes: Max Dose 50.4 Gy	
Stage 2 plan	
Objectives	Constraints
Rectum: Max EUD 0 Gy (A=2)	PTV-Prostate: Max Dose 22 Gy x 1.1
Bladder: Max EUD 0 Gy (A=2)	PTV-Prostate: Min Dose 22 Gy x 0.95
Bowel: Max EUD 0 Gy (A=2)	PTV-Prostate: Min DVH 22 Gy to 90%
Femoral Heads: Max EUD 0 Gy (A=2)	External: Max Dose 22 Gy x 1.1
External: Max Dose 20 Gy	
External: Fall-Off 20.9 Gy to 0 Gy in 1 cm	
PTV-Prostate: Uniform Dose 22 Gy	
PTV-Prostate: Min Dose 22 Gy	

Figure: Solid lines: mean DVH of the sum plans averaged over all 10 patients. Dashed lines: worst OAR DVH of all patients with respect to the clinical constraints. The crosses represent the target coverage goals and clinical OAR constraints of respectively colored organs.

Conclusion: Raysearch MCO can generate highly conformal prostate VMAT plans with minimal workload in the settings of prostate-only irradiation and prostate plus lymph nodes irradiation with SIB. Further studies will compare MCO to manual planning and other automated planning methods.

EP-1639

Single-click generation of whole breast IMRT treatment plans

G. Wortel¹, R. Harmsen¹, J. Trinks¹, A. Duijn¹, R. De Graaf¹, A. Scholten¹, C. Van Vliet-Vroegindewij¹, E. Damen¹

¹The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: To develop and evaluate automated Whole Breast (WB) IMRT treatment planning by FAST; our in-house developed Framework for Automatic Segmentation and Treatment planning.

Material and Methods: The automatic planning is started when the physician has defined the target volume (using delineation software). FAST opens our treatment planning system Pinnacle3, creates a patient record, imports the CT, and auto-segments the OARs. A medial and lateral tangential beam are created, each consisting of an open segment giving approx. 80% of the dose, supplemented with a limited number of IMRT segments. The open beam is set up such to just include the PTV on the medial side. As we do not allow the beam to cross the patient midline (to enable possible RT of the contralateral breast), the beam is shifted and the collimator is rotated until the beam crosses the patient midline. The heart is automatically blocked from the field. On the lateral side, the beam is opened outside the patient in order to be robust against contour changes. Finally, the plan is optimized with a fixed set of objectives on the heart, lungs, PTV and conformity. The optimized plan can be evaluated, and possibly modified, by the RTT.

FAST is able to create 8 plans for different combinations of heart margin (either 0 or 5 mm) and beam energies (either 6 or 10 MeV), which takes 20 minutes. The physician and RTT can select the most suitable plan.

To investigate the benefits of automatic planning of WB treatments, a preclinical test was performed on 10 patients where our RTTs verified whether the best generated plan met our clinical standards, and estimated how much time was saved by automatic planning.

Results: The preclinical test showed that for 60% of patients, the selected plan meets clinical requirements without further modifications. In two cases, the beam setup was rejected because it included too much lung. The auto-segmentation of the heart was incorrect in one case, which resulted in an erroneous beam setup. The final case only required some fine-tuning.

The time spent on a single treatment plan can be reduced by up to 2h if the plan requires no or little fine tuning (up to 1.5h if the beam setup has to be redone manually). Considering that approx. 600 WB treatments are performed in our institute per year, this leads to a total yearly time-saving of approx. 1000h.

As FAST offers a clear overview of possible plans with different clinical trade-offs, the RTT can make a well-considered decision regarding the heart margin and beam energies. A comparison between the FAST plan and the clinically-used plan showed that, in 70% of cases, this leads to a different configuration being chosen.

Conclusion: We have found that the use of FAST for WB plans significantly reduces the workload on our planning department while maintaining plan quality, and have therefore introduced it into our clinic as of October 2015. In the near future we plan to also implement SIB and locoregional breast techniques.

EP-1640

Evaluation of automatic treatment planning system: comparison with manual planning for liver SBRT.

E. Gallio¹, C. Fiandra², F.R. Giglioli¹, A. Girardi², T. Rasoarimalala³, U. Ricardi², R. Ragona²

¹A.O.U. Città della Salute e della Scienza, Department of Medical Physics, Torino, Italy

²University of Turin, Radiotherapy Unit Department of Oncology, Torino, Italy

³International Center of Theoretical Physics, Department of Applied Physics, Trieste, Italy

Purpose or Objective: Version 9.10 of Pinnacle³ TPS (Philips Medical Systems) includes Auto-Planning (AP) module. The user defines beams, optimization goals for PTV-coverage and threshold doses for each organ at risk (OARs). The AP engine tries to meet the goals and further lower dose to OARs with minimal compromise to the target coverage by multiple optimization iterative loops and by automatically creation of objectives and optimization on additional structures. The aim of this study was to evaluate and compare AP plans with different TPS manual ones for liver stereotactic body radiotherapy (SBRT) treatments.

Material and Methods: Ten patients with liver tumour were included in the study. Six plans were created for each patient. Two plans were generated with AP of Pinnacle³ TPS (version 9.10) using SmartArc technique and two with traditional planning (MP), always with Pinnacle SmartArc, by two different expert medical physicists. Others two experts performed two VMAT plans with Monaco TPS (version 5.0, Elekta) (VM). Dosimetry comparison was done in terms of the PTV coverage, gEUD, OARs (normal liver, kidneys, spinal cord, bowel, heart, rib cage, stomach and major vessels) sparing, as well as homogeneity index (HI), conformity index (CI) and gradient index (GI). Also total monitor units, number of beam segments and beams complexity metrics (plan average beam area BA, plan average beam irregularity PI and plan average beam modulation PM) were evaluated.

Results: Preliminary results of three patients indicated that, for same gEUD (p value = 0.99), there were not significant differences between AP, MP and VM for CI (p = 0.83). Relevant differences were found instead about beams complexity metrics (p = 0.23 for BA, 0.01 for PI and 0.05 for PM), HI (p = 0.03), monitor units and OAR sparing. In particular, median and mean values of monitor units were respectively 3212 and 3646 ± 1529 for AP, 2930 and 2923 ± 447 for MP and 5006 and 4850 ± 570 for VM. Similar data were found for number of beam segments. Also for OARs, in particular for healthy liver, results showed different behaviour of TPS. The healthy liver median volume below 15 Gy was 592 cc for AP, 596 cc for MP and 659 cc for VM; the mean values were 625 ± 150 cc for AP, 632 ± 120 cc for MP and 673 ± 46 cc for VM.

Conclusion: Analysis of first three patients demonstrated that AP and MP employed much less monitor units respect to VM and showed a minor PI. However, in particular complex cases, AP and MP had more difficulty to spare the organs at risk than VM. Furthermore, there was sensible intra-patients variability for AP and MP. AP was less human employment time consuming than both manual planning systems. At the congress, results of all ten patients will be presented.

EP-1641

Clinical experiences with RapidPlan knowledge-based treatment planning

E. Adams¹, C. South¹, M. Hussein¹, A. Barnard¹, S. Bailey¹, S. Chadwick¹, S. Eplett¹, S. Dymond¹, C. Navarro¹, T. Jordan¹, A. Nisbet¹

¹St. Luke's Cancer Centre- Royal Surrey County Hospital, Radiotherapy Physics, Guildford, United Kingdom

Purpose or Objective: RapidPlan (RP) knowledge-based treatment planning software has been in clinical use at our institution since November 2014 and, to date, has been used to plan in excess of 100 patients. Models have been created for a variety of treatment sites, and plans have been compared with class-solution based methods of optimising in terms of plan quality and efficiency of planning and delivery.

Material and Methods: A prostate model was generated based on 5-field IMRT plans with three prescribed dose levels (78Gy/71Gy/60Gy, delivered in 37 fractions). Prior to routine clinical use of the model, planning and delivery efficiency were investigated using twenty patients, who were planned first using local objective templates, and then reoptimised using RP-generated objectives. Six planners of varying experience participated, and the same planner performed both optimisations for a patient. The planners timed how long each method took to generate a plan, and also noted how the RP plan compared with the standard plan, and whether further modifications were required after the initial RP optimisation.

Following final adjustments to the model, it was put into routine clinical use for all prostate cases with three dose-levels. Further models were created for cervix patients treated with RapidArc and post-prostatectomy patients; both single dose-level. For all models, a record was kept of situations where RapidPlan was unable to generate an acceptable distribution to allow further investigation and modification of model parameters as required. Additionally, the applicability of the models to situations outside the original scope was investigated.

Results: The results of the double-planning study can be seen in Table 1 & Fig. 1. RapidPlan produced a plan that was of equal or higher quality in 85% of cases, and the planning times were significantly reduced with a median time saving of 70 mins per patient (range 0-240min). The spread on the timings was much smaller for RP, indicating that the planning times were less dependent on case complexity and planner experience when using RapidPlan. Monitor units were found to be slightly higher with RP (p=0.03); however, this is unlikely to be clinically significant.

Considerable reductions in planning time were also seen for the cervix and post-prostatectomy models. Continuing evaluation of all models in routine use has indicated that they work well for the majority of the population. The models were also found to give a good starting point for situations outside the initial scope in some instances, e.g. the cervix model was used successfully for both a single dose-level prostate + nodes and a two dose-level endometrium + para-aortic nodes.

Table 1: Results of double-planning prostate IMRT patients

	Standard	RapidPlan
Planning time (min) (median ± SD)	80 (±88)	18 ± 13
% final plans better	15	45
MU (mean ± SD)	659 (±52)	695 (±61)

Fig 1: Planning time for conventional optimisation methods compared to RapidPlan for planners (A-F) of varying experience.

Conclusion: RapidPlan has been found to produce good quality plans more efficiently than class-solution based methods in the majority of cases. Continual monitoring of model behaviour is recommended to allow refinement in order to ensure optimum performance for all patients.

EP-1642

Comparison between a conventional IMRT planning method and a new automated planning method.

M. Michel¹, C. Bertaut¹, J. Castelli^{1,2,3}, R. De Crevoisier^{1,2,3}, C. Lafond^{1,2,3}

¹Centre Eugène Marquis, Radiothérapie, Rennes, France

²Inserm, U1099, Rennes, France

³Université de Rennes-1, LTSI, Rennes, France

Purpose or Objective: The inverse planning for IMRT is variable due to a high number of parameters to be defined by the operator. So the quality of treatment plan depends on the level of operator expertise. The aim of this study was to evaluate the automatic "AutoPlanning" planning tool implemented in Pinnacle v9.10 TPS (Philips) for IMRT Step&Shoot (S&S) and VMAT techniques for three localisations: prostate, pelvis and head and neck (H&N) with integrated boost technique with three dose level.

Material and Methods: Twelve patient cases, four by localisation, were planned both for S&S and VMAT. The AutoPlanning method (AP) was compared with those obtained with a conventional manual planning method. The plan quality evaluation was based on the dose distributions (HDV and isodose), the dose homogeneity (HI), dose conformity (Conformal Number (NC) and CONformal INdex (COIN)) and complexity indexes (Plan Area (PA)) and Monitor Units (MU) number. The agreement between planned and measured doses was evaluated with Gamma index test with criteria of 3% and 3mm; the mean gamma value and the percentage of accepted points were also compared. The dosimetric QA was performed by Octavius 4D device (PTW).

Results: HDV AP plans showed equivalent quality compared to the manual plan. With AP for pelvis case, the median dose for bladder decreased by 6% and 4% for S&S and VMAT techniques respectively. With AP for H&N case, the parotids were better saving: the dose received by 30% of the volume decreased by 12% and 14% for S&S and VMAT techniques respectively; this sometimes causes a deteriorate of intermediate risk PTV coverage (PTV 63 Gy). The homogeneity index showed a lower interpatient variation for plan with AP: the standard deviation was 0.006 for S&S with AP against 0.030 for S&S with manual method. In case of prostate and pelvis, plans computed from the automated method showed greater conformity than those issued by the manual method but not in case of H&N. With regard to complexity of plan, the decrease in the area of the irradiation field (- 9.2 cm² on average) and the increase of the MU number (+ 104.5 MU on average) showed worse efficiency of automated plans than manual plans. The

agreement between planned and measured doses was similar between the two planning methods.

Prostate	Rectal wall		Bladder wall		HI	CN	COIN	PA	MU	Gamma	Accepted

VMAT AP	92%	96%	35.33	25.84	0.110	0.349	0.524	43.1	766.2	0.436	95.3		

Table 1: Comparison of dose values, dosimetric and efficiency indexes for the prostate, pelvis and head&neck cases calculated with a conventional planning method (S&S and VMAT) and with AutoPlanning method (S&S AP and VMAT AP). The bold and underlined values are those most favorable.

Conclusion: We validated the feasibility of the automated planning AutoPlanning method in S&S and VMAT in three localisations. However, intake of AutoPlanning can be considered variable according to the center experience. The manual actions are limited with AutoPlanning because the operator does not restart the optimization once the plan is finish, unlike the manual planning, where the operator re optimizes the plan sometimes several times according to his own expertise.

EP-1643

Rapidplan: 'knowledge-based' model with Tomotherapy plans

A. Botti¹, E. Cagni¹, R. Micera², S. Nicola², L. Orsingher¹, M. Orlandi¹, C. Iotti², L. Cozzi³, M. Iori¹

¹Arcispedale S. Maria Nuova, Medical Physics, Reggio Emilia, Italy

²Arcispedale S. Maria Nuova, Radiotherapy, Reggio Emilia, Italy

³Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Milan, Italy

Purpose or Objective: In the radiotherapy planning process the expertise and experience of the operator is essential. This represents a critical element which can limit the quality of a therapy especially when using advanced technologies such as volumetric modulated arc therapy (VMAT). The automation of 'knowledge-based' planning procedures stands as a possible solution to improve the consistency of the plans. RapidPlan (RP) (Varian Medical Systems, USA), uses libraries of plans to create models that, basing on the delivery technique and patient's anatomy, predicts the dose-volume histograms of the organs at risk (OAR) and propose optimization constraints, avoiding long and multiple interactive optimization processes for new patients. In this scenario, it is useful to understand whether knowledge-based models, created using plans with consolidated technique, could supply the lack of the planning experience for a new treatment technique. In this study, HT (Hi-Art, Accuray, USA) plans of prostate cancer patients were used to create two RP models suitable for RapidArc (RA) plans. The aim of the work was to evaluate the feasibility and the performance of these models.

Material and Methods: In order to create the RP models, 2 groups of HT plans for prostate cancer patients, that included sparing of the rectum, bladder, and femoral heads, were selected: low risk group (LR), consisting of 35 plans, aimed to deliver 70 Gy to prostate PTV (PTVp) in 28 fractions - intermediate risk group (IR) consisting of 30 simultaneous integrated boost (SIB) plans with a prescribed dose of 70 Gy to PTVp and 56 Gy to vesicles PTV (PTVv) in 28 fractions. In order to prevent outliers, for all selected plans, structures and dose distributions were verified and validated by a radiation oncologist. The dose distributions of each plan were

linked to a virtual RA plan into the Eclipse TPS. Two full arcs with photon beam energies of 6MV and 30°/330° complementary collimator angle were set.. Two evaluation groups, consisting of 5 new knowledge based plans (KBP) each, were used to validate LR and IR models. KBP were compared with clinical plans (CP) in term of PTVs homogeneity, using HI = 100X (D2% - D98%)/D50%, and DVH endpoints, as shown in table 1.

Results: The KBP dose-volume constraints, generated by HT based models, were suitable for the RA optimization process . The 2 models were effective to suggest optimization objectives consistent with the criteria set by an expert RA planner. The quantitative comparison analysis between CP and KBP over the entire cohort of patients was summarized in Table 1. These preliminary results, do not evidence any substantial differences between the benchmark and the test plans.

Table 1
Average differences between test and original plans (KBP-CP). Ranges [in parenthesis] are also indicated.

Structures	DVH endpoints	LR	IR
PTVp	HI [%]	-1.3 [-3.2, 1.2]	1.0 [-3.5, 3.2]
PTVv			-3.3 [-6.2, 2.2]
Rectum	V ₆₀ [%]	1.0 [-3.5, 5.2]	-0.7 [-4.1, 4.2]
	V ₆₅ [%]	0.9 [-1.4, 3.3]	0.8 [-2.9, 3.2]
	V ₇₀ [%]	0.5 [-1.0, 1.2]	1.4 [-1.1, 0.8]
Bladder	V ₆₀ [%]	1.2 [-2.1, 3.1]	1.8 [-2.0, 3.2]
	V ₇₀ [%]	0.5 [-1.5, 2.2]	0.2 [-1.0, 2.4]
Right femur	D _{max} [Gy]	-1.3 [-2.5, 1.2]	-0.8 [-3.3, 1.8]
Left femur	D _{max} [Gy]	-2.0 [-4.5, 2.2]	-0.6 [-3.5, 1.5]

Fig 1
Example of DVH comparison for the validation experiment (IR case). The lines with triangles are for the benchmark clinical plans (CP), while the lines with squares are for the model-based optimisation (KBP). No interactive optimization process were used for KBP.

Conclusion: RP, commonly used with models based on the same technique of the KBP plans (IMRT/VMAT), is able to create models trained using HT dose distributions to generate comparable RA plans, comparable to CP. The study was carried out for prostate cancer patients.

Fast, high quality, semi-automated and fully-automated prostate radiotherapy treatment planning

P.A. Wheeler¹, M. Chu¹, O. Woodley¹, A. Paton², R. Maggs¹, D.G. Lewis¹, J. Staffurth³, E. Spezi¹, A.E. Millin¹

¹Velindre Cancer Centre, Medical Physics, Cardiff, United Kingdom

²Bristol Haematology and Oncology Centre, Radiotherapy Physics Unit, Bristol, United Kingdom

³Cardiff University, School of Medicine, Cardiff, United Kingdom

Purpose or Objective: Automated IMRT planning has been successfully developed for many treatment sites including prostate, lung, breast and head & neck. Evaluative studies have shown automated planning is clinically feasible, yields high quality treatment plans and improves efficiency. Clinical implementation is however slow due to the lack of available automated solutions or comprehensive scripting facilities within many treatment planning systems. This work addresses this shortfall through the application of prostate VMAT class solutions to implement fully automated planning in

commercially available scriptable systems and semi-automated planning in non-scriptable systems.

Material and Methods: Class solutions for use with Raysearch Laboratories' VMAT optimiser have been developed for prostate & seminal vesicles (Psv) and prostate, seminal vesicles & pelvic node (PPN) treatment sites. These solutions use novel optimisation methodologies to generate high quality, patient individualised plans in a single iteration round and require no decision making from an operator. These approaches were applied within Oncentra Master Plan v4.3 (OMP) and Raystation v4.6 to create semi-automated (OMP(SA)) and fully automated (RAY(FA)) treatment planning solutions respectively.

10 Psv and 10 PPN patients were planned using both OMP(SA) and RAY(FA) plan generation techniques. For 5 Psv patients an experienced IMRT planner aimed to manually improve upon the OMP(SA) results to generate the 'ideal' treatment plan (OMP(Ideal)). Furthermore these 5 patients were planned by an external centre with limited VMAT experience to assess if the semi-automated solution could improve their working practices (OMP(External)). Plan quality was assessed using DVH metrics specified by the PIVOTAL trial and, with the exception of PPN OMP(SA), total planning time was recorded for each technique.

Results:

Table 1: Mean difference in DVH metrics for a given organ when compared to OMP (SA)

	Psv							
	RAY (FA)		OMP (Ideal)		OMP (External)		PPN RAY (FA)	
	Mean ± SD	ps<0.05	Mean ± SD	ps<0.05	Mean ± SD	ps<0.05	Mean ± SD	ps<0.05
Rectum (Volume / %)	-0.4 ± 0.5	Y	-1.0 ± 0.6	Y	5.5 ± 0.9	Y	-1.2 ± 1.3	Y
Bladder (Volume / %)	-0.7 ± 0.5	Y	-1.0 ± 1.1	N	0.2 ± 1.9	N	-1.3 ± 1.2	Y
Bowel (Volume / cc)	-	-	-	-	-	-	-1.4 ± 1.9	Y

49/50 treatment plans assessed in the study passed PIVOTAL trial constraints, with OMP(External) failing on PTV coverage for one patient. Upon review RAY(FA), OMP(SA) and OMP(Ideal) were considered of comparable quality across all metrics and offered improved rectal sparing when compared OMP(External). For Psv treatments the mean planning time (± SD) was 10.3±1.4, 65.2±13.5, 229.0±35.8 and 255.2±48.0 minutes for RAY(FA), OMP(SA), OMP(External) & OMP(Ideal) respectively. Average planning time for PPN RAY(FA) was 38.2 ± 5.4 minutes.

Conclusion: Semi-automated and fully automated planning yield high quality plans with significantly improved efficiency.

Optimal treatment parameters for left-sided whole breast cancer irradiation using TomoDirect

M. Scius¹, P. Meyer¹, C. Niederst¹, N. Dehaynin¹, D. Jarnet¹, M. Gantier¹, D. Karamanoukian¹

¹Centre Paul Strauss, Medical Physics, Strasbourg, France

Purpose or Objective: To determine the optimum combination of treatment parameters between pitch, field width (FW) and number of irradiation fields for left-sided whole breast irradiation using static tomotherapy (« TomoDirect™ »).

Material and Methods: 15 patients already treated with conformal radiotherapy for left-sided breast cancer without lymph nodes were selected for this study. A total of 180 TomoDirect™ plans were created by varying the field width (2.5 and 5 cm), the pitch (0.125, 0.250 and 0.5 cm/projection) and the number of irradiation fields (2 and 4). Modulation factor (MF) was set to 2 and dynamic jaws were not available. Prescribed dose was 50 Gy in 25 fractions without tumoral boost. Constraints were applied on the planning treatment volume (PTV) to ensure that 98% of the PTV receives at least 95% of the prescribed dose and 2% receives at most 107%. Treatment plans were assessed collecting Homogeneity Index (HI) for the PTV, mean doses (heart, ipsilateral and contralateral lung) and maximum dose (contralateral breast) for the organs-at-risk (OAR), integral dose to the patient and beam-on time. To assess whether breast size has an impact on dose homogeneity to the PTV, we separated the 15 patients into 2 cohorts of small (volume < 600 cc) and large (> 600 cc) PTV and compared HI.

Results: Modifying the pitch has no effect on either plan quality (PTV and OAR) or on irradiation time. Increasing the number of beams from 2 to 4 has no significant effect on OAR doses, but improves the HI of the PTV (0.068 ± 0.010 for 2 fields and 0.061 ± 0.011 for 4 fields) without altering significantly irradiation time (4.48 ± 1.27 min for 2 fields and 4.82 ± 1.30 min for 4 fields). Comparison of HI between small and large PTV shows that PTV volume has no significant effect on HI. Also, HI improvement does not depend on PTV volume, meaning that switching from 2 to 4 fields of irradiation is always beneficial (~ 10% better). Beam-on times are lowered using a FW = 5 cm (3.49 ± 0.37 min) rather than a FW = 2.5 cm (5.81 ± 0.70 min). On the other hand, the FW has no significant impact on OAR or PTV doses, except for the integral dose that is respectively 95.72 ± 35.22 Gy.L for a FW = 2.5 cm and 105.3 ± 38.1 Gy.L for a FW = 5 cm. Keep in mind that these results are obtained with a fixed MF = 2.

Conclusion: While setting the modulation factor to 2, pitch value seems to have no impact on planning quality or on irradiation time. A field width of 5 cm with 4 fields of irradiation is a good combination of treatment parameters for treating left-sided whole breast cancer with TomoDirect™ if dynamic jaws are available. If not the case, a field width of 2.5 cm is more suitable so that the integral dose to patients is lowered and radiation-induced secondary malignancies are minimized. This study will be completed by delivery QA to confirm that delivered doses match calculated ones.

EP-1646

HDR brachytherapy with hypofractionated EBRT for high risk prostate cancer

Y. Hashimoto¹, T. Akimoto², Y. Ishii¹, S. Kono¹, S. Izumi¹, K. Maebayashi¹, J. Iizuka³, K. Tanabe³, M. Kiyozuka⁴, N. Mitsuhashi⁵, K. Karasawa¹

¹Tokyo Women's Medical University Hospital, Radiation Oncology, Tokyo, Japan

²National Cancer Center Hospital East, Division of Radiation Oncology and Particle Therapy, Chiba, Japan

³Tokyo Women's Medical University Hospital, Urology, Tokyo, Japan

⁴Misawa Municipal Hospital, Department of Radiology, Misawa, Japan

⁵Radiation Therapy Center, Hitachinaka General Hospital, Ibaraki, Japan

Purpose or Objective: From the biological aspects of prostate cancer, hypofractionated external beam radiation therapy (EBRT) or high-dose-rate brachytherapy (HDR-BT) has been considered as a treatment choice for prostate cancer to improve local control, especially for high risk disease because the alpha-beta ratio for prostate cancer was around 1.5-3 Gy, lower than that for other cancers. Therefore, the purpose of this study is to evaluate outcomes and toxicities of hypofractionated EBRT combined with HDR-BT for high risk prostate cancer.

Material and Methods: We retrospectively analyzed 111 patients with localized prostate cancer (T1-3N0M0) that was defined as high risk disease based on the D'Amico classification, which includes cases of stage T2c to T3b or those with Gleason score of 8 to 10 or prostate-specific antigen (PSA) greater than 20 ng/mL. All patients had received hypofractionated EBRT (45 Gy in 15 fractions every other weekday for 5 weeks) followed by HDR-BT (18 Gy in 2 fractions for one day) between June 1, 2007 and September 30, 2011 at our institution. Androgen deprivation therapy (ADT) consisted of 3 to 6 months' neoadjuvant ADT before and during radiation therapy and 6 months' adjuvant ADT after radiation therapy. Biochemical failure was defined as PSA nadir plus 2.0 ng/mL according to the Phoenix definition. We scored genitourinary (GU) and gastrointestinal (GI) toxicities based on the Common Terminology Criteria for Adverse Events Version 4, and calculated the rates of overall and biochemical-free survival using the Kaplan-Meier method, timed from the completion of the HDR-BT to death or earliest failure. Statistical analyses were performed by using SPSS software.

Results: During follow-up (median, 62 months; range, 4 to 99 months), 24 of 111 patients (21.6%) experienced biochemical failure (median, 41.5 months; range, 12.7 to 72.1 months). The rates of 5-year overall survival and biochemical-free survival were 99.0% and 80.3%, respectively. At the time of analysis, only 1 patient had died of other disease. Among 24 patients with biochemical failure, 1 patient developed bone metastasis, 2 patients developed pelvic lymph node recurrence, and 21 patients diagnosed with PSA failure alone. GU acute toxicity was Grade 1 or less in 99 patients and Grade 2 in 12 patients. GU late toxicity was Grade 1 or less in 108 patients and Grade 2 in 3 patients. GI toxicity including rectal bleeding was Grade 1 or less in 109 patients and Grade 2 in 2 patients.

Conclusion: The results of this study suggest that hypofractionated EBRT combined with HDR-BT can be feasible for high risk prostate cancer, although follow-up period is not long enough to get a definitive conclusion.

EP-1647

Feasibility of hippocampal sparing radiation therapy for glioblastoma using helical Tomotherapy

K. Thippu Jayaprakash¹, R. Jena¹, K. Wildschut²

¹Cambridge University Hospitals, Department of Oncology, Cambridge, United Kingdom

²Cambridge University Hospitals, Department of Radiation Physics, Cambridge, United Kingdom

Purpose or Objective: With improvements in survival for good performance status patients with glioblastoma, some patients will survive to develop significant neurocognitive dysfunction. This retrospective planning study quantifies hippocampal radiation doses in twenty-five patients with glioblastoma receiving radical chemo-radiation therapy, and evaluates the potential for dose reduction using helical IMRT (Tomotherapy).

Material and Methods: We identified twenty-five glioblastoma patients treated with helical IMRT (Tomotherapy) with concurrent and adjuvant temozolamide between October 2011 and December 2013 from our radiotherapy electronic database and conducted a retrospective analysis. Hippocampi were contoured in CT and MRI co-registered image data sets used for clinical radiotherapy planning and hippocampus planning risk volumes (PRV) were created by adding five-millimetre isotropic margin which were checked by a neuro radiologist. Clinical treatment dosimetry plans were overlaid to obtain dose statistics. Four selected patients were planned for hippocampus avoidance radiotherapy without compromising tumour PTV coverage using currently established hippocampus dose volume histogram (DVH) constraints.

Results: Mean hippocampus PRV maximum, minimum and mean radiation doses were 54.7, 24.15 and 38.62 Gy respectively. Hippocampus PRV V7.3, V14.9 and V20 were 99.95%, 98.41% and 95.72% and hippocampus V3 was 100%. In seventeen patients ipsilateral hippocampus was within PTVs and in seven patients both hippocampi were outside PTVs with only minimal overlapping volumes but DVH based dose constraints were not achieved.

Location	Right frontal		Right temporal		Left parietal		Posterior fossa	
Group	Treatment	HA	Treatment	HA	Treatment	HA	Treatment	HA
Max dose	53.17	51.88	51.28	45.33	56.88	55.91	52.63	61.02
Min dose	14.96	2.27	12.4	2.85	31.63	4.11	25.34	6.28
Mean dose	33.39	9.09	28	6.71	43.09	15.55	42.79	37.79
V 7.3 Gy	100	58.7	100	29.17	100	67.43	100	99.29
V 14.9 Gy	100	25.51	98.24	16	100	38.91	100	91.4
V 20 Gy	100	16.22	82	12.12	100	28.68	100	80

With hippocampus avoidance planning (HA), in four patients hippocampus PRV minimum doses and in 3 patients mean hippocampus PRV doses were reduced and significant reductions in DVH based dose constraints were achieved in 3 patients when compared to clinical treatment plans (table).

Conclusion: Our analysis showed hippocampus PRVs received significant radiation doses and currently established hippocampus DVH based dose constraints were not achieved during cranial radiotherapy for glioblastoma using helical IMRT without hippocampus avoidance planning. Our planning study demonstrated significant dose reductions were possible with hippocampus avoidance radiotherapy planning in selected patients. More clinically correlated DVH objectives for hippocampus are required for better optimisation for hippocampus avoidance cranial radiotherapy in glioblastoma for this to be considered for all patients.

EP-1648

A comparison of 6 planning RT techniques for breast treatments

M. Zeverino¹, N. Ruiz Lopez¹, M. Marguet¹, W. Jeanneret Sozzi², J. Bourhis², F. Bochud¹, R. Moeckli¹

¹CHUV - Institute of Radiation Physics IRA, Institute of Radiation Physics IRA, Lausanne, Switzerland

²CHUV, Radiation Oncology, Lausanne, Switzerland

Purpose or Objective: To provide a comparison of 6 different treatment planning strategies, adopted for breast conserving-adjuvant RT, on the dose to the PTV and OARs.

Material and Methods: 22 patients CT data sets were retrospectively used for planning comparison. Patients were split in two groups of 6 left- and 5 right-sided cases (G1 and G2) according to the different dose prescription (50 Gy in 25 fractions and 42.4 Gy in 16 fractions for G1 and G2, respectively). The 6 techniques involved were: Field in Field (FiF), 2 Fields static-IMRT (sIMRT-2ff), 4 Fields static-IMRT (sIMRT-4FF), VMAT, Helical Tomotherapy (HT) and Tomo Direct (TD). Dose limits applied to PTV and OARs were taken from the RTOG protocol n.1005. Treatments plans were optimized to reduce dose to Ipsilateral Lung (IL), Contralateral Breast (CB) and, for left-sided cases, Heart (H) while maintaining an acceptable PTV coverage and

homogeneity. The Wilcoxon matched-paired signed-rank test was used to compare the results. The threshold for statistical significance was $p \leq 0.05$.

Results: The highest mean value $V95\% = 98.8\%/99.2\%$ (G1/G2) was observed for TD and it was statistically significant with respect to all others techniques except VMAT. Similar results were obtained for D98%. The lowest mean $V105\% = 0.2\%/0.1\%$ (G1/G2) was found for HT resulting statistically significant if compared to all other techniques except FiF/VMAT in G1 /G2, respectively. Mean D2% was also found lowest for HT (52.1Gy/43.1Gy in G1/G2) resulting statistically significant with respect to all other techniques except versus TD in G2. For IL mean V5(Gy), V10(Gy) and dose mean were lowest for TD in both groups (20.1%/19.1%, 14.2%/13% and 5.8%/4.9% in G1/G2, respectively) being statistically significant versus all other techniques in G1. The lowest values of mean $V20(\text{Gy}) = 7.0\%/7.9\%$ were observed for HT in both groups. CB dose maximum was found as lowest in G1 for TD (290.9cGy) and for FiF in G2 (252.6cGy) both resulting statistically significant versus all other techniques except for FiF in G1 and TD in G2 confirming a substantial equivalence for the two techniques. Minor absolute dose differences were observed for H.

Conclusion: 6 different techniques were employed to design an optimal plan for conserving breast-adjuvant RT fulfilling the dose limit criteria provided by RTOG 1005 protocol. TD provided superior target coverage maintaining a level of homogeneity similar to HT which achieved the highest value. IL dose was minimized with TD while dose to CB was lowest using both FiF and TD techniques.

⁵S. Orsola-Malpighi Hospital- University of Bologna, Medical Physic Unit, Bologna, Italy

⁶EBG MedAustron- Medical University Wien, Department of Radiotherapy, Wien, Austria

Purpose or Objective: Preoperative Radiotherapy (RT) may theoretically improve resectability in locally advanced pancreatic cancer. However, effective doses of RT are limited by the tolerance of surrounding tissues. Stereotactic radiotherapy (SRT) with intensity-modulated technique (IMRT) based on the use of a Simultaneous Integrated Boost may theoretically allow to deliver a low dose to the duodenum (site of more common toxicity) and a high dose to the vessel invasion (more common reason of unresectability). Aim of this study was to perform a planning feasibility analysis of a modulated dose prescription within a pancreatic tumor treated by SRT.

Material and Methods: 15 patients with a histological confirmation of pancreatic head adenocarcinoma with vascular involvement were included. The following definitions for targets were used: duodenal PTV (PTVd) was defined as the GTV overlapping the duodenal planning at risk volume (PRV) (from the pylorus to the duodenojejunal junction adding 5 mm in craniocaudal direction (CC), 3 mm in the other directions); vascular CTV (CTVv) was defined as the surface of contact or infiltration between tumor and vessel plus 5 mm margin around the vessel (including the whole

circumference of the vessel). The vascular PTV (PTVv) was considered as the CTVv plus an anisotropic margin (5 mm CC, 3 mm in other directions). The tumor PTV (PTVt) was defined as the GTV plus an anisotropic margin (5 mm CC, 3 mm in other directions) including the PTVv and excluding the PTVd. The following doses were prescribed [in 5 daily fractions (fr)] to the PTVs: 30 Gy (6 Gy/fr) to the PTVd, 45 Gy (9 Gy/fr) to the PTVv, and 37.5 Gy (7.5 Gy/fr) to the PTVt, respectively. Constraints were based on AAPM TG101 recommendations: Dmax of PRVduodenum < 32.0 Gy, Dmax of PRVspinal cord < 30.0 Gy, Dmax of PRVstomach < 32.0%, D700cc liver < 21.0 Gy, D200 cc kidneys < 17.5 Gy. All plans were generated with Masterplan Oncentra TPS and the treatment was delivered with a step and shot IMRT technique. The primary end point was the rate of patients in whom the constraint Dmean > 90% was achieved for the 3 different PTVs. Secondary end points were the percentage of patients in whom a PTVv near minimum dose (D98%) > 90%, a PTVv D95% > 95%, and a median dose (D50%) > 95% were achieved.

Results: PTVv Dmean > 90%, PTVv D2% < 115% and OARs Dmax constraints were achieved in all patients. Both PTVv D98% > 90% and PTVv D95% > 95% were achieved in 6 patients (40%).

Conclusion: Although the objective of PTVv D95% > 95% was achieved only in 40% of patients, the study showed that in 100% of patients it was possible to administer a strongly differentiated mean and median dose, and in particular a low dose to the overlap region between the target and duodenum, a high dose to the site of vascular infiltration, and an intermediate dose to the remaining target volume. Prospective trials based on clinical application of this strategy seems to be justified at least in selected patients.

EP-1650

IMRT versus VMAT for breast: a dosimetric point of view

S. Moorthy¹

¹Salmaniya Medical Complex, Oncology & Hematology, Salmaniya, Bahrain

Purpose or Objective: Whole breast irradiation is part of breast conservative management for early breast cancer. In addition to that boost dose to tumor bed improves local recurrence rates and is currently the standard of care. Our aim of the current study was to evaluate intensity modulated radiation therapy (IMRT) for whole breast versus its dosimetric properties of volumetric modulated arc therapy (VMAT).

Material and Methods: Eighteen consecutive women with left sided breast cancer were taken for this retrospective study. IMRT treatment plans were created for patients who already received treatment with VMAT. The plans were created in Monaco planning system using Monte Carlo (MC) algorithm. The Elekta Infinity linear accelerator with Agility MLC is used for VMAT delivery. Our clinic uses simultaneous integrated boost (SIB) technique to treat whole breast patients. The dose prescribed was 60Gy/25# to tumor bed and 45Gy/25# for whole breast. The plans were evaluated based on QUANTTEC dose-volume protocol. Data were statistically analyzed using Wilcoxon Signed Rank test.

Results: VMAT technique statistically significant in target coverage and dose conformity than IMRT. In addition to that lesser ipsilateral & contra lateral lung dose and reduced contra lateral breast dose with VMAT. Critical structures like Left descending artery(LAD), Spinal Cord and heart also received lower doses with VMAT than IMRT. All the dosimetric parameters and its statistical values were provided in table1. Statistics shows VMAT more significant for LAD, Ipsilateral lung dose and Conformity Index.

Dosimetric Parameter		IMRT	VMAT	P value
TARGET	V95(%)	98.35	99.21	0.04
	V100(%)	95.72	96.38	0.04
	Conformity Index (CI)	0.96	0.98	0.03
	Heterogeneity Index (HI)	1.09	1.08	0.06
ORGANS AT RISK (OAR)	Ipsilateral Lung V20Gy(%)	25.85	18.56	0.03
	Heart V25Gy(%)	4.11	3.22	0.05
	Contra lateral Lung V5Gy(%)	18.0	15.28	0.04
	Both Lung V20Gy(%)	21.27	15.71	0.05
	Contra lateral Breast Mean (Gy)	6.55	3.54	0.04
	LAD Maximum Dose (Gy)	28.32	25.91	0.02
	Cord Maximum Dose (Gy)	23.51	18.94	0.04

Table 1: Dosimetric parameters represents the statistical values of IMRT versus VMAT for Breast patients with simultaneous integrated boost (SIB) method

Conclusion: From this study, we infer that, our switch over from IMRT to VMAT treatment technique provided better dosimetric effect for left sided breast cancer patients. Also VMAT provided significant improvement target coverage and conformity. It reduced the dose to normal tissues further to IMRT.

EP-1651

Reducing the probability of radiation-induced hepatic toxicity by changing the treatment modality

S.H. Son¹

¹Incheon St. Mary's Hospital, Radiation Oncology, Incheon, Korea Republic of

Purpose or Objective: To estimate and compare the risk of radiation-induced hepatic toxicity (RIHT) in helical tomotherapy and fixed-beam intensity-modulated radiotherapy (IMRT) for the treatment of hepatocellular carcinoma (HCC).

Material and Methods: Twenty patients with unresectable HCC treated with tomotherapy were selected. We performed tomotherapy re-planning to reduce the non-target normal liver volume receiving a dose of more than 15 Gy (NTNL-V15Gy), and we created a fixed-beam IMRT plan (FB-P). We compared the dosimetric results as well as the estimated probability of RIHT among the tomotherapy initial plan (T-IP), the tomotherapy re-plan (T-RP), and the FB-P.

Results: Comparing the T-RP and FB-P, the homogeneity index was 0.11 better with the T-RP. However, the mean NTNL-V15Gy was 6.3% lower with the FB-P. These differences result in a decline in the probability of RIHT from 0.216 in the T-RP to 0.115 in the FB-P. In patients whose NTNL-V15Gy was higher than 43.2% with the T-RP, the probability of RIHT markedly reduced from 0.533 to 0.274.

Conclusion: By changing the treatment modality from tomotherapy to fixed-beam IMRT, we could reduce the liver dose and the probability of R1HT without scarifying the target coverage, especially in patients whose liver dose is high.

EP-1652

A planning study of dose escalation FET PET active gliomas by IMRT, VMAT and IMPT

A.I.S. Holm¹, K. Seiersen¹, P. Borghammer², J. Petersen¹, S. Lukacova³

¹Aarhus University Hospital, Department of Medical Physics, Aarhus C, Denmark

²Aarhus University Hospital, Department of Nuclear Medicine & PET Centre, Aarhus C, Denmark

³Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

Purpose or Objective: Gliomas are the most common brain tumor in adult patients and radiotherapy plays an important role in the treatment. Nonetheless, the clinical outcome for these patients remains poor, due to early local failure, suggesting the need for higher tumor doses. This study investigates the feasibility of dose escalating an amino acid 18F-fluoro-ethyl-tyrosine (FET) PET defined biological target volume (BTV) in glioma patients by IMRT, VMAT and IMPT.

Material and Methods: Seven patients were eligible for this study. All patients received a pre therapeutic FET-PET/CT and MRI. To compare, standard IMRT treatment plans giving 60 Gy in 30 fractions to the BTV and 46 Gy to the CTV(46 Gy) were calculated. CTV(46 Gy) was defined as tumor and/or tumor cavity plus 2 cm. The BTV was generated from the FET PET image and covered a tumor-to-brain cut-off ratio of FET uptake ≥ 1.6 (pre-surgery) ≥ 2.1 (post-surgery). Both BTV and CTV(46 Gy) were checked visually and adapted to anatomic barriers. Planning target volumes, PTV boost and PTV(46 Gy) were generated by adding 3 mm uniformly to the BTV and CTV(46 Gy), respectively. The standard IMRT plans were used to define the base level of dose to the organs at risk (OAR) and PTV(46 Gy) homogeneity. To evaluate the dose to the OAR the mean OAR was used and the PTV(46 Gy) homogeneity was defined as the volume of PTV(46 Gy) subtracted PTV boost which received 107% of the prescribed 46 Gy. Then, IMRT, VMAT and IMPT dose escalating treatment plans were calculated in order to get the highest achievable mean PTV boost dose, without increasing the mean dose to critical OAR and without decreasing the PTV(46 Gy) homogeneity. For all plans the dose boost was given as the integrated boost over 30 fractions. All treatment plans were carried out using the Eclipse treatment planning system (Varian Medical systems, Palo Alto, CA, USA).

Results: A standard IMRT plans were calculated for all patients and the base level for PTV(46 Gy) homogeneity was found to range between 65 % to 86 %, with a median value of 77%. Dose escalating, while maintaining this homogeneity, was found feasible using all three techniques. The obtainable mean and maximum doses were respective 77.1 Gy and 82.5 Gy for IMRT, 79.2 Gy and 87.4 Gy for VMAT and 85.1 Gy and 89.9 Gy for IMPT. On top of the significant increase in mean and maximum PTV boost dose obtained for IMPT, the PTV(46

Gy) homogeneity can be decreased to a median value of 30.4%.

Conclusion: Dose escalating a FET PET based target volume to above 77 Gy in 30 fractions by IMRT, VMAT, and IMPT without increasing both the PTV(46 Gy) homogeneity and the mean dose to the OAR was found feasible. For IMPT the PTV(46 Gy) homogeneity could be substantially reduced, implicating the reduction of the risk of brain necrosis despite the increased mean and maximum PTV boost doses.

EP-1653

Radiosurgery of brain metastases. A dosimetric comparison between VMAT and Dynamic arc plans

A. Clivio¹, J.J. Stelmes², C.N. Azinwi², G. Nicolini¹, S. Cima², E. Vanetti¹, K. Yordanov², F. Martucci², M. Valli², A. Richetti², S. Presilla¹, G. Pesce²

¹Ente Ospedaliero Cantonale, Medical Physics Unit, Bellinzona, Switzerland

²Oncology Institute of Southern Switzerland, Radiation Oncology, Bellinzona-Lugano, Switzerland

Purpose or Objective: Brain metastases are a very frequent situation in advanced cancer and whole brain radiotherapy (WBRT) has long been considered the standard of care. Stereotactic radiosurgery has been shown to be effective in terms of survival and quality of life for patients with a better prognostic profile and a limited number (1 to 3) of brain metastases. More recent experiences have shown the efficacy of stereotactic radiation for multiple brain metastases as well. This may allow deferment of WBRT, in order to limit the risk of acute toxicity and late neurocognitive decline. The goal of the present study was to test from a dosimetric point of view a new planning software, BrainMetastases ® (BM) (BrainLab®, Feldkirchen - Germany), and to compare it with RapidArc (RA) ® plan TPS. (Varian®, Palo Alto CA, USA)

Material and Methods: We retrospectively re-planned 12 patients treated for 2 or more brain metastases in our institute. Median age was 53 (range 41-63). The most frequent number of metastases per patient was 3 (range 2-10). The new BM software creates a dynamic arc plan following a simple PTV and geometrical constrains and calculates it with the pencil beam algorithm. For all the patients we studied, a plan using both BM and RA with different prescriptions (1x20Gy, 5x7Gy, RTOG protocol) and for RA plans we also considered two different plans with 6MV and the 10FFF beams. Finally the dosimetric parameters were extracted from the DVHs.

Results: As PTV constraint we decided that the prescribed dose should cover the 90% of the PTV volume. With this normalization we obtained a better conformity index for RA plan and a smaller Healthy Brain mean dose with the BM plan. In particular for the patients with 3 metastases with 6MV beam and the 5x7Gy prescription the CI99% was 1.0 ± 0.18 and 1.56 ± 1.30 and Healthy Brain mean dose 3.0 ± 1.2 Gy and 2.4 ± 1.1 Gy and V20Gy 13.0 ± 6.4 cm³ and 9.6 ± 6.5 cm³ respectively for RA and BM technique. Also the time for optimization and calculation are 14.4 ± 5.53 minutes and 3.63 ± 1.48 minutes. The algorithm implemented in BM is the pencil beam and evaluated the dose every 5° and in Eclipse is Acuros XB and the calculation is performed every 2°. A more detailed analysis concerning the OAR sparing will be reported.

Conclusion: Plan optimisation using BM software provides a satisfactory dose distribution with a good conformity index and organs at risk sparing; the results are comparable with a VMAT plan. Reduction of time for optimisation and calculation seems to favour the BM software, with a similar OAR safety. Nevertheless these assumptions need to be balanced with the clinical experience which is currently ongoing in different institutes.

EP-1654

Robustness to set-up errors for treatment plans for superficial tumors in head and neck radiotherapy

D. Den Boer¹, E. Slooten¹, G. Wortel¹, E. Lamers-Kuijper¹, O. Hamming-Vrieze¹, C. Van Vliet-Vroegindewij¹, E. Damen¹

¹Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: Clinical target volumes (CTV) in the head and neck region are typically located just beneath the skin. Therefore, planning target volumes (PTV) will be outside the body contour. Moreover, for IMRT and VMAT treatment plans the build-up region is excluded from the PTV in the treatment planning system and optimization is done on the remaining part of the PTV (in our institute excluding the PTV outside the patient and a margin of 4 mm beneath the skin). This study evaluates the robustness of such treatment plans to set-up errors.

Material and Methods: Seven head-and-neck treatment plans were evaluated (VMAT, SIB with 54.25 Gy to the CTV and 70 Gy to the CTVboost in 35 fractions, CTV to PTV margins were 3 mm, Pinnacle Treatment Planning system). To investigate the effect of set-up errors on CTV coverage, a patient-shift on the treatment table is simulated as a shift of the isocenter. The isocenters were shifted in steps of 1 mm up to 10 mm for each of these treatment plans, in both directions ("into the patient" and "out of the patient", see Figure 1a; direction chosen in such a way that shifts out of the patients have the most effect). Subsequently, it was evaluated up till which step in mm the DVHs of the simulated (shifted) treatment plans were clinically acceptable (V95% > 99%).

Results: The effects of the shifts on the V95% of both the CTVboost and the CTV can be seen in Figure 1b. For the CTVboost regions (indicated by the blue line), it was found that the V95% was still 99% up to a shift of 3 mm (irrespective of the direction, into or out of the patient). For the elective region the V95% is still high enough (above 99%) up to a shift of 6-7 mm (6 mm into the patient, 7 mm out of the patient).

Figure 1 a) Effect of set-up error is simulated by shifting the original isocenter used for the delivered treatment plan (indicated by blue crosshairs) in the direction out of or into the patient (as indicated by the white arrow). The displacement of 10 mm into the patient is indicated by the yellow crosshairs, 10 mm in the direction out of the patient by the white crosshairs. CTVboost and CTV are indicated by red and orange colorwash respectively. b) The V95% values of the CTVboost and CTV due to the shifts of the isocenter.

Conclusion: This work shows that treatment planning in the head and neck region with a CTV to PTV margin of 3 mm and subsequent subtraction of a build-up region of 4 mm results in adequate CTV coverage up till setup errors of 3 mm. Since in clinical practice setup errors are well below 3 mm, this is a safe strategy.

EP-1655

VMAT FFF irradiation in deep inspiration breath hold

J. Demoucron¹, J.L. Dumas¹, A. Hadj Henni¹, E. Costa¹, M. Robilliard¹, A. Mazal¹

¹Institut Curie, Radiothérapie, Paris, France

Purpose or Objective : Radiotherapy treatment on a lung moving tumor requires much caution. Among various treatments possibilities, the patient can be irradiated in deep inspiration breath hold during VMAT delivery. The purpose of this study was to investigate the feasibility of such irradiation. First, dosimetric effects of beam interruptions on VMAT delivery were determined. Then we studied the way to optimize dosimetry with multiple sub-arcs permitting breath hold. Finally another way to irradiate has been adjusted for a faster treatment while keeping VMAT advantages. We need to use a flattening filter free beam (FFF) to keep the irradiation time as low as possible.

Material and Methods: Dosimetric effect of beam interruptions delivery was studied depending on modulation, beam off numbers, dose rate and accelerator (TrueBeam, Clinac 2100C/S). We compared: absolute and relative dose and MLC Dyna/Trajectory Log files. Two rotations of 194° (clockwise/counterclockwise) were divided until 6 segments. Their overlapping or spacing have been compared (Eclipse). Dosimetric FFF plans with sub-arcs method was studied for 2 rotations of 360° depending energy, dose rate, segments numbers and treatment time.

Results: The maximal dose variation with beam interruptions was equal to 0.23%. TrueBeam Logfile showed that 10% of the control points have a difference higher than 0.05 mm between real and planning positions versus 70% with Clinac. The PTV volume receiving 95% of the prescribed dose V95% was equal to 99,35% with two arcs of 194° and 92,35% with one arc. When irradiation was performed with 6 segments spacing of 20°, V95% reach 98,08% with a dose reduction for the organs at risk (spinals cords: 2,2 Gy against 2,6 Gy). The sub-arc method provided 6 arcs of 12 seconds compared to the standard 2 arcs of 40 seconds. Using FFF beams, the planning dosimetry was close to the standard treatment (Volume factor of injury cover equal 0.96 against 0.95) with a better OAR protection (spinals cords: Dmax=18,51 Gy with X6FF/2arcs, 11,75% with X10-FFF/6 arcs). For one rotation of 360°, the standard treatment needs 131 seconds versus three arcs of 12 seconds with FFF and sub-arcs.

Conclusion: We observed no significant dosimetric effect caused by beam interruptions. In order to have a shorter and a safer irradiation, the gantry rotation can be divided in several segments of 20° spacing. The dose distribution difference is insignificant and the OAR are better protected. The use of FFF and segmentation allows reducing the irradiation time by six.

EP-1656

Feasibility of an "off-target isocenter" technique for cranial intensity-modulated radiosurgery

J.F. Calvo-Ortega¹, S. Moragues-Femenia¹, M. Pozo-Massó¹, J. Casals-Farran¹

¹Hospital Quirón Barcelona, Radiation Oncology, Barcelona, Spain

Purpose or Objective: To evaluate the dosimetric effect of placing the isocenter away from the planning target volume on intensity-modulated radiosurgery (IMRS) plans to treat brain lesions.

Material and Methods: Fifteen patients, who received cranial IMRS at our institution, were randomly selected. Each patient

was treated with an IMRS plan designed with the isocenter located at the target center (plan A). A second off-target isocenter plan (plan B) was generated for each case. In all plans the 100% of the prescription dose covered the 99% of the target volume. The plans A and B were compared for the target dosage (conformity and homogeneity indices) and organs at risk (OAR) dose sparing. Peripheral dose falloff was compared by using the metrics V12 (volume of normal brain receiving more than 12 Gy) and CI 50% (conformity index at the level of the 50% of the prescription dose).

Results: The values found for each metric (plan B vs. plan A) were (mean \pm SD): CI (1.28 ± 0.15 vs. 1.28 ± 0.15 , $p = 0.978$), HI (1.29 ± 0.14 vs. 1.34 ± 0.17 , $p = 0.079$), maximum dose to brainstem (2.95 ± 2.11 vs. 2.89 ± 1.88 Gy, $p = 0.813$); maximum dose to optical pathway (2.65 ± 4.18 vs. 2.44 ± 4.03 Gy, $p = 0.195$) and maximum dose to eye lens (0.33 ± 0.73 vs. 0.33 ± 0.53 Gy, $p = 0.970$). The values of the peripheral dose falloff were (plan B vs. plan A): V12 (5.98 ± 4.95 vs. 6.06 ± 4.92 cm³, $p = 0.622$), and CI 50% (6.08 ± 2.77 vs. 6.28 ± 3.01 , $p = 0.119$).

Conclusion: The off-target isocenter solution resulted in dosimetrically comparable plans as the center-target isocenter technique, by avoiding the risk of gantry-couch collision during the CBCT acquisition.

EP-1657

DVH analysis automation in Tomotherapy

M.E. Perez Alvarez¹, J.C. Zapata Jiménez¹, C.B. Carrascosa Fernández¹, J. Torres Donaire¹, J. Arjona Gutierrez¹, A. Gil Agudo¹

¹Hospital General Universitario de Ciudad Real, Radiofísica y Protección Radiológica, Ciudad Real, Spain

Purpose or Objective: The extraction of the data from DVH, with the aim of perform an analysis of a large number of patients in a research project, is a time-consuming process. Furthermore, in the case of Tomotherapy, the resolution obtained from the DVH is poor. This lack of resolution may suppose an additional source of error of this analysis. With the aim of solving these problems, we have developed an easy macro using the Microsoft Excel®, which allows performing the analysis of as many patients as you wish with a single click, improving the resolution and allowing the analysis of up to 7 structures in each histogram.

Material and Methods: a. Input data: 1. The dose range displayed on the DVH has to be the same in all patients. 2. Up to 7 structures can be chosen in each patient, and the same structure has to be identified with the same color in all the analyzed patients. The seven colors that can be chosen are red, green, blue, cyan, yellow, magenta and black. 3. Thereafter, a screenshot of the DVH has to be saved. b. Programming: Macro in ImageJ: 1. Open the DVH in RGB format image. 2. Split images on the RGB channels. 3. One image is obtained for each structure once the image subtraction has been performed, obtaining one single histogram for each structure. 4. The line tool will allow obtain either the dose reached in a given volume or the volume enclosed in an isodose. 5. The macro generates a plot profile and a list of values, which are saved in an independent .xls archive. Macro in Excel: 1. Opens the .xls files generated by the ImageJ macro. 2. Opens the .xls files. 3. Finds the maximum of every list. 4. Calculates the value of the histogram corresponding to this maximum. 5. Store this value in an .xls archive where all the data analyzed are stored.

Results: I.e., in a case of prostate cancer with seven structures under study, a total of 16 items are analyzed: PTV prostate and PTV nodes: 98% and 2% of volume. Rectum: V50, V60, V65, V70 and V75. Bladder: V65, V70, V75 and V80. Femoral head (left and right): V50 Penile bulb: V90 a. Time per patient: Manual: 10 min Macro: 30 s (time necessary for the preparation of the histogram). b. Resolution: Manual: X axis (dose): 16,95 points per Gy. Y axis (% volume): 0,37

points per 1% of volume. Macro: X axis (dose): 14,84 points per Gy. Y axis (% volume): 3,78 points per 1% of volume.

Conclusion: This new macro is a powerful and user-friendly tool designed to help the investigators to perform a quicker data analysis, allowing to perform it up to ten times faster. This is especially useful in the case of analyzing structures with multiple control points, as is the case of rectum and bladder. Likewise, the results obtained with the macro provide a better resolution than measured data, specially, in the y-axis, where the resolution may be improved about ten times. These kind of macros may be programmed to obtain data from as many patients and as many values as desired in the seven structures of the DVH.

EP-1658

Comparing of two different techniques for WBRT with SIB for patients with single brain metastasis

A. Ozen¹, H. Ozden¹, O. Demirkaya¹, K. Duruer¹, N. Coruhlu¹, E. Metcalfe¹, D. Etiz¹

¹Eskisehir Osmangazi University Faculty of Medicine, Department of Radiation Oncology, Eskisehir, Turkey

Purpose or Objective: The aim of this study was to evaluate and compare the non-coplanar IMRT and coplanar VMAT techniques for the treatment of patients with single brain metastasis and their influence on the absorbed dose by the OARs.

Material and Methods: Treatment planning computed tomography (CT) scans of 6 patients with single brain metastasis who had received palliative whole brain radiotherapy (WBRT) with simultaneous integrated boost (SIB) was recruited. Each patient re-planned with 9 fields non-coplanar IMRT and coplanar VMAT for dosimetric comparison. Details of the field arrangement in IMRT plan are presented in Table 1. Two coplanar full arcs by Varian Millennium 120 MLCs were used in all VMAT plans. Arcs were arranged with 30 degrees collimator to protect MLC leak. Prescribed WBRT dose was 30 Gy in 10 fractions and SIB dose was 39 Gy in 10 fractions. Radiation doses to OARs and targets, conformity and homogeneity index and monitor units from two techniques were tested statistically by paired t-test considering significant level of p-value <0.05.

Table 1. Details of the field arrangement for non-coplanar IMRT

Beam Gantry Angle Collimator Angle Couch Angle

1	10	45	0
2	60	45	0
3	130	45	0
4	170	45	0
5	220	45	0
6	270	45	0
7	320	45	0
8	290	0	90
9	330	0	90

Results: Median PTV30 and PTV39 was 1390 (range: 1110-1810) and 18.3 (range: 2.9-45.6) cc. Radiation doses to both eyes were significantly higher in coplanar VMAT technique ($p < 0.05$) (Table 2). There was no significant dose difference for both lens and targets between both techniques. Monitor unit was significantly higher in IMRT technique (median: 2076 (range: 1759-2201) vs. 617 (range: 584-695), $p < 0.001$).

Table 2. Dose result comparisons of non-coplanar IMRT and coplanar VMAT

	IMRT	ARC	
	Median (Range)	Median (Range)	p
Eye L maximum dose (Gy)	12.36 (8.30-15.70)	14.86 (13.22-17.73)	<0.05
Eye L mean dose (Gy)	5.34 (4.42-6.40)	7.83 (7.27-9.66)	<0.05
Eye R maximum dose (Gy)	11.53 (7.20-14.94)	14.81 (13.85-17.35)	<0.05
Eye R mean dose (Gy)	5.91 (4.33-6.60)	7.97 (7.66-9.02)	<0.05
Monitor Unit	2076 (1759-2201)	617 (584-695)	<0.001

Conclusion: Non-coplanar IMRT is superior to coplanar VMAT in sparing eye without of any worse results on targets. But, negative aspects of non-coplanar IMRT technique such as duration of treatment as a result of high MU values, can affect significantly negative in routine practice.

EP-1659

Is VMAT better than field-in-field technique in simultaneous integrated boost for breast cancer?

H.H. Lee¹, C.H. Chen¹, Y.W. Hsieh², S.H. Hung², C.J. Huang¹

¹Kaohsiung Medical University Hospital, Radiation Oncology, Kaohsiung, Taiwan

²Antai Tian-Sheng Memorial Hospital, Radiation Oncology, Pingtung, Taiwan

Purpose or Objective: This study investigated conformation number (CN), homogeneity index (HI), and doses to heart, ipsilateral lung, contralateral lung and breast from two distinct radiotherapy techniques for early left-sided breast cancer patients after lumpectomy. We compared volumetric modulated arc therapy (VMAT) and field-in-field (FiF). Both technique utilized hypofractionation with simultaneous integrated boost (SIB).

Material and Methods: From archival CT scans, we selected 7 situations: 4 tumor locations in upper-outer quadrant (the most common), 1 in upper-inner quadrant, 1 in lower-outer quadrant, and 1 in lower-inner quadrant. SIB provided differential dosing to the whole breast and the resection cavity at each fraction; hence reduced the number of treatment fractions. In both VMAT and FiF, fractionation schemes were 28 daily fractions of 1.8 Gy to the whole breast and 2.15 Gy to the tumor bed adding up to a total dose of 60.2 Gy. They were biologically equivalent to the sequential boost-technique comprising 25 fractions of 2 Gy to the whole breast PTV followed by a boost irradiation in 6 fractions, using an alpha/beta ratio of 4 Gy for tumor response, based on the linear-quadratic cell survival model. Planning target volume (PTV)-breast and PTV-boost were defined by expanding whole breast isotropically by 5 mm and 3 mm, respectively. Dose volume constraints for ipsilateral lung: V20Gy < 20%, V5Gy < 40%; for contralateral lung: V5<5%; for contralateral breast: mean dose <3 Gy; for the heart: mean dose<10Gy and V20Gy < 15%. The goal was to encompass the PTV in all direction with the 95% isodose line, and volumes receiving higher than 110% of the prescribed dose were minimized. One experienced VMAT planner developed all VMAT plans while the other experienced FiF planner developed all FiF plans. The optimal CN is 1 since $CN=(TV95\%/TV)\times(TV95\%/V95\%)$. The optimal HI is 0 since $HI=(D2\%-D98\%)/D$. CN, HI, and doses to normal tissues were compared by the Wilcoxon signed-rank test.

Results: VMAT significantly improved both CN for PTV-boost (0.66 vs. 0.29) and PTV-breast (0.82 vs 0.55), HI for PTV-breast (25.01 vs 32.54), mean dose to heart (4.08 vs 7.71), V20-heart (3.14 vs 13.12), V20-left lung (11.49 vs 24.29) and V5-left lung (31.54 vs 35.98), $p = 0.018$. The mean healthy breast dose was similar between VMAT and FiF (2.39 and 1.68 Gy, respectively); and the HI for PTV-Boost was also similar between VMAT and FiF (10.95 and 13.72, respectively). However, FiF did better in sparing contralateral lung. The mean dose to contralateral lung by VMAT and FiF were 1.75 Gy vs 0.46 Gy, respectively ($p = 0.018$).

Conclusion: VMAT significantly improved conformity and homogeneity in hypofractionated SIB plans for breast cancer.

Doses to heart and ipsilateral lung were significantly decreased, yet more contralateral lung received low doses that less than 2 Gy averagely. Doses to contralateral breast showed no difference between VMAT and FiF.

EP-1660

VMAT planning and delivery for total marrow irradiation

S. Houghton¹

¹The Harley Street Cancer Centre, Medical Physics, London, United Kingdom

Purpose or Objective: To develop a volumetric arc therapy (VMAT) technique for delivering Total Marrow Irradiation (TMI) treatments at this institution using RapidArc™; to assess its benefits over the standard parallel-opposed technique, and evaluate the feasibility of delivering it.

Material and Methods: 5 previously treated TMI patients were retrospectively planned with RapidArc™. The treatments were delivered as quality assurance (QA) plans and verified using the Octavius™ phantom and PTW™ 2D array. The conventional parallel-opposed technique was modelled in the Eclipse™ Treatment Planning System and the dose distributions compared with the RapidArc™ plans.

Results: The VMAT plans were highly conformal, demonstrating significant dose reductions to organs at risk (OAR). The average median dose to the OARs with VMAT was 5.4Gy±1.3 and ranged from 2.8Gy in the oral cavity to 8.1Gy in the spleen. These are gains of between 25% and 73% compared to the conventional parallel-opposed technique which had an average median dose of 11.6±0.2. Target coverage was similar between the two plans with a D99 of 10.7Gy±0.4 for conventional TMI and 10.8±0.2Gy for VMAT TMI. The VMAT TMI plans had slightly higher global maximums than the parallel opposed plans: 13.6Gy±0.1 for VMAT; 12.6Gy±0.4 for parallel-opposed. The plan verification showed good agreement between the Eclipse distributions and measured data. The study gamma analysis pass rate averaged 99.0 ± 0.5 for all anatomical regions and plans.

Figure 24A: Patient 1: Coronal views through the calculation point used in the standard technique showing increased target conformality and OAR sparing with RapidArc (right) compared to the standard technique (left). Note the high dose to the lung region adjacent to the calculation point in the standard plan (left).

Conclusion: VMAT planning for TMI has the potential to significantly reduce doses to OARs, thereby increasing the therapeutic ratio, and giving the potential for dose escalation. The verification process confirmed good agreement between calculated and measured data. VMAT TMI is a technically feasible alternative to the standard TMI technique but further evaluation is required before clinical implementation.

EP-1661

Comparing different planning techniques for brain tumour radiotherapy

G. Cooke¹, C. Golby¹, S. Erridge¹, S. Peoples¹, L. Seaton¹, T. Ronaldson¹, L. Wawrzyniak¹, L. McIntosh¹
¹Edinburgh Cancer Centre- Western General Hospital, Oncology Physics, Edinburgh, United Kingdom

Purpose or Objective: The use of volumetric modulated arc (VMAT) is well established for many clinical sites. However, brain tumours are often treated using a 3D cranial radiotherapy (3DCRT) technique with one or two phases. The use of VMAT for cranial radiotherapy is a positive alternative that has been explored by many centres, particularly for brain metastases. Although VMAT provides a more conformal dose across the target volume than conventional planning techniques the main disadvantage is the low dose bath to normal tissue. The potential for additional neurotoxicity must be considered when deciding the best method of treatment. A planning study was conducted to investigate the difference between 3DCRT, co-planar partial arc VMAT and co-planar full arc VMAT.

Material and Methods: Ten patients, who had been clinically treated with VMAT, were selected for this study. Planning target volume (PTV) and organs at risk (OARs), including chiasm, brainstem and normal brain (brain-PTV) were all outlined on these plans. Planning risk volumes (PRVs) were created for each OAR structure. Each patient had three plans produced delivering 6000cGy to the isocentre: two phase 3DCRT with MLC altered to keep each OAR below their tolerance dose, partial arc VMAT and a full arc VMAT plan. For VMAT planning, arcs were applied to the plan and objectives were set for each OAR and PTV in the VMAT optimiser. Full arcs were applied first and then gantry angles amended for an appropriate partial arc (range 169°-239°). Where OARs overlapped the PTV an overlap structure was drawn to limit the dose to the OAR and maximise the coverage to the PTV.

Results: The dose received by 95% of the PTV and the 10cc dose to normal brain are shown in Table 1. Table 1 shows the dose received by 95% of the PTV is greater for VMAT plans than 3DCRT plans. On average, the dose received by 95% of the PTV, for a 3CRT plan, was 5450cGy. In a partial arc VMAT plan, 95% of the PTV received 5659cGy and a full arc VMAT, 5643cGy. The dose colour wash showed a more conformal dose when using VMAT over conventional planning. Table 1 shows that the average maximum dose to 10cc of the normal brain was 5263cGy using 3DCRT, but 4082cGy for partial arc VMAT and 4148cGy for full arc VMAT. Partial arc VMAT, normal brain doses were lower in 7/10 patients.

Patient	Conventional Plan		Partial Arc VMAT Plan		Full Arc VMAT Plan	
	PTV (cGy)	Brain (cGy)	PTV (cGy)	Brain (cGy)	PTV (cGy)	Brain (cGy)
1	5301	6032	5703	4728	5608	4133
2	5409	5592	5741	3896	5649	4172
3	5875	4459	5825	3576	5817	3700
4	5719	4578	5816	4143	5802	4120
5	5779	4371	5798	3617	5843	3813
6	5149	5550	5338	4082	5334	4449
7	5148	5084	5337	4226	5324	3862
8	5362	5598	5738	4123	5733	4436
9	5516	5577	5693	4175	5731	4275
10	5237	5791	5598	4256	5591	4515

Table 1 95% of PTV and 10cc normal brain doses for 10 patients planned three ways

Conclusion: A Planning comparison of 10 patients, each planned using 3DCRT, partial arc VMAT and full arc VMAT was carried out. VMAT plans showed a more favourable PTV coverage compared to 3DCRT. Normal brain dose was lower than 3DCRT. Partial arc VMAT normal brain dose was lower for 7/10 patients than full arcs.

EP-1662

Comparison of VMAT for single fraction lung cancer radiotherapy with and without flattening filter

S. Barbiero¹, F. Matteucci², D. Fedele³, M. Avanzo¹
¹Centro di Riferimento Oncologico, Medical Physics Unit, Aviano, Italy
²S. Chiara University Hospital, Radiation Oncology Department, Pisa, Italy
³Casa di Cura S. Rossore, Radio-Oncology Department, Pisa, Italy

Purpose or Objective: to compare flattening filter free (FFF) and flattening filtered (FF) intensity-modulated arc therapy (VMAT) plans for stereotactic body radiotherapy (SBRT) in patients with lung lesions, delivered in a single fraction of high dose radiation.

Material and Methods: 25 patients were treated with FFF SBRT for lung tumors with a Varian TrueBeam STx LINAC using VMAT. The lesions were treated with single dose of 24 Gy. Two plans, with and without FF, for each patient, were created using Varian Eclipse treatment planning system. Plans were compared and differences were analyzed in terms of dose volume histograms (DVH), number of monitor units (MUs) and beam on time.

Results: No statistically significant differences were found between FFF and FF plans in coverage of the PTV and doses to the main organ at risk (OAR). The PTV conformity index was the same with FFF and with FF VMAT (1.03 ± 0.10). In FFF plans, the maximum doses to spinal cord, heart, esophagus and trachea were 2.9 ± 1.9, 0.8 ± 1.2, 3.3 ± 4.4 and 1.5 ± 1.7 Gy respectively. Average lungs V5, V20 and mean doses were 14.6 ± 7.5%, 6.1 ± 3.7% and 1.1 ± 0.6 Gy. In FF plans maximum doses were 3.2 ± 2.6, 0.8 ± 1.3, 3.1 ± 4.4 and 1.8 ± 2.0 Gy to spinal cord, heart, esophagus and trachea, and average lungs V5, V20 and mean dose were 15.5 ± 7.9%, 6.3 ± 3.9% and 0.4 ± 0.6 Gy. The average number of MU was slightly higher with FFF beams than with FF (7159 ± 609 vs 7097 ± 699), but the difference was not significant. Beam delivery times were 15.4 with FF beams to 6.7 minutes without filter. Average reduction of treatment time after filter removal was 2.31 ± 0.01 (t-student test p<0.01).

Conclusion: The use of FFF VMAT for single fraction SBRT of lung cancer patients yielded dose distributions dosimetrically equivalent to FF beams, with a significantly reduction of treatment delivery time.

EP-1663

A tool for collision prediction in linac-based intracranial radiosurgery planning

T. Felefly¹, F. Azoury¹, C. El Khoury¹, J. Barouky¹, N. Farah¹, R. Sayah¹, N. Khater¹, D. Nehme Nasr¹, E. Nasr¹
¹Hôtel Dieu de France - Saint Joseph University, Radiation Oncology, Beirut, Lebanon

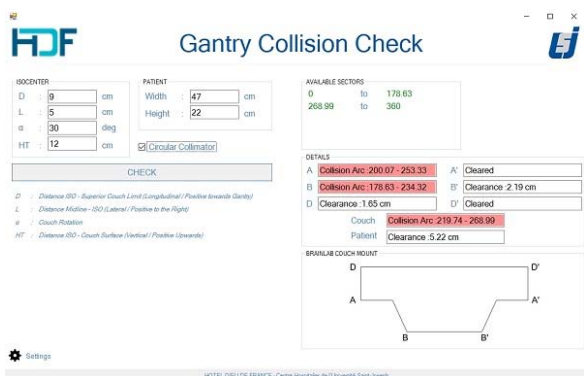

Purpose or Objective: Gantry collision is a concern in linac-based stereotactic radiosurgery (SRS). Without collision screening, the planner may compromise optimal planning by avoiding advantageous beam angles deemed risky, unnecessary replanning delays can occur, and incomplete treatments may be delivered. To address these concerns, we developed a software for collision prediction based on simple machine measurements.

Material and Methods: Couch points vulnerable to collision including the lateral couch edge were identified. Trigonometry-based formulas to calculate distance from each point to the gantry rotation axis, given the isocenter coordinates relative to the couch position, and the couch rotation angle, were generated. For each point, collision occurs when this distance is superior to the gantry-to-isocenter distance, taking into account the complexity of the gantry collimator facet and the presence of a circular SRS collimator. Once a collision is identified for a specific point, the arc of collision was calculated using a separate formula. The patient was modeled as a parallelepiped with

preset height and width, and same formulas were applied for collision detection. A computer code incorporating these formulas was generated. A modifiable "Settings" window including the couch and gantry head dimensions as well as gantry-to-isocenter distance was created. The inputs required are the isocenter coordinates relative to the couch position, the couch rotation angle, the patient dimensions, and the presence or absence of a circular SRS collimator. The software outputs the collision-free gantry angles, and for each point, the shortest distance to gantry or the colliding sector when collision is identified, assuming a full gantry rotation. The software was tested for accuracy on a TrueBEAM equipped with BrainLab accessories for fifteen pretreated plans and ten colliding virtual cases with and without circular collimators.

Results: The software accurately predicted the absence of collision for fourteen of the pretreated plans, and detected collision for one case that required replanning after failing the pre-treatment dry run (difference of 1.7° in colliding gantry angle). The root-mean-square deviation between the measured and predicted gantry angle of collision for the virtual cases was 1.520.01° - 3.39°. The largest differences were observed for extreme couch rotations.

Conclusion: This tool accurately predicts gantry-couch collision for linac-based SRS and is easy to implement in any facility without the need for optical imaging or complex tridimensional machine modeling.

EP-1664

Comparison between intensity modulation techniques in prostate cancer treatment

S. Fondelli¹, S. Russo¹, I. Peruzzi¹, R. Barca¹, M. Esposito¹, B. Grilli Leonulli¹, L. Paoletti¹, F. Rossi¹, P. Alpi¹, A. Ghirelli¹, S. Pini¹, P. Bastiani¹

¹Azienda Sanitaria Firenze, Radioterapia, Bagno a Ripoli, Italy

Purpose or Objective: Volumetric Modulated Arc Therapy (VMAT) is a highly conformed delivery technique. VMAT comparison to other advanced techniques, as IMRT, in terms of plan quality, delivery efficiency and accuracy is great topic discussion in literature. Aims of this work are to assess VMAT dosimetric results compared to IMRT ones on prostate site and to evaluate the acute toxicity profile for patient treated by VMAT techniques.

Material and Methods: A comparison was made between IMRT and VMAT plans elaborated by treatment planning system (TPS) Elekta Monaco® on the first 30 consecutive patients treated with VMAT moderately hypofractionated radiotherapy: 70.2Gy/26 fractions of 2.7Gy. All patients had histologically confirmed prostate cancer; median age was 76 years old; ECOG-performance status value was 0-1; According to the National Comprehensive Cancer Network Criteria patients were stratified into low, intermediate and high risk groups as follow: one patient was low, 8 were intermediate and 16 were high risk. IMRT and VMAT plans were elaborated by TPS Elekta Monaco® using a two-stage constrained optimization based on both biological and physical cost functions. Plans were compared by evaluating D105%, D95%,

D93%, D90%, Dmean and D0.5% for the PTV coverage, while for Organs at Risk (OARs), in addition to Dmean and D0.5%, the % of organ receiving 57, 61, 65.8 and 68.4 Gy (rectum), 57, 61, 65.8 and 68.4 (bladder), 35, 39.5 and 43.9 Gy (femoral heads) were considered of interest. Toxicities were assessed according to the RTOG/EORTC scale for acute and late adverse effects.

Results: Dosimetric analysis shows that PTV coverage is better with VMAT technique and that PTV Dmean is higher than about 1 Gy in VMAT treatments: median value for the PTV Dmean was 70,6 Gy in VMAT technique vs 69,7 Gy in IMRT (Table 1).

Table 1

PTV	VMAT	IMRT
D _{mean} (Gy)	70.6	69.7
D _{0.5%} (Gy)	74.5	72.9
D _{90%}	99.8 %	99.8 %
D _{93%}	98.6 %	98.6 %
D _{95%}	95.9 %	95.4 %
D _{105%}	5.8 %	1.6 %

Regarding OARs sparing, VMAT technique offers a higher sparing of bladder (of about 5% of volume at 57,61 and 65Gy) and femoral heads (of about 15% of volume at 30 Gy) (Figure 1).

Figure 1

VMAT treatments were completed in all patients without interruptions: average overall treatment time was 38 days. During RT, acute genitourinary toxicity was recorded as Grade 1 in 13 patients (52%) and Grade 2 in 7 (28%); acute rectal toxicity was recorded as Grade 1 in 4 patients (16%) and Grade 2 in 3(12%).

Conclusion: Respect to IMRT, VMAT offers higher plan quality with a better PTV coverage. Regarding OARs, VMAT offers higher sparing of bladder and femoral heads. Besides, VMAT is able to provide a considerable reduction in treatment time

offering a better delivery efficiency. Acute toxicity profile assessed by hypofractionation schedule VMAT treatments was safe.

EP-1665

Scalp-Sparing focal radiotherapy for gliomas using VMAT or Helical Tomotherapy: a feasibility study

S. Scoccianti¹, G. Simontacchi¹, C. Talamonti², A. Compagnucci², M. Casati², C. Arilli², D. Greto¹, F. Meacci¹, P. Bonomo¹, I. Desideri¹, G.A. Carta¹, M. Loi¹, L. Livi¹

¹Azienda Ospedaliera Universitaria Careggi, Radiation Oncology, Firenze, Italy

²Azienda Ospedaliera Universitaria Careggi, Medical Physics, Firenze, Italy

Purpose or Objective: Both transient and permanent alopecia have a huge psychological impact on patient's quality of life. Sparing the scalp during focal cranial RT for gliomas is a challenging issue during the treatment planning process due to the fact that the scalp is often strictly adjacent to the cortical or subcortical target. In addition, clear constraints for this structure to be used during the inverse planning are not available in literature, most of them being very strict. We report our preliminary experience with scalp sparing technique for patients with high grade gliomas.

Material and Methods: Five patients previously treated with focal RT were reviewed. During the contouring process, the scalp volume was defined as a ring region of interest (ROI) including the tissue between the skin and the skull, up to a maximum thickness of 5 mm. The hairless skin of the face and the neck was excluded from the scalp ROI. The gross tumor volume (GTV) included the surgical bed plus any contrast enhanced lesion on a postoperative T1-weighted MRI scan. The clinical target volume (CTV) was obtained by adding an isotropic 2-cm margin to the GTV. CTV was then edited according to the anatomical barriers (meninges, ventricles, tentorium and midline except for lesion near to the corpus callosum). CTV was expanded by 2 mm to get the planning target volume (PTV). For the inverse planning, primary constraint for the scalp was $D_{max} \leq 16$ Gy, secondary constraint was $D_{max} \leq 25$ Gy, tertiary constraint was $D_{max} \leq 35$ Gy. Tomotherapy and VMAT plans were generated for a prescription dose of 60 Gy in 30 fractions. Other intracranial organs at risk (optic chiasm, brainstem, cochlea, pituitary gland and hippocampus) were contoured.

Results: The primary constraint ($D_{max} \leq 16$ Gy) for the scalp was unachievable. The secondary constraint ($D_{max} \leq 25$ Gy) was met only in a case both with Tomotherapy and VMAT. The tertiary constraint ($D_{max} \leq 35$ Gy) was met in all the cases with Tomotherapy (the scalp volume receiving > 35 Gy was always $< 0,1$ cc) but only in two cases out of 5 with VMAT. Target coverage and sparing of the other organs at risk were acceptable in all the treatment plans.

Conclusion: Meeting the constraints for the scalp is not always feasible for cortical or subcortical targets that need to be treated with a total dose of 60 Gy. We are enrolling patients with gliomas treated with the above-mentioned scalp sparing technique in a prospective study in order to assess the clinical results in terms of transient and permanent alopecia.

EP-1666

A modified left-sided breast cancer irradiation in Tomotherapy: comparison to hybrid-IMRT technique

C.L. Kuo¹, C.C. Chen¹, L.C. Lin², S.W. Lee¹, S.Y. Ho¹

¹Chi Mei Medical Center-Liouying, Radiation oncology, Tainan, Taiwan

²Chi Mei Medical Center, Radiation oncology, Tainan, Taiwan

Purpose or Objective: In order to reduce heart and ipsilateral lung dose, a modified left-sided breast planning technique in Tomotherapy was introduced and compared to Hybrid-IMRT technique.

Material and Methods: A modified planning technique in Tomotherapy was designed for left-sided breast cancer

patients. It was based on Limited-Tomotherapy planning technique [An-Cheng Shiau et al., 2014] but applying optimal pitches [Mingli Chen et al., 2011] to achieve better conformity and lower heart and ipsilateral lung dose. First, the optimized off-axis distance was determined. Then the optimal pitches were chosen according to the optimized off-axis distance. The last thing was applying optimal pitches with Limited-Tomotherapy planning technique, which had several artificial contours like Complete-block, Directional-block for near PTV area and the virtual bolus, on the optimized process of the left-sided breast Tomotherapy planning. Hybrid-IMRT plans were designed by tangential-fields and IMRT fields combined. The prescription dose was 50 Gy in 25 fractions to PTV. The lung and heart dose volume were measured and analyzed in Beam's-eye-view of tangential-fields with field heart volume (FHV) and field lung volume (FLV).

Results: The maximum volume of FHV and FLV are 15.49c.c and 84.27c.c. The modified planning technique could reduce 12.44% dose in Dmean of heart and 11.36% in lung and both techniques had similar coverage of PTV. The modified planning technique could increase the minimal dose of PTV (37.35 ± 3.87 Gy vs. 29.52 ± 6.75 Gy) and the homogeneity index ($HI = PTV_{95\%} - PTV_{10\%}$) was better (0.9877 ± 0.0053 vs. 0.9632 ± 0.0565). The Dmean of heart in Hybrid-IMRT technique was higher than in the modified planning technique (3.01 ± 2.29 Gy vs. 2.40 ± 2.07 Gy). The Dmean of lung was higher in Hybrid-IMRT technique than in the modified planning technique (5.72 ± 1.44 Gy vs. 5.04 ± 1.47 Gy).

Conclusion: The modified planning technique showed better dose reduction in heart and lung. It was because of there were more flexibility in the optimized planning process. It should be useful in left-sided breast irradiation in Tomotherapy.

EP-1667

Dose fall off patterns and the OAR effect - experience of Linac based frameless radiosurgery

A. Munshi¹, B. Sarkar¹, S. Roy¹, T. Ganesh¹, B.K. Mohanti¹

¹Fortis Memorial Research institute, Radiation Oncology, Haryana, India

Purpose or Objective: Sharpness of fall off of dose beyond the PTV edge is one of the key parameters of efficient cranial stereotaxy. This study presents the dosimetric data and dose fall off patterns of consecutive patients treated for cranial SRS on a linear accelerator.

Material and Methods: Thirty patients of brain lesions underwent frameless SRS at our centre between March 2013 and December 2014. All patients underwent radiotherapy planning contrast CT scan with 1 mm slices. VMAT planning was done for all cases (4mm MLC leaf size). From the center of the PTV volume, straight lines were drawn in the axial plane in anterior, posterior, medial, lateral, superior, inferior directions and in the direction of nearest organ at risk (OAR). Along each line the distance of the 80%, 50% and 20% isodoses from the edge of the PTV were measured. The distance required for dose fall off from 100% prescription dose (PTV edge) to 80%, 50% and 20% were noted. The final readings were converted to dose fall off percentage per mm (%/mm)

Results: OAR doses were validated according to TG-21 specified limits. The mean \pm SD fall (% per mm) for 100%-80% was 7.5 ± 2 . For 100%-50% the fall rate was 5 ± 1.3 and for 100%-20% it was 4.2 ± 1.6 . The mean of sharpest fall off rate (% per mm) was 10.6 ± 5.8 for 100-80%, 6.6 ± 3.6 for 100-50 % and 5.9 ± 7.5 for 100-20%. For an OAR distance > 2 cm from PTV edge (12 patients), the dose fall off pattern remained unaffected. For rest of the eighteen patients with OAR distance < 2 cm from PTV edge, the dose fall off became sharper in the direction of OAR.

Conclusion: An important influencing factor remains vicinity to the OAR. It is possible to achieve falloff rates of 100-80% within a distance of 2 mm and a 100% to 50% fall within 7 mm. This data can help enable select patients for upfront STS versus fractionated SRT during initial assessment of patients.

EP-1668

Treatment planning study of c-IMAT versus s-IMRT in cervical and upper thoracic esophageal carcinoma

R. Zhang¹, W. Bai¹, Y. Cao¹, R. Li¹

¹Fourth Hospital of Hebei Medical University, Radiotherapy, Sijiazhuang- Hebei, China

Purpose or Objective: To compare and analyze the characteristics of static intensity-modulated radiotherapy(s-IMRT) versus constant dose rate and constant angle speed intensity modulated arc therapy(c-IMAT) in the treatment of upper thoracic and cervical esophagus cancer. By Delta4 verified the commissioning of c-IMAT implementation in the Varian Clinical 231X accelerator.

Material and Methods: Eleven esophageal neoplasms patients treated with step-and-shoot s-IMRT at our hospital, were replanned using c-IMAT. The plans were generated with Oncentra ver4.1 planning system, PTV were prescribed to 60 Gy in 30 fractions. Planning objectives for PTV corresponding with the IMRT plans, were at least 95% planning target volume reached the prescription dose and V110 no more than 10%. The maximum dose of spinal-cord was constrained below 45 Gy. Pared-sample T-test were applied to dose volume values for PTV and OAR from DVH.

Results: There were no significant differences between s-IMRT and c-IMAT in PTVmin, D90, D95, D98, V90, V95, V100, V105, V110, D max or total lung V10, V20, V25, V30 and average lung dose (all P>0.05). However, the differences were significant in terms of D2, D50, V105, PTVaverage, HI and CI of PTV, V5 and V15 of the total lung (all P<0.05)(see table1 and figure1). And treatment times were reduced significantly with c-IMAT(81s vs. 238.4s, p < 0.05), while, MU increased by a factor of 1.2, s-IMRT is 513.5MU versus c-IMAT is 624.1 MU (P=0.000). For the gamma Index ($\pm 3\%$, $\pm 3\text{mm}$), the s-IMRT (94.0 \pm 0.9 %) is higher than c-IMAT(91.9 \pm 1.1%), but all can meet the clinical demands ($\geq 90\%$).

Table 1 The dosimetric parameters comparison of c-IMAT and s-IMRT in target volume and OAR(x \pm s)

plan	PTV D ₂ (cGy)	PTV D ₅₀ (cGy)	PTV V ₁₀₅ (%)	PTV _{average} (cGy)
s-IMRT	6461.6 \pm 29.1	6249.0 \pm 19.8	31.2 \pm 6.4	6251.1 \pm 19.5
c-IMAT	6350.7 \pm 40.8	6195.3 \pm 25.9	13.2 \pm 6.6	6197.5 \pm 24.8
P value	0.004	0.009	0.006	0.008
plan	PTV HI	PTV CI	Lung V ₅ (%)	Lung V ₁₅ (%)
s-IMRT	0.094 \pm 0.006	0.666 \pm 0.202	36.9 \pm 4.4	22.3 \pm 2.6
c-IMAT	0.074 \pm 0.009	0.794 \pm 0.019	39.3 \pm 4.7	25.3 \pm 2.8
P value	0.013	0.000	0.029	0.016

Note: D₂ is the minimum dose received by the 2% of the volume, D50 and so on, V5 is percentage of accepting dose equal or more than to 5 Gy volume to the total lung volume, V15 and so on.

Figure 1. Dose distribution of three slices for s-IMRT (left) and c-IMAT (right) plan of one case

Conclusion: In Varian Clinical 231X accelerator designed c-IMAT plan can achieve similar or better dosimetry with s-IMRT, having better PTV homogeneity and conformal index, much less treatment time advantage, and so the c-IMAT plan can be implemented smoothly and quickly into a busy cancer center, but the total MU and the average does of lung increased compared with s-IMRT. Hence in the treatment of upper thoracic and cervical esophagus cancer patients an evaluation of weight loss must be performed during treatment for C-IMAT.

EP-1669

The reaserch of postoperative endometrial carcinoma delivered with CDR-CAS-IMAT on Varian 231X

R. Zhang¹, Y. Gao², X. Fan³, W. Bai¹, Y. Cao¹

¹Fourth Hospital of Hebei Medical University, Radiotherapy, Sijiazhuang- Hebei, China

²Hebei General Hospital, The Physical Examination Center, Sijiazhuang, China

³Fourth Hospital of Hebei Medical University, Department of Gynecology, Sijiazhuang- Hebei, China

Purpose or Objective:

Introduction Postoperative endometrial carcinoma patients with large volume of target area and the shape of the target area is concave, treatment with IMRT is time consuming. Treated with VMAT can produce similar or better dose distributions, also can reduce treatment time and the monitor units (MU)[1,2]. However, VMAT can only be implemented on the new generation accelerators such as the Varian RapidArc and Elekta Synergy, which prevents most existing linacs from delivering in VMAT. R Zhang et al.[3] had been proposed an alternative planning approach for VMAT using constant dose-rate and constant gantry speed arc therapy (CDR-CAS-IMAT) implementation on Varian 23EX for thoracic esophageal carcinoma, the results showing that the treatment times compared with the IMRT technology were decreased significantly can be reached to 62.9%.

Objective The purpose of this study is to investigate using CDR-CAS-IMAT on Varian 231X, by comparing with the IMRT to evaluate the performance of CDR-CAS-IMAT on postoperative endometrial carcinoma patients and then provide guidance for clinical treatment.

Material and Methods: 30 postoperative endometrial carcinoma patients treated with IMRT on Varian 231X were replanted using CDR-CAS-IMAT. The plans were generated on Oncentra v4.1 planning system, PTV was prescribed to 50.4

Gy in 28 fractions. Plans were evaluated based on the ability to meet the dose volume histogram. The homogeneity index (HI), conformity index (CI) of target volume, the dose of organs at risk, radiation delivery time and monitor units were also compared. Paired T-test model analysis was used to analyse the two sets of data.

Results: The results showing that postoperative endometrial carcinoma can be implemented CDR-CAS-IMAT plans on conventional Varian 23EX Linac for smoothly and quickly at busy cancer center. Comparing with the IMRT technology CDR-CAS-IMAT plans can meet the clinical demand(see Figure1), gives comparable OAR and improved CI of PTV (see Table 1), can reduction treatment time ((84.6±7.8)s Vs. (422.7±46.7)s), MU((787.5±78.5)MU Vs.(927.4±79.1)MU) and high dose irradiated volume; while increase the low dose irradiated volume of healthy tissues and the volume of the bladder and bowel irradiated 40 Gy and 30Gy, respectively. This point needs to pay attention to implementation in clinical. There were no significant differences in other statistical index.

Figure 1. Treatment plan sections dose distribution of CDR-CAS-IMAT (left) Vs. IMRT (right) [Transverse plane(top), Coronal plane(middle) and sagittal plane(bottom)]

Table 1. The dosimetric parameters comparison of CDR-CAS-IMAT and IMRT in target volume and OARs ($\bar{x} \pm s$)

plan	HI (PTV)	CI (PTV)	HI (CTV)	CI (CTV)	D90 (CTV) (cGy)	D95 (CTV) (cGy)	D98 (CTV) (cGy)
CDR-CAS-IMAT	0.12 ± 0.021	0.85 ± 0.03	0.09 ± 0.02	0.46 ± 0.05	5232.5 ± 34.0	5196.2 ± 27.8	5153.2 ± 21.0
IMRT	0.13 ± 0.02	0.81 ± 0.03	0.11 ± 0.02	0.43 ± 0.05	5215.7 ± 31.5	5162.5 ± 31.2	5085.3 ± 34.9
t value	-1.36	3.85	-3.18	4.21	2.13	4.65	7.79
P value	0.193	0.001	0.005	0.001	0.049	0.000	0.000

plan	V95 (CTV) (%)	V98 (CTV) (%)	V100 (CTV) (%)	Cord D2 (cGy)	Rectum V40 (%)	Bladder V50 (%)	Bowel V30 (%)
CDR-CAS-IMAT	99.99 ± 0.1	99.8 ± 0.14	5232.5 ± 34.0	3743. ± 118.5	41.8 ± 5.9	17.9 ± 4.4	39.5 ± 6.4
IMRT	99.98 ± 0.02	98.9 ± 0.6	5215.7 ± 31.5	3806.1 ± 98.5	44.1 ± 4.7	16.7 ± 4.1	36.5 ± 7.3
t value	2.29	6.00	2.13	-2.65	-2.47	2.14	3.00
P value	0.035	0.000	0.049	0.017	0.025	0.048	0.008

Note: D90 is the minimum dose of 90% volume accepted, D95 and so on; V90 is the volume which the target volume irradiated 90% prescription dose, V95 and so on. D2 is the minimum dose of 2% volume accepted;

Conclusion: Endometrial carcinoma patients with CDR-CAS-IMAT on Varian Clinical 23IX can get equivalent or superior dose distribution compared with the IMRT technology. CDR-CAS-IMAT have much less treatment time and MU can reduce the uncertainty factor and patient discomfort in treatment.

Impact of flattening filter free photon beam on Rapid-arc radiotherapy for gynecological malignancies

L. Kumar¹, V. Kishore², G. Yadav¹, K. Raman¹, M. Bhushan¹, T. Suresh¹, P. Kumar¹, M. Suhail¹, M. Pal¹

¹Rajiv Gandhi Cancer Institute And Research Centre, Medical Physics Division- Radiotherapy Department, Delhi, India

²Bundelkhand Institute Of Engineering & Technology- Janshi-India, Department Of Applied Science & Humanities, Janshi, India

Purpose or Objective: Aim of this study was to determine the dosimetric impact of flattening filter free beam (FFF) of 6 and 10 MV energies on rapid-arc (RA) radiotherapy planning for gynecological malignancies.

Material and Methods: RA plans were generated using double arc for a cohort of ten patients using 6 and 10 MV FFFB. Plans were generated to deliver a dose of 50.4 Gy in 28 fractions for Planning target volume (PTV) and ALARA were used as an objective for Organs at risk (OARs). Plans were analysed for PTV Coverage, conformity Index (CI), homogeneity index (HI), dose to OAR's, integral dose to normal tissue (NTID) and total no. of monitor units (MUs).

Results: The volume of PTV receiving prescription dose were 95.03+ 0.09% and 95.09+ 0.10%, HI were 1.062+ 0.008 and 1.066+ 0.008, CI were 1.007+ 0.016 and 1.012+ 0.013, mean NTID were 272.2+ 37.1 and 261.1+ 33.2 (liter-Gy), MUs number were 629.6+ 31 and 647.2+ 44 for FFFB using 6 and 10 MV respectively. There were no statistically significant (p>0.05) difference found in mean doses to bladder, rectum, bowel and both femoral heads for FFFB using 6 and 10 MV respectively. There were significant (p <0.05) difference found in HI, MU number and NTID for FFFB using 6 and 10 MV respectively.

Conclusion: FFFB of 6MV was found superior in comparison to 10MV for RA planning in case of gynecological malignancies. It offers better HI, CI, less number of MUs (2.8%) and delivers more NTID (4.3%) for similar target coverage and OAR's sparing.

Stereotactic body radiotherapy for early-stage lung cancer using flattening filter free beams

J. Zhang¹, X. Peng¹, D. Hong²

¹Cancer Hospital of Shantou University Medical College, Department of Radiation Oncology, Shantou, China

²The First Affiliated Hospital of Shantou University Medical College, Department of Endocrinology, Shantou, China

Purpose or Objective: The purpose of this study is to investigate the treatment plan dosimetry and delivery efficiency between the single-arc and double-arc techniques using stereotactic body radiotherapy with flattening filter free beams for early-stage lung cancer.

Material and Methods: Nineteen patients were included in this investigation, and each patient was arranged single-partial-arc (SA) and double-partial-arc (DA) techniques using the Eclipse 10.0 treatment planning system. The prescription dose was 48Gy/4 fractions and the photon beam energy was 6 MV flattening filter-free (FFF) beams from Truebeam linear accelerator. The treatment plans were appraised by Radiation Therapy Oncology Group (RTOG-0915) criteria for planning target volume (PTV) coverage and organs at risk (OAR) sparing. All plans were normalized to 100% of prescribed dose at least covering 95% of the PTV. Treatment efficiency was evaluated via monitor units (MUs) and treatment times were compared.

Results: The PTV volumes range from 20.46 to 88.37 cm³. Compared to the SA and DA plans, there was no significant difference in PTV coverage, except the maximum dose in the PTV. The maximum dose of SA technique was slightly higher than that of DA technique. The mean PTV conformity index (CI) for SA and DA was 1.06±0.05 and 1.01±0.03 respectively.

The mean PTV homogeneity index (HI) was 0.14 ± 0.04 for SA and 0.09 ± 0.03 for DA. For the OAR sparing, there was no significant difference between the SA and DA. A significant difference was observed in the number of MUs and the treatment time, SA presents a reduction of 10.3% and 24.5% respectively.

Conclusion: SA showed no significant difference in PTV coverage and OAR sparing compared with DA, however, the CI and HI of DA were better than those of SA. SA improved the greater treatment efficiency, and achieved less MUs number. In order to reduce patient treatment time, SA is worth to consider.

EP-1672

mARC vs. IMRT treatment of prostate and head-and-neck cancer with flat and FFF energies

Y. Dzierma¹, K. Bell¹, F. Nuesken¹, J. Palm¹, J. Fleckenstein¹, N. Licht¹, C. Rube¹

¹Universitätsklinikum des Saarlandes, Department of Radiation Oncology, Homburg/Saar, Germany

Purpose or Objective: The modulated arc (mARC) is a VMAT-like rotational technique specifically designed for "burst mode" delivery of high dose rates. Only few studies have assessed the performance of this radiotherapy modality, and it is unclear how efficient it will prove for target volumes of high vs. low complexity. We therefore present a planning and delivery study for two frequent clinical applications: a relatively simple target volume for prostate cancer without lymph node involvement and a highly complex target volume for hypopharynx cancer. In each case, plan quality, treatment time and scattered dose are compared for mARC vs. IMRT using flat or flattening-filter-free (FFF) beams.

Material and Methods: Contours were retrospectively created for 10 prostate cancer patients and 8 head-and-neck cancer patients treated at our clinic. IMRT plans were set up using 11 beams and 55 segments. mARC plans for both energies were made using one rotation for prostate and two rotations for head-and-neck patients, with 4° arclets of spaced equidistantly every 8°. The Varian Eclipse treatment planning system with the AAA dose algorithm and a 2.5 mm dose grid was used for all plans. Plan quality was assessed using PTV coverage and sparing of organs at risk. All plans were delivered on an anthropomorphic phantom, where scattered dose was measured with thermoluminescent dosimeters (TLDs), and treatment times were recorded.

Results: All plans were visually assessed by a senior radiation oncologist and were deemed acceptable for treatment. Only few significant differences were found for PTV coverage and OAR sparing. For prostate cancer plans, no significant differences in OAR sparing were found except for the bladder, which was better spared by mARC than IMRT for both beam energies. For head-and-neck cancer cases, the mARC technique achieved a higher index of conformity and better sparing of the parotids.

While differences in plan quality were minor, treatment times could be drastically reduced by the combination of mARC with FFF beams. Average treatment times for prostate cancer were reduced from 7 min for 6 MV IMRT to 2-3 min for FFF mARC. For the complex head-and-neck target volume, times were again reduced from ca. 9 min (IMRT, 6 MV) to 5:30 min (mARC, FFF 7 MV), even though FFF 7 MV required significantly more monitor units than 6 MV plans.

The scattered dose was considerably lower for the mARC as compared with IMRT for all plans. For the prostate, scattered dose was further reduced by the FFF beam energy. For hypopharynx cancer, this effect was partially obscured by the higher monitor units.

	6 MV IMRT	FFF 7 MV IMRT	6 MV mARC	FFF 7 MV mARC
Prostate cancer patients				
Monitor units	451 (384-511)	465 (421-523)	466 (384-506)	481 (447-511)
Treatment time (min:sec)	7:07 (6:42-7:27)	6:25 (6:12-6:42)	3:50 (3:28-4:36)	2:35 (2:26-3:12)
Dose at navel (mGy)	29.4 (25.0-38.4)	21.0 (15.1-28.0)	13.5 (11.2-15.7)	10.9 (8.5-13.3)
Dose at sternum (mGy)	4.46 (4.00-5.04)	2.32 (2.05-2.67)	2.81 (2.53-3.31)	1.99 (1.20-1.70)
Dose at lens (mGy)	2.48 (2.18-2.76)	0.84 (0.76-0.94)	2.41 (1.85-3.94)	0.73 (0.63-1.03)
Hypopharynx cancer patients				
Monitor units	598 (485-729)	779 (628-918)	406 (363-459)	758 (644-897)
Treatment time (min:sec)	9:09 (8:33-10:09)	7:46 (7:22-8:08)	6:19 (6:09-6:29)	5:30 (5:25-5:37)
Dose at breast (mGy)	24.1 (20.4-27.7)	20.5 (16.8-25.7)	17.9 (13.4-22.6)	15.4 (12.3-18.4)
Dose at gonads (mGy)	1.30 (0.93-1.55)	1.05 (0.82-1.33)	0.56 (0.49-0.62)	0.68 (0.58-0.75)

Comparison of plan efficiency (monitor units and treatment time) and scattered dose. Where a significant difference was found (Wilcoxon's signed rank test with $p = 0.05$), the best plan is marked in green.

Conclusion: Target volumes of high and of low complexity were analysed in this work. For both scenarios, the mARC technique achieved plan qualities comparable or even better than for IMRT, with a considerable reduction in treatment time (ca. 64 % for prostate and 40 % for hypopharynx) and scattered dose.

EP-1673

Hippocampal-sparing radiotherapy for glioblastoma patients using the VMAT technique

J. Hofmaier¹, S. Kantz¹, M. Söhn¹, M. Alber, K. (2)Parodi³, C. Belka¹, M. Niyazi¹

¹University Hospital of LMU Munich, Radiation Oncology, München, Germany

²Aarhus University, Department of Oncology, Aarhus, Denmark

³Faculty for Physics of LMU Munich, Medical Physics, München, Germany

Purpose or Objective: To investigate the feasibility of hippocampal-sparing radiotherapy for glioblastoma patients using volumetric modulated arc therapy (VMAT). Since neurocognitive decline has been associated with hippocampal dose, hippocampal sparing could potentially improve neurological outcome of patients undergoing cranial irradiation.

Material and Methods: Datasets of 27 patients who received 3D-CRT for glioblastoma were included in this planning study. Dose distributions for the 3D-CRT plans were calculated in Elekta Oncentra Masterplan with a pencil beam algorithm. VMAT plans were optimized using the research TPS Hyperion V2.44 (equivalent to Elekta Monaco 5.1) which relies on Monte Carlo dose calculation. It was attempted to reduce the dose to the contralateral hippocampus as much as possible without compromising other treatment parameters such as target coverage, homogeneity index, conformity index and dose to other organs at risk including brain stem, chiasm, optic nerve and lenses. Parameters for both techniques were compared applying the Wilcoxon signed-rank test. The influence of tumor localization on hippocampal dose exposure was investigated with the Mann-Whitney U test. The correlation between PTV size and hippocampal dose was assessed with Spearman's rank correlation coefficient.

Results: With VMAT compared to 3D-CRT, the median reduction of the mean contralateral hippocampus dose was 56% ($p < 0.01$). Other treatment parameters could be improved or at least be kept stable. Particularly, the median V30Gy of the brain was reduced from 58.7% to 48.2% ($p < 0.01$). The median homogeneity index improved from 0.18 for 3D-CRT to 0.15 for VMAT ($p < 0.01$), the median conformity index from 0.70 to 0.80 ($p < 0.01$). For VMAT, a smaller PTV size correlated with improved hippocampal sparing ($p = 0.01$). A

parietal tumor localization was a predictor for a higher contralateral hippocampal dose ($p=0.01$).

Conclusion: A substantial reduction of the dose to the contralateral hippocampus is technically feasible when VMAT is used instead of our standard 3D-CRT planning strategy. The amount of sparing that can be achieved strongly depends on the individual patient geometry. Whether this approach is able to conserve the neurocognitive status without compromising the oncological outcome for patients with glioblastoma needs to be investigated in the setting of prospective clinical trials.

EP-1674

Should VMAT be routinely applied to treat sacral bone metastases?

V. Soyfer¹, B. Corn¹, Y. Meir¹, N. Honig¹, N. Shtraus¹

¹The Tel-Aviv Sorasky Medical Center, Radiation Oncology, Tel Aviv, Israel

Purpose or Objective: Bone metastases are a frequent and disturbing complication of cancer. The challenge of optimizing dose coverage of the concave shape of the sacrum along with its close proximity to the rectum, intestines and femoral heads lead us to investigate whether the VMAT technique is advantageous when compared to 3D treatment.

Material and Methods: Twenty three consecutively treated patients with sacral metastases in 2013-2014 were included in a comparative treatment-planning study evaluating VMAT and 3-D planning. The statistical analysis included the T-test, assuming Unequal Variance (one tail). Calculation of the p-value for the comparative results applied. Our null hypothesis was that VMAT is better than 3D technique, and our alternative hypothesis was that 3D technique is superior to VMAT.

Results: The PTV coverage was identical in VMAT and 3D planning. Median values and V15 for the intestinal exposure showed no statistically significant difference between the 3D planning and VMAT: 9.28 Gy (SD 2.25) and 47.0 ml (SD 68.62) versus 8.97 Gy (SD 2.18) and 18.45 ml (SD 69.56), respectively. However, on an individual *per case* assessment it appears that the lower exposure of the bowel depends on the small bowel/ sacrum volumes ratio. The benefit for VMAT emerges if such a ratio exceeds one. The median values for the rectum 3D and VMAT were 11.34 Gy (SD 5.14) and 7.7 Gy (SD 2.76), respectively. The median 3D and VMAT exposure of the femoral head were 1.78 (SD 2.94) Vs 4.006 (SD 2.1) on the left and 1.74 (0.9) Vs 4.26 (SD 1.8) on the right side for the 3D and VMAT, respectively.

Conclusion: Good sacral coverage is achievable with either 3-D or VMAT approaches. VMAT is advantageous vis-à-vis the rectal exposure and when relatively large amounts of small bowel course through an individual patient's fields. The 3-D approach, however, retains benefit for femoral protection, a finding that may have implications for patients with arthritis and osteopenia.

EP-1675

Total body irradiation with Tomotherapy

L. Simon^{1,2,3}, F. Izar⁴, G. Moliner¹, M. Barides^{2,3}, R. Ferrand¹

¹Institut Universitaire du Cancer de Toulouse - Oncopole, Department of Medical Physics, Toulouse, France

²INSERM, CRCT-UMR1037, Toulouse, France

³Université Toulouse III Paul Sabatier, UMR 1037, Toulouse, France

⁴Institut Universitaire du Cancer de Toulouse - Oncopole, Department of Radiation Oncology, Toulouse, France

Purpose or Objective: In Conventional Radiotherapy (CRT), Total Body Irradiation (TBI) is generally performed at long Source Skin Distance using diodes to drive the delivered dose. The dose distribution is usually not well assessed (measured only in a few points) and was shown to be strongly heterogeneous. This technique also leads to acute and late toxicity. Helical Tomotherapy (Accuray Inc., Sunnyvale, CA)

for TBI is implemented in some centers. Compared to CRT, Tomotherapy allows the delivery of the prescribed dose with a high level of accuracy and homogeneity. Organs-at-risk can be spared and the dose distribution is known before the treatment. Two technical issues have to be solved. First, the patient must be treated using two plans, head first (HF) and feet first (FF) due to limited supero-inferior (SI) table motion. At the junction of these two plans, the dose must be delivered with particular care. Moreover, the planning target volume (PTV) is the entire body, including the skin. A safety margin in the air surrounding the body should be added to take into account setup errors. Using inverse planning, however, can result in over-fluence peaks in the skin region. The aim of this work is to present our solution for these two issues, our optimized planning protocol and our clinical results after one year of practice (outcome for 15 patients).

Material and Methods: Patient treatment position is shown hereafter. Thermoplastic masks are placed on the head and the thorax (not the legs). Two CTs are acquired (HF and FF). At the planning station, the whole body (cropped 3 mm under the skin) is divided into 10 PTVs. At the junction (~halfway up the thighs), 4 PTVs (thickness 2 cm) are drawn to deliver the dose with the degraded penumbra methodology: decreased dose is delivered during HF plan and increased dose during FF plan. Different sets of doses were tested. The resulting dose distribution in the presence of simulated set-up errors (SSUE) is computed to find the combination that insures optimal dose coverage of the junction. Moreover, to insure dose coverage of legs in presence of SSUE, several Virtual Boluses (VB) were tested. A VB is a bolus added at planning, but not present during treatment. Several thicknesses and densities were tested on a phantom study: in presence of SSUE, the dose coverage and dose increase (due to the methodology) were assessed.

Results: The best combination of PTV doses at the junction is presented in table: V95% stays higher than 96% even in the case of a SSUE of 1 cm (SI). The optimal VB is an 8 mm thick VB (density=0.4). This allows a good coverage (V95%>95%) for a large lateral SSUE (up to 2.9 cm). Underestimation of dose using this VB (planning vs measure) is 1.5%.

	Dose plan HF	Dose plan FF	Total Dose
Slice 1	10.74	1.26	2
Slice 2	7.56	4.44	2
Slice 3	4.44	7.56	2
Slice 4	1.92	10.08	2

Conclusion: This study presents our optimized planning parameters. Since November 2014, 15 patients were treated with a dose of 2 or 12 Gy. Dose to lungs was limited to 9 Gy.

Most of the patients have been treated for acute leukemia with allogeneic transplant.

EP-1676

Sparing potential of scanned protons for the treatment of intramammary nodes in breast radiotherapy

A. Dasu¹, A.M. Flejmer², A. Edvardsson³, P. Witt Nyström⁴

¹Linköping University, Department of Radiation Physics, Linköping, Sweden

²Linköping University, Department of Oncology, Linköping, Sweden

³Lund University, Department of Medical Radiation Physics, Lund, Sweden

⁴Uppsala University Hospital, Department of Oncology, Uppsala, Sweden

Purpose or Objective: Breast cancer patients are among the long-term survivors of radiotherapy and therefore the long-term cardiopulmonary toxicity due to the treatment should be reduced to a minimum. However, complication rates could be further increased when intramammary nodes are included in the target due to their proximity to the heart and the lungs. Several techniques could be used to decrease the dose to the normal tissues and consequently the rates of late complications, including proton beam radiotherapy and respiratory gating. This study aims to investigate the potential for normal tissue sparing for the treatment of intramammary nodes in breast cancer radiotherapy using scanned proton beams with or without respiratory gating.

Material and Methods: The study was performed on CT-datasets acquired from ten left-sided patients during enhanced inspiration gating (EIG) and free-breathing (FB). The patients were planned with intensity modulated proton therapy (IMPT) for locoregional breast treatment. The prescribed dose to the target was 50 GyRBE in 25 fractions, assuming an RBE of 1.1. Different plans were performed for breast and supraclavicular nodes respectively breast, supraclavicular and intramammary nodes (IMN). The implications of including IMN in the target volume were evaluated from the point of view of the doses to the organs at risk for cardiopulmonary complications.

Results: Inclusion of the IMN in the target volume led to a small increase of the cardiopulmonary burden. Thus, in FB cases the average dose to the heart increased from 0.3 to 0.4 GyRBE and the average dose to the lung increased from 6.1 to 6.6 GyRBE, while the average dose to the left anterior descending artery (LAD) decreased from 4.1 to 3.8 GyRBE. For EIG cases the average dose to the heart was almost unchanged (0.2 GyRBE), the average dose to the lung increased from 6.9 to 7.4 GyRBE and the average dose to the LAD decreased from 3.3 to 2.6 GyRBE. Other dosimetric parameters of interest showed a similar trend when IMN were included in the target. These parameters are much lower than those that could be achieved in conventional radiotherapy with photons, especially with respect to the cardiovascular burden, irrespective of whether respiratory gating is used or not.

Conclusion: The results of this study indicate that radiotherapy with scanned proton beams has the potential of significantly limit the cardiopulmonary burden compared to photon RT when including the IMN in breast cancer radiotherapy.

EP-1677

Comparison of different techniques in lung SABR using VMAT with deep inspiration breath hold

N. Kayalilar¹, Z. Ozen¹, B. Gunhan¹, F. Karakose¹, K. Yakar Ilbak¹, H. Sertel¹, R. Ibrahimov¹, A. Arifoglu¹, S. Gurdalli¹, M.U. Abacioglu¹

¹Neolife Medical Centre, Radiation Oncology, Istanbul, Turkey

Purpose or Objective: Stereotactic ablative radiotherapy (SABR) for the lung primary and metastatic tumors aims to increase the local control, survival and quality of life. Deep

inspiration breath hold (DIBH) using 4D CT for simulation minimizes respiratory motion and reduces the toxicity risk by decreasing margins. In this study, we aimed to compare the dosimetric results of different devices and techniques of SABR using volumetric arc therapy (VMAT) with DIBH in the lung tumors.

Material and Methods: CT datasets of 7 patients with right-sided lung cancer performed with RPM system (Varian, Palo Alto) was used. Median PTV was 13.2cc. Dose prescription objective was to cover 98% of the target volume by D98% which was 50 Gy/5 fractions. Four different VMAT plans were made on Eclipse TPS (Varian, Palo Alto) using AAA algorithm. Plan A consisted of TrueBeam, 120HDMLC, 6MV-FFF, without jaw tracking, Plan B TrueBeam, 120HDMLC, 6MV-FFF, with jaw tracking, Plan C TrueBeam, 120HDMLC, 6MV, without jaw tracking, Plan D with Trilogy, 120MilleniumMLC, 6MV, without jaw tracking. Three partial arcs using 210 degrees were used to generate the plans under the same optimization conditions. Monitor Unit (MU), beam-on time (BOT), Gradient Index (GI), lung V20 and V5, dose at 2 cm from PTV (D2cm), PTV(Dmax) and PTV(Dmin) were assessed for comparison. Wilcoxon test was used for statistical evaluation.

Results: No statistically significant differences were found for total MU, D2cm and PTV(Dmin) between the four plans. Mean PTV(Dmax) values were lower in Plan C with HDMLC compared to Plan D with MilleniumMLC (122.9%±3.9 vs 126.8%±3.7, $p=.018$). At GI assessment; there was no significant difference between plans with and without jaw-tracking. However, there was a significant difference between Plan C and Plan D (4.4±0.5 vs 4.8±0.6, $p=.018$); and between Plan A (FFF) and Plan C (FF) (4.2±0.4 vs 4.4±0.5, $p=.018$). V20 and V5 was lower in Plan C compared to Plan D (2.8%±1.5 vs 3.3%±1.5, $p=.028$ and 15.1%±5.3 vs 16.0%±5.6, $p=.018$); V5 was lower in Plan A compared to Plan C (14.4%±5.1% vs 15.1%±5.3). BOT was significantly shorter between Plan A and Plan C (167.5 sec±20.4 vs 390.5 sec±47.8, $p=.018$).

Conclusion: In SABR with VMAT using DIBH, we observed some improvements by using HDMLC compared to MilleniumMLC and FFF compared to FF beams. However, we could not observe additional benefit with jaw tracking in the FFF mode. Major advantage of FFF was the shorter BOT, which may finally improve the patient compliance in SABR using DIBH technique.

EP-1678

VMAT in locally advanced lung cancer; does it add benefit?

M. Kamaleldin¹, M. Al Daly², S. Talima²

¹Cairo University- Fac. of Medicine, Radiation Physics, Cairo, Egypt

²Cairo University- Fac. of Medicine, Clinical oncology, Cairo, Egypt

Purpose or Objective: In locally advanced NSCLC Concurrent chemo/Radiation is the key most important treatment approach. However delivering adequate radiation dose to improve treatment results is limited by the tolerance of nearby structures (lungs, esophagus, heart etc...), and by the intrafractional uncertainties resulting from prolonged treatment time of the conventional techniques. We have compared VMATplanes Vs. 3D CRT in inoperable advanced lung cancer cases.

Material and Methods: Ten cases of previously treated lung cancer with 3DCRT planes (minimum of 4 beams) were replanned with VMAT optimization using 2 half arcs. Both planes were performed on Eclipse© planning system (version 11) with AAA-algorithm and linear accelerator UNIQUE © of energy 6Mv , dose rate of 600 cGy/min , and 120 multileaf collimator. The dose was prescribed as 60Gy / 30fr for the CTV surrounded with margin of 1.5cm for the PTV. Plans were compared for coverage , avoidance of organs at risk , and total number of MU.

Results: The mean GTV volumes ranged from 149.44 to 526.53 cc. VMAT plans show good results in comparison with 3DCRT in both conformity index (0.81±0.09 Vs 0.68±0.07 respectively, p-value of 0.009), and heterogeneity index (0.11±0.03 Vs 0.14±0.02, p value= 0.042). Furthermore, minimum doses to PTV in VMAT plans are higher than 3DCRT plans (57±1.22 Vs 55.1±0.86, p value= 0.001).

In risk structures, the lung volume receiving 10Gy, 20Gy and 30Gy were reduced in VMAT plans (with relative reduction of 2.27%, p=0.002; 4.87%, p=0.001; 11.8% respectively). Mean lung dose was also reduced (15 Vs 17.69) but not statistically significant. V30 of the heart was reduced compared to 3DCRT (7.53±6.2 10.43±6.8 with p value of 0.051). The maximum dose of esophagus with VMAT was 47.7 Vs 48.69 with 3D CRT (not statistically significant). Moreover, D 50 of the esophagus was less with VMAT (19.94 Vs 23.63) with p value of 0.22.

Regarding monitor units, the mean values were (461.40±124.42 Vs 227.90±13.52) for VMAT and 3D CRT respectively.

Conclusion: In spite of large PTVs included in our study VMAT planes showed tendency toward reduction of mean and high lung dose and heart doses. Reduction in esophageal doses was not statistically significant , This was obtained without impairment of PTV coverage that was improved in some cases. VMAT for advanced lung cancer can help to improve therapeutic ratio and may open the door for dose escalation

EP-1679

A single centre experience of using helical tomotherapy (HT) for craniospinal irradiation (CSI)

M. Singhera¹, T. Falco¹, K. Blythe¹, R. Begum¹, T. Greener¹, R. Beaney¹, N. Mikhaeel¹

¹Guy's and St Thomas' NHS Foundation Trust and King's Health Partner's Academic Health Sciences Centre, Radiotherapy, London, United Kingdom

Purpose or Objective: CSI is one of the most complex radiotherapy (RT) treatments. Conformal 3D RT techniques require many fields (field within field / segments) to achieve homogeneity and minimise doses to organs at risk (OAR) and involve field junctions. The planning process is time consuming and the actual treatment delivery is long, frequently exceeding 30 minutes. HT offers an excellent alternative with the ability to treat patients in supine position, without junctions and with better dose distribution. The aim of this study is to evaluate the use of HT in CSI with emphasis on dosimetric parameters and treatment duration.

Material and Methods: Retrospective analysis of treatment planning and dosimetric indices was undertaken on seven patients who received cranio-spinal radiotherapy with HT at our centre. The HT plan was delivered using 51 beam angles per rotation, with a constant modulation factor of 2.0, field width of 5 cm and one of two pitches (0.43 or 0.28) to optimise treatment plans. An iterative inverse planning algorithm based on least squares minimization was used which optimises multi-leaf collimator at each beam angle. Dose was calculated by convolution and superposition. Patients were imaged daily covering different areas of the body and corrections applied for directional errors. Data analysis was done using descriptive statistics.

Results: Helical tomotherapy plans for seven adult patients were analysed. Five patients had a haematological malignancy and two had a medulloblastoma. Five patients with a haematological diagnosis received a dose of 30Gy in 1.5Gy/#. Two patients with medulloblastoma received 35 Gy delivered in 1.67Gy/#. Details of treatment planning and plan evaluation parameters of seven patients are presented in Table 1.

Patients	1	2	3	4	5	6	7	Average
Pitch	0.4	0.4	0.2	0.2	0.2	0.4	0.4

Beam 'on-time' (minutes)	9.5	9.3	8.6	10.2	11.9	11.6	11.6	10.3±1.3

PTV: Planning target volume, DmaxPTV: Maximum dose to PTV, Dmin: Minimum dose to PTV

Overall HT plans achieved excellent PTV coverage with mean V95 of 33.5 Gy for medulloblastoma patients. The mean V95 was 28.3 Gy for those with a haematological diagnosis. The mean homogeneity index was 1.0. Organs at risk doses were well below tolerances required. In particular averaged mean heart dose was 10.9±1.3, mean lung dose was 8.6±2.2 and mean liver dose was 9.8±1.2. The mean D50% for lung was 7.2 Gy±3.8 and mean D10% was 20.2Gy±3.6. The mean D50% for the heart was 10.1Gy±1.3 and mean D10% was 14.7Gy±2.1.

Conclusion: HT for CSI has many advantages including: the ability to treat patients in supine position, no need for junctions, excellent PTV coverage, low doses to OAR and shorter treatment time.

EP-1680

Treatment planning of stereotactic radiosurgery for single brain metastases: impact of leaf width

E. Lamers-Kuijper¹, E. Van der Bijl¹, A. Van Mourik¹, C. Van Vliet-Vroegindewij¹, E. Damen¹

¹The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: Stereotactic radiosurgery of brain metastases requires highly conformal dose distributions. Besides beams setup, characteristics of the linear accelerator collimator may also play a role. In this study we compared the impact of leaf width on the dose outside the target for stereotactic radiosurgery of single brain metastases.

Material and Methods: For 10 patients with one lesion, treatment plans were generated using two MLC types: Elekta Agility with 0.5cm leaf width and Elekta MLCi2 with 1cm leaf width. Two VMAT arcs were used, one coplanar arc and one non-coplanar arc (couch 90°) Five patients had a PTV volume ≤ 4 cm³ with a prescription dose of 24Gy in 1 fraction, and 5 patients had a PTV volume between 4 and 14 cm³ with a prescription dose of 18Gy in 1 fraction. All plans were required to fulfill clinical requirements: V100%Dpres>95%VPTV, D0<150%Dpres and OAR doses as low as possible and never above clinical constraints. The maximum dose in the PTV is kept the same per patient in both plans. The quality of the dose distribution outside the PTV was evaluated using the mean dose in two ring structures, adjacent to the PTV.

Results: The mean dose was evaluated in the first 2 rings of 5 mm around the PTV(table 1). The difference in mean dose for the small lesions(Dpres=24 Gy) of the first ring of 5 mm is 1.8 Gy in favor of the Agility and 0.9 Gy for the larger lesions(Dpres=18 Gy)also in favor of the Agility. The difference is smaller for the larger lesions (figure1). Also for the second ring of 5 mm, adjacent to the first ring, the difference is 1.1 Gy vs 0.8 Gy also in favor of the Agility.

Patient	24Gy						18Gy						
	Ring5mm(Gy)			Ring10-5mm(Gy)			Ring5mm(Gy)			Ring10-5mm(Gy)			
	MLCi1	Agility	Diff	MLCi1	Agility	Diff	MLCi1	Agility	Diff	MLCi1	Agility	Diff	
1	12.2	10	2.2	5.6	4.6	1	6	12.4	10.9	1.5	5.5	4.7	0.8
2	12.9	10.9	2	6.3	5.3	1	7	14.6	13.8	0.8	4.5	3.8	0.7
3	11.9	10.4	1.5	5.6	4.8	0.8	8	13.5	12.3	1.2	7.6	6.2	1.4
4	19.9	17.9	2	5.4	4	1.4	9	14.5	13.8	0.7	5.2	4.6	0.6
5	16.5	15.1	1.4	8.4	7.1	1.2	10	13.3	12.9	0.4	7.2	6.7	0.5
mean	14.2	12.9	1.8	6.2	5.2	1.1	mean	13.7	12.7	0.9	6	5.2	0.8
SD	3.5	3.5	0.3	1.2	1.2	0.2	SD	0.9	1.2	0.4	1.3	1.2	0.4

Table 1: Mean dose in the rings around the PTV at 5 mm and 10 mm for small lesions (PTV volume < 4 cm³) and the larger lesion (PTV volume between 4 and 14 cm³)

Figure 1: The mean dose difference in the first 5 mm ring around PTV. In the right upper corner the typical leaf setting for the Agility on the right and the MLCi1 on the left.

Conclusion: For the small lesions with a volume smaller than 4 cm³ the Agility shows a steeper gradient in the two surrounding rings than the MLCi1. Therefore we recommend the use of the Agility for treating the smaller lesions.

EP-1681

A treatment planning strategy for SBRT of multiple T1-2 lung tumors

A. Tjihuis¹, E. Van der Bijl¹, J. Kneegjens¹, C. Van Vliet-Vroegindeweij¹, E. Damen¹

¹The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: To obtain a planning technique for SBRT treatment of multiple lung tumors, which is suitable for all relative positions of the tumors.

Material and Methods: For 10 patients with two tumors, treated with 3 x 18Gy, VMAT plans were generated in Pinnacle, using various approaches: simultaneous versus sequential optimization, with or without the dose distribution of one tumor as background for optimization of the other tumor. The quality of the treatment plans was judged on coverage (PTV V100% >95%), conformity (V100%/PTV volume), inhomogeneity (PTV D0 < 165%) and dose constraints on OARs.

Results: Simple addition of beams for two independently planned tumors does not yield optimal results since the mutual low dose contributions cannot be taken into account properly. Simultaneous optimization on both targets results in pairs of open leaves in-between the lesions (Fig 1). We therefore concluded that the strategy that yields the most conformal plans is the subsequent planning of the tumors using a dual-arc for both, where the dose distribution resulting from the planning of the first target is used as a background dose while optimizing the beams for the second target. During optimization of the first tumor, no limit is applied for the dose to the second PTV, since this can be compensated for in the optimization procedure for this PTV. After optimization of the second PTV, the number of monitor units in each beam pair might be adjusted slightly to conform to the required target coverage. This strategy works for two or more isocenters as well as for one mutual isocenter. For three or more tumors, iterating the above method yields good results

Two examples of simultaneous optimizing on both targets (fig1)

Conclusion: We developed a generic planning strategy to obtain high quality lung SBRT-treatment plans for patients with multiple lung tumors. The strategy uses a dual-arc VMAT for each tumor, while taking the dose distribution covering the first target is used as background during dose optimization for the second target. This method is clinically in use since March 2015, since then 15 patients have been treated using this method.

EP-1682

Breast and regional lymph nodes RT: V-MAT/RapidArc and Tomotherapy comparison

M. Valli¹, L. Negretti², S. Cima¹, M. Frapolli¹, A. Polico¹, G. Nicolini³, E. Vanetti³, A. Clivio³, A. Richetti¹, G. Pesce¹, F. Martucci¹, C. Azinwi¹, K. Yordanov¹, S. Presilla³

¹Oncology Institute of Southern Switzerland, Radiation Oncology, Bellinzona-Lugano, Switzerland

²Clinica Luganese, Radiation Oncology, Lugano, Switzerland

³Ente Ospedaliero Cantonale, Medical Physics Unit, Bellinzona, Switzerland

Purpose or Objective: Two centers compared VMAT/RapidArc (RA) and Tomotherapy (TOMO). for the irradiation of breast and regional lymph nodes.

Material and Methods: Five left and five right breasts plus regional nodes have been contoured by two dedicated radiation oncologists. Two senior physicists checked the treatment plans studied by dedicated dosimetrists. The Anatom-e tool was tested for improving definition and avoiding interpersonal variability in the contouring. Prescription, according to ICRU, was 50 Gy in 25 daily fractions. We considered both lungs, the heart, the left anterior descending coronary artery (LAD), the contralateral breast and the thyroid as Organa at Risk (OAR). The dose constraints were: PTV V95=95%, ipsilateral lung V20%, heart mean dose < 10Gy, heart max dose < 35Gy, LAD max dose ≤ 20Gy, thyroid max dose < 45 Gy and contralateral breast max dose ≤ 5 Gy. We have studied the treatments in free breathing modality, perfectly aware of the higher dose received by heart and LAD in comparison to the respiratory-gated modality, routinely used in the RA center.

Results: We summarized the results of this comparison in Table 1

Table 1. Left and right breast plus lymphnodes.

	TOMO	RA
LEFT BREA ST + LN	% (±SD)	% (±SD)
V95% PTV	94.9 (±0.5)	95.1 (±1.0)
V20Gy/ipsilateral lung	15.9 (±1.3)	22.2 (±3.2)
	Median dose Gy (±SD)	Median dose Gy (±SD)
LAD	4.7 (±0.9)	15.7 (±4.5)
Heart	3.5 (±3.8)	9.0 (±1.7)
Contralateral breast	5.1 (±1.4)	4.2 (±1.1)
	Median min (±SD)	Median min (±SD)
Beam-on time	6.91min (±0.21)	1.03min (±0.03)
RIGHT BREAST + LN	% (±SD)	% (±SD)
V95 PTV	95.0 (±0.5)	94.9 (±0.1)
V20 ipsilateral lung	19.4% (±3.1)	21.2% (±1.5)
	Median dose Gy (±SD)	Median dose Gy (±SD)
LAD	2.0 Gy (±1.1)	7.7 Gy (±0.9)
Heart	5.9 Gy (±0.8)	6.8 Gy (±1.5)
Contralateral breast	3.8 Gy (±0.5)	4.2 Gy (±0.4)
	Median min (±SD)	Median min (±SD)
Beam-on time	5.5min (±0.28)	1.07min (±0.01)

Conclusion: Both techniques allow a good coverage and dose uniformity for the PTV, with proper sparing of the OAR. TOMO

allows greater heart and LAD sparing in left cases, when compared to RA with no gating. Of note beam-on time, in RA modality, is highly decreased.

EP-1683

Left breast IMRT with SIB: a user improved technique to reduce heart and lung dose

S. Naccarato¹, R. Ruggieri¹, G. Sicignano¹, F. Ricchetti¹, S. Fersino¹, A. Fiorentino¹, N. Giaj Levra¹, R. Mazzola², A. Alongi¹

¹Ospedale Sacro Cuore Don Calabria, Radiation Oncology, Negrar, Italy

²Radiation Oncology School, University of Palermo, Palermo, Italy

Purpose or Objective: Many strategies have been explored in attempt to reduce the cardiac dose and the lung dose during breast irradiation. Here we investigated the efficacy of user optimised collimator rotation and jaws setting, in static gantry IMRT with simultaneous integrated boost (SIB), on heart and lung dose sparing.

Material and Methods: From September 2010 to March 2014, 69 patients were treated for left breast (PTV-breast) cancer with SIB at surgical bed (PTV-boost) in 25 fractions: the prescribed doses (Dp) were 50 Gy and 60 Gy, respectively. All plans were generated with Varian Eclipse™ v.10.0.28 TPS, using 5-7 IMRT sliding-window fields equally spaced along a 190° arc, with 6MV photon beams and a Varian Millennium120™ multileaf collimator. Dose computation were performed by AAA algorithm, with a 2.5 mm grid size. The first 41 patients were planned by fixing a null collimator rotation, and by leaving the optimizer Varian DVOTM v.10.0.28 free to search for the optimal setting of the jaws (IMRT-A). In the next 28 patients the arrangement of the two outermost tangential fields were set to maximally spare the heart and the left lung. In details, the collimator was rotated so as to align the medial jaw with the projection of the chest wall (IMRT-B). Further, for the most lateral field the jaws were collimated to the lateral and central portions only of the PTV-breast. The remaining 3-5 fields covered entire target according to the BEV projection of the target. By selecting the Fixed Jaws Parameter of the two outermost fields into DVO the same jaws aperture defined in BEV were assured during optimization process. Plans aimed to cover at least 95% of the PTVs volume with a dose ≥ 95% of the Dp (V95% ≥ 95%), with V107% < 2%, for PTV-boost. Heart volume receiving more than 20 Gy (V20) < 10%. Left lung V20 < 20%. Right breast mean dose (Dmean) < 2Gy and right lung Dmean < 3Gy. By hypothesis testing, several dose-volume metrics were then compared across the two groups of plans.

Results: As detailed in Table 1, although a slightly reduced V95% to PTV-breast was associated with IMRT(B), both techniques assured to any patient the required target dose coverage. In terms of dose sparing to the OARs, IMRT(B) was associated with a 25.6% reduction in the median of Dmean to the heart, while the heart V5, V10 and V20 were respectively reduced by 21.1%, 49.8%, and 52.1% (all p < 0.002). Further, the median of Dmean to the left lung decreased by 21.2%, while V5, V10 and V20 to this organ decreased by 5.4%, 36.8% and 28.6%, respectively (all p < 0.003). No significant differences resulted for Dmean to the right breast and lung.

Table 1 Comparison of median (range) values of dose-volume metrics for PTV coverage and OAR sparing as a function of IMRT plan modality

		IMRT-A	IMRT-B	p-value	
PTV-breast	V95% (%)	97.6 (94.5-99.9)	96.5 (93.8-99.1)	0.003	§
PTV-boost	V95% (%)	99.8 (97.9-100.0)	99.8 (98.0-100.0)	0.408	#
	V107% (%)	1.6 (0.0-15.1)	0.1 (0.0-13.0)	0.057	#
Hearth	Dmean (Gy)	9.4 (6.0-16.6)	7.0 (4.1-13.0)	<0.001	§
	V5Gy (%)	71.8 (41.5-97.8)	56.6 (25.7-98.4)	0.002	§
	V10Gy (%)	33.9 (7.1-75.7)	17.0 (2.2-62.4)	<0.001	*
	V20Gy (%)	7.5 (0.3-32.9)	3.6 (0.0-11.8)	0.001	*
Left lung	Dmean (Gy)	14.6 (10.6-19.9)	11.5 (7.6-19.1)	<0.001	*
	V5Gy (%)	91.2 (72.9-100)	86.3 (51.1-99.8)	0.003	*
	V10Gy (%)	54.4 (29.7-89.2)	34.4 (22.4-90)	0.0002	*
	V20Gy (%)	21 (12.4-45.3)	15 (6.2-30.2)	<0.001	*
Right breast	Dmean (Gy)	1.7 (0.4-2)	1.4 (0.7-6.6)	0.493	#
Right lung	Dmean (Gy)	2.2 (1.1-4.9)	1.5 (0.6-7)	0.209	#

Abbreviations: § two-tailed t-Student test, # two-tailed Mann-Whitney test, \$ one-tailed t-Student test, * one-tailed Mann-Whitney test.

Conclusion: Similar PTVs coverage were obtained with both IMRT techniques, the selection from an experienced user of collimator rotation and fixed jaws settings for the two outermost tangential fields in a 5-7 fields sliding-window IMRT (IMRT-B) resulted in a significant reduction of the dose to the heart and the ipsilateral lung.

EP-1684

Optimization of a VMAT technique for three dose level irradiation of head and neck cancer

M. Bougtib¹, M. Malisan², M. Crespi², C. Foti², M. Guernieri², E. Moretti²

¹International Master on Medical Physics, Trieste University, Trieste, Italy

²Azienda Ospedaliero-Universitaria di Udine, Medical Physics, Udine, Italy

Purpose or Objective: It was reported in literature that increasing the number of arcs from 1 to 4-8 improves the quality of head and neck (HN) VMAT plans with simultaneously integrated boost (SIB). Aim of this work is to optimize the performance of triple-arc VMAT (TAV) against conventional IMRT for three dose level irradiation of advanced HN cancer.

Material and Methods: A retrospective planning study was conducted on a sample of 10 patients with HN cancer previously treated with IMRT. PTVs were delineated for 3 different dose levels (70, 63 and 56 Gy in 35 fractions) delivered by a SIB technique. All plans were generated with 6 MV x-rays for a Varian Clinac iX linac. Optimization and calculations were done in the Varian Eclipse system (v. 10.0.28). IMRT plans included 7 equally placed beams using sliding window technique. Three TAV plans were generated for each patient: triple full-arc plan, 3F (collimator angles (CA): 0°, 20°, 340°); double full + partial arc plan, 2FP0 (CA: 20°, 340°; 0° for partial arc); double full + partial arc plan, 2FP90 (CA: 20°, 340°; 90° for partial arc). Dose normalization was set as D(95%)=70 Gy for the primary tumour and involved nodes (PTV70), while planning objectives were D(95%) 95% of prescription dose for the high- and low-risk target volumes (PTV63 and PTV 56). OARs taken into account into optimization included the brainstem, spinal cord, parotids, oral mucosa, larynx, mandible, vertebrae, thyroid. The healthy tissue was defined as the body volume excluding the PTVs. Planning objectives are shown in Table 1. The parameters used for plan comparison include PTV coverage, dose homogeneity (HI) and conformity (CI), OAR sparing, healthy tissue integral dose (HTID) and number of MUs.

Results: Table 1 shows the results of PTV coverage, homogeneity, conformity, and doses to OARs for the 4 planning techniques. Similar coverage of all PTV's is obtained in all the techniques. TAV plans show better homogeneity and conformity in PTV70 compared to IMRT, though the difference is significant only for HI of the 2FP90 technique. For spinal cord and vertebrae the 2FP90 plans show significant reductions of maximum dose. No significant

changes are observed in terms of mean dose to parotids or maximum dose to mandible, while oral mucosa and thyroid result better spared with TAV techniques. Though smallest for IMRT, the mean HTID is not significantly different from the TAV techniques. Finally, MU's for all TAV techniques are significantly lower than for IMRT; no reduction is observed when using one partial arc instead of 3 full arcs.

Table 1. Planning objectives and plan comparison among 7-field IMRT and triple arc VMAT. Results are averaged over the 10 patients of the sample. Statistical significance of Wilcoxon signed rank test is reported in the last column.

	D _{mean} (Gy) ≤ 40	35.1	32.9	32.5	32.6	a), b)
Healthy tissue D _{mean} (Gy dm ³)	---	86.4	90.5	90.0	90.4	none
	MU	1632	529	515	532	a), b), c)

Legend: a) IMRT vs 3F; b) IMRT vs 2FP0; c) IMRT vs 2FP90; d) 3F vs 2FP0; e) 3F vs 2FP90; f) 2FP0 vs 2FP90.

Conclusion: TAV techniques allow same PTV coverage and OAR sparing as 7-field IMRT, with one third of MU's and better dose homogeneity. HTID results lowest in IMRT, but differences are not significant. As for the optimal TAV configuration, 2FP90 including one partial arc with a 90° collimator angle seems to spare spinal cord and brainstem significantly better than 3F or 2FP0 techniques.

EP-1685

Influence of flat, flattening filter free beam model and different MLC's on VMAT based SRS/SRT

B. Sarkar^{1,2}, A. Pradhan³, A. Munshi¹, S. Roy¹, T. Ganesh¹, B. Mohanti¹

¹Fortis Memorial Research Institute, Radiation Oncology, Gurgaon, India

²GLA University, Physics, Mathura, India

³GLA University, Mathematics, Mathura, India

Purpose or Objective: Linear accelerator (Linac) based stereotactic radiotherapy (SRT) and stereotactic radiosurgery (SRS) using Volumetric modulated arc therapy (VMAT) got a wide spread application for treating intracranial lesions. In recent time linacs were facilitated with flattening filter free beam and miniature MLC's. This development was intended to facilitate a superior dose conformity and quicker therapy delivery. This study was designed to study the dosimetric outcomes and monitor units of the stereotactic treatment plans attributed to different commercially available MLC and beam models.

Material and Methods: Ten patients having twelve target volumes, who received the stereotactic treatment in our clinic using Axesse linear accelerator (reference arm), were retrospectively considered for this study. The test arms includes plans using Elekta Agility with FFF, Elekta Agility with flat beam, Elekta APEX, Varian Millennium 120, Varian Millennium 120HD and Elekta Synergy in Monaco treatment planning system. Calculation grid size and planning constraints were not altered in the test plans. To objectively evaluate the efficacy of MLC-beam model, the resultant dosimetric outcomes were subtracted from the reference arm parameters.

Results: Figure 1 represent total seven (one reference arm and six test arm) plans for an evaluated patient. Maximum dose and mean dose of PTV/GTV V105%, V100%, V95%, D1%, showed a maximum inter MLC- beam model variation of 1.5% and 2% for PTV and GTV respectively. Average PTV heterogeneity index and conformity index shows a variation in the range 1.08-1.11 and 0.56-0.63 respectively. Mean dose difference (excluding reference arm) for all organs varied between 1.7cGy -194.5cGy (mean dose 16.1 cGy SD=57.2 cGy) and 1.1cGy-74.8cGy (Mean dose= 6.1 cGy SD=26.9 cGy) for multiple and single fraction respectively.

Conclusion: The dosimetry of VMAT based stereotactic treatment plan yield minimal dependency on beam characteristic (model) and MLC width. All tested MLC and beam model could fulfil the desired PTV coverage respecting OAR dose constraints. The only notable difference was the halving of the MU for FFF beam as compared to plane beam. This has the potential to reduce the total patient on couch time by 15% (approximately 2 minutes).

EP-1686

Frameless radiosurgery in brain metastasis with Tomotherapy: a comparison toward dosimetric index

A. Ciarmatori^{1,2}, G. Guidi^{1,3}, A. Bruni⁴, N. Maffei^{1,3}, C. Vecchi³, M.G. Mistretta¹, P. Ceroni¹, S. Gaito⁴, P. Giacobazzi⁴, T. Costi¹

¹Azienda Ospedaliero Universitaria "Policlinico" di Modena, Medical Physics Department, Modena, Italy

²Alma Mater Studiorum University, Post Graduate School in Medical Physics, Bologna, Italy

³Alma Mater Studiorum University, Physics and Astronomy Department, Bologna, Italy

⁴Azienda Ospedaliero Universitaria "Policlinico" di Modena, Radiation Oncology Department, Modena, Italy

Purpose or Objective: Effectiveness of stereotactic radiosurgery (SRS) in treatment of brain metastasis have been demonstrated. In this work we have, retrospectively investigated dosimetric features of frameless SRS delivered with Tomotherapy and compared with reported result in literature in term of Paddick Conformity Index (CI), Homogeneity Index (HI) and Gradient Score Index (GSI).

Material and Methods: 68 patient treated between 2008 and 2013 in our institution with frame-less set-up (only thermoplastic mask) have been enrolled. 89 Lesions have been stratified for dimension (lower or greater than 5 cc) and for prescription strategies. ICRU 62 (D95>95%, D110<10%) guidelines were utilized for 40 patients while ICRU83 (D50=Prescription, D98>95%, D107<2%) recommendations were utilized in the remaining 28. Dosimetric index for describing Target Coverage, Target Homogeneity and Organ at Risk (OAR) sparing were selected among the most used in similar studies (Pubmed Line, keyword: "Dosimetric Index", "Radiosurgery", "Tomotherapy", "Brain").

Results: CI, HI and GSI are the most cited feature for describing respectively Target Coverage (21 studies), Target Homogeneity (12 studies) and OARs sparing (5 studies). Mean and standard deviation of CI, HI and GSI in the cohort were, respectively, 1,59 ± 0,38, 1,06 ± 0,04 and 51 ± 16. A multivariate logistic regression analysis of the PTV volume showed significant influence (p<0.05) on CI while prescription strategies influenced GSI. ICRU83 recommendations seems to

guarantee a better sparing of normal tissue. Obtained index are aligned with reported results in analogous studies with Tomotherapy. Gammaknife perfexion seems to be the technique able to guarantee better results in term of CI. OARs sparing in case of no co-planar beam delivered by LINAC exhibit worse performance than modulated technique.

Conclusion: Treatment of brain metastasis with Tomotherapy showed encouraging results in term of dosimetric outcome. Lesion size and prescription strategies showed a statistically significant influence on dosimetric distribution. Clinical outcome with frameless immobilization has proven feasible, well tolerated and able to increase patient compliance as exclusive treatment of brain oligo-MTS.

Improving target dose homogeneity in intensity-modulated radiotherapy for sinonasal cancer

J.Y. Lu¹, B.T. Huang¹, W.Z. Zhang¹

¹Cancer Hospital of Shantou University Medical College, Radiation Oncology, Shantou, China

Purpose or Objective: It is challenging to achieve homogeneous target dose distribution in intensity-modulated radiotherapy (IMRT) for sinonasal cancer (SNC). To overcome this difficulty, we proposed a base-dose-compensation (BDC) planning technique, in which the treatment plan is further optimized based on the original plan with half of the prescribed number of fractions and finally the number of fractions of treatment plan was restored from a half to the total.

Material and Methods: CT scan data of 13 patients were included. Generally acceptable original IMRT plans were created and further optimized individually by (1) the BDC technique and (2) a local-dose-control (LDC) planning technique, in which the original plan is further optimized by addressing hot and cold spots. We compared the target dose coverage, organ-at-risk (OAR) sparing, total planning time and monitor units (MUs) among the original, BDC, LDC IMRT plans and additionally generated volumetric modulated arc therapy (VMAT) plans.

Results: The BDC technique provided significantly superior dose homogeneity/conformity by 23%-48%/6%-9% compared with both the original and LDC IMRT plans, as well as reduced doses to the OARs by up to 18%, with acceptable MU numbers. Compared with VMAT, BDC IMRT yielded superior homogeneity, inferior conformity and comparable overall OAR sparing. The planning of BDC, LDC IMRT and VMAT required 30, 59 and 58 minutes on average, respectively.

Conclusion: The BDC planning technique can achieve significantly better dose distribution with shorter planning time in the IMRT for SNC.

EP-1688

Evaluation of automatic brain metastasis planning for multiple brain metastasis

Y. Mori¹

¹Aichi Medical University, Department of Radiology and Radiation Oncology, Aichi, Japan

Purpose or Objective: Recently Automatic Brain Metastasis Planning (ABMP) Element [BrainLAB] was commercially released by BrainLAB. It covers multiple off-isocenter targets at a time inside a multi-leaf collimator field and enables stereotactic radiosurgery (SRS) / stereotactic radiotherapy (SRT) with a single group of lineac-based dynamic conformal multi-arc for multiple brain metastases. In this study, dose planning of ABMP (ABMP-single isocenter dynamic conformal arc [ABMP-SIDCA]) for stereotactic radiosurgery of small multiple brain metastasis was evaluated in comparison with those of conventional multi-isocenter DCA (iPlan [BrainLAB]-MIDCA) and Gamma Knife [Elekta] SRS (GKRS).

Material and Methods: Simulation planning was performed with ABMP-SIDCA and GKRS was made in a case of multiple

small brain metastasis (9 tumors of 0.2 to 0.7 ml in volume) which were originally treated with iPlan-MIDCA. First, dosimetric comparison was done between ABMP-SIDCA and iPan-MIDCA in the setting with PTV (planned target volume) margin of 2mm and D95=95% dose (19 Gy). Second, dosimetry of GKRS was compared with that of ABMP-SIDCA with PTV margin of 0, 1mm, and 2mm, and D95=100% dose (20 Gy).

Results: First, CI (1/Paddick's CI) and GI (V[half of prescription dose] / V[prescription dose]) in ABMP-SIDCA (mean, 1.36 and 5.12) were compatible with those of iPlan-MIDCA (mean, 1.53 and 4.84). Second, PIV (prescription isodose volume) of GKRS (mean, 0.23 ml) was between that of no margin- and 1mm-margin ABMP-SIDCA (mean, 0.10 ml and 0.28 ml). Considering dose gradient, the same tendency was observed. The mean of V[half of prescription dose] of GKRS, no margin-, and 1 mm margin-ABMP-SIDCA were 0.87 ml, 0.60 ml, and 1.37 ml respectively.

Conclusion: The conformity and dose gradient with ABMP-SIDCA was as good as those of conventional MIDCA by each lesion. If the conditions permit minimal PTV margin (1mm or less), ABMP-SIDCA might provide excellent dose fall-off compatible with GKRS and enable a short treatment time. The author has no COI. However this study was performed by use trial of ABMP Elements provided by BrainLAB (Tokyo).

EP-1689

Which technique is dosimetrically superior in the treatment of breastcancer: VMAT or Fixed Field IMRT

S. Murphy¹, H. Drury-Smith²

¹CancerPartnersUK Ltd., Radiotherapy CPOK, Southampton, United Kingdom

²Sheffield Hallam University, Dept. of Allied Health Professions, Sheffield, United Kingdom

Purpose or Objective: To determine in terms of target coverage and organ at risk (OAR) doses which concomitant boost technique is superior in the treatment of breast cancer; VMAT or fixed field IMRT.

Material and Methods: 30 previously treated breast patients (15 Left, 15 Right) were re-planned with both VMAT and fixed field concomitant IMRT techniques. A two dose prescription was used similar to previous planning studies (1-3) using the same dose constraints as per the IMPORT HIGH trial (1). 40Gy in 15 fractions was planned to the whole breast while boosting the tumour bed to 48Gy in 15 fractions. A base plan consisting of the existing forward planned tangent fields delivered approximately 38Gy to the whole breast while the tumour bed was boosted with approximately 10Gy using an inverse planned IMRT option. A single partial arc starting and finishing at the tangent angles formed the VMAT portion and the ff-IMRT trial used the 2 existing tangent beam angles followed by 3 further equally spaced beams. Target coverage, heart, ipsilateral lung, contralateral lung and contralateral breast dose was measured. A Two-tailed t-Test sample for means was used to compare the dosimetric differences between the techniques using excel software. Statistical significance was defined as P<0.05.

Results: Maximum dose D2% was statistically lower for VMAT; 103.2% vs. 103.7% for ff IMRT whereas minimum doses were equivalent. No differences were found with ipsilateral lung mean and V5Gy doses, contralateral breast mean dose, heart mean dose, heart V5Gy and V10Gy doses. VMAT demonstrated statistically lower V2Gy doses to the contralateral lung (0.7% vs.1.6%) and heart for both left (19.0%/22.6%), and right (5.5%/8.8%) sided patients respectively. Whereas ff-IMRT boasted significantly lower ipsilateral lung V20Gy, V18Gy and V10Gy doses (7.9/8.6/13.1 vs. 8.1/8.8/13.4%) with VMAT respectively

Conclusion: Despite both VMAT and ff-IMRT plans reaching statistical significance in a number of OAR and target parameters there is no clear superior option and whether the differences are clinically significant is a different question. Both techniques met all mandatory dose constraints and the

majority of cases surpassed all optimal dose constraints demonstrating the high quality of the planning technique. The incorporation of deep inspiration breath hold (DIBH) ensured doses to the heart were exceptionally low; mean heart dose for left breast cases averaged 1.4Gy for both treatment options. As neither technique has proven superior, the significantly reduced treatment times associated with VMAT make this a more desirable option to implement clinically.

EP-1690

Conversion of the Tomotherapy plans to the IMRT plans for prostate patients with hip prosthesis

T. Piotrowski¹, M. Olmińska², J. Litoborska², B. Pawatowski³, A. Jodda²

¹Poznan University of Medical Sciences, Electroradiology, Poznan, Poland

²Greater Poland Cancer Centre, Medical Physics, Poznan, Poland

³Poznan University of Technology, Technical Physics, Poznan, Poland

Purpose or Objective: To evaluate the SharePlan software in conversion of helical tomotherapy (HT) to a step and shoot IMRT (sIMRT) for patients with high-risk prostate cancer and hip prosthesis.

Material and Methods: Analysis was performed for 16 consecutive patients treated on HT.

The HT plans were converted to sIMRT plans. 3DCRT, sliding window IMRT (diMRT) and VMAT plans for a c-arm linear accelerator (CLA) were created manually.

The doses in planning target volume (PTV), bladder, rectum, bowels, femoral heads and hip prosthesis were compared using: (i) a qualitative analysis of doses in averaged dose-volume histograms, (ii) a quantitative, ranking procedure performed for each patient separately, and (iii) statistical testing based on the Friedman ANOVA and Nemenyi method.

Results: For the bladder, rectum, and femoral head, the best dose distributions were observed for HT and sIMRT and then for diMRT, VMAT, and finally for 3DCRT (p-values were, respectively, 0.002, 0.004 and p=0.024). For the bowels, 3DCRT was significantly different from the rest of the techniques (p=0.009). For the hip prosthesis, the differences were only between 3DCRT and HT/sIMRT (p=0.038).

The first part of Table 1 shows mean doses and standard deviations computed from the average dose-volume histograms for planning target volume, hip prosthesis and organs at risk. The values presented in per cent and normalised up to the prescribed dose (46 Gy). The second part of Table 1 shows the statistical testing of the differences between dose distributions in these structures. The results of the Friedman ANOVA testing noted as the p-value. Results of the Nemenyi analysis presented as the groups (A, B, C). Statistical testing performed on the 0.05 significance level.

Technique	PTV	Bladder	Rectum	Bowels	Femur	Prosthesis
	Mean Dose (SD) [%]					
3DCRT	100.6 (0.5)	96.1 (2.3)	87.0 (6.1)	58.9 (42.2)	46.4 (16.7)	37.2 (10.7)
diMRT	100.2 (0.4)	81.4 (14.5)	84.7 (12.4)	31.8 (19.8)	43.4 (12.3)	28.4 (8.7)
VMAT	100.8 (1.0)	82.2 (17.5)	82.7 (16.2)	32.5 (20.3)	45.1 (18.4)	31.4 (9.9)
sIMRT	100.7 (0.6)	63.3 (13.4)	59.1 (12.7)	26.4 (16.3)	30.3 (12.2)	22.9 (9.7)
HT	100.9 (0.6)	63.9 (13.7)	57.7 (10.4)	27.4 (14.6)	32.9 (13.2)	23.3 (9.8)
	Similarity/Dissimilarity of the results					
Technique	p = 0.881	p = 0.002	p = 0.004	p = 0.009	p = 0.024	p = 0.038
3DCRT	A	A	A	A	A	A
diMRT	A	B	B	B	A	AB
VMAT	A	B	B	B	A	AB
sIMRT	A	C	C	B	B	B
HT	A	C	C	B	B	B

SD - standard deviation

Despite the greater scoring in the ranking procedure, HT/sIMRT did not differ statistically from diMRT/VMAT. The scores were, respectively, 75% and 72% to 61% and 64%.

Figure 1 shows the ranking procedure for the dose distributions obtained in the planning target volume, hip prosthesis and organs at risk for: helical tomotherapy (HT, brown bars), plans converted on the SharePlan station

(sIMRT, blue bars) and plans prepared manually for C-arm linear accelerators (3DCRT - red bars, diMRT - green bars and VMAT - purple bars).

Conclusion: The SharePlan is an efficient tool for the conversion of HT plans for patients with prostate cancer and hip prosthesis. Dose distributions in sIMRT and in HT plans are similar and are generally better than in CLA plans.

EP-1691

A planning approach for lens sparing proton craniospinal irradiation in pediatric patients

N. Bizzocchi¹, B. Rombi¹, P. Farace¹, C. Algranati¹, R. Righetto¹, M. Schwarz¹, M. Amichetti¹

¹S. Chiara Hospital, Proton Therapy Center, TN, Italy

Purpose or Objective: Several reports support the potential benefits of proton therapy (PT) when compared to photon techniques in craniospinal irradiation (CSI) to reduce late toxicity and risk of secondary malignancies. PT is increasingly regarded as the gold standard for CSI, particularly in pediatric patients. Nevertheless, lens sparing with good coverage of the cribriform plate remains a challenge, especially in very young patients, as the lens dose increases significantly with decreasing age (Cochran et al, Int J Radiat Oncol Biol Phys 2008;70:1336-42). The technique and the beam arrangement used at our center for lens sparing in the treatment of the whole brain for our first 6 y.o. male patient, is described and compared with data reported in other studies.

Material and Methods: CSI is delivered by active scanning PT with three isocenters, using three cranial beams plus two additional postero-anterior spinal beams. Cranial and caudal field junctions are planned by the ancillary-beam technique (Farace et al, Acta Oncol 2015; 54:1075-8). The three-beams arrangement for brain irradiation includes two lateral opposed beams (gantry angle 90° and 270°), with couch angle ±15° to minimize the overlap between the cribriform plate and the lens, and an additional posterior beam. Single-field-optimization of the three equally-weighted beams is performed. A total dose of 36 Gy in 20 fractions is prescribed following international radiation guidelines for high risk medulloblastoma. During optimization, coverage of the cribriform plate is assumed as the priority goal and lens sparing as a secondary objective. Our technique is compared with two more conventional approaches: i) two opposed-lateral beams and ii) two angled (±20°) posterior-oblique beams.

Results: In figure A and B the dose distribution obtained by the lens-sparing technique on two slices at the level of the cribriform plate and of the lenses are shown. The coverage of the cribriform plate is similar in all beam arrangements. In Figure C, the dose volume histogram for the three beams' arrangement is shown. Adequate target coverage is obtained by all beam arrangements. In addition, the lens-sparing technique allowed to markedly decrease the dose to the

lenses, as shown also in the Table. Dose values are smaller (Dmax 16.7%, i.e. around 6 Gy) than those reported in other studies. In our case, the opposed-lateral setup is associated to larger lens doses (56.6%) than those reported using the same technique in another study (26.4%), suggesting that our specific case was a difficult one, presumably age-related.

Dose to the lens (% of prescription dose)

	Delivery mode	Beam arrangement	Dmax	Dmean
First pediatric patient	Active	Lens sparing	16.7%	6.6%
		posterior-oblique	49.4%	34.9%
		opposed-lateral	56.6%	40.4%
Published studies	Passive	posterior-oblique*	68.5%	48.1%
	Passive	posterior-oblique**		40.0%
	Passive	opposed-lateral**		74.0%
	Active	opposed-lateral***	26.4%	

* Gielber et al, Radiat Oncol 2013;8:32 (18 patients).

** Cochran et al, Int J Radiat Oncol Biol Phys 2008;70:1336-42 (39 patients).

*** Lin et al, Int J Radiat Oncol Biol Phys. 2014;90:71-8 (10 patients).

Figure. Dose distribution obtained by the lens-sparing technique at the level of the cribriform plate (A) and of the lens (B). The PTV (red line) and the 98% isodose (orange isofill) are shown. (C) dose volume histogram of the PTV (red), right (orange) and left (cyan) lens. Lens-sparing, posterior-oblique and opposed-lateral distributions are reported by continuous, dotted and dashed lines respectively.

Conclusion: The beam arrangement we applied allowed both an optimal coverage of the cribriform plate and lens sparing. The low maximal dose to the lenses might reduce the risk of radiation-associated cataract.

EP-1692

Dosimetric analysis of testicular doses in prostate radiotherapy at different energy levels

C. Onal¹, G. Arslan¹, Y. Dolek¹, E. Efe¹

¹Baskent Universitesi Tip Fakultesi- Adana Hastanes, Department of Radiation Oncology, Adana, Turkey

Purpose or Objective: To evaluate the incidental testicular during prostate radiation therapy with intensity-modulated radiotherapy (IMRT) and volumetric-modulated arc radiotherapy (VMAT) at different energies.

Material and Methods: Dosimetric data of 15 intermediate-risk prostate cancer patients treated with radiotherapy was analyzed. The prescribed dose was 78 Gy in 39 fractions. Dosimetric analysis compared testicular doses generated by 7-field IMRT and VMAT with a single arc at 6, 10, and 15MV

energy levels. Doses from the treatment planning system were verified with metal-oxide-semiconductor field-effect transistor detectors. Detectors were placed within a solid, flat phantom at 10 cm depth, from the center of the irradiated field out to 30 cm, with 2 cm distances and 1 cm depth for scattered doses. Values measured from the treatment planning system were compared with values from the detectors.

Results: The mean distance between center of the prostate and the testes was 13.5±1.4 cm (range, 11.6-16.8 cm). For a complete course of 39 fractions, mean testicular doses from the IMRT and VMAT measured in the treatment planning system were 16.3±10.3 cGy vs. 21.5±11.2 cGy ($p=0.03$) at 6 MV, 13.4±10.4 cGy vs. 17.8±10.7 cGy ($p=0.04$) at 10 MV, and 10.6±8.5 cGy vs. 14.5±8.6 cGy ($p=0.03$) at 15 MV, respectively. Mean scattered testicular doses in the phantom measurements were 99.5±17.2 cGy, 118.7±16.4 cGy, and 193.9±14.5 cGy at 6, 10, and 15 MV, respectively, in the IMRT plans. In the VMAT plans, corresponding testicular doses were 90.4±16.3 cGy, 103.6±16.4 cGy, and 139.3±14.6 cGy at 6, 10, and 15 MV, respectively. The scattered testicular doses were significantly higher in the IMRT versus the VMAT plans.

Conclusion: Testicular doses during radiotherapy were high enough potentially to impair the endocrine function of Leydig cells. Higher photon energy and IMRT plans resulted in higher incidental testicular doses compared to lower photon energy and VMAT plans.

EP-1693

Constant dose rate VMAT and step-and-shoot IMRT in head and neck cancer: a comparative plan analysis

A. Didona¹, C. Zucchetti², A.C. Dipilato², M. Iacco², M.B. Panizza³, A. Frattegiani³, V. Bini⁴, C. Ariste³, R. Tarducci²

¹Ospedale Santa Maria della Misericordia, S.C. Fisica Sanitaria, Perugia, Italy

²Santa Maria della Misericordia Hospital, Medical Physics, Perugia, Italy

³Santa Maria della Misericordia Hospital, Radiation Oncology, Perugia, Italy

⁴Perugia University, Internal Medicine, Perugia, Italy

Purpose or Objective: Constant dose rate VMAT (CDR-VMAT) introduces rotational arc radiotherapy for linacs incapable of dose rate variation. The goal of this study was to evaluate CDR-VMAT adequacy for the treatment of head and neck (H&N) cancer compared to Step-and-Shoot IMRT.

Material and Methods: Ten patients (five with oropharyngeal cancer -OPC- and five with hypopharyngeal cancer -HPC-) were enrolled in this study. For each patient, were defined three PTVs: PTV66Gy, PTV60Gy and PTV54Gy with a dose prescription of 66 Gy, 60 Gy and 54 Gy all delivered in 30 fractions. OARs included mandible, spinal cord, brain stem, parotids, salivary glands, esophagus, larynx and thyroid. All patients were previously treated using step and shoot IMRT with seven 6 MV coplanar beams. A protocol for CDR-VMAT plans which consisted of two arcs was established: first arc with start angle was of 182° and a stop angle of 178° in a clockwise direction; the second one in a counterclockwise direction from 178° to 182°; the final arc spacing was set to 4 degree and collimator angle to 45°. For each patient, a CDR- VMAT plan was generated according to this protocol. A dose rate of 300 MU/minute was selected for both IMRT and CDR-VMAT plans. All plans were performed with Pinnacle3 treatment planning system (v 9.8) with identical dose constraints to OARs and dose prescription to targets; it was required that PTVs D95% be 95% of prescribed dose and OARs be spared as more as possible. Dose distributions were compared by evaluating PTVs' Dmean, D2%, D50%, D98% and Homogeneity Index (HI) defined as

$$HI = \frac{D_{2\%} - D_{98\%}}{D_{50\%}}$$

For spinal cord, brain stem and mandible the analysis included the maximum dose (in terms of D2%); for parotids, salivary glands, esophagus, larynx and thyroid Dmean and a number of different dose-volume data in the range V20Gy e V50Gy were compared. For comparison of the efficiency of IMRT and CDR-VMAT, the MUs and treatment delivery time were also recorded and evaluated.

Results: Results are shown in Table.

		IMRT	CDR-VMAT	p value
PTV _{60Gy}	D _{98%}	60,5 ± 1,4 Gy	60,7 ± 1,7 Gy	0,799
	D _{50%}	65,7 ± 0,4 Gy	65,8 ± 0,2 Gy	0,759

	V _{15Gy}	61,4 ± 9,2 % / 62,8 ± 6,3 %	58,2 ± 5,3 % / 61,9 ± 7,5 %	0,477 / 0,877
	V _{30Gy}	38,4 ± 5,3 % / 37,7 ± 5,6 %	33,9 ± 4 % / 32,3 ± 3,6 %	0,037 / 0,019
	V _{50Gy}	8,2 ± 4,4 % / 5,2 ± 3,9 %	7,1 ± 3,4 % / 4,7 ± 3,5 %	0,121 / 0,347
Salivary Gland RL	D _{mean}	46,2 ± 12,3 Gy / 44,4 ± 11,1 Gy	39,1 ± 12,6 Gy / 37,2 ± 13,8 Gy	0,005 / 0,028
	V _{15Gy}	96,3 ± 8,1 % / 96,8 ± 9,7 %	93,7 ± 10,8 % / 93,9 ± 12,5 %	0,197 / 0,109
	V _{30Gy}	84,5 ± 22,4 % / 87,3 ± 21,9 %	67,9 ± 31,7 % / 62,4 ± 28,8 %	0,027 / 0,042
	V _{50Gy}	47,1 ± 43,5 % / 37,4 ± 36,1 %	29,3 ± 36,9 % / 20,6 ± 32,2 %	0,017 / 0,05
Delivery time / MU	183 ± 18 s / 613 ± 92	145 ± 21 s / 743 ± 73	0,005 / 0,016	

Differences were analysed using the paired samples Wilcoxon test (significance level 0,05). Although differences were not always statistically significant, on the one hand CDR-VMAT improved HI and decreased D2% for PTVs, on the other hand it showed a reduction in the volume of the OARs receiving medium and high doses and medium doses to larynx, thyroid, parotid and salivary glands. In respect of some organs, such as the esophagus, a larger number of patients enrolled in the study would likely have resulted in statistically significant differences. Compared with IMRT, CDR-VMAT reduced delivery times although MUs were higher.

Conclusion: Our study showed that CDR-VMAT offers an additional option of rotational arc radiotherapy for linacs without variable dose rate with a lower cost.

EP-1694

Angle-restricted tomotherapy to reduce the risk of heart for left-sided breast cancer patients
H.P. Yeh¹, C.H. Hsieh^{1,2}, H.J. Tien¹, C.H. Chang¹, C.T. Lin¹, P.W. Shueng¹

¹Far Eastern Memorial Hospital, Division of Radiation Oncology- Department of Radiology, New Taipei City, Taiwan

²National Yang-Ming University, School of Medicine- Institute of Traditional Medicine, Taipei, Taiwan

Purpose or Objective: The aim of this study was to evaluate the feasibility of complete-directional-complete block (CDCB) technique and to find the optimal restricted angle of helical tomotherapy (HT) in planning of locoregional irradiation including the internal mammary chain (IMC) in left-sided breast cancer.

Material and Methods: Treatment plans were generated for 6 left-sided breast cancer patients with a planning target volume (PTV) included the breast/chest wall, supra-clavicular, axillary nodes and IMC. In HT plans, complete block (CB) and CDCB were designated to spare the contralateral tissues: (1) CB was a rectangular structure with the ends connected to 10-cm away from the margin of the PTV (2) the directional-blocking area of CDCB was determined by the intersection of CB and the beam aperture passed through the 0.5 cm margin of IMC. To find the optimal CDCB, the angle of 0, 10, 15 and 20 degree of the beam according to the geometric center of IMC were used. A prescribed dose of 50 Gy in 25 fractions was planned for HT plans using CB, CDCB 0,10,15,20 and conventional 5-field intensity-modulated radiotherapy (cIMRT). The dose coverage, homogeneity index (HI), conformity index (CI) of the target, and the dose volumes of critical structures were compared.

Results: The coverage, HI and CI of PTV in HT-CDCB 0,10,15,20 were better than those in cIMRT but did not differ from HT-CB. The mean V20 Gy of the ipsilateral lung for HT-CDCB 15 (22.2%±3.1%, p=0.029) and HT-CDCB 20 (22.1%±3.5%, p=0.045) were significant reduced compared to cIMRT (27.9%±3.4%). With the increasing angle of CDCB, the cardiac V30 Gy for HT-CDCB was gradually decreased and significantly lower than for cIMRT and HT-CB. Compared with cIMRT (24.3 Gy±6.9 Gy), the mean dose of left anterior descending coronary artery was effectively reduced 38.6%, 43.3%, 45.8% and 48.1% in CDCB 0,10,15,20, respectively. There was no significant difference in contralateral breast for all plans. However, the mean dose of contralateral lung in HT-CDCB 20 was 6.1% higher than cIMRT (1.7 versus 1.6 Gy) and 14.5% than HT-CDCB 15

Conclusion: CDCB technique is feasible for locoregional irradiation including the IMC in left-sided breast cancer patients treated with helical tomotherapy. Considering the mean dose of the contralateral lung, the optimal angle for CDCB could be 15-degree that not only achieved similar PTV coverage, homogeneity and dose conformity but also allowed better sparing heart and bilateral lungs compared with cIMRT.

EP-1695

Dosimetric comparison of Helical Tomotherapy and VMAT for endometrial cancer

A. Dizmen¹, O. Yazıcı¹, A.M. Kocer¹, N. Kaplan¹, F. Ertan¹

¹Ankara Oncology Hospital, Radiation Oncology, Ankara, Turkey

Purpose or Objective: The purpose of the present study was to evaluate dosimetric comparison of volumetric modulated arc therapy (VMAT) and helical tomotherapy (HT) for patients with endometrial cancer.

Material and Methods: Fourteen patients with endometrial cancer were retrospectively studied. All whole pelvis (WP) patients were treated with 50.4 Gy in 28 fractions. The dose distributions for the planning target volume (PTV), organs at risk (OARs), monitor unit (MU) and homogeneity index (HI= D2-D98/Dmedian) were analyzed.

Results: The V93 and D100 of PTV were 99.8%, 99.4% and 46.3 Gy, 48.2 Gy for the VMAT and HT, respectively (p:0.004, p:0.003). The V20 for the bowels was 44.5 Gy and 51.1 Gy for the VMAT and HT, respectively (p:0.001). The sparing OARs were comparable between the VMAT and HT plans. There is a significance difference between MU for the VMAT and HT plans and the value was given by 645 and 5236 MU (p:0.001) and the average homogeneity index was 0.07 and 0.04 (p:0.002), respectively.

Conclusion: Both HT and VMAT plans yielded with homogeneous dose distribution when sparing of OARs effectively. Although some dosimetric parameters have shown significant differences statistically but they were

small. VMAT is a well suited technique with shorter treatment time but HT plans have better HI than VMAT.

EP-1696

Can we increase the dose with particle therapy versus IMRT? A dosimetric study for sinonasal cancer

A. Cavallo¹, A. Mirandola², E. Orlandi³, B. Vischioni⁴, N.A. Iacovelli³, C. Fallai³, L. Licitra⁵, M. Ciocca², E. Pignoli¹

¹Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics Unit, Milan, Italy

²Fondazione CNAO, Medical Physics Department, Pavia, Italy

³Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology 2, Milan, Italy

⁴Fondazione CNAO, Radiation Oncology Department, Pavia, Italy

⁵Fondazione IRCCS Istituto Nazionale dei Tumori, Head and Neck Medical Oncology Unit, Milan, Italy

Purpose or Objective: Dosimetric comparison among treatment plans from different RT techniques (photons, protons and carbon ions) within a prospective multicentric trial aiming at the evaluation of the impact of combined treatment modalities on target coverage and OARs sparing for sinonasal tumors.

Material and Methods: High risk PTV (HR-PTV), which comprised gross disease, and low risk volume (LR-PTV), with elective neck, were defined for 5 pts. Four treatment plans were generated for each pt: a pure sequential (SEQ) and a pure SIB photon plan, a particle sequential plan with protons and carbon ion boost (p+C) and a combined plan with photons and carbon ion boost (ph+C). Prescription doses (PD) to HR-PTV were 70 Gy (2 Gy/die) for photon plans and 75 GyE for plans with a carbon ion boost (21 GyE in 7 frs). PD to LR-PTV were 56 Gy (1.6 Gy/die) for SIB modality and 54 Gy (2 Gy/die) for sequential plans. Varian Eclipse TPS was used to optimize VMAT photon plans with coplanar and non-coplanar arcs. Particle plans were calculated using Siemens Syngo TPS and IMPT optimization strategy. The highest priority during optimization was given to spare neurological structures, followed by PTVs coverage and then remaining OARs. A dedicated software (VODCA, MSS Medical Software Solution GmbH, Switzerland) was used to sum up photon and particle plans and to compare DVHs from different approaches. We considered different parameters: the most significant for PTVs coverage were volume encompassed by 70 Gy isodose (V70Gy), conformity index and homogeneity index. As for OARs, V10Gy was reported for temporal lobes, brain and mean dose (Dmean) for contra-lateral optic nerve, chiasm, cord, brainstem, cochleae. Integral dose was recorded to evaluate healthy tissue (HT, patient volume minus larger PTV). Differences in techniques were analyzed by paired Student's 2-sided t-tests for each dosimetric parameter, taking p-value <0.05 as statistically significant.

Results: All plans could be considered clinically acceptable. The photon ones showed a better conformality and homogeneity for HR-PTV against p+C plans. Although minimum dose (as percentage of PD) was higher for photon plans, V70Gy was statistically relevant in favor of p+C plans vs the other modalities. Despite a higher PD for plans with carbon ion boost, a significant advantage on some OARs was recorded: Dmean in p+C plans was significantly lower for contra-lateral optic nerve, chiasm and cochleae, as it is V10Gy for temporal lobes and brain. This finding was reinforced by a statistically significant difference in integral dose for p+C plans vs the others, but also for ph+C plans vs SIB. See averaged DVHs in Fig. 1.

Conclusion: Although less homogeneous and conformed, particle plans allow a higher PD to HR-PTV compared to photons. Due to their specific physical characteristics, combined particle treatments can potentially better spare OARs and HT in terms of intermediate and low doses.

EP-1697

Evaluating patient dose difference in case of linac transfer under treatment

A. Vasseur¹, C. Bertin², J.Y. Gosselin¹, B. Foulon¹

¹Centre d'Oncologie et de Radiothérapie du Parc, Radiothérapie - Auxerre, Auxerre, France

²IRMA Informatics & Radiation Physics for Medical and Technical Applications, Chrono-Environnement UMR CNRS 6249, 25211 Montbéliard, France

Purpose or Objective: To allow or not the patient transfer between 2 energy-matched Linacs, differing only by their MLC generation, in case of breakdown.

Material and Methods: Two linacs were beforehand matched in terms of energy (TPR20,10) and each separate calculation model in the TPS validated. This retrospective comparison was performed with the calculated dose from the TPS to assess the impact of transferring a patient from one machine to another, for some fractions (n=1 to 5) over the whole treatment (N fractions). One should note that 3D plan verification failed in general if the measurements occurs on the wrong machine.

Fifty VMAT plans were studied (head & neck, whole brain, rectum, prostate, other; 10 plans of each), corresponding to 60 PTVs and 100 OARs. Dose was re-computed with the non-planned machine, without any optimization, if up to n=5 fractions are transferred.

Reported dose-metrics (see ICRU-83) are Dmean (mean dose), Dmax (max dose), D95% and HI (homogeneity index) for all ROIs, and well-known parameters are used for some OARs, depending of OAR type (V20, V74,...). Each parameter is expressed as relative to the initial planned treatment.

Results: There is a systematic over-dose delivering when transferring a patient from the "new generation" Linac (Mnew) to the "old" one (Mold). The opposite is checked. Dmean and Dmax variations are linearly dependent of the number of transferred fractions (R²=0.91), for PTVs and OARs. No linear correlation could be found for others metrics, which seem to strongly depend on each anatomy. Variations are always more important for OARs than for PTVs. The maximum difference was found as the Dmean on a right femur for a rectum treatment (11.4%). This value is increased to 15% and set as the maximum available for n=5.

Conclusion: Dose differences are here mainly due to thickness variations of MLC leaves, over other design improvements (leaf profiles, rounded leaf ends,...), as dose variation is related to leaf thickness and OARs are on the other hand more affected by linac transfer than PTVs (protected ROIs are more often under leaves than targets).

The linear correlation between Dmax (or Dmean) and n associated to a maximum variation achievable leads to an empiric formula predicting how much the dose metrics will be affected, in case of a transfer from Mnew to Mold, without recalculating the whole plan (see eq.). This can be easily reversed.

$$D_{max|mean}^{initial} \leq D_{max|mean}^{final} \leq \frac{N+0.75n}{N} D_{max|mean}^{initial}$$

This conclusion must be obviously applied only for $N \geq 10$ (then excluding SRS/SBRT).

EP-1698

New sliding window IMRT planning design for head and neck patients with dental prostheses.

M. Lopez Sanchez¹, M. Perez^{1,2}, V. Hernandez¹, J.A. Vera¹, M. Gonzalez¹, J.M. Artigues¹

¹Hospital Universitari Sant Joan de Reus, Medical Physics, REUS, Spain

²UNED Universidad Nacional de Educación a Distancia, Ciencias, Madrid, Spain

Purpose or Objective : A percentage of patients receiving head and neck radiotherapy treatments wear dental prostheses: implants or dental fillings. The high atomic number composition of this prostheses, most of times unknown, results in a possible inaccurate dose calculation. The purpose of this study is to develop a method for minimize dosimetric alterations caused by prostheses of unknown composition, preventing radiation beams passing through them.

Material and Methods: Varian Medical Systems, Palo Alto, CA: TPS Eclipse with IMRTOptimization "Dose Volumen Optimizer" version 10.0.28 and dosecalculation algorithm "Analytical Anisotropic Algorithm" version 10.0.28. The images, contoured volumes and prescriptions of two patients treated in clinical routine are used (Table I).

Steps to be followed:

1. From images of each patient, identify and outline the prostheses. Also contour the artefacted region and overwrite HU to the HU of the surrounding tissue.
2. Create a sliding window IMRT plan with slightly ($<10^\circ$) modified conventional gantry angles (7-9 fields in our centre) to minimize incidence upon prostheses and optimize dosimetry as usual. This plan is called REFERENCE PLAN.
3. Copy the REFERENCE PLAN. The two or three fields that pass through the prosthesis before entering the PTV are selected, and in each field the area of the incident fluence on the prosthesis is removed using the editing fluence tool available in our TPS (Figure 1). Remove the remaining fields. This result from two or three fields with partially erased fluences is called the BASE PLAN.
4. Create a new plan with the remaining angles present in the REFERENCE PLAN but not in the BASE PLAN. Optimize this plan to fulfil the prescription considering the dose contribution of the BASE PLAN. This is called the SUPPLEMENT PLAN. The treatment plan is the sum of the BASE PLAN and SUPPLEMENT PLAN.

With this method the achieved dosimetry hasn't an increased dose calculation uncertainty due to the presence of materials of high atomic numbers. Nevertheless, the dosimetry obtained in this way could cause a loss of quality in terms of PTV coverage or higher doses to organs at risk. Therefore, it is compared to a regular dosimetry (7-9 field same spaced), in which the presence of the prosthesis was not taken into account.

0 0 1 281 1551 Maru y Miguel 12 3 1829 14.0 96 Normal 0 21 false false false ES JA X-NONE

Results: Table I shows the dosimetric parameters comparison between new planning design proposed and usual design regardless of prosthesis. The absorbed dose distributions in the PTVs are similar in both cases. Regarding organs at risk, there are no significant differences in spinal cord, dose to parotids are increased up to a 20% in the new design.

TABLE I. ABSORBED DOSE FOR PTV AND OAR

	Patient 1		Patient 2	
	Conventional Design	New Design	Conventional Design	New Design
Prescribed Dose(PTVN)(Gy)	52.8	52.8	54.1	54.1
D _{98%} (PTVN)(Gy)	50.6	50.3	51.95	51.9
D _{50%} (PTVN)(Gy)	54.5	53.6	57.0	58.5
D _{2%} (PTVN)(Gy)	71.0	73.3	73.3	74.6
Prescribed Dose(PTVT)(Gy)	70.0	70.0	70.0	70.0
D _{98%} (PTVT)(Gy)	65.2	65.7	65.4	65.7
D _{50%} (PTVT)(Gy)	69.5	71.3	70.9	71.2
D _{2%} (PTVT)(Gy)	72.6	74.8	73.8	75.0
D _{50%} (ParotidR)(Gy)	11.6	11.6	19.9	21.9
D _{50%} (ParotidL)(Gy)	28.9	34.7	17.6	20.1
D _{2%} (Spinal Cord)(Gy)	39.8	36.4	43.1	42.5
D _{2%} (PRVSpinal Cord)(Gy)	41.6	37.8	45.3	45.2
Volume(PTVN)(cm ³)	332.8	332.8	435.0	435.0
Volume(PTVT)(cm ³)	32.3	32.3	130.3	130.3
Volume(prostheses)(cm ³)	1.6	1.6	12.1	12.1
CI(PTVN)	1.52	1.34	1.54	1.58
CI(PTVT)	1.33	1.33	1.23	1.36
HI(PTVN)	0.37	0.42	0.37	0.39
HI(PTVT)	0.11	0.13	0.12	0.13

PTVT and PTVN are respectively the high and low dose treatment volumes defined by the physician. D_v is the absorbed dose that covers a given volume fraction V. HI is the homogeneity index defined by ICRU 83 [9]. CI is the conformation index defined by ICRU 62 and ICRU 83 for D_{100%} isodose of the evaluated volume in the worst case

Conclusion: With this method calculations inaccuracies caused by the high density materials are avoided. We recommend the discussion of the use of the technique proposed with the physician for each treatment of head and neck patient with dental prostheses. The techniques in this study are being developed currently for VMAT technique.

EP-1699

10MV un-flattened photon beams in prostate and pelvic node VMAT SABR; is the high energy necessary?

N. Kanakavelu¹, S.O. Osman², D.M. Irvine¹, C.A. Lyons², S. Jain³, A.R. Hounsell¹, C.K. McGarry¹

¹Belfast Health and Social Care Trust, Radiotherapy Physics-Northern Ireland Cancer Centre, Belfast, United Kingdom

²Queen's University Belfast, Centre for Cancer Research and Cell Biology, Belfast, United Kingdom

³Belfast Health and Social Care Trust, Clinical Oncology-Northern Ireland Cancer Centre, Belfast, United Kingdom

Purpose or Objective: To evaluate and compare the plan quality and efficacy of flattened and flattening-filter-free (FFF) photon beams in external beam RT for high-risk prostate cancer patients in the context of hypo-fractionated Stereotactic Ablative Radiotherapy (SABR) to the prostate and pelvic lymph nodes (LN).

Material and Methods: 10 prostate cancer (PCa) patients who previously received RT to the prostate and pelvic nodes, were planned in Varian Eclipse using two full arcs with 6MV flattened, 6MV and 10MV FFF photon beams. The prescribed dose was 40Gy in 5 fractions for the planning target volume to prostate PTV(psv) (prostate and seminal vesicles) and 25Gy in 5 fractions for the PTV(LN). All plans were optimized using the same objectives and constraints. Plans were then evaluated for PTV coverage, dose fall-off, OAR doses for the rectum, bladder, small bowel, prostatic urethra, neurovascular bundle, femoral heads, penile bulb and the sigmoid colon. Physical dose metrics, EUDs, tumour control probability (TCP) and normal tissue complication probability (NTCPs) using the LKB model were investigated. The number of monitor units and the treatment delivery times were also compared. Statistical differences were evaluated using a paired sample Wilcoxon signed rank test with a significance level of 0.05%

Results: All evaluated plans were highly conformal CI =1.2 and CN ≥0.94. There was no significant difference in the PTV dose coverage using all energies compared. Significant increase in high dose (R50) and low dose (R25) spillage outside the PTV in 6MV flattened beams compared to FFF plans was observed. Superior plans were obtained using 10 MV FFF beams in terms of mean and minimum rectal dose, high and low dose spill outside the PTV and treatment time were also minimal. Despite the significantly lower monitor units (MU) in 6MV plans, these plans delivery times were the largest among the three compared techniques due to dose rate limitations (maximum dose rate 600MU/min). Furthermore, the high dose spillage was found to be higher for 6MV. When comparing 6MV FFF and 10MV FFF plans, only minor difference were identified favouring 10 MV FFF plans.

Mus delivery time (s)	2309 ± 118 [†]	2351 ± 157 [†]	2030 ± 97
	149.2 ± 0.12 [†]	149 ± 5.95 [†]	203.52 ± 9.47

* Significantly different compared to 6FFF Rx = volume of x% isodose/PTV

[†] Significantly different compared to 6MV CI = R95

Conclusion: Using two full arcs, highly conformal SABR VMAT plans for prostate and pelvic lymph node were achieved with 6MV FFF and 10MV FFF photon beams. A minor increase in the number of MU in 6MV FFF plans was observed; however, the increase in the treatment time was found to be negligible. Significant reduction in the high dose spillage was obtained with 10MVFFF beams suggesting that although both energies are suitable for use in prostate and lymph node SABR 10MV FFF is superior.

EP-1700

SRS treatment planning for multiple cranial metastasis with a single isocentre approach using VMAT

R. Bill¹, L. Howard², M. Gilmore²

¹The Royal Liverpool and Broadgreen University Hospital NHS Trust, Medical Engineering and Physics, Liverpool, United Kingdom

²The Clatterbridge Cancer Centre, Medical Physics, Bebington, United Kingdom

Purpose or Objective: This study evaluates a single isocentre technique for SRS for patients with multiple cranial metastases and compares to the local approach of a single isocentre per metastasis.

Material and Methods: At our centre, SRS treatment for multiple cranial metastases is planned in iPlan (Brainlab, Germany) using a single isocentre per metastasis, with an arrangement of nine static non-coplanar fields (SCF). An alternative VMAT-based approach, described by Clark et al (2012), uses RapidArc™ to give highly conformal dose distributions with a single isocentre. Eight patients each with three metastases, previously treated using our SCF technique, were re-planned using the single isocentre RapidArc approach. Plans were compared using PTV ICRU dose conformity (CI), Paddick gradient index (GI), ICRU homogeneity (HI) and whole brain doses. Plans were prescribed to the 80% isodose, with 100% coverage of the target volume. The Wilcoxon's signed rank test was used to compare CI, HI and GI between the two techniques.

Results: There was a statistically significant improvement in the CI for RapidArc (p=0.003), suggesting superior conformity to the tumour. On average, iPlan plans were more homogeneous (p=0.03). In general RapidArc gives a higher maximum dose to PTVs (p=0.002). iPlan has a superior GI around each PTV (p<0.001); RapidArc has three unexpectedly high GI per metastasis values from three different patients with single tumour volumes less than 0.1cm². GI per plan is greater for RapidArc than iPlan. However this is misleading as iPlan treats a greater volume to 2, 5 and 12.5 Gy by 1.3%,

3.1% and 5.6%, respectively; more patients are required to determine statistical significance.

Conclusion: RapidArc gives an improved CI around each metastasis as well as a lower whole brain dose at 2, 5, and 12.5 Gy compared to iPlan. This suggests that the RapidArc single isocentre technique offers a potential option for the treatment of multiple metastases, but further studies into optimal arc arrangement, whole brain doses and dosimetric delivery are required. In particular, the work of Evan et al (2013) suggests that 4-arc VMAT may further improve dose conformity, dose fall-off and whole brain doses relative to the 2-arc method discussed here. Ongoing work includes a comparison to a 4-arc arrangement together with analysis of beam-on and treatment times. In addition, investigation into the most suitable plan quality metrics such as those suggested by Paddick (2000) will be carried out.

EP-1701

VMAT or IMRT- what is better solution in sparing bone marrow in WPRT of patients after prostatectomy
M. Poncyljusz¹, P.F. Kukulowicz¹, B. Czyzew¹, A. Jankowska¹
¹The Maria Skłodowska-Curie Memorial Cancer Centre and Institute of Oncology, Department of Medical Physics, Warsaw, Poland

Purpose or Objective: For postprostatectomy patients at higher risk of nodal involvement the irradiation of pelvic lymph nodes may improve the therapeutic ratio. Larger volumes irradiated for these patients result in increased doses delivered to OAR. IMRT and VMAT techniques allow to better protect OAR in comparison to 3D-CRT. The aim of this study was to compare IMRT and VMAT techniques in terms of sparing of OAR. The main attention was paid to pelvic bones' marrow protection.

Material and Methods: Ten patients were selected retrospectively for this planning study. The 3D-CRT, IMRT and VMAT plans were created for each of patients. Treatment plans were generated for prostate bed (PTV1) and pelvic lymph nodes (PTV2). The delivered dose to the sum of PTV1 and PTV2 was 46Gy in 23 fractions and additionally dose 18 Gy in 9 fractions was delivered to PTV1 Target coverage (at least 98% of the PTV received $\geq 95\%$ of the prescription dose) and OAR sparing were compared across techniques. The following OAR were delineated: rectum, bladder, bowel bag and pelvic bones. The Wilcoxon test was used to compare the dosimetric parameters. Dose-values: bowel bag V30Gy[cc], pelvic bones V30Gy[%], V40Gy[%], bladder V40Gy[%], V50Gy[%], V60Gy[%], rectum V40Gy[%], V50Gy[%], V60Gy[%] were considered.

Results: The dosimetric qualities of 3D-CRT, IMRT and VMAT plans were comparable for target coverage (the mean value of PTV1 V95%, the mean value of PTV2 V95% all $>99\%$). The IMRT and VMAT plans resulted in significant reduction in pelvic bones V30Gy[%], V40Gy[%], bladder V40Gy[%], V50Gy[%], V60Gy[%], rectum V40Gy[%], V50Gy[%], V60Gy[%] and bowel bag V30Gy[cc] in comparison to 3D-CRT plans. A comparison between IMRT and VMAT techniques shown better sparing bone marrow (pelvic bones V30Gy[%]) and increase of following values: bowel bag V30Gy[cc], bladder V60Gy[%], rectum V60Gy[%] in VMAT plans. Differences between values of V40Gy[%] and V50Gy[%] for bladder and rectum across mentioned techniques were statistically not significant.

Conclusion: The lower doses delivered to pelvic bones and thus also to red marrow for IMRT and VMAT techniques allow to expect the lower hematological toxicity. A comparison between IMRT and VMAT techniques shows, that the VMAT technique reduces the delivered dose to pelvic bones. However IMRT provided better rectum, bladder and bowel bag sparing at higher doses. All these results should be taken into consideration when IMRT and VMAT techniques being used in WPRT of patients after radical prostatectomy.

EP-1702

Cardiac dose evaluation in left breast cancer radiotherapy: Direct and Helical Tomotherapy
A. Fozza¹, L. Berta², S. Aimonetto², F. Migliaccio¹, A. Peruzzo Cornetto², L. Vigna², T. Meloni³, F. Munoz¹
¹AUSL Valle d'Aosta, Radiation Oncology, Aosta, Italy
²AUSL Valle d'Aosta, Medical Physics, Aosta, Italy
³AUSL Valle d'Aosta, Radiology Department, Aosta, Italy

Purpose or Objective: The aim of the present study was to retrospectively evaluate the delivered doses to the cardiac structures for two different tomotherapy techniques in adjuvant radiotherapy for early stage left breast cancer patients

Material and Methods: Five consecutive conservatively operated left breast cancer patients, who underwent adjuvant radiotherapy, were retrospectively considered. CT simulation was acquired with patients in a supine position, using the breast immobilisation device. Image acquisition was performed with a 2.5 mm slice thickness in a free breathing modality without contrast agent administration. The prescription dose was 45 Gy/20 fr and 50 Gy/20 fr, respectively to the PTV2 (left whole breast) and PTV1 (tumour bed), obtained as a 5 mm isotropic expansion of the CTVs, with a 5 mm margin from the skin. The following volumes were used for plans optimisation: lungs, right breast, spinal cord and PRV, heart. For each patient, two independent optimisations were carried out using a fixed ganty technique, Tomodirect (TD) and helical technique (HT). For TD planning two tangential plus other two-four static beams were used. For HT planning, the contralateral lung and breast were directionally blocked. All plans were optimized in order to minimize dose to OAR according to our internal protocol (lung V20<10%, V10<20%, V5<42%, contralateral breast: Dmax<5Gy, contralateral Lung: V5<5%) and to obtain a coverage of D95>95% and Dmax(1cc) <105% for PTVs. In a second time, cardiac structures have been identified on the basis of the University of Michigan Cardiac Atlas, and DVH parameters (D1%, Daverage, V20, V10, V5) for the left and right ventricle (LV, RV), left main coronary (LMC) artery, right coronary (RC) artery and left anterior descending coronary (LAD) artery were retrospectively evaluated for all plans using the plan evaluation tool of the RayStation software v 4.7.2

Results: Constraints on target coverage and OAR constraints were respected for both techniques in all plans. All results are reported in table 1. HT plans achieved a better conformation for the high doses for the whole heart (figure 1). The average maximum doses were 23 \pm 7 and 15 \pm 2 for TD and HT modality respectively. However HT showed a larger low-dose bath and the average doses were 20% higher than TD. For the LV the D1%, V10 and V5 for HT plans were 8 \pm 3, 0.6 \pm 1, 13 \pm 15, vs 19 \pm 10, 6.0 \pm 2.8, 34 \pm 12 for TD plans. Considering LAD artery the V20 was 0.1 \pm 0.1 with HT vs 29 \pm 18 for TD. On the average, the greater differences in DVH parameters between HT and TD plans were observed for V5 in LV, (-21.7%), V5 in RV (+14.3%) and V20 in LAD artery (-28.7%)

Table1: DVH parameters in cardiac structures for TD and HT

Conclusion: In the light of the dosimetric results herein reported, the cardiac structures should be contoured for plans optimisation and evaluation, especially when high conformal techniques are employed

EP-1703

The usefulness of VMAT in patients irradiated to the chest wall after left-sided mastectomy
 M. Spalek¹, P. Meżeniński², J. Gatecki¹, E. Dąbrowska², A. Zawadzka², P. Kukotowicz²

¹The Maria Skłodowska-Curie Memorial Cancer Center, Radiotherapy, Warsaw, Poland

²The Maria Skłodowska-Curie Memorial Cancer Center, Medical Physics Department, Warsaw, Poland

Purpose or Objective: Intensity-modulated radiation therapy is routinely used to irradiate patients after left-sided mastectomy to the chest wall. Volumetric modulated arc

therapy (VMAT) is a combination of IMRT and the arc technique. The use of gantry rotation during irradiation allows for very fast and accurate delivery of the planned dose. The aim of this study was to evaluate the usefulness of VMAT for patients who receive a post-left-sided-mastectomy chest wall irradiation.

Material and Methods: 10 radiation therapy treatment plans were prepared for both IMRT and VMAT. The prescribed dose was 45 Gy in 2.25 Gy per fraction (overall treatment time - 4 weeks). The dose distributions were evaluated in terms of: the volume of the CTV and PTV which receives 90% and 95% of prescribed dose; the volume of the left lung which receives 20 Gy or more (VL20); the mean dose to the left lung; the volume of the heart which receives 20 Gy or more (VH20); the mean dose to the heart; the volume of the both lungs which received 20 (VLR20) and 30 Gy (VLR30) or more; the mean dose to the both lungs; the number of monitor units (MU) per single fraction. To evaluate differences between techniques, the Wilcoxon matched-pair signed rank test was used.

Results: Radiation therapy plans for both VMAT and IMRT fulfilled all criteria required by the treatment protocol in dose constraints for target volumes and organs at risk (OAR). VL20 was non-significantly higher in VMAT (28%) than IMRT (25.8%). The mean dose to the left lung was 10.3 Gy in VMAT, and 15.7 Gy in IMRT. The mean dose to the heart was 11.5 Gy in IMRT and 11.6 Gy in VMAT. VH20 was higher in VMAT than in IMRT plans: 10.6% vs 7.8% respectively. VLR20, VLR30 and the mean dose to the both lungs were similar in both techniques (VLR20 IMRT: 11.5% vs VMAT: 12.4%; VLR30 IMRT: 5.8% vs VMAT: 6.3%; the mean dose to the both lungs IMRT: 9.7 Gy vs VMAT: 10.2 Gy respectively).

There were no significant differences between IMRT and VMAT in doses to CTV, PTV and OAR. The number of MU was significantly lower in VMAT plans (VMAT: 641 MU vs IMRT: 1049 MU, p <0.007).

Conclusion: VMAT and IMRT produced similar dose distribution in the CTV and PTV, and similar OAR dose sparing. However, the number of MU in VMAT was significantly lower than in IMRT. The decrease in the number of MU, and consequently the treatment time, may reduce the influence of intrafraction movement on dose distribution. It also allows to treat more patients in the same unit of time.

EP-1704

Helical Tomotherapy for left-sided breast: dosimetric comparison to Volumetric-Modulated Arc Therapy
 F. Ertan¹, R. Tarriseven¹, O. Yazici¹, A.M. Kocer¹, M.B. Altundag¹

¹Ankara Oncology Hospital, Radiotherapy, Ankara, Turkey

Purpose or Objective: The aim was to evaluate the dose distribution of target volume and organs at risk (OARs) using helical tomotherapy (HT) and volumetric modulated arc therapy (VMAT) for left sided breast cancer patients.

Material and Methods: We compared two techniques for ten left sided breast cancer patients. Planning target volume (PTVchestwall) includes left sided chest wall and PTVSCF-AKS contains supraclavicular, axillary lymph nodes. The delivered dose was 50Gy within 25 fractions. The generated plans were evaluated in terms of dose distribution of PTV, doses of left lung, heart, contralateral breast and total monitor units. During CT simulation, the patient was positioned supine on a breast board. The patient's left arm raised above the head and the head turned to the right side. CT slices were obtained at 3 mm intervals extending from the chin to the upper abdomen during free breathing. Tomotherapy planning parameters; the field width, modulation factor and pitch, were assigned to 5cm, 2 and 0.287, respectively, for all plans. To decrease right lung dose, the complete block was applied. For VMAT planning parameters, two half arc were used and the angle was addressed according to patient's anatomy. The plans were constructed using Anisotropic

Analytical Algorithm (AAA). Grid size was 0.2cm. Depends on the patient, 0.5 and 1cm bolus was used.

Results: In Table-1, The value of D2, D98 for PTVchest wall and PTVSCF-AKS ; V20,V10 for ipsilateral lung; maximum dose for contralateral breast; V25, V10,mean dose for heart and total monitor unit were displayed respectively for VMAT plans. In Table-2, the same parameters for each volume were given for HT plans.

TABLE-1: Plan results for VMAT

PTV50 Chest wall D ₂ (cGy)	PTV50 Chest wall D ₉₈ (cGy)	PTV50 SCF-AKS D ₂ (cGy)	PTV50 SCF-AKS D ₉₈ (cGy)	Ipsi-lateral Lung V ₂₀ (%)	Ipsi-lateral Lung V ₁₀ (%)	contra lateral breast max dose (cGy)	heart (mean cGy)	heart V ₂₅ (%)	heart V ₁₀ (%)	Total MU
5330	4790	5279	4880	16.2	50.0	51.7	480	0.0	6.0	484
5353	4773	5327	4905	17.5	53.2	46.7	422	0.6	20.3	477
5332	4808	5238	4968	15.8	42.6	49.5	456	1.0	7.3	471
5262	4766	5282	4844	18.9	43.7	63.3	605	2.9	10.0	422
5282	4819	5263	4853	14.2	48.8	60.8	509	0.4	6.6	508
5317	4808	5365	4816	19.8	56.0	45.9	452	6.1	32.0	493
5330	4809	5309	4825	23.8	35.0	69.6	325	3.0	35.0	463
5243	4828	5244	4828	19.3	41.5	49.6	468	4.6	30.0	440
5212	4768	5251	4951	26.4	50.5	56.0	624	8.0	23.5	393
5250	4815	5265	4830	16.0	45.0	48.0	490	3.5	15.0	440

Conclusion: Based on the results of this study, HT plans have reduced the heart doses and shown better homogenous dose distribution. However, contralateral breast dose cannot be provided within the dose constraints using HT. The reduced treatment time and planning time were feasible for VMAT. In terms of lung dose, there was no significant difference between two techniques.

EP-1705

Dosimetric comparison (VMAT and 3DCRT) in breast cancer with regional nodes and SIB of the tumor bed

A. Seguro¹, L. Díaz², G. Ruiz¹, R. García¹, M.D. De las Peñas³, E. Amaya³, M. Hernández³, P. Samper³, J.M. Jimenez¹

¹Hospital Rey Juan Carlos, Medical Physics, Móstoles Madrid, Spain

²Hospital Universitario Puerta del Mar, Radiation Oncology, Cádiz, Spain

³Hospital Rey Juan Carlos, Radiation Oncology, Móstoles Madrid, Spain

Purpose or Objective: To evaluate and assess the potential advantage of volumetric modulated arc therapy (VMAT with Monaco v.3.3) over 3D conformal radiotherapy (3DCRT with XiO v.4.8) in the treatment of breast cancer with axillar and supraclavicular involvement and simultaneous integrated boost (SIB) of the tumor bed with respect to volume coverage and doses to organ at risk (OAR).

Material and Methods: 2 techniques were compared in 15 patients. All were women with adjuvant radiotherapy indication and laterally of the tumor was not considered. Treatment schedule consisted of 50Gy/2Gy daily to breast and regional nodes and SIB over tumor bed to 60Gy (BED 66Gy 2Gy/ daily fr.) all in 25 fractions. 3DCRT employed 6 to 8 coplanar hemifields with one isocentre in the gap between breast and supraclavicular volumes and VMAT was developed with a restriction of the angulation for the arc to 200°-220° avoiding contralateral breast. Optimization was performed to get the best plan for each technique for each individual patient. Target coverage and dose to OAR were analyzed using mean dose, % of the prescribed dose to 95 % of the target volumes, heterogeneity (V107, D1%, D2%) and QUANTEC-constraints respectively.

Results: Although we did not have significant differences in the coverage of PTV (prescription was at least 95% of the prescribed dose to 95% of the target) we got better homogeneity in terms of mean dose to PTV with VMAT, with mean differences from 50.5Gy to 51.5Gy for VMAT in front of 53 to 54Gy in 3DCRT. The greatest benefit was obtained with the dose delivered to ipsilateral lung with a decrease of at least 10% in V20 that always was below 25% in VMAT technique.

Conclusion: We consider VMAT as most appropriated technique for these treatments, because gives a perfect coverage to the target volumes and better protection to OAR.

EP-1706

Evaluation of different radiosurgical planning techniques using iPlan®

C. Navarro¹, K. Thippu Jayaprakash², S. Dymond¹, S. Chris¹, L. Turner¹, R. Shaffer², E. Adams¹, A. Nisbet¹, T. Jordan¹

¹St Luke's Cancer Centre- Royal Surrey County Hospital, Radiotherapy, Guildford, United Kingdom

²St Luke's Cancer Centre- Royal Surrey County Hospital, Department of oncology, Guildford, United Kingdom

Purpose or Objective: To evaluate and compare dosimetric parameters of different radiosurgical plans with an aim to determine the optimum technique for treating single brain metastases with a linear accelerator.

Material and Methods: A prospective study was conducted on iPlan (Brainlab V4.5, Germany) for 11 intracranial targets of varying volumes and shapes (volume <20cc) using a range of radiosurgical planning techniques. The study was performed both on the CT of an anthropomorphic phantom (STEEV, Computerised Imaging Reference Systems, USA) and on a single patient planning CT. Plans were generated to treat 5 spheres of varying volumes (1.4 cc - 17.5 cc) and 2 irregular targets (8 cc and 17.4 cc) in the phantom. Minimum and maximum plan target volume (PTV) dose, Paddick conformity index (CI), mean dose to normal tissue and total monitor units (MU) were recorded for plans with varying number of arcs (3-4) or fields (7-9), table spread (90° -120° arc), gantry spread (90° -120° arc) and beam energy. All planning parameters were fixed except for the element to be tested. For the patient planning study, plans were generated for 4 target lesions at various locations using 3-4 dynamic conformal arcs (DCA) and 9 static fields.

Results:

Phantom planning study
DCAs showed higher PTV doses than static field plans (1-2% difference). 6 MV plans produced the highest maximum and minimum doses to PTV followed by 6 MV Flattening Filter Free (FFF) and 10 MV FFF (4% difference between energies).

The remaining dosimetric parameters were affected only up to 1% by other planning factors except for increasing the margin between PTV and multi leaf collimators (MLC) edge (range, 1-3 mm) (1-7% difference). The best CI was seen with 9 static fields compared with DCA regardless of number of arcs used (2% difference). CI improved with the following - decreasing PTV to MLC margin (up to 10% difference), increasing number of static fields (1-2% difference), using 10 MV FFF (2% difference) and with arc length & table spread for irregular shaped targets (1% difference).

Patient study

Similar results were obtained with all techniques. Total mean number of MUs were 3144, 3166, 3121 for 3DCA, 4DCA and 9 static fields plans respectively. The mean CI was 2.3, 2.1 and 2.2 using 3DCA, 4DCA and 9 static field plans respectively. The normal tissue mean doses were 1.3% for all three techniques.

Conclusion: All evaluated radiosurgical plans were acceptable for clinical use. The technique was chosen based on delivery efficiency and dose to normal brain. 10 MV FFF was more efficient and more conformal. 4DCA delivers lower dose to a larger volume of the brain compared to 9 static fields which delivers higher dose to a smaller volume. The MLC margin is a compromise between CI and doses to the PTV. To conclude 4DCA 10MV FFF was chosen for clinical use, the MLC margin depends on the target volume.

EP-1707

Tomotherapy dose painting hypofractionated treatments on GBM based on DW-MRI: a feasibility study.

M. Orlandi¹, A. Botti¹, E. Cagni¹, L. Orsingher¹, R. Sghedoni¹, C. Patrizia¹, C. Iotti¹, M. Iori¹

¹Arcispedale S. Maria Nuova, Fisica Medica, Reggio Emilia, Italy

Purpose or Objective: To investigate the feasibility in Tomotherapy (HT) of a hypofractionated DP (Dose Painting) treatment on GBM (Glioblastoma Multiforme) cancer patients using ADC maps derived from DW-MRI.

Material and Methods: Five patients, who underwent GBM radiotherapy, were retrospectively considered, prescribing a dose escalated from 25 to 50 Gy in 5 fractions. The objective was that at least the 95% of the CTV received at least 25 Gy. DPBN dose prescription maps were generated from ADC-MRI, registered with planning CT, for each patient. The ADC pixel values (mm²/s) within the CTV were converted to dose values (Gy) using the equation Eq. 1 where Dmin and Dmax are the minimum and maximum total dose of prescription (25-50 Gy). Imin and Imax are the minimum and maximum significant values of ADC selected on the basis of the ADC differential histogram, inside the CTV region.

Then it was necessary to discretize each DPBN maps in 9 isodose levels (Deveau et al., Acta Oncol. 2010) in order to obtain a corresponding DPBC map. The final DPBC map was realized minimizing, with an iterative process, the difference between DPBN and DPBC, evaluated by means of Quality Factor (QF) (Vanderstraeten et al., Phys. Med. Biol. 2006). The QF is, defined as in Eq. 2 and Eq. 3 where *i* is the *i*-th voxel. Then plans were optimized on a standard HT TPS and a TPS Dose Distribution (TDD) was obtained. For each patient the TDD was compared with the prescribed DPBN using a Qi distribution, defined as the ratio of TDDi and DPBNi. The quality of the treatment plans was evaluated in term of QF and Q0.9-1.1, that represents the volume of the CTV in which the Qi ranges from 0.9 to 1.1. Eventually the delivery of the DP plans was assessed with Octavius system (PTW).

$$D(I) = \begin{cases} D_{max} & I < I_{min} \\ D_{min} + \frac{I - I_{min}}{I_{max} - I_{min}} \cdot (D_{max} - D_{min}) & I_{min} < I < I_{max} \\ D_{min} & I > I_{max} \end{cases} \text{ Eq. 1}$$

$$Q_i = \frac{DPBC_i}{DPBN_i} \text{ Eq. 2}$$

$$QF = \frac{1}{n} \sum_i |Q_i - 1| \text{ Eq. 3}$$

Results: Fig. 1 reports the different distributions obtained for Patient 1.

Tab. 1 shows quantitative DVH and quality analysis of the treatment doses for the CTVs, mean values OAR Dmax for all five patients, and γ results for the DQA performed. The constraints for the OAR were respected in all the five plans as well as the coverage of the CTVs with the minimum prescribed dose of 25 Gy. The QF ranges from 0.126 to 0.176, while the mean value of Q0.9-1.1 was 68% ± 7%. The delivery time ranges from a minimum of 38.3 minutes to a maximum of 63.6 minutes. All DQA performed are within the acceptance criteria with a mean value of γ of 87.4%.

Optic nerves	15.69	4.36	27.46	7.63	54

Tab. 1 - Quantitative results for CTVs and Dmax for OAR with dose converted to standard 2 Gy per fractions.

Conclusion: Our results provides the feasibility of a ADC-based dose painting treatment in GBM cancer patients, respecting dose constraints to OAR and minimum target coverage. The plans obtained are deliverable, even if there is some concern about the HT delivery time. Clinical studies should be conducted to evaluate toxicities and tumor response of such a strategy.

EP-1708

Re-irradiation of pelvic sidewall disease: comparing normalisation techniques for stereotactic RT

M. Llewelyn¹, E. Wells², N. Bhuvu¹, A. Taylor¹

¹Royal Marsden NHS Foundation Trust, Department of Gynaecology, London, United Kingdom

²Royal Marsden NHS Foundation Trust, Department of Radiotherapy, London, United Kingdom

Purpose or Objective: Management of pelvic sidewall recurrence in gynaecological cancer is a challenging clinical scenario with only 10-20% 5-year survival. For patients previously treated with radiotherapy, salvage surgery has high morbidity and outcomes are poor. Recent radiotherapy advances including stereotactic radiotherapy provide the opportunity for more effective salvage techniques. Systematic assessment is required to determine optimal treatment approaches.

The aims of this study were: (1) To determine target and OAR dose targets for pelvic re-irradiation (2) To compare ICRU 83 normalisation and prescription (ICRU) to the stereotactic radiosurgery convention of prescribing to a covering isodose

allowing maximum doses of ~125% (SRS) using both fixed field IMRT and VMAT techniques.

Material and Methods: A systematic literature search was undertaken to assess pelvic re-irradiation outcomes and cumulative dose constraints for organs at risk including bowel, bladder and rectum were derived. Dosimetric assessment was undertaken for 10 patients treated for recurrent gynaecological cancer assuming prior pelvic radiotherapy of 50Gy (EQD2). Plans were produced to deliver 30Gy in 5 fractions using ICRU-fixed, ICRU-VMAT, SRS-fixed and SRS-VMAT techniques. Doses to GTV, PTV and OAR were compared and conformity index measured for each technique.

Results: All 50 plans met the planning objectives for PTV and GTV coverage. PTV volume ranged from 10 - 99 cc (mean 38 cc). Mean GTV dose with ICRU-fixed and ICRU-VMAT was 30.1Gy; with SRS-fixed and SRS-VMAT it was 30.4 Gy, increasing the EQD210 from 40 Gy to 48.4 Gy. Conformity index was ICRU-fixed 1.19, ICRU-VMAT 1.10, SRS-fixed 1.04 and SRS-VMAT 1.05. All bladder and rectal targets were met for all plans except one patient with bladder involvement. The dose limiting structure was bowel with mean Dmax 27 Gy (range 13-33 Gy), D2cc 21 Gy (13-30), D5cc 17 Gy (7-27) and no significant differences between techniques. Dose targets were exceeded for 3 patients with no correlation to PTV volume, only proximity of GTV to bowel.

Conclusion: Re-irradiation is a valuable option for treating sidewall recurrence and can be delivered within acceptable dose constraints with both normalisation techniques. SRS type normalisation increases mean GTV doses by 21% (EQD2) compared to ICRU normalisation without increasing OAR doses. Using our proposed bowel tolerances of Dmax 31 Gy, D2cc 27.1 Gy, D5cc 18.1 Gy, there is potential for further dose escalation in 50-70% patients.

EP-1709

Comparison of IMRT and VMAT plan quality for hypofractionated post-mastectomy chest wall irradiation
A. Zawadzka¹, E. Dąbrowska^{1,2}, P. Mężeniński¹, J. Gatecki³, P. Kukotowicz¹, M. Spatek³

¹The Maria Skłodowska-Curie Memorial Cancer Center, Medical Physics Department, Warsaw, Poland

²University of Warsaw, Department of Biomedical Physics, Warsaw, Poland

³The Maria Skłodowska-Curie Memorial Cancer Center, Radiotherapy Department, Warsaw, Poland

Purpose or Objective: Volumetric Modulated Arc Therapy (VMAT) is a novel variation of Intensity Modulation Radiotherapy (IMRT) which allows to deliver dose during the beam rotation with a variable dose rate. The main advantage of this technique is treatment time shortening, what may be crucial especially due to a risk of intrafraction motion. On the other hand not only the treatment time but also a plan quality should be taken into account. The aim of this study was to compare VMAT hypofractionated post-mastectomy chest wall RT plans with IMRT plans.

Material and Methods: Plans for seventeen patients with post-mastectomy chest wall radiotherapy were selected for the study. The clinical target volume included chest wall and internal mammary nodes. The prescribed dose (PD) were: 40.05 Gy delivered in 15 fractions (5 - left side; 3 - right side) and 40.5 Gy delivered in 15 fractions (4 - left side; 5 - right side). For each patient IMRT and VMAT plans were generated. The dose distribution was prescribed to the mean dose to the CTV. The comparison was made on the basis of: the volume of CTV and PTV which receives 90% and 95% of prescribed dose, the volume of the ipsilateral lung which receives 20 Gy or more (VL20), the mean dose to the ipsilateral lung, the volume of the heart which receives 20 Gy or more (VH20), the mean dose to the heart, the total volume of both lungs which received 20Gy (VLR20) and 30 Gy (VLR30) or more, the mean dose to the both lungs, the maximum dose to the spinal cord and the number of monitor units (MU) per single

fraction. For statistical analysis, the Wilcoxon matched-pairs signed-ranks test was used.

Results: All treatment plans fulfilled dose volume constraints for CTV, PTV and OAR regardless of the technique used. There was no statistically significant difference in dose distribution in CTV, PTV and OAR ($p > 0.05$). VMAT plans results in a statistically significant lower number of MU ($p=0.041$ for PD = 40.05Gy and $p=0.043$ for PD = 40.50Gy) The number of MU was on average 1363.6 ± 221.1 MU and 764.0 ± 132.6 MU for IMRT and VMAT plans, respectively when the plans with PD of 40.05Gy were analyzed. Similar results were obtained for plans with PD of 40.50 Gy (on average 1010.2 ± 57.4 MU vs 775.4 ± 76.7 MU for IMRT and VMAT respectively).

Conclusion: VMAT in comparison with IMRT technique improves efficacy of plan delivery for equivalent plan quality. The decreased number of monitor units allows to deliver a single fraction faster, so it to reduce the probability of intrafraction motion.

EP-1710

Use of FFF beams for SBRT treatments: impact of the size of the PTV?

L. Vieilleveigne¹, S. Bessieres¹, M. Ouali², C. Lanaspéze¹

¹Institut Claudius Regaud, Radiophysique, Toulouse, France

²Institut Claudius Regaud, Statistiques, Toulouse, France

Purpose or Objective: Flattening filter free (FFF) beams are most frequently utilized for treatments where higher fraction doses need to be delivered, including hypofractionated stereotactic body radiation therapy (SBRT). There are various treatment modalities now available for SBRT: conventional static fields, dynamic conformal arc (DCA) or Volumetric Modulated Arc Therapy (VMAT). In the present study, we wanted to obtain some criteria for a conscious choice of the employment of FFF beams and of the DCA or RA technique depending the size of the PTV.

Material and Methods: Treatment planning was carried out using version 11 of Eclipse (Varian, Palo Alto, CA, USA) with Analytical Anisotropic Algorithm (AAA). All plans were designed for a Varian TrueBeam STx linear accelerator (Varian Medical Systems) equipped with a high definition Millennium multi-leaf collimator (HDMLC). Twenty four PTVs from 1.52 cm³ to 445.24 cm³ were studied. For each PTV, DCA and VMAT plans were prepared utilizing two flattened photon beam of 6 MV (6FF) and 10 MV (10FF) and two nonflattened beams of nominal energy 6 and 10 MV (6FFF, 10FFF). For a meaningful comparison, all DCA and RA plans satisfied 100% of the prescription dose to at least 98% of the PTV. Parameters such as conformity index, gradient index, healthy tissue mean dose, organs at risk mean dose, number of monitor units, beam on time (BOT) were used to quantify obtained dose distributions. A Friedman and Spearman's rho test were performed in order to establish statistical significance.

Results: The data indicate no significant differences between conformity with flattened beams and those using unflattened beams for VMAT technique. For DCA technique, it is notable that 6FFF tends to be slightly better than 6FF beams and even for large volumes. As PTV volume increases, 10FFF is less suitable for DCA technique and forward planning becomes more challenging and inappropriate. The MUs in the FFF plans were always greater than in FF plans. Dose to healthy tissues were reduced for all PTV sizes for FFF beams, except for the DCA 10FFF for large PTV volume. The BOT for FFF beams is much lower. DCA was found to be more appropriate for small PTV and VMAT for median and large PTV. The MUs were significantly different between techniques. VMAT plans generated larger number of MU compared to DCA.

Conclusion: The plans developed with flattened and unflattened beams look very similar in terms of conformity index. FFF beams provide a better sparing of OAR except for

DCA 10FFF and reduced treatment times when compared to FF. Further study on the role of tumor location is recommended to establish more conclusive results. A concern with the use of VMAT with SBRT is whether the motion of the tumor leads to significant dosing discrepancies. DCA remains immune to the MLC interplay effect.

EP-1711

To revise helical irradiation of the total skin HITS as completed-HITS in cutaneous lymphoma patient

H.J. Tien¹, P.W. Shueng¹, S.C. Lin², C.T. Lin¹, H.P. Yeh¹, C.H. Chang¹, C.H. Hsieh¹

¹Far Eastern Memorial Hospital, Radioation Oncology, Taipei, Taiwan

²Far Eastern Memorial Hospital, Hematology, Taipei, Taiwan

Purpose or Objective: To modify helical irradiation of the total skin (HITS) technique as the completed-HITS (CHITS) with face covering and the bone marrow dose declined according to the relapse pattern and hematologic toxicities of cutaneous lymphoma patient.

Material and Methods: A 36-year-old woman was diagnosed as therapy-refractory cutaneous CD4+ T-cell lymphoma, T3N0M0B0, stage IIB. HITS with face sparing using 30 Gy in 40 fractions, 4 times per week was prescribed in March, 2012. The adverse effects included leukopenia. One year later, the new patches were noted in right eyebrow and lower eyelid which was spared. According to the relapse pattern and hematologic toxicities, HITS was revised to improve the plan results as CHITS. First, the clinical target volume (CTV) was increasing the face targeting to be really whole skin irradiated. Second, the planning target volume (PTV) were separated into head, chest, abdomen and pelvis with upper thigh to maintaining the appropriate PTV coverage and the margin for PTV was reduced from 5.0 mm to 3.0 mm according to the previous daily image-guided data. Third, the central cord complete block (CCCB) was designed from head to thigh but not from head to abdomen only. The CCCB distance away from PTV was changed from 2.5 cm to 2.2 cm to reduce the internal organs and bone marrow dose. Additionally, the iliac bone, cervical, thoracic, lumbar spine, femoral head and pelvic bone were contoured to be references to limit the marrow dose. The uniformity index (UI), conformity index (CI), dose of organs at risk were used to evaluate the plans. For reducing the toxicity of normal organs, we also performed low-dose CHITS of 12 Gy in 12 fractions.

Results: The UI for head, chest, abdomen and pelvis of CHITS were 1.16, 1.12, 1.08 and 1.15 that were similar to HITS of 1.12, 1.12, 1.08 and 1.12, respectively. For the low-dose CHITS, the UI is also similar to CHITS. The conformity of CHITS was similar to HITS (1.40 versus 1.37). The mean dose of heart, whole lung, right parotid gland, left parotid gland, liver, right kidney, left kidney, intestine, bladder, rectum, uterus with ovary, and cervix with vagina were reduced in 15.1% to 45.0%. The mean dose of cervical spine, thoracic spine, lumbar spine, right iliac bone, left iliac bone, sacrum, right lower pelvic bone, left lower pelvic bone, right femur, left femur were reduced in 21.6% to 63.8%. For the low-dose CHITS, the normal organ dose were reduced in 47% to 88% due to low dose treatment.

Conclusion: The modifications of adding face skin irradiation, reduced PTV margin, the distance away from PTV from CCCB and virtual structure constraints enabled the CHITS technique reduced doses of normal organs and bone marrow successfully with keep of uniformity and conformity as HITS technique. The low-dose CHITS had the similar results in target uniformity and conformity and much lower normal organ dose compared to HITS technique.

EP-1712

Increased tumour control probability (TCP) with inhomogeneous dose escalated distributions in NSCLC

C. Fleming¹, S. O'Keefe¹, J. Armstrong², B. McClean¹

¹St. Luke's Radiation Oncology Network, Dept. of Physics, Dublin, Ireland Republic of

²St. Luke's Radiation Oncology Network, Dept. of Radiation Oncology, Dublin, Ireland Republic of

Purpose or Objective: The theoretical benefit of dose escalation in NSCLC has been shown by Fenwick whilst others have demonstrated a clinical dose response relationship (Partridge, Rengan). Additionally, inhomogeneous dose distributions have been suggested as a method for increasing the absolute dose to the target within normal tissue constraints (Warren). The aim of this planning study was to combine these concepts and explore the potential tumour control probability (TCP) benefit that an inhomogeneous plan targeting dose escalation to the iGTV could deliver whilst respecting normal tissue tolerances.

Material and Methods: Between January 2014 and April 2015 20 patients with non-small cell lung cancer (NSCLC) underwent 4D-planning CT with motion tracking via the RPM system (Varian Medical Systems, Palo Alto, California) for definitive (chemo)radiation therapy at our institution. The 4DCT scan was binned into 10 phases and the MIP and AVIP datasets were generated. The iGTVsum was the sum of three datasets (0%, 50% and MIP). An iGTV to iCTV margin of 6mm (scc) or 8mm (adenocarcinoma) was used with a further 5mm to the PTV. OARS were contoured on the AVIP CT set, including: combined lung; spinal cord; oesophagus and heart. Mean iGTVsum volume of 94.51cm³ (range: 12.44 - 608.69cm³) and mean PTV volume of 315.51cm³ (range: 97.02 - 1279.64cm³). Six plans were created: homogeneous plans treating the entire PTV to 60Gy in 20 fractions using both 3DCRT and RapidArc; and four inhomogeneous RapidArc plans developed to deliver 65-80Gy in 5Gy escalated increments to iGTVsum (median) and 60Gy to PTV, all in 20 fractions.

Results: There is a significant ($p < 0.05$) difference in TCP for all escalated plans, ranging from 79.8% for the 65Gy boost to 94.9% for the 80Gy boost, in comparison to 63.1% for the homogeneous RapidArc plan. There is a significant difference between the MLD for the various escalated plans (Table 1); however, this difference is not clinically significant given that tolerance for MLD is in the 17-20Gy region. Similarly, the predicted NTCP for the lung for the dose escalated plans ranged from 6.2-7.1%. In terms of the V20Gy the only significant difference was between the 3D plan and all the RapidArc plans (Table 1).

Mean Lung Dose (Gy)

	60H 13.30Gy	60.65 13.35Gy	60.70 13.45Gy	60.75 13.59Gy	60.80 13.72Gy	60.3D 14.92Gy
60H 22.70%		0.243	0.006*	0.000*	0.000*	0.000*
60.65 22.85%	0.590		0.021*	0.003*	0.000*	0.000*
60.70 22.84%	0.653	0.927		0.032*	0.001*	0.000*
60.75 22.98%	0.334	0.296	0.454		0.001*	0.000*
60.80 23.02%	0.321	0.154	0.188	0.752		0.001*
60.3D 27.3%	0.000*	0.000*	0.000*	0.000*	0.000*	

The only significant mean oesophageal difference was between the 3D plan (20.6Gy) and all the escalated plans (17.7-18Gy); however, dose to 1cc of the oesophagus was significantly higher for the 80Gy and 3D plans. All spinal cord and heart doses were below tolerance for the escalated plans.

Conclusion: Treatment intensification in NSCLC via targeted dose escalation with modern delivery techniques offers the potential for a significant increase in tumour control probability without a clinically significant increase in predicted OAR toxicity.

EP-1713

Dose-volume analysis of genitourinary toxicity in 3-D conformal radiotherapy for prostate cancer

P. Bagala¹, G. Ingrosso¹, M.D. Falco¹, S. Petrichella², M. D'andrea³, M. Rago¹, A. Lancia¹, C. Bruni¹, E. Ponti¹, R. Santoni¹

¹University of Rome Tor Vergata, Department Of Diagnostic Imaging- Molecular Imaging- Interventional Radiology and Radiotherapy, Rome, Italy

²Campus Bio-Medico, Computer Science and Bioinformatics Laboratory- Integrated Research Centre, Rome, Italy

³National Cancer Institute Regina Elena, Laboratory of Medical Physics and Expert Systems, Rome, Italy

Purpose or Objective: We investigated the associations between acute and late genitourinary (grade ≥ 2) toxicity and clinical and dosimetric parameters in three-dimensional conformal radiotherapy for localized prostate cancer in order to carry out a dose-volume response evaluation. A dose-volume parameters analysis of the bladder of patients subjected to prostate cancer radiotherapy was reported.

Material and Methods: We considered 86 patients consecutively treated with high dose conformal image guided radiation therapy for localized prostate cancer. For the purpose of our analysis, we defined two bladder volumes: "whole bladder", i.e. the bladder in its entirety as a solid organ, and "inferior bladder", corresponding to the only distal part of the bladder. We carried out an univariate analysis between acute and late genitourinary toxicity and clinical parameters (age, "whole bladder" and "inferior bladder" volumes, smoking status, pre-radiotherapy urinary symptoms, hormonal therapy). We used the point biserial correlation coefficient to correlate dose-volume parameters (Vx) and genitourinary (grade ≥ 2) toxicity. Finally, a fitting of the normal tissue complication probability (NTCP) cut-off volume model with toxicity data was performed.

Results: Mean follow-up was 51.9 months (range: 41.9-75.4 months). In 60 patients we observed an acute genitourinary toxicity (grade ≥ 2), while a late genitourinary toxicity (grade ≥ 2) was recorded in 6 patients. At univariate analysis, we found a correlation between acute genitourinary toxicity and smoking status ($P < 0.001$). Statistically significant associations ($P < 0.05$) between late genitourinary toxicity and Vx dose levels were calculated from 77 Gy and 77.5 Gy, for the "whole bladder" and the "inferior bladder", respectively. For acute toxicity, we found a statistically significant correlation with the dose of 80 Gy ($P < 0.05$), for both "whole bladder" and "inferior bladder". From the NTCP cut-off volume model we detected a bladder volume of 6 cc as the cut-off volume corresponding to a late genitourinary toxicity of 50% at doses ≥ 77 Gy.

Conclusion: Genitourinary toxicity seems to be correlated with bladder maximal doses, quantified as hotspots.

EP-1714

Hyper- versus hypofractionated radiotherapy in a radioresistant head and neck cancer model

L.G. Marcu¹, D. Marcu¹

¹University of Oradea, Faculty of Science, Oradea, Romania

Purpose or Objective: Cancer stem cells (CSCs) and hypoxia are known contributors of tumour resistance in radiotherapy. These parameters influence the radiotherapy schedule for optimal tumour control. Since hypofractionation is becoming increasingly popular among solid tumours, our aim is to evaluate the efficacy of hypo- versus hyperfractionated radiotherapy (RT) on hypoxic head and neck cancer (HNC).

Material and Methods: An *in silico* HNC was developed starting from a CSC. To grow a tumour with biologically valid parameters, the CSC generates all heterogeneous lineages of a tumour, with a probability of CSC symmetrical division 1.9%, mean cell cycle time 33h and volume doubling time 52 days. Pre-treatment CSC percentage is 5.9%. Four different fractionation schedules have been simulated as shown in Table 1. Hypoxic tumours with partial oxygen tension values ranging from 3 to 9 mmHg have been treated and tumour control assessed.

Table 1. Dose fractionation schedules simulated in current study

Radiotherapy schedule	Fractionation pattern
Conventional RT	2 Gy/day; 5 days a week; 7 weeks
Hypofractionated 5d RT	2.2 Gy/day; 5 days a week; 6 weeks
Hypofractionated 6d RT	2.2 Gy/day; 6 days a week; 5 weeks
Hyperfractionated RT	1.2 Gy/twice daily; 5 days a week; 7 weeks

Results: Treatment resistance is determined by the interplay between CSCs and hypoxia. While the modelled conventional and hypofractionated RT schedules are biologically equivalent, hypofractionation is more efficient on CSC kill than conventional treatment. However, for moderately hypoxic tumours (6 mmHg partial oxygen tension) (see figure 1) only hyperfractionated RT offers full control on CSC population within the clinically required treatment time. This observation might be explained by the advantage of two fractions a day through (i) overcoming tumour repopulation between consecutive doses, (ii) redistribution of surviving cells along the cycle; (iii) better reoxygenation. For each decrease in mmHg the number of fractions needed for tumour control increases exponentially. This behaviour is also influenced by the percentage of CSC, which changes during radiotherapy. Thus a tumour with a mean oxygen tension below 6 mmHg and a pre-treatment CSC population of 5.9% needs a greater than 84Gy dose (overall dose given via hyperfractionated RT) or the addition of adjuvant therapies in order to be eradicated.

Figure 1. Radiotherapy schedules for hypoxic HNC with 6 mmHg mean partial oxygen tension.

Conclusion: Hypoxic HNC are better controlled by hyperfractionated than by hypofractionated RT. However, oxyc and mildly hypoxic tumours could benefit from hypofractionation, which reduces overall treatment time and normal tissue effects. The interplay between CSCs and hypoxia dictates the RT treatment strategy for optimal tumour control.

EP-1715

A Neural Network predictions and follow-up toxicity correlation to validate re-planning during RT

N. Maffei^{1,2}, G. Guidi^{1,2}, E. D'angelo³, B. Meduri³, P. Ceroni¹, G. Mistretta¹, A. Ciarmatori^{1,2}, G. Gottardi¹, P. Giacobazzi³, T. Costi¹

¹Az. Ospedaliero-Universitaria di Modena, Medical Physics, Modena, Italy

²University of Bologna, Physics and Astronomy, Bologna, Italy

³Az. Ospedaliero-Universitaria di Modena, Radiation Oncology, Modena, Italy

Purpose or Objective: To correlate a Neural Network (NN) predictive model to clinical outcome of toxicities of patients undergone Radiation Therapy (RT). A re-plan strategy was evaluated highlighting challenges and advantage of an Adaptive RT (ART) workload. Clinical outcomes were assessed to validate an algorithm based on IGRT and deformable image registration.

Material and Methods: A cohort of 30 Head and Neck (H&N) patients, previously treated by Tomotherapy and CHT concomitant, was investigated: 19 male and 11 female [48÷89 years] with mean KPS index 95.5. To take into account inter-fractions organ warping, 900 pre-treatment MVCT study were deformed by RayStation and a dose accumulation analysis was performed. Exported data were used to train the predictive NN tool: a MATLAB toolbox developed to identify patients eligible for re-planning. Using a retrospective approach, the toxicity data were investigated with a mean follow-up period of 12 months. Weight (before and after RT), smoker number and toxicity information were considered. Correlation was assessed using SPSS statistic.

Results: Analysis on the follow-up DB showed that 74% of patients were affected by early toxicity: 40% (G1), 25% (G2) and 9% (G3); 41% by late toxicity: 30% (G1), 10% (G2) and 1% (G3). Correlating the medium-high grade of early toxicity with the dose of the event occurred, a 2nd order polynomial correlation was detected with a R2 value of 0.93 for G2 and 0.92 for G3.

Figure 1 Patients percentage with an early toxicity of G2 (yellow rhombus) and G3 (red square) vs. Dose at which toxicity occurred during treatment.

The correlation of smoking and low toxicity (i.e. dysphagia, dysgeusia, mucositis, salivation) showed a mean G1 increased. An increased frequency of early (21%) and late (19%) toxicity was detected for smoker patients, with an ANOVA multivariate significance of 3.8% and 0.6% respectively. Simultaneously, a NN weekly method was carried out to follow and predict anatomical variations during RT. A benefit due to a review of the initial plan was estimated for 89.6% of patients. The need of re-planning was correlated with weight loss. 37% of patients do not need a re-plan and 25% of them had a weight loss <5%. 63% of patients would benefit for a re-plan: during the 2nd week for 25% of cases with a weight decrease <10%; during the 4th week for remaining 38% of cases (25% of them had a weight loss >10%).

Weight loss (%)	No Re-plan	Week for Re-plan					
		1	2	3	4	5	6
<5%	25%	0%	0%	0%	0%	0%	0%
5 - 10%	12%	0%	25%	0%	13%	0%	0%
>10%	0%	0%	0%	0%	25%	0%	0%
Total	37%	0%	25%	0%	38%	0%	0%

Table 2 Re-planning strategy suggested by NN outcome vs. normalized weight loss.

Conclusion: The machine learning approaches could support decision making in ART workload. Descriptive and inferential analysis showed a correlation between NN outcome and follow-up data, making robust the predictive approach based on organ warping and dose deformation. An increased

number of cases have to be analyzed to train self-learning algorithm and to ensure personalization of patients' treatment. Patients with an abnormal weight loss, smoker and with a high dose delivered should be investigated to avoid early and late toxicities.

EP-1716

Prospective electronic toxicity registration to audit NTCP models and dose constraints

T. Janssen¹, A.L. Wolf¹, J. Kneijens¹, L. Moonen¹, J. Belderbos¹, J.J. Sonke¹, M. Verheij¹, C. Van Vliet-Vroegindeweij¹

¹Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: In 2012 we started with the prospective, electronic registration by the treating physician of all grade2 toxicities (CTCAE v4.0) for all patients irradiated at our department. Simultaneously we set up an infrastructure to couple this data to dose and treatment parameters. The aim of this work is to show the feasibility of such an infrastructure to audit toxicity prediction models and dose constraints in daily clinical practice.

Material and Methods: As a showcase we consider the relation between the esophagus V50Gy and ≥2 grade esophagitis in locally advanced NSCLC patients receiving concurrent chemoradiotherapy (CCRT; 24 x 2.75 Gy and daily 6mg/m2 cisplatin). Clinically we use the criterion V50Gy < 50% as a dose constraint based on a previously developed NTCP model (Kwint et al. IJROBP 2012). The applicability of this model to current daily clinical practice, however, is not evident since CCRT patients currently receive intravenous pre-hydration (1L, NaCl 0.9%) which was shown to decrease esophagitis (Uyterlinde et al. R&O 2014).

For all CCRT patients (excluding re-irradiations of the thoracic region) treated since January 2013, the planned V50Gy and the registered esophagitis grade 2 were automatically retrieved. Patients with toxicity registration in at least 50% of the consultations were included. We calculated the cumulative incidence of grade ≥2 esophagitis per V50Gy and compared this with the expected incidence based upon the model by Kwint et al. using a x2 test. ROC analysis was performed to assess the predictive value of V50Gy.

Results: For 286 patients, a total of 1842 consultations were performed. The incidence of toxicity was electronically registered in 76% of these visits. For 229 patients (80%) the incidence of toxicity was registered in >50% of consultations. Median follow up was 3.5 months. A graphic comparison of the observed and predicted incidence of grade ≥2 esophagitis is shown in figure 1a. The observed incidence of grade 2 esophagitis was 51.1% while the model predicts 52.1% (p=0.89). ROC analysis (figure 1b) resulted in an area under the curve of 0.69. To rule out a selection bias towards increased toxicity, the analysis was repeated for all 286 patients, assuming that no toxicity occurred for missing registrations, with very similar results.

Conclusion: The observed and predicted dose-effect of grade ≥ 2 esophagitis were almost identical. This implies that our esophagus dose parameter accurately predicts toxicity for our current patient population and treatment protocol. This result is surprising, since esophagitis incidence was expected to decrease because of the introduced pre-hydration. While the origin of this discrepancy requires further investigation, it does show that the electronic toxicity scoring system and connection to the dose parameters appears to be a useful and valuable tool to audit the applicability of dose constraints in daily clinical practice.

EP-1717

Impact of radiation induced cell death kinetics on reoxygenation and tumour response.

A. Gago-Arias¹, I. Espinoza¹, B. Sánchez-Nieto¹, J. Pardo-Montero²

¹Pontificia Universidad Católica de Chile, Institute of Physics, Santiago, Chile

²Clinical University Hospital, Department of Medical Physics, Santiago de Compostela, Spain

Purpose or Objective: The radiosensitivity of cells has an oxygen dependence that leads to an undesired resistance of hypoxic tumour cells. This is well known[1] and the linear quadratic response model has been extended to account for it.[2] In order to properly model tumour responses, the information about the distribution of oxygen at a microscopic scale must be available.[3] Modelling works usually derive this distribution by solving the reaction-diffusion equation in a voxelized tumour geometry that includes a vascularization distribution model.[4] However, the oxygen available to the cells increases during radiotherapy due to, among other factors, cell killing. This reoxygenation process can turn hypoxic cells into oxic, changing the cells radiosensitivity during the treatment. In this work we implement two models of cell death kinetics, CDKM, to analyse how they affect reoxygenation and hence the response of tumours to radiotherapy.

Material and Methods: Two CDKMs are compared:

a) Delayed cell killing model, DCDKM: The number of dead cells after irradiation varies with time according to an exponential expression. Cells can die shortly or long after irradiation, mimicking early and late apoptosis.

b) Instantaneous cell killing model, ICDKM: Cell death occurs immediately after irradiation (early apoptosis scenario).

Using these models, oxygen distributions are recomputed before the delivery of each fraction, considering the

decrease in oxygen consumption due to cell death caused during the previous fractions. The oxygen consumption can be computed globally, by voxel averaging surviving fractions, or locally, at a subvoxel scale. The differences in reoxygenation and tumour response arising under different CDKM and oxygen consumption scenarios depend on the vascular fraction, VF, and the fractionation scheme. This was illustrated for a conventional schedule and a hypofractionated treatment.

Results: In the conventional treatment, the doses needed to achieve 50% tumour control (D50) are ~ 10 and 2 Gy larger under the ICDKM (for VFs of 1% and 3%, respectively). Differences are larger in the hypofractionated scheme, for which the TCP remains equal to zero under the DCDKM for a VF equal to 1%. For a VF equal to 3%, D50 values are ~ 20 Gy larger under the DCDKM. Similar results were found under the global and local oxygen consumption calculations.

Conclusion: This work shows that the kinetics of cell death can have a great impact in the simulation of reoxygenation and tumour response. Radiation response models should account for cell death kinetics to properly evaluate tumour response, especially in hypofractionated schemes.

Estimation of tumor radio-sensitivity using mathematical models and analysis of the oxygenation role

A. Belfatto¹, D.A. White², R.P. Mason², Z. Zhang³, S. Stojadinovic³, G. Baroni¹, P. Cerveri¹

¹Politecnico di Milano University, DEIB, Milano, Italy

²The University of Texas Southwestern, Radiology, Dallas, USA

³The University of Texas Southwestern, Radiation Oncology, Dallas, USA

Purpose or Objective: The project aims at predicting tumor radiation starting from pre-treatment information related to cancer volume and oxygenation.

Material and Methods: Eighteen Copenhagen rats, implanted with prostate tumor, underwent two irradiations (2x15Gy). Nine rats were treated in standard conditions (Air), while the remaining group (Oxy) inhaled oxygen. Before the first irradiation, an interleaved blood (BOLD) and tissue (TOLD) oxygen level dependent (IBT) MRI sequence was performed. Four indices were computed, namely, BOLD and TOLD signal intensity variation (dSI), and the change in longitudinal (dR1) and transverse (dR2*) relaxation rate. The tumor volume evolution was monitored by means of weekly caliper measurements. A two-equation system describing the uncontrolled growth and the response to treatment of the active cells population, along with the dead cell clearance dynamics, was implemented in Matlab® (MathWorks, Natick, Massachusetts, USA). Three parameters, namely the volume doubling time, the radiation sensitivity (α) and the dead cell clearance time, were learned on a subject-specific basis using a genetic algorithm. Finally, a feed forward neural network (FF-ANN) was trained (Fig. 1) to predict α starting from the MRI indices and initial volume, for each group (Air/Oxy).

Fig 1. FF-ANN scheme.

Results: An inverse correlation of the radio-sensitivity parameter assessed by the model was found with respect the $dR2^*$ (-0.65) for the Oxy group. A further subdivision according to positive and negative values of $dR2^*$ showed a larger average radio-sensitivity for the Oxy rats with <0 and a significant difference in the two distributions according to the Wilcoxon-Mann-Whitney test ($p < 0.05$). Finally, the Pearson correlation coefficient ($R^2 > 0.9$) revealed a strong agreement of the FF-ANN output with the target radio-sensitivity.

Conclusion: These preliminary findings support the hypothesis that the change in the $R2^*$ can be related to tumor oxygenation and, consequently, to its radio-sensitivity. In particular, the sign of the tendency is in accordance with the fact that an oxygenation increase reduces the tumor relaxation rate as reported in the literature. Moreover, the different distributions of α , outlined in the Oxy subgroups according to the $dR2^*$, suggest that some subjects would benefit from oxygen inhalation more than others, reasonably due to their initial vascularization. Finally, the performance of the FF-ANN is promising, although it would require a larger dataset to validate its prediction ability.

⁸University of Milan, Radiation Oncology, Milan, Italy

⁹European Institute of Oncology, Medical Imaging and Radiation Sciences, Milano, Italy

¹⁰CNAO Centro Nazionale di Adroterapia Oncologica, Radiobiology, Pavia, Italy

Purpose or Objective: Administration of monoclonal antibody Epidermal Growth Factor Receptor (MoAb-EGFr) inhibitor every week during Radiotherapy (RT) of head and neck cancer (HNC) has shown improved outcomes as compared to RT alone in terms of locoregional disease control, progression free and overall survival, thanks to its radiosensitizing effect. MoAb-EGFr concentration varies day by day after injection, and radiosensitizing effect accordingly. A radiobiological (RB) model accounting for this variation (Pedicini, et al. Radiat Oncol. 2012;7:143) can be applied to shorten the treatment by optimizing daily RT dose, still maintaining unchanged the biological effect on the

tumour (in terms of surviving cells) as compared to standard RT (7 weeks, PTV1: GTV, 70Gy; PTV2 = GTV+margin, 63Gy; PTV3: lymph nodes: 58.1Gy) and potentially reducing healthy tissue toxicity. In this study, such RB model was adopted in the clinical protocol FAMOSO (Frazionamento Accelerato MODOlato in SIB-IMRT dei tumori testa-collo) for the treatment of HNC tumours with simultaneous integrated boost (SIB), aiming to test the feasibility of accelerated modulated fractioning and to assess toxicity and response rate.

Material and Methods: From literature data, showing that higher concentrations of MoAb-EGFr correspond to steeper tumor cell survival curves, radiobiological parameters were derived and included in the RB model to obtain the daily dose to be delivered to each target volume. To date, 2 of the 10 expected pts (pt1: cT4cN1 oropharyngeal; pt2: cT2 cN3 supraglottic squamous cell carcinoma) have been recruited and treated with SIB-IMRT with a curative intent.

Results: The RB model suggested a 6 week treatment with daily increasing dose/fractions as follows: PTV1: 1.70, 1.95, 2.15, 2.30, 2.35Gy; PTV2: 1.50, 1.75, 1.95, 2.05, 2.10Gy; PTV3: 1.40, 1.60, 1.80, 1.90, 1.95Gy. Both pts recruited in the FAMOSO protocol concluded the radiation treatment : pt1 with no change of the planned schedule; pt2 with interruption of MoAb-EGFr after the 5th administration and, consequently, the last 10 RT fractions of RT were administered with standard fractionation. The total dose to the PTV1 were 62.7 and 61.8 Gy, respectively. Maximum acute skin and mucosal toxicity was G3. With a follow up of 6 and 2 months, a partial response was obtained for pt1, while pt2 is still under evaluation.

Conclusion: New treatment strategies, even accelerated, are feasible when combining RT with radiosensitizing drugs. The RB model is adequate to set up the treatment provided radiobiological parameters are available from clinical data. The preliminary clinical data of the protocol FAMOSO give encouraging results, suggesting that the treatment schedule is feasible with acceptable acute toxicity. Longer follow up is needed to confirm toxicity findings and assess response rate, and of course more patients have to be studied.

EP-1720

Impact of contouring variability on tumour control and normal tissue toxicity in liver SBRT

M. Robinson¹, D. Eaton², R. Patel², D. Holyoake¹, M. Hawkins¹

¹University of Oxford, Radiation Oncology, Oxford, United Kingdom

²National Radiotherapy Trials Quality Assurance Group, Mount Vernon Hospital, Northwood, United Kingdom

Purpose or Objective: Variability in the contouring of gross tumour and the derived planning target volumes (PTVs) between clinicians is well-known in radiotherapy. This study aims to quantify the impact of variability in contouring in terms of tumour control and normal tissue toxicity in Liver SBRT.

Material and Methods: The National Radiotherapy Trials Quality Assurance (RTTQA) Group planning benchmark case for the ABC07 Trial was used (addition of stereotactic body radiotherapy to systemic chemotherapy in locally advanced biliary tract cancers; CRUK A18752, sponsor University College London). 12 centers performed contouring independently using radiotherapy trial protocol as per RTTQA pre-trial QA process. Each centre applied margins to derive PTV as per local practice. A standardised Volumetric Modulated Arc Therapy (VMAT) plan was produced based on gold standard contours and applied to all 12 sets of submitted contours aiming to deliver 50Gy in 5 fractions. However, due to large GTV this was unavoidably de-escalated to 40Gy to meet trial mandatory mean non-GTV Liver constraint. Tumour control was assessed through biologically effective dose (BED) to 98, 95 and 90% of the gold standard PTV. 65Gy BED, although disappointingly low for SBRT, was considered

as a cut off for acceptable therapeutic intent. NTCP modeling of radiation induced Liver disease was also performed.

Results: Non-GTV Liver mean dose ranged from 13.1 to 17.0Gy, breaching mandatory trial constraint of <15.2Gy in three cases. NTCP ranged from 0.0 to 0.3 assuming an alpha/beta of 1.0 for normal Liver and negligible assuming alpha/beta of 2.0 or more. At D98%, four sets of contours did not achieve 65Gy BED to gold standard PTV, two sets failing to reach 65Gy BED at D90%.

Conclusion: Significant variability exists in contours drawn by different centers/clinicians in the setting of pre-trial QA to the extent where 10% or more of the PTV receives a BED insufficient for local control in a proportion of cases and NTCP is significantly affected. Given this variability, the pre-trial and on-trial RTTQA process is essential if the effect of contour variability on tumour control rates and treatment toxicity is to be mitigated.

EP-1721

Feature extraction from duodenal dose surface maps to predict toxicity in pancreatic chemoradiation

A. Witztum¹, S. Warren¹, M. Partridge¹, M.A. Hawkins¹

¹CRUK/MRC Oxford Institute for Radiation Oncology, University of Oxford, Oxford, United Kingdom

Purpose or Objective: To use spatial features from dose surface maps of the duodenum to predict acute duodenal related toxicity in pancreatic chemoradiation.

Material and Methods: Dose surface maps were produced for the duodenum describing the spatial surface dose distribution. Traditional metrics were extracted including mean and max dose, surface area receiving 25, 35, 45 and 55 Gy as absolute and fraction of the surface. Spatial metrics extracted include the length of the duodenum which received less than 25, 35, 45 and 55 Gy to at least 10-90% of the circumference (in 10% intervals). Different thresholds for the length of the duodenum achieving these constraints were tested in order to find the best predictor of toxicity. Toxicity results from 19 patients from the ARCII clinical trial (EudraCT: 2008-006302-42) were used as a proof of concept. 6 and 11 patients had grade (Gr) and Gr ≥ 2 toxicity respectively.

Results: The best predictors for patients with grade (Gr) ≥ 3 toxicity were at higher doses of 55 Gy. While restricting the dose < 55 Gy to at least 10% of the circumference for at least 10% of the length of the duodenum, or at least 20% of the circumference for at least 20% of the length accurately predicted toxicity for 74% of the patients studied, this only had a sensitivity of 17% and 33% respectively (specificity of 100% and 92%). Figure 1 indicates a better predictor may be restricting dose < 55 Gy to at least 20% of the circumference for at least 70% of the length which, although only accurately predicts toxicity for 58% of the patients, has a sensitivity and specificity of 67% and 54%. It was found that the relative percentage of the circumference spared was a better predictor than absolute circumferential length spared. However, similarly to the spatial metrics, predictions of patients with at least Gr 3 toxicity was seen in the higher dose regions such as mean dose of 60 Gy, maximum dose to a pixel of 62 Gy and when 70% of the surface area receives 55 Gy. Gr 2 toxicity could not be predicted.

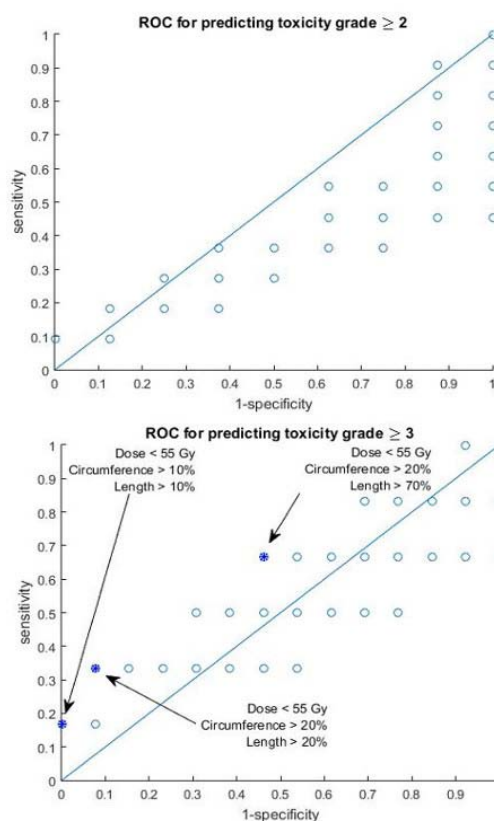

Figure 1: ROCs for grade ≥ 3 and grade ≥ 2 toxicity. Each point represents a different dose-surface feature and threshold that was tested.

Conclusion: In this small sample we have shown that spatial features can be extracted from dose surface maps to aid toxicity prediction, and that high doses to the duodenum appear to be correlated with Gr 3 toxicity. An improved understanding of how these spatial features correlate to toxicity can improve traditional constraints on the duodenum. Further work is required to build a more complete picture of this result, and the analysis will now be extended to a larger patient cohort.

EP-1722

Simulation of the radiation response of a hypoxic prostate tumor in the rat

I. Liedtke-Grau^{1,2}, R.O. Floca³, P. Peschke⁴, I. Espinoza¹, C.P. Karger²

¹Pontificia Universidad Católica de Chile, Institute of Physics, Santiago, Chile

²German Cancer Research Center DKFZ, Department of Medical Physics in Radiation Oncology, Heidelberg, Germany

³German Cancer Research Center DKFZ, Software Development for Integrated Diagnostics and Therapy, Heidelberg, Germany

⁴German Cancer Research Center DKFZ, Clinical Cooperation Unit Radiation Oncology, Heidelberg, Germany

Purpose or Objective: In a previous work a model which simulates the radiation response of hypoxic tumors was developed. The task of this work is to validate the model by using preclinical experimental dose response data of rat prostate tumors for single and multiple irradiations.

Material and Methods: The model is voxel-based and simulates the spatio-temporal behavior of tumors considering six radio-biological processes. Important input data are the oxygenation levels of each tumor subvolume at the time of irradiation, which are given as pre-calculated oxygen frequency histograms. The experimental data for validation include growth curves, dose response curves and TCD50s for 1, 2 and 6-fraction (Fx) experiments. A very high α/β value of 84.7 ± 13.8 Gy was determined. A strategy of adjustment was

defined to fit the model to the experimental data in terms of growth curve, dose response curves, TCD50 and α/β value.

Results: The experimental data are well described for an O₂-independent response. For this case an α/β of 74.7 ± 5.5 Gy was obtained.

When including the effects of O₂, we aimed to reproduce this high experimental value starting from smaller intrinsic α/β values. Unexpected shifts towards lower doses of the 2-Fx curves with respect to the 1-Fx curves were observed. This effect could be explained by a strong reoxygenation between the 1st and the 2nd Fx. Known reoxygenation mechanisms in the model include shrinkage, angiogenesis and the increase of available O₂ due to the presence of dead cells. The latter was found to be the dominant mechanism of the three. When switching off these mechanisms, the unexpected shifts were still observed. A fourth reoxygenation mechanism, which is inherent to the original model, was identified. It implicitly arises by assuming that the distributions of cells at specific O₂ levels remained the same after irradiation. To eliminate this effect, the histograms were updated to consider the actual O₂ levels of the surviving cells. After doing so, the unexpected shifts of the curves were no longer observed and higher simulated values of α/β were obtained.

Conclusion: This work constitutes the first stage of experimental validation with preclinical data of a computer model which simulates the radiation response of hypoxic tumors. It was confirmed that reoxygenation plays an important role in the dose response of tumors. Additionally, important information on how to further improve the model was gathered.

EP-1723

Radiobiological analysis of rib fracture incidence in lung SABR

A. Carver¹, J. Uzan¹, C. Eswar¹, A. Pope¹, A. Haridass¹

¹The Clatterbridge Cancer Centre - Wirral NHS Foundation Trust, Department of Clinical Physics, Bebington- Wirral, United Kingdom

Purpose or Objective: SABR (Stereotactic Ablative Radiotherapy) is only possible in a subset of patients with small tumors and favourable anatomy as the very high BED increases the risk of complications. Lung SABR is often delivered to tumors that are more peripheral thus; the ribs are structures now exposed to significantly higher doses than historically has been the case. The first fifty-two SABR (Stereotactic Ablative Radiotherapy) patients treated at our centre were monitored for rib fracture and chest pain. In this study, we fit the data to the LKB model of normal tissue response.

Material and Methods: Fifty-two patients were treated with either, 55 Gy in 5# (40 patients), 60 Gy in 8# (6 patients) or 54 Gy in 3# (6 patients) depending on the size and location of the tumor. For each patient a chest wall volume was delineated. The chest wall volume encompassed the rib and chest wall between the ribs. Data were fitted to the Lyman-Kutcher-Burman (LKB) model, a model using the normal cumulative density function to produce a sigmoidal dose response curve. The model consists of three parameters TD50, which determines the dose at which 50% of treatments will result in a complication, m which governs and slope and the volume parameter, n. We assumed $\alpha/\beta = 3$ Gy.

Results: Of the 52 patients there were 5 occurrences of rib fracture (NTCP = 9.6% -6.4%/+11.4%). Leaving the volume parameter free in the fit produced best-fit parameters of $n = 0.01$, TD50 = 370 Gy and $m = 0.45$. Due to the small NTCP it is difficult to extrapolate to find TD50. This is shown graphically in Figure 1; a small change in the slope will have a very large effect on the point at which the NTCP is equal to 50%. Consequently, the uncertainties were large, n could not be constrained although very small values were preferred. At 95% confidence TD50 > 220 Gy and $m > 0.2$, assuming that rib fracture is approximately a serial complication. Figure 1

shows the correlation between TD50 and m at the best-fit value of the volume parameter.

Conclusion: We conclude that the rate of rib fracture is relatively low (<10%) in SABR patients. NTCP modelling suggests that a very low volume parameter is most consistent with the data. This is in agreement with what might be naively expected. Due to small number of patients and events analysed to date it is not possible to constrain parameters tightly. This may be helped by re-parameterising the curve. We are now studying the effects of low absolute NTCP values and physically bounded parameters on the confidence intervals.

EP-1724

Model-based effect estimates reduce sample-size requirements in randomized trials of proton therapy

A.L. Appelt¹, S.M. Bentzen², I.R. Vogelius¹

¹Rigshospitalet, Department of Oncology, Copenhagen, Denmark

²University of Maryland School of Medicine, Division of Biostatistics and Bioinformatics- University of Maryland Greenebaum Cancer Center- and Department of Epidemiology and Public Health, Baltimore, USA

Purpose or Objective: Standard power calculation methods for randomized trials do not account for patient-to-patient differences in effect of novel radiotherapy (RT) techniques. The expected advantage of a new technique can often be related to heterogeneous dose metrics in individual patients. Here, we investigate if model-based outcome assessment can affect sample size requirements for a randomized trial of proton versus photon RT for lung cancer with reduction of severe radiation-induced lung toxicity (RILT) as primary endpoint.

Material and Methods: We estimated the number of patients needed to demonstrate an advantage of proton versus photon RT in a randomized trial, with $\alpha=0.05$ and 80% power. We simulated outcomes using Weibull survival distributions with baseline probability of freedom from RILT at 2 years of 85% for patients without clinical risk factors. Heterogeneous gain from proton therapy was quantified by change in mean lung dose (Δ MLD), randomly normally distributed in the proton arm with mean 4.2 Gy and s.d. 2 Δ MLD values were translated into hazard ratios (HR) using the QUANTEC dose-response relationship, adjusted for clinical prognostic factors (comorbidity, tumour location, smoking status, age) evenly distributed between the trial arms. Simulated follow-up was distributed over a time period of 2 years. Monte Carlo simulations (3000 per data point) were used to assess trial power. Sample size estimates were calculated as follows: *Standard:* Comparison of treatment arms using log-rank statistics; and *Model-based:* Cox proportional hazards regression fitted to the change in dosimetric predictor, here Δ MLD. The consequence of a misspecified dose metric was assessed by assuming an underlying true effect metric that was correlated to, but not equal to, Δ MLD.

Results: Sample size estimates differed considerably for the two approaches; see Table 1. 744 patients were needed to show the advantage of proton versus photon RT with standard comparison of trial arms, while superiority of protons based on a direct fit to the effect metric (Δ MLD) required only 549 patients. The advantage of using the model-based method

was maintained as long as the effect metric used for Cox regression had a linear correlation with the true effect metric of at least 0.50. The conclusions held if the trial cohort consisted of an expected high benefit population (22% reduced sample size), but the effect was even stronger if the cohort was a population with modest expected benefit (31% reduced sample size).

	Estimated trial size
Standard population	
$\Delta\text{MLD}=4.2$ Gy, s.d. 2 Gy, normal risk factor prevalence	
Standard (log-rank)	744 patients
Model-based (Cox regression to ΔMLD)	549 patients
Model-based (misspecified effect metric, correlation 0.80)	614 patients
Model-based (misspecified effect metric, correlation 0.50)	743 patients
High benefit population	
$\Delta\text{MLD}=5.8$ Gy, s.d. 2.7 Gy high risk factor prevalence	
Standard (log-rank)	218 patients
Model-based (Cox regression to ΔMLD)	169 patients
Low benefit population	
$\Delta\text{MLD}=2.6$ Gy, s.d. 1.3 Gy, low risk factor prevalence	
Standard (log-rank)	2300 patients
Model-based (Cox regression to ΔMLD)	1587 patients

Table 1: Standard trial design (log-rank statistics) compared to model based Cox regression. Risk factors included were: pre-existing pulmonary co-morbidity (HR = 2.27), mid or inferior tumour location (HR = 1.87), current smoker (HR = 0.62), and old age (HR = 1.66). The consequences of a misspecified effect metric were examined for correlations ranging from 0.95 to 0.45; example results are shown.

Conclusion: We have demonstrated that the required patient sample size for randomized trials in radiation oncology may be considerably reduced by taking heterogeneous dose-effect into account. Dual planning provides support for the statistical outcome modelling that increases trial power even if the dose-response model is moderately misspecified. The outcome of a trial in the example studied would be a randomized measure of 'benefit per Gy ΔMLD ' with confidence interval.

EP-1725

Predictors of diarrhea after whole-pelvis post-prostatectomy radiotherapy

C. Sini¹, C. Fiorino², L. Perna², B. Noris Chiorda³, V. Sacco³, M. Pasetti³, A. Chiara³, R. Calandrino², N. Di Muzio³, C. Cozzarini³

¹Fondazione Centro San Raffaele, Medical Physics, Milano, Italy

²San Raffaele Scientific Institute, Medical Physics, Milan, Italy

³San Raffaele Scientific Institute, Radiotherapy, Milan, Italy

Purpose or Objective: Gastrointestinal (GI) toxicity is a side-effect induced by whole pelvis intensity modulated radiotherapy (WP-IMRT), affecting importantly patients' quality of life. The aim of this study was to identify predictors of diarrhea in a cohort of chemo-naïf patients treated with WP-IMRT after prostatectomy.

Material and Methods: The Inflammatory Bowel Disease questionnaire (IBDQ) was used to assess the degree of GI symptoms after WP-IMRT, investigating 4 distinct areas: bowel and systemic symptoms, emotional and social functions. This study focused on the most clinically relevant item 5 relative to the bowel domain, in order to evaluate the frequency of liquid defecation. Patient-reported scores at baseline, at RT mid-point and end, and every 3 months after RT end were prospectively collected. The responses are scored on a 7-point scale where 7 corresponds to the best function and 1 to the worst. Clinical/dosimetric data in 115 patients treated with adjuvant (n=65) or salvage (n=50) WPRT in a single Institute were available (static field IMRT:19; VMAT:55; Tomotherapy:41). Dose-volume histograms (DVHs) for intestinal loops and sigmoid colon were calculated. The 25th percentile of the score variation between baseline and half/end RT was considered as end-point ($\Delta\text{-IBDQ5}\leq-3$). Associations between diarrhea and clinical/DVH parameters were assessed by logistic uni- and backward multi-variable analyses. A previously introduced method based on DVH

differences between patients with/without diarrhea toxicity was used to select the most discriminative DVH parameters.

Results: No significant correlation emerged for sigmoid colon, then the analysis was focused on intestinal loops. Patients without basal score and with $\text{-IBDQ5}\leq-3$ were excluded from the analysis: 23/77 pts showed acute GI toxicity. At univariate analysis, volumes receiving 5 to 40Gy (V5-V40) were correlated with $\text{-IBDQ5}\leq-3$ ($p<0.03$). Multivariate analysis confirmed a leading role of dosimetric variables, while no significant correlation for clinical parameters was found. Best cut-off values (assessed by ROC) discriminating patients with/without $\text{-IBDQ5}\leq-3$ were: V20<250cc, V30<150cc and V40<90cc. The overall incidence equal to 10% and 50% resulted for the group of patients with DVH parameters lower/higher than thresholds, respectively ($p=0.0028$, OR=4.9, AUC=0.68).

Conclusion: Low-medium IMRT doses to intestinal loops were correlated to diarrhea symptom at half/end of RT. This study proposed new dose volume constraints, that may be used to prevent much radiation-induced GI morbidity.

EP-1726

Biological modelling to identify proton therapy candidates in focal boosting of prostate tumours

J. Pedersen¹, O. Casares-Magaz¹, J. B. B. Petersen¹, J. Rørvik², L. Bentzen³, P. R. Poulsen¹, A. G. Andersen¹, L. P. Muren¹

¹Aarhus University Hospital, Department of Medical Physics, Aarhus C, Denmark

²Haukeland University Hospital, Department of Radiology, Bergen, Norway

³Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

Purpose or Objective: MRI-based focal tumour boosting is currently under clinical investigation for prostate cancer patients, e.g. in the FLAME trial. These highly conformal, focal dose distributions can be difficult to achieve with photons, depending on the size and location of the boost volume (i.e. proximity to critical organs at risk). Selected patients might therefore be candidates for proton therapy. In previous work we have established an MRI-based tumour control probability (TCP) model. Combined with published rectum and bladder normal tissue complication probability (NTCP) models we have in this study explored the use of biological (TCP and NTCP) models to identify prostate cancer patients that might be suitable candidates for proton therapy if treated according to FLAME-like trial protocols.

Material and Methods: CT scans of seven patients from a prospective trial in our institution were used for planning. To obtain realistic boost geometries, MRI-based index tumours from a different cohort were used (matched on prostate volume), propagated with rigid registration on the prostate volume. VMAT plans (Eclipse, Varian Medical Systems) with and without a boost to the index lesion (95 Gy / 35 fx) were created; both plans delivered a conventional dose (77 Gy / 35

fx) to the non-involved prostate. Planning constraints used were based on institutional procedures as well as from the FLAME trial, with small modifications in the boost plans. The dose distributions (with/without boost) were used to calculate the TCP and NTCP values for each patient. The TCP model used apparent diffusion coefficient maps to estimate cell densities while the NTCP models used were the conventional Lyman model for the rectum (late rectal bleeding grade ≥ 2 ; Rad. Onc, 73, 21-32, 2004) and the Poisson LQ model for the bladder (contracture; Ågren PhD thesis, 1995).

Results: The TCP increased from a median (range) of 0.45 (0.08-0.83) with the conventional approach to 1.0 (no range) with the focal boost. While there were only minor differences in the rectum NTCPs with vs. without the boost there were considerable differences in the NTCP for the bladder for two of the patients (more than a doubling of the NTCP with the boost; Table 1). These two patients had the index lesion that was closest to the bladder.

Table 1: NTCP values for each patient for rectum and bladder. First value is with boost, second value without boost.

Patient	Rectum		Bladder	
	With boost	Without boost	With boost	Without boost
Patient 1	1%	1%	12%	5%
Patient 2	1%	1%	3%	1%
Patient 3	1%	1%	1%	0%
Patient 4	1%	2%	8%	4%
Patient 5	2%	3%	4%	2%
Patient 6	2%	2%	1%	0%
Patient 7	2%	2%	0%	0%

Figure 1: The upper part of the figure shows the dose distribution for one patient with the tumour boost (the index lesion is the peanut shaped delineation inside the PTV of the prostate). The dose color wash range is between 74 Gy and the max dose, which is 104 Gy.

The lower part of the figure shows the same view of the same patient without the boost arm, but conventional treatment. The dose color wash range is between 74 Gy and the max dose, which is 81 Gy.

Conclusion: We have established a biological modelling based method to identify prostate cancer patients where the focal boost cannot be achieved with state of the art photon-based treatment without a considerable increase in the NTCPs. Further work will consider the feasibility of proton planning, given both inter- and intra-fractional organ motion patterns.

EP-1727

A decision support system for localised prostate cancer treated by external beam radiation therapy

S. Walsh¹, M. Field², M. Barakat², L. Holloway³, M. Bailey⁴, M. Carolan⁴, G. Goozee³, G. Delaney³, A. Miller⁴, M. Sidhom³, P. Lambin¹, D. Thwaites², A. Dekker¹

¹MAASTRO clinic, Knowledge Engineering, Maastricht, The Netherlands

²University of Sydney, Medical Physics, Sydney, Australia

³Ingham Institute, Medical Physics, Sydney, Australia

⁴Illawarra Cancer Care Centre, Medical Physocs, Wollongong, Australia

Purpose or Objective: This study presents a universally applicable decision support system (DSS), with respect to the prediction of five-year biological no evidence of disease (5y-bNED) for localised prostate cancer (PCa) patients treated by external beam radiation therapy (EBRT).

Material and Methods: To develop a DSS this study utilised the traditional approach of model training based upon meta-analysis data (MAD: n=5218) from the literature with model validation based upon routine clinical care data (CCD: n=827) from clinics with a rapid learning healthcare (RLHC) environment. The following standard clinical features for PCa patients were investigated to train and validate a tumour control probability model (TCP) and a predictive machine learning model (PML): primary tumour stage (T), lymph node stage (N), metastasis stage (M), prostate specific antigen (PSA), Gleason score (GS), clinical-target-volume (CTV), total dose (D), and fractional dose (d). These features were selected as they are typically known within all clinics treating PCa patients, thus maximising the generalizability of the DSS.

Results: The DSS is comprised of two distinct models. The TCP model was found to be well calibrated with poor discriminative ability. Training resulted in an adjusted weighted R2 value of 0.76, a weighted mean absolute residual (wMAR) of 4.7% and an area under the curve (AUC) of 0.67 [0.65, 0.69]. Validation resulted in an adjusted weighted R2 value of 0.51, a wMAR of 2.0% and an AUC of 0.57 [0.51, 0.63]. Contrastingly, the PML model was found to be poorly calibrated with good discriminative ability. Training resulted in an adjusted weighted R2 value of 0.27, a wMAR of 8.3% and an AUC of 0.66 [0.64, 0.68]. Validation resulted in an adjusted weighted R2 value of 0.90, a wMAR of 16.2% and an AUC of 0.61 [0.56, 0.65]. Subset analysis shows that the DSS performs best in high-risk PCa patients with validation resulting in an AUC of 0.66 [0.60, 0.72] with a wMAR of 1.0%.

Conclusion: A DSS developed with MAD has been validated in CCD extracted using RLHC infrastructure. The DSS uses standard clinical features to estimate with good accuracy (wMAR < 4.7%) and reasonable fidelity (AUC > 0.61) the 5y-bNED rate and classification, respectively, of PCa patients. The performance of the DSS in the validation high-risk PCa cohort (wMAR = 1%) and patients (AUC = 0.66) for whom therapy could be potentially adapted or individualised based on the DSS has clinical relevance and should be prospectively validated.

EP-1728

Dose individualisation through biologically-based treatment planning for prostate cancer patients

E. Gargioni¹, P. Mehta¹, A. Raabe¹, R. Schwarz¹, C. Petersen¹

¹University Medical Center Hamburg - Eppendorf UKE, Department of Radiology and Radiotherapy, Hamburg, Germany

Purpose or Objective: The use of biological information on tumour control and normal-tissue complications for treatment plan optimisation can be used for individualising the dose prescription. For patients with prostate cancer, moreover, the tumour localisation by means of MR-images facilitates the use of such information for a simultaneous dose escalation in the so-called dominant intraprostatic lesions (DIL), thus further improving the treatment outcomes. However, a correct modelling of the tumour-control

probability depends on the accuracy of the alpha-beta ratio for prostate cancer, the value of which is still a matter of discussion in the scientific community. Therefore various scenarios should be investigated for understanding the limits of the biologically-based dose escalation to the tumour during prostate radiotherapy.

Material and Methods: This work investigates the potential and limits of biologically-based treatment planning for ten prostate-cancer patients with localised disease in the case of alpha-beta-ratios of 1.5 Gy, 3 Gy, and 4.5 Gy, respectively. The MR images of these patients were used for contouring the intraprostatic lesion as GTV and were matched with the CT images in EclipseTM. Biologically-based 7-fields IMRT plans were optimised by minimising the NTCP for rectal bleeding and bladder contracture and by maximising the TCP for the GTV. For all patients, the dose prescription for the PTV (whole prostate) was 72 Gy in 40 fractions.

Results: The results of this plan-comparison study show that the individual GTV dose coverage depends on the alpha-beta ratio for prostate cancer, while the calculated dose distribution (in particular the mean dose values and the D3%) for rectum and bladder are not influenced by this parameter. Also, the total dose to the GTV could be individually optimised and varied between 76 Gy and 87 Gy, depending on the position of the DIL within the prostate. Finally, the optimised total dose to the GTV increased when modelling the TCP with a lower alpha-beta ratio, with individual differences up to 3 Gy.

Conclusion: Biologically-based optimisation tools allow for individualised dose escalation in dominant intraprostatic lesions and, in principle, could be safely used for the treatment planning of prostate cancer. In fact, a variation of the alpha-beta ratio for prostate cancer between 1.5 Gy and 4.5 Gy causes a variation of the dose coverage of the GTV of up to about 3 Gy in total, thus showing an acceptable robustness of the TCP model with respect to this parameter. Biologically-based optimisation tools, finally, have the advantage of reducing optimisation time, contouring process, and dose hot spots. Studies are currently being carried out in order to further validate the TCP and NTCP models for prostate cancer treatment in the case of hypofractionated schedules.

EP-1729

The impact of CBCT-imaging and verification time on prostate motion using 4D TPUS Clarity system

P.P.E. Pang^{1,2}, K. Knight², M. Baird², H.S.A. Boo¹, M.Q.J. Loh¹, W.S.J. Chan¹, S.N. Aryani¹, K.L.J. Tuan¹

¹National Cancer Centre Singapore, Division of Radiation Oncology, Singapore, Singapore

²Monash University, Faculty of Medicine, Nursing and Health Sciences- Department of Medical Imaging & Radiation Sciences, Melbourne

Purpose or Objective: Accuracy of radiotherapy to the prostate is often challenged by geometrical uncertainties due to inherent organ motion attributed to daily variations of the bladder and rectal volumes and contents. This study aims to simulate the use of 4D Clarity ultrasound image guidance without CBCT imaging to analyse the magnitude and trend of prostate motion during treatment (74Gy given in 37 fractions). The impact of CBCT imaging and verification time on prostate motion will be analysed.

Material and Methods: 175 intra-fraction monitoring sessions from 5 patients who underwent radical prostate volumetric modulated arc therapy (VMAT) monitored using 4D transperineal ultrasound scan (TPUS) resulted in a total of 1461.2min of data (184,085 positioning points) being analysed. All patients were instructed to comply with a full bladder protocol (i.e. 300-450ml in 30-45min) without

specific rectal preparation protocol. Mean prostate motion was calculated and analysed in relation to time in the subsequent fractions. Overall treatment time was defined from acquisition of CBCT to treatment beam off time and imaging time was defined from time of CBCT acquisition to first beam on. Imaging time was subtracted from the overall treatment time for analysis of prostate motion without CBCT for verification. The remaining duration was representative of treatment time using 4D Clarity ultrasound image guidance alone. The impact of CBCT imaging and verification time on prostate motion was analysed.

Results: Mean (median) imaging and overall treatment time was 4.6min (4.4 min) and 8.4min (8.3 min) respectively. Mean (median) prostate motion during overall treatment time was 0.7mm (0.6mm) Inf, 1.0mm (0.9mm) Post and 0.1mm (0.2mm) Lt respectively. Mean prostate motion without CBCT was 0.6mm (0.5mm) Inf, 0.9mm (0.8mm) Post and 0.1mm (0.1mm) Lt. Figure 1 demonstrates the observed prostate displacement over time in a single session from one of the patients. In general, the mean (median) maximum prostate drift during actual treatment alone tends to trend towards the following directions at 3.6mm (3.4mm) Inf, 7.4mm (5.2mm) Ant and 2.7mm (2.8mm) Lt. Magnitude of the median maximum prostate displacement increased relatively by 38.4%, 16.7% and 46.6% in the Inf, Ant and Lt directions respectively with added imaging time.

Figure 1: Demonstrates the observed prostate displacement over time.

Conclusion: Prolonged overall treatment time due to CBCT imaging and verification time increases the intra-fraction prostate motion. We propose the use of 4D Clarity TPUS in place of TPUS with CBCT to reduce imaging time before radiotherapy to reduced total verification time leading to reduced prostate movement. Consequently, the magnitude of intra-fraction prostate motion could be reduced from reduced image acquisition and reconstruction time. This reduces the total in room time per patient and maximises patient through-put and treatment efficiency which is important in a busy radiotherapy centre.

EP-1730

Clinical evaluation of new approach for determining ITV target volume in NSCLC treated with 4D SABR

X. Li¹, Q.H. Deng¹, L.D. Zhang², B. Xia², Z.B. Wu¹, Y. Ren², J. Gu², Z.S. Zheng², S.L. Ma¹, G. Li³

¹The First People's Hospital of Hangzhou, Radiation Oncology, Hangzhou, China

²Hang Zhou Tumor Hospital of Zhejiang Province, Radiological Physics, Hangzhou, China

³Xiaoshan Hospital of Zhejiang, Radiological Physics, Hangzhou, China

Purpose or Objective: To investigate the Geometric difference between six different ITVx delineation methods from 4D-CT

for patients with Non Small Cell Lung Cancer (NSCLC) treated with Stereotactic Ablative Radiotherapy (SABR) technique.

Material and Methods: Between December 2013 and March 2014, 46 patients who underwent SABR were included in this retrospective study. All patients underwent imaging acquisition with 4D-CT scans, The tumor motion range, volume, marching index (MI) and encompassment index (EI) of ITV10, IT-

VYeo, ITVEI+EE(End of Inspiration + End of Expiration), ITVODD (delineated from five odd p-hases), ITVEVEN (delineated from five even phases), ITVAVG (Average sequences) , and IT-VMIP (Maximum Intensity Projection sequences) were calculated and evaluated, finally, a method , which was not sensitive to the tumor volume and motion characteristic was selected for clinical use.

Results: The mean tumor motion (RLR, RAP, RCC, and R3D) were 3.5mm(1.4mm-8.4mm), 4.5mm(1.1mm-8.6mm), 9.5mm(0m-10mm),12.3mm (2.5-55.3 mm) respectively. Compared with ITV10, the volume of ITVx were underestimated by25.7%, 35.6%, 17.9%, 12.8%, 3.6%, 4.8% (P=0.000) respectively. MI comparisons between six ITVx delineation methods and ITV10 had statistical significance: 0.69, 0.62, 0.80, 0.86, 0.93, 0.91 (P=0.006) EI showed no statistical significance: 0.98, 0.98, 0.97, 0.97, 0.99, 0.98 (P=0.13) , the tumor volume and motion amplitude were certified not the independent factors for the MI of ITVODD and ITVEVEN.

	Range	Mean±SD	Comparison	P value
RVI _ITVMIP	0.53-0.91	0.74±0.12	ITV10 - ITVMIP	0.00
RVI _ITVAVG	0.36-0.88	0.64±0.13	ITV10 - ITVAVG	0.00
RVI _ITVEI+EE	0.71-0.88	0.82±0.51	ITV10 - ITVEI+EE	0.00
RVI _ITVYeo	0.75-0.95	0.87±0.06	ITV10 - ITVYeo	0.00
RVI _ITVODD	0.88-0.98	0.97±0.02	ITV10 - ITVODD	0.53
RVI _ITVEVEN	0.83-0.96	0.95±0.04	ITV10 - ITVEVEN	0.17

Conclusion: ITVODD/EVEN was not sensitive to tumor size or motion characteristic and was proved to have a good marching with ITV10 meanwhile having a relative high contouring efficiency, it can be recommend as a universal ITV delineation method to the institutions which was not equipped with the deformable registration systems.Introduction

EP-1731

Changes of the prostate motion errors in the intra-fraction early phase for prostate cancer patients

H. Tamamura¹, T. Kaneda², Y. Ogawa², M. Shibata², T. Kobayashi³, A. Hirata³

¹Fukui Prefectural Hospital, Nuclear Medicine, Fukui, Japan

²Fukui Prefectural Hospital, Radiology, Fukui, Japan

³Fukui Prefectural Hospital, Urology, Fukui, Japan

Purpose or Objective: In recent years, 3DCRT and IMRT have been used frequently as a treatment approach for prostate cancer patients. In particular, there is a tendency that a short-term treatment is performed with the use of a high dose rate machine. For this reason, even a small movement of the intra-fraction prostate motion error is also important. In this study, we divided one time of irradiation of 3DCRT and IMRT into 2 stages, i.e., the early phase and the late phase, and examined the intra-fraction prostate motion errors in a single irradiation.

Material and Methods: A total of 154 patients with prostate cancer were treated from January 2005 to December 2013. Three gold markers were inserted into their prostate gland before starting radiotherapy. Patients treated with 3DCRT (88 pts) were fixed at their lower limbs using HF-A (TOYO MEDIC) in the supine position, and those treated with IMRT (66 pts) were secured their whole body using MOLDCARE RI II (ALCARE). We measured the travel distance of the center of gravity of the three gold markers in the prostate gland using the real-time tumor tracking system. We defined the travel distance of the first half (the early phase) and latter half (the later phase) of the intra-fraction prostate motion errors right after the initiation of irradiation. In addition, we analyzed the differences caused by the fixation methods (fixture).

Results: A total of 9,750 times of irradiation (3DCRT : 4,732; IMRT : 5,018) were analyzed in this study. The overall duration of daily irradiation was 13.83±2.24 minutes. The travel distance of the prostate was 1.50±1.13 mm in the entire one time irradiation, 1.75±1.21 mm in the early phase, and 1.24±0.98 mm in the later phase. The statistical analysis using the Bonferroni method showed a significant difference between the both phases (p<0.001). The intra-fractional prostate motion errors in the early phase were 1.96±1.36 mm by 3DCRT and 1.55±1.01 mm by IMRT. A significant difference was observed in the intra-fractional prostate motion errors in the early phase between two fixation methods. In contrast, the intra-fraction prostate motion errors in the later phase were almost equal regardless of the fixation methods.

Conclusion: The temporal movement of the prostate during daily irradiation becomes larger in the early phase of irradiation, and this result is influenced by the set-up methods and the patient fixing devices. Since the dose gradient is steep in 3DCRT and IMRT, even a minimal movement of the prostate associated with the intra-fraction prostate motion errors is likely to cause a fatal irradiation error of a high dose rate machine. Therefore, the movement of the prostate in the early phase would require careful attention in the treatment of prostate cancer patients.

EP-1732

Quantitative estimation of gamma passing rates from characteristics of respiratory motion

K. Tanaka¹, M. Nakamura², K. Fukumoto¹, T. Kosuga¹, M. Yanagawa¹, A. Miyai¹, S. Tachiiri³, S. Otsu³, K. Kuwabara¹

¹Kyoto City Hospital, Department of Radiology, Kyoto, Japan

²Kyoto University, Department of Radiotherapy, Kyoto, Japan

³Kyoto City Hospital, Department of Radiation Oncology, Kyoto, Japan

Purpose or Objective: The purpose of this study is to quantitatively estimate gamma (γ) passing rates from characteristics of respiratory motion.

Material and Methods: A VMAT plan for lung cancer patients, which was designed using Pinnacle3 (ver. 9.2; Philips Ltd, USA), was used. Measurements were performed on the Elekta Synergy (Elekta Oncology Systems Ltd, Crawley, UK), which has a 160-leaf independently moving MLC with 5-mm leaf width. Beam energy was set to 6 MV photon beam. The I¹mRT Phantom (IBA Dosimetry GmbH, Schwarzenbruck, Germany) was set on a motor-driven base (QUASAR Programmable Respiratory Motion Platform; Modus Medical, London, ON, Canada). The motor-driven base moved in a direction parallel to the couch direction at angle of 0 deg. A total of 148 respiratory patterns was tested. The doses delivered to the Gafchromic EBT3 films (Kodak, Rochester, NY), inserted in the coronal plane of the I¹mRT Phantom, were compared with under moving and static conditions without dose normalization. The irradiated films were scanned in the same orientation using a resolution of 72 dpi in the 16-bit red-channel color scale. Four pinholes were made on each film to identify the irradiated center. All of the films were analyzed using commercially available radiation dosimetry software (DD system, ver. 10.4; R¹Tech Inc., Tokyo, Japan). The passing rates of the γ with the criterion of 3%/3 mm (γ3%/3mm) were calculated in the area receiving more than 30% of the isodose. In addition, mean respiratory position (μ) and its standard deviations (σ) were calculated from respiratory curves during beam irradiation.

Results: Absolute value of μ (|μ|) and σ ranged from 0.0 to 8.5 mm, and from 1.5 to 6.7 mm, respectively. Multi-regression analysis revealed that the impact of σ on the γ3%/3mm had 0.66-fold greater than that of |μ|. Means±SDs of the γ3%/3mm and the |μ|+0.66σ (|μ|+0.66σ) were 83.1±14.0% (range, 38.7-100.0%), and 8.7±3.1 mm (range, 4.6-14.2 mm), respectively. A strong correlation between the γ3%/3mm and |μ|+0.66σ was observed (R=-0.90).

Conclusion: We have demonstrated that the $\gamma 3\%/3\text{mm}$ can be quantitatively estimated from the characteristics of respiratory motion. From the results of multi-regression analysis, reducing the amplitude of respiratory motion would provide high $\gamma 3\%/3\text{mm}$.

EP-1733

Deep inspiration breath-hold technique using an Arduino
P. Gallego¹, J. Pérez-Alija¹, S. Olivares¹, S. Loscos¹, E. Ambroa², A. Pedro¹

¹Hospital Plato, Oncología, Barcelona, Spain

²Hospital General de Cataluña, Radioterapia, Sant Cugat, Spain

Purpose or Objective: A large effort has been made in recent years to develop techniques to reduce the dose to normal tissue (especially heart dose) for patients receiving radiation treatment for breast cancer. The deep inspiration breath-hold technique (DIBH) can decrease radiation dose delivered to the heart and this may facilitate the treatment to the internal mammary chain nodes. The aim of this work was both to develop a DIBH method using an Arduino Uno microcontroller board (SmartProjects, Ivrea, Italia) and a simple software to visualize the patient's level of inspiration. This method provides a cheaper solution to the more expensive commercial ones.

Material and Methods: Arduino is an open-source electronics platform based on an easy-to-use hardware and software. We plugged a tri-axial low-g digital acceleration sensor (Bosch's BMA180) to our Arduino board. This accelerometer is then placed on the patient and used as a surrogate to measure the expansion of the patient's thorax during breathing. Even though we chose the gravitational 1g range and our BMA 180 provides a digital full 14 bit output signal, this is still not enough to accurately measure the acceleration changes produced in the patient's thorax during her breath cycle. We thus measure the orientation change in our BMA180 inside the gravitational field. However, this orientation change is good enough to accurately measure the changes in the patient's breath cycle. With an In-house developed software programmed in Python 2.7 we are able to visualize these measures and, accordingly, the patient's breathe cycle.

Results: We were able to build a DIBH system using both an Arduino board and an accelerometer. We visualize the patient's breathe cycle with an In-house software and establish a threshold based on its amplitude. We provide patients with a real-time breathe cycle visualization, so they can have a visual feedback mechanism in order to properly hold their breath when required.

Conclusion: Several DIBH methods are commercially available. These methods can decrease the radiation dose delivered to the heart. We have developed an In-house DIBH system with all the functionalities required to implement this technique in our clinic. Building this system is really cheap and amounts to nearly 60 Euros. We are more than happy to freely provide the software needed to implement this method.

EP-1734

IGRT for prostate cancer: intrafraction variation analysis and CTV-PTV margin determination

C. Italia¹, R. La Rosa², P. Della Monica³, S. Masciullo⁴, O. Ceccarini⁵, E. Brembilla⁵, M. Camerlingo⁴, M. Cardinali⁵, F. De Osti⁴, S. Gusmini⁴, C. Riva⁴, F. Romeo⁴

¹Policlínico San Pietro/Policlínico San Marco, Radiotherapy, Ponte San Pietro/Zingonia, Italy

²Policlínico San Marco, Medical Physics, Zingonia, Italy

³Policlínico San Pietro, Medical Physics, Ponte San Pietro, Italy

⁴Policlínico San Pietro, Radiotherapy, Ponte San Pietro, Italy

⁵Policlínico San Marco, Radiotherapy, Zingonia, Italy

Purpose or Objective:

- 1.to evaluate first set-up accuracy and corrections needed before treatment administration
- 2.to assess intrafraction variability
- 3.to determine CTV-PTV margins according to intrafraction uncertainties

Material and Methods: Forty-five consecutive prostate cancer patients, undergoing radical or postoperative image-guided radiation therapy with or without gold seed implant in a newly opened department, were considered. On each session a first set of portal images was obtained at 0° and 90° degrees, using a low-dose MV imager. Positioning errors were measured in the three directions and corrected if > 1 mm. After treatment a second set of images was daily produced and displacements measured. Comparison between before-treatment images and planning DRRs represents set-up accuracy. Comparison between end-of-treatment images and planning DRRs shows intrafraction variability Systematic and random errors were analysed and incorporated in the Van Herk formula ($2.5 \Sigma + 0.7 \sigma$), to determine ideal CTV-PTV margins.

Results: All patients were suitable for the analysis. Results are summarized in the table.

FIRST SET-UP	AXIS	MEAN (mm)	Σ (mm)	σ (mm)	CTV/PTV margin
	R-L (left:+)	-0.3	1.7	3.1	6.3
A-P (anterior:+)	-0.8	2.3	3.7	8.4	
C-C (caudal:+)	+0.2	2.0	3.2	7.2	
INTRA-FRACTION	AXIS	MEAN (mm)	Σ (mm)	σ (mm)	CTV/PTV margin
	R-L (left:+)	+0.2	0.5	1.2	2.2
	A-P (anterior:+)	-0.3	0.7	1.4	2.7
	C-C (caudal:+)	+0.1	0.4	1.1	1.7

Σ = systematic error σ = random error

A total of 6632 images were analysed. Mean errors were <1 mm for all measurements. In intrafraction shift analysis systematic errors were <1 mm, random errors were <2 mm and calculated CTV-PTV margins ranged from 1.7 to 2.7 mm.

Conclusion: Good accuracy and precision for first positioning procedures were found. If hypothetically IGRT were omitted and CTV-PTV margins were based on first set-up errors only, margins ranging from 6.3 to 8.4 mm in the various directions would be mandatory. On the contrary, according to the policy of our department, with the use of daily IGRT and based on our excellent results of intrafraction variation analysis, CTV-PTV margins can be limited to 2.2, 2.7 and 1.7 mm, respectively in lateral, anteroposterior and craniocaudal direction.

EP-1735

Impact of respiratory motion on breast tangential radiotherapy using the field-in-field technique

H. Tanaka¹, T. Yamaguchi¹, M. Kawaguchi¹, S. Okada¹, Y. Kajiura¹, M. Matsuo¹

¹Gifu University, Radiology, Gifu, Japan

Purpose or Objective: The field-in-field (FIF) technique has become a widely performed method of administering tangential whole breast radiotherapy. However, as the FIF technique requires the precise setting of the position of the multi-leaf collimators (MLCs) in order to reduce hot spots, there is concern that its use could significantly change the dose distribution to the target volume due to respiratory

motion. This study aimed to evaluate whether the FIF technique is more vulnerable to the impact of respiratory motion than irradiation using physical wedges (PWs).

Material and Methods: Ten patients with early stage breast cancer were enrolled. All patients had undergone breast-conserving surgery and implantation of 4 surgical clips on the tumor bed, 2 of which had been placed in the nipple side of the tumor bed and 2 on each medial and lateral side of the tumor bed. Computed tomography (CT) was performed during free breathing (FB). After the FB-CT data set acquisition, 2 additional CT scans were obtained during a held breath after light inhalation (IN) and light exhalation (EX). Based on the FB-CT images, 2 different treatment plans (FIF-plan and PW-plan) were created for the entire breast for each patient and copied to the IN-CT and EX-CT images. The prescribed dose was 50 Gy in 25 fractions. The amount of change of in the volume of the target receiving 107%, 95%, and 90% of the prescription dose (V107%, V95%, and V90%, respectively), on the IN-plan and EX-plan compared with the FB-plan were evaluated. The length of movement of each surgical clip from EX-CT to IN-CT in 3 directions (horizontal, anteroposterior, and craniocaudal) and three-dimensional vector displacement were measured.

Results: The average displacement length was largest in the anteroposterior direction and the average three-dimensional vector displacement was 7.4mm. The V107%, V95%, and V90% were significantly larger for the IN-plan than for the FB-plan in both the FIF and PW plans. While the amount of change in the V107% was significantly smaller in the FIF than in the PW plan, the amount of change in the V95% and V90% was significantly larger in the FIF plan. Thus, the increase in the V107% was smaller while the increases in the V95% and V90% were larger in the FIF than in the PW plan.

Conclusion: The amount of change in dose parameters due to respiratory motion was smaller with the FIF technique than with irradiation using PWs, within an acceptable range.

EP-1736

The quantitative measurement of liver motion in CT during respiration

Y.L. Tsai¹, P.C. Yu¹, H.C. Chang¹, C.Y. Chang¹, P.W. Fu¹, C.W. Lin¹, Y.C. Chiu¹, S.N. Chi¹, C.J. Wu¹
¹Cathay General Hospital, Radiation Oncology, Taipei, Taiwan

Purpose or Objective: To evaluate the motion of different liver segments in CT during respiration to facilitate target delineation and ITV expansion for liver cases.

Material and Methods: Eleven patients with whole liver scanning during free breath in both regular helical CT and 10-phase-gated 4D CT were investigated. It included 1 esophagus, 3 lung, 5 breast, 1 liver, and 1 thymoma patients. Nine representative points in 1 cm diameter (in liver segment 1, 2, 3, 4a, 4b, 5, 6, 7, 8, respectively) were drew in the image of helical CT and adaptive deformed to 4D CT, using SmartAdapt, a tool in Eclipse version 11.5. The coordinate of centroid represented the location of point. Distances of deformed points from phase 0 CT (end-inspiration) to phase 50 CT (end-expiration) denoted the maximal motion of liver in different liver segments. The accuracy of the adaptive deformation was measured by the accuracy ratio of whole liver deformation, which was the overlapping liver area of deformed helical CT and 4D CT divided by whole liver area in 4D CT.

Results: Mean moving distances along X-, Y-, Z-axis from phase 0 CT to phase 50 CT were -0.10 ± 0.32 (mean \pm SD)(cm), 0.24 ± 0.24 , and 0.60 ± 0.36 , respectively, averaging from the 9 points of 11 investigated patients. The result indicated liver moving to the right, back, and upside while expiration. For specific liver segments, the motion along X-, Y-, Z-axis were S1: -0.23 ± 0.31 , 0.15 ± 0.16 , 0.55 ± 0.29 , S2: -0.06 ± 0.32 , 0.15 ± 0.29 , 0.57 ± 0.43 , S3: -0.04 ± 0.23 , 0.32 ± 0.19 , 0.61 ± 0.26 , S4a: -0.19 ± 0.27 , 0.08 ± 0.23 , 0.23 ± 0.28 , S4b: -0.14 ± 0.13 , 0.27 ± 0.20 , 0.66 ± 0.28 , S5: -0.01 ± 0.27 , 0.35 ± 0.25 , 0.57 ± 0.23 , S6: -0.05 ± 0.41 , 0.25 ± 0.25 , 0.75 ± 0.32 , S7: -0.20 ± 0.40 , 0.26 ± 0.21 , 0.95 ± 0.33 , S8: 0.01 ± 0.42 , 0.32 ± 0.29 , 0.55 ± 0.38 . All segments moved to the right except segment 8 with mean moving distance 0.01cm to the left. Otherwise, all segments moved to the back and upside while expiration. Segment 7 was the most mobile one on the Z-axis with 0.95 ± 0.33 cm upwards. The accuracy ratio of whole liver deformation were 0.96 ± 0.03 for phase 0 CT, and 0.97 ± 0.02 for phase 50 CT, respectively, denoting the adaptive deformation is quite accurate.

Location	Respiration caused liver motion from phase 0 CT (end-inspiration) to phase 50 CT (end-expiration)		
	X-axis	Y-axis	Z-axis
S1	-0.23 ± 0.31	0.15 ± 0.16	0.55 ± 0.29
S2	-0.06 ± 0.32	0.15 ± 0.29	0.57 ± 0.43
S3	-0.04 ± 0.23	0.32 ± 0.19	0.61 ± 0.26
S4a	-0.19 ± 0.27	0.08 ± 0.23	0.23 ± 0.28
S4b	-0.14 ± 0.13	0.27 ± 0.20	0.66 ± 0.28
S5	-0.01 ± 0.27	0.35 ± 0.25	0.57 ± 0.23
S6	-0.05 ± 0.41	0.25 ± 0.25	0.75 ± 0.32
S7	-0.20 ± 0.40	0.26 ± 0.21	0.95 ± 0.33
S8	0.01 ± 0.42	0.32 ± 0.29	0.55 ± 0.38
Mean	-0.10 ± 0.32	0.24 ± 0.24	0.60 ± 0.36

The numbers are presented in mean \pm SD (cm)

The numbers >0 indicate the direction to the left (X-axis), back (Y-axis), upside (Z-axis)

Conclusion: The liver motion in CT during respiration is different between different liver segments. The most mobile one is segment 7 on the Z-axis. The quantitative motion measurement could be a useful reference for ITV expansion to ensure preciseness in target delineation for liver cases.

EP-1737

Intrafraction motion and ITV dose coverage in thoracic SBRT: preliminary analysis of 101 CBCT images

P. Antognoni¹, L. Pozzi², D.P. Doino¹, S. Gottardo¹, C. Mordacchini², M. Reso¹, F. Stucchi¹, C. Bianchi², R. Novario²
¹Ospedale di Circolo Fondazione Macchi, Department of Radiotherapy, Varese, Italy
²Ospedale di Circolo Fondazione Macchi, Department of Medical Physics, Varese, Italy

Purpose or Objective: To evaluate the impact of intra-fraction organ motion on the dosimetric coverage of ITV by the analysis of a preliminary data set of 101 CBCT images acquired in 7 patients treated according to an SBRT protocol for primary and metastatic thoracic tumors.

Material and Methods: Between 2013 and 2015 seven pts, 5 males and 2 females, median age 77 yrs (range: 35-85 yrs) received SBRT for primary or metastatic thoracic tumors: 4 primary lung cancer, 2 mediastinal lymphnode metastasis, 1 lung metastasis. All pts had a 4D-CT high-resolution simulation in 10 respiratory phases for ITV definition. GTV and ITV volumes were 4.5-21.4 cm³ and 6.8-39.4 cm³, respectively. ITV-PTV margins were 5 mm (median), range: 3-5 mm. All pts were treated by IG-IMRT volumetric modulated arc therapy with 2 modulated arcs. Doses were prescribed according to ICRU 83 (median PTV dose) and 99% of PTV had to be encompassed by 90% isodose. Total doses were: 20 Gy x 3 in 1 pt, 12 Gy x 4 in 1 pt, 10 Gy x 5 in 1 pt, 7.5 Gy x 8 in 1 pt, 6 Gy x 8 in 3 pts. Before CBCT acquisition in all pts 2 planar (AP-LL) set-up EPID images (kV/MV) were taken for preliminary set-up analysis. In absence of rotations on EPID imaging, CBCT images (Nr.=44) were acquired for on-line set-up corrections which were applied before of each 1st SBRT treatment arc. Intra-fraction motion was evaluated by further CBCT images acquired before starting and at the end of the 2nd treatment arc. Structure matching on CBCT was automatically done first on bone and then on soft tissue. In-room mean elapsed time between 1st and last CBCT was 26 min (range:11-47 min). On-line set-up corrections between 1st and 2nd arc were applied for errors of 3mm. For the whole series of 7 pts mean differences between planned and shifted ITV position along the 3 spatial axes (CC, AP, LL) were then calculated on 57 CBCT images, 35 taken between 1st and 2nd arc, 22 at the end of 2nd arc. For each patient isodose distribution was recalculated on the TPS after correction of the isocenter position of the 2 arcs applying the mean differences found. Finally, differences in ITV median dose, V90, V95, and D98 were calculated.

Results: Mean ITV displacements after the 1st arc were 1.2 mm \pm 1.6 mm, 0.5 mm \pm 1.4 mm, 0 mm \pm 1.1 mm for CC, AP and LL directions, respectively. Mean displacements at the end of 2nd arc were 0.1 mm \pm 1.4 mm, 0.7 mm \pm 1.0 mm, 0.3 mm \pm 0.9 mm for CC, AP and LL directions, respectively. Differences between planned and delivered ITV median dose ranged from -0.2% to -1.8%; V90 was \geq 99.8% in all pts, V95 range was 86.7%-99.7%; D98 was \geq 92.7% in all pts (Fig. 1).

Fig. 1: DVH of ITV for each patient calculated according to the original treatment plan and after application of mean intra-fraction shift.

Conclusion: Our preliminary analysis of 101 CBCT in 7 pts aimed at evaluating intra-fraction organ motion during V-MAT SBRT of thoracic targets shows that ITV dosimetric coverage is only minimally influenced by intra-fraction ITV displacement, provided that on-line corrections are applied

before each treatment arc. Our findings need to be prospectively confirmed in a larger patient series.

EP-1738

The impact of active breath control on IMN coverage in left sided post-mastectomy breast patients

A. Barry¹, K. Rock¹, C. Sole¹, M. Rahman¹, M. Pintilie², A. Fyles¹, C. Koch¹

¹Princess Margaret Hospital, Department of Radiation Oncology, Toronto, Canada

²Princess Margaret Hospital, Department of Biostatistics, Toronto, Canada

Purpose or Objective: The inclusion of the Internal Mammary Nodes (IMNs) in managing left sided post-mastectomy radiotherapy (PMRT) patients has a potential benefit in patient outcomes and disease control. Larger treatment fields result in higher doses to normal tissue but advancing technological techniques, such as the use of Active Breath Control (ABC) mean acceptable dose parameters may be achieved.

Material and Methods: 50 randomly selected patients with left sided breast cancer receiving PMRT underwent CT simulation with and without ABC, 100 radiotherapy (RT) plans were generated. 30 additional patients requiring left sided PMRT with free-breathing (FB) CT simulation scan were selected at random as a control group. The IMNs were delineated as a target volume within the first 3 intercostal spaces as were organs at risk (OAR)- left anterior descending coronary artery (LADCA), heart, lung and contralateral breast (CB). Modified wide-tangent photon fields, with the inclusion of chest wall, IMNs, axilla and supraclavicular fossa as a 4-field technique were generated for all 130 plans. Statistical analysis was completed using Wilcoxon Signed Rank test, Mann Whitney test and Pearson and Spearman Correlation Coefficients.

Results: IMN PTV coverage in plans with ABC was reduced compared to FB (94 vs 98% p<0.001), meeting dosimetric criteria for coverage in 90% of plans (range 79-100%). ABC significantly reduced dose to all OARs compared to FB - median reduction in mean heart dose (MHD) (6.3Gy vs 1.9Gy p<0.001), lung V20 (15% vs 11% p<0.001), LADCA max dose to 0.2cc (49Gy vs 17.8Gy p<0.001) and LADCA mean dose (40Gy vs 10Gy p<0.001), with no difference in the D5 to the CB (2.2Gy vs 2.1Gy p=0.36).

In the control vs ABC group, there was no difference in IMN PTV coverage (median 94.5% vs 96% p=0.21). There was significant median reduction in MHD (3.5Gy vs 1.9Gy p<0.001), lung V20 (14% vs 11% p<0.001), LADCA maximum dose to 0.2cc (43.9Gy vs 17.8Gy p<0.001) and LADCA mean dose (22.6Gy vs 10Gy p<0.001) for the ABC group, but an increase in D5 to the CB with the use of ABC (1.5Gy vs 2.1Gy p<0.001).

BMI was not directly correlated with IMN PTV coverage, or increase/decrease in OAR constraints.

Conclusion: Our data supports the standard use of ABC in left sided PMRT patients that require the inclusion of the IMNs. We have demonstrated adequate IMN PTV coverage with significant sparing of OARs. The impact of these dosimetric reductions on long-term normal tissue effects requires further evaluation in prospective studies.

EP-1739

Deep inspiration breath hold with 'AlignRT' in 3D conformal mediastinal radiotherapy for lymphoma

J.L. Brady^{1,2}, R. Begum³, C. Hartill⁴, A.G. Greener³, N.G. Mikhaeel^{1,2}

¹Guy's and St Thomas' NHS Foundation Trust, Department of Clinical Oncology, London, United Kingdom

²King's Health Partners, Academic Health Sciences Centre, London, United Kingdom

³Guy's and St Thomas' NHS Foundation Trust, Department of Medical Physics, London, United Kingdom

⁴Guy's and St Thomas' NHS Foundation Trust, Department of Radiotherapy, London, United Kingdom

Purpose or Objective: Deep inspiration breath hold (DIBH) technique may reduce radiation dose to heart and lungs during mediastinal radiotherapy (RT) for lymphoma.

AlignRT is an optical surface tracking system which can be used to monitor inspiration depth during DIBH. Data is acquired from planning CT scan to generate a 3D surface contour of the patient whilst in breath hold (BH). At treatment the real-time contour of the patient is monitored by cameras and compared to the reference contour.

We initiated a prospective study to assess the feasibility of DIBH with AlignRT in mediastinal lymphoma, and to evaluate its dosimetric benefits, compared to free breathing (FB) RT. This is the first report of AlignRT use in this indication.

Material and Methods: Eligible patients were due to receive RT to the mediastinum for Hodgkin or high grade non Hodgkin lymphoma.

Patients were positioned supine on a thoracic board with arms raised. After coaching FB and BH CT scans were performed. 3D conformal plans were produced for both FB and DIBH volumes for each patient and compared in terms of PTV coverage (V95, D95), cardiac doses (MHD, V30, V15), lung doses (MLD, V20, V5), spinal cord max. dose and breast doses in females (mean, V10, V5). The optimal plan was selected for treatment. Data was then transferred to the AlignRT software.

Feasibility was determined by the proportion of patients able to manage the technique, and the incidence & nature of setup errors.

Results: Between March & September 2015 8 patients were eligible for DIBH RT. 1 patient could not maintain BH at planning and proceeded with FB RT. For another cardiac constraints could not be met with a conformal plan and treatment changed to intensity modulated RT (IMRT). For 6 patients DIBH and FB plans were created & compared (see table). Prescribed dose was 30.6Gy/ 17 #.

PTV coverage was similar for DIBH and FB. MLD was significantly lower in DIBH plans (mean difference 1.58Gy). Lung V20 was also reduced by 6.45%. Lung V5 was reduced by 3.25% but the difference was not significant. Cardiac doses were better in the DIBH plans with a reduction in MHD of 2.49Gy, and V15 by 10.44%. There was no significant difference in breast or spinal cord doses. In all cases the DIBH plan was chosen for treatment.

Table. Comparison of radiation dose parameters in FB and DIBH 3D conformal plans

Mean doses / volumes	FB (n=6)	DIBH (n=6)	Difference	P value (95% CI) (2 sided paired t test)
PTV				
V95 (%)	97.46	98.32	0.86	0.074 (-0.12 to 1.85)
D95 (Gy)	29.45	29.59	0.14	0.102 (-0.04 to 0.34)
Lung				
MLD (Gy)	10.45	8.87	-1.58	0.009 (-2.56 to -0.61)
V20 (%)	22.75	16.3	-6.45	0.043 (-12.61 to -0.29)
V5 (%)	54.24	50.99	-3.25	0.056 (-6.64 to 0.14)
Heart				
MHD (Gy)	11.47	8.98	-2.49	0.019 (-4.37 to -0.60)
V15 (%)	37.13	26.69	-10.44	0.007 (-16.37 to -4.32)
Breast (n=4)				
Mean dose (Gy)	5.41	5.05	-0.37	0.377 (-1.50 to 0.76)
Breast V5 (%)	21.98	20.16	-1.81	0.25 (-5.84 to 2.23)
Breast V10 (%)	15.62	11.29	-4.333	0.188 (-12.46 to 3.79)
Spinal cord				
Max point dose (Gy)	29.68	27.08	-2.61	0.074 (-5.58 to 0.37)

Set up issues were encountered in 2/6 DIBH patients early in treatment. These were not correctable & required replans. Both completed treatment with the new plans without incident. Investigation concluded the most likely cause was an exaggerated and hard to reproduce BH during the planning CT. Patient instructions have been revised .

Conclusion: Our early experience indicates that DIBH RT using Align RT is feasible. A minority of patients may not tolerate DIBH and careful coaching is needed to achieve a reproducible level of deep inspiration. DIBH RT can reduce radiation doses to heart and lungs during mediastinal RT, without any increase in breast dose or compromise to PTV coverage.

EP-1740

Application of virtual reality guide hypnosis in the control of respiration motion for radiotherapy

R. Li¹, N. Fu¹, J. Ouyang^{1,2}, Y. Mao^{1,3}, Y. Liu^{1,4}, S. Dang⁵, J. Hu^{6,7}, J. Deng⁸, S. Yu¹, Y. Zhu¹, Y. Chen¹, Y. Xie^{1,9}

⁹Key Lab for Health Informatics of Chinese Academy of Sciences, Lab for Wearable Devices, Shenzhen, China

Purpose or Objective: To propose a comfortable, harmless and stable method to guide the hypnosis for the control of respiratory motion during radiotherapy.

Material and Methods: The virtual reality (VR) technology was applied in the hypnosis guidance to control the respiratory motion. A VR demo was made depending on a pre-designed hypnosis scene, which follows the Stanford hypnotic susceptibility scale¹ and the experienced design of hypnotists, to make volunteers relax. 46 healthy volunteers, including 22 female and 24 male, are taken in the hypnosis experiments. The respiratory motion for each volunteer was recorded, which takes 10 min before hypnosis (BH) and 20 min in VR-guide hypnosis state (VRGHS) and 10 min after hypnosis (AH). BH and AH are united into normal state (NS).

Results: Two comparative experiments were conducted to study the difference of amplitudes of respiratory motion between NS and VRGHS. Obvious difference has been observed between VRGHS and NS as a whole. As a result, compared with NS, the mean amplitudes of respiratory waves in VRGHS reduces 18.8% and standard deviation (STD) reduces 20.7%. Similarly, the female volunteers group drops 16.8% in mean value and 23.6% in STD, and the male volunteers group has a mean deduction of 20.9% in amplitudes, with a drop of 17.7% in STD. In addition, 15/22 female show high grade significant ($p < 0.0005$) difference between VRGHS and NS, 20/24 in male. Conclusively, it's showed that the statistical differences of VRGHS are obviously, lower than NS.

Table 1. Mean deduction and STD deduction between VRGHS and NS (BH and AH)

	Female Volunteers				Male Volunteers			
	VRGHS VS. BH		VRGHS VS. AH		VRGHS VS. BH		VRGHS VS. AH	
	Rate	Count	Rate	Count	Rate	Count	Rate	Count
Mean Deduction	14.8%	17/22	18.7%	17/22	22.6%	23/24	19.2%	21/24
STD Deduction	19.0%	16/22	28.3%	18/22	20.9%	18/24	14.5%	17/24

Table 2. Statistics of significant difference level grade of amplitudes between VRGHS and NS

	Female Volunteers		Male Volunteers	
	VRGHS VS. BH	VRGHS VS. AH	VRGHS VS. BH	VRGHS VS. AH
G ₁ ($p < 0.05$)	0/22	1/22	0/24	2/24
G ₂ ($p < 0.005$)	0/22	0/22	3/24	1/24
G ₃ ($p < 0.0005$)	15/22	13/22	16/24	17/24
Total	15/22	14/22	19/24	20/24

treatment delivery. In the screening procedure, three of the four patients' breathing regularity was improved with AVB. Across a course of SBRT, AVB also demonstrated to improve the regularity of breathing displacement and period over free breathing. This was also the first study to assess the impact of AVB on liver tumor motion via fiducial marker surrogacy. Results from the first four patients have been reported here and demonstrate clinical potential for facilitating regular and consistent breathing motion during CT imaging and treatment delivery.

EP-1743

Analysis of the deviation of lung tumour displacement caused by different breathing patterns

G. Hürtgen¹, S. Von Werder², C. Wilkmann², O. Winz³, C. Schubert¹, N. Escobar-Corral¹, J. Klotz¹, C. Disselhorst-Klug², A. Stahl⁴, M.J. Eble¹

¹Uniklinik RWTH Aachen, Department of Radiooncology and Radiotherapy, Aachen, Germany

²RWTH Aachen University, Department of Rehabilitation- & Prevention Engineering, Institute of Applied Medical Engineering

³Uniklinik RWTH Aachen, Department of Nuclear Medicine, Aachen, Germany

⁴RWTH Aachen University, III. Institute of Physics B, Aachen, Germany

Purpose or Objective: By applying motion correction strategies for the treatment of lung tumours the variability of breathing induced tumour movement is more important. To analyse the different motion potential of lung tumours a clinical trial is carried out. FDG-PET scans are performed simultaneously with an accelerometer-based system, which detects the breathing motion. Specific breathing instructions are given to the patient, to analyse the correlation of the sensor information and the tumour displacement, caused by different breathing patterns.

Material and Methods: The study is performed with patients with a single pulmonary metastasis. For the detection of the breathing motion six tri-axial accelerometers are placed on the patient's thorax and abdomen. Thereby, information on the breathing cycle (in-/expiration), breathing mode (thoracic/abdominal) and breathing depth can be distinguished. Up to five different measurements are obtained: 'free breathing', 'deep thoracic', 'flat thoracic', 'deep abdominal' and 'flat abdominal'. Simultaneously, a respiratory gated FDG-PET scan is taken to correlate the patient's respiratory states with the tumour movement. For each of the ten reconstructed PET images the centre of the tumour is determined to visualize the mean tumour trajectory.

Results:

In the figure the analysis of the reconstructed sensor and PET data is shown for six patients, for each of the different breathing scenarios (fb: free breathing, da: deep abdominal, fa: flat abdominal, dt: deep thoracic, ft: flat thoracic). The upper part of the figure shows the mean tumour amplitude from the PET data and the mean breathing depth from the sensor data. The lower part shows the mean tumour position from the PET data and the breathing mode reconstructed from the sensor data. To visualise the offset of the different tumour movements between the different scenarios, for each patient the mean positions are normalised to the smallest mean position of each patient. The figure shows, that for the given scenarios different amplitudes and offsets of the tumour are observed, as well as a change in the sensor signals. The results show a flexibility of the tumour movement in its amplitude and absolute position, which depends on the actual breathing patterns of the patient.

Conclusion: The performed clinical trial indicates that the movement of the tumour depends on the actual breathing pattern. This shows that it is important for the prediction of the tumour position to take the information on the breathing pattern into account. The detection of the breathing parameters with the sensors give the possibility for further investigations of a correlation between tumour offset and amplitude with reconstructed breathing depth and mode, which could be further used for individual motion prediction.

Acknowledgment: The work was funded by the Federal Ministry of Education and Research BMBF, KMU-innovativ, Förderkennzeichen: 13GW0060F. Additionally, the Authors thank Florian Büther (EIMI Münster, Germany) for his support.

⁴Nagoya City University Graduate School of Medical Science, Department of Radiology, Nagoya, Japan

⁵Nagoya Proton Therapy Center, Department of Radiation Oncology, Nagoya, Japan

⁶Yokohama CyberKnife Center, Department of Radiation Oncology, Yokohama, Japan

⁷Yokohama CyberKnife Center, Department of Neurosurgery, Yokohama, Japan

Purpose or Objective: The purpose of this study was to evaluate the clinical accuracy of the Synchrony Respiratory Tracking System (SRTS) of the CyberKnife (CK).

Material and Methods: We analyzed 65 patients with lung lesion who had been treated with the SRTS from August 2012 to August 2015. Respiratory motion data were obtained from cine magnetic resonance (MR) images. MR scans were performed with a 1.5-Tesla whole-body clinical MR scanner, and the cine MR images of sagittal plane were obtained. We collected respiratory motion data of each patient from the cine MR images using in-house software. The dynamic motion phantom (DMP) was used to reproduce the motion of both the tumor and the surface of the patient's abdomen. We used a 20 mm diameter plastic ball as the target. A gold marker was placed at the center of the ball. Treatment plans were created based on static CT scans and standard CK treatment parameters. Each plan utilized ten beams with several different source positions. All of the beams in each plan were aimed at the center of the ball target, and were set to 200 MU for 15 seconds of data acquisition. The CK was subsequently operated with the SRTS, with a CCD camera mounted on the head of the linac. The central axis of the CCD camera was matched to the central axis of the linac beam using a custom-built jig. The recording by CCD camera was performed during the tracking of the ball target by the linac. The tracking error was defined as the distance from the center of the images to the center of the ball in the images recorded by CCD camera. The tracking error was measured at 30 Hz using in-house software. The probability in excess of 95% (Ep95) for each direction was estimated. The SRTS accuracy was defined as the median value of Ep95 for ten beams (Ep95med)

Results: The mean value and standard deviation of Ep95med was 2.5 ± 0.9 mm. The Spearman's correlation coefficient determined by the rank test indicated that the range of motion of the tumor was significantly related to Ep95med ($P < 0.01$).

Conclusion: The accuracy of SRTS was considered to be clinically acceptable. However, suitable margin to the clinical target according to the range of motion of the tumor seems to be necessary for the safe treatment to each patient.

EP-1745

Radiotherapy in breast cancer with voluntary deep-inspiration breath-hold using BrainLab Exactrac

E. Ippolito¹, R. D'Angelillo¹, A. Sicilia¹, S. Silipigni¹, B. Floreno¹, E. Molfese¹, A. Di Donato¹, P. Trecca¹, D. Gaudino¹, G. Stimato¹, S. Ramella¹, L. Trodella¹

¹Campus Bio-Medico University, Radiotherapy, Rome, Italy

Purpose or Objective: Adjuvant radiotherapy in left-sided breast cancer with voluntary deep-inspiration breath-hold technique (vDIBH) may reduce the irradiation dose to the heart. The aim of this study is to estimate the heart, lung and PTV dosimetric constraints and the reproducibility of vDIBH radiotherapy using BrainLab Exactrac monitoring system.

Material and Methods: 10 women with left breast cancer who had undergone breast-conserving surgery and who required adjuvant radiotherapy to the whole breast, were enrolled and were shortly trained before simulation CT-scan to hold their breath. The first scan was acquired in free-breathing (FB_CT) and the second one in vDIBH (vDIBH_CT). Target and organ-at-risk (OAR) volumes were delineated in both CT scans and for both of them computerized treatment planning was performed using two tangential fields

technique. We compared the dose distribution for the heart, left anterior descending coronary artery (LAD), ipsilateral lung and planning target volume (PTV) using standard defined parameters: mean dose and maximal dose applied to the LAD; percentage of the heart volume receiving at least 5 Gy (V5Gy) and 10 Gy (V10Gy); percentage of the ipsilateral lung volume receiving at least 20 Gy (V20Gy); and the volume of the PTV receiving 95% of the prescribed dose (V95%). The online monitoring during EPI acquisition and treatment were made by BrainLab Exactrac system. Daily real time electronic portal imaging (EPI), in CINE modality (captured during the beam delivery) were performed in order to check the reproducibility of the technique. Wilcoxon test has been used to compare dosimetric heart, lung and PTV parameters between FB_CT and vDIBH_CT treatment plans. The mean displacement, detected with the portal images, was calculated for each treatment beam and for each patient.

Results: A significant reduction in heart V5 and LAD Dmax (2.71 vs 0.99 Gy $p=0.02$ and 16.56 vs 6.90 Gy $p=0.012$ respectively) parameters was recorded for vDIBH_CT treatment plans (see Table 1 for complete results). There were no significant differences between vDIBH and FB treatments in lung dosimetric parameters and target volume coverage. 1694 portal images were evaluated. During treatment, the mean displacements observed in the longitudinal, vertical and lateral direction were 0.132 mm (SD= 0.011), 0.013 mm (SD= 0.137), 0.116 mm (SD= 0.010).

Dosimetric Parameters		vDIBH	FB	p
Heart V5Gy	Mean \pm SD	0.992 ± 1.6	2.708 ± 2.357	0,02
	Median	0,392	2,6	
Heart V10Gy	Mean \pm SD	0.119 ± 0.267	0.427 ± 0.377	0,04
	Median	0,000	0,5	
LAD maximum dose	Mean \pm SD	$6,9 \pm 4,198$	$13,562 \pm 5,678$	0,012
	Median	5,2	13,555	
LAD mean dose	Mean \pm SD	$3,1 \pm 1,76$	$5,525 \pm 1,993$	0,012
	Median	2,850	5,5	
Lung V20Gy	Mean \pm SD	$5,79 \pm 2,556$	$4,463 \pm 2,866$	0,441
	Median	6,410	4,720	
95% PTV	Mean \pm SD	$98,58 \pm 1,002$	$98,224 \pm 1,089$	0,401
	Median	98,94	98,92	

vDIBH: voluntary deep inspiration breath hold

FB: free breathing

LAD: left artery descending

Conclusion: vDIBH technique reduces cardiac irradiation compared with conventional free-breathing treatment plans, without jeopardizing the proper coverage of the target. vDIBH for left-side whole breast irradiation can be accurately implemented using BrainLab Exactrac system with high and accurate reproducibility (mean shift < 0.15 mm).

EP-1746

Stereo/monoscopic motion tracking of the prostate using room-mounted x-ray image guidance

T. Stevens¹, D. Parsons¹, J. Robar¹

¹QEII Health Sciences Centre - Dickson Building, Medical Physics, Halifax- Nova Scotia, Canada

Purpose or Objective: Intrafraction internal motion of the prostate currently limits the accuracy of external beam radiotherapy, requiring expanded ITV boundaries and introducing geometric uncertainty. Techniques to monitor prostate motion at the millimeter scale are thus needed. Room-mounted dual x-ray systems can provide stereoscopic localization of the prostate via implanted fiducial markers, however the treatment head frequently blocks one of the x-ray tubes as the gantry rotates. We implemented a monoscopic 3D localization algorithm, allowing localization even when one of the x-ray tubes is obstructed. We show that this technique allows accurate localization throughout the treatment fraction, improving the tracking capabilities of room-mounted x-ray systems.

Material and Methods: A gold fiducial marker was placed in the prostate of an anthropomorphic phantom, and initially aligned to isocentre. The linac couch was used as a translation stage, and programmed with a realistic prostate motion trajectory. Continuous dual x-ray images (140 kVp,

0.63 mAs) were acquired at 1 Hz. For stereoscopic localization, the intersection of the ray lines connecting the detected image locations with the corresponding sources was found, whereas monoscopic localization first computed a prostate position probability density function (PDF) based on previously published motion covariances, and then finds the maximum likelihood position along the ray line passing through this PDF. Stereo- and monoscopic localization results were compared to the ground truth provided by the linac log file.

Results: Both stereo- and monoscopic localization produced sub-mm accuracy (Figure 1). Monoscopic localization was nearly as accurate as stereoscopic localization, despite only directly resolving two dimensions. The left-right dimension tracked slightly less well with monoscopic localization as this dimension is less correlated with the other two axes, and thus harder to predict using the monoscopic algorithm.

Figure 1: The linac couch was used to move a phantom and implanted fiducial according to a realistic prostate motion trajectory (left). The fiducial was tracked in 3D using both monoscopic (middle) or stereoscopic (right) localization.

Conclusion: The ability to use room-mounted x-ray systems to achieve sub-mm accuracy with either monoscopic or stereoscopic localization creates new opportunities for intrafraction tracking. Stereoscopic tracking can be used when both x-ray tubes are unobstructed, to produce the most accurate localization, and bridged by monoscopic tracking during obstructions. The knowledge of prostate position during treatment can potentially be used to gate treatment, or be fed back into dynamic MLC updates in order to produce more conformal dose delivery.

EP-1747

Assessment of PTV margins accounting for prostate intrafraction motion in SBRT with online IGRT

A. Magli¹, M.R. Malisan², C. Fontanella³, M. Crespi², M. Guernieri², F. Titone¹, C.T. Sacco³, E. Moretti², C. Foti²

¹University Hospital Udine, Radiation Oncology, Udine, Italy

²University Hospital Udine, Medical Physics, Udine, Italy

³University Hospital Udine, Medical Oncology, Udine, Italy

Purpose or Objective: There is little consensus on the magnitude of PTV margins for IGRT of the prostate cancer when a hypofractionation scheme is applied and daily correction is required, rather than averaging over many fractions. The aim of this work was to assess PTV margins suitable for SBRT of prostate cancer uncertainties after daily online correction. Moreover, intra-fraction prostate motion is analyzed with the aim to identify its main causes (bladder filling, rectum distension, elapsed treatment time).

Material and Methods: Between 2013 and 2014, 43 patients with low or intermediate risk prostate cancer were treated with 7-fraction SBRT in supine position, with implanted fiducial markers (FM), empty rectum and full bladder. To reduce organ motion, patients were premedicated with butylscopolamine and rectum gas was removed before the treatment. At each session pre-treatment kV/kV imaging was acquired to align the patient by matching the FM's, while additional CBCT imaging was performed after treatment delivery to assess the intra-fraction motion. The van Herk's formula was applied to calculate the PTV margins of

prostate/seminal vesicles. To investigate the causes of organ motion, the bladder volume and the rectum wall distension were estimated from each CBCT with respect to the simulation CT images. Correlation between these anatomical factors and intrafraction PTV motion was assessed for each axis, as well as for the composite shift of the prostate volume. The treatment time elapsed from pre-treatment kV/kV to post-treatment CBCT imaging was also included in the statistical analysis.

Results: 301 pre-treatment kV/kV images and 301 post-treatment CBCTs were analyzed. After daily IGRT correction, margins accounting for residual uncertainties are estimated 3 mm for AP, 3 mm for Longitudinal axis and 2 mm for Lateral intra-fraction motion. A systematic increase of bladder filling with respect to simulation images was observed; however, these changes did not influence the prostate displacement ($p = 0.55$). Similarly, variations of the prostate position occurred independently from changes of the rectal distension ($p = 0.32$). A trend between internal prostate motion in the AP direction and elapsed treatment was observed ($p = 0.057$). Finally, a significant correlation was observed between the intrafraction composite shift of the prostate volume and the elapsed treatment time ($p = 0.036$).

Conclusion: Our data suggest a good control of intrafraction motion with butylscopolamine medication and by careful emptying of the rectum before treatment. The prostate intrafraction motion is shown to be dependent on elapsed treatment time. In conclusion, in image-guided SBRT with online correction, PTV margins can be kept in the range of 3 mm provided that the elapsed treatment time is kept as low as possible.

EP-1748

An experimental comparison of advanced respiratory motion management techniques

S. Ehrbar^{1,2}, R. Perrin³, M. Peroni³, K. Bernatowicz³, T. Parkel⁴, I. Pytko^{1,2}, S. Klöck^{1,2}, M. Guckenberger^{1,2}, S. Lang^{1,2}, D.C. Weber³, A. Lomax³

¹University Hospital Zurich, Department of Radiation Oncology, Zurich, Switzerland

²University of Zurich, Faculty of Medicine, Zurich, Switzerland

³Paul Scherrer Institute PSI, Center for Proton Therapy, Villigen, Switzerland

⁴Centre Suisse d'Electronique et de Microtechnique CSEM S.A., Innovative Design, Landquart, Switzerland

Purpose or Objective: Respiratory tumor motion enlarges the intra-fractional tumor position uncertainty. These uncertainties result in increased treatment volumes (PTV) and hence higher radiation dose to organs at risk (OAR). Also interplay effects between the moving target and dynamic treatment delivery have to be considered. Motion-management techniques (MMT) aim to reduce or deal with this intra-fractional respiratory tumor motion in the following ways: The internal target volume (ITV) concept with a PTV enclosing the whole tumor motion, the mid-ventilation (MidV) principle with probabilistic tumor margins, respiratory gating of the irradiation beam and treatment couch tracking with real-time compensation of the internal tumor motion. Dosimetric performances of these four techniques were investigated with film measurements in a sophisticated lung phantom.

Material and Methods: The anthropomorphic, deformable and dynamic lung phantom LuCa (CSEM and PSI) was operated with 5 different respiration patterns with 10 to 20 mm internal tumor motion amplitude. 4DCT scans were taken and individual SBRT treatment plans were prepared, adapting the PTV according to the four MMT (ITV, MidV, gating, tracking) and five respiration patterns. A dose of 8x6 Gy was prescribed to the 65%-isodose line enclosing the PTV using VMAT stereotactic treatment planning. The phantom was irradiated with all individual treatment plans using the corresponding respiration pattern and MMT, together with static measurements. The internal tumor motion was

monitored with Calypso (Varian) for gating and tracking treatments, and compensated with the PerfectPitch couch (Varian) for tracking. The dose in the moving tumor was measured with Gafchromic EBT2 (ISP) films. Changes in homogeneity indices ($\Delta H1-99$) between the films and the planned dose distributions and their gamma agreement scores using 3%/3mm (G53%/3mm) were evaluated. The film areas receiving more than the planned minimum dose ($A > D_{min}$) were calculated. OAR doses from the treatment plans were compared.

Results: The results for each MMT are summarized in Table 1, giving the median values with 25% and 75% percentiles over the five measurements with different respiration patterns. All techniques achieved a good coverage of the tumor. Median values for $A > D_{min}$ were above 99% for all techniques and ITV and MidV concepts showed lower gamma agreement scores (median: 88.9% and 87.7%) compared to gating and tracking (94.2% and 94.8%). For ITV and MidV concepts larger increases in inhomogeneity were found (median: 4.3 and 5.6 percentage points respectively) than for gating and tracking (2.8 and 2.3). Gating and tracking were able to reduce OAR dose in all cases, when compared to ITV concept.

Table 1: Evaluated parameters from film measurements inside the tumor and planned OAR dose parameters

	G53%/3mm (%)	$\Delta H1-99$ (pp)	$A > D_{min}$ (%)	Lung Dmean (Gy)	Lung V050y (%)	Heart Dmean (Gy)	Spinal cord Dmax (Gy)
ITV	88.9 (82.3-95.7) [97.9]	4.3 (3.5-5.9) [5.1]	99.8 (99.6-99.9) [99.5]	8.3 (7.9-8.9)	14.1 (13.0-15.5)	1.4 (1.3-1.5)	11.1 (10.9-11.7)
MidV	87.7 (74.5-91.5) [97.0]	5.6 (3.9-7.5) [2.1]	99.1 (96.9-99.5) [100]	7.9 (7.2-8.0)	12.8 (11.3-13.4)	1.1 (1.1-1.3)	10.4 (10.2-10.4)
Gating	94.2 (93.2-96.4) [96.5]	2.8 (2.3-4.2) [1.6]	99.9 (99.4-99.9) [99.0]	7.2 (7.1-7.3)	11.6 (11.3-11.8)	0.8 (0.6-0.9)	10.2 (9.5-10.8)
Tracking	94.8 (91.7-96.0) [96.7]	2.3 (1.1-2.8) [1.8]	100 (99.9-100) [99.8]	7.2 (7.2-7.2)	12.1 (11.9-12.2)	1.0 (1.0-1.1)	9.8 (9.7-9.8)

Values: Median (Qu-Qu), [static measurement], pp:percentage points

Conclusion: Tracking and gating showed a superior agreement with the planned dose distribution and at the same time reduced the dose to OAR in comparison to the passive motion management techniques.

Real-time 4D ultrasound tracking of liver and kidney targets for external-beam radiotherapy
D.S.K. Sihono¹, J. Boda-Heggemann¹, L. Vogel¹, S. Keigel¹, J. Thölking¹, F. Lohr¹, F. Wenz¹, H. Wertz¹

¹University Medical Center Mannheim- University of Heidelberg, Department of Radiation Oncology, Mannheim, Germany

Purpose or Objective: Hypofractionated SBRT is an effective low-toxic therapy option for liver metastases. In our department, liver SBRT is performed in DIBH with ABC (Active Breathing coordinator) and image-guidance with breath-hold CBCT. For additional monitoring of the movable target and/or surrogate structures, an ultrasound-based tracking system has been developed. We evaluated the feasibility and the accuracy of this system on a motion phantom and healthy volunteers.

Material and Methods: The tracking accuracy of a 4D ultrasound system (Clarity Anticosti, Elekta, Sweden) was evaluated using an ultrasound phantom (BAT, Nomos) and a motion platform (CIRS, USA) with different settings to obtain optimal parameters to track structures moving with respiration. An initial evaluation was performed with 5 healthy volunteers to assess the performance in a quasi-clinical setting. An ultrasound dataset was acquired in ABC-based breath hold (breath hold time 20 sec, free breathing phases of 5-6 breathing cycles). Tracked structures were renal pelvis as a centroid structure and a portal vein/liver vein as a non-centroid structure. The scanning range of the ultrasound probe was varied. The motion component in superior-inferior direction was compared with the motion of an external marker on the body surface and the data from ABC.

Results: a) Phantom data: The tracking accuracy increased with decreasing scanning range. For a cycle time (sinusoidal

motion) of 10 s and an amplitude of 10 mm, the mean and standard deviation of differences between the measured and the reference position values were 0.57 ± 0.48 mm and 0.31 ± 0.20 mm in 15° and 5° scanning range respectively, while for a cycle time of 5 s were 1.33 ± 1.20 mm and 0.34 ± 0.25 mm for 8° and 4° scanning range respectively. For a fixed scanning range, the accuracy of ultrasound tracking decreased with a decrease of cycle times.

b) Volunteer data: The system's tracking success rate was 90.77% of all breath-hold phases. The renal pelvis tracking success rate was 95.42%, while 86.79% for portal vein. A compromise between scanning range and cycle times had to be established depending on target. A working scanning range was between 10° - 40° . For angles $<10^\circ$ there is a higher risk that the target is sometimes outside the ultrasound. This will lead to a reduced tracking success rate. Tracking curves (SI direction) were in good accordance with breathing curves of ABC and a fiducial placed on the infradiaphragmatic abdominal wall.

Conclusion: The ultrasound system showed good performance on a motion phantom and healthy volunteers. A positioning setup that provides good ultrasound visual over a long period in clinical environment could be established. Further improvement of the tracking algorithm could improve accuracy along with respiratory motion if using large scanning angles for detection of high-amplitude motion and non-linear transformations of the tracking target.

EP-1750

Monitoring of intra-fraction prostate motion with a new 4D ultrasound device

M. Fargier-Voiron¹, P. Pommier², S. Rit¹, D. Sarrut¹, M.C. Biston²

¹Université de Lyon- CREATIS, Physics, Lyon, France

²Centre Léon Bérard, Physics, Lyon, France

Purpose or Objective: The emergence of hypofractionated protocols in prostate cancer treatment requires a better accuracy in dose delivery because of an increased risk of toxicity to the safe tissues. The aim of this study was to evaluate intrafraction motions of the target volumes for prostate cancer patients imaged with a new transperineal ultrasound (TP-US) device.

Material and Methods: The accuracy of the tracking of the TP-US (Clarity®, Elekta, Stockholm, Sweden) probe was first investigated by comparing the measured positions of a target volume in a phantom with the Clarity device and the simultaneous use of a transmitter based positioning device (RayPilot, Micropos Medical, Sweden). Then intra-fraction motions measured with the TP-US were analyzed for 13 prostate patients (426 sessions) and 14 post-prostatectomy patients (438 sessions). The fraction of time that the target volume was displaced by more than 3 and 5 mm was calculated for tracking times ranging between 60-420s, for each session and each patient. The mean displacements were also calculated for each direction. Percentages of sessions for which thresholds of 3 mm and 5 mm were exceeded during 15 s and 30 s in each direction were determined.

Results: Differences between TP-US and transmitter based devices were below 1.5 mm for all directions. The observed motions were patients and sessions dependent and increased with the treatment time. During the first minute, 3D displacements above 3 mm were seen 5% and 1.9% of the time, for prostate and post-prostatectomy patients, respectively while they reached 38% and 10.8% of the time after 7 min of treatment. Maximum 3D displacements above 5 mm were observed after 7 min 11.6% and 1.6% of the time for prostate and post-prostatectomy patients, respectively. Mean displacements in AP, SI and LR directions were -0.9 ± 0.8 mm, 0.9 ± 0.8 mm and -0.3 ± 0.5 mm for prostate patients and -0.9 ± 0.5 mm, 0.2 ± 0.4 mm and 0.1 ± 0.4 mm for post-prostatectomy patients. The maximum percentage of sessions for which the prostate and post-prostatectomy volumes exceeded the 3 mm tracking limits for at least 15 s was observed in the AP direction (Table 1). Conversely, minimum

displacements were observed in the lateral direction for prostate patients (4.5%), and in the SI direction for post-prostatectomy patients (0.7%).

Table 1:

		AP (%)	SI (%)	LR (%)
Prostate	3mm tracking limit exceeded = 15s	30.0	24.6	4.5
	3mm tracking limit exceeded = 30s	24.4	21.8	4.2
	5mm tracking limit exceeded = 15s	6.3	4.5	1.2
	5mm tracking limit exceeded = 30s	5.4	4.0	0.9
Post-prostatectomy	3mm tracking limit exceeded = 15s	11.4	0.7	4.1
	5mm tracking limit exceeded = 30s	9.4	0.7	3.4
	3mm tracking limit exceeded = 15s	1.8	0.0	0.7
	5mm tracking limit exceeded = 30s	1.6	0.0	0.7

Conclusion: Results for prostate patients are in agreement with the previously published data [1]. 4D TP-US modality is a promising alternative to irradiating and/or invasive IGRT modalities for intrafraction prostate motion management. In contrast, smaller displacements were observed for post-prostatectomy patients than those reported in the literature [2]. Further investigations are in progress to determine the causes of these discrepancies. References: [1] Langen KM et al. Int J Radiat Oncol Biol Phys. 2008;71(4):1084-90 [2] Klayton T et al. EP-1751

Time-resolved analysis of Varian RPM-gated exposures on three versions of Truebeam linac

R.B. King¹, C.E. Agnew², B.F. O'Connell², K.M. Prise¹, A.R. Hounsell², C.K. McGarry²

¹Queen's University Belfast, Centre for Cancer Research and Cell Biology, Belfast, United Kingdom

²Belfast Health and Social Care Trust, Radiotherapy Physics-Northern Ireland Cancer Centre, Belfast, United Kingdom

Purpose or Objective: To design a moving phantom capable of time-resolved 2D dosimetry with the goal of validating gated radiotherapy treatments. A preliminary study was carried out to validate the arrangement with gated-exposures using the Varian real-time position management™ (RPM) system, installed on four different Truebeam® linacs (operating v.1.5, 1.6 and 2.0).

Material and Methods: The phantom consists of a PTW OCTAVIUS® 1000 SRS array combined with a programmable moving platform and is capable of measuring 2D dose profiles with a 100 ms acquisition rate. In this preliminary study the array oscillated sinusoidally (2.5 cm amplitude) with 3 different breathing periods (3, 4 and 6 s) while irradiated with a 6 MV, 4 × 4 cm² field. Amplitude gating was employed to activate four Truebeams when the array was within ±20% and ±30% of the central position and at the 20% extremes of its motion. Additional time-resolved information on the activation of the linac was acquired via oscilloscope traces of the targetBNC output, and analysis of corresponding trajectory log files. All data sources were analysed using MATLAB 7.10, where GUIs were developed to interpret the variation in position of the 2D dose profiles and to compare the time-resolved data contained within the four data sources.

Results: Fig. 1 shows results obtained via each of the acquisition methods during a gated exposure. A phase correction term is included in the OCTAVIUS, log file and target signal data (Fig. 1 (a), (b) and (c) respectively), so that the first two segments agreed with the RPM data. In this example, the agreement is not maintained throughout the entire exposure. Both the OCTAVIUS and target signal data (Fig. 1 (d) and (f) respectively) are delayed with respect to the RPM trace data and flags.

Fig. 1 Comparison between RPM data and other data sources during the first (a-c) and last (d-f) segments of a gated exposure. (a, d) RPM motion traces (dashed grey) and position information derived from OCTAVIUS measurements (solid blue). (b, e) Log file beam-on flags (cyan) for the same period. (c, f) Target signal measured during the exposure. Dashed vertical green and red lines indicate RPM beam enable and disable flags respectively.

As indicated in Table. 1, this anomaly was observed on Truebeam versions 1.5 and 1.6 but not on version 2.0. The opposite trend was observed in the log file comparison (Fig. 1 (e)), where the beam-on flags lead the RPM beam-enable flags. For all irradiations it was observed that log file beam-on flags led the corresponding target beam-on signal and that the time delay between the two signals was proportional to the number of segments.

Table. 1 Time difference between RPM beam enable flag for final exposure segments and the corresponding beam-on time recorded in the target signal oscilloscope trace and log file. Colour used to highlight time difference (Blue < -0.1, -0.1 ≤ Green ≤ 0.1, Red > 0.1 s).

Oscillation Period (s)	Gating Constraints (cm)		Accrued Time Discrepancy (s)					
	Min	Max	Truebeam 1.5		Truebeam 1.6		Truebeam 2.0	
			Target	Log File	Target	Log File	Target	Log File
3	-0.5	0.5	0.397	-0.179	0.118	-0.467	0.038	-0.565
	-0.75	0.75	0.119	-0.244	0.204	-0.146	0.035	-0.348
	0.75	1.25	0.249	0.009	0.352	0.109	0.029	-0.210
	-1.25	-0.75	0.047	-0.199	0.080	-0.168	0.051	-0.201
4	-0.5	0.5	0.118	-0.306	0.118	-0.319	0.049	-0.398
	-0.75	0.75	0.045	-0.247	0.038	-0.249	0.027	-0.251
	0.75	1.25	0.355	0.165	0.402	0.192	0.047	-0.134
	-1.25	-0.75	0.017	-0.171	0.065	-0.132	0.021	-0.175
6	-0.5	0.5	0.131	-0.170	0.123	-0.169	0.035	-0.268
	-0.75	0.75	0.044	-0.136	0.061	-0.095	0.027	-0.155
	0.75	1.25	0.347	0.222	0.230	0.109	0.029	-0.114
	-1.25	-0.75	0.337	0.189	0.363	0.240	0.036	-0.100

Conclusion: Preliminary tests with the new phantom have indicated that the RPM system can accurately enable the linac output when the phantom position is within set gating parameters. However, using this novel arrangement, it was discovered that a discrepancy occasionally occurred on RPM systems installed on Truebeam versions 1.5 and 1.6. For some exposures a difference of up to 0.4 s was observed between data recorded by the RPM system and data extracted from the OCTAVIUS and target signal. The phantom also highlighted a consistent discrepancy in the time information recorded in the log files, where the cycle period of each exposure segment was underestimated by 10 ms, leading to differences of up to 0.6 s between the log file and “true” target signal data.

EP-1752

A study of suitable conditions for stereotactic radiation therapy using VMAT for lung cancer

K. Kubo^{1,2}, H. Monzen², M. Tamura², M. Hirata², Y. Nishimura³

¹Tane General Hospital, Radiation Oncology, Osaka, Japan

²Kinki University, Graduate School of Medical Science- Department of Medical Physics, Osakasayama, Japan

³Kinki University, Faculty of Medicine- Department of Radiation Oncology, Osakasayama, Japan

Purpose or Objective: The dose variation of stereotactic body radiation therapy using volumetric modulated arc therapy (VMAT SBRT) for lung cancer varies due to the interplay effect between multileaf collimator (MLC) motion and tumor motion. The aim of this study was to assess the relationship between dose variation and factors related to the interplay effect and clarify optimal conditions for VMAT SBRT.

Material and Methods: Respiratory motion data and MLC motion data were obtained from 30 patients who underwent treatment with VMAT SBRT for lung cancer. We calculated number of breaths (NB) during irradiation, maximum craniocaudal tumor motion (Amp), and MLC motion complexity (MCSv, modulation complexity score applied to VMAT). Parameters assessed for each treatment plan were MCSv, a divisor combination of Amp and MCSv (AmpMCSv), and a multiplier combination of AmpMCSv and NB (IVS, interplay effect variable score). Static and dynamic measurements were performed with a PinPoint chamber (0.015cm³, PTW, Germany) in a Quasar phantom (Modus Medical Devices, Canada). Pearson's correlation analysis was used to assess the effect of dose variation on individual parameters.

Results: A wide range of NB (28.9 to 100.7 times) was observed. The standard deviation of dynamic measurement ranged from 1.3 to 12.5 cGy. Dose variation was negatively correlated with AmpMCSv ($r = -0.52$, $p < 0.05$) and IVS ($r = -0.62$, $p < 0.05$). IVS was obtained stronger correlation than AmpMCSv by considering NB. Significant dose variation was found in cases with the lowest NB (28.9 times).

Conclusion: Patients that had fewer than 40 NB, <150 s irradiation time, and a respiratory cycle of >4 s had the highest dose variation, and therefore required careful attention during VMAT SBRT treatment.

⁷Centro Nazionale di Adroterapia Oncologica, Bioengineering Unit, Pavia, Italy

⁸University of Milan, Department of Oncology and Hemato-Oncology, Milan, Italy

Purpose or Objective: To investigate intra-fraction breast motion during long-lasting (10-20 min) breast Helical Tomotherapy (Accuray, Madison, WI, USA) by means of optical tracking.

Material and Methods: Twenty locoregional breast cancer patients underwent Helical Tomotherapy irradiation after receiving conservative surgery or mastectomy. Non-invasive monitoring of respiratory motion during the entire treatment course, from setup verification to dose delivery, was achieved through infrared tracking of a passive marker placed near the surgical scar. In order to obtain the displacement deriving from the patient movement only, we subtracted the trace of an additional marker placed on the treatment couch. Respiratory signals were analyzed in terms of peak-to-peak amplitudes and baseline drifts, obtained by low-pass moving average filtering with a time window of 60 sec. Anisotropic Clinical Target Volume (CTV) safety margins expansion due to intrafraction organ motion was calculated relying on a synthetic representation of the specific patient respiratory pattern, obtained by adding half of the most probable respiratory amplitude to the non-respiratory movement of the scar trace in each anatomical direction (Fig.1).

Results: The most probable measured breathing amplitudes among all patients was (median±inter-quartile range): 0.25±0.12 mm (right-left), 1.31±0.63mm (inferior-superior) and 1.22±0.70 mm (posterior-anterior). Each patient featured a small inter-fraction variability of expected motion ranges, thus confirming a good reproducibility of respiratory motion during the entire course of treatment. Scar baseline drifts were mostly in posterior and in the inferior direction for all patients in most fractions, with the exception of patient P2, who exhibited a relevant baseline shift in superior and anterior direction with a large variability (Tab.1). The distribution of right-left shifts resulted in almost zero median, with a narrow interquartile range. Patient P20 showed stationary breathing, with a median baseline shift around zero in all anatomical directions. Conversely, patient P15 had a wide inferior-superior and posterior-anterior motion with large interquartile ranges. Resulting anisotropic safety margin expansions across all patients with the exception of P2, considered an outlier, were 1.58-2.44 mm in right-left, 4.41-3.65 mm in inferior-superior and 3.78-2.15 mm in the posterior-anterior directions, respectively.

	Scar Baseline distribution						n Fr	TOT Treatment Time [min]

iqr = inter-quartile range; n FR = number of fraction

Conclusion: Respiratory and non-respiratory motion during prolonged treatment induces significant position errors. Resulting CTV to Planning Target Volume (PTV) margins are within the 5 mm isotropic expansion generally used in clinic. Non-invasive continuous monitoring of intra-fraction motion should be implemented for an accurate definition of PTV.

EP-1754

The accuracy of ExacTrac X-ray intra-fraction verification at non-zero couch rotation

D.L.J. Barten¹, N.D. Sijtsema¹, M. Zahir¹, J.P. Cuijpers¹
¹VUMC, Radiotherapie, Amsterdam, The Netherlands

Purpose or Objective: Submillimeter accuracy of patient positioning is mandatory in stereotactic radiation therapy (SRT), since a high dose per fraction is given to relatively small lesions using tight PTV margins. SRT treatment techniques normally use couch rotations to achieve optimal irradiation. In frameless SRT intrafraction positioning verification at non-zero couch angles is recommended to ensure correct dose delivery. In this study the accuracy of the frameless ExacTrac X-Ray verification system at non-zero couch angles was assessed.

Material and Methods: An Alderson head phantom with a hidden marker was immobilized in a BrainLAB frameless mask on the Novalis Tx system. The phantom was positioned using the ExacTrac X-Ray system at couch angle 0°. For 13 different couch angles the phantom position was determined using the i) infrared (IR) optical markers, ii) X-ray verification imaging and iii) MV images taken from the AP direction. In the latter only deviations in the couch rotation plane were measured, assuming negligible deviations in the vertical direction. The Winston-Lutz test was performed to validate this assumption. The AP-MV imaging was used as the golden standard and was compared with the ExacTrac IR and X-ray results for each couch angle to determine the accuracy of the ExacTrac system. All data were relative to couch angle 0° and calculated in the Linac coordinate system. A one sample T-test was performed to determine statistically significant ($p < 0.05$) differences between the systems.

Results: Deflection of the couch in the vertical direction was within 0.23 mm at couch angle 0° and variation at other couch angles is less than 0.1mm. X-Ray verification at different couch angles showed significant differences with the AP-MV imaging of 0.23 ± 0.12 mm and 0.30 ± 0.21 mm on average for longitudinal and lateral direction respectively. Maximum deviations between AP-MV imaging and ExacTrac X-ray were found at couch angle 30° of 0.63mm in lateral and 0.50mm in longitudinal direction. Verification with the IR

markers shows larger deviations than the X-ray verification. Largest mean deviations for longitudinal and lateral direction were -1.55mm (at couch angle 270°) and 1.14mm (at couch angle 90°).

Conclusion: X-Ray verification at non-zero couch angles using the ExacTrac system is sufficiently accurate to be used in SRT. Deviations in X-Ray verification were largest at couch angle 30° but this will be of minimal importance clinically, since in non-coplanar SRT treatment techniques multiple couch angles are used. The IR system shows deviations that exceed accuracy requirements for SRT.

EP-1755

Visualization of respiratory and cardiac motion via TomoTherapy exit detector fluence

N. Corradini¹, P. Urso¹, C. Vite¹

¹Clinica Luganese, Radiotherapy Center, Lugano, Switzerland

Purpose or Objective: To demonstrate that respiratory and cardiac motion is observable and quantifiable on the CT detector during TomoDirect breast treatments.

Material and Methods: A preliminary study for motion management in breast radiotherapy was performed using the exit detector fluence of tangential static IMRT fields on TomoTherapy. Two patients in treatment for left breast cancer were selected randomly for study. After their radiotherapy treatments, the raw pulse-by-pulse detector data was downloaded from the CT detector for analysis. The pulse-by-pulse detector data is sampled at a frequency of 300 Hz. The exit detector channels with fluences corresponding to the breast and heart surfaces were identified within the recorded treatment sinograms. These channels' fluences were then investigated at the temporal projections in which respiratory and cardiac motion were expected (Figures 1a-b).

Figure 1. (a) Example of the pulse-by-pulse exit detector fluence for a breast patient. (b) Example of a single fluence profile for an entire patient treatment. (c) Zoom of single channel fluence at the breast surface used for respiratory motion estimation. (d) Zoom of single channel fluence at the heart surface used for cardiac motion estimation.

Results: Sinusoidal and waveform variations in fluence were observed where respiratory and cardiac motion was expected. The sinusoidal motion recorded on the detector data at the expected breast surface averaged a period of 2.8 ± 0.1 sec during the 4 fractions that were analyzed. The cardiac waveform motion recorded on the detector data at the expected heart surface averaged a rate of 86.4 ± 2.0 bpm during the 3 fractions that were investigated (Figures 1c-d).

Conclusion: The fluence variations we have observed on the pulse-by-pulse detector data would fit reasonably within respiratory and cardiac motion. These preliminary results are indicative of the ability for visualization and quantification of

organ motion during tangential breast treatments on TomoTherapy. Further studies into these breast treatment exit detector fluences are necessary for this method's verification and future development of method robustness. The future applications for this method include better dosimetric understanding of tangential breast treatments as well as possible dynamic delivery compensation for organ motions to reduce the patient's lung and heart dose.

EP-1756

Differential motion of adjacent lung tumours eligible for SBRT with a single isocentre

M.M.G. Rossi¹, H.M.U. Peulen¹, J.S.A. Belderbos¹, J.J. Sonke¹
¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Department of Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: Stereotactic Body Radiotherapy is increasingly used for early stage Non Small Lung Cancer (NSCLC) or oligometastatic disease. For patients with two adjacent homolateral tumours, high quality treatment plans can be designed to simultaneously treat both tumors with a single isocentre. The accuracy of treatment delivery is then potentially compromised. A compromise needs to be made for differential motion of the two tumors. The aim of this study was to quantify inter- and intra-fractional differential motion of adjacent tumours eligible for SBRT with a single isocentre.

Material and Methods: Patients treated with SBRT for lung tumours since 2014 were retrospectively selected from our database. Patients were included if they presented with 2 adjacent homolateral tumours with a distance between the 2 lesions of ≤ 5 cm (Figure 1). Prior to each treatment session patients received a CBCT (CBCTprecor) for tumour alignment. Both GTVs in the CBCTprecor were local-rigidly registered to the planning CT scan (pCT) using two separate shaped regions of interest. These registration results were then subtracted to give the differential motion. The post treatment CBCT (CBCTpostRT) and post correction CBCT (CBCTpostcor) were similarly used to quantify the difference in intra-fraction motion (IFM) between the two lesions. Subsequently the group mean (GM), systematic (Σ) and random (σ) position variabilities were calculated for Left/Right (LR), Cranial/Caudal (CC) and Anterior/Posterior (AP) directions.

Figure 1. Coronal slice of two peripheral adjacent tumours in left upper lobe

Results: Nine patients were included in this analysis, 7 male 2 female, median age was 63 years. The median distance between the tumours was 2.7 cm (range 1.2-4.7cm) All tumours were peripherally located, with a median Gross Tumour Volume (GTV) of 1.95cc (range 0.2-38.2cc) and median tumour amplitude, derived from the 4D pCT of 0.2, 0.4 and 0.4 cm in LR, CC and AP directions respectively. The inter-fraction differential tumour motion in terms of GM, Σ and σ is shown in Table 1. Systematic displacements in CC and AP were somewhat larger than the random displacements. In 5 patients the tumours moved on average towards each other, in the remaining 4 patients the tumours moved further apart. Differential IFM (table 1) was typically

somewhat smaller than inter-fraction motion. Inter-fraction motion did not significantly correlate with the inter tumor distance for the systematic component but was highly correlated ($r > 0.75$; $p < 0.02$) to the random component.

Table 1: Inter- and intra-fractional differential motion of adjacent tumours in terms of mean (GM), systematic (Σ) and random variations (σ)

(cm)	LR	CC	AP
Inter-fraction Motion			
GM	-0.001	0.09	-0.04
Σ	0.10	0.22	0.27
σ	0.12	0.14	0.15
Intra-fraction Motion			
GM	0.05	-0.05	0.08
Σ	0.12	0.13	0.19
σ	0.12	0.07	0.24

Conclusion: Differential motion of 1-3 mm (systematic and random variation) was observed in this small retrospective study between adjacent lung tumours eligible for single isocentre SBRT. However, as a compromise can be made for tumour alignment, the values reported in this study should be divided by two when calculating margins.

EP-1757

Intra-fraction patient movements during SBRT: CBCT vs Surface Optical Markers

P. Tabarelli De Fatis¹, A. Fassi², M. Liotta¹, I. Meaglia³, P. Porcu³, C. Bocci³, G. Baroni², G. Ivaldi³

¹Fondazione Salvatore Maugeri, Medical Physics, Pavia, Italy

²Politecnico di Milano, Dipartimento di Elettronica Informazione e Bioingegneria, Milano, Italy

³Fondazione Salvatore Maugeri, Radioterapia, Pavia, Italy

Purpose or Objective: To evaluate and to compare the intra-fraction movements, during Stereotactic Body Radiation Therapy (SBRT), obtained with two different methods: Cone Beam CT (CBCT) and an infrared Optical Tracking System (OTS).

Material and Methods: 10 patients (pts) with lung lesions (primary tumour or metastasis) were irradiated with a total dose ranging from 36 to 42 Gy in 3 fractions using one or two 6 MV photons volumetric-modulated arcs by a Varian Clinac linear accelerator. Pts were positioned with the arms raised on a breast setup system (PosiboardTM, Civco) with a vacuum customized cushion. The OTS SMART-DX (BTS Bioengineering, Milano, Italy) was used to record the 3D coordinates of multiple passive markers (6-8) placed on the patient's thoraco-abdominal surface. Ungated CT images were acquired for treatment planning (TP). 4DCT images were used for clinical target volume (CTV) delineation and a 5mm isotropic planning target volume (PTV) was generated. Before the daily treatment a CBCT was acquired and registered to the planning CT to obtain and apply the setup corrections (only translations allowed). After the irradiation a second CBCT was performed and rigidly registered to the first CBCT with a mutual information algorithm focusing on the CTV region. A rigid transformation was also estimated from surface markers coordinates acquired by the OTS just before the two CBCT scans. Setup corrections were subtracted from the roto-translation parameters obtained from both CBCT and OTS, in order to evaluate intra-fraction patient reproducibility. The results for both CBCT and OTS methods were evaluated and compared regardless of rotations coordinates always found to be less than 1 degree.

Results: In 39 analyzed fractions the mean absolute values of translational displacements obtained with the CBCT method was 0.6 ± 0.9 mm in the latero-lateral (LL) direction, 0.7 ± 1.0 mm in the antero-posterior (AP) direction and 1.0 ± 1.0 mm in the cranio-caudal (CC) direction. The same analysis achieved in 26 fractions with surface markers, revealed absolute displacements of 1.1 ± 1.1 mm in LL, 1.5 ± 0.9 mm in AP and 1.7 ± 1.7 mm in CC direction. Comparing the shifts obtained with the two systems in the same sessions, the resulting mean difference was 1.1 ± 1.2 mm in LL, 1.8 ± 1.3 mm in AP and 1.7 ± 1.6 mm in CC.

Conclusion: The differences between the intra-fraction patient displacements observed through CTV overlapping using CBCTs and through the surface markers registration seem to be clinically acceptable for the PTV considered. The relatively greater spread using markers is probably due to the larger portion of patient's surface covered by the OTS compared to the CTV region. Considering the adopted PTV margin, the non-invasive OTS could be therefore used to monitor the intra-fraction movements as alternative to a post treatment CBCT, possibly using markers positioned in a restricted area around the target.

EP-1758

Cyberknife Stereotactic Radiation Therapy for lung cancer: role of the LOT simulation.

I. Bossi Zanetti¹, A. Bergantin¹, A.S. Martinotti¹, I. Redaelli¹, P. Bonfanti¹, M. Invernizzi¹, A. Vai¹, L.C. Bianchi¹, G. Beltramo¹

¹Centro Diagnostico Italiano, Cyberknife, Milano, Italy

Purpose or Objective: SBRT is now an accepted treatment for inoperable pts with stage I lung cancer and oligometastatic disease. Particularly for SBRT, tumor motion must be taken into consideration due to high dose per fraction. It is unclear which system provides the best accuracy for target localization. The aim of this study is to evaluate the role of lung optimization treatment (LOT) simulation for the best tumor tracking using Cyberknife SBRT.

Material and Methods: From September 2014 to July 2015 we evaluated 143 consecutive pts referred to our department for tracking modality. For everyone a CT scan was performed in expiratory and inspiratory phase. During the simulation the position and setup were the same as those during the treatment. The real-time images were compared to the DRRs where the target was evidenced. Cyberknife includes a small 6 MV LINAC mounted on a robotic arm, two diagnostic X-ray sources (installed in the ceiling of the treatment room) attached to digital image collectors, placed orthogonally to the patient to provide real-time treatment guidance, and a table remotely controlled that can move around different axes and adjust the patient position.

Results: According to the accuracy of the LOT system in target identification we observed these solutions: we treated 102 pts (71%) with Xsight lung technique, 80 pts in 2-view modality in which the target was recognized and tracked from both X-Ray cameras and 22 pts in 1-view modality, in which only one camera was used. Xsight lung along with Synchrony Respiratory Tracking can automatically track and adjust the beam to tumor motion, using the lesion as a fiducial. The GTVs were expanded by 3 mm in all directions to create the CTVs. We used different margins for PTVs. In the 2-view modality the CTV on expiratory CT was expanded by 2mm in all directions, while for 1 view modality two different CTVs were generated on both CT scan to include the entire inhale-to-exhale tumor motion, and added together to create an ITV expanded by 2 mm in the direction followed by the X-Ray camera and 3mm in the other direction. For the other 40 lesions (29%), when the tumor cannot be clearly identified by either of the two cameras, fiducials have been necessary.

Conclusion: LOT simulation system is a very effective, useful and non-invasive technique. Dramatically reducing PTV margins and consequently the risk of potential toxicities related to the high doses, LOT simulation system and Xsight lung are considered the best choice in the management of lung lesions in our clinical practice.

Treatment of moving targets with active scanning carbon ion beams

P. Fossati¹, M. Bonora², E. Ciurlia², M. Fiore², A. Iannalfi², B. Vischioni², V. Vitolo², A. Hasegawa², A. Mirandola², S. Molinelli², E. Mastella², D. Panizza², S. Russo², A. Pella², B. Tagaste², G. Fontana², M. Riboldi³, A. Facchetti², M. Krengli⁴, G. Baroni³, M. Ciocca², F. Valvo², R. Orecchia¹

¹European Institute of Oncology, Radiotherapy Division, Milano, Italy

²Fondazione CNAO, Clinical Area, Pavia, Italy

³Politecnico of Milan, Bioengineering Department, Milano, Italy

⁴University of Piemonte Orientale, Radiotherapy Department, Novara, Italy

Purpose or Objective: We report the preliminary clinical results organ motion mitigation strategies in the treatment of moving target with active scanned carbon ion beams.

Material and Methods: Since September 2014 26 patients with tumors located in the upper abdomen and chest were treated with active scanned carbon ion beams. Patients were affected by pancreatic adenocarcinoma, HCC, biliary tract cancers and sarcoma of the spine retroperitoneum and heart. Tight thermoplastic mask was selected as the optimal abdominal compression device. 4D CT scan with retrospective reconstruction, with phase signal obtained with Anzai system (Anzai Medical CO., LTD), was employed for planning. Automatic assignment of raw data to respiratory phases was checked and, if necessary, modified by the medical physicist. Planning was performed using end expiration phase. Planning CT scans were visually checked for motion artifacts. Contouring was performed on end expiration phase and on the adjacent 30% expiration and 30% inspiration phases. Beam entrance was selected in order to avoid the bowel in the entrance channel. The lung diaphragm interface was contoured in the different respiratory phases and beam angles were chosen to avoid passing tangential to the lung diaphragm ITV. IMPT was used for plan optimization. Plans were recalculated in adjacent phases and if DVHs were degraded in an unacceptable way they were modified iteratively. Weekly verification 4D CT scans were performed and, if needed, a new plan was re-optimized adaptively. Set up was verified with gated orthogonal X rays and non-gated cone beam CT in treatment room. Threshold for gate-on signal was initially set at 10% pressure signal dynamic and qualitatively adjusted in an asymmetric way according to results of plan recalculation in 30% expiration and inspiration. Gating signal was fed to the accelerator to enable beam delivery. Each slice was re-scanned 5 times to smear out possible interplay effects. Acute and early toxicity was scored according to CTCAE 4.0 scale.

Results: GTV and diaphragm excursion between end expiration and adjacent 30% phases was reduced to less than 5 mm. GTV (D95%) and critical OARs (D1%) DVH in 30% inspiration and expiration phases showed on average minimal (less than 1%) differences as compared to planning end expiration plan. Toxicity was minimal with no G3 event. G2 toxicity was observed in 15% of the patient during treatment and in 10% of the patients at 3 months. Median follow up was rather short (3 months) nevertheless in 23 patients the dose limiting OAR was either stomach or small bowel or esophagus, therefore early toxicity data are informative.

Conclusion: Active scanning with carbon ion beams for the treatment of moving target using abdominal compression, 4D simulation, robust planning, gating and rescanning is feasible and safe. Longer follow up is needed to evaluate oncological outcome.

EP-1760

Correlation and directional stability of principal component of respiratory motion in the lung

H. Hanazawa¹, Y. Matsuo¹, M. Nakamura¹, H. Tanabe², M. Takamiya³, Y. Iizuka¹, K. Shibuya⁴, T. Mizowaki¹, M. Kokubo², M. Hiraoka¹

²Institute of Biomedical Research and Innovation, Division of Radiation Oncology, Kobe, Japan

³Kyoto University Graduate School of Engineering, Department of Nuclear Engineering, Kyoto, Japan

⁴Yamaguchi University Graduate School of Medicine, Department of Therapeutic Radiology, Ube, Japan

Purpose or Objective: Application of principal component analysis (PCA) to fiducial marker coordinate during respiratory cycle provides new axes including the first principal component (1st PC), which presents maximal motion direction. The purpose of this study is to investigate correlation of respiratory motion between the markers implanted in the lung and interfractional variation in directionality of the 1st PC.

Material and Methods: Marker motion data in consecutive 9 patients who had 4 or 5 gold fiducials implanted in the lung and received tumor-tracking stereotactic body radiotherapy in 4 fractions were analyzed. Superior-Inferior (SI)/ Left-Right (LR)/ Anterior-Posterior (AP) positional data were acquired using a pair of orthogonal fluoroscopy in every fraction with the frame rate of 6.25 or 12.5 per second. Fifty-five datasets were eligible. The acquired SI/LR/AP coordinates were processed by PCA for each marker in all patients to calculate cumulative contribution ratio, principal component scores from 1st to 3rd PC and eigenvector of the 1st PC. Motion amplitude was defined as the 95th percentile of 1st PC scores. We evaluated (1) contribution ratio (CR) of the 1st PC, (2) correlation of the 1st PC scores between different markers in each fraction and (3) angles formed by 1st PC eigenvector of the first fraction and those of the others (defined as Ang1i (i=2, 3, 4)) for each marker.

Results: Mean \pm standard deviation (SD) of motion amplitude in the 1st PC direction was 20.2 ± 11 mm. Median contribution ratio (CR) of 1st PC was 0.933 (range: 0.721-0.996). Median correlation coefficient of 1st PC score among the markers was 0.985 (range: 0.938-0.999). For all markers, Ang1i varied from 1.19 to 23.3 degrees (deg) as shown in the Figure. Mean \pm SD of Ang1i in 7 patients whose 1st PC directions seemed stable was 3.4 ± 1.03 deg, while 2 patients had larger variation (18.8 and 11.3 deg on average). The markers with larger interfractional variations in directionality had the tendency to be more affected by heartbeat or possess small motion amplitude with round shape orbit.

Figure.

Interfractional variation in motion direction for each marker.

Abbreviations: deg = degrees, Pt = patient, m = marker

Conclusion: The 1st PC of the marker coordinate during breathing generally provided a good explanation of its respiratory motion in the lung. Strong correlations in motion along the 1st PC direction between different markers were indicated. Interfractional variation in motion direction stayed small in most cases.

EP-1761

Assessment of motion mitigation and setup monitoring in gating treatments with accelerated particles

⁴CNAO, Clinical Division, Pavia, Italy

⁵University of Milan, Oncology, Milan, Italy

⁶European Institute of Oncology, Radiotherapy, Milan, Italy

⁷CNAO, Scientific Director, Pavia, Italy

Purpose or Objective: The aim of this study is to evaluate the efficacy of motion mitigation tools in reducing respiration-induced target motion and to investigate the concordance of redundant breathing motion monitoring systems during gating treatments in radiotherapy with accelerated particles.

Material and Methods: In our institution, a gating protocol for carbon ion therapy has been developed and since 2014 it is applied to lesions affected by non-negligible organ motion. It involves both abdominal compression (through tight thermoplastic body masks) and active beam rescanning. 4DCT is used to image anatomy variations between end-inspiration (EI) and end-expiration (EE) phases. Treatment is optimized on the EE phase and it is delivered in a gate-on window centered on it. Both 4DCT binning and gate-on trigger rely on the Anzai load cell system (Anzai Medical CO, LTD). To quantify the efficacy of abdominal compression, we evaluated the 3D GTV displacements observed between EE and EI phases of the planning 4DCT. A B-spline-based deformable registration algorithm was used to calculate the displacement field between EE and EI. GTV contours, as segmented in EE, were then propagated to the EI. In addition, an in-room optical tracking system (OTS) provided continuous breathing monitoring by localizing a set of surface markers. Each time the gating window was opened by the Anzai system, markers coordinates were stored and compared offline, in terms of 3D displacements, with the initial setup configuration. This solution allowed us to measure and quantify the intra-fraction concordance of surface surrogates.

Data of six patients with thoracic and abdominal lesions has been evaluated.

Results: A median (interquartile) 3D GTV displacement (EE-EI) of 5.8 (2.0) mm, in a range of 1.4-10.9 mm, was observed. The maximum displacements (absolute values) were noticed in superior-inferior direction (range: 0.1-9.3 mm). Overall mean values of markers 3D displacements between setup conditions and data acquired during irradiation by the OTS were found to be lower than a millimeter (range: 0.1-0.7 mm). We observed an intra-fractional significant difference among different irradiation fields, thus suggesting a small trend towards progressive deterioration of reproducibility during treatment delivery.

Conclusion: Target 3D displacements, as calculated from the EE and EI phases, can be considered relevantly lower than those reported in literature for thoraco-abdominal lesions. These preliminary results suggest that patient's respiratory pattern (and thus target trajectory) can often be reduced by means of appropriate immobilization/compression tools. During treatment delivery, sub-millimeter values of 3D discrepancies in surface surrogates detection demonstrate that the Anzai and the OTS operate consistently, therefore a

strategy combining these systems may increase set up control and motion monitoring robustness.

EP-1762

Impact of physiological breathing motion for breast cancer radiotherapy proton beam scanning

A.M. Fleimer¹, B. Chehrizi², D. Josefsson³, I. Toma-Dasu⁴, A. Dasu⁵

¹Linköping University, Department of Oncology, Linköping, Sweden

²Stockholm University, Department of Physics, Stockholm, Sweden

³Linköping University, Department of Radiation Physics, Linköping, Sweden

⁴Stockholm University and Karolinska Institutet, Medical Radiation Physics, Stockholm, Sweden

⁵Linköping University, Medical Radiation Physics, Linköping, Sweden

Purpose or Objective: To study the impact of breathing motion on proton breast treatment plans using scanned proton beams.

Material and Methods: The study cohort was composed of twelve thoracic patients who had CT-datasets acquired during breath-hold at inhalation phase, breath-hold at exhalation phase and in free breathing mode. Proton treatment plans were designed for the left breast for the breath-hold at inhalation phase and were subsequently recalculated for the breath-hold at exhalation phase. Similarly, plans devised for the CT acquired in free breathing mode were recalculated for the extreme breath-hold phases. Four different field arrangements were used for each patient: two plans with three fields and two with one field. The dosimetric features of the plans were compared from the point of view of their coverage of the target and the doses to the organs at risk.

Results: Breathing motion led to a degradation of the dose coverage of the target (heterogeneity index increased from about 6% to 8-11%). Exhalation tended to decrease the lung burden (average dose 3.1-4.2 GyRBE), while inhalation increased it (average dose 4.7-5.8 GyRBE). The absolute values depended on the field arrangement, but the trend was similar across the plans considered. Smaller differences in dosimetric parameters were seen for the heart (average dose 0.1-0.2 GyRBE) and the left anterior descending artery (2.0-4.0 GyRBE). The absolute values of the dosimetric parameters corresponding to various breathing phases were rather small and their expected clinical impact is therefore quite small. Furthermore, the plans parameters in either breathing phase were generally superior to the corresponding ones that could be achieved with photon plans.

Conclusion: The results of this study indicated that the differences between the mean dosimetric parameters of the plans corresponding to the two extreme breathing phases are not significantly different, thus suggesting that breathing might have little impact for the chosen beam arrangements in proton scanned beam planning for breast cancer. Further investigations are needed to investigate the impact of interplay effects and whether the conclusions might be extended beyond the population considered in this study.

EP-1763

Experimental analysis of interplay effects in flattening filter free VMAT treatment techniques

T. Gauer¹, T. Sothmann², R. Werner²

¹University Medical Center Hamburg, Department of Radiotherapy, Hamburg, Germany

²University Medical Center Hamburg, Department of Computational Neuroscience / Department of Radiotherapy, Hamburg, Germany

Purpose or Objective: In SBRT of lung lesions, respiratory motion is commonly considered by 4DCT imaging to define the internal target volume (ITV). Dose optimization is often performed on average CT using VMAT-based treatment

techniques. However, average CT data ignores individual respiratory motion patterns during dose delivery and thus fluctuations in density distribution in the ITV. Additionally, interaction of MLC dose modulation and variable target motion might result in under-dosage of the target volume (interplay effect). This study analyses the efficiency of flattening filter free dose delivery and its impact on interplay effects in lung SBRT.

Material and Methods: SBRT treatment plans were created for a lung tumor phantom using VMAT techniques employing the flattening filter (FF) and flattening filter free (FFF) mode (600MU and 1400MU per min). The phantom consists of a high resolution 2D detector array plus solid-water, bone, lung and tumor inserts. It is mounted on a 4D motion platform to simulate regular and irregular tumor motion trajectories extracted from clinical 4DCT data with max peak-to-peak amplitudes of 1.6/2.3cm in SI and 1.2/2.4cm in AP. The ITV includes a 2cm x 2cm lung tumor (CTV) plus 1.8cm safety margin in SI. Changes in dose distributions through interplay effects were investigated by analyzing static reference and dynamic dose measurements in FF and FFF mode at regular and irregular tumor motion using a planning structure-based evaluation method.

Results: VMAT techniques in FF and FFF mode achieved almost identical dose distributions at static measurements (plan comparison). FFF allowed for approximately 40% shorter treatment time. For regular tumor motion (TM), FFF resulted in greater under- and over dosages of approximately 5-10% compared to FF in the CTV (cf. figure 1 for dose differences of dynamic and static measurements). However, corresponding γ -passing maps illustrate the increased interplay effect. Furthermore, FFF generated considerable under-dosages in the CTV in case of irregular TM. γ -passing rates (local γ of 3% / 1mm) decreased from 68% to 62% for regular TM and 41% to 34% for irregular TM within the ITV (cf. figure 1). Dose area histograms for CTV and ITV complementarily confirm above changes in dose differences and γ -maps.

Figure 1: Analysis of interplay effects by differences of dynamic and static dose measurements for VMAT techniques with flattening filter (FF) and flattening filter free (FFF) beams at regular and irregular tumor motion (TM). Corresponding gamma-passing maps are presented using local gamma-criteria of 3% / 1mm. Dose area histograms are shown for clinical and internal target volume.

Conclusion: FFF dose delivery in lung SBRT provides shorter treatment times. However, the risk of interplay effects is increased, in particular for irregular tumor motion. Further

analysis is required to evaluate the appropriateness of FFF in lung SBRT.

EP-1764

development and validation of a tool to evaluate prostate motion due to patient's breathing

C.M.V. Panaino¹, T. Giandini², M. Carrara², S. Frasca³, B. Avuzzi³, S. Morlino³, D. Bosetti³, N. Bedini³, S. Villa³, T. Rancati⁴, D. Bettega¹, R. Valdagni³, E. Pignoli²

²Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics Unit, Milan, Italy

³Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology 1, Milan, Italy

⁴Fondazione IRCCS Istituto Nazionale dei Tumori, Prostate Cancer Program, Milan, Italy

Purpose or Objective: An electromagnetic (ELM) system (Calypso, Varian Medical System, Palo Alto, CA, USA) based on sub-millimeter high frequency localization of three transponders permanently implanted in the prostate, was recently introduced for continuous real-time tracking of the tumor. Several studies of the tracks acquired over thousands of patients were reported in literature and allowed to give a detailed insight of intra-fraction prostate motion. Aim of this work was to develop and validate a tool to selectively filter the signal produced by the ELM transponders and to apply it for the evaluation of the amplitude of prostate motion only due to patient's breathing.

Material and Methods: To selectively filter the signal produced by ELM transponders a software was developed in the Matlab environment (version R2014b). Briefly, the developed software computes the power density spectrum (PDS) of the recorded tracks and isolates the 'breathing peak', i.e. the peak which is centered at the frequency corresponding to the breathing average frequency of each single analyzed session. A bandpass filter on the breathing peak is then applied to the original tracking data, in order to isolate the motion of the prostate due to the breathing of the patient. The software was validated with data recorded with QUASAR moving phantom, provided with a home-made insert of three transponders. Simulated breathing frequencies of 10, 12, 14, 16, 18, 20, 22 and 24 cycles per minute were recorded for at least one minute with the ELM system. After validation, tracks of 6 prostate patients who underwent EBRT were analyzed for a total of 180 treatments sessions. For each session, the corresponding maximum amplitude of prostate motion along the three main directions was obtained. Intra patients average data and standard deviations were reported along with the overall maximum amplitude.

Results: For the in-phantom validation, the developed software automatically computed the correct cycles per minute within a 0.52% uncertainty. The average amplitudes of prostate motion due to patient's breathing are listed in Table 1. As expected, the smallest motion resulted in left-right direction. The limited standard deviations indicate a low intra-patient motion variability. For each patient, the overall maximum amplitude turned out to be not negligible, but at the same time less than 0.5 mm.

TABLE 1 - Amplitudes of prostate motion due to patient's breathing

	# sessions	Left-Right (mm)		Cranio-Caudal (mm)		Antero-Posterior (mm)		overall
		average	std. dev.	average	std. dev.	average	std. dev.	maximum (mm)
Pt #1	33	0.10	0.05	0.22	0.04	0.15	0.06	0.29

Conclusion: A tool to quantify prostate motion due to patient's breathing was successfully developed, validated and applied to a consistent number of treatments sessions. Although small compared to the motion caused by the modifications of near organs (i.e. bladder and rectum), the achieved results show that the motion associated to patient's breathing should be carefully considered in the definition of an adequate Internal Target Volume.

This work was partially funded by Associazione Italiana per la Ricerca sul Cancro AIRC (grant N-14300)

Monitoring of intra-fraction eye motion during proton radiotherapy of intraocular tumors

R. Via¹, A. Fassi¹, G. Angellier², J. Hérault², M. Riboldi¹, J. Thariat², W. Sauerwein³, G. Baroni¹

¹Politecnico di Milano University, DEIB - Department of Electronics and Information and Bioengineering, Milano, Italy

²Centre Antoine Lacassagne, Cyclotron Byomédical, Nice, France

³University Hospital Essen University Duisburg-Essen, NCTeam- Strahlenklinik, Essen, Germany

Purpose or Objective: In proton therapy treatments of intraocular tumors, patients actively participate by fixating a red diode, prepositioned according to planning prescriptions, to stabilize gaze direction. This work aims to evaluate safety margins effectiveness against involuntary eye movement that may occur in the course of the treatment.

Material and Methods: A custom eye tracking system (ETS), able to monitor eye position and orientation through 3D video-oculography techniques, was installed in a proton therapy (PT) treatment room (fig.1). All ocular PT centers are equipped with an in-room orthogonal X-ray imaging system used to verify treatment geometry. Tantalum radio-opaque markers, sutured to the sclera of the diseased eye, aid to determine the gaze angle of the eye during simulation, and the correct eye position at treatment. During simulation, the ETS monitored the eye simultaneously with X-ray acquisition to assess the tantalum markers pose relative to eye position and orientation. As a result, the ETS was able to assess eye motion and markers position in physical coordinates during dose delivery.

A first analysis was performed on two patients with three and two monitored treatment fraction respectively. Both patients had four implanted markers. To enable 3D localization of markers identified in X-ray images, the geometry of the imaging system was calibrated by means of the Direct Linear Transform (DLT) algorithm. We measured the distance between markers 3D position seen by the ETS during irradiation and identified on setup verification X-ray images acquired prior dose delivery to quantify intra-fraction eye motion. Margins expansions of 2.5 mm were applied laterally and distally. Median, interquartile range (IQR) and maximum values for the clip-to-clip distance are reported in table 1.

Figure 1 Clinical setup of the eye tracking system (ETS)

Results: The mean retro-projection error (\pm SD) for the DLT calibration of the X-ray system was 0.06 ± 0.03 mm. Median values of markers deviation during irradiation, considering both patients, ranged between -0.54 mm/ 0.75 mm, -1.06 mm/ 0.85 mm and -0.55 mm/ 0.90 mm in the LL (latero-lateral), SI (superior-inferior) and AP (antero-posterior) direction, respectively.

Table 1 Results of the ETS monitoring of markers position during irradiation. LL (latero-lateral), SI (superior-inferior) and AP (antero-posterior) refers to conventional anatomical axes.

Factors influencing on intrafraction variation in lung Stereotactic Body Radiation Therapy

M. Rico Osés¹, E. Martinez¹, B. Bermejo², E. Villafranca¹, P. Navarrete¹, M. Errasti¹, M. Barrado¹, M. Campo¹, I. Visus¹, S. Flamarique¹, L. Bragado³, A. Manterola¹, A. Sola¹, S. Pellejero³, G. Asin¹, M.A. Dominguez¹, F. Mañeru³, F. Arias¹

¹Complejo Hospitalario de Navarra, Department of Radiation Oncology, Pamplona, Spain

²Complejo Hospitalario de Navarra, Department of Preventive Medicine, Pamplona, Spain

³Complejo Hospitalario de Navarra, Department of Radiophysics, Pamplona, Spain

Purpose or Objective: In the present study we compare three different treatment-delivery techniques in terms of treatment time (TT) and its relation with intrafraction variation (IFV). Besides that, we analyzed different clinical factors that could influence on the IFV. Finally we appreciated the soundness of our margins.

Material and Methods: Patients diagnosed of stage I lung cancer and lung metastases up to 5cm treated with SBRT in our centre were included in this study. All patients went through a 4DCT scan to create an internal target volume (ITV) and a 5mm margin was added to it to create a PTV. Each patient had a pretreatment Cone Beam CT (CBCT) and a posttreatment CBCT. We compared the CBCTs with their reference 4D-CT to quantify the translational tumor shifts as well as the 3D composite vector. For our patients three different treatment-delivery techniques were employed: fixed fields (FF), arcs dynamically collimated (AA) or a combination of both (FA). We studied if TT was different among these ways of treatment and we search if there were any correlation between TT and IFV. We analyzed the influence of patients' clinical characteristics (age, sex, performance status, pulmonary function, treatment time) and tumours' characteristics (location, nature, size) on IFV.

Results: A total of 45 patients with 52 lesions were studied from which 147 fractions could be analyzed. Mean IFV for x, y and z axis were 1 ± 1.16 mm, 1.29 ± 1.38 mm and 1.17 ± 1.08 mm, respectively. 96.1% of the displacements were encompassed by the 5mm margin given. TT was significantly longer in FF therapy (24.76 ± 5.4 min), when compare with AA (15.30 ± 3.68 min) or FA (17.79 ± 3.52 min) ($p < 0.001$). Despite that, IFV did not change significantly between the three groups ($p = 0.471$). Age ($p = 0.003$) and left vs. right location ($p = 0.005$) were related with 3D shift ≥ 2 mm. The multivariate analysis showed that only age significantly influenced on IFV (OR=1.07, $p = 0.007$).

Conclusion: The election of AA, FF or FA does not impact in the IFV although FF treatments take significantly more time. Our 5 mm margin can be considered acceptable as it accounts for more than 95% of tumor shifts. Age is the only clinical factor that influence significantly on the IFV in our analysis.

Deep Inspiration Breath Hold - a promising technique in patients with left-sided breast cancer.

P. Mezenski¹, J. Gatecki², M. Spatek², A. Zawadzka¹, P. Kukolowicz¹

¹The Maria Sklodowska-Curie Memorial Cancer Center, Medical Physics, Warsaw, Poland

²The Maria Sklodowska-Curie Memorial Cancer Center, Radiotherapy, Warsaw, Poland

Purpose or Objective: Clinical data suggest that every 1 Gy of the mean dose to the heart increases the risk of major coronary events by approximately 3% and the risk of coronary arteries damage by approximately 7%. The literature data show that the radiation dose delivered to the heart can be reduced by applying the Deep Inspiration Breath Hold (DIBH) technique. The aim of this study was to evaluate dose delivered to the heart and coronary arteries for a group of patients after breast conserving surgery (BCS) irradiated with 3D-CRT-SIB (3D Conformal Radiotherapy Simultaneous-Integrated Boost).

Material and Methods: For 10 left-sided breast cancer patients, computed tomography-based treatment planning were performed at FB (Free Breathing) and DIBH mode. The CTV (Clinical Target Volume) covering the whole left breast and the post-lumpectomy tumor bed (boost). Important organs at risk (heart, territory of coronary arteries and lungs) were delineated. To form the PTV (Planning Target Volume) from CTV, the margin of 6 mm was added. For both DIBH and FB, treatment plans were prepared by medical physicist. The prescribed doses were 54Gy (2.7Gy/fraction) to PTV boost and 45Gy (2.25 Gy/fraction) to PTV breast. The mean dose

delivered to the heart and the volume of heart receiving the dose of 20Gy or more were evaluated. Volume of the territory of the coronary arteries receiving the dose of 20Gy or more was also assessed. All 10 patients were treated with the DIBH technique.

Results: DIBH compared to FB reduced the mean dose delivered to the heart (average 4.4 Gy vs. 2.1Gy). The heart volume receiving the dose of 20 Gy or more was reduced to almost zero (average 0.1% vs 6 %). DIBH allowed to diminish to zero the volume of coronary arteries receiving 20Gy or more (average of 0% vs. 16.9%). The early treatment tolerance was good - no toxicity higher than Grade 1 skin toxicity according to RTOG Acute Radiation Morbidity Scoring Criteria was observed.

Conclusion: DIBH technique reduces the dose delivered to the heart in comparison to FB, thus it may reduce the late cardiotoxicity of radiotherapy. In each patient with the left breast cancer qualified to postoperative radiotherapy, the DIBH technique should be taken into consideration

EP-1768

The impact of interplay effect in SBRT lung treatments for 6MV and 6MV-FFF beams using EBT3 film.

D. Elezaj¹, W. Ottosson¹, M. Sjölin¹

¹Herlev Hospital, Department of Oncology, Herlev, Denmark

Purpose or Objective: In hypofractionated stereotactic body radiotherapy (SBRT) for lung tumors, the interplay effect between tumor respiratory motion and multileaf collimator (MLC) motion can play an important role in dynamic plans. This study was designed to investigate the interplay effect for Rapidarc (RA) SBRT lung treatments, using GafChromic EBT3 film and a respiratory motion phantom.

Material and Methods: A heterogeneous programmable respiratory motion phantom (Quasar, Modus Medical Devices Inc.), with a "tumor" (30 mm diameter) inside a cylindrical "lung" insert, was used to simulate a breathing motion in the superior/inferior direction. Two amplitudes (10 mm, 20 mm) and two breath rates (BRs) (period: 6 s, 4 s) were investigated. RA plans were created, based on the 4D CT scans of the phantom, one for each amplitude and beam quality investigated a) 6MV (600 MU/min) and b) 6MV-flattening filter free (FFF) (1400 MU/min). All plans were optimized to keep the MLC modulation about 200 MU/Gy. The internal target volume (ITV) was prescribed a fractionation dose of 22.5 Gy, where the planning target volume (5 mm margin to ITV) was covered by 67%. Each plan consisted of four half arcs, each measured individually. Measurements were carried out both in static condition and with motion for the two BRs. GafChromic EBT3 film were placed centrally in the tumor, and the measurements were compared with calculated dose distributions where gamma analysis per field was evaluated (Verisoft v.4.0, PTW-Freiburg).

Results: All static measurements were in good agreement with the calculated dose, with a mean local gamma (LG) passing rate (3%/2mm) above 96,8% ($\pm 0,9$) for all fields. With 10 mm motion, the mean LG passing rate (3%/2mm) for all fields in one plan was, with period 6 s: 88,4% ($\pm 2,4$) for 6MV and 82% ($\pm 3,5$) for 6MV-FFF, and with period 4 s: 78% ($\pm 12,6$) for 6MV and 73,9% ($\pm 7,7$) for 6MV-FFF. Worst case observed was with 20 mm motion, period 4 s and 6MV-FFF, with a mean LG passing rate (3%/2mm) of 50,7% ($\pm 15,2$). Only the 6MV plan with amplitude 10 mm and period 6 s passed a typical clinical acceptance criterion of 90% using 3%/3mm LG passing rate.

Conclusion: The impact of interplay effect was highest for the largest motion amplitude (20 mm), fastest BR (4 s) and for the shortest delivery time (6MV-FFF beam). Although the results illustrate LG per field, the motion blurring may become dosimetrically significant when the fields are summarized, particularly for motions above 10 mm.

EP-1769

Evaluation of the intra-fraction patient movement for SBRT treatments in our Institution

D. Martínez¹, F. Candela¹, A. Camara¹, M.T. Garcia-Martinez¹

¹Hospital Universitario de la Ribera, Radiofísica y Protección Radiológica, Alzira, Spain

Purpose or Objective: The purpose is to evaluate the intra-fraction patient movement for SBRT treatments, obtaining a reference level in function of the pathology, starting point for future improvements. The parameters considered to be improved are the settings of these treatments: positioning, immobilization devices and maybe patient training.

Material and Methods: Data from 233 SBRT fractions (from 05/2013 to 09/2015) of 105 patients (SBRT different treatments) were studied.

All patients have internal fiducial markers, and were treated with two Varian (clinac 2100C and 2100CD) linear accelerators both with Portal Vision AS500 - IAS3, the treatment planning system (TPS) was Philips Pinnacle v9.8, and the Record and Verify (R&V) was Mosaic (Elekta). The treatment plan was mainly 3DRT.

The treatment procedure for each fraction was:

Before each treatment session a new CT was made. All ROIs and fiducials were contoured in it. The displacements from external CT marks to isocenter were updated according to this.

The patient was positioned on the couch with all the immobilization devices needed, and initially aligned with the lasers on the CT marks. Then it was moved to the isocenter according to the updated physics displacements.

Two Portal Images (orthogonal, 0° - 90°) were done until their position corresponded to the one of the treatment plan. Fiducials were used to check the position against the portal vision. When the correct position was found, the first treatment field is irradiated.

For each treatment field, a Portal Image was made. It was checked with the corresponding RDR, repositioning the patient if necessary. Finally the field was irradiated. If the movement detected was greater than a half of the PTV margin, the 0° and 90° images were performed once again.

The treatment positions (couch coordinates) for each field were obtained from the R&V. The cases were classified according to two main categories:

Reposition in low % number of fractions: No action required by now.

Reposition in high % number of fractions: The immobilization devices and positioning of the patient should be checked improved.

Results: Position had to be corrected intra-fraction due to the PV images in 36 of the 233 fractions (15.4%).

45 beams needed patient reposition, that means in average 1.25 repositions for each patient that needed to be repositioned.

These patients were treated with 245 beams (18.4% of the treatment beams needed reposition).

In Average, the movement magnitude (field to field) was 8 mm (4 movements greater than 3 cm), and the total session time was increased in 7'59'', due to the reposition process.

Conclusion: The three most frequent tumor localizations were: lung, abdominal and cranial. With the collected data, patient setup must be improved in abdominal pathology.

Localization	Sesions with fields repositioned	Total fractions	(%)
Lung	20	124	16.13%
Abdominal	7	31	22.58%
Cranial	3	21	14.29%

There were other pathologies with low number of cases (Spinal cord, rectum...), so the study may not be yet representative.

This process implies an increase in the treatment time, but this is necessary for a SBRT efficiency treatment.

EP-1770

Predictive modeling of respiratory lung motion using single-phase CT and finite-element analysis

⁴Shiraz University of Medical Sciences, Department of Radiology, Shiraz, Iran Islamic Republic of

⁵Shiraz University of Medical Sciences, Department of Radiology & Medical Imaging Research Center, Shiraz, Iran Islamic Republic of

Purpose or Objective: Information regarding lung motion can be highly valuable in modern radiotherapy. During recent years, 4DCT has been used to obtain such required information. This technology is, however, not available to all centres. It is, therefore, desirable to have a predictive model to aid the planning and delivery processes, although this has proven to be a challenging task given the complexities involved. The aim of this work is to develop a biomechanical finite-element model (FEM) of respiratory lung motion that only requires a CT dataset from the end-inhalation phase of the breathing cycle as input.

Material and Methods: A radiology specialist identified 10-18 uniformly-distributed landmarks per lung on each of the end-inhalation and end-exhalation 4DCT datasets for 13 lungs. After segmentation and surface preparation, the first 7 lungs (3 left and 4 right) were used to tune the FEM in the Abaqus FEA software environment. A hyperelastic model with reported parameters was used. Varying magnitudes of pressure were applied to 9 different segments of lung surface. These magnitudes were adjusted until the mean of the squares of the 3D distances between the predicted and actual landmark positions in the end-exhalation CT dataset became < 1 mm. Our tuned FEM was hence obtained. This model was then applied to the study 4DCT datasets comprising 6 lungs (3 left and 3 right). The 3D error vectors between the corresponding landmarks in the end-exhalation phase were calculated and analysed.

Results: Among all landmarks in the 6 lungs in the study set, the mean length of the 3D error vectors was < 2 mm, while the minimum and maximum lengths were 0.1 mm and 7.1 mm, respectively.

Conclusion: Overall, the tuned model shows reasonable accuracy in predicting the end-exhalation position of the landmarks in the lungs, using the input anatomy of only a single end-inhalation phase. These promising results encourage further development and evaluation of the model as well as its tuning over a larger number of patients.

EP-1771

Biological consequences of dynamic dose interplay in VMAT SBRT lung treatments

M. Sjölin¹, D. Elezaj¹, W. Ottosson¹, J.M. Edmund¹

¹University Hospital Herlev, Department of Oncology, Herlev, Denmark

Purpose or Objective: A dynamic dose delivery for stereotactic body radiotherapy (SBRT) of the lung in free breathing can result in dose blurring, interplay or interference effects which may cause a considerable deviation between the prescribed and delivered dose. Here, we investigated the per fraction dose effects by high-spatial resolution measurements.

Material and Methods: GafChromic EBT3 film measurements were carried out in the isocenter plane of a 3 cm diameter tumor in a movable cylindrical cedar lung insert (Quasar phantom). The motion was in the cranial-caudal direction. Motion frequencies were 10 and 15 breaths per minute (bpm), and amplitudes were 10 and 20 mm. Volumetric modulated arc therapy (VMAT) plans for both 6 MV (600 MU/min) and 6 MV flattening filter free (FFF) (1400 MU/min) beams were created for each amplitude. The gross tumor volume including motion (GTV-IM) generated from a most intensive projection of a 4D CT, was prescribed a mean dose of 22.5 Gy. The GTV-IM was enclosed by the 90 % isodose. The motion effects on the GTV-IM were quantified biologically using the generalized equivalent uniform dose (gEUD, $a=-10$), and dosimetrically by the mean (Dmean) and minimum dose (Dmin). All deviations are given relative to the corresponding planned parameters. Static measurements were performed for each beam and amplitude and served as a baseline.

Results: For the static 10 mm amplitude cases, the relative deviation in gEUD was +0.2% (6 MV) and -1.6 % (6 MV FFF), Dmean = 0.4 and -0.7%, and, Dmin = 1.6 and - 3.5%. For the 10 and 15 bpm and 10 mm amplitude, the reduction in the gEUD ranged between -1.8 and -3.2%. A similar trend in Dmean between -0.8 and -2.6% was observed and Dmin about -10%. The largest relative reduction in gEUD of -7.5% was observed for the 20 mm amplitude and 15bpm for the 6 MV FFF beam. Dmean and Dmin were -4.2 and -21.4% for this case, respectively.

Conclusion: This phantom study indicates that VMAT treatment in free breathing for lung SBRT tumors could lead to 3% under dosage in tumor gEUD for a motion amplitude of 10 mm and 7.5% for a 20 mm amplitude. Tumor movements of more than 10 mm for this treatment technique should consequently be avoided.

EP-1772

Comparison of dynamic 2D MRI with 4DCT lung tumor volumes for accurate real time imaging on linac-MR

S. Baker¹, E. Yip², J. Yun², K. Wachowicz², Z. Gabos¹, G. Fallone³

¹Cross Cancer Institute, Radiation Oncology, Edmonton, Canada

²Cross Cancer Institute, Medical Physics, Edmonton, Canada

³Cross Cancer Institute and University of Alberta, Medical Physics- Physics and Oncology- Medical Physics Division, Edmonton, Canada

Purpose or Objective: The hybrid linac MR system is capable of acquiring 2D images at 4 frames per second during radiation delivery. Moving lung tumours can potentially be localized, in real time, by automatic contouring of these images, allowing radiation to "track" the tumour. This study aimed to compare the accuracy of the dynamic 2D MRI of a linac-MR for lung tumour delineation to 4-dimensional computed tomography (4DCT), the current standard for radiotherapy planning for lung cancer treatment.

Material and Methods: A total of five non-small cell lung cancer patients with tumours under 5 cm in size undergoing stereotactic body radiotherapy were recruited for this study. A planning 4DCT with 3 mm slice thickness was acquired for each patient using a belt system and retrospectively sorted into 10 bins, each assumed to estimate the actual size of the target in ten respiratory phases. Three of these bins representing end inhale, end exhale and mid-cycle, along with the motion encompassing maximum intensity projection (MIP), were contoured on axial slices by a radiation oncologist using the Computation Environment for Radiotherapy Research (CERR) platform (default lung window). The same patients were scanned using a Philips 3T MRI on a single 20 mm sagittal slab using a balanced SSFP sequence (TE/TR = 1.1/2.2ms, Pixel Size 3x3mm, 4fps) with the patient undergoing free breathing for 3 minutes (650 images). A radiation oncologist, using the CERR platform, with the default MR window, contoured these 650 sagittal

slices, representing the real time location of the tumour. To compare the 3D CT target volume with a 2D target area from the MRI, the contoured 3D volume was projected onto the 2D sagittal plane, resulting in a 2D area that could be fairly compared with the sagittal 2D MR area.

Results: The projected 2D CT bin areas for the 5 patients had a mean (standard deviation) area of 4.12(0.35), 5.17(0.40), 2.99(0.34), 9.28(0.52) and 3.96 (0.35) cm². This is compared to the MR contoured areas of 5.02 (0.45), 7.13(0.67), 2.63(0.41), 7.52(0.57) and 4.07(0.41) cm² (Figure 1). While there are differences that may be attributed to binning errors from 4D CT reconstruction and intra-observer variations, contours from real time MRI do not appear to be systematically biased on target area compared to the CT contours.

Figure 1. Mean area for five lung tumors on CT, MRI and MIP. Error bars represent standard deviation.

Conclusion: Lung tumor target areas on dynamic MR are similar to those on 4DCT and confirm the accuracy of real time tumor imaging. With the platform's ability for real time tumor tracking, reductions in irradiated lung volume can be achieved compared to motion encompassing treatment strategies, as indicated by the much larger MIP volumes.

EP-1773

Dosimetric benefits and reproducibility of DIBH technique guided by an optical system

F. Rossi¹, S. Russo¹, R. Barca¹, S. Fondelli¹, L. Paoletti¹, P. Alpi¹, B. Grilli Leonulli¹, M. Esposito¹, A. Ghirelli¹, S. Pini¹, P. Bastiani¹

¹Azienda Sanitaria Firenze, S.C. Fisica Sanitaria, Firenze, Italy

Purpose or Objective: Surface imaging (SI) systems have been recently introduced in radiotherapy to check patient setup and to manage gated treatment procedure. The absence of additional radiation exposure, the execution rapidity and comfortable for the patients, make this approach particularly interesting. Aim of this work is the evaluation of a deep inspiration breath-hold (DIBH) technique guided by an optical system in terms of normal-tissue sparing, and positional reproducibility.

Material and Methods: The Catalyst™ (C-RAD Sweden) is a valid solution for respiratory gated treatments offering visualization of the respiratory pattern and direct beam control. In combination with the C-RAD Sentinel™ system used for CT acquisition phase, Catalyst™ offers coverage for the whole chain from gated imaging to gated beam delivery (see figure 1). 20 patients that underwent BCS and left side adjuvant radiotherapy during 2015 were included in this study. Treatments were performed in DIBH with 3D conformal tangential beams. Median dose to the whole breast was 50 Gy in 25 fractions. For each patient a free breathing (FB) and a DIBH treatment plans were calculated and dose volume histograms were compared. The reproducibility of the DIBH

during treatment was monitored by capturing 3D surfaces with Catalyst™ system before and after set-up correction and at the end of the treatment fraction. Interfraction and intra-fraction variability were quantified in mean and SD displacements in translation (Lat, Long, Vert) and rotations (Rot, Roll, Pitch) over all the treatment fractions of the enrolled patients.

Figure 1: DIBH procedure guided by C-RAD optical systems with visual coaching.

Results: DIBH technique provided a significant dose reduction in Heart Mean Dose (1,3Gy FB vs 0,4 Gy BH), and LAD mean dose (10,7 Gy FB vs 2,0 Gy BH). Better PTV coverage (V 95% 88,9% FB vs 92,6% BH) in DIBH plans and no difference in Lung parameters (V10, V20 and Dmedia) were achieved. Inter-fraction variability before setup correction was relevant, but inter-fraction variability after setup correction was extremely reduced. Intra-fraction variability was <2.1 mm in translations and <1° in rotations, as showed in table 1.

Table 1: Quantification of set-up variability in DIBH treatments.

Setup variability	Lat [mm]	Long [mm]	Vert [mm]	Rot [°]	Roll [°]	Pitch [°]
Inter-fraction before correction	1,9 (2,1)	10,1 (9,0)	-6,9 (4,3)	0,8 (1,0)	0,5 (1,7)	0,8 (1,1)
Inter-fraction after correction	-0,4 (0,4)	-0,7 (0,5)	-0,1 (0,3)	0,5 (0,3)	0,4 (0,6)	-0,3 (0,5)
Intra-fraction	1,4 (0,5)	2,1 (0,4)	1,7 (0,5)	0,7 (0,2)	0,8 (0,1)	0,8 (0,3)

Conclusion: In our experience DIBH is a reproducible and stable technique for left breast irradiation showing significant reduction of mean dose to the heart and LAD and a limited inter-fraction and intra-fraction DIBH variability. This is a good promise in reducing the late cardiac toxicities associated with radiation therapy.

EP-1774

A novel phantom for dosimetric verification of gated SIB radiotherapy treatment plans

D. Soultan¹, A. Yock¹, M. Cornell¹, J. Murphy¹, B. Gill², W. Song³, V. Moiseenko¹, L. Cerviño¹

¹University of California San Diego, Department of Radiation Medicine and Applied Sciences/ Radiation Oncology Pet/CT Center, San Diego, USA

²British Columbia Cancer Agency, Department of Radiation Oncology, Vancouver, Canada

³Sunnybrook Hospital, Medical Physics, Toronto, Canada

Purpose or Objective: To validate a novel phantom intended for 4D PET/CT scanning and dosimetric verification of gated radiotherapy plans. To benchmark the use of the phantom for PET-driven, simultaneous integrated boost (SIB) radiotherapy planning and ion chamber validation.

Material and Methods: A multipurpose phantom and a set of inserts were designed and manufactured to simulate gated SIB radiotherapy, from 4D PET/CT scanning to treatment planning and dose delivery. The first phantom holds a 3D-printed insert that mimics the variable PET tracer uptake in

heterogeneous tumors. The insert has an outer low-uptake volume encompassing a high-uptake inner volume. SUV ratio of 1:2 was intended. The second phantom accommodates applicators that can hold Farmer ion chamber in a location matching the center of the inner volume and in four locations matching the outer volume. 4D PET/CT scans of the phantom were acquired with three breathing wave forms of ideal sinusoid and two patient-specific breathing patterns fed to the moving platform. Patient-specific wavefronts were selected to represent a regular and an irregular breather. Two scenarios were investigated for image reconstruction, planning and delivery: a gate 30-70 window, and no gating. ITVs were delineated on the obtained 4D PET/CT scans and 21 VMAT-SIB treatment plans were generated with two fractionation regimens:

- Conventional fractionation: 2 Gy/fx to outer ITV, 2.4Gy/fx to high SUV inner ITV, 30 fx.
- Hypo-fractionation delivered in both flattening filter and flattening filter free (FFF) modes: 8 Gy/fx to outer ITV, 9 Gy/fx to inner ITV, 5 fx. Treatment plans were delivered in two gating scenarios: no gating and gate 30-70. Two ion chamber readings for the inner ITV, and two readings for one arbitrarily selected outer ITV were acquired. Measured doses in the inner ITV and the outer ITV were compared to planned doses.

Results: For both fractionation regimens and both delivery modes, measured doses in outer and inner ITV were between 93 and 99% of planned doses. Measured dose as compared to planned dose demonstrated independence from breathing pattern or gating window. In particular, measured doses in FFF mode were consistent with measured doses in filtered beam mode, 94-96% of planned dose.

Conclusion: The phantom has been validated for end-to-end use from 4D PET/CT scanning and radiotherapy planning, to dosimetric verification. Measured doses for SIB plans were in reasonable agreement for all three breathing patterns and for both gating windows and delivery modes.

Electronic Poster: Physics track: Inter-fraction motion management (excl. adaptive radiotherapy)

EP-1775

CBCT based prostate IGRT accuracy and PTV margins
C. Blay¹, A. Simon², E. Dardelet², R. Viard³, D. Gibon³, O. Acosta², P. Haigron², B. Dubray⁴, R. De Crevoisier¹

¹Centre Eugene Marquis, Radiotherapy, Rennes, France

²Rennes University 1, Campus de Beaulieu- LTSI, Rennes, France

³Aquilab, Aquilab, Lille, France

⁴Centre Henri Becquerel, Radiotherapy, Rouen, France

Purpose or Objective: *Purpose:* Image guided radiotherapy (IGRT) is the standard treatment of prostate cancer, widely based on Cone Beam CT (CBCT). The accuracy of CBCT based prostate registration is however not well established, conditioning the choice of the Planning Target Volume (PTV) margins. The goal of the study was to quantify the uncertainty of this registration and propose therefore appropriate margins.

Material and Methods: *Materials and methods:* A total of 306 prostate CT to CBCT alignments were analyzed in 28 prostate cancer patients treated by IGRT. The prostate was manually delineated on all the CBCT. Three prostate alignment modalities were afterwards simulated and compared, based on skin marks, on CBCT registration performed by the technologist at the fraction (IGRT) and on the prostate contours. The IGRT uncertainty (IU) was defined as the difference between the contour based and the CBCT alignments, in each space direction. Dice index (DI) were calculated. Margins were calculated, based on the IU and the Van Herk formula.

Results: *Results:* The mean (min;max) absolute values of the IU were, in mm: 1.5 (0;10), 0.7 (0;12) and 0.9 (0;7), in

antero-posterior (A/P), cranio-spinal (CS) and lateral directions, respectively. After IGRT alignment, 25 prostate (11% of cases) still projected partially out of the PTV, corresponding to an average prostate volume (min; max) of 2.3 cc (0.0;12.6). The mean + standard deviation of the DI were 0.84 + 0.08, 0.90 + 0.07 and 0.93 + 0.03 for the skin marks, CBCT and contours registration, respectively. For at least 95% of the IGRT registrations covering 100% of the prostate, the required A/P, CS and lateral PTV margins (mm) should be at least 4.5, 2.0 and 3.0, respectively. The Van Herk PTV margins (mm) were 5.5, 4.1 and 3.0 in the A/P, CS and lateral directions, respectively.

Conclusion: *Conclusions:* CBCT based prostate registration presents uncertainties requiring at least 3 to 5 mm PTV margins.

EP-1776

Assessment of setup uncertainties in modulated treatments for various tumour sites

E.S. Sandrini¹, L.R. Fairbanks¹, S.M. Carvalho¹, L.R. Belatini¹, H.A. Salmon¹, G.A. Pavan¹, L.P. Ribeiro¹

¹Grupo COI, Física Médica, Rio de Janeiro, Brazil

Purpose or Objective: The aim of this study was to analyse the patients setup errors for various tumor sites based on clinical data from modulated treatments using cone beam computed tomography (CBCT) image guidance and portal imaging for breast site. It was also calculated the planning target volume (PTV) margins of all disease sites and stipulated action level for online correction.

Material and Methods: The patients analyzed in this study were treated in our institution between January 2012 and December 2014 with VMAT and IMRT via flash technique for breast cancer. The various tumor sites were divided into six categories; 175 breast (1173 fractions); 53 thorax (475 fractions); 60 prostate (585 fractions); 100 H&N (858 fractions); 100 SNC (789 fractions) and 77 pelvis (620 fractions).

For every treatment fraction, it were acquired KV-CBCT images using the on-board imager (OBI) (Varian Medical Systems), and for breast cancer it were acquired MV portal images using the Electronic Portal Imaging Device (EPID) (Siemens AG) in the first week and twice per week. The registration procedure was performed for all treatments sites according to the tumor localization. For prostate site, it was also analyzed the physiological state of bladder and rectum. It were calculated the systematic (Σ) and random (σ) errors of couch shift obtained, and PTV margin ($2,5\Sigma + 0,7\sigma$).

Results: The Σ and σ for all treatment sites are summarized in table 1 as well PTV margins.

Table 1. The systematic and random errors and PTV margins

	Systematic Error (Σ)			Random Error (σ)		
	Lateral (mm)	Longitudinal (mm)	Vertical (mm)	Lateral (mm)	Longitudinal (mm)	Vertical (mm)
Breast	1.67	1.30	1.57	1.87	1.43	1.85
Thorax	2.15	2.45	1.66	3.33	3.84	3.44
Prostate	2.30	1.32	2.00	2.71	1.78	2.73
Prostate operated	1.94	1.39	1.97	2.89	2.31	2.66
H&N	1.22	1.18	1.25	1.94	1.94	2.07
SNC	1.00	1.27	0.85	1.47	1.56	1.19
Pelvis	1.71	2.16	2.28	3.75	2.72	3.65
PTV margins						
	Lateral (mm)		Longitudinal (mm)	Vertical (mm)		
Breast	5.47		4.25	5.22		
Thorax	7.70		8.82	6.56		
Prostate	7.66		4.54	6.90		
Prostate operated	6.87		5.10	6.79		
H&N	4.40		4.32	4.57		
SNC	3.52		4.28	2.95		
Pelvis	6.91		7.29	8.25		

The largest magnitude of Σ and σ for H&N was 1.94 mm, SNC was 1.56 mm, breast was 1.87 mm, thorax was 3.33 mm, pelvis was 3.75 mm and prostate was 2.89 mm. The PTV margins required are <4.5 mm for brain and H&N lesions, <5.5 mm for breast cancers, but range from 4.5 to 9 mm for thorax, prostate and pelvis lesions.

These values indicate the setup variations of each patient. The variations were smaller for the breast, SNC and H&N cohorts than the prostate, pelvis and thorax cohorts. The pelvis and breast cohorts showed the greatest variation in lateral direction and the prostate cohorts in vertical direction. The largest variation were presented in thorax cohorts in longitudinal direction and the lowest were in the SNC cohorts.

Conclusion: As the setup errors vary according to each immobilization systems, the analysis of each institution's specific setup errors is essential for determining the PTV margins. The results were also used to define action level for online correction.

EP-1777

MRT investigation of prostate and lymph nodes movements: implications on planning target volume?

U. Björelund¹

¹Sundsvalls Sjukhus, Sjukhusfysik, Sundsvall, Sweden

Purpose or Objective: The purpose of this project is to gather knowledge on the movement of pelvic lymph nodes relative to the prostate, seminal vesicles and bones in the pelvis and how this may affect the patient treatment plan.

Material and Methods: Until present, 10 patients have been included in the study. All patients have diagnosed prostate cancer and were treated with radiation therapy with curative intent. The patients followed the normal preparation and treatment procedure at our clinic - however, six additional MRI scans were acquired (baseline: before RT, on treatment day 1, 3, 5, 20 and 35) see figure. In each image set, several structures were delineated including fiducial markers, bony structures and lymph nodes. A radiologist identified lymph nodes along the common spread paths of prostate cancer. No suspected pathological nodes were found. Oncentra (Elekta) was used for image registration. Baseline images were defined as reference images and all other examinations were registered to the reference in two separate ways; bone matching and fiducial markers matching. For the bone matching, four structures were outlined; the disc between

S1-S2, head of the right and left femur and the pubic symphysis. For the fiducial marker matching, the three gold markers in the prostate were outlined. In both cases the images were manually matched. Lymph node, seminal vesicle and prostate movements and morphological change were evaluated in MATLAB. Lymph nodes were grouped into regions: para-aortic (PA), common iliac (CI), pre-sacral (PS), internal iliac (II), obturator (Obt), and external iliac (EI) lymph nodes.

Results: We found that prostate moves up to 10 mm in anterior-posterior direction and up to 5 mm in right-left and cranio-caudal directions relative to bony anatomy from baseline scan. The lymph node group with the largest movements in right-left direction were CI with up to 20 mm difference from baseline. In the anterior-posterior and cranio-caudal directions, the maximum movement was 9 mm relative to bone from baseline scan. For the lymph nodes in the EI and PS regions, a significant difference was found depending on whether bone or fiducial markers were used for registration in right-left or cranio-caudal directions. In the other cases, no statistically significant difference between bone matching and fiducial marker matching was found

Conclusion: Preliminary findings suggest that the pelvic lymph nodes are more mobile than expected, indicating the need to account for that in treatment planning. However, more patients need to be included in the study before a conclusion can be drawn on the implications on the treatment plan.

EP-1778

On the feasibility of performing a 3D-scan with your own smartphone

J. Pérez-Alija¹, P. Franco¹, E. Ambroa², S. Olivares¹, S. Loscos¹, A. Pedro¹

¹Hospital Plato, Oncología y Radioterapia, Barcelona, Spain

²Hospital General de Cataluña, Oncología y Radioterapia, Sant Cugat, Spain

Purpose or Objective: Optical 3D Surface Scanner (3D-OSS) is a simple and easily reproducible method for patient alignment, and is an accurate tool to show anatomical changes, for example, in breast locations. The aim of this study was to evaluate the feasibility of both achieving within a few minutes an 3D-OSS using a smartphone and creating an image fusion between this 3D-OSS and the CT scanner, in a simple, cheap and reliable way.

Material and Methods: A smartphone and a free commercial app (TRNIO, www.trnio.com) were used to create an 3D-OSS. This app takes a series of pictures of your object as you move your smartphone around it. After a scan is completed, a 3D model will be generated on your phone. This 3D map is available for downloading on the TRNIO website. Although there are several image reconstructing algorithms available, in order to first show the feasibility of the method described here we will be using the commercial app. In the meantime,

we are now ourselves developing an In-house software to do this. The RANDO Man Phantom (The Phantom Laboratories, Salem, New York) was used as a model. RANDO represents a 175cm tall and 73.5kg male figure. The phantom is constructed with a natural human skeleton which is cast inside soft tissue-simulating material. An image fusion was carried out between a RANDO OSS and a RANDO CT scan. A Body structure was created in our CT scan. In order to fusion it with the 3D-OSS we used MeshLab (a free processing system for 3D triangular meshes).

Results: Image fusion was successfully performed and the accuracy of it was measured both using predefined corresponding landmarks in the CT and visual confirmation. We performed this process for two locations on the phantom, Head & Neck and Body, and in both cases we got an accurate agreement.

Conclusion: This study was carried out using an existing commercial app in order to prove the feasibility of the method, using only a smartphone and free software. Therefore, we think it reasonable to believe that making your own 3D-OSS system could be done both in a simple and in a much cheaper way than the usually commercial alternatives available on the market.

EP-1779

Margins to compensate for deformity of the prostate/seminal vesicle in IGRT using fiducial-markers
Y. Hamamoto¹, N. Sodeoka¹, S. Tsuruoka¹, H. Inata¹, S. Nakayama¹, H. Takeda¹, T. Manabe¹

¹Saiseikai Imabari Hospital, Radiology, Ehime, Japan

Purpose or Objective: In external beam radiotherapy for prostate cancer, image-guidance using fiducial-markers decrease set-up error and inter-fractional organ-motion error. However, daily deformity and/or rotation of the prostate/seminal vesicle could not be adequately detected by the verification of fiducial-marker position alone. The purpose of this study was to know how many margins should be added to compensate for the daily deformity and/or rotation of the prostate/seminal vesicle in the image-guided radiotherapy using fiducial-markers.

Material and Methods: Three-hundred ten fractions of nine patients with prostate cancer were examined. Patient setup was performed according to the position of two intra-prostate fiducial-markers (first-stage). Thereafter, with considering deformity and/or rotation of the prostate/seminal vesicle, the patient position was moved to the best position to achieve an alignment of contours of the prostate/seminal vesicle on daily cone-beam CT and contours of the clinical target volumes delineated on treatment planning CT (second-stage). Distance of movement in the second-stage was measured.

Results: An alignment in the second-stage was needed in 47 fractions of 310 fractions (15.2%). In 43 fractions (13.9%), movement of 1 mm was needed only in antero-posterior (AP) direction. Movement of 2 mm in AP direction, movement of 1 mm in cranio-caudal (CC) direction, and movement of 1 mm in AP and CC directions were needed in two fractions (0.6%), in one fraction (0.3%), and in one fraction (0.3%), respectively. No fraction needed an alignment in left-right direction.

Conclusion: With regard to image-guided external beam radiotherapy based on intra-prostate fiducial-marker position, margins of 1-2 mm in AP direction are necessary to compensate for the daily deformity and/or rotation of the prostate/seminal vesicle.

EP-1780

Dosimetric impact of isocenter accuracy in CBCT-guided SRS treatment of vestibular schwannomas

J. Casals-Farran¹, J.F. Calvo-Ortega¹, S. Moragues-Femenia¹, M. Pozo-Massó¹, J. Fernández-Ibiza¹, E. Puertas-Calvo¹, C. Arias-Quiroz¹

¹Hospital Quiron Barcelona, Radiation Oncology, Barcelona, Spain

Purpose or Objective: Linac radiation isocenter describes a path while gantry and couch are rotating during the treatment delivery of typical non-coplanar SRS plans. The aim of this study is to investigate the dosimetric impact of this isocenter "wobble" in SRS of a vestibular schwannoma (VS), and to validate the PTV margin used in our clinical practice.

Material and Methods: Five VS cases were enrolled in this study. The PTV was generated in the Eclipse TPS by expanding the CTV by an isotropic 2 mm margin, according to our SRS policy. A SRS non-coplanar plan ("reference plan") was designed in the Eclipse TPS by using static gantry IMRT technique. Eleven beams (6 MV) from a Varian Clinac equipped with a 120 Millennium MLC were used. Dose of 12.5 Gy (100%) was prescribed to cover 99 % of PTV.

On the other hand, fifteen CBCT-guided end-to-end (E2E) tests using a skull phantom were performed. E2E test permits to quantify the radiation isocenter misalignments in the X (lateral), Y (anterior-posterior) and Z (superior-inferior) directions.

For each VS case, eight X-Y-Z shifts generated from "mean \pm 1.96 x SD" misalignments reported by E2E tests were simulated in the Eclipse TPS, resulting in eight "shifted plans". The following metrics were computed for each shifted plan and compared to the reference plan values: i) dose coverage of the CTV (D99%_CTV), ii) maximum dose to brainstem, iii) mean doses to cochlea, and iv) V10Gy, V5Gy and V2.5Gy of the brain (including the PTV).

Results: 1) Isocenter misalignments revealed by E2E tests were (mean \pm SD): -0.4 ± 0.7 mm, -0.2 ± 0.5 mm and 0.2 ± 0.4 mm, in the X, Y and Z directions, respectively. Gaussian behavior was observed for each direction ($p > 0.05$; Shapiro-Wilk test). The probability of having shifts ≥ 2 mm is less than 1% in Lat, AP, and SI directions.

2) Target coverage was assured in the shifted plans; D99%_CTV: $103.1\% \pm 5.8\%$.

3) Shifted plans vs. reference ones revealed not statistically differences ($p > 0.05$; Two-tailed Student t-test) in brainstem maximum dose (7.1 ± 3.0 Gy vs. 7.2 ± 3.1 Gy); cochlear mean dose (5.3 ± 4.1 Gy vs. 5.1 ± 4.4 Gy); V10Gy brain (2.3 ± 1.5 cm³ vs. 2.3 ± 1.6 cm³); V5Gy brain (8.6 ± 5.1 cm³ vs. 8.6 ± 5.8 cm³); and V2.5Gy brain (43.4 ± 26.7 cm³ vs. 43.5 ± 30.1 cm³).

Conclusion:

1) The radiation isocenter "wobble" did not increase significantly the doses to brainstem, cochlea and brain.

2) Our study demonstrated that the 2 mm PTV margin used in our clinical practice was adequate for SRS treatment of VS.

EP-1781

Dosimetric impact of CBCT isocenter misalignment on target dose coverage in cranial SRS

S. Moragues-Femenia¹, J.F. Calvo-Ortega¹, M. Pozo-Massó¹, J. Casals-Farran¹

¹Hospital Quirón Barcelona, Radiation Oncology, Barcelona, Spain

Purpose or Objective: Perfect (zero error) coincidence of CBCT and linac's isocenters is practically impossible to achieve in clinical practice, due to the presence of several geometric errors in the treatment unit. Our aim is to analyze the dosimetric impact of CBCT isocenter-linac isocenter misalignment on the target dose coverage and tumor control probability (TCP) in cranial SRS plans.

Material and Methods: A Varian Clinac 2100 CD was used. Misalignment of CBCT isocenter with respect to (w.r.t.) radiation linac isocenter was measured during 23 consecutive months. A 5 mm tungsten ball was centered at the room laser isocenter and MV portal images were acquired for four cardinal gantry angles (couch was at zero position). After portal image acquisition, CBCT scan was acquired.

All images were analyzed: (a) deviation of the radiation isocenter w.r.t the ball center was measured in each MV image using an in-house code; (b) deviation of the central voxel of the CBCT matrix ("CBCT isocenter") w.r.t. the ball center was measured in the Eclipse TPS. Finally, 3D misalignment of the CBCT isocenter w.r.t the linac isocenter was derived from (a) and (b).

To analyze the dosimetric impact of the CBCT isocenter misalignment, 10 cranial SRS cases were randomly selected from our database. For each case, the isocenter in the original plan ("reference plan") was shifted according to the misalignments obtained for CBCT isocenter. Eight X-Y-Z shifts generated from "mean \pm 1.96 x SD" of the measured CBCT isocenter misalignments were simulated for each SRS plan (i.e., 8 "shifted plans" were obtained for each SRS case). Target dose coverage (D99%) and TCP (estimated according to Radiat Oncol. 2015 Mar 8;10:63) were computed for each shifted plan and results were compared to the reference plan ones.

Results: i) Misalignments of CBCT isocenter w.r.t. radiation linac isocenter were (mean \pm SD, all in mm): 0.5 \pm 0.3; -0.3 \pm 0.2 and -0.6 \pm 0.3 for X (lateral), Y (anterior-posterior) and Z (inferior-superior) directions, respectively.

ii) Target dose coverage (D99%) was degraded from 100% to a mean value of 93% (range: 80% to 100%).

iii) The average loss of TCP was estimated to be about -5% (range: -18% to 0%) among the 80 shifted plans generated in this study.

Conclusion: Our simulations demonstrated that the reduction of target coverage and TCP due to CBCT isocenter misalignment w.r.t linac isocenter may be important. Our study shows clearly the need of add margin to the target to compensate for CBCT isocenter misalignment.

EP-1782

Effect of daily variation in rectal and bladder filling: an analysis of planned versus actual dose

A. Abhishek¹, T. Kataria¹, D. Gupta¹, T. Ghosh¹, T. Basu¹, S. Bisht¹, S. Goyal¹, M. Tayal¹, M. Ramu¹

¹Medanta The Medicity- Gurgaon- India, Radiation Oncology, Gurgaon, India

Purpose or Objective: In the era of Image guided radiotherapy (IGRT), ensuring accurate delivery of planned high dose is very important. Daily variations in organ volume may result in difference between planned and actual dose delivered to an organ. In the present study we planned to analyze the daily variations in bladder and rectal filling and its effect on actual dose delivered when compared with original planned dose.

Material and Methods: Five consecutive cases of carcinoma prostate, who recently concluded their IGRT, were selected

for the study. All cases were high risk prostate cancer, planned for radical IGRT for a dose of 50 Gy in 25 fractions to prostate and pelvic nodes, followed by Cyberknife boost for 3 fractions. Daily cone beam CT - XVI (X-ray volume imaging) acquired during daily treatments for each patient was exported to planning systems and after fusion with original planning CT, daily bladder and rectal contours were delineated on each 125 scans (B1-B25 and R1 - R25). Using superimposition of all new 250 contours on respective original plan, dose delivered daily to partial volumes of these organs was recorded using new actual DVH (dose volume histogram) and then statistically compared with their respective original bladder and rectal (B0 and R0) DVH using SPSS v18.

Results: Even with strict bladder and rectal protocols, daily volumes varied in all individual cases. The range of bladder volume variation (B1-B25) recorded for 5 cases were: 30.7%-211.1%, 26.9%-119.1%, 27.8%-107.2%, 15.4%-305.8% and 27% - 92.6% of B0, respectively. Overall actual mean volumes were within 25% variation range (mean actual 76% of B0). For rectum, R1-R25 volumes varied from 30.9%-205.9%, 47.5%-155.1%, 33.8%-150.2%, 44.6%- 208.1% and 43.4%- 140.2%. of R0, respectively. Overall mean actual rectal volume were very similar to original rectal volume (101.6% of R0). Overall actual bladder dose (D1-D25) was lesser than original bladder (D0) dose. Statistically significant lower actual mean dose (range 13 to 30%) was observed when recorded for 25cc to 85 cc of bladder volume (p<0.05). For lower volumes less than 20 cc, difference was not significant. For rectum, difference between delivered and planned dose was statistically non significant for any volume. A comparison of volume to dose data showed a difference in planned and mean actual V15, V20 and V25 for bladder and V5 to V30 for rectum, which was statistically significant (p< 0.05).

Conclusion: Strict bladder and rectal protocols both for simulation and delivery is important in planning pelvic radiotherapy due to physiological variations in their daily volumes. Exact duplication of bladder and rectal volumes is difficult, however by using image guidance and ensuring at least 25% concordance of daily with original planning volumes of these organs, possible differences in actual delivered dose can be mitigated and accurate delivery of planned dose can be ensured.

EP-1783

Translational and rotational set-up uncertainties in Head and Neck cancer treatments using CBCT

M. Di Biase¹, M. Trignani¹, G. Caponigro¹, A. Di Pilla¹, F. Perrotti¹, A. Augurio¹, S. Giancaterino², P. Bagalà², M.D. Falco², D. Genovesi¹

¹SS Annunziata Hospital, Radiotherapy, Chieti, Italy

²SS Annunziata Hospital, Medical Physic, Chieti, Italy

Purpose or Objective: The aim of this study was to assess setup errors, both translational and rotational, for head and neck (H&N) cancer patients treated with intensity-modulated radiotherapy (IMRT) and volumetric-modulated arc therapy (VMAT) using daily pretreatment CBCT imaging guidance.

Material and Methods: A total of 57 CBCTs referred to 7 patients treated with an Elekta Agility Linear Accelerator were analyzed. Patients were treated in a supine position; as immobilization system for head and shoulder a thermoplastic fixation mask was used. Tattoos on the surface mask were placed on the laser projection. Axial CT-planning slices at 5 mm intervals were acquired and reconstructed at 2 mm. Image data set were sent to the Oncentra Masterplan Planning System. Planning CT was also sent via DICOM to XVI software for the co-registration with the CBCT scan. For the CBCT acquisition we used the "fast head and neck S20". The 3D-3D co-registration with the CT planning scan was performed using the Grey level algorithm. Translations were measured in medio-lateral (x), supero-inferior (y) and antero-posterior (z) directions, as well as in rotation around axes. Online correction for translational displacements were applied, on the basis of literature data, when the discrepancy exceeded 3 mm. Rotation corrections were recorded with a

cut-off of $\leq 3^\circ$; for rotations $>3^\circ$, patients were repositioned. Our protocol consisted of 5 consecutively CBCTs scans for the first week of treatment and 1 CBCT weekly during radiation therapy course. For each patient, mean translational displacements were off-line calculated on CBCT acquired during the first 5 fractions; these values were considered as systematic set-up errors and the corresponding displacements were then corrected if they exceeded 3 mm. Mean (M), median (MD), standard deviation (SD) and range of the displacements related to first 5 CBCTs scans and those corresponding to the all following CBCTs scans were calculated. Wilcoxon test was performed to evaluate statistically significant differences between the displacements related to the first week of treatment with those related to the remaining weeks.

Results: The M, MD, range and SD values are shown in Table 1.

	Median (°)		-0.60
	1 st quartile (°)		-1.20
	3 rd quartile (°)		-0.20
y	Mean (°)		-0.28 ± 1.09
	Range (°)		-4.00 to 2.30
	Median (°)		-0.10
	1 st quartile (°)		-0.90
	3 rd quartile (°)		0.90
z	Mean (°)		-0.60 ± 0.75
	Range (°)		-2.90 to 0.80
	Median (°)		-0.50
	1 st quartile (°)		-1.15
	3 rd quartile (°)		0.00

Based on this table, all translational values were <3 mm and within 2 mm for all CBCTs and the rotations were $<3^\circ$ and within 2° . Moreover, the Wilcoxon test showed none statistically significant correlation between the M calculated during first five fractions and the following CBCTs scans.

Conclusion: In our study, we have analyzed translational and rotational set-up uncertainties in Head and Neck cancer treatments using CBCT. We found that all the displacements were within 2 mm and 2° , well below the offset established (3 mm and 3° respectively). In the future we intend to reduce the margin from CTV to PTV considering the accuracy of our set-up.

EP-1784

Effect of body mass index on setup errors in patients treated with pelvic image guided radiotherapy
 O. Ozdemir¹, Z. Alicikus¹, T. Yagibasan¹, I.B. Gorken¹
¹Dokuz Eylul Univ. Health Sciences Institute, Radiation Oncology, Izmir, Turkey

Purpose or Objective: To retrospectively evaluate the effect of body mass index (BMI) on set-up errors in patients treated with image guided radiotherapy (IGRT) for pelvic malignancies. Additionally, based on these findings, we intended to determine optimal PTV margins in pelvic IGRT for patients with similar BMI values

Material and Methods: The data from 73 patients who received pelvic IGRT between March 2014 and February 2015 were analyzed. BMI of each patient were calculated and patients were grouped as underweight (<18.5), normal weight (18.5-24.9), overweight (25-29.9) and obese (≥ 30) according to National Institutes of Health classification. According to World Health Organization criteria, patients whose ages ≥ 65 were evaluated as elderly. All patients received pelvic volumetric modulated arc therapy with Varian Truebeam STx @ linear accelerator. Before each treatment, orthogonal kV and CBCT images were taken and matched with bony anatomy and soft tissues respectively. The requisite couch shifts were made with online procedure and mean absolute shifts of X, Y, Z, 3D vectorial (V) axes for each imaging modality were obtained. Non-parametric tests were used for statistical analyses. Estimated CTV to PTV

margins for set-up uncertainties calculated separately for each group by using "Van Herk formula"

Results: The median age was 65 (36-86) and 70% were male. Totally 513 CBCT and 2064 kV images were evaluated. Mean absolute shifts in X, Y, Z, V axes with kV imaging were 3.39, 2.58, 2.85, 6.11 mm while with CBCT imaging 3.47, 2.90, 3.22, 6.54 mm, respectively. According to BMI groups; mean absolute shifts in X, Y, Z, V axes with kV imaging were 2.82, 2.67, 2.73, 5.54 mm for BMI <25 ; 3.57, 2.28, 2.81, 6.16 mm for BMI 25-29.9; 3.78, 3.14, 3.12, 6.82 mm for BMI ≥ 30 while with CBCT imaging 3.16, 2.87, 2.82, 6.01 mm for BMI <25 ; 3.65, 2.92, 3.34, 6.74 mm for BMI 25-29.9; 3.49, 2.89, 3.51, 6.81 mm for BMI ≥ 30 respectively. Between BMI groups, only V axis shifts in kV imaging were statistically different (p:0.039). This difference is explained by sex distribution differences in BMI groups and significantly higher obese group ratio in females (p:0.002). In females mean shifts in all axes were greater than males (p<0.05). Absolute shifts in V axis with CBCT imaging were statistically different between age groups and were significantly greater for 65 age group (p:0.041). In all patients, depending on absolute shift data; estimated CTV to PTV margins in X, Y, Z, V axes with kV imaging were 4.29, 3.99, 4.52, 5.62 mm; with CBCT imaging 4.71, 5.24, 4.93, 6.80 mm respectively

Conclusion: In our study we did not find any statistically significant difference in none of the axes between absolute shifts according to BMI groups. However; because of greater shifts observed in females and 65 age group, more attention is needed in this group of patients' set-ups and PTV margins for these groups in planning process must evaluated more detailed

EP-1785

Comparison of setup errors and comfort levels of two immobilisation systems for head and neck cancer
 P. Damodara Kumaran¹, S. John², R. Isiah², S. Das²
¹All India Institute Of Medical Sciences, Department Of Radiation Oncology, Delhi, India
²Christian Medical College, Radiation Oncology, Vellore, India

Purpose or Objective: This is a Prospective observational study. This study aims to quantify and compare the systematic and random error in two types of immobilization devices namely five point ray cast and BrainLAB immobilization system. This study also looks at the effect of weight loss on the setup error and patients comfort grade in both the immobilization devices. All patients of Head and Neck malignancy planned with Intensity Modulated Radiotherapy [IMRT] were assigned either a five point ray cast or BrainLAB ray immobilization as fixation device.

Material and Methods: Patient diagnosed to have head and neck malignancy were assigned to either of the group and prospectively analysed the displacement errors. In both the groups, systematic and random errors were analysed. The CTV-PTV margin was calculated using Van Herks formula and compared. The upper neck and lower bony neck points were also analysed in terms of systematic error, random error and CTV-PTV margin. All the patients were serially monitored with weekly weight and its impact was analysed on the setup errors and margins. Patients' comfort level was analysed at the completion of treatment in both the immobilization devices.

Results: The five point ray cast and BrainLAB immobilization was found to be similar in terms of systematic errors and random errors, except in the anterior-posterior [AP] and medial-lateral axis [ML]. BrainLAB showed significant less margin in ML axis [3.61 Vs 3.14 mm, p=0.0005] and in AP axis [3.33 Vs 2.66 mm, p=0.0001] The total margin required was similar in both the groups. The margin requirement in the upper neck fields was marginally better in the BrianLAB system than the five point ray cast. Weight loss of more than 3kg required more margins, but was not statistically significant. Comfort levels were same in both the groups.

Conclusion: The total CTV-PTV margin requirement for five point ray cast and BrainLAB immobilization is less than 5mm in all three directions. In patients requiring only upper neck irradiation BrainLAB system is recommended. Overall Five point ray cast and BrainLAB immobilization was comparable in terms of setup errors, margins and comfort levels.

EP-1786

Rectal distension impact on prostate CBCT-based positioning assessed with 6 degrees of freedom couch
J. Charret¹, J. Salleron², M. Quivrin³, F. Mazoyer³, E. Martin³, D. Peiffert², G. Créhange³

¹Institut de Cancerologie de Lorraine, Radiothérapie, Nancy, France

²Institut de Cancerologie de Lorraine, Biostatistique, Nancy, France

³Centre Georges Francois Leclerc, Radiothérapie, Dijon, France

Purpose or Objective: The prostate requires a daily correction of its position in relation with rectal distension. With 6 degrees of freedom (DOF) couch, it is possible to correct the pitch and the roll. In this study, we sought to determine whether rectal distension might have an impact on any of these prostate translations and/or rotations during a protracted course of external beam radiation therapy for a localized prostate cancer

Material and Methods: The data from 15 patients with localized prostate cancer patients treated with 6 DOF couch in a single institution. Before each fraction, a CBCT was performed. The automatic fusion algorithm was set to fuse on soft tissue and it allowed correction for translations in three dimensions and rotation in the transverse plane ("roll") and axial plane ("pitch"). The rectum was contoured on each CBCT by one radiation oncologist. We determine the Cross Sectional Area (CSA) and relative CSA (CSArel) by dividing with the CSA of planning CT. The median was used to classify the patients in two groups: patients with a stable CSA and patients with an unstable CSA. The CSArel was compared between these two groups with a linear mixed model with group as fixed effect and patient as random effect

Results: Two hundred and ninety seven kV-CBCT were analyzed. Seven patients had a small and stable rectum : CSArel (1.07±0.09). The other eight patients had an unstable rectum: CSArel (1.37±0.07). The average pitch in the group with a stable rectum was 0.73° (+/-0.32) versus 0.04° (+/-0.28) (p=0.112). The pitch was not correlated with the CSA rel (p=0.477, r=0.041). The average roll in the group with a stable rectum was 0.14° (+/-0.27) versus 0.03° (+/-0.25) (p=0.781). The roll was not correlated with the CSA (p=0.279, r=0.063). The average CSArel was higher and more variable in the unstable group (p=0.009) and (p=0.024) respectively

Conclusion: Rectal distension had neither impact on the pitch nor on the roll, which suggest that a 6 DOF couch have little interest in daily practice for prostate IGRT

EP-1787

View of interest of automatic registration for CBCT localisation of head and neck cancer

C. Draulans¹, J. Meyskens¹, K. Geboers¹, S. Gysbrechts², I. Scheelen², M. Martens¹

¹AZ Turnhout, Radiation Oncology, Turnhout, Belgium

²AZ Turnhout, Radiation Oncology Physics, Turnhout, Belgium

Purpose or Objective: Use of IMRT in patients with head and neck carcinoma may lead to over- or underdosage of OAR and CTV due to changes in patients anatomy. CBCT is a valuable tool for patient setup verification and monitoring of dosimetric variation during radiotherapy. We evaluated the dependence of an automatic registration process on the size of a user defined view of interest (VOI). We compared these results with the manual registration defined by a physician, defined as gold standard.

Material and Methods: We retrospectively reviewed the records of 36 consecutive patients (107 fractions) with head and neck cancer who received radiation therapy between January 2015 and September 2015 at the Hospital of Turnhout. Three CBCT images at well-defined time points (start-, mid- and end-treatment) of each patient were matched to a reference CT image using the Siemens Syngo RT Therapist version R 4.3. Images were acquired with MVision™ (6 MV photon beam tuned for imaging). Auto global registration is the automatic alignment of planning and treatment images using voxel based registration. Manual VOI function allows restricting the voxel based automatic registration to a user defined region. Registrations were performed with 2 VOI sizes (large (VOI = whole CBCT) and small (VOI = delineated CTV + body of adjacent vertebra)). Automatic registrations (AR) were compared with a manual registration (MR) made by a physician. It was only possible to make translational corrections in the vertical, longitudinal and lateral direction. To quantify overall distance between gold standard and automatic registration, the 3D-difference (d) was calculated:

$$d = \sqrt{((AR - MR)^2_{\text{lateral}} + (AR - MR)^2_{\text{longitudinal}} + (AR - MR)^2_{\text{vertical}})}$$

Results: The CBCT images of 107 fractions were analysed. Automatic registration results depend on the volume of VOI (large or small). A paired t-test calculated the mean 3D difference for the automatic registrations with small VOI was significantly smaller (p < 0.001) than the mean value for automatic registrations using the large VOI. 3D differences were divided in multiple ranges. Small VOI resulted in differences ≤ 2 mm between automatic registration and radiation oncologist registration in 56,1% of the cases. When using large VOI, it resulted in differences ≤ 2 mm in 6.5% of the cases. Compared with radiation oncologist registration, small VOI resulted in differences > 6 mm in 5.6% of the cases. Large VOI resulted in differences > 6 mm in 24.3% of the cases.

Table 1: Summary showing 3D differences (mm) between automatic registration (large VOI and small VOI) and manual registration by a radiation oncologist

	Large VOI	Small VOI
Mean (standard deviation)	4.88 mm (2.14)	2.36 mm (1.93)
Median	4.58 mm	2.00 mm
Maximum	10.36 mm	11.36 mm
d = 0-2 mm	6.54 %	56.07 %
d = 2-4 mm	31.78 %	30.84 %
d = 4-6 mm	37.38 %	7.48 %
d > 6 mm	24.30 %	5.61 %

Conclusion: Automatic registrations can produce results which are comparable to manual registrations by radiation oncologist. Registration parameters for CBCT affect differences between automatic and manual registration although patients wear a plastic mask during radiation therapy. Using a small VOI (delineated CTV + body of adjacent vertebra) results in small differences between automatic and manual registration. If large VOI is used it can result in differences > 6 mm in more than 20% of the cases.

EP-1788

Accurate and stable immobilisation with Lorca Marin masks for head and neck IMRT verified by IGRT

I. Prieto¹, D. Esteban¹, A. Ilundain¹, E. Marquez¹, J. Olivera¹, J. Luna¹, J. Vara¹, W. Vasquez¹, A. Perez¹

¹Fundación Jimenez Díaz, Radiation Oncology, Madrid, Spain

Purpose or Objective: IMRT needs accurate and repeatedly image controls to verify online the patient position and check that the tumor is properly included. The aim of this work is to analyze the setup accuracy and stability resulting from the use of the Lorca Marin thermoplastic masks during the complete course in head and neck cancer treatment with intensity modulated techniques.

Material and Methods: 50 consecutive head and neck cancer treatments with IMRT were analyzed. Lorca Marin customized masks named *Nature* were used to immobilize head and neck. These 2-oxepanone polymer thermoplastic masks are 3-points immobilization with frontal and mental reinforcement and 3.2 mm thickness. 3-standard references were marked on the surface of the mask and on the middle chest of the patient for accurate positioning every day. Cone-beam computed tomography scan to verify online the position was performed during 5 consecutive days and after, weekly cone-beam (CBCT) until the end of the treatment. After weekly matching process using automated soft-tissue registration, translational movements along the three axes (x, y, z) were collected and the average for each treatment and each axis was calculated. Displacement's mean of the 50 averages and the standard deviations were analyzed and compared.

Results: The resulting displacement average after analyzing 50 treatments was less than 1 mm along the three axes: $x = (0.62 \pm 0.51)$ mm, $y = (0.83 \pm 0.63)$ mm, $z = (0.65 \pm 0.59)$ mm. These setup displacements have remained under 3 mm in 100% of treatments. These results achieve the International Commission on Radiation Units and Measurements recommendations regarding the setup margin to compensate the immobilization and positioning errors.

Conclusion: The type of patient immobilization devices and their contribution in the setup errors must be taken into account for IMRT. Additionally, the use of different image-guidance systems can significantly alter the size of the required margins. Lorca Marin thermoplastics masks with weekly CBCT show enough accuracy and stability for IMRT head and neck cancer patients.

EP-1789

Immobilization and dosimetric performance of a MRI compatible frame for head and neck patients

A. Perez-Rozos¹, I. Jerez Sainz¹, M. Toledo², M. Lobato Muñoz¹, J. Medina Carmona²

¹Hospital Virgen de la Victoria, Radiation Oncology. Medical Physics., Malaga, Spain

²Hospital Virgen de la Victoria, Radiation Oncology. Radiation Oncology, Malaga, Spain

Purpose or Objective: Use of CT/RMI image registration for Head&Neck cancers is challenging because of the difficult to maintain the same position in simulation CT and in MRI system. A number of immobilization devices used in radiotherapy are not appropriate for use in MRI because of compatibility problems with the materials or with the acquisition coils. A novel head and neck board, fully compatible with Head and neck MRI coils (ExaFrame, Anatge(R)), has been presented and in this work we analyse setup accuracy of both conventional and MRI compatible board.

Material and Methods: Attenuation measurements were done using a diode array (MapCheck2, SunNuclear) inside water equivalent phantom and 6MV photons (TPR20,10=0.685, Elekta Synergy) for orthogonal beams. Attenuation is evaluated in the area of mask fixation and in body area of frame. Five consecutive patients with head and neck tumors were assigned to simulation with MRI compatible frame using head and shoulder mask with four fixation points. Immobilization and reproducibility is improved using a customized silicone mold between patient's nose bridge and mask. Reproducibility Every treatment day CBCT images were acquired for treatment isocenter, and shifts in patient position were automatically measured using simulation CT as reference (xvi, Elekta). Displacements in antero-posterior (Vert), cranio-caudal (Long) and medio-lateral (Lat) directions, and rotations about major axis were calculated and compared with conventional carbon fiber immobilization. A total of 150 CBCT images were acquired for CompMRI frame. A group of 30 patients with conventional board was used as control (900 CBCT images). Distribution of displacements, rotation and 3D displacements were compared between both groups.

Results: Attenuation measurement is shown in the image, and is lower than 4% for orthogonal incidence. No artifacts on MRI image were observed. Reproducibility between MRI and CT simulation was better than 1 mm in all cases studied, based in direct versus automatic registration. The mean and standard deviation of shifts for the CompMRI board versus conventional board are shown in table 1. An analysis of variance differences using a Fisher test gives statistically significant differences between variances of two groups ($p < 0.01$). The distributions of the absolute displacements were similar in both groups.

	Lat (mm)	Vert (mm)	Long (mm)	Roll (°)	Tilt (°)	Pitch (°)
C-MRI	0.8 ± 0.6	-0.3 ± 0.9	-1.5 ± 1.2	-0.7 ± 0.7	-0.1 ± 0.5	-0.1 ± 0.3
Conventional	0.8 ± 2.7	-1.7 ± 3.9	-1.0 ± 3.2	-0.4 ± 1.2	0.1 ± 1.2	-0.2 ± 1.0

Conclusion: Our data show that the C-MRI board have low attenuation and a better immobilization and reproducibility than the conventional board. Position reproducibility from MRI simulation and CT simulation was excellent. Combination of MRI compatible board with silicone fixation provided robust immobilization and can be safely used for MRI-CT registration procedures eliminating the use of deformable and complex software algorithms. These data could be used for a potential reduction of margins for the PTV.

EP-1790

Assessment of Uterine Fundus Coverage with IGRT using daily CBCT in cervical cancer

Z. Ozen¹, N. Kayalilar¹, A. Arifoglu¹, B. Günhan¹, R. Ibrahimov¹, F. Karaköse¹, S. Gurdalli¹, M.U. Abacıoglu¹

¹Neolife Medical Centre, Radiation Oncology, Istanbul, Turkey

Purpose or Objective: Inclusion of uterine fundus in the pelvic CTV for definitive treatment of cervical cancer is controversial. We aimed to demonstrate the fundus coverage by using daily CBCT with a rigorous bladder filling protocol.

Material and Methods: Five patients with cervical cancer without uterine fundus involvement were scanned by 2.5 mm slice thickness CT after a 30 minute, 500 cc water consumption. PET/CT and MR fusion was performed to delineate GTV and used as surrogates to see the potential motion of uterus at different imaging modalities due to bladder and rectal fillings. CTV1 was contoured to include GTV+cervix+uterus modified to be covered in simulation CT, PET/CT and MR. PTV margin of 15 mm was added according to guidelines. VMAT IMRT plans were performed to give 45 Gy in 25 fractions. Image guidance with daily kV CBCT was performed on TrueBeam STx and Trilogy linacs (Varian, Palo Alto) throughout the external phase of the treatment, which was followed by HDR brachytherapy. When the CTV1 was missed on CBCT, the bladder filling was modified accordingly; CBCT was repeated and treated after ensuring the coverage.

Results: Uterine fundus was contoured on a total of 125 CBCT images of 5 patients. Overall on 24 of 125 fractions (19.2%) CTV1 was out of PTV. Mean volume of CTV1 out of PTV was 0.92 cc (range 0.02-2.78 cc). Mean Dmin for fundus was 133 cGy when the CTV1 was out of PTV, while it was 176 cGy when CTV1 was covered on CBCT.

Conclusion: Although the inclusion of the uterine fundus in the CTV for the definitive treatment of cervical cancer without fundus involvement is controversial, potential microscopic spread is a concern. Rigorous bladder filling is a way to minimize the interfraction motion of the uterus,

however daily image guidance with CBCT still showed a residual replacement of the uterus in up to one fifth of the fractions in this study. Further studies on managing this problem like adaptive treatment by using plan of the day concept to cover the CTV are ongoing.

EP-1791

Improving patient posture reproducibility by using the predicted couch position and tight tolerances

L.J. Mesch¹, W.J.M. De Kruijf²

¹Institute Verbeeten, Radiation Therapy, Tilburg, The Netherlands

²Institute Verbeeten, Medical Physics & Instrumentation, Tilburg, The Netherlands

Purpose or Objective: With online imaging inter-fraction motion is very small. However, when a patient is wrongly positioned on an immobilisation device, the patient posture cannot be corrected with a simple couch shift or rotation. The couch position indicates the accuracy with which the patient is positioned with respect to the immobilisation device on a day-by-day basis. The purpose of this work is to improve patient posture reproducibility by predicting the couch position before the first treatment (preventing a systematic error in couch position), and by using this couch position at the LINAC more directly than only for verification purposes.

Material and Methods: All patients with a planning-CT are treated with an immobilisation device attached to the treatment couch. A software tool, "planinfo", predicts the couch position from the geometrical information of the planning-CT in the EPD and the isocentre coordinates in the treatment plan. Before the treatment session the couch is positioned at the predicted couch position of the patient set-up point, given in the set-up notes. The patient is instructed to move until the lasers align with the patient tattoos. We do not need to have the lasers exactly on the tattoos, because we perform an online imaging procedure. Patient rotations with respect to the lasers are to be avoided. Next, the couch is shifted to the isocentre, an online imaging procedure is performed and the patient is treated. We do not use the couch position at the first treatment fraction as a reference, preventing systematic errors in couch position.

Results: Table 1 shows the tolerances that we use for the 5 immobilization devices, the average difference between the predicted and the treated couch position in the first half of 2015 and the standard deviation of the differences for all treatment fractions in this period. These values are better than the couch position values reported by others in literature, because we do not shift the couch to align the patient with the lasers, but we shift the patient in the immobilization device to achieve this. Radiation therapists indicate that it is more straightforward to position the patient with this method. For head and neck the values are comparable with literature [2,3], because the masks more rigidly relate the patient position to the couch than other immobilization devices. However, with our method we do not need to mark any lines or points on the immobilisation mask. Table 1 also shows the number of overrides with our current tolerance tables. This is about 1 % of all treatment fractions. For palliative treatments with its own immobilization device (home-made head base with a cushion) it is about 5 %.

Table 1: Comparison of the difference in predicted and treated couch position for the first half of 2015.

Immobilization	Fractions	Override percentage	Direction	Tolerance (mm)	Average (mm)	Standard deviation (mm)
Head and Neck	3389	0.9 %	Vertical	10	0.0	2.1
			Longitudinal	10	2.2	2.8
			Lateral	10	1.3	3.1
Thorax	6062	1.0 %	Vertical	10	1.1	2.8
			Longitudinal	15	-1.0	5.7
			Lateral	15	-0.2	4.6
Mamma	8529	0.4 %	Vertical	10	0.2	3.4
			Longitudinal	15	0.1	4.3
			Lateral	15	-0.6	4.1
Pelvis	7766	1.2 %	Vertical	10	1.1	3.7
			Longitudinal	15	-1.5	4.3
			Lateral	15	-0.3	5.1
Palliative	766	5.9 %	Vertical	10	0.5	2.5
			Longitudinal	15	-0.1	6.2
			Lateral	15	-0.9	6.6

Conclusion: We have improved the patient setup considerably. Currently, all patients with a planning-CT are treated according to the method described above. We use tight tolerances to ensure patient posture reproducibility.

EP-1792

Pre-fraction shift and intra-fraction drift of the prostate due to perineal ultrasound probe pressure

H. Ballhausen¹, F. Manapov¹, A. Kolberg¹, P.D. Thum¹, U. Ganswindt¹, C. Belka¹, M. Li¹

¹Ludwig-Maximilians-Universität München, Department of Radiation Oncology, München, Germany

Purpose or Objective: In image guided radiotherapy of the prostate, during trans-abdominal ultrasound imaging, the pressure applied by the ultrasound probe against the abdomen has been shown to displace the prostate. In this study trans-perineal imaging is evaluated. The impact of varying probe pressure on pre-fraction shift and intra-fraction drift of the prostate is measured.

Material and Methods: Two separate experiments were performed: Before treatment (10 patients) varying ultrasound pressure was applied to the perineum. In a series of scans, the probe was moved against the perineum and the corresponding shifts of the prostate were detected. Linear regression was performed. During treatment (15 patients, 273 fractions) intra-fraction drift of the prostate was tracked (total of 27 hours and 24 minutes).

Results: Per 1 mm shift of the ultrasound probe in cranial direction, a displacement of the prostate by 0.42 ± 0.09 mm in cranial direction was detected. The relationship was found to be linear ($R^2=0.97$) and highly significant ($p<0.0001$). After initial contact of the probe and the perineum (no pressure) a shift of the probe of about 5 to 10 mm was typically necessary to achieve good image quality, corresponding to a shift of the prostate of about 2 to 4 mm in cranial direction. There was found also a systematic ($p=0.03$) shift of <0.1 mm in anterior direction, but not significant shift in lateral direction ($p=0.14$). The compression of the tissue between probe and prostate was well visible in consequent scans. During treatment, the prostate was drifting at a rate of -0.075 mm per minute in cranial direction on average. While small, this systematic trend on the longitudinal axis was significant ($p=0.0014$). There was no significant trend on neither the lateral nor the vertical axis ($p=0.62$ resp. $p=0.19$). Also, due to the perineal probe, the prostate had fewer degrees of freedom in caudal direction.

Conclusion: The pressure applied by a perineal ultrasound probe has a quantitatively similar impact on prostate displacement as trans-abdominal imaging. Shifts are predominantly in cranial direction (typically 2 to 4 mm) with some component in anterior direction (typically <1 mm). Slight probe pressure can improve image quality, but excessive probe pressure can distort the surrounding anatomy and potentially move risk organs closer to the high dose area. Tentatively, probe pressure could also have beneficial effects in stabilizing the prostate.

EP-1793

Analysis of setup error in patients affected by oropharyngeal cancer treated with tomotherapy

P. Bonomo¹, L. Marrazzo², G. Carta¹, M.H. Baki¹, C. Talamonti², C. Arilli², F. Paia¹, I. Desideri¹, G. Simontacchi¹, S. Scocianti¹, D. Greto¹, S. Pallotta², L. Livi¹

¹University of Florence, Radiation Oncology, Firenze, Italy

²University of Florence, Medical Physics, Firenze, Italy

Purpose or Objective: In head and neck cancer radiotherapy, it is still unresolved whether the use of daily image guidance (IG) allows the safe adoption of reduced PTV margins. Moreover, the extended time required for IG on a daily basis unavoidably represents a limiting factor for patients throughout in centers with busy workload. The purpose of our analysis is: 1) evaluating the interfraction error of patients undergoing tomotherapy for oropharyngeal cancer (OPC) with the aim of margins reduction and 2) investigating whether the mean error calculated on the first 5 fractions may avoid the need of performing IG on a daily basis.

Material and Methods: A cohort of 20 OPC patients radically treated with tomotherapy was retrospectively analyzed. Conventionally, a 5-mm CTV to PTV margin policy was used. All patients underwent integrated mega-voltage computed tomography (MVCT) before every fraction and were treated after correction of shifts in the medial-lateral (X), supero-inferior (Y), and antero-posterior (Z) directions, as well as in the medial-lateral rotation (roll). These “on-line” variations were registered for every patient. In order to test the reproducibility of the procedure, for a subset of 10 patients (for a total of 301 MVCT’s) a “re-matching” was performed: shifts adopted at time of treatment were reset and a manual re-alignment was then blindly performed. Mean values and standard deviations were calculated and compared for the two sets of data. To test the hypothesis of the applicability of a mean-error strategy, the mean shifts calculated on the first 5 fractions were applied on the subsequent fractions and the mean residual error was evaluated.

Results: A total of 619 MVCT’s was analyzed. The mean X, Y, Z and roll errors for the 20 analyzed patients are reported in Figure 1.

Figure 1. Mean value of the setup errors (x, y, z, roll) for the 20 patients in the study.

The mean of the absolute X, Y, Z and roll errors were 1,8 mm, 3,4 mm, 2,4 mm, and 0,5° respectively. The mean “off-line” shifts were very similar to the “on-line” ones (as shown in Table 1).

	On-line matching				Off-line matching			
	x	y	z	roll	x	y	z	roll
	-1,4	0,3	0,2	0,4	-1,8	0,3	0,0	0,6
	0,8	0,3	-0,8	-0,4	1,2	0,7	-2,2	-1,1
	-1,7	-1,3	-0,1	0,4	-1,7	-1,0	-1,1	1,0
	1,5	0,6	2,5	-0,1	1,2	0,5	3,2	0,0
	0,8	0,5	0,3	0,0	1,7	0,7	1,0	0,0
	0,7	-1,7	1,0	0,3	0,7	-2,2	1,0	0,7
	1,7	1,4	1,8	0,0	1,8	2,2	2,2	0,2
	2,5	-0,3	0,0	0,2	2,4	0,0	0,9	-0,1
	0,9	-1,3	3,7	0,5	1,2	-0,8	3,9	0,7
	1,8	-0,9	1,0	-0,3	2,2	-1,3	1,1	-0,4
mean ± s	0,8±1,3	-0,2±1,0	1,0±1,4	0,1±0,3	0,9±1,5	-0,1±1,3	1,0±1,8	0,1±0,7

Table 1. Comparison between the on-line and off-line matching for 10 patients.

The equivalence between the “on-line” and “off-line” shifts was extremely high (Pearson’s correlation coefficient, $p < 0.05$), therefore further validating the integrity of the data. For the majority of patients the random component of the setup error was predominant, so the mean error strategy was not effective in reducing the setup error. Only in 5 cases

a clear systematic component in the setup error was identified, which was effectively reduced with the application of the mean shifts.

Conclusion: The use of a reduced 3-mm PTV expansion margin can be safely implemented in the context of daily IG in OPC. On the other hand, in cases where a clear systematic component of the setup error is detected, the strategy of correcting for the mean error derived from the first 5 MVCT’s is efficient in reducing residual setup errors, possibly allowing the adoption of a non-daily IG policy in these cases.

EP-1794

Quantification of stomach movement using CBCT images
R. Carrington¹, E. Spezi², B. Thomas³, S. Gwynne⁴, T. Crosby³, J. Staffurth⁵

¹Velindre Cancer Centre, Medical Physics, Cardiff, United Kingdom

²Cardiff University, School of Engineering, Cardiff, United Kingdom

³Velindre Cancer Centre, Clinical Oncology, Cardiff, United Kingdom

⁴Singleton Hospital, Clinical Oncology, Swansea, United Kingdom

⁵Cardiff University, Institute of Cancer and Genetics, Cardiff, United Kingdom

Purpose or Objective: We have shown a significant increase in predicted stomach toxicity when dose escalating from 50Gy to 60Gy in lower oesophageal tumours (1). The modelling was conducted on a single planning CT image, however the stomach undergoes continual volume and position changes during radiotherapy (2). Thus, the received dose by the stomach deviates from the planned dose. Previous work has used endoscopically placed clips and fluoroscopy to analyse movement (3) & (4). To the authors’ best knowledge, this study is the first to quantify the stomach’s movement and volume change during radiotherapy using Cone Beam Computed Tomography (CBCT) images.

Material and Methods: The stomach volume was outlined on the planning CT and 4 CBCT images taken over the course of treatment (first 3 fractions then once weekly) for 4 patients. Image registration between the planning CT and CBCTs was undertaken using the Velocity software package, with the quantification analysis of stomach movement and volume change being carried out in the CERR software environment using in-house Matlab scripts. The difference in maximum and minimum x,y,z, coordinates, change in centre of mass (COM) and total volume between each CBCT image and planning image for the stomach volume and PTV/stomach volume overlap was calculated.

Results: The mean and range of displacement across all image sets and patients for the maximum and minimum x,y,z coordinates of the stomach was 5.4mm (0.0-23.4), 6.7mm (0.0-36.1) and 10.5mm (0.0-42.0), respectively. The mean and range of displacement for the COM x,y,z coordinates across all image sets was 4.0mm (7.0-14.6), 3.3mm (1.0-11.7) and 8.7mm (1.0-31.4) respectively. The mean change in total stomach volume was 22.2% (0.4-64.5), whilst the mean change in PTV/stomach volume overlap was 25.8% (2.1-74.9) between the CBCT and planning CT images across all patients.

Conclusion: This study has shown that the position and volume of the stomach of a patient over the course of treatment is highly variable. In order to minimise the risk of toxicity of the stomach during treatment using high dose regimes (>50Gy) a stomach filling protocol may be required. Further work with a larger patient dataset is ongoing and the feasibility of stomach filling protocols will be explored.

EP-1795

Evaluation of CBCT protocols in craniospinal RT for pediatric medulloblastoma: a preliminary study
E. Madon¹, A. Sardo¹, S. Sirgiovanni¹, V. Richetto¹, A. Mussano², U. Monetti², A. Urgesi²
¹A.S.O.U.S. Città della Salute e della Scienza di Torino, Fisica Sanitaria, Torino, Italy
²A.S.O.U.S. Città della Salute e della Scienza di Torino, Radioterapia, Torino, Italy

Purpose or Objective: The use of IGRT technologies, such as cone beam CT, improves treatment delivery accuracy: given that reduction of radiation dose is particularly relevant in pediatrics, an ideal IGRT method would minimize dose while enabling adequate visualization of relevant anatomy for target localization. However, setup accuracy parameters and predictors have not been extensively evaluated. We describe the preliminary results of a prospective evaluation of a low-dose CBCT protocol for IGRT in pediatric craniospinal radiation therapy.

Material and Methods: Various low-dose CBCT protocols with CTDI of 0.1-2 mGy/scan were prepared, and patient and IGRT characteristics were recorded in real-time. Different reconstruction algorithms were used to optimize cone beam images and registrations. Setup accuracy was quantified by hexapod table translations and rotations (6 dof) between planning CT vs daily CBCT acquisition. The shift vector magnitudes in polar coordinates were calculated. Descriptive statistics were performed (t-test). All these evaluations were made for craniospinal and for posterior fossa irradiation.

Results: Table 1 shows the parameters values (dose and image quality) of the examined protocols. Taking into account to the results, clinical protocols were defined for the three target volumes considered. Two patients (180cGy/13frs CSI + 180cGy/17frs post fossa) were studied with 30 daily pre-treatment CBCT. For the first patient, early phase of radiation therapy was delivered with anaesthesia. In CSI treatment, where junctions between beams are critical, only translations movements were considered. In cranial isocenter localization mean table shifts were 5.84 ± 0.98 mm (fast low dose,A) and 3.84 ± 3.21 mm (fast low dose) 3.6 ± 1.99 mm (fast high dose), with and without anaesthesia respectively; in the spinal setup evaluation mean table shift was 7.3 ± 2.1 mm (fast low dose,A) and 8.7 ± 0.2 mm (fast low dose), 6.8 ± 0.2 mm (fast high dose). Difference between setup accuracy according to patient's cooperation, with and without anaesthesia, is statistically relevant (p<0.05) for cranial localisation and not for the spine localisation and the statistical significance persists considering also the overall

treatment. On the other hand difference between setup accuracy according to patient dose does not show statistical difference.

Conclusion: CBCT-derived table shifts for investigations with LD-CBCT and with HD-CBCT were statistically similar, suggesting that for pediatric radiation therapy setup evaluation can be safely performed with lower-dose IGRT. Moreover, these data support implementation of a LD-CBCT protocol also in pediatric hyperfractionated accelerated radiotherapy.

EP-1796

Definition of thresholds to detect anatomy changes using Delivery Analysis software for Tomotherapy.
C. Dejean¹, M. Gautier¹, J. Feuillade¹, A. Mana¹
¹Centre Antoine Lacassagne, Academic Physics, Nice, France

Purpose or Objective: To determine the analysis parameters for quantitative assessment of the dosimetric impact of differences between the measured and calculated MVCT detectors sinograms. This difference is directly related to patient positioning and/or anatomical changes.

Material and Methods: Tomotherapy HD v5.0 associated to Delivery Analysis (DA) software (beta version) has been used for patient treatments. Consistency of MLC functioning is assessed by comparing opening-closing time measured by detectors versus calculated during planning. The quality assurance of the device validates its functioning. Detector response stability is continuously monitored (sd/mean<0.05%). DA software analyzes the difference of the detectors sinogram between a reference fraction and the fraction of the day, its influence is measured through the patient. The specific differences to a patient will therefore depend on its positioning and/or anatomical variations. From the analysis of each treatment session, alert thresholds will be defined.

Results: Considering margins used and expected dose accuracy, parameters of 2mm (DTA) and 3% (dose) were used associated to a threshold of 99% for gamma index analysis. We use them as a baseline to verify detectability on various treatments. With this level of detectability, the presence of gas in pelvic localizations, a loss of weight linked to a variation of 5mm thickness is detected. In the context of lung tumors, a reduction in tumor volume (associated with lung density change) is detected. The interpretation of these differences is not easy because of the movement of such gases, we have then added a condition for further analysis: three consecutive fractions not meeting the criterion result in a complete analysis or 15% of non consecutive fractions (conventional fractionation). A less than 95% result is immediately analyzed to determine visually on the MVCT scanner the reason : if it is weight loss, a new planning is realized.

Conclusion: Two strong points should be noted: a color code is associated to analysis results (red/green : fail/pass) and permits a relevant and fast systematic analysis. This information also applies to non-imaged areas, such as for medulloblastoma: although the MVCT is not acquired over the

entire treated length, it is possible to determine their spatial localizations. Thus, it is possible to adapt the scan lengths. On the other hand, to provide education, therapists can easily see the impact of their choices, eg set-up compromises.

EP-1797

Pelvic lymph node PTV margins in prostate IMRT

L. Duvergé¹, J. Castelli^{1,2,3}, S. Cadet⁴, A. Simon^{2,3}, N. Jaksic¹, C. Lafond^{1,2,3}, P. Haignon^{2,3}, R. De Crevoisier^{1,2,3}

¹Centre Eugene Marquis, Radiotherapy, Rennes, France

²INSERM, U 1099, Rennes, France

³University Rennes 1, LTSI, Rennes, France

⁴Therenva, Therenva, Rennes, France

Purpose or Objective: Very few data are available on the intrapelvic motion of pelvic lymph nodes (LN), likely associated with the linked pelvic vessels. The objectives of the study were to quantify the interfraction pelvic vessel motion and to deduce therefore rational PTV margins around the LN CTV, in a scenario of pelvic bone based prostate IGRT.

Material and Methods: The planning CT scans (CT0) and 7 per-treatment weekly CT scans of 20 patients having received IMRT for prostate cancer were used. The main pelvic vessels were manually delineated: common iliac (CI), external iliac (EI) and internal iliac (II) of both sides. The central lines of the vessels were first defined thanks to a 3D workstation (EndoSize®, Therenva) dedicated to the preoperative sizing before endovascular interventions. A pelvic bone registration was then performed. For a given vascular segment, the distance between its central line CLO from CT0 and its central line CLi from the weekly CTs were calculated. The central line CLO of each vascular segment was sampled every mm. The distance corresponded to the mean value of the distances between corresponding points of the two central lines (CLO and CLi). The correspondance was established by considering the cross-section plane orthogonal to CLO at a given point and its intersection with CLi. For each patient, the mean and the standard deviation (SD) of the measurements of the 7 fractions were determined. The systematic error (ξ) of the whole population was calculated as the SD of the mean values. The random error (σ) of the whole population was calculated as the root mean square of the standard deviation values. The margins were calculated both with M. Van Herk formula (*IJROBP* 2000) and by geometrically computing margins covering 99% of the vessels displacements.

Results: The results are given for the first 10 patients. The mean (range) lengths (in mm) for IC, EI and II were 47 (18-84), 95 (78-120) and 38 (20-55), respectively. The systematic and random errors and the corresponding margins are given in the Table.

		Common Iliac	External Iliac	Internal Iliac
Ant/post	Systematic Error (ξ)	1.3	0.9	1.0
	Random Error (σ)	1.2	0.8	0.7
	Van Herk Margins	4.1	2.8	3.1
	99% Margins	5.1	4.3	4.6
Lateral	Systematic Error (ξ)	0.8	0.5	0.9
	Random Error (σ)	0.7	0.6	1.0
	Van Herk Margins	2.6	1.8	2.9
	99% Margins	3.6	2.7	4.0
Sup/Inf	Systematic Error (ξ)	0.7	0.7	1.7
	Random Error (σ)	0.7	0.7	1.6
	Van Herk Margins	2.2	2.3	5.2
	99% Margins	2.5	2.9	5.1

Table: Vessels displacements (systematic and random errors) and corresponding PTV margins (according to Van Herk formula and covering 99% of the displacements) around the LN CTV (in mm)

Conclusion: Pelvic LN PTV margins should be around 5 mm for the common and internal iliac CTV and 4 mm for the external iliac CTV.

EP-1798

Is there a true dosimetric improvement in lung SBRT using a 6-Degree of Freedom couch in IGRT era?

S. Menna¹, S. Chiesa², A.R. Alitto², L. Azario¹, G.C. Mattiucci², S. Teodoli¹, N. Dinapoli², L. De Filippo², M. Balducci², V. Valentini²

¹Università Cattolica del Sacro Cuore, Physics Institute & Operative Unit of Medical Physics, Rome, Italy

²Università Cattolica del Sacro Cuore, Radiation Oncology Department- Gemelli-ART, Rome, Italy

Purpose or Objective: To investigate dosimetric impact of rotational errors on Stereotactic Body Radiation Therapy (SBRT), using Protura 6-Degree of Freedom (6-DoF) Robotic Patient Positioning System (CIVCO Medical Solution).

Material and Methods: Patients enrollment included: lung primary or metastatic tumors, maximum 3 lesions, preferably not in central position and until 5 cm. The target should be clearly evident at staging imaging. PTV was obtained adding 0.3 cm as margins to target (CTV). A kV-Cone Beam CT (kV-CBCT) was acquired before dose delivery. After 3D manual match, translational and rotational shifts were applied by the Protura Couch. Using MIM 5.5.2 software, a CT was generated by rigid registration in the CBCT wrong position, i.e. patient position at the moment of CBCT. Then, translational shifts were applied, obtaining a translated CT (tCT), i.e. CT in wrong position with only translational errors correction. Then, rotational errors were corrected too, obtaining roto-translated CT (rtCT). Initial treatment plan was copied to translated CT (tTP) and roto-translated CT (rtTP). Finally, dosimetric parameters were compared.

Results: From July to September 2015, 13 patients were enrolled (10 with primary tumours and 3 with metastatic lesions; 9 peripheral and 4 central lesions; mean volume 13,26 cc) with a median age of 74 yrs (range 58-86); 52 CBCT studies, 52 tTP and 52 rtTP were performed. No correlation was observed between magnitude of translational and rotational shifts. Dosimetric evaluation showed no important variations in CTV V95% for rotations (mean \pm SD 0.00 \pm 0.05). Ninety-one percent (91%) of all PTV V95% was \geq 95% in roto-translated plans; in the worst case a mean rotation of -0.3° caused a decreasing in V95% = 93%. Small differences due to rotations were found in all Organs at Risk (OAR) matrices reported in Table 1.

	Spinal Cord Dmax (Gy)	Heart Dmax (Gy)	Esophagus Dmax (Gy)	Total Lung V(%) 20	Total Lung V(%) 12.5	Total Lung V(%) 5
MEAN	0,0	0,0	0,0	0,0	0,0	0,0
SD	0,3	0,8	0,2	0,0	0,0	0,2
MAX	0,8	4,2	0,5	0,1	0,1	0,4
MIN	-0,8	-3,0	-0,3	-0,1	-0,1	-0,6

After rotational corrections, an improvement was observed in constraints values for OARs than reference planning dose (Table 2), although only 3% of all data had an improvement $>5\%$.

Spinal Cord Dmax (Gy)	Heart Dmax (Gy)	Esophagus Dmax (Gy)	Total Lung V(%) 20	Total Lung V(%) 12.5	Total Lung V(%) 5
37,8%	31,1%	28,9%	48,9%	57,8%	42,2%

Multiple regression and pairwise confront (post-hoc test) showed significant linear correlations between esophagus Dmax and roll ($p=0.007$) and pitch ($p=0.020$) rotation, total lung V12.5 and yaw ($p=0.048$). Regarding PTV coverage, V95% and V105%, no significant difference between tTP and rtTP was observed (Mann-Whitney test $p>0.05$).

Conclusion: These preliminary data show an improvement for OARs if rotational shifts are applied. Dosimetric benefits on lung tumours are small that is PTV margins are optimal for all shifts detected. Dosimetric evaluation in other sites is ongoing.

EP-1799

3, 5 or 7 fractions with no image guidance in moderately hypofractionated prostate treatments

R. Bermúdez Luna¹, A. López Fernández¹, C. Rodríguez Rodríguez¹, M.V. De Torres Olombrada², T. García Cañibano²

¹Hospital Universitario de Fuenlabrada, Medical Physics, Fuenlabrada, Spain

²Hospital Universitario de Fuenlabrada, Radiation Oncology, Fuenlabrada, Spain

Purpose or Objective: Radiotherapy treatments are delivered in our centre using two twin linacs. This provides the possibility of treating patients in either of them. In case of breakdown of one of the linacs, the number of patients interrupting their treatment can be minimised as they can be treated in the linac that continues working.

With the aim of optimally doing so, the IGRT workflow is exceptionally changed in case of linac breakdown and image guidance (IG) is only performed when considered strictly necessary.

Prostate cancer patients treated in our radiotherapy department receive a moderately hypofractionated IMRT treatment with daily IG.

The purpose of this work was to assess the dosimetric differences that would result in prostate treatments if IG was not performed in 3, 5 or 7 fractions due to linac breakdown in the most sensitive patients to the lack of IG according to our IGRT protocol.

Material and Methods: 20 prostate plans were retrospectively modified and analysed. All of them were moderately hypofractionated treatments with prescription doses to the prostate and seminal vesicle (SV) PTVs of 70 Gy (2.5 Gy/fraction) and 56 Gy (2 Gy/fraction), respectively. They corresponded to patients whose daily positioning shifts after an initial correction of the systematic error showed a standard deviation ≥ 4 mm or an absolute displacement mean value ≥ 3 mm.

Seven positioning shifts were randomly selected for each patient out of their recorded treatment data. Beams corresponding to 3, 5 or 7 fractions were accordingly displaced in the TPS, as if no IG had been performed.

Results: Dosimetric differences observed for the prostate and SV CTVs were negligible.

Mean absolute variations in the mean rectal dose when not performing IG in 3, 5 or 7 fractions were 35.2 ± 27.2 cGy, 50.9 ± 33.8 cGy and 63.2 ± 47.1 cGy, respectively. The results obtained for the bladder were: 19.5 ± 12.9 cGy, 30.0 ± 19.8 cGy and 39.1 ± 31.8 cGy.

The table shows the percentage of cases classified by their corresponding absolute variation in the mean dose.

Fractions without image guidance	Absolute variation in the mean dose (ΔD)		
	$\Delta D \leq 0.5$ Gy	$0.5 \text{ Gy} < \Delta D \leq 1$ Gy	$1 \text{ Gy} < \Delta D$
Rectum			
3	80%	15%	5%
5	55%	30%	15%
7	50%	25%	25%
Bladder			
3	95%	5%	0%
5	90%	10%	0%
7	75%	20%	5%

Conclusion: This work has been carried out with the data corresponding to the most sensitive patients to the lack of IG. The observed dosimetric effect is greater than the one that would correspond to the mean patient population.

In case of exceptionally not performing IG in 3, 5 or 7 fractions due to a breakdown in one of the twin linacs, the prostate and SV CTVs would still be treated correctly with the CTV to PTV margins currently used in our centre.

Regarding the organs at risk, the rectum showed the most important dosimetric variations. The dosimetric impact is greater when changing from 3 to 5 fractions without IG than when changing from 5 to 7.

Even in this group of patients, the effect of not performing IG in 3 or less fractions would be negligible. Not performing IG in a greater number of fractions could be relevant in cases in which the calculated dose distribution in the rectum is close to its corresponding dose restrictions because further optimisation was not possible.

EP-1800

Setup verification for breast cancer RT: Manual and automatic match of EPID images compared to CBCT

E.L. Lorenzen¹, K.L. Gottlieb¹, M. Nielsen¹

¹Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

Purpose or Objective: Cone beam computed tomography (CBCT) is generally superior in imaging the patient anatomy due to the 3D representation and the use of kV imaging compared to MV imaging in electronic portal imaging devices (EPIDs). However, EPIDs have the advantage that the treatment fields can be used for the exposure, thereby adding no additional dose to the patient and requiring little additional time. The purpose of this work was to evaluate the use of EPID using both manual and automatic match by comparison to CBCT for setup verification in breast cancer radiotherapy.

Material and Methods: Both CBCT and EPID images were acquired in the same patient position for 29 fractions in 10 breast cancer patients. CBCT images were registered automatically to the planning CT using XVI by Elekta based on a grey-value translational match of the thorax wall. EPID images of the medial tangential fields were registered to digitally reconstructed radiographs (DRRs) using either a manual match of the thorax wall by a experienced user using iView by Elekta or an automatic match using IGPS by Fractoria. For the EPID registrations the 3D-table corrections were approximated based on the 2D registrations and the beam angle.

Results: Bland-Altman plot of the difference in EPID and CBCT registrations is shown in Figure 1. The mean differences were close to zero for both manual and automatic match of the EPID images. The limits of agreement (1.96 times the standard deviation of the difference) were lower for the manual than the automatic match indicating better agreement with the CBCT. The results of linear regression are shown in Table 1. The manual match had a higher correlation coefficient (R^2) than the automatic match. The match based on EPID generally underestimated the registration obtained by the CBCT as shown by the trend in Figure 1 and by the slope in the regression shown in Table 1 being significantly lower than one.

Figure 1. Bland-Altman Plot of the difference between EPID and CBCT registrations. In a) the EPID images were matched manually in iView and in b) the match was performed automatically using IGPS. The vertical solid line indicates the mean difference and the vertical dashed lines the limits of agreement. Linear regression was performed to test for trends in the differences. Estimated coefficients for the linear regression and the corresponding p-value for the null hypothesis that the slope = 0 are shown.

	EPID vs. CBCT		
	a (SE)	b (SE) [mm]	R ²
Manual match	0.31 (0.05)	-0.42 (0.22)	0.30
Automatic match	0.25 (0.07)	-0.27 (0.30)	0.13

Table 1. Estimated coefficients and correlation coefficients R² based on linear regression between the EPID and the CBCT registration using the model: EPID = a*CBCT + b. Standard errors (SE) are given in brackets.

Conclusion: EPID registrations generally underestimated the registrations found by the CBCT. While an automatic matching method of the EPID potentially could improve on this, the automatic matching method evaluated in the current study showed inferior performance compared to manual matching.

EP-1801

Management of inter-fraction patient movement for SBRT treatments without an on-site 3D imaging.

F. Candela-Rodriguez¹, D. Martinez-Rodriguez¹, A. Camara-Turbi¹, M.T. Garcia-Martinez¹
¹Hospital Universitario de la Ribera, Radiofísica y Radioprotección, Alzira, Spain

Purpose or Objective: To validate the methodology we use for managing the inter-fraction patient movement in stereotactic body radiotherapy (SBRT) treatments. This methodology consists of the use of internal markers, one CT scan per fraction, and the portal vision system every fraction.

Material and Methods: A group of 132 SBRT treatments (1 to 5 fractions of 6.5 to 20 Gy each) were retrospectively analyzed. From this, we have considered a total of 227 fractions suitable for analysis.

The treatment technique was mainly 3DRT, using two Varian linear accelerators (clinac 2100C / 2100CD), both with Portal Vision AS500 - IAS3, Philips Pinnacle v9.8 treatment planning

system (TPS), and Mosaik (Elekta) Record and Verify (R&V). Adequate immobilization systems were used and internal fiducial marks were inserted.

A new CT scan was performed before each fraction in 172 cases, where treatment volumes and organs at risk were delineated by the Physician (after registration with the initial one). Treatment plan was recalculated to verify dosimetric consistency, and the isocenter position was updated according to the new anatomy). For setting purposes, a new set of orthogonal RDR images (gantry 0° and 90°) were sent to the PV. The remaining 55 cases were treated using the initial CT and were used here for validation proposes.

On the couch, the patient was initially aligned on the CT marks, and then it was moved to the updated isocenter position. Two Portal Images (orthogonal, 0° - 90°) were done and registered with the corresponding RDR using the fiducial marks. If the displacements were greater than 0.5mm, the patient was moved.

We have performed this study for different anatomy locations (118 lung cases, 85 abdomen cases and 24 others cases), expecting different results.

Results: Isocenter position had to be corrected in the treatment room as showed in the table below, for all locations considered:

ALL LOCATIONS (227 cases)	TOTAL (227 cases)	without CT (55 cases)	with CT (172 cases)
	[Vrt] [Lat] [Lng] [Total]	[Vrt] [Lat] [Lng] [Total]	[Vrt] [Lat] [Lng] [Total]
cases with move > 0.5 cm	12% 16% 27% 47%	15% 18% 29% 31%	13% 16% 27% 45%
cases with move > 1 cm	1% 4% 7% 20%	2% 7% 7% 23%	1% 3% 7% 19%
cases with move > 1.5 cm	1% 1% 1% 3%	2% 2% 2% 9%	1% 1% 1% 3%

cases with move > 2 cm	0% 0% 0% 0%	0% 0% 0% 0%	0% 0% 0% 0%

Conclusion: For lung cases, we needed to reposition 23% cases less than without pre-fraction CT scan, 3% less for abdomen cases, and 25% more for the rest, not considered due to the low statistic (24 cases).

The pretreatment CT scan is very time consuming both for the Radiation Oncology and Radiation Physics departments, but on-site positioning is easier and so the treatment can be performed more comfortably for the patient.

Also, the dosimetric verification prior to each fraction allows us to assess the suitability of the new displacements to meet the clinical goals.

EP-1802

Mechanical sag patterns of the cone-beam CT imaging system of Elekta linear accelerators

S.J. Zimmermann¹, P. Rowshanfarzad², M.A. Ebert², H.L. Riis¹
¹Odense University Hospital, Radiofysisk Laboratorium, Odense, Denmark

²University of Western Australia, School of Physics, Crawley, Australia

Purpose or Objective: The cone-beam CT (CBCT) imaging system mounted on a linear accelerator (linac) is an important tool for validation of patient position. A correct patient positioning relies on high image-quality obtained through mechanical stability of the CBCT unit and coincidence between the MV and kV radiation isocenters. The quality assurance (QA) of the CBCT unit should ideally validate the mechanical performance of each component and identify the origin of deviations. Most QA studies of CBCT imaging systems have been based on dedicated phantoms placed on the treatment couch. These phantoms do not allow for extraction of the sag patterns for the kV source arm and

imager separately. To access these information, we applied a method previously used for QA of Elekta linac gantry heads and portal-imaging systems.

Material and Methods: The sag pattern of the CBCT unit of an Elekta linac was investigated using five tungsten-carbide ball-bearings of diameter 4.8 mm. One ball-bearing was attached to the treatment couch top and four were attached to the kV source. Image acquisition was carried out for small-field of view with an average of 343 planar images in each gantry rotation. An in-house software coded in MATLAB was used to extract the ball-bearing positions in the images and to calculate the sag patterns of the CBCT unit.

Results: The results of six gantry rotations are listed in Table 1. The cross-plane sag of the kV source was found to be approximately 10 times larger than the sag of the gantry head, while the in-plane sag was almost two times larger. The cross-plane source sag corresponds to a gantry angle displacement of up to 0.3 degrees. The kV panel sag was comparable to the sag of the MV panel. The kV source-to-panel distance variation was almost half the amount for the MV system. The algorithm also allows for extraction of the skewness and panel-tilt data, but they are not presented in the Table. The kV system was found to have high reproducibility.

Range	Source Sag Cross-plane (mm)	Source Sag In-plane (mm)	Panel Sag Cross-plane (mm)	Panel Sag In-plane (mm)	ΔSDD Radial (mm)
CCW (mean±SD)	4.90±0.08	2.13±0.01	0.53±0.02	1.39±0.01	7.23±0.60
CW (mean±SD)	5.03±0.05	2.76±0.03	0.31±0.03	1.20±0.01	6.59±0.74
Largest RMSD	0.14	0.14	0.13	0.01	1.08
CCW vs CW	0.02	0.06	0.08	<0.01	0.21
Smallest RMSD					
CCW vs CW					
Worst reproducibility CW	1.66	0.73	0.12	0.50	2.58
Worst reproducibility CW	1.67	0.97	0.08	0.42	2.43
CCW, CW † (mean±SD)	0.56±0.05	1.19±0.13	0.43±0.11	1.57±0.48	11.18±1.17

Table 1. Data for the range of the source and panel sag of one Elekta CBCT unit. The data are divided into cross-plane, in-plane and radial (ΔSDD) directions. Mean, standard deviation (SD), root-mean-square deviation (RMSD), and reproducibility in terms of standard deviation are displayed. For comparison, the data of the average values of the gantry arm and the EPID panel (from [1]) are listed in the row marked with †.

Conclusion: The measurements and analysis in this study quantify the sag pattern of the CBCT unit components. The Elekta kV flexmap do not compensate for all sag contributions such as panel rotation and tilt, source sag, and radial source-panel distance variations. A new kV flexmap is suggested for compensation of some additional flex contributions with the exception of panel rotation which cannot be measured in our setup or separated from skewness. The new kV flexmap could improve the reconstructed volumetric cone-beam CT image quality.

EP-1803

An immobilization device-based procedure to predict couch coordinates and set-up tolerance levels

C. Camacho¹, E. Escudero¹, A. Lloret¹, C. Castro¹, M.D. Molina¹, Y. Mohadr¹, C. Quilis¹, J. Garcia-Miguel¹, A. Herrerros¹, J. Saez¹

¹Hospital Clinic i Provincial, Radiotherapy, Barcelona, Spain

Purpose or Objective: We propose and evaluate a simple method to predict absolute couch coordinates (ACC) based on different landmarks identified on two immobilization devices. We analyze the inter-observer variability of the method and establish set-up tolerance levels.

Material and Methods: Two immobilization devices were evaluated in this study: the Portrait Head and Neck Device by Qfix and the PosiRest-2 by Civco, used in HN and thorax/breast positioning respectively. Each device was indexed on the treatment table (Varian Exact Couch) and one plastic screw was matched to the room lasers were the ACC were read. The isocenter ACC were obtained by taking simple distance measurements on the CT from isocenter to the screw. We studied the inter-observer variability by having 5 different observers repeating all measurements. A total of 46 patients were analyzed: 22 breasts, 12 lungs and 12 HNs. All

patients were set-up according to a NAL-3 protocol. A total of 1020 treatment sessions were recorded. We compared predicted couch positions to treatment couch positions acquired after the systematic error correction (4th day). We established device and location specific tolerance levels to accommodate 95% of all sessions. We finally studied if there was any correlation relating these differences and patient random set-up error.

Results: The average of the standard deviations of predicted positions among the 5 observers was <2 mm for all coordinates (vert, lat, long) and devices. There was strong correlation between almost all predicted positions and the systematic error corrected positions ($r>0.9$) but for the lateral coordinate prediction on the HN device (cause by having small values (<7 mm)). No correlation was found between predicted vs. corrected deviations positions and random error. Thus, this difference cannot be used to predict difficult to set-up patients. In order to accommodate 95% of all treatment sessions couch positions the following tolerances (2σ) were obtained (in mm) for (vert, lat, long): breast (12, 23, 30); lung (12, 20, 22); hn (7, 7, 7).

Conclusion: Our designed procedure based on immobilization device landmarks offers a simple and reproducible method to correctly predict absolute isocenter coordinates. Difficult to set-up patients (large random error) cannot be isolated from the differences between predicted and treated positions on a specific day. However, the procedure allows obtaining tight set-up tolerance levels to prevent gross set-up errors.

EP-1804

A comparative analyse of prostate positioning guided by transperineal 3D ultrasound and cone beam CT

M. Li¹, H. Ballhausen¹, N.S. Hegemann¹, M. Reiner¹, S. Tritschler², F. Manapov¹, U. Ganswindt¹, C. Belka¹

¹Department for Radiation Oncology, University Hospital Munich, Munich, Germany

²Department for Urologie, University Hospital Munich, Munich, Germany

Purpose or Objective: The accuracy of the Elekta ClarityTM transperineal three-dimensional ultrasound system (3DUS) was assessed for prostate positioning and compared to seed- and bone-based positioning in kilovoltage cone beam computed tomography (CBCT) during a definitive radiotherapy.

Material and Methods: The prostate positioning of 7 patients, with fiducial markers implanted into the prostate, was controlled by 3DUS and CBCT. In total, 177 transperineal ultrasound scans were performed and compared to bone-matches and seed-matches in CBCT scans. Setup errors detected by the different modalities were compared. Using seed-match as reference, systematic and random errors were analysed, and optimal setup margins were calculated for 3DUS.

Results: The discrepancy between 3DUS and seed-match in CBCT was 0 ± 1.7 mm laterally, 0.2 ± 2.0 mm longitudinally and 0.3 ± 1.7 mm vertically and significant only in vertical direction. Using seed-match as reference, systematic errors of 3DUS were 1.2 mm laterally, 1.1 mm longitudinally and 0.9 mm vertically, and random errors were 1.4 mm laterally, 1.8 mm longitudinally, and 1.6 mm vertically. Using the optimal margin recipe by van Herk, the optimal setup margins for 3DUS were 3.9 mm, 4.0 mm and 3.3 mm in lateral, longitudinal and vertical directions respectively.

Conclusion: Transperineal 3DUS is feasible for image guidance for patients with prostate cancer and seems comparable to fiducial based guidance in CBCT in the retrospective study. While 3DUS offers some distinct advantages such as no need of invasive fiducial implantation and avoidance of extra radiation, its disadvantages include the operator dependence of the technique. Further study of transperineal 3DUS for image guidance in a large patient cohort is warranted.

EP-1805

Design and testing of the Rotating Whole-Body Linac-MRI Hybrid System

B.G. Fallone¹¹Cross Cancer Institute University of Alberta, Medical Physics, Edmonton, Canada

Purpose or Objective: The first whole-body clinical linac-MRI hybrid (linac-MR) began installation in November 2013 at our clinic. System components were transported through the maze of an existing clinical radiotherapy vault and reassembled within the vault without removal of any part of the vault. The world-first images from a linac-MR on a human volunteer were obtained in July 2014. Specific imaging and dosimetric evaluation are reported.

Material and Methods:

The linac-MR (Figure) consists of an isocentrically mounted 6 MV linac that rotates in-unison with a bi-planar 0.5 T MRI in transverse plane. The B_0 field and the central axis of the 6 MV beam are parallel to each other. Feasibility of operation of concurrent MR imaging and linac-irradiation was confirmed in 2008 within a head prototype, while the current functional whole-body rotating linac-MR system is built on the engineering and physics developed and tested on the head prototype. The magnetic fringe field are optimized with the parallel configuration to results in insignificant entrance-dose increase and to avoid large increases in dose at tissue/air interfaces and any increase at beam exit due to electron return effect.

Results:

Table: Specifications of current rotating linac-MR system

Feature	Characteristic
Linac	6 MV
MLC	120 Leaves (Standard, Micro)
MR	0.5T (Good Image Resolution) (Negligible Geometric Distortion)
Maximum Pre-treatment Field of View	40 cm x 75 cm
Patient Space	Exterior Opening: 110 cm Diameter Interior Space: 60 cm x 110 cm (Rotating) Result: Suitable for Treating <u>All</u> Tumors (Including Peripheral Tumors — Breast)
Patient Table Movement Inside the Aurora RT	Vertically ± 25 cm Laterally ± 25 cm
Linac-MR Configuration	Aligned — Rotate Together
MR Position	Rotates 360 degrees
Beam-Orientation	Parallel to Magnetic Field (minimal dosimetric perturbation)
Bunker and Maze Size	Standard for Linacs (Installation Through Maze)
MR Cryogens and Venting	None Required
Beam Modulation	IMRT, VMAT
Soft-tissue imaging	Four Images/sec During Tx
Treatment Planning	Real-time Adaptive
Servicing	Ramp up/down in Minutes To Allow Servicing of Linac

Currently, the whole body system is mechanically well balanced and rotates at 1 rpm, and provides because of its open-magnet design imaging and irradiation to tumours in all locations, including peripheral areas and breast. The system provides radiation output resulting in minimal dose perturbations in entrance dose, at internal tissue-air/lung interfaces as designed and no exit dose-increases. 3D magnetic field mapping demonstrates minimal perturbation in magnetic field homogeneity with gantry rotation which is easily and effectively shimmed by gradient coils. The Larmor Frequency varies with gantry angle due to the B_0 interaction with room shielding and to the directional changes of the Earth's magnetic relative, and closely follows predictions calculated previously. Angle dependent 3D magnetic field maps and Larmor Frequency are used to automatically and optimally create image acquisition parameters for any gantry angle. Metrics obtained at different rotating angles show that the image quality is comparable to those of clinical MRI systems, and thus satisfy the requirements for real-time MR-guided radiotherapy.

Conclusion: The system highlights (Table) are:

6 MV linac; High-quality MR images during irradiation; parallel configuration to avoid strong angle-dependent shimming, and increased dose at beam exit and tissue-air/lung interfaces; imaging and irradiation of all tumours including peripheral areas and breast; installation through the maze of existing vaults; cryogen-free superconducting magnet; magnet turns on or off in minutes for safe servicing of magnetic components.

EP-1806

A novel predictive approach to quantify parotids warping using SIS epidemic model

N. Maffe^{1,2}, G. Guidi^{1,2}, C. Vecchi², A. Ciarmatori¹, G. Mistretta¹, P. Ceroni¹, B. Meduri³, P. Giacobazzi³, T. Costi¹¹Az.Ospedaliero-Universitaria di Modena, Medical Physics, Modena, Italy

²Alma Mater Studiorum University of Bologna, Physics and Astronomy, Bologna, Italy

³Az. Ospedaliero-Universitaria di Modena, Radiation Oncology, Modena, Italy

Purpose or Objective: In the field of Adaptive Radiation Therapy (ART), non-linear transformation models should be considered to take into account complex motion and anatomic variations. In order to follow and then predict intra-organ dynamic, a novel voxel-by-voxel approach has been proposed using epidemic model. The susceptible-infected-susceptible (SIS) model was applied to radiotherapy treatments to predict morphological variations in the Head and Neck (H&N) region and to follow single voxel motion and warping.

Material and Methods: 360 daily MVCT studies of 12 H&N patients treated by Tomotherapy® were retrospectively analyzed. Deformable image registration (DIR) and automatic structures re-contouring were performed by RayStation® treatment planning system (TPS). The study focused on parotid glands (PG) identified by previously studies such as organs systematically affected by warping. Using the epidemic model, PG shrinkage was evaluated considering each voxel as a single subject and the deformed vector field (DVF) as an infection. A dedicated IronPython® script was developed to export daily coordinates and DVF displacements from the deformed mesh grid obtained by the TPS for each vertex of the region of interest (ROI) contouring. Finally, the SIS model was developed by a MATLAB® home-made simulation tool.

Results: The patients' validation was obtained by splitting susceptible (S) and infectious (I) cases; 0.4cm of voxel displacement was set as clinical threshold within a [0÷1cm] range of warping. Correlation between epidemic model and daily PG shrinkage was carried out by dynamic time warping (DTW) algorithm applied to the SIS parameters. A DTW distance of 2.39 ± 0.66 was obtained setting the contact rate at 7.55 ± 0.69 and the recovery rate at 2.45 ± 0.26 ; birth rate was not counted in a constant population hypothesis. A physician's multiple-blind evaluation confirmed that PG warping evolution could be predicted, applying the SIS model, in almost 65% of patients.

Figure 1 SIS simulation during the 6 week of RT: Susceptible (S) and Infectious (I) trends are in blue and green. Vertices dynamic allows identifying gradual PG warping during treatment and possible set-up errors.

Conclusion: Combining epidemic model with ART and image systems can on-line support and validate daily setup and assess anatomical warping. In this novel approach, contrariwise to a time series analysis of the whole organ, specific and localized intra-organ variation could be detected. Moreover, integrating a dose accumulation evaluation, the SIS model could aid clinic decision making to suggest possible re-planning during the 6 weeks of therapy. A 3D model of the ROI can be generated and its evolution during the treatment course can be investigated.

Replanning effects in Tomotherapy treatment using dose accumulation and dose deformation strategies

A. Ciarmatori^{1,2}, G. Gabriele¹, N. Maffei^{1,3}, C. Vecchi³, M.G. Mistretta¹, P. Ceroni¹, B. Meduri⁴, P. Giacobazzi⁴, T. Costi¹

¹Azienda Ospedaliero Universitaria di Modena, Medical Physics Department, Modena, Italy

²University of Bologna, Post Graduate School in Medical Physics, Bologna, Italy

³University of Bologna, Physics Department, Bologna, Italy

⁴Azienda Ospedaliero Universitaria di Modena, Radiation Oncology Department, Modena, Italy

Purpose or Objective: Quantification of the delivered dose is one of the most important feature in inter-patient variability in radiation treatment. Difference between planned and accumulated doses contains different uncertainties due to set-up errors, patient movement and anatomy variations. Shrinkage of Parotid Glands (PG) in Head and Neck (H&N) patients is a major issue in accumulation of the delivered dose. This study investigates Target and Organs at Risks (OARs) variations during the treatment course and their dosimetric consequences. We evaluated the effect of replanning on the deformed structure during the course of treatment.

Material and Methods: Six patients with H&N cancer treated by Tomotherapy (SIB 66 Gy, 60 Gy, 54 Gy in 30 Daily Fractions) have been, retrospectively, enrolled. Through Planned Adaptive® software each delivered fraction have been recalculated on daily imaging to obtain the daily dose (DMVCT). Deformable image registration (DIR), using Raystation (v.4.7.2), have been performed to propagate the structures along the treatment course. The planned doses were mapped (DDVF) using the deformed vector field (DVF) matrix. The DVF obtained from the reverse DIR was used to deform DMVCT to match the planning kVCT; we obtain a voxel by voxel association of DMVCT in a single image dataset. DDVF and DMVCT were compared performing 3D-γ analysis (2 mm, 2%) to evaluate the agreement on 3D distribution and warped structures. Two replanning strategies were adopted during the 18th fractions: (1) re-plan on original target and deformed OARs (D18,OAR) and (2) re-plan on deformed target and deformed OARs (D18).

Results: DDVF and DMVCT did not show a good consistency (3D γ -passing rate = $85 \pm 1\%$, $p < 0.001$). DDVF was significantly ($p < 0.01$) lower than DMVCT in term of average doses in PG ($12.2 \pm 10.3\%$). Smaller differences were founded in average doses to the PTVs ($2.6 \pm 2.1\%$). γ -passing rate and dosimetric variation to PG and PTVs did not show relevant correlation ($p > 0.05$). Parotid gland showed a systematic shrinking during the course of treatment quantifiable in about 4% volume reduction for week of treatment. Full accumulation of dose showed an increase of the average dose to PG of $3.0 \text{ Gy} \pm 3.3 \text{ Gy}$ [$-4.6 \text{ Gy} \div 7.7 \text{ Gy}$]. PTV volume variations were negligible ($4.7 \pm 1.6\%$). The average doses of the PTVs increase of $1.6 \text{ Gy} \pm 1.3 \text{ Gy}$ [$-0.5 \text{ Gy} \div 3.4 \text{ Gy}$]. Retrospective re-planning analysis showed that 5 out of 6 (83%) patients enrolled could had benefit from ART. By ART the PG average dose decreased $-2.0 \text{ Gy} \pm 1.4 \text{ Gy}$ [$-3.8 \text{ Gy} \div -0.2 \text{ Gy}$] in first replanning strategy (D18,OAR) and $-3.2 \text{ Gy} \pm 1.7 \text{ Gy}$ [$-5.0 \text{ Gy} \div -0.2 \text{ Gy}$] in case of both Target and OARs deformation (D18).

Patient	Plan	PTV 54 D _{mean} [Gy]	PTV 60 D _{mean} [Gy]	PTV 66 D _{mean} [Gy]	Right Parotid D _{mean} [Gy]	Left Parotid D _{mean} [Gy]
#1	Planned	60,4	61,9	65,4	39,1	30,2
	Delivered	+1,7 Gy (+2,8%)	+1,2 Gy (+1,9%)	+2,1 Gy (+3,2%)	+4 Gy (+10,2%)	+8,2 Gy (+26,8%)
#2	Planned	55,8	59,4	66,5	29,6	28,8
	Delivered	+2,9 Gy (+5,2%)	+2 Gy (+3,4%)	+3,4 Gy (+5,1%)	+2,2 Gy (+7,4%)	+4,3 Gy (+14,9%)
#3	Planned	60,2	63	68,9	25,1	19,3
	Delivered	+2,4 Gy (+4%)	+3,4 Gy (+5,4%)	+2,2 Gy (+3,2%)	+2,3 Gy (+9,2%)	+7,7 Gy (+40,4%)
#4	Planned	60,8	63,3	67,5	28,8	28
	Delivered	+3 Gy (+4,9%)	+2,6 Gy (+4,1%)	+1,9 Gy (+2,8%)	+3,3 Gy (+11,5%)	+3,8 Gy (+13,6%)
#5	Planned	57,2	59,7	65,9	20,7	33
	Delivered	0 Gy (0%)	-0,4 Gy (-0,7%)	-0,5 Gy (-0,8%)	-0,9 Gy (-3,9%)	-4,6 Gy (-13,9%)
#6	Planned	57,6	62,3	65,1	39,9	26,8
	Delivered	+0,6 Gy (+1%)	+0,3 Gy (+0,5%)	+0,2 Gy (+0,3%)	+3,4 Gy (+8,5%)	+2,7 Gy (+10,1%)

Conclusion: DDVF do not describe adequately the delivered dose in the patient. Difference between planned and delivered doses in PTVs is reasonable, conversely anatomical variations seems to be a cause of overdosage in PG. Re-planning on 18Th MVCT could brought significant benefits, in terms average dose of PG.

EP-1808

A biological modeling based comparison of two strategies for adaptive radiotherapy of bladder cancer

L.J. Lutkenhaus¹, A. Vestergaard², A. Bel¹, M. Høyer³, M.C.C.M. Hulshof¹, C.M. Van Leeuwen¹, O. Casares-Magaz², J.B. Petersen², J. Søndergaard³, L.P. Muren²

¹Academic Medical Center, Radiotherapy, Amsterdam, The Netherlands

²Aarhus University Hospital, Medical Physics, Aarhus, Denmark

³Aarhus University Hospital, Oncology, Aarhus, Denmark

Purpose or Objective: Several adaptive strategies have been implemented to account for anatomical changes during radiotherapy for bladder cancer. To obtain target structures, either the first four CBCT scans can be used (CBCT-based strategy), or the interpolation of bladder volumes on pretreatment CT scans (CT-based strategy). The purpose of this study was to determine whether the CBCT-based or CT-based strategy is more favorable in terms of tumor control probability (TCP) and normal tissue sparing.

Material and Methods: Ten patients from each of the two participating institutes were analyzed, adopting the clinically used adaptive strategy and dose prescription from each institute. With the CBCT-based strategy, a library of three plans was created, corresponding to a small, medium and large bladder. Patients received 70 Gy to the bladder tumor, 60 Gy to the non-involved bladder and 48 Gy to the lymph nodes, in 30-35 fractions. With the CT-based strategy, a library of five plans was created using two pre-treatment CT scans, with full and empty bladder, respectively. Patients received 55 Gy to the tumor and 40 Gy to bladder and lymph nodes, in 20 fractions.

Tumor control: TCP was calculated for the combined target volumes of tumor and bladder, using the Linear-Quadratic model with an α/β ratio of 13 Gy. Since tumor cell density in the non-involved bladder wall was unknown, it was varied between 10^2 and 10^7 cells/cm³. To investigate the effect of the different dose prescriptions, the TCP was recalculated for the CT-based strategy with the dose scaled to 70 Gy in 35 fractions.

Normal tissue sparing: for rectum and bowel cavity, the equivalent dose in 2 Gy fractions (EQD2) was calculated using α/β values of 5 and 8 Gy, respectively, and DVH parameters were extracted. In addition, the planning target volume for each chosen plan divided by the daily bladder volume was calculated. Differences in parameters between groups were assessed using a Wilcoxon signed-rank test.

Results: A higher TCP for the CBCT-based strategy compared to the CT-based strategy was found, independent of modeled cell density in the non-involved bladder wall (Figure 1). For a low cell density, median TCP for the CBCT-based strategy was 75%, compared to 49% for the CT-based strategy. These results were comparable to 3-year local control rates

previously reported. In addition, scaling the dose from the CT-based strategy to 70 Gy increased the median TCP to 72%. For the CT-based strategy, a lower median rectum V30Gy and lower median bowel V45Gy compared to the CBCT-based strategy were observed (Figure 1). This difference is reflected in the finding that the PTV is on average 3.9 times larger than the daily bladder volume for the CBCT-strategy, compared to 2.2 times for the CT-based strategy (p<0.01).

Figure 1: A: TCP for both strategies, for a varying tumor cell density. TCP for the CT-based strategy is always lower, for all patients, compared to the CBCT-based strategy.

B: Bowel cavity V_{45Gy}, and rectum V_{30Gy}, for both strategies. * = p < 0.05, ** = p < 0.01.

Conclusion: Total bladder TCP is higher for the CBCT-based strategy, which is due to prescription differences. The adaptive strategy based on CT scans results in the lowest rectum V30Gy (EQD2) and bowel cavity V45Gy (EQD2).

EP-1809

Intrafractional patient movement during an online adaptive replanning procedure for cranial SRS

M. Pozo-Massó¹, J.F. Calvo-Ortega¹, S. Moragues-Femenia¹, J. Casals-Farran¹

¹Hospital Quiron Barcelona, Radiation Oncology, Barcelona, Spain

Purpose or Objective: To investigate the patient's movement during the preparation of an adaptive cranial radiosurgery (SRS) procedure and its dosimetric impact.

Material and Methods: Cranial radiosurgical treatments are planned in our department using IMRT technique. A Varian Clinac 2100 CD equipped with the OBI system and the Eclipse TPS are used. Patients are immobilized using the BrainLAB mask system. A CBCT scan is acquired after the initial laser-based patient setup (CBCTsetup). In order to take into account the roll and tilt patient's rotation errors, not supported by the linac couch, an online adaptive replanning procedure was designed (Med Dosim. 2013 Autumn;38(3):291-7). It consists of a 6D registration-based mapping of the reference plan onto actual CBCTsetup, followed by a reoptimization of the beam fluences ("6D plan", computed on the CBCTsetup) to achieve similar dosage as originally was intended, while the patient is lying in the linac couch. Once the 6D plan is computed, it is activated in the record and verify network and the actual patient's position is again verified by CBCT imaging (CBCTtx): CBCTsetup/CBCTtx 4D match is performed on the OBI workstation. Twelve online procedures with detected roll or tilt rotation errors larger than 0.5° were enrolled in this study. Intrafractional patient's shifts during the time lag between CBCTsetup and CBCTtx was investigated, as well as the capability of the online adaptive method to compensate them. The plan 6D plan was recalculated on the CBCTtx ("6D plan Tx") taking into account the actual treatment isocenter position. Both plans (6D plan vs. 6D plan Tx) were compared using DVHs.

Results:

- 1) The magnitudes of the intrafraction shifts were 0.4 mm (SD: 0.7 mm), 0.6 mm (SD: 0.5 mm) and 0.3 mm (SD: 0.4 mm) in lateral, anterior-posterior and superior-inferior directions, respectively. The intrafractional rotational shifts were 0.1° (SD: 0.1°), 0.0° (SD: 0.1°) and 0.1° (SD: 0.2°) in tilt, yaw and roll directions, respectively. The time lag where these shifts were happen was 16 ± 2 minutes.
- 2) Dose differences < 1% were found for targets and organ-at-risks between each 6D Plan (computed on the CBCTsetup) and its respective 6D Plan Tx (computed on the CBCTtx).

Conclusion:

- 1) Patient's rotational errors during online replanning were negligible.
- 2) Patient's translational errors during online replanning were compensated enough after CBCTsetup/CBCTtx 4D alignment performed on the OBI workstation, with no appreciable dosimetric impact.

EP-1810

Dose uncertainties due to inter-fractional anatomical changes for carbon ion therapy

D. Panizza¹, S. Molinelli¹, A. Mirandola¹, G. Magro², S. Russo¹, E. Mastella¹, A. Mairani¹, P. Fossati³, F. Valvo⁴, R. Orecchia⁵, M. Ciocca¹

¹Fondazione CNAO, Medical Physics Unit, Pavia, Italy

²Università degli Studi di Pavia, Physics Department, Pavia, Italy

³Fondazione CNAO, Clinical Radiotherapy Unit, Pavia, Italy

⁴Fondazione CNAO, Clinical Directorate, Pavia, Italy

⁵Istituto Europeo di Oncologia, Scientific Directorate, Milano, Italy

Purpose or Objective: To investigate the impact of inter-fraction anatomical variations in pancreatic and pelvic tumor patients when using carbon ion therapy through a retrospective adaptive approach.

Material and Methods: We collected daily MVCT scans for 10 selected patients, previously treated with helical tomotherapy for tumors located in the abdomen and pelvic region. On the first MVCT, taken as a reference, a dummy target volume was contoured, based on clinical experience, and organs at risk (OAR) original contours were imported from the planning CT scan and modified according to anatomical variations. The Hounsfield Unit (HU) to water equivalent path length (WEPL) calibration curve was experimentally determined and implemented in our TPS. According to prescription dose and OARs dose limits of

clinical protocols approved at CNAO, a plan was then optimized on the first MVCT. For each patient, a number of MVCTs equal to the treatment sessions planned according to our fractionation scheme were fused on the reference one and structures were registered and manually corrected. The reference plan was recalculated on each MVCT scan to simulate a real treatment fraction. The cumulative dose was calculated by adding the contribution of each different fraction and then registered on the reference MVCT. This dose distribution was compared against the reference one in terms of target dose coverage and dose to OARs.

Results: For the pelvis cases, results show no significant change in the target coverage, with an average PTV D95% decrease of 1% and a maximum daily variation of -6%, while the mean homogeneity index (HI) difference is less than 0.01. For the abdominal area, however, a clinically relevant loss in target coverage is found: PTV D95% decreases, on average, of 7%, with a maximum daily variation of -23%. Target dose becomes less homogeneous, as shown by an average increase in the PTV HI of 0.08. For both districts, no clinically significant difference is found in the OAR DVHs. The 3D dose distribution analysis shows, for pelvic tumors, slight differences between planned dose and recalculated cumulative dose. For pancreatic carcinoma, local deviations up to 30% with respect to the planned dose can be found in the daily 3D dose distributions, particularly in healthy tissues behind the target volume.

Conclusion: Results confirm that the use of beam directions crossing OARs with a high degree of inter-fractional variation, as in the abdominal region, should be minimized for actively scanned carbon ion beams. However, it is useful to stress that results obtained are patient-dependent and more statistics is needed to draw a general conclusion for a larger population. Research projects are ongoing focused on the improvement of in-room 3D imaging techniques and the development of dose fast calculation platforms for online treatment plans evaluation procedures that account for changing anatomy effects.

EP-1811

Accuracy of dose calculations on CBCT scans of lung cancer patients using a vendor-specific approach

M. De Smet¹, D. Schuring¹, S. Nijsten², F. Verhaegen²

¹Catharina Hospital, Department of Radiotherapy, Eindhoven, The Netherlands

²Maastricht University Medical Center, Department of Radiation Oncology MAASTRO- GROW School for Oncology and Developmental Biology, Maastricht, The Netherlands

Purpose or Objective: In modern radiotherapy, Cone-Beam CT (CBCT) images are widely used for position verification. These CBCT images could also be used for dose recalculation, providing information for treatment evaluation and adaptive planning. However, dose calculations on CBCT are not straightforward and the accuracy for clinical cases is not well known [1-5]. The final goal was to determine for lung cancer patients the accuracy of dose calculations on CBCT images of two different vendors: Elekta and Varian.

Material and Methods: Lung cancer patients with CBCT imaging (n=10 for Elekta, n=6 for Varian) and a repeated planning CT scan on the same day were selected. The original treatment plan and delineated structures were copied to the repeated CT and CBCT scans, and the dose was recalculated. For CBCT dose calculations, an adapted HU-to-electron density (HU-ED) table was used which was obtained by comparing CT values of corresponding points on the CBCT and repeated planning CT scan. For Varian, a bi-annual CBCT HU calibration was executed, while for Elekta the absence of CBCT HU-calibration was compensated by using a patient-specific HU-ED table. Planning CT data were used to compensate for the limited FOV (Elekta) or scan length (Varian) of the CBCT. Finally, clinically relevant dose metrics were compared between the repeated CT and CBCT in order to assess the accuracy of dose calculations on CBCT for both vendors.

Results: Figure 1 displays the mean differences of the dose metrics between repeated CT and CBCT, for Varian and Elekta CBCT scans. For Varian, a good agreement between the dose distributions recalculated on CBCT and repeated CT was observed when a thorax-specific HU-ED table was used. For Elekta, the dose metrics showed larger deviations with the thorax-specific HU-ED table, however, using a patient-specific HU-ED table resulted in similar accuracy as for Varian CBCT dose calculations. Differences between repeated CT and CBCT dose metrics were below 3% for both vendors.

Figure 1. Average and standard deviation (error bars) of the absolute relative difference of the dose metrics between repeat CT and CBCT, for Varian (n=6) and Elekta (n=10) CBCT scans of lung cancer patients. Calculations were performed with a thorax-specific HU-ED table, as well as a patient-specific HU-ED table for Elekta CBCT. MLD = Mean Lung Dose, MHD = Mean Heart Dose, Oes = Oesophagus.

Conclusion: Differences between Elekta and Varian CBCT, including hardware, reconstruction software, HU calibration, FOV and scan length, resulted in different challenges for CBCT dose calculations for the different vendors. For Elekta CBCT scans, the procedure with a patient-specific HU-ED table resulted in similar accuracy as for Varian CBCT dose calculations with a general HU-ED correction for all thorax patients, but is more time-consuming. The vendor-specific corrective methods used in this study, resulted in dose calculations feasible for treatment re-evaluation for both Elekta and Varian CBCT scans.

EP-1812

Adaptive VMAT for cT1-2aNOMO laryngeal cancer: potential risk of target volume over dosage

H.P. Bijl¹, E.W. Korevaar¹, M. Gelderman¹, J.A. Langendijk¹, R.G.J. Kierkels¹

¹University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands

Purpose or Objective: At our department, patients with cT1-2aNOMO laryngeal cancer are treated with volumetric-modulated arc therapy (VMAT). The treatment plan quality is monitored by plan evaluations on weekly repeat CTs. The purpose of this study was to determine plan quality during treatment by recalculating the actually given dose based on repeat CT.

Material and Methods: Three patients treated with accelerated radiotherapy (66-70 Gy in 2 Gy fractions) were selected because of over dosages exceeding 78 Gy at the transition from air to tissue. Each clinical VMAT plan (plan I) was optimized towards homogeneous dose distributions in the planning target volumes (PTV) and low as possible dose to the critical organs such as the swallowing organs at risk. The treatment plan quality was evaluated using weekly repeat CTs. In addition, two more treatment plans were made including a density override of 0.5 g.cm⁻³ for the PTV-in-air overlap region (plan II), and the PTV-in-air + 5 mm region (plan III). All plans were evaluated with the PTV-in-air region assigned a density override value of 0.0 and 1.0 g.cm⁻³ to simulate the initial planning scenario and to simulate extension of CTV-in-air, resp. Finally, the "actual given dose"

of the clinical target volume (CTV) was estimated by accumulated repeat CT dose evaluations.

Results: The repeat CTs showed an extending CTV towards the laryngeal air cavity over the course of treatment. Repeat CT evaluations indicated increasing max doses up to 80 Gy. Evaluation of plan I on the initial planning CT, using a density override of 1.0 g.cm⁻³, showed a potential dose hotspot with similar max dose values (80-87 Gy). When no density override was assigned the PTV (D98%) coverage of plan I was sufficient. In contrast, plan II and III showed slightly to moderate PTV under dosage (65 Gy), albeit within the PTV-in-air region. However, the accumulated CTV dose (D100) demonstrated no clinically relevant under dosage in the CTV (methods plan II: 67.4 Gy and plan III 65.2 Gy). Furthermore, the plan optimization approach as used in plan II and III resulted in reduced and acceptable max dose values within the targets (76.9 Gy and 74.3 Gy, resp).

Conclusion: Unacceptable high doses of up to 80 Gy were observed in VMAT plan evaluations based on weekly repeat CTs. To avoid these over dosages, high fluence profiles in PTV-in-air regions should be avoided during planning optimization. An alternative VMAT optimization and evaluation approach has been proposed for cT1-2aNOMO laryngeal cancer patients.

EP-1813

Clinical implementation of an adaptive planning technique for lung VMAT radiotherapy

M. Naisbit¹, G. Ward¹, J. Lilley¹

¹Leeds Cancer Centre, Medical Physics, Leeds, United Kingdom

Purpose or Objective: At the Leeds Cancer Centre approximately 40% of lung patients receiving VMAT radiotherapy (RT) display a reduction in tumour volume when imaged using CBCT during treatment. The aim of this work was to develop a method to assess whether the dosimetric impact of observed anatomical changes is sufficiently significant to justify a treatment replan.

Material and Methods: Twelve lung patients receiving FFF VMAT RT planned on the Monaco 3.3 treatment planning system (Elekta) were identified. All had been rescanned, recontoured and replanned due to noted tumour shrinkage. For lung replans the clinical aim is to continue treating the original target volumes, so a rigid registration was performed between the planning CT and the rescan CT using a mutual information algorithm. Target volumes and OAR were transferred from the planning CT to the rescan CT and assessed by a physicist and clinician team to ensure they were clinically appropriate. The original plan was recalculated on the rescan CT studyset and dose volume histogram (DVH) statistics calculated for targets and OARs on the rescan studyset.

Results: For patients who displayed tumour changes without other significant internal changes the transferred target structures were deemed clinically acceptable with minor editing. Comparison of the transferred structures to the replan structures indicated that differences in remarking the targets were larger than image registration and transferral errors. Small variations in spinal cord and lung contours suggest that it is more accurate to re-contour these structures on the rescan CT, especially if they are receiving a dose close to tolerance. This method of adaptive planning was found to significantly reduce the replanning time. A notable limitation of the process was observed for patients who display other significant internal anatomical changes such as a change in lung volume or mediastina position, resulting in inaccurate transferred structures. Based on the DVH statistics for the transferred targets and re-contoured OAR, 9/12 plans required a full treatment replan. Although the target coverage was clinically acceptable the loss of tumour tissue meant that nearby OAR received doses above their tolerance.

Conclusion: A method has been developed to assist the adaptive planning process for lung patients receiving FFF VMAT radiotherapy. This provides a means of assessing the dosimetric effect of tumour changes to determine whether a new treatment plan is necessary. It showed that for 25% of patients who received full treatment replans no replan was necessary, as the dosimetric effect of tumour shrinkage was insignificant in terms of both target coverage and OAR doses. Therefore it allows significant time savings in the treatment replanning process. Use of the technique is limited to patients who display tumour volume changes with no other significant changes to internal/external anatomy.

EP-1814

Fractionated stereotactic radiotherapy using Gamma Knife Icon with adaptive re-planning (a-gkFSRT)

F. Stielner¹, F. Wenz¹, Y. Abo-Madyan¹, S. Mai¹

¹University Medical Center Mannheim- University of Heidelberg, Department of Radiation Oncology, Mannheim, Germany

Purpose or Objective: The Gamma Knife Icon (Elekta AB, Schweden) allows frameless treatment of patients in a precise stereotactic environment using a combination of cone-beam computer tomography (CBCT) for positioning, a thermoplastic mask system for positioning and fixation and an infrared based camera system "high definition motion management" (HDMM) for patient tracking during treatment. Using these novel options, the Gamma Knife Icon provides the possibility for adaptive fractionated stereotactic radiotherapy (a-gkFSRT). Here we report the treatment of the first patient with a-gkFSRT.

Material and Methods: The first patient treated with Gamma Knife Icon at the University Medical Center Mannheim received MR imaging with an individual cushion for pre-planning with the treatment planning system (TPS) GammaPlan 11.0.1 (Elekta AB, Schweden) 7 days before treatment. For every fraction of the treatment a daily CBCT was performed to verify the actual skull/tumour position. An automatic co-registration was performed to determine the daily shift in translation and rotation. The TPS adapted automatically the shot positions to the daily position and recalculated the dose distribution (online adaptive planning). During the treatment the HDMM system recorded the intra-fractional patient motion. Further we recorded the times for positioning, image guidance and treatment to define a clinical treatment slot.

Results: The total treatment time for fraction 2-5 was around 20 minutes. The positioning of the patient needed 0.8 min, CBCT positioning plus acquisition 1.03 min plus 0.62 min, CT data processing and adaptive planning 2.66 min and treatment 15.6 minutes. The mean values and standard deviations for the 5 daily CBCTs compared to the reference scan are for rotation $-0.59^\circ \pm 0.49 / 0.18 \pm 0.20 / 0.05^\circ \pm 0.36$ and for translation are $0.94\text{mm} \pm 0.52 / -0.08\text{mm} \pm 0.08 / -1.13\text{mm} \pm 0.89$. The adaptive re-planning (duration 1.25 minutes) every day was very accurate and yielded quality measures e.g. coverage, selectivity and gradient for the delivered dose identical regarding to the initial values. Using the HDMM system over all fractions we saw an intra-fractional movement of $0.13 \pm 0.04\text{mm}$. The intra-fractional movement was controlled by the HDMM system and showed similar results as a repeated CBCT after treatment ($<0.32^\circ$ and 0.20mm).

Conclusion: The Gamma Knife Icon allows combining the accuracy of the stereotactic Gamma Knife system with the flexibility of fractionated treatment of a linear accelerator with mask system and CBCT. Further the Icon system introduces a new online patient tracking system to the clinical routine. The inter-fractional accuracy of patient positioning was controlled with a thermoplastic mask and CBCT. The adaptive re-planning was quick and yielded high quality plans. Identical dose was delivered each day because of adaptive re-planning.

EP-1815

Towards adaptive Tomotherapy: planning CT to MVCT deformable image registration for dose calculation

M. Branchini^{1,2}, S. Broggi², M.L. Belli^{1,2}, C. Fiorino², G.M. Cattaneo², L. Perna², R. Calandrino²

¹University of Milan, Medical Physics Specialization School, Milan, Italy

²IRCCS San Raffaele Scientific Institute, Medical Physics, Milan, Italy

Purpose or Objective: The aim of this study was to report the results of the validation of a previously developed method for dose of the day calculation in head and neck Tomotherapy based on deformable image registration (DIR) of the planning CT to MVCT taken during treatment.

Material and Methods: kVCT/MVCT images of ten HN patients treated with Helical Tomotherapy (HT) with a simultaneous integrated boost (54/66/69 Gy/30 fr) were retrospectively analyzed. For each patient the planning kVCT (CT-plan) was elastically registered (DIR) to the MVCT acquired at the 15th therapy session (MVCT15) with a B-Spline deformation algorithm using Mattes mutual information (open-source software 3D Slicer), resulting in a deformed CT (CTdef). At the same day, a kVCT was acquired with the patient in the same treatment position (CT15) and taken as reference. Then, CTdef and CT15 were re-sampled to the same slice thickness (3mm) through linear interpolation. The original HT plans were recalculated both on CTdef and CT15 in the HT planning station using the DQA (dose quality assurance) module, considering the two set of images as phantoms: images were rigidly aligned with the CT-plan, mimicking the true daily repositioning. Dose distributions on CTdef and CT15 were compared in order to assess the reliability of the method; local dose differences $<2\%$ of the prescribed dose (DD2%) and global gamma-index values (2%-2mm; considering points with dose $>20\%$ of the prescribed one) were assessed for all the available transversal slices (step: 6 mm) with Mapcheck SNC Patient Software (Sun Nuclear).

Results: The results of DIR was qualitatively satisfactory when comparing CTdef against CT15. On average, $94.4\% \pm 0.9\%$ of points passes the gamma analysis test and $87.9\% \pm 1.1\%$ of the body's voxel were found for DD2% (on average 27 slices available for each patient). If excluding 3 patients where a relevant number of slices were cut due to the narrow FOV of the MVCT15, the values further improved to $95.7\% \pm 0.8\%$ and $89.1\% \pm 1.3\%$ for gamma and DD2% respectively.

Figure: in column A the absolute dose differences between CTdef and CT15; in column B gamma distributions (in red and blue voxels with gamma >1).

Conclusion: CT to MVCT DIR using an open source system was proven to be an accurate method for calculating the dose of

the day in HT treatments for HN cancer. This study represents the first proof of the dosimetric accuracy of DIR from kVCT to MVCT. The suggested method is sufficiently quick and reliable to be considered as an appropriate tool for dose of the day calculation in clinical strategies for adaptive Tomotherapy of head and neck cancer.

EP-1816

A hybrid approach for head-neck cancer using on-line image guidance and off-line adaptive planning

R. Srivastava¹, P. Sharma¹, G. Saini², J. Sethi², A. Aggarwal², K. Goyal², M. P¹

¹International Oncology Centre-Fortis Hospital, Medical Physics, Noida, India

²International Oncology Centre-Fortis Hospital, Radiation Oncology, Noida, India

Purpose or Objective: A prospective study to evaluate the dosimetric benefits of treatment plan adaptation for patients who had undergone Repeated CT (ReCT) and replanning due to treatment-induced anatomical changes during radiotherapy.

Material and Methods: Five patients of head and neck cancer, who have undergone rescanning and replanning due to weight loss and tumour shrinkage, were selected for the study. For each patient, ReCT has been taken at mid treatment. The ReCT image for each patient was registered with the initial planning CT image and CBCT image of mid treatment fraction individually. The rigid registration was performed automatically and final manual adjustment was used for better alignment. After the rigid registration, a deformable registration was also performed automatically using vertex-vertex correspondence between the reference image set and the target image sets. Contours were conducted for target volumes and OARs (Organ at risk). The initial treatment plan was created on initial CT using Eclipse treatment planning system (v. 11.0). This initial treatment plan was transferred to ReCT and CBCT and the dose recalculated. The replanning has been done on ReCT and this replan was delivered as a modified plan to the patient. The initial CT plan, which was optimized and calculated on initial CT, was compared dosimetrically with initial CT plan calculated on ReCT & CBCT and ReCT plan optimized and calculated on ReCT.

Results: Rescanning in mid treatment shows 27% (13%-42%) reduction of parotid volumes and therefore 21% (7%-35%) increase in parotid mean doses. Initial plan calculated on ReCT and CBCT found 15% (9%-26%) increase in PRV spine maximum doses which was reduced by replanning on ReCT. The body maximum doses increased by 6.5% (4%-8%) in four patients and 22% in one patient when initial CT plan was calculated on ReCT and CBCT.

Conclusion: Adaptive radiotherapy involves the modification of the initial plan to account for patient specific anatomical changes (replan). Replanning on ReCT in head and neck patients during the course of radiotherapy is an ultimate solution with regard to doses of spinal cord, parotid glands and skin.

EP-1817

Dosimetric evaluation of new method for patient specific CBCT scan calibration

A. Fidanzio¹, S. Menna¹, F. Greco², A. Porcelli², G. Benecchi³, L. Azario¹, A. Piermattei¹

¹Università Cattolica del Sacro Cuore - Policlinico A. Gemelli, Physics Institute, Rome, Italy

²Fondazione A. Gemelli, UOC Fisica Sanitaria, Rome, Italy

³Azienda Ospedaliero Universitaria di Parma, UOC Fisica Sanitaria, Parma, Italy

Purpose or Objective: The dose delivered in radiotherapy can be influenced by several factors such as patient setup variations and anatomical changes. Generally CT scans are carried at fixed interval times to verify the presence of anatomical changes but this is time consuming and frequently

it cannot assure a timely control. The Cone Beam CT (CBCT), generally carried out during the fractionated radiotherapy, allows a more timely verification of morphological changes. The calibration in terms of relative electron densities (RED) of CBCT images allows their use for hybrid plan calculation needed to decide for an eventual adaptive strategy. However the CBCT calibration suffers of some problems such as time stability and patient variability. This work reports the dosimetric assessment of an original patient-specific CBCT calibration method.

Material and Methods: A homemade software was developed to automate the HU calibration of CBCT in terms of RED adopting the following procedure: 1) two CT and CBCT scans with negligible morphological changes are selected for a patient, 2) in these images the HU values of different ROIs, relative to correspondent anatomical regions, are acquired to obtain a correlation function between CBCT and CT HUs, 3) the correlation function is used to determine the CBCT calibration curve HUs versus RED from the CT calibration curve; 4) finally the CBCT calibration curve is optimized by an algorithm that minimize the differences of patient's radiological thicknesses measured on the CT and CBCT patient's slices. This procedure has been verified for H&N, lung and pelvic body regions in a Rando phantom and for 5 patients for VMAT irradiations by a linac Varian TrueBeam STx with the on-board imager (140 kV x-ray tube). Using Eclipse TPS the dosimetric assessment of the method was based on comparisons between: isocenter doses; γ -gamma analysis between dose matrices of planes passing through the isocentre and DVH comparisons.

Results: The calibration procedure required about 5 minutes for each patient. Dosimetric comparison supplied agreements (i) within 2% for the isocenter doses; (ii) γ % greater than 0.97% for head and neck, 98% for lung and 99% for pelvic regions and the γ_{mean} values were all within 0.4. The PTV V95 and mean dose were within 2%. While the mean dose of principal OARs was within 3%.

Conclusion: The CBCT calibration method used here seem to be accurate enough to calculate hybrid planes, useful to discuss and to evaluate the opportunity of an adaptive radiotherapy strategy.

EP-1818

Using ROIs projected on EPID as a predictor of plan deterioration due to anatomical changes

O. Piron¹, N. Varfalvy¹, L. Archambault¹

¹CHU de Quebec-Université Laval, Radio-oncologie, Quebec, Canada

Purpose or Objective: One of the side effects of radiotherapy is the patient's anatomical changes. 2D relative γ analysis from daily EPID images is a fast and simple method to detect anatomical changes that could have a strong dosimetric impact on the treatment plan. An action threshold determines if the error relative to the first fraction is significant or not, and thus requires a replanning. The aim of this study is to validate the threshold for lung cancer and to assess the relevance of including additional information of regions of interest (ROIs) from EPID images.

Material and Methods: EPID images were acquired for every beam and all fractions of 24 lung cancer patients. Of these, 8 patients were selected to evaluate the dosimetric impact of these changes. The PTV1 V95(%) was computed for both the planning CT and original contours deformed onto CBCT acquired at the last fraction. These values were then compared with 2D image relative γ analysis of EPID images when the PTV1 anatomical structure is projected on these images or not.

Results: The results of γ analysis were classified into 4 different categories using a k-means clustering analysis. These categories indicate the degree of discrepancy between the EPID image acquired on a treatment day and the reference from the first fraction. The first category

illustrates a small disparity from the reference whereas the fourth category show strong differences. Our hypothesis is that these categories can be used to identify patients in need of treatment adaptation. The Figure 1 shows the V95(%) parameter extracted from either the planning CT or the daily CBCT plan, as function of the average γ value for all beams. This average γ value is evaluated on the whole EPID image (Figure 1a) or the projected PTV1 image (Figure 1b). The horizontal dash line represent the dose tolerance for PTV1 (99%). There is a correlation between the average γ and the PTV1 V95(%) but the projected PTV1 on the EPID image does provide additional information regarding the degree of error. However, the V95(%) variation from the original and deformed contours is related to the degree of error as indicated in Table 1.

Table 1

Category	Nb of cases	$\left(\frac{V95(\%)_{CT} - V95(\%)_{CBCT}}{V95(\%)_{CT}}\right)$
1	4	1.47
2	2	3.49
3+	2	10.32

Conclusion: In summary, we demonstrated that PTV1 projection on the EPID plan does not provide new information on the plan deterioration. However, this method was more sensitive to anatomical changes and could be used as an indicator instead of the mean γ on the whole EPID image. In the following steps, the organs at risk projections will be evaluated to verify if they do provide new information. This approach is valuable for the treatment quality, but does not increase the dose to the patient or the time required for treating a fraction. Image acquisition and analysis can be easily automatized to further minimize the impact on the clinical workload.

EP-1819

Plan of the Day is the optimal approach to address organ motion for cervical cancer IMRT

R. Jadon¹, E. Spezi^{1,2}, L. Hanna¹, N. Palaniappan¹, M. Evans¹, E. Hudson¹, J. Staffurth^{1,3}

¹Velindre Cancer Centre, Clinical Oncology, Cardiff, United Kingdom

²Cardiff University, Medical Physics, Cardiff, United Kingdom

³Cardiff University, School of Medicine, Cardiff, United Kingdom

Purpose or Objective: Intensity modulated radiotherapy (IMRT) for cervical cancer is challenging due to organ motion within the CTV, comprising cervix, uterus, vagina, parametrium and pelvic nodes. Large CTV-PTV margins to compensate for this motion result in large volumes of organs at risk (OARs) within the PTV, negating the benefits of IMRT. Furthermore, there is significant intra-patient variation in organ motion therefore individualised adaptive strategies may be appropriate.

One option is Composite Strategy (CS) where a composite is formed from CTVs using planning scans and initial on-treatment cone beam CT (CBCT) scans. A second is Plan of the Day (PotD), where a plan library is created and the most appropriate plan chosen each day based on CTV position.

Material and Methods: Retrospective analysis of planning scans (full bladder (FB) and empty bladder (EB)) and on-treatment CBCTs for patients treated with radical radiotherapy for cervical cancer was performed.

CBCT scans were rigidly co-registered with FB scans on Oncentra Masterplan. On each scan the primary CTV (pCTV) comprising cervix, uterus, vagina, parametrium was outlined. On the FB scan bowel bag, bowel loops, rectum and bladder were outlined as OARs.

We modelled:

- 1) Standard margin: a 2cm isotropic CTV-PTV margin around the pCTV
- 2) CS: a composite was formed from pCTVs from FB, EB, and day 1-3 CBCTs, with a 1cm margin to PTV
- 3) PotD: a 3-plan library was created using pCTVs from FB and EB scans. A third mid-volume CTV was generated using deformable image registration on Velocity (v3.1, Varian Medical Systems) and custom software developed in Matlab. A 1cm margin was added to each CTV to generate PTVfull, PTVmid and PTVempty. If none of the 3 plans covered the CTV then a 'back-up' standard 2cm margin was chosen. The remaining CBCT scans for each patient were used to compare PTV volumes, CTV coverage, and OARs within PTV. Statistical differences were tested using Mann Whitney-U.

Results: 141 scans were assessed for 14 patients (FB, EB and 7-13 CBCTs each). The table below shows mean measures of the 3 strategies. The 3-library PotD could only be used in 58% of scans assessed, and the back-up plan was used for the remainder. Despite this PotD significantly reduced mean bowel, bowel bag, rectum and bladder in the PTV, whilst maintaining CTV coverage.

	Mean PTV Volume (cc)	Mean CTV coverage (%)	Mean Bowel in PTV (cc)	Mean Bowel bag in PTV (cc)	Mean Rectum in PTV (%)	Mean Bladder in PTV (%)
Standard margin	1061.65	99.6	111.8	366.5	71.9	59.3
Composite Strategy	798.36	99.9	84.8	295.4	62.8	55.45
Change from standard margin	Reduced 24.8%	Improved 0.19%	Reduced 24.1%	Reduced 19.4%	Reduced 12.7%	Reduced 6.5%
p-value (compared with standard margin)	0.007	0.137	0.265	0.15	0.137	0.7
Plan of the Day Strategy	765.2	99.6	68.3	228.2	49.9	43.44
Change from standard margin	Reduced 27.9%	No change	Reduced 38.9%	Reduced 37.7%	Reduced 30.5%	Reduced 26.7%
p-value (compared with standard margin)	0.012		0.05	0.006	0.000	0.027

Conclusion: Adaptive strategies show promise. PotD, even when the plan library was only used in 58% of scans, increased OAR sparing compared with CS. Dosimetric analysis of these strategies with IMRT planning is ongoing.

EP-1820

On the use of deformable image registration to evaluate the need to perform ART in head and neck cancer

P. Delgado-Tapia¹, M. Lizondo¹, A. Latorre-Musoll¹, N. Jornet¹, T. Eudaldo¹, P. Carrasco¹, A. Ruiz-Martinez¹, C. Cases¹, M. Ribas¹

¹Hospital de la Santa Creu i Sant Pau, Servei de Radiofísica i Radioteràpia, Barcelona, Spain

Purpose or Objective: ART is a time-consuming process and the question "do we need to replan?" is not always easy to answer. In this work, we investigate: (i) if Deformable Image Registration (DIR) software can provide reliable criteria to decide if we need to replan; (ii) if we can use DIR to replan the treatment without performing a new planning CT.

Material and Methods: Five patients, treated using a SIB-IMRT technique, were included in this retrospective study. For all patients, a new planning CT (CT2) had been performed after observing anatomical changes between the initial planning CT (CT1) and CBCT images.

For this study, CT1 was registered with CBCT by using a DIR algorithm (SmartAdapt v13.5, Varian Medical Systems). We obtained a new CT (CTdef) by applying the deformation field both on CT1 and on contoured structures. We copied and recalculated the initial plan to CTdef. To assess whether replan was really needed at that time, we proposed a two-step algorithm (figure):

Impact of changes on targets coverage. This evaluation was twofold. On one hand, we assessed the dosimetric coverage and homogeneity of CTVCTdef by comparing D98% and D2% to initial ones. On the other hand, we defined a geometric overlapping index (OI) as the percentage of CTVCTdef volume inside PTVCT1.

Impact of changes on OARs coverage. We focus on two dose-volume indices, V30Gy of parotid glands and D2% of spinal cord on CTdef. The tolerance limits were set as the range of variability of those indices by shifting the isocenter of the original plan on CT1 up to 3mm (the CTV to PTV margin) in each direction.

Only those patients with $\Delta D98\% > 2.5\%$, $\Delta D2\% > 2.5\%$ or $OI < 0.95$, and/or OARs indices out of their variability range (as long as initial OAR indices fulfilled our institution constraints) should be replanned.

As all patients had been replanned anyway, we copied and recalculated those plans (planned on CT2) to CTdef. The aforementioned indices were re-evaluated (replacing CT1 by CT2) to check if CTdef would be a valid planning CT.

Results: Table 1a shows the dosimetric differences when recalculating the original plan on CTdef. Only patient #2 (highlighted data) should have been replanned.

The differences between using a new CT or the CTdef for dose planning are shown in Table 1b. CT2 and CTdef are equivalent since plans on CT2 can be transferred to CTdef with equivalent dosimetric results.

Patient #3 was excluded because, additionally to anatomical changes, new findings lead to include new tumour sites.

Structure	Parameter	Patient #					
		1	2	3	4	5	
1 a)	CTV	OI	1,00	0,94	0,99	1,00	1,00
	CTV	$\Delta D_{98\%}$ (%)	-1,3	4,1	2,1	-1,2	0,4
	CTV	$\Delta D_{2\%}$ (%)	-2,1	-0,6	0,5	-2,5	0,0
	Right par	V_{30Gy} (%) [range]	84 [55-72]	---	11 [10-30]	26 [13-30]	66 [41-56]
	Left par	V_{30Gy} (%) [range]	22 [6-25]	79 [54-74]	30 [18-40]	31 [30-41]	53 [30-47]
	Spinal cord	$D_{2\%}$ (Gy) [range]	43 [41-48]	28 [21-26]	55 [55-64]	33 [26-35]	35 [24-32]
1 b)	CTV	OI	0,98	0,95	---	1,00	0,99
	CTV	$\Delta D_{98\%}$ (%)	1,5	1,3	---	-0,5	1,6
	CTV	$\Delta D_{2\%}$ (%)	0,3	-0,1	---	-0,9	0,7
	Right par	V_{30Gy} (%) [range]	84 [70-89]	---	---	18 [5-16]	66 [50-60]
	Left par	V_{30Gy} (%) [range]	50 [47-73]	84 [56-77]	---	16 [15-24]	66 [41-55]
	Spinal cord	$D_{2\%}$ (Gy) [range]	27 [26-34]	26 [23-27]	---	41 [35-40]	42 [21-26]

Table 1. Impact of changes on targets and OARs. 1.a) Comparison between original plan on CT1 and on CTdef. 1.b) Comparison between replan on CT2 and on CTdef.

Conclusion: The proposed algorithm is a useful tool to decide whether is necessary to replan a treatment, thus avoiding unnecessary ART for a significant number of patients. We showed that CTdef provides a valid new planning CT for those patients which must be replanned, thus avoiding unnecessary scans.

EP-1821

Adaptive external radiation therapy of cervical cancer with different uterine fundus positions

A.B.L. Marthinsen¹, F.C. Vidaurre¹, L. Rolstadaas¹, M. Eidem¹, S. Danielsen¹, M. Sundset², A.D. Wanderås¹

¹St. Olavs Hospital, Department of Oncology, Trondheim, Norway

²St. Olavs Hospital, Department of Gynecology, Trondheim, Norway

Purpose or Objective: Adaptive strategies for external radiation therapy of cervical cancer may counteract that parts of the target volume may receive too low radiation doses due to interfractional uterus movement. This has become more important when using advanced radiation delivery techniques (IMRT/VMAT) with highly conformal dose distribution to the target volume. We have retrospectively tested a simple adaptive strategy with different PTV shapes covering possible movement of the fundus of the uterus.

Material and Methods: For 5 cervical cancer patients treated with external radiation, the planning CT and CT scans taken throughout the treatment course were used as a basis for the study. For each patient the uterus was delineated as CTV in the planning CT with a uniform CTV-PTV margin of 1 cm. Two additional PTVs were delineated to account for a +/- 0.5 cm shift in the position of fundus uterus in the anterior-posterior direction. The PTV of the affected lymph node areas was added to the 3 PTVs to make up a final PTV for treatment planning, and corresponding VMAT plans were made for each case. The conventional treatment plan was based on the uterus position in the planning CT, and the two other plans were used as possible adaptive "plan of the day" for each treatment fraction. 8 - 19 CT scans were taken throughout the treatment course for each patient, and the volume of the part of uterus receiving less than 95% of the prescribed dose for each fraction was calculated for both conventional and adaptive strategies.

Results: For the conventional treatment, parts of uterus receiving less than 95% of the prescribed dose was found in 4 of the 5 patients recorded, corresponding to 29 of the overall 52 CT scans taken throughout the treatments. The mean volume of the under dosed part of the uterus was 18.4 cm³. The adaptive approach improved the dose coverage for all the under dosed fractions; 4 fractions in 3 of the patients received adequate doses to the whole uterine volume, and for the other fractions the mean volume of the under dosed part of uterus was reduced by 30 - 67% for the actual patients.

Conclusion: For external radiation of cervix cancer, the proposed simple adaptive technique, based on only one planning CT, increased the volume of the uterus receiving > 95% of the prescribed dose for all the fractions tested. However the approach did not give adequate dose distribution to the whole uterus for all fractions for the adaptive PTVs used in this study.

EP-1822

limits and potentialities of the use of CBCT for dose calculation in adaptive radiotherapy

S. Meroni¹, V. Mongioj¹, T. Giandini¹, F. Bonfantini¹, A. Cavallo¹, M. Carrara¹, C. Stucchi¹, C. Cavatorta¹, E. Pignoli¹

¹Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics, Milan, Italy

Purpose or Objective: To evaluate the feasibility of using CBCT images for dose calculation and to identify the most convenient calculation approach for replanning in Adaptive Radiotherapy (ART). For large cone beam geometry, scattered radiation and beam hardening cause uncertainties in the estimation of tissue electron densities (pel). Different strategies have been adopted over the last decade to face this problem but there is no agreement on the results obtained with each technique.

Material and Methods: By using a CIRS 062 phantom, conversion curves (Hounsfield Unit, HU, to ρ_{el}) for two different Varian CBCT models and for head and pelvis protocol were measured. Diffusing material was added to the phantom to simulate the typical dimensions of the anatomical districts. A dosimetric analysis was then performed for CIRS phantoms and patients treated for H&N and prostate cancers, by comparing dose distributions calculated on the same CBCT using different HU- ρ_{el} conversion curves. For each case, the plan-CT and CBCT images were registered rigidly. A VMAT plan was generated on the plan-CT and transferred to the CBCT. The dose was calculated on the CBCT without heterogeneities corrections, using the plan-CT conversion table and using the CBCT site-specific conversion tables. The distributions were compared to the reference distribution (Dref) with 3D gamma analysis, Dref being the dose calculated on the plan-CT using its proper conversion curve. For each comparison the *net disagreement* was calculated, i.e. the percentage of points that exceeded gamma criteria without taking into account discrepancies due to registration errors (DTA = 2mm for phantoms, 3 mm for patients).

Results: For the CIRS phantoms, the CBCT conversion curves gave good results for dose calculation: mean net disagreement for gamma criteria DD= 1% was lower than 1%. For the pelvis region, the best results were obtained without applying heterogeneity corrections to the calculation. The dosimetric discrepancies with respect to Dref were few and mostly below 2% of the local dose. For H&N patients, calculations with the CBCT site-specific conversion curves showed the smallest discrepancies with Dref. On average, 0.4% of the points showed discrepancies larger than 1%.

Conclusion: The differences between the results found for phantoms, pelvis and H&N patients highlight the importance of careful evaluations for each anatomical region. The error introduced by calculating the dose on a CBCT is acceptable for ART. CBCT dose calculation could be used to monitor the entity of anatomical variations in the patients. An important limitation on the use of CBCT for treatment planning is the FOV dimension, often not sufficient to include the whole PTV or patient shoulders in case of H&N treatment. This affects dose calculation due to the lack of scattered radiation causing underdosages in cranial and caudal slices.

EP-1823

Characterization of kV- and MV-CBCT for personalized adaptive treatment therapy on RayStation TPS

A. Balazs¹, T. Torbjørn Furre¹, K. Karsten Eilertsen¹
¹Oslo University Hospital- Norwegian Radium Hospital, Medical Physics, Oslo, Norway

Purpose or Objective: Modern treatment therapy, with the combination of intensity modulated fields, dose escalation and small margins, is unthinkable without equipment that facilitates IGRT. Hence, the latest generations of linacs are equipped with modern kV and MV detectors, with enhanced image quality and precision. RayStation TPS exploits this development further, making it possible to use these image series to execute personalized adaptive treatment planning, by using the acquired CBCT during treatment.

Our goal with this project is to characterize the geometrical and dosimetric (in terms of HU) accuracy of different CBCT types from different machines (Elekta XVI, Varian TrueBeam OBI and Siemens Artiste kView).

Material and Methods: Using CatPhan phantom, planning CT with a Philips BigBoard Brilliance, Head&Neck protocol were acquired and imported to RayStation TPS. The advantage of using CatPhan is, that it has both geometrically known and accurate measures, and inserts with known CT numbers. CBCT series were acquired by using Head&Neck protocols. The captured image series were then imported to RayStation, where, after rigid image registration, all the characteristics of the CBCT images were investigated, and doses recalculated on the CBCT image series.

Histograms over the image slices were subject to investigation in IDL, to verify the accuracy of CT numbers and geometrical reconstructions from RayStation

Results: Some differences were observed between the different CBCT modalities and the planning CT, investigating the different material types and geometries:

-The preliminary investigation of geometrical accuracy shows that both the Elekta XVI modules deforms the phantoms dimensions by about 1 mm. Most of the inserts shows CT# within acceptable limits. As for the Siemens kView, a carbon target modulated 1MV energy is applied to acquire the CBCT images, resulting in almost 30% underdosage in the Teflon material.

-The data were successfully reconstructed and analyzed with IDL as well showing good agreement between the data from RS and raw image data.

Material	Representative CT# by means of HU from the various machines					
	Phantom manual	Philips Big Board	Varian TrueBeam	Elekta XVI 1	Elekta XVI 2	Siemens Artiste kView*
Air	-1000	-994	-1000	-760	-869	-425
PMP	-200	-199	-166	-156	-176	-52
LDPE	-100	-70	-82	-115	-77	49
Polystyrene	-35	-20	-34	-119	14	-10
Acrylic	120	120	119	78	125	132
Delrin	340	339	350	225	337	323
Teflon	950	957	894	655	696	509

*Siemens Artiste kView is a MV-CBCT with average energy 1 MeV

Material	Calculated average doses for different CBCT modalities (Gy)				
	Philips Big Board	Varian True Beam	Elekta XVI 1	Elekta XVI 2	Siemens Artiste kView*
Air	10.28	10.32	10.25	10.26	9.98
PMP	10.04	10.06	10.02	10.03	9.89
LDPE	8.01	8.14	8.03	7.75	8.00
Polystyrene	5.74	5.96	5.75	5.45	5.79
Acrylic	5.60	5.82	5.64	5.44	5.67
Delrin	7.95	8.13	7.98	7.91	7.91
Teflon	10.00	10.03	9.98	10.04	7.19

*Siemens Artiste kView is a MV-CBCT with average energy 1 MeV

Conclusion: Our study shows, that CBCT series are precisely reconstructed in RayStation, both geometrically and by means of CT#. However, careful investigation of the electron densities of the imported CBCT's is necessary in order to avoid inaccurate dosimetric outcomes.

Further investigations are necessary to map the reason for the differences between image series acquired with these machine types as a step towards implementing deformable image registration using CBCT.

EP-1824

A new strategy approach for dose tracking and novel radiobiological models for adaptive radiotherapy

S. Strolin¹, E. Mezzenga², A. Sarnelli², S. Marzi¹, G. Sanguineti³, L. Marucci³, M. Benassi², L. Strigari¹

¹IFO - Istituto Regina Elena, Laboratory of Medical Physics and Expert Systems, Roma, Italy

²Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori IRST IRCCS, Medical Physics Department, Meldola FC, Italy

³IFO - Istituto Regina Elena, Department of Radiotherapy, Roma, Italy

Purpose or Objective: To test the feasibility of dose tracking approach in Head-and-neck (HN) cancer, two deformable image registration (DIR) strategies has been implemented and compared.

Material and Methods: Planning (pCT) and weekly (w-CT) acquired computed tomography (CT) scans of a cohort of 15 Head-and-neck (HN) cancer patients already prospectively enrolled in our Institute for a study on adaptive approach have been imported in Raystation TPS version 4.6.102.4 (RaySearch Laboratories AB, Stockholm, Sweden). The recently available hybrid algorithm was used including body contour as focus ROI and with/without manually contoured ROIs as controlling ROIs indicated as RH/H, respectively. DICE index was used to assess the goodness of propagation of contours generated by both DIR approaches. Doses/volumes statistics and radiobiological data were calculated and compared according DIR strategy.

Results: For GTVs the median DICEs were 0.88 and 0.63 for RH and H, respectively, while for parotid gland were 0.94 and 0.82, and for spinal cord were 0.94 and 0.88, respectively. Although dose differences on GTVs show the median variations within 1% with minimal values up to 8%, TCP values were 63.7%, 69.7% and 61.9 % for planned, RH and H approach, respectively. Moreover, the average NTCP for homo-lateral parotids it was 36 %, 46 % and 34 %; while for contra-lateral parotids was 28%, 36% and 27% based on planned, RH-based and H-based accumulated DVHs, respectively.

Conclusion: RH strategy generates structures well in agreement with ones manually contoured, supporting the goodness of generated deformation matrix, resulting an appropriate strategy to perform dose tracking in HN cancer patients eligible for ART. Home-made tools/routine, as developed in this work, are mandatory to evaluated results and permit the adoption of a dose tracking strategy.

EP-1825

Delivered dose determination in large organ deformations: Pre-requirement for adaptive RT for LACC.

P.V. Nguyen¹, F. Lakosi¹, J. Hermesse¹, S. Nicolas¹, A. Cifor², M. Gooding², P.A. Coucke¹, T. Kadir², A. Gulyban¹

¹C.H.U. - Sart Tilman, Radiotherapy Department, Liège, Belgium

²Mirada Medical Ltd, Physics, Oxford, United Kingdom

Purpose or Objective: To create robust methodology for accumulating delivered dose to organs on the basis of daily cone beam computer tomography (CBCT) images using Radial Basis Function with Robust Point Matching (RBF-RPM) deformation algorithm. Clinical evaluation includes clinical target volume (CTV) coverage for patient with locally advanced cervical cancer (LACC).

Material and Methods: Between June and September 2015 five consecutive LACC patients were scanned with empty and full bladder conditions for treatment planning purposes. Primary CTV was delineated in both scans creating an internal target volume (ITV) concept and the distance between the tip of the uterus was measured. Primary ITV and lymph node CTVs were expanded with 10 mm margin to generate the planning target volume (PTV). Advanced treatment planning technique (VMAT or IMRT) were used for delivering a total dose of 45 Gy in 25 fractions with daily online correction CBCT. On every CBCT the 1) current position of the primary CTV were delineated and 2) the planned dose matrix were co-registered and eventually transposed to CBCT rigidly. Using the Mirada RTx (version 1.6.2, Mirada Medical, Oxford, United Kingdom) between the planning reference CT (= full bladder) and each CBCT a "CTV-guided" deformation (using the RBF-RPM algorithm) matrix were generated to deform the dose matrices from CBCT to the planning CT. The dose parameters on the initial CTV were evaluated on a single fraction basis (worst and average) and summed dose basis compared to the reference plan value.

Results: The average tip movement of the uterus was 2.2 cm (range 0.5-5.7 cm). A total of 118 CBCTs were eligible to perform the CTV delineation and the dose matrix transformation (rigid CT to CBCT, deformation CBCT to CT). Visual verification of each individual deformation grid were considered as clinically plausible and smooth (Figure 1). The changes in CTV_V95% were -4.7% (range [-7.0, -3.62], -0.3% [-1.4, 2.2] for the single fraction worst and mean, while for the summed actual delivery -0.6% [-3.7, 1.76]. Deviation of CTV_D95% resulted in -2.7 Gy [-5.8, -1.1] and -0.4 Gy [-0.9, -0.2] for the single fraction worst and mean, while for the summed actual delivery -0.5 Gy [-2.1, 0.1].

Conclusion: Using VMAT/IMRT for LACC treatment in combination with ITV concept and 10 mm margin provides a safe treatment option in the presence of large daily organ deformation. The dose accumulation using the RBF-RPM algorithm is feasible and provides a powerful tool to evaluate delivered dose not only to CTV but also to organs at risk. This methodology allows an environment to test various adaptive strategies (e.g. library of plans based LACC radiotherapy) and CTV to PTV margins in a safe retrospective manner.

EP-1826

An empirical post-reconstruction method for beam hardening correction in CT reconstruction

B. Yang¹, H. Geng¹, W.W. Lam¹, K.Y. Cheung¹, S.K. Yu¹

¹Hong Kong Sanatorium & Hospital, Medical Physics and Research Department, Happy Valley, Hong Kong SAR China

Purpose or Objective: Beam hardening artifacts in X-ray computed tomography is caused by the polyenergetic spectrum of X-ray source. In this abstract we describe an empirical post-reconstruction method which removes the artifacts successfully.

Material and Methods: Our proposed post-reconstruction method has similar approach as a well-known correction method first developed by Joseph and Spital (J&S). Our method also requires prior knowledge of the X-ray spectrum and consists of three stages of correction. The first step is a so-called soft tissue correction which determines the equivalent length of soft tissue T_e by solving the non-linear equation:

$$P_i = \sum \omega \exp(-\mu(s)\rho(s)T_e)$$

In the second step, this image is segmented into soft tissue T_s and high density T_b (e.g. bone) region by setting a threshold. Different from J&S, we consider $\mu(s)\rho(s)T_b$ as part of the density map of high density region and calculate the projection data:

$$B_i = \sum \omega \exp(-\mu(b)\mu(s)\rho(s)T_b)$$

The third step applies the soft tissue correction again by solving the non-linear equation:

$$\exp(-\ln(P_i) + \ln(B_i)) = \sum \omega \exp(\mu(s)\rho(s)T_s)$$

, therefore a density map $\rho(s)T_s$ is reconstructed. The final image will be the sum of $\rho(s)T_s$ and $\rho(s)T_b$. We created a 128 x 128 pixel numerical phantom which was a circular phantom consisting of water, four small regions containing bone and a small region containing fat. For validating the robustness of the method, we also replaced the four small regions with those containing aluminum and titanium. The projection data consisted of 140 radial samples and 100 angular samples over 180 degree from a 100 kVp parallel X-ray beam.

Results: The results of the post-reconstruction method for the phantom containing bone, aluminum and titanium are shown respectively. Within each figure, top left is the true phantom image; the middle is the direct filtered back projection (FBP) result with no correction; the top right is the post-reconstruction result; the profile plot is sampled at the center of phantom. For the cases of bone and aluminum, the beam hardening artifacts are removed successfully. Even in the most challenging case of titanium, the artifacts are suppressed greatly. Compared with the results using method from J&S, the density values of reconstructed high density

region are closer to the real values with deviation +5.3%, +0.4% and +10.2% for bone, aluminum and titanium respectively.

Figure 1 Results of phantom containing aluminum.

Conclusion: Our proposed empirical post-reconstruction method works well in beam hardening correction.

EP-1827

Dual energy Computed Tomography based tissue characterisation for Radiotherapy treatment planning
 N. Tomić¹, H. Bekerat¹, F. DeBlois¹, J. Seuntjens², R. Forghani³, S. Devic²

¹Jewish General Hospital, Radiation Oncology, Montreal, Canada

²McGill University, Oncology, Montreal, Canada

³Jewish General Hospital, Diagnostic Radiology, Montreal, Canada

Purpose or Objective: It is known that both kVp settings, as well as geometric distribution of various materials, lead to significant change of the HU values, being the largest for high-Z materials and lowest kVp setting used for CT scanning. On the other hand, it is well known that dose distributions around low-energy brachytherapy sources (103Pd, 125I) are highly dependent on the architecture and composition of tissue heterogeneities in and around the implant. Both measurements and Monte Carlo calculations show that the errors caused by improper tissue characterization are around 10% for higher energy sources and significantly higher for low energy sources. We investigated the ability of dual-energy CT (DECT) to characterize more accurately tissue composition.

Material and Methods: Figure 1.a shows the RMI-467 heterogeneity phantom scanned in DECT mode with 3 different setups: the first set-up in which we placed high electron density (ED) plugs within the outer ring of the phantom is called Normal one, as we assume that in clinical practice this would be the most commonly used geometrical distribution of tissue ED plugs. In the second set-up we arranged high ED plugs within the inner ring and in the third one, ED plugs were randomly distributed. All three setups were scanned with the same DECT technique using a single-source DECT scanner with fast kVp switching (Discovery CT750HD; GE Healthcare). Images were reconstructed into 1.25-mm slices with a 40-cm display field of view and a 512 X 512 matrix and transferred to a GE Advantage workstation for advanced DECT analysis. Spectral Hounsfield unit curves (SHUACs) were then generated from 50 to 140-keV, in 10-keV increments, for each tissue equivalent plug.

Results: Figures 1.b-d represents HU to ED calibration curves for monochromatic CT images at 50, 80 and 140 keV respectively. As expected, the dynamic range of HU shrinks with increased photon energy as the attenuation coefficient ranges decrease. The same figures also suggest that the spread of HUs for the three different geometrical setups is the smallest at 80 keV. To quantify variation in HUs with photon energy, we calculated relative variation for various tissue equivalent materials (LN 450 Lung, Breast, Liver, CB2-30%, CB2-50%, Cortical Bone) and plotted for several different photon energies in Fig.1.e.

Figure 1 Impact of electron density spatial distribution on reconstructed Hounsfield Units on virtual monochromatic DECT images: a) three experimental setup (left – high Z material plugs in outer ring; center – high Z plugs in inner ring; right – standard random plug distribution); b-d) HU-ED curves for three different experimental setups at 50 keV, 80 keV, and 140 keV respectively; e) relative variation of the reconstructed HUs for various materials taken from different reconstructed virtual monochromatic energy images.

Conclusion: Spectral Hounsfield unit curves demonstrate the lowest HU variation at 80 keV for the three different geometries used in this work. Among all the energies and all materials presented, the largest difference appears at high Z tissue equivalent plugs. This suggests that 80 keV virtual monochromatic DECT reconstructions may enable more accurate dose calculations at both megavoltage and kilovoltage photon energies.

EP-1828

Liver SBRT: benefits from breath-triggered MRI in treatment position for accurate lesion contouring
 L. Parent¹, A. Tournier¹, M. Rives², F. Izar², R. Aziza³, Y. Sekkal³, N. Morel³, S. Ken¹

¹Institut Universitaire du Cancer Toulouse Oncopôle, Engineering and Medical Physics Department, Toulouse, France

²Institut Universitaire du Cancer Toulouse Oncopôle, Radiotherapy Department, Toulouse, France

³Institut Universitaire du Cancer Toulouse Oncopôle, Imaging Department, Toulouse, France

Purpose or Objective: As part of the stereotactic body radiotherapy (SBRT) program in our institution, magnetic resonance imaging (MRI) acquisition in treatment position for the liver was implemented. Significant liver motion can be observed due to breathing motion. The aim of this study is to report the benefits of setting out a time-correlated and breath-triggered MRI protocol optimized for radiotherapy (RT) planning in order to account for liver breathing motion.

Material and Methods: Prior to imaging, three internal gold fiducials were implanted under echo or CT guidance in the vicinity of the lesion site in order to improve images registration, patient's positioning and target volume tracking during treatment.

A 4D CT scan was acquired on a GE Healthcare Optima CT580 RT. Patient immobilization and positioning was set up with

ORFIT dedicated thermo-plastic nets, supports and cushions. Images were reconstructed in six phases across the respiratory cycle with CT50 being the exhale image set used for MR image registration.

MRI was acquired with a body coil on a 1.5T SIEMENS Aera. The patients were set up with the same patients' immobilization and positioning devices as for CT imaging thanks to a MR compatible ORFIT table. Axial Single Shot Fast Spin Echo T2-weighted with fat suppression Spectral Adiabatic Inversion Recovery (SPAIR) and motion reduction method (BLADE) was first acquired with breath triggering on exhale. Then ultra-fast gradient echo T1-w with parallel acquisition and Dixon reconstruction techniques (VIBE DIXON) allowed the acquisition in exhale breath hold. Finally injected T1-w Fast Low Angle Shot (Turbo FLASH) imaging sequence was acquired with breath triggering on exhale.

Results: The lesion was not always visible on 4D CT scan, even on images with contrast enhancement hence the need of MRI to better define the lesion. Target motion range was assessed based on fiducials' displacement.

The use of the same table and immobilization device for MRI minimized uncertainties due to patient position for image registration.

T1-w VIBE DIXON sequence was useful to register MR sequences based on fiducials' position, as they were the most visible on this sequence. The two breath-triggered (expiration phase) sequences (T2 SPAIR BLADE and injected T1-w Turbo FLASH) provided a motion artifact free image necessary to accurately delineate the lesion.

An example of MR/CT50 registration and target volume definition is illustrated on Figure 1.

Figure 1: Example of registered image for a breast metastasis in liver segment V (a): injected CT50 with target contour delineated in red thanks to the MRI sequences. (b): T1 DIXON_w. (c):T2 SPAIR BLADE, (d): injected T1-w Turbo FLASH

Conclusion: The use of the same table and immobilization device for CT and MRI combined with the use of MR imaging sequences optimized to account not only for the dedicated table and immobilization devices but also for the gold seeds visualization and the tumor delineation allow high precision target delineation.

EP-1829

Evaluation of metal artifact reduction (MAR) algorithm for patients with a bilateral hip implant

A. Morel¹, J. Molinier¹, L. Bedos¹, N. Aillères¹, D. Azria¹, P. Fenoglietto¹

¹ICM - Val d'Aurelle, Radiothérapie, Montpellier, France

Purpose or Objective: Analyze the information stemming from three methods of images acquisition for soft tissues between a bilateral hip implant.

Material and Methods: Six patients with a bilateral hip implant were selected for this study. For every patient, 3 series of images were compared. The two first ones were performed with GE Optima CT580 simulator, one by using the metal artifacts reduction (MAR) algorithm and the other one without. The third series was acquired by Cone Beam Computed Tomography (CBCT) during the first session of treatment. For every series, the same rectangular ROI was drawn on a frontal slice, in the soft tissues situated between the two prostheses. The average Hounsfield Units (HU) and the standard deviation (σ), corresponding to the noise in the image, were collected. According to the same methodology, the images of 12 patients without hip implant were studied in order to have a reference of the average Hounsfield Unit (HUref) in this anatomic region and to compare it with the obtained results for images of patients with a bilateral hip implant.

Results:

For the cohort of patients without hip implant, HUref was of $11,2 \pm 43.5$ HU. For the bilateral hip implant cohort, the HU results with MAR algorithm were the closest of HUref (HUref(MAR)= -37.1 HU ; HUref(CBCT)= -262.6 HU ; HUref(no MAR)= -409.5 HU). The noise in the image was reduced too in comparison with images without MAR reconstruction and CBCT (σ (MAR)= 104.9 HU ; σ (CBCT)=153.2 HU ; σ (no MAR)= 211 HU).

Conclusion: The reconstruction quality of soft tissues between a bilateral hip implant was improved with MAR algorithm by reducing artifacts, noise and by increasing the HU accuracy. Dosimetric impact remains to be assessed (= -409.5 HU). The noise in the image was reduced too in comparison with images without MAR reconstruction and CBCT (σ (MAR)= 104.9 HU ; σ (CBCT)=153.2 HU ; σ (no MAR)= 211 HU).

EP-1830

Comparison of the MRI sequences in ideal fiducial marker-based radiotherapy for prostate cancer

O. Tanaka¹, M. Hattori¹, S. Hirose¹, T. Iida¹, T. Watanabe¹

¹Gifu Municipal Hospital, Department of Radiation Oncology, Gifu, Japan

Purpose or Objective: Image guided radiotherapy for prostate cancer is a sophisticated treatment modality. However, the contouring the prostate is difficult to achieve with CT alone. To overcome the uncertainty of contouring the target on CT images, MRI is used in the registration of CT in addition to MRI using a fiducial marker. However, the visualization of the markers tends to be difficult in MRI. The aim of the present study is to find an optimal MRI pulse sequence for defining the marker as well as the prostate outline by comparing five different sequences.

Material and Methods: A total of 21 patients were enrolled in the present study. The two gold fiducial markers were placed on the prostate 3 weeks before the CT/MRI examination. MRI was performed using a five-channel sense cardiac coil. We obtained five T1-weighted spin-echo sequences (repetition time [TR]/echo time [TE] in milliseconds: 400/8) (T1WI), T2-

weighted fast spin-echo (3000/80) (T2WI), T2*_T2-weighted gradient echo (4000/80) (T2*2D), T2*_3-dimensional T2-weighted gradient echo [TR/TE1/deltaTE](37/14/7.3) (T2*3D), and contrast-enhanced T1-weighted spin-echo (607/12) (CE-T1WI) in all cases. Contrast-enhanced T1-weighted MRI was performed with gadopentetate dimeglumine. The quality comparison of the five sequences (T1WI, T2WI, T2*2D, T2*3D and CE-T1WI) was conducted by a single radiation oncologist and two radiation technologists. These observers subjectively scored all of the images based on the five following evaluation items: the definition of outline of the prostate; apex vs. soft tissue; base vs. bladder; base vs. seminal vesicle; and gold fiducial marker detection. A score from 1 to 3 (1 [poor], 2 [moderate], 3 [good]) was assigned to each of the items accordingly. Higher score was regarded as denoting better visualization. We compared the mean scores for each item.

Results:

Table
The mean imaging score of the magnetic resonance imaging (MRI) pulse sequences to define the gold fiducial marker

	Outline of prostate	Apex vs. soft tissue	Base vs. Bladder	Base vs. SV	Fiducial marker definition
Observer 1					
T1WI	1.8	1	1.2	1.2	1
T2WI	2.7 †	2.3 †	2	2 †	1
T2*2D	2	1	1.3	1	1.1
T2*3D	1.7	1.2	1.1	1.1	2 †
CE-T1WI	1.6	1.4	1.6	1.1	1
Observer 2					
T1WI	2	1.6	1	1.2	1
T2WI	2.5	2.3 †	2.4	2.3 †	1
T2*2D	2	1.3	1.3	1	2 †
T2*3D	1.8	1.4	1.1	1	2.3 †
CE-T1WI	2	1.7	1.9	1.6	1.3
Observer 3					
T1WI	1.8	1.2	1.6	1.2	1
T2WI	2.2	2	2	2	1.2
T2*2D	2	2.1	1.4	1.7	2.4 †
T2*3D	2.1	1.7	1.8	1.8 †	2.3 †
CE-T1WI	1.6	1.9	1.6	1.4	1.5

Abbreviations: SV, seminal vesicle.

One radiation oncologist and two radiation technologists subjectively scored the images based on 5 evaluation items. Scores of 1 to 3 (1 [poor], 2 [moderate], 3 [good]) were assigned to all items. Higher scores denoted the superior definition of the prostate edge and gold fiducial markers.

† The significantly highest score among five sequences ($p < 0.01$).

‡ A significantly higher score than that in three other sequences ($p < 0.01$).

Our data are shown in the Table. T2WI was significantly superior to the other sequences in terms of the definition of the prostate. T2*3D was significantly superior to the other sequences in terms of the definition of the fiducial marker.

Conclusion: The most important purpose of the study was to accurately identify the marker. T2*3D was the best sequence for achieving this objective. The superiority of T2*3D in defining the marker meant that although T2WI provided the highest level of precision in the outline of the prostate, T2*3D provided a better balance between the contouring of the prostate and defining the marker.

EP-1831

Inter-physician variability in delineation of clinical target volume of uterine cervical carcinoma

Y.S. Kim¹, J. Joo¹, E. Choi¹, S. LEE¹

¹Asan Medical Center- Univ of Ulsan, Radiation Oncology Department, Seoul, Korea Republic of

Purpose or Objective: As intensity modulated radiation therapy (IMRT) is becoming a standard option for cervical cancer radiation therapy (RT), one of the major uncertainty components is the definition of the clinical target volume (CTV). Despite several guidelines, wide discrepancy can still exist. The aim of this study is to determine inter-observer variability in delineating CTV for definitive and postoperative RT for cervical cancer.

Material and Methods: Eight radiation oncologists from different centers whose subspecialty are gynecologic cancer contoured CTV on the planning computed tomography (CT) scan of two patients, each of definitive and postoperative RT case (Fig. 1).

For volumetric analysis, we compared delineated volumes in terms of the individual/median volume ratio, generalized conformity index (Clgen). For spatial difference information, center of mass (COM) was used. IMRT plan was made based on one of the collected CTVs, and dose coverage was compared.

Results: The CTV volume for definitive case was 213-918 ml, with individual/median volume ratio of 0.51-1.41. The Clgen was 0.53. The mean values of the three-dimensional distances of the average COM to each COM were 7.8 mm. The largest difference was seen in superior-inferior direction, depending on common iliac lymph node region coverage and the length of inclusion of vagina. On dose coverage analysis, 95% of prescription dose covered 80.3% (range, 62.2 - 96.0%) of planning target volumes (PTV) generated by 8 physicians. Parametrial and paravaginal areas were most frequently underdosed. The CTV volume for postoperative RT case was 266-562 ml, with individual/median volume ratio of 0.65-1.38. The Clgen was 0.563. The mean values of the three-dimensional distances of the average COM to each COM were 5.3 mm in postoperative case. Ninety-five percent of prescription dose covered 80.9% (range, 66.4 - 94.8%) of planning target volumes (PTV) from 8 hospitals. Presacral, tumor bed and paravaginal areas were most frequently underdosed.

Conclusion: A large inter-physician variability in CTV delineation concerning the magnitude and relative location of volumes was observed. Continuing education of proposed

guidelines on CTV definition and knowledge of commonly missed/disconcordant CTV areas cannot be overemphasized to avoid such difference.

EP-1832

Improved 4DCT quality using true phase based triggers

P. Freislederer¹, H. Von Zimmermann¹, C. Heinz¹, K. Parodi², C. Belka¹

¹Klinik und Poliklinik für Strahlentherapie und Radioonkologie, Departement of Radiation Oncology, München, Germany

²Ludwigs-Maximilians-University, Departement of Physics, Munich, Germany

Purpose or Objective: For Toshiba Aquilion LB CT scanners, the reconstruction quality of 4DCTs is strongly dependent on the accuracy of cycle based online trigger pulses. Two consecutive triggers are used to define a breathing cycle which is divided into respiratory phases of equal duration. As a consequence, any deviation in the length of the inspiration or expiration period in relation to the whole breathing cycle will result in image artifacts and a higher probability of misinterpretations. The aim of this work is to improve 4DCT quality by using amplitude based triggers for each individual breathing cycle.

Material and Methods: The trigger signals for the 4DCT reconstruction are originally provided by the Sentinel™ optical surface scanner (C-RAD AB, Sweden) using a threshold method in order to generate online trigger pulses. These always have to occur before the actual maximum of the curve and are used to reconstruct the 4DCT phases based on an equally divided breathing cycle (0% - 90% in 10% steps) for phase-based reconstruction. A second 4DCT is reconstructed using the true inhalation peak triggers created by an offline tool, also with phases of equal time for each cycle. Furthermore, a single trigger for each breathing phase is sent to the CT for a third reconstruction of all motion states based on the amplitude (e.g. 10%, 20%, etc.) of the breathing curve in relation to the maximum and minimum of one cycle. The absolute volume of a tumor inside of a moving chest phantom, which serves as a direct measure for reconstruction quality, has been determined for each motion state of the reconstructed 4DCT for 10 different curves (2 sinusoidal, 8 patient breathing curves),

Results: Reconstructing the 4DCT solely according to the online trigger pulses proposed by Sentinel™ can lead to a mean deviation in the volume of the tumor of up to $2,98\% \pm 4,65\%$ compared to the CT reconstruction of the same tumor without any movement. When selecting the optimal trigger point at maximum inhalation offline and dividing the breathing curve into phases of equal duration, the error in volume is reduced to $0,19\% \pm 2,84\%$. Generating an amplitude based set of trigger pulses for each individual breathing cycle, the error in volume has been observed with $0,25\% \pm 0,29\%$.

Conclusion: Although the method of reconstructing 4DCTs using the amplitude-based information for each breathing cycle provides the best representation of the tumor volume, it appears to be quite impractically as every trigger file for each phase has to be sent into the CT for a single reconstruction of this motion state. This will be hard to accomplish in a clinical workflow and is prone to errors. A reconstruction of the 4DCTs based on equally divided respiration phases over time with the trigger points set to the true maximum of the breathing curve serves as a valid compromise, with minimal extra workload clinically and improved 4DCT image quality.

EP-1833

Improved proton stopping power ratio estimation for a deformable 3D dosimeter using Dual Energy CT

V.T. Taasti¹, E.M. Høye¹, D.C. Hansen¹, L.P. Muren¹, J. Thygesen², P.S. Skyt¹, P. Balling³, N. Bassler³, C. Grau⁴, G. Mierzwińska⁵, M. Rydygier⁵, J. Swakoń⁵, P. Olko⁵, J.B.B. Petersen¹

¹Aarhus University Hospital, Dept. of Medical Physics, Aarhus C, Denmark

²Aarhus University Hospital, Dept. of Clinical Engineering and Dept. of Radiology, Aarhus C, Denmark

³Aarhus University, Institute of Physics and Astronomy, Aarhus C, Denmark

⁴Aarhus University Hospital, Dept. of Oncology, Aarhus C, Denmark

⁵Institute of Nuclear Physics, PAN, Krakow, Poland

Purpose or Objective: The highly localized dose distribution in proton therapy (PT) makes this treatment modality sensitive to organ motion and deformations. E.g. in proton pencil beam scanning interplay effects may be significant, resulting in dose degradations. Due to the complexity of PT dose delivery, investigations of the consequences of motion and of motion mitigation strategies may benefit from the use of 3D dosimetry. A new family of silicone-based 3D dosimeters is currently being developed. These dosimeters can be moulded into anthropomorphic shapes and can be deformed during beam delivery, which allows for simulation of organ motion and deformation.

Treatment planning with protons is based on CT scans of the patient anatomy and a conversion of the HU for the tissue to a stopping power ratio (SPR) relative to water. To ensure that the same procedure can be performed for the dosimeter it must be verified that its SPR is estimated correctly from its HU. The aim of this study was therefore to investigate if the use of Dual Energy (DE) CT and dedicated DE calibrations can improve the calculation of the SPR for the dosimeter compared to use of Single Energy (SE) CT together with the stoichiometric calibration method.

Material and Methods: A thin slab of the dosimeter material was placed in a water tank and irradiated with a 60 MeV proton beam. The range of the protons was measured with and without the dosimeter intersecting the beam to determine the range difference. The SPR of the dosimeter was calculated from its thickness and the range difference. The dosimeter was subsequently CT scanned with a Dual Source CT scanner (Siemens Somatom Definition Flash). First a CT scan was obtained in SE mode with a tube voltage of 120 kVp, and this scan was used in the stoichiometric calibration. Next a set of CT scans was obtained in DE mode with a tube voltage pair of 80/140Sn kVp (Sn: 0.4 mm extra tin filtration); this CT image set was used for SPR calculation with two published DE calibrations. The CTDIvol of the two scanning modes was set to be the same (~20 mGy).

Results: From the range measurements, the SPR of the dosimeter was calculated to be $SPR_{meas} = 0.97$. The two DE calibration methods both gave an estimate of $SPR_{est} = 1.01$, whereas the SE stoichiometric calibration estimate was $SPR_{est} = 1.10$. The measured SPR did not fall on the stoichiometric calibration curve of the reference tissues (Figure; the high content of silicon makes the dosimeter not tissue equivalent). The dosimeter was found to have a HU corresponding to bone (CT number = 135 HU) but a SPR corresponding to fat.

Figure: Stoichiometric calibration curve. The HU shift for the dosimeter needed for a correct SPR estimation based on the curve is indicated with a red arrow.

Conclusion: The stoichiometric method overestimates the measured SPR by 13%. Using DE this error is reduced, to an overestimation of 3%. If the stoichiometric method is used for the 3D dosimeter its HU must be corrected in the treatment planning system.

EP-1834

Towards MRI-only radiotherapy planning: "patch-based method" for generation of brain pseudo-CT

S. Aouadi¹, A. Vasic¹, S. Paloor¹, P. Petric¹, R.W. Hammoud¹, N. Al-Hammadi¹

¹National Center for Cancer Care & Research A Member of Hamad Medical Corporation, Radiation Oncology, Doha, Qatar

Purpose or Objective: To create a pseudo-CT (pCT) from T1-weighted Brain MRI using "nonlocal means patch-based method" and to assess the result for MRI-only radiotherapy planning and verification.

Material and Methods: In five patients with brain tumors, CT and contrast-enhanced T1-weighted fast-spin-echo sequences (1.5T GE MRI, TR = 756ms, TE= 7.152ms, reformatted resolution of 1.01x1.01x3mm3), were registered. MRIs were preprocessed by removing background and making tissues contrast more consistent. 2D patches, defined as MRI squares of 5x5voxels, in each voxel position, were pre-computed for all MRIs and labeled with HU values of registered CTs to form a database of patches with corresponding target HU values.

The most similar patches (k=8) to each given patch in test MRI, were locally searched (ROI=15x15x15 mm3) from the database and their corresponding CT intensities were fused to predict its pCT value. Efficient local search region delimitation was possible by affine mapping between test and database MRI images. "Structural similarity measure" and "sum of squared difference" between database and test patches were used respectively for CT voxels positions selections and intensities weighting, when averaging them to estimate pCT value.

Geometric and dosimetric assessments of the pCT were performed for all patients using leave one out cross-validation. Voxel-wise Mean Absolute Error (MAE) and Mean Errors (ME) were computed to assess pCT and DRR intensities. Bone and air cavities geometry were quantified by dice indices. MAE Water Equivalent Path Length (MAE_WEPL) was computed for multiple 3D rays from the center of the head toward the upper hemisphere to evaluate the radiological path length.

VMAT planning was done on generated pCT for all patients in Varian Eclipse (AAA algorithm) and RaySearch RayStation (Collapsed Cone algorithm) TPS for PTV, defined in a heterogeneous region including bone, air and soft-tissues. PTV, OARs and VMAT plans were copied to CT and dose computed for validation. DVH and other dosimetric parameters were compared between pCT and CT plans.

Results: Figure 1 gives the visual assessment of the generated pCT and DRR. Mean MAE, ME and MAE_WEPL values for pCT evaluation were 138.5 ($\sigma=15.3$), 29 ($\sigma=16.1$), and 32.5($\sigma=3.36$), respectively. DICE index for bone and air cavities was 0.76 ($\sigma=0.02$) and 0.63 ($\sigma=0.1$), respectively. DRR average errors were: MAE=169.3 ($\sigma=11.2$) and ME =125.5 ($\sigma=33.8$).

Table 1 gives average dosimetric errors between pCT and CT for PTV and OARs, computed on Eclipse and RayStation TPS. The absolute dosimetric agreement between pCT and CT is within 1% for PTV and within 2% for OARs except for optic nerves in Eclipse (P-value = 0.57 > 0.05).

Table 1. Average over all patients of dosimetric measurements obtained for PTVs and OARs on Eclipse and RayStation.

Conclusion: A promising study on the generation and validation of CT-substitute from standard clinical T1 MRI is presented. Further work will be done to assess and improve the method on more patients and different clinical sites.

EP-1835

Dosimetric effect of metal artifact reduction function by three calculation algorithms for H&N

J. Park¹, S. Ju¹, J. Kim¹, J. Kim², C. Hong², D. Kim²

¹Samsung Medical Center, Radiation Oncology, Seoul, Korea Republic of

²Samsung Medical Center proton Center, Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: The study aims at evaluating the dosimetric effect of the metal artifact reduction (MAR) function for three different types of dose calculation algorithms in H&N radiotherapy.

Material and Methods: A virtual H&N patient (vH&N) was designed based on a round-shaped dosimetric phantom (cheese phantom). Two types of metal (tungsten 4.59g/cm³ and Cerrobend alloy 9.4g/cm³: Ø3 cm) were inserted into the vH&N to simulate an H&N patient with dental prosthesis. We obtained two types of CT image sets with MAR-on and MAR-off conditions and imported a contour set for the PTV, parotid, and spinal cord, which from a Nasopharynx case. An IMRT with five step & shoot beams was created for the MAR-off CT image set using the Monte Carlo dose calculation algorithm (MC, iPlan, BrainLAB) by following RTOG1197 guidelines. Two different plans were calculated by applying pencil beam (PB) and collapsed cone convolution (CCC) dose calculation algorithms with the same beam parameters and MLC shape. The same procedure was applied to the MAR-on CT image set. A total of six plans with the same beam parameters were generated. We calculated dose at five points of interest and compared with the doses measured at the same points. The 2D axial dose distribution was evaluated through film dosimetry by applying Gamma analysis with 3 mm and 3% criteria for all plans.

Results: The differences between the measured and calculated doses at the five points of interest for the MAR-on CT image set were significantly low compared to those for the MAR-off CT image set in all dose calculation algorithms (-1.6±1.8 vs -5.8±9%). The dose differences were the lowest in MC followed by CCC and PB. The most significant dose difference between MAR-on and MAR-off was observed in PB followed by MC and CCC. In the gamma analysis, the mean pass rate was significantly high in MAR-on compared to that in MAR-off (89.8±8 vs 61.6±16%). The pass rate was the highest in MC followed by CCC and PB. The most significant pass rate difference between MAR-on and MAR-off was observed in CCC (91.8 vs 45.4%) followed by MC (96.7 vs 62.3%) and PB (81.1 vs 77.1%).

	MAR on	MAR off
Measured dose difference	-1.6±1.8	-5.8±9
Gamma pass rate		
MC	96.7	62.3
CCC	91.8	45.4
PB	81.1	77.1
Overall	89.8±8	61.6±16

[Table 1] Measured dose differences and Gamma pass rates (%)

Conclusion: The dose calculation results with the MAR-on CT image set and MC showed better fit to measured data compared to the MAR-off CT image set with the other dose calculation algorithms. PB was more sensitive to metal artifacts for dose calculation of H&N followed by MC and CCC. MAR-on could thus provide a more realistic dose distribution for H&N with metal prosthesis.

EP-1836

HU to electron density conversion with virtual monochromatic images generated by dual-energy CT
V. González-Pérez¹, A. Bartrés¹, E. Arana², V. Crispín¹, V. De los Dolores¹, V. Campo¹, L. Oliver¹

¹Fundación Instituto Valenciano de Oncología, Servicio de Radiofísica y Protección Radiológica., Valencia, Spain

²Fundación Instituto Valenciano de Oncología, Servicio de Radiología, Valencia, Spain

Purpose or Objective: To assess dual-energy CT (DECT) and Metal Artifact Reduction algorithm (MAR) for radiotherapy planning. In particular, conversion of HU to electron density is evaluated in terms of monochromatic energy and the use of MAR in the presence of metal materials.

Material and Methods: Dual energy CT was performed using a Discovery CT750 HD scanner (GE Healthcare, USA). The DECTs were performed using fast kV-switching gemstone spectral imaging (GSI) between 80 kV and 140 kV. The CT data were reconstructed both with and without MAR to the monochromatic energies of 60 keV, 90 keV and 120 keV.

CIRS phantom model 062 (CIRS Inc., USA) was used to calibrate HU to electron density in that set of monochromatic energies. Two additional sets of CT were performed after including a home-made steel insert both on the periphery and in the center of the phantom, and different images were compared in the presence of artefacts.

Results: Different calibrations for monochromatic energies showed good HU to electron density linear correlation in all cases (R² ranging from 0.91 to 0.998). Linearity was better for higher virtual monochromatic energies. The slope maximum change in HU to electron density curves was 24.4% when comparing polienergetic "standard" CT with 120 keV virtual image. For monochromatic energy curve calibrations, differences are up to 38.0% between 60 and 120 keV monochromatic energy.

No significant differences were found in calibrations between using MAR or not. The maximum slope change in HU to electron density curves was 2.4% for 120 keV monochromatic images after MAR reconstruction.

The maximum change of the HU of an insert after the inclusion of artefacts was of 34,0 HU for 120 keV monochromatic energy compared to 50.7 HU for a conventional CT (Figure 1).

Figure 1: CIRS 062 Phantom used for HU to electron density conversion after inclusion of a steel-made insert at the phantom center. Standard polienergetic CT image (left) and monochromatic 120 keV (right)

Conclusion: The reduction of metal-related artefacts is improved at high monochromatic energies due to both the decrease of beam hardening effect and the use of MAR algorithm.

Therefore, using high keV monochromatic DECT virtual images and MAR algorithm is technically viable in radiotherapy planning since HU to electron density calibrations are feasible with monochromatic DECT image. DICOM standard is used for monochromatic virtual images and they were successfully exported to XiO treatment planning system (Elekta, Crawley, UK).

EP-1837

Impact on patient positioning using four CT datasets for image registration with CBCTs in lung SBRT

M. Oechsner¹, B. Chizzali¹, J.J. Wilkens^{1,2}, S.E. Combs^{1,2}, M.N. Duma^{1,2}

¹Klinikum Rechts der Isar- TU München, Department of Radiation Oncology, München, Germany

²Institute of Innovative Radiotherapy- Helmholtz Zentrum München, Department of Radiation Sciences, München, Germany

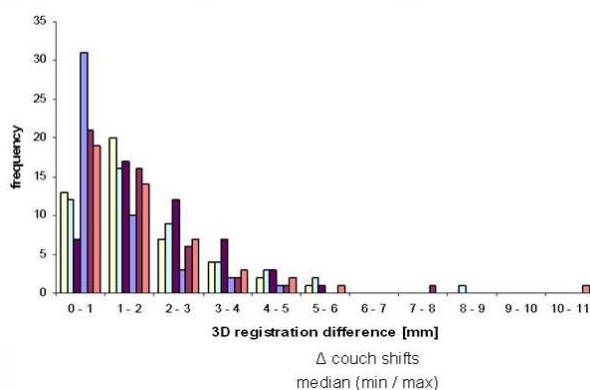

Purpose or Objective: A variety of CT datasets are available in lung stereotactic body radiotherapy (SBRT) for defining the target volume or treatment planning, e.g. slow planning CT (PCT), average intensity projection (AIP), maximum intensity projection (MIP) or mid-ventilation CT (MidV). The aim of this retrospective patient study was to evaluate the differences of using these four CT datasets for image registration with free breathing cone beam CTs (CBCT). Couch shifts between

the registrations were analyzed and correlated to different factors, e.g. tumor motion, size and location.

Material and Methods: CT datasets of 47 lung SBRT patients were retrospectively selected for this study. All patients had a PCT and a 4DCT scan. AIP and MIP CT datasets were calculated from the 10 phases of the 4DCTs. Additionally, a MidV CT was selected for each patient representing the mean position of the tumor. These four CT datasets were retrospectively registered to free breathing CBCTs which were acquired before patients' first treatments. Automatic image registration was performed with the Eclipse 13.0 registration software (Varian). 3D translational registrations were applied and the coordinates in left-right (x), anterior-posterior (y) and superior-inferior (z) direction were evaluated. Coordinates of each of the registered four CT datasets were compared to the coordinates of the other registered CT datasets (e.g. PCT-CBCT vs MIP-CBCT). Additionally, a 3D movement vector was calculated. Furthermore, we searched for correlations between registration differences and tumour parameters: 3D motion of the tumor, GTV volume and the distance between the carina of trachea and the GTV in z-direction (SI position). The Wilcoxon test was used to identify statistically significant difference between the fusion pairs (p-value <0.05). Correlations were analyzed using Spearman's rank correlation (rs).

Results: The table depicts median, minimal and maximal registration differences in x, y, z, and 3D direction between the CT datasets. Some differences were statistically significant (p<0.05). AIP-CBCT and MIP-CBCT achieved the smallest differences. The largest difference in 3D direction was observed for MIP-CBCT vs MidV-CBCT (10.5 mm). The figure depicts the frequency of shifts in 1 mm step sizes between the image registrations. Only 3D tumor motion showed a good correlation to the registration differences between AIP-CBCT and MIP-CBCT (rs: 0.73) or MIP-CBCT and MidV-CBCT (rs: 0.70).

□ AIP-CBCT vs PCT-CBCT □ MIP-CBCT vs PCT-CBCT ■ MidV-CBCT vs PCT-CBCT
 □ AIP-CBCT vs MIP-CBCT ■ AIP-CBCT vs MidV-CBCT ■ MIP-CBCT vs MidV-CBCT

registration	Δx [mm]	Δy [mm]	Δz [mm]	$\Delta 3D$ [mm]
AIP-CBCT vs PCT-CBCT	-0.5 (-2.1 / 2.7)	-0.1 (-2.9 / 2.2)	0.0 (-5.1 / 3.2)	1.4 (0.3 / 5.6)
MIP-CBCT vs PCT-CBCT	-0.5 (-1.3 / 2.9)	-0.4 (-4.0 / 1.8)	-0.3 (-8.7 / 3.3)	1.8 (0.4 / 8.8)
MidV-CBCT vs PCT-CBCT	-0.4 (2.0 / 2.2)	0.0 (-2.9 / 3.9)	-0.4 (-3.9 / 5.8)	1.9 (0.2 / 5.9)
AIP-CBCT vs MIP-CBCT	-0.1 (-1.0 / 1.2)	0.3 (-0.8 / 1.5)	0.1 (-3.0 / 4.3)	0.5 (0.1 / 4.4)
AIP-CBCT vs MidV-CBCT	-0.1 (-3.8 / 1.6)	-0.2 (-2.8 / 2.3)	0.2 (-6.3 / 2.7)	1.1 (0.1 / 7.6)
MIP-CBCT vs MidV-CBCT	-0.2 (-2.8 / 1.6)	-0.5 (-2.8 / 2.2)	0.0 (-9.9 / 5.7)	1.3 (0.1 / 10.5)

Conclusion: Using different CT datasets for image registration with free breathing CBCTs can result in distinctly different couch shifts. Automatic AIP-CBCT and MIP-CBCT

fusion achieved the best agreement. Differences > 5mm were observed, which can be larger than the safety margins. This has to be considered if the CT dataset for treatment planning and image registration is chosen.

EP-1838

Proton therapy planning for brain tumors using MRI-generated PseudoCT

³Magna Graecia University, ImagEngLab and Experimental and Clinical Oncology, Catanzaro, Italy
⁴Friedrich-Alexander Universität Erlangen-Nürnberg, Radiation Oncology, Erlangen, Germany

Purpose or Objective: To investigate the dosimetric and range accuracy of using MRI pseudoCT for proton therapy planning vs. single energy x-ray CT, for brain tumors.

Material and Methods: A cohort of 15 glioblastoma patients with CT and MRI (T1 and T2) imaged after surgical resection. T1-weighted 3D-MPRAGE was used to delineate the GTV, which was subsequently rigidly registered to the CT volume. A pseudoCT was generated from the aligned MRI by combining segmentation- and atlas-based approaches. The spatial resolution both for pseudo- and real CT was 0.6x0.6x2.5mm. Three orthogonal proton beams were simulated on the pseudo CT. Two co-planar beams were set on the axial plane. The third one was planned parallel to the cranio-caudal (CC) direction. Each beam was set to cover the GTV at 98% of the nominal dose (18Gy). The proton plan was copied and transferred to the real CT, including aperture/compensator geometry. Dose comparison between pseudoCT and CT plan was performed beam-by-beam by quantifying the range shift of dose profile on each slice of the GTV. The GTV's relative V98 was computed for the CT.

Results: For beams in axial plane the median absolute value of the range shift was 0.3mm, with 0.9mm and 1.4mm as 95th percentile and maximum, respectively. Worst scenarios were found for the CC beam, where we measured 1.1mm (median), 2.7mm (95th-percentile) and 5mm (maximum). Regardless the direction, beams passing through the surgical site, where metal (Titanium MRI compatible) staples were present, were mostly affected by range shift. GTV's V98 for CT was not lower than 99.3%.

Conclusion: The study showed the feasibility of an MRI-alone based proton plan. Advantages include the possibility to rely on better soft tissue contrast for target and organs at risk delineation without the need of further CT scan and image registration. Additional investigation is required in presence of metal implants along the beam path and to account for partial volume effects due to slice thickness.

EP-1839

exploiting planning CT data for accurate WEPL on CBCT reconstructions used in adaptive radiotherapy

J.H. Mason¹, M.E. Davies¹, W.H. Nailon²
¹University of Edinburgh, Institute for Digital Communications, Edinburgh, United Kingdom
²Edinburgh Cancer Centre- Western General Hospital, Department of Oncology Physics, Edinburgh, United Kingdom

Purpose or Objective: To allow the use of cone beam computerised tomographic (CBCT) imaging for adaptive radiotherapy, its quantitative accuracy must be improved. However, since it is physically hindered by data insufficiency and large scatter contributions, this a difficult task without incorporating additional information. Here we propose a framework for utilising planning CT images within the reconstruction process to significantly improve the accuracy of CBCT and illustrate its potential use in proton therapy.

Material and Methods: The proposed framework involves estimating the scatter kernel as a low frequency difference between the CBCT measurements and synthetic projections of the planning CT. After correcting for the scatter contribution the CT is exploited once again as a regularisation in an iterative reconstruction, which promotes an image with a sparse difference image gradient, through minimising the total variation (TV) of this difference. To illustrate the technique's performance, we calculated the proton water equivalent path length (WEPL) through reconstructions of a Phantom Lab SK200 chest phantom. To simulate the planning CT, we manually deformed the original CT image to induce anatomical changes.

Results: The figure below demonstrates the reduction in WEPL error of our proposed approach over other techniques. The calculation was taken through to the centre of each reconstructed volume for 180 equispaced angles, against the non-distorted CT, by using a fixed lookup table to convert from Hounsfield units to proton stopping power.

Conclusion: The technique allows accurate CBCT imaging, which may facilitate its usage in adaptive radiotherapy. Although there still remain a number of improvements in robustness before this could be considered as a clinical framework, these illustrative results are encouraging.

EP-1840

Motion artifacts in 4DCT: frequency and correlation with breathing pattern

M. Valenti¹, G. Scipioni², M. Parisotto¹, G. Mantello³, F. Fenu³, M. Cardinali³, S. Maggi⁴

¹Azienda Ospedaliero Universitaria Ospedali Riuniti, Medical Physics, Ancona, Italy

²Università Politecnica delle Marche, Facoltà di Medicina e Chirurgia, Ancona, Italy

³Azienda Ospedaliero Universitaria Ospedali Riuniti, Radiotherapy, Ancona, Italy

⁴Azienda Ospedaliero Universitaria Ospedali Riuniti, Medical Physicis, Ancona, Italy

Purpose or Objective: Four dimensional computed tomography (4DCT) is a consolidated simulation technique for lung tumor radiotherapy treatment. Several works report about a relevant incidence of motion artifacts in 4DCT acquisition [1,2,3,4]. In this work we retrospectively analyze 4DCT scans performed in free breathing for 29 lung tumor patient. Our analysis was focused on diaphragm, where artifacts are more frequent and evident [1]. The aim of this work is to evaluate: frequency of motion artifacts in our patient group, critical breathing phases for artifacts and correlation between breathing pattern shape and artifacts incidence.

Material and Methods: 4DCTs have been acquired in free breathing on a Discovery 690 CT-PET (GE) scanner equipped with RPM (Real-time Positioning Management) system. Scan is performed in cine mode with different couch position and ten equally spaced sets of CT images are retrospectively created using phase based sorting in Advantage 4D application. A trained operator visually checked each single phase for all the patient to individuate presence of diaphragm artifacts. A comprehensive description of different aspects of artifacts is given in [1]. We analyze and report here the percentage of patient affected by artifacts in at least one phase and the relative incidence of artifacts for each phase in our patient group. Furthermore we search a relation between breathing pattern and the frequency of artifacts.

Results: At least one phase with artifacts is present in 96% of the patients. The average number of phases with artifacts for patient is $4,1 \pm 2,4$ (one standard deviation). In fig. 1 we show the frequency of artifacts for each phase calculated as the ratio between number of patient with artifacts in the α phase and total number of patient. Finally, we find a linear correlation between the module of derivative of breathing pattern averaged over all patient and artifact relative incidence.

Fig.1

Conclusion: In fig. 1 we can identify two local minimum corresponding to phases 0% and 50%, respectively the end inhale and the end exhale phase of respiration. Local maximum is present around mid inhale and mid exhale (phases 10% and 80%) i. e. when motion of breathing surrogate marker is faster. We find a linear correlation between average of module of derivative of breathing pattern and artifacts incidence. We can argue that the movement speed of patient thorax or abdomen, that is where RPM marker is positioned, seems to play a relevant role in terms of artifacts incidence. Currently 4DCT scan with cine mode and RPM system suffer of a very high incidence of motion artifacts in a critical area like diaphragm given that, in our study, 96% of the patient have this problem.

Dose comparison study for CT and MR-only prostate IMRT treatment planning

M. Maspero¹, G. Schubert², M. Lindstrom², M. Hoel¹, P.R. Seevinck³, G.J. Meijer¹, M.A. Viergever³, J.J.W. Lagendijk¹, C.A.T. Van den Berg¹

¹UMC Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands

²Philips Healthcare, Medical Systems MR, Vantaa, Finland

³UMC Utrecht, Imaging Science Institute, Utrecht, The Netherlands

Purpose or Objective: In MR-only RT the planning CT is replaced by MR-based synthetic-CT (sCT). Dose validation is necessary in order to justify the use of sCT for RTTP in terms of accuracy and efficacy. One way to perform such a study is to recalculate the CT-plan on the sCT in order to assess the quality/consistency of the images for accurate dose planning. The feasibility of dose calculation on sCT obtained with model-based segmentation of Dixon MR images has been previously demonstrated [Schadewaldt et al., Med. Phys. 41, 188 (2014)] on VMAT plans. This study aims at evaluation of 5 beams IMRT prostate plans calculated on sCT vs CT using a Monte Carlo based TPS.

Material and Methods: Twelve prostate patients underwent CT (a) as well as MRI on the same day within 1-2 hours for RT treatment planning. A 3D multi echo sequence with Dixon reconstruction and high bandwidth, to assure geometric fidelity, was included in the clinical prostate MR exam for sCT generation (adding less than 2.5 min to the actual scan time). All scans were performed on a 3T MR scanner (Philips

Ingenia) with in-house-built flat table top. The sCT (b) were generated by the technique described by Schadewaldt et al, using mDixon acquisition and model-based segmentation to assign fixed HU to 5 tissue classes. The RT plans were recalculated in Monaco v5.10 (Elekta) on sCT without any further optimization utilizing the delineations from the planning CT after rigid registration of CT on sCT. The alignment (translation-only) of isocenters of the two plans allowed voxelwise dose comparison and γ -analysis.

CTs and sCTs are inherently different, as they are acquired at different time points and, furthermore, the patient anatomy can slightly vary during the positioning on CT and MR. Fig (c) highlights the differences, in terms of ED, of sCT minus CT for a transversal slice of one of the patients: differences in body contour and bone structure can be observed, as well as the lack of prostate markers and air pockets on sCT. VOIs (d) defined as the intersection of the body contour of CT and sCT (V_{Body}) and as 75% (V_{75}) of the prescribed dose (77 Gy) are considered in order to minimize such physiological differences during the comparison (e).

CT (a) and sCT (b) with the relative Electron Density (ED) difference (c). Fig. (d) highlights the VOIs utilized to characterize the voxelwise dose deviations (e).

Results: The dose on sCT results in a slightly systematic higher dose (1.3%, 0.9%) in V_{75} and in V_{Body} , respectively, when compared to CT, as shown in the Table in terms of dose difference and relative dose difference over the whole study population. The highest average dose calculated in a patient (i.e. worst case scenario) is lower than 1.5 and 0.2 Gy in V_{75} and V_{Body} respectively. In this type of comparison, differences in patient positioning between CT and sCT contribute to the observed difference in dose.

	Average Deviation $sCT - CT$ [Gy]	Average Rel Deviation $\frac{sCT - CT}{CT}$ [%]	$\gamma_{3\%/3mm}$ [%]	$\gamma_{2\%/2mm}$ [%]
$V_{75\%}$	0.92 ± 0.25	1.30 ± 0.36	99.3 ± 0.8	94.5 ± 4.1
V_{Body}	0.10 ± 0.04	0.86 ± 0.58	98.8 ± 0.9	95.8 ± 2.3

Average Deviation, Average Relative Deviation and Gamma passed rate (mean \pm std) over all the patients for $V_{75\%}$ & V_{Body} .

Conclusion: This study evaluated the accuracy of dose calculation on sCT MR-only generated for prostate IMRT

plans. Further investigations on the contributions to the observed differences are subject of current and on going research.

EP-1842

A dosimetric analysis of MRI only treatment planning of the brain

E. Goodwin¹, D. Bird¹, J. Lilley¹, R. Speight¹

¹St James Institute of Oncology, Medical Physics and Engineering, Leeds, United Kingdom

Purpose or Objective: MRI only treatment planning is gaining interest as it removes errors associated with image registration from the planning pathway. As access to MRI becomes more widespread in radiotherapy departments, it will become more feasible to carry out MRI only planning. This study aimed to assess the dosimetric accuracy of treatment plans calculated using an MRI only approach for 3D conformal radiotherapy (3DCRT) and volumetric modulated arc therapy (VMAT) brain treatments.

Material and Methods: Ten retrospective patients (five glioblastoma multiforme (GBM) patients treated with 3DCRT, and five meningioma patients treated with VMAT) were selected. A synthetic CT (sCT) was created for each patient by manually contouring the patient external, bone and sinus. The electron density (ED) of the patient, bone and sinus were forced to 1.0, 1.68 and 0.11 g/cm³ respectively, these values were derived by contouring the structures in ten representative CT study-sets. A treatment plan was calculated for each patient using the sCT, the original planning CT, and using the MRI study-set with a homogenous ED of unity. The resulting dose distributions were quantitatively analysed using the dose to the isocentre and clinically relevant DVH statistics (fig 2). A qualitative analysis of dose difference maps and DVHs was also undertaken.

Results: A paired, two-tailed student t-test found that the dose to the isocentre was statistically indistinguishable ($p < 0.05$) between the sCT and the CT based dose distributions for all plans, whereas this was not the case for the homogenous density calculation. A mixed linear regression analysis of the DVH statistics showed that the ED map was a significant predictor of the dose values ($p < 0.05$) when comparing CT to homogenous density, but did not find the ED to be a significant predictor of the DVH statistics when comparing sCT and CT calculated dose distributions. The qualitative analysis supported these findings: the dose difference maps showed that there was generally good agreement between the CT and the sCT calculated dose distributions, with the main areas of difference between them occurring near the patient external (see fig. 1). Comparison of the CT and sCT DVHs also showed them to be similar, with marked differences to those calculated assuming homogenous density

Figure 1: Left, dose distribution calculated using CT ED. Centre, subtraction of CT dose minus sCT dose. Right, subtraction of CT dose minus homogeneous ED dose.

Meningioma Cohort		Isocentre	V98 (>90%)	V95 (>95%)	V5 (<105%)	V2 (<107%)
Patient 1	CT	1.013	0.980	0.987	1.042	1.048

	sCT	0.997	0.841	0.865	1.082	1.095
	Homogenous	1.016	0.874	0.893	1.129	1.139
Patient 4	CT	1.000	0.808	0.833	1.090	1.098
	sCT	1.012	0.821	0.844	1.095	1.103
	Homogenous	1.024	0.837	0.859	1.139	1.149
Patient 5	CT	1.000	0.855	0.869	1.117	1.141
	sCT	1.009	0.855	0.870	1.117	1.140
	Homogenous	1.016	0.877	0.893	1.153	1.179

Figure 2: Dose to isocentre and DVH statistics for all Meningioma (VMAT) and GBM (3DCRT) patients. Doses are expressed as a fraction of the prescription dose.

Conclusion: The dosimetric accuracy of treatment plans calculated using a forced density technique is equivalent to planning on CT and does not appear to be a limiting factor for MRI only planning of brain patients.

EP-1843

Synthetic CT calculation from low-field MRI: feasibility of an MRI-only workflow for glioblastoma RT

N. Nesvacil¹, H. Herrmann¹, E. Persson², C. Siversson³, B. Knäusl⁴, P. Kuess⁵, L.E. Olsson⁶, D. Georg⁵, T. Nyholm⁷

¹Medical University of Vienna, Department of Radiotherapy & Comprehensive Cancer Center, Vienna, Austria

²Skåne University Hospital, Department of Radiation Physics, Lund, Sweden

³Spectronic Medical AB Helsingborg & Lund University, Department of Medical Radiation Physics, Malmö, Sweden

⁴Medical University of Vienna, Department of Radiotherapy & Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

⁵Medical University of Vienna, Department of Radiotherapy & Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

⁶Lund University, Department of Medical Radiation Physics, Malmö, Sweden

⁷Umea University, Department of Radiation Sciences-Radiation Physics, Umea, Sweden

Purpose or Objective: An MRI-only EBRT treatment planning workflow based on synthetic CTs (sCT) could help reduce MRI/CT registration uncertainties, while taking into account the improved soft tissue contrast of MRI for volumes definition, and reducing patient scanning time by avoiding the use of multiple imaging modalities for RT planning.

The aim of this pilot study was to develop a model for creating sCTs for glioblastoma, based on commercial software and to further explore the potential of a low-field open MRI scanner dedicated to RT.

Material and Methods: Using a clinical protocol optimized for RT planning T1 weighted MR (0.35T, Siemens Magnetom C!) and CT scans (Siemens Somatom Definition AS) were acquired for 6 patients with slice thickness of 4mm (MRI) and 2mm (CT). Target and OAR (brainstem, chiasm, cochlea, eye, hippocampus, lens and optic nerve) structures were delineated on MRI. The CTV was defined as the GTV (resection cavity) isotropically expanded by 1.5cm. For PTV the CTV was expanded by 0.5cm.

Synthetic CTs were generated from the MRI by the commercial MriPlanner software (Spectronic Medical AB, Helsingborg, Sweden) utilizing the Statistical Decomposition Algorithm (Siversson et al, Med Phys. 2015; 42).

The sCTs were tested for dosimetric validity compared to CT images. Delineated structures were transferred from MRI to

CT via rigid image registration. For each patient a 6MV RapidArc plan was created on the CT using Eclipse (Varian Med. Sys.) and recalculated on the rigidly registered sCT using the same number of monitor units. The prescribed dose to D50% of the PTV was 60Gy in 30fx.

Results: Visual comparison showed good agreement between CT and sCT. (Fig. 1) The slightly blurred appearance of the sCT is an effect of the lower slice resolution of the MRI compared to the CT. Dosimetric results are reported in Table 1.

Figure 1) Isodose distributions of a Rapid Arc plan calculated on the CT and recalculated on the sCT (created from the 0.35T MRI)

	Average Mean ΔDose (%)	Standard Dev (%)
PTV	-0.18	0.59
CTV	-0.21	0.63
GTV	-0.19	0.62
Brainstem	-0.18	0.85
Chiasm	-0.32	0.67
Cochlea Left	0.20	0.47
Cochlea Right	-0.36	0.78
Eye Left	0.17	1.57
Eye Right	-0.09	1.38
Hippocampus Left	-0.08	0.29
Hippocampus Right	-0.01	0.11
Lens Left	0.13	1.85
Lens Right	0.23	3.07
Optic Nerve Left	-0.04	1.46
Optic Nerve Right	-0.03	0.76

Conclusion: In this pilot study the MriPlanner software, which was previously verified for prostate images acquired at higher field strengths, was successfully applied to glioblastoma cases.

In the present study a patient fixation device was used for CT acquisition but not for MRI. This may lead to slight geometrical differences between CT and MRI, which may propagate to the dosimetric analysis. Nevertheless, the results of this study indicate that low-field MRI is suitable for

generating sCTs which could be used for EBRT treatment planning for glioblastoma. Additional improvements of MRI protocols and patient fixation may reduce dosimetric differences between CT and sCT even further.

EP-1844

Feasibility of generating mid-position CT from 4DCT using commercial deformable registration systems

M. Van Herk¹, A. McWilliam², P. Whitehurst², C. Faivre-Finn^{1,3}

¹University of Manchester, Institute of Cancer Sciences, Manchester, United Kingdom

²Christie Hospital, Radiotherapy Physics, Manchester, United Kingdom

³Christie Hospital, Clinical Oncology, Manchester, United Kingdom

Purpose or Objective: Publications have shown the benefit of motion compensation (MC) of 4D CT to create a mid-position CT for planning of lung tumours. The MC process creates a single sharp image in which all information of the 4D scan is combined, improving signal to noise ratio, while the absence of motion blurring improves the identification of tumour and organ-at risk boundaries compared to a maximum intensity or average scan. Furthermore, margins to account for the residual respiration motion relative to the mid-position scan can be small. Unfortunately, there are as yet no commercial solutions available to create such scans and their use is limited to a few hospitals. The aim of this work is to apply two commercial deformable registration systems, combined with open source software, to create mid-position scans, and to evaluate their performance for potential clinical use.

Material and Methods: 4D phase sorted CT scans (Philips Brilliance, 10 frames) of 8 patients were selected. Tumour peak to peak motion had to exceed 8 mm and there was no selection on scan quality. Deformable registration between all frames and the first was performed using Elekta's Admira and Mirada's RTx. The deformation vector fields (DVF) were exported in DICOM format. Using the open source Conquest DICOM server, the DVFs and 4D CT were converted into Nifti format. A script in the DICOM server then called open source command tools of NiftyReg to first calculate the average DVF. Subsequently for each frame, the average DVF was subtracted from the frame DVF and the CT frame was deformed with this DVF to the mid-position. The resulting MC 4D data was written out for analysis. To provide a measure of quality of the MC process, the overall standard deviation of the difference of each MC CT frame with the average MC CT was calculated.

Results: The quality of the MC scans made with the two commercial systems is evaluated in Fig. 1 both quantitatively (frame by frame) and visually (average scans). Because post-processing was identical for both systems, only the quality of the DVF affects the results. Overall there is very little performance difference between the systems, with the average residual SD for both systems being within one Hounsfield unit. It is furthermore visible that certain frames (particularly 1, 2, 7 and 10) have a larger residual. These lie between in- and exhale and show a higher motion speed of the anatomical structures leading, on average, to more blurring and artefacts.

Fig.1. Top. Evaluation of 8 MC scans (SD of residual difference to average scan) with two commercial system (red and blue).

Bottom: average and motion compensated scans of two systems and system 1 with selected frames.

Conclusion: Using a combination of commercial and open source software, mid-position CT scans were created. The performance of both commercial deformable registration packages was similar. For some motion compensated frames, registration performance is poorer. For practical implementation of the mid-position scan in our clinic, we propose to exclude such frames, likely leading to a more robust performance.

⁹University Hospital Carl Gustav Carus at the Technische Universität Dresden, Dept. of Radiotherapy, Dresden, Germany

¹⁰Helmholtz-Zentrum Dresden-Rossendorf, Institute of Radiooncology, Dresden, Germany

Purpose or Objective: 7 Tesla (7T) MRI has recently shown great potential for high-resolution soft-tissue neuroimaging and visualization of micro-vascularisation in glioblastoma (GBM). Its value for the delineation of GBM in radiation

therapy planning (RTP) has not yet been established. We hypothesize that 7T MRI allows for improved GTV delineation over 1.5T or 3T MRI and have designed a clinical study to investigate this. However, increases in power deposition, susceptibility artefacts and geometrical distortions could significantly compromise the quality and interpretability of 7T MR images. In this study we aim for qualitative and quantitative assessment of these effects when incorporating 7T MR images into the neurosurgical navigation and RTP software.

Material and Methods: MR images were acquired with a Siemens Magnetom 7T whole-body scanner and a Nova Medical 32-channel head coil. 7T MRI pulse sequences were selected to visualize both intracranial anatomy and tumour (MP2RAGE) and perilesional edema (T2-SPACE, SPACE FLAIR). Moreover, multi-echo gradient recalled echo (GRE) T2*-weighted images were selected to visualize microvascularisation. A pilot study with 3 healthy volunteers was performed to optimize the anatomical image contrast by tuning the pulse sequences and scan protocols. Subject tolerability and side effects were assessed after each scan. A new anthropomorphic 3D phantom (CIRS Model 603A) was used to assess the geometrical image accuracy. A study-specific workflow for the transfer and processing of the 7T MR images from the scan facility to the RTP and neurosurgical navigation software was developed to enable integrating these images.

Results: Images from the four pulse sequences could be acquired within 50 minutes. The scans were well tolerated. All three volunteers reported slight vertigo while being moved in and out of the scanner. No other side effects of the 7T field were reported. Increased geometrical distortion was observed in the cortex in close proximity to air-filled cavities (fig 1). Regional loss of signal and contrast could be minimized by placing dielectric pads between the head and the coil. Regions of increased signal were identified in the occipital and temporal lobes caused by residual B1-inhomogeneities. Flow-artefacts were observed near major intra-cranial vessels. Image transfer and processing did not degrade image quality. Overall system-related geometrical distortion was ≤ 2 mm. Detailed results of the geometric distortion analysis are reported in the phantom study by Peerlings et al.

Figure 1.

Sagittal 7T MRI SPACE-FLAIR image of a healthy volunteer. Increased geometrical distortion near the skull base, the ventral part of the temporal cortices and the orbito-frontal cortex due to close proximity of air-filled cavities.

Conclusion: Integration of high quality and geometrically reliable 7T MR images into neurosurgical navigation and RTP software is technically feasible. Quantification of object-related geometrical distortion needs further analysis before clinical implementation.

⁵Athinoula A. Martinos Center for Biomedical Imaging- MGH & Harvard Medical School, Department of Radiology, Charlestown, USA

Purpose or Objective: Treatment planning in radiation therapy based on MRI requires the generation of pseudo CTs for correct attenuation and dose calculation. We present a new algorithm for pseudo-CT generation which is based on localised correlations of intensity values extracted from T1-weighted and T2-weighted MRIs to CT HU values, which doesn't require UTE MRI sequences.

Material and Methods: The images of 15 patients, treated for brain tumors, were used to implement and test the algorithm. Each image sets includes a T1-weighted MRI, a T2-weighted MRI (each acquired with 3D-MPRAGE protocol with i.v. contrast agent) and a CT. The latter two were coregistered for each patient to match the T1-weighted MRI. Both of the MRIs in each set were segmented into 6 different tissue classes (white matter, gray matter, cerebrospinal fluid, bone, skin/soft tissue and air) based on an SPM8 segmentation algorithm (<http://www.fil.ion.ucl.ac.uk/spm/software/spm8/>).

In order to generate a pseudo-CT for one individual, we used the image sets of the remaining 14 patients to generate the voxel-wise T1, T2 to CT correlations for each of the tissue classes. These were then used as two dimensional lookup tables to translate the T1 and T2 values of the individual to pseudo-HU values. After the application of post-processing steps including smoothing, we compared the generated pseudo-CT to the acquired CT, by calculating the bias and the mean absolute error of the difference.

We repeated this procedure for all 15 patients.

Figure 1: Sagittal views for a selected patient for T1-weighted MRI (a), T2-weighted MRI (b), and CT (c). The pseudo-CT resulting from our algorithm is shown in (d). An example plot of T1, T2 to CT HU value correlation/lookup table for bone tissue is shown by (e), (HU over T1 and T2).

Results: The generated pseudo-CTs for the fifteen patients show low mean absolute error (138 ± 17 HU) and bias (-8 ± 29 HU) in comparison to the acquired CT. These values are in the same range as a suggested algorithm by Sue et. al, which makes use of UTE MRI acquisitions (Med Phys. 2015 Aug;42(8):4974-86.).

Conclusion: Many suggested pseudo-CT generation methods employ a complicated ultra-short echo time (UTE) MRI for better bone segmentation.

With our new approach, we show that pseudo-CTs of reasonable quality can be generated without the use of UTE MRI acquisitions. Currently, we are still improving our algorithm and at a pretty early stage of the overall development, thus further significant improvement can be expected.

Furthermore, we plan to expand our algorithm to the application in pediatric oncology with the aim to reduce necessity of CT acquisitions (ionizing radiation exposure) for growing patients.

EP-1847

Comparison of stopping power estimators from dual-energy computed tomography for protontherapy

G. Vilches-Freixas¹, J.M. Létang¹, S. Rit¹

¹Université de Lyon- CREATIS- CNRS- UMR5220- Inserm-U1044- INSA-Lyon- Université Lyon 1, Centre Léon Bérard, Lyon, France

Purpose or Objective: Proton range in patients is determined from the stopping power ratio (SPR) of tissues relative to water along the beam path. SPR map can be derived from dual-energy computed tomography (DECT) and the Bethe-Bloch equation. In this study, we propose and compare the accuracy and the precision of several procedures to estimate the SPR from DECT.

Material and Methods: Image-based method of [1] and projection-based basis material decomposition (BMD) method of [2] were investigated. 2 variants for BMD were considered: water/compact bone basis (W/CB) and photoelectric/Compton basis (Ph/Co) with exponent optimization for the given DE spectra. BMD assumes that linear attenuation coefficient at any energy can be obtained

by a linear and energy-independent combination of these basis functions. Electron density ρ_e and effective atomic number Z_{eff} are common DECT outputs. For each decomposition method, 4 empirical relationships to convert DE outputs to SPR were evaluated which were all calibrated with materials used by [3] for the stoichiometric calibration. The first approach [4] was a calibrated relation between the logarithm of the mean excitation energy of tissues Im and Z_{eff} ($Z_{eff}, \ln Im$). The second approach consisted in reconstructing the electronic cross section at 100 keV $\sigma_{e,100}$ from the BMD results. To avoid intermediate variable Z_{eff} , a novel calibrated relation between $\sigma_{e,100}$ and Im values ($\sigma_{e,100}, Im$) was proposed. The third method involved a calibration curve between ($\sigma_{e,100}, SPR/\rho_e$). The last approach consisted in the direct conversion of ρ_e into SPR through the ($\rho_e, SPR/\rho_e$) relation proposed by [5]. Only the last method can be considered independent of the energy spectra.

Virtual DECT acquisitions of the ImagingRing (medPhoton, Salzburg) of the phantom Gammex 467 were carried out by means of deterministic Monte Carlo simulations in Gate with realistic detector response model. Scatter-free fan-beam acquisitions with 720 projections were considered. Realistic Poisson noise corresponding to a 20mGy central dose was added to the projections.

Results: Relative errors of SPRs of phantom inserts estimated using 4 empirical relationships for each decomposition method are shown in Table 1 as $\mu \pm \sigma$. A penalty was imposed to pixel values with Im , Z_{eff} and σ_e values outside human range. Lung tissue inserts show maximum error. ($\sigma_{e,100}, SPR/\rho_e$) approach is the least appropriate in terms of precision. ($\sigma_{e,100}, Im$) and ($Z_{eff}, \ln Im$) behave in the same manner. Results show that the method proposed by [5] provides better accuracy and precision.

Table 1: Relative errors in the SPRs of phantom inserts for different DECT methods and empirical relationships considered in this study to convert dual-energy data to SPR.

	BMD (W/CB)	BMD (Ph/Co) opt.	Image-based
$(Z_{eff}, \ln Im)$	4.1 ± 4.8	4.0 ± 5.5	1.2 ± 2.1
$(\sigma_{e,100}, Im)$	4.2 ± 5.0	3.9 ± 5.4	-
$(\sigma_{e,100}, SPR/\rho_e)$	-1.8 ± 7.4	-6.9 ± 13	-
$(\rho_e, SPR/\rho_e)$	0.8 ± 3.4	-0.3 ± 3.3	-0.1 ± 3.0

Conclusion: Comparison of different calibration methods to convert DE data into SPR was carried out. A novel relationship between σ_e and Im was proposed and behaves similarly to ($Z_{eff}, \ln Im$) curve. Energy independent poly-line ($\rho_e, SPR/\rho_e$) curves present better accuracy and precision. DECT is a promising technique to determine the SPR of human tissues. Optimization of the acquisition parameters and the algorithm to extract the required patient information is mandatory.

⁵Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden, Department of Radiation Oncology, Dresden, Germany

⁶German Cancer Consortium DTK, Dresden, Germany

⁷Heidelberg Ion-Beam Therapy Center, Heidelberg, Germany

Purpose or Objective: Proton and ion therapy require accurate prediction of particle ranges in tissue. In current clinical practice, computed tomography (CT) images are voxel-wise converted to ion-stopping power ratio maps using direct heuristic relations. The general validity of these approaches is, however, limited due to the different physical regimes of photon and ion interaction. Using a more sophisticated method based on dual-energy CT (DECT), which provides access to the physical quantities influencing photon attenuation, Hünemohr et al. (2014) reported an improved ion-range prediction for homogeneous tissue surrogates. Here, we present a major modification of the latter method, enabling a proper treatment of heterogeneities and mixtures on several structural levels, which represent a crucial feature of the realistic clinical situation.

Material and Methods: We treat the stopping-power ratio as the product of the electron density relative to water and a correction factor that implicitly involves the logarithmic dependence on the mean excitation energy (I -value). The relative electron density, being an important parameter in both photon and ion energy loss, can be derived directly from DECT scans using a universal and robust method. The correction factor, however, has to be determined with an empirical method. For this purpose, we propose to use the information from CT images that is complementary to the relative electron density, i.e. the electronic photon absorption cross section relative to water. Using the attenuation sum rule and Bragg's additivity rule, the relative cross sections and correction factors were calculated for single elements, tissue base materials like water, lipid, etc. and tabulated real tissues.

Results: For a therapeutic beam energy of 200 MeV/u, the correction factor varies between 1.15 and 0.70 for single elements with atomic numbers between 1 and 100. Building up compounds from a certain number of elements, a maximum spread of possible values for the correction factor can be quoted for a given relative cross section, due to the mathematical structure of the variable space. In practice, this could be used as an uncertainty estimate for a given calibration. The accessible variable space is drastically reduced by admitting only tissue base materials such as water, lipids and hydroxylapatite. The space is further reduced by admitting only mixtures of real tissue materials. For human tissue, the correction factor is thus limited overall to a small range around one (0.96 - 1.02).

Conclusion: With the definition of the correction factor in the stopping-power ratio prediction and its relation to the relative cross section, a mathematically rigorous treatment of tissue mixtures was made possible. Such mixtures influence CT imaging of patients e.g. in the form of volume averaging in a CT voxel. This thorough treatment of mixtures is thus essential for the clinical applicability of DECT-based ion-range prediction.

EP-1849

Validation of synthetic CTs for MR-only planning of brain cancer

C. Glide-Hurst¹, R. Price^{1,2}, J.P. Kim¹, W. Zheng¹, I.J. Chetty¹

¹Henry Ford Health System, Department of Radiation Oncology, Detroit, USA

²Wayne State University, Medical Physics, Detroit, USA

Purpose or Objective: The development of a synthetic CT (synCT) derived from MR images is necessary to support MR-only treatment planning. While we have previously developed a synCT solution for the brain, no clear quality assurance workflow currently exists for synCT validation. This work uses a novel MR-CT compatible 3D anthropomorphic skull phantom (Fig 1A) to evaluate the uncertainty in an MR-only workflow in the brain.

Material and Methods: MR images of the phantom were acquired on a 1.0T High-Field Open MR-Simulator (Philips Medical Systems, Cleveland, OH). Triple echo ultra-short echo time combined with mDixon (UTE/Dixon), T1-FFE, T2-

TSE, and FLAIR images MR images were acquired using an 8-channel head coil. Bone-enhanced images were generated via an optimal weighted combination of inverted UTE and water/fat maps automatically generated from mDixon. Images were then semi-automatically segmented using Gaussian mixture modeling before generating synCTs via a previously described region-specific, voxel-based, weighted summation method. SynCTs were validated by calculating the mean absolute error (MAE) between SynCT and CT-SIM. DRRs from CT-SIM and SynCT were generated of the phantom and geometric fidelity was assessed via bounding box and landmark analysis. On-board planar (MV/KV) and volumetric (CBCT) images were acquired of the phantom and rigid registration was compared between datasets across three linear accelerator platforms.

Results: The MAE of the synCT for the skull phantom (Fig 1E) was 131 HU. Embedded landmarks between the phantom CT-SIM DRRs and SynCT DRRs for both right lateral and anterior projections were <1 mm (1G). However, slight image intensity variations were observed across the DRRs in the synCT as compared to the CT-SIM. Bounding box analysis of the skull revealed that anterior-posterior DRRs were <1 mm different between synCT and CT-SIM while lateral DRRs had a slightly higher uncertainty in the anterior-posterior dimension (~2 mm). MV and KV planar image registrations were within 0.7 mm for all linear accelerators. CBCT/CT-SIM and CBCT/SynCT rigid registrations were <0.4 mm different.

Conclusion: DRRs yielded comparable geometry between CT and synCT. Future work will involve an intensity normalization for synCT DRRs. Image registrations were within clinically acceptable ranges. Efforts are needed to combine geometric and dosimetric errors of the entire synCT pipeline; establishing QA workflows to quantify these uncertainties are necessary for MR-only treatment planning.

EP-1850

The earlier evaluation of response to neoadjuvant chemoradiation therapy in sarcoma using DCE-MRI

Y. Kuang¹, W. Xia², L. Chen², X. Gao²

¹University of Nevada Las Vegas, Department of Medical Physics, Las Vegas, USA

²Suzhou Institute of Biomedical Engineering and Technology, Medical Imaging Department, Suzhou, China

Purpose or Objective: Due to the spatial heterogeneity of tumors, the change of tumor size and the whole-tumor average method used in routine care do not reliably identify patients' histologic response to therapy in sarcomas, thus compromising tumor control in the context of precision medicine. In this study, we investigated the utility of dynamic contrast-enhanced MRI (DCE-MRI) combined with the voxel-wise image analysis approach as an early predictive biomarker for efficacy of neoadjuvant chemoradiation therapy in sarcoma.

Material and Methods: Serial DCE-MRI scans were performed on days before therapy (time point 1, TP1) and after 2 weeks of chemoradiation therapy (time point 2, TP2) in twelve

patients with high-risk extremity soft tissue sarcoma. A two-tier registration was used to align the tumor VOI within each dynamic frame at TP1 and align the volumes at TP2 to the volumes at TP1. After registration, the voxel-wise transfer constant K^{trans} within a VOI covering the whole tumor normalized to a reference region of normal tissue area closed to the tumor was calculated. The responder threshold was determined by linear regression via evaluating the 95% confidence interval $[-T, T]$ in the residuals from the reference region. The difference of the voxel-wise ΔK^{trans} within the tumor between TP1 and TP2 was calculated. Three classes of voxels within the tumor VOI were determined: voxels having ΔK^{trans} value exceed threshold T were designated in red, below $-T$ were designated in blue, and otherwise designated in green indicating no significant change. The volume fractions with respect to three sub-volumes of the tumor VOI were computed as F_+ (red voxels), F_- (blue voxels) and F_0 (green voxels).

Results: The histopathology at the time of surgery confirmed that 3 patients were optimal responders to preoperative treatment ($\geq 95\%$ pathologic tumor necrosis percentage) and 9 patients were sub-optimal responders ($< 95\%$ necrosis percentage). F_0 , ΔK^{trans} and F_- had significantly positive, positive and negative correlations with necrosis percentage ($p < 0.05$), respectively. The change of tumor size had no correlation with necrosis percentage.

(a) to (d): The voxel-wise K^{trans} analysis for an optimal-responder ($\geq 95\%$ tumor necrosis percentage). (a) Voxel-wise K^{trans} colormap at TP1; (b) Voxel-wise K^{trans} colormap at TP2; (c) Voxel-wise K^{trans} map of three classes of voxels depicted as red (increased K^{trans}), green (no change beyond 95% confidence intervals), and blue (decreased K^{trans}); (d) Scatter plots of three classes of voxels.

(e) to (h): The voxel-wise K^{trans} analysis for a sub-optimal responder (30% tumor necrosis percentage). (e) Voxel-wise K^{trans} colormap at TP1; (f) Voxel-wise K^{trans} colormap at TP2; (g) Voxel-wise K^{trans} map of three classes of voxels depicted as red (increased K^{trans}), green (no change beyond 95% confidence intervals), and blue (decreased K^{trans}); (h) Scatter plots of three classes of voxels.

The areas under the curve (AUC) values and P-values of the ROC analysis.

Biomarkers	AUC	P
F_+	0.556	0.782
F_0	0.852	0.079
F_-	0.889	0.052
$\Delta size$	0.556	0.782
mean ΔK^{trans}	0.815	0.116

Conclusion: The results suggest that F_0 and F_- are more sensitive to early therapy response compared, which could provide the early prediction of treatment outcome while retain spatial localization of heterogeneous response to treatment in sarcoma.

EP-1851

Quantitative assessment of glucose metabolic rate within NSCLC histologies using dynamic 18F-FDG PET

T. Meijer¹, D. Vriens², M. Looijen-Salamon³, E. Visser⁴, L.F. De Geus-Oei², J. Bussink¹

¹Radboud University Medical Center, Radiation Oncology, Nijmegen, The Netherlands

²Leiden University Medical Center, Nuclear Medicine, Leiden, The Netherlands

³Radboud University Medical Center, Pathology, Nijmegen, The Netherlands

⁴Radboud University Medical Center, Nuclear Medicine, Nijmegen, The Netherlands

Purpose or Objective: Biological behavior differs between histologies of non-small cell lung cancer (NSCLC). Tumour biology and glucose metabolism influence radiosensitivity. The first goal of this study is to calculate glucose metabolic rate constants k_1 (glucose transporter (GLUT) influx), k_2 (GLUT efflux), k_3 (hexokinase phosphorylation) and blood volume (VB) in adeno- versus squamous cell NSCLC using dynamic 18FDG PET. Heterogeneity of these parameters will be assessed within different tumour regions. This will improve understanding tumour biology and potentially form the basis for dose modifications in radiotherapy.

Besides 18FDG PET as a tool indicating radioresistant tumour areas, PET may be used for tumour delineation in radiotherapy planning. Manual tumour delineation of stage III NSCLC for radiotherapy planning takes a lot of effort. The second objective of this study is to correlate tumour dimensions obtained by thresholds of standardized uptake value (SUV; static PET), metabolic rate of glucose (MRglu; dynamic PET) with pathological data. The most appropriate method may quicken tumour delineation for radiotherapy planning.

Material and Methods: Patients with curatively resected NSCLC were included in this prospective study ($n=35$). Dynamic 18FDG-PET scans were acquired during 60 minutes. Patlak analyses using the data acquired between 15-60 minutes post-injection were performed to calculate parametric images of MRglu. The last time frame was used as static PET scan. Tumour volumes were delineated using 50% of maximum, 40% of maximum above background and FLAB algorithm. Maximum SUV (SUVmax) and maximum MRglu (MRglu;max) were calculated. In on-going analysis, volumes acquired by the segmentation methods are correlated with pathology volumes to determine the optimal delineation method for NSCLC. Within the most appropriate method, pharmacokinetic rate constants k_1 , k_2 , k_3 , VB are currently being calculated using an irreversible two-compartment model.

Results: Initial results showed that SUVmax was higher in squamous cell NSCLCs versus adenocarcinomas (median 17.8 (9-33) versus 11.6 (6-32) respectively, $p=0.002$). Also the MRglu;max was higher in squamous cell carcinomas (median 462.6 nanomol/min/g (266.4-1366.2) versus 301.5 (129.7-1096.5) respectively, $p=0.004$).

Static volumes were larger compared to the dynamic volumes ($p<0.001$). Applying FLAB algorithm on static PET resulted in the largest volumes ($p<0.001$).

Conclusion: These preliminary data support differences in glucose metabolism between adeno- and squamous cell NSCLC. In the ongoing analyses, metabolic rates of glucose will be studied in more detail and will be correlated to survival. Furthermore, tumour volumes acquired by several segmentation methods will be correlated with pathology volumes to determine the optimal delineation method. This optimal segmentation method may aid in radiotherapy delineation.

EP-1852

Predictive role of FDG-PET/CT image-derived parameters in locally advanced oropharyngeal cancer

S. Broggi¹, I. Dell'Oca², C. Fiorino¹, E. Incerti³, M. Picchio³, M.L. Belli⁴, P. Mapelli³, A. Chiara², N. Di Muzio², G.M. Cattaneo¹, R. Calandrino¹

¹IRCCS San Raffaele Scientific Institute, Medical Physics, Milano, Italy

²IRCCS San Raffaele Scientific Institute, Radiotherapy, Milano, Italy

³IRCCS San Raffaele Scientific Institute, Nuclear Medicine, Milano, Italy

⁴University of Milan, Medical Physics Specialization School, Milan, Italy

Purpose or Objective: To investigate the predictive role of FDG-PET/CT image-derived parameters in patients with locally advanced oropharyngeal cancer undergoing IMRT, by

means of helical tomotherapy (HTT), with a simultaneous integrated boost (SIB) on FDG-positive volumes (BTV).

Material and Methods: 41 patients (median age: 60; range: 41-81) treated between November 2005 and April 2014 at our Institution for advanced squamocellular oropharyngeal disease were analyzed. Most of the patients (95%) were of stage III-IV; 38 patients had positive lymph nodes (N, 32 with more than one N). HTT was delivered with a SIB approach in 30 fractions at different dose levels, concomitantly: 69 Gy (2.3 Gy/day) to FDG-positive volumes (primary tumor (T) and N), 66 Gy (2.2 Gy/day) to the tumor volume and enlarged nodes and 54 Gy (1.8 Gy/day) to the subclinical and elective treated nodes. PET metabolic parameters of FDG-positive volumes (T, N and T+N), including maximum and mean standardized uptake value (SUVmax and SUVmean), metabolic tumor volume (MTV) estimated at different thresholds 40-50-60% (MTV-40, MTV-50, MTV-60) and total lesion glycolysis (TLG-40, TLG-50, TLG-60) were considered. BTV volumes for T (BTV-T), N (BTV-N) and T+N (BTV-T+N) were also considered. Log rank univariate and Cox regression multivariate analysis were used to evaluate prognostic values of PET derived parameters and cancer specific overall survival (CSOS), local recurrence-free survival (LRFS) and loco-regional recurrence-free survival (LNRFS). The best cut-off values of PET derived parameters discriminating between patients with/without death/relapse were assessed by ROC analysis.

Results: The median follow-up was 37 months (range: 3-125 months). The 3-year CSOS, LRFS and LNRFS were 88.5%, 85% and 80%, respectively. At univariate analysis MTV-T-60>4.4cc was found the most significant PET parameter correlated to CSOS (HR: 0.09, p=0.0078), LRFS (HR: 0.07, p=0.0017) and LNRFS (HR: 0.16, p=0.01). TLG-T-60, SUVmean(T+N), MTV-T+N-60 were also found to be correlated with CSOS and LRFS. At multivariate analysis BTV-T+N>30.9cc and MTV-T-60>4.4cc were found the variables most significantly correlated with CSOS (AUC: 0.885; 95%CL: 0.739-0.965). MTV-T-60>4.4cc confirms its independent predictive role for LRFS (AUC: 0.807; 95%CL: 0.647-0.917) and for LNRFS (AUC: 0.744; 95%CL: 0.577-0.872).

CCOS, LRFS and LNRFS according to MTV_T_60>4.4cc and MTV_T_60≤ 4.4cc

Conclusion: FDG PET/CT performed as guide for HTT SIB treatment in patients affected by advanced oropharyngeal cancer is predictive of patient's outcome. MTV-T-60 was found the best predictor for CSOS, LRFS and LNRFS. FDG-PET/CT image-derived parameters might be useful to select more personalized treatment strategies.

EP-1853

Correlation between biomarkers derived from PET/CT and diffusion-weighted MRI in esophageal cancer

L. Goense¹, P.S.N. Van Rossum¹, I.M. Lips¹, S.E. Heethuis¹, A.H.M.W. Van Iier¹, M.G.E.H. Lam², A.N. Kotte¹, M. Van Vulpen¹, R. Van Hillegersberg³, J.P. Ruurda³, G.J. Meijer¹

¹UMC Utrecht, Radiotherapy, Utrecht, The Netherlands

²UMC Utrecht, Radiology and Nuclear Medicine, Utrecht, The Netherlands

³UMC Utrecht, Surgery, Utrecht, The Netherlands

Purpose or Objective: Both the standardized uptake value (SUV), acquired by 18F-fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG PET/CT), and the apparent diffusion coefficient (ADC) acquired by diffusion-weighted magnetic resonance imaging (DW-MR) are well established measures for treatment response assessment in neoadjuvant esophageal cancer treatment. However, these functional imaging parameters may refer to different aspects of tumor pathophysiology. Currently it is unclear whether these two prognostic biomarkers provide similar information or represent independent biomarkers. Therefore the aim of this study was to evaluate the correlation between SUV and ADC measurements in untreated esophageal tumors.

Material and Methods: This prospective study included 33 patients with histologically proven esophageal cancer who underwent 18F-FDG PET/CT and DW-MR examinations within 3 weeks before therapy. Tumor glucose metabolism was evaluated by the maximum and mean SUV (SUVmax and SUVmean) on the 18F-FDG PET/CT images. Minimum and mean ADC values (ADCmin and ADCmean, calculated with b values of 0,200 and 800 s/mm²) were measured in the same lesions. Lesions with a diameter larger than 3 cm were matched and a voxelwise analysis of ADC and SUV was performed. Spearman's rank correlation coefficients were used to assess the correlation between 18F-FDG PET and ADC metrics. Also the tumor ADCmean and SUVmax was compared between squamous cell carcinomas and adenocarcinomas, and between moderately and poorly differentiated tumors.

Results: Mean ADCmean and ADCmin of the 33 included esophageal cancer tumors were 1.8 ± 0.4 and 0.8 ± 0.4 , * 10^{-3} mm²/s, respectively. Mean SUVmean and Mean SUVmax were 8.3 ± 4.2 and 17.4 ± 9.6 , respectively. The SUV and ADC values as measures of glucose metabolism and cell density, respectively, showed weak to very weak non-significant correlations only (ADCmin vs SUVmax; $r=0.30$, $p=0.09$), [ADCmin vs. SUVmean $r=0.30$ $p=0.09$], [ADCmean vs SUVmax $r=0.17$ $p=0.36$], [ADCmean vs SUVmean $r=0.14$ $p=0.43$] (Figure 1). The voxel-wise analysis of 16 esophageal tumors with diameters larger than 3 cm showed a weak but significant negative correlation between ADC and SUV in 11 patients. ADCmean was significantly related to histological tumor grade (2.0 ± 0.3 in moderately differentiated tumors vs. $1.6 *10^{-3}$ mm²/s in poorly differentiated tumors ($p=0.014$)). No difference between squamous cell carcinoma and adenocarcinoma was found. SUVmax showed no differences with regard to tumor type and differentiation grade.

Figure 1: Scatter plots of SUVs and ADC values from 33 esophageal cancer tumors. **A:** Scatter plot of ADC_{min} vs. SUV_{max} . **B:** Scatter plot of ADC_{min} vs. SUV_{mean} . **C:** Scatter plot of ADC_{mean} vs. SUV_{max} . **D:** Scatter plot of ADC_{mean} vs. SUV_{mean} .

Conclusion: This study indicates that both glucose metabolism measured by PET/CT and restriction measured by DW-MR are independent cellular phenomena in newly diagnosed esophageal cancer. Therefore, SUV with ADC values may have complementary roles as imaging biomarkers in the evaluation of survival and response to neoadjuvant treatment in esophageal cancer.

EP-1854

Mammographic texture features for determination breast cancer molecular subtype

M. Arenas Prat¹, L. Díez-Presa¹, J. Torrents-Barrena², M. Arquez¹, C. Pallas¹, M. Gascón¹, M. Bonet¹, A. Latorre-Musoll³, S. Sabater⁴, D. Puig²

¹Hospital Universitari Sant Joan de Reus, Radiation Oncology, Reus, Spain

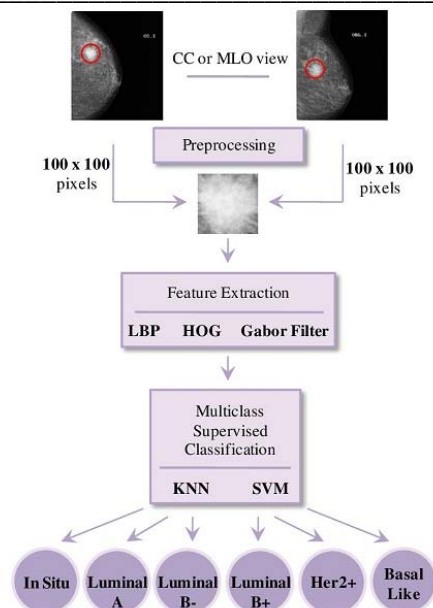

²University Rovira i Virgili, Computer Science and Mathematics, Tarragona, Spain

³Hospital de la Santa Creu i Sant Pau, Physics, Barcelona, Spain

⁴Complejo Hospitalario Universitario, Radiation Oncology, Albacete, Spain

Purpose or Objective: To determine molecular subtypes of breast cancers using texture-feature-driven machine learning techniques on mammographic images.

Material and Methods: We used mammograms of 61 ductal carcinomas (grade 2-3, median age 60, mean tumor size 28mm). A physician defined a 100x100 ROI around tumors on mammographic images. Extraction of texture features was performed using three independent descriptors: Local Binary Patterns (LBP), Histogram of Oriented Gradients (HOG) and Gabor Filter (GF). Then, a supervised classification was applied using two independent classifiers: K-Nearest Neighbors (KNN) and Support Vector Machines (SVM) (both linear- and radial-type). Both classifiers were trained to identify the molecular subtype (Luminal A, Luminal B (Her2-), Luminal B (Her2+), Her2+, Basal Like and carcinoma in situ) using the first 38 mammograms. We assessed the accuracy of our machine learning technique using the last 23 mammograms.

Results: Accuracy of SVM-R classifier was 52% irrespective of the texture descriptor we used. SVM-L/KNN classifiers achieved an accuracy of 48/39, 35/30 and 21/35% for LBP, HOG and GF descriptors. When simplifying the classification problem to only two subtypes, Luminal A and Luminal B (Her2-), classifier accuracies astonishingly improved. SVM-R accuracy was 75% irrespective of the texture descriptor and SVM(L)/KNN accuracies were 38/75, 50/50 and 63/75% for LBP, HOG and GF.

Conclusion: Our texture-feature-driven machine learning technique provides a reliable classification into molecular subtypes using mammographic images only. Accuracy improves when simplifying to only two subtypes. We expect even better accuracies by increasing the number of patients used for the training stage of our machine learning technique.

EP-1855

Computed Tomography lung texture changes due to radiotherapy for non-small cell lung cancer

J. Chalubinska-Fendler¹, W. Fendler², Ł. Karolczak³, C. Chudobiński⁴, J. Łuniewska-Bury⁵, A. Materka³, J. Fijuth¹

¹Medical University of Lodz, Radiotherapy Department- Chair of Oncology, Lodz, Poland

³Lodz University of Technology, Institute of Electronics, Lodz, Poland

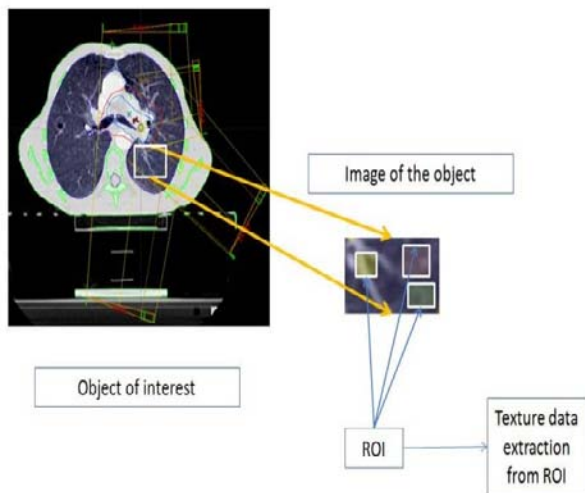

⁴Regional Oncological Centre- Lodz, Radiology Department, Lodz, Poland

⁵Regional Oncological Centre- Lodz, Brachytherapy Department, Lodz, Poland

Purpose or Objective: Radiation induced lung toxicity (RILT) may occur in 5-20% of patients irradiated due to Non-Small Cell Lung Cancer (NSCLC) but may be asymptomatic during the course of radiotherapy (RTx). Computed tomography (CT) image changes induced by RILT present after 3-9 months since RTx, mostly as lung fibrosis. Early changes on lung tissue image, i.e. during treatment, are not possible to diagnose by the naked eye, but could be detect by computer-assisted texture analysis.

Material and Methods: Fifteen patients aged 63.7+/-6.4 years, with NSCLC undergoing RTx were tested using CT before RTx and after receiving 40Gy of dose prescribed to PTV. Images were entered into a texture analysis program - MaZda® which extracted 284 texture parameters based on: signal intensity, variability of signal intensity, autocorrelation, direction of change, Fourier spectrum, Wavelet spectrum and repeatability of intensity change patterns. From every patient 10 regions of interest (ROIs)

were extracted (see image) at both timepoints from two sections of lung tissue - one that received the highest planned dose in healthy tissue and one that received low or no dose of RTx. Linear discriminant analysis (LDA) with 5-fold cross-validation and backward stepwise selection of variables was used to construct best classification models to separate irradiated from non-irradiated regions of the lung and differentiation of patients with RILT and without.

Results: LDA based on seven parameters allowed for differentiation (area under the ROC curve 0.86) of regions of healthy tissue and regions from tumour's site. The 7 variables were Wavelet-transform functions of different frequencies. However, despite those differences, CT-images from the 40Gy timepoints differed significantly depending on the received dose. An LDA model based on six parameters (3 autocorrelation functions, kurtosis and 2 wavelet function parameters) differentiated non-irradiated regions from irradiated ones - ROC AUC 0.89 (95%CI 0.75-1.00). Preliminary data from follow up showed that patients in whom RILT developed (N=7) could be differentiated from those free from complications (ROC 0.96 95%CI 0.89-1.00). However, parameters used in this LDA-based classifier relied on CT texture parameters extracted from both irradiated and non-irradiated ROIs, making ROI selection a crucial part of the texture analysis process.

Conclusion: Texture of CT-scans contains enough information to detect RTx-induced changes, although the method may be affected by pretreatment differences, which necessitates a robust placement of ROIs for analysis.

EP-1856

Predictive factors based on textural features - reliability of patient classification

T.L. Jacobsen¹, U. Bernchou², T. Schytte³, O. Hansen³, C. Brink²

¹University of Southern Denmark, Department of Physics-Chemistry- and Pharmacy, Odense, Denmark

²Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

³Odense University Hospital, Department of Oncology, Odense, Denmark

Purpose or Objective: Textural analysis of lung tumors in PET or CT images is currently of interest in a number of publications e.g. to predict overall survival after radiotherapy. Given that tumor volume is a known independent predictor in radiotherapy of lung cancer, a textural feature must be volume independent to gain independent predictive power. Furthermore, the feature value should be stable against small variations in the delineated tumor volume. This study analyses how changes in PET based tumor volume and delineation affect different published textural features.

Material and Methods: PET delineated tumors for 158 NSCLC patients were used to calculate textural features as proposed by Amadasun et al [IEEE Trans. Syst., Man, Cybern., Syst. 1989]. Delineations of the tumors were made semi-automatically based on EANM guidelines for VOI41 and VOI50 (delineation at the 41% and 50% level of SUVmax). Additional smoothed delineations were made to resemble delineations made by humans. Furthermore, dilated versions of VOI41 were analyzed to determine the response of the textural features to large changes in delineation. Textural features are typically used to divide a patient population in two groups based on a given textural cut-value, e.g. the median value. Thus, the textural feature should preferably be stable towards small delineation variations in terms of patient classification. Such stability was tested using ROC curves, in which the initial delineation (VOI41) was used as ground truth classification based on the median value. Volume dependence of the textural features was assessed through the Spearman correlation coefficient.

Results: Coarseness, busyness, contrast, and complexity were all confirmed to have a significant correlation with volume (absolute Spearman > 0.58). The figure shows coarseness' ability to classify the patients consistently for different delineations. The large area under the ROC curve (almost unity) between VOI41, VOI50, and the smoothed VOI, shows that the patient classification is almost independent of small variations of delineation. The figure also shows how successive dilations of tumor volume reduce the area under the curve. Similar findings were observed for the textures busyness and contrast. A mathematical examination of the textural features provided an easy way to correct for the volume dependence of coarseness and contrast. Neither of these modified versions was found to have volume dependence (absolute Spearman < 0.22); while at the same time having the same stability characteristic as their original versions.

Conclusion: All original textures had strong correlation with volume, which for PET delineation of lung tumors could be a confounding factor within a textural predictor. Through small changes to the original definition it is possible to make coarseness and contrast volume independent; a property which is needed for the features to be used as independent predictive factors.

⁶University of Sydney, Faculty of Physics, Sydney, Australia

⁷Princes of Wales Hospital, Department of Radiology, Sydney, Australia

⁸Western Sydney University, Faculty of Medicine, Sydney, Australia

⁹Liverpool Hospital, Department of Anatomical Pathology, Sydney, Australia

Purpose or Objective: The purpose of this study was to prospectively evaluate the role of quantitative diffusion weighted imaging (DWI) and dynamic contrast enhanced (DCE) imaging used in combination for multi-parametric MRI prediction of treatment response in rectal cancer.

Material and Methods: This study used a voxel-by-voxel multi-parametric histogram analysis strategy to assess tumour heterogeneity and its changes in response to chemoradiotherapy (CRT). Twenty patients with locally advanced rectal cancer undergoing neoadjuvant CRT prospectively underwent MRI on a 3T wide bore Siemens Skyra at 3 time-points: Pre-CRT, week 3 CRT, and post-CRT. The study protocol consisted of: (i) T2-weighted images (ii) DWI using RESOLVE, which was previously shown to be robust with respect to geometrical distortions. Images were acquired with b-values 50 and 800s/mm² and 1 & 3 averages. ADC maps and calculated b=1400s/mm² images were produced as part of protocol (iii) DCE consisted of pre-contrast VIBE scans with flip angles 2° and 15° in order to calculate native T1, followed by gadoversetamide (0.1mM/kg) injection and 60 phases using TWIST with a 5s temporal resolution. ADC and Ktrans parameter maps were registered to T2-weighted images. Semi-automated segmentation was used to define the volume of interest from hyperintense tumour on the b-value=1400 images. A voxel-by-voxel technique was used to produce colour coded histograms of ADC and Ktrans, as well as combined scatterplots and difference histograms for each time-point. CRT response was defined according to histopathology tumour regression grade (TRG) (AJCC 7th Edition). A complete protocol and analysis strategy was successfully developed which has utilized commercial, in-house developed and works-in-progress (Siemens OncoTreat) software.

Results: Of 20 patients, 1 had clinical stage T2N2M0, 5 had T3N0M0, 4 had T3N1M0, 7 had T3N2M0, and 3 had T4N2M0. Eight patients had a good response (TRG0-1) and 11 patients had a poor response (TRG2-3) to CRT. Pathology for 1 patient is pending. We found the calculated b-value=1400 images useful for visualization of tumour. In good responders, the week 3 histograms and maps showed both a shift in distribution of ADC of pixels to higher values and Ktrans of pixels to lower values compared to the pre-CRT histogram. Figure 1 shows results for a good responder who had histologic TRG 1. The figure shows voxel-by-voxel combined scatterplots and colour coded ADC and Ktrans histograms side by side for pre-CRT (top panel), week 3 CRT (middle panel) and post-CRT (bottom panel).

Conclusion: Multi-parametric histogram analysis of ADC and Ktrans appears to be a promising and feasible method of assessing tumour heterogeneity and its changes in response to CRT in rectal cancer.

EP-1858

Variation of apparent diffusion coefficient in penile bulb after radiotherapy

P. Volonghi¹, E. Scalco¹, T. Rancati², A. Messina³, E. Pignoli⁴, A. Cicchetti², B. Avuzzi⁵, D. Bosetti⁵, R. Valdagni^{2,5}, G. Rizzo¹

¹CNR, Institute of Molecular Bioimaging and Physiology, Segrate, Italy

²Fondazione IRCCS Istituto Nazionale dei Tumori, Prostate Cancer Program, Milano, Italy

³Fondazione IRCCS Istituto Nazionale dei Tumori, Radiology, Milano, Italy

⁴Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics, Milano, Italy

⁵Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology 1, Milano, Italy

Purpose or Objective: Functional imaging is widely used to evaluate the response to radiotherapy (RT) in patients with prostate cancer. In particular, variations of Apparent Diffusion Coefficient (ADC) are normally evaluated in the prostate (benign and malign zones), but organs at risk are usually not considered. The aim of our work was to investigate the changes of ADC values after RT and to correlate them to the dose in the penile bulb, as an organ which is considered to have an impact on sexual function toxicity.

Material and Methods: Twelve patients with prostate cancer treated with RT were considered. Diffusion-weighted MRI (DWI) images were acquired using four different b values (0, 150, 800 and 1000 s/mm²) at 1.5T before and after RT. A VOI-based approach was used to estimate ADC, considering the contours of the penile bulb as delineated by a radiotherapist (on T2-weighted MRI images). Specifically, for each b-value, the mean signal intensity in the bulb was calculated and the exponential model was fitted to these averaged values using linear regression algorithm. The patient set can be divided in two groups according to the time distance between the end of RT and the post-treatment DWI acquisition: A) patients with DWI acquired in acute phase (5 subjects, range of 6-15 days after the end of RT), B) patients with DWI acquired in non-acute phase (7 subjects, range of 76-179 days). Correlation of ADC variations with timing of post-RT DWI and mean dose to the penile bulb (corrected for fractionation using the linear-quadratic model and alpha/beta=3Gy) were investigated with linear regression analysis.

Results: Before RT, the ADC values were comparable for all patients. Considering group A, the mean ADC value before RT was $1.24 \times 10^{-3} \text{ mm}^2/\text{s}$, lower than the ADC after RT ($1.38 \times 10^{-3} \text{ mm}^2/\text{s}$) (Figure 1). Moreover, an increase in mean dose to the penile bulb corresponded to higher variations of ADC ($p < 0.05$, Table 1). On the contrary, in group B, the mean ADC values remained almost unchanged ($1.22 \times 10^{-3} \text{ mm}^2/\text{s}$ before RT, $1.20 \times 10^{-3} \text{ mm}^2/\text{s}$ after RT) (Figure 1); nevertheless, the linear regression analysis showed an ADC decrease tendency depending on time, as highlighted by the negative correlation between ADC changes and the amount of days after RT ($p < 0.05$, Table 1).

Figure 1. Mean ADC values in group A (mean time distance between end of RT and post-DWI: 9.2 days) and group B (mean time distance: 120 days).

Table 1. Results for linear regression correlation (R squared and p values), between ADC changes and mean dose to the penile bulb/days from RT completion and DWI acquisition (Timing). Results are reported for the two patient groups described in the text.

	Group A		Group B	
	R ²	p	R ²	p
Timing	0.02	0.83	0.60	0.04
Mean dose	0.90	0.01	0.10	0.48

Conclusion: In patients with DWI acquired early after RT completion, ADC value in penile bulb increased and its increment was correlated with higher mean dose to the penile bulb; this behavior could be explained by the inflammatory status that normally follows RT. The group of patients acquired at least three months after RT, on average, didn't show a difference in ADC value, but it was observed that increasing time from RT completion was correlated with decreasing of ADC values. This can be possibly explained by a physiological resolution of the inflammation phase and the possible beginning of fibrosis. These preliminary results obviously need confirmation in a larger population.

EP-1859

Tumor control assessment on cervical lymph nodes using texture analysis on CT and T2w-MRI images

E. Scalco¹, S. Marzi², A. Vidiri³, G. Sanguineti⁴, A. Farneti⁴, G. Rizzo¹

¹CNR, Institute of Molecular Bioimaging and Physiology IBFM, Segrate Milano, Italy

²Regina Elena National Cancer Institute, Medical Physics Laboratory, Rome, Italy

³Regina Elena National Cancer Institute, Radiology and Diagnostic Imaging Department, Rome, Italy

⁴Regina Elena National Cancer Institute, Department of Radiotherapy, Rome, Italy

Purpose or Objective: To investigate whether structural patterns of cervical lymph nodes (LNs) on CT and T2-weighted Magnetic Resonance (T2-w MR) images, using texture analysis, predict tumor control to chemoradiotherapy (CRT) of head and neck squamous cell carcinoma (HNSCC).

Material and Methods: 14 patients with pathologically confirmed HNSCC treated with CRT were considered. All patients underwent two serial MR examinations (including T2-w images), one before (MR1) and one mid-CRT (MR2). All slices containing pathologic LNs were manually contoured by a dedicated HN radiologist both MR studies; in addition, LNs on MR1 were automatically deformed on planning CT (pCT) by an elastic registration method. Seventeen volumetric and textural features were then extracted from MR1, MR2 and the pCT: volume-based indices (volume, orientation, eccentricity, equivalent diameter), histogram-based indices (mean intensity, variance, entropy, skewness, kurtosis), GLCM (Grey-Level Co-occurrence Matrix)-based indices (energy, ASM, correlation, homogeneity, entropy, contrast, dissimilarity) and fractal dimension. During at least 1 year of follow-up (median follow-up time, 2 years) 9 LNs were classified as being controlled (without evidence of disease during follow-up on MRI and PET-CT) and were labeled as RC LNs; 7 LNs were classified as having regional failure (pathology proven residual tumor at neck dissection after CRT or during the follow-up) and were labeled as RF LNs. Both pre-treatment features (MR1 and pCT) and mid-treatment features (MR2 and differences between MR1 and MR2) were considered to discriminate between RC and RF. The classification analysis was performed using Fisher's linear discriminant analysis and the accuracy was estimated using the leave-one-out approach.

Results: Box-and-whisker plots of the features with higher classification accuracy in the two groups are reported in Figure 1. In general, pre-RT features had a higher discriminative power than mid-treatment parameters. Entropy measured on CT (93.8%) reached the best accuracy, with higher values of entropy related to RF LNs. The best parameter of MR1 was kurtosis (accuracy=81.3% with higher values for RC LNs). Half-way through RT, the best indices were skewness for MR2 (accuracy=78.6% with higher values for RC LNs) and the variation in contrast (accuracy=71.4% with higher positive variations for RF LNs).

Figure 1. Boxplot of the best features for each acquired image. Median value in the group and classification accuracy were reported

Conclusion: Our preliminary results show that RC LNs have a lower CT entropy and higher MR1 kurtosis, suggesting that more homogeneous LNs before treatment may better respond to CRT, probably due to limited areas of necrosis and hypoxia. Pre-RT features had a higher discriminative power over mid-treatment ones, probably due to transitory inflammatory processes masking and confounding MR2

parameters regardless response. Texture analysis on T2w and CT images could be effective in tumor control assessment and warrants further investigation.

EP-1860

PET/MR in radiation oncology - how to correct for attenuation caused by flat table top?

P. Andrzejewski¹, S. Witoszynski², I. Rausch³, M. Hacker², D. Georg¹, B. Knäust¹

¹Medical University Vienna, Department of Radion Oncology and Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Wien, Austria

²Medical University Vienna, Department of Biomedical Imaging and Image-guided Therapy- Div. of Nuclear Medicine, Vienna, Austria

³Medical University Vienna, Center for Medical Physics and Biomedical Engineering-, Vienna, Austria

Purpose or Objective: The implementation of hybrid PET/MR scanners overcame the issues of PET-MR images registration, which proved to carry complementary information useful in many aspects of RT. However it introduced new challenges. To assure the same patient positioning during imaging and RT, dedicated MR-compatible flat table tops (FTT) are required. While these FTT cause attenuation and scatter which do not play a role in MR scanners, PET image quality (IQ) is significantly degraded. The goal of this study was to evaluate the impact of a FTT on PET IQ and to introduce a correction method.

Material and Methods: PET images of a 12l cuboid canister and round cylinder filled with 40 MBq 18F-FDG in an aqueous solution; 0.9% NaCl and 0.2mmol/l Gd-DO3A-butrol as well as a modified NEMA phantom (all spheres of 11.3ml volume), filled with 18F-FDG in 8:1 activity ratio were acquired in both a Biograph TrueV PET/CT and a Biograph mMR PET/MR (Siemens). Measurements were performed with and without the presence of the FTT (X-tend ApS). A transmission scan (PET-TS) of the FTT was performed in a GE Advance PET with an inbuilt 68Ge/68Ga source. MR markers visible in PET were used for coregistration. An attenuation map (μ Map) was derived from PET-TS and additionally used for PET(MR) image reconstruction. Activities measured in the spheres of the NEMA phantom and longitudinal activity profiles in the cylinder were compared between PET/CT and PET/MR images acquired with scanner inbuilt attenuation correction (AC) methods. Canister images were evaluated by computing the uniformity index (UI) using a sliding window approach with a 5x5 voxel ROI (0.8ml volume) on slice-by-slice basis. Advantages of the use of PET-TS were compared to standard correction methods.

Results: The (MAX-MIN)/AVR ratios of the mean activity measured in the six spheres of the modified NEMA phantom were as follows (without and with the FTT, respectively): in PET/CT 1.7% and 6.2%; in PET/MR 2.6% and 6.8%. The longitudinal activity profiles measured in the cylinder are shown in the Figure (A-B). The best IQ was found in PET/CT without FTT. Compared to these images, PET/MR images were degraded. PET/CT with FTT exhibited attenuation artefacts. In PET/MR scans both scatter and attenuation artefacts were observed. IQ was significantly improved by the use of FTT's PET-TS μ Map (cf. Figure C-G).

Figure – A-B: activity profiles through a cylindrical phantom positioned on the flat table top; A – images acquired in a PET/CT scanner, B – images acquired in a PET/MR scanner. The measured activity dropped in the proximity of the FTT compared to the cylinder centre by 22.5% in the PET/CT and by 33.2% in PET/MR. Additionally, 12.2% activity deficit was recorded in the top part of the cylinder, in the close vicinity of the phantom's wall. C-D: PET/CT (UI of 17% and 22%) and E-F: PET/MR (UI of 25% and 46%) images acquired without and with FTT, respectively. The attenuation correction was based on respective CT or MR images acquired in the hybrid scan. G: (UI of 26%) depicts a PET/MR-acquired image corrected for attenuation with the PET-TS derived μ Map.

Conclusion: The use of the PET-TS derived μ Map can reduce artefacts in PET/MR. The deteriorated AC visible in PET/CT images is caused by the transformation from CT attenuation to PET attenuation that is not valid for materials used in the FTT. This proves that CT based AC may not be sufficient to perform AC in PET/MR scanner. Although the UI measure provides an indication of IQ, it is of limited use for evaluating systematic artefacts caused by incorrect AC. Further improvements are currently explored to improve the quality of the PET-TS μ Map and to integrate it better into the image reconstruction.

EP-1861

Effect of respiratory motion on extracted textural features in tumour CT images

S. Alobaidli¹, S. McQuaid², J. Scuffham², C. South², A. Nisbet², P. Evans¹

¹University of Surrey, Department of Electronic Engineering, Guildford, United Kingdom

²Royal Surrey Hospital NHS Foundation Trust, Department of Medical Physics, Guildford, United Kingdom

Purpose or Objective: Texture analysis in CT is dependent on image resolution which is deteriorated by respiratory motion. The aim was to characterize the effect of respiratory motion on the performance of Laplacian of Gaussian (LoG) filters in extracting textural features as they have been shown in the literature to correlate to response and patient survival in non-small cell lung cancer.

Material and Methods: The modulation transfer function (MTF) was calculated in an in-house designed phantom that represents different scales of spatial frequency. This was made of Polymethyl methacrylate (PMMA) with size 131 mm x 121 mm x 30 mm. It had four sections; each with a square lattice of cubes of different sizes to give spatial frequencies (0.08, 0.1, 0.12, 0.166 1/mm). The cubes were filled with a solution of sucrose and high purity water with low (2%), medium (4%), and high (8%) concentration. The phantom was scanned static and moving on a GE discovery CT scanner (GE healthcare, Ohio, USA) with a reconstructed voxel size of 0.98 mm x 0.98mm x 1.25 mm. The phantom was attached to a dynamic thorax phantom (CIRS Company, Virginia, USA) to simulate a respiratory motion of 4 seconds period and a 1.00

cm amplitude. A Fourier Transform (FT) was used to calculate the MTF of the images for the static and moving phantom. The MTF of five commonly used LOG filters were calculated. The response of the filters was compared with the MTF of the images to determine if the motion would affect the response of the filter.

Results: The limiting resolution of the scanner, measured as the spatial resolution where the MTF was reduced to 50% and 10%, was 3.3 mm and 1.6 mm for the static and 6.6 mm and 3.3 mm for the motion acquisition respectively. The limiting resolution for each of the filters with and without motion is presented in Table (1). The results demonstrated a loss of information when using small-size filters due to the limiting resolution of the scanner. Larger-size filters are less affected by motion due to their narrower bandwidth while medium-size filters' limiting resolution appear to cover the range allowed by the scanner MTF when motion is present.

Table 1: The limiting resolution in mm for the scanner and LoG filters

Without Motion						
MTF (mm)	Scanner	Filter 4x4 mm	Filter 6x6 mm	Filter 8x8 mm	Filter 10x10	Filter 12x12
MTF50	3.3	2.8	4.0	5.0	6.2	10.0
MTF10	1.6	1.3	1.8	3.1	5.0	6.6
With Motion						
MTF (mm)	Scanner	Filter 4x4 mm	Filter 6x6 mm	Filter 8x8 mm	Filter 10x10	Filter 12x12
MTF50	6.6	7.1	6.6	6.8	7.7	10.0
MTF10	3.3	3.8	4.2	4.5	5.5	6.6

Conclusion: The results show a substantial decrease in LoG filters performance due to motion. Medium-size filters appeared to cover the frequency range allowed by the combined MTF of the scanner and respiratory motion. Accurate quantification of image texture therefore requires an implementation of motion correction methods.

EP-1862

Impact of 4DPET/CT on normal tissue sparing for SBRT of central lung tumors

S. Adebahr^{1,2}, D. Schuster¹, R. Wiehle¹, A. Chirindel^{1,3}, T. Schimek-Jasch¹, T. Fechter¹, M. Mix⁴, A.L. Grosu¹, U. Nestle^{1,2}

¹University Medical Center Freiburg, Department of Radiation Oncology, Freiburg, Germany

²German Cancer Consortium DKTK, Partner Site Freiburg, Freiburg, Germany

³PET/CT Centre NW-Switzerland and Claraspital Basel, Nuclear Medicine, Basel, Switzerland

⁴University Medical Center Freiburg, Department of Nuclear Medicine, Freiburg, Germany

Purpose or Objective: In SBRT 4DCT is the standard imaging method for target volume delineation. For SBRT of centrally located lung tumors we have previously reported that the addition of co-registered 4DPET data to 4DCT based target volume increases inter-observer agreement and may help to avoid geographic misses (1). However, it is not clear whether a better depiction of the tumor and demarcation to mediastinal structures translates into relevant normal tissue sparing. Here we compare normal tissue exposure in 4DCT versus 4DPET/CT based SBRT plans.

Material and Methods: For 10 consecutive patients with centrally located lung tumors 4DCT - and 4DPET/CT based internal and respective planning target volumes (PTVs) were generated by 4 contourers (1). SBRT plans were calculated for consensus-PTV structures, prescribing 8x7.5 Gy to the PTV. Planning was optimized likewise for 4DCT and 4DPET/CT plans with respect to dose constraints of the EORTC 22113-08113 Lungtech trial. With respect to DVHs normal tissue exposure of different organs at risk (OARs) is analyzed, normal tissue complication probability (NTCP) and tumor control probability (TCP) are being calculated.

Results: For 6/10 patients with larger 4DPET/CT-PTV than 4DCT-PTV OAR exposure was mainly higher in 4DPET/CT based plans. However, 4/10 patients with smaller 4DPET/CT-PTV than 4DCT-PTV revealed a mostly better sparing of the OARs employing 4DPET/CT and have been further analyzed. Depending on tumor location mean Dose (Dmean) of heart, esophagus, great vessels, main airways, vertebral body, chest wall, lungs-GTV, trachea and spinal cord could be reduced by

up to 3.8,1.4, 2.3, 2.9, 2.1, 2.5, 1, 2.1 and 0.8 Gy, respectively when employing additional 4DPET information. Likewise Dmax of the respective OARs could be reduced by up to 2.2, 4.1, 6.3, 3.8, 6.5, 22.1, 0.5, 10.3 and 1.5 Gy, respectively. Differences in the dose distribution of the PTV remained small with Δ Dmean and Δ Dmax being 0.3 Gy maximum. Preliminary results in TCP and NTCP modeling suggest no difference in TCP for 4DPET/CT versus 4DCT-SBRT plans and a subtle translation into improved NTCP for 4DPET/CT-based plans. For one patient the NTCP of the proximal bronchial tree could be reduced by 25% by employing additional 4DPET information in the planning process.

Conclusion: For SBRT of centrally located tumors the PTVs based on additional information of coregistered 4DPET might translate in a better NTCP for several OARs in comparison to the equivalent 4DCT-based treatment plan, with remaining an equal TCP.

³University Hospital Bonn, Nuclear Medicine, Bonn, Germany

⁴University Hospital Zurich, Nuclear Medicine, Zurich, Switzerland

⁵University Hospital Zurich, Diagnostic and Interventional Radiology, Zurich, Switzerland

⁶University Hospital Zurich, Otorhinolaryngology, Zurich, Switzerland

Purpose or Objective: Prediction of therapy outcome using radiomics has been a growing field of research in the last few years. The aim of this study was to identify a set of stable texture features computed on CT perfusion (CTP) maps with respect to CTP calculation parameters and image discretization.

Material and Methods: 11 patients with head and neck (HN) cancer and 11 patients with lung cancer who underwent CTP before treatment were included in the study. Software for calculation of the texture features was developed based on 3D definitions of first-order statistical parameters (n = 5), the Gray-Level Co-Occurrence Matrix (n = 14), the Neighborhood Gray Tone Difference Matrix (n = 4), the Gray Level Size Zone Matrix (n = 11) and fractal dimension. In total, 35 texture parameters were computed for three perfusion maps: blood volume (BV), blood flow (BF) and mean transit time (MTT) and their 3D wavelet transforms (n = 8). First, the variability of texture parameters with respect to the image discretization method (set number of bins in comparison to set intervals) was studied using the intraclass correlation (ICC) two-way mixed model. Second the correlations of texture parameters with tumor volume were investigated using Spearman correlation. To further examine the stability of texture parameters the ICC was calculated for factors influencing the perfusion maps determination (Table 1). The stability was first analyzed according to tumor site and only the features stable for both sites were included in the final set. Finally, the parameters were grouped according to inter-parameters Spearman correlations and only the parameter with the highest ICC was chosen. The acceptance level was 0.9 and 0.7 for the ICC and Spearman correlation, respectively.

Results: Texture parameters were computed in the three perfusion maps and their 3D wavelet transforms, which resulted in 945 texture features defined for each of the two tumor sites. The discretization of images using set number of bins and set intervals gave the similar number of stable texture parameters (Table 1). 40 parameters were correlated with tumor volume. Potentially standardizable factors introduced more variability into texture features than non-standardizable. The highest variability was observed for pixel size. It caused instability in about 80% of parameters for both HN and lung tumors. Ten parameters were found to be stable in both HN and lung for potentially non-standardizable factors after the correction for inter-parameters correlations:

- BF: entropy, sum entropy, LHH low gray-level size emphasis
- MTT: long size low gray-level emphasis
- BV: difference entropy, coarseness, long size high gray-level emphasis, HLH information measure of correlation 2, LLL covariance, LLL average.

Table 1. Studied CT perfusion calculation parameters and image discretization. Set of the reference parameters is underlined.

CTP parameters	Type	Levels		Unstable parameters HN (%)	Unstable parameters lung (%)
		HN	lung		
Image discretization (fixed number of bins)	Potentially standardizable factors	16, 32, <u>64</u>		42	40
Image discretization (fixed intervals)		Blood volume and bloodflow: 0.5%, 1%, 2%		41	43
Hounsfield unit (HU) intervals for exclusion of non-soft tissue from the analysis		Mean transit time: 5%, 10%, 20%			
		lower threshold: <u>-20 HU</u>	lower threshold: -450 HU, -400 HU, -350 HU, <u>-200 HU</u> , -250 HU, -200 HU, -150 HU	33	26
		upper threshold: 120 HU, 140 HU, 160 HU, <u>180 HU</u> , 200 HU, 220 HU, 240 HU	upper threshold: <u>200 HU</u>		
Voxel size (mm ³)		1x1x5, 2x2x5, 3x3x5, 4x4x5, <u>5x5x5</u>	1x1x3, 2x2x3, 3x3x3, 4x4x3, <u>5x5x3</u>	88	82
Artery contouring (AF)	Non-standardizable factors	Perfusion maps calculated on 5 different contours of artery		29	27
Noise threshold in perfusion maps calculation		10%, 12%, 14%, 16%, 18%, <u>20%</u> , 22%, 24%, 26%, 28%, 30%		31	15

Conclusion: The set of stable texture parameters in CTP was identified. Pixel size, image discretization and HU intervals have to be standardized to build a reliable prediction models based on CTP texture analysis.

A 18FDG-PET texture analysis study on early stage Hodgkin Lymphoma patient outcome prediction

G. Feliciani¹, A. Fama², P. Ciammella³, F. Fioroni¹, M. Casali⁴, B. Elisa², A. Podgornii³, A. Versari⁴, F. Merli², M. Iori¹

¹IRCCS - Arcispedale Santa Maria Nuova, Medical Physics, Reggio Emilia, Italy

²IRCCS - Arcispedale Santa Maria Nuova, Hematology, Reggio Emilia, Italy

³IRCCS - Arcispedale Santa Maria Nuova, Radiation Oncology, Reggio Emilia, Italy

⁴IRCCS - Arcispedale Santa Maria Nuova, Nuclear Medicine, Reggio Emilia, Italy

Purpose or Objective: The aim of the study was to employ texture analysis to predict early stage Hodgkin Lymphoma (HL) patients' outcome after chemotherapy and to give a quantitative description of HL characteristics. Predicting an early cancer's response to chemotherapy could enhance clinical care management by enabling the personalization of treatment plans based on predicted outcome.

Material and Methods: We reviewed medical records of patients with early stage HL diagnosed between January 2012 and December 2014 treated with standard combined modality therapy. 24 pre-treatment PET scans of the patients, acquired with a GE discovery STE, were selected for the analysis. A local nuclear medicine physician, blinded for the

clinical outcome and interim PET (iPET) results, reviewed all PET scans. Volume of Interests (VOIs) were segmented employing cubes of volume 27 cm³ and 64 cm³ and centering them on the highest metabolic active mediastinic area. Texture analysis (TA) was applied through CGITA open source software and TA features correspondence with iPET results was assessed. Furthermore, we segmented isolated lymphnodes with a 40% of SUVmax isocontour algorithm. Each lymphnode was analyzed with TA as a "stand-alone patient" in order to increase the number of observations. TA features correspondence with iPET outcome of each lymphnode was assessed. Kruskal Wallis non-parametric test was employed to select most predictive features. Features, which showed prognostic power (or patient stratification ability), were employed to build Receiver Operating Curve (ROC) in order to score their sensibility and specificity.

Results: After iPET revision, 17 patients were considered disease free after 2 cycles of ABVD whereas the remaining 7 patients had a positive iPET. Results obtained employing the 27 cm³ cubes showed that 4 features are able to predict iPET response with statistical significance (p<0.02) and a high efficiency up to 85% employing "uniformity feature". Using 64 cm³ cubes, we were able to isolate a feature named short zone emphasis, which has a discrimination sensibility of 100% with specificity 65% and indicates for ABVD resistant tumors the presence of short active zone in the surrounding of the mediastinic region highest metabolic active area. Lymphnode analysis showed that 5 out of 74 TA features could separate iPET responders and non-responders patients with statistical significance (p<0.01). In particular, "coarseness" feature has a discrimination efficiency of 73% (sensibility 77% and specificity 70%). Patients with lymphnodes that appear coarser have a higher probability of being positive at iPET.

Conclusion: In this work we presented a method to predict early stage HL patient outcome and to quantitatively describe tumor morphology combining textural features. This method requires further validation in larger prospective study.

EP-1865

DCE-CT lung tumour and aorta enhancement: is it an appropriate input vessel for kinetic modelling?

M. La Fontaine¹, W. Van Elmpot², M. Kwint¹, J. Belderbos¹, J.J. Sonke¹

¹Netherlands Cancer Institute, Radiotherapy, Amsterdam, The Netherlands

²MAASTRO, Radiation Oncology, Maastricht, The Netherlands

Purpose or Objective: Dynamic contrast-enhanced Computed Tomography (DCE-CT) is a quantitative imaging modality to characterize heterogeneity in tumour vascularization. Problems in DCE-CT kinetic modelling have been reported due to lung tumour enhancement arriving prior to aortal enhancement. Studies have attempted to correct the issue by shifting the enhancement curve in time, segmenting different input vessels and/or dual-input kinetic modelling. The purpose of this project was to develop a methodology for a detailed spatio-temporal analysis of the heterogeneous lung tumour enhancement for the purpose of applying different input vessels in kinetic modelling.

Material and Methods: Nine patients with non-small cell lung cancer (NSCLC) received DCE-CT scans (Siemens Definition Flash) prior to radiation therapy using shuttle mode acquisition with a longitudinal FOV of 13 cm. The DCE-CT scans were first motion corrected (Siemens VPCT) and subsequently, the primary lung tumour was contoured by a radiation oncologist. Using an in-house model, tumour and aorta time attenuation curves were analysed by gamma-variate function fitting. The arrival time of the contrast agent was estimated by a threshold of 1% of the maximum enhancement of the fit. To determine the percentage of tumour enhancement prior and after aortic enhancement, the arrival times of the gamma-variate fit of the tumour and aorta were compared. Tumour voxels were considered acausal if the arrival time was greater than 2 s before the

aorta arrival time, to correct for acquisition time differences and fitting uncertainties.

Results: Gamma-variate fitting was able to capture contrast arrival time in the DCE-CT images for all 9 patients. Two of the patients displayed clear tumour enhancement prior to aortal enhancement. For these patients, the percentage of the tumour with acasual enhancement with/without a 2 s allowance was 64%/73% and 37%/54%. The mean and standard deviation of the enhancement time differences between the tumour voxels with acasual enhancement and the aorta with/without a 2 sec allowance were $-1.8 \text{ s} \pm 0.6 \text{ s}/-3.4 \text{ s} \pm 1.1 \text{ s}$, and $-1.4 \pm 0.6 \text{ s}/-2.6 \pm 1.3 \text{ s}$, for each patient.

Figure 1. Lung tumour enhancement time (colorbar) prior to the aorta. The lung tumours for both patients with acasual enhancement in relation to the aorta are given in 'a.' and 'b.' The colorbar maximum was set to the start of the aorta enhancement time: parts of the tumour in light and dark blue enhanced prior to the aorta given a 2 s allowance.

Conclusion: Our study found apparent acasual enhancement in lung tumours in relation to the aorta for a subset (22%) of the NSCLC patient population examined. For these patients, gamma-variate fitting was able to determine both the percentage of the tumour with acasual enhancement times and the effective enhancement time difference between the tumour voxels and the aorta. These findings highlight the tumor vascular heterogeneity and warrant new kinetic analysis models to incorporate different tumor enhancement analysis and the selection of an appropriate input function.

EP-1866

Traceable calibration chain of PET/CT scanners for I-124

L. Joulaeizadeh¹

¹VSL, Ionizing Radiation, Delft, The Netherlands

Purpose or Objective: PET scanners are used for several decades in a wide range of diagnostic experiments. In the treatment of thyroid cancer with I-131, quantitative information of a PET scan using I-124 is used to determine the release dose to the tumor and critical organs during the treatment. To guarantee comparison of absolute quantification among institutes, measurements have to come along with uncertainty estimates and have to be traceable (i.e. linked) to international measurement standards. However, despite recent advances, PET/CT calibrations are not traceable to any measurement standard. As a result, scans taken at different scanners are not or hardly comparable with each other.

Material and Methods: VSL (National Metrology Institute in The Netherlands) maintains and develops the national measurement standards, and is able to supply support to the development of calibration chains and standard measurement protocols, thereby guaranteeing traceability to internationally accepted measurement standards. The purpose of this project is to develop a metrological infrastructure and service for on-site calibration of PET/CT scanners. VSL has the facilities to measure the activity of radionuclide solutions in a secondary level traceable to the primary standard at NPL (National Metrology Institute in UK). In 2012 and 2013 in the context of a large national multi-center trial (19 hospitals), a hospital in The Netherlands has performed non-traceable inter-comparison for I-124.

Traceable measurements to validate concept method have been performed by VSL in 2015 for few scanners in The Netherlands. A cylindrical PMMA phantom including 6 holes to position vials of I-124 has been used. Activities inside the vials have been standardized using the secondary standard at VSL with an uncertainty in the range of 2.5% (k=2). Then the phantom has been measured in different scanners.

Results: The results show differences between the measured activities in two setups which is typically around 40% for activities around 1 MBq, however goes rapidly high by lowering the activity.

Conclusion: PET/CT calibrations for I-124 are not traceable to any measurement standard. The reason is lack of any calibration chain and protocol. Calibration measurements have been introduced and examined for few PET/CT scanners. The results of these measurements strongly propose the need of traceable calibration chain.

EP-1867

Dosimetric comparison between jaw tracking and static jaw nodes in volumetric-modulated arc therapy

Y.T. Hsieh¹, C.Y. Chou¹, B.S. Huang¹

¹Chang Gang Memorial Hospital- Linkou, RTO, Taoyuan, Taiwan

Purpose or Objective: To compare the dosimetric differences between jaw tracking (JT) and non-jaw-tracking (nJT) techniques in volumetric-modulated arc therapy (VMAT) for Hepatocellular Carcinoma (HCC) treatment.

Material and Methods: The dose distribution around critical organs close to the tumor in HCC is critical owing to its high fractionation dose in Stereotactic Body Radiation Therapy (SBRT). Varian TrueBeam™ (Varian Medical Systems) system provides the JT technique, which keeps the main jaws of the LINAC dynamically as close as possible to the MLC aperture during dose delivery, hence minimize the leakage and transmission of the MLC and further reduces the dose to the organ at risk (OAR). In order to validate the advantage of OAR dose sparing by using JT technique in SBRT for HCC, treatment plans using JT and nJT techniques were designed for dosimetric comparison. Fifteen HCC patients were selected, all treated with doses of 50 Gy in 5 daily fractions with VMAT using 10 MV FFF beams. The maximum dose rate enabled for FFF beams is 2400 MU/min for 10 MV. Each VMAT plan was individually designed using two full and one partial arcs with collimator rotation of 30° and 330° to obtain the best adherence to planning objectives for each patient. All dose distributions were computed with the Analytical Anisotropic Algorithm (AAA, version 13.6) implemented in the Eclipse planning system with a calculation grid resolution of 2.5 mm. Planning objectives to target coverage aimed to cover CTV with 100% and PTV with at least 95% of the prescribed dose. The main OARs considered were: spinal cord, kidneys, stomach, duodenum, small bowel, chest wall and liver. JT and nJT Planning were performed with the same objectives constraint while plan optimization and the mean doses of OARs were obtained for plan comparison.

Results: At the same CTV and PTV dose coverage, every comparative result shows that JT plan did lower the dose received by OAR and improve the dose fall-off around the low dose region. The significant OAR dose reduction for the JT plan in this study are as follows: the mean doses to the liver was 130cGy less, the V15 of liver was 100 c.c. smaller, the maximum spinal cord dose was 300 cGy lower, and the mean kidney dose was 200 cGy lower than that in the nJT plan.

Conclusion: JT technique did show superior OARs sparing than nJT plans in HCC. The dose reduction is of clinical importance, especially for high fractionation dose SBRT treatment.

EP-1868

Standardization of amino-acid PET windowing for GTV definition in recurrent glioblastoma

O. Oehlke¹, T. Papke², M. Mix³, I. Götz⁴, T. Schimek-Jasch¹, T. Spehl⁵, P.T. Meyer³, A.L. Grosu⁶, U. Nestle⁶

¹University Medical Center Freiburg, Dept. of Radiation Oncology, Freiburg, Germany

²University Medical Center Freiburg and Ortenau Klinikum Offenburg, Dept. of Radiation Oncology and Dept. of Neurology, Freiburg and Offenburg, Germany

³University Medical Center Freiburg, Dept. of Nuclear Medicine, Freiburg, Germany

⁴University Medical Center Freiburg and Ortenau Klinikum Offenburg, Dept. of Radiation Oncology, Freiburg and Offenburg, Germany

⁵University Medical Center Freiburg and Ortenau Klinikum Offenburg, Dept. of Nuclear Medicine and Dept. of Radiology, Freiburg and Offenburg, Germany

⁶University Medical Center Freiburg and German Cancer Consortium DKTK, Dept. of Radiation Oncology, Freiburg, Germany

Purpose or Objective: With its high sensitivity and specificity compared to MRI, amino-acid PET is increasingly used for diagnosis and radiotherapy treatment planning in recurrent glioblastoma. Defining the exact tumor extent is exceedingly crucial for planning of high-precision reirradiation (SFRT, IGRT). Up to date, no standard for a visual or (semi-)automatic method for GTV delineation in amino-acid PET exists. In the present study, we investigated whether pre-defined PET windows would lead to a more consistent contouring of the tumor and - as a model with MRI-defined ground truth - normal tissues among observers.

Material and Methods: Pre-reirradiation imaging data (MRI and FET-PET) of 17 patients with recurrent glioblastoma were retrospectively evaluated. Two different pre-set window levels were created for FET-PET data, either normalized to SUVmax or normalized to the SUVmean of the contralateral non-tumor bearing hemisphere (SUVmean contra). The GTV was delineated in both data sets by 5 observers (radiation oncology and nuclear medicine specialists). Additionally, normal tissue with (superior sagittal sinus or lacrimal gland) and without physiological FET uptake (eye and lateral ventricle) were contoured. A reference contour for normal tissues was delineated in contrast-enhanced T1 MRI, and overlap volume (OV) and Kappa index (KI) were calculated for each structure.

Results: GTV volumes were larger by trend when normalized to SUVmean contra, but not significantly different between the two PET image normalization methods ($18,72 \pm 17,44$ ml for SUVmean contra vs. $14,68 \pm 12,34$ ml for SUVmax, $p=0,41$). Linear regression of inter-observer variability showed a significantly better agreement of the GTV contours when PET images were normalized to SUVmean contra ($t=3,5$). The intra-method comparison of PET data normalized to SUVmax or SUVmean contra showed the highest consensus for GTV (OVmean=0,5 and 0,52 and KI=0,64 and 0,66, respectively), whereas the lacrimal gland was the structure with the least congruency (OVmean=0,37 and 0,42 and KI=0,46 and 0,52, respectively). There was no overall significant difference between both PET windows (OVmean $p=0,83$; KI $p=0,87$). Correlation of normal tissue contours with MRI reference was poor (SUVmax vs. MRI: OVmean 0,11-0,37, KI 0,19-0,53; SUVmean contra vs. MRI: OVmean 0,13-0,36, KI 0,22-0,52) and not significantly different between the two normalization methods ($p=0,7$ and $0,89$ for OVmean and KI, respectively).

Conclusion: Normalization on the SUVmean of the contralateral hemisphere in FET-PET images helps to reduce inter-observer variability in the visual delineation of the GTV in patients with recurrent glioblastoma. However, neither improvement nor difference in the consistency of normal tissue delineation, as a model with MRI-defined ground truth, between the different windows was seen.

EP-1869

Metabolic response between primary tumor and lymph nodes in NSCLC patients during treatment course

N.M. Bruin¹, W.V. Vogel¹, J.B. Van de Kamer², J.L. Kneegjens², J. Belderbos², J.J. Sonke²

¹The Netherlands Cancer Institute, Departments of Radiation Oncology and Nuclear Medicine, Amsterdam, The Netherlands

²The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: Repetitive functional imaging during the course of irradiation is a promising method to identify non-small cell lung cancer (NSCLC) patients that have poor or favourable response to radiotherapy [1]. In locally advanced lung cancer patient, the primary tumour (PT) and involved lymph nodes (LN) are delineated and irradiated. It is currently, however, unknown if all intrathoracic lesions within the same patient demonstrate the same metabolic response. The purpose of this study was therefore to investigate the correspondence in response rate of the PT and involved LNs.

Material and Methods: Eight locally advanced NSCLC patients included in an ongoing prospective clinical trial (NCT02315053) for repeat quantitative evaluation of tumour metabolism (using FDG-PET) weekly during treatment were analysed. Patients were treated with concurrent chemoradiation (CCRT) with curative intent, in 24 fractions of 2.75 Gy combined with daily cisplatin 6 mg/m² with an overall treatment time of 32 days. All patients underwent a PET/CT for treatment planning and weekly low dose FDG PET/CT scans of the thorax in treatment position prior to the daily chemotherapy and radiotherapy administration. For the PT and each treated LN with a baseline SUVmax \geq 3 (median 3 LNs per patient; range 2-4), the SUVmax was normalized separately to the baseline value at the start of treatment. Consistency in the response between PT and LNs was evaluated by Bland-Altman analysis over the cohort (corrected for the number of lymph nodes per patients and excluding the baseline used for normalization) as well as total least squares linear regression with the PT for each LN separately.

Results: Considerable variability in metabolic response for individual time points was observed in the pooled analysis of all patients (Fig 1a) with Bland-Altman limits of agreement (LA) of 46% and a bias of 10%. Despite these LA, the correlation in the response between PT and LN was reasonably high with a median value of 0.86 with an interquartile range of 0.21. The median slope of the regression analysis was of 1.1 with an interquartile range of 0.7, indicating that the LNs typically respond a little faster than the PT. However, within a patient, several involved lymph node stations exhibited a considerably different response as illustrated in Fig1b.

Figure 1: Top) Bland-Altman analysis of the relative response of primary tumour and lymph nodes. Dashed lines indicate the bias and limits of agreement. Bottom) Example patient illustrating considerable variability in the relative metabolic response of two different lymph nodes.

Conclusion: A reasonable high correlation in response during chemoradiation between the primary lung tumour and lymph nodes was observed, but a large inter- and intra-patient variability was observed. These preliminary results suggest that treatment plan modification based on metabolic treatment response should be tailored to individual lesions.

Improving Tumor Response Assessment using DWMRI corrected by reversed gradient method and DCEMRI

A. Lopez Medina¹, S. Reigosa¹, J. Del Olmo¹, D. Aramburu Nunez², F. Salvador¹, I. Landesa³, J. Alba³, M. Salgado¹, I. Nieto⁴, V. Ochagavia⁴, V. Muñoz⁴

¹Hospital do Meixoeiro, Medical Physics Department, Vigo Pontevedra, Spain

²Memorial Sloan Kettering Cancer Center, Quantitative Imaging Department, New York, USA

³University of Vigo, SignalTheory and Communications Department, Vigo, Spain

⁴Hospital do Meixoeiro, Radiotherapy Department, Vigo Pontevedra, Spain

Purpose or Objective: Apparent diffusion coefficient (ADC), derived from diffusion-weighted MRI (DW-MRI) is a promising assessment method during radiotherapy treatment, but geometric distortion is its main disadvantage. This study investigates the use of the reversed gradient method (RGM) in DW-MRI for reduction in geometric distortion and vascularization from dynamic studies of MRI (DCEMRI), as a surrogate measure of oxygenation in H&N cancer.

Material and Methods: We studied the variation of ADC of three oropharynx cancer patients included in ARTFIBIO project. Three functional imaging scans were performed before treatment: PET/CT, DWMRI and DCEMRI; two MRI scans during the treatment; and three months after the treatment, the initial studies were repeated. Geometric distortion of DWMRI was corrected using RGM (SPM8 software, HySCO options). DCEMRI analyses were performed using Dynamika® v4.0 (www.imageanalysis.org.uk). Registration and mutual information were calculated with ARTFIBio tools. Mutual information of T2-weighted and DW-MRI was calculated for corrected and uncorrected DW-MRI. Initial Rate Enhancement (IRE) from DCEMRI was selected as a possible biomarker associated with vascularization / hypoxia.

Results: Table shows the increment in mutual information for the initial ADC maps of the three patients when correcting by RGM. For two first patients, a large increment is observed and for the third patient, although the mutual information didn't show it, the visual appreciation is quite relevant. In Figure A, the visual improvement of corrected images can be appreciated.

We also measured the variation of ADC during the treatment (Figure B), and three months later. The colour in the dots shows the initial IRE values in arbitrary units. As the dose is delivered, best-vascularized dots move to the upper part of the cloud corresponding to different instants along the treatment.

Patient	b = 0 s / mm ²		Corrected by Reversed gradient	b = 600 s / mm ²		Corrected by Reversed gradient
	Anterior shift	Posterior shift		Anterior shift	Posterior shift	
#1	0.563	0.656	0.872	0.655	0.325	0.900
#2	0.308	0.454	0.775	0.381	0.445	0.730
#3	0.439	0.548	0.548	0.545	0.522	0.567

Conclusion: RGM improves registration and provides accurate ADC in tumors. We suggest correction of distortion with the RGM should form part of an imaging method for treatment response using ADC to assess tumor response or tumor cell density variation with treatment in cancer patients, and DCEMRI can be useful for characterizing hypoxia in H&N cancers. Supported by ISCIII Grant DTS14/00188

EP-1871

Optimization of gross tumour volume definition in lung-sparing VMAT for pleural mesothelioma

A. Botticella¹, G. Defraene², K. Nackaerts³, C. Deroose⁴, P. Nafteux⁵, S. Peeters², D. De Ruyscher²

¹University Hospital Gasthuisberg, Laboratory of Experimental Radiotherapy- Oncology Department, Leuven, Belgium

²KU Leuven - University of Leuven- University Hospitals Leuven, Department of Oncology- Experimental Radiation Oncology, Leuven, Belgium

³KU Leuven - University of Leuven- University Hospitals Leuven, Respiratory Diseases/Respiratory Oncology Unit, Leuven, Belgium

⁴KU Leuven - University of Leuven- University Hospitals Leuven, Department Imaging and Pathology- Nuclear Medicine and Molecular Imaging, Leuven, Belgium

⁵KU Leuven - University of Leuven- University Hospitals Leuven, Department of Thoracic Surgery, Leuven, Belgium

Purpose or Objective: High dose lung-sparing pleural radiotherapy for malignant pleural mesothelioma (MPM) is difficult. Accurate target delineation is critical. The optimal imaging modality to define radiotherapy target volumes has not been studied in depth. This is the aim of the present study.

Material and Methods: Twelve consecutive patients with a histopathological diagnosis of stage I-IV MPM (6 left-sided and 6 right-sided) were included. CT scans with IV contrast, 18F-FDG PET/CT scans and MRI scans (post-contrast T1-weighted, T2 and diffusion-weighted images [DWI]) were obtained and downloaded from the institutional database onto a standalone image fusion workstation (MIM Software Inc., Cleveland, OH, USA) for image registration and contouring. CT scans were rigidly co-registered with 18FDG-CT-PET, with MRI scans and with DWI scans. Four sets of pleural GTVs were defined: 1) a CT-based GTV (GTVCT); 2) a PET/CT-based GTV (GTVCT+PET/CT); 3) a T1/T2-weighted MRI-based GTV (GTVCT+MRI); 4) a DWI-based GTV (GTVCT+DWI). Only the pleural tumor was contoured; mediastinal nodes were excluded. "Quantitative" and "qualitative" (visual) evaluation of the volumes was performed.

Results: Compared to CT-based GTV definition, PET/CT identified additional tumour sites in 12/16 patients. Compared to either CT or PET/CT, MRI and DWI identified additional tumour sites in 15/16 patients. Mean GTVCT, GTVCT+PET/CT, GTVCT+MRI and GTVCT+DWI (+ standard deviation [SD]) were respectively 630.1 mL (+302.81), 640.23 (+302.83), 660.8 (+290.8) and 655.2 mL(+290.7). Mean Jaccard index was lower in MRI-based contours versus all the others.

Conclusion: To the best of our knowledge, this is the first study showing that the integration of MRI into the target volume definition in hemithoracic radiotherapy in MPM may allow to improve the accuracy of target delineation and reduce the likelihood of geographical misses.

EP-1872

Benchmarking texture analysis for PET in oesophageal cancer

B. Berthon¹, K. Foley², C. Marshall¹, R.T.H. Leijenaar³, E. Spezi⁴

¹Cardiff University, Wales Research & Diagnostic PET Imaging Centre, Cardiff, United Kingdom

²Cardiff University, Institute of Cancer & Genetics, Cardiff, United Kingdom

³Maastricht University Medical Centre, GROW-School for Oncology and Developmental Biology- Department of Radiation Oncology MAASTRO Clinic, Maastricht, The Netherlands

⁴Cardiff University, School of Engineering, Cardiff, United Kingdom

Purpose or Objective: Texture and shape metrics are increasingly used for oncological applications such as the prediction of response to therapy. Commercial and freely available software tools have been used to publish significant results. However, it is unclear if these tools provide matched or even similar values, which is crucial when comparing such studies and drawing conclusions affecting patient management. In this work, we benchmark texture analysis software for PET in oesophageal cancer.

Material and Methods: PET-STAT, a texture analysis tool written in the Matlab-based open source software CERR, was benchmarked against the open source software CGITA and the Radiomics package, on oesophageal cancer PET-CT scans. The PET scans and tumour outlines in DICOM format were processed on-site with PET-STAT and CGITA and remotedly for Radiomics. Image resampling in PET-STAT matched the number of discrete intensities used in CGITA, where it was fixed, and in Radiomics, where the image bin width was set to 0.5 SUV. Texture and shape metrics present in PET-STAT and Radiomics or CGITA were matched by their mathematical

description. The metrics calculated were Maximum, Mean intensity, SUVpeak, Volume, Total Lesion Glycolysis; histogram-based Standard Deviation, Skewness, Kurtosis, Entropy (HEp) and Energy; grey level cooccurrence matrix (GLCM)-based Entropy, Homogeneity and Dissimilarity; Coarseness (C); grey level size-zone-based Intensity Variability, Large Area Emphasis and Zone Percentage, and shape metrics Maximum Diameter, Compactness, Sphericity, Spherical disproportion. No C was found in Radiomics, no shape metrics nor HEp were found in CGITA.

Results: Differences up to 7% in volume were observed between PET-STAT and CGITA, which disappeared when using data loaded from CERR, were due to different interpretation of the DICOM images and outline data. Errors of 7% in volume in one case compared with Radiomics may be due to different RTSTRUCT export or import in the study workflow. SUVpeak was up to 12% different between software packages due to different hard coded resampling of the PET image or kernel sizes used. Differences of up to 44% were observed in the calculation of shape metrics between Radiomics and PET-STAT. This was due to differences in the triangulation technique used to calculate the contour surface area. Furthermore, differences of up to 30% across the cases considered, were found to be due to different equations used for resampling the image to discrete intensities, as well as different methods for computing the GLCM and GLSZM.

Table 1. Feature values obtained for PET-STAT (PS) for each case with associated difference (in % PET-STAT) with CGITA (CG) and Radiomics (R).

Conclusion: Our benchmarking work on oesophageal cancer PET imaging reported a number of non trivial differences in texture and shape metric values when using different software packages. This highlights the importance of commissioning and validating texture analysis tools and recommends that detailed descriptions of the metric and software implementation are available.

EP-1873

Multimodality functional imaging for characterizing tumour volume

J. Del Olmo¹, S. Reigosa¹, A. Lopez Medina¹, F. Salvador¹, J. Nogueiras², J. Mañas³, M. Arias³, D. Fabri⁴, B. Sanchez Nieto⁴, M. Salgado¹

³Hospital do Meixoeiro, Radiology Department, Vigo Pontevedra, Spain

⁴Pontificia Universidad Católica de Chile, Physics Department, Santiago de Chile, Chile

Purpose or Objective: Biologically guided radiotherapy needs an understanding of how different functional imaging techniques link together. We analyse three functional imaging techniques that can be useful to characterize tumour behaviour: DWMRI, DCEMRI and PET/CT with FDG.

Material and Methods: An oropharynx cancer patient included in the ARTFIBIO project with a swollen node was selected. The pre-treatment imaging protocol was: MRI (DWMRI, DCEMRI) and PET/CT with FDG. Geometric distortion of DWMRI was corrected using the reversed gradient method (RGM) and the SPM8 software. DCEMRI analyses were performed using Dynamika® v4.0 (www.imageanalysis.org.uk). All the datasets were registered using ARTFIBio tools.

The parameters for classifying subvolumes were (Figure A): Initial Rate Enhancement (IRE) from DCEMRI, that measures the initial slope of gadolinium concentration and related to vascularization, Apparent Diffusion Coefficient (ADC) from DWMRI, previously corrected by the RGM, related to tumour density, and SUV from PET/CT with FDG. Thus, three subvolumes have been delimited: node, hypoxic volume (low IRE) and necrotic volume (red region in DWMRI b0, high ADC, very low IRE).

Results: We have analysed the relationship between the three selected parameters (ADC, IRE and SUV) for the whole node and for the badly vascularized region excluding the necrotic region. When we considered the whole node (Figure B), we observe a complex relationship between these three parameters, but when we only consider the badly vascularized region (low IRE, low ADC), we observe a clear relationship between these parameters, that suggest that vascularization quantified by IRE must be related to oxygenation, as lowest vascularized dots (blue dots, figure C), correspond to high SUV for the same ADC, indicating an enhancement of the Pasteur effect in the badly vascularized region.

Conclusion: Several functional imaging techniques can be required to customize treatment, but an appropriate registration process must be applied. ADC maps can be used for tumour cell quantification, but distortion correction algorithm must be previously applied, RGM looks quite suitable. Oxygenation process can be estimated from DCEMRI in head and neck cancer, as vascularization is related to oxygenation in these cancers, and as our results suggest. PET/CT and MRI studies provide information about malignancy grade of the tumour, considering glucose metabolism, tumour cell density (from ADC maps) and oxygenation (DCEMRI).

³The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

⁴Linköping University, Department of Radiation Physics and Department of Medical and Health Sciences, Linköping, Sweden

⁵Stockholm University, Department of Physics, Stockholm, Sweden

Purpose or Objective: Identification of outcome predictive factors at an early stage of radiation therapy allows for adaptation and individualisation. Such predictive factors are crucial for advanced head and neck (H&N) cancer patients since the treatment failure is often caused by poor loco-regional control. An early treatment adaptation would allow a dose escalation in the most radioresistant tumour regions. The aim of this study was to early identify sub-regions in H&N tumours non-responding to the treatment. This was achieved by applying a previously developed method using [18F]-fluorodeoxy-D-glucose positron emission tomography (FDG PET) to evaluate the early responsiveness of lung tumours.

Material and Methods: Thirteen patients with advanced H&N cancer were imaged with FDG PET before the start and during the second week of concurrent chemoradiotherapy (after about 19 Gy of delivered dose to the primary gross tumour volume, GTVprim). The acquired PET images were co-registered to the planning CT and a systematic analysis was performed to calculate an operational parameter at voxel level, the effective radiosensitivity α_{eff} which accounts for the accumulated dose distribution at the time of the second PET scan and variations in the FDG uptake. Volumetric maps of α_{eff} values within GTVprim, as well as the average ($a_{\alpha_{eff}}$) and negative fractions ($nf_{\alpha_{eff}}$) of α_{eff} values were determined. Patients were stratified in responders and non-responders to treatment based on previously determined criteria for overall survival at 2 years for concurrent chemoradiotherapy in lung cancer ($a_{\alpha_{eff}} > 0.004$ Gy⁻¹ and $nf_{\alpha_{eff}} \leq 30\%$). The spatial distribution of the α_{eff} values was mapped for the non-responders to treatment for future adaptation strategies.

Results: The previously proposed method was feasible for H&N cancer patients and predicted good response in 54% of the patients having simultaneously $a_{\alpha_{eff}} > 0.004$ Gy⁻¹ and $nf_{\alpha_{eff}} \leq 30\%$. Figure 1a shows an example of the effective radiosensitivity map for a selected slice of the GTVprim in one of the H&N cancer patients. The corresponding binary image with threshold on the negative portion of the α_{eff} distribution is presented in Figure 1b (white: $\alpha_{eff} > 0$; black: $\alpha_{eff} < 0$). Calculated volumetric maps of the effective radiosensitivity values showed that it was possible to segment confined sub-regions in the tumour which might indicate resistance to the treatment (Figure 1b).

Conclusion: Confined tumour sub-regions showing lack of metabolic response which might correlate to resistance to treatment could be identified at an early stage during the radiotherapy regime. Investigations on different dose boosting strategies are on-going to account for the quantitative information available from the α_{eff} volumetric maps.

Figure 1 (a) Effective radioactivity maps of a selected slice of the primary gross tumor volume and (b) corresponding binary image (white: eff=0; black: eff=0)

²Gustave Roussy, Radiothérapie, Villejuif, France

³DOSIsoft, Recherche et Développement, Cachan, France

⁴CEA, Service Hospitalier Frédéric Joliot, Orsay, France

Purpose or Objective: Patients suffering from high-grade gliomas currently have a median survival time of 14 months despite treatment. Our purpose was to investigate whether MR perfusion and relative Cerebral Blood Volume (rCBV) maps could predict tumor recurrence areas and improve treatment planning.

Material and Methods: This retrospective study included 19 patients suffering from high grade gliomas (3 and 4) who received standard radiotherapy [60 Gy, 2 Gy/fraction] and Temodal chemotherapy. Subjects underwent pre-treatment CT, gadolinium-enhanced T1-weighted, T2 FLAIR acquisitions and a DSC-MR scan. rCBV maps were calculated using READE View Advantage Workstation (GE) and normalized to the normal white matter perfusion value. The PLANET software (DOSIsoft) was used to register all MR images to the planning CT. A senior radiologist and a senior radiotherapist delineated Gross Tumor Volumes (GTV) on anatomical MR images. The Planning Target Volumes (PTV) were defined by a physicist. Threshold of 1.7 was applied to the rCBV maps to define hyper-perfused volumes (Vperf). Follow-up anatomical MR images were used to localize recurrence areas (GTV'). Correlations between all volumes were analyzed using several indexes. I1 is the percentage of Vperf not included in the GTV. I2, I3, and I5 are respectively the percentage of GTV' included in Vperf, GTV, and PTV. I4 is the percentage of Vperf not included in the GTV which was predictive of tumor recurrence outside GTV. This index is meaningful only if GTV' and GTV are different.

Results: Indexes obtained for each patient are presented in Table 1. For two patients, a threshold of 2 was applied to the rCBV maps at the physician request to facilitate the hyper-perfused area visualization. I1 values are in a range of 4 to 82% (mean = 43%) and are greater than 20% for almost 90% of the patients, indicating that hyper-perfused areas and GTV can be different. Hence, rCBV maps provide supplementary information. At least 40% of GTV' is included in Vperf for 16 patients (I2 index). For 10 patients, GTV' is not completely included in the GTV (I3 < 85%). In all these cases except one, the I4 index is greater than 20%, suggesting that a part of Vperf is predictive of the recurrence localization (Figure 1). I5 being almost always equal to 1 points out that all recurrence areas received the same dose as the GTV.

$$I1 = \frac{V_{\text{perff}} - (V_{\text{GTV}} \cap V_{\text{perff}})}{V_{\text{perff}}} \quad I2 = \frac{V_{\text{GTV}'} \cap V_{\text{perff}}}{V_{\text{GTV}'}} \quad I3 = \frac{V_{\text{GTV}'} \cap V_{\text{GTV}}}{V_{\text{GTV}'}}$$

$$I4 = \frac{(V_{\text{GTV}'} - V_{\text{GTV}}) \cap V_{\text{perff}}}{V_{\text{perff}} - V_{\text{GTV}}} \quad I5 = \frac{V_{\text{GTV}'} \cap V_{\text{PTV}}}{V_{\text{GTV}'}}$$

	I1	I2	I3	I4	I5
1	16	42**	80	59	100
2	63	7	38	33	100
3*	82	67**	35	28	100
4	60	54**	46	14	100
5*	47	47**	42	62	100
6	64	64**	46	47	100
7	4	59**	97	0	100
8	7	76**	99	2	100
9	32	66**	97	1	100
10	26	25	47	97	92
11	76	58**	97	0	100
12	46	45**	55	54	100
13	50	54**	48	48	100
14	25	61**	96	2	100
15	23	60**	86	4	99
16	17	44**	96	20	100
17	53	65**	89	1	100
18	32	38	77	39	100
19	15	46**	96	1	100

Table 1. Volume comparison indexes in 19 patients. The * sign indicates patients for whom a threshold of 2 was applied to rCBV maps at the request of the physicians. Yellow rows indicate patients for whom GTV' is not entirely included in GTV. The ** sign indicates patients for whom at least 40% of GTV' is included in Vperf.

Figure 1. Volume comparison on pre-treatment gadolinium-enhanced T1-weighted for patient 1. A large part of GTV' (green) and Vperf (yellow) are included in GTV (red) in the left hemisphere. In the right hemisphere, the hyper-perfused area is predictive of tumour recurrence. GTV' is completely included in PTV (pink).

Conclusion: Our results suggest that rCBV perfusion maps can be predictive of recurrence localization. I1, I2 and I4 values are however entirely dependent on the threshold applied to rCBV maps and their evolution while the threshold increases will be studied. As recurrence areas are always included in the PTV, an improvement of treatment planning would consist in boosting hyper-perfused area rather than changing the GTV delineation. An in-depth analysis of the pre-treatment rCBV values observed in recurrence areas will be conducted to better describe potential boost areas.

⁹University of California San Diego, Department of Radiation Medicine and Applied Science, San Diego, USA

Purpose or Objective: Gastrointestinal morbidity after radiotherapy (RT) for prostate cancer may be related to the biomechanical properties of the rectum. In this study we present a magnetic resonance imaging (MRI) based method to quantitate the thickness and elasticity of the rectal wall in prostate cancer patients treated with RT.

Material and Methods: Four patients previously treated with RT for prostate cancer underwent an MRI session with step-wise rectal bag deflation (from a maximum tolerable volume to 0 ml, in 50 ml steps), with a probe inserted inside the bag to monitor the internal rectal pressure. MRIs were acquired using Dixon sequences (4 mm axial slice thickness) at each deflation step. Rectal walls were defined from the recto-sigmoid junction to 3 cm above the anal canal as the space between the inner and outer wall surfaces. The wall thickness was determined and biomechanical properties (strain and stress) were calculated from the pressure measurements and the MRI-segmented rectal walls.

Results: The integral rectal pressure varied for the maximum tolerable volume (range: 150 - 250 ml) across patients and ranged from 1.3 - 4.0 kPa (SD = 1.2 kPa). Wall thickness was found to vary between patients and also across different rectum segments, with a mean (SD) thickness for the different segments at the 50 ml distension volume of 1.8 - 4.0 (0.6) mm. Stress showed larger variation than strain, with mean (SD) values for the different segments ranging between 1.5 - 7.0 (1.5) kPa (Fig. 1).

Figure 1. (Left panel) 2D map of strain for the 50 ml distension volume. Axial coordinate indicates the longitudinal position of the central point of each slice along the curved centre of axis, abscissa coordinate is the angular position from - π to π , where coordinate 0 corresponds with the most anterior point at most caudal part of the analysed surface. (Right panel) Box plot for the strain measurements at the 50 ml distension volume, and for the five rectal segments analysed.

INTEGRAL RECTAL PRESSURE (kPa)

AT EACH DISTENSION VOLUME

PATIENT	50ml	100ml	150ml	200ml	250ml
1	0.32	0.65	0.65	1.30	-
2	0.35	0.70	1.77	-	-
3	0.40	0.79	1.59	2.38	3.96
4	0.81	1.13	1.50	2.58	-
Mean	0.47	0.82	1.41	2.09	-
SD	0.23	0.22	0.51	0.69	-

Table 1. Pressure decrements, at each distension, for the 4 patients analysed, values missing correspond with non-tolerable distension volumes for the specific patient.

Conclusion: We have developed a method to quantify biomechanical properties of the rectal wall. The resulting rectal wall thickness, strain and stress differed between patients, as well as across different rectal wall sections. These findings could provide guidance in future predictive outcome modelling in order to better understand the rectal dose-volume response relationship.

EP-1877

Lung cancer textural analysis: to contrast or not to contrast?

A. Farchione¹, N. Dinapoli², R. Gatta², A.R. Larici¹, C. Masciocchi², A. Damiani², P. Franchi¹, A. Castelluccia², G. Mantini², L. Bonomo¹, V. Valentini²

¹Università Cattolica del Sacro Cuore - Policlinico A. Gemelli, Radiology Department, Rome, Italy

²Università Cattolica del Sacro Cuore - Policlinico A. Gemelli, Radiation Oncology Department, Rome, Italy

Purpose or Objective: In the literature the choice of images for textural analysis depends on what is available in routine clinical practice. An important consideration is that, heterogeneity within unenhanced and contrast-enhanced images may provide different information as each indicates different components of the tissue being imaged. The aim of our study was to evaluate the influence of contrast medium administration on morphological and textural "features" derived from CT images in Patients (Pts) with NSCLC.

Material and Methods: Pre-operative CT of NSCLC patients, acquired pre- and post- contrast medium administration but using the same technical parameters (CT scanner Light Speed GE Medical Systems, Milwaukee WI USA; thickness and increase layer; kernel reconstruction), were retrospectively included. For each series (pre- and post- contrast medium administration) a thoracic radiologist semi-automatically segmented tumour volumes using a commercial software (Eclipse Varian Aria v.11). Finally morphological and textural tumour features (area/volume, mean, kurtosis, skewness, standard deviation, entropy) were extracted using an ad-hoc developed software (Moddicom). The results of pre- and post-contrast analysis were compared (using Wilcoxon Signed Rank test for paired data).

Results: 39 NSCLC patients were admitted in this study. Analysis revealed that entropy and skewness had statistically significant higher values in the post-contrast acquisitions (p value = 0.007 in both cases); mean values were greater in the post-contrast acquisitions, even though the difference was not statistically significant. Kurtosis and area/volume showed statistically significant higher values in the pre-contrast acquisitions (p value respectively 0.046 and 0.036); standard deviations values were greater in the pre-contrast acquisitions, even though the difference was not statistically

significant. Results are summarized in table 1 with an example of studied patient in figure 1.

	Contrast	Without Contrast	P value
Area/Volume	-	+	0.036
Mean	+	-	n.s.
Skewness	+	-	0.007
Kurtosis	-	+	0.046
Standard Deviation	-	+	n.s.
Entropy	+	-	0.007

Conclusion: Contrast medium administration significantly influences morphological and textural features derived from CT of NSCLC. The difference can be related both to technical factors and to different tissue components of which it is expression. As these features are known predictors of different NSCLC outcomes and may be included in predictive models useful for the creation of therapeutic decision-making systems, the standardization of technical protocols seems appropriate.

EP-1878

Feasibility of gel phantoms in MRI for the assessment of kurtosis for prostate brachytherapy

Z.G. Portakal¹, J.W. Phillips², C.E. Richards³, E. Spezi⁴, T. Perrett⁵, D.G. Lewis⁵, Z. Yegingil¹

²Swansea University, College of Medicine- Institute of Life Science, Swansea, United Kingdom

³Swansea University, Collage of Medicine, Swansea, United Kingdom

⁴Cardiff University, School of Engineering, Cardiff, United Kingdom

⁵Velindre Cancer Centre, Department of Physics, Cardiff, United Kingdom

Purpose or Objective: Diffusion-weighted MRI is widely used in clinical imaging for sensitizing the signal to the local diffusion properties of water to generate quantitative information such as the apparent diffusion coefficient (ADC) or information about diffusion anisotropy by assuming the diffusion process to be Gaussian. However, the ADC is influenced by a number of factors, e.g., cellularity, cell

membrane integrity, and viscosity. Diffusion kurtosis imaging (DKI) was established to provide a more complete characterization of water diffusion based on the fact that diffusion process in vivo are non-Gaussian. In view of the complex histologic composition of prostate cancer, DKI could potentially serve as a more effective model for the assessment of the disease. The assessment of the appropriate scanning sequence for DKI involves the make of gel phantoms with a purpose of defining the feasibility of DKI in MRI for early stage prostate cancer patients treated by HDR/LDR brachytherapy.

Material and Methods: Sets of homogenous agar, agarose and polyvinyl alcohol (PVA) gel phantoms were created, as shown in Figure 1, to optimise DKI parameters to be representative of prostate cancer. For this purpose, different concentrations of agar (1.0% - 1.5% - 2.0% - 2.5% - 3.0% - 3.5% weight/volume percentage (w,v)), agarose (0.5% - 1.0% - 1.5% - 2.0% - 2.5% - 3.0% w,v) and PVA (5.0% - 7.5% - 10.0% - 12.5% - 15.0% - 20% w,v) were used. A Siemens MAGNETOM® Skyra 3T system was used to acquire an MR scan of the phantoms using a single-shot spin-echo echo-planar sequence with different diffusion weighting levels “b value” (0 to 4000 s/mm² in intervals of 500). Analysis of DKI was performed on a pixel-by-pixel basis in-house software (MATLAB).

Results: As the concentration of the gel increases, there are more restrictions to the water diffusion; therefore, the non-Gaussianity of the diffusion propagator and the kurtosis increases. According to the kurtosis (K) and diffusion coefficient (D) results, the measured kurtosis decreases for decreasing b(max). This sensitivity of diffusion kurtosis was obtained in all of the phantoms but more in agarose gels in comparison with PVA and agar samples.

Figure 2a shows the signal intensities (I) of agarose phantoms for each b values as well as the importance of noise floor in high b values (Fig. 2b).

Conclusion: We demonstrated the feasibility of making and using gel phantoms for the assessment of isotropic diffusion kurtosis to use in the characterization of early stage prostate cancer treated with prostate brachytherapy. We have shown that the rectified noise floor, which exists in standard magnitude data, increases the systematic error of the diffusion coefficients D and K . Further studies are in progress to minimize the impact of noise floor in DKI.

EP-1879

Difference between PET and RMI fusion on delineation variability for liver metastases

R. Tanguy¹, A. Gaumier¹, M.P. Sunyach¹, G. Beldjoudi¹
¹Centre Léon Bérard, Radiation Therapy, Lyon, France

Purpose or Objective: Liver metastases delineation on the dosimetric computed-tomography (CT) scan is associated with high inter-observer variations. Many authors are using a fusion of the dosimetric CT scan with a magnetic resonance imaging (MRI) to define the target volume and lower the inter-observer variations. In our center we are using PET-CT / dosimetric CT fusion or RMI / dosimetric CT fusion to delineate liver lesions depending on physicians habits. We wanted here to evaluate the benefit of each imaging registration on contouring variability.

Material and Methods: Four patients (pts) were treated with stereotactic body radiation therapy (SBRT) for 6 liver metastases. Each pt had a CT scan simulation, a liver-MRI and a PET CT before treatment. Four physicians delineated the liver lesions on the fused PET-CT and on the fused RMI. For each pt, each physician made 2 contours on the CT scan in the following order: first with the PET-CT fusion available (PET/CT), then with the CT/MRI fusion available (RMI/CT). The percentages of common contoured volumes (CCV) on PET-CT and RMI were defined using the formula: (common volume of all the physicians of the group / delineated volume of the physician) x 100. The Jaccard index (ratio between common volume and the union volume obtained using the boolean operators) was also calculated.

Results: The volume of the delineated lesions were (mean+/-SD) 18.8 cc +/- 12cc vs 20.8 cc +/- 13.6 cc on PET/CT and RMI/CT respectively (p=0.63). The common contour volume wasn't statistically different between the two contouring

modalities with (mean+/-SD) 56.2% +/- 21.5% vs 63.34% +/- 13.9% for PET/CT and RMI/CT respectively (p=0,1) even if there was a trend for a lesser variability for RMI fusion. The overall Jaccard index (mean±SD) was 0.34±0.15 and 0.46±0.19 for PET/CT and RMI/CT respectively (p=0.26).

Conclusion: A PET/CT fusion didn't improve the volume variation among the radiation oncologists compared to a RMI fusion. The CCV and Jaccard index were still unsatisfying with both PET/CT and RMI/CT fusion and we are planning to assess the potential impact of a liver metastases contour made by a radiologist to further improve the inter-observer variability.

EP-1880

Validation of the use of digital camera for the prediction of skin toxicity in breast radiotherapy

M. Poli¹, S. Bresciani¹, A. Miranti¹, A. Di Dia¹, A. Maggio¹, M. Gatti², P. Gabriele², M. Stasi¹

¹Candiolo Cancer Institute - FPO- IRCCS, Medical Physics, Candiolo, Italy

²Candiolo Cancer Institute - FPO- IRCCS, Radiotherapy, Candiolo, Italy

Purpose or Objective: Skin reactions are one of the most common side effects in breast cancer patient treated with radiotherapy. In this work a preliminary validation of the use of a digital camera, as a cheap and easy tool for early prediction of acute skin side effects, is presented.

Material and Methods: Twelve patients undergoing breast radiotherapy were photographed once a week with a digital camera system, composed of a reflex Canon 30D (CMOS sensor, 8.2 Megapixels) and a Tamron SP AF17-50mm f/2.8 XR. Patients were treated with two different techniques: conventional 3DCRT with Varian TrueBeam STx linac (8 patients) and Tomotherapy HD (4 patients). All photographic shots were acquired in manual-raw mode with the same exposure and white balance setup. Shots were converted in the best quality format available (TIFF) and post-processed in Lab color space (Color Space Converter plugin for ImageJ, NIH) to amplify color differences. From the channel related to image redness (a^*), a skin redness level was obtained for each photographed fraction by using ImageJ. In particular, two regions of interest (ROIs) were identified: one inside the treatment field (IF) and one out-of-field (OF). Redness value histograms, related to each ROI, was acquired, plotted and used to evaluate the degree of skin redness level. ROI-redness (RR) was defined as the maximum redness value of the related histogram. The OF ROI defined the redness baseline. IF RR values were plotted as a function of the corresponding fraction number and fitted with a line; the slope of this of this line is defined as RR gradient. For each patient, skin toxicity, evaluated with RTOG criteria, was compared to the RR gradient.

Results: G1 and G2 toxicities were experienced by 10 and 2 patients, respectively. A strong relation between RR gradient and skin toxicity was found: an average RR gradient of (0.24±0.09) redness/fraction was found for G1 patients, while an average RR gradient of (0.54±0.15) redness/fraction was found for G2 patients. Due to the small statistical power of the present sample, p-values were not evaluated. The trend of the fit may be correctly assessed since the first 2 weeks of treatment. Changes in skin redness were found when comparing patients treated with conventional 3DCRT with those treated with Tomotherapy. In fact, several hot spots were noticed for the conventional treatments rather than for the volumetric irradiations, that resulted in a more homogeneous skin redness.

Conclusion: Digital reflex camera can be used for quantitatively evaluate skin reactions. Moreover, it should be used to predict acute skin toxicity since the first 2 weeks of treatment. Early detection of acute skin reactions should improve patients' quality of life. The proposed method seems to be sensitive to the radiotherapeutic technique (3D CRT vs Tomotherapy). The present results may be expanded by the study of the correlation with fractionation and other treatment parameters.

EP-1881

Diffusion MRI predicts radiotherapy response in brain metastases

F. Mahmood¹, H.H. Johannesen², P. Geertsen¹, R.H. Hansen²

¹University of Copenhagen - Herlev Hospital, Radiotherapy Research Unit RRU- Department of Oncology, Herlev, Denmark

²University of Copenhagen - Herlev Hospital, Department of Radiology, Herlev, Denmark

Purpose or Objective: Radiotherapy (RT) response is generally related to changes in gross tumor volume (GTV) manifesting months later. An earlier knowledge of the treatment response may influence treatment decision. In this prospective study we investigated the correlation of parameters derived from diffusion weighted MRI (DW-MRI) acquired during RT with later GTV change of brain metastases.

Material and Methods: Nineteen metastases (N=19) from eight patients, treated with whole-brain irradiation (30 Gy in ten fractions) were analyzed. Patients were scanned with a 1T MRI system to acquire DW- ($b = 0, 50, 100, 150, 400, 500, 600, 800$ s/mm²), T2*W-, T2W- and T1W scans, before start of RT (pre-RT), at the ninth/tenth fraction (end-RT) and two to three months after RT (follow-up). DW-MRI data were fitted using a bi-exponential two-compartment model to derive the perfusion fraction (f), pseudo diffusion (D_p) and the apparent diffusion coefficient (ADC). Regions of interest (ROI) were outlined by an experienced radiologist using both low b-value images ($b=0$ s/mm²) and high b-value images ($b=800$ s/mm²) for comparison. GTV change was determined using T1W images and Eclipse (Varian Medical Systems) freehand contouring tool.

Results: Three metastases showed total remission, fourteen showed partial response and two showed progression. Using the high b-value ROI fifteen out of seventeen metastases with total or partial response showed increased (or unchanged) f providing the highest specificity (least false positives). Using the low b-value ROI fourteen out of seventeen metastases with total or partial response showed markedly increased (or unchanged) ADC providing the highest specificity. In both cases progression of metastases was associated with decreased (or unchanged) f and ADC , respectively, i.e. no false negatives (Fig. 1).

Fig. 1: Metastases are divided into primary disease and marked individually: Relative change in DW-MRI parameters (f , D_p , ADC) from pre-RT to end-RT, as a function of relative volume change between pre-RT and follow-up (T1W-MRI). With the $b=800$ ROI (first column), f has the highest specificity with no false negatives, and with the $b=0$ ROI, ADC has the highest specificity with no false negatives.

Conclusion: Data indicated that specific DW-MRI parameters (f and ADC) were capable of predicting RT response in brain metastases. This may become important in individualizing patients' prognoses and offering alternative (additional) treatments with less delay. (More data is available and currently being analyzed).

Brain connectivity changes in the presence of a glioblastoma

N. Tuovinen¹, M. Nunes², F. De Pasquale¹, C. Falletta Caravasso¹, E. Giudice³, R. Miceli³, G. Ingrassio³, R. Santoni³, K. Bühler², U. Sabatini¹

¹Fondazione Santa Lucia, Radiology, Roma, Italy

²VRVis Zentrum für Virtual Reality und Visualisierung, Biomedical Visualization, Vienna, Austria

³Tor Vergata University General Hospital, Department of Diagnostic Imaging- Molecular Imaging- Interventional Radiology and Radiotherapy, Rome, Italy

Purpose or Objective: The aim of this study is to investigate brain connectivity of post-surgical tumor patient with resting-state fMRI and diffusion tractography (DTI). This is done to understand changes occurring due to the combined effect of tumor and surgery. Common resting state (RS) network called Default Mode (DMN) and white matter (WM) tracts connecting its regions were identified. The purpose was to study whether the functional connectivity reflects the underlying structural connectivity architecture.

Material and Methods: RS- (TR/TE=2.00s/30ms) and DTI-data (64-directions, 3T Philips Achieva) were acquired for one healthy subject and a glioblastoma patient. FSL was used for preprocessing and RS-network identification (MELODIC). DTI were corrected for eddy current distortion and BedpostX was run to generate the basis for probabilistic tractography using ProtrackX. Masks derived for Prefrontal Cortex (PFC), Posterior Cingulate Cortex (PCC), Left and Right Angular Gyrus (L/RAG) from DMN were used to identify the connecting fibers. Combined masks from healthy and disrupted DMN regions were applied to identify all the possible connecting tracts. A plugin for MITK with CUDA rendering system supporting volume rendering of multiple datasets and tracts was developed to enhance our research and visualization.

Results: The healthy subject had undisrupted DMN. Patient DMN shows functional connectivity in PCC weakened and pushed inferior. The tract in the tumoral hemisphere connecting PFC to PCC was interrupted. In addition, LAG was pushed anterior by the tumor. In this case, DTI revealed displacement of the WM tracts connecting PCC to LAG anterior of the tumor.

Conclusion: Our findings suggest that connectivity is somehow preserved in tumor patient. Surgery could explain the interruption of the tract on tumoral hemisphere between PFC to PCC. The displacement of the tract between PCC and LAG can be explained by anatomical shift caused by the tumor. The changes identified in the DMN were in strong agreement with the interruption and displacement of the tracts revealed by tractography. The weakening of the PCC could be explained by the interrupted tract, whereas the displacement of the tract did not seem to affect the strength of LAG. In conclusion, our results suggest that the structural damage induces abnormal functional connectivity. This agreement of functional and structural connectivity strengthens the belief that functional connectivity estimates neural connectivity.

EP-1883

Functional brain connectivity in glioblastoma patients pre- and post-radiotherapy

N. Tuovinen¹, F. De Pasquale¹, C. Falletta Caravasso¹, E. Giudice², R. Miceli², G. Ingrosso², R. Santoni², A. Laprie³, U. Sabatini¹

¹Fondazione Santa Lucia, Radiology, Roma, Italy

²Tor Vergata University General Hospital, Department of Diagnostic Imaging- Molecular Imaging- Interventional Radiology and Radiotherapy, Rome, Italy

³Institut Claudius Regaud, Department of Radiation Oncology, Toulouse, France

Purpose or Objective: The aim of this study is to investigate longitudinal functional brain connectivity of post-surgical tumor patients with resting-state fMRI. This is done to understand changes occurring due to the combined effect of tumor, surgery and radiotherapy (RT). Special interest was given to connectivity changes in a common resting state (RS) network called Default Mode (DMN) and especially its functional hub posterior Cingulate Cortex (pCC).

Material and Methods: RS-data (TR/TE=2.00s/30ms, 3T Philips Achieva) was acquired for three glioblastoma patients pre- and post-RT. Patient1 had a tumor lesion near pCC, patient2 had a lesion near Prefrontal Cortex (PFC) and patient3 near the Right Frontal Eye Field (RFEF). Karnofsky performance scores (KPS) were evaluated. KPS for patient1 remained 80, for patient2 remained 90 and for patient3 decreased from 80 to 70 post-RT. FSL was used for preprocessing and DMN identification (MELODIC). pCC node was derived from DMN and pCC-to-brain connectivity maps were computed. Maximum, minimum and mean dose (cGy) on contours of GTV and pCC were calculated and percentual

isodoses for 30/50/70/90% were evaluated from the treatment planning.

Results: DMN was recognizable in all timepoints although topology changes during the treatment were noted. When looking at the seed-to-brain connectivity maps (Fig.1) seems that RT given on the affected network hub pCC (patient1) helps to improve the global connectivity to frontal regions of the DMN. In addition, connectivity becomes more focused post-RT. In patient2, RT given on PFC region seems to increase local connectivity temporarily in the frontal region. For patient3 whose RT was not involving DMN, the functional connectivity becomes more specific post-RT.

Figure 1: PCC-to-brain connectivity maps pre and post-RT and percentual isodose curves for three glioblastoma patients.

	cm ³	Dose _{min} (cGy)	Dose _{max} (cGy)	Dose _{mean} (cGy)
Patient1 GTV	41,9	5895,4	6252,8	6033,2
Patient1 pCC	3,5	5923,9	6019,1	5971,5
Patient2 GTV	6,2	6036,4	6290	6168
Patient2 pCC	4,7	650,4	1478,9	1061,1
Patient3 GTV	8,4	5988,4	6255,2	6130
Patient3 pCC	6,2	1040	3116	1518,4

Table 1: Minimum, maximum and mean doses received to Gross Tumor Volume and pCC.

Conclusion: Interestingly, RT near pCC seems to increase global connectivity. This might be due to the fact that we are treating a central node and thus the communication between the brain regions is re-established when the central node improves its connectivity. In addition, seems that RT near prefrontal cortex helps to increase connectivity locally. However, as this node is not an important connectivity hub, there is no improvement in connectivity to far away regions. When RT was not involving DMN, we noted a deterioration of functional connectivity. Interestingly, this patient showed also decrease in clinical performance reflecting these connectivity changes.

EP-1884

Voxel based topological PET SUV changes of bone marrow for LACC RT effect on hematological toxicity

A. Gulyban¹, P.V. Nguyen¹, J. Hermesse¹, P.A. Coucke¹, F. Lakosi¹

¹Liege University hospital, Radiation Department, Liege, Belgium

Purpose or Objective: To evaluate the topological voxel-based FDG-PET SUV changes of bone marrow including dose from radiotherapy for locally advanced cervical cancer patients and their effect on hematological toxicity.

Material and Methods: Between February 2013 and December 2014 fourteen patients were treated with using advanced radiotherapy delivery technique (IMRT or VMAT). Diagnostic FDG-PET with low-dose CT whole body scans were performed before and after radiotherapy (preRT and postRT - PET/CT). During the chemotherapy (six planned cycle) hematological toxicities were gathered for hemoglobin (HGB), white blood cell count (WBC), absolute neutrophil count (ANC) and for platelet count (PLT). Co-registration

between the three CTs (2x PET/CT and planning CT) were performed using the optical flow uni-modality deformation algorithm of Mirada RTx (version 1.6.2, Mirada Medical, Oxford, UK). Based on the CT information two region of interest (ROI) were defined: Body (only extracranial region) and bone marrow "BM" (using auto-thresholding followed by manual exclusion of CT contrast agents). Each non-CT modality were resampled to match the preRT-PET ROI statistics of original and resampled dataset were compared. Voxel-based data were extracted for each patient dataset and heuristic programmatic statistical correlation were performed using Python (version 2.7). Sub-regions defined as followings: within/outside of irradiated region (voxels above/below 1 Gy), active/non-active BM (above/below the preRT SUV average), and dose to absolute/relative volume of X Gy (where X represents any dose between 0 and 50 Gy). Correspondence between SUV changes and the dose were tested as well. All information was used to identify correlation with observed hematological toxicity (on logarithmical scale) with $p < 0.05$ significance level.

Results: The average number of voxel were 662.352 and 50.652 for Body and BM. 70/75 parameters of original and resampled volumes were within ± 0.1 g/ml or Gy and considered as clinically equivalent. PreRT and postRT SUV changes in function of delivered dose correlated significantly. For HGB no predictive value were identified. Absolute volume receiving at least 30 Gy of dose of the active BM determined nadir WBC ($p = 0.033$) and nadir ANC ($p = 0.014$) (see Figure 1), while total BM only correlated with nadir WBC ($p = 0.041$). Nadir PLT was determined by preRT SUV of the irradiated (>1 Gy) active BM and the slope of the SUV changes between preRT and postRT SUV.

Conclusion: Active and total bone marrow region receiving at least 30 Gy should be monitored to reduce possible hematological toxicity. Voxel-based evaluation of functional imaging with dose information is a valuable option especially in combination with programmatic heuristic statistical testing.

EP-1885

Novel algorithm for IVIM MRI in cancer patients: comparison to pCASL MRI

S. Stieb¹, T. Weiss², M. Wurnig³, O. Riesterer¹, A. Boss³, C. Rossi³

¹University Hospital Zurich, Department of Radiation Oncology, Zurich, Switzerland

²University Hospital Zurich, Department of Neurology, Zurich, Switzerland

³University Hospital Zurich, Department of Diagnostic and Interventional Radiology, Zurich, Switzerland

Purpose or Objective: Intravoxel incoherent motion (IVIM) MRI provides simultaneous estimates of both, perfusion and diffusion traits of tissue. In standard algorithms, a fixed threshold is set to separate the perfusion from the diffusion component of the MR signal acquired. This fixed threshold does not account for potential differences between tissue types or for a variation of the perfusion component induced by a pathological condition. In this study, the validity of a novel multi-step parameter-free IVIM algorithm independent on a priori assumptions was tested in a cohort of brain tumor patients and compared to arterial spin labeling (ASL) measurements.

Material and Methods: Six patients with malignant brain tumors grade III-IV (glioblastoma $n=3$, anaplastic astrocytoma $n=3$) have been included in this prospective study. Patients underwent a single MR examination comprising morphological imaging, diffusion weighted imaging for IVIM and pseudocontinuous arterial spin labeling (pCASL) for estimation of the cerebral blood flow (CBF). The diffusion coefficient (DC), perfusion fraction (fp) and pseudo-diffusion coefficient (D^*) were computed pixel-wise using a multi-step parameter-free algorithm for IVIM. Regions-of-Interest (Rois) were drawn over tumor areas, necrotic regions, edema, and gray matter. Spearman correlation was used to evaluate the correlation between the different parameters.

Results: In all patients, adequate image quality of IVIM datasets allowed for the pixel-wise computation of the perfusion and diffusion maps in good quality. Quantitative ASL perfusion values were in the order of 60 ml/100g/min, and tumor and perifocal edema slightly lower (Table 1). The statistical evaluation of the RoI analysis showed that CBF positively correlates with the perfusion-dependent IVIM parameter D^* (ρ CBF vs. D^* : 0.574) and the product $fp \cdot DC$ (ρ CBF vs $fp \cdot D^*$: 0.432). A slightly negative correlation between CBF and DC (-0.424) and CBF and fp (-0.217) was found.

	CBF [ml/100g/min]	DC [10^{-3} mm ² /s]	fp	D^* [10^{-3} mm ² /s]
Tumor	57.7 \pm 12.7	0.852 \pm 0.129	0.142 \pm 0.042	15.4 \pm 12.0
Gray matter	63.7 \pm 16.3	0.816 \pm 0.108	0.153 \pm 0.075	10.1 \pm 15.2
Perifocal edema	44.5 \pm 11.8	1.144 \pm 0.191	0.185 \pm 0.126	10.0 \pm 8.3

Table 1: Mean values (\pm standard deviation) of perfusion (CBF) and of IVIM parameters for different tissue types.

Conclusion: Perfusion-related IVIM parameters correlated well with tissue perfusion measured by ASL. The new parameter-free algorithm for IVIM seems therefore to be reliable for perfusion measurements in brain tumor patients.

EP-1886

The feasibility of atlas-based automatic segmentation of MRI for H&N radiotherapy planning

R. Speight¹, K. Wardman², M. Gooding³, R. Preswick⁴

¹St James Institute of Oncology, Medical Physics and Engineering, Leeds, United Kingdom

²University of Leeds, Department of Medicine, Leeds, United Kingdom

³Mirada Medical Ltd, Oxford Centre for Innovation, Oxford, United Kingdom

⁴St James Institute of Oncology, Clinical Oncology, Leeds, United Kingdom

Purpose or Objective: Atlas-based autosegmentation is an established tool for segmenting structures for CT-planned head and neck radiotherapy. MRI is being increasingly integrated into the planning process. The aim of this study is to assess the feasibility of MRI-based atlas-based autosegmentation for organs-at-risk (OAR) and lymph node

levels, and to compare the segmentation accuracy with CT-based autosegmentation.

Material and Methods: 14 patients with locally advanced head and neck cancer in a prospective imaging study underwent a T1-weighted MRI and a PET-CT (with dedicated contrast-enhanced CT) in an immobilisation mask. Organs at risk (orbits, parotids, brainstem and spinal cord) and the left level II lymph node region were manually delineated on the CT and MRI separately. A ‘leave one out’ approach was used to automatically segment structures onto the remaining images separately for CT and MRI. Contour comparison was performed using multiple positional metrics: Dice index, mean distance to conformity (MDC), sensitivity index (Se Idx) and inclusion index (In Idx).

Results: Figure 1 illustrates example manual and autocontours generated on the CT and MRI scans. Automatic segmentation using MRI of orbits, parotids, brainstem and lymph node level was acceptable with a DICE coefficient of 0.73-0.91, MDC 2.0-5.1mm Se Idx. 0.64-0.93, In Idx 0.76-0.93. Segmentation of the spinal cord was poor (Dice coefficient 0.37). The process of automatic segmentation was significantly better on MRI compared to CT for orbits, parotid glands, brainstem and left lymph node level II by multiple positional metrics; spinal cord segmentation based on MRI was inferior compared with CT.

Fig. 1 Example manual (red) and auto contours (blue) for the spinal cord as well as left and right parotids for patient 2. Top images are CT showing large dental artefacts and poor auto contours and bottom images are MRI showing more accurate auto contours.

Conclusion: Accurate atlas-based automatic segmentation of OAR and lymph node levels is feasible using T1-MRI; segmentation of the spinal cord was found to be poor. Comparison with CT-based automatic segmentation suggests that the process is equally or more accurate using MRI. These results support further translation of MRI-based segmentation methodology into clinical practice.

EP-1887

Automated 3D MRI pancreas segmentation

K. Sheng¹, S. Gou², P. Hu³

¹David Geffen School of Medicine at UCLA, Radiation Oncology, Los Angeles, USA

²Xidian University, Key Lab of Intelligent Perception and Image Understanding of Ministry of Education, Xi'an, China

³UCLA, Radiology, Los Angeles, USA

Purpose or Objective: With the advent of MR guided radiotherapy, internal organ motion can be imaged simultaneously during treatment. The real time MRI is particularly advantageous for abdominal organs that typically show poor CT contrast. To use the images for motion adaptive radiotherapy, the MR images need to be segmented but manual segmentation of the data is not practical due to data volume and speed requirement. In this study, we evaluate the feasibility of pancreas MRI segmentation using state-of-the-art segmentation methods.

Material and Methods: T2 weighted half-Fourier acquisition single-shot turbo spin-echo (HASTE), contrast free and contrasted T1 weighted 3D Fast Low Angle SHot (FLASH) Volumetric Interpolated Breath-hold Examination (VIBE) images were acquired on three patients and two healthy volunteers for a total of 12 imaging volumes. Four automated segmentation methods, including mean-shift merging (MSM), distance regularized level set (DRLS), graph cuts (GC) and dictionary learning (DL) methods were used to segment the pancreas. The segmentation results were compared to manual contours using Dice’s index (DI), Hausdorff distance and mean absolute surface distance (MASD).

Results: All VIBE images were successfully segmented by at least one of the auto-segmentation method with DI >0.83 and MASD ≤2.4 mm using the best automated segmentation method. All automated segmentation methods failed in segmenting two HASTE images, showing >1 cm MASD. Hausdorff distance exceeding 1 cm is observed on most segmentation results, indicating mismatch in fine segmentation details. The use of contrast minimally improved the segmentation accuracy. DL is statistically superior to the other methods in Dice’s overlapping index (p<0.05). For the Hausdorff distance and MASD measurement, DRLS and DL performed slightly superior to the GC method, and substantially better than MSM. DL required least human supervision and was faster to compute.

Figure shows 3D rendering of the pancreas contour based on (a) a HASTE image and (b) a VIBE image. The manual ground truth is shown in red, automated segmentation in green.

Conclusion: Automated segmentation of the pancreas with accuracy useful for organ motion tracking is achieved based on T1 weighted VIBE images. Automated pancreas segmentation based on T2 weighted HASTE images is not as robust. Considering the segmentation accuracy, levels of human supervision and computational speed, dictionary learning is the preferred segmentation method for real time MRI pancreas segmentation.

EP-1888

Accuracy and limitations of deformable image registration with SmartAdapt® in the thorax region

S. Sarudis¹, A. Karlsson Hauer², D. Bibac³, A. Bäck²

¹Sahlgrenska University Hospital, Therapeutic Radiation Physics, Borås, Sweden

²Sahlgrenska University Hospital, Therapeutic Radiation Physics, Gothenburg, Sweden

³Södra Älvsborgs Sjukhus, Diagnostic Imaging and Laboratory Medicine, Borås, Sweden

Purpose or Objective: Systematically determine the accuracy and limitations of the deformable image registration (DIR) algorithm in SmartAdapt® and present a workflow which minimises the errors and uncertainties in a deformation process.

Material and Methods: Deformable image registrations were performed on 4-dimensional computed tomography (4DCT) scans of a dynamic thorax phantom (CIRS, 008A) and patients with lung tumours that did a 4DCT scan within their regular preparation procedure before receiving external beam radiation therapy. To evaluate the performance of the DIR algorithm, the tumour in the phantom and the organs of interest for each patient (tumour, lungs, heart and spinal cord) were manually delineated in each breathing phase of the 4DCT, and the Centre of Mass Shift (CMS) and Dice Similarity Coefficients (DSC) between the deformed and manually delineated target volumes were calculated. Target shifts between 0 - 53 mm and absolute volumes between 0.5 - 1600 cm³ were evaluated. The phantom scans were repeated twice with image thicknesses of 1 and 3 mm to determine the impact on the deformation accuracy. All deformations were performed using SmartAdapt® v11.0.

Results: Target motion and volume changes are generally reproduced with CMS agreement of <2 mm and DSC >0.90. However large failures in deformed target volumes may occur when the target position is adjacent to voxels with the same intensity as the voxels within the target, if the volume of interest is set too small or if the target shift is large relative to its absolute volume. In these cases the DSC may decrease to zero meaning there is no overlap in any point between the deformed and the true target volumes. In general, the deformation accuracy decreases as the complexity and the image thickness increases. The deformed volumes may vary in shape and position between individual deformations even though all parameters in the deformations process are kept constant. Visual verification of the deformed volume before approval is therefore crucial to keep the accuracy as high as possible.

Conclusion: In general, SmartAdapt® offers a useful tool for DIR with CMS agreement of <2 mm and DSC >0.90 between the deformed and the manually delineated target volumes. More complex deformations containing large relative changes in target volume and position are less accurate with DSC decreasing to zero. Every deformation process should be repeated until visual inspection of the deformed volume is satisfactory in order to keep the accuracy as high as possible.

EP-1889

Quality assurance of image registration algorithms using synthetic CT/MRI/PET datasets

A. Perez-Rozos¹, M. Lobato Muñoz¹, I. Jerez Sainz¹, J. Medina Carmona²

¹Hospital Virgen de la Victoria, Radiation Oncology. Medical Physics., Malaga, Spain

²Hospital Virgen de la Victoria, Radiation Oncology, Malaga, Spain

Purpose or Objective: To develop a method to generate synthetic datasets to perform quality assurance of multimodality registration algorithms.

Material and Methods: Relevant geometries, resembling phantoms and human body, are generated using in-house software and PENGEO (PENELope) routines to represent clinically relevant situations. Every region of interest is characterized using user defined parameters: material density, uptake index parameter, T1, T2 and proton density parameters. Using these parameters and geometry it is possible to generate three datasets: synthetic-CT dataset, a synthetic-PET dataset, and a synthetic-MRI dataset. For synthetic CT Hounfield units are assigned using material density and a standard calibration curve; for synthetic PET SUV values are assigned using uptake index parameter for every ROI and then applying a gaussian blur filter to mimic PET resolution; synthetic MRI signal values are assigned using T1, T2, proton density and repetition and echo times using parametrization formulas that calculate signal values for T1, T2 or proton weighted sequences. Known rotations, shifts, and deformations can be applied to every dataset. The different datasets could be imported in treatment planning systems as usual and then apply the registration and fusion algorithms, that would have to recalculate the previously applied rotations and shifts.

Results: In the image we show an example of a mathematical phantom with a cortical bone ring, soft tissue with three spheres and two parallelepiped regions. Some regions are visible only in PET or MRI datasets. In lower part of image it is shown an example of PET image shift and rotation and the corresponding CT-PET image registration.

Conclusion: Use of synthetic datasets allows for comprehensive quality assurance of registration algorithms of several systems used in radiation therapy.

EP-1890

Accurate organs at risk contour propagation in head and neck adaptive radiotherapy

T.T. Zhai^{1,2}, H.P. Bijl², J.A. Langendijk², R.J. Steenbakkers², C.L. Brouwer², H.J. Van der Laan-Boomsma², N.M. Sijtsma², R.G. Kierkels²

¹Cancer Hospital of Shantou University Medical College, Department of Radiation Oncology, Shantou, China

²University of Groningen- University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands

Purpose or Objective: Adaptive radiotherapy for head and neck cancer patients aims to correct for geometrical changes due to tumour shrinkage, mucosal swelling and weight loss. These changes are monitored by weekly acquired repeat CT scans (rCTs) on which the actual treatment plan is evaluated.

The resulting large workload requires automated contour propagation from planning CT (pCT) to the rCTs. Consequently, decisions to re-plan are directly based on the propagated contours. Therefore, we investigated whether deformable propagated organs at risk (OARs) contours of head and neck cancer patients can be used for clinical treatment plan evaluation on rCTs.

Material and Methods: Planning CTs and weekly acquired rCTs of ten head and neck cancer patients were included in the analysis (in total: 10 pCTs and 67 rCTs). The following OARs were delineated on each pCT: parotid glands, submandibular glands, pharyngeal constrictor muscle, cricopharyngeal muscle, oral cavity, mandible, thyroid, supraglottic larynx, glottic area, and spinal cord. Hence, the transformation between each rCT and pCT was derived using an intensity based deformable image registration algorithm. The transformation was used to automatically propagate all contours to the rCTs (AC). All propagated contours were evaluated by an expert and corrected if necessary (corrected contours: CC). To validate deformable contour propagation for treatment plan evaluation, the AC and CC were compared by the Dice Similarity Coefficient (DSC). The AC to CC contour distances were evaluated using the combined gradient of the distance transform (ComGrad) method. Furthermore, dosimetric parameters were compared.

Results: The ACs were very similar to the CCs with an average (\pm SD) DSC for all structures of 0.93 ± 0.07 (range: 0.57-1.00), indicating no or minor corrections required for the majority of contours. The DSC was lower than 0.8 for 10% of the pharyngeal constrictor muscle and 12% of the cricopharyngeal muscle contours, respectively. For all other structures the DSC was larger than 0.9 for 93% of the contours. The average 90th percentile AC to CC contour distance was below the size of an image voxel (0.66 ± 0.25 mm; range: 0.00 - 1.50 mm). The dosimetric parameters revealed only small differences between the AC and CC dose values. Only in 3% of all analyzed contours the difference in accumulated dose between the AC and CC was more than 2 Gy. In Figure 1 the fractional ipsilateral parotid gland dose of AC and CC is shown for five representative cases.

Figure 1. The fractional mean dose of the automated (AC) and corrected (CC) ipsilateral parotid gland contours of 5 patients

Conclusion: Deformable OARs contour propagation from the planning CT to weekly acquired repeat CTs in the head and neck area resulted in similar contours and dosimetric values compared to the ground truth manually corrected contours. Only smaller contours such as the swallowing muscles, required manual review when used for decision making on replanning. Automatic contour propagation makes it feasible to include more patients in an adaptive radiotherapy schedule.

EP-1891

Determination of physical body outline in relation to outline visualisation in MRI for RT planning

S. Weiss¹, M. Helle¹, S. Renisch¹

¹Philips GmbH Innovative Technologies, Research Laboratories, Hamburg, Germany

Purpose or Objective: The geometric accuracy of MR-only based RT planning is influenced by several aspects, most of which have been evaluated thoroughly and solutions been provided: differently shaped MR and treatment tables, skin indentations by MR coils, geometrical distortions in MRI, and accuracy of segmentation. This work evaluates whether the body outline as visualized by MRI precisely matches the physical body outline, or whether there is potentially any skin layer that is not visualized by MRI. Correct delineation of the body outline is important because it directly influences attenuation and hence dose delivered to treatment and risk organs.

Material and Methods: Standard ultra-sound gel was doped with 10% Gd-contrast agent, and a lump of gel was applied to the thigh of a male volunteer. Two polyethylene foils (50 μ m and 12 μ m thickness) were immersed in doped gel in a phantom and located beside the gel on the thigh to serve as a reference. A two-channel surface coil (diameter 7cm) was used to acquire axial images with a 3D T1w-FFE-mDIXON sequence as used for MR-only RT planning in prostate. Images were acquired at standard resolution (1.7mm²x2.5mm) and high resolution (0.5mm²x2mm) in a 200mm²x10mm FOV on a 1.5T scanner (Philips Achieva). Read-out was chosen in LR direction to avoid any water-fat shift perpendicular to the skin.

Results: None of the reconstructed images (TE1, TE2, water, in-phase, opposed-phase) revealed any hypo-intense layer between the outermost MR-visible layer and the gel (c.f. Fig: thin white arrows). However, the 50 μ m PE foil in the phantom was clearly visible in the highly resolved images (bold white arrows), and the 12 μ m foil was just about visible (bold grey arrows). Initial scans had shown that plain gel generates a much stronger signal than the outer skin layer, so that the gel signal obscures the skin signal, which complicates image interpretation. Doping with 10% contrast agent resulted in a match of signal strength of gel and skin and resolved this. Image interpretation was unambiguous with respect to water-fat shift, since it was chosen parallel to the skin surface in the evaluated region.

Conclusion: It can be concluded that any MR-invisible skin layer that may be present on top of the outermost MR-visible layer but not be visualized due to lack of free water or other MRI effects has a thickness of less than 20 μ m. Such a thin layer would have a negligible effect on simulation of attenuation maps and respective dose planning, which is clinically done with a spatial resolution of 4mm.

EP-1892

Using deformable image registration to integrate diagnostic MRI into the planning pathway for HNSCC

R. Chuter^{1,2}, R. Prestwich³, A. Scarsbrook¹, J. Sykes⁴, D. Wilson¹, R. Speight¹

¹St James's University Hospital, Medical Physics and Engineering, Leeds, United Kingdom

²The Christie, Medical Physics and Engineering, Manchester, United Kingdom

³St James's University Hospital, Clinical Oncology, Leeds, United Kingdom

⁴University of Sydney, Institute of Medical Physics, Sydney, Australia

Purpose or Objective: To assess the accuracy of Gross Tumour Volume (GTV) delineation for head and neck

squamous cell carcinoma (HNSCC) through the use of diagnostic position MRI (MRI-D) images deformably registered to the planning CT. This study assessed whether optimising image registration of MRI-D to planning CT (pCT) is an adequate surrogate for delineation on a gold standard (GS) treatment position MRI (MRI-RT) rigidly registered to the pCT.

Material and Methods: Fourteen patients with HNSCC underwent a pCT and T1-weighted MRI in both a diagnostic and treatment position. The GTV was delineated on all images by a single radiation oncologist and intra-observer variability was assessed over 5 patients having been contoured on 3 occasions. GS structures were defined as contours from MRI-RT transposed to pCT using rigid registration. The GS was compared to contours produced by 4 methods: MRI-D transposed to pCT with deformable image registration (DIR) over the whole image (DIR-Whole); MRI-D transposed to pCT with rigid registration or DIR optimised on a 3cm ROI around the GTV (Rigid-ROI and DIR-ROI respectively); and on pCT alone. Registrations were performed with Mirada RTx v1.4 (Mirada Medical, Oxford UK) and 6 contour comparison metrics were calculated with ImSimQA v3.1 (OSL, Shrewsbury UK).

Results: MRI delineation reduced intra-observer variability compared to pCT. DIR-whole resulted in GTVs significantly closer to the GS as determined by multiple positional metrics in comparison with CT-only delineation (normalised results are shown in Figure 1). The mean Dice Similarity Coefficient was 0.6 and 0.72 for pCT and DIR-whole respectively with $p=0.019$. Use of MRI-D with Rigid-ROI or DIR-ROI provided no advantage over CT-only delineation.

Figure 1 - Normalised positional indices comparing GTV delineated on planning CT or MRI-D coregistered to the planning CT by a) DIR whole, b) Rigid ROI or c) DIR ROI, to GS of MRI-RT rigidly coregistered to the planning CT. An * denotes a significant difference of $P < 0.05$. Conformity measures utilised were: Conformity Index (CI), Mean Distance to Conformity (MDC), Centre of Gravity Distance (CGD), Dice Similarity Coefficient (DSC), Sensitivity Index (Se.Idx) and Inclusiveness Index (Inc.Idx).

Conclusion: In the absence of dedicated MRI-RT, image registration software can aid the integration of MRI-D into the treatment pathway. MRI-D is most accurately integrated into the radiotherapy planning pathway when contours are transposed to pCT with DIR over the whole patient.

EP-1893

Automatic contouring of soft organs for image-guided prostate radiotherapy

X. Cai¹, C.B. Schönlieb¹, J. Lee¹, J. Scaife², H. Karl³, M. Sutcliffe⁴, M. Parker³, N. Burnet²

¹University of Cambridge, Department of Applied Mathematics and Theoretical Physics, Cambridge, United Kingdom

²University of Cambridge, Department of Oncology, Cambridge, United Kingdom

³University of Cambridge, Department of Physics, Cambridge, United Kingdom

⁴University of Cambridge, Department of Engineering, Cambridge, United Kingdom

Purpose or Objective: Image-guided radiotherapy (IGRT) is a primary modality in treatment for cancer types such as prostate or neck cancer. Its pipeline involves the analysis of planning- and treatment-day CT scans (kV CT and MV CT in our case). In particular, to explore the relationship between the delivered dosage and its side effects on nearby normal tissues, an automatic contouring method for the precise delineation of target and adjacent critical organs during the treatment is essential and is also the main aim of our work.

Material and Methods: Our proposed 3D automatic contouring method constitutes a robust iterative approach on a 3D active contour segmentation model, customised for the IGRT application. The model contains two main driving principles: two data fidelity terms and one regularization term which keep the distance of the auto-contoured organ as close as possible to its true location and sufficiently close to the initialization given by the registered planning scan; and another regularization term which imposes smoothness of the contour around the segmented soft organ. The desired contour in the treatment scan is then computed iteratively, solving a convex minimization problem with an efficient solver called ADMM in each iteration. The initialization at the first iteration is obtained by transferring the manual contour in the planning scan to the treatment scans using a spline-based image registration method. Then, the global minimizer found after the first iteration is used to update the initialization for the next iteration to find the new global minimizer, which ensures the stability and robustness of the approach. We stop the iteration when the preset maximum iteration number (=10 in our case) is reached.

Results: We test our method by contouring the rectum of four patients with prostate cancer. Results are given in Fig. 1 and Table 1. Fig. 1 visually validates that our method indeed achieves accurate results and improves upon a registration of the planning contour alone. Table 1 gives the quantitative results for the registered planning contour and our proposed method. Each iteration of our method costs less than 10 seconds.

Fig. 1: Contouring results of Patient 1 in slices. Green: contour obtained by registration of the planning scan. Red: manual contour. Yellow: contour computed by our method.

	Registration method (initialization)			
	mean(acc)	std(acc)	mean(sen)	std(sen)
Patient 1 (37 scans)	69.9%	4.2%	53.9%	5.1%
Patient 2 (36 scans)	69.4%	4.0%	53.2%	4.7%
Patient 3 (37 scans)	68.3%	6.1%	52.2%	7.2%
Patient 4 (37 scans)	61.2%	3.4%	44.1%	3.7%
	Our automatic contouring method			
	mean(acc)	std(acc)	mean(sen)	std(sen)
Patient 1 (37 scans)	91.8%	3.2%	76.2%	3.2%
Patient 2 (36 scans)	89.8%	3.4%	71.2%	4.3%
Patient 3 (37 scans)	83.3%	4.0%	71.0%	3.9%
Patient 4 (37 scans)	85.9%	3.5%	73.6%	3.4%

Table 1: Mean and standard deviation (std) of the accuracy (acc) and sensitivity (sen) of the spline-based registration method and our method on the treatment scans of four patients.

Conclusion: Our proposed 3D automatic contouring method achieves an accuracy of >0.8 and sensitivity of >0.7, which is comparable to the performance of manual contours clinically. We are currently working on a fully automated setup (parameters selection) of the method which is learned from a set of 3700 manually contoured treatment scans.

EP-1894

Evaluation of a novel method for automatic segmentation of rectum on daily MVCT prostate images

M. Romanchikova¹, D.I. Johnston², K. Harrison³, M.P.F. Sutcliffe⁴, J.E. Scaife⁵, S.J. Thomas⁶, N.G. Burnet⁵

¹Cambridge University Hospitals, Medical Physics and Clinical Engineering, Cambridge, United Kingdom

²University of Cambridge, School of Clinical Medicine, Cambridge, United Kingdom

³University of Cambridge, Cavendish Laboratories, Cambridge, United Kingdom

⁴University of Cambridge, Mechanical Engineering, Cambridge, United Kingdom

⁵University of Cambridge, Oncology, Cambridge, United Kingdom

⁶Cambridge University Hospitals NHS Foundation Trust, Medical Physics and Clinical Engineering, Cambridge, United Kingdom

Purpose or Objective: Rectal toxicity is a major complication from radiotherapy (RT) for prostate cancer. The VoxTox project aims to link rectum dose to the observed toxicity for 500 prostate cancer patients who received intensity modulated RT on TomoTherapy with daily image guidance (IG).

Rectum dose is calculated using IG megavoltage CT (MVCT) scans. MVCT images have lower soft tissue contrast and signal-to-noise ratio than conventional CT. To date, there are no auto-segmentation methods for rectum delineation on MVCT. With 200,000 rectum contours required, an experienced oncologist would need over 2 years to complete the outlining.

To automate this task, we developed an in-house auto-contouring software to outline the rectum. Our software can complete the outlining in several days.

The aim of this work is to evaluate the quality of auto-generated contours and to provide a basis for further refinement of the algorithm. The method can be extended to evaluate other auto-segmentation tools.

Material and Methods: Rectum contours were produced using a Matlab code based on 2D Chan-Vese segmentation method. The contours were overlaid on the corresponding MVCT images centred at 87 Hounsfield Units (HU) and width of 220 HU.

7110 slices from 689 daily IG MVCT scans of 20 patients were inspected by a trained doctor.

A contour quality index was defined where 1 was 'very poor' and 5 was 'very good' (clinically acceptable).

Contouring errors were categorized as

- 1) too large;
- 2) too small;
- 3) cut air pocket (contour cut through gas pocket in rectal lumen);
- 4) missed air pocket (contour excluded gas pockets);
- 5) shift (contour is shifted with respect to actual organ location);
- 6) shape (sharp corners present in contour).

Results:

Contour quality:

70% of contours were scored as "very good" (Figure 1a), and 12% were "good". 13% of contours were of "average" quality, and 4% were "poor" or "very poor".

Figure 1: Auto-contoured (red line) and reference (yellow line) rectum. a) Clinically acceptable error-free contour. b),c),d): Error examples.

Error distribution:

The most frequent error was under-contouring ("too small", 21% of all reviewed images), followed by "cut air pocket" (14%). We observed an even error distribution across scans and patients (Table 1).

Error category	Prevalence across all images (n=7110)	Prevalence across scans (n = 689)	Prevalence across patients (n = 20)
Too large	5%	25%	95%
Too small	21%	68%	100%
Cut air pocket	14%	49%	100%
Missed air pocket	2%	11%	70%
Shifted	3%	18%	80%
Odd shape	3%	22%	95%
Error-free	70%	14%	0%

Table 1: Prevalence of errors across images and scans. Left: entire data set; centre: scans where ≥ 1 image has the error; right: patient data sets where ≥ 1 image has the error.

Conclusion: Our auto-contouring method produces clinically usable contours for the majority of cases and offers a considerable time- and resource-saving potential. We identified six error categories, four of which can be automatically detected during the auto-outlining and will drive the re-contouring process. The presented method can be used to evaluate the performance of other auto-segmentation tools for cavitory organs.

EP-1895

Towards adaptive radiotherapy: a new registration-segmentation framework for focal prostate cancer

Y. Feng¹, K. Cheng¹, D. Montgomery¹, D. Welsh¹, J. Lawrence², L. Forrest³, S. McLaughlin⁴, D. Argyle², W. Nailon¹

¹Edinburgh Cancer Centre, Department of Oncology Physics, Edinburgh, United Kingdom

²University of Edinburgh, Royal Dick School of Veterinary Studies, Edinburgh, United Kingdom

³University of Wisconsin-Madison, School of Veterinary Medicine, Madison, USA

⁴Heriot Watt, School of Engineering and Physical Sciences, Edinburgh, United Kingdom

Purpose or Objective: Commercial treatment planning systems can combine pre-treatment magnetic resonance (MR) images with radiotherapy planning computed tomography (CT) images using rigid or non-rigid registration. However, these systems lack the ability to combine registration with automatic image analysis/segmentation methods that may be helpful in prostate cancer boost therapy when mapping of a

dominant focal lesion between MR, where it is visible, and CT, where it is not visible. Here we present preliminary technical results from a new combined registration-segmentation framework for mapping of the dominant cancer foci defined on MR onto radiotherapy planning CT images in prostate cancer. The approach has the potential to be used in adaptive radiotherapy.

Material and Methods: Diagnostic MR and radiotherapy planning CT images acquired on General Electric Genesis and Signa scanners respectively were selected from 14 patients previously treated with external beam radiotherapy. Organs at risk (OAR), gross tumour volumes (GTV) and focal lesions were defined on all MR and CT images. The approach consists of two parts: 1) a rigid image registration method based on scale invariant feature transform (SIFT) and mutual information (MI); 2) a non-rigid registration method based on the cubic B-spline and a novel similarity function. Using this as prior data scale-invariant features were identified on the MR and corresponding planning CT. The mutual information (MI) between the images was used to steer the level set and thereby identify the location of the tumour and OARs on the CT based on local image information.

Results: The performance of the approach was established first by calculating similarity ratios for the rigid and non-rigid approaches in the framework (Table 1). The mean similarity ratio for the rigid approach was 67.43% and increased to 91.84% for the non-rigid approach. The registration results obtained on the GTV, OARs and focal lesion contours were assessed by an expert observer. Clinically acceptable results were found in 12 of the 14 patients and in 13 patients the non-rigid component of the framework performed better than the rigid approach. Figure 1 shows the performance in a typical case where the rigid registration approach places the focal lesion outside of the prostate and the non-rigid approach places the lesion inside of the prostate.

Case ID	Rigid registration similarity index	Non-rigid registration similarity index
1	53.26%	88.43%
2	86.24%	95.01%
4	80.45%	95.69%
5	93.22%	97.53%
6	82.84%	99.47%
7	66.32%	69.57%
8	49.95%	94.62%
9	51.28%	89.79%
11	48.27%	91.66%
12	77.64%	81.19%
13	59.73%	89.26%
14	78.36%	86.73%
15	100%	100%
16	39.36%	100%
18	44.49%	98.67%

Table 1. Similarity index obtained for rigid and non-rigid registration of the dominant focal lesion between diagnostic MR and radiotherapy planning CT.

Figure 1: Left: Reconstructed prostate volume from the diagnostic MR images showing the dominant focal lesion. Middle: Reconstructed prostate volume from the radiotherapy planning CT images showing the dominant focal volume placed outside of the prostate following rigid registration. Right: Radiotherapy planning CT images showing dominant focal volume inside of the prostate following non-rigid registration.

Conclusion: This framework has the potential to track the shape variation of tumor volumes and could therefore, with more validation, be used for focal radiotherapy.

EP-1896

An atlas based auto-contouring technique incorporating interobserver variation

L. Bell^{1,2}, J. Dowling³, E.M. Pogson^{1,2}, P. Metcalfe^{1,2}, L. Holloway^{1,2,4,5}

¹University of Wollongong, Centre for Medical Radiation Physics, Wollongong, Australia

²Ingham Institute, Liverpool & Macarthur Cancer Therapy Centres, Liverpool, Australia

³Australian e-Health Research Centre, CSIRO, Queensland, Australia

⁴University of Sydney, Institute of Medical Physics, Sydney, Australia

⁵University of New South Wales, SWSCS, Sydney, Australia

Purpose or Objective: The clinical efficacy of adaptive radiotherapy requires time efficient contouring that is highly accurate to maximise the benefits of exceedingly conformal techniques. Atlas based auto-contouring is a fast, patient specific method for target volume definition however current methods fail to account for interobserver variation. Current approaches utilise a training cohort of manually defined contours, whereby the assumption is made that the manual contour is the 'gold standard' contour for that patient. A novel method of atlas-based auto-contouring that incorporates interobserver variation is presented and assessed for whole breast radiotherapy.

Material and Methods: A cohort of 28 CT datasets with whole breast CTVs delineated by eight independent observers was utilised. For optimal atlas accuracy, the cohort was divided into four categories based on mean body mass index and laterality. An average atlas was generated from all datasets but one in each category, using the MILXView platform. Observer CTVs were merged in atlas space to generate a contour probability model accounting for inter-patient and inter-observer differences. The probability model was thresholded to 50% to generate a whole breast CTV auto-contour. The time taken to auto-contour each patient was recorded. For each category, the dataset not included in atlas generation was registered to the atlas, enabling the auto-contour to be propagated and clipped to the patient surface. The auto-contour was compared to the generated 'gold truth' consensus contour generated using the STAPLE algorithm, as well as the smallest and the largest CTV for a best and worst case scenario. This comparison was performed using the Dice Similarity Coefficient (DSC) and Mean Absolute Surface Differences (MASD).

Results: The time required to auto-contour each patient was 3min, 43 sec on average. DSC and MASD of the whole breast radiotherapy auto-contour and each target volume averaged across patients in each category are presented in the table.

	DSC				MASD (mm)			
	Large Left	Large Right	Small Left	Small Right	Large Left	Large Right	Small Left	Small Right
STAPLE	0.81	0.85	0.71	0.79	7.99	3.47	6.17	5.16
Smallest CTV	0.77	0.86	0.71	0.79	9.28	3.64	4.81	5.16
Largest CTV	0.81	0.8	0.71	0.79	7.5	4.71	6.13	5.07

Conclusion: This atlas-based auto-contouring method incorporating interobserver variation was shown to be accurate (DSC>0.7, MASD <8mm for all) and efficient (time was <4min). Variations in the auto-contour and STAPLE contour occur at superior and inferior slices contributing to larger MASD values.

EP-1897

Construction of a virtual T1-weighted 4D MRI: a feasibility study

C. Paganelli¹, G. Buizza¹, S. Cacciatore¹, P. Summers², M. Bellomi², G. Baroni¹, M. Riboldi¹

¹Politecnico di Milano, Dipartimento di Elettronica-Informazione e Bioingegneria, Milano, Italy

²Istituto Europeo di Oncologia, Division of Radiology, Milano, Italy

Purpose or Objective: To derive a well-contrasted T1-weighted 4D MRI. Four-dimensional MRI is typically achieved by retrospective sorting of fast, dynamically acquired T2-weighted slices, that allow better contrast and spatio-temporal trade-off than dynamic T1-weighted acquisitions. In

order to overcome the limits of T1-weighted 4D MRI, we present a preliminary study to derive a virtual T1-weighted 4D MRI, based on T2-weighted 4D images and a T1-weighted breath-hold acquisition.

Material and Methods: Free-breathing, sagittal, dynamic multi-slice T2-weighted MRI series of the liver were acquired on a 1.5T scanner (Siemens Avanto) in five healthy volunteers with a balanced steady state free precession sequence (TrueFISP, 20 slices, 20 dynamics, 1.28x1.28x5 mm resolution, 150 msec per slice). Slices were then retrospectively sorted in 4D volumes according to an image-based method. A volumetric axial T1-weighted acquisition was also performed at breath-hold during inhalation (VIBE, 60 slices, 1.25x1.25x4mm resolution). The proposed method involved applying the motion field derived from the T2-weighted 4D MRI dataset to the T1-weighted breath-hold acquisition. Specifically, a rigid registration of the breath-hold acquisition was performed onto the T2-weighted series at the corresponding inhale phase. Then, we performed a deformable registration between each respiratory phase and the inhale phase of the T2-weighted 4D scan. The derived motion fields for all respiratory phases were then used to warp the T1-weighted breath hold acquisition (i.e. deriving the virtual T1-weighted 4D MRI).

Results: The performance of the rigid registration was evaluated by computing the distance of the organ profile between the registered T1-weighted breath-hold volume at the inhale phase and the T2-weighted 4D scan at the same respiratory phase in two region of interests (liver and kidney). The distance between the two volumes was below the maximum voxel size (i.e. 5mm). The derived virtual T1-weighted 4D MRI at exhale was able to compensate for the motion obtained from the T2-weighted 4D scan (Figure, A: T1-weighted and T2-weighted volumes; B: overlap of virtual T1-weighted at exhale (red) with T2-weighted at exhale (green) and virtual T1-weighted at exhale (red) with T2-weighted at inhale (green)). Both diaphragm and vessels resulted closer to the T2-weighted 4D MRI at the exhale phase than the inhale phase, with a residual distance in the liver profile measuring 2.1 ± 1.5 mm (uncompensated motion).

Conclusion: Our results provide preliminary demonstration of a well-contrasted virtual T1-weighted 4D MRI and the subsequent description of tumor motion and composition according to T1 and T2 weightings. Future work will be focused on the validation of the method relying on an MRI phantom, which can provide a ground truth T1-weighted 4D MRI.

EP-1898

A workflow for automatic QA of contour propagation for adaptive radiotherapy

W. Beasley^{1,2}, A. McWilliam^{1,2}, N. Slevin^{1,3}, R. Mackay^{1,2}, M. Van Herk¹

¹The University of Manchester, Institute of Cancer Sciences, Manchester, United Kingdom

²The Christie NHS Foundation Trust, Christie Medical Physics and Engineering, Manchester, United Kingdom

³The Christie NHS Foundation Trust, Department of Clinical Oncology, Manchester, United Kingdom

Purpose or Objective: Automatic segmentation of daily images is an essential component of any online or offline adaptive radiotherapy (ART) workflow. Propagating contours from a planning CT (pCT) to an on-treatment image, through deformable image registration, is the common method for automatic segmentation, and there are several such algorithms available. Initial validation of these algorithms is essential before clinical use, but such testing is inevitably performed on a limited patient cohort and cannot guarantee absence of propagation failures in clinical use. We present here a workflow for automated QA of contour propagation performance on an individual patient basis. The validity of the technique is demonstrated for a cohort of head and neck cancer patients.

Material and Methods: The workflow for automated QA on an on-treatment Cone Beam CT image obtained on fraction N (CBCT_N) is described below (Fig 1). Structures are first outlined on the pCT (A). Structures are then propagated from pCT to CBCT1 (CBCT taken during fraction 1) and manually reviewed once (B). On treatment day N, structures are propagated to CBCT_N (B). For QA, the structures on CBCT_N are propagated back onto CBCT1, such that there are two sets of structures on CBCT1 (C). The correspondence between these structures indicates the quality of the propagation on day N (D). The structures are compared using the Dice similarity coefficient (DSC) and the mean distance-to-agreement (DTA). The workflow was tested on ten head and neck cancer patients. Parotids were outlined on the pCT and six weekly CBCTs (CBCT1-6). A commercial automatic segmentation algorithm (ADMIRE, Elekta) was used to propagate structures onto the weekly CBCTs from the pCT, and the true accuracy was evaluated by comparing the propagated structures with manual delineation using DSC and DTA (defined as consistency metrics). Errors were then introduced into some of the contours by deliberately combining contours and CBCTs of different fractions. It was investigated whether the consistency metrics correlated with the true accuracy, and whether they could be used to identify the introduced errors.

Results: There was a strong correlation between the consistency metrics and the true accuracy ($r = 0.85$ and $r = 0.70$ for DSC and DTA, respectively), indicating that the new method is suitable to automatically infer contour propagation accuracy. In addition, a simple threshold on the consistency metrics enabled accurate automatic identification of introduced errors (fig 1E).

Conclusion: The presented workflow enables the accuracy of a propagated contour to be tested automatically for any patient, and for errors to be identified. This method can be used as part of an online ART protocol, to automatically detect contour propagation issues that require manual review and contour editing.

⁵Institute of Cancer Research and Royal Marsden NHS Foundation Trust, Radiotherapy Department, Sutton, United Kingdom

⁶St George's Hospital NHS Trust, Orthopaedic Surgery, London, United Kingdom

⁷Siemens Healthcare, Diagnostic Imaging, Erlangen, Germany

Purpose or Objective: Many commonly used metallic orthopaedic implants cause artifacts in MR and CT images and are a serious challenge for obtaining high quality anatomical images for radiotherapy (RT) planning. We investigate the utility of SEMAC (Slice Encoding for Metal Artifact Correction [Ai et al. Invest Radiol 47: 267-76, 2012]) in patients with hip replacements and spine fixation devices, and consider the impact of metal artifacts on the registration of MR and CT images for RT planning.

Material and Methods: This study was approved by the Ethics Committee. MRI was undertaken on a 70 cm bore system (1.5T MAGNETOM Aera, Siemens) adapted with a home-built flat bed. SEMAC fast-spin-echo (FSE) pulse sequences were developed to approximate the coverage, image quality and contrast of the conventional FSE protocol (WARP works-in-progress software package, Siemens Healthcare). MR and CT images were registered using standard RT software (Pinnacle, Philips); conventional FSE and SEMAC FSE pulse sequences were compared on a purpose-built test object (spine fixation device suspended in gelatine) and on clinical examinations. Six patients with bilateral hip replacements and two patients with metallic fixation devices on the spine were scanned. For the spine fixation devices the visibility of the spinal canal was assessed. For the hip replacement patients, the internal surface of the pelvic girdle was scrutinised. Conventional and SEMAC FSE images were compared to detect relative geometrical distortion.

Results: The conventional FSE protocol shows extensive areas of signal loss and signal pile up around the spine fixation device test object. Signal loss volume was reduced from approximately 16.0 ± 0.5 cm³ to 12.9 ± 0.5 cm³ when the SEMAC FSE protocol was used. The two spine patients were shown to have metallic implants adjacent to the spine canal, which was partially affected by signal loss in three separate slices for conventional FSE protocols. Using the SEMAC FSE protocol, areas of signal loss and signal pile up are significantly reduced; the spinal canal is visible throughout the scanned volume (Figure 1). Geometrical distortion and signal loss were visible in all of 12 hip replacements scanned, but the metal artifacts do not reach the prostate, bladder and the seminal vesicles. In 8 of those hip replacements the signal loss extended to the internal surface of the acetabulum with conventional FSE protocols. Using SEMAC FSE techniques the signal loss is reduced and for only four of the hip replacements it was not possible to visualise the complete internal surface of the pelvic bones.

Figure 1

Conclusion: This work demonstrates improvement in geometric accuracy and reduction in signal loss around common metallic implants using SEMAC FSE sequences, with a positive impact on CT-MR registration. This technique will enable better contouring confidence in the location of target volumes and organs at risk which are close to metallic implants.

EP-1900

Geometric accuracy of MRI for stereotactic radiosurgery planning of Acoustic Neuromas at 3 Tesla

M.A. Schmidt¹, E. Wells², K. Davison³, A. Riddell³, L. Welsh⁴, F. Saran⁴

¹The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, CR-UK & EPSRC Cancer Imaging Centre, Sutton, United Kingdom

²Royal Marsden NHS Foundation Trust, Medical Physics, London, United Kingdom

³Royal Marsden NHS Foundation Trust, Radiology Department, London, United Kingdom

⁴Royal Marsden NHS Foundation Trust, Neuro-Oncology Unit, London, United Kingdom

Purpose or Objective: MR-CT co-registration is a mandatory requirement to accurately plan Stereotactic Radiosurgery (SRS) for Acoustic Neuromas (AN). MRI scans are subjected to susceptibility-related magnetic field inhomogeneity in the proximity to air spaces and this effect is enhanced at higher magnetic fields. We investigate the geometrical distortion of anatomical MRI head images acquired at 3 Tesla (3T), and consider protocol requirements for SRS.

Material and Methods: This work was approved by the Research Ethics Committee and undertaken at 3T (Skyra, Siemens). 3D MR images of a structured test object were obtained (500 Hz/pixel, 1 mm³ isotropic resolution) and displacements from the true position were estimated over the head volume. High resolution magnitude and phase images were acquired for field mapping on five volunteers after shimming over the entire head volume; (TE1/TE2/TR = 2.46/7.38/12 ms, 800Hz/pix, approximately 1mm³ isotropic, sagittal 3D acquisition, standard head coil). The phase images were processed off-line to produce field maps (in-house software, IDL 8.2, USA). Field maps were assessed over the whole head and over the area surrounding the ear canal for range of magnetic field values and accuracy of phase unwrapping algorithm. In addition, field mapping was performed with the same sequence on a uniform test object with the phase encoding direction both head/foot and anterior/posterior to evaluate the effect of eddy currents on field map accuracy. From the volunteer field maps, the displacement of any signal from its true origin was calculated for the anatomical MRI pulse sequences used in SRS (SRS Planning Protocol: 900Hz/pix bandwidth, 1mm³ isotropic voxel size).

Results: Geometric displacements assessed with a structured test object were found to be under 1 mm within a central volume of 20 x 20 x 20 cm³. From images of a uniform test object, the field mapping errors were estimated to be under 0.30 ppm over that volume. In all five subjects a macroscopic gradient was observed along the head/foot direction (Fig1a). The total range of magnetic field values is under 7 ppm over the head for all subjects, including the oral cavity. However, steep field gradients were detected adjacent to air spaces in the ear canal (Fig 1b). The maximum field change in this area is under 3.5 ppm for all subjects. For the SRS Planning Protocol displacements associated with susceptibility-related field inhomogeneity are therefore under 1 mm for the head and 0.5 mm around the ear canal. For MRI examinations undertaken with lower receiver bandwidth (and thus lower readout gradients) the geometric accuracy can be compromised by susceptibility effects.

Magnitude images (top) and field maps (bottom) for same location.

Conclusion: It is possible to maintain geometric accuracy at 3T by using high readout gradients. SRS planning MRIs benefit from the superior image quality achieved at 3T with careful setting of the receiver bandwidth. These findings have implications for SRS and MR-guided Radiotherapy in general.

EP-1901

Patient-specific deformable image registration quality assurance based on feature points

P.C. Park¹, E. Koay², J. Yang¹, Y. Suh¹, P. Das², C. Crane², S. Beddar¹

¹The University of Texas MD Anderson Cancer Center, Department of Radiation Physics, Houston, USA

²The University of Texas MD Anderson Cancer Center, Department of Radiation Oncology, Houston, USA

Purpose or Objective: Despite high prevalence of DIR, the lack of patient-specific quality assurance method poses challenge to truly integrate the DIR into clinical practice. We addressed this problem by developing a DIR-QA platform that quantifies geometrical error in registration based on stable feature points

Material and Methods: Our DIR-QA software uses a scale-invariant feature transform algorithm to identify feature points on diagnostic images within a specified volume (e.g. liver).

We generated feature points on reference CT images (full-exhale) from 4DCT scans of the abdomen and measured correspondence of the feature points on the target CT image (full-inhale) by having three radiation oncologists and four medical physicists to identify 100 corresponding feature points. This correspondence served as the gold standard for point-by-point assessment of DIR, and provided measurements of the inter-operator variability. The intra-operator variability was measured using 3 preselected feature points that were randomly presented to the operator 3 times during the task of finding the machine-generated feature points.

Results: Over a thousand unique feature points were identified within the liver volume, and 100 feature points were successfully tested for inter-operator variability in the QA process. The mean of standard deviation of inter-operator variability was 0.8 mm, 0.8 mm, and 1.4 mm in left-right, anterior-posterior, and superior-inferior directions respectively. Similarly, the intra-operator variability was 0.7 mm, 0.8 mm, and 1.0 mm.

Conclusion: Our DIR-QA platform demonstrated inter- and intra-operator variability on the order of one voxel (1mm by 1mm by 2.5mm). Machine-generated feature points can serve as a measure of the quality of deformable image registration.

Purpose or Objective: To investigate the accuracy and robustness, against image noise and artifacts (typical of CBCT images), of various commercial algorithms for deformable image registration (DIR), to propagate regions of interest (ROIs) in computational phantoms based on patient images. This work is part of an Italian multi-institutional study.

Material and Methods: Thirteen institutions with six available commercial solutions provided data to assess the agreement of DIR-propagated ROIs with automatically drawn ROIs considered as ground-truth for the comparison. The DIR algorithms were tested on real patient data from three different anatomical districts: head and neck, thorax and pelvis. For each dataset, two specific Deformation Vector Fields (DVF) were applied to the reference data set (CTref) using the ImSimQA software. To each one of these datasets two different level of noise and capping artifacts were applied to simulate CBCT images (fig.1, panel a -b). Every center had to perform DIR between CTref, two deformed CTs

and four CBCT for each anatomical district. The different software used in this study were: VelocityAI, Mirada, MIM, RayStation, ABAS, SmartAdapt. A four way ANOVA was performed to identify major predictors of DIR performances followed by a post hoc Scaffè test for analyzing intergroup differences; the logit transform of the Jaccard Conformity Index (JCI) was used as metric.

Fig. 1. Examples of the two simulated CBCT images (panel "a" and "b") JCI values against image quality (panel c): "0" states for "clear" CT images, and CBCT "1" and "2" for the two CBCT version of the deformed images. DIR performances of the different centers (panel "d").

Results: More than 2000 DIR-mapped ROIs were analyzed, and many results were carried out. We report only the most relevant results for clinical applications. The ANOVA test states that the differences in DIR performances are not statistically significant between the head and neck and prostate cases, while lung case shows a significant difference; they depend from the strength of the deformation; and they are very sensitive to image quality (capping artifacts and noise) (Fig1 panel c). There is statistical evidence that the center #7 performs worst then the others with significant differences respect all the other centers except the number #2 and #11 (fig1, panel d).

Conclusion: This work illustrates the effect of image noise to DIR performances in some clinical scenarios with well-known DVFs. Some clinical issues (like ART or Dose Accumulation) need accurate and robust DIR software. This work put in evidence the presence of an important inter-software variability (in terms of JCI parameter), and the need of accurate system commissioning and quality control about the robustness of some commercial system against image quality. Regarding the results in fig1, panel c, the worst scenario (CBCT2) the DIR performances appear slightly better than in CBCT1: what does it mean? Probably the results are very sensitive to image quality but there is a threshold in image degradation above which adding noise or artifacts doesn't impact on DIR algorithms. This finding suggests the opportunity to test other situations to tune at a finest level noise and artifacts.

EP-1903

Application of the Enhanced ChainMail algorithm with inter-element rotation in adaptive radiotherapy

K. Bartelheimer^{1,2}, J. Merz¹, H. Teske^{1,2}, R. Bendl^{1,2,3}, K. Giske^{1,2}

¹German Cancer Research Center DKFZ, Medical Physics in Radiation Oncology, Heidelberg, Germany

²National Center for Radiation Research in Oncology, Heidelberg Institute for Radiation Oncology HIRO, Heidelberg, Germany

³Heilbronn University, Faculty of Computer Science- Medical Informatics, Heilbronn, Germany

Purpose or Objective: In adaptive radiotherapy positioning uncertainties, due to e.g. tissue deformations in the course of fractionated therapy, can result in a dose delivery that strongly deviates from the planned dose. Especially with regard to particle therapy, it is therefore important to quantify such deviations and to evaluate the need for

replanning [Tilly 2013]. Since the current deformable image registration (DIR) methods still fall short concerning anatomically correct deformations and therefore do not reach the required accuracy expectations, we have developed a tissue-dependent transformation model. With this we aim at improving the characteristic deformation behavior of rigid and soft tissue without the need of time-consuming tissue delineation.

Material and Methods: We adapted the Enhanced ChainMail (ECM) algorithm [Schill 1998], which was originally developed for surgical simulations, to CT-images by assigning each voxel of the image elastic properties according to its HU-value. The deformation, initialized by shifts of anatomical landmarks, is then propagated by adjusting the deformation limits for every individual element. In addition to deformation limits for stretching, contraction and shear between neighboring elements (voxels), we also introduced an element orientation, which allows for an initial rotation to decay within elastic material.

Results: The ECM algorithm has successfully been applied to phantom as well as real CT-images. Due to the simple deformation rules the algorithm takes less than two minutes for a high-resolution CT-image (dimension: 512 x 512 x 170), but still approximates the shape and geometry of the deformed image in a physically realistic manner. Since tissue parameters can be assigned based on HU-values, the deformation is adapted to different material properties without the necessity of segmentation of different organs. This is in contrast to finite element methods, which represent the state of the art in deformation accuracy [Brock 2006].

Fig. 1: Rotation of a vertebra surrounded by soft tissue. The vertebra is automatically rotated rigidly, whereas the rotation decays in soft tissue as can be seen by the deformed grid cells.

Conclusion: This is one of the first applications of the ECM-based transformation model for DIR in radiotherapy. With the extension by inter-element rotation, the algorithm is now able to register deformed and locally rotated organs in CT-images without the requirement of time-consuming segmentation. On the long-term the ECM-algorithm will allow for fast and physically realistic registrations, promising to cope with the strict accuracy requirements in deformation detection for particle therapy.

³Paul Scherrer Institut PSI, Center for Proton Therapy, Villigen, Switzerland

⁴University of Milan, Department of Health Sciences, Milan, Italy

Purpose or Objective: We present a deformable image registration (DIR) framework for adaptive radiotherapy treatments of prostate cancer (PCa). The objective is the generation of virtual CTs by warping the CT planning in an adaptive IGRT framework. Previous studies on the use of CBCT as a support for dose recalculation and re-planning decisions for head and neck cancer showed promising results. For the pelvic region, similar studies are not yet available, mainly due to limitations in CBCT image quality and in the overall field of view. We developed an algorithm in order to perform DIR, making specific efforts to overcome the poor signal-to-noise ratio that limits CBCT use for treatment planning purposes.

Material and Methods: The planning CT and 5 CBCT images of 2 PCa patients treated with ultra-hypofractionated IGRT at the European Institute of Oncology (Milan, Italy) were included in this study. The CT image resolution was 1.25x1.25 mm² in-plane and 2.5 mm in the cranio-caudal direction, whereas the voxel size of CBCT reconstruction was set to 0.39x0.39x2.0 mm³. The Insight Segmentation and Registration Toolkit (ITK) was used to implement the DIR framework featuring: (1) Mattes Mutual Information metric, with the advantage of rescaling the images internally while building up the discrete density function; (2) Regular step gradient descent optimizer, which sets the parameters in the direction of the gradient to calculate the step size; (3) The B-Spline interpolator to handle the deformable transformation of the images. In order to verify the proposed approach, the obtained Virtual CTs were compared with the corresponding CBCTs. For this purpose we applied an automatic approach to the scale invariant feature (SIFT) method, which extracts and matches features from each pair of the fixed and the transformed images, thus quantifying geometrical errors in Virtual images. SIFT allows DIR methods assessment through the evaluation of landmark residual errors.

Results: For each pair of CBCT and registered CT, 31 matching points were found on average (range 12-42). The resulting residual error along each anatomical axis had the same order of magnitude of the voxel size (0.39, 0.39, 2.0 mm along x, y and z, respectively) as seen in Fig. 1.

Fig. 1: Landmark distance residual errors distribution for patient 1 (left) and patient 2 (right).

Conclusion: The implemented DIR framework provides a registration accuracy within the voxel size. Our results point out the potential of using CBCT and DIR for IGRT in PCa patients. Future studies envision the implementation of DIR for dose recalculation and margin evaluation in adaptive IGRT of PCa patients, taking into account the existing limitations in the field of view. **Acknowledgment:** This study was

partially funded by AIRC (grant N-13218) and by CAPES (grant 9374/13-2).

EP-1905

Feasibility of automatic contour propagation of spinal bone metastases for online MR-Linac treatment

G.G. Sikkes¹, L.T.C. Meijers¹, C.N. Nomden¹, A.N.T.J. Kotte¹, G.H. Bol¹, B. Van Asselen¹, E.N. De Groot¹, I.H. Kiekebosch¹, B.W. Raaymakers¹

¹UMC Utrecht, Radiation Oncology Department, Utrecht, The Netherlands

Purpose or Objective: Accurate identification of the clinical target volume and organs at risk remains one of the most observer-dependent and time-consuming processes in radiotherapy treatment planning. An online adaptive procedure at the MRI linear accelerator (MR-Linac) requires fast contouring to adapt the treatment plan to the daily anatomy. Automatic contouring software can be a helpful tool to speed up this process. The purpose of this study was to evaluate the feasibility of automatic contour propagation for online adaptive treatment of spinal bone metastases on the MR-Linac.

Material and Methods: Two healthy volunteers underwent an MR-scan twice of the lumbar spine with an interval of two months. The MR-scans were acquired on an Ingenia 1.5T scanner (Philips, Best Netherlands) according to the clinical stereotactic spine protocol. The first MR-scan series contained a transversal mDixon scan with a Field of View (FOV) length of 30 cm, which is considered the reference. The second series contained, besides the same mDixon, a transversal T1 TSE and T1 VISTA both with a FOV of 20 cm. These scans were considered as the daily MRI. Ten contours were manually delineated on the reference; the whole vertebral compartments of thoracic 12 until lumbar 5, both kidneys, aorta and myelum (figure 1a). Automatic contouring software 'Advanced Medical Image Registration Engine' (ADMIRE v1.12, Elekta, Stockholm Sweden), was used for MR-based deformable registration and contour propagation of all contours between the reference and the 3 daily MR-sequences. The processing time required by ADMIRE to create contours on each MR-sequence was scored. The contour propagation on different MR-sequences was evaluated visually. A scoring system with a scale from 1-3 was used for visual evaluation of all contours: contours clinical acceptable, according to the clinical guidelines (score 1), contours need some adjustments (score 2) and contours need major adjustments (score 3). All adjustments (score 2) were specified for location of the contour failure and the adjustment time.

Results: The mean processing time needed for automatic registration and contour propagation was 56 (range 35-89) seconds. The mean processing time decreased when a 20 cm length of FOV was used to 41 (range 35-47) seconds. In total, 98% of the automatically delineated contours were clinically acceptable (score 1) (figure 1b). In the remaining 2% small adjustments (score 2) were made at the border of a 20 cm FOV. No score 3 was observed. The additional time needed for manual adjustments was 28 seconds.

Conclusion: MR-based contour propagation using automatic contouring software is fast enough for an online treatment at the MR-Linac. A limited FOV is usable for contour propagation, which allows tailoring of the FOV to the target of each individual patient. These high numbers of clinically acceptable contours will need to be confirmed in an ongoing study, first on several volunteers and then on patients pathology.

EP-1906

Importance of true cord delineation in spine SBRT and rigid vs. deformable MRI-to-CT registration

L. Goddard¹, P. Brodin², A. Lee¹, K. Mani¹, W. Bodner¹, M. Garg¹, W.A. Tomé³

¹Montefiore Medical Center, Radiation Oncology, Bronx, USA

²Albert Einstein College of Medicine and Montefiore Medical Center, Institute for Onco-physics, Bronx, USA

³Institute for Onco-physics Albert Einstein College of Medicine and Montefiore Medical Center, Director- Division of Medical Physics, Bronx, USA

Purpose or Objective: Spine stereotactic body radiation therapy (SBRT) employs high doses per fraction. In this study, we assessed the importance of delineating the true cord (TC) for dose planning constraints, rather than using thecal sac (TS) as a surrogate. We also evaluated different MRI-to-CT registration methods for matching the MRI cord to the CT myelogram (CTM, here considered as the gold standard for TC visualization).

Material and Methods: Fifteen spine SBRT patients with both CTM and MRI scans were selected. The TS and TC were delineated according to RTOG protocols and the MRI contours were fused to the CT volume using either rigid or deformable image registration. To compare the performance of the rigid vs. deformable registration, Dice similarity coefficients and Hausdorff distances (largest distance from a point in one contour to the closest point in the other contour) were calculated.

The importance of TC delineation was evaluated by comparing the TC and TS from the CTM by determining the minimum distance between any of the circumference points on the two structures, and the number of points that were closer than 1mm (indicating that parts of the TC were close to the edge of the TS). For 3 fraction spine SBRT, we used this minimum distance to estimate the potential max point dose that could be received by the TC if this is not delineated and constrained directly in treatment planning, given a TS max dose constraint of 21.9 Gy. We also estimated the subsequent risk of radiation myelopathy based on a published dose-response model from a clinical spine SBRT series.

Results: The average Dice coefficient (\pm standard deviation) for the TS was 0.84 ± 0.06 for rigid and 0.81 ± 0.07 for deformable registration, and respectively 0.73 ± 0.10 and 0.67 ± 0.14 for the TC. For some patients rigid registration was superior and vice versa for others, no method was clearly superior.

Patient #	Minimum distance (Cord to Thecal sac) [mm]	% of Cord closer than 1mm from Thecal sac [%]	Potential max point dose to Cord (SBRT) [Gy]	Potential max point dose to Cord (EQD2) [Gy _{2/3}]	Estimated potential myelopathy risk [%]
1	1.71	0.0	18.2	36.6	4.6
2	0.02	13.3	21.9	50.7	10.0
3	2.07	0.0	17.4	33.8	4.1
4	1.01	0.4	19.7	42.1	6.0
5	0.64	5.5	20.5	45.3	7.2
6	1.65	0.0	18.3	37.0	4.7
7	0.92	1.9	19.9	42.9	6.2
8	0.49	4.2	20.8	46.5	7.7
9	0.96	0.6	19.8	42.6	6.2
10	0.59	3.8	20.6	45.7	7.3
11	0.60	5.3	20.6	45.6	7.3
12	1.53	0.0	18.5	37.9	4.9
13	0.02	16.0	21.9	50.8	10.0
14	0.67	5.6	20.4	45.0	7.1
15	0.02	8.7	21.9	50.7	10.0

For CTM-based TC and TS, results are presented in Table 1, where 11 of 15 patients had parts of the cord < 1mm of the TS circumference. Based on a 21.9 Gy max TS point dose in 3 fractions, the potential max TC point dose is 20.0 Gy \pm 1.4 Gy, assuming a dose fall-off of 10% per mm. This is equivalent to 43.6 Gy2 \pm 5.3 Gy2 in 2 Gy fractions given $\alpha/\beta = 2$. As seen in Table 1 this could lead to a potential risk of radiation myelopathy higher than 5% in 11 out of the 15 patients. Figure 1 shows the comparison of TC and TS and highlights the parts where the TC protrudes out close to the TS edge (color-coded in red).

Conclusion:

The TC position between MRI and CTM appears comparable, with rigid registration providing sufficient results, although care should be taken as large individual differences may exist. Based on our results, delineating the TC is essential in spine SBRT, and CTM provides a robust option that can be obtained and planned for treatment on the same day. If planning constraints for the TS are used as surrogate for the TC, parts of the TC that are very close to the TS edge may receive unacceptably high dose.

EP-1907

Accuracy of software-assisted contour propagation from planning CT to cone-beam CT in head and neck

C. Hvid¹, U. Elstrøm², K. Jensen¹, C. Grau¹

¹Aarhus University Hospital, Dept of Oncology, Aarhus C, Denmark

²Aarhus University Hospital, Dept of Medical Physics, Aarhus C, Denmark

Purpose or Objective: Recent years have seen a number of studies documenting accuracy and time savings for various software solutions used for automated contouring of target volumes and organs at risk (OAR) in radiotherapy, thus easing the heavy workload associated with replanning needed for implementing adaptive treatment strategies. The vast majority of studies have been performed on CT images and experience with other imaging modalities is limited. This study aims to determine the accuracy of a deformable image registration (DIR) algorithm for OARs in the neck region, when applied to cone beam CT (CBCT) images.

Material and Methods: For 30 head and neck cancer patients 14 OARs including parotid glands, swallowing structures and spinal cord were delineated. Contours were propagated by DIR to CBCTs corresponding to the first and last treatment fraction. An indirect approach propagating contours to the first and then the last CBCT was also tested. Propagated contours were compared to a gold standard (manually corrected contours) by Dice similarity coefficient (DSC) and Hausdorff distance (HD). Dose was recalculated on CBCTs and dosimetric consequences of uncertainties in DIR were reviewed. Time consumption for editing automated contours was recorded.

Results: Mean DSC values of ≥ 0.8 were considered adequate and were achieved in base of tongue (0.91), oesophagus (0.85), glottic (0.81) and supraglottic larynx (0.83), inferior pharyngeal constrictor muscle (0.84), spinal cord (0.89) and all salivary glands in the first CBCT. For the last CBCT by direct propagation, adequate DSC values were achieved for base of tongue (0.85), oesophagus (0.84), spinal cord (0.87) and all salivary glands. Using indirect propagation only base of tongue (0.80) and parotid glands (0.87) were ≥ 0.8 . Mean relative dose difference between automated and corrected contours was within $\pm 2.5\%$ of prescribed dose except for oesophagus inlet muscle (-4.5%) and oesophagus (5.0%) for the last CBCT using indirect propagation. Mean editing time was significantly faster than contouring from scratch ($p < 0.005$).

Conclusion: Compared to a golden standard of manually corrected contours the DIR algorithm was accurate for use in CBCT images of head and neck cancer patients and the minor inaccuracies had very little consequence for mean dose in most clinically relevant OAR. Accuracy was higher for the first CBCT compared to the last. The indirect method of propagating contours to the last CBCT via the first CBCT yielded worse results than direct propagation from pCT.

EP-1908

An image processing technique for simulating CT image sets for IGRT quality assurance

R. Franich¹, J.R. Supple¹, S. Siva², M.L. Taylor¹, T. Kron^{1,3}

¹RMIT University, School of Applied Science, Melbourne, Australia

²Peter MacCallum Cancer Centre, Department of Radiation Oncology, Melbourne, Australia

³Peter MacCallum Cancer Centre, Physical Sciences, Melbourne, Australia

Purpose or Objective: CT-based IGRT QA requires corresponding image sets with quantifiable geometric differences. These differences are rarely known to a reasonable degree when comparing patient images. This problem lends itself to highly controlled mathematical phantoms such as those generated with software such as XCAT [1]. However there are drawbacks when using such phantoms as the anatomic structures are typically defined by precise surfaces and are filled with homogeneous attenuation coefficients. This leads to unrealistic images, even when accurately simulating imaging systems [2,3], as features observed in patient images are not present. The aim of this work was to address some of these issues with an image processing procedure to better simulate these features. Here we present a simulated 4D planning CT image set.

Material and Methods: XCAT2 was used to generate attenuation coefficient phantoms of the thorax, incorporating breathing and cardiac motion. Five frames were generated spanning 0.2 seconds (approximate acquisition time for a single phase of a respiratory correlated 4DCT) and averaged, accounting for time averaging effects. A Gaussian filter was then applied to smooth the resulting steps in intensity at the boundaries of structures. Tissue inhomogeneities were then simulated by applying salt and pepper noise followed by another Gaussian filter to expand each individual "dot". The final step was to add random noise with a Gaussian distribution (with standard deviations for each tissue type calculated from patient images) simulating statistical uncertainty inherent to the imaging system. All processing was performed plane-by-plane in the transverse direction. Combinations of noise simulation parameters were investigated.

Results: The left pane in Figure 1 shows an example of a transverse slice through the liver of the average of the five frames of an XCAT attenuation coefficient phantom which has been converted to Hounsfield units. The right pane shows the same slice after image processing.

Figure 1: (a) Example transverse slice through the liver of an XCAT attenuation phantom, and (b) the corresponding slice from the simulated image set.

Conclusion: Image processing applied to XCAT attenuation coefficient phantoms has been used to simulate features observable in patient 4DCT image sets. The image processing technique is time and resource efficient and does not require generation of simulated projection images and 3D reconstruction.

Quantitative and qualitative assessment of thoracic CBCT image quality for multiple imaging systems

M. Williams¹, L. Davies², S. Hall², P. Wheeler¹

¹Velindre Cancer Centre, Medical Physics, Cardiff, United Kingdom

²Velindre Cancer Centre, Radiotherapy, Cardiff, United Kingdom

Purpose or Objective: A Varian TrueBeam with OBI was commissioned in 2014. During early clinical use concerns were raised regarding thoracic CBCT image quality in comparison with that observed in Elekta XVI images. Streaking artefacts caused by respiratory motion were the primary reason for the perceived poor quality. This study compared the image quality of the TrueBeam OBI with the other CBCT systems at the centre, a Varian Trilogy OBI and Elekta XVI, using quantitative and qualitative methods.

Material and Methods: A static Catphan phantom (The Phantom Laboratory) was used to assess image quality quantitatively, and to create a HU calibration curve for the XVI.

A Quasar phantom (Modus Medical Systems) with moving inserts was used to investigate the effect of motion on CBCT image quality. A systematic pattern of motion artefacts was revealed. Artefacts (created by a high density object moving along the axis perpendicular to the slice) were assessed in an axial slice. Circular profiles were used to quantify the artefacts on the three systems.

Clinical image quality was assessed through a qualitative study where two experienced observers independently scored 24 randomly selected clinical thoracic CBCT scans (8 per system). CBCT images were viewed alongside the planning CT scan, with the PTV outline being the only visible delineated structure. Scoring was based on a five point scale and reflected the image quality for matching purposes, the clinical task. Eight anatomical regions, sharpness, contrast, impact of artefacts, and the overall image quality were scored. Comments were also recorded.

Results: Quantitative assessment using the Catphan revealed no differences between systems that was deemed significant. The variation in magnitude of the streaking artefacts in the Quasar phantom was found to depend on scan time, but not on the system, as shown in Table 1.

System	Scan protocol	Scan time (s)	Max Peak - Min Trough
TrueBeam OBI	Thorax	60	215.0
TrueBeam OBI	Thorax 2min	120	130.4
TrueBeam OBI	Thorax 4min	180	97.2
Trilogy OBI	Thorax	60	223.2
XVi	Lung	90	207.3
XVi	Oesophagus	120	135.7

The Mann-Whitney test was applied to each observer's scores for each metric of the clinical image analysis. No significant ($p < 0.05$) differences between any systems for any metric for either user were detected.

Conclusion: Investigations to date indicate no significant difference between the systems assessed. Image quality must allow matching of the CBCT to CT with confidence. Staff were thus reassured that all systems were assessed as "acceptable" (mean score of 3) for most metrics. It was felt that patient size was often the cause of particularly good or poor scores; therefore improvement of patient size dependent protocols is identified as a key area of future work.

EP-1910

Evaluation of diffusion-weighted imaging properties of a RT-specific positioning solution for PET/MR

R. Winter¹, S. Leibfarth¹, H. Schmidt², N. Schwenzer², D. Zips³, D. Thorwarth¹

¹University Hospital Tübingen, Section for Biomedical Physics, Tübingen, Germany

²University Hospital Tübingen, Diagnostic and Interventional Radiology, Tübingen, Germany

³University Hospital Tübingen, Radiation Oncology, Tübingen, Germany

Purpose or Objective: PET/MRI may be highly beneficial for radiotherapy planning (RTP) in head and neck (HN) cancer in terms of increased accuracy in target volume definition (TVD) and integration of functional tissue properties. As the integration of imaging data into RTP requires co-registration, PET/MR examination in RT treatment position is favorable. Therefore, we propose a solution using a dedicated hardware setup.

Moreover, accuracy of TVD depends on the spatial accuracy of the imaging data. Since diffusion-weighted MR imaging (DWI) based on echo planar imaging (EPI) is prone to spatial inaccuracy, the aim of this study was to evaluate the quality of DWI with RT scan setup using dedicated distortion correction.

Material and Methods: The RT hardware setup consists of a flat table overlay and two coil holders for flexible body matrix coils (Siemens mMR), in addition to an in-house designed overlay add-on for RT mask fixation (cf. Fig1).

The evaluation of DWI quality using the RT setup was based on MR-only scans of n=3 healthy volunteers. Each time, two scans were performed: (I) using the RT setup with a pair of 6-channel flexible RF coils, (II) a reference scan, using a standard 16-channel HN coil. The protocol included T2w SPACE, T2w TSE, and DWI ($b = 150$ and 800 s/mm²).

DWI data was collected with reversed phase encode blips in order to use a correction method for susceptibility-induced distortions as implemented in the open source toolkit FSL.

The geometric accuracy of DWI was assessed on a ROI basis by comparing pairwise distortion corrected and uncorrected b150 images to T2w images. Four ROIs were placed in submandibular glands and cervical spine. In addition to spatial distances between ROI centers, the Dice similarity index (DSI) was calculated to assess ROI similarity.

Furthermore, ADC values derived from ROIs of the corrected b150 images were compared between RT and reference scans.

One set of DW images acquired with RT setup had to be excluded from analysis due to strong MR image artifacts.

Results: DWI suffered from geometric distortions with both scan setups but correction with FSL led to significantly reduced effects. These were of the same order as differences in ROI delineation between T2w images due to minor involuntary patient motion. The average displacements of the ROIs' centers of mass between DW and T2w images were 4.6 ± 2.3 mm / 5.9 ± 3.4 mm (RT / REF) and 1.0 ± 0.4 mm / 1.5 ± 0.9 mm for standard DWI and distortion corrected DWI, respectively (cf. Fig2 A). Fig2 B presents the average DSI per ROI pair: 0.4 ± 0.1 / 0.4 ± 0.2 (RT / REF) and 0.8 ± 0 / 0.7 ± 0.1 , accordingly.

ADC values differed by $7 \pm 14\%$ on average comparing the RT with the standard coil setup.

Conclusion: The presented PET/MR hardware solution for HN imaging enables for RT-specific patient positioning. Using dedicated correction methods, spatial distortions in DWI can be significantly reduced allowing for accurate usage of DWI in RTP. ADC values of distortion corrected maps of the RT scan setup were found to be adequate.

Fig1: RT-positioning hardware consisting of a flat table overlay and dedicated coil holders (Qfix, Avondale, PA, USA) that allow for PET/MR imaging of the HN region by using flexible RF coils. An overlay add-on enables the fixation of a RT mask on the table overlay.

Fig2: (A) Boxplot presenting the distance between ROI centers of mass of DW ($b=150$) and T2w images for both uncorrected and distortion corrected DW images. To estimate the error of misalignments due to motion of the scanned subject, also T2w images were compared. (B) DSI boxplot for the respective ROI sets. DSI ranging from 0 to 1, with DSI = 1 for congruent and DSI = 0 for disjoint ROI sets.

⁵Nuclear Science and Technology Research Institute, Nuclear Science and Technology Research, Tehran, Iran Islamic Republic of

Purpose or Objective: New treatment modalities are developed with the aim of escalating tumor absorbed dose

and simultaneously sparing the surrounding normal structures. Nevertheless, in order to decrease the growth of cancerous cells, a high dose of ionizing radiation is needed which would generally cause the side effects on healthy organs. The use of nanotechnology in cancer treatment offers some exciting possibilities including destroying cancer tumors with minimal damage to healthy tissues. Zinc Oxide nanoparticles (ZnO NPs) are wide band gap semiconductors and seem to have a good effect on increasing the absorbed dose of target volume especially when doped with a high Z element. The aim of this study is to evaluate the effect of ZnO NPs doped with Gadolinium on dose enhancement factor at different concentrations irradiating by 6MV photon beams.

Material and Methods: In order to study the influence of this NP on dose enhancement, PRESAGE dosimeter was fabricated by the reported procedure and calibrated against ionization chamber, delivering certain levels of absorbed doses. Then various concentrations of ZnO NPs and also ZnO NPs doped with 5% Gd were incorporated in to PRESAGE composition and irradiated by 6 MV photon beams. By using a UV-Vis spectrophotometer, optical density changes and also dose enhancement factor (DEF) were determined.

Results: Figure 1 shows the color changes of PRESAGE containing various concentrations of NPs.

Fig1. PRESAGE filled cuvettes with and without NPs at dose of 10Gy. 1) PRESAGE without NPs. 2) PRESAGE with 20µg/ml ZnO NPs doped with %5 Gd. 3) PRESAGE with 4000µg/ml ZnO NPs doped with %5 Gd. 4) PRESAGE with 4000µg/ml ZnO NPs. Table 1 shows DEF acquired by various concentrations of NPs. Table 1. DEF of various concentrations of NPs.

Structure	DEF
PRESAGE with 20µg ml ZnO doped with %5 Gd	1.004
PRESAGE with 4000µg ml ZnO NPs doped with %5 Gd	1.82
PRESAGE with 4000µg ml ZnO NPs	1.65

Conclusion: The results of this study revealed that ZnO NPs doped with Gd are new proposing substances for enhancing the absorbed dose and increasing the therapeutic ratio even in high energy photon beams. Various reasons may cause the DEF for 6MV photon beams such as photoelectric effect for low energy photon beams in continues X-ray spectrum, attenuated photons or pair production effect. Using these NPs not only reduces the needed MU to deliver a certain amount of absorbed dose, but also can lead to great succeeds in reducing treatment time. The concentration of NPs has a direct relation with DEF.

EP-1912

The mechanism research of radio-dynamic treatment
Q.S. Zhang¹, Q.Y. Sun¹, G.P. Xiao¹, J. Zeng¹, L. Wang¹, L.L. Chen², C.M.C. Ma²

¹Topgrade Medical - Yiren Hospital, Radio-therapy Center, Beijing, China

²Fox Chase Cancer Center, Radiation Therapy, Philadelphia, USA

Purpose or Objective: Photodynamic therapy (PDT) is an effective treatment modality for specific superficial tumors, which uses laser light to activate photosensitizers that have been selectively absorbed by tumor cells. However, the finite penetration depth of laser light has limited clinical applications of PDT. This work investigates the outcomes of using Cerenkov light emission from 45MV photon beams on a LA45 accelerator to activate photosensitizers for cancer therapy. We named this new treatment technique as Radio-dynamic therapy (RDT).

Material and Methods: Firstly, Monte Carlo simulations were utilized to simulate various energies of Cerenkov light and its spectroscopy in excited target areas and their efficiency for photosensitizer activation. Then, the inner excitation efficiency from Cerenkov light in RDT theoretically compared with the efficiency of exotic excitation from the external laser light in PDT. In addition, we also tested the difference of excitation efficiency between a patented catalyst coenzyme was added as a substrate and without the coenzyme. Next, utilize a specific probe of DMA (Singlet O₂ fluorescent probe-9, 10-dimethylantracene) to detect singlet oxygen. Finally, we also compared our results with previous experimental results that reported in previous literatures.

Results: Our Monte Carlo results showed that the Cerenkov light intensity induced at 45MV photon beams on a LA45 is 8 - 10 times of the Cerenkov light intensity induced at 6MV beam on a conventional accelerator. In RDT, excitation efficiency to photosensitizers at 400-450nm peaked wavelength (Soret Band) equals 20 times of laser light at 630nm in PDT. The homogenous inner excitation in RDT is also about 20 times (continuous spectrum excitation and inner scattering) of the exotic excitation and exponential attenuation laser light in the target of using PDT. Furthermore, the patented catalyst coenzyme enhanced the excitation efficiency of photosensitizers by 3-6 times under different conditions. In clinical situation, the new technique RDT also showed favorable outcomes for early and late stage of specific cancers and it also good at metastatic cancers treatment.

Conclusion: Our results indicated that the process of using the Cerenkov light emission from 45MV photon beams to excite photosensitizers has similar process and efficiency as conventional laser in PDT. Compared these advantages with conventional PDT, RDT may be developed into a potential treatment modality for cancer of various stages and other diseases.

³Sahlgrenska University Hospital, Department of Oncology, Göteborg, Sweden

⁴Karolinska University Hospital, Department of Medical Physics, Stockholm, Sweden

⁵Skåne University Hospital- Lund University, Department of Oncology, Lund, Sweden

⁶Skane University Hospital- Sweden, Department of Oncology and Radiation Physics, Lund, Sweden

⁷Umeå University, Department of Radiation Sciences, Umeå, Sweden

⁸Akademiska University hospital, Radiation Physics, Uppsala, Sweden

Purpose or Objective: To develop an infrastructure for structured and automated collection of interoperable radiation therapy (RT) data into a Swedish national quality register.

Material and Methods: The present study was initiated in 2012 with the participation of seven of the 15 Swedish clinics delivering radiation therapy. A national RT nomenclature and a database for structured unified storage of RT data at each clinic (Medical Information Quality Archive; MIQA) have been developed. Aggregated data from the MIQA databases are sent to a Swedish national RT register located on the same IT framework (INCA) as the national diagnosis-specific quality registries.

Results: The suggested naming convention has to date been integrated into the clinical workflow at 12 sites and MIQA is installed at six of these. Involvement of the remaining Swedish RT clinics is ongoing, and they are expected to be part of the infrastructure by 2016. RT data collection from Aria®, Mosaic®, Eclipse™, and Oncentra® is supported. Manual curation of RT-structure information is needed for approximately 10% of target volumes, but rarely for normal tissue structures, demonstrating a good compliance to the RT nomenclature. Aggregated dose/volume descriptors are calculated based on the information in MIQA and sent to INCA using a dedicated service (MIQA2INCA). Correct linkage of data for each patient to the diagnosis-specific quality registries on the INCA platform is assured by the unique Swedish personal identity number.

Conclusion: An infrastructure for structured and automated prospective collection of syntactically interoperable radiation therapy data into a national register for RT data in Sweden has been implemented. Future developments include adapting MIQA to other treatment modalities (e.g. proton therapy and brachytherapy) and finding strategies to harmonize structure delineations.

The database is built on the same platform as used by the diagnosis specific quality registers in Sweden hosting information about additional treatments, clinical and patient reported outcomes.

EP-1914

Nationwide audit of small fields output calculations in Poland

W. Bulski¹, K. Chelminski¹

¹The Maria Skłodowska-Curie Memorial Cancer Center, Medical Physics Department, Warsaw, Poland

Purpose or Objective: Modern radiotherapy routinely involves the use of small radiation fields, either for the delivery of stereotactic treatments, or as components of intensity-modulated radiation therapy (IMRT). The purpose of the small field dose rate dependence audit is to check dosimetric data in the treatment planning system (TPS), as used for patient Intensity Modulated Radiation Therapy (IMRT) treatments, related to a radiotherapy treatment unit equipped with an MLC.

Material and Methods: The methodology worked out in the framework of the IAEA Coordinated Research Project E2.40.18 was used. The audit participants were asked to calculate the number of MUs for 5 MLC-shaped field sizes (10×10 cm², 6×6 cm², 4×4 cm², 3×3 cm² and 2×2 cm²) to deliver 10 Gy on axis at 10 cm depth, 100 cm SSD in water, using their treatment planning system. These calculations had to be repeated for each photon beam energy used for IMRT treatments. Eventually, they had to calculate the dose rate (Gy/MU) for each of the five MLC defined field sizes and normalize each value to the 10×10 cm² value. These results were compared with the benchmark data from the publication: "The Radiological Physics Center's standard dataset for small field size output factors" (Followill *et al.*, Journal of Applied Clinical Medical Physics, 2012). Since this dataset did not provide data for certain beam qualities the interpolation/extrapolation was performed fitting the second degree polynomials to the RPC measured values.

Results: The audit was performed in 32 (out of 35) Polish radiotherapy centres for different linacs, TPS, MLC types and beam energies. The beam qualities ranged from 4 MV to 20 MV. In total, 81 beams were checked (Varian 41, Elekta 24, Siemens 16). When compared to the treatment planning system-calculated mean output factors, the RPC's mean measured values agreed for all field sizes and energies within 1% difference for Elekta machines. For Varian machines the difference exceeded 1% for 3×3 cm² and 2×2 cm² fields for 6 MV beams (1.6% and 2.3%). For Siemens machines the differences exceeded 1% for 2×2 cm² fields for both beam qualities 6 MV and 15 MV (1.6% and 1.7%).

Conclusion: The RPC's measured values provide a consistent dataset for small field output factors that can be used as a redundant QA check of a treatment planning system dosimetry data for small-field treatments. The RPC's measured values have a small uncertainty (standard deviation < 2%), while the values calculated from the various planning systems and their beam models had a greater uncertainty, especially for the smallest field sizes. Such QA dataset against which the institution can compare its measured or calculated values is helpful to ensure accurate IMRT dose delivery by identifying discrepancies prior to any patients being treated. Any discrepancies noted between the standard dataset and calculated values should be investigated with careful measurements and with attention to the specific beam model.

EP-1915

Development of video based quality assurance system for the medical linear accelerator

J.S. Shin¹, Y. Han², E. Shin¹, H.C. Park², D.H. Choi², D.H. Lim²
¹Samsung Medical Center, Radiation Oncology, Seoul, Korea Republic of

²Samsung Medical Center- Sungkyunkwan University School of Medicine, Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: The medical linear accelerator(LINAC) is the most widely used in the modern radiation therapy. Recently, advanced radiation therapy technique require a high precision of the LINAC. Therefore, more precise quality assurance(QA) of the LINAC is required. In this study, we developed QA system using a video image for mechanical QA of LINAC. The our QA system may measure the mechanical isocenter offset(gantry, collimator, couch) and the couch movement. The purpose of this study was: ①the Simplification of mechanical QA procedures, ②the quantification of the measurement results, ③the improvement of the measurement accuracy by eliminating the observers dependence.

Material and Methods: The our QA system developed in this study use a method of analysis based on the recorded image by camera(Figure 1). Our QA system has configured the hardware into three parts. The first, it is a indicating unit pointing to the isocenter. The second, it is a recording unit for recording an image. Finally, the third, it is an analysis unit for analyzing the image. For the accuracy evaluation of the our QA system, we performed the two experiments. The first, it is the mechanical isocenter offset check for rotation of gantry and collimator. We measured the mechanical isocenter, and evaluated for the accuracy of the measurement about intentional offset distances(±1mm, ±2mm). The second, it is couch movement check(direction of X, Y and Z). We compared the measured results by our QA system and the movement values shown in the R&V.

Figure 1. The configuration of the developed QA systems in this study.

Results: In the mechanical isocenter offset check, the mean error is about 0.09 mm for gantry rotation, the maximum error is about 0.28 mm was measured. And the mean error is about 0.11 mm for collimator rotation, the maximum error is about 0.31 mm was measured. In the couch movement check, the mean error in the X-direction is about 0.17 mm, the mean error in the Y-direction is about 0.19 mm, and the mean error in the Z-direction is about 0.24 mm.

Conclusion: In this study, we developed the QA system to improve the inefficient of the mechanical QA using conventional methods. At present, our QA system may measure the mechanical isocenter offset check and the couch movement check. The accuracy of measurement result is sufficient to measure the tolerances recommended in the guidelines.

NRF funded by the Ministry of Science, ICT & Future Planning (2012M3A9B6055201 and 2012R1A1A2042414), Samsung Medical Center grant[GFO1130081]

EP-1916

The IROC Houston QA Center's international activities outside North America

D. Followill¹, S. Kry¹, A. Molineu¹, J. Lowenstein¹, P. Alvarez¹, P. Taylor¹, H. Nguyen¹, N. Hernandez¹, T. Nguyen¹, C. Lujano¹, T. Keith¹

¹MD Anderson Cancer Center, IROC Houston QA Center, Houston, USA

Purpose or Objective: Purpose/Objective: To describe the extent of IROC Houston's, formerly the Radiological Physics Center, QA activities and audit results for radiotherapy institutions outside of North America (NA).

Material and Methods: Material/Method: The IROC Houston's QA program components were designed to audit the radiation dose calculation chain from the NIST traceable reference beam calibration, to inclusion of dosimetry parameters used to calculate tumor doses, to the delivery of the radiation dose. The QA program provided to international institutions includes: 1) remote TLD/OSLD audit of machine output, 2) credentialing for advanced technologies, and 3) review of patient treatment records. IROC Houston uses the same standards and acceptance criteria for all of its audits whether for North American or international sites.

Results: Results: IROC Houston's QA program has reached out to radiotherapy sites in 43 different countries since 2013 through their participation in clinical trials. In the past two years, 2,778 international megavoltage beam outputs were audited with OSLD/TLD. While the average IROC/Inst ratio is near unity for all sites monitored, there are international regions whose results are significantly different from the NA region as seen in Table 1. In the past 2 years, 477 and 87 IMRT H&N phantoms were irradiated at NA and international sites, respectively. Regardless of the OSLD beam audit results, the overall pass rate (87 percent) for all international sites (no region separation) is equal to the NA sites. Of the

182 international patient charts reviewed, 10.7 percent of the dose calculation points did not meet our acceptance criterion as compared to 13.6 percent for NA sites. The lower pass rate for NA sites results from a much larger brachytherapy component which has been shown to be more error prone.

Geographical Region	Beam Output Audits (IROC/INST)			
	Sample count	Mean	Std Deviation	P value ($\alpha=0.05$)
N America	29284	0.999	0.019	control
Australia/New Zealand	544	0.989	0.018	0.000
China/ Hong Kong	187	1.002	0.017	0.053*
Republic of Korea	397	0.997	0.022	0.013
Japan	84	0.991	0.017	0.000
Taiwan	95	0.993	0.029	0.002
E Europe/ Russia	104	1.005	0.038	0.002
W Europe	657	1.000	0.029	0.914*
India/ Sri Lanka	71	1.009	0.042	0.000
Middle East	268	0.995	0.022	0.000
Africa	48	1.006	0.024	0.011
Latin America	37	1.003	0.023	0.272*
SE Asia	104	0.992	0.023	0.000

* not significantly different from N America (one way ANOVA)

Table 1. OSLD/TLD output audit results by geographical region since 2013.

Conclusion: Conclusion: The IROC Houston QA Center has expanded its QA services worldwide and continues a long history of improving radiotherapy dose delivery in many countries.

EP-1917

Measurements of reactive oxygen species production induced by gold nanoparticles in radiotherapy

P. Cerello¹, L. Bocchini¹, A. Gobbato¹, A. Attili¹, C. Cutaia², V. Ferrero³, C. Pontremoli⁴, L. Radici², M. Stasi², S. Visentin⁴

¹Istituto Nazionale di Fisica Nucleare INFN, Sezione di Torino, Torino, Italy

²A.O. Ordine Mauriziano, Medical Physics, Torino, Italy

³University of Torino, Department of Physics, Torino, Italy

⁴University of Torino, Department of Molecular Biotechnology and Health Sciences, Torino, Italy

Purpose or Objective: Metallic nanoparticles have shown radiosensitizing properties in cancer radiotherapy, with both conventional and hadron beams. In particular, Gold Nano Particles (GNPs) are emerging as promising enhancers for radiotherapy. However, the exact mechanisms behind the extra damage are yet unknown, although Reactive Oxygen Species (ROS) production, known to be crucial in radiotherapy, is a strong candidate. A direct measurements of ROS production was performed in typical radiotherapy treatment conditions.

Material and Methods: A protocol for measuring the OH^{*} radical production in Phosphate-buffered saline (PBS) solution, based on the fluorimetric properties of oxygen-quenched Terephthalic acid, was designed and validated. Correction factors associated to GNP-induced adsorption, absorption and diffusion at the fluorimetric excitation and emission wavelengths were carefully evaluated. ROS production induced by 6 and 15 MV photon beams was then measured in standard PBS solution, as well as in the presence of GNPs of 5 nm and 20 nm diameters, at 5 μ mol and 10 μ mol concentrations.

Results: A relevant ROS extra production was observed for 5 nm diameter GNPs, up to about 40% at 10 μ mol and 20% at 5 μ mol as a function of the delivered dose. Measurements with 20 nm diameter GNPs are consistent with a ROS production increase of the order of 10%, albeit with a large experimental error. The ROS enhancement is consistent with the hypothesis of a linear dependence on the GNP surface to volume ratio, within the experimental errors.

Conclusion: Further measurements with 10 nm and 2 nm GNPs are planned, in order to verify the linear dependence on the inverse GNP radius with higher precision over a wider size range.

EP-1918

Radiotherapy quality assurance in the TREC trial
 N. Abbott¹, G.W. Jones¹, P. Parsons¹, D.G. Lewis¹, E. Spezi²,
 M. Kaur³, L. Magill³, R. Gray⁴, S.P. Bach⁵, D. Sebag-Montefiore⁶

¹Velindre Cancer Centre, Medical Physics, Cardiff, United Kingdom

²Cardiff University, School of Engineering, Cardiff, United Kingdom

³University of Birmingham, Birmingham Clinical Trial Unit, Birmingham, United Kingdom

⁴University of Oxford, Clinical Trial Service Unit, Oxford, United Kingdom

⁵University of Birmingham, Birmingham, United Kingdom

⁶University of Leeds, Leeds, United Kingdom

Purpose or Objective: Transanal Endoscopic Microsurgery (TEM) and Radiotherapy in Early Rectal Cancer (TREC) [1][2] is a randomised phase II feasibility study to compare radical TEM surgery versus short course pre-operative radiotherapy (25Gy in 5 fractions over 5 days) with delayed local excision for treatment of early rectal cancer.

The QA programme for TREC is co-ordinated by the UK Radiotherapy Trials Quality Assurance (RTTQA) group [3][4]. We describe the development of a standardised analysis pipeline and the results of this analysis.

Material and Methods: To ensure consistency and therefore comparability between radiotherapy centres involved in TREC, a detailed radiotherapy protocol was developed. To assess the quality of the plans, 3 (PTVmin, PTVmax, ICRUmax) quantities were measured and recorded. Further investigation was carried out if the relevant objective was not met.

TEMS patients in TREC were treated across 18 UK centres. Radiotherapy plan data was submitted for each of the 87 TEM patients in DICOM format and processed with the Computational Environment for Radiotherapy Research (CERR) software [5]. This enabled i) outlining of target and organ-at-risk structures, ii) dose distribution and dose volume histograms to be assessed (independently) and iii) data format standardisation and automated analysis.

Results:

ROI Objective	Definition
PTV min	D99% \geq 95% (23.75 Gy)
PTV max	D5% $<$ 105% (26.25 Gy)
ICRU max	D2% $<$ 110% (27.5 Gy)
	Lateral patient dose distant from PTV $<$ 80% to 85%

Table 1: Summary of quantities assessed during review of radiotherapy plans

Figure 1: Distribution of PTV coverage

Table 1 shows the ROI objectives outlined in the TREC protocol. Figure 1 shows the distribution of PTV coverage for the 87 TEM patients analysed. All plans achieved D2% $<$ 110% (Figure 1, marker A) and 95% of plans achieved D5% $<$ 105% (B). Cases of poor coverage (C) were investigated and in 4 cases it was found that the outlined PTV extended beyond the patient surface. In these cases PTV was retracted to within the patient surface and coverage was recalculated.

Conclusion: Deviation from the clinical trial protocol has the potential to confound the study question and quality assurance is therefore essential when comparing different treatments. A high level of conformance was found across the 18 treating centres, with 95% of plans achieving both the minimum and maximum PTV objectives. Our analysis of the radiotherapy plans demonstrates good understanding and adherence to the TREC protocol.

STAR-TREC is an upcoming trial that will amend and extend the TREC pilot. RTTQA findings from TREC will be used to strengthen and improve the STAR-TREC protocol, for example, use of standardised structure names and use of plan-optimisation PTVs to assess target coverage.

EP-1919

A cost-effective and fast end-to-end test for treatment accuracy evaluation

A. Wopereis¹, K. Ishakoglu¹, E. Seravalli¹, J. Wolthaus¹
¹UMC Utrecht, Radiotherapy, Utrecht, The Netherlands

Purpose or Objective: End-to-end tests are used to measure the overall accuracy of the radiation therapy chain, excluding patient specific factors. An end-to-end test is a prerequisite to the overall success of any IGRT program. In this work the performance of a cost-effective and fast end-to-end test to assess the geometrical accuracy of the radiotherapy workflow is described.

Material and Methods: The in-house developed phantom for end-to-end testing is depicted in figure 1a. It consists of two Perspex slabs in which a piece of Gafchromic EBT3 film of 4x4cm² can be placed in. Two notches tighten the film and determine the center and the orientation of the phantom/film respectively. The phantom can be positioned in such a way to have the film in the coronal and sagittal orientation. The total weight of the phantom is about 1kg. A high resolution computed tomography (CT) scan is made of the phantom and a treatment plan (figure 1b) including collimator, gantry and table rotations is computed on this CT. The treatment plan is sent to the linear accelerator. Simulating an actual patient treatment, the phantom is set up on the treatment table using the lasers. Then, cone beam CT guidance is used to adjust the phantom's position with respect to the planning CT. After applying the suggested table shift the plan is irradiated. The films are analyzed using an in-house written Excel macro. The shift required to align the film with the calculated dose plane represents the targeting error. The use of the described phantom for end-to-end testing was compared against two commercial available phantoms.

Figure 1 a. End-to-end phantom on the treatment table; b. dose distribution of the plan used for the test; c. corresponding film measurement.

Results: The phantom is light, easy to handle and to set up. Moreover, it is cheap compared to available commercial systems. The phantom allows to assess the overall geometrical accuracy of the treatment chain with sub mm

accuracy. The end-to-end test procedure requires on average 70 min preparation time, 30 min at the linear accelerator, 20 min analysis and administration. It allows end-to-end testing to be performed more frequently to assure the accuracy over time.

Conclusion: The developed end-to-end test is quick, cost-effective and easy to implement clinically. It allows to frequently highlight geometrical inaccuracies in an image-guided radiation therapy environment.

EP-1920

Harmonising the clinical trials QA group reports on phantom measurements around the globe

C. Clark¹, C. Field², D. Followill³, A. Haworth⁴, S. Ishikura⁵, J. Izweska⁶, C. Hurkmans⁷

¹NCRI Radiotherapy Trials, QA Group, London, United Kingdom

²NCIC Clinical Trials, QA group, Kingston, Canada

³Imaging and Radiation Oncology Core, QA group, Houston, USA

⁴Trans-Tasman Radiation Oncology, QA Group, Newcastle, Australia

⁵Japan Clinical Oncology, QA Group, Tokyo, Japan

⁶International Atomic Energy Agency, Dosimetry Laboratory, Vienna, Austria

⁷European Organisation on Research and Treatment of Cancer, QA Group, Brussels, Belgium

Purpose or Objective: The Global Harmonisation Group was created in 2009 to harmonise and improve the quality assurance (QA) of radiation therapy implemented worldwide in multi-institutional clinical trials. The aim is to achieve a consistent platform to provide and share QA processes in clinical trials such that the workload for both the institutions and the QA groups is reduced and streamlined. As part of this aim, the group reviewed their reporting techniques to better understand each other's approaches and agree on core information which would be included as part of future creation of a standard template. This could potentially lead to the ability to use each other's reports in lieu of unnecessary duplication

Material and Methods: A survey was created to find a list of core information which could be included in future dosimetry credentialing reports. Answers were requested to give opinion from each group as to what should be included as a minimum in these reports. Some QA groups use site visits or postal phantoms, whereas some use a virtual phantom (i.e. local QA measurement) and others use both. The questions were divided to allow responses for both types. Questions were circulated amongst the groups beforehand and all comments and contributions were incorporated.

Results: All seven current member groups replied. Results were divided into three categories, 1)information which all groups agreed should be included 2)information which the majority use and the others often use which could be discussed as being agreed on inclusion and 3)information which was not used by all groups, but which could be used by those who did (see table 1).

information which all groups agreed should be included in all reports	<ul style="list-style-type: none"> • dates of irradiation and report • name of organisation issuing report • overall pass/fail for the audit • planning system used, type of delivery (eg IMRT) • machine type used (eg Imap, Tomo) • dose calculated by institution • dose measured by auditor • information on position of measurement
information which the majority of groups agreed should be included in all reports	<ul style="list-style-type: none"> • named audit group personnel • named RT centre personnel • signature of responsible physicist • disclaimer about the scope of the audit • TPS algorithm used • energy used • phantom used (and description) • description of normalisation point
information which was not used by all groups but which could be shared by those who did	<ul style="list-style-type: none"> • whether gantry angles were collapsed or not • gamma index software used • gamma index pass criteria • gamma index threshold used • calculations grid size used • whether local or global gamma calculation • correction for daily output dose • dose measured locally by institution (on local QA phantom)

Table 1 Agreed information in clinical trial QA group reports

Conclusion: The survey showed that there is a wide variation in the information currently provided in the reports from the various QA organisations, which may hamper their mutual acceptance. Following discussion there were several pieces of information which were agreed should always be included and these constitute the beginning of an agreed list of included core information. There are several more pieces of information which the majority always include and the others use often or sometimes. These could be discussed to understand when and why they are not used and perhaps considered for inclusion. There are some others where not all members use the information because they do not use a gamma index analysis, however these could be included for those who do use the gamma index. There is also some information which sometimes included, but which is always included when needed. These cases will be discussed and decided if these should be included in specific cases, perhaps including a flowchart to aid standardisation. Some groups have already reviewed or are in the process of reviewing their reports to ensure inclusion of core information.

EP-1921

Novalis certification of stereotactic radiation therapy programs: methodology and current status

J. Robar¹, T. Gevaert², M. Todorovic³, T. Solberg⁴

¹Dalhousie University, Radiation Oncology, Halifax, Canada

²Universitair Ziekenhuis Brussel UZB- Vrije Universiteit Brussel VUB, Department of Radiotherapy, Brussels, Belgium

³University Medical Center Hamburg-Eppendorf UKE, Department of Radiotherapy and Radio-Oncology, Hamburg, Germany

⁴University of Pennsylvania, Department of Radiation Oncology, Philadelphia, USA

Purpose or Objective: To present an overview and the current status of Novalis Certification, which provides a comprehensive and independent assessment of safety and quality in stereotactic radiosurgery (SRS) and stereotactic body radiation therapy (SBRT), ensuring the highest standards and consistency of practice.

Material and Methods: The Novalis Certification program includes a review of SRS/SBRT program structure, adequacy of personnel resources and training, appropriateness and use of technology, program quality management, patient-specific quality assurance and equipment quality control. Currently ten auditors support the program, with six in North America, three in Europe and one in Asia, each bringing a minimum of a decade of experience in stereotactic practice. Centres applying for Novalis Certification complete a self-study 30 days prior to a scheduled one-day site visit by one to two reviewers. Reviewers generate a descriptive 77-point report which is reviewed and voted on by a multidisciplinary expert panel of 3 medical physicists, 2 radiation oncologists and 2 neurosurgeons. Outcomes of reviews may include mandatory

requirements and optional recommendations, with the former requiring resolution prior to award of Certification.

Results: To date, 14 institutions have received Novalis Certification, including 6 in Europe, 3 in North America, 4 in Australia and 1 in Asia. An additional 90 certification applications are pending; approximately one half and one third of these are sites in Europe and North America, respectively. Nine of the 14 reviews have resulted in mandatory requirements, however all of these were addressed within three months of the audit report. Individual reviews have produced from 2 to 9 specific recommendations ranging from programmatic to technical in nature.

Conclusion: Novalis Certification is a unique and active peer review program assessing safety and quality in SRS and SBRT, while recognizing high calibre of practice internationally. The standards-based approach is capable of highlighting outstanding requirements and providing recommendations to enhance both new and established programs.

¹Clinica IMQ Zorrotxaurre, Radiation Therapy, Bilbao, Spain

²Centro de Investigación Biomédica de La Rioja, Medical Physics, Logroño, Spain

³Complejo Hospitalario de Navarra, Medical Physics, Pamplona, Spain

Purpose or Objective: Log files contain information about Varian accelerators deliveries of dynamic treatments. This information includes actual and expected leaf positions throughout the treatment. Log files have been proposed by several authors to evaluate leaf position errors. In this study, log files of Clinac (dynalogs) and Truebeam (trajectory log files) accelerators have been analyzed to compare leaf positioning errors of dynamic treatments in different generations of clinical linear accelerators.

Material and Methods: More than 30000 log files have been analyzed, coming from four Clinac accelerators (one Trilogy, two Clinac 21EX, one Clinac 2100CD equipped with Millennium 120MLC) and one Truebeam accelerator (Truebeam STx 2.0 equipped with HD 120 MLC) of three different institutions. Analyzed Truebeam log files correspond to VMAT and dIMRT treatments whereas Clinac log files only correspond to dIMRT treatments.

Clinac accelerators control system has approximately a 50ms delay (one control cycle time). At each control cycle, MLC controller compares the planned to the actual positions. But in this comparison, the actual position is delayed 50 ms from the planned one. This effect causes that measured positions appear in dynalogs one cycle out of phase with respect to the planned positions. Therefore, error statistics present an error component proportional to leaf speed. A recent research of our group has studied this effect and, as a result, we have proposed to calculate error statistics without time delay effect to evaluate the MLC positioning deviations. In Truebeam accelerators this effect does not exist due to the proactive design of the MLC control system.

Leaf positioning RMS errors and 95th percentile errors were calculated to evaluate MLC performance with and without time delay effect. Log files were analyzed using an in-house Matlab program.

Results: In Clinac accelerators, the mean RMS error was 0.35, 0.34, 0.33 and 0.29 mm for each linac. The mean 95th percentile error was 0.62, 0.61, 0.62 and 0.58 mm. Without time delay effect, the mean RMS error was 0.038, 0.042, 0.040 and 0.026 mm for each linac. The mean 95th percentile error was 0.054, 0.057, 0.057 and 0.046 mm.

In Truebeam accelerator, the mean RMS error and the mean 95th percentile for VMAT treatments were 0.038 mm and 0.07 mm. For IMRT treatments, the mean RMS error and the mean 95th percentile were 0.027 mm and 0.052 mm.

Conclusion: Truebeam MLC positioning errors are substantially lower than those of Clinac machine models, mainly due to the proactive design of Truebeam control system. However error statistics without time delay effect in Clinac machines, have the same order of magnitude of Truebeam ones.

EP-1923

Regular assessment of isocentre and positioning accuracy in image guided stereotactic radiotherapy

C. Heinz¹, S. Neppel¹, W. Haimerl¹, C. Belka¹, M. Reiner¹

¹Ludwig-Maximilians-University, Department of Radiation Oncology, Munich, Germany

Purpose or Objective: As the number of stereotactic radiotherapy applications is increasing and image guided techniques are superseding frame based solutions in cranial as well as in extracranial stereotactic applications the need to include imaging and positioning devices in the regular quality management is obvious. A very common test to check the deviation between the radiation isocentre and the room lasers is the Winston-Lutz test. However, this test lacks significance in combination with image guided stereotactic treatment since the patient is positioned by the image guidance devices rather than by the room lasers. The purpose of this project was, to implement a practical workflow to assess the isocentre and positioning accuracy of image guided stereotactic applications.

Material and Methods: The concept of our approach is based on the Winston-Lutz test except that positioning is done automatically by the image guidance devices rather than by the room lasers. Therefore a pelvis phantom including a metal sphere is roughly positioned on the treatment couch. By the use of an image guidance device (e.g. CBCT, non-coplanar imaging) translational and rotational correction values are acquired and sent to a 6-DOF robotic couch. After the phantoms position is adjusted by movements of the robotic couch, the metal sphere inside the phantom should be positioned exactly at the radiation isocentre of the linear accelerator. The result of the image guided positioning is recorded by portal images. For this purpose a small radiation field (2x2 cm²) is applied from up to 8 different gantry angles. Afterwards the radiation field isocentre, the isocentre position of the metal sphere as well as the deviation is calculated by a software that was developed in-house.

Results: This end-to-end test provides quantitative information on the achievable positioning accuracy of an image guided stereotactic application in the clinical situation. Besides, the deviations of the radiation isocentre from the mechanical isocentres of the gantry, collimator and couch can be analyzed using the same setup. The test is not restricted to a specific image guidance modality.

Conclusion: A regular assessment of all systems included in stereotactic patient positioning is highly recommended. Due to the short execution time this test is suitable for regular assessments in the QA routine.

EP-1924

Implementation of a safety checklist to improve quality and safety of physician plan review process

L. Fong de los Santos¹, S. Park¹, K. Olivier¹

¹Mayo Clinic, Radiation Oncology, Rochester, USA

Purpose or Objective: The physician review of the treatment plan upon completion by the treatment planner is a critical clinical process, since it is during this exchange where the physician verifies and confirms the treatment intent. Several near misses in our practice raised the awareness of our group regarding the quality and safety of this process. Moreover, there was no standardization of the review process and no additional safety barrier to detect if the prescription defined by the physician matches the treatment intent. Our goal is to use a safety checklist to improve the quality and safety as

well as the communication dynamics during the plan review process.

Material and Methods: A safety checklist was developed and implemented using checklist's best practices as well as input from physicians, physicists and treatment planners (Figure. 1).

PHYSICIAN PLAN REVIEW AFTER PLANNING PROCESS

Items must be verbally verified by physician:

Verify Site and Plan name: _____

Verify total dose: _____ (cGy)

Verify daily dose: _____ (cGy)

Verify # of fractions: _____

Previous irradiation relevant for this plan? Yes No

For individual plans and sum plan (if applicable):
Reminder: Plans that are composed of multiple plans need to be reviewed individually.

Review Planning Template Report in ICIS

Verify isodose lines for target coverage and OAR

Review DVH curves for target and OAR

To be filled out by dosimetry after review process is completed:

MD: _____ Dosimetrist: _____

Were there any discrepancy detected?
 Yes No

Was the checklist process followed?
 Yes No

Revised: 08/28/2014

We used the "Static sequential with verification" method to perform the checklist. This method uses both initial configuration and mutual redundancy; the treatment planner writes down and calls the values on the checklist and the physician confirms that those values match the treatment intent. As part of a department practice quality improvement (PQI) project, we used a series of Plan, Do, Study, Act (PSDA) quality improvement cycles, and assessed the effectiveness of the safety checklist and the success of the project implementation. During each plan reviewed by the physician, we tracked two metrics: 1) Effectiveness of the checklist to catch a deviation and 2) Compliance of the physician to the checklist process. Additionally, we used a survey to assess communication dynamics between physician and planner.

Results: The safety checklist was used during a period of 6 months across our entire practice: 40 physicians and 24 planners. 1773 treatments plans were reviewed using the safety checklist process. This sample represents close to 95% of all clinical plans done in our practice during this period of time. The safety checklist helped catching 19 near-misses and also helped achieving 99% overall compliance to the plan review process. Pre- and post-implementation surveys shows improvement on communication dynamics and interaction between physician and treatment planner. Upon completion of the PQI, this safety checklist has become our standard operating procedure for the physician plan review process.

Conclusion: A safety checklist was successfully implemented as a safety barrier as part of the physician plan review process. The utilization of the safety checklist improved communication dynamics, process compliance and standardization, thus, improving the quality of the review process and the overall safety of our practice. This work presents evidence that Safety Checklists are an effective tool in error management as well as a tool to improve process compliance and team communication.

EP-1925

Online open source software to assess adverse events of patients undergoing radiochemotherapy

A.H. Thieme¹, D. Kaul¹, C. Stromberger¹, P. Ghadjar¹, V. Budach¹

¹Charité-Universitätsmedizin Berlin, Klinik für Radioonkologie und Strahlentherapie, Berlin, Germany

Purpose or Objective: Radiochemotherapy is inherently associated with adverse events and complete, accurate and examiner-independent documentation is essential for everyday clinical work as well as for clinical trials. Acute toxicity during treatment might make it necessary to adapt the current treatment, to interrupt irradiation or to skip or postpone a cycle of chemotherapy. Late effects may become symptomatic even years after treatment has been completed. The common approach to collect toxicity data is to use paper-based documentation which has to be manually fed into databases for evaluation. This method turned out to be time-consuming, error-prone and impractical. In order to address these issues, the software "Toxicity" was developed at the department of Radiation Oncology, Charité Universitätsmedizin Berlin.

Material and Methods: The software can be used simultaneously by multiple users on different computers to add, modify or view patient data, treatment information and adverse events. The software supports the National Cancer Institute Common Toxicity Criteria Adverse Event (CTCAE v4.03), Late Effects of Normal Tissue (LENT-SOMA) classification systems, laboratory values and other special data types, e.g. tone audiograms. The user can look up the definition of each item while entering values and get a graphical representation. Data for adverse events is collected every week for acute and every 3 months for late effects. Questionnaires are specific to the tumor entity, body area and treatment. The collected data is stored centrally in a MySQL database and is statistically analyzable. The software was developed in the cross-platform programming language C Sharp and the target platform is Windows, Mac OS X and Unix.

Results: To evaluate objective user acceptance, we compared the quality of adverse events documentation in our department between 01/2015 and 06/2015 (paper-based documentation) to the quality of documentation between 07/2015 and 10/2015 (software-based documentation). For patients treated until June 2015 patient files were obtained. For patients who had been treated after July 2015 data from "Toxicity" was automatically exported. In the 4 months the "Toxicity" system was used 7336 items were recorded. We can see a statistically significant increase of information recorded per patient.

Conclusion: Our first experience with the "Toxicity" software demonstrates favorable accuracy of adverse events documentation of patients undergoing radiochemotherapy and its applicability as a tool for clinical trials.

EP-1926

Hybrid of cloud computing and workstations for radiotherapy planning

L. Zou^{1,2}, Z. Xie², W. Zhang², Y. Xie¹, L. Xing³¹Shenzhen Institutes of Advanced Technology- Chinese Academy of Sciences, Institute of Biomedical and Health Engineering, Shenzhen, China²Sichuan Provincial People's Hospital, Department of Radiotherapy- Cancer Center, Chengdu, China³Stanford University, Department of Radiation Oncology, Stanford, USA

Purpose or Objective: The goal of this work is to develop a hybrid environment composed of treatment planning system(TPS) workstations and a private cloud infrastructure(Radiotherapy Planning Cloud, RTPCloud) for radiotherapy planning in routine job.

Material and Methods: The Eclipse(v11.0) workstations were distributed by Varian Medical Systems. The RTPCloud was based on OpenStack and leveraged the virtual GPU hardware (Nvidia Grid k1) and multi-core CPU server (Dell PowerEdge R910) to act as infrastructure as a service(IaaS) cloud. In the cloud, we created three kinds of virtual machine images: Dev-vmi, Workstation-vmi, DCF-vmi. All of them will be used for creating functional clusters. All of Eclipse modules were transplanted to Workstation-vmi. In addition to what Workstation-vmi has, Dev-vmi has a full script development and run environment. DCF-vmi only has calculation agent components of Eclipse's distributed calculation framework(DCF). All of the functional clusters derived from those images are scalable and their lifecycles are managed by OpenStack REST API. NoMachine is the remote desktop client to access virtual machines in the cloud.

Results: Any NoMachine-enabled computer in the hospital local area network becomes a Eclipse workstation, when an authorized user remotely accesses his virtual workstation. In this manner, we got at least three times as concurrent users as vender's distribution, and overcome office's location constraint. Script development and run cluster gives advanced users an isolated environment for automation of manual job without occupying those rare clinic workstations. The initial outcome is the ContourAutoMargin(CAM), which is developed in AutoHotkey script. It realized an automation of verbose operation of structures for planning. 10 to 20 minutes manual work per patient case will be done by clicking only one button. DCF Agent Cluster derived from DCF-vmi improves the performance of high compute-intensive calculation(e.g. Dose calculation) of planning.

Conclusion: Benefits from cloud computing maximize the utilization ratio of the expensive software features and optimize the radiotherapy planning procedure. The hybrid environment is a very powerful solution with high cost performance, and will boost the radiotherapy planning in clinic and research.

EP-1927

Practical dosimetry solutions to enhance cell biology studies

E. Claridge Mackonis¹, L. Hammond¹, N. Suchowerska¹¹Chris O'Brien Lifecare, Radiation Oncology, Camperdown-Sydney, Australia

Purpose or Objective: Our current study of the effects of combined therapies on triple negative and HER2 positive breast cancer has motivated an evaluation of the experimental design for the parallel radiation exposure of several cell samples, each representing a different therapeutic combination. To evaluate the synergistic effects between radiotherapy, chemotherapy and nanoparticles, the radiation dose must be accurately known. We focus on radiation beam energies and dose rates typically used in the clinical environment.

Material and Methods: The cells in clonogenic assays are adherent onto the base of the flasks. The dose to the base of

six different flask designs from two manufacturers, was measured using GAFCHROMICTM EBT3 film. The flasks were exposed to a 6MV photon beam from a Novalis Tx linear accelerator or to a 50kVp, 150kVp or 280kVp photon beam from a Pantak kilovoltage unit. For the megavoltage beam, the flasks were positioned on virtual water slabs and irradiated from below, with the linac gantry at 180°. For the kilovoltage beam, the flasks were positioned on the face of the cone applicator with the beam directed towards the ceiling. For all exposures, the film was placed immediately beneath the flask. A CT scan was taken of each flask design under the exposure conditions for the MV beam and a plan constructed to calculate the dose to the cell layer using the Varian Eclipse™ treatment planning system. The calculated monitor units and dose distribution were compared to the measured values.

Results: For the 6MV photon beam, the dose distributions to the cell layer in the axial and sagittal planes for three flask designs are shown in figure 1. The film measurements were consistent with the planned data. For the kV beams, where the dose distribution is sensitive to scatter conditions, it was found that the calculated dose across all wells and flasks, was inconsistent with measurement. Air channels on the perimeter of the flask, specific to the flask design, need to be filled for reproducible dosimetry. Furthermore, for the 96 well flask, the perimeter wells were found to have a different dose to interior wells.

Figure 1: Dose distribution at cell layer shown in the transverse and coronal views

Conclusion: This work indicates that when radiation is used as a therapeutic agent, insufficient attention to dosimetry can substantially compromise cell biology studies leading to false conclusions. For studies of combined therapeutic interventions, we provide practical solutions to the parallel radiation exposure of numerous cell samples, such that additional variables are minimised. Our findings are applicable to any cell study where radiation exposure is involved.

EP-1928

The Nano-X image-guided adaptive gantry-less linac: imaging and dosimetry under phantom rotation

I. Feain¹, C.C. Shieh¹, P. White², R. O'Brien¹, W. Counter¹, M. Jackson³, S. Downes², P. Keall¹¹University of Sydney, School of Medicine, Camperdown, Australia²Prince of Wales Hospital, Nelune Comprehensive Cancer Centre, Sydney, Australia³School of Medicine, University of NSW, Sydney, Australia

Purpose or Objective: Innovative solutions for delivering high-quality, safe, affordable and appropriate treatment are needed to redress a staggering global underutilisation of radiotherapy. Nano-X will be a novel image-guided adaptive radiotherapy machine, quite different to conventional systems. Its key-differentiating feature is a rotating patient couch and a gantry-less linac. We present the first experimental results demonstrating imaging and dosimetric

equivalence between conventional and Nano-X treatment geometries.

Material and Methods: Experiments were performed during Sep-Oct 2015 on an Elekta Agility with MLC, XVI imaging system and a custom-built phantom rotation platform.

Dosimetry:

An IBA MatriXX Evolution 2D ionization chamber array was mounted to the phantom rotator. A Head and Neck IMRT treatment plan, with seven equiangular beams, was used. Two treatments were delivered: the first under conventional conditions with the MatriXX stationary and the linac delivering treatment at planned gantry angles. The second, mimicking a Nano-X treatment, involved rotating the MatriXX to the planned angle, with the linac gantry static and vertical.

Imaging:

A CATphan CT imaging QA phantom was mounted to the phantom rotator. Two sets of measurements were acquired: the first involved a cone-beam CT acquired under conventional conditions with the CATPhan stationary and the linac rotating. The second, mimicking a Nano-X treatment, involved rotating the CATphan, with the linac gantry static and vertical. Both datasets were reconstructed using Feldkamp-Davis-Kress (FDK) back projection.

Results:

Dosimetry: 2D distributions were compared between rotated-gantry (conventional geometry) and rotated-MatriXX (Nano-X geometry) beams using 3%/3 gamma analysis. Measurements were repeated on consecutive days and the departmental tolerance of 90% was defined as our pass rate. Results for ranged from 92.7% to 98.2% on Day 1 and 95.8% to 98.9% on Day 2, for the same angled beams.

Imaging: Figure 1 shows the CATphan images acquired in Nano-X (Fig 1a) and conventional linac (Fig 1b) geometries. The mean absolute pixel value of the difference image (histogram shown in Fig 1c) was 28 Hounsfield units (HU), consistent with Poisson noise. The line profile (Fig 1b) shows the two imaging geometries have high agreement in both pixel intensities and spatial information.

Conclusion: We have demonstrated imaging and dosimetric equivalence between the Nano-X gantry-less linac and conventional linac geometries.

EP-1929

Characterisation of a gridded electron gun in magnetic fields: implications for MRI-Linac therapy

B. Whelan¹, D. Constantin², R. Fahrig², P. Keall¹, L. Holloway³, B. Oborn⁴

¹University of Sydney, Radiation Physics Lab, Marrickville, Australia

²Stanford University, Radiological Sciences Lab, Palo Alto, USA

³Liverpool Hospital & Ingham Institute, Cancer Therapy, Liverpool, Australia

⁴Illawarra Cancer Care Centre, Medical Physics, Illawarra, Australia

Purpose or Objective: With recent advances towards MRI-Linac radiotherapy, characterisation of electromagnetic interactions of the two devices is an important research area. One of the most sensitive components is the linac electron gun. Previous work focused on characterising non-gridded guns in parallel and perpendicular magnetic fields. However, the majority of Linac vendors use gridded guns, which have important applications in beam gating and variable energy/dose rate linacs. No studies on medical gridded guns could be found in the literature, so the purpose of this work is twofold: To develop and present a realistic model of a gridded gun, and to test the sensitivity of this gun in parallel and perpendicular magnetic fields with particular focus on different gun operating modes.

Material and Methods: The geometry of the gridded gun used on Varian high energy linacs was measured with 3D laser scanning quoted as accurate to 0.1 mm. Based on the scan, a detailed CAD model was developed. From this, key geometry was extracted and a Finite Element Model (FEM) was developed using commercial software (Opera/SCALA). The high voltage and grid voltage (HV: cathode to anode, grid: cathode to grid) were read directly from a Varian Trilogy in service mode. Two operating modes were simulated: 6MV photon beam: HV=16kV, grid=100V, & 18MV photon beam: HV=7kV, Grid = 30 V. The model was solved for each mode in parallel fields between 0 and 200 G, and perpendicular fields between 0 and 50 G.

(A) The cathode(left) and anode section of the electron gun. (B) The CAD model which was developed. (C) A solved FEM simulation

Results: Zero field emission current was 487 and 106mA for 6MV and 18MV respectively. Injection current is around 20% less, as the grid blocks some of the beam. In parallel fields 50% current loss occurred at 112 (6MV) and 77G (18MV), whilst in perpendicular fields these values were 19 and 13G. The behavior of the two different operating modes in the presence of magnetic fields is similar, but 18MV is around 50% more sensitive to magnetic fields than 6MV. This dependence on the HV of the electron gun has not previously been shown. In all cases, a grid potential of -100V resulted in zero injection current, showing the suitability of this gun for beam gating.

Conclusion: A FEM model of a gridded electron gun has been developed based on a commercial gun. The sensitivity to both parallel and perpendicular magnetic fields has been quantified. Different operating modes show substantially different sensitivity. This original result has implications for electron gun, waveguide, and shielding design in MRI-Linacs.

EP-1930

Cancer patient experience of slow, single arc rotation to simplify radiation therapy delivery

B. Whelan¹, M. Welgampola², L. McGarvie², K. Makhija¹, I. Feain¹, L. Holloway³, M. Berry³, M. Barton³, R. Turner⁴, M. Jackson⁴, P. Keall¹

¹University of Sydney, Radiation Physics Lab, Marrickville, Australia

²Royal Prince Alfred Hospital, Institute of Clinical Neurosciences, Sydney, Australia

³Liverpool Hospital and Ingham Institute, Cancer Therapy Centre, Liverpool, Australia

⁴University of New South Wales, Faculty of Medicine, Sydney, Australia

Purpose or Objective: Conventionally in radiotherapy, a large beam forming apparatus is rotated around a stationary patient in order to achieve multiple beam angles. However, for a number of emerging and existing treatment modalities such as proton therapy, heavy ion therapy, MRI guided therapy, and synchrotron based therapies, such an approach results in prohibitively expensive and complex treatment systems. At the same time, much of the world has no access whatsoever to even conventional radiation therapy treatments. Replacing the gantry rotation with patient rotation could lead to much simpler and more cost effective treatment units. However, it is often assumed that patient acceptance would be a major barrier to widespread use of such a system. The purpose of this work was to test this assumption by investigating patient tolerance to slow single arc rotation.

Material and Methods: The Epley Omniax (Figure 1) is a clinically approved medical device conventionally used in balance disorder therapy, and can rotate 360 degrees around each axis. We used this device to test patient tolerance to slow, single arc rotation. Each patient underwent slow, single arc rotation in two orientations; sitting and lying. Patients were rotated a full 360 degrees in increments of 45 degrees. The rotation was paused for 30 seconds at each 45 degree increment to simulate beam delivery; in total this simulates the delivery of 8 beams. Patients were rotated in both an upright (sitting) and lying position in the same session. Response was monitored via validated psychometric questionnaires for claustrophobia, anxiety, and motion sickness. Thus far, 10 of a planned 15 current or former cancer patients have been recruited.

Figure 1: The Epley Omniax was used to test patient response to both upright and lying rotation to enable simplified and cost effective treatment machines

Results: Patient tolerance has been high - 9 out of 10 have completed the study without incident, and in general patient feedback has been positive. One patient was unable to complete the lying rotation, but was still able to complete the sitting rotation without issue. No detectable differences in anxiety or motion sickness have been observed from either sitting or lying rotation. A summary of the patient cohort and results thus far is outlined in table 1. Accrual for this study is ongoing.

Table 1: Outline of patient cohort and key results. Where 'percent' is used, 100 is the maximum possible score and 0 the minimum. The last two entries show the difference in patient's anxiety and motion sickness scores before and after the study.

	Mean	Std. Dev.	Range
Age (years)	62	13	39-78
Weight (kgs)	77	12	65-100
Time since last RT treatment (months)	34	60	0-168
Claustrophobia Score (percent)	24	18	1-50
Difference in Anxiety Score (Before/after - percent)	2.2	32	0-78
Difference in motion sickness score (Before/after - percent)	-6	10	-25-0

Conclusion: Patient rotation could enable much simpler treatment for both conventional and advanced treatments - however, it is often assumed that patient tolerance to rotation would be very low. The results generated thus far show that there is at least a cohort of patients who would find slow rotation an acceptable therapeutic intervention.

Abstract withdrawn

EP-1932

Quality assurance in implementing a national dose escalation trial in NSCLC - report from NARLAL2

T.B. Nielsen¹, C. Brink¹, D.S. Moeller², L. Hoffmann², C.M. Lutz², A.L. Appelt³, M.D. Lund³, M.S. Nielsen⁴, W. Ottosson⁵, A.A. Khalil², M.M. Knap², O. Hansen⁶, T. Schytte⁶

¹Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

²Aarhus University Hospital, Department of Oncology and Medical Physics, Aarhus, Denmark

³Vejle Hospital, Department of Oncology, Vejle, Denmark

⁴Aalborg University Hospital, Department of Oncology, Aalborg, Denmark

⁵Herlev Hospital, Radiotherapy Research Unit and Department of Oncology, Herlev, Denmark

⁶Odense University Hospital, Department of Oncology, Odense, Denmark

Purpose or Objective: Potential severe or lethal toxicity in regards to dose escalation of locally-advanced NSCLC patients calls for caution. A national quality assurance program was conducted over a period of three years in Denmark in order to prepare for the heterogeneous FDG-guided dose escalation phase 3 trial: NARLAL2.

Material and Methods: A national work group consisting of clinical oncologists and medical physicists was established. Different workshops were conducted in order to standardise 1) delineation of organs at risk (OAR) and target, 2) PET determination, 3) treatment planning, and 4) IGRT and adaptive strategy. In the standard arm, the planning target volume (PTV) is prescribed a homogeneous mean dose of 66 Gy / 33 fractions (fr). For the experimental arm, the mean dose is heterogeneously escalated up to 95 Gy / 33 fr for the most FDG-PET active part of the primary tumour and 74 Gy / 33fr for malignant lymph nodes 4 cc. The escalation is always limited in favour of OAR constraints. Dose constraints were added to reduce the risk of severe complications. Besides the traditional spinal cord, heart and oesophagus delineations, thorax wall, aorta, bronchi, trachea, and connective tissue (here defined as any remaining voxels in mediastinum not included in other OARs or GTV) were delineated. A maximum dose of D1cc < 74 Gy for these OARs was chosen as safe dose constraints (D1cc < 70 Gy for oesophagus). An online catalogue with examples of such delineations was created for oncologists. The randomisation is performed when both the standard and escalated plans are clinically accepted. The two treatment plans, delineations and images are prospectively exported to a national database, which requires a consistent naming convention for delineations within each centre. Endpoint of trial is local control and the standard procedure for suspicion of tumour recurrence is biopsy. For cases where biopsy is not applicable, a central committee has been established to evaluate each case. Blood samples are obtained during the treatment course for future examination.

Results: Dose-volume-histogram data for the standard (solid) and escalated (dashed) arms for one patient is presented (Figure 1). Centres entering the NARLAL2 trial must successfully pass a workshop evaluation on delineation, PET determination, treatment planning, and IGRT strategy. Additionally, all participating centres should expect to enrol ≥ 5 patients/year, use 4D-CT and PET, inverse treatment planning, daily online match on soft tissue, and have an adaptive treatment strategy. Planning and treatment of the initial two patients within each centre are thoroughly investigated by a small QA work group consisting of 2 clinical oncologists and 4 physicists. Furthermore, every six month each centre will be visited by an external oncologist in order to ensure that guidelines are still followed throughout the duration of the trial.

Conclusion: The NARLAL2 trial started patient accrual in January 2015 based on this extensive QA work.

EP-1933

End-to-end dosimetric audit - comparison of TLD and lithium formate EPR dosimetry

E. Adolfsson¹, P. Wesolowska², J. Izewska², E. Lund³, M. Olsson⁴, A. Carlsson Tedgren³

¹Department of Radiation Physics, Radiation Physics-Department of Medical and Health Sciences- Linköping University, Linköping, Sweden

²International Atomic Energy Agency, Vienna, Austria

³Radiation Physics, Department of Medical and Health Sciences- Linköping University, Linköping, Sweden

⁴Department of Medical Physics, Karolinska University Hospital, Stockholm, Sweden

Purpose or Objective: The purpose of the study was to compare a lithium formate dosimetry system with a lithium fluoride TL dosimetry system as used in a solid phantom developed for remote end-to-end audits of advanced radiotherapy treatments, such as IMRT and VMAT. This type of inter-dosimeter comparison is of benefit for better understanding of advantages and limitations in the use of these dosimeters in remote audit programs for radiotherapy.

Material and Methods: A phantom was designed by a multinational coordinated research group (Coordinated Research Project E24018) with the intention to be used for remote end-to-end audits of advanced radiotherapy treatment (IMRT and VMAT). The phantom is made of polystyrene and includes solid water volumes representing a target region (PTV) and an organ at risk (OAR) with two measurement points in each. For an audit, the phantom is to be loaded with either TLD or EPR dosimeters and sent to external clinics to be treated using their local procedure for IMRT or VMAT. Dimensions of the active volume of the dosimeters used were: 20 mm length and 3 mm diameter for TLD, 5 mm height and 4.5 mm diameter for the EPR dosimeter. In addition, gafchromic film is used in the audit but this is not a subject of the current study. Irradiations were performed using VMAT technique and the doses determined by the TLDs and EPR dosimeters were compared with the TPS calculated doses.

Results: The absorbed dose determined by the EPR and TL dosimeters agreed within 2% with the TPS calculated doses in the PTV. In the OAR the discrepancy was larger; the dose determined by the EPR system was 3% lower compared to the TPS dose while the dose determined by the TLD was 5% higher than the TPS dose. The dose difference in the OAR was expected to be larger due to the steep dose gradients in this region over the dosimeter volume and the phantom positioning uncertainties involved.

Conclusion: Both dosimetry systems agree with the TPS calculated doses within 2% in the PTV and 5% in the OAR. This study shows that both dosimetry systems give results acceptable for this application and can be used for remote dosimetry audits of IMRT or VMAT. The EPR dosimeters have higher resolution due to their smaller size. This is an advantage of the EPRs over the TLDs since it is possible to resolve dose gradients to a higher extent.

EP-1934

Event reporting and learning in radiotherapy: evaluation over 4 years

M. Molla Armada¹, D. Garcia¹, M. Beltran², R. Verges¹, C. Pacheco¹, R. Angles³, X. Fa², J. Saez², J.M. Lobo¹, C. Montiel¹, M.T. Bordas¹, J. Giralt¹

¹Hospital Universitario Vall d'Hebron, Radiation Oncology, Barcelona, Spain

²Hospital Universitario Vall d'Hebron, Medical Physics, Barcelona, Spain

³Hospital Universitario Vall d'Hebron, Quality and Safety, Barcelona, Spain

Purpose or Objective: Radiotherapy is one of the primary treatment options in cancer management. Radiotherapy is recognised as one of the safest areas of modern medicine; however, when errors occur, the consequences for the patient can be significant.

The rapid development of new technology has significantly changed the way in which radiotherapy is planned and delivered. Quality and safety programs in radiotherapy have been recommended by international bodies, such as ESTRO and AAPM.

The purpose of this work is twofold: to report on the long-term use of an event reporting and learning system in an RT department to record and classify events, and to compare a restricted access system to an open-access system

Material and Methods: A voluntary web-based safety information database for RT was designed for reporting individual events in RT and was clinically implemented in 2011. An event was defined as any occurrence that could have, or had, resulted in a deviation in the intended delivery of cancer care. The aim of the reporting system was to encourage process improvement in patient care and safety.

During the RT process, when something goes wrong and results in event, it is initially recorded and reported within the RT Department. Initially only the management group registered events. From June 2012 all team at RT Department (radiation oncologist, radiation therapists, medical physicists, nurses, technicians, dosimetrists, medical secretary) can directly register events. All events were analyzed inside a management group who selected and proposed actions to be taken.

Results: We analyzed events from 2011 to 2014 for 6108 patients who have undergone radiation treatment at our hospital. Over this period of time 298 events were reported. After the event reporting system became open access (June 2012), the registered number of events increased significantly: from 22 in 2011 to 44 in 2012, 120 in 2013 and 112 in 2014. The spectrum of reported deviations extend from minor workflow issues to errors in treatment delivery. The distribution of the professional who registered the event was:

	2011	2012	2013	2014
Radiation Oncologist	59%	18%	6%	4%
Medical Physicists	4.5%	7%	2%	2%
Dosimetrists	-	5%	-	7%
Radiation Therapists	32%	70%	91%	87%
Nurses	4.5%	-	-	-
Medical Secretary	-	-	-	1%
N° of Events	22	44	120	112

Dose errors were detected in 29 patients. In 9 patients affected more than 1 session (5 patients in 2011, 3 patients in 2012, 1 patient in 2013 and no patients in 2014).

The number of corrective actions has increased because of the increasing number of registered events: 2 in 2011, 4 in 2012, 7 in 2013 and 9 in 2014.

Conclusion: Event reporting and learning systems in radiotherapy can provide valuable data for patient safety treatment. An open access event reporting improved identification of areas which needed process and safety improvements. The major indication of the effectiveness is the reduction in dose errors.

EP-1935

Impact of standardised codes of practice and related audit on radiotherapy dosimetry over 20 years

R. Thomas¹, M. Bolt², G. Bass¹, A. Nisbet², C. Clark¹

¹National Physical Laboratory, Radiation Dosimetry, Teddington, United Kingdom

²Royal Surrey County Hospital, Medical Physics Department, Guildford, United Kingdom

Purpose or Objective: Reference dosimetry audit measurements in UK radiotherapy centres have been carried out over the last 20 years. This work examines the variation in local dosimetry calibration in a network of radiotherapy centres, draws conclusions on the implementation of an absorbed dose based protocol for MV photon beams and includes the measured effect of a change in the nationally recommended electron code of practice (CoP) from an air kerma based to an absorbed dose based protocol.

Material and Methods: Data from reference dosimetry audits conducted in radiotherapy centres by the National Measurement Institute (NMI) for photon, electron and kV x-rays have been collated, recording the NMI:Centre ratio for reference output measurements, beam quality, and field chamber comparison. A total of 81 MV photon, 98 electron and 30 kV photon beams were measured during 68 visits between June 1994 and February 2015. The change in the national standard deviation has been assessed over time, and differences due to the change between the two electron CoPs during this period has been quantified. The improvement in consistency for MV beams since the adoption of a CoP traceable to a primary standard of absorbed dose is assessed.

Results: The mean NMI:Centre difference for radiation output calibration was less than 0.25% for all modalities. A total of 7 measurements were reported to be outside the +/- 2% tolerance. There was a statistically significant difference (p=0.008) in the mean result for the respective air kerma based electron CoP, +0.75% (n=14) with the absorbed dose based protocol giving +0.20% (n=84).

The variation in MV results has decreased steadily over time (see Figure 1). The standard deviation has halved when comparing the first and last 20 results, being 0.85% (2000) and 0.35% (2015). This trend has also been noted within regional audit groups. A linear correlation was observed between the 'NMI:Centre output ratio' and the 'NMI:Centre field chamber comparison ratio'.

There has been no significant difference observed between regional audit and national audit for the measured NMI:Centre ratios, but some regions have had many more NMI audits than others, some having no beams audited for a particular modality, and others having more than 20.

Conclusion: Data has been collated from 20 years of NMI reference dosimetry audits, and key trends and changes have been noted. The introduction of the 2003 absorbed dose-based electron CoP has decreased the difference between NMI and centre measured outputs. The use of a single absorbed dose based MV CoP, introduced just prior to the start of these audits, has contributed to the improved consistency demonstrated in these results. This not only shows the impact of a rigorous traceability chain developed by close collaboration between NMI and end users but also demonstrates that the NMI audit programme is likely to be a contributing factor to this improvement in consistency in dosimetry nationally.

Figure 1: MV photon audit results plotted in order of completion (solid blue line). The running standard deviation of the previous 20 results shows a steady reduction in variation (dashed orange line).

EP-1936

Dose plan quality in the DBCG HYPO trial: an evaluation based on all treatment plans in the study

M. Thomsen¹, M. Berg², S. Zimmermann³, C. Lutz¹, S. Makocki⁴, I. Jensen⁵, M. Hjelstuen⁶, S. Pensold⁷, M.B. Jensen⁸, B. Offersen⁹

¹Aarhus University Hospital, Medical Physics, Aarhus, Denmark

²Lillebaelt Hospital, Medical Physics, Vejle, Denmark

³Odense University Hospital, Oncology, Odense, Denmark

⁴Technical University Dresden, Radiotherapy and Oncology University Clinic Carl Gustav Carus, Dresden, Germany

⁵Aalborg University Hospital, Medical Physics, Aalborg, Denmark

⁶Stavanger University Hospital, Oncology, Stavanger, Norway

⁷Academic Teaching Hospital Dresden-Friedrichstadt, Praxis for Radiotherapy, Dresden, Germany

⁸Rigshospitalet Copenhagen University Hospital, Danish Breast Cancer Cooperative Group, Copenhagen, Denmark

⁹Aarhus University Hospital, Oncology, Aarhus, Denmark

Purpose or Objective: In the DBCG HYPO trial a number of radiation therapy (RT) parameters were prospectively determined for each individual treatment plan. These parameters were reported to a database and analyzed to determine the plan quality in the trial.

Material and Methods: Patients (pts) for breast-only RT after surgery for early node-negative breast cancer from 8 RT centre in 3 countries were included in the trial between May 2009 and March 2014. They were randomized to either 40 Gy/15 fx or 50 Gy/25 fx. A number of plan-quality parameters such as doses to CTV-breast and organs at risk were determined for each plan. The use of respiratory gating during treatment was reported. Definitions on compliance to protocol guidelines, as well as minor and major deviations (Table 1) were agreed upon before trial start. After closing the trial, the QA parameters were analyzed and scored.

QA parameter	Full compliance	Minor deviation	Major deviation
CTV _{breast} with D _z ≥ 95% (#pts; percentage)	V _{095%} ≥ 95% (1492; 80.8%)	92% < V _{095%} < 95% (232; 12.6%)	V _{095%} ≤ 92% (121; 6.6%)
CTV _{breast} with 105% < D _z ≤ 107% (# 40Gy/15fx pts; percentage)	V _{CTV} ≤ 2% (842; 92.3%)	2% < V _{CTV} < 5% (36; 3.9%)	V _{CTV} ≥ 5% (32; 3.5%)
CTV _{breast} with 107% < D _z ≤ 110% (# 40Gy/15fx pts; percentage) (# 50Gy/25fx pts; percentage)	V _{CTV} ≤ 2cm ³ (903; 99.0%) (901; 96.4%)	2 cm ³ < V _{CTV} < 5cm ³ (6; 0.7%) (16; 1.7%)	V _{CTV} ≥ 5cm ³ (3; 0.3%) (17; 1.8%)
Dose max. in CTV _{breast} (# pts; percentage)	D _{max} ≤ 110% (1835; 99.4%)	110% < D _{max} < 112% (10; 0.5%)	D _{max} ≥ 112% (2, 0.1%)
Heart volume (left-sided pts) with dose >35 Gy (# 40Gy/15 fx pts; %) >40 Gy (# 50Gy/25 fx pts; %)	V _{35Gy/V40Gy} ≤ 5% (465; 99.8%) (476; 99.8%)	5% < V _{35Gy/V40Gy} < 7.5% (0; 0.0%) (0; 0.0%)	V _{35Gy/V40Gy} ≥ 7.5% (1; 0.2%) (0; 0.0%)
Heart volume (left-sided pts) with dose >17 Gy (# 40Gy/15fx; %) >20 Gy (# 50Gy/25 fx; %)	V _{17Gy/V20Gy} ≤ 10% (465; 99.8%) (476; 99.8%)	10% < V _{17Gy/V20Gy} < 15% (1; 0.2%) (0; 0.0%)	V _{17Gy/V20Gy} ≥ 15% (0; 0.0%) (0; 0.0%)
Ipsilateral lung volume with dose >17 Gy (# 40Gy/15fx pts; %) >20 Gy (# 50Gy/25 fx pts; %)	V _{17Gy/V20Gy} ≤ 25% (908; 99.6%) (926; 99.0%)	25% < V _{17Gy/V20Gy} < 30% (3; 0.3%) (6; 0.6%)	V _{17Gy/V20Gy} ≥ 30% (0; 0.0%) (2; 0.2%)

Results: A total of 1847 pts (904 right-sided and 943 left-sided) were treated with either 40 Gy/15 fx (912 pts) or 50 Gy/25 fx (935 pts). 388 of the left-sided pts were treated with gated RT, and 440 without. No information about gating was available for the remaining 115 pts. D_{max}(CTV) was less than 110% of the prescription dose in 99.4% of the plans. More than 2 cm³ of the CTV received 107-110% of the dose in 1% of the hypo-fractionated plans. For the normo-fractionated plans, this deviation was observed in 3.5% of the plans. For 92.3% of the hypo-fractionated plans, less than 2% of the CTV was covered with doses above 105%, whereas 3.9% and 3.5% of the plans had minor and major deviations, respectively. For 80.8% of the pts, the part of the CTV covered with at least 95% of the prescription dose was in compliance with the guidelines. Minor and major deviations were observed for 12.6% and 6.6% of the pts, respectively. By taking laterality into consideration, 90.8% of the right-sided pts were in compliance with the guidelines compared to only 71.2% of the left-sided pts. For the left-sided pts with available information about gating, it was found that 87.4% and 59.3% of the pts treated with and without gated RT, respectively, were in compliance, thus indicating that shielding of the heart resulted in CTV under-dosage. This was supported by compliance to the protocol heart dose guidelines for 941 left-sided pts. Only one hypo-fractionated pt showed a major deviation in V_{35Gy} and a minor deviation in V_{17Gy} (data missing for one pt). The lung dose satisfied the protocol guidelines for 99.4% of the pts.

Conclusion: A high degree of compliance with protocol guidelines was found for the DBCG HYPO trial. Only a few pts received CTV doses above 107% of the prescription dose. The CTV volume covered with less than 95% dose deviated from protocol guidelines for about 40% of the left-sided pts treated without gated RT. With gated RT this number decreased to about 12%, almost equal to that of right-sided pts. This indicates that gated RT for left-sided pts reduces the necessity of CTV dose compromise due to heart shielding.

EP-1937

UK stereotactic ablative radiotherapy trials normal tissue dose constraints tolerance consensus

G.G. Hanna¹, R. Patel², K. Aitken³, S. Jain¹, K. Franks⁴, N. Van As³, A. Tree³, S. Harrow⁵, D.J. Eaton², F. McDonald³, M. Ahmed³, F. Saran³, G. Webster⁶, V. Khoo³, D. Landau³, M.A. Hawkins⁷

¹Centre for Cancer Research and Cell Biology, Department of Radiation Oncology, Belfast, United Kingdom

²National Radiotherapy Trials Quality Assurance Group, Radiotherapy Physics, London, United Kingdom

³Royal Marsden NHS Foundation Trust, Department of Clinical Oncology, London, United Kingdom

⁴St. James's Institute of Oncology- Leeds Cancer Centre., Department of Clinical Oncology, Leeds, United Kingdom

⁵Beatson West of Scotland Cancer Centre, Department of Clinical Oncology, Glasgow, United Kingdom

⁶Guy's and St. Thomas' NHS Foundation Trust, Department of Medical Physics, London, United Kingdom

⁷CRUK/MRC Oxford Institute of Radiation Oncology-University of Oxford, New Technical Radiotherapy/Advanced Radiation Oncology Group, Oxford, United Kingdom

Purpose or Objective: Stereotactic ablative radiotherapy (SABR) is routinely used for the treatment of early stage lung cancer and is increasingly used to treat other primary tumour sites. There are currently 6 UK studies (of which 3 are randomised) investigating the utility of SABR in the treatment of oligometastatic disease (breast, lung, prostate), lung, prostate, pancreas and hepatobiliary primary malignancies. These are supported by CRUK and currently open or in set-up to begin recruitment in 2016. In addition, a NHS Commissioning Through Evaluation (CTE) programme was commenced in 2015 to evaluate SABR in situations where clinical trials are not available. In an attempt to standardise protocols and the associated radiotherapy planning we sought to generate consensus normal tissue dose constraints tolerances across these UK studies.

Material and Methods: Members of the various SABR studies' trial management groups, facilitated by the UK Radiotherapy Trials Quality Assurance Group (RTTQA), met to generate a unified table of normal tissue dose constraints. As a starting point, the UK SABR Consortium Guidelines, the AAPM TG-101 report and other seminal publications were used to define a baseline reference. These initial constraints values were revised, where appropriate, by taking into consideration any updated or more robust data that better informed a given dose constraint value in the opinion of the panel.

Results: Following an iterative process, agreement was reached on all dose constraints covering the central nervous system, thorax, abdomen, pelvis, skin and bone. It was agreed to use a point maximum dose volume of 0.5cc for the purposes of describing the maximum dose for all organs except the spinal cord. For the spinal cord 0.1cc is to be used. The group reached the consensus that for the purpose of these trials single fraction should not be used outside CNS. We recommended the use of 3, 5 and 8 fractions regimens. These dose constraints will be used for the forthcoming SABR studies and for the implementation of the CTE SABR programme for oligometastatic disease and HCC. The group will review the evidence annually to update the guidelines.

Conclusion: A UK national agreement on SABR dose constraints has been successfully achieved. It is hoped that this unified approach will facilitate standardised implementation of SABR across the UK and will permit meaningful toxicity comparisons between SABR studies and further refinement of the constraints. Any further trials developed in the UK will adopt the consensus.

EP-1938

Evaluation of pre-treatment verification for hyperthermia treatment plans

D. Marder¹, N. Brändli², G. VanStam¹, G. Lutters¹

¹Kantonsspital Aarau, Radio-Onkologie-Zentrum KSA-KSB, Aarau, Switzerland

²Kantonsspital Aarau, Medizintechnik Service Center, Aarau, Switzerland

Purpose or Objective: The BSD-2000/3D system (BSD Medical Cooperation, Salt Lake City, USA) is used to treat deep seated tumors with hyperthermia (to temperatures of 41-43°C) in combination with radiotherapy. Treatment planning for this system is done with the software SigmaHyperplan (Dr. Sennewald Medizintechnik GmbH, Munich, Germany). In this study a method and first results for pre-treatment verification of clinical patient treatment plans using a 3D SAR scanning phantom developed at the Kantonsspital Aarau are presented.

Material and Methods: Treatment plans for individual patients were generated with SigmaHyperplan and applied to a saline phantom model. The result is a set of data for the

specific absorption rate (SAR) distribution. The measurement data is obtained with a saline phantom consisting of a tube with elliptical cross section. The tube is inserted into the BSD-2000/3D Sigma60 and a probe inside is moved in 3 spatial dimensions. The probe, a commercial isotropic SAR sensor, is scanned in 2 cm steps for a distance of 20 cm in horizontal and vertical directions and relative SAR values are recorded. Planned and measured data in the central plane of the applicator are compared for the location of the focus to assess the transferability of treatment plans to the treatment machine.

Results: The location of the focus maximum can be determined from the graphs and compared to the location of the maximum from the simulation. For the investigated plans an agreement between simulation and measurement was found with deviations of the focal area between 0 and 2 cm.

Conclusion: Good agreement for the investigated patient plans was found between simulation and measurement. With an automated measurement system higher resolutions and 2D or 3D comparisons would be possible. The method described allows the transferability of a patient treatment plan to the treatment machine to be verified, however it does not check the correct heating of the patient.

EP-1939

An optimal grid block design for spatially fractionated radiation therapy

S. Gholami¹, H.A. Nedaie², F. Longo³, M.R. Ay¹, A. S.Meigooni⁴
¹Tehran University of Medical Sciences, Medical Physics, Tehran, Iran Islamic Republic of
²Tehran University of Medical Sciences, Radiation Oncology Department- Cancer institute, Tehran, Iran Islamic Republic of
³University of Trieste and INFN Trieste, Department of Physics, Trieste, Italy
⁴Comprehensive Cancer Centers of Nevada, Radiation Oncology, Las Vegas- Nevada, USA

Purpose or Objective: In the present work, we performed model calculations of cell survival to design a Grid block with optimal therapeutic ratio. The optimal Grid block was manufactured and dosimetric characteristics of the Grid were introduced.

Material and Methods: The Geant4 toolkit (Version 9.6.p02) was used to simulate the head of the Varian2100C linear accelerator for a 6 MV photon beam based on the vendor detailed information. The dose distributions of a Grid block with hole-diameters of 0.5 cm, 0.75 cm, 1.0 cm, 1.25 cm, and 1.5 cm with constant center-to-center spacing of 1.8 cm, were calculated separately using the Monte Carlo simulation technique. A dose profile from Monte Carlo simulation, across a single hole of the Grid, has been utilized to calculate therapeutic ratio for different Grid blocks separately. The Hug-Kellerer (H-K) radiobiological model (Equation 1) which is more appropriate at doses higher than 12 Gy was utilized to calculate survival fraction of cell lines under a single hole of the Grid. The values of α/β ratios for tumor cells and normal cells were considered to be 10 Gy and 2.5 Gy, respectively.
 Equation 1:

$$\left\{ \begin{aligned} SF &= \sum V_i e^{(-k_1 D_i + k_2 (1 - \exp(-k_3 D_i)))} \\ \alpha &= k_1 - k_2 \cdot k_3 \quad \beta = k_2 \cdot k_3^2 \cdot (\ln(2) - 1/2) / (\ln(2))^2 \end{aligned} \right.$$

Where the V_i represents the relative cell numbers receiving the same dose ranging from D_i and D_{i+1} . The therapeutic advantage of the Grid irradiation was considered in terms of the normal tissue cell survival ratio (Grid/open field ratio) for the same tumor cell survival.

A Grid with optimal TR value was selected to manufacture. Dosimetric characteristics of the Grid were measured using ionization chamber in water phantom and Gafchromic film dosimeter in Solid Water™ phantom materials.

Results: The results from the Monte Carlo studies showed that increasing the spacing between the Grid holes with a given hole diameter keep the TR value of the Grid block nearly unchanged ($\pm 4\%$). Moreover, a Grid block with a hole-diameter of 1.0 cm and 1.25 cm may lead to about 19% higher clinical responses relative to the Grids with hole-diameters smaller than 1.0 cm or larger than 1.25 cm. Dosimetric measurements of the optimal Grid were in good agreement ($\pm 5\%$) using different dosimetry techniques. Table 1 shows comparison between different dosimetric features of the manufactured Grid and the dosimetric features that were predicted by Monte Carlo simulation.

Table 1

	Geant4-Monte Carlo simulation	Ionization chamber dosimetry	Film dosimetry	Max difference
Output factor	0.87	0.85	0.83	-4.6%
Valley-to-Peak ratio	21%	20.4 %	19.8 %	-5.7%
TR (15 Gy to dmax)	1.95	2.00	1.87	-4.1 %
EUD (15 Gy to dmax)	6.14	6.3	6.0	-2.6%

Conclusion: Designed Grid block leads to have an optimal therapeutic ratio for spatially fractionated radiation therapy.

EP-1940

Individual cases review in KROG-0806 study Phase III randomized trial for breast cancer patients

Y.B. Kim¹, J. Yoon¹, H. Han¹, H. Cha¹, J. Choi¹, M. Lee¹, C.O. Suh¹
¹Yonsei University, Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: Korea Radiation Oncology Group (KROG)-0806 study has been the phase III randomized trial to investigate the efficacy of internal mammary node(IMN) irradiation in breast cancer patients. Previous dummy run study evaluated protocol compliance of participating institutions. The purpose of this study is to assess the protocol compliance based on individual cases review (ICR).

Material and Methods: For ICR, patients were divided into eight subgroups based on IMN irradiation (non-irradiation (N) vs. Irradiation (R), tumor laterality (left-side (L) vs. right-side (R)) and type of surgery (breast-conserving surgery (B) vs. mastectomy (M)), respectively: NLB, NRB, NLM, NRM, RLB, RRB, RLM and RRM. We extracted 15% among patients enrolled in each subgroup using the SURVEYSELECT procedure with the simple random sample. Then, all participating institutions were requested to upload the following information: planning computed tomography (CT) images, structure sets, and radiation doses as well as the documents containing treatment techniques and all beams' eye views with questionnaire. We performed the comparison of the dose distribution among 8 subgroups. Major and minor violations are determined according to IMN treatment and dose delivered to IMN.

Results: The information of 102 patients was collected. Institutions used the different treatment techniques such as standard tangents (42.2%), partial wide tangent (23.5%), 30/70 photon/electron mix (17.6%), IMN-electron only (4.9%), and reverse hockey stick (11.8%). The IMN average doses in subgroups were as follows: Arm1[NLB(14.9Gy±10.7Gy), NRB(18.5Gy±13.0Gy), NLM(27.7Gy±16.4Gy), NRM(27.5Gy±15.1Gy)] and Arm2[RLB(48.3Gy±4.5Gy), RRB(50.9Gy±4.1Gy), RLM(49.3Gy±4.1Gy), RRM(51.3Gy±3.2Gy)]. The dose differences between Arm1 and Arm2 groups were statistically significant. Dose variations in IMN were much greater in Arm1 than Arm2. In Arm1 group,

major violation was found as 7 out of 51 cases. By contrast, there were no major violation and one minor violation in Arm2.

Conclusion: This ICR study with KROG-0806 showed the satisfactory protocol compliance in IMN irradiation and the major violation from several cases of IMN non-irradiation group. Quality assurance process using ICR is needed to evaluate and improve the quality of clinical trial in the field of radiation oncology.

EP-1941

Assessment of variation in planning benchmark case for ABC-07 trial of liver SBRT

D. Eaton¹, M. Robinson², R. Patel¹, M. Hawkins²

¹National Radiotherapy Trials QA group RTTQA, Mount Vernon Hospital, Northwood, United Kingdom

²CRUK/MRC Oxford Institute for Radiation Oncology, University of Oxford, Oxford, United Kingdom

Purpose or Objective

Quality assurance of radiotherapy clinical trials ensures protocol compliance and robustness of outcome data. Benchmark cases are used to assess consistency of outlining and planning by different centres, and provide feedback before a centre starts recruitment. For a complex technique such as liver SBRT, it also facilitates sharing of best practice and supports centres with less experience.

Material and Methods: The planning benchmark case was a large (6cm) cholangiocarcinoma with target and organ-at-risk contours already outlined. This case was sent to all centres interested in joining the ABC-07 multicentre phase II trial (Addition of stereotactic body radiotherapy to systemic chemotherapy in locally advanced biliary tract cancers; CRUK A18752; Sponsor University College London). Centres were asked to produce a plan with prescription dose of 50Gy in 5 fractions, having PTV coverage D95% > 95% (optimal, 90% mandatory) and mean liver dose < 13Gy. If this was not possible, the prescription dose was reduced to 45Gy in 5 fractions and mean liver dose limit increased to 15Gy.

Results: 14 cases were submitted, covering a range of planning systems and treatment platforms. 5/10 VMAT, 1/1 IMRT and 0/3 Cyberknife plans were able to cover 95% of the PTV with $\geq 90\%$ of 50Gy, whilst maintaining the mean liver dose below 13Gy, as shown in the table.

Modality (prescription dose)	Number of centres	D95% (% of 50 Gy)	Max (D0.1cc) (% of PD)	Mean liver dose
VMAT (50Gy)	5	44.9 - 48.2 Gy (90 - 96%)	103 - 117%	12.7 - 12.9 Gy
IMRT (50Gy)	1	48.2 Gy (96%)	106%	12.8 Gy
VMAT (45Gy)	5	42.6 - 45.0 Gy	103 - 126%	12.9 - 14.9 Gy
Cyberknife (45Gy)	3	42.7 - 44.9 Gy	114 - 129%	14.6 - 15.0 Gy

Conclusion: Achieving the planning objectives for this case was challenging and only 5/12 centres submitted an optimal plan. The other 7 centres are repeating the exercise after feedback on what was achievable with similar equipment. Achieving the optimal plan for this case involved reduced conformity of medium doses in order to spare other parts of the liver, and thereby reducing the total mean liver dose. This approach is contrary to typical Cyberknife planning, so it may not be the optimum treatment platform for these cases, although it is possible that differences between technologies and centres were accentuated by this large and challenging case, and may be reduced for smaller lesions. All patients treated within this trial will be prospectively reviewed, which will further inform this question.

EP-1942

Initial experience with the Elekta Leksell Gamma Knife Icon system: commissioning, QA and workflow

S.W. Blake¹, L. Winch¹, H. Appleby¹

¹Bristol Haematology & Oncology Centre, Radiotherapy Physics, Bristol, United Kingdom

Purpose or Objective: Icon enables fractionated stereotactic radiotherapy using a frameless patient positioning system (PPS). For submillimetre precision, the planning MRI scans are registered to a CBCT scan set acquired using Icon. Patient position is then adjusted using the Icon scan. Movement is monitored using an Intra Fraction Motion Management (IFMM) system.

This presentation reports on the commissioning of Icon plus baseline and ongoing QA measurements.

This is the first use of Icon in the UK.

Material and Methods: CTDI was assessed for both the low and high dose settings and image quality checked using CatPhan. kVp measurements were made and dose to the imager assessed to confirm the Elekta presets and baseline values.

A new Focus Precision Check tool containing diodes and ball bearings was used to ensure the accuracy of the PPS relative to the radiation focus and CBCT image positions.

The IFMM system was verified using a moveable phantom. A reflector was attached to the phantom and moved independently in the x,y and z directions in 0.5 mm steps.

If the IFMM monitored position is outside tolerance for more than 2 seconds, the treatment pauses and the couch is retracted. Treatment resumes following a re-scan, with the plan recalculated on the new CBCT reference. To test this system an output measurement was interrupted using a remotely moved reflector.

An end-to-end check on a fractionated pituitary plan was made. The plan was recalculated on a CBCT scan of the spherical solid water phantom containing inserts for chamber and film. A film was positioned at the central axis with 2 additional films displaced 5 & 10 mm above and below.

Results: The Icon system performed within specification. Patient doses were acceptable and image quality resulted in good registration with the MRI scan sets.

Ongoing QA results were highly reproducible demonstrating positioning ability of the system to within 0.5 mm. The IFMM readout agreed with the independent system to within 0.04mm and repositioning following interruption had no significant effect on the diode doserate. The end to end film dosimetry agreed to within $\pm 3\%$ of the planned dose.

The Icon system has allowed us to use new clinical pathways with little loss in positional accuracy including:

- Single fraction patients who would not tolerate a fixed frame.
- Fixed frame patients who have their CT scan with Icon.
- Fractionated patients.

Conclusion: Icon is an efficient system which has enabled the delivery of fractionated stereotactic radiotherapy plus improvements for single fraction patients. Accuracy is comparable with fixed frame treatments.

EP-1943

Implications of gold nanoparticles used for dose enhancement in proton radiotherapy

R. Ahmad¹, G. Royle², K. Ricketts¹

¹UCL, Division of Surgery and Interventional Science, London, United Kingdom

²UCL, Medical Physics and Bioengineering, London, United Kingdom

Purpose or Objective: Heavy metal nanoparticles (NPs) have been widely investigated within x-ray radiotherapy as radiosensitisers, where gold NPs (GNPs) have been deemed to be effective at enhancing the dose to the tumour. Few studies have been carried out for protons, where an extensive investigation of the enhancing factors needs to be carried out to determine the implications that introducing GNPs can have on known dose profiles. In the present work, we demonstrate our model which uses Geant4 to carry out Monte Carlo simulations of NP concentrations being irradiated by a proton beam. These simulations offer an indication as to

the macroscale effects that occur with varying concentrations of GNPs.

Material and Methods: Within our model, concentrations of NPs were simulated by calculating the inter-particle spacing of various concentrations, where this spacing was used to model a controllable concentration, whilst minimizing computational time. Investigations were carried out on the effect of concentration over a range of clinically relevant concentrations in line with previous studies (0.01 mg/ml, 0.1 mg/ml and 6.5 mg/ml) [1], [2], [3] at two incident proton energies (60 MeV and 226 MeV). Various results were recorded, such as the energy deposited across the phantom, types of secondary particles produced, the particle track lengths and energy deposited by secondary particles.

Results: The results highlight a measurable shift of the distal edge (Fig.1) in the order of millimeters due to the introduction of gold, which can be seen predominantly at high concentrations (6.5 mg/ml) achievable through direct injection. This shift was deemed to be energy dependent, where at lower energies (60 MeV) it was on the order of microns. As demonstrated by other groups, the enhancement was attributed to an increase in the number of secondary electrons, which was proportional to GNP concentration as expected. Our model demonstrates that the magnitude of the effects observed can be related to the concentration.

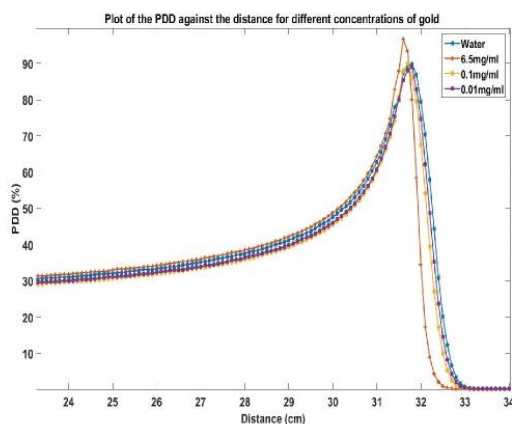

Figure 1: A zoomed in section of the peak, where the plot shows readings at every millimeter using a 226 MeV proton beam, highlighting the differences due to gold concentrations.

Conclusion: This study has demonstrated bulk effects of multiple NPs on dosimetry, extending previous work on single NP models by other groups [4]. Results show that injectable concentrations can affect the range of protons, proving to be more significant at higher energies. Future work will investigate the effects that GNPs can have on treatment plans, assessing any changes that need to be made.

EP-1944

Lessons from the findings of 31 QUATRO audits in Europe
J. Iżewska¹, M. Coffey², P. Scalliet³, E. Zubizarreta⁴, T. Santos¹, I. Vouldis¹, P. Dunscombe⁵

¹IAEA - International Atomic Energy Agency, Dosimetry and Medical Radiation Physics, Wien, Austria

²School of Medicine- Trinity Centre for Health Sciences- St. James' Hospital, Discipline of Radiation Therapy, Dublin, Ireland Republic of

³Cliniques Universitaires Saint Luc- Université Catholique, Radiotherapy, Brussels, Belgium

⁴IAEA - International Atomic Energy Agency, Radiotherapy and Radiobiology, Wien, Austria

⁵University of Calgary, Medical Physics, Calgary, Canada

Purpose or Objective: A methodology has been developed for comprehensive clinical quality audits of radiation therapy programmes called Quality Assurance Team for Radiation Oncology (QUATRO). The purpose of these audits, which are distinct from accreditation, is to assist the audited centres in identifying and implementing opportunities for improving the quality of services offered to patients. Aggregating the findings from audits carried out over 10 years in Europe sheds light on the degree to which various dimensions of quality are satisfied and suggests interventions which are likely to be effective in improving quality in the audited centres.

Material and Methods: Thirty one centres in Europe have been audited with this methodology since 2005. The voluntary, confidential audits are conducted by multidisciplinary teams and take 5 days on-site to complete. Reports to the audited centres include both commendations, i.e. positive findings, and recommendations for quality improvement. A subset of the audited centres were designated Centres of Competence (CCs) through QUATRO. A coding key has been developed to aggregate and analyse the extensive data generated from this audit series.

Results: 600 commendations and 759 recommendations for improvement were noted in the 31 audit reports. Positive attributes of the audited centres included patient centredness, communication, facilities (with the marked exception of the availability of treatment units) and quality control. Areas for improvement included staffing and equipment levels, professional development, documentation and quality management. Overall, 10 centres were designated as CCs. Of the 600 commendations, 220 were given to 10 CCs and 380 to other centres. Of the 759 recommendations, CCs received 82 while the other centres 677. The levels of physicists and RTT staffing generally met international recommendations in CCs whereas in the other centres major staff shortages were recorded. RTT understaffing was most acute but other staff groups also needed strengthening. Education, training and professional development of all staff, but especially RTTs, was seen as a weakness in many centres.

Conclusion: QUATRO audits provided the radiotherapy centres with an opportunity for an in depth analysis of their practices. The detailed reports constitute a template for practice improvement and highlight the need to develop strategies on the future development of radiotherapy services. The analysis of the 31 audits has also identified the need for common action items for enhancing the quality of radiotherapy in the audited centres. In particular, there is a need for extending the reach of educational programmes and for expanding the educational offerings to include quality management and associated topics.

EP-1945

Plan submission comparison for commissioning of spinal and nodal SABR for oligometastases

R. Patel¹, T. Williams², J. Payne², D.J. Eaton¹, Y. Tsang³, P. Ostler³, N. Van As⁴

¹Mount Vernon Cancer Centre, Radiotherapy RTTQA, Northwood, United Kingdom

²Mount Vernon Cancer Centre, Radiotherapy Physics, Northwood, United Kingdom

³Mount Vernon Cancer Centre, Radiotherapy, Northwood, United Kingdom

⁴Royal Marsden Hospital, Radiotherapy, London, United Kingdom

Purpose or Objective: NHS England selected 17 centres of varying experience to take part in the Commissioning through Evaluation (CtE) programme in order to improve access to SABR for patients with Oligometastatic disease. A QA group was formed from members of a national trials QA group and a national SABR development group to ensure patient safety and treatment quality across participating centres, which utilise a variety of different equipment and techniques.

Material and Methods: A bespoke QA programme was created for the 5 anatomical treatment sites which included spine and nodal metastasis. Prior to treatment centres were required to complete a QA process which included planning benchmark cases. Participating centres were provided with a pre-outlined planning CT. They created PTV expansions using local protocols. The centres were then required to create a plan based on a 30 Gy in 3 fraction prescription for the nodal case and a 24 Gy in 3 fractions prescription for the spine case. Both cases required a D95% of the prescription dose for the PTV coverage whilst ensuring OAR tolerances were met. All planning benchmarks were submitted and centrally analysed using VODCA 5.4 plan review software. The coverage of the PTV and CTV with the prescription dose, doses to OARs and measures of conformity were calculated. The values for the different submissions were compared to ensure plans were of suitable quality and comparable across different treatment platforms.

Results: A total of 10 and 11 plans were submitted for the spine and nodal benchmark cases respectively, including all 4 NHS cyberknife centres and the remainder using VMAT. 27% of the nodal and 18% of the spine plans had unacceptable deviations and the centres were given feedback and asked to resubmit their QA. The PTV coverage and max dose were compared for the different treatment techniques with the standard deviation. These can be seen in the table below.

Spine						
Modality	Mean PTV Coverage (%)	S.D.	Mean Max Point Dose (Gy)	S.D.		
All	92.2	3.4	31.3	2.7		
Cyberknife	94.3	2.9	32.2	2.8		
VMAT	90.9	3.4	31.4	2.3		
Nodes						
Modality	PTV 1		PTV 2		Mean Max Point Dose (Gy)	S.D.
	Mean PTV Coverage (%)	S.D.	Mean PTV Coverage (%)	S.D.		
All	90.5	5.8	96.5	3.1	38.0	3.3
Cyberknife	95.0	2.5	97.4	2.2	41.7	3.5
VMAT	87.4	5.3	95.9	3.6	36.0	1.1

A 2 tail Mann-Whitney test was performed on the PTV coverage data for both plans. This indicated that there was a significant difference between cyberknife and VMAT plans ($p=0.02$).

Conclusion: Cyberknife plans on average achieved superior PTV coverage when compared to VMAT plans. This was more evident for the spine PTV and nodal PTV 1, with both volumes being close to OARs, than for the nodal PTV 2 where OARs did not restrict the dose. The VMAT plans involved larger PTV and PRV expansions which would partly explain the difficulty in achieving the required PTV coverage. However, several of the VMAT plans had similar PTV coverage to the cyberknife plans, hence the greater variation in PTV coverage of the VMAT plans may reflect possible inexperience in SABR planning for some centres. Following resubmissions, all centres participating in the CtE programme have been able to produce acceptable benchmark plans regardless of treatment platform.

EP-1946

Small animal irradiation by using Tomotherapy: dosimetric and preclinical results

A. Miranti¹, A. D'Ambrosio², G. Cattari³, E. Garibaldi³, S. Bresciani¹, P. Gabriele³, M. Stasi¹

¹Candiolo Cancer Institute - FPO-IRCCS, Medical Physics, Candiolo TO, Italy

²Candiolo Cancer Institute - FPO-IRCCS, Laboratory of Cancer Stem Cell Research and Department of Oncology- University of Torino, Candiolo TO, Italy

³Candiolo Cancer Institute - FPO-IRCCS, Radiotherapy, Candiolo TO, Italy

Purpose or Objective: Preclinical studies are critical steps in the medical research process, normally requiring dedicated instruments. For those centers in which both preclinical research and clinical practices are conducted, the dosimetric

feasibility of small animal irradiation with clinical devices may be of economical and scientific interest. The aim of the present work is to investigate the feasibility of small animal irradiation with Tomotherapy Hi-Art by analyzing dosimetric results, toxicity and tumour response in xenograft models.

Material and Methods: Xenograft models were established by injecting human derived glioblastoma multiforme stem-like cells in immunocompromised NOD-SCID mice both subcutaneously (10 groups) and intracranially (7 groups). Mice of each group were anesthetized and placed in a plexiglas cage pie to perform CT scans for treatment planning purposes. Target volumes and organs at risk (OARs) were outlined on CT scans: for subcutaneous xenografts, target volumes were delineated on the right flank and contoured OARs were lung and gastro-intestinal tract. For orthotopic models, a ring-shaped target structure was delineated on mice's head; contoured OAR was lung. Three fractionation schedules were tested: 4Gy/1 fraction, 4 Gy/2 fractions and 6 Gy/3 fractions. TomoDirect IMRT technique was applied, with gantry fixed at 0° and 180. 5 subcutaneous and 1 orthotopic groups of xenografts were irradiated by covering the target volume with a 0.6 cm bolus layer in order to reduce the impact of the build-up effect. Irradiations originally performed without bolus were simulated with a 0.6 cm virtual bolus in order to compare dosimetric results. Before irradiation, a MVCT image has been acquired to correct irradiation setup. Mice were observed daily and sacrificed when they showed signs of suffering or when tumour volume reached the established endpoint. Different radiobiological outcomes were evaluated, regarding both radiotoxicity (survival experiments) and tumour response (assessed by caliper or bioluminescence imaging), comparing irradiated mice as respect to their controls.

Results: Dosimetric results showed that the presence of the bolus layer significantly impact the maximum dose received by both target volumes and OARs (t-test, $p<0.05$). Survival analysis showed that irradiation with a dose of 6 Gy in 3 fractions in the presence of a bolus layer prolong mice survival (Log-rank test, $p<0.02$), showing to be the safest irradiation protocol. Tumour volume response and mice survival were significantly different in irradiated xenografts as compared to their controls (t-test, $p<0.03$; Log-rank, $p<0.05$) demonstrating also the radiobiological potential of Tomotherapy in inducing tumour growth stabilization.

Conclusion: Tomotherapy systems may be a useful mean for small animal irradiation.

EP-1947

Evaluation of dosimetric properties of 3D printed flat bolus for external beam radiotherapy

R. Ricotti¹, A. Vavassori¹, R. Spoto^{1,2}, D. Ciardo¹, F. Pansini³, A. Bazani³, S. Noris^{1,4}, F. Cattani³, R. Orecchia^{1,2}, B.A. Jereczek-Fossa^{1,2}

¹European Institute of Oncology, Department of Radiation Oncology, Milan, Italy

²University of Milan, Department of Oncology and Hemato-oncology, Milan, Italy

³European Institute of Oncology, Unit of Medical Physics, Milan, Italy

⁴University of Milan, Tecniche di Radiologia Medica per Immagini e Radioterapia, Milan, Italy

Purpose or Objective: To evaluate the dosimetric properties of acrylonitrile butadiene styrene (ABS) and polylactide (PLA) plastics, and their suitability for bolus printing applied in high-energy radiotherapy to overcome the skin-sparing effect.

Material and Methods: The measurements were performed with Vero® System (Brainlab AG, Feldkirchen, Germany) delivering 200 monitor units (dose rate of 500 MU/min) with a 6 MV photon beam, 5x5 cm open field with 90-degree gantry angle at 100 cm surface to surface distance (SSD) on a water-equivalent RW3 slab phantom in three configurations: without bolus, with a commercial bolus and with the eight 3D

printed boluses. Gafchromic EBT3 film (International Specialty Products, Wayne, NJ) placed between phantom slabs provided dose profile measurements. An Epson Expression Scanner 10000 XL (Epson, Long Beach, CA) was used to determine the optical density of the films and film analysis were performed using Film QA Pro software (Ashland Inc., Bridgewater, NJ).

Results: The mean value of Hounsfield unit (HU) of the 3D printed boluses was provided analyzing their Computed Tomography (CT) scans. Negative HU were due to the air gap inside the infill pattern. The mean HU increased with the percentage infill, resulting in higher bolus density (Tab. 1). This reduced the distance from the surface of the phantom where the maximum dose occurs (d_{max}) as shown in Fig.1. Build-up peaks shifted towards the phantom surface when any bolus was used. ABS and PLA boluses with an infill percentage of 40% had comparable performance to the commercial bolus.

	%infill	HU	density [g/cm ³]	d_{max} [mm]
no Bolus	--	--	--	16.9
commercial Bolus	--	0	1.0	7.4
ABS	10	-694.0	0.28	10.6
	20	-593.8	0.39	9.4
	40	-393.5	0.60	5.6
	60	-166.5	0.87	0
PLA	10	-629.7	0.35	14.5
	20	-492.5	0.49	11.6
	40	-245.2	0.78	9.2
	60	-51.2	0.97	0

Conclusion: The dosimetric analysis of the 3D printed flat boluses showed that they can decrease the skin-sparing as a commercially available bolus. The performed analysis accurately describes the physical behavior of these plastic materials, in order to represent them in treatment planning system for precise treatment delivery. Moreover, patient-specific boluses could be outlined from patient CT images and 3D printed, thus shaping the actual anatomy of the patient. This procedure may represent a viable alternative to commercially available conventional boluses, potentially improving the fitting between bolus and skin surfaces.

Purpose or Objective: Multicentre comparisons of dosimetric parameters are important to ensure the same quality of the treatment in radiotherapy centres, and allow to identify systematic errors. In this study, small fields dosimetric parameters were collected in a national context using a common acquisition procedure and a specific dosimeter. The aim of this study was to provide indicative values for each Linac model for small field dosimetry measurements. This can be useful for centres with reduced experience in small fields dosimetry.

Material and Methods: Thirty-four centres with different LINACs joined this project: 2 Siemens, 7 Elekta Agility, 6 Elekta Beam Modulator, 12 Varian CLINAC and 7 Varian TrueBeam. All measurements were performed using the new IBA unshielded silicon diode RAZOR and the Stealth flat ionization chamber fixed on the gantry as reference. The RAZOR was positioned at 10cm depth in water phantom and SSD=90cm. In and Cross-line beam profiles ranging from 0.6-5cm (nominal field size). The actual in-plane (I) and cross-plane (C) FWHM were considered to calculate the effective field size, defined as $(A*B)^{0.5}$. Output factors (OF) were calculated and normalized to the 3x3 cm². OF were calculated for both nominal (OF_N) and effective (OF_E) field sizes. The penumbra width was defined as the distance between the 80% and 20% isodose levels. Two identical diodes were adopted to speed up the data collection.

Results: OF_N were in agreement over the different models up to 1x1 cm² field size. Higher agreement was obtained with OF_E, for the smallest fields different trends were obtained depending on vendors and models, see Fig.1. Penumbra measurements were in agreement each other for each field size and accelerator model.

Conclusion: This study shows a high consistency of small field dosimetry in the involved radiotherapy departments using this new generation silicon diode; consequently, the values reported may actually be used by other centers as indicative values, especially in the case of small fields when suitable detectors are not commonly available. Moreover, these results confirm that the new RAZOR silicon diode can be used to assess dosimetric accuracy in small-field delivery. In general, the adopted methodology removes much of the ambiguity in reporting and interpreting small field dosimetric quantities and facilitates a clear dosimetric comparison across a population of linacs.

EP-1949

Developing a Radiotherapy Quality Assurance programme as part of the HIPPO trial (NCT02147028)

D. Megias¹, H. Yang¹, P. Sanghera², M. Phillips³, L. Senthil⁴, A. Jackson⁵, G. Whitfield^{6,7}

¹Mount Vernon Hospital, National Cancer Research Institute Radiotherapy Trials Quality Assurance Group, Middlesex, United Kingdom

²Queen Elizabeth Hospital, Hall Edwards Radiotherapy Research Group, Birmingham, United Kingdom

³Cancer Research UK, University College London Cancer Trials Centre, London, United Kingdom

⁴Queen Elizabeth Hospital, Neuroradiology, Birmingham, United Kingdom

⁵The University of Manchester, Wolfson Molecular Imaging Centre, Manchester, United Kingdom

⁶The University of Manchester- Manchester Academic Health Science Centre, Radiotherapy Related Research, Manchester, United Kingdom

⁷The Christie NHS Foundation Trust, Clinical Oncology, Manchester, United Kingdom

Purpose or Objective: Outlining of target and OAR volumes is integral to the radiotherapy process but inherently subject to variability. The hippocampus is a small structure not commonly contoured by clinicians requiring considered anatomical interpretation in its delineation. HIPPO is a randomised phase II trial of Hippocampal Sparing (HS) versus Conventional Whole Brain Radiotherapy after surgical resection or radiosurgery in favourable prognosis patients with 1-4 brain metastases. We set out to inform the development of a dedicated HIPPO RTQA programme through evaluation of hippocampal contouring.

Material and Methods: Two clinical oncologists from different UK radiotherapy centres and a radiologist from each centre independently outlined the hippocampus on 2 different 1 mm slice thickness planning CT datasets after registration with the T1 weighted gadolinium enhanced MRI (3D volumetric MRI, axial acquisition, 1 mm slice thickness, no slice gap, 1 x 1 x 1 mm voxels) on their planning system. The datasets were re-registered by one of the centres. The four hippocampal contours for each case were anonymised and reviewed collectively and a gold standard contour defined. We compared each contour with its respective gold standard using the DICE coefficient and volume difference.

Results:

Table 1

Outliner	Case 1		Case 2	
	DICE similarity coefficient	Volume difference (cm ³) between outline and gold standard.	DICE similarity coefficient	Volume difference (cm ³) between outline and gold standard.
1	0.84	0.05 (-1%)	0.79	1.9 (+26%)
2	0.83	0.5 (+8%)	0.86	1.01 (+15%)
3	0.87	0.15 (+3%)	0.75	0.41 (+7%)
4	0.81	0.5 (+8%)	0.81	0.75 (-13%)

Conclusion: Reasonable concordance of the outlines in comparison to the gold standard was achieved in both cases. In case 1, all 4 outlines achieved a DICE coefficient greater than 0.80 and a hippocampal volume less than 0.5cm³ different to the gold standard. However, in case 2, despite DICE coefficients greater than 0.79 suggesting good spatial relationship between the clinicians' and the gold standard contour, greater variability was evident with a larger range in volume outlined. During collective review, some systematic differences were noted between the two participating centres' outlines, despite a high level of agreement on hippocampal boundaries during the review, highlighting CT-MRI co-registration as a potential source of variability between different centres and planning software. As a result of these findings, the pre-trial outlining benchmark case requires all centres to independently co-register the CT and MRI images and export the registration object as part of data submission. In order to comprehensively quality assure hippocampal outlining as part of the HIPPO RTQA programme, an on-trial component of the first two HS patient contours being reviewed prospectively before treatment is also undertaken. The implementation and quality assurance of less familiar outlining practice in the development of radiotherapy techniques requires careful consideration. This process has informed the development of a dedicated RTQA programme for the HIPPO trial highlighting the importance of aligning QA with clinical practice. HIPPO is funded by Cancer Research UK and The Brain Tumour Charity

EP-1950

Monte Carlo dose calculation of Viewray hybrid MRI-Co60 radiotherapy system: a repeatability study

E. Placidi¹, S. Teodoli¹, N. Dinapoli², L. Boldrini², G.C. Mattiucci², V. Valentini², A. Piermattei¹, L. Azario¹

¹Università Cattolica del Sacro Cuore -Policlinico A. Gemelli, Institute of Physics, Rome, Italy

²Università Cattolica del Sacro Cuore -Policlinico A. Gemelli, Radiation Oncology Department- Gemelli-ART, Rome, Italy

Purpose or Objective: The ViewRay MRI-Co60 hybrid system (MRIdian® [1,2]) is a novel technology that provides soft tissue imaging during radiotherapy thus allowing real adaptive radiotherapy possibilities and image guidance. The combination of Co60 with 0.35 Tesla MRI allows for MR-guided intensity modulated radiation therapy (IMRT) step and shoot delivery with multiple beams (3 Co60 heads 120° apart). MRIdian dose calculation takes advantage of a full Monte Carlo-based algorithm. The aim of this work was to evaluate the repeatability of the dose calculation of MRIdian plans for rectal cancer treatments.

Material and Methods: Ten patients affected by locally advanced rectal cancer (cT3-cT4; cN0, cN+) were manually segmented on Eclipse TPS v11. MRIdian step and shoot IMRT plans (7 groups of 3 fields each) were calculated 5 times for each patient. The prescribed dose for PTV2 was 45 Gy and 55 Gy for PTV1 through simultaneous integrated boost. The PTV1 V95, the conformity index CI [3] and the Wu's homogeneity index HI were computed for each patient. The coefficient of variation (CV), defined as the ratio of the standard deviation to the mean, was calculated for each set to express the precision and repeatability of the Monte Carlo dose calculation. The estimated beam-on time was also recorded for each plan.

Results: The time for the optimization and the final dose calculation was less than 5 minutes for each plan having a total of 21 fields (7 groups of 3 heads). The mean CV for the conformity index was found to be equal to $1.6 \pm 0.5\%$ whilst both the mean V95(PTV1) and the HI resulted in a CV smaller than 1%. The CV for the estimated beam-on time for the 10 patients was found to be $4.3 \pm 2.1\%$ (mean \pm std).

Conclusion: MRI-guided radiotherapy is a novel approach that may be advantageous over current treatment techniques by allowing PTV reduction. Dose optimization and calculation time is done with full Monte Carlo with a very short calculation time.

The three plan parameters under consideration proved that the Monte Carlo dose calculation is stable with a difference of the order of 4% in the estimated beam-on time.

⁵National Cancer Center Singapore, Division of Radiation Oncology, Singapore, Singapore

⁶CHU de Quebec, Division of Radiation Oncology, Quebec, Canada

⁷University of California- San Francisco, Division of Radiation Oncology, San Francisco, USA

Purpose or Objective: Spine SBRT is an emerging treatment for patients with spinal metastases and rapidly being adopted in the clinic without treatment planning evaluation guidelines. Although the a priori treatment planning constraints were met in all cases in our previous study, large inter-institutional variations in 95% of the PTV volume (D95) and D50 were observed. The purpose of this study was to minimize the inter-institutional variations in planning.

Material and Methods: Seven institutions in Japan, Canada, Singapore and USA participated and planned three cases with a total of ten apparatus. The spine cases included a 5th lumbar spine (case 1), 5th thoracic spine (case 2), and 10th thoracic spine metastases (case 3). Targets and organs at risk (OAR) were contoured by one experienced radiation oncologist according to International Spine Radiosurgery Consortium Consensus Guidelines and a 2 mm planning target volume (PTV) applied. The DICOM files were sent to each institute for planning. The treatment planning guidelines in the previous study included, prescribed dose of 24 Gy in two fractions with more than 70% prescribed dose to encompass D95, D0.035 < 140% of the prescribed dose, and a maximum dose to the spinal cord planning organ at risk volume (PRV) or thecal sac < 17 Gy. New guidelines added (D95 should be as high as possible(AHAP), D50 should be between 110% to 115% of prescribed dose and AHAP and D0.035 should be between 125% to 135% of the prescribed dose). The dose volume histograms (DVHs) were centrally reviewed.

Results: In our previous study the PTV D95 ranged from 70.0% to 99.6 % in case 1 (mean \pm SD; 21.21 \pm 2.43

Gy), 70.4% to 98.8% in case 2 (20.32 \pm 2.22 Gy), and 70.0% to 94.2% in case 3 (19.78 \pm 1.97 Gy), respectively and D50 for PTV ranged from 99.2% to 116.3% in case 1 (25.62 \pm 1.34 Gy), 91.7% to 119.6% in case 2 (25.97 \pm 2.18 Gy) and 84.2% to 114.2% in case 3 (25.57 \pm 2.14 Gy), respectively. In this study PTV D95 ranged from 80.4% to 100.0% in case 1 (21.96 \pm 1.67 Gy), 76.3% to 95.8% in case 2 (20.91 \pm 1.67 Gy), and 70.4% to 94.2% in case 3 (20.3 \pm 1.86 Gy), respectively and D50 for PTV ranged from 109.6% to 115.4% in case 1 (27.02 \pm 0.53 Gy), 110.0% to 117.5% in case 2 (27.06 \pm 0.63 Gy) and 107.5% to 115.0% in case 3 (26.89 \pm 0.67 Gy), respectively.

Conclusion: We succeeded to minimize the inter-institutional variations. This study highlights dose constraints of D95, D50 and D0.035 should be used to minimize the variations.

EP-1952

Monte-Carlo calculation of the secondary electron spectra inside and around gold nanoparticles

E. Gargioni¹, T. Dressel¹, H. Rabus², M.U. Bug²

¹University Medical Center Hamburg - Eppendorf UKE, Department of Radiology and Radiotherapy, Hamburg, Germany

²Physikalisch-Technische Bundesanstalt, Division 6.6 Radiation Effects, Braunschweig, Germany

Purpose or Objective: The use of nanoparticles (NP) in cancer therapy has been intensively investigated in the last few years. The advantage of using metal NP (such as gold, platinum, silver, hafnium oxide) during radiotherapy is that the amount of secondary electrons produced by the primary particles is higher than for soft tissue. Due to this enhanced secondary-electron emission around NP, stronger DNA damage is caused in the surrounding cells. The enhancement of energy deposition around gold NP has been determined in a number of studies, often with contradictory results, thus showing that the absorbed dose is not the appropriate physical quantity to estimate DNA damage in the presence of gold. Therefore it is necessary to systematically investigate the dependence of DNA damage from the spectra of the emitted secondary electrons and from corresponding nanodosimetric parameters.

Material and Methods: In this work, the secondary electron spectra produced inside and around gold NP were determined by means of Monte-Carlo simulations. The transport of secondary electrons created by different clinical photon sources inside and emerging from a NP surrounded by water was simulated using Geant4. The secondary electron spectrum inside gold NP of two different sizes (diameter: 12 and 30 nm) was calculated for mono-energetic photon sources (10 and 60 keV), an intra-operative x-ray source (maximum energy 50 keV), a conventional x-ray tube (200 keVp) and a clinical linear accelerator (6 MV).

Results: The energy spectra of the secondary electrons created inside the NP have a mean energy varying between about 6 keV for the mono-energetic 10-keV photons and about 65 keV for the 6-MV spectrum. This corresponds to a decrease of the mean ionization cluster size of about a factor of four for the linear accelerator. Therefore a corresponding decrease of the number of induced DNA double strand breaks is expected. Moreover, the spectra inside and around the gold NP with a diameter of 12 nm barely distinguish from those inside the gold NP with a diameter of 30 nm. However, the total amount of secondary electrons emerging from the smaller gold NP is increased by about a factor of three.

Conclusion: Further studies will be carried out in the future for determining the correlation between secondary electrons production and ionization cluster size distributions for other NP diameters and materials. Finally, a comparison between physical damage at nanometric level and cell survival experiments will be also performed.

Patient Safety & Quality Control Working Group of the Spanish Society of Radiation Oncology.

J. Pardo-Masferrer¹, E. Del Cerro- Peñalver², E. Jiménez-Jiménez¹

¹Hospital Universitario Son Espases. On behalf of the Patient Safety and Quality Control Working Group of the Spanish Society of Radiation Oncology, Radiation Oncology, Palma de Mallorca, Spain

²Hospital Universitario Quiron Madrid. On behalf of the Patient Safety and Quality Control Working Group of the Spanish Society of Radiation Oncology, Radiation Oncology, Madrid, Spain

Purpose or Objective: The aim of the Patient Safety and Quality Control Working Group of Spanish Society of Radiation Oncology (SEOR) was to analyse if the current Spanish legislation (SL): Royal Decrees 1566/1998 (Quality Criteria in RT) and 815/2001 (Justification of medical exposure to ionizing radiation) include the international recommendations on PS, and to implement appropriate measures to correct any possible deficiencies in this regard.

Material and Methods: The following documents were reviewed: "Towards Safer Radiotherapy", "Radiotherapy Risk Profile", "Failure Modes and Effects Analysis (FMEA)", "Preventing Accidental Exposures from New External Beam Radiation Therapy Technologies", "Safety in Radiation Therapy: A Call to Action meeting recommendations", and "Safety is not accident" (2nded.). From these documents, 11 topics were selected to compare with obligations regarding PS in RT specified in the SL: qualification, training, staffing, documentation/standard operating procedures, incident learning, communication/questioning, QC and preventive maintenance, accreditation, map of processes/risks and prospective risk assessment, strategies and tools development for minimizing risks and safety culture.

Results: SL include none of these issues: Relationship between staffing criteria and PS, Specifications about the number and quality of the documents that depend on a map of processes, Incident tracking, analysing, sharing and learning, Open communication and respectful questioning, Peer review, Maps of processes, Risks and prospective risk assessment, Strategies and tools for minimizing risks and, Safety culture. Due to lack of legal regulations, the SEOR board decided, in 2014, to create a Patient Safety and Quality Control Working Group (PSQCWG) to promote the knowledge and culture of QC and PS among professionals, to develop actions to improve information and training on QC and PS, and develop and implement systems to inform and report adverse events (errors and near misses) in order to learn from them and improve PS. Its challenges are:

To inform and assist to SEOR members in PS and QC procedures development
To organize regular training meetings, on PS and QC issues
To provide training/regular information to RO departments due to the occurrence of an event or detection of a weak point in the process map
To develop and deliver to RO departments an anonymous and easy-access system of events notification
To elaborate SEOR recommendations on PS, adapting the international recommendations to Spain
To submit proposals to the SEOR Board proposing amendments to the Spanish current health legislation

Conclusion: Being PS improvement a priority, by creating PSQCWG, the SEOR intends to implement safe practices in RT, promoting research on PS and QC, and develop their own recommendations on PS, according to the internationally elaborated and adapting them, if necessary, to the reality of our country by updating Spanish legislation.

EP-1954

Quality of Contouring in Radiation Oncology - Where to draw the line?

S. Vinod¹, M. Min¹, M. Jameson¹, L. Holloway¹

¹Liverpool Hospital, Cancer Therapy Centre, Liverpool, Australia

Purpose or Objective: Volume delineation is a potential source of error in radiotherapy, which can result in poorer clinical outcomes and increased toxicities. The aims of this study were to review the literature on interobserver variability (IOV), assess the dosimetric effects of IOV and identify interventions shown to reduce IOV.

Material and Methods: Medline and Pubmed databases were queried for relevant articles using the keywords "radiotherapy" and "volume delineation", "contouring", "observer variation", "interobserver variability", "variation", "systematic error", "quality assurance", "delineation", "interobserver" and "intraobserver" to identify articles which evaluated IOV target or organ-at-risk (OAR) volume delineation for multiple (>2) observers. The search was limited to English language articles published from 1/1/2000-31/12/2014. Reference lists of identified articles were scrutinised to identify relevant studies.

Results: 116 studies were identified, with the most common sites studied being breast cancer (n=20), lung cancer (n=17), genitourinary cancers (n=16) and OARs (n=29). The commonest volumes assessed were CTV (n=47) and GTV (n=38). CT alone (n=91) was the predominant dataset used for contouring. 81 studies used statistical tests to analyse the significance of their results. 31 studies evaluated the effect of additional imaging on IOV, with PET shown to reduce IOV in lung and rectal cancers and lymphoma but not head and neck cancers. There were mixed results for the benefits of MRI in brain tumours and breast cancers but it reduced IOV in OAR delineation. 25 studies evaluated the dosimetric effects of IOV, with most studies showing differences in OAR doses but the effect on PTV coverage was variable. 25 studies evaluated the effect on an intervention to reduce IOV. IOV was significantly reduced in 7/9 studies evaluating guidelines, and all 6 studies evaluating the provision of an autocontour to edit. Teaching interventions showed significant improvement in IOV in 4 studies, improvement without statistical analysis in 4 studies and no difference in 1 study.

Conclusion: Despite the large number of studies evaluating IOV, only a minority evaluated the dosimetric consequences of this or the use of interventions to reduce this. Additional imaging datasets reduced IOV in some cancer types. Guidelines or protocols and the provision of an autocontour reduced IOV in volume delineation.

EP-1955

Teaching radiation interactions and dosimetry through Monte Carlo simulations: VisualMC

C. Baker¹, A. Nahum¹

¹The Clatterbridge Cancer Centre - Wirral NHS Foundation Trust, Physics Department, Bebington- Wirral, United Kingdom

Purpose or Objective: An appreciation and understanding of the interaction of radiation with matter is essential for all professionals working in radiotherapy, whether from a superficial and qualitative or deep and quantitative perspective. The underlying theory is challenging to fully grasp at any level, often leading to confusion and a difficulty in retaining information. Interactive teaching, particularly with visualisation, provides students with a more enjoyable learning experience and promotes deeper learning. Here we describe a Monte Carlo (MC) simulation package designed to achieve educational objectives through interactive learning.

Material and Methods: A MC system originally designed for students to visualise the paths of electrons, positrons and photons as they traverse matter has been extended to score

energy deposition and particle fluence. The software package, written in Matlab, incorporates interaction sampling methods employed in general-purpose Monte Carlo codes.

Users select the incident particle type, energy, target material and (optionally) particle cut-off energies. Modes of operation include; 3D views of particle tracks from a broad beam incident on selected media, views of interaction probabilities and outgoing particle energy and direction, or energy deposition and charged particle fluence scored as a function of depth for a user-defined number of incident particles.

In addition, the 'physics' underlying radiation transport can be modified, by 'switching off' multiple Coulomb scattering, delta-ray production and radiative energy losses, in order to observe the effect this has on energy deposition and so gain a greater understanding of the physics involved.

Results: The MC teaching software, 'VisualMC', has been packaged as a stand-alone application and made available to university students via citrix. Practical sessions are used to introduce students to the software, after which the software can be accessed remotely by students to perform their own radiation transport 'experiments' to gather results for assessed assignments.

VisualMC output. Top: 10 MeV photons incident on a 1 cm thick Pb slab, showing photon (green), electron (red) and positron (blue) tracks. Bottom: Energy deposition with depth of 10 MeV electrons incident on water, multiple Coulomb scattering, radiative losses and delta-rays 'switched off'.

Conclusion: A MC-based software package has been developed to support the teaching of radiation interactions and radiotherapy dosimetry. The software has been incorporated into academic programmes at undergraduate and postgraduate levels, providing practical exercises for students of radiotherapy and medical physics.

EP-1956

Twitter as a tool for radiotherapy medical education: The #radonc Journal Club

R. Simcock¹, Z. Husain², M. Katz³

¹Brighton and Sussex University Hospitals NHS Trust, Sussex Cancer Centre, Brighton, United Kingdom

²Yale Medical Group, Yale Therapeutic Radiology, New Haven, USA

³Lowell General Hospital, Radiation Oncology, Lowell, USA

Purpose or Objective: Radiation technology is expanding at an exponential rate. Accompanying discoveries in molecular and radiation biology there are multiple developments in both hardware and software solutions. This expansion in information presents huge challenges to radiotherapy professionals to maintain adequately appraised in new data. Continuing Professional Development (CPD) is threatened by the huge volume of information and lack of financial and physical (workforce) resources to support study. Social media (SoMe) provides a new tool for medical education which is free and open access (FOAM, foameducation.org). Twitter presents a tool for CPD which can usefully connect multidisciplinary professionals in radiation oncology.

Material and Methods: The hashtag #radonc denotes information on twitter that is pertinent to radiation oncology. (A similar #medphys tag is used for specific medical physics subjects). On a monthly basis a #radonc journal club is held on the twitter platform. A paper is discussed in an open dialogue. The paper under discussion is introduced on twitter and via the www.radiationnation.com website. At the end of a week of asynchronous comment a hosted discussion is held for one hour with the paper's author. Participation is free and open to all.

Results: The #radonc journal club has been in place since 2014 and grown in participant numbers. In July 2015 the journal club had 86 participants from the USA, Canada, Australia, UK, Spain, Philippines, and Saudi Arabia. Over 600 tweets were sent which created over 1.5 million page impressions (symplur.com). Participants have mainly identified themselves as Radiation/Clinical Oncologists although there have been strong contributions from medical physicists, RTTs and patients and their advocates. The journal club continues with plans to host multiply timed chats to cope with demand from users in separate time zones. Further effort is being spent on using contributors to #radonc to provide SoME sourced FOAM to be hosted on the Radiation Nation website.

Conclusion: The #radonc twitter club is a successful, free, International initiative to use social media to promote discussion and interaction in radiotherapy education.

Partial breast irradiation with brachy- and teletherapy: comparative dosimetry of treatment plans

G. Stelczer^{1,2}, C. Pesznyák^{1,2}, N. Mészáros¹, C. Polgár¹, T. Major¹

¹National Institute of Oncology, Radiotherapy Centre, Budapest, Hungary

²Budapest University of Technology and Economics, Department of Nuclear Techniques, Budapest, Hungary

Purpose or Objective: To compare the dose distributions of partial breast irradiations in treatment plans of high dose rate multicatheter brachytherapy and intensity modulated radiotherapy with special respect to dose to organs at risk.

Material and Methods: 15 patients with early-stage breast cancer treated with interstitial partial breast brachytherapy (BT) irradiation were selected for the study. The total dose was 30.1 Gy given by 7 x 4.3 Gy fractionation. Target volume and organs at risk (non-target breast, contralateral breast, both lungs, skin, ribs and heart for left sided lesion) were outlined and treatment plans were made using geometrical and graphical optimization with Oncentra brachy (Elekta) planning system. The PTV was created around the resection cavity with a margin of 20 mm minus tumor-free surgical margin in each direction limited to skin and chest wall. Skin was delineated as a 5 mm shell inside the body contour. Then, the CT data with the contours were transferred to an external beam treatment planning system (Eclipse, Varian),

and using the same patient anatomy and fractionation schedule virtual plans for intensity modulated radiotherapy (IMRT) were made. The PTV in IMRT plans was created by 5 mm volumetric extension around the PTV used in BT plans. PTV_{eval} was formed from PTV with geometrical limitation to the skin. Detailed dose-volume histogram analysis was carried out for the PTVs, breasts, lungs, skin, ribs and heart. Means, standard deviations were calculated and the corresponding parameters were statistically compared. Wilcoxon matched pairs analysis was performed for test of significance.

Results: The target coverage represented by V90 was better for IMRT (100% vs. 97%, $p < 0.05$), but the D90 was higher for BT (103% vs. 100%, $p < 0.05$). The conformity numbers were 0.73 for BT and 0.84 for IMRT ($p < 0.05$). The V100, V90 and V50 for non-target breast were 1.7% vs. 0.2% ($p < 0.05$), 2.8% vs. 4.3% ($p < 0.05$) and 11.5% vs. 23.9% ($p < 0.05$) for BT and IMRT plans, respectively. For ipsilateral lung the V5 was not significantly different in the two groups, but the V10 was lower for BT (11.7% vs. 20.5%, $p < 0.05$). For contralateral breast and lung no significant differences in D0.1ccm were observed. For patients with left sided lesion the dose to heart was less with IMRT for D0.1ccm (15.3% vs. 22.7%, $p < 0.05$). The most exposed skin volume (0.1 ccm) received significantly less dose with BT (64.4% vs. 92.4%). The same is true for ribs with values of 51.3% vs. 71.2%. With BT the ribs never received the prescribed dose, while with IMRT the D0.1ccm exceeded the prescribed dose in five cases.

Conclusion: With both BT and IMRT techniques acceptable target coverage can be obtained, but the conformity of dose distributions is better with IMRT. The dose to organs at risk is less with BT compared to IMRT, except for the heart. Generally, the BT and IMRT can be alternative techniques for partial breast irradiation, but in individual cases the recommended technique depends on the tumour location.

EP-1958

Treatment results of Mammosite catheter in combination with whole breast irradiation

A. Gitt¹, H. Böse-Ribeiro¹, C. Nieder², P.G. Kup¹, H. Hermani¹, H. Bühler¹, H.Y. Ergöncü³, D. Drüppel³, I.A. Adamietz¹, K. Fakhrian¹

¹Marien Hospital Herne- Ruhr-University Bochum, Radiation Oncology, Herne, Germany

²Nordland Hospital Bodø, Department of Oncology and Palliative Medicine, Bodø, Norway

³St. Anna Hospital Herne, Department of Senology, Herne, Germany

Purpose or Objective: To report the initial outcomes of patients treated with the MammoSite brachytherapy device (MSBT) as a boost followed by external whole breast irradiation (WBI).

Material and Methods: From June 2011 to March 2014, 107 patients (typically pT1-2, pN0-1, M0) were treated with breast-conserving therapy (BCT) and adjuvant radiotherapy with MSBT (15 Gy in 2.5 Gy fractions) followed by WBI (median 50.4 Gy). Toxicity was classified according to the Common Terminology Criteria for Adverse Events v3.0. The median follow-up was 21 months.

Results: So far no ipsilateral breast-tumor recurrences were observed, 102 patients (95%) were alive at last follow-up. Two patients (2%) developed distant metastasis. Five patients (5%) died during follow-up, only one as a result of breast cancer. The 2-year disease-free survival was 95 ± 3%. The incidence of asymptomatic and symptomatic seroma in 90 days after MSBT was 28% and 10%, respectively. Infectious mastitis was observed in 3 patients (3%), who were treated successfully with antibiotics. Only 3 patients (3%) developed a radiodermatitis > grade 2 after WBI.

Conclusion: The boost technique used in this study seems to provide excellent local control with acceptable toxicity, similar to the results observed with other forms of interstitial accelerated partial-breast irradiation as a boost. Long-term

follow-up is necessary to refine the patient selection criteria and to assess efficacy and late toxicities.

EP-1959

Dosimetric consequences from minimal displacements in APBI brachytherapy using the SAVI applicator

S. Pella¹, C. Shereen², D. Nicolae³, H. Mikko³, P. Janeil³

¹Florida Atlantic University, Physics- Medical Physics Graduate Program, Boca Raton, USA

²Florida Atlantic University, Physics, Boca Raton, USA

³Florida Atlantic University, Physics, Boca Raton, USA

Purpose or Objective: Evaluate the necessity of a complete CT scan before each treatment in the APBI and the use of additional immobilization devices

Material and Methods: A retrospective study was performed on 25 patients treated in the 2013-2015 period with APBI brachytherapy. The CT scans of each patient taken before each treatment were imported in to the planning system. Each CT scan was registered with the initial one. Dosimetric evaluations respective to the initial CT scan image series were performed. The deviation of dose received by the skin and ribs in each treatment were calculated and minimum, maximum and average dose received by skin and ribs were recorded and compared to the initial plan's results.

Results: Small deviations in displacements were observed from the SAVI applicator to the ribs and the skin surface. Dosimetric evaluations revealed, very small changes in the inter-fractionation position make significant differences in the maximum dose to these critical organs. As a result, the maximum dose varied between 10% and 32% in ribs and skin surface.

Conclusion: The CT scan before each treatment is necessary to minimize the uncertainty in setup and any intervention if deemed necessary. This study indicates, in 30% of the cases needed re-planning between treatments to minimize the risk of critical organs to be overdosed. We conclude that the physicist should evaluate the position of the device by analyzing the CT images before each treatment and consider re-planning is the deviations are high. Also this study reveals the urgent need of improving the immobilization methods when treating APBI with SAVI applicator. This type of treatment will benefit of deformable registration at each treatment and adaptive planning

EP-1960

Exclusive brachytherapy of vaginal cuff: ethical considerations on quality of life after treatment

F. Piro¹, M.A. Martilotta¹, A. Massenzo¹, L. Marafioti¹

¹Ospedale Mariano Santo, U.O. Radioterapia Oncologica Cosenza, Cosenza, Italy

Purpose or Objective: To evaluate efficacy, clinical and psychological impact of chronic toxicity, of exclusive BRT of vaginal cuff in patients (pts) affected by endometrial cancer after hysterectomy (EC)

Material and Methods: From January 2010 to December 2014 we studied 108 pts with EC treated with exclusive BRT. Treatment was performed with cylinder in vagina to sterilize vaginal cuff, fractionation 6 - 30 Gy, prescription to 0.5 cm from surface of cylinder, active length almost 3 cm. We evaluated efficacy, quality of life and impact on sexual activity after BRT filling out a test designed to investigate following areas: 1) social relations and personal emotions, 2) couple intimacy and sexuality, 3) impact of treatment on sexuality and doctor-patient relationship before BRT

Results: 96 evaluable pts median follow-up 24 months (range 9-60); median age 62 years (40-88); histology revealed 2 cr. squamous and 94 adenocarcinoma; grading G1 for 15%, G2 for 65% and G3 for 20% of cases; all pT1b stage; lymph node

status performed in 72 (75%) pts. median 4 (0-40) in other 24 (25%) NX; diameter of the cylinder used in 76 (84%) pts. was 3-4 cm remaining 20 (26%) diameter 1-2. Only 3 (3%) pts resulted disease progression. Psychological evaluation was performed on 69 pts (Median age 61; 44 - 71), the other 27 cannot be estimated because not interested. In the first area test showed for a third of pts a change of social relations judged value "from much up to very much", while in half of respondents, there was same value in personal sphere. Considering couple intimacy the 71% of women had undergone a change, and 81% reported decrease of sexual desire. In third area half of pts said they were informed about impact of BRT on sexual life evaluating changes induced by it " from much up to very much"; 71% of women surveyed have been recommended to have therapeutic relationships, 73% of respondents reported painful intercourse and 91% of pts found it unsatisfactory. 13% of pts has explicitly requested psychological support

Conclusion: Apart from grading and lymph node status, BRT of vaginal cuff is effective in preventing local recurrence. Despite of use of larger diameter cylinders, remains problem of toxicity management post BRT. Analysis of impact on quality of life of these pts causes several issues: whether treatment should always be recommended, if we have to review informed consent and if a psychological support pre-treatment is necessary. An appropriate supportive therapy during and after BRT is always necessary

EP-1961

Factors influencing the risk of uterus perforation in high-dose rate tridimensional brachytherapy

L.G. Sapienza^{1,2}, R.C. Camargo¹, I. Migowski¹, E.S. Sandrini¹, E. Anderson¹, F. Campana¹, G. Baiocchi³, H.A. Salmon¹

¹*Clinicas Oncológicas Integradas COI-RJ, Radiation Oncology, Rio de Janeiro, Brazil*

²*A. C. Camargo Cancer Center, Radiation Oncology, São Paulo, Brazil*

³*A. C. Camargo Cancer Center, Gynecologic Oncology, São Paulo, Brazil*

Purpose or Objective: To evaluate the factors associated with uterine perforation in a population treated with tandem and ovoids high-dose rate tridimensional (HDR 3D BT) brachytherapy for gynecological cancer, without ultrasonographic guidance.

Material and Methods: Computed tomographic images used for HDR 3D BT of 47 cases of gynecological cancer (46 cervical and 1 endometrial cancer) were studied. The perforation rate (PR) was determined by software Oncentra MasterPlan V3.3 (Veenendaal, Netherlands). The categorical variables tested were: bladder filling (empty vs. full), age (≤ 60 years vs. >60 years), uterine lateral position (left or right vs. central) and uterine sagittal position (anterior vs central or retrograde). For statistical analysis, multiple logistic regression was performed (SPSS V.20).

Results: The study evaluated 186 insertions. The treatment was performed using 4 fractions of 7 Gy in 45 patients (95.7%) and 3 fractions of 7 Gy in two patients (4.3%). Median age was 47 years (range, 24 - 82). The total PR was 21.5% (40 events). The site of the perforation was: 67.5% posterior wall (27 cases), 17.5% left lateral (7 cases), 7.5% cranial (3 cases), 5% anterior wall (2 cases) and 2.5% right lateral (1 case). In forty-three cases (91.5%), the perforation occurred in the opposite direction of the uterus anatomic position. Factors that increased the PR in univariate analysis were: empty bladder ($p < 0.001$), anterior uterine position ($p = 0.010$) and age ($p = 0.010$). In multivariate analysis, only empty bladder remained as an independent prognostic factor for perforation ($p = 0.002$).

Conclusion: In our series, the modifiable factor empty bladder correlated with uterine perforation. Although uterine anatomic position did not influenced significantly the incidence of uterine perforation, it determined the direction of the perforation in more than 90% of the cases. Our data

suggest a potential value of image guidance for brachytherapy insertion.

EP-1962

CT-based optimisation of single source line HDR vaginal vault brachytherapy: a dosimetric study

I. Barillot¹, A. Ruffier-Loubiere¹, G. Bernadou¹

¹*Hôpital Bretonneau, Cancer centre H.S. Kaplan, Tours, France*

Purpose or Objective: To compare CT-based dose distribution to CTV and organs at risk (OAR) of HDR vaginal vault brachytherapy (VVB) with stump applicator according to 2 prescription modes: standard prescription to 5 mm from the applicator surface versus individualised prescription according to the thickness of the vaginal wall.

Material and Methods: This study was performed between January 2013 and December 2014, on a cohort of 61 consecutive patients (pts) with endometrial cancer referred for a post operative HDR VVB. Mean age was 68 years. According to FIGO stage, 21% were Ia G3, 54% Ib, 10% II and 15% III. 24 Gy in 4 fractions were delivered as sole treatment in 33 pts; whereas 28 pts received 10 Gy in 2 fractions after 45 Gy pelvic irradiation. The CT was performed with applicator in situ before the first fraction. The size of the applicator was determined according to the clinical examination, but was modified if significant air gaps were observed on CT. CTV was defined as the vaginal vault and the upper third of the vagina; intestine as the lower third of the peritoneal cavity. Bladder and rectum were delineated entirely. Using brachyvision®, the Standard Plan (SP) was calculated for delivering the fraction dose (FD) on a reference line placed at 5 mm of the applicator surface irrespective of the location of OAR. The Individualised Plan (IP) was calculated from a line that conformed to the outer contour of the CTV with the following constraints: CTVD90 = FD \pm 5%, D2cc to rectum and bladderFD and D2cc to Intestine \leq (FD-1Gy). The CTVD90 and D2cc to OAR were used for the plans comparison

Results: According to constraints (in, above, under), 6 different groups could be defined: Gp1 : D90 and D2cc in; Gp2 : D90 in and D2 cc above; Gp3 D90 and D2cc above; Gp4 : D90 above and D2cc in ; Gp5 D90 under and D2cc in ; Gp D90 under and D2cc above. Results of the comparison are summarised in the following table.

	SP	IP					
	nb pts	Gp1	Gp2	Gp3	Gp4	Gp5	Gp6
Gp1	2	2					
Gp2	6	3	1				2 (D2cc were significantly lowered at price of decrease of D90)
Gp3	12	3			8	1	
Gp4	8	5			3		
Gp5	15	6				4	5 (D90 slightly improved at price of slight increase of D2 cc)
GP6	18	1	6		1	6	4

Conclusion: CT-based individualised single source line HDR VVB was feasible and resulted in optimisation of the dose distribution to CTV and/or OAR in the majority of cases. In only 20% of cases, individualisation didn't change the dose distribution. Consequently, CT-based dosimetry became the standard procedure in our department since January 2015. The assessment of the clinical impact will be the next step.

EP-1963

Dosimetric evaluation of image guided brachytherapy using tandem-ovoid and tandem-ring applicators

R. Rangarajan¹, S. Saravanan¹

¹*Government Royapettah Hospital, Department of Radiation Oncology, Chennai, India*

Purpose or Objective: The aim of the study is to evaluate the differences in dosimetry between tandem-ovoid and tandem-ring gynaecologic brachytherapy applicators in image guided brachytherapy

Material and Methods: 100 CT datasets of cervical cancer patients (stage IB2 - IIB) receiving HDR application (50 tandem-ovoid and 50 tandem-ring) were studied. The external beam radiotherapy dose was 50Gy. Brachytherapy was delivered using a CT-MRI compatible tandem-ovoid (50 patients) and a tandem-ring applicator (50 patients) to a dose of 8Gy/# in 2 fractions. Bladder and rectum were contoured using oncentra planning system. DVHs were calculated and D2cc was recorded for bladder and rectum and compared with the corresponding ICRU point doses. The point B dose, the treated volume, high dose volume and the treatment time was recorded and compared for the two applicators.

Results:

Applicator	Mean D2cc Bladder (Gy)	Mean ICRU Bladder (Gy)	Mean D2cc Rectum (Gy)	Mean ICRU rectum (Gy)	ICRU/D2cc ratio Bladder	ICRU/D2cc ratio Rectum
Tandem-Ring	6.57	5.56	3.95	5	0.847	1.265
Tandem-ovoid	7.30	5.63	4.79	5.65	0.772	1.179

Conclusion: The results indicate that the OAR doses assessed by DVH criteria were higher than ICRU point doses for bladder with both tandem-ovoid and tandem-ring applicators whereas DVH based dose was lower than ICRU dose for rectum. The point B dose, the treated volume and high dose volume was found to be slightly higher with tandem-ovoid applicator whereas the total treatment time was higher with the tandem-ring applicator. The mean D2cc dose for bladder and rectum was lower with tandem-ring applicators. The clinical implication of the above dosimetric differences needs to be evaluated further.

EP-1964

Measurement of vaginal dose with image guided vaginal vault brachytherapy

L. Bleakley¹, M. Zahra¹, L. White¹, W. Keough²

¹Western General Hospital- Edinburgh Cancer Centre, Clinical Oncology, Edinburgh, United Kingdom

²Western General Hospital - Edinburgh Cancer Centre, Medical Physics, Edinburgh, United Kingdom

Purpose or Objective: The aim of this study is to evaluate an accurate method to define vaginal dose distribution in the delivery of vaginal vault brachytherapy (VBT) utilising a single channel cylinder.

Material and Methods: A retrospective analysis of all 3D single channel cylinder VBT plans held on BrachyVision™ 10.0 treatment planning system obtained between April 2011 and December 2013. All patients received treatment to the top 4cm of the vagina at 0.5cm depth prescription point with fractional doses of 5.5Gy or 7Gy. Dose assessment is conducted using both point dose values and DVH parameters for vaginal wall. A vaginal apex dose point (VAdp) was defined as a midline point on the single channel cylinder, positioned at the apex representing vaginal surface dose (Gy). A second rectal / vaginal dose point (RVdp), positioned 0.5cm posterior to vaginal wall (ICRU rectal point) is also used. This is potentially a good surrogate for vaginal mucosa dose due to its proximity to vaginal cylinder. A presumed vaginal wall thickness of 0.5cm was used to grow a volume representing the upper 4 cm of vaginal mucosa; the D2cc (Gy) and D5cc (Gy) are recorded. Pearson's correlation coefficient is used to calculate correlation between dose point values and dose volume parameters obtained. A p-value <0.05 was considered statistically significant in this study.

Results: A total of 113 CT data sets are analysed. 69% (n = 78) of patients had a prescribed fractional dose of 5.5Gy and 31% (n = 35) received 7Gy fractional dose.

	5.5Gy Fractional Dose		7.0Gy Fractional Dose	
	Mean vaginal fraction dose with SD (Gy)	Range (Gy)	Mean vaginal fraction dose with SD (Gy)	Range (Gy)
D2cc	8.4 ± 0.30	7.71 – 9.81	10.7 ± 0.47	10.03 – 12.84
D5cc	7.8 ± 0.19	7.24 – 8.43	9.91 ± 0.28	9.21 – 10.77
VAdp	6.31 ± 0.41	4.30 – 7.54	7.95 ± 0.57	7.17 – 9.84
RVdp	4.0 ± 0.39	3.37 – 6.50	5.03 ± 0.30	4.41 – 5.81

No correlation was identified between RVdp and D2cc for 5.5Gy plans (r=0.004, p=0.974) and 7.0Gy plans (r=0.009, p=0.957). Similarly no correlation was identified between the RVdp and D5cc for 5.5Gy plans (r=0.170, p=0.138) and 7.0Gy plans (r=0.071, p=0.687). The D2cc showed a weak correlation with VAdp for 5.5Gy (r=0.200, p=0.083) and 7Gy plans (r=0.351, p=0.039); however only statistically significant with 7Gy plans. No relationship exists between VAdp and D5cc for 5.5Gy (r=0.146, p=0.202) and 7Gy plans (r=0.068, p=0.699).

Conclusion: The RV dp is not a good surrogate for vaginal dosimetry. The VAdp could possibly be considered to predict D2cc values however dose volume parameters remain the accurate method when recording dose to vaginal mucosa from delivery of VBT.

EP-1965

Quantification of CT planning scans assessing OAR doses when delivering vaginal vault brachytherapy

L. White¹, W. Keough², L. Bleakley¹, M. Zahra³

¹Edinburgh Cancer Centre- Western General Hospital-, Radiotherapy, Edinburgh, United Kingdom

²Edinburgh Cancer Centre- Western General Hospital-, Medical Physics, Edinburgh, United Kingdom

³Edinburgh Cancer Centre- Western General Hospital-, Clinical Oncology, Edinburgh, United Kingdom

Purpose or Objective: The aim of this study is to establish whether one initial CT planning scan for vaginal vault brachytherapy (VBT) patients is adequate to ensure surrounding OAR (bladder, rectum, sigmoid colon and small bowel) do not breach their dose constraints, or whether patients should be CT planned before each VBT fraction due to variations in OAR volumes and organ movement.

Material and Methods: Patients were scanned twice with a segmented single central channel vaginal cylinder in situ. The first CT scan (A) was carried out, as per departmental protocol, two weeks prior to treatment delivery and the subsequent scan (B) on the first day of treatment. All patients were treated using scan A. OAR dose deviations were retrospectively calculated by applying the same dwell positions and loadings to scan B. The total EQD2 OAR dose received by VBT and EBRT was then assessed for tolerance breach (bladder 80Gy; rectum, sigmoid colon and small bowel 70Gy). Both scans were analysed using Pearson correlation coefficient to determine relationships between % differences of OAR volumes and the OAR D2cc dose % differences. Additional bladder, rectum and GI structure (sigmoid colon and small bowel) contours were created combining the two scans (A+B); to simulate the worst case scenario structure movement between treatments.

Results: 42 patients were scanned twice in total. 5 patients were prescribed 21Gy in 3 fractions after 45Gy in 25 fractions EBRT, 27 patients were prescribed 11Gy in 2 fractions after 45Gy in 25 fractions EBRT and 10 patients were prescribed 21Gy in 3 fractions of VBT only. Scan B CT plans showed all patients receiving VBT only or EBRT with 2 fractions of VBT had total EQD2 doses within published OAR dose tolerances. 4 out of 5 (80%) patients treated with EBRT and 21Gy of VBT exceeded at least one OAR dose tolerance and when contours were combined 100% of these patients exceeded at least one

OAR dose tolerance. No relationship was identified between the % difference of OAR volumes and D2cc OAR % variations.

Conclusion: Patients treated with 45Gy in 25 fractions EBRT + 21Gy in 3 fractions VBT are at greater risk of breaching OAR dose tolerances when using a single planning scan for all treatments. There is no significant relationship between the % difference of bladder, rectum, sigmoid and small bowel volumes and % dose difference. The OAR dose variation between each scan is most likely due to the unpredictable day to day movement of the structure and cannot be replicated by standardised organ filling procedures. Departmental protocols have been amended to CT plan this subgroup of patients before each treatment fraction to take into account position of structure at that time. Use of a multichannel applicator could also help minimise the dose to these structures.

EP-1966

Late toxicity outcomes of CT-based brachytherapy planning for locally advanced cervical cancer

J. Tang¹, B.A. Choo¹, V. Koh¹, J. Low², J. Ng², A. Illancheran², Y. Lim³, S.E. Lim³, D. Tan³

¹National Cancer Institute Singapore, Radiation Oncology, Singapore, Singapore

²National Cancer Institute Singapore, Gynaecology, Singapore, Singapore

³National Cancer Institute Singapore, Medical Oncology, Singapore, Singapore

Purpose or Objective: A report of late rectal and bladder toxicity outcomes of a computed tomography(CT)-based image guided brachytherapy(IGBT) technique for treatment of cervical cancer.

Material and Methods: Between 2008-2014, 95 women with International Federation of Gynecology and Obstetrics stage IB to IVA cervical carcinoma treated with definitive concurrent cisplatin based chemotherapy and external beam radiation therapy (EBRT) 50.4Gy in 28 fractions followed by 3-4 fractions of high-dose-rate (HDR) IGBT was retrospectively reviewed. At each implantation, all patients had a urinary catheter insitu and received bowel enema before undergoing planning CT-simulation. A high-risk clinical target volume (HRCTV) encompassing any visible tumor and the entire cervix, rectum and bladder was contoured on the simulation CT according to Radiation Therapy Oncology Group Gynaecology Contouring Atlas. Prescription dose range of 5.5-7Gy was prescribed to the HRCTV. Doses to Point A, ICRU rectal and bladder points were recorded. Toxicities were recorded using NCI-CTCAE version 3.

Results: The median follow-up time was 29 months. The mean Point A dose was 6Gy (4.6-7.6Gy). The ICRU rectum and bladder points were 4.69Gy (2.5-5.7Gy) and 4.23Gy (1.95-7.2Gy) respectively. 22 patients(23%) and Grade 2 proctitis and 10 patients(11%) had Grade 3 proctitis. 4 patients (4%) had Grade 2 cystitis and 2 patients(2%) had Grade 3 cystitis. No patients had \geq Grade 4 toxicity.

Conclusion: Despite bladder and bowel preparation protocol, late rectal toxicity was significant in a high proportion of patients. Implementation of an interstitial IGBT using the EMBRACE protocol might help to limit these late rectal toxicities.

EP-1967

Preliminary results of a new brachytherapy schedule in postoperative endometrial carcinoma

A. Rovirosa¹, K. Holub¹, A. Herreros², C. Ascaso³, J. Sánchez⁴, G. Oses², J. Mansilla⁵, J. Sola², A. Huguet², S. Garrida², J. Saez², C. Camacho², A. Camarasa², C. Quilis², M. Arenas⁶, S. Sabater⁷, M. Del Pino⁸, J. Pahisa⁸, A. Biete¹

³Faculty of Medicine- University of Barcelona, Public Health Dpt., Barcelona, Spain

⁴Hospital Clinic i Universitari, Economics Dpt., Barcelona, Spain

⁵Hospital Rebagliati, Radiation Oncology Dpt., Lima, Peru

⁶Hospital sant Joan de Reus, Radiation Oncology Dpt., Tarragona, Spain

⁷Hospital General de Albacete, Radiation Oncology Dpt., Albacete, Spain

⁸Hospital Clinic i Universitari, Gynecological Cancer Unit., Barcelona, Spain

Purpose or Objective: To analyze the preliminary results of a new daily high-dose-rate brachytherapy (BT) schedule in vaginal-cuff relapse (VCR) and toxicity in postoperative endometrial carcinoma (EC).

Material and Methods: From September 2011 to December 2014, 102 patients (p) were treated with HDRBT in FIGO stages: IA-30p, IB-39p, II-8p, IIIA-4p, IIIB-1p, IIIC1-8p, IIIC2-5p, IIIC3-1p, IVB-6p. Pathology: 79/102 endometrioid adenocarcinoma and 23/102 other types. Radiotherapy: Group 1: 74p/102p 1 BT fraction of 7Gy after external beam irradiation (mean 45Gy, range 44.0-50.4); Group 2: 28p/102p BT alone by 3 daily fractions of 6Gy. Chemotherapy: 20/102 patients. Toxicity evaluation: RTOG scores for bladder and rectum and the objective criteria of LENT-SOMA for vagina. Statistics: Chi-square and Fisher exact tests.

Results: Mean age (years): Group 1: 65.4 (40-88), Group 2: 66.7 (39-90). Mean follow-up (months): Group 1: 24.48 (8.04-52.56); Group 2: 26.88 (8.76-54.48). VCR: No relapses with the present mean follow-up. Toxicity: Group 1 - early problems (all G1-2) in rectum (5.5%), bladder (6.8%) and vagina (14.9%). Late toxicities: rectum 2.7% (all G1), bladder 0% and vagina 27% (G1-G2). Group 2 -early toxicity: bladder 10.7% (all G1), vagina 28.1% (all G1-G2), rectum 0%; late toxicity was only found in vagina in 17.8% (G1-2). No significant differences were found in toxicities between the two groups.

Conclusion: The present brachytherapy schedule consisting in 1 fraction/7Gy after external beam irradiation and 3 fractions/6Gy administered daily seem a safe regime in terms of local control and toxicity for postoperative EC. These results seem similar to those found in our Hospital in 2 previous series with low dose per fraction and an increased number of fractions. Grant: AECC Foundation

EP-1968

Vaginal mucosal doses in the treatment of cervical cancer using HDR brachytherapy

W. Keough¹, L. Bleakley¹, L. White¹, M. Zahra¹

¹Edinburgh Cancer Centre- Western General Hospital, Oncology, Edinburgh, United Kingdom

Purpose or Objective: To develop a reliable method of determining the radiation dose to the vaginal mucosa in the treatment of cervical cancer.

Material and Methods: Forty six cervical cancer patients were treated with EBRT and HDR brachytherapy therapy from July 2010 - Dec 2013. They received 45Gy in 25 fractions of EBRT to the entire pelvis followed by 3 HDR brachytherapy fractions using a tandem and ring applicator with a HRCTV D90 of 80-85Gy. A volume to represent the vaginal mucosa was obtained by using a non-uniform expansion of the 5mm ring applicator cap; this was expanded by 5.0 mm in all directions except the sup/inf which was expanded by 7.0 mm. In addition, a rectal vaginal (RV) point dose was determined using a point 5.0 mm posterior to the intersection of the superior-posterior junction of the build up cap (figure 1 sagittal view). Total doses were calculated for vaginal volumes of 5.0cc (D5 v), 2.0cc (D2 v), and the RV point. In addition, the slope was calculated for the vaginal mucosa between D5 v and D2 v. Pearson correlation coefficients (with p values = 0.01) were assessed to identify

correlations between the slope, D5 v, D2 v, HRCTV D90, HRCTV volume, and the RV point.

Results: Total doses from 3 fractions for the D5 v median 48.7Gy (range 31.4 - 76.6Gy), D2 v median 64.0Gy (range: 43.2 - 112Gy) and RV median dose 16.3Gy (range: 11.6 - 25.3Gy). The RV point exhibited a weak correlation with D2 v ($r=0.56$; $p=0.0001$) and D5 v ($r = 0.55$; $p=0.0001$) respectively. A moderate correlation was observed between the HRCTV volume and the D2 v ($r = 0.69$; $p=0.0001$), the HRCTV volume and D5 v ($r = 0.73$; $p=0.0001$) and a weak correlation with the HRCTV volume and the RV Point ($r=0.57$; $p=0.0001$). The slope correlated with D2 v ($r= -0.96$; $p=0.0001$) and D5 v ($r=-0.87$; $p=0.0001$) and a weak correlation with the RV point ($r=-0.52$; $p=0.0002$). No correlation was found between the HRCTV D90 and the D2v ($r=-0.20$; $p=0.1826$), the D5v ($r=-0.24$; $p=0.1082$), or the RV Point ($r=0.02$; $p=0.8431$).

Conclusion: The expansion volume of the ring applicator cap can provide a suitable surrogate for determining the vaginal mucosa dose, as this part of the vagina is in close proximity to the ring and tandem contributing to the volume of vaginal mucosa receiving the highest vaginal dose. The RV point does not correlate with the D2v and D5v and therefore can not be used as a suitable surrogate point for the dose to the vaginal mucosa. Additional work is currently ongoing to correlate the D2v and D5v with clinically measured vaginal morbidity.

High-dose-rate image-guided interstitial brachytherapy for recurrent cervical adenocarcinoma

K. Yoshida¹, H. Yamazaki², T. Takenaka³, T. Kotsuma⁴, K. Masui², Y. Uesugi¹, T. Shimbo¹, N. Yoshikawa¹, H. Yoshioka¹, Y. Yoshioka⁵, E. Tanaka⁴, Y. Narumi¹

¹Osaka Medical College, Radiology, Takatsuki, Japan

²Kyoto Prefectural University of Medicine, Radiology, Kyoto, Japan

³National Hospital Organization Himeji Medical Center, Radiology, Himeji, Japan

⁴National Hospital Organization Osaka National Hospital, Radiation Oncology, Osaka, Japan

⁵Osaka University Graduate School of Medicine, Radiation Oncology, Suita, Japan

Purpose or Objective: In order to evaluate the usefulness of high-dose-rate image-guided interstitial brachytherapy (HDR-ISBT) for recurrent uterine cervical adenocarcinoma, we analyzed our clinical experience.

Material and Methods: We investigated 28 patients treated with HDR-ISBT at National Hospital Organization Osaka National Hospital between May 2003 and December 2010. All patients received radical surgery and 7 patients also received post-operative radiotherapy as previous treatments. Histologic finding was adenocarcinoma and squamous cell carcinoma for 11 and 17 patients. In 11 adenocarcinoma patients, 6 patients had endometrioid adenocarcinoma and the other 5 patients had mucinous adenocarcinoma. The median tumor size was 23 mm (range; 5-79 mm). In 21 patients who had no irradiation history, 9 patients were treated with HDR-ISBT alone and the other 12 patients were treated with HDR-ISBT plus external beam radiotherapy (EBRT). Forty-eight to 54 Gy in 8 to 9 fractions were delivered as monotherapy and 30 to 33 Gy in 5 to 6 fractions as combination of EBRT. In 7 patients who had irradiation history, slight lower doses (42 to 48 Gy in 7 to 8 fractions) were selected. We implanted 7-15 (median, 12) applicators under transrectal ultrasonography guidance. We used free-hand implantation with ambulatory technique for later 25 patients. Magnetic resonance imaging (MRI)-assisted image-based treatment planning was performed for later 17 patients. Clinical target volumes (CTV) were the gross tumor volume with or without 10 mm of vaginal margin for patients with or without non-irradiation history.

Results: The median follow-up time was 43 months (range; 4-115 months). The median D90(CTV)s were 120%prescribed

dose (PD), 122%PD and 118%PD for patients who had endometrioid adenocarcinoma, mucinous adenocarcinoma and squamous cell carcinoma. The 3-year local control and overall survival rates were 72% and 73% for adenocarcinoma. The 3-year local control and overall survival rates were 88% and 77% for squamous cell carcinoma. No significant difference was observed. The 3-year local control rates were both 67% for endometrioid adenocarcinoma and mucinous adenocarcinoma. Grade 3-4 late complications occurred by HDR-ISBT in 5 patients (18%).

Conclusion: Our treatment result of image-based HDR-ISBT showed that slight inferior result was observed in cervical adenocarcinoma although there was no significant difference.

EP-1970

Dose to organs at risk on CT versus MRI based brachytherapy for cervix cancer

K. Akbarov¹, I. Isayev¹, E. Guliyev¹, N. Aliyeva¹

¹National Oncological Centre, Radiotherapy, Baku, Azerbaijan

Purpose or Objective: Brachytherapy is one the most important components in the treatment of cervical cancer. Recently 3D planning for brachytherapy has been used which could be done both by CT and MRI imaging based. We compared the high risk clinical target volumes contoured on CT and MRI and dose distribution in the target volumes and organs at risk.

Material and Methods: Twenty three patients with IIA-IIIb stage cervical cancer were planned for HDR brachytherapy with ring-tandem applicators. Treatment consisted of four 7 Gy fractions by two insertion procedures. On MRI and CT sets we contoured HR CTV and organs at risk on 42 plans: for 19 patients two plans and for four patients only one. Medical physicists received task to make planning on CT and MRI images independently at the same day before irradiation. The mean HR CTV volume, dose received by at least 90% of the volume (D90) and the dose to 2 cc for the organs at risk were evaluated.

Results: The mean volume of HR CTV was 77.5 cc on CT based contours and 60.3 cc on MRI imaging. This difference in HR CTV volume reflected on the dose to organs at risk - physicists have to increase it to achieve prescribed dose in target volume. Thus, while assessing mean D2cc for rectum, bladder and sigmoid we find out that it was lower in case of MRI based planning compare to CT based planning - 66.2 Gy and 70.3 Gy, 85.1 Gy and 89.6 Gy, 62.3 Gy and 66.7 Gy respectively. Mean D90 also was significantly higher in MRI compared to CT imaging plans - 94,2% versus 79,4% of prescribed dose.

Conclusion: In spite that superiority of MRI compared to CT imaging based contouring and planning for HR CTV dose distribution has been already showed in previous studies we found that it also allows indirectly significantly decrease the dose to organs at risk during HDR brachytherapy for cervical cancer.

EP-1971

Result of IGBT for cervical cancer using ring applicator with 'Siriraj Ring Cap' extension

P. Dankulchai¹, Y. Chansilpa¹, J. Petsuksiri¹, L. Tuntipumiamorn¹, P. Nakkasair¹, C. Kakanaporn¹

¹Faculty of Medicine Siriraj Hospital Mahidol University, Radiology, Bangkok, Thailand

Purpose or Objective: To retrospectively assess treatment outcome of image guided brachytherapy (IGBT) with or without hybrid technique for cervical cancer using VariSource™ titanium ring applicator with 'Siriraj Ring Cap' extension (as figure 1). In case of narrow vaginal opening, hybrid brachytherapy technique could be performed using this applicator with extension.

Figure 1: VariSource™ titanium ring applicator with 'Siriraj Ring Cap' extension

Material and Methods: Between January and December 2014, 29 patients with locally advanced cervical cancer were underwent combination external beam radiotherapy with or without concomitant chemotherapy and IGBT with or without hybrid technique using VariSource™ ring applicator with ‘Siriraj Ring Cap’ extension (at least one fraction). 117 dosimetric planning and clinical outcome of treatment were evaluated.

Results: For high risk clinical target volume (HR CTV) the median was volume 37.4 cm³ (range; 15.3-76.1 cm³) and the median of D90 was 85.3Gy (range; 76.4-90.5Gy). The median of D2cc for bladder, rectum, sigmoid, and bowel loop were 84Gy (range; 68.3-89.7Gy), 66.1Gy (range; 56.8-76.3Gy), 65.6 (range; 49-77.1Gy), and 61.9Gy (range; 45.8-78.1Gy), respectively. 81.2% (95 of 117 plans) were performed using VariSource™ ring applicator with ‘Siriraj Ring Cap’ extension, while mean of coverage of the HR CTV was 89.2% (range; 57-99%). 18.8% (22 of 117 plans) were applied using tandem with ovoids, and mean of coverage of the HR CTV was 79.9% (range; 53-96%). Median follow up was 10.6 months. The actuarial 1 year loco-regional recurrence free survival rate was 90.5% (95% confidence interval (CI); 67-98%), progression free survival rate was 85.7% (95% CI; 62-95%), and overall survival rate was 95.4% (95% CI; 71-99%). One patient had a grade 2 late rectal complication. No grade 3-5 late complications have been recorded so far.

Conclusion: IGBT with or without hybrid technique using VariSource™ titanium ring applicator with ‘Siriraj Ring Cap’ extension is applicable for locally advanced cervical cancer resulting in an excellent local control rate and limited morbidity.

EP-1972

Application of adaptive brachytherapy in the treatment of cervical cancer in accelerated mode

O. Kravets¹, A.A. Fedyanina¹, O.V. Kozlov¹, M.A. Kuznetsov¹, A.V. Gavrilova¹, E.A. Romanova¹

¹N.N. Blokhin's Federal State Scientific Institution Russian Cancer Research center, Radiosurgery department, Moscow, Russian Federation

Purpose or Objective: The effectiveness of radiation therapy in the management of cervical cancer of all stages is well established. Radiation therapy usually consists of a combination of external beam therapy and brachytherapy. Further exploration of new approaches and methodologies is a promising direction of development. Given the radiobiological aspects and an important economic factor, i.e. reduction of hospital stay. The aim of this study was to estimate the effectiveness of the treatment of cervical cancer patients using adaptive image-guided brachytherapy (IGBT) during split course.

Material and Methods: In the period from May 2014, 38 patients with primary cervical cancer were treated with combined radiotherapy using the new split-adaptive methodology for IGBT. We used conformal radiation techniques: BOX method, IMRT or RapidArc. Total dose on the pelvic area and regional metastases was 50 Gy. Further HDR IGBT brachytherapy was followed with dosimetry planning MRI - images. The treatment was on 1st and 2nd, 8th and 9th days, ring tandem applicators implantation under general anesthesia. Between the fractions 1 and 2 and 3 and 4, the patients were with applicator under the supervision of medical staff during the day. Monitoring planning was conducted according to MRI-studies; as a result treatment plan was composed for every 2 fractions. The position of the applicator in relation to the tumor and critical organs during the day doesn't change provided that the methodology is being correctly observed. Dose plans were optimized for maximal tumor dose (D90) and coverage (V100 and V80). The dose parameters in the target volume are the following: D 90 = 7.3 (5.9-9.1) Gy, V 100 = 91.5 (79.2-99.1) %, V 80 = 97.8 (90.5 -100). Of the patients it was T2bN0M0 - 7 patients, T3bN0M0 - 5, T2b-3bN1M0 - 18, T2b-3bN1M1 - 8.

Results: in the results the values of dose rates (D 2 cc / D 0,1 cc) to organs of risk (bladder, rectum and sigmoid) are the following: 3.7 (1.7-7) / 4.8 (2.2 -9.4) Gy; 3.1 (1.2-6) / 4.2 (1.4 - 8.3) and 3.9 (2.2-5.7) / 5.5 (3.5 -7.6) Gy. During follow-up time for 12 months no any acute or late toxicity of grade 2 were observed and not observed any difference in comparison with the fractionation scheme used previously. No one local recurrence were observed, regional recurrence in 2 (2 and 7 months), distant metastasis in 1 (12 months). The patients have undergone the treatment satisfactorily. The number of surgical implantations decreases from 4 to 2. According to preliminary data, local radiation reactions are not multiple.

Conclusion: The main advantage of this method is the dose delivery in a shorter period of time, which allows for a greater control of the tumor. This method allows to reduce the time of course of brachytherapy to 9 days. Evaluating the effectiveness of treatment shows good tolerance of this treatment with satisfactory results. This clinical study is currently ongoing.

EP-1973

MRI-guided brachytherapy and 3D/IMRT radiotherapy for cervical carcinoma. A prospective study

E. Villafranca Iturre¹, P. Navarrete Solano¹, A. Sola Galarza¹, J.C. Muruzabal², C. Sánchez³, M. Rico¹, M. Errasti¹, M. Barrado¹, M. Campo¹, I. Visus¹

¹Hospital of Navarra, Radiation Oncology, Pamplona, Spain

²Hospital of Navarra, Gynecology, Pamplona, Spain

³Hospital of Navarra, Radiology, Pamplona, Spain

Purpose or Objective: To evaluate dosimetric and clinical findings of MRI-guided HDR brachytherapy (HDR-BQ) for cervical carcinoma.

Material and Methods: From 2008 to 2014: 50 patients. All patients had a CT, MRI and pelvic-para-aortic lymphadenectomy. Treatment: pelvic(+/-)para-aortic3D/IMRT radiotherapy(45Gy) and weekly cisplatin followed by HDR-BQ and pelvic node/ parametrial boost 60Gy. Two implants at week 6th and 7 th were done: 5 fractions of 6Gy and from 2011 4 fractions of 7Gy. MRI/TAC was done in each implant. There where defined: GTV, CTV-IR, CTV-IR; OAR: rectum, bladder and sigmoid.

Results: Patients: T1b2-T2a: 3p, T2b 36p, T3a: 2p; T3B 9p; N0: 31p, N1 19p. With a median follow up of 50.6 months(8.1 - 89.2 months), 5 patients had local recurrence, 6 lymph node recurrence, 6 distant metastasis and 36 without recurrence. Local control at 5 years was 88%; 1b2-11B: 93%, 111: 70%. (p:0.07). Lymph node Regional Disease Free Survival(RDFS) 5y was 88%; 1B2-11B: 89%, 111: 83% (p:ns); for pN0: 94%; pN+ iliac-para-aortic: 77% (p: 0.08). Metastasis Free Survival 5y was 78%; 11BN0: 78%, 11BN1: 89%, 111: 63%. Overall

survival(OS) at 3 years was 82% and at 5 years was 63%; IB2-IIB 5yr: 70%; III 5yr: 27% (p: 0.01); For pN0 5yr 74%; pN+ iliac-paraortic 5yr: 45% (p: 0.03).

Dosimetric parameters: D90<6-7Gy(prescription dose) in 5p before 2011(since then interstitial implants were associated in 47%). The Local RFS: D90< 6Gy 87%, D90> 6Gy: 90% (p:ns); OS: D90< 6Gy 58%, D90> 6Gy: 67% (p:ns). D2cc-Sigma: 1.7-6.2 Gy (md 3.8 Gy); D2cc-rectum: 2-6.1 (md 4.2); D2cc-bladder 3.4-5.7 (md5.25).

Conclusion: Use of interstitial HDR-BQ guided by RM increased CTV-HR dose and local control, like EMBRACE results. Nodal boost improves RDFS and perhaps OS.

EP-1974

Application of the self-made applicator in brachytherapy for recurrent cervical cancer at vaginal

G. Cheng¹, Z. Zhao¹, M. He¹, D. Shi¹

¹China-Japan Union Hospital of Jilin University, Department of Radiation Oncology, Changchun, China

Purpose or Objective: To elaborate the application of self-made applicator which invented by our department (Patent No: 201420583680.X) in brachytherapy for recurrent cervical cancer at vaginal residue. This study especially pays attention to the doses evaluation of GTV and the OARs in brachytherapy by this technical.

Material and Methods: 14 patients from 2013-2014 in our hospital who suffered from recurrent cervical cancer at vaginal residue in 0.5-3.5 years after radical hysterectomy and external beam radiotherapy (45 Gy/25 fractions) ±chemotherapy ±brachytherapy were treated with MRI based and ultrasound guided brachytherapy using the self-made applicator. The self-made applicator was made of silica balls in matrix distribution connecting with a hole in front and behind it, making it formed into a straight line. The diameter of silica ball is 1 cm, the aperture of the hole is 1.5 mm. Therefore this self-made applicator could provide with the needle inserting smoothly and tidy and the depth of the needle can be adjusted. Moreover, this applicator can be used by superposition of multilayer, so it could be easily adapted to any shape. The prescribed dose of brachytherapy was 7 Gy×3-6 fractions, one week apart was planned. The GTV included the tumor, the CTV comprised the GTV with a 10 mm circumferential margin and OARs were delineated. And then we recorded the GTV D90, D100 and D2cc of rectum, small intestines, bladder and sigmoid colon under the self-made applicator.

Results: After plenty years of using the conventional applicators in brachytherapy, we found the radical hysterectomy cause the vaginal cuff end stenosis, the top of the conventional applicator, such as the Utrecht interstitial applicator cannot get close to the cancer region well which tumor invaded towards pelvic, so it was unable to achieve a high dose to the tumor, or it may induce an excess dose to normal tissues. In this research, we found the self-made applicator showed a high GTV dose and an acceptable OARs dose. Specifically, the GTV D90 and D100 for using self-made applicator were 724±64 cGy and 436±39 cGy, and the average D2cc for rectum, sigmoid colon and bladder was 370±21, 265±16 and 423±44 cGy, the total dose when transformed to EQD2 models was under the constraints.

Conclusion: The self-made applicator show excellent dose parameters on dose coverage and sparing exposure to OARs, which was more beneficial to the recurrent cervical cancer at vaginal residue invaded towards pelvic.

EP-1975

18F[FDG]PET guided brachytherapy for carcinoma of the uterine cervix

S. Meregalli¹, G. Gardani¹, S. Brenna¹

¹Ospedale S. Gerardo, Radiotherapy, Monza, Italy

Purpose or Objective: Concomitant chemo-radiation and intracavitary brachytherapy (BT) is the standard treatment

for locally advanced cervical carcinoma. In an our previous experience we reported the feasibility of [18F]FDG-PET in the BT treatment planning as functional imaging technique able to visualize neoplastic tissue. The purpose of this analysis was to evaluate, after an adequate follow-up, the site of recurrence and, in case of local relapse, if it was PET positive during BT. Survival and the late toxicity were also analysed.

Material and Methods: From June 2007 to May 2010, thirteen women with locally advanced cervical carcinoma were enrolled into the study. All patients underwent external beam radiation therapy (EBRT) to whole pelvis (box technique to a total dose of 50.4 Gy) with weekly concomitant cisplatin chemotherapy. HDR BT was performed weekly (5 Gy per fraction; 5 to 6 fractions). All BT fractions were planned by CT scan and, in the first and in the fourth fraction, FDG-PET/CT was also employed. Local control rate, progression free survival, overall survival and treatment related toxicities under RTOG criteria were evaluated

Results: At the median follow-up of 61 months, the estimated 5-year progression-free survival (PFS) and the 5-year overall survival (OS) were 56% and 70% respectively. The 5-year local control rate was 84.6%. Only one patient had a local relapse corresponding to a PET positive area in BT guided planning. No G3-4 acute or late gastrointestinal or genitourinary toxicity has been recorded.

Conclusion: In our experience, PET in BT planning of the cervical carcinoma gives some added useful information. The main goal of our analysis remains to define the site of possible recurrence: the recognition of a local relapse in PET positive area may suggest the opportunity of dose escalation

EP-1976

Concomitant radio-chemotherapy and brachytherapy for advanced cervical cancer: outcomes and toxicity

L. Pollara¹, F. Cuccia¹, V. Figlia¹, A. Palmeri¹, M. Gucci¹, N. Luca¹, D. Aiello¹, G. Evangelista², F. Sciumè²

¹Scuola di specializzazione di Radioterapia-Università degli studi di Palermo, ARNAS Civico Palermo, Palermo, Italy

²Ospedale ARNAS Civico, U.O. Radioterapia Oncologica, Palermo, Italy

Purpose or Objective: To evaluate clinical outcomes and acute/late toxicities in patients with locally advanced cervical cancer treated with chemotherapy (CT) and external beam radiation therapy (EBRT), followed by high-dose rate brachytherapy (HDR-BRT) delivered with the Fletcher-Williamson tandem and ovoid applicator

Material and Methods: we evaluated 40 patients, median age 57 years (range 40-83), treated between January 2007 and October 2014. According to FIGO classification, 10% were stage IB, 7,5% IIA, 45% IIB, 5% IIIA, 27,5% IIIB, 5% IV. All patients underwent pelvic +/- paraaortic EBRT (10/40 patients); following the GEC-ESTRO recommendations, fractionation scheme for pelvic irradiation was 45-50.4 Gy in 25-28 daily fractions (1.8 Gy/fr). The addition of a parametrial boost (10 Gy in 5 daily fractions) was performed in 10/40 patients (25%). BRT with Fletcher applicator was performed in all patients after EBRT, with the fractionation scheme 22,5 Gy in 5 fractions (twice a day with 6 hours inter-fraction interval). Concomitant CT was administrated in all patients, neoadjuvant CT was administrated in 15%. Treatment related toxicity was evaluated weekly during therapy and at each follow-up control, using RTOG/EORTC Radiation Morbidity Criteria. Response was investigated with periodical cervical cytology and CT scans; every treatment was evaluated in terms of BED10 and EQD2, with a median BED10 of 90.43 Gy (range 75.5-104.1) and median EQD2 of 75.33 Gy (range 86.7-62.9).

Results: With a median follow-up of 30 months (range 12-87), we observed acute/late genitourinary and gastrointestinal toxicity ≥ grade 2 in 10% of patients, including one G4 GI acute toxicity (diarrhea requiring parenteral support)

occurred during concomitant EBRT-CT and resolved after a week of medical therapy. At 12 months from the end of treatment, response rate was 87.5% (35/40); we recorded 4 persistent disease and 1 locoregional recurrence (after 6 months), occurred in all patients with stage III. After 12 months of follow-up, we reported disease progression (1 central and 1 systemic) in 2 patients (5%), respectively at 17 and 48 months from the end of radiation therapy. Patient showing central relapse underwent radical hysterectomy and patient with systemic disease started chemotherapy.

Conclusion: In our experience, the association of concomitant EBRT-CT and HDR-BRT (Fletcher applicator) represents a well tolerated treatment for patients with advanced cervical cancer, with good results in terms of acute and late toxicity and local control

EP-1977

The importance of immobilization of gynecological applicators in high dose rate brachytherapy

S. Pella¹, H. Mikko², D. Nicolae³, C. Casey⁴, C. Shereen⁴, P. Janeil⁴

¹South Florida Radiation Oncology- Florida Atlantic University & Advanced Radiation Physics Inc., Medical Physics, Boca Raton, USA

²University of Toronto, Medical Physics, Toronto, Canada

³Florida Atlantic University, Physics, Boca Raton, USA

⁴Florida Atlantic University, Physics, Boca Raton, USA

Purpose or Objective: To investigate the need for the implementation and development of immobilization and localization devices and other improvements in safety measures in addition to those currently in use in current HDR treatment protocols involving gynecological applicators.

Material and Methods: 55 treatment plans from 27 cervical cancer patients treated with three to 5 intra-cavity cylinder insertions were used. We performed a retrospective study of a dosimetric evaluation due to a possible minor displacement of the cylinder after scanning to the treatment delivery time. The 55 plans that were dosimetrically analyzed post treatment involved treatments for 27 different patients. 22 patients had a hysterectomy with bilateral salpingo-oophorectomy. In 16 of these twenty two patients the procedure had an abdominal hysterectomy bilateral salpingo-oophorectomy). Three of the patients had hysterectomies only. The vaginal cylinder applicators which were placed within the patients by a radiation oncologist for administering the treatments included the Capri, Miami, and multi-lumen catheter applicator.

Results: For the 55 patients whose point dose data were gathered, dose variation at the hottest spot due to a simulated 1mm displacement in the superior inferior direction calculated by normalizing to the average of the endpoints was found to have a minimum value of 0.02% and a maximum value of 12.66% with an average value of 1.43% and a standard deviation of 2.02%. Dose variation at the hottest spot due to a simulated 1mm displacement in the medial lateral direction calculated by normalizing to the average of the endpoints was found to have a minimum value of 12.32% and a maximum value of 22.71% with an average value of 16.96% and a standard deviation of 2.76%. The measurement of dose variation due to a displacement of one degree of rotation along the central axis of the applicator was found to have a minimum value of 0.00% and a maximum value of 2.76% with an average value of 0.63% and a standard deviation of 0.62%. The standard deviation and the mean nearly coincide. The measurement of dose variation due to a displacement of five degrees of rotation along the central axis of the applicator was found to have a minimum value of 0.06% and a maximum value of 13.71% with an average value of 2.15% and a standard deviation of 3.00%.

Conclusion: The point dose variation due to hypothetical 1 mm medial lateral displacement of a vaginal cylinder applicator make a difference in terms of Grade 1 rectal toxicity as defined by Common Terminology Criteria for

Adverse Events v 4.0 in some patients receiving HDR VCBT alone or shortly after EBRT. The point dose variation due to hypothetical 1 mm medial lateral displacement of a vaginal cylinder applicator according to this analysis did reach a crudely obtained cutoff value for RTOG grade greater than or equal to 2 late rectal morbidity for any of the patients receiving HDR VCBT alone or shortly after EBRT.

EP-1978

Individualized approach to brachytherapy in cervical cancer patient: a case report study.

B.H. Zobec Logar¹, R. Hudej¹

¹Institute of Oncology Ljubljana, Radiotherapy, Ljubljana, Slovenia

Purpose or Objective: In some cervical cancer patients with extensive parametrial involvement, not all of the tumor can be sufficiently covered with MRI-based image guided brachytherapy using a standard intracavitary/interstitial applicator. An approach with individually designed applicator with oblique needles offers a possibility of better tumor dose coverage in these patients. In this study we tested the feasibility of the 3D printing for the individualized brachytherapy applicator add-on.

Material and Methods: A patient in this case report study had extensive parametrial involvement to the pelvic wall. In order to improve the tumor dose coverage we decided to use additional oblique needles for the second application. A preplan for the second application was created based on the dosimetry information from the first application. The information on the optimal location of the oblique needles in the preplan was used to design an individualized interstitial template cap for the ring applicator, which was manufactured with a 3D printing technique. The whole procedure of the cap design and manufacture was performed in 5 days.

Results: The HR-CTV coverage at the time of the first application (Figure 1a) was suboptimal (D90=69%, D100=35%, V100=77%).

The volume of the HR-CTV not covered with the prescribed isodose was 19.8 ccm. Oblique needles applied at the time of the second application contributed significantly to a better dose coverage of HR-CTV (D90=109%, D100=55%, V100=93%). The part of the volume not sufficiently covered with the prescribed dose in the first application was boosted using only oblique needles at the end of the second treatment until the dose restrictions for the OAR were reached (Figure 1b). DVH parameters for HR-CTV of the second application were improved accordingly: D90=119%, D100=61%, V100=96%. The volume of the HR-CTV not covered with the prescribed isodose was reduced to 2.4 ccm. The position on the ring, oblique angle and the insertion depth of the oblique needles in the second application were measured on the MR images and compared with the pre-plan. The average differences were relatively small (position on the ring: 10°, oblique angle: 8°, insertion depth: 4 mm).

Conclusion: Individualized approach to cervical cancer patients with extensive parametrial involvement at the time of brachytherapy can contribute significantly to an improved dose coverage of the HR-CTV. An individualized 3D printed interstitial cap for the ring applicator with oblique needles is an efficient option for these patients.

EP-1979

Aduvant vaginal brachytherapy without external beam radiotherapy for endometrial cancer

P. Vargas Arrabal¹, R. Del Moral¹, I. Tovar¹, M. Zurita¹, R. Guerrero¹, I. Linares¹, J. Expósito¹, C. Prieto¹, S. Rodriguez¹, A. Ruiz¹

¹Hospital Universitario Virgen de las Nieves, Radiation Oncology, Granada, Spain

Purpose or Objective: The aim is to report the results obtained in patients diagnosed of endometrial carcinoma stage IA-IIA treated with surgery followed by adjuvant brachytherapy at our institution.

Material and Methods: From 2006 until 2013, 116 patients with endometrial carcinoma stage IA-IIA have been treated with surgery and exclusive vaginal brachytherapy. Median age of the series was 62 years. Total hysterectomy, double anexectomy, pelvic lymphadenectomy and peritoneal washing was made in 61,4 %. The majority of the pathological FIGO stages were IB (77,2 %). Exclusive brachytherapy was performed using vaginal cylinders with 3 cm of diameter (50,9 %). The reference isodosis covering the proximal 3 cm of the vagina (96,4 %). The dose was specified at 5 mm distant from the surface of the cylinder. Dose schedule with high dose rate brachytherapy was 21 Gy in 3 fractions. The median of dose equivalent received in the rectum was 31,8 Gy and in bladder 38 Gy.

Results: At the moment of this analysis there are 4 relapses: 2 of them live with disease, and 2 death for tumor; 110 cases live without disease (94,82 %), and 2 cases death for another cause. With median follow-up of 26 months, free disease survival was 90.2% and 2 years overall survival was 88.3%. No toxicity was reported in the 52,6%, and when it was present the most frequent was cystitis (12.3%).

Conclusion: The exclusive vaginal brachytherapy is effective in ensuring vaginal control, with few toxic effects. So, this schedule should be an adjuvant treatment for these patients.

EP-1980

Lower dose per fraction brachytherapy for patients with stage 1 endometrial cancer following surgery

J. Kim¹, K.J. Lee¹, K. Park¹, J. Lee¹, Y.J. Kim¹, W. Jung¹, S.C. Kim², H.S. Moon², W. Ju², Y.H. Kim²

¹Ewha Womans University, Radiation Oncology, Seoul, Korea Republic of

²Ewha Womans University, Gynecology and Obstetrics, Seoul, Korea Republic of

Purpose or Objective: The purpose of this study is to analyze the efficacy and complication rates of postoperative high

dose rate (HDR) vaginal brachytherapy (VBT) to determine whether VBT with lower dose per fraction (3-4 Gy/fraction) is as effective as pelvic external beam radiotherapy (EBRT) for patients with stage 1 endometrial carcinoma

Material and Methods: From March 2000 to April 2014, 43 patients with FIGO stage I endometrial cancer underwent adjuvant radiotherapy following surgery. Twenty five patients received postoperative HDR VBT alone, while 18 patients received postoperative EBRT to the whole pelvis. Among these patients, three patients were treated with EBRT plus VBT. The median treatment dose of EBRT was 50.0 Gy (45.0-50.4 Gy) and HDR VBT dose was five to six fractions of 3 or 4 Gy to a total dose of 15-24 Gy. The tumor dose was prescribed at a depth of 5mm from the cylinder surface and delivered twice per week.

Results: The median follow up period of all patients was 54.4 (range 9-142) months. Five year disease free survivals (DFS) and overall survivals (OS) for all patients were 91.5% and 91.2%, respectively. Five year DFS of EBRT and brachytherapy was 87.2% and 96.0%, respectively (p=0.46), and five year OS of EBRT and brachytherapy was 86.9% and 95.7%, respectively (p=0.43). There were no differences in 5 year DFS or OS according to radiation treatment group. There were no locoregional recurrences for all patients. Two patients who received EBRT and one patient who received brachytherapy alone developed distant metastatic disease. There were one patient who had grade 3 gastrointestinal complication and one patient who had pelvic bone insufficiency fracture. Two patients who had severe complication were treated with EBRT.

Conclusion: HDR VBT with lower dose per fraction alone showed high DFS and OS with no severe adverse effect. HDR VBT with small fraction size may be adequate for early stage endometrial cancer following surgery.

EP-1981

Comparing MRI vs CT based applicator reconstruction and planning techniques for adaptive cervix cancer BT

F. Cheung¹, A. Chang², T. Wong¹, F. Choi², M. Chan², I. Soong², A. Law², M. Lee¹, R. Yeung²

¹Pamela Youde Nethersole Eastern Hospital, Department of Medical Physics, Hong Kong, Hong Kong SAR China

²Pamela Youde Nethersole Eastern Hospital, Department of Clinical Oncology, Hong Kong, Hong Kong SAR China

Purpose or Objective: Controversies still exist in the method of treatment planning and applicator reconstruction in adaptive cervix brachytherapy. This study aims to compare any difference between MRI and CT applicator reconstruction and the treatment planning process at our institution.

Material and Methods: Our analysis included 15 patients from our institution with stage IB2-IVA cervical cancers between January to October 2015, all patients treated with chemoradiation and brachytherapy. We followed the Vienna schedule for HDR brachytherapy at week 6 and 7, with 2 weekly insertions with 2 consecutive fractions per week. MRI- and CT- based treatment planning and applicator reconstruction were done for every patient. Contours and dosimetry of tumor target (HRCTV D₉₀) and organs at risk (D_{2cc} bladder, rectum, sigmoid and small bowel) were compared. Applicator reconstruction techniques, possible challenges and errors between the 2 imaging modalities were analysed.

Results: Both CT- and MR- based applicator reconstruction uncertainties were less than 1 mm for either tandem-and-ovoids (T&O) or tandem-and-ring (T&R) applicators. Compared with T&O applicators, use of rigid T&R applicators gave more accurate applicator reconstruction. When an applicator library was used, the T&O reconstruction uncertainties always occurred in posterior-anterior direction while T&R reconstruction uncertainties were found when it rotated. Applicator holes for interstitial needles could provide additional markers to define correct applicator rotation on MRI. The D_{2cc} rectum value was the most sensitive

to the T&O reconstruction. Without availability of MRI markers for needle visualization, manual MR-based needle reconstruction could be challenging especially in tissues of similar signal intensities. Measurement of remaining interstitial needle length outside patient could open up a potential solution path.

Conclusion: Despite minor distortions around centre of the magnet, MRI distortions do not play a major role in applicator reconstruction uncertainties. Both CT- and MR-based applicator reconstruction are feasible when used with applicator library, providing accurate source pathway reconstruction. Applicator holes for interstitial needles and physical measurement of needle outside patient could provide valuable information to improve the reconstruction accuracy.

EP-1982

Adjuvant brachytherapy of the lip cancer after surgical resection

A. Chyrek¹, G. Bielęda¹, A. Chicheł¹

¹Greater Poland Cancer Centre, Brachytherapy Dep., Poznan, Poland

Purpose or Objective: The aim of this work is to evaluate outcomes after adjuvant brachytherapy of the lip cancer after surgical resection with close (<5mm) or positive margins.

Material and Methods: A total of 20 patients (3 women and 17 men in median age of 65,5) diagnosed between 2010 ad 2014 with clinical T1 - T2 N0 lip carcinoma were treated primarily by surgical tumor resection with or without lymphadenectomy. After histopathological result (40% positive, 60% close margins) they were qualified for adjuvant brachytherapy. At the discretion of the attending physician 25% of patients were treated by high dose rate (HDR) and 75% by pulse dose rate (PDR) brachytherapy. The mean biologically effective dose (BED) given to the clinical target volume were 71,285 Gy (range 62,6 - 75 Gy). The mean follow up (counted from the end of BT course to the last control visit or recurrence) were 24 months. For statistical calculations we used the Kaplan-Meier method and the U Mann-Whitney test.

Results: Sole patient in the group had nodal recurrence 6 months after treatment. The rest of the patients had no evidence of recurrence during the follow up. Estimated 4-year disease-free survival rate was 95%. The acute skin toxicity according to RTOG scale was 65%, 30% and 5% for grade I, II, and III respectively; the late skin toxicity was 25%, 5% and 5% for grade I, II, and IV respectively. We also found a statistically significant correlation between the higher BED and appearance of acute toxicity greater than I grade ($p=0,014$) and occurrence of any late toxicity ($p=0,047$).

Conclusion: Adjuvant brachytherapy in the treatment of the T1-T2 lip tumors achieves a long loco-regional control with relatively low toxicity and it may be taken into consideration for the adjuvant therapy of the lip cancer after surgical resection with close (<5mm) or positive margins. Such regimen allows to prevent reoperations along with large reconstructive surgery.

EP-1983

Intensity modulated perioperative interstitial HDR brachytherapy for recurrent neck metastases

T. Soror^{1,2}, G. Kovács¹, I.U. Teudt³, M. Ritter⁴, C. Melchert¹, J.E. Meyer⁵, B. Wollenberg⁴

¹Interdisciplinary Brachytherapy Unit, University of Lübeck, Lübeck, Germany

²National Cancer Institute- Cairo University, Dept. of Radiation Oncology, Cairo, Egypt

³Asklepios Klinik Altona, Dept. of Otolaryngology- Head and Neck Surgery, Hamburg, Germany

⁴University of Lübeck, Dept. of Otolaryngology- Head and Neck Surgery, Lübeck, Germany

⁵Asklepios Klinik St. Georg, Dept. of Otolaryngology- Head-Neck and Plastic Surgery, Hamburg, Germany

Purpose or Objective: Patients with head and neck cancers can develop recurrences in previously treated areas, which usually involve the neighbor carotid artery. In the majority of these patients a complete surgical resection is not possible, R1/R2 resections are frequent. We proved the feasibility and long-term outcome of perioperative intensity modulated brachytherapy (IMBT) as a salvage treatment option for advanced neck metastases in combination of carotid artery preservation.

Material and Methods: From 2006 to 2014, nine patients at the University Hospital of Schleswig-Holstein Campus Luebeck had received an interdisciplinary salvage treatment with debulking surgery and perioperative HDR-IMBT for advanced recurrent neck metastases. Median age was 53 years, range: 38- 66, the mean follow-up was 66 months. Surgery was performed with primary wound closure in seven patients, while myocutaneous flap was used in two patients. Active phase of IMBT started 4-12 days following surgery. The prescription dose was 2.5Gy twice daily (average total dose: 27Gy, range: 15-30Gy). Dose non-homogeneity ratio (DNR) never exceeded 0.42. We used the manual dose-volume optimization method and planned biologically correct hot/cold spot areas within the dose distribution. The reference isodose was defined within a maximum of 10 mm lateral distance from the interstitial tube and the Dmax was defined in 400% on the catheter surface.

Results: For initial treatments, all patients received previous surgery; eight patients received also external beam radiation with an average dose of 64Gy. Two and five year overall survival estimates were 78% and 67% respectively. The median survival rate was 65 months. Only two patients had a second neck recurrence after 62 and 65 months. Early toxicities (grade I-II) recorded in four patients and were limited to local edema and skin infection, no treatment related grade 3 or 4 toxicities recorded.

Conclusion: Salvage debulking surgery combined with perioperative HDR-IMBT seems to be feasible and safe treatment option for selected recurrent neck metastases with minimal treatment related toxicities.

EP-1984

Interstitial brachytherapy for the isolated lymph node metastasis from different solid cancers

M. He¹, G. Cheng¹, H. Zhao¹, Z. Zhao¹

¹China-Japan Union Hospital of Jilin University, Department of Radiation Oncology, Changchun, China

Purpose or Objective: To assess the feasibility, safety and clinical outcome of MRI based and ultrasound guided high-dose-rate interstitial brachytherapy technical in isolated lymph node metastases from different solid cancers.

Material and Methods: From January 2013 to May 2014, 11 patients (six males and four females) with isolated nodal metastases were treated with MRI based and ultrasound guided high-dose-rate brachytherapy. All patients had previously been treated with radical radiotherapy or chemoradiation with or without surgery. Seven lymph node metastases were cervical, three metastases were at the supraclaviculares, one metastasis located at a left inguinal nodal. Pathologically, six metastases were squamous carcinoma, three were small cell cancer and two were adeno carcinoma. The mean lesion diameter was 38.5 mm (range 21.0- 78.0 mm). The brachytherapy were achieved by inserting the titanium needle to the target, avoiding vascular and organ injury under the ultrasound guidance, following by MRI scanning and delineating the targets. The metastases were treated by single-fraction irradiation using the afterloading technique using an Iridium-192 radiation source. The prescribed salvage dose of brachytherapy was 5

Gy/fraction, twice- daily to a total dose of 10-20 Gy (one week apart) according to the dose of the external beam radiotherapy. The total dose ranged from 76-84 Gy when transformed to EQD2 models. Patients were followed up by contrast-enhanced CT or MRI 4 weeks and then every 3 months after the end of treatment. The primary end point was local tumor control. Secondary end points of the adverse events, distant metastases and progression-free survival were also included.

Results: The first follow-up examination after 4 weeks revealed 10/11 coverage of all nodal metastases treated. There was no peri-interventional mortality or major complications. The mean follow-up period was 12.2 months (range 7-15 months). After a median follow up of three months, the median local tumor control was 90%. 2 out of 10 patients (20%) showed local tumor progression 6 and 8 months after brachytherapy. 2 patients (20%) who died of distant metastasis. The grade III-IV complications occurred in 1 patient (10%). The mean progression-free interval was 13 months (range 6-16 months).

Conclusion: We consider that the interstitial brachytherapy technical will provide a relative high and accurate dose irradiation to bulky lymph node metastasis for improving the local tumor control in patients with different solid cancers.

EP-1985

Proposal to improve commissioning of HDR brachytherapy with results from the first 2 SagiNova units

A.L. Palmer¹, O. Hayman², A. Toussaint³, O. Sauer³

¹Portsmouth Hospitals NHS Trust & University of Surrey, Medical Physics Department, Portsmouth, United Kingdom

²Portsmouth Hospitals NHS Trust, Medical Physics Department, Portsmouth, United Kingdom

³University of Würzburg, Department of Radiation Oncology, Würzburg, Germany

Purpose or Objective: Commissioning of HDR brachytherapy treatment equipment is essential to avoid errors and assure quality. However, it is estimated that worldwide, less than one-quarter of centres undertake robust local commissioning tests at installation [1], important checks may be omitted [2], or systematic errors may remain [3]. The purpose of this work is to: (i) reinforce the need for local HDR commissioning and propose a list of recommended tests; (ii) publish results of the commissioning for a new-to-market HDR brachytherapy system from two centres.

Material and Methods: A literature review was conducted on existing guidance for HDR system commissioning, HDR treatment errors and known factors affecting sub-optimal quality. The case for robust local commissioning of HDR equipment was assessed in terms of mitigating potential errors and improving quality of treatment delivery. A schedule of required commissioning tests was established and implemented at two centres, in England and Germany, for the commissioning of a new HDR brachytherapy treatment system, SagiNova (Eckert & Ziegler Bebig GmbH) with Co-60 sources.

Results: Evidence was found that errors do occur [4], particularly in the absence of robust commissioning and QC. There is little contemporary guidance for commissioning of HDR brachytherapy treatment equipment, which is required to build on the QC guidance in ESTRO Booklet No. 8 from 2004. The table provides our proposal for efficient, robust, and easily implemented commissioning tests. For the SagiNova system, results from the two centres showed satisfactory performance in all tests. The mean error for source dwell positions in straight catheters was 0.5 mm (± 0.5 mm $k=2$) and in clinical treatment applicators was 0.6 mm (± 1.0 mm $k=2$) compared to TPS planned positions. The 'end to end' system check with IPEM 'BRAD' system [5] had prescription point $<0.4\%$ ($\pm 2.5\%$ $k=2$) and 97% gamma pass

rate (3%, 2mm) compared to TPS calculations. By comparing results between centres a quality improvement was identified and implemented comprising an update of the dwell-position database at one centre.

Minimum proposed HDR commissioning tests

- Electrical and mechanical safety
- Radiation shielding (treatment unit and environment)
- Equipment safety interlocks (hardware and software)
- Manufacturer acceptance test schedule
- Source dwell positions in straight catheters (QC check system e.g. ruler, video camera, and autoradiographs)
- Source dwell positions in all clinical treatment applicators (autoradiograph dwells with radiograph applicators)
- Dwell times (accuracy, linearity, correction for transit dose)
- Transit times and transit dose (to-, from-, inter-dwell)
- Source strength (certificate, measurement, TPS, treatment unit)
- Decay correction (TPS and treatment unit)
- TPS applicator reconstruction (accuracy, consistency with physical applicators, validation of source path)
- TPS dose calculation (source data, point doses, isodose, DVH, independent dose calculation system)
- 'End to end' system check (image applicators in phantom, reconstruct, plan, deliver, measure dose)
- Additional functionality checks (in vivo dosimetry, TPS functions, image fusion)

Conclusion: It is not sufficient to rely on type-testing by manufacturers and instead local commissioning must be implemented to assure quality and mitigate the risk of treatment errors in HDR brachytherapy. Suitable tests are not always performed and a schedule of minimum commissioning tests has been proposed. The first two installations of the new SagiNova HDR system demonstrated clinically acceptable results. An improvement of the source dwell database was identified, confirming the value of interdepartmental checks and robust commissioning.

EP-1986

New design of brachytherapy water phantom for absolute dosimetry

V. Stserbakov¹

¹North-Estonian Regional Hospital Cancer Center Radiotherapy, Department of Radiotherapy and Oncology, Tallinn, Estonia

Purpose or Objective: To simplify technical design of brachytherapy water phantom for performing absolute dosimetry using standard instruments and equipment available in radiotherapy department. To perform absolute measurements for source-to-ionization chamber distance - 4 cm.

Material and Methods: CNMC WP-380 water tank used for locating ionization chamber and the holder of the radioactive source. To minimize dimensional correction factors for ionization chamber it was taken 0,125 cm³ PTW 31010 ionization chamber. For reducing uncertainty of the source position inside mould probe we used "curved catheter" method in the design of the catheter holder to make an effect of "pressing down" the end part of cable to lower wall of the probe. Holder designed in this way that amount of other than water surrounding source material was maximally reduced. Source-to-ionization chamber distance was set by

using "head pin" device. Swinging of the pin like a swinging of the pendulum was used for identifying the contact of pin with ionization chamber surface. It helps to avoid specific challenges of other technical decisions for source-to-ionization chamber distance setting. For pin swinging the water tank should be mounted on to wheeled stand. Final mechanical uncertainty for distance we estimate as ± 0.15 mm, which correspond to the inaccuracy in dose: ± 0.8 %. GammaMed Plus remote afterloader with source Ir-192 HDR (diam. 0.9 mm) was used. Varian BrachyVision V10(TG-43) treatment planning system (TPS) was used for comparison.

Figure: 1 - Ionization chamber; 2 - "Head pin" positioning device; 3 -Holder; 4 - Mould probe.

Results: Ionization chamber calibration factor ND,w = $3.042 \cdot 10^8$ Gy/C. Beam quality factor for Ir-192 kQ = 0.994 was found by interpolation. Decay factor is 1.76. Reading: 787 pC/min. Correction kT,P = 1.022. Result for dose rate: 0.428 Gy/min. Source-to-chamber distance is 42.02 mm (summation of: 39.54 mm - positioning device length; 0.05 mm - device correction; 3.43 mm - chamber radius; -1.0 mm source-to-catheter upper surface distance; 0.05 mm - chamber dimensional correction). At the source-chamber distance 42.02 mm the TPS gives dose rate 0.434 Gy/min (or difference with measurements 1.4%). Taking into account absolute calibration of the source activity correction (-1%) by well-chamber, final difference reduces to 0.4%.

Conclusion: Proposed simple design of radiation source holder with ionization chamber positioning device demonstrated agreement (within 1%) measured-to-TPS values for dose rate at the distance - 4 cm.

EP-1987

Feasibility study of patient specific QA system for HDR brachytherapy in cervical cancer

B. Lee¹, H. Kim¹, J. Sim², S. Ahn¹, J. Kim¹, Y. Han¹, S. Huh¹, D. Kim³, M. Yoon²

¹Samsung Medical Center, Department of Radiation Oncology, Seoul, Korea Republic of

²Korea University, Department of Bio-convergence Engineering, Seoul, Korea Republic of

³Kyung Hee University Hospital at Gangdong, Department of Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: This study was conducted for the purpose of establishing a quality assurance (QA) system for brachytherapy that can ensure patient-specific QA by enhancing dosimetric accuracy for patient therapy plan. The patient-specific QA is designed to measure point absorbed dose and 2D dose distribution for patient therapy plan

Material and Methods: We fabricated a solid phantom that allowed for the insertion of an applicator for patient-specific QA and used an ion chamber and a film as measuring devices. The patient treatment plan were exported to the QA dose calculation software, which calculated the time weight of dwell position stored in the plan DICOM(Digital Imaging and Communications in Medicine) file to obtain an overall beam quality correction factor and apply this correction to dose calculations. Experiments were conducted after importing the patient treatment planning source data for the fabricated phantom and inserting the applicator, ion chamber, and film into the phantom. On completion of dose delivery, the doses to the ion chamber and film were checked against the corresponding treatment plan to evaluate the dosimetric accuracy. For experimental purposes, five treatment plans were randomly selected.

Results: The beam quality correction factors for ovoid and tandem were found to be 1.15 and 1.10-1.12, respectively. The beam quality correction factor in tandem fluctuated by approximately 2%, depending on changes in the dwell position. Doses measured using the ion chamber showed differences ranging from -2.4% to 0.6%, as compared to the planned doses. As for the film, the passing rate was 90% or higher when assessed using the gamma value of local dose difference at 3% and Distance to agreement at 3 mm.

Conclusion: This study intended to establish a QA system for the purpose of enhancing the dosimetric accuracy of treatment planning for high-dose-rate brachytherapy. Experiments and assessments related to patient-specific QA were implemented as planned. As a result, the self-fabricated phantom was found to be suitable for QA in clinical settings. The proposed patient-specific QA for treatment planning is expected to contribute to reducing dosimetric errors in brachytherapy, and thus, enhance treatment accuracy.

EP-1988

Calibration of ionisation well chambers at the Polish SSDL
W. Bulski¹, P. Ulkowski¹, A. Kowalczyk¹, E. Gruszczyńska¹, K. Chelmiński¹

¹The Maria Skłodowska-Curie Memorial Cancer Center, Medical Physics Department, Warsaw, Poland

Purpose or Objective: In Poland, there are 32 centres performing brachytherapy, which treated 10948 patients in 2014. In total, all these centres use about 50 HDR machines with Ir-192 sources. Each source has to be replaced every three months, and the new sources have to be calibrated. In every centre this is done by measuring the source output with a well ionization chamber. Each centre has at least one such chamber which in turn has to be calibrated against the secondary standard. The Polish Secondary Standard Dosimetry Laboratory offers such calibrations for which it is accredited by the Polish Centre for Accreditation. The SSDL in Warsaw is the only laboratory in Poland and in central and eastern Europe performing calibration of such type of chambers. The service started in 2012 and since then 36 calibrations have been performed. In this presentation the calibration results are analyzed.

Material and Methods: The calibration procedure for well chambers was established at the SSDL in 2012. As a secondary standard, a PTW well chamber type TW33004 has been used.. At the Polish SSDL, the extended uncertainty of the calibration coefficient for user's chambers is 2.8% (k=2). The calibrations are performed using the Ir-192 source of the MicroSelectron HDR unit. Until May 2015 the SSDL calibrated 30 well chambers from the following manufacturers:

vaginal mucosa the D0.1cc was considered. Statistical significance of the results was proven by a Wilcoxon test for paired samples (significant p-value <0.05)

Results:

Parameter	GrO	SurfIPSA	homogIPSA	HIPO
V90 (%)	95.46 ± 4.20	93.55 ± 4.62	95.65 ± 3.93	95.19 ± 4.31
D90 (%)	100.15 ± 9.52	97.49 ± 10.25	98.02 ± 6.35	96.79 ± 6.30
DHI	0.66 ± 0.13	0.65 ± 0.14	0.81 ± 0.10	0.79 ± 0.08
COIN	0.84 ± 0.09	0.79 ± 0.09	0.84 ± 0.06	0.84 ± 0.06
D _{bladder,2cc} (%)	58.17 ± 13.66	57.10 ± 13.31	57.51 ± 13.69	57.76 ± 13.52
D _{rectum,2cc} (%)	73.52 ± 2.22	72.47 ± 4.11	72.64 ± 4.11	72.08 ± 4.46
D _{mucosa,0.1cc} (%)	246.27 ± 36.38	259.89 ± 45.45	209.81 ± 44.83	234.76 ± 49.41
CC%	0.53 ± 0.21	0.43 ± 0.20	0.81 ± 0.12	0.90 ± 0.10

Table 1 shows the obtained values for D90, V90, COIN, DHI and %CC for the investigated OM. No significant differences resulted among the OM in terms of target coverage (D90 and V90) and bladder and rectum sparing (D2cc).

The figure shows average DVHs of the PTV over all 12 cases. DVHs obtained with homogIPSA and HIPO show a steeper gradient, resulting in smaller volumes exposed to high doses. homogIPSA and HIPO result in significantly better values of COIN, DHI e %CC values. Furthermore, homogIPSA shows the lowest value for the D0.1cc to the mucosa. No differences were evidenced between the use of MVC applicators with diameters of 25mm and 30mm.

Conclusion: HIPO and homogIPSA should be preferred due to their ability to get improved dose homogeneity to the target and reduced hot spots to the vaginal mucosa. This is achieved by a more effective distribution of source dwelling times between central and peripheral catheters. It has to be noted that all investigated OM require experience of the planner and are not completely user independent.

EP-1991

The dosimetric characteristics of GMS BT-125-1 I-125 radioactive seed

R. Yang¹

¹Peking University Third Hospital, Radiation Oncology, Beijing, China

Purpose or Objective: To investigate the dosimetric characteristics of GMS BT-125-1 I-125 radioactive seed, including dose rate constant, radial dose functions and anisotropy functions.

Material and Methods: Dosimetric parameters of GMS BT-125-1 I-125 seed, including dose rate constant, radial dose functions and anisotropy functions were calculated using the Monte Carlo code of MCNP5, and measured using thermoluminescent dosimeters (TLDs). Monte Carlo calculations were also performed for the PharmaSeed BT-125-1 I-125 seed, PharmaSeed BT-125-2 I-125 seed and model 6711 I-125 seed. The dosimetric parameters of GMS BT-125-1 I-125 seed were compared with those of PharmaSeed BT-125-

1 I-125 seed, PharmaSeed BT-125-2 I-125 seed and model 6711 I-125 seed. The measured results were compared with those of Monte Carlo simulation for GMS BT-125-1 I-125 seed.

Results: The MCNP5 calculated dose rate constant of GMS BT-125-1 I-125 seed was 1.011. The experimental measured dose rate constant of GMS BT-125-1 I-125 seed was 0.967. For radial dose function, the difference between GMS BT-125-1 I-125 seed and PharmaSeed BT-125-2 I-125 seed were typically less than 2.0% with a maximum of 3.3%. The largest differences were 8.1% and 6.2% compared with PharmaSeed BT-125-1 and model 6711 I-125 seed, respectively. For anisotropy functions, the difference between GMS BT-125-1 I-125 seed and PharmaSeed BT-125-2 I-125 seed was typically <10% with a maximum of about 9.6% when the polar angle was larger than 10 degree, and 22.9% when the polar angle was smaller than 10 degree. Compared with Monte Carlo simulation, the largest differences of radial dose functions and anisotropy functions were 14.5% and 29.1%, respectively.

Conclusion: The measured dose rate constant, radial dose functions and anisotropy functions for GMS BT-125-1 I-125 seed showed good agreement with Monte Carlo calculated values. The dosimetric parameters of GMS BT-125-1 I-125 seed are similar to those of PharmaSeed BT-125-2 I-125 seed.

EP-1992

Design and characterization of a new HDR brachytherapy Valencia applicator for larger skin lesions

J. Vijande¹, C. Candela-Juan², Y. Niatsetski³, R. Van der Laarse³, D. Granero⁴, F. Ballester¹, J. Perez-calatayud⁵

¹Universitat de Valencia Dep. de Fisica Atomica- Molecular Y Nuclear, Atomic Molecular and Nuclear Physics, Burjassot, Spain

²National Dosimetry Centre, National Dosimetry Centre, Valencia, Spain

³Elekta, Brachytherapy, Veenendaal, The Netherlands

⁴ERESA- Hospital General Universitario, Department of Radiation Physics, Valencia, Spain

⁵La Fe University and Polytechnic Hospital, Radiation Oncology Department-, Valencia, Spain

Purpose or Objective: The aim of this study was: (i) to design a new high-dose-rate (HDR) brachytherapy applicator for treating surface lesions larger than 3 cm in diameter and up to 5 cm size, using the microSelectron-HDR afterloader (Elekta Brachytherapy); (ii) to calculate by means of the Monte Carlo (MC) method the dose distribution around the new applicator when it is placed over a water phantom; and (iii) to validate experimentally the water dose distributions.

Material and Methods: The new applicator is made of tungsten, and consists on a set of interchangeable collimators without flattening filter. It makes use of three catheters to allocate the source at prefixed dwell positions and times to produce a homogeneous dose distribution at 3 mm depth in the water phantom. The Penelope2008 MC code was used to optimize dwell positions and dwell times. Next, the dose distribution in a water phantom and leakage dose distribution were calculated. Finally, MC data were validated experimentally by measuring: dose distributions with radiochromic EBT3 films (ISP) for an 192Ir mHDR-v2 source; percentage depth-dose (PDD) curve with the parallel-plate ionization chamber Advanced Markus (PTW); and absolute dose rate with EBT3 films and the PinPoint T31016 (PTW) ionization chamber.

Results: PDD and off-axis profiles were obtained normalized at a depth of 3 mm along the central applicator axis in a cylindrical water phantom. These data can be used for treatment planning. Leakage was also scored. The dose distributions, PDD, and absolute dose rate calculated agree within experimental uncertainties with the doses measured.

Conclusion: The new applicator and the dosimetric data provided here will be a valuable tool in clinical practice, making treatment of large skin lesions simpler, faster, safer, and with minimized dose to surrounding healthy tissues when

compared to electron therapy or brachytherapy with moulds and flaps.

Dose evaluation at organs at risk in vaginal cuff brachytherapy

J. Wiercińska^{1,2}, R. Kabacińska¹, J. Tertlikiewicz^{2,3}, A. Lebioda^{2,3}, A. Wronczewska³, R. Makarewicz^{2,3}

¹Oncology Center Bydgoszcz, Medical Physics Department, Bydgoszcz, Poland

²Collegium Medicum- Nicolaus Copernicus University- Toruń, Department of Oncology and Brachytherapy, Bydgoszcz, Poland

³Oncology Center Bydgoszcz, Brachytherapy Department, Bydgoszcz, Poland

Purpose or Objective: Vaginal cuff brachytherapy with the dose prescribed at 0.5 cm depth from the applicator surface has been the standard treatment for gynaecological cancer patient after hysterectomy for years. The implementation of computed tomography based (CT-based) plans caused changes in the standard approach in our hospital. We narrowed the planning target volume (PTV) in order to meet our in-house constraints requirement for organs at risk (OARs) in some cases. The aim of the study was to analyze doses at OARs in real adjusted image-based plans and in standard 0.5 cm normalized plans.

Material and Methods: Treatment plans of recent, consecutive 70 patients treated with high dose rate vaginal cuff CT-based brachytherapy were analyzed retrospectively. Dose normalization points and optimization methods were adjusted whenever standard approach wasn't suitable to meet all dose constraints for OARs (adjusted plan - AP). The second, standard treatment plan (SP) was created for every AP. APs were divided into three groups based on overdosage at definite OAR: Bladder Group (B group), Rectum Group (R group) and Bladder & Rectum Group (B&R group). Comparison of doses at the most exposed 0.1cc (D0.1cc) and 2cc (D2cc) of bladder and rectum between AP and SP was made in all three groups.

Results: Vaginal cylinders of 10 to 35 mm radius were used. For 54% of all 70 cases the standard approach wasn't deemed suitable, and the treatment plan was adjusted (SP- 32 cases, AP-38 cases). 53% of the APs were assigned to the R group, 21% to the B group and 26% to the B&R group. Mean values of rectum doses in R Group were 96.6% and 112.0% for RD0.1cc and 74.4% and 83.6% for RD2cc for AP and SP respectively. Mean values of bladder doses in B Group were 97.2% and 108.0% for BD0.1cc and 79.3% and 86.9% for BD2cc for AP and SP respectively. In B&R Group mean values of RD0.1cc were 93.1% and 108.9% and mean values of RD2cc were 71.8% and 81.1% for AP and SP respectively, mean values of BD0.1cc were 94.4% and 105.9% and mean values of BD2cc were 77.5% and 84.4% for AP and SP respectively. The doses are presented as a percentage of prescribed dose. Dose differences between both plans in all three groups were statistically significant.

Conclusion: Standard approach with dose points at 0.5 cm from the applicator surface is not suitable for all patients and can increase the risk of bladder or rectum complications. CT-based plan allowing dose evaluation at OARs should be practiced on a daily basis.

EP-1994

On the dosimetric effect of heterogeneities and finite patient dimensions on Co-60 HDR brachytherapy

K. Zourari¹, E. Pantelis¹, P. Papagiannis¹

¹Athens University- Medical School, Medical Physics Laboratory, Athens, Greece

Purpose or Objective: Brachytherapy has recently advanced towards personalized planning dosimetry with the commercial availability of image-based treatment planning systems for Ir-192. This marks an improvement over TG-43 based planning dosimetry that relies on source specific data

pre-calculated in a standard sized geometry of homogeneous water, hence disregarding patient-specific radiation scatter conditions and the radiological differences of tissue or applicator materials from water. The aim of this work is to perform a comparative study of the effect of these factors in Co-60 and Ir-192 HDR brachytherapy.

Material and Methods: Ten clinical cases were studied for each of three disease sites considered (gynaecological, esophagus and breast). Two treatment plans were prepared for each case using the TG-43 option of a commercially available system (SagiPlan) with an Ir-192 (Ir2.A85-2) and a Co-60 (Co0.A86) HDR source. The plans were exported in dicom RT format. Corresponding personalized dosimetry data was obtained from Monte Carlo simulation using the MCNP6 code. Monte Carlo input files were prepared automatically from the parsing of information in the dicom RT data using a custom software tool (BrachyGuide). Personalized and TG-43 based dose distributions were compared in the 3D anatomical space of each patient using isodose distributions, % dose difference maps, Dose Volume Histograms and relevant indices of clinical interest. The statistical and clinical significance of differences between personalized and TG-43 based dosimetry in Co-60 HDR brachytherapy was examined, and evaluated relative to corresponding results for Ir-192.

Results: Results indicated that the effect of tissue heterogeneities and patient specific scatter conditions is less for Co-60 than for Ir-192 HDR treatments. In general, Co-60 and Ir-192 sources of identical shape and construction have been found to deliver clinically comparable dose distributions despite definite differences in their physical characteristics. This is confirmed in terms of personalized dosimetry in this study. A lower dose to critical organs close to the target by Co-60 sources was observed along with a small increase in the overdose volume (V150 to V400). The choice of isotope was not found to have an impact on the prescribed dose.

Conclusion: Co-60 may be used as an effective alternative to Ir-192 for HDR brachytherapy, producing similar plans of equivalent target coverage, but with a logistical benefit and without the need for an image based algorithm for personalized dosimetry.

EP-1995

Potential OAR dose reduction with Fletcher shielded applicator and ACE algorithm for cervix brachy

C. Jones¹, A. Taylor², M. Bidmead¹

¹The Royal Marsden NHS Foundation Trust, Medical Physics, London, United Kingdom

²The Royal Marsden NHS Foundation Trust, Radiotherapy, London, United Kingdom

Purpose or Objective: The dose delivered to the cervix HRCTV is often limited by OAR tolerances. A new applicator with shields in the anterior and posterior areas of the ovoids has been developed to try to reduce OAR doses. The current dose calculation formalism (TG43) calculates dose to water and does not take into account tissue heterogeneity. The Advanced Collapsed cone Engine (ACE) is the Elekta implementation of TG186; it models tissue heterogeneity and the effect of shielding.

Material and Methods: Eleven patients were selected that had received CT/MR planned brachytherapy for cervical cancer using Elekta Fletcher tube and ovoids. The HRCTV and OARs had been outlined on the MR. For this study the applicator library was used to perform a best fit match of the shielded CT/MR Fletcher tube and ovoid model with the CT of the insertion. The shielded applicators have a slightly different geometry compared to the unshielded Fletcher applicators. The 25mm shielded ovoids were overlaid on 35mm standard ovoids and 30mm shielded ovoids were overlaid on 40mm standard ovoids. The dwell positions, dwell weights and A points were maintained from the clinical plan. The plans were calculated

with and without shield attenuation using TG43 and were calculated with TG186 fixing the dwell times. It was not possible to perform a TG186 calculation without the shields in place. The TG186 calculation used a HU based mass density and all contoured organs were set to 'female soft tissue' except bladder which was set to 'water' to provide the chemical composition.

The HRCTV D90 and D2cc for rectum, bladder, small bowel and sigmoid were recorded and EQD2 doses calculated assuming 50.4Gy in 28 fractions external beam component.

Results: Table 1 gives the difference in HRCTV D90 and OAR D2cc doses between the different dose calculations.

	TG186 (shields)- TG43 (noshields)		TG186 (shields)- TG43 (shields)		TG43 (shields)- TG43 (noshields)	
	% diff	EQD2 diff (Gy)	% diff	EQD2 diff (Gy)	% diff	EQD2 diff (Gy)
HRCTV D90	-2.5	-1.0	-2.0	-0.9	-0.5	-0.2
Rectum D2cc	-15.8	-4.2	-10.1	-2.4	-6.5	-1.9
Bladder D2cc	-3.4	-1.0	-2.6	-0.7	-0.8	-0.2
Sigmoid D2cc	-4.9	-0.7	-3.2	-0.5	-1.8	-0.2
Bowel D2cc	-3.2	-0.9	-1.9	-0.5	-1.5	-0.3

The combination of shields and TG186 dose calculation reduced the rectum D2cc by an average of 15.8% (5.6%-31.7%) compared to the TG43 dose calculation with no shields in place. This equates to a reduction in EQD2 of 4.2Gy (0.6Gy-13Gy) and is associated with an average HRCTV EQD2 reduction of 1Gy. The reduction is due to the physical effect of the shielding and the more accurate dose calculation. These results show that the effect of the algorithm is the largest contributor as TG43 underestimates the effect of the shields.

Conclusion: This study demonstrates that using shielded applicators has the potential to reduce the rectum D2cc. The rectal dose is rarely our dose limiting organ due to the routine use of a rectal retractor, however any reduction in rectal dose would be beneficial. Two patients in this cohort had rectal D2cc doses greater than 70Gy in the clinical plan. For these two patients the shielded TG186 plan reduced the rectal D2cc dose significantly by 5.7Gy and 13Gy compared to the unshielded TG43 plan. Further work is needed to assess the TG186 calculation without shields and the effect of applicator geometry on the position of OARs.

EP-1996

Post IVD verification and recalibration of MOSkins using a certified low dose emitting Sr-90 source

A. Romanukha¹, M. Carrara², G. Rossi³, C. Tenconi², M. Borroni², E. Pignoli², D. Cutajar¹, M. Petasecca¹, M. Lerch¹, J. Bucci⁴, G. Gambarini⁵, A. Rosenfeld¹

¹University of Wollongong, Centre for Medical Radiation Physics, Wollongong, Australia

²Fondazione IRCCS Istituto Nazionale dei Tumori, Diagnostic Imaging and Radiotherapy Department, Milan, Italy

³University of Milan, Department of Physics, Milan, Italy

⁴St George Hospital Cancer Care Centre, Radiation Oncology Unit, Kogarah, Australia

⁵National Institute of Nuclear Physics, Physics, Milan, Italy

Purpose or Objective: In vivo dosimetry (IVD) measurements in HDR brachytherapy (BT) have to be validated by performing a quality assurance check of the functionality of the dosimeters right after the treatment. Recalibration is also usually required due to the high delivered doses per fraction involved. The standard procedure using Ir-192 is burdensome due to limited availability of the operating theater, where the afterloader containing the Ir-192 source is located, as well as due to the transport and setup of the water equivalent phantom. In this work, a procedure involving the use of a certified low dose emitting Sr-90 source was proposed to both perform QA and recalibration of MOSkin dosimeters right after IVD in HDR Ir-192 BT without the need of the BT theater and phantom setup.

Material and Methods: The MOSkin is a type of MOSFET detector developed at the Centre of Medical Radiation

Physics (CMRP) in the University of Wollongong that was integrated into present HDR Ir-192 BT procedures for real time IVD. The standard MOSkin calibration/verification technique employs the Ir-192 source used in HDR procedures, in which case the detector is placed into a water equivalent phantom, and irradiated three times with a known dose. The average of the three measurements is calculated as the calibration coefficient. Instead of using Ir-192, in this study the use of a certified low dose emitting Sr-90 source was investigated. A very small phantom that allows a fixed position of the detector in relation to the source was established. Three MOSkins were tested at three stages of their lifetime, roughly 15 Gy apart. At each one of these stages, each MOSkin was calibrated by performing three measures both with Sr-90 and Ir-192. The sensitivity ratio of the average values obtained with Sr-90 and Ir192 was calculated for each measurement.

Results: Both Sr-90 and Ir-192 measurements confirmed a small reduction of MOSkin sensitivity with accumulated dose, at 1.1% with every 10 Gy, which is proportional to the change in threshold voltage of the dosimeter to the first order of approximation. The sensitivity ratio of Sr-90 and Ir-192 measurements remained at a constant value of 9.0±0.2% for all three stages of MOSkin life, and among the three dosimeters employed in the experiment.

Conclusion: A stable proportional relationship was established between the Ir-192 and Sr-90 calibration methods, demonstrating that Sr-90 can be used effectively for MOSkin recalibration as well as for post treatment verification of their functionality after IVD sessions. The procedure involving Sr-90 is much more convenient because it does not necessitate the use of the BT operating theater and can be easily performed everywhere without any particular radioprotection requirements. Additionally it is not necessary to know the dose delivered by Ir-192 and Sr-90 to MOSkin but rather the time of irradiation of the MOSkin on each of them respectively, assuming activity changes of Sr-90 are negligible.

EP-1997

Geometrical and source positioning accuracy verification of Varian HDR afterloader and applicators

C.L. Ong¹, F. Janssen¹, L. Murrer¹, M. Unipan¹, A. Hoffmann¹

¹MAASTRO clinic, Radiotherapy, Maastricht, The Netherlands

Purpose or Objective: In high-dose rate (HDR) brachytherapy, accurate dose delivery is highly dependent on the geometrical and temporal source positioning accuracy. In this study, we measured the source position and dwell time accuracy of the Varian GammaMedplus iX afterloader as well as the dead space of a variety of Varian applicators.

Material and Methods: The source position and dwell time accuracy were optically measured using Varian's source step viewer and a videocamera. The Perma-Doc phantom was used for dosimetric verification of the afterloader's source positioning accuracy. The most distal source position and the dead space of the applicators (titanium/stainless steel/plastic needles, titanium Fletcher-type and flexible tube) were measured radiographically using kV imaging and dosimetrically using EBT3 film. For these measurements an X-ray marker and the Ir-192 source were successively inserted into the applicators, respectively. The distance between the external end of the applicators and the center of the most distal X-ray marker and the first dwell position on film were measured (Fig.1).

Results: The dwell time deviation measured at different source positions is <0.1s, and is in accordance with vendor specifications. For the most proximal source position, a systematic longer dwell time of 0.13s was observed. This deviation should be negligible when multiple dwell positions are used. Position verification using the source step viewer shows deviations of 0.5-1mm (vendor specs: ± 1mm). At the most distal position, the source was always retracted by 1 mm relative to the nominal position to straighten the source

cable. This effect was taken into account during treatment planning. Position verification using the PermaDoc phantom confirmed this 1 mm retraction. All radiographically measured dead spaces complied with the specifications, except for the plastic needles which were 1 mm shorter than indicated. The center of the active source is at 2.42 mm from the tip of the capsule. Combined with the 1 mm source retraction, the center of the dose distribution at the most distal position located always 3.5 mm behind the internal end-point of the source channel. Radiographic and dosimetric dead space measurements showed good agreement ($<0.5\text{mm}$) for all applicators.

Figure 1: KV images of a stainless steel needle with x-ray markers (Right above). Distances between the physical end-point and middle of the dose distribution were measured on an EBT3 films (right under). The figure in the middle shows a small discrepancy of 0.25mm for the first source position identified using kv-images and EBT3 film.

Conclusion: Measured source position and dwell time accuracy comply with the vendor's specifications. Small deviations were found for the dwell time accuracy at the most proximal source position. Similar tests should be performed regularly to warrant the mechanical accuracy of the afterloader and the quality of the applicators and transfer tubes.

EP-1998

Real-time dosimetry for HDR brachytherapy

L. Moutinho¹, I.F.C. Castro¹, H. Freitas¹, K.A. Silva¹, P.J. Rachinhas², P.C.P.S. Simões², J.F.C.A. Veloso¹

¹3N- Physics Department- University of Aveiro, Physics Department, Aveiro, Portugal

²Hospitais da Universidade de Coimbra, Serviço de Radioterapia, Coimbra, Portugal

Purpose or Objective: Dose verification and quality assurance in radiotherapy (RT) should be assessed in order to provide the best treatment possible and minimize risks for patient. In certain treatments there are no tools capable of performing real-time dose measurement. In addition, in-situ real-time dosimetry would enhance brachytherapy (BT) by providing technical conditions to perform treatment readjustment and real-time dose correction. Considering the current challenges, we developed a dosimeter intended for in-situ and real-time dosimetry in High Dose Rate brachytherapy (HDR-BT), e.g., prostate and breast.

Material and Methods: The dosimeter developed has a sensitive 3 m long optical fiber probe of 1mm or 0.5 mm diameter comprehending a 5 mm length scintillating optical fiber. To read the signal produced at the probe, 1x1 mm² Silicon Photomultipliers (SiPM) from Hamamatsu were used. A custom made readout system with SiPM temperature compensation was used. The main concerns when performing dosimetry at high dose rates with high energy isotopes is the eventuality of Cherenkov light production. This form of noise accounts to the total noise signal, known as stem effect.

The dosimeter was placed in a PMMA phantom and the response was evaluated with a 10.07 Ci Ir-192 HDR-brachytherapy source (Nucletron). Measurements were repeated twice, first using a dummy probe without scintillator for stem effect quantification and second using an ionization chamber (IC) read by an electrometer for reference.

Results: The studies carried out allowed assessing the amount of stem effect produced in the optical fiber cable. In the conditions described above, the stem effect contribution is lower than 1% for both 0.5 and 1 mm probes. The measurements of the fiber dosimeter response as a function of the dose are represented in Figure 1. The small difference from the reference IC is due to the different detector volumes of the fiber dosimeter and the ionization chamber. The dosimeter shows a linear response with dose rate being capable of detecting μGy dose variations.

Figure 1: Fiber optic dosimeter stem-effect and response for 0.5 and 1 mm diameter versions compared to ionization chamber response.

Conclusion: The first round of in-vitro tests in clinical setting demonstrated that the fiber optical based dosimeters developed are suitable for dosimetry in regimes such as HDR prostate BT. The versatility of this kind of device and easiness of use allows application in other radiotherapy modalities. Besides fulfilling all the requirements for a dosimeter in HDR-BT, the high sensitivity of this device makes it a suitable candidate for application in LDR-BT.

Comparison of intraoperatively linked and loose seed in prostate brachytherapy using sector analysis

N. Katayama¹, M. Takemoto², A. Takamoto³, K. Hisazumi¹, H. Ihara¹, K. Katsui¹, S. Ebara³, Y. Nasu³, S. Kanazawa¹

¹Okayama University Hospital, Department of Radiology, Okayama, Japan

²Himeji Red Cross Hospital, Department of Radiotherapy, Himeji, Japan

³Okayama University Hospital, Department of Urology, Okayama, Japan

Purpose or Objective: An intraoperatively built custom-linked (IBCL) seeds system is a push-button seed delivery system that allows the user to create intraoperatively customized linked seeds, using a combination of seeds, connectors, and spacers. To date, only three studies have compared the implant quality of IBCL seeds to loose seeds for use in permanent prostate brachytherapy (PPB). However, they did not use sector analysis. Therefore, we compared the implant quality of IBCL seeds to loose seeds in PPB using sector analysis.

Material and Methods: Between June 2012 and January 2015, 64 consecutive prostate cancer patients underwent brachytherapy with IBCL seeds (n = 32) or loose seeds (n = 32). All the patients were treated with 144Gy of brachytherapy alone. IBCL and loose seeds were alternately used basically. All patients were treated by the same radiation oncologist and urologist. We used the same dose-

volume targets in the IBCL seed group and the loose seed group. Brachytherapy was performed using a dynamic dose calculation technique. Computed tomography/magnetic resonance imaging fusion-based dosimetry was performed 1 month after brachytherapy. Post-implant dose volume histogram (DVH) parameters, prostate sector dosimetry, operation time, seed migration, and toxicities were compared between the two groups. A sector analysis tool was used to divide the prostate into six sectors (anterior and posterior sectors at the base, mid-gland, and apex). Analyses were performed using the 2-sample *t* test for continuous data that followed a normal distribution, the Mann-Whitney test for continuous data that did not follow a normal distribution, and the Chi-squared test for categorical data. Probability (*P*) values of < 0.05 were considered significant.

Results: In prostate sector dosimetry, V100 (95.3% vs. 89.7%; *P* = 0.014) and D90 (169.7 Gy vs. 152.6 Gy; *P* = 0.013) in the anterior base sector were significantly higher in the IBCL seed group than in the loose seed group. Other post-implant DVH parameters did not differ significantly between the two groups. The seed migration rate was significantly lower in the IBCL seed group than in the loose seed group (6% vs. 66%; *P* < 0.001). There was no significant difference in mean operation time between the two groups; however, mean operation time per seed was significantly longer in the IBCL seed group than in the loose seed group (1.31 min vs. 1.13 min; *P* = 0.003). The median follow-up was 18 months (range, 1-36 months). No significant differences in toxicities were seen between the two groups.

Conclusion: Our study showed more dose coverage post-operatively in the anterior base prostate sector and less seed migration in IBCL seeds implantation compared to loose seeds implantation.

EP-2000

Template guided saturation biopsy of prostate: what is the optimal volume for brachytherapy?

S. Kanaev¹, S.N. Novikov¹, R.V. Novikov¹, N.D. Ilin¹, E.A. Peskunov¹, M.Y. Gotovchikova¹

¹N.N. Petrov Institute Oncology, Radiation Oncology & Nuclear Medicine, Saint-Petersburg, Russian Federation

Purpose or Objective: to evaluate results of saturation biopsy in candidates for focal, hemigland high dose rate (HDR) brachytherapy or irradiation with "low-dose tunnel for urethra"

Material and Methods: Template guided saturation biopsy was performed in 52 primary patients with suspicion to prostate cancer and PSA below 10 ng/ml. Biopsy was performed under US control with the help of brachytherapy grid and 5mm distance between samples. During positioning and biopsy procedure we put special attention for accurate sampling of prostate in periurethral region. The number of cores varied from 17 to 50 (average 33 cores). Finally in 31 patients with confirmed prostate cancer results of biopsy were used for brachytherapy planning.

Results: Saturation biopsy revealed prostate cancer in 31 of 52 evaluated patients. Involved volume ranged from 5% to 100% (average - 57%). Focal nature of PC diagnosed in 6 (19.4%), multifocal - in another 25 (80.6%) patients. Hemigland invasion mentioned in 10 cases. Saturation biopsy detected PC in periurethral cores in 22 (70.9%) of 31 evaluated patients: invasion of one core revealed in 1, 2 cores - in 6, 3 and more cores - in another 14 cases. In 10 patients extent of involvement in periurethral cores varied between 10% and 50%, in another 12 observations exceeded 50%. According to results obtained on saturation biopsy we performed HDR brachytherapy with "urethra low dose tunnel" (D10=80%) in 9 patients with noninvolved periurethral cores. Theoretically hemigland brachytherapy was possible in 10 of 31 evaluated patients.

Conclusion: in low risk patients with prostate cancer results of template guided saturation biopsy can significantly influence strategy of HDR brachytherapy

EP-2001

Radical salvage brachytherapy (BT) for local recurrences after previous radiation treatment

S. Rodríguez Villalba¹, M. Santos Ortega¹, M. Depiaggio¹, L. De la Torre², J. Martínez², J. Canovas², J. Richart¹, A. Otal¹, J. Perez Calatayud¹

¹Clinica Benidorm, Radiotherapy Department, Benidorm, Spain

²Hospital Marina Baja, Urology Department, Villajoyosa-Alicante, Spain

Purpose or Objective: We presented a retrospective analysis in 11 patients with histological proven local-recurrent prostate cancer, undergoing salvage BT, treated between February 2009 and December 2014.

Material and Methods: The previous radical treatments were: 3 Low dose rate BT (LDR-BT) (145 Gy), one combined treatment with external radiotherapy (EBRT) (45 Gy) and LDR-BT (100 Gy), and 7 EBRT (68-74 Gy). Four patients have been rescued with LDR-BT and seven with High-Dose-Rate-BT (HDR-BT). All patients have a complete study with abdominal CT scan, pelvic MRI, and bone scan to diagnose local disease exclusively. LDR-BT patients received 145 Gy with 125I. HDR patients, has been treated with 30 Gy in 3 fractions of 10 Gy separated ten days. Median time to Biochemical failure (BF) from the first treatment was 48 months (12-114). All patients received previous hormonotherapy. Median time to rescue was 69 months (33-156). Toxicities were evaluated according with CTCAE scale (version 4.0).

Results: Median follow-up: 26,5 months (3-72 m). The overall survival time was 98 months (65-174). At the end of the follow up, March of 2015, all patients are alive, nine (82%) without evidence of disease, one patients had a retroperitoneal failure 7 months after the salvage-BT and other patient was diagnosed of a solitary bone metastases at 12 months. Median PSA nadir post-salvage-BT was 0.1 ng/ml (0-0,29). There were not grade 3 GU or GI toxicities. 100 % of LDR-BT patients presented acute GU-toxicity grade 2. Fifty-seven % of the HDR-BT patients had GU-toxicity grade 1 (0% grade 2).

Conclusion: Prostate BT is an effective and well tolerated reirradiation treatment in local-recurrent prostate cancer patients, with, few long-term toxicities, mainly in those treated with HDR-BT.

EP-2002

Focal prostate brachytherapy: aspects of multi-modality registration and dosimetry feasibility

T. Brun¹, S. Ken¹, C. Popotte¹, J. Bachaud¹, P. Graff-Cailleaud¹, M. Delannes¹, B. Malavaud¹, D. Portalez¹, R. Aziza¹

¹Cancer University Institute of Toulouse Oncopole, DIPM, Toulouse, France

Purpose or Objective: The different conventional treatments for prostate cancer are multiple and for low-risk tumors, focal brachytherapy can be a therapeutic alternative option to active surveillance. However, this focal treatment remains still under evaluation and within the frame of the focal brachytherapy project conducted in Toulouse, we will present in this study two parts of the project: first, the contribution of multi-modal rigid and non-rigid registrations for localization and delineation of the treated volume, then the dosimetry evaluation after registration.

Material and Methods: First step of prostate brachytherapy at our Institute consists in a contour-based non-rigid registration between MRI and US performed with Koelis software where positive biopsy trajectory is retrieved and a fiducial non-radioactive marker is implanted to localize the tumor focus. As a result of this localization, dosimetry was performed using VariSeed software, dose prescription is

160Gy to the PTV (GTV + 2mm) and Bard Quicklink system is used to implant I125 radioactive seeds. Multi-modal manual rigid and non-rigid transformations between MR and CT scans were performed on the first 9 patients with three software solutions: the treatment planning system Variseed, a research platform 3D Slicer and a commercial solution Mirada. MR onto CT registrations were approved by an expert uro-radiologist and quantitative evaluations of the registrations were performed by calculating the means of vectors displacement marked on four relevant points of interest detected on the I125 seeds. For the dosimetry, an assessment of the impact of these readjustments on the initial dose matrix was also performed in Mirada by applying the deformation to the initial contours and injecting the initial dose matrix.

Results: For the first 9 patients, evaluation of registration gives means of vectors displacement of 1.52mm [0.36-2.6] with Variseed, 0.62mm [0.26-1.29] with 3D Slicer and 0.42mm [0.24-0.81] with Mirada. Examples of fusions are illustrated in Figure 1. Concerning the dosimetric data and considering the most relevant criteria from the initial outline, the D90%(Gy) to the prostate and respectively for the target has a mean difference of +0.68Gy and -12Gy. The D30%(Gy) and the D10%(Gy) to the urethra respectively have a mean difference of -0.99 and -5.58Gy. Lastly, D1cc(Gy) to the rectum has a mean difference of +4,37Gy.

Figure 1: Multi-modal registration with the three different software solutions. First row shows the planning CT scan at one-month follow-up with the I125 seeds, second row presents the MR T2-weighted images at one-month follow-up with the seeds visible in hypo-intense signal and the last row shows fusion between MR/CT modalities. Results of the manual rigid registration obtained with Variseed (A). Rigid+non-rigid registration obtained with 3D Slicer (B). Rigid+non-rigid registration obtained with Mirada (C).

Conclusion: Target volume definition remains a crucial step for focal brachytherapy as only confirmed tumor biopsy sub-volumes of the prostate are treated. Registration procedures tested in our institute confirmed the need to implement precise rigid and non-rigid fusion of image to delineate relevant target volumes on different modalities. In addition, dosimetry evaluation on the registrations showed the impact of the deformations in high dose gradients.

EP-2003

HDR brachytherapy in monotherapy of one fraction in patients with prostate cancer at low risk

A.C. Orduz Arenas¹, I. Jiménez García¹, R. Martínez Gutiérrez¹, P. Cucarella Beltran¹, S. Blanco Parajón¹, H.A. González Suárez¹

¹Hospital Universitario Central de Asturias, Oncología Radioterápica, Oviedo, Spain

Purpose or Objective: The High-dose-rate brachytherapy as monotherapy in one fraction, is a treatment option in patients with low-risk prostate cancer and can be used as an alternative to the low-dose-rate brachytherapy. Compared to the low-dose-rate, the HDR as monotherapy has not proven long-term results with regard to disease control. It is not known what dose of treatment should be used to increase the biochemical control, survival control disease and reduce unaffordable toxic effects.

Material and Methods: Results on patients treated with high-dose-rate brachytherapy as monotherapy are presented below.

Sample: A series of 75 patients between 2008 and 2013 treated with high-dose-rate brachytherapy (HDR) single dose of 19 Gy (62) and 20.5 Gy (13) were selected.

A technique of guided-ultrasound brachytherapy and dynamic-calculated intraoperative dose was used.

Results: The results show an overall survival of 91.3% of patients, with survival free of disease of 97% and a biochemical control of 72.5%.

Patients toxicity: Acute urinary toxicity: 53.8% (grade 2). Chronic urinary toxicity: 49.2% (grade 2). Acute gastrointestinal toxicity: 86.2% (grade 1). Chronic gastrointestinal toxicity: 89% (grade 1). Acute urinary retention rate of 2.9%.

Conclusion: HDR prostate brachytherapy as monotherapy in one single fraction of 19 Gy does not provided adequate biochemical control and survival free disease rates. It is necessary more studies to establish what would be the most appropriate dose to obtain higher rates of disease control

EP-2004

Urethra dose homogeneity constraints in LDR prostate brachytherapy could diminish urinary morbidity

V. González-Pérez¹, J.L. Guinot², L. Oliver¹, A. Bartrés¹, V. Campo¹, V. De los Dolores¹, J.V. Ricós³, A. Cano¹, V. Crispín¹

¹Fundación Instituto Valenciano de Oncología, Servicio de Radiofísica y Protección Radiológica, Valencia, Spain

²Fundación Instituto Valenciano de Oncología, Servicio de Radioterapia, Valencia, Spain

³Fundación Instituto Valenciano de Oncología, Servicio de Urología, Valencia, Spain

Purpose or Objective: Evaluate the relationship between RTOG G2-G3 urinary morbidity after prostate brachytherapy and urethral doses at the end of real-time dosimetry planning.

Material and Methods: From November 2007 to December 2010, 204 prostate cancer patients underwent monotherapy I-125 seeds brachytherapy in our institution. Real-time US guided dosimetry planning was performed with Variseed 7.0 or 8.0. Of the 204 patients, 11 (5.4%) developed an acute urinary retention and required a urinary catheter from 2 weeks to 7 months (G2 morbidity), and 7 patients (3.4%) required a transurethral resection of the prostate (G3 morbidity).

In a retrospective study, detailed urethral dosimetry was evaluated at the end of the real-time implant. Assessed values included maximum dose, V80, V100, V150 and D90 for both overall urethra and segmented urethra (as base, midgland and apex urethra). 1.5-mm and 2.5-mm urethral expansions were also reviewed for all dosimetry parameters. To check if dose homogeneity around urethral regions was related to morbidity, subtraction of expanded minus non-expanded urethral dosimetry parameters was also performed. In total, 111 parameters were reviewed.

T-Student test and U Mann-Whitney test were used to compare differences between patients free of urinary morbidity from those presenting G2 and G3 morbidity. p <0.05 was considered significant.

Results: No correlation was found between non-expanded urethra doses and urinary morbidity.

Best result (p=0.005) for distinguishing free-morbidity cohort from G2-G3 morbidity-cohort was obtained for subtraction of the maximum dose of the non-expanded minus 2.5-mm-expanded overall urethra.

Diagnostic capability was determined by calculating the area under the curve (AUC) in the receiver operating characteristic (ROC) curves. This parameter had an AUC value of 0.786. It was predictive of G2-G3 complications with 71.4% specificity and 72.2% sensibility for a dose difference threshold of 48 Gy.

Conclusion: A non-homogenous dose region around urethra at the end of the real-time implant is a risk factor for development of urethral morbidity.

Several studies have found dosimetry correlations between CT post-plan and urinary morbidity. This study focuses on US real-time dosimetry parameters. It allows us to consider new constraints and dosimetry alerts during treatment planning. A prospective study is under consideration, where a new constraint of a 40-50 Gy maximum dose difference around a 2.5-mm expansion of the urethra will be implemented if feasible.

EP-2005

Analysis of PSA kinetics after HDR brachytherapy in prostate cancer patients

W. Burchardt¹, J. Skowronek¹

¹Greater Poland Cancer Centre, Brachytherapy Department, Poznan, Poland

Purpose or Objective: The PSA level after definitive treatment using radiotherapy decreases but still remains detectable. The aim of this study is to analyze clinical and dosimetric factors which influence the PSA level in the blood serum of patients with prostate cancer after HDR (High Dose Rate) brachytherapy.

Material and Methods: 53 patients after HDR brachytherapy were qualified to the study from June 2008 to December 2010. The patients were from T1c to T2c, iPSA from 1.5 to 19.6 ng/ml with prostate adenocarcinoma (Gleason Scale < 7) and belonged to the low and intermediate risk of recurrence. 20 patients had androgen deprivation therapy. Patients were treated with HDR brachytherapy 3 x 15 Gy or 3 x 10.5 Gy. Median follow-up was 3 years. The PSA Bounce threshold was >0.2 ng/ml and the biochemical failure definition was nadir PSA +2.0 ng/ml. The influences of clinical and dosimetric parameters were assessed. Statistical analysis was performed assuming significance level $p < 0.05$.

Results: PSA Bounce occurred in 22% after average 10.7 months. The time to PSA increase in BF group after brachytherapy HDR was 36 months. It was observed that patients with PSA nadir below 0.1 ng/ml were more likely to have normal follow-up than PSA Bounce, biochemical failure (BF), clinical failure (CF). The amplitude of the PSA increases were significantly different between subgroups. The further analysis demonstrated only a significant difference between the subgroup HDR_Bounce (median 0.7 ng/ml) and HDR_BF (median 2.6 ng/ml). The time to PSA increase was significantly different between the subgroups of the group HDR. It applies to patients with PSA Bounce (median 10.5

months) and biochemical failure (median 36 months). The analysis of others dosimetric and clinical factors (including hormone therapy) didn't show any significant effect on the studied HDR subgroups.

Conclusion: The percentage of patients who had a PSA Bounce was 22%. Predisposing factors for PSA Bounce after HDR brachytherapy were nadir PSA (median > 0.1 ng/ml) and time to PSA increase (median < 12 months). There was no influence of other analyzed clinical, dosimetric factors and use of hormone therapy to occurrence of the PSA Bounce.

EP-2006

IPSS time recovery in patients with prostate cancer after I-125 prostate brachytherapy

J. Olivera Vegas¹, W. Vázquez Rivas¹, A. Pérez Casas¹, I. Prieto Muñoz¹, J. Luna Tirado¹, L. López², C. Gonzalez-Enguita², C. Quicios², D. Esteban Moreno¹, A. Ilundain Idoate¹, M. García Castejon³, M. Rincón Pérez³, S. Gomez-Tejedor³, J. Vara Santos¹, J. Penedo³

¹Hospital Universitario Fundación Jiménez Díaz, Oncología Radioterápica, Madrid, Spain

²Hospital Universitario Fundación Jiménez Díaz, Urology, Madrid, Spain

³Hospital Universitario Fundación Jiménez Díaz, Radiophysics, Madrid, Spain

Purpose or Objective: To evaluate evolution and average time to IPSS (International Prostate Symptom Score) recovery, in patients who have been submitted to I-125 prostate brachytherapy (Low dose rate brachytherapy).

Material and Methods: Between March 2011 and December 2013 we performed 66 prostate brachytherapy in patients with low / intermediate risk prostate cancer. 4 patients also received external radiotherapy. 14 patients received previous hormone therapy. A 145 Gy dose was prescribed if exclusive brachytherapy was given and 108 Gy if combined with external radiotherapy. All patients were treated with Quicklink Delivery System® (BARD) and real-time planification. Of the 66 treated patients 5 did not have initial IPSS, 13 did not have complete follow up, and the 48 remaining have a suitable follow up. The variables that have been evaluated were: Prostate volume, Qmax, number of implanted seeds, number of needles and Urethra's D1; "p value" was obtained from Mann-Whitney test. The prostate average volume was 33.73 cc, Qmax: 18.7 ml/sec, number of seeds: 60.2, number of needles: 16.1 and urethra's D1: 138% to the prescribed dose.

Results: With an average follow up of 27 months, 41 of 48 patients (85.4%) recovered their IPSS, with an average recovery time of 9 months. 7 patients (15%) showed progressive worsening without recovery, and 3 (4.5%) of them developed acute urinary retention (AUR) one month after the implant. In a multivariate analysis the main factor that influenced AUR was the prostate volume, with $p = 0.0583$, (in these 3 patients prostate volume average was 42.47 cc, higher than the average non AUR) and other factors that seem to influence were IPSS and Qmax values, without statistical significance ("p" value) (In these patients Qmax average was 7.63 and IPSS average was 9.33, worse than non AUR).

Conclusion: 85% of patients with complete follow-up, recovered its basal IPSS. The average time to recovery was 9 months, and the incidence of acute urinary retention was lower than 4.5%.

EP-2007

A multicenter study of exclusive brachytherapy in younger patients with prostate cancer

E. Villafranca Iturre¹, P. Fernandez², R. Martínez-Monge³, C. Gutierrez⁴, A. Sola Galarza¹, E. Collado⁵, I. Herruzo⁶, A. Hervás⁷, V. Muñoz³, J. Muñoz²

¹Hospital of Navarra, Radiation Oncology, Pamplona, Spain

³Clínica Universitaria de Navarra, Radiation Oncology, Pamplona, Spain

⁴Instituto Catalán de Oncología, Radiation Oncology, Barcelona, Spain

⁵Hospital Universitario y Politécnico La Fe, Radiation Oncology, Valencia, Spain

⁶Hospital Regional Universitario Carlos Haya, Radiation Oncology, Málaga, Spain

⁷Hospital Ramón y Cajal, Radiation Oncology, Madrid, Spain

⁸Hospital de Meixoeiro, Radiation Oncology, Vigo, Spain

⁹Hospital Infanta Crisitna, Radiation Oncology, Badajoz, Spain

Purpose or Objective: To evaluate biochemical progression-free survival (BDFS) in men 60 years of age or younger with prostate cancer who underwent exclusive permanent brachytherapy

Material and Methods: 528 patients(p) with LR/IR. T1:423p T2: 105p; Gleason 6: 520p, gleason 7: 8p; neoadjuvant hormoneotherapy: 48p.; initial PSA: 10: 492p, > 10: 36p. Md follow-up 63m (1-173m). BDFS was defined ASTRO definition. Patients were selected from RECAP database, helped by URONCOR and GEG groups.

Results: Dosimetry: pD90: md147 Gy (45-215 gy); pD90 > 165 Gy: 19.8%; pD100: md86.2 Gy; pV150: md54.6% prostate volumen: 36 cc (14-93 cc) . D10 urethra: md142%(112-191 %); D2cc rectum: 79.2 %.Toxicity: Acute: genitourinary: g2: 6.1%; g3: 0.6%; rectal: g2: 20%, g3: 3.7%. Late: genitourinary: g2: 7.7%; g3: 4.6%; rectal: g2: 2%, g3: 0.5%. Both were related with pV150: Acute GUg₂: 71.7% (pV150> 50%) vs. 28.1% (<50%); late GUg₂: 81.8% (> 50%) vs. 18.2% (<50%). p:ns. For the entire group, 40p had biochemical failure; 25p localF, 7p regionalF and 5p metastases and 5 p (1.05%) dead with prostate cancer. The actuarial 5-year and 10-y BDFS was 93.2% and 88.7%. Overall survival at 5y: 97.3% and 10y: 91.7%. No factor had influence in the analysis of prognostic factors of BDFS. However BDFS 10y pD90 < 145 Gy: 86% vs. D90 145-165Gy: 87.8% vs. D90 > 165 Gy: 92.5% (HR: 1.47, p: 0.46).

Conclusion: This is one of the biggest series at the moment in younger men with permanent brachytherapy. Patients 60 years of age or younger have a high probability of 10-year BDFS. There is a trend to get better results with D90> 165 Gy.

EP-2008

Robustness of the OARs recommendations made by GEC-ESTRO according to inter-observer variability

R. Chicas-Sett^{1,2}, J. Bautista-Ballesteros², F. Celada-Alvarez², S. Roldán², A. Torregrosa³, J. Betancourt⁴, J. Burgos², D. Farga², M. Perez², V. Carmona², A. Tormo², J. Benlloch¹, J. Perez-Calatayud²

¹Universidad Católica de Valencia "San Vicente Mártir", Doctoral School, Valencia, Spain

²Hospital Universitari i Politécnic La Fe, Radiation Oncology, Valencia, Spain

³Hospital Universitari i Politécnic La Fe, Radiology, Valencia, Spain

⁴Hospital Universitari i Politécnic La Fe, Urology, Valencia, Spain

Purpose or Objective: To investigate the interobserver variability in contouring of rectum in high-dose rate brachytherapy (HDRBT) for the treatment of prostate carcinoma. The HDV dosimetric parameters are obtained and reported in accordance with the GEC/ESTRO recommendations.

Material and Methods: Four blinded observers retrospectively contoured the rectum of five patients treated with HDRBT in the radiation oncology department. A contouring consensus was previously established to agree in the anatomical limits determination in the rectal contouring. HDV dosimetric parameters analyzed were the included on the GEC-ESTRO recommendations: D0.1cc, D1cc and D2cc and the rectal volume were calculated. These endpoints were

compared between and within the observers. The coefficient of variation (CV) defined as a measure of the spread of data as a proportion of its mean (expressed as a percentage), was estimated to assess the interobserver variation. For each parameter, the mean and SD of the two measurements recorded (taken with one week apart) from the treatment planning study made by transrectal ultra-sonogram (TRUS) were estimated for each of the 4 observers. The effect of interobserver variation in the total dose recorded was analyzed by estimating the accumulative dose (EQD2) for the rectum. For our study, the dosimetric parameter to rectum was evaluated regarding to single 15Gy prostate HDRBT plan and assuming that rectum received full-dose EBRT (46 Gy). The total EQD2 (equivalent dose in 2 Gy per fraction, assuming alpha/beta ratio of 3) doses were estimated.

Results: The patient data are represented in Table 1 showing the results of the mean reported D0.1cc, D1cc and D2cc for the rectum contoured twice for each case. The interobserver coefficient of variation for reported D0.1cc, D1cc and D2cc was 5.7%(SD 6,28), 4.5%(SD 1,94) and 4%(SD 2,24), respectively. The total D2cc parameter for the patients with the highest interobserver variation in rectum delineation, may result in recorded rectum dose difference up to 2,6 Gy by EQD2.

Table 1 Mean (standard deviation) of D0.1cc, D1cc, and D2cc parameters of the rectum obtained in two different times for each patient based on the single 15 Gy HDRBT plan.

Case	Rectum		
	D _{0.1} (Gy)	D ₁ (Gy)	D ₂ (Gy)
1	12,12 (0,28)	10,61 (0,59)	9,42 (0,15)
2	12,26 (0,37)	10,48 (0,53)	9,046 (0,33)
3	12,39 (0,30)	10,93 (0,43)	9,65 (0,32)
4	13,04 (0,50)	11,43 (0,16)	10,02 (0,40)
5	15,51 (2,62)	12,38 (0,79)	10,86 (0,84)

Conclusion: Interobserver variations in reported parameters were high for the D0.1cc (CV: 16%) in a worst-case scenario. Even if the D2cc parameter corresponds to low interobserver variation, we found that the greatest variation is present in high prostate volume cases. Variation in delineation of the rectum may be a potential source of uncertainty in the BT planning and delivery process. Nevertheless, in our study the impact of interobserver variation on the total dose (EQD2) for the reported D2cc has a mean of +/- 1.5 Gy. This study represents a small analysis of a single center experience, but it will be completed with a multicenter study in a second part.

EP-2009

Feasibility and early toxicity of HDR alone in pts with recurrent/locally advanced prostate cancer

S.R. Bellia^{1,2}, P. Blanchard², L. Calmels², M. Edouard², P. Maroun², P. Chaurin², A. Bossi²

¹Istituto Scientifico Romagnolo per la Cura e lo Studio dei Tumori IRST IRCCS, Radiation Oncology, Meldola, Italy

²Gustave Roussy, Radiation Oncology and Medical Physics, Villejuif, France

Purpose or Objective: High Dose Rate Brachytherapy (HDR-BT) as stand-alone treatment is gaining popularity as salvage strategy for patients (pts) with an isolated, intraprostatic Prostate Cancer (PCa) recurrence after External Beam Radiotherapy (EBRT) and may represent the only treatment available for the management of pts diagnosed with PCa and challenging clinical scenarios (for ex, pts previously irradiated in the pelvis for other primaries). We present a retrospective analysis of our series of PCa pts managed with HDR-BT alone with particular emphasis on dosimetry and early toxicity results.

Material and Methods: From March 2014 to June 2015, 13 pts have been treated with HDR-BT alone in our centre: nine with salvage intent for an intraprostatic relapse after EBRT, and four for primary management after pelvic EBRT for other malignancies (follicular lymphoma, rectal cancer and B-cell

lymphoma). All patients had biopsy-proven disease and got pre-treatment local and distant staging (Choline PET-CT, pelvic/prostatic MRI and bone scan). HDR-BT was performed by transperineal insertion of intraprostatic catheters under spinal anaesthesia and trans-rectal ultrasound guidance using an Ir-192 source. A total dose of 24 Gy to the whole gland was prescribed in two separate fractions of 12 Gy, 2-4 weeks apart. Dosimetric constraints for prostate and organ at risk (OAR) sparing were defined; we aimed at a prostate D90 > 95% and a V100 > 85% while the urethral Dmax was kept < 120% and the D10 < 115%; the rectal D2cc was kept < 75%. Patient reported genitourinary (GU) and gastro-intestinal (GI) symptoms according to the NCI.CTCv3 were assessed before HDR-BT and every 4-6 months afterward.

Results: The median age of the pts was 68.5 (range 63-77) years; the pre-treatment PSA was 5.71 (range 0.067-11.04) ng/ml. The median interval from the end of the previous EBRT and HDR-BT was 8.75 (range 3-16 years) years. The median prostate D90 and V100 for the 26 HDR-BT fractions analysed were respectively 97.17% and 86.7% of the prescribed dose but in 4 pts the D90 was < 95% and in 8 the V100 was < 85%. The median urethral Dmax was 105.73% and the median D10 was 94.71%; the median D2cc for the rectum was 45.98%. After a median follow-up of 13.9 (range 2-28) months, acute GU grade 1 and 2 toxicities were reported in 4 and 3 pts respectively while one patient reported a grade 2 acute GI toxicity. Eleven pts were evaluable for late toxicities: five reported a late GU grade 1 and two pts a grade 2 toxicity. Any late GI toxicity has been reported so far. Nine pts (69%) are biochemical disease-free while none of the 4 pts showing a rising PSA developed an intraprostatic relapse.

Conclusion: HDR-BT in 2 fractions of 12 Gy may represent an interesting alternative for the management of pts with an isolated intraprostatic recurrence after EBRT and for challenging clinical situations when EBRT is contraindicated. The early toxicity profiles seem correct and clinical results promising.

EP-2010

Audit OAR comparing nationally-adopted prostate seed technique with GEC-ESTRO and ABS guidelines.

C. Sims¹, P. Kelly¹

¹Cork University Hospital, Radiotherapy, Cork, Ireland Republic of

Purpose or Objective: The aim is to compare OAR dosimetry for the nationally-adopted technique for PSB with existing GEC-ESTRO and ABS guidelines. This modified MountSinai technique prescribes 160Gy to the prostate gland without a margin. The dose volume constraints (DVCs) used are: urethra(UD₃₀) < 181Gy and rectum (RV₁₀₀) < 1cc.

By comparing the institutional technique to international standards we aim to demonstrate if:

- All constraints perform similarly using clinical plans.
- Institutional plans would be considered reasonable when GEC-ESTRO and ABS guidelines are applied.
- The addition of GEC-ESTRO and ABS DVCs to institutional practice may be of clinical utility.

Material and Methods: The first 50 PSB implants performed in Institution were retrospectively re-contoured as per ABS and GEC ESTRO recommendations in Variseed (version 8.0). A PTV with margin of 3mm was added to the prostate except posterior aspect. The prescribed dose was altered to 145Gy to the PTV, as per GEC-ESTRO and ABS guidelines. The GEC-ESTRO and ABS DVCs were then applied.

Results: The median prostate V100 was 95.34% for CUH (IQR 95.34-97.66%) met by 58% of cases. The median V100 was 94.17% for ABS and GEC-ESTRO (IQR 92.68-95.61%) met by 36% of cases (p=0.007). The median D90 for CUH was 175.46Gy (IQR 168.98-186.67Gy). The median D90 for GEC-ESTRO and ABS was 159.08Gy (IQR 152.46-165.41Gy). D90>prescription dose was achieved by 92% for all groups.

The median RV100 using the institutional technique was 0.27cc (IQR 0.12-0.59cc) and the <1cc target was met by 92% of cases. The ABS rectal constraint is RV100<1.3cc, at day 30. The median ABS RV100 was 0.46cc (IQR 0.28-0.91cc) and the <1.3cc target was achieved in 88% of cases. The GEC-ESTRO rectal constraint D0.1<200Gy and D2cc<145Gy were met by 70% and 100% of the plans respectively. The median urethral UD30 using the institutional technique was 178.10Gy (IQR 175.27-180.59Gy). The GEC-ESTRO urethral constraints of UD30<188.5Gy and D10<217.5Gy were met by 100% and 100% of plans respectively. The ABS urethral constraint UD5<150% was met by 98% and UD30<125% was met by 82% of cases.

Conclusion: Comparing the Institutional DVCs for rectum and urethra with ABS and GEC-ESTRO guidelines shows that they are concordant. Institutional and ABS urethral constraint UD30 appears conservative when GEC-ESTRO urethral constraints are applied. While validated DVCs are vital for optimal prostate seed brachytherapy, prospective documentation of toxicities is crucial.

EP-2011

High-dose-rate brachytherapy combined with external beam radiotherapy for high-risk prostate cancer

S. Kariya¹, K. Kobayashi¹, I. Yamasaki², S. Ashida², K. Tamura², K. Inoue², T. Shuin², T. Yamagami¹

¹Kochi Medical School, Department of Radiology, Nankoku, Japan

²Kochi Medical School, Department of Urology, Nankoku, Japan

Purpose or Objective: The aim of this study is to examine if adjuvant hormonal therapy is needed for all of the high-risk prostate cancer patients treated with high dose rate-brachytherapy (HDR-BT) combined with external beam radiotherapy (EBRT).

Material and Methods: Between July 1999 and June 2010, 121 patients considered as high-risk group (T stage > or = 2c, PSA > 20 ng/ml, or Gleason score (GS) > or = 8) were treated with HDR-BT and EBRT at Kochi Medical School Hospital in Japan. Patient age ranged from 52 to 82 (median 71) years old. Eighty-two patients had received neoadjuvant hormonal therapy, which was stopped at the beginning of radiotherapy in all cases. Patients were treated with EBRT to 40 Gy in 20 fractions or 39 Gy in 13 fractions and HDR-BT to 18 Gy in 2 or 3 fractions for prostate and seminal vesicle. Adjuvant hormonal therapy was not performed until biochemical failure or clinical recurrence became apparent. PSA failure was defined as the Phoenix definition of nadir + 2 ng/mL. The overall survival (OS) rates, disease-specific survival (DSS) rates, and biological relapse-free survival (bRFS) rates were estimated using the Kaplan-Meier method. Log-rank test and Cox proportional hazards regression analysis were used for univariate and multivariate analyses, respectively, to examine these factors in relation to bRFS: age, clinical T stage (cT), initial PSA level (iPSA), GS, needle core biopsy positive ratio (% core), and use of neoadjuvant hormonal therapy (NHT). Follow-up ranged from 4 years 3 months to 13 years 3 months (median 6 years 10 months).

Results: The 5-year OS, CSS, and bRFS rates were 91.3, 98.2, and 88.0%, respectively. The 7-year OS, CSS, and bRFS rates were 86.4, 98.2, and 88.0%, respectively. In log-rank test, the group with cT < or = 2b was superior to that with cT > or = 2c (p = 0.0297), and that with iPSA < or = 10 ng/mL was superior to that with iPSA > 10 ng/mL (p = 0.0137). On multivariate Cox regression analysis, cT remained an independent predictor of bRFS (hazard ratio, 3.82; 95% confidence interval [CI], 1.11-13.14; p = 0.0337).

Conclusion: In the high risk prostate cancer group treated with HDR-BT followed by EBRT, the subgroup with cT < or = 2b gained a good bRFS rate without adjuvant hormonal therapy.

EP-2012

Are there differences in quality prostate indicators among 9-Gy vs 15-Gy HDR brachytherapy boost?

R. Tortosa¹, P. Soler¹, N. Chinillach¹, C. Ruiz¹, M. Vila¹, M. Sanchez¹

¹Hospital IMED Elche, Radiation Oncology, Elche Alicante, Spain

Purpose or Objective: The dose coverage in patients diagnosed with high risk prostate adenocarcinoma with seminal vesicles affection don't suppose any problem in dose escalation with HDR Brachytherapy. But we wonder if the quality prostate implant indicators will show any differences between standard patients (15-Gy HDR) and those with seminal vesicles affection(9-Gy HDR). To evaluate it, a multivariate analysis has been performed in our Radiation Oncology Department

Material and Methods: 120 patients with high risk prostate adenocarcinoma were selected for the study and divided into two groups. The treatment schedule was external beam radiotherapy plus high dose rate brachytherapy as a boost:

- Group A: 9-Gy boost - T3b high grade (seminal vesicles affection) 46-Gy to pelvic areas, up to 60-Gy in prostate and seminal vesicles (2-Gy per fraction) daily and 9-Gy HDR to prostatic gland and 1-2cm. of proximal seminal vesicles.

- Group B: 15-Gy boost - High grade (no seminal vesicles affection)46-Gy to pelvic areas (2-Gy per fraction) daily treatment and 15-Gy HDR to prostatic gland.

Volumetric Modulated Arc Therapy (VMAT) was the selected technique for external radiotherapy delivered in a Varian DHX Clinac (Varian, Palo Alto, Ca.) with Millennium 120-MLC. Brachytherapy was performed with VariSource iX afterloader (Varian, Palo Alto, Ca.). The aim is to demonstrate whether there are any differences in both groups for dose homogeneity index (DHI) and homogeneity index (HI). A multivariate analysis was developed using as variables three of prostate (PTV volume, D90, D100), two of urethra (Dmax, D10) and two of rectum (Dmax, D10).

Results: The multivariate analysis for both groups shows a p-value of 0.452 to obtain the probability for DHI > 0,75 and a p-value of 0.897 to obtain a probability for HI>0.70. In Figure 1, the plots of the results are presented:

Conclusion: According to dose homogeneity, the analysis states that there were no significant differences for both studied groups. These results suggest the possibility of increasing the boost dose in T3b patients

EP-2013

Single fraction HDR BT boost using ultrasound plng for prostate cancer: dosimetrics and toxicity

M. Barkati¹, O. Lauche¹, D. Taussky¹, C. Ménard¹, G. Delouya¹

¹Centre Hospitalier de l'Université de Montréal, Radiation Oncology, Montréal, Canada

Purpose or Objective: To validate the feasibility of a single-fraction High Dose Rate Brachytherapy (HDRBT) Boost for prostate cancer using real-time Transrectal Ultrasound (TRUS) based planning.

Material and Methods: From August 2012 to September 2015, 113 patients underwent a single-fraction HDRBT boost of 15 Gy using real-time TRUS based planning. External beam radiation therapy (EBRT) (37.5 Gy/15f or 44Gy/22f or 45Gy/25f) was performed before (30%) or after (70%) HDRBT

boost. We analyzed prostate, urethra and rectum dosimetrics data. Genito-Urinary (GU) and Gastro-Intestinal (GI) toxicity were assessed 4 and 12 months after the end of combined treatment using the International Prostate Symptom Score Scale (IPSS) and the Common Terminology Criteria for Adverse Events (CTCAE) v3.0.

Results: Prostate D90 between 105% and 115% was achieved for 99% of patients, prostate V150 40% for 99%, prostate V200 < 11% for 96%, urethra D10 <120% for 99%, urethra V125=0% for 100% and rectum V75<1cc for 95% of patients. Median IPSS score was 4 at the baseline and didn't change at 4 and 12 months after combined treatment. No patients developed ≥ grade 2 GI toxicity. With a median follow-up of 10 months, only two patients experienced biochemical failure. Cumulative percentage of patients with PSA ≤ 1 at 4 and 18 months was respectively 47% and 74 %.

Conclusion: Single-fraction HDRBT boost of 15 Gy using real-time TRUS based planning in combination with EBRT is a safe treatment with promising results. A longer follow-up is needed to assess long-term outcome and toxicities

EP-2014

Retrospective analysis of interstitial brachytherapy in gynecological and digestive tumours

C. De la Pinta Alonso¹, E. Fernandez-Lizarbe¹, A. Montero Luis², A. Polo Rubio¹

¹Ramon y Cajal Hospital, Radiation Oncology, Madrid, Spain

²Madrid Hospital Group, Radiation Oncology, Madrid, Spain

Purpose or Objective: The aim of this study was to evaluate the acute and late toxicities and disease-specific and overall survival after interstitial brachytherapy for the treatment of gynecological and digestive tumors.

Material and Methods: A retrospective study was carried out on a series of 19 patients referred for interstitial brachytherapy in our center between 2008 and 2013 with histologically proved locally advanced or recurrent gynecological malignancies and digestive tumors. Patients with distant metastases were excluded. Treatment consisted of brachytherapy alone (5p) (gynecological recurrence and anal carcinoma), or after surgery (1p) (rectal carcinoma) or after surgery and radiochemotherapy (4p) or after radiochemotherapy (9p). The radiochemotherapy with cisplatin-based chemotherapy regimens. Previously, recurrent patients (4p) were been treated with radiotherapy with or without concurrent chemotherapy. Medium dose of external beam radiotherapy was 51,7 Gy (range 45-70 Gy) followed by interstitial brachytherapy median implant dose 22,3 Gy (range 9-38,5Gy). Inclusion criteria were as follows: Hb minimum 10gm/dl and performance status 70% or more.

Results: Median age was 59 years (range 36-82). With a median follow-up of 14 months, local control was achieved on clinical examination or magnetic resonance imaging 93,8% patients. Among 19 patients studied, 3 lost follow-up and they were excluded from late toxicities and survival analysis. Eleven of the 19 patients (57,9%) experienced Radiation Therapy Oncology Group (RTOG) grade I or II acute toxicities proctitis (36,3%), cystitis (81,8%) and epithelitis (18,2%). Not acute toxicities grades 3 or 4 were reported. Two of the 16 patients (12,5%) experienced RTOG grade I or II late toxicities proctitis (6,25%) and cystitis (6,25%). Two of the 16 patients (12,5%) experienced RTOG grade III or IV late toxicities rectal ulcer (6,25%) and vulvar necrosis (6,25%). Using Kaplan-Meier analysis overall survival after minimum follow-up of 14 months was 93% and disease-free survival was 75% (persistent tumor were included in this group). One patient had a locoregional recurrence and died of tumor.

Conclusion: Interstitial brachytherapy is a good choice to deliver high-dose radiation in gynecological tumor after external beam radiotherapy or as an exclusive treatment in

recurred and previously radiated digestive tumors. This treatment offers adequate locoregional control with acceptable range of complications.

EP-2015

Acute toxicity in HDR BT of skin cancer with very high viscosity addition silicone custom made molds

C. Sanz Freire¹, S. Pérez Echagüen², G.A. Ossola Lentati²

¹Center For Biomedical Research Of La Rioja, Medical Physics Department, Logroño, Spain

²Center For Biomedical Research Of La Rioja, Radiation Oncology Department, Logroño, Spain

Purpose or Objective: To study normal skin acute toxicity in Non-Melanoma Skin Cancer (NMSC) patients treated with High Dose Rate (HDR) Plesiotherapy and very high viscosity addition silicone (VHVAS) rubber custom-made molds. VHVAS rubber features excellent mechanical and physical properties which benefit the stability and reproducibility of the implant. On the other hand, the high electron density relative to water of these materials will increase the scatter production, which may be relevant at the mold-skin interface.

Material and Methods: Our standard applicators are polymerized VHVAS molds with catheters embedded. This VHVAS model features 99.5% recovery factor after compression and maximum 0.20% linear dimensional variations. Dosimetric properties of this VHVAS have been characterized by our Group elsewhere. Silicone attenuation relative to water is <5% up to 3 mm thickness. Maximum scatter relative to water measured at the mold interface is <14%. Treatment is delivered with a Ir-192 based VARIAN MS Gammamed+ HDR unit. All treatments are 3D simulated. A sample of 15 Patients with 21 lesions (8 basal cell carcinomas, 13 squamous cell carcinomas) representing all treated locations were considered. Average age is 83.1 years [96-58], 47% without any concomitant diseases and life expectancy >5 years. Median lesion area is 5.4 cm² [1.0-46.6], treatment depth is 4.0 mm [2-15] and microscopic disease margin is 4 mm [2-5]. Standard fractionation is 5.5 Gy/fr, 10-12 fr, twice a week. Acute toxicity was retrospectively assessed following the RTOG criteria.

Results: DVH analysis showed high dose areas having: D1cc=8.5 Gy/fr [5.4-14.4], D0.5cc= 9.0 Gy/fr [5.4-16.3], D0.1cc= 10.3 Gy/fr [6.2-22.9]. All patients presented radiodermatitis 1 month after treatment (G2: 89%, G3: 11%). 32% presented radiodermatitis at 3 months (G1: 26%, G2: 6%) and only one patient presented radiodermatitis G1 at 6 months. Toxicity score correlation to CTV volume, treatment depth, BED prescribed dose, D1cc, D0.5cc and D0,1cc had no statistical significance ($p>0.05$). Treated area was found to be predictive of radiodermatitis persistence at 3 months after treatment ($p=0.036$). Lesions located in the legs showed longer recovery time from radiodermatitis than other locations (4 months vs 1.8 months average).

Conclusion: The use of these VHVAS moulds was well-tolerated by all patients. Our treatments yield similar results to other groups with similar treatment schemes in terms of acute toxicity. We can conclude that VHVAS custom made molds have a good safety profile.

EP-2016

A method to transform 2D LDR brachytherapy plans into contemporary 3D PDR dose distributions

E. Rodenburg¹, J. Wilkes¹, J. Wiersma¹, R. Ordoñez Marmolejo¹, R. Dávila Fajardo¹, A. Bel¹, B. Pieters¹

¹Academic Medical Center / University of Amsterdam, Department of Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: Formerly in the 2D Low-Dose Rate (LDR) era no information about Dose-Volume Histogram (DVH) parameters of organs at risk (OARs) was available in

brachytherapy plans. To enable research on late dose effects for children treated with Pulsed-Dose Rate (PDR), 3D dose distributions and DVH parameters are required. In this study a method was developed to enable calculation of DVH parameters.

Material and Methods: Before 2001 pediatric head and neck (H&N) patients received LDR brachytherapy as a part of their treatment. Of 16 LDR plans (1989-2001) only hard-copy CT data, orthogonal x-ray images of the implant and documented 2D dose information were available. The documented 2D dose information consisted of source strength, catheter numbering, catheter loading, and treatment time. The hard-copy CT data was digitized, transferred to DICOM format and imported in Oncentra Brachy (Elekta, v4.3). The visible OARs were delineated and used catheters were reconstructed. The Ir192-LDR line sources from the original 2D plans were simulated by loading the reconstructed catheters with Ir192-PDR source tracks of the same length as the LDR sources, with a step size of 2.5mm. Simulation of a line source dosimetry was necessary because the planning system did not support LDR planning. All PDR source dwell times were made equal, but scaled to the documented 2D dose distribution to obtain the 3D dose distribution at time of treatment. Scaling was performed at a 2D LDR isodose level below 30% of the prescribed dose in a plane where the documented 2D dose distribution and transformed 3D dose distribution geometrically match. Scaling below 30% is done to avoid effects due to the non-uniform isodose distribution very close to a stepping PDR source. To check the reliability of the method the Total Reference Air Kerma (TRAK) for both 2D LDR and 3D PDR plans were determined and compared. The difference was tested with the Wilcoxon Signed Rank Test for paired variables. To illustrate the applicability of the method the maximum dose, defined as the D0.1cm³, on e.g. chiasm was determined.

Results: Of 16 LDR plans 2D data were transformed into 3D dose distributions. OARs and DVH parameters of chiasm were determined. The mean 2D TRAK was 0.95cGy/1m (IQR 0.89). The mean 3D TRAK was 0.89cGy/1m (IQR 0.74). The mean difference of 2D TRAK and 3D TRAK was statistically not-significantly different from 0 ($P=0.45$). For 7 patients the CT data incorporated the chiasm area. The mean chiasm maximum dose was 233.6cGy (range 4.6-399.2) using the described method.

Conclusion: With the described method it was possible to transform 2D LDR brachytherapy plans into a 3D dose distribution. This method shows the possibility to use information from 2D LDR brachytherapy plans in scientific studies in which 3D dose information is needed.

EP-2017

High dose-rate endoluminal brachytherapy as a treatment of primary and recurrent esophageal cancer

N.H. Nicolay^{1,2}, J. Wagner¹, J. Oelmann-Avendano¹, J. Debus^{1,2}, P.E. Huber^{1,2}, K. Lindel¹

¹Heidelberg University Hospital, Radiation Oncology, Heidelberg, Germany

²German Cancer Research Center, Radiation Oncology, Heidelberg, Germany

Purpose or Objective: To evaluate outcomes and toxicities after high dose-rate (HDR) endoluminal brachytherapy for the treatment of esophageal cancer patients.

Material and Methods: We analyzed the patient records of 36 patients treated with high dose-rate endoluminal brachytherapy for histologically confirmed esophageal cancer. Brachytherapy was either applied as a boost treatment for definitive radiotherapy and radiochemotherapy regimens or as a salvage treatment for recurrent tumors. Single radiation doses between 4 and 6 Gy were delivered to the endoscopically visible tumor including 2 cm margins in 2 to 4 sessions. Recurrence-free and overall

survival as well as acute and late toxicities were retrospectively analyzed.

Results: Brachytherapy was performed as initially planned in all but one patient. 18 patients had a complete endoscopic response at the first follow-up examination. Loco-regional recurrence was observed in 24 patients after a median time of 3 months; 1- and 2-year recurrence-free survival rates were 51% and 51% for the patients treated for primary tumors and 11% and 6% for patients treated for tumor recurrence, respectively. Median overall survival was 18 months; estimated overall survival rates at 1, 2 and 3 years were 63%, 50% and 30% after primary brachytherapy, and 60%, 25% and 6% after treatment for recurrent cancers. Adenocarcinoma histology, non-complete remission after treatment and treatment for recurrent cancers were associated with significantly reduce prognosis. Mild to moderate dysphagia was the most common side effect in 17 patients; 8 patients suffered from loco-regional grade 3 toxicities, and no grade 4 or 5 toxicities were observed.

Conclusion: Endoluminal brachytherapy during the course of esophageal cancer treatment can be safely applied and results in good functional outcomes regarding dysphagia with moderate local toxicity and low side effects to the lung and heart.

EP-2018

Treatment with high dose rate plesiotherapy and custom moulds in skin cancer. Long term results

L. Membrive¹, A. Reig¹, P. Foro¹, N. Rodriguez¹, J. Sanz¹, A. Ortiz², J. Quera¹, E. Fernandez-Velilla¹, O. Pera¹, R. Jimenez¹, N. Becerra¹, J. Flores¹, M. Algara¹

¹Hospital de la Esperança, Radiation Oncology, Barcelona, Spain

Purpose or Objective: To describe the technique used in our department for treatment of cutaneous tumors with HDR plesiotherapy using custom moulds and to analyze long term results.

Material and Methods:

Custom made mould fabrication:

We used this applicator in irregular areas of skin.

The treatment sequence is:

- Creation of the mould with thermoplastic material with a thickness of 5 mm.
- Parallel placement of transfer guide tubes with 1 cm of separation.
- CT simulation and definition of the volume treat. The volume has to be delimited 5 mm in deep.
- Dosimetry.
- Treatment of the patient.

We used 3 different schedules:

- 54 Gy in 18 fractions
- 66 Gy in 33 fractions
- 40 Gy in 10 fractions

Results: From September 2008 until September 2015 53 patients had been treated with this technique.

The average age was 77 years (63-91), the histology was squamous in 6 cases, basocellular in 46 cases, melanoma in situ in 1 case.

The mean dose was 54.8 Gy (40-66). The treatment was adjuvant after surgery in 41,5% of the patients.

After a mean time of follow up was 34,1 months there were 2 local relapses (3.77%) in the treatment location. No deaths related to disease were observed.

Conclusion: Treatment with HDR plesiotherapy using custom moulds is a technique used to treat small lesions and/or irregular surface locations. Planning with CT scan allows to know the dose in organs at risk using dose-volume histogram. This treatment offers a high local control of the disease and can be used alone or as adjuvant treatment after surgery in case of positive margins or presence of adverse factors.

EP-2019

The safety and efficacy of external beam radiotherapy combined yttrium 90 SIRT

T.H. Wang¹, R.C. Lee², Y.W. Hu¹, P.I. Huang¹, C.S. Liu¹

¹Taipei Veterans General Hospital, Department of Oncology, Taipei, Taiwan

²Taipei Veterans General Hospital, Department of Radiology, Taipei, Taiwan

Purpose or Objective: Previous literatures showed prior liver external beam radiotherapy (EBRT) may increase liver toxicity after yttrium-90 (90Y) selective internal radiation therapy (SIRT). In contrast, the safety of EBRT followed by SIRT is unclear. We investigated the safety and efficacy of EBRT followed by SIRT in hepatocellular carcinoma (HCC) patients.

Material and Methods: Between October 2011 and May 2015, a total of 11 HCC patients who had treated with SIRT followed by liver salvage EBRT were enrolled. The SIRT 3-dimensional absorbed dose distribution of each patient was retrospectively calculated on a voxel base, using post-treatment bremsstrahlung SPECT/CT images. The physical dose and biological effective dose (BED) of SIRT and EBRT were generated and summed for evaluation. The dose-volume histograms (DVHs) of the EBRT, SIRT, and combined therapy were analyzed. Liver-related toxicities were collected by chart-review and classified as Common Terminology Criteria for Adverse Events version 4.

Results: The median time interval of SIRT and EBRT was 95 days (IQR: 66.5-129.5 days). Eight patients (73%) had undergone EBRT for portal vein thrombosis (PVT) and 6 patients (55%) for residual hepatic tumor. The mean SIRT, EBRT, and combined therapy normal liver BED were 52.1±21.0 Gy, 17.9±6.1 Gy, and 69.5±15.0 Gy, respectively. The summed DVH of each patient is depicted in Figure 1. The image study three months post-irradiation showed primary disease PR in 4 patients (67 %) of patients and thrombosis improved in 6 patients (75%) after EBRT. Two patients had no evidence of disease after combined therapy. The median survival was 359.9 days. Total 3 patient (27 %) had developed ≥grade 2 liver toxicities. Patient who experienced hepatotoxicity had higher summed BED (107.0±7.3 Gy vs 58.9±13.5 Gy; P = 0.02). The univariate analysis of summed DVH showed that the fraction of normal liver exposed to more than 70 Gy (V70) was the strongest predictor of hepatotoxicity (9.4±7.2% vs 29.9±4.4%; P=0.007), as presented in Table 1.

Figure 1: DVH of 11 patients

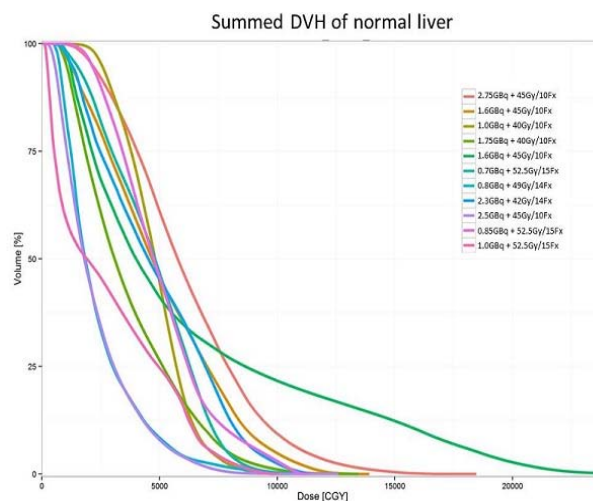

Table 1. Dosimetric parameter univariate analysis

	Hepatotoxicity		p value
	No (N = 8)	Yes (N = 3)	
V10 (%)	89.9 (13.0)	98.7 (0.9)	0.093
V20 (%)	72.1 (20.5)	85.4 (7.8)	0.180
V30 (%)	56.2 (22.7)	72.5 (10.8)	0.184
V40 (%)	42.6 (20.3)	60.5 (11.0)	0.142
V50 (%)	29.7 (15.5)	49.1 (8.6)	0.058
V60 (%)	17.9 (10.8)	39.2 (5.5)	0.007
V70 (%)	9.4 (7.2)	29.9 (4.4)	0.004
V80 (%)	4.8 (4.7)	21.1 (6.2)	0.051
V90 (%)	2.4 (2.8)	14.9 (7.5)	0.137

Values are shown as mean (SD)

Conclusion: Salvage EBRT after SIRT was effective for HCC patients with PVT. The 3D dose summation and BED-DVH of combined therapy help to predict liver toxicity. By carefully selecting patients, the combined therapy bring acceptable toxicities incidence.

EP-2020

Vertical type surface brachytherapy applicator improvement with a 3d printed dose compensation body
 K. Buchauer¹, G. Henke¹, L. Plasswilm¹, J. Schiefer¹
¹Kantonsspital St. Gallen, Departement of Radiation Oncology, St Gallen, Switzerland

Purpose or Objective: Unflattened surface HDR Brachytherapy applicators commonly suffer from dose fall off on the side of the dose distribution. Recent research documented that in addition to missing dose at the side of the applicator vertical type HDR Brachytherapy surface applicators are subject to underdose in the middle of the treatment region. This artifact is clinically relevant because tumor cells in the middle of the treated area can end up irradiated insufficiently. In this work we present a surface-dose compensation body generated with a 3D printer that specifically addresses the dose irregularities of a vertical type HDR Brachytherapy surface applicator. In order to overcome the limitation of increased treatment time of applicator flattening for horizontal type applicators we utilize the possibility of using a source position nearer to the surface to generate a flattened dose distribution together with reduced treatment time.

Material and Methods: A 40 mm Varian VariSource GM11010080 applicator was used for the modification (Varian Medical Systems, Inc., Palo Alto, CA, USA). The source position is 1.5 cm from applicator tip. The depth of evaluation is 0.5 cm solid water material. A consumer grade 3D printer "UP! 3D, Beijing TierTime Technology Co. Ltd." was used to print out a negative form with ABS plastic. Lippowitz type low temperature melting metal was used to mold the positive form of the flattening elements. All dose measurements and flatness evaluations were performed with Gafchromic EBT3 film Lot #: 12021402 and the FilmQA software, flatness and symmetry toolbox (both Ashland Speciality Ingredients, Bridgewater, NJ, USA).

Results: The generated compensation element is of toroidal shape, for the standard source position 1.5 cm from applicator tip, has a maximum thickness of 1.5 mm in surface direction. The output of the applicator with flattening element occurred to be 75% of the unflattened one. The diameter of 80% nominal dose area increased from 35.2 mm with the unflattened applicator to 50.2 mm with the flattening element in place. The asymmetric central low-dose artefact can be compensated to a clinical acceptable minimum dose. When utilizing the source position 1 cm from tip a prototype filter could bring the width of the 80% dose area to 45.0 mm, above the nominal applicator size, and output to 112 % of an unflattened applicator. The position 0.5 cm from tip is still considered flattable with increased low dose area in out of

field tissue due to applicator geometry when quick treatment is of clinical interest. The first source position on applicator tip is not flattable for clinical use.

Conclusion: The presented prototype of a dose compensation body can remove the dose artefacts of a vertical type HDR Brachytherapy surface applicator including the clinical relevant underdosed central region. With the appropriate flattening body it is now possible to utilize a source position nearer to surface and compensate for dose output loss when using a dose flattening element.

EP-2021

Cosmesis and acute toxicity outcomes in skin lesions treated with High-Dose-Rate Brachytherapy.

H. Pérez-Montero¹, A. Campos¹, M.P. Crespo¹, B. Gil¹, A.M. Cabezas¹, T.C. Chávez¹, V. Rodríguez¹, N. Gascón¹, J.F. Pérez-Regadera¹

¹Hospital 12 de Octubre, Radiation Oncology, Madrid, Spain

Purpose or Objective: Skin cancer is the most common malignancy in white population. The most prevalent histologies are basal cell carcinoma (BCC) followed by squamous cell carcinoma (SCC). They are locally aggressive lesions that rarely metastasize and their prognosis depends on local control. Due to their localization and superficial nature, cosmetic result of the treatment is of primary importance. High-Dose-Rate brachytherapy (HDR-BT) is a safe and effective treatment option for these carcinomas and for other skin lesions. There are two main techniques for its delivery: interstitial brachytherapy and plesiotherapy. We have evaluated early local control, acute toxicity and cosmetic outcomes in all patients treated with HDR-BT in our center.

Material and Methods: We assessed 47 patients who had 52 skin lesions. There were 29 SCCs, 14 BCCs, 4 keloid scars, 3 adenocarcinomas, 1 lentigo maligna and 1 Merkel cell carcinoma. Median age of treated patients was 78 years (34-93). Data was collected prospectively. All lesions were treated with HDR-BT at our institution between December 2014 and August 2015 by interstitial brachytherapy or plesiotherapy. Average total dose delivered was 35,63 Gy and Median dose delivered was 40,5 Gy.

Acute toxicity was graded using the Common Terminology Criteria for Adverse Events, version 4.0 and cosmetic outcomes were classified using the Radiation Therapy Oncology Group cosmetic rating scale.

Results: Average follow-up from completion of treatment was 5.5 months (2-10.1). The overall crude recurrence rate was 3,8% (n = 2). Grade 0 acute toxicity was observed in 7.7% of treated lesions (n = 4), grade 1 in 63.5% (n = 33), grade 2 in 21.2% (n = 11) and grade 3 in 7.7% (n = 4). No acute toxicity greater than grade 3 was observed. All acute toxic events were resolved between the first and the second month after brachytherapy. Cosmetic results were excellent or good in 92.3% of the cases (n = 48), fair in 3.8% (n = 2) and not evaluable in 2 patients whose tumours were not cured.

Fig 1. 2 cases of SCC before HDR-BT and 1,5 months post-treatment

Conclusion: HDR-BT seems to be a good alternative for treatment of epitheliomas in special locations, above all in elderly patients with comorbidities that preclude surgery. Its ability to treat a wide area with minimal alteration of normal tissues allows a high probability of cure with excellent cosmetic results and without affecting functionality.

We can conclude that HDR-BT could be a valid alternative to surgery with acceptable acute toxicity, good early local control and exceptional cosmetic outcomes in skin lesions.

EP-2022

Compare EBRT and brachytherapy in the treatment children's vaginal rhabdomyosarcoma.

O. Kozlov¹, I. Nechushkina², M. Nechushkin¹

¹NN Blokhin Cancer Research Center, Radiosurgery Brachytherapy, Moscow, Russian Federation

²NN Blokhin Cancer Research Center, Institute of Pediatric Oncology, Moscow, Russian Federation

Purpose or Objective: Rhabdomyosarcoma of the vagina is very rare disease, mainly girls were 1-3 years, only a few patients were 13-15 years old. Early studies have shown the advantage of intracavitary radiation therapy over surgical treatment and EBRT. There are new methods of planning EBRT from CRT moved to VMAT and IMRT. The emergence of new techniques in the EBRT and brachytherapy inspired us to the evaluation of methods of treatment children's vaginal rhabdomyosarcoma.

Material and Methods: From 1980 till 2015 38 patients received intracavitary brachytherapy with source Co-60 and Ir-192. In our cancer center were made special applicators for different designs. The main treatments were applicators for direct 8 mm diameter and a length of about 6-7 cm. Were specially made Co-60 tube source (LDR). Children were immobilized for several days. The active length was 4-5 cm. Since the 90s we switched to using stepping source Ir-192 HDR. Normalisation point changed from 5 mm to 2 mm from the surface of applicator. This made it possible to irradiate the entire vagina.

Planning is optimized for the creation of uniform dose distribution throughout the vagina. Accordingly, it was necessary to calculate dose distribution for these cases. For calculations were chosen CT and MRI and patient anatomy was extended, contoured target and OAR's. The calculation of CRT / IMRT / VMAT / Brachy. CTV was 6.5 cm³.

Unlike cervical cancer, in OAR's we added the urethra, which is located close to vagina, and which dose close to 100%. We have calculated % dose to the rectum, bladder, urethra and ovaries. For EBRT, we calculated the mean dose to OAR's, Brachytherapy for rectum and bladder, we calculated dose to 1 cm³, and the entire volume of urethra and ovaries.

Results: In both cases (EBRT and Brachy) ovaries was about 2% (2.0% -2.3%) of normalisation dose. However, it is worth considering that brachytherapy is given high dose per fraction, so radiobiological dose above.

CRT / IMRT / VMAT / Brachy:

Rectum: 37.7 / 26.6 / 29.9 / 37.2 %

Bladder: 58.7 / 39.6 / 37.1 / 30.8 %

Uretra: 99.0 / 99.2 / 97.2 / 50.2 %

Conclusion: Although improvement in EBRT (from CRT to IMRT and VMAT) and decrease in dose to OAR's, brachytherapy maintains its position in the treatment of this localization. When less integral dose brachytherapy and dose on OAR's (not whole body is irradiated, but only part of it), which significantly reduces late effects. In modern time, we should pay attention to other radionuclides, which can give uniform dose distribution (example Yb-169).

EP-2023

Radiation resistance induced immunity evasion by evoking PD-L1 expression

X. Gong¹, C. Zhou², X. Li², C. Zhao²

¹Shanghai Pulmonary Hospital, Radiation Oncology Department, Shanghai, China

²Shanghai Pulmonary Hospital, Oncology Department, Shanghai, China

Purpose or Objective: To characterize PD-L1 expression in non-small-cell lung cancer (NSCLC) cell lines, and explore the relationship between immunology escaping and tumor cell proliferation and apoptosis with receiving radiotherapy.

Material and Methods: Evaluating the PD-L1 protein and CD8+ T cells with immunohistochemistry in tumor tissue from NSCLC patients. In vitro assay, to detect the expression of PD-L1 in different NSCLC cell lines after conventional and hypofractionated radiation therapy by westernblotting and study the difference between A549 and radiation resistance A549 cell line by flow cytometry and westernblotting. To analysis PI3K/Akt and stat3 proliferation pathway and Bcl2 family apoptosis signaling pathway in A549 radiation resistance cell by westernblotting. Small interfering RNA (siRNA) was used to A549 radiation resistance cell, and then to observe the difference in PI3K/Akt and stat3 pathway. As for in vivo study, immunohistochemistry was used to detect the relationship between the expression of PD-L1 and NF-KB protein in control group, anti-PD-L1 group, radiation group and radiation plus anti-PD-L1 group.

Results: We found that patients whose tumor expression the higher PD-L1 protein, who had the more radiation resistance and had less CD8+ T cell around tumor microenvironment. PD-L1 protein improved obviously in NSCLC cell lines after receiving conventional radiation, but there is not the same tendency after hypofractionated radiation. We found that A549 radiation resistance cell had activation in PI3K/Akt and stat3 pathway and its' NF-KB protein would be up-regulation. When the A549 acquired radiation resistance, it would be apoptotic less. We observed the activation of the anti-apoptosis protein bcl2 and the inhibition of the pro-apoptosis protein bim in A549 radiation resistance cell. After siRNA interfering to this cell, it's PD-L1 protein decreased. A549 radiation resistance cell came to be apoptotic. While it's pAkt, pstat3 and NF-KB didn't change.

Conclusion: Conventional radiation would be easy to induce radiation resistance by overexpressing the PD-L1. When the lung cancer cell express PD-L1 more, the tumor would escape from CD8+ T cell. NF-KB protein is the key to up-regulation PD-L1. When PD-L1 overexpression, lung cancer would be apoptosis less and immunity escaping. SiRNA interfering PD-L1 can eliminate the radiation resistance of the A549 cell line. It provide the evidence for the combination of the anti-PD-L1 drug and radiation therapy in clinic.

Optimising hyperthermia induced radiosensitisation for treating HPV+ cervical tumours

A.L. Oei¹, C.M. Van Leeuwen², R. Ten Cate¹, H.M. Rodermond¹, M.R. Buist³, L.J.A. Stalpers¹, J. Crezee², H.P. Kok², J.P. Medema¹, N.A.P. Franken¹

¹Academic Medical Center AMC Amsterdam- The Netherlands, LEXOR Laboratory for Experimental Oncology and Radiobiology- Department of Radiation Oncology, Amsterdam, The Netherlands

²Academic Medical Center AMC Amsterdam- The Netherlands, Department of Radiation Oncology, Amsterdam, The Netherlands

³Academic Medical Center AMC Amsterdam- The Netherlands, Department of Gynecologic Oncology, Amsterdam, The Netherlands

Purpose or Objective: Hyperthermia (raising the tumour temperature to 40-43°C) is an effective treatment in combination with radiotherapy for several tumour sites, including cervical cancer, which is mainly caused by infection with the Human Papillomavirus (HPV). The aim of our study is to improve treatment strategies for cervical carcinoma by (#1) unravelling mechanisms of hyperthermia induced radiosensitization, (#2) optimization of time interval between hyperthermia and radiotherapy and (#3) investigating the benefit of additional treatments.

Material and Methods: HPV-positive cervical cell lines SiHa and HeLa were used. Cells were treated with (#1) hyperthermia alone (42°C for 1h), (#2) by perthermia and irradiation in different time intervals between the two therapies and (#3) hyperthermia and radiation with additional agents PARP1-inhibitor (i.e. a drug blocking a DNA repair protein) and cisplatin. Clonogenic survival assays and γ H2AX stainings (a staining to visualize DNA double strand breaks) were carried out in order to determine the effectiveness of the (combined) treatments. Protein levels of p53 and DNA repair proteins were investigated using western blot. Apoptosis was measured in cell lines using the Nicoletti assay and cell cycle distribution was analyzed using the BrdU-assay.

Results: (#1) The high-risk HPV types 16 and 18 produce the oncoprotein, early protein 6 (E6), which binds to p53 before both proteins get degraded. Therefore, p53 cannot induce cell cycle block nor apoptosis, limiting the radiation effects. Hyperthermia increases the effectiveness by preventing the formation of the E6-p53 complex, rescuing p53 from degradation, resulting into functional p53 causing apoptosis and cell cycle arrest. (#2) Higher levels of p53 are present immediately after hyperthermia and remain up to four hours after treatment. The main therapy, radiotherapy or chemotherapy, should be applied within this time frame to yield a beneficial effect. (#3) Combination treatment of radiotherapy, hyperthermia, cisplatin and PARP1-inhibitors resulted in a lower survival fraction due to an increased number of DNA double strand breaks as compared to radiation alone. Cisplatin and PARP1-inhibition significantly enhanced the combined hyperthermia/radiation treatment.

Conclusion: Our findings provide new insights for patients suffering from HPV-positive cervical cancer. Hyperthermic-radiosensitization, makes radiotherapy significantly more effective by rescuing p53 from getting degraded. Adding PARP1-inhibitor or cisplatin further improves the effectiveness of hyperthermic-radiosensitization, which will increase clinical outcomes substantially.

EP-2025

The potential role of gold nanoparticles in proton beam radiosurgery for arteriovenous malformations
 A. Nor¹, M. Morris¹, F. Vernimmen¹, M. Shmatov²
¹Cork University Hospital, Radiation Oncology, Cork, Ireland Republic of
²Ioffe Institute, Theoretical Physics, St Petersburg, Russian Federation

Purpose or Objective: To theoretically evaluate therapeutic gain from radiation dose enhancement by gold nanoparticles (AuNP) based on their physical interaction with protons.

Material and Methods: Nanoparticles range in size from 1 x 10⁻⁹m to 100 x 10⁻⁹m, and exert their effect by either entering the cell, or by attaching to the cell membrane surface. Radiation enhancement by gold nanoparticles (AuNP) is based on the generation of much localized secondary radiation when irradiated. This results in a Dose Enhancement Factor (DEF) and has been well described for photon irradiation and is most pronounced with kilo voltage photons, but happens also with Mega Voltage (MeV). For protons the DEF obtained with metallic nanoparticles has recently been studied. We took the definition of DEF as being: DEF=(D_{pure} + DGNP - D_{wnp})/D_{pure}, where D_{pure} is the dose deposited in pure water.

Results: In vivo studies on tumors in mice have shown a considerable delay in tumor growth for mice receiving AuNPs with protons compared to protons alone. Protons have a high cross-section for gold over a large range of clinical energies, and the interaction produces Auger electrons with a very short range. The sphere of DEF around the AuNP is influenced by its size. For an AuNP of r = 22nm and 80 MeV protons the radius of the sphere of DEF is in the order of 18nm, with dose enhancement factors of up to 2 described. We obtained a value of 1.06 at 1 nm from a nanoparticle with radius 25 nm and taking D_{pure} as being: D_{pure} [Gy] 8.16 x Sw [MeV x cm²/g], where Sw is the stopping power of water. This small radius means that in order to be effective the AuNPs need to be in very close contact with the target. In the treatment of AVMs the prime target is the endothelial cell. Angiogenesis occurring in AVMs is driven by endothelial cells stimulated by vascular angiogenic factors binding on cell membrane receptors. AVM endothelial cells over express these receptors compared to their counterparts in normal brain vessels. IMC-1121B, a human antibody to VEGFR2, when linked with an AuNP has the potential to selectively increase the local AuNP concentration on the membrane of AVM endothelial cells. For conventional dose/fractionation schedules the radiobiological effects are governed by DNA damage in the cell nucleus. Membrane location could also be exploited because a cell membrane initiated effect is described, whereby activation of the acid sphingomyelinase/ceramide pathway occurs after doses >10 Gy, leading to endothelial apoptosis.

Conclusion: Successful AVM radiosurgery is amongst others dose dependent. Therapeutic gain in proton radiosurgery is possible with AuNP-VEGFR2ab located on the cell membrane, combined with doses > 10 Gy. This approach needs to be researched further, but offers the possibility for better obliteration rates and/or shorter latent intervals.

EP-2026

Effect of PARP-1 inhibition on human soft tissue sarcoma cells radiosensitivity

M. Mangoni¹, M. Sottili¹, C. Gerini¹, I. Meattini¹, I. Desideri¹, P. Bonomo¹, D. Greto¹, M. Loi¹, R. Capanna², G. Beltrami², D. Campanacci², L. Livi¹

¹University of Florence, Experimental and Clinical Biomedical Sciences, Firenze, Italy

²Careggi University Hospital, Department of Orthopaedic Oncology, Florence, Italy

Purpose or Objective: Soft-tissue sarcomas (STS) are aggressive tumours with a poor prognosis and there is a major clinical need for novel strategies. Poly-ADP ribose polymerase (PARP)-1 promotes base excision repair and DNA strand break repair. Inhibitors of PARP (PARPi) have shown to enhance the cytotoxic effect of irradiation (IR), and evidences suggest that PARPi could be used to selectively kill cancers defective in DNA repair. Sarcomagenesis is linked to aberrant biological pathways and some STS have defect in DNA repair systems, so there is a rationale for using PARPi in STS. We investigated the effect of PARP inhibition on STS cell lines survival after IR and on radiation-induced DNA damage foci.

Material and Methods: Cell proliferation analysis was performed on human fibrosarcoma, liposarcoma, leiomyosarcoma and rhabdomyosarcoma cell lines with increasing doses of olaparib (0.25; 0.5; 1; 2; 4 μM) 3 h after cells seeding. The numbers of cells were assessed after 5 days and results normalized to the untreated control. For clonogenic assays, fibrosarcoma, liposarcoma, leiomyosarcoma and rhabdomyosarcoma cells were irradiated with 2, 4 or 6 Gy, with or without olaparib (1 μM) iniparib (10 μM) or veliparib (5 μM) pre-treatment. The plating efficiency of the combined treatments were normalized to PARPi-treated cells. The linear-quadratic survival expression was fitted to the data by nonlinear regression. The radiosensitization enhancement ratio for the PARPi at 50% survival (ER50) was as follows: ER50 = Dose at 50% survival without PARPi/Dose at 50% survival with PARPi. The impact of PARP inhibition on $\gamma\text{-H2Ax}$ foci formation was evaluated in rhabdomyosarcoma cells treated with olaparib 1 μM after 48 h, and irradiated at 4 Gy. Cells were probed with primary antibody to $\gamma\text{-H2AX}$.

Results: Continuous treatment with olaparib for 5 days resulted in a dose-dependent inhibition of proliferation in all the STS cell lines. Significant radiosensitization was observed in all human STS cell lines using PARPi, with an ER50 ranging from 1.2 to 3.41. Rhabdomyosarcoma showed the greatest increase in radiosensitivity, with an ER50 of 3.41 with veliparib. Fibrosarcoma showed an ER50 of 2.29 with olaparib and 2.21 with veliparib. Leiomyosarcoma and liposarcoma showed similar radiation responses after PARP inhibition, with the higher radiosensitization in presence of veliparib (ER50 1.62 and 1.46, respectively). The combination of olaparib and radiation in rhabdomyosarcoma cells resulted in an increased number of γH2AX foci as compared to control and irradiation alone.

Conclusion: We demonstrated that PARPi are potent radiosensitizers on human STS in vitro models. The different PARPi radiosensitizing effects observed in various cell lines may be explained by the presence of different genomic aberrations in DNA repair machinery in specific STS subtypes. These preliminary data encourage to further study association of PARPi with IR as a promising treatment for STS.

Fractionated radiotherapy plus anti-angiogenic therapy in an orthotopic glioma transplantation model

V. Albrecht¹, J. Schuster¹, M. Proescholdt², D. Piehlmaier³, K. Unger³, C. Belka¹, M. Niyazi¹, K. Lauber¹

¹LMU Munich, Clinic for Radiotherapy and Radiation Oncology, Munich, Germany

²University Hospital Regensburg- Germany, Department of Neurosurgery, Regensburg, Germany

³Helmholtz Center Munich - German Research Center for Environmental Health GmbH- Neuherberg- German, Research Unit of Radiation Cytogenetics, Neuherberg, Germany

Purpose or Objective: Glioblastoma (GBM) is the most common primary brain tumor in adults. Despite intense treatment, including surgery and radiochemotherapy, prognosis is dismal with a median overall survival time of only 15 months. The vascular endothelial growth factor-A (VEGF-A) has been identified as one of the key regulators of neoangiogenesis in these highly vascularized tumors. Therefore, disruption of the VEGF-A signaling cascade by neutralizing VEGF-A and preventing ligation of its receptors appeared to be a promising approach for targeting neoangiogenesis. However, in recent phase III trials application of the VEGF-A blocking antibody bevacizumab in combination with radiochemotherapy failed to prolong overall survival in newly diagnosed GBM despite increasing progression-free survival and improving performance status. The aim of our study was to analyze the treatment effects of radiotherapy in combination with bevacizumab in a clinically relevant setting. Therefore, we established an orthotopic, syngeneic mouse glioblastoma model and subjected it to fractionated radiotherapy in combination with the bevacizumab mouse analogue G6-31.

Material and Methods: GL261 mouse GBM cells were stereotactically transplanted into the frontal lobe of C57/BL6 mice and tumors were allowed to grow for one week. Radiation therapy was performed with a Small Animal Radiation Research Platform (SARRP, Xstrahl) which incorporates contrast agent-CT (CA-CT)-based imaging followed by high precision radiation delivery. Fractionated irradiation with daily doses of 2 Gy up to a cumulative dose of 20 Gy was administered with or without accompanying VEGF-A blockade by the mouse bevacizumab analogue G6-31. Overall survival and tumor size were monitored, histological analyses, and transcriptomic profiling of tumor and normal tissue are currently being performed.

Results: Stereotactic implantation of GBM was successfully accomplished, fractionated irradiation was implemented by CA-CT-based image guidance, and tumor growth was successfully monitored by serial CA-CT scans. The single agent treatments led to a significant delay in tumor growth and prolongation of survival as compared to the sham-treated controls. Importantly, the strongest therapeutic effects were observed with the combined treatment. Histological details, including vessel density and structure, as well as markers of cell death induction, and transcriptomic profiling of tumor and normal tissue are currently under investigation.

Conclusion: This pilot study shows that syngeneic, orthotopic glioblastoma transplants combined with stereotactically delivered radiotherapy are feasible and clinically relevant in vivo models for evaluating the therapeutic efficacy of multimodal treatment approaches based on fractionated irradiation.

EP-2028

Dependence of dose enhancement on the cluster morphology of Gold Nano Particle in radiation therapy

A. Sang Hee Ahn¹, C. Kwangzoo Chung², H. Youngyih Han², P. Hee Chul Park², C. Doo Ho Choi²

¹Sungkyunkwan University, Department of Health Sciences and Technology- Samsung Advanced Institute for Health Sciences and Technology, Seoul, Korea Republic of

²Samsung Medical Center, Sungkyunkwan University School of Medicine Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: Injected gold nano particles(GNPs) to a body for dose enhancement are known to form cluster morphology. We investigated the dependence of dose enhancement on the morphology characteristic with an approximated morphology model by using Monte Carlo simulations.

Material and Methods: For MC simulation, TOPAS v.b-12 was used. GNPs of 50 and 100 nm diameter were tested. GNP cluster morphology was approximated as a body center cubic by placing 8 GNPs at the corner and one at the centered of a $2 \times 2 \times 2 \mu\text{m}^3$, $1 \times 1 \times 1 \mu\text{m}^3$, $0.5 \times 0.5 \times 0.5 \mu\text{m}^3$, or $0.25 \times 0.25 \times 0.25 \mu\text{m}^3$ (for 100 nm GNP) or $0.18 \times 0.18 \times 0.18 \mu\text{m}^3$ (for 50 nm GNP) cube located in a $4 \times 4 \times 4 \mu\text{m}^3$ water filled cube phantom. $4 \mu\text{m} \times 4 \mu\text{m}$ square shaped beams of spectrum-energetic 50, 100 kVp photons and 70, 170 MeV protons were irradiated to the water filled cube phantom with GNPs in it. We computed the distribution of secondary electrons as a function of distance from the surface of the GNP at the cube center and calculated the ratio (SER) together with dose enhancement ratio (DER) for 4 different cubes geometries. For scoring particles, 10 nm width of concentric shell shaped detector was constructed up to 100 nm from the center point of the cube. 10^8 histories of protons and 2×10^{10} histories of photons were used for simulation. All counted values at each detector were summed to obtain the total dose and secondary electrons in a sphere of 100 nm radius and were normalized to $2 \times 2 \times 2 \mu\text{m}^3$ cube morphology.

Figure 1. Schematic diagram of the GNPs cluster morphology Monte Carlo simulation geometry. (a) Body Center Cubic model (R is distance of GNP) and (b) Sensitive detector (material: water) each shell has 10 nm thickness.

Results: DER and SER increase as the distance of the GNPs reduces. The largest DER as well as SER was obtained for $0.25 \times 0.25 \times 0.25 \mu\text{m}^3$ cube for 100 nm $0.18 \times 0.18 \times 0.18 \mu\text{m}^3$ for 50 nm GNP. In case of 50 nm GNPs, DER increment was 1.421, 1.396, 1.017, and 1.014 for 50 kVp, 100 kVp photons, 70 MeV and 170 MeV protons, respectively. SER increment was 1.319, 1.303, 1.021, and 1.018, for 50 kVp, 100 kVp photons, 70 MeV and 170 MeV protons, respectively. For 100 nm GNPs, we observed the qualitatively same results but increment ratio was larger for all tested radiations.

Conclusion: As shown in this study, DER with GNPs was larger when they are closely packed in the phantom. Therefore, better therapeutic effects can be expected with close-packed GNPs.

Feasibility study of Fe₃O₄/TaOx nano particles as a radiosensitiser for radiation therapy

A. Sang Hee Ahn¹, L. Nohyun Lee², S. Sung Won Shin³, C. Chang hoon Choi³, H. Youngyih Han⁴, P. Hee Chul Park⁴, C. Doo Ho Choi⁴

¹Sungkyunkwan University, Department of Health Sciences and Technology- Samsung Advanced Institute for Health Sciences and Technology, seoul, Korea Republic of

²Kookmin University, School of Advanced Materials Engineering College of Engineering, Seoul, Korea Republic of

³Samsung Medical Center, Department of Radiation Oncology, Seoul, Korea Republic of

⁴Samsung Medical Center, Sungkyunkwan University School of Medicine radiation oncology, Seoul, Korea Republic of

Purpose or Objective: To investigate the feasibility of using multifunctional Fe₃O₄/TaOx (core / shell) nano particles developed for CT and MRI contrast agent as dose enhancing radiosensitizers.

Material and Methods: Firstly, to verify the imaging detectability of Fe₃O₄/TaOx nano particles, *in-vivo* tests were conducted. Approximately 600 mg/kg of 19 nm diameter Fe₃O₄/TaOx nano particles dispersed in phosphate buffered saline (PBS) were injected to ten nude Balb/c mice through the tail vein. Mico-CT (Siemens Inveon) was scanned for 5 mice and MRI (BioSpec, 70/20 USR, BRUKER Co.) scan was conducted for rest of mice. For both imaging, 4 consecutive scanning was performed at pre- and post-injection (5 min, 30 min, and 1 hour). Difference between pre- and post-injection images was analyzed by computing the pixel histogram and correlation coefficient factor using MATLAB in the user defined ROI (region of interests). Secondly, to quantify the potential therapeutic enhancement with nano materials, DER (Dose Enhancement Ratio) and number of SER (Secondary Electron Ratio) were computed using MC simulation (TOPAS v.b-12). Diameter of 19 nm circular beams of mono-energetic 10 MeV, 70 MeV, 150 MeV protons were irradiated to a Gold(Au), Tantalum(Ta), TaOx, Fe₃O₄/TaOx (core / shell), and Fe₃O₄ nano particle located at the center of $4 \times 4 \times 4 \mu\text{m}^3$ water filled cube phantom. DER and SER were computed

by placing a 1 nm thickness of shell detector at the surface of the particle.

Results: In CT, MRI imaging, the aorta, the blood vessel, and the liver were clearly visualized after intravenous injection of Fe₃O₄/TaOx nano particles. There was large different between pre and post-injection images of Histogram data and Coefficients of correlation factor in CT and MR are 0.006, 0.060, respectively. When 10 MeV protons were irradiated for a Gold(Au), Tantalum(Ta), TaOx, Fe₃O₄/TaOx, Fe₃O₄ nano particle, DER was 9.089, 7.724, 4.424, 3.660 and 3.255 respectively. Similarly, SER increment was 9.629, 8.401, 5.060, 4.341, and 3.590 for Gold(Au), Tantalum(Ta), TaOx, Fe₃O₄/TaOx, Fe₃O₄ nano particle, respectively. For 70 MeV proton beams, DER was similar to those for 10 MeV, but increment ratio was lower for 150 MeV protons.

Figure 1. Result of Monte Carlo simulation calculation for Gold, Tantalum, TaOx, Fe₃O₄/TaOx, Fe₃O₄ nano particle. (a) DER and enhancement ratio (DER), (b) number of secondary electron ratio (SER).

Conclusion: Fe₃O₄/TaOx nano particles have potential as a multifunctional agent which enhances the accuracy in cancer detection through visualization of developed tumor lesion and increases the therapeutic effect in proton therapy. The dose enhancement with Fe₃O₄/TaOx was estimated as half of the Gold. However, tumor targeting such as combined with magnetic field may overcome the low DER

Gadolinium enhanced x-rays radiotherapy of murine adenocarcinoma Ca755

A. Lipengolts¹, A. Cherepanov², V. Kulakov², I. Sheino², E. Grigorieva¹, V. Klimanov³

¹Russian Cancer Research Center, Institute of Clinical and Experimental Radiology, Moscow, Russian Federation

²Burnasyan Federal Medical Biophysical Centre, Department of radiation technologies, Moscow, Russian Federation

³National Research Nuclear University, Department of Experimental and Theoretical Physics, Moscow, Russian Federation

Purpose or Objective: The goal of radiotherapy is to deliver into tumor volume certain amount of radiation to kill all tumor cells and at the same time to minimize radiation damage of surrounding healthy tissues. To reach the goal modern conventional radiotherapy uses multifield irradiation with beam changing its shape and intensity. However this approach is not efficient enough in case when healthy and tumor tissues are highly diffused with each other. In this case partial healthy tissues damage is inevitable. Yet another approach is possible. Using some physiological mechanism tumor can be saturated with a high atomic number element capable to interact with external radiation more likely than the elements of biological tissues. That leads to dose increase at the site of the element location. For that purpose such elements as iodine, gold etc. and external x-rays radiation of energy up to 600 keV can be used. The main obstacle in implementing that method is how to deliver necessary amount of a high atomic number element into a

tumor. Attempts of developing tumor targeting drug, which would be capable to deliver necessary amount of high atomic number element into the tumor haven't succeed yet. Another possible way to deliver such elements into the tumor is to utilize some pathological processes caused by tumorigenesis such as blood barrier disruption in case of brain tumors or high vascularization inherent to some tumors. In this work the efficacy of x-rays irradiation with disodium gadopentetate (Gd-DTPA) administration in treating highly vascularized transplanted tumor in mice was studied.

Material and Methods: C57Bl/6 mice with transplanted adenocarcinoma Ca755 were used in the study. Animals were divided into three groups. 1st group undergo no treatment. 2nd group was irradiated with 10 Gy of x-rays. Animals in 3rd group were administered with 0.3 ml of 0.5M water solution of Gd-DTPA, containing 23 mg of gadolinium and then irradiated as well. Administration of Gd-DTPA was performed with single systemic injection. Irradiation was performed using x-rays generator with anode voltage of 200 kV. Antineoplastic efficacy was estimated by measuring tumor volume and life span of mice.

Results: Tumor growth rate plots are presented in Figure.

Tumor growth delay for test group was 13 days whereas in irradiated control group tumor growth delay was just 4 days. Median life span was 22 days, 37 days and 46 days for control group, irradiated control group and test group respectively. In test group 25% of animals have full tumor regression whereas in both control groups no tumor regression was observed. Endpoints of antitumor evaluation, i.e. T/C% ratio and gross log₁₀ tumor cell kill are represented in Table.

Group	T/C, %	Tumor growth delay, days	Gross tumor cell kill log ₁₀	Antitumor activity (Teicher 2004)
Irradiated control group (irradiation only)	37±6	4	0.5	-
Test group (irradiation + Gd-DTPA injection)	10±3	13	1.6	+++

Conclusion: Obtained results show that systemic injection of extracellular drug with gadolinium prior irradiation with x-rays provide enough amount of gadolinium in highly vascularized tumors and lead to significant increase of antineoplastic efficacy of x-rays irradiation.

Research on p53 and endostatin gene-radiotherapy induced by EGFR-targeted adenovirus vector in NSCLC

N. Wu¹, D. Han¹, G. Cheng¹, M. He¹

¹Jilin Cancer Hospital, Department of Radiation Oncology, Changchun, China

Purpose or Objective: With the development of molecular biology and gene engineering, more and more attention has been paid to gene-radiotherapy of malignant tumors. The combination of gene therapy and radiotherapy is regarded as

one of the effective methods for the treatment of tumors. This research focused on the Egr-1 promoter with radiation-induced effect, p53 and endostatin genes with function of inducing apoptosis and anti-angiogenesis, and EGFR-targeted adenovirus vector with higher cell infection efficiency. The therapeutic effect of adenovirus vectors Ad.Egr-wtp53-endostatin and Ad.CMV-sCAR-EGF combined with radiotherapy in non-small cell lung cancer is here reported.

Material and Methods: The adenovirus vectors Ad.Egr-wtp53-endostatin containing both wild type p53 and antiangiogenic molecule endostatin genes downstream of early growth response-1 (Egr-1) and Ad.CMV-sCAR-EGF containing coxsackie virus receptor extracellular segment (sCAR) and epidermal growth factor (EGF) were constructed using gene recombination technique. The infection efficiency in non-small cell lung cancer cell lines (A549, LK-2 and Lu65) of Ad.Egr-wtp53-endostatin mediated with Ad.CMV-sCAR-EGF expressed fusion protein sCAR-EGF was detected. The expression of wild type p53 and endostatin genes by the radiation-sensitive promoter Egr-1 in non-small cell lung cancer cell lines were observed. Immunodeficient mice (NOD/scid) subcutaneously implanted with A549 cells were treated by conventional radiotherapy (2Gy×6) and/or gene therapy (intratumor injection of adenovirus vectors Ad.Egr-wtp53-endostatin and Ad.CMV-sCAR-EGF 24 h before the first and fourth local doses). Immunologic mechanisms were explored.

Results: The fusion protein SCAR-EGF expressed from Ad.CMV-sCAR-EGF significantly increased infection efficiency of Ad.Egr-wtp53-endostatin in human non-small cell lung cancer cell lines. Cancer control was most significantly improved in the group receiving local radiotherapy combined with gene therapy as shown by prolongation of mean survival time by 75.2%, reduction in average tumor weight by 88.7%, decrease in pulmonary metastasis by 76.9% and decrease in intratumor angiogenesis by 80.4% as compared to local radiotherapy alone ($P < 0.05$). Immunologic studies showed stimulated natural killer (NK) and cytotoxic T lymphocyte (CTL) activity as well as increased interferon- γ (IFN- γ) and tumor necrosis factor- α (TNF- α) secretion in this combined treatment group as compared with the group receiving local treatment alone ($P < 0.05$).

Conclusion: The experimental findings in the present study showed that adenovirus vectors Ad.Egr-wtp53-endostatin and Ad.CMV-sCAR-EGF in combination with local radiotherapy could improve the tumor control. These observations may set the stage for developing clinical protocols with recombinant adenovirus-mediated gene-radiotherapy in non-small cell lung cancer.

EP-2032

Radiotherapy gets improved by a nanotechnology based enzyme therapy in glioblastoma primary cultures

L. Fernández Fornos¹, V. Barberá², M. Saceda³, P. García-Morales⁴, J. Sanz⁴, M. Fuentes⁴, M. Ventero⁴, P. Lucero-Calabuig⁴, P. Dorado Rodríguez¹, D. Espósito¹, S. Miranda Labajos¹, A. Pomares Arias¹, M. Ruiz Sánchez¹, E. García Miragall¹

¹Hospital General Universitario de Elche- ERESA, Servicio de Oncología Radioterápica, Elche, Spain

²Hospital General Universitario de Elche, Laboratorio de Genética Molecular, Elche, Spain

³Universidad Miguel Hernández de Elche, Fundación para el Fomento de la Investigación Sanitaria y Biomédica de la Comunidad Valenciana FISABIO, Elche, Spain

⁴Universidad Miguel Hernández de Elche, Instituto de Biología Molecular y Celular, Elche, Spain

Purpose or Objective: One of the main effects of radiotherapy is the generation of free radicals as a consequence of the incidence of radiation on the aqueous molecules present in the cells. The enzyme D-aminoacid oxidase (DAO) is also able to generate free radicals when converting D-aminoacids in their corresponding cetoacids. Our principal aim is to increase radiotherapy effects, using

the combination of radiotherapy and DAO, in primary cultures from glioblastoma.

Material and Methods: We have used primary cultures and established cell lines from patients with glioblastoma. Recombinant DAO carrying the C-terminal domain of the major lytic amidase (CLyA) specific for binding to choline was immobilized to magnetic nanoparticles having a magnetite core covered with Diethylaminoethyl (DEAE) cellulose. Primary cultures were irradiated at 7 and 15 Gy. After irradiation, cultures were treated in the absence or in the presence of DAO (free or immobilized in nanoparticles) and D-alanine (enzyme substrate). After irradiation, cells were harvested and cell cycle distribution was determined by flow cytometry.

Results: We have demonstrated in primary cultures from glioblastoma, that the treatment with DAO after irradiation, potentiates dramatically the effect of the radiation alone, increasing especially the percentage of cells in the sub-G1 phase, an indicator of cell death. Some representative results are included in the attached file. DAO immobilized in magnetic nanoparticles is more effective than free enzyme, since DAO is more stable at 37°C immobilized in nanoparticles.

Conclusion: The combination of radiotherapy and enzymatic therapy with DAO based on the nanotechnology, induce an increase in cell death when it is compared with radiotherapy alone.

EP-2033

Combining Hedgehog inhibition with metformin to induce radiosensitization in prostate cancer cells

S. Isebaert¹, A. Gonnissen¹, C. McKee², R. Muschel², K. Haustermans¹

¹University Hospital Gasthuisberg, Radiation Oncology, Leuven, Belgium

²CRUK/MRC Oxford Institute for Radiation Oncology, Oncology, Oxford, United Kingdom

Purpose or Objective: There are several indications that the Hedgehog (Hh) pathway could be a potential target for radiosensitization. Furthermore, a link between Hh signaling and the cellular energy metabolism has been described recently, more specific at the level of AMP-activated protein kinase (AMPK). Activation of AMPK, in turn, has also been shown to result in radiosensitization. Therefore, it seems worthwhile to explore whether the combination of Hh signaling inhibitors and AMPK activators such as metformin could further increase the response to radiotherapy. This combination strategy is being tested in prostate cancer (PCa) cells, as there is increasing evidence that the Hh pathway plays an important role in the development as well as progression to more advanced disease stages of PCa.

Material and Methods: Three PCa cell lines (PC3, DU145, 22Rv1) were treated for 72h with the SMO inhibitor GDC-0449 (1µM, 10µM) or GLI1/2 inhibitor GANT61 (1µM, 10µM), with or without metformin (5mM). The effects on cell survival, proliferation and radiation sensitivity were investigated by means of Sulforhodamine B (SRB) assays, Bromodeoxyuridine (BrdU) assays and colony assays. The effects on gene and protein expression (qRT-PCR/Western blotting), cell cycle distribution (flow cytometry, PI staining) and DNA repair (flow cytometry, γH2AX) were also examined, both in the absence and presence of ionizing radiation (4Gy).

Results: GDC-0449 on its own did not significantly affect cell proliferation, survival or radiation sensitivity of any of the PCa cell lines tested. Treatment with 10µM GANT61 on the other hand did result in a significant reduction of cell survival in all cell lines and induced radiosensitization in the 22Rv1 cells (DEF(SF0.5)=1.39±0.11, p=0.002) (Fig 1A). The latter could be ascribed to the drug's effect on apoptosis (Fig1B). Similar results as for GANT61 were observed after metformin monotherapy (DEF(SF0.5)=1.36±0.08, p=0.012). Moreover, metformin induced a significant downregulation of GLI1, both at the gene and protein expression level. While the

combination of metformin and GDC-0449 resulted in no additional effects, addition of metformin to GANT61 further enhanced the radiosensitization effects as induced by single agent treatment in the 22Rv1 cells.

Conclusion: The GLI1/2 inhibitor GANT61 as well as metformin induced radiosensitization in the 22Rv1 PCa cells. The combination of both agents further enhanced the response to radiotherapy, indicating that this might be a more powerful radiosensitization strategy as compared to either agent alone. Investigations are currently ongoing to explore the underlying working mechanisms.

EP-2034

Targeting hypoxic cancer cells by inhibition of checkpoint kinases ATR and CHK1

M. Joel¹, G. Hasvold¹, R.G. Syljuåsen¹

¹Institute for Cancer Research, Department of Radiation Biology, Oslo, Norway

Purpose or Objective: The checkpoint kinases ATR and CHK1 are considered promising targets for cancer treatment due to their roles in regulation of the S and G2 checkpoints and in the repair of DNA double strand breaks through homologous recombination. Interestingly, severe levels of hypoxia (<0.1% O₂) have been shown to activate ATR/CHK1 signaling, which could likely make hypoxic cancer cells sensitive to inhibitors of these kinases. The aim of this project is to explore whether inhibition of ATR or CHK1 could be used to selectively target hypoxic cancer cells, both in combination with ionizing radiation and on its own.

Material and Methods: Cancer cell lines U2OS, HCT116, H460, A549 and H1975 were treated with inhibitors of ATR (VE821, VE822) or Chk1 (AZD7762, UCN01) in the absence and presence of hypoxia (InVivo2 hypoxia chamber) and X-ray-irradiation. Cells were analyzed by flow cytometry, immunoblotting and clonogenic survival assays.

Results: We previously measured clonogenic survival, cell cycle distribution and activation of DNA damage signaling pathways in U2OS and HCT116 cancer cells at different oxygen concentrations (21%, 0.2% and 0.0% O₂) in combination with the CHK1 inhibitors UCN-01 and AZD7762 and ionizing radiation. We found that hypoxia alone did not alter the sensitivity to CHK1 inhibitors, but inhibition of CHK1 after reoxygenation following periods of extreme hypoxia (0.0% O₂) did result in decreased clonogenic survival and an increased fraction of γ-H2AX positive cells. Hypoxic cells were also found to be radiosensitized at least to the same extent as normoxic cells by CHK1 inhibition. Currently we are performing similar studies in lung cancer cell lines H460, A549 and H1975 treated with the ATR inhibitors VE821 and VE822. We have found that the number of γ-H2AX positive cells after ATR inhibition was higher in cells incubated at hypoxia (0.0% O₂, 20h) compared to normoxia (21% O₂). The ATR inhibitors also abrogated the radiation-induced G2 checkpoint. Clonogenic survival assays are ongoing.

Conclusion: These studies help determine the potential of using inhibitors of ATR and CHK1 to eradicate radioresistant hypoxic cancer cells

⁵University of Bern, Pathology Institute, Bern, Switzerland

⁶Catholic University of Daegu, Radiology and Biomedical Engineering, Daegu, Korea Republic of

⁷CEA, INAC/SCIB LAN, Grenoble, France

Purpose or Objective: An alternative approach for the improvement of radiotherapy consists in increasing differentially the radiation dose between tumors and healthy tissues using nanoparticles (NPs) that have been beforehand internalized into the tumor. These high-Z NPs can be photo-activated by monochromatic synchrotron X-rays, leading to a local dose enhancement delivered to the neighboring tumor cells. This enhancement is due to secondary and Auger electrons expelled from the NPs by the radiations. In order to carry the NPs into the tumor center, macrophages are currently under study for their phagocytosis and diapedesis abilities. In this study we characterized J774A.1 macrophages' internalization kinetics and subcellular distribution of iron NPs and compared them to the internalization abilities of the F98 glioblastoma cell line.

Material and Methods: Three aspects of internalization were examined: first, the *location of internalized NPs* in J774A.1 macrophages and F98 glioblastoma cells following a 24h incubation with iron NPs (0.3 mg/mL in the cell culture medium) was determined by optical microscopy after cell slicing. Subsequently, the *iron intake* after a 24h incubation with NPs (0.3 mg/mL and 0.06 mg/mL in the cell culture medium) was characterized for the two types of cells using ICP-MS. Finally, the *internalization dynamics* were studied by live phase-contrast microscopy imaging for 11 hours and by absorbance measurements for 24 hours using a plate reader.

Results: F98 tumor cells and J774A.1 macrophages are both able to endocytose NPs: we measured -61 ± 10 pg of internalized iron per macrophage compared with -33 ± 5 pg per F98 cell (initial iron concentration: 0.3 mg/mL in culture medium). F98 internalizing NPs for 10 hours showed stress signs during the first minutes after the NPs injection, but behaved like F98 control cells during the rest of the experiment. Finally, we determined that the internalization kinetics for J774A.1 had a typical saturation time of one hour.

Conclusion: Macrophages seem to be promising vectors for NPs, being able to endocytose and retain in their cytoplasm larger quantities of NPs than tumor cells. Our following studies will attempt to shed light on their other potential abilities as "Trojan Horses".

EP-2036

A flow cytometry-based screen for compounds that increase S-phase damage after Wee1 inhibition

C. Naucke¹, P. Juzenas¹, S. Hauge¹, T. Stokke¹, R.G. Syljuäsen¹

¹Norwegian Radium Hospital/ Oslo University Hospital, Department of Radiation Biology- Institute for Cancer Research, Oslo, Norway

Purpose or Objective: Inhibitors of Wee1 are in clinical trials for cancer treatment in combination with radiation or chemo-therapy. The antitumor effects have largely been attributed to their role in G2 checkpoint abrogation. However, our previous work has shown that Wee1-inhibition also causes DNA damage in S phase. To understand mechanisms behind the S-phase damage and to identify promising combination treatments, we initiated a flow

cytometry-based screen for compounds that increase S-phase damage when combined with the Wee1-inhibitor MK1775.

Material and Methods: The screen was performed in 384-well plates by using a pipetting robot and a flow cytometer equipped with a plate loader. REH leukemia suspension cells were treated with the LOPAC 1280 and Selleck Cambridge cancer 384 compound libraries in the presence and absence of the Wee1 inhibitor MK1775 (4h, 400nM), stained with the DNA-stain Hoechst and the DNA damage marker γH2AX, and analyzed by flow cytometry using the FlowJo software. In addition to drugs present in the compound libraries, three additional Chk1-inhibitors (LY60638, MK8776 and UCN01) were included in subsequent validation experiments.

Results: The Chk1 inhibitor AZD7762 was among the top hits of 1664 tested compounds, giving synergistically increased S-phase damage when combined with MK1775. Similar effects were found with with three other Chk1-inhibitors. In addition, the screen identified several expected negative and positive regulators of the S phase damage, such as inhibitors of Cyclin-Dependent-Kinase (CDK) and Topoisomerase, and some unexpected hits such as Dasatinib.

Conclusion: This study helps understanding how Wee1-inhibition causes S-phase damage, and will likely identify combinations of MK1775 and drugs relevant for future clinical studies. These drug combinations may also be useful to apply together with radiation therapy to eliminate radioresistant S-phase cells.

Radiation-induced abscopal effect in normoxic and hypoxic conditions in lung adenocarcinoma

S. Tubin¹, M.A. Mansoor², S. Gupta³

¹Institut für Strahlentherapie, Radioonkologie, Klagenfurt, Austria

²National Cancer Institute- National Institutes of Health, Radiotherapy Development Branch- Radiation Research Program- Division of Cancer Treatment and Diagnosis, Rockville, USA

³Albert Einstein College of Medicine, Department of Radiation Oncology, Bronx- New York, USA

Purpose or Objective: Many experimental evidences proved the existence of radiation-induced abscopal effect (RIAE), a phenomenon of non-targeted radiobiological effect which is rarely, unintentionally induced in vivo, mostly with high doses per fraction. We explored different biological, biochemical and physical factors on which the type and intensity of RIAE could depend and whose manipulation could lead to induction of strong, clinically applicable RIAE. Also, the radio-sensitizing potential of abscopal signals (AS) and the status of RIAE in hypoxia (H) were examined. After observation of AS transmission by tumor cells exposed to H, which were able to affect proliferation of normoxic (N) and H cells, irradiated as well as unirradiated, we introduce a new scientific term: "Hypoxia-induced abscopal effect" (HIAE).

Material and Methods: A549 and H460 lung cancer cells were incubated in H (Oxygen<2%) or N for 3 days and then irradiated (2 or 10Gy) or not. After 24h, unirradiated H (HCM) or N (NCM) conditioned media (CM) and irradiated H (HRCM) or N (NRCM) CM were collected. H-resistant (HR) clones A549/HR and H460/HR were generated by 3 weeks-exposure of cells to H. 2 identical sets of unirradiated N cells and HR clones were exposed to HCM, NCM, HRCM or NRCM and only 1 set was irradiated (2Gy) to evaluate the radio-sensitizing potential of AS. Cell growth was monitored using real time cell electronic sensing system. Cell survival was assessed by colony forming assay. Levels of basic fibroblast growth factor (GF)(bFGF), placental GF (PlGF), Soluble fms-like tyrosine kinase (sFlt-1) and vascular endothelial GF (VEGF) were assessed in CM.

Results: AS released by cells exposed only to H were active affecting proliferation and radio-sensibility of N cells and HR clones. Those effects depended on cell histotype, respiratory status of cell-inducers and cell-recipients of AS (N vs. H) and duration of cell-exposure to H (24 vs. 72h). Depending on time-exposure to H, HIAE promoted both increased and reduced proliferation. The type and intensity of RIAE depended on dose and notably changed if AS were transmitted by N or H irradiated cells (Tab.1, Fig.1).

Treatments	A549	A549/HR	H460	H460/HR
N-RCM (2Gy) vs. H-RCM (2Gy)	↓ (60%) sFLT-1, PIGF	↑ (20%)	↑ (25%) bFGF	↓ (20%)
N-RCM (10Gy) vs. H-RCM (10Gy)	↓ (40%) sFLT-1, PIGF	↑ (15%)	No diff sFLT-1, PIGF, VEGF	↓ (30%)
N-RCM (2Gy)+2Gy vs. H-RCM (2Gy)+2Gy	↓ (70%)	↓ (20%)	↑ (20%)	↓ (80%)
N-RCM (10Gy)+2Gy vs. H-RCM (10Gy)+2Gy	↓ (50%)	↓ (7%)	No diff	↓
N-CM+2Gy vs. H-CM+2Gy	↓ (65%)	↓ (20%)	↑ (25%)	↓

Table 1: Comparison of radiation-induced abscopal effects in normoxic and hypoxic conditions on proliferation of A549, A549/HR, H460, and H460/HR cells

Figure 1: Comparison of radiation-induced abscopal effects in normoxic and hypoxic conditions on proliferation of A549, A549/HR, H460, and H460/HR cells

In H460 RIAE caused radio-resistance, a phenomenon similar to adaptive response but in this case acquired via AS by cells that have never been irradiated. Manipulating the respiratory ambient of cell-receivers of AS the effects of both RIAE and HIAE on proliferation and radio-sensibility changed significantly. The comparative analysis of GF levels with cell proliferation and survival showed a correlation between anti-proliferative sFLT-1 and almost all CM types for both cell lines.

Conclusion: Our results proved that exposing of cells to H and irradiation of H cells lead to significant HIAE and RIAE, respectively, which are able to affect cell proliferation and radio-sensibility. Both phenomena depend on several factors whose manipulation is possible and leads to induction of clinically applicable RIAE.

EP-2038

Manipulation of radiation-induced bystander effect in prostate adenocarcinoma

S. Tubin¹, M. Valeriani², M.F. Osti³, G. Minniti³, S. Bracci³, S. Gerardo⁴

¹Landeskrankenhaus Klagenfurt, Radiotherapy, Klagenfurt, Austria

²Sant'Andrea Hospital- Rome- La Sapienza University, Radiotherapy, Rome, Italy

³Sant'Andrea Hospita- Rome- La Sapienza University, Radiotherapy, Rome, Italy

⁴Sant'Andrea Hospita- Rome- La Sapienza University, Laboratory Medicine, Rome, Italy

Purpose or Objective: Radiation-induced bystander effect (RIBE) has been described only for certain cancer types as the appearance of radiation effects in not directly irradiated cells. This study evaluated the ability of prostate adenocarcinoma (ADC) to induce RIBE exploring the factors that may affect its intensity. The idea was to produce a strong, clinically applicable RIBE, that could lead to development of innovative approaches in modern radiotherapy treatment of prostate cancer, especially for those patients with hormone-refractory ADC in which radiotherapy might have a limited role.

Material and Methods: 2 prostate ADC cell lines of different differentiation, PC-3 - hormone-resistant and DU-145 - hormone-sensitive, have been irradiated using wide range of doses (15 cGy-3000 cGy in 1 fraction) to obtain radiation-conditioned medium (RCM) which was then used to "treat" the unirradiated cells and to evaluate the cytokines level. Each sample of RCM was subjected to triple immunoassay assessment of the following cytokines: Eotaxin, Interferon-gamma, Interleukin(IL)-2, IL-4, IL-6, IL-8, IL-10, IL-12, Macrophage Inflammatory Protein-1-alpha, Tumor Necrosis Factor-alpha and Vascular Endothelial Growth Factor. Using a spectrophotometer cell growth was assessed. All comparisons were made to the negative control using paired t-tests. Significance was set at p-value < 0.05, 2-tailed test.

Results: Prostate ADC was able to induce RIBE which intensity depended on dose and tumor differentiation grade: the strongest RIBE for PC-3 was achieved with 2000 cGy and for DU-145 with only 15 cGy (Fig.1).

Figure 1. Bystander effect in prostate adenocarcinoma: the strongest proliferative blocking in PC-3 achieved with 20 Gy (left graph) and in DU-145 with 0.15 Gy (right graph)

For DU-145 there wasn't correlation between cytokines level and RIBE intensity while for PC-3 IL-6 correlates with strongest RIBE. The dose required to kill all cells exposed to irradiation was different for 2 cell lines: for DU-145 a lethal dose was reached with 2500 cGy, while PC-3 resisted to 3500 cGy after which tumor repopulation was observed starting 2 weeks after irradiation from just a few survived cells that have undergone particular "giant" differentiation.

Conclusion: RIBE intensity can be manipulated by modifying radiation dose and depends on differentiation grade. IL-6 correlates with strongest RIBE after exposure of PC-3 to a very high dose of radiation thus indicates its possible involvement in bystander signals transmission.

EP-2039

The impact of surgical wound fluids after IORT on the breast cancer stem cell phenotype

W.M. Suchorska^{1,2}, K. Kulcenty¹, D. Murawa³

¹Greater Poland Cancer Centre, Radiobiology Lab- Department of Medical Physics, Poznan, Poland

²Poznan University of Medical Sciences, Department of Electroradiology, Poznan, Poland

³Greater Poland Cancer Centre, Department Surgical Oncology I, Poznan, Poland

Purpose or Objective: Breast cancer is the most common cancer in women. The conventional conservative treatment

for early breast cancer includes a wide local excision with adjuvant radiotherapy. Clinical data suggest, that perturbations induced by surgery and the subsequent wound fluids, which are rich in cytokines and growth factors, may stimulate residual disease. Numerous studies demonstrate, that 90% of the local recurrence after surgery occur in the same quadrant as the primary cancer. It has been proposed, that cancer cells displaying the stem-like phenotype play a critical role in local recurrence, invasion and metastasis. One of the new possibilities in conservative cancer treatment is intraoperative radiotherapy (IORT). IORT delivers high dose of radiation as one single fraction at the time of surgery. It was previously reported, that IORT alters the microenvironment through the modulation of wound healing response. Thus we wondered, whether wound fluids can induce the enrichment of breast cancer stem cell phenotype in breast cancer cell lines and whether IORT plays inhibitory role in this process.

Material and Methods: Wound fluids from patients which underwent IORT (IR-WF), as well as control group without radiotherapy treatment (WF), were collected week after the surgery. Three human cancer cell lines with different molecular status (basal - MDA-MB-468, luminal - MCF7 and Her2-positive - BT-474) were then incubated with wound fluids (WF, IR-WF) in complete culture medium (10%). After four days of incubation the cancer stem-cell phenotype was established.

Results: Flow cytometry and RT-qPCR analysis revealed, that wound fluids from patients who received IORT decreased the phenotype of cancer-stem cells in the basal (MDA-MB-468) and luminal subtype (MCF7) of cancer cell lines compared to IORT-untreated patients. Such changes were not confirmed in HER2-positive cell line (BT-474).

Conclusion: The surgical wound fluids from both groups (WF and IR-WF) affect the putative stem cell phenotype. In IR-WF group, the lower stem cell phenotype was observed compared to fluids harvested after surgery alone.

⁵German Cancer Research Center DKFZ- Heidelberg and German Consortium for Translational Cancer Research DKTK, Partner Sites Dresden, Dresden, Germany

⁶Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden- Helmholtz-Zentrum Dresden-Rossendorf, OncoRay - National Center for Radiation Research in Oncology, Dresden, Germany

Purpose or Objective: To determine the influence of two different injection schedules on the pimonidazole hypoxic fraction (pHF) in three different head and neck human squamous cell carcinoma (HNSCC) xenograft tumour models.

Material and Methods: Three different HNSCC cell lines (FaDu, UT-SCC-5, UT-SCC-14) grown as xenograft tumours in nude mice (5 per cell line) where examined with different pimonidazole injection schedules. Either one single injection 60 minutes prior to tumour excision (100 mg/kg BW i.p.) or

three injections (each 33 mg/kg BW i.p.) starting 180 minutes before tumour excision with 60 minutes interval between injections. Both groups were given the perfusion marker Hoechst 33342 i.v. 1 minute prior to tumour excision. Tumours were snap frozen and consecutive central cross-sections (10µm) where stained with antibodies for pimonidazole and CD31. Using image analysis the pHF and other parameters of the microenvironment were determined.

Results: No statistically significant differences in pHF nor in visual staining patterns were observed after single versus multiple injections of pimonidazole (table and figure 1).

Table 1: Mean values of the pHF [SD] in %.

Tumour model	pHF single injection	pHF multiple injections
UT-SCC-5	23.49 [1.76]	27.54 [1.49]
UT-SCC-14	23.18 [2.63]	19.59 [2.04]
FaDu	9.17 [2.02]	10.25 [2.73]

Fig. 1: pHF for the cell lines for single and multiple pimonidazole injection (mean value for pHF of the two analysed sections per tumour, closed symbols for single, open for multiple injections)

Conclusion: In the HNSCC xenograft models investigated here pimonidazole detects predominantly chronic hypoxia. Assessment of cycling hypoxia requires alternative methods. Our data suggest that cycling hypoxia occurs either at a low level in our models or that hypoxia cycles so rapid that pimonidazole cannot bind sufficiently or cycling hypoxia levels are not low enough for pimonidazole reduction.

Vitamin D protects HUVEC from RT-induced senescence and apoptosis by modulating MAPK/Sirt1 axis

F. Marampon¹, G. Gravina¹, C. Festuccia¹, A. Colapietro¹, E. Di Cesare¹, V. Tombolini²

¹University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy

²Policlinico Umberto I "Sapienza" University of Rome, of Radiotherapy, Rome, Italy

Purpose or Objective: Radiotherapy toxicity is related to oxidative stress-mediated endothelial dysfunction. Here, we investigated on radioprotective properties of Vitamin D (Vit.D) on human endothelial cells (HUVEC).

Material and Methods: HUVEC, pre-treated with Vit.D, were exposed to ionizing radiation (IR): ROS production, cellular viability, apoptosis, senescence and western blot for protein detection were performed. The role of MAPKs pathway was investigated by using U0126 (10 µM) MEKs/ERKs-, SB203580 (2.5 µM) p38-inhibitor or by over/expressing MKK6 p38-upstream activator.

Results: Vit.D reduced IR-induced ROS production protecting proliferating and quiescent HUVEC from cellular apoptosis or senescence, respectively, by regulating MAPKs pathways. In proliferating HUVEC, Vit.D prevented IR-induced apoptosis by activating ERKs while in quiescent HUVEC counteracted IR-induced senescence by inhibiting the p38-IR-induced activation. MEKs&ERKs inhibition in proliferating or MKK6/mediated p38 activation in quiescent HUVEC,

respectively, reverted anti-apoptotic or anti-senescent Vit.D properties. SirT1 protein expression levels were up-regulated by Vit.D. ERKs inhibition blocked Vit.D-induced SirT1 protein up-regulation in proliferating cells. In quiescent HUVEC cells, p38 inhibition counteracted the IR-induced SirT1 protein down-regulation, while MKK6 transfection abrogated the Vit.D positive effects on SirT1 protein levels after irradiation. SirT1 inhibition by sirtinol blocked the Vit.D radioprotective effects.

Conclusion: Vit.D protects HUVEC from IR induced/oxidative stress by positively regulating the MAPKs/SirT1 axis.

EP-2042

Meta-analysis: can amifostine reduce chemoradiotherapy and radiotherapy toxicity in advanced NSCLC?

A. Devine¹, L. Marignol¹

¹*Applied Radiation Therapy Trinity, Discipline of Radiation Therapy, Dublin, Ireland Republic of*

Purpose or Objective: Trials of amifostine in patients with advanced non-small cell lung cancer (NSCLC) receiving chemoradiotherapy (CRT) or radiotherapy (RT) alone report varying treatment-related toxicity. A review and meta-analysis was conducted to examine amifostine's effect on toxicity and efficacy of CRT or RT alone in such patients.

Material and Methods: Searches of electronic databases yielded 16 eligible trials comprising 1057 patients. Data extracted from randomised and non-randomised trials were compiled in a review; results of randomised trials were pooled and using meta-analyses to estimate the effect of amifostine on treatment toxicity and efficacy.

Results: Amifostine reduced the risk of >Grade 2 acute oesophagitis by 26% (risk ratio [RR], 0.74; 95% confidence interval [CI], 0.65-0.86; $p < 0.0001$) and the risk of acute pulmonary toxicity by 44% (RR, 0.56; 95%CI, 0.41-0.75; $p = 0.0001$). Amifostine did not alter risk of late pulmonary toxicity (RR, 0.84; 95% CI, 0.65-1.08; $p = 0.17$). Risk of complete response was unchanged (RR, 1.64; 95% CI, 0.99-2.73; $p = 0.06$), partial response was unchanged (RR, 0.92; 95% CI, 0.73-1.16; $p = 0.48$). Statistical heterogeneity was high for toxicity but low for response. Non-randomised trials reported varying incidence of toxicities and survival/response. Studies were medium-high quality.

Conclusion: Statistical heterogeneity casts doubt over amifostine's efficacy in this setting, despite evidence of decreased incidence of acute oesophageal and pulmonary toxicity but not late pulmonary toxicity. Amifostine did not compromise CRT or RT efficacy.

EP-2043

The ANDANTE project: a re-evaluation of the risk from scattered neutrons during proton therapy

A. Ottolenghi¹, V. Smyth¹, K. Trott¹

¹*Universita degli Studi di Pavia, Dipartimento di Fisica, Pavia, Italy*

Purpose or Objective: It is well known that proton therapy generates a small but significant exposure to scattered neutrons. The success of paediatric proton treatments leads to a concern about second cancers arising in later life from the neutron exposure. However there are difficulties involved with estimating the risk from exposure to neutrons. The usual approach is through the concept of relative biological effectiveness (RBE) of neutrons compared to photons, since the risk from photon exposure is much better known (ICRP Publication 103. Ann. ICRP 37 (2-4), 2007) The RBE for neutrons has been evaluated using cellular and animal models. But this causes uncertainty when applying the method to humans. The ANDANTE project (<http://www.andanteproject.eu/>) has investigated the relative risk of cancer from neutrons compared to photons in the context of proton therapy, using three different disciplines in parallel.

Material and Methods: Physics: Charged particle spectra generated by both neutron and photon beams were characterised using Monte Carlo simulation and measurements. A track structure model was used to model the formation of complex lesions in DNA from the different spectra as an indicator of relative likelihood of cancer induction. A method was developed for reconstructing the scattered neutron doses outside the treatment volume during proton therapy, using available clinical data, in order to be able to predict second cancer risks. Stem cell radiobiology: Stem cells from thyroid, salivary gland, and breast tissue were given well characterised exposures to both broad- and narrow-spectrum neutron beams, and to 200 kV X-rays. The relative risk of damage from neutrons compared to photons was estimated using a number of endpoints. Part of the cell population was transplanted into mice. Detailed histopathological and molecular investigations were performed looking for pre-malignant lesions and signs of malignancy. Epidemiology: The results from the track structure modelling and stem cell experiments were combined to generate a relative risk model. Dose reconstruction and data analysis tools were developed for a multi-centre prospective epidemiological study using data from paediatric proton therapy treatments, which will test the relative risk model. The project has made initial plans for the study as a collaboration between centres in Europe and the USA.

Results: The track structure model reproduced the peak in relative risk between neutrons and photons at a neutron energy of around 1 MeV, similar to the ICRP model. The stem cell experiments successfully demonstrated a new methodology, but did not provide conclusive evidence to contradict the ICRP model. The feasibility of a prospective epidemiological study was demonstrated.

Conclusion: The results from the ANDANTE project do not contradict ICRP. In the longer term, the prospective study will provide greater certainty on the RBE for neutrons and how this applies to humans receiving proton therapy.

EP-2044

Radiation-induced lung fibrosis is associated with M2 interstitial and hybrid alveolar macrophages

L. Meziani¹, M. Mondini¹, B. Petit², M.C. Vozenin², E. Deutsch¹

¹*Institut Gustave Roussy, INSERM U1030, Villejuif, France*

²*Centre Hospitalier Universitaire Vaudois, Radio-Oncologie/Radiothérapie, Lausanne, Switzerland*

Purpose or Objective: Radiation-induced fibrosis is a delayed complication of radiotherapy often associated with chronic inflammatory process and macrophage infiltration. Nowadays, macrophages are suggested to be important cellular contributors to fibrogenic process, but their implication in the context of RIF is not well known.

Material and Methods: To investigate the role of macrophages in RIF we have used a classical experimental model of lung fibrosis developed in C57Bl/6 mice after 16Gy thorax-IR. We then profiled both alveolar macrophages (AM) and interstitial macrophages (IM) during the various steps of the fibrogenic process.

Results: We confirmed the fact that total lung irradiation at 16Gy (IR) induces an interstitial fibrosis associated with delayed recruitment of pulmonary macrophages. We found a transient depletion of AM associated with cytokine secretion during the acute post-IR phase (15 days), followed by an active repopulation and an enhanced number of AM during the late post-IR phase (20 weeks). Interestingly, AM were mostly recruited from the bone marrow and exhibit a hybrid polarization (M1/M2) associated with up-regulation of Th1 and Th2 cytokines. The number of M2-polarized IM significantly increased during the late time points after irradiation and a down-regulation of Th1 cytokine was measured in tissue lysate. These results suggest a differential contribution of hybrid AM vs M2-IM to fibrogenesis. Interestingly, in contrast to activated hybrid AM, activated

M2-IM were able to induce fibroblast activation *in vitro* mediated by an enhanced TGF- β 1 expression suggesting a profibrotic role of M2-IM. Specific depletion of hybrid AM using intranasal administration of clodrosome increased radiation-induced fibrosis score and enhanced M2-IM infiltration suggesting a protective role of hybrid AM.

Conclusion: These present study shows a dual and opposite contribution of alveolar *versus* interstitial macrophages in radiation-induced fibrosis and identify M2-IM as a potential therapeutic target to treat radiation-induced fibrosis.

EP-2045

In vivo monitoring of skin collagen state by multiphoton microscopy in the course of irradiation

N.D. Gladkova¹, V.V. Dudenkova^{1,2}, V.V. Elagin¹, K.V. Babak³, A.V. Maslennikova^{3,4}

¹State Medical Academy, Research institute of biomedical technologies, Nizhny Novgorod, Russian Federation

²Lobachevsky State University, General physics, Nizhny Novgorod, Russian Federation

³Lobachevsky State University, Biophysics, Nizhny Novgorod, Russian Federation

⁴State Medical Academy, Oncology and Radiotherapy beam diagnostics, Nizhny Novgorod, Russian Federation

Purpose or Objective: Adverse events in normal tissues during and after a course of cancer radiation treatment are one of the most pressing problems of modern radiation oncology. From among numerous works in this field, there are but a few concerned with the radiation-induced alterations of collagen, the processes of its degradation and subsequent remodeling. A new imaging technique - multiphoton microscopy (MPM) allows studying tissue collagen state on fibers and bundles level without additional staining due to second harmonic generation (SHG) phenomenon. The method has the key advantage of a potential in vivo application. This study's objective was in vivo evaluation of changes occurring at rat's skin collagen upon the exposure of conventional irradiation.

Material and Methods: Rat's ear was chosen as a model for detecting collagen changes. Experiments were carried out under Nizhny Novgorod Medical Academy ethical committee permission. Three male animals, 2 months old at the time of experiment, were used. Rat's ear was irradiated under general anesthesia (Zoletyl, 50 mg/kg, Virbac Sante Animale, France) by a Co60 unit Terabalt (UJP, Czech Republic) by a local field with single dose of 2 Gy up to the total dose of 24 Gy. The 3D imaging of collagen structure was performed by MPTflex (JenaLab, Germany) - a system for in vivo optical biopsies based on near infrared femtosecond laser technology. MPM imaging was carried out two times a week beginning from the first day of irradiation and once a week for three months after its completion. Cross-sectional images were obtained beginning from the horny layer with the step of 5 μ m up to the total depth of 100 μ m. Excitation was implemented with a pulsed (200 fs) titanium-sapphire laser at a wavelength of 740 nm and a pulse repetition frequency of 80 MHz; SHG collagen imaging was performed at 373-387 nm. Cross-sectional images of 512x512 pixels were obtained; the field size was 130x130 μ m. Numerical processing of the images was performed by ImageJ program. Mean fluorescence intensity and its standard deviation was calculated for all images. Coefficient S (a ratio of standard deviation/mean fluorescence intensity) was used for evaluation of collagen state.

Results:

Fig. 1. Examples of the MPM images of rat's ear: a - before irradiation, b - 24 Gy, c - 24 Gy, 3 month after irradiation, d - correspondent coefficient S.

Visual evaluation of MPM images demonstrated no noticeable changes of collagen packing and structure independent on the dose and time from radiation beginning (Fig.1, a, b, c). Numerical processing revealed subtle, but clear differences of coefficient S between intact and irradiated collagen. After radiation beginning, a decrease of magnitude of coefficient S and the decrease of title angle of the graph was observed (Fig.1 d). In a month after radiation completion, a magnitude remained decreased, but tilt angle of the graph returned to the initial level (Fig.1 d).

Conclusion: Numerical processing of MPM-images demonstrated changes of optical properties of collagen upon expose of clinically relevant doses of gamma-irradiation. The radiobiological interpretation of these changes require further study.

EP-2046

Modulation of radiation-induced oral mucositis (mouse) by dermatan sulfate

S. Gruber¹, E. Bozsaky¹, K. Frings¹, M. Arnold¹, V. Gernedl¹, S. Hetzendorfer¹, J. Mayer¹, S. Morava¹, S. Pfaffinger¹, P. Kuess², W. Dörr¹

¹Medical University of Vienna, Department of Radiotherapy-ATRAB - Applied and Translational Radiobiology and Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

²Medical University of Vienna, Department of Radiation Oncology and Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

Purpose or Objective: Oral mucositis is the most frequently occurring, dose limiting early adverse event of head-and-neck cancer radio(chemo)therapy. The purpose of the present study was to quantify the mucoprotective effect of dermatan sulfate (DS), and to characterise the associated changes in the expression of markers for epithelial proliferation, cell junctions, inflammation and hypoxia.

Material and Methods: The study comprises a functional and a histological arm. For the functional investigations, mice were irradiated with 5x3 Gy/week over one (days 0-4) or two weeks (days 0-4, 7-11). Each protocol was concluded by irradiation with graded top-up doses (day 7/14), to generate complete dose-effect curves. Daily doses of DS (4 mg/kg subcutaneously) were applied over varying time intervals. Mucosal ulceration, was analysed as clinically relevant endpoint during the functional studies. In the histological study, groups of three mice were sacrificed every second day, the tongues were excised and subjected to histological/immunohistochemical processing.

Results: DS significantly increased isoeffective doses for the induction of oral mucositis in almost all protocols, and

furthermore prolonged the latency to epithelial ulceration and reduced ulcer duration. Proliferation measurements with BrdU did not show any substantial effects of DS. The adherens junction protein β -catenin did significantly increase during irradiation, which occurred earlier with additional DS treatment. The hypoxia markers HIF-1 α and GLUT-1 showed a progressive increase during irradiation alone, which, however, was also not influenced by DS. IL-1 β and NF- κ B as markers of inflammation were dramatically increased during irradiation. While DS treatment abolished the radiation-induced increase of IL-1 β , however, no systematic effect on the expression of NF- κ B was observed.

Conclusion: DS has a significant mucoprotective effect. This is not based on stimulation of epithelial proliferation nor on modulation of radiation-induced hypoxic changes. In contrast, reduced or modulated inflammatory processes and/or increased/modified function of adherens junctions may have a mechanistic role. This hypothesis, however, needs to be validated in further studies.

1H NMR based metabolomic approach to monitoring of the head and neck cancer treatment toxicity

L. Boguszewicz¹, A. Hajduk², J. Mrochem-Kwarciak³, A. Skorupa¹, M. Cizek¹, A. Heyda², M. Sokol¹, K. Skladowski²

¹Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Department of Medical Physics, Gliwice, Poland

²Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, I Radiotherapy Clinic, Gliwice, Poland

³Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Analytics and Clinical Biochemistry Department, Gliwice, Poland

Purpose or Objective: Anticancer treatment affects composition and concentrations of metabolites in body fluids. In case of head and neck (HNC) cancers the acute radiation syndrome (ARS) was studied only at the genomic, proteomic and lipidomic levels. We aimed to identify and investigate molecular processes of treatment toxicity in HNC patients using high resolution NMR and NMR-based metabolomics.

Material and Methods: Forty five patients with HNC were treated with radiotherapy (RT) or cisplatin-based chemoradiotherapy (CHRT). Blood samples were collected within a week after RT/CHRT completion. The ARS was evaluated using Multi-parameter Monitoring (MPM) - an original evaluation system designed by the study investigators. The patients were divided into two classes (of high and low ARS) on the basis of the highest individual ARS value observed during the treatment. The NMR spectra of the serum samples were acquired on 400.13 MHz Bruker spectrometer at 310 K. The referenced to alanine and bucketed to 0.002 ppm spectra were analyzed using principal component analysis (PCA) and orthogonal partial least squares discriminant analysis (OPLS-DA). Additional statistical analyses (Mann-Whitney test, Pearson correlation) were performed on quantified metabolites.

Results: In the high ARS group we observed the increased signals of N-acetyl-glycoprotein - the NMR marker of inflammation, and acetate - a product of beta-oxidation of adipose tissue fatty acids. The high ARS group showed also the decreased signals of metabolites involved in energy metabolism: branched chain amino acids (BCAAs), alanine, creatinine, carnitine and glucose as well as decreased choline containing compounds reflecting disturbed membrane metabolism. Furthermore, we observed the positive correlations between C-reactive protein (CRP) and N-acetyl-glycoprotein as well as acetate and a percentage weight loss during the treatment. CRP was also negatively correlated with alanine and BCAAs.

Conclusion: 1H NMR is an efficient tool for detection of RT/CHRT toxicity markers in human serum. The results indicate at least three concomitant processes related to high treatment toxicity (high ARS): inflammation, altered energy metabolism and disturbed membrane metabolism. The combination of clinical and molecular approaches could deliver comprehensive information on treatment response, allowing monitoring and/or prediction of tolerance/toxicity of therapy as well as its outcome. Such approach gives a step forward into personalized therapy.

EP-2048

Serum cytokines as a predictive factor in hepatoma patients treated with radiotherapy

J. Seong¹, H. Cha¹, E.J. Lee¹

¹Yonsei Cancer Center- Yonsei University Health System, radiation oncology, Seoul, Korea Republic of

Purpose or Objective: Cytokines, which are involved in chronic inflammation, are also related to tumor aggressiveness and resistance to treatment in many cancers. However, there are limited reports on the significance of cytokines in tumor response to radiotherapy (RT). The aim of this study was to analyze serum cytokine levels and identify their association with treatment outcome in patients with hepatocellular carcinoma (HCC) treated with RT.

Material and Methods: Patients with HCC who treated with RT were eligible for this prospective study. Blood samples were collected before and after completion of the whole RT course. Serum cytokine levels measured using Cytokine Bead Array kits were analyzed with respect to patients' clinical profiles and treatment responses.

Results: Between September 2008 and October 2009, 51 patients were included in the analysis. Median follow-up duration was 12.3 months (range, 0.5-62.3). Forty-seven patients were diagnosed with modified UICC stage III or IV disease at the time of RT. Baseline serum IL-8 level increased with increasing stage and the IL-6 level was highest in patients with a history of pre-RT treatment (treatment-non-naïve). A higher baseline serum IL-6 level was also observed in patients with treatment failure, including overall, infield, and outfield failure, than in those without treatment failure. In subgroup analysis, a significant difference in serum IL-6 level was observed only in treatment-non-naïve versus treatment-naïve patients. Median overall survival and progression-free survival (PFS) were 13.9 and 7.7 months, respectively. Elevated serum IL-6 level was significantly associated with PFS for patients with infield failure (HR 1.011, p<0.0001).

Conclusion: The current findings suggest that assessment of baseline serum IL-6 level may be helpful to predict treatment outcome after RT for HCC, especially in patients who undergo treatment before RT.

EP-2049

Diffusion MRI for following tumor modifications after neoadjuvant radiotherapy

F. Lallemand¹, N. Leroi², M. Bahri³, E. Balteau³, A. Noel⁴, P. Coucke⁵, P. Martinive⁵, A. Plenevaux³

¹University of Liège and CHU, Radiotherapy and Cyclotron Research Centre and Laboratory of Tumor and Development, Liège, Belgium

²University of Liège and CHU, Radiotherapy Laboratory of Tumor and Development, Liège, Belgium

³University of Liège, Cyclotron Research Centre, Liège, Belgium

⁴University of Liège, Laboratory of Tumor and Development Biology, Liège, Belgium

⁵University of Liège and CHU, Radiotherapy, Liège, Belgium

Purpose or Objective: Neoadjuvant radiotherapy (NeoRT) improves tumor local control and tumor resection in many cancers. The timing between the end of the NeoRT and surgery is driven by the occurrence of side effects or the tumor downsizing. Some studies demonstrated that the

timing of surgery and the RT schedule could influence tumor dissemination and subsequently patient overall survival. We demonstrated the impact of NeoRT on metastatic spreading in a Scid mice model. After an irradiation of 2x5Gy, we show more metastasis in the lung when the mice are operated at day 4 compared to day 11 (1). Here, our aim is to evaluate with functional MRI (fMRI) the impact of the radiation treatment on the tumor microenvironment and subsequently to identify non-invasive markers helping to determine the best timing to perform surgery for avoiding tumor spreading.

Material and Methods: We used two models of NeoRT in mice we have previously developed: MDA-MB 231 and 4T1 cells implanted in the flank of mice (1). When tumors reached the planned volume, they are irradiated with 2x5 Gy and then surgically removed at different time points after RT. Diffusion Weighted (DW) -MRI was performed every 2 days between RT and surgery. For each tumors we acquired 8 slices of 1 mm thickness and 0.5 mm gap with an "in plane voxel resolution" of 0.5 mm. For DW-MRI, we performed FSEMS (Fast Spin Echo MultiSlice) sequences, with 9 different B-value (from 40 to 1000) and B0, in the 3 main directions. We also performed IVIM (IntraVoxel Incoherent Motion) analysis, in the aim to obtain information on intravascular diffusion, related to perfusion (F : perfusion factor) and subsequently tumor vessels perfusion.

Results: With the MBA-MB 231 we observed a significant increase of F at day 6 after irradiation than a decrease and stabilization until surgery. No other modifications of the MRI signal, ADC, D or D^* were observed. We observed similar results with 4T1 cells, F increased at day 3 than returned to initial signal (fig 1). The difference in the peak of F can be related to the difference in tumor growth between MBA-MB 231 in four weeks and 4T1 in one week.

Figure 1: Graphs representing F factor in tumor bearing mice before and after radiotherapy in MDA-MB 231(n=6) (Scid model) and in 4T1 (n=4) (BalbC model); (*= $p < 0, 05$)

Conclusion: For the first time, we demonstrate the feasibility of repetitive fMRI imaging in mice models after NeoRT. With these models, we show a significant difference between the pre-irradiated acquisition and day 6 or day 3 for perfusion F . This change occurs between the two previous time points of surgery demonstrating a difference in the metastatic spreading (1). These results are very promising for identifying noninvasive markers for guiding the best timing for surgery.

EP-2050

The assessment of fractal dimension with Dual Energy CT gives information on lung cancer biomarkers

V. González-Pérez¹, E. Arana², A. Bartrés¹, S. Oliver¹, B. Pellicer¹, J. Cruz², M. Barrios², L.A. Rubio⁴

¹Fundación Instituto Valenciano de Oncología, Servicio de Radiofísica y Protección Radiológica, Valencia, Spain

²Fundación Instituto Valenciano de Oncología, Servicio de Radiología, Valencia, Spain

³Fundación Instituto Valenciano de Oncología, Servicio de Anatomía Patológica, Valencia, Spain

⁴Fundación Instituto Valenciano de Oncología, Servicio de Biología Molecular, Valencia, Spain

Purpose or Objective: To assess whether texture analysis of images obtained with Dual Energy CT (DECT) is related to KRAS and Ki-67 lung cancer biomarkers.

Material and Methods: A retrospective review (May 2013 - January 2015) of 125 lung cancer patients with lung GSI (Gemstone Spectral Imaging) and perfusion CT imaging on a DECT was fulfilled. For 25 of them, the fraction of Ki-67 positive-tumour cells was analysed and for 19 patients KRAS-positive (mutation detected) or KRAS-negative (mutation not detected) character was evaluated (11 positive, 8 negative). DECT examination was performed on a Discovery CT 750 HD scanner (GE Healthcare, USA).

For the perfusion exam, blood volume, blood flow and permeability-surface studies were analyzed. At GSI exam, images related to absorption in Hounsfield units (HU), iodine concentration and monochromatic virtual images reconstructed at 40, 60, 80, 100, 120 and 140 keV were assessed. Tumour fractal dimension was measured with the use of *Mapfractalcount* plug-in for ImageJ (National Institute of Health, USA) software.

After extraction of DNA from paraffin embedded tissue using QIAamp DNA Investigator Kit (Qiagen), analysis of the KRAS gene exons 2 (codons 12/13) and 3 (codon 61) were performed in order to identify possible associated mutations with real-time PCR kit cOBAS® KRAS Mutation Test (Roche Diagnostics, SL).

T-Student test or U Mann-Whitney test were used to compare differences between KRAS-positive from KRAS-negative cohorts. Pearson correlation coefficient was used to study linear relationship between fractal dimension and the fraction of Ki-67 positive-tumour cells.

Results: Best result ($p=0.02$) for distinguishing KRAS-positive cohort was obtained for lesion fractal dimension at 140 keV virtual image. This parameter showed an AUC=0.80. It was predictive of KRAS-positive with 90.9% sensitivity and 75.0% specificity for a fractal dimension threshold of 2.352.

There was a correlation of lesion fractal dimension in blood volume image and the fraction of Ki-67 positive-tumour cells ($p=0.04$).

Conclusion: Ki-67 positive-tumour cells and KRAS-positive biomarkers lead to tumour heterogeneity that modify radiographic image. Fractal dimension parameter quantifies such imaging heterogeneity and could allow to differentiate them.

A higher fractal dimension (higher heterogeneity) of lesion at virtual monochromatic images is measured for KRAS-positive mutation, while a higher fraction of Ki-67 positive-tumour cells is associated with a more homogeneous blood volume at perfusion.

EP-2051

Hsp70 as a tumor specific biomarker in primary glioblastoma multiforme patients

F. Laemmer^{1,2}, C. Delbridge², K.A. Kessel^{1,3}, S. Stangl¹, J. Hesse¹, B. Meyer⁴, J. Schlegel², D. Schilling^{1,3}, G. Multhoff^{1,3}, T.E. Schmid^{1,3}, S.E. Combs^{1,3}

²Institute of Pathology- TU Muenchen, Neuropathology, Muenchen, Germany

³Institute of Innovative Radiotherapy- Helmholtz Zentrum Muenchen, Radiation Sciences, Muenchen, Germany

⁴Klinikum rechts der Isar- TU Muenchen, Neurosurgery, Muenchen, Germany

Purpose or Objective: The standard treatment regimen of patients with primary glioblastoma multiforme (PGBM) consists of neurosurgery, radio- and chemotherapy. Despite this multimodal treatment the overall survival of patients with PGBM is still approximately 15 months.

The stress-inducible heat shock protein 70 (Hsp70) contributes to tumor cell survival and is associated with poor prognosis, metastasis and therapy resistance. Therefore, the aim of this study is to analyze Hsp70 in PGBM tumor samples as a future prognostic biomarker and possible therapy target.

Material and Methods: Formalin fixed paraffin embedded (FFPE) sections of 44 human PGBM patients (isocitrate dehydrogenase wildtype) were analyzed by immunohistochemistry for Hsp70 (cmHsp70.1, IgG1, multimmune GmbH, Munich, Germany). Taking the intensity of Hsp70 staining into account, quantitative expression analysis of tumor cells with stained cytoplasm was performed. Two categories of Hsp70 staining were defined: Up to 40% and more than 40% positive tumor cells within the tumor regions. The Hsp70 immunoreactivity was correlated with the survival of the patients using the Cox regression analysis.

Results: Preliminary data show that the median survival of PGBM patients can be predicted by the Hsp70 immunoreactivity of the tumor cells. Regression analysis showed that patients with Hsp70 expression of more than 40% have a higher risk of disease progression with a hazard ratio of 2.59 ($p=0.045$).

Hsp70 expression in FFPE IHC section (Hsp70 positive tumor cells are brown)

Conclusion: These data provide the first evidence that Hsp70 expression in FFPE sections of PGBM patients is associated with disease progression. Moreover, measuring Hsp70 in FFPE sections of PGBM patients before radiotherapy treatment may be used as biomarker for the success of the therapy. The independency of Hsp70 expression and O6-methylguanin-DNA methyltransferase (MGMT) is currently under investigation.

EP-2052

Expression of molecular biomarkers in wound drainage fluids: a pilot study in head and neck cancer

M. Sottili¹, M. Mangoni¹, P. Bonomo¹, A. Deganello², A. Javarone², T. Gualtieri², I. Desideri¹, M. Loi¹, I. Meattini¹, F. Paiar¹, L. Livi¹

¹University of Florence, Experimental and Clinical Biomedical Sciences, Firenze, Italy

²University of Florence, Department of Surgery and Translational Medicine, Firenze, Italy

Purpose or Objective: In recent years, it has been suggested that wound drainage fluids (WDF) of patients operated for head and neck squamous cell carcinoma (HNSCC) may be characterized by molecular biomarkers with potential prognostic and predictive value. The detection of adverse features in the early perioperative setting could possibly lead to a refinement of current adjuvant treatments in high-risk patients. The purpose of our study is to report on the

feasibility and preliminary results of a pilot prospective study on WDF analysis in HNSCC.

Material and Methods: 14 consecutive surgically resected HNSCCs were studied. WDF were collected 1 day and 3 days after surgery from the cancer operative bed (COB). In 5 patients, WDF was collected also from free flap donor site (FFDS). WDF were centrifuged for 15 min at 3500 rpm, then divided in aliquots and stored at -80°C until analysis. The aim of the present study was to evaluate the expression of factors involved in tumor growth and progression 1 day and 3 days after surgery. EGF, VEGF, SDF-1 and osteopontin levels were measured in WDF using commercially available enzyme-linked immunosorbent assay (ELISA) kits. Each sample was analyzed in duplicates and then averaged for a mean value. Quality control pools of low, normal, or high concentrations for all parameters were included in each assay. The obtained results were expressed as pg/ml (EGF, VEGF, SDF-1) or ng/ml (osteopontin).

Results: A mean of 67 ml of WDF from COB and 51 ml from FFDS at day 1, and 42 ml from COB and 20 ml from FFDS at day 3 were collected for each patient. EGF expression was significantly reduced from day 1 to day 3 after surgery both in COB (140.7 ± 10.55 vs. 45.12 ± 13.35 pg/ml, $p < 0.001$) and in FFDS (157.1 ± 4.08 vs. 95.59 ± 32.89 pg/ml, $p < 0.05$). VEGF expression increased from 1 to 3 day both in COB (1277.74 ± 64.54 vs. 1616.81 ± 151.4 pg/ml, $p < 0.05$) and in FFDS (1227.51 ± 19.39 vs. 1400.25 ± 77.66 pg/ml, $p < 0.05$). The expression of markers of invasiveness and metastasis increased from day 1 to day 3: osteopontin expression significantly increased from day 1 to day 3 both in COB (9.97 ± 0.68 vs. 16.87 ± 0.56 ng/ml, $p < 0.001$) and in FFDS (9.51 ± 1.23 vs. 15.83 ± 1.08 ng/ml, $p < 0.01$). SDF-1 expression increased from day 1 to day 3 in COB (646.8 ± 65.39 vs. 1084.22 ± 148.8 pg/ml, $p < 0.05$). No differences in SDF-1 expression were detected in FFDS.

Conclusion: Preliminary data from pilot study evidenced that microenvironment induced by surgery favors residual tumor cell proliferation and progression. Growth factor expression is higher early after surgery (24 hours); on the contrary, expression of markers of invasiveness and metastasis increases from day 1 to day 3 after surgery. The few samples of WDF from FFDS do not allow to evidence differences of biomarkers expression between COB and FFDS.

⁷San Raffaele Scientific Institute, Lymphocyte Activation Unit- Immunology- Transplantation and Infectious Disease Division, Milan, Italy

⁸San Raffaele Scientific Institute, Unit of Cellular Immunology, Milan, Italy

⁹San Raffaele Scientific Institute, Medical Physics, Milan, Italy

Purpose or Objective: Hematologic toxicity and in particular decrease in the peripheral blood leukocyte and lymphocyte count is an important side effect of pelvic radiation therapy. The aim of this study was to investigate the kinetic of the redistribution of circulating leukocytes after pelvic irradiation in a animal model with in vivo non-invasive imaging modality.

Material and Methods: A rat model was used to investigate a possible selective accumulation of circulating lymphocytes to specific anatomical districts after radiation treatment focused to the urinary bladder. Eight Fisher rats were adoptively transferred with 4×10^7 VivoTag-750-labelled syngeneic primary splenocytes at two hours before the bladder irradiation. Two of eight rats were used as controls. Animals were transurethrally catheterized to allow contrast agent instillation. A kV cone beam computed tomography (CBCT) was acquired for each rat, to precisely deliver 6 MeV monofraction photon field. Rats were divided into three groups ($n=2$ /group) receiving different levels of dose: 15, 20 and 25 Gy. A bolus thickness equal to 1cm was positioned on the rat skin surface in the pelvic region. Ultrasound images of the pelvic region were acquired at baseline, at 2, 4 and 6 days after irradiation to monitor thickness variations of the bladder wall tissue. In vivo fluorescent imaging was used to evaluate accumulation sites of labelled leukocytes.

Results: A significant increase in the bladder wall thickness was found 4 days after irradiation in animals treated with a dose equal to 25 Gy. A fluorescent signal, secondary to labelled splenocytes accumulation, emerged in the liver and lymph nodes of all adoptively transferred rats, 2 and 6 days after irradiation, as expected. A modest specific signal (30% increase) at the bladder level resulted only in two animals receiving the higher dose (Figure 1.a), when compared to the non-irradiated (Figure 1.b). No specific fluorescent signal was detected at the bladder levels in animals treated with 20 and 15 Gy.

Conclusion: The relocation of peripheral leukocytes in the damaged tissue depends on the radiation dosage and it may be evaluated by means of a non-invasive imaging technique. Further analyses are currently ongoing.

EP-2054

Expression of DNA-PK in squamous cell lung cancer has gender differences and depends on smoking

J. Jaal¹, L. Mägi¹, T. Jögi², M. Kase³, A. Minajeva¹, V. Markus², T. Vooder⁴, R. Roosipuu⁵, J. Jaal²

²Tartu University Hospital, Dept of Radiotherapy and Oncological Therapy, Tartu, Estonia

³East-Tallinn Central Hospital, Cancer Centre, Tallinn, Estonia

⁴Centre for Thoracic Diseases, Dept of Thoracic Surgery, Ruhr, Germany

⁵Tartu University Hospital, Dept of Pathology, Tartu, Estonia

Purpose or Objective: Lung cancer is one of the most frequent and deadly types of cancer in Europe. Several aspects of non-small cell lung cancer (nsclc) in men and women continue to indicate potential male-female differences. Among these, higher treatment responses to current therapies in women are supposed, since women have better prognosis in any stage of the disease. In most stages of nsclc cytotoxic anti-cancer therapy (radiotherapy, chemotherapy) is used. It is known that treatment efficacy of cytotoxic anti-cancer therapy depends on tumor DNA-repair. Therefore, the aim of this study was to evaluate gender differences in the expression of DNA repair enzyme DNA protein kinase (DNA-PK).

Material and Methods: Surgically excised nsclc tissues ($n=111$, 50 adenocarcinomas, 61 squamous cell carcinomas) were examined for DNA-PK expression. After immunohistochemistry, the staining intensity of DNA-PK was quantified using an arbitrary score ranging from 0 (no staining) to 3 (strong signal). Also, the proportion (%) of DNA-PK positive (DNA-PK+) tumor cells was determined. All parameters were examined by 2 independent researchers in 10 randomly chosen microscopic fields (magnification $\times 40$).

Results: Immunohistochemical parameters were examined by 2 independent researchers whose results were in good accordance ($p < 0.0005$). Staining intensities of DNA-PK and the proportion of DNA-PK+ tumor cells varied, being in the whole nsclc group 2.4 ± 0.4 (mean \pm SD) and $86.3 \pm 9.1\%$ respectively. There were no significant gender differences in adenocarcinoma. However, we detected significant differences among nsclc patients with squamous cell carcinoma. Both, DNA-PK staining intensity and the proportion of DNA-PK+ tumor cells were significantly higher in men than in women, 2.5 ± 0.3 and $86.3 \pm 8.8\%$ vs 2.1 ± 0.6 and $79.6 \pm 11.9\%$ respectively (DNA-PK intensity: $p < 0.01$; DNA-PK+ proportion: $p = 0.03$). Additionally, we found that in squamous cell carcinoma, the expression of DNA-PK depends on smoking and pack-years. There was a correlation between pack-years and DNA-PK intensity ($p = 0.04$), as well as between pack-years and the proportion of DNA-PK+ tumor cells ($p = 0.04$).

Conclusion: Expression of DNA-PK in squamous cell lung cancer has gender differences and depends on smoking. Significantly lower expression of tumor DNA-PK was found in women with this histological subtype of nsclc. Latter might be one of the reasons why cytotoxic anti-cancer therapy is more efficacious in women than in men. In further studies, the combination of DNA repair inhibitors and cytotoxic anti-cancer therapy should be tested.

EP-2055

Fibro-inflammatory circulating proteins as biomarkers for response in locally advanced rectal cancer

P. Bulens^{1,2}, A. Debucquoy², I. Joye^{1,2}, O. De Wever³, A. Wolthuis⁴, A. D'Hoore⁴, E. Van Cutsem⁵, V. Vandecaveye⁶, X. Sagaert⁷, C. Deroose⁸, O. Gevaert^{2,9}, K. Haustermans^{1,2}

¹University Hospital Leuven, Radiation Oncology, Leuven, Belgium

⁵University Hospital Leuven, Digestive Oncology, Leuven, Belgium

⁶University Hospital Leuven, Radiology, Leuven, Belgium

⁷University Hospital Leuven, Pathology, Leuven, Belgium

⁸University Hospital Leuven, Nuclear Medicine, Leuven, Belgium

⁹Stanford University, Medicine- Division of Biomedical Informatics, Stanford, USA

Purpose or Objective: Selecting good responders after chemoradiation (CRT) for locally advanced rectal cancer (LARC) could lead to the omission of total mesorectal excision (TME) in patients with pathologic complete response (pCR). In the current study, we assessed the value of several blood biomarkers associated with the fibrotic response to CRT (IGF-1, IGFBP-2, HGF & GDF-15) as markers for general fibro-inflammatory response and as tumor response predictors in a group of 80 patients.

Material and Methods: ELISA analysis of IGF-1, IGFBP-2, HGF and GDF-15 was conducted on prospectively collected serum samples of 80 LARC patients on 3 time points (before, during, after CRT). The fibro-inflammatory response was scored on H&E sections of the resection specimen. Changes in concentration were analysed using a Kruskal-Wallis test. Correlation of concentration at each time point and the difference between these time points (Δ) with fibro-inflammatory response and tumor response (pCR and ypT0-1) were assessed using a Mann-Whitney-U test.

Results: Higher Growth Differentiation Factor 15 (GDF-15) concentration before CRT correlated with the presence of a fibro-inflammatory response ($p = 0.04$), but was not observed for the other proteins nor for GDF-15 at other time points. General increase in GDF-15 concentration during treatment (median 0.81 ng/ml before, 2.16 ng/ml during, 2.37 ng/ml after CRT; $p < 0.0001$) was measured (Figure 1). Although no significant general concentration changes occurred for IGF-1, IGFBP-2 or HGF, we did find a correlation between the variation in expression of IGFBP-2 during treatment (Δ IGFBP-2 TP3-TP2) with tumor response (pCR $p = 0.02$; ypT0-1 $p = 0.02$). Other proteins did not correlate with tumor response.

Figure 1. GDF-15 Concentration at different time points (TP) during treatment. (TP1: before CRT; TP2: during CRT; TP3: after CRT)

Conclusion: GDF-15 serum concentration increases during CRT for LARC and a higher concentration measured before start of treatment is correlated with the presence of a fibro-inflammatory response. These results suggest that GDF-15 could be used as an early predictor of fibro-inflammatory response and thereby indirectly as predictor for disease-free

survival. This will be evaluated when follow-up data are available for this patient cohort.

The correlation of variation in expression of IGFBP-2 with tumor response (pCR and ypT0-1) opens a novel possibility for selecting good responders to CRT. We aim to combine these findings with imaging analyses (DW-MRI, PET) at different time points during treatment to develop a predictive model for selecting LARC patients in whom surgery could be omitted.

EP-2056

Preclinical investigation of hypoxia induced genes in different prostate cancer cell lines.

T. Wittenborn¹, S. Nielsen¹, M. Busk¹, M.R. Horsman¹, J. Overgaard¹, J. Alsner¹, B.S. Sørensen¹

¹Aarhus University Hospital, Department of Experimental Clinical Oncology, Aarhus, Denmark

Purpose or Objective: Hypoxia is a common feature in prostate cancer and is known to reduce the response to radiotherapy. Hypoxic modifiers can to a large extent overcome these obstacles, and a proper classification of tumors into hypoxic and non-hypoxic fractions is necessary. Previously our department has developed a gene profile consisting of 15 genes, which demonstrated prognostic and predictive impact for hypoxic modification in head and neck squamous cell carcinomas (HNSCC). In the current study we investigated the 15 gene profile in different prostate cancer cell lines.

Material and Methods: For the in vitro experiments the prostate cancer cell lines investigated were PC-3, DU-145, and LNCaP. Cell lines were cultured under normoxic (21% O₂) or hypoxic conditions (0% O₂) for 24 hours, totRNA was extracted and gene expression levels measured by qPCR. Individual reference genes were selected (PSMC4, TBP, NDFIP1) and applied in the normalization of the relative expression levels, together with the reference genes previously used in the HNSCC study. For in vivo experiments, the PC3 cell line was inoculated on the flank of female NMRI nu/nu mice, whereas the LNCaP and DU-145 cell lines were inoculated on the flank of severely immunocompromised CIEA/NOG mice. Two hypoxia-sensitive tracers (18F-FAZA and Pimonidazole) were administered in order to determine hypoxic and non-hypoxic regions on excised tumor sections. These regions were isolated by laser-assisted microdissection, after which totRNA was extracted and gene expression levels measured by qPCR.

Results: In the in vitro experiments, all prostate cancer cell lines had 14 of the 15 genes induced by hypoxia. The only discrepancy was ALDOA, which was not upregulated in the hypoxic cells. In vivo experiments are still ongoing but preliminary results from PC3 xenografts have been produced. These show a hypoxia induced upregulation in 10 out of the 15 genes, of which 4 were significantly upregulated (ADM, ANKRD37, FAM162A, and LOX).

Conclusion: In this study we investigated the 15 gene hypoxic profile in three different prostate cancer cell lines. A hypoxia dependent induction of genes was observed in both in vitro and in vivo experiments. From the performed experiments, and looking only at oxygen dependency, it appears that the gene profile could be suitable for prostate cancers as well as HNSCC.

EP-2057

Radiotoxicity prediction by gene expression profiling when simulating therapy in matched fibroblasts

M.A. Schirmer¹, C.P.N. Mergler¹, L.H. Droege¹, M. Guhlich¹, J. Gaedcke², M. Ghadimi², M. Rave-Fränk¹

¹Klinikum der Universität Göttingen, Radiotherapy and Radiation Oncology, Göttingen, Germany

²Klinikum der Universität Göttingen, General and Visceral Surgery, Göttingen, Germany

Purpose or Objective: Acute radiotoxicity might put a vital threat to the patient and may require interruption or

preterm stop of the therapy thus jeopardizing the intended treatment outcome. Despite numerous research attempts there is still no robust feature established in clinical routine to predict radiotherapy-induced toxicity prior to therapy start.

Material and Methods: The study cohort comprised 40 patients who underwent neoadjuvant radiochemotherapy (N-RCT) for rectal cancer (28x1.8 Gy, 5 times weekly, concomitant with two cycles 5-FU-based chemotherapy). From each of those patients dermal fibroblasts were cultured from skin specimen gained outside of the radiotherapy planning target volume at occasion of surgery conducted about six weeks upon N-RCT completion. Acute radiotoxicity was thoroughly monitored throughout the N-RCT series and documented according to CTC classification. Maximal acute toxicity (MAT) was defined by the highest CTC grade of the four items "cystitis", "proctitis", "enteritis", and "dermatitis". MAT was grouped into grades 0/1 (n=16), 2 (n=16), and 3/4 (n=8). N-RCT was simulated in the cultured fibroblasts for five consecutive days (1.8 Gy each at d1-d5 with addition of 5-FU at a concentration reflecting clinical steady-state levels) followed by a 7-day wash-out period. Gene expression of nine candidate genes (*CAT*, *CDKN1A*, *CTGF*, *SMAD2/3/4/7*, *TGFB1*, *TGFB1R1*) supposed to mediate early radiation-induced toxicity was ascertained by quantitative real time PCR. Samples for these RNA analyses were harvested at d2 and d5 (each 4 hours upon application of the radiation fraction) as well as at day 12 upon the wash-out period. *GAPDH* and *HPRT1* transcript levels served as reference.

Results: MAT was related to radiation-induced expression changes of four of the considered genes in fibroblasts. The strongest impact was obtained for *SMAD7* and *CAT* at d5. The higher the MAT score, the lower the induction of *SMAD7* and *CAT* by radiation was ($p=0.001$ and 0.003). However, upon the wash-out period at d12 no statistical differences in dependence on the MAT score were seen anymore for these two genes. In contrast, a high MAT score was linked to low radiation-induced induction of *CTGF* ($p=0.005$) and to a faster decrease of the massively induced *CDKN1A* ($p=0.03$) at d12. At d2, a trend ($p=0.06$) for *CAT* in relation to MAT in the same direction as at d5 was noticed with no correlation of any of the other genes at this early time point.

Conclusion: Radiation-induced expression changes in patient-matched fibroblasts may serve as biomarkers to predict clinical radiotoxicity. Induction of *SMAD7* and *CAT* may mitigate TGFbeta signalling and reactive oxygen species load thus saving normal tissue during radiotherapy. A protective role might also be attributed to sustained elevation of *CDKN1A*. The link between post-radiation induction of *CTGF* in fibroblasts and low MAT remains to be clarified. Understanding the mechanistic basis of these findings might pave the way for better protection of irradiated normal tissue.

EP-2058

A novel multi-SNP model predictive of erectile dysfunction following radiotherapy in prostate cancer

J.H. Oh¹, S. Kerns², H. Ostrer³, B. Rosenstein⁴, J.O. Deasy¹

¹Memorial Sloan Kettering Cancer Center, Department of Medical Physics, New York, USA

²University of Rochester Medical Center, Department of Radiation Oncology, Rochester, USA

³Albert Einstein College of Medicine, Departments of Pathology and Genetics, New York, USA

⁴Mount Sinai School of Medicine, Department of Radiation Oncology, New York, USA

Purpose or Objective: Erectile dysfunction (ED) is one of the most common complications encountered after radiotherapy in prostate cancer patients. The goal of this study was to investigate whether single nucleotide polymorphisms (SNPs) are associated with late ED in men treated with radiotherapy for prostate cancer. To this end, we designed a novel

machine learning-based multi-SNP model using a genome-wide association study (GWAS) dataset.

Material and Methods: We analyzed 236 evaluable patients with at least one year of follow-up for the development of ED. The severity of ED was assessed using either the patient-administered Sexual Health Inventory for Men (SHIM) or the clinician-assigned Mount Sinai Erectile Function (MSEF) scoring schema. There were 133 patients with Grade 2 or more ED. For our analysis, the cohort was split into two groups (cases/controls: MSEF 0,1 / 2,3; cases/controls: SHIM ≤ 7 / ≥ 16). Genome-wide SNP data were available from Affymetrix Genome-Wide Human SNP Array 6.0. After a quality test including SNP missing rate $>5\%$, minor allele frequency (MAF) $<5\%$, and Hardy-Weinberg equilibrium ($p < 10^{-5}$), 613,496 SNPs remained.

For the validation purpose of our proposed model, the dataset was split into a training dataset (2/3 of samples) and a validation dataset (1/3 of samples). Our model building process was performed using the bootstrapped data from the training dataset. Our idea is to convert the binary outcomes into preconditioned continuous outcomes based on normal tissue complication probability (NTCP) using principal component analysis (PCA) and logistic regression. The preconditioned outcomes were used in the model building process using random forest regression. Then, the model was tested using the validation dataset. The final predicted outcomes were compared with the original binary outcomes to estimate the predictive performance. We iterated this process 100 times and the performance was averaged. We compared the performance of our proposed method (preconditioning random forest regression: PRFR) with other methods including preconditioning lasso (PL), lasso logistic regression (LLR), and random forest classification (RFC).

Results: Univariate analysis was performed using the training dataset. With a threshold of $p=0.001$, 367 SNPs remained. These SNPs were fed into our model. As shown in Figure (A), the averaged performance with the validation dataset was AUC=0.62, which is better than other methods: RFC (0.57), PL (0.58), and LLR (0.57). The 79 patients in the validation dataset were binned into 6 groups according to the predicted risk of ED. Figure (B) shows the comparison of the model-predicted incidence of ED with observed incidence.

Conclusion: Our machine learning-based multi-SNP model showed the potential to better predict the radiation-induced late ED. However, we need to validate our model using other datasets.

Figure. Comparison of our machine learning-based multi-SNP model with other methods (A) and comparison of the model-predicted incidence of ED with observed incidence with events/patients on the top of the standard error bars in 6 bins (B).

EP-2059

Changes in hypoxia in serial F-MISO/PET-CT during chemoradiation in HNSCC

H. Kerti¹, A. Bunea¹, L. Majerus¹, M. Mix², C. Stoykow², N. Wiedenmann¹, P.T. Meyer², A.L. Grosu¹

¹University Hospital Freiburg, Department of Radiation Oncology, Freiburg, Germany

²University Hospital Freiburg, Department of Nuclear Medicine, Freiburg, Germany

Purpose or Objective: Tumor hypoxia, a common feature of locally advanced head and neck cancer (HNSCC), is associated with higher malignancy and increased radioresistance. The decrease of tumor hypoxia during

fractionated radiation treatment is assumed to be decisive for treatment success. [18F]-Fluoro-Misonidazole PET (F-MISO-PET) allows noninvasive assessment of hypoxia during treatment. The purpose of the present study was to noninvasively assess the time course of tumor hypoxia.

Material and Methods: A prospective serial imaging study was conducted in patients undergoing definitive chemoradiation (dRCTX, total dose 70Gy) for locally advanced HNSCC, accompanied by cisplatin in weeks 1, 4 and 7. Tumor hypoxia was assessed by F-MISO-PET by static scans acquired 2.5 h p.i. Tumor volumes were determined for FDG PET/CT scans and the coregistered F-MISO/CT scans. At baseline MRI, FDG-PET/CT and F-MISO-PET were acquired (week 0). Additional F-MISO-PET/CT scans were acquired in treatment weeks 2 and 5. Normal sample distribution was confirmed with Shapiro-Wilk test. Unpaired t-test analysis of the mean SUV_{max}(tumor)/SUV_{mean}(muscle) ratios of F-MISO-PET in weeks 0, 2 and 5 were performed. Significance-level was defined as $p < 0.005$.

Results: Between 2012 and 2014 18 patients (16 men, two women, mean age 60 years), treated for HNSCC with dRCTX were included. All received a total dose of 70 Gy in 35 fractions. Concomitant cisplatin chemotherapy was administered in weeks 1, 4 and 7. 14 patients had all F-MISO-PET scans, while 4 had two F-MISO-PET scans (week 0, 5). The mean follow-up time was 14.6 months (range: 4 - 28 months). Mean SUV_{max}(tumor)/SUV_{mean}(muscle) in weeks 0, 2 and 5 were 1.9 (n=18, SD \pm 0.1), 1.5 (n=14, SD \pm 0.1) and 1.2 (n=18, SD \pm 0.1), respectively. Unpaired t-test for SUV_{max}(tumor)/SUV_{mean}(muscle) between week 0 and 5 was performed, showing a significant decrease ($p < 0.0001$). Between weeks 0 and 2 ($p = 0.0346$) and between weeks 2 and 5 the decrease again was highly significant ($p = 0.0113$). In two patients no residual hypoxia was measured in week two, resulting in SUV_{max}(tumor)/SUV_{mean}(muscle) = 1.0. In week 5 this was found in seven patients. In two patients hypoxia had increased in week 2 but decreased in week 5 compared to pre-treatment measurements. In one patient hypoxia had increased by the end of treatment.

Conclusion: Differences in hypoxia between weeks 0-2, 2-5 and 0- 5, respectively, show statistical significance. This is crucial in the process of re-oxygenation. As concluded in previous works, change of treatment strategy, e.g. by means of dose escalation might be most efficient early during treatment. However further analysis, with more patients and correlation to disease-free and overall-survival are needed.

EP-2060

Correlation of imaging data with known predictive/prognostic factors in Oropharyngeal cancer
 J. Lynch¹, M. Zhao², J. Scuffham³, P. Evans⁴, C. Clark⁵, K. Wood¹, S. Whitaker¹, A. Nisbet⁵
¹Royal Surrey County Hospital, Head & Neck, Guildford, United Kingdom

²University of Surrey, Medical Imaging, Guildford, United Kingdom

³Royal Surrey County Hospital, Nuclear Medicine, Guildford, United Kingdom

⁴University of Surrey, Physics, Guildford, United Kingdom

⁵Royal Surrey County Hospital, Medical Physics, Guildford, United Kingdom

Purpose or Objective: There is increasing interest in maximising data extraction from the multimodality imaging performed in cancer patients in order to predict treatment outcomes. This is particularly relevant in Oropharyngeal cancer where concomitant chemoradiotherapy is the standard treatment in stage III and IV disease but there is significant variation in patient outcomes and both treatment intensification and de-intensification strategies are being investigated.

The aim of this prospective pilot study was to look at how data obtained from pre- and per-treatment 18F-FDG-PET/CT scans and textural features from pre- and per-treatment contrast enhanced planning CT scans correlated with known prognostic indicators including smoking history and HPV status.

Material and Methods: Eligible patients included those undergoing primary concomitant chemoradiotherapy for Stage III/IV SCC of the Oropharynx. Each patient underwent a contrast enhanced planning CT and an 18F-FDG-PET/CT scan immobilised in the treatment position prior to the start of treatment and then again after 8-10 fractions of radiotherapy. The SUV_{max} and SUV_{mean} were recorded on both the pre- and per- treatment 18F-FDG-PET/CT. Texture analysis was performed using TexRad software on both the pre- and per-treatment planning CT scans. The smoking history for each patient was established on enrolment to the study and HPV status was determined using p16 IHC on biopsy of the primary tumour. Ethical approval was gained from the relevant bodies.

Results: Eighteen patients were recruited. HPV status was positive in 13 patients and negative in 5 patients. The SUV_{max}/mean in HPV negative patients was 21.6/13.3 on the pre-treatment 18F-FDG-PET/CT versus 15.2/10.5 for HPV positive patients ($p = 0.09/0.25$). Pre-treatment CT texture analysis showed a difference in the normalised entropy between the two groups with a significant difference detected using the smallest filter ($p = 0.04$). The SUV_{max}/mean on the pre-treatment 18F-FDG-PET/CT for patients with no or minimal smoking history (<10 years) was 13.7/9.5 versus 19.1/12.9 for those with a smoking history of >10years ($p = 0.1/0.13$). No significant difference in the entropy/entropy ratio between the two groups was detected. No significant differences were shown in the change in SUV or entropy ratio between the pre-and per-treatment scans in any of the groups.

Conclusion: These results suggest differences in the imaging characteristics between patients in different prognostic categories may be detected at the pre-treatment stage and are worthy of further investigation in a larger patient cohort and may in the future add further information to that provided by the molecular profiling of tumours. This study did not show any significant differences in the data obtained between patients in terms of their early response to treatment however this data can be revisited once follow up data for this patient cohort matures.

EP-2061

Over-expression of EGFR and/or cox-2 in locally advanced squamous cervical cancer (LASC)
 M. Aylas¹, J. Pérez -Regadera Gómez¹
¹Hospital Universitario 12 de Octubre, Radiation Oncology, Madrid, Spain

Purpose or Objective: This study looking for the prognosis value of over-expression of EGFR and/or COX-2 in patients with locally advanced squamous cervical carcinoma (LASC).

Material and Methods: 118 patients with FIGO IB2-IVA st. were treated with RT-CT radical (Tab A). Anti-EGFR monoclonal Ac.(clone H11 Ref. M-3363 -Dako). The Immunoreactivity was based on semiquantitative analysis scored as the % of stained cells. Moderate/high EGFR staining (>31 to ≥70%, respectively) were considered (+). Anti-COX-2 monoclonal Ac. (clone CX-2949 Ref. M361 - Dako). Moderate/high COX-2 staining (>31 to ≥70%, respectively) were considered (+). Pelvic radiotherapy in 21 patients with RT-3D, dose 46 Gy. In 97 cases (82%) was extended to the para-aortics, dose 45 Gy. A single application of LDR BCT was delivered on 51 pts (43.5%). Isotope: Cs-137. Dose to point A: 30 Gy. HDR BCT to 64 pts (54%) in 3 or 4 applications. Isotope: Ir-192; Microselectron®. Dose 30 Gy to point A (33 pts) and a dose of 7 Gy to CTV/application (31 pts). CT: CDDP: 40 mg/m²/ iv weekly.

Results: Mean time follow-up for 118 pts: 56.5 months ±DS 10.5 (median 56). Mean time follow-up of lost pts (8): 48 months ± DS 10.5 (median 46). Clinical characteristics and treatments in Tab n°1 and n°2.

Table n°2. Description of treatments given

n° patients	Description
118	Chemotherapy: Cisplatin: Average dose of cisplatin / patient 340mg (p23-30, p33-340 mg) Average number of cycles: 5.5
	External radiation therapy: Pelvic: 21 46 (5x30 cGy) Pelvic and para-aortic: 97 45 Gy (5x180 cGy)
	Brachytherapy LDR: 51 28 Gy (p25-22,p25-35) / 225 cc (r: 30-40cc)
	Brachytherapy HDR: 64 3 or 4 applications of 70y to CTV (31 pt) / 1 or 4 applications of 70y to point A (33 pt)
	External radiation therapy in nodes: 3 Dose / Total dose 15-20 Gy / 65-70 Gy (5x180 + 5x200 cGy)
	External radiation therapy in central pelvis: 25 Dose / Total dose 30 Gy / 35 Gy

Table A: Inclusion and Exclusion criteria

Inclusion criteria:	Exclusion criteria:
- Patients diagnosed of cervical carcinoma by biopsy with immunohistochemical determination for EGFR and COX-2	- Patients not valid for standard chemotherapy (e.g. creatinine >2 mg/dL, hepatic profile alteration, neutrophils < 2000/mm ³ , platelets < 100.000/mm ³)
- Age over 18 and under 85 years	- Other treatment schemes different to radio-chemotherapy and/or interventions which would delay the concomitant treatment
- FIGO IB2-IVA stage	
- Squamous histology	
- Patients treated solely with radical radiochemotherapy.	

EGFR: 33 pts without overexpression vs. 85 pts (72%) with overexpression. COX-2: 77 pts without overexpression vs 41 (35%) with over-expression. 24% were EGFR/COX-2 (+), 58% were EGFR (+)/ COX-2 (-) or vice versa and 18% were EGFR/COX-2 (-). 94 pts (80%) with CR, 22 pts with PR and 2 pts stabilisation. Actuarial OS at 3/5 yrs:79% (CI 95%:70-85) and 77% (CI 95%:68-84). Actuarial DFS at 3/ 5 yrs:71% (CI 95%: 62-78) for both. Actuarial PFFS at 3/5 yrs:81% (IC 95%: 72-87) for both. We observed 13 local failures, 4 regional failures, 6 joint failures; 1 pure para-aortic failure, 9 exclusive metastasis to distance. We found that EGFR overexpression is age related >50 yrs old (p=0.01). The most advanced stages (III-IVA) are related to joint overexpression of both markers (p=0.02). Tab n°3 and n°4 summarize our results.

Variable	Total	DFS > 5 years N (CI 95%)	DFS < 5 years N (CI 95%)	p value	PFFS > 5 years N (CI 95%)	PFFS < 5 years N (CI 95%)	p value

The EGFR overexpression or COX-2 or both together, did not reach significance in the univariate analysis for DFS and PFFS.

Conclusion: We did not find an association between overexpression of EGFR and/or COX-2 regarding the DFS and PFFS, despite being described in literature that these markers play a role in tumoral biology and in its evolution. There is a need for homogeneous, prospective studies with a standardized determination for these markers.

EP-2062
c-Myc silencing impairs oncophenotype and radioresistance of Embryonal Rhabdomyosarcoma Cell Lines.
F. Marampon¹, G. Gravina¹, C. Festuccia¹, C. Alessandro¹, E. Di Cesare¹, V. Tombolini²
¹University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy
²Policlinico Umberto I "Sapienza" University of Rome, of Radiotherapy, Rome, Italy

Purpose or Objective: We previously reported that the disruption of MEK/ERK/c-Myc axis affects in vitro and in vivo growth, angiogenic signaling and radiosensitivity of the embryonal rhabdomyosarcoma (ERMS) cell lines. Herein, we investigated the role of c-Myc in vitro invasion, migration, neo-angiogenesis and radioresistance of ERMS cells.

Material and Methods: RD and TE671 cells expressing the c-Myc dominant negative MadMyc chimera protein or shRNA-c-Myc were used.

Results: c-Myc depletion affected ERMS cells in vitro migration and invasion abilities by reducing the sialylation levels of NCAM and decreasing the MMP-9, MMP-2 and u-PA gelatinolytic activity. Although c-Myc down-regulation affected HIF1-α, VEGF and TSP1 proteins expression, no effects were seen on in vitro neo-angiogenesis. Rapid, but not prolonged, c-Myc down-regulation radiosensitized ERMS cells by impairing the expression of DSB repair proteins such as RAD51 and DNA-PKcs but not Ku80.

Conclusion: Herein c-Myc acts as a key master regulator of in vitro migration, invasion and radioresistance. In fact, c-Myc depletion alone seems to be sufficient to block the in vitro pro-metastatic abilities and to radiosensitize ERMS cells. In addition, our data suggest c-Myc as important, but not essential, in controlling the molecular machinery responsible for cancer neo-angiogenesis. In conclusion these data strongly suggest that the targeting of c-Myc can be tested as a promising strategy for an anti-cancer therapy.

EP-2063

Apoptotic pathway activation in prostate neoplastic cells after 12 Gy-IORT

C. Pisani¹, N. Domagala², F. Copes², F. Mercalli³, A. Volpe⁴, D. Beldi¹, F. Boccafroschi², R. Boldorini³, M. Krengli¹

¹University Hospital Maggiore della Carità, Radiotherapy, Novara, Italy

²University Hospital Maggiore della Carità, Health Sciences Department, Novara, Italy

³University Hospital Maggiore della Carità, Pathology, Novara, Italy

⁴University Hospital Maggiore della Carità, Urology, Novara, Italy

Purpose or Objective: To evaluate apoptotic pathways involved in prostate cancer treated with intraoperative radiotherapy (IORT) with 12 Gy, studying the effects on cancer cells, prostatic intraepithelial neoplasia (PIN) and normal cells

Material and Methods: Since 2005, 111 patients treated at University Hospital of Novara, Italy with local advanced prostate adenocarcinoma were treated with radical prostatectomy and 12 Gy IORT followed by 50 Gy postoperative radiotherapy. In this setting, we selected a sample of 10 patients for a preliminary feasibility study. Selection criteria for this phase were: no neoadjuvant hormone therapy, Gleason score > 7. Proteins involved in the apoptotic cascade (Bax, Caspases -3 and -9) were studied before and after 12 Gy single shoot in neoplastic cells, high grade PIN areas and in normal prostate cells. Immunofluorescent detection of antigens (anti-Bax, anti-caspases-3 and -9), were performed on bioptic sample and on surgical specimens 5-mm slices. On surgical specimens there were also detected Bcl-2, and ki-67 with immunohistochemical analysis. A count of positive spots for immunofluorescence (Bax+, Caspases-3 and -9+/all nuclei, 40x magnification) was performed on tumor cells, PIN, healthy tissue areas. Bax and caspases immunofluorescent positivity was compared in different areas and in neoplastic areas before and after single shoot high dose

Results: A significant increase in Bax, Caspases-3 and -9 expression was detected in tumor and PIN areas comparing IORT treated and untreated samples (p<0.05). After 12 Gy-single dose, healthy areas expressed significantly lower level of Bax and caspases positive with respect to neoplastic cells (p<0.0001), while in PIN areas, Bax positive cells were significantly more present than in neoplastic areas (p=0.0001). Mean Bcl-2 in neoplastic cells is 17% (range: 1-23), mean ki-67 in neoplastic area is 4.5% (range: 1-17). With multivariate analysis, we find that cancer cells with Ki-67 ≥ 8% show a trend toward greater expression of Bax (p=0.0641)

Conclusion: After 12 Gy irradiation, Bax and caspases resulted overexpressed in tumor and PIN cells, in particular in prostate cancer with higher proliferation index. PIN areas seem to be more radiosensitive than neoplastic areas and healthy cells do not activate apoptosis after single shoot, showing an intrinsic radioresistance. This preliminary study represents the basis for an extensive work in which we would correlated clinical parameters with pathology and apoptotic factors. In fact, the comprehension of these relationships could allow to better understand the mechanisms of high dose per fraction and, radioresistance in order to personalize treatments

EP-2064

Radiation induces metabolic switch to lactate production to support tumour cell survival

K. Dittmann¹, C. Mayer¹, H.P. Rodemann¹

¹Institut für Strahlenbiologie und Molekulare Umweltforschung, Division of Radiobiology, Tübingen, Germany

Purpose or Objective: Purpose: Radiation treatment of tumor cells resulted in a reduction of endogenous ATP levels. Aim of this study was to elucidate the molecular scenario standing behind this observation.

Material and Methods: Endogenous ATP-levels were determined by ATP-ELISA. HIF1a, PDK1, LDH and PDH expressions were visualized by western blotting. Lactate production was quantified by lactate-assay. Cellular survival was proved by clonogenic survival assay.

Results: Results: Ionizing radiation induced expression of Hif1 alpha even at clinical relevant doses of 2 Gy. Hif1alpha induced activation of mitochondrial PDK1, which results in PDK1 dependent phosphorylation of pyruvate dehydrogenase (PDH). PDH is responsible for conversion of pyruvate to acetyl-CoA, which fuels the TCA cycle. Thus, irradiation blocks TCA cycle and mitochondrial activity. Simultaneously Hif1alpha induced expression and activity of lactate dehydrogenase (LDHA) to convert glucose to lactate. Indeed we observed a clear increase in lactate production in tumor cell lines in response to irradiation. Furthermore, inhibition of PDH activity was associated with mitophagy and ATP-depletion, which explains the radiation induced ATP drop down. In addition, this radiogenic switch to lactate production reduced production of mitochondrial derived radicals and increased cellular radio-resistance. Pretreatment with the Hif1 alpha inhibitor BAY87-2243 prevented the radiogenic switch to lactate metabolism and radio-sensitized the tumor cells. In addition, tumor cells are strictly dependent from high glucose supply after irradiation and can be radio-sensitized by blockage of radiogenic glucose uptake with glucose transporter SGLT inhibitor Phlorizin.

Conclusion: In summary, we could show, that tumor cells switch in a Hif1 alpha dependent manner to anaerobe glucose metabolism to generate ATP, which renders cells radio-resistant. Blockage of Hif1 alpha stabilization or blockage of glucose uptake radio-sensitized tumor cells.

EP-2065

Effects of spontaneous γH2AX level on radiation-induced response in human somatic cells

S. Vasilyev¹, A.I. Velichevskaya², T.V. Vishnevskaya², A.A. Skryabin¹, A.A. Belenko², A.A. Sleptsov¹, O.V. Gribova³, Z.A. Startseva³, I.N. Lebedev¹

¹Institute of Medical Genetics, Laboratory of Cytogenetics, Tomsk, Russian Federation

²Tomsk State University, Biological Institute, Tomsk, Russian Federation

³Tomsk Cancer Research Institute, Radiology Department, Tomsk, Russian Federation

Purpose or Objective: Phosphorylated histone H2AX (γH2AX) foci are well-known markers of DNA double-strand breaks in human cells. Spontaneous γH2AX foci form on unrepaired DNA double strand breaks, shortened telomeres and sites with altered chromatin conformation. The presence of such permanent γH2AX foci in cell is an important component of epigenetic background and potentially lead to the activation of DNA repair system. The objective of this study was to analyze the effects of spontaneous γH2AX level on radiation-induced response in human somatic cells.

Material and Methods: Spontaneous γH2AX foci and radiation-induced micronuclei were analyzed in peripheral blood lymphocytes of 54 healthy individuals after exposure to 2 Gy ionizing radiation in vitro. Further, a transcriptome analysis was performed using gene expression microarrays in lymphocytes of two sub-groups of individuals: 1)

radiosensitive individuals with low spontaneous level of γ H2AX foci (n=3) and 2) radioresistant individuals with high spontaneous level of γ H2AX foci (n=3).

Results: An inverse correlation was found between the spontaneous level of γ H2AX foci and the frequency of micronuclei after irradiation ($R=-0,37$, $p=0.025$). After gene expression analysis with microarrays, several genes were identified whose differential expression could be associated with an efficiency of DNA repair and radiation sensitivity. XRRA1 gene with unknown functions, recently associated with radioresistance in tumor lines, was down-regulated both before and after irradiation in radioresistant group. Furthermore, in unirradiated samples of radioresistant individuals thrombospondin gene (THBS1), well-known radiosensitizer, was down-regulated. However, several genes were significantly up-regulated, including HERC2, important player in the assembly of DNA repair foci, and histone genes (H1, H2A, H4). After irradiation, several DNA repair genes (WHSC1, POLN, ERCC5, DCLRE1C) were significantly up-regulated, but EIF2A and PNLPA5 genes, involved in apoptosis and autophagy, were down-regulated in radioresistant group. This is consistent with low levels of apoptosis and increased proliferation in lymphocytes of these individuals.

Conclusion: The obtained results indicate that spontaneous γ H2AX foci activate DNA damage response in human somatic cells and provide opportunities to clarify the role of the expression of identified genes in the formation of chromosomal aberrations in human cells after exposure to radiation.

EP-2066

Phospholipase C ϵ as a biomarker of prostate cancer radioresistance

A. Tyutyunnykova¹, G. Telegeev², A. Dubrovka^{3,4,5}

²The Institute of Molecular Biology and Genetics of NASU, Molecular Genetics, Kyiv, Ukraine

³Technische Universität Dresden and Helmholtz-Zentrum Dresden-Rossendorf, OncoRay-National Center for Radiation Research in Oncology- Faculty of Medicine and University Hospital Carl Gustav Carus, Dresden, Germany

⁴Helmholtz-Zentrum Dresden-Rossendorf, Institute of Radiation Oncology, Dresden, Germany

⁵German Cancer Consortium DKTK, DKTK, Dresden, Germany

Purpose or Objective: Radiotherapy is a curative treatment option in prostate cancer. Nevertheless, many men with prostate cancer develop recurrence of their disease. Identification of the predictive biomarkers and signaling mechanisms indicative of tumor cell radioresistance bears promise to improve cancer treatment. In our study we show that Phospholipase C epsilon (PLC ϵ) might contribute to prostate cancer radioresistance.

Material and Methods: Gene expression profiling of prostate cancer cells and their radioresistant derivatives, western blot analysis to assess PLC ϵ expression in the parental and radioresistant cells and in cell cultures after irradiation, radiobiological cell survival analysis of the cells with genetic modulation of PLC ϵ expression by siRNA or cDNA transfection as well as chemical inhibition of PLC ϵ activity, fluorescent microscopy to analyze co-expression of PLC ϵ with other markers of radioresistance. Normal 0 21 false false false EN-US X-NONE X-NONE

Results: The results of gene expression analysis, which were validated by western blotting revealed significant upregulation of PLC ϵ in prostate cancer radioresistant cells that can also be seen after irradiation of the parental cells with a single dose of 4Gy. Radiobiological survival assays demonstrated that siRNA induced PLC ϵ knockdown or chemical inhibition of PLC ϵ activity by Edelfosine leads to prostate cancer cell radiosensitization. In contrast,

overexpression of PLC ϵ in cells transfected with plasmid DNA results to an increase in cell radioresistance. Microscopic analysis revealed a high expression level of β -catenin in prostate cancer cells overexpressing PLC ϵ .

Conclusion: These results indicate that PLC ϵ plays a role in prostate cancer radioresistance that can be mediated through activation of the WNT/ β -catenin signaling pathway.

EP-2067

The adhesion of tumor cells to endothelial cells is increased by photon irradiation

H. Bühler¹, P. Nguemgo-Kouam¹, A. Kochanek¹, B. Priesch¹, H. Hermeni¹, K. Fakhrian¹, I.A. Adamietz¹

¹Marienhospital Herne- Ruhr-Univers., Klinik für Strahlentherapie und Radio-Onkologie, Herne 1, Germany

Purpose or Objective: In general the prognosis for cancer patients is poor even though only 10% die from the primary tumor. The majority of the deaths are due to metastasis. Given the fact, that more than 70% of cancer patients receive radiotherapy it seems important to clarify if radiation is involved in initial steps of the metastatic cascade - despite of innumerable clinical studies that confirm no enhanced risk of metastasis after radiotherapy. In this project we investigated whether the irradiation with photons increases the adhesion of cultured tumor cells (TC) to a layer of endothelial cells (EC) macroscopically and whether this might be caused by the induction of adhesion proteins.

Material and Methods: The experiments were performed with glioblastoma (U87, U373) and breast cancer cell lines (MDA-MB-231, MCF7), and with primary HUVEC cells. The cells were irradiated with 0, 0.5, 2, 4, or 8 Gy. Adhesion of TC to EC, both irradiated or not, was determined with 2 different methods: the VybrantTM cell adhesion assay and the Ibidi pumpsystem that allows to mimic the physiological blood stream in the vasculature. In addition, the expression of the adhesion-related proteins E-selectin, VCAM1, ICAM1, N-cadherin, integrin β 1, and PECAM1, 4h after irradiation with 4 Gy, was analyzed by qRT-PCR and by Western blotting.

Results: Irradiation increased significantly the adhesion of TC to EC. With glioblastoma cells the highest increase of about 40% was observed when both cell types were irradiated. In contrast, with breast cancer cells the highest effect of about 25% was obtained for irradiated TC in combination with non-irradiated EC. Analysis of the expression patterns in all cell types revealed a significant increase of adhesion proteins after irradiation in more than 80% of the experimental data sets.

Conclusion: We assume that the irradiation of tumor cells as well as of endothelial cells with photons might enhance adhesive interactions of these cells and thereby might promote the first steps of metastasis. Since clinical studies reveal no enhanced risk of metastasis due to irradiation we speculate that the therapeutic effect of radiotherapy might be additionally enhanced when the induced stickiness could be blocked effectively.

EP-2068

Effect of a 0.2 T magnetic field during radiation on DNA damage and repair in prostate cancer cells

S. Baker¹, Z. Jin², A. Ghila³, B. Warkentin⁴, M. Hendzel², G. Fallone⁵, R. Pearcey¹

¹Cross Cancer Institute and University of Alberta, Radiation Oncology, Edmonton, Canada

²Cross Cancer Institute and University of Alberta, Experimental Oncology, Edmonton, Canada

³Cross Cancer Institute and University of Alberta, Medical Physics, Edmonton, Canada

⁴Cross Cancer Institute and University of Alberta, Medical Physics- Oncology- Medical Physics Division, Edmonton, Canada

⁵Cross Cancer Institute and University of Alberta, Medical Physics- Physics and Oncology- Medical Physics Division, Edmonton, Canada

Purpose or Objective: Real time MR-guided radiotherapy is an emerging technology. The effect of magnetic field exposure on radiosensitivity is unknown. This study aimed to determine the effect of magnetic field exposure on the repair of radiation-induced DNA double-strand breaks in human prostate cancer cells.

Material and Methods: Human PC-3 prostate cancer cells and benign prostatic hypertrophy (BPH) cells were cultured and plated into 96-well dishes and irradiated with 2 Gy of 6 MV photons on a linear accelerator. Each cell line was exposed to either 2 Gy of ionizing radiation alone (IR) or 15 minutes of 0.2 T magnetic field concurrently with 2 Gy IR (IR + B). Cells were fixed at 15 minutes or 24 hours following IR and immunostained with fluorescent-labelled antibody to γ H2AX, a marker of DNA double-strand breaks. For each experimental scenario, the number of γ H2AX foci per cell were determined using a Molecular Devices MetaXpress High Content Imaging Platform, for sample sizes between 3370 and 8402 cells. To classify response, radiation-induced damage was associated with cells having more than five foci.

Results: Magnetic field exposure resulted in a significantly higher percentage of PC-3 cells with five or fewer γ H2AX foci at 24 hours following IR (42 vs 37 percent, $p < 0.01$) but had no significant effect on BPH cells (89 vs 88 percent, $p = 0.26$). In both cell lines, magnetic field exposure significantly reduced the percentage of cells with five or fewer γ H2AX foci 15 minutes following IR ($p < 0.01$) (Table 1).

Table 1. Percentage of BPH and PC-3 cells with ≤ 5 γ H2AX foci at 15 minutes and at 24 hours after exposure to 2 Gy of ionizing radiation alone (IR) vs 2 Gy of ionizing radiation with 15 minutes of concurrent 0.2 T magnetic field exposure (IR + B).

Time of cell fixation	BPH			PC-3		
	IR	IR + B	P-value	IR	IR + B	P-value
	Percentage of cells with ≤ 5 γ H2AX foci			Percentage of cells with ≤ 5 γ H2AX foci		
15 min	40	28	<0.01	17	14	<0.01
24 h	88	89	0.26	37	42	<0.01

Conclusion: The preliminary results suggest that the presence of a magnetic field during irradiation reduces DNA damage at 24 hours post-irradiation for PC-3 human prostate cancer cells. Conversely, magnetic field exposure increased the DNA damage present 15 minutes following IR in both cell lines, suggesting a different mechanism at play, such as altered free radical flux or differences in the kinetics of the initiation of the DNA damage response. Cell viability assays, gene expression profiling and testing of other cell lines will yield important insights into the implications for real time MR-guided radiotherapy.

EP-2069

CDC73 deficiency: a syndrome with multiple tumours is predicted to show excessive radiosensitivity

R. Lewis^{1,2,3}, E.C. Bourton³, C.N. Parris^{2,3}, P.N. Plowman^{1,2}
¹St Bartholomew's Hospital, Radiotherapy, London, United Kingdom

²Queen Mary's University, Barts Cancer Institute, London, United Kingdom

³Brunel University, Biosciences, Uxbridge- Middlesex, United Kingdom

Purpose or Objective: It has previously been demonstrated that prolonged expression of the γ -H2AX DNA repair biomarker in irradiated peripheral blood lymphocytes correlated with excess toxicity from radiotherapy treatment in patients. γ -H2AX fluorescence in cells has been established as an indicator of double strand breaks, and a marker for DNA damage and repair of cells after irradiation. This case study illustrates that the peripheral blood lymphocytes of a patient with CDC73 deficiency retained γ -H2AX fluorescence over 24 hours to a greater degree than a patient with normal DNA repair.

CDC73 deficiency is an autosomal dominant inherited syndrome. The gene on chromosome 1q31 encodes a tumour suppressor that is known to be involved in transcriptional and post-transcriptional control pathways. The protein is a component of the PAF protein complex, which associates with the RNA polymerase II subunit POLR2A and with a histone methyltransferase complex, and is involved in regulation of transcription coupled nucleotide excision repair.

A patient with CDC73 mutation with a typical history of primary hyperparathyroidism, an ossifying fibroma of the jaw, renal cysts and a renal cell carcinoma developed a carotid body paraganglioma which was to be treated with stereotactic radiotherapy. There was concern that the syndrome (associated with multiple tumours) would lead to unusual radiation sensitivity following standard radiotherapy prescriptions, and this study aimed to establish if this would be the case.

Material and Methods: Peripheral blood lymphocytes (PBLs) from the patient were irradiated with 2Gy and fixed at 30 minutes and 24 hours, stained for γ -H2AX and compared with PBLs from a normal and radiosensitive patient (patient P - thyroid cancer with excessive toxicity to radiotherapy). They were also compared with known DNA repair defective immortalised fibroblasts from AT5BIVA (patient with classical ataxia telangiectasia). The cells were analysed on an Imagestream flow-cytometer.

Results:

Conclusion: It may be confidently predicted that this patient with CDC73 deficiency would demonstrate more vigorous radiation reactions in normal tissues for any standard dose of radiotherapy, due to a possible defect in DNA repair and this should be considered when planning his Cyberknife treatment for the carotid body paraganglioma. The exact mechanism for this will need to be considered along with current knowledge of the role of CDC73.

EP-2070

Cell cycle analysis of γ -H2AX in irradiated normal or DNA-defective cells with image flow cytometry

R. Lewis^{1,2,3}, P.N. Plowman^{1,2}, C.N. Parris^{2,3}
¹St Bartholomew's Hospital, Radiotherapy, London, United Kingdom

²Queen Mary's University London, Barts Cancer Institute, London, United Kingdom

³Brunel University, Biosciences, Uxbridge- Middlesex, United Kingdom

Purpose or Objective: The quantitation of nuclear γ -H2AX foci in cells has been established as an indicator of double strand breaks, and therefore a marker for DNA damage and repair of cells after irradiation. The new generation image flow cytometer by Amnis Imagestream Mark II enables the rapid and simultaneous processing of images on multiple channels of large numbers of cells. It also has a unique feature or "wizard" which allows the identification of cell cycle distribution based on the fluorescence intensity of nuclear staining, in this case using the far red fluorochrome Draq5. This study aims to use this facility to establish whether there are different numbers of γ -H2AX foci in cells depending on the phase of the cell cycle. This is a novel

study and the outcome will inform future studies using γ -H2AX staining.

Material and Methods:

Fibroblast Cell Lines (SV40 immortalised)

– MRC5-SV1 - Repair normal.

– AT5BIVA - Classical ataxia telangiectasia.

Irradiation Cells

Irradiated with 2 Gy gamma radiation; harvested and fixed in 50:50 V:V methanol acetone. Time points: Un-irradiated, 30 min, 3, 5 and 24 hrs post irradiation.

Immunocytochemistry

Primary antibody: Anti-phospho-histone H2AX (Ser139), mouse monoclonal antibody clone JBW301 (1/10,000, Millipore).

Secondary antibody: Rabbit anti-mouse AlexaFluor488 (1/1000, Invitrogen).

DNA counterstained with Draq 5 (Biostatus Ltd.)

Imaging flow cytometry

Images of 5-10,000 cells captured

Results:

Statistical Analysis • 30 minute time point, comparing mean foci count for G0/G1, S and G2/M with one-way ANOVA test:
– MRC5-SV1 (repair normal); $F(4,4010)=163.5$, $p < 0.001$
AT5BIVA (DNA repair defective); $F(2,2919)=421.3$, $p < 0.001$

Conclusion: We have identified cells in different phases of the cell cycle by analysing intensity of the Draq 5 nuclear stain and negating the need for extra staining. These data have shown a statistically significant difference between foci numbers in different phases of the cell cycle at one time point for a normal cell line and a DNA repair deficient cell line. Further work will look at differences in the cell cycle distribution between the two cell lines

EP-2071

Mitophagy and Apoptosis: mitochondrial responses to carbon ion radiation in tumor cells

X. Jin¹, X. Zheng¹, F. Li¹, Q. Li¹

¹Institute of Modern Physics- Chinese Academy of Sciences, Division of Radiation Medical Physics, Lanzhou, China

Purpose or Objective: Although mitochondria are known to play an important role in radiation-induced cellular damage

response, the mechanisms by which tumor cells respond to the mitochondrial damage induced by high linear energy transfer (LET) radiation are largely unknown.

Material and Methods: Human cervical cancer cell line HeLa and human breast cancer cell lines MCF-7 and MDA-MB-231 were irradiated with high linear energy transfer (LET) carbon ions at low and high doses. Mitochondrial functions, dynamics, mitophagy, intrinsic apoptosis and total apoptosis, and survival fraction were investigated after irradiation.

Results: Compared with unirradiated cells, carbon ion irradiation resulted in the loss of mitochondrial membrane potential and fragmentation, suggesting mitochondrial damage was induced. Mitophagy and intrinsic apoptosis of tumor cells were the major responses to the carbon ion radiation induced mitochondrial damage. After exposure to low doses of carbon ions, cells initiated mitophagy to keep viability while tending to death via apoptosis at high doses.

Conclusion: Tumor cells through mitophagy and apoptosis respond to the mitochondrial damage caused by high-LET radiation according to the radiation dose. A threshold model depicting the fate of irradiated cells could provide a mechanistic explanation for differential mitochondrial damage response to high-LET radiation at low and high doses. Our data shed new light on understanding the mechanisms underlying high-LET radiation induced cell death.

EP-2072

Spatiotemporal dynamics of DNA damage in cells exposed to mixed beams of ionising radiation

B. Brzozowska^{1,2}, A. Sollazzo¹, L. Cheng¹, L. Lundholm¹, A. Wojcik^{1,3}

¹Stockholm University, Centre for Radiation Protection Research. Department of Molecular Bioscience. The Wenner-Gren Institute, Stockholm, Sweden

²University of Warsaw, Faculty of Physics. Department of Biomedical Physics, Warsaw, Poland

³Jan Kochanowski University, Institute of Biology. Department of Radiobiology and Immunology, Kielce, Poland

Purpose or Objective: A particular problem of modern external beam radiotherapy like IMRT and proton therapy is exposure of patients to scattered neutrons with a relative biological effectiveness (RBE) higher than X-rays. The interesting question is if there is an additive or synergistic effect of high and low linear energy transfer (LET) radiations when given together. If they act additively, then the risk of cancer can be deduced from the results of exposure to the single agents. Otherwise, RBE values must be generated for the mixed exposure scenarios or corrected to account for the synergism.

Material and Methods: The goal of this study was to analyse the kinetics of formation and repair of ionising radiation-induced foci (IRIF) in cells exposed to alpha particles, X-rays and a mixed beam of both radiations. To this end human cells were transfected with plasmids coding for the DNA repair protein 53BP1 that are tagged with the green fluorescent protein (GFP). Cells were exposed to mixed beams in a dedicated exposure facility built at Stockholm University (SU). The facility is composed of a 50 MBq Am-241 alpha source and an YXLON 200 X-rays source. The alpha source is mounted on an inverted plate in a custom-designed irradiator which is kept inside a 37°C cell incubator.

Results: Spatiotemporal dynamics of 53BP1 foci formation and repair were recorded by time-lapse photography and image analysis. The distributions of cell frequencies with the specific size of foci and the size of foci itself were analysed. Moreover, Monte Carlo simulations (the PARTRAC code) were used not only for calculating radiation hits, but also for the biological damage in the DNA in terms of single and double strand breaks.

Conclusion: Exposure to a mixed beam induces complex DNA damage above the level expected from the additive action of

both radiations. Clustered DNA damage poses serious problems for the DNA repair and error-prone repair of DNA damage is associated with cancer induction. Increased damage complexity following exposure to mixed beams will suggest a higher than expected risk of cancer induction in modern radiotherapy. The results are consistent with the previous studies carried out at SU with different cell types and different biological assays. A synergistic interaction of the beam components was observed at the level of micronuclei, gammaH2AX foci and chromosomal aberrations.

EP-2073

Angio/lymphangiogenic, inflammatory and immune responses in head and neck cancer: proton vs photon
A. Claren¹, M. Plesu², J. Doyen¹, J. Feuillade¹, M. Dufies², S. Giulano², J. Hérault¹, G. Pagès²

¹Centre Antoine Lacassagne, Radiotherapy, Nice, France

²Institut de Recherche sur le Cancer et le Vieillissement de Nice, CNRS UMR 7284- INSERM U1081, Nice, France

Purpose or Objective: Due to its higher precision in tumor targeting, proton therapy could become the treatment of choice for head and neck cancer (HNC). Recent studies have shown that proton irradiation suppresses angiogenic genes and impairs tumor cell invasion/growth. According to the type of radiation, dose and fractionation, the objective of our study was to investigate the effect of proton (P+) versus photon (X) irradiations in squamous cells carcinoma (SCC), in respect of their proliferation, genes expression and proteins secretion involved in proliferation, angio/lymphangogenesis, metastasis and anti-tumor immunity.

Material and Methods: Human SCC CAL33 cells were irradiated 1 to 3 times and evaluated on their proliferation (Cell counting), genes expression (qPCR) for proliferation (TRF2, PLK1), angio/lymphangiogenic (VEGF-A, VEGF-C, VEGF-D) inflammatory (IL6, IL8, CCL2, CXCL12) and immune (PD-L1) responses and protein synthesis (ELISA).

Results: Cell proliferation was evaluated at 48h and at 3 weeks after 1 irradiation and showed a significant decrease in both X and P+, as compared to control but more important in P+. After 3 irradiations, cell proliferation at 48h was reversed and more decreased in X vs P+. Genes expression was investigated at 48h after 1 and 3 irradiations at 2 and 8 Gy. After 1 irradiation, the prevalence of gene expression levels associated with a poor outcome was higher in X than P+ at 8 Gy. After 3 irradiations, genes expression was increased for all but more important for P+ at 8 Gy. The highest expression was noted for VEGF-C (2 to 10 fold increase). The most frequent overexpression was noted for PD-L1. VEGF-C protein induction 48h after 1 and 3 irradiations was increased in both X and P+ groups but decreased in high dose P+, as compared to X.

Conclusion: Cell proliferation activity is in favor of P+ after a single irradiation, and X after multiple irradiations. Genes expression are overall increased in both X and P+, in a dose and fraction dependent manner, implicated in proliferation (TRF2), angio/lymphangiogenic (VEGF-A, VEGF-C, VEGF-D) and immune (PD-L1) responses. VEGF-C protein induction is increased after both X and P+ single and multiple irradiations, but in favor of P+, suggesting a lower lymphangiogenesis/metastatic dissemination immediately after P+. Our study sets the molecular basis for novel therapeutic approaches applicable to HNC in combination with X or P+ radiotherapy, such as angio/lymphangiogenic inhibitors or immune therapy as anti-PD1 or anti-PD-L1.

Electronic Poster: RTT track: Strategies for treatment planning

EP-2074

The comparison of properties for radiotherapy with flattening filter-free and flattening filter beam

J.H. Gu¹, H.S. Won¹, J.W. Hong¹, N.J. Chang¹, J.H. Park¹

¹Seoul National Univ. Bundang Hospital, Radiation Oncology, Seongnam-Gyeonggi-Do, Korea Republic of

Purpose or Objective: The aim of this study was to appraise multiple properties for radiation therapy techniques applying flattening filter-free (3F) and flattening filter (2F) beam to the radiation therapy.

Material and Methods: Alderson RANDO phantom was scanned for computed tomography images. Treatment plans for intensity modulated radiation therapy (IMRT), volumetric modulated arc therapy (VMAT) and stereotactic body radiation therapy (SBRT) with 3F and 2F beam were designed for prostate cancer. To evaluate the differences between the 3F and 2F beam, total monitor units (MUs), beam on time (BOT) and gantry rotation time (GRT) were evaluated and measured with TrueBeam™ STx and Surveillance And Measurement (SAM) 940 detector was used for photoneutron emitted by using 3F and 2F.

Results: In using 3F beam, total MUs in IMRT plan increased the highest up to 34.0% and in the test of BOT and GRT, the values in SBRT plan by 3F beam decreased the lowest 39.8, 38.6% respectively. The values of photoneutron occurrence in SBRT plan using 3F beam decreased the lowest 48.1%.

Conclusion: According to the results, total MUs increased by using 3F beam than 2F beam in all treatment plans but BOT, GRT and photoneutron decreased by using 3F beam. From above the results, using 3F beam can have an effect on decreasing intra-fraction setup error and risk of radiation-induced secondary malignancy.

EP-2075

Evaluation of conventional versus IMRT based Prophylactic Cranial Irradiation treatment planning

E.H. Thøgersen¹, A.I.S. Holm²

¹Aarhus University Hospital, Medical Physics, Herning, Denmark

²Aarhus University Hospital, Medical Physics, Aarhus, Denmark

Purpose or Objective: Patients with Small-Cell Lung Cancer (SCLC) have a high risk of developing brain metastasis. Prophylactic Cranial Irradiation (PCI), is applied to SCLC patients that response to chemotherapy. It is well known that PCI is associated with an increase in median overall survival. There are approximately 84 incidences per year in central region DK. Radiotherapy (RT) to this group of patients is conventionally performed using opposed MLC defined static fields. However, treatment planning can be time consuming. The aim of this study is to evaluate time-effectiveness, by changing the treatment technique from conventional to IMRT based treatment planning of PCI patients.

Material and Methods: This retrospective study included twenty SCLC patients, all treated with conventional planned PCI. Each patient received 25 Gray in 10 fractions. An IMRT template was made (Eclipse Version 11.0, Varian Medical Systems, Palo Alto, CA) and for each patient an IMRT plan was generated by one IMRT optimization. One intermediate dose calculation was performed during optimization before the final dose calculation. The contoured structures used for comparison between IMRT and conventional planning were: ITV, PTV and left/right lens. The plans were evaluated and compared on; max- and minimum doses, the mean/maximum doses to the lenses, and the homogeneity index (HI). The HI was defined by D5%/D95%. Quality assurance of the IMRT plans was performed by recording Portal Dosimetry Images

(PDI) for ten of the plans, and by independent dose calculation checks using RadCalc (RadCalc Version 6.2, LifeLine Software Inc, Tyler, USA).

Results: The observed differences between the conventional and the IMRT plans were limited. In average the maximum dose was 0.3 percentage points (pp) lower for IMRT than for conventional plans. The ITV coverage was better for the IMRT plans, with an average ITV minimum dose of 95.9 % compared to 94.1% (+1.8 pp). However, the PTV coverage was slightly worse for the IMRT plans, a decrease of 0.4 pp in V95%. The only relevant organs at risk are the lenses, were the maximum dose on average were lowered 0.3 Gray and the mean dose on average was lowered 0.1 Gray. The average HI for the IMRT plans was 4.0 while 5.1 for the conventional plans. The 10 PDI measurements were all accepted with a reference gamma index value of 5% dose agreement within 3 mm distance to agreement, and no further measurements were performed. Independent dose calculation checks were performed for QA. The time spend on treatment planning was approximately 20 minutes for IMRT plans and could easily be up to 3 hours when using the conventional technique.

	Property	Conventional	IMRT	Difference (Conv. - IMRT)
BODY	Maximum dose	106.4 %	106.1 %	-0.3 pp
ITV coverage	Minimum dose	94.1 %	95.9 %	+1.8 pp
PTV coverage	V95%	99.6 %	99.2 %	-0.4 pp
Lenses	Maximum dose	4.0 Gy	3.7 Gy	-0.3 Gy
	Mean dose	2.8 Gy	2.7 Gy	-0.1 Gy
Homogeneity	D5% / D95%	5.1	4.0	-1.1

Conclusion: It was possible to significantly reduce the time spend on dose planning by changing the treatment technique from conventional to IMRT for PCI patients while attaining comparable dosimetric quality of the treatment plans. Furthermore, both the treatment time and the time spend on quality assurances are comparable for the two techniques.

EP-2076

Stereotactic body radiation therapy using Tomotherapy for refractory metastatic bone pain: case study

B. Bosco¹, A. Fong¹

¹Sydney Radiotherapy and Oncology Centre, Radiation Oncology, Wahroonga NSW, Australia

Purpose or Objective: To illustrate the technique and outcome of stereotactic body radiation therapy (SBRT) using Tomotherapy for refractory bone pain from metastatic disease. Tomotherapy SBRT planning parameters and dosimetric evaluation are outlined.

Material and Methods: In 2013, a 70 year old female patient presented with metastatic non-small cell lung carcinoma, following resection of lung primary in 2012. CT and MRI confirmed a lytic lesion on right of sacrum. Patient's sacrum initially treated with 30Gy/10Fx. Pain recurred 2 months post RT and managed by palliative care. 6 months post RT patient returned for consideration of re-treatment. Pain was refractory to everything apart from 15mg of oxycodone every hour. RO discussed the patient and risks of re-irradiation within the multidisciplinary setting. The consensus was to offer the patient SBRT, 24Gy in 3 fractions to the sacrum. Helical Tomotherapy was used to plan and treat patient. The irregular PTV volume was 201.12cm³. Dose volume constraints included: colon (0.035cc<18.4Gy, 20cc<14.3Gy), sacral plexus (0.035cc<11Gy, 5cc<7Gy), cauda equina (0.035cc<16Gy, 5cc<14Gy), and skin (0.035cc<26Gy, 10cc<23Gy). No hotspots were to be located over the nerve roots.

Results: Tomotherapy planning parameters included field width of 2.5cm, pitch of 0.2 and a modulation factor of 1.5. Beam on time was 400.3 seconds. PTV coverage statistics were D99 = 22.5Gy (93.75%), V95 = 98.57%, VTD = 90.53%, Median = 25.37Gy (105.71%), D1 = 27.8Gy (115.83%). OAR dose included colon 0.035cc = 8.1Gy, 20cc = 6.8Gy; sacral plexus 0.035cc = 27.3Gy, 5cc = 25.3Gy; cauda equina 0.035 = 26.2Gy, 5cc = 21Gy; skin 0.035cc = 15.4Gy, 10cc = 12.3Gy. The conformity index statistics were R100% = 0.97, V105%

outside PTV = 2cc, R50% = 4.21, Dmax > 2cm from PTV = 16.45Gy (68.5%).

One week post SBRT, patient's pain stable and mobility improving. Whole body bone scan 2 months post SBRT showed decreased activity and size of sacral lesion. 4 months post SBRT patient returned with significant left sacral pain with concern of further metastatic disease. PET confirmed no uptake in left sacrum. Pain associated with insufficiency fracture with cause unknown, SBRT or bone metastasis likely contributors. 5 months post SBRT patient improved dramatically, completely ambulant with PET/CT showing no evidence of recurrence/metastatic disease. 13 months post SBRT, patient remains asymptomatic, CT shows no evidence of metastatic disease.

Conclusion: This case study illustrates how the use SBRT can result in pain control for patients with refractory metastatic bone pain where there may be no other options available apart from palliative care, even in cases where the treatment volume is relatively large. This data is also informative since the patient shows no definite evidence of metastatic disease. Further studies could lead to improved therapies for the control of metastatic bone pain.

EP-2077

A decision protocol to propose proton versus photon radiotherapy: in silico comparison

A. Chaikh¹, J. Balosso¹

¹CHU de Grenoble - A.Michallon, Radiothérapie et Physique Médicale, Grenoble, France

Purpose or Objective: Proton therapy cancer treatment offer potential clinical advantages compared with photon radiation therapy for many cancer sites. However, the treatment cost with proton is much higher than with conventional radiation. The objective of this study is to discuss how to improve a procedure, already described by others worldwide, to provide quantitative clues to select the patient for proton treatment instead of photon.

Material and Methods: The respective medical and clinical benefits of proton and photon therapy are assessed by in silico comparison following four successive steps. First, the dosimetric analysis is made using parameters derived from dose volume histogram (DVH) for target volume and organs at risks. Second, the DVHs are exported from TPS to calculate TCP and mostly NTCP radiobiological indexes. In the third step, a statistical comparison is done using non-parametric test to calculate p-value, then bootstrap method is used to estimate the confidence intervals including the lower and upper limit of agreements. Then the correlation between data from proton and photon treatment planning is assessed using Spearman's rank test. Finally, the cost-effectiveness and quality adjusted life years (QALYs) can be used to measure the outcome of the therapy and check if the therapeutic gain of proton therapy worth the increased expenses of it versus photon.

Results: The results with in silico data can be taken into account to make a proposal of a decisional procedure. The dosimetric and radiobiological analysis can be used to check the medical benefit with either proton or photon. The statistical tests allow to check if the dosimetric or radiobiological benefits for a specific patient can be included in the confidence interval of agreement of a representative population, the most homogenous possible. A Markov model can be used to simulate the life of patients treated with proton / photon radiation. The virtual evaluation may indicate for which cancer sites proton therapy could be more cost-effective than photon therapy.

Conclusion: The introduction of model based clinical trials with the possibility of individual assessment is a coming approach well adapted to the fast improvement of medical technology. The presently rising offer of proton therapy is a good example. The QALY concept based on objective dosimetric and clinical expected / modeled outcome may be a valuable response to this new challenge. However, large

cumulated medical data are needed to reduce steps by steps the uncertainties in the assumptions used in the present models.

EP-2078

PROSPECT: Phase 2 rescanning of seromas in patients to evaluate CTV reduction in breast cancer

G. Smith¹, P. Robson², H. Probst³

¹The Clatterbridge Cancer Centre - Wirral NHS Foundation Trust, Radiotherapy Planning, Bebington- Wirral, United Kingdom

²The Clatterbridge Cancer Centre - Wirral NHS Foundation Trust, Radiotherapy, Bebington- Wirral, United Kingdom

³Sheffield Hallam University, Faculty of Health and Wellbeing, Sheffield, United Kingdom

Purpose or Objective: A single centre feasibility study to assess the reduction in sequential boost volume treated by rescanning patients during their final week of whole breast radiotherapy.

Material and Methods: Patients requiring a sequential boost treatment who had a tumour bed seroma greater than 1cm on the initial radiotherapy planning (RTP) CT scan were considered for entry into the study.

Thirty patients were sequentially recruited at the planning stage if they met this inclusion criteria. Patients were consented for entry into the trial and a second RTP CT scan (RTP 2) was conducted in their final week of whole breast radiotherapy. RTP 2 scan was used to determine the volume treated for their sequential boost.

Both scans had the CTV outlined by the chief investigator and the CTV volume changes were annotated.

Results: 83% of patients had a substantial reduction in CTV (>25%) in RTP 2 compared to RTP 1. The mean CTV reduction overall was 41.9% with a median reduction 42.5%. The mean time between scans was 27 days; median time 29 days. Mean time from start of whole breast radiotherapy treatment to RTP 2 was 14 days.

Conclusion: This study shows that rescanning breast patients during the final week of whole breast radiotherapy leads to a significant decrease in treated boost volume in the majority of patients.

EP-2079

IMRT vs. dynamic conformal arc radiation therapy for stereotactic spinal radiotherapy

V. Santos¹

¹Mercurius Health- SA, Centro Oncológico Dra. Natália Chaves - Unidade de Radioterapia de Lisboa - Quadrantes - Joaquim Chaves Saúde, Lisboa, Portugal

Purpose or Objective: Patients with spinal tumors have better outcomes with increased dose prescription. Due to the complex geometry of the treatment site and to the close proximity of the spinal cord, dose escalation is only possible with advanced techniques. This case study aims to determine if intensity-modulated radiation therapy (IMRT) could be a better option than dynamic conformal arc radiation therapy (DCA) for stereotactic spinal treatments.

Material and Methods: Six patients previously treated with DCA were re-planned with IMRT. The same patient-specific criteria were followed in the new IMRT plan. Plan quality was compared by analyzing the dose-volume histogram (DVH) for the planning target volume (PTV) and for the spinal cord (SC). The conformity index (CI) and the monitor units (MU) number were also compared.

Results: Both techniques provided adequate PTV coverage and SC sparing. Results favored IMRT in most of the analyzed PTV parameters: Dmax, D95, V95 and V100. DCA showed better results in PTV Dmin and D99 and had advantageous lower MU number. SC had superior dose sparing with IMRT plans. The CI was also improved by the IMRT technique.

Conclusion: In general, IMRT plans proved to be a better planning solution, although with a significant higher number of MUs. IMRT treatments must be performed with higher accurate imaging guidance systems.

EP-2080

Redefining the possible: planning multiple complex head lesions using non-coplanar VMAT arcs

V. Guy¹, R. Sims¹, A. Falkov¹

¹Auckland Radiation Oncology, Auckland Radiation Oncology, Auckland, New Zealand

Purpose or Objective: To demonstrate the ability to include multiple lesions over the scalp, face and brain using non-coplanar VMAT beams and a single isocentre
73 yo man referred for post-op RT to multiple scalp lesions, including bilateral spread to periauricular and parotid nodes. Diagnostic work up also showed an incidental right sided meningioma that was indicated for possible concurrent treatment.

Material and Methods: The patient was scanned in a Klarity shell, on a Philips Big Bore CT. The dataset was imported into the TPS and diagnostic T1 and T2 MRI's were fused for assisting in contouring.

The scalp and bilateral periauricular and parotid regions were contoured as a single CTV and a 0.3cm PTV margin was added. The meningioma was contoured separately, also with a 0.3cm PTV margin applied.

50.4Gy in 28 fractions was prescribed and the plan was generated in RayStation (v4.0.3) on an Elekta Synergy machine with 4° gantry spacing and a maximum delivery time of 90 seconds per beam. Two full transverse VMAT arcs were used with a partial sagittal arc added (floor at 270°). Isocentre placement was key due to potential collision risks.

Results: Exceptional conformality was achieved. The introduction of the sagittal arc created a ring of dose around the skull providing excellent brain sparing as shown in Figure 1.

QA was performed using a 3D diode array with 99.6% pass rate at 3%/3mm criterion (6/1605 failed diodes). Absolute dose measurements were done using a pinpoint ionisation chamber inside both the scalp and meningioma PTVs indicating agreement with the TPS to within $\pm 3.0\%$.

XVI imaging was performed on fractions 1 to 3, then weekly, using grey scale match. Bony anatomy matched with $<1^\circ$ rotation. Treatment delivery averaged at 10 minutes making this beam arrangement extremely efficient to treat.

Treatment was tolerated very well. Some changes to taste, dysphagia and mild to moderate xerostomia developed during the later stages of treatment. This was managed with general analgesia. There was no evidence of recurrence at three month follow up and the RO is now awaiting further diagnostic MRI's.

Conclusion: Combining traditional transverse arcs with a partial non-coplanar arc is a safe and efficient technique to treat multiple head and neck volumes and provides exceptional sparing and dosimetric accuracy. The sagittal arc was integral to this conformal distribution over these complex PTV's.

EP-2081

Impact of baseline shifts on 4D cone-beam CT images using a 4D phantom driven by lung tumor motions

H. Moriwaki¹, K. Shiraiishi², A. Sakumi², T. Ikeda¹, W. Shimizu¹, K. Yoda³

¹Mitsui Memorial Hospital, Radiation Oncology, Tokyo, Japan

²University of Tokyo Hospital, Radiation Oncology, Tokyo, Japan

³Elekta KK, Research Physics, Tokyo, Japan

Purpose or Objective: We have evaluated clinical impacts of the breathing instability for lung cancer patients on 4D cone-beam CT images using an XVI version 5.0 unit (Elekta, Crawley, UK) using a moving phantom driven by actual patient's tumor motions.

Material and Methods: The XVI unit calculated 10-phase binned 3D volume data based on the tumor positions on each of the projection images and the resulting 10-phase binned breathing curve was stored in the unit. The breathing curve consisting of the 10 sets of the 3D coordinates were compared to the 4D input data which had been fed into the phantom controller. In order to simulate the tumor baseline shifts during relatively long treatment, a 1D phantom, QUASAR™ Respiratory Motion Phantom (modusQA, city or state, USA), was employed, wherein measured patient tumor motions had been fed into the phantom controller beforehand.

Results: When the breathing motions were stable without significant tumor baseline shifts, the tumor motion shown on the 4D CBCT images agreed with the true patient tumor motions. However, when the baseline shifts were significant, the reconstructed images showed unclear and blurred tumors. In particular, the tumor position deviations were significant during the period of large baseline shifts. Moreover, during that period, the tumor was located outside the internal target volume (ITV) region, thereby causing possible treatment failure. To avoid this failure, either breathhold or constrained breathing may be more appropriate than free breathing. Furthermore, a quick beam delivery such as volumetric modulated arc therapy (VMAT) or flattening filter free beams may minimize the impact of the baseline shifts on the CBCT images.

Conclusion: We have confirmed that the XVI version 5.0 unit accurately calculated 10-phase binned 1D phantom positions for stable breathing. However if baseline shift occurs significantly during the projection data acquisition, the reconstructed tumor positions may be incorrect. It is recommended that a sufficient period of preparation time may be required for a patient before treatment. volume (ITV) region, thereby causing possible treatment failure. To avoid this failure, either breathhold or constrained breathing may be more appropriate than free breathing. Furthermore, a quick beam delivery such as volumetric modulated arc therapy (VMAT) or flattening filter free beams may minimize the impact of the baseline shifts on the CBCT images.

EP-2082

Static beam tomotherapy (TD) as an optimisation method in whole breast radiation therapy (WBRT)

M. Squires¹, S. Cheers¹, A. Fong¹, B. Archibald-Heeren¹, Y. Hu¹, A.Y.M. Teh¹

¹Radiation Oncology Centres, Gosford, Gosford, Australia

Purpose or Objective: To evaluate static beam tomotherapy (TD) as a method of dose optimisation for the delivery of whole breast radiation therapy (WBRT).

Material and Methods: Treatment plans of 27 women previously optimised with IMRT on RayStation v4.5 (Raysearch, Stockholm, Sweden) were replanned using TomoDirect (Accuray, Sunnyvale, California, United States). TD parameters included a field width of 2.5cm, a pitch of 0.251 and a modulation factor of 2.000. A simple two field (medial and lateral) beam arrangement was utilised, with no OARs included in the optimisation. A simple ring volume (+0.2cm-+2.0cm) was used to control integral dose. Planning optimisation time was recorded. Prescriptions were normalised to 50Gy in 25 fractions prior to comparison.

Results: Both groups fell within ICRU62 target homogeneity objectives (TD D99 = 48.0Gy vs IMRT = 48.1Gy, p = 0.26; TD D1 = 53.5Gy vs IMRT = 53.0Gy, p=0.02; HI TD = 0.110 vs IMRT = 0.099, p=0.03), with TD plans showing higher median doses (TD median = 51.1Gy vs IMRT = 50.9Gy, p = 0.03). No significant difference was found in prescription dose coverage (TD VTD = 85.5% vs IMRT = 82.0%, p = 0.09). TD plans produced a statistically significant reduction in V5 ipsilateral lung doses (TD V5 = 23.2% vs IMRT = 27.2%, p = 0.04), whilst other queried OAR metrics remained statistically comparable (TD ipsilateral lung V20 = 13.2% vs IMRT = 14.6%, p = 0.30; TD heart V5 = 2.7% vs IMRT = 2.8%, p = 0.47; TD heart V10 = 1.7% vs IMRT = 1.8%, p = 0.44). TD user optimisation time decreased (TD = 9.8m vs IMRT 27.6m, p<0.01), saving an average planning time of 17.8 minutes per patient.

Conclusion: TD represents a viable and superior alternative WBRT technique, both in terms of plan quality metrics and user efficiency.

EP-2083

Utilising flattening filter free (FFF) beams to reduce treatment delivery times for breast patients

M. Le Mottee¹, A. Michalski¹, R. David^{1,2}, C. Lee^{1,2}, A. Windsor^{1,3}, B. Done¹

¹Central Coast Cancer Centre, Radiation Oncology, Gosford, Australia

²The University of Newcastle, The School of Mathematics and Physics, Newcastle, Australia

³University of New South Wales, Faculty of Medicine, Randwick, Australia

Purpose or Objective: This is a feasibility study to compare treatment delivery times of four different techniques for DIBH left sided whole breast RT to minimise the treatment delivery time without compromising the target coverage. In addition to technique comparison, the possible use of flattening filter free beams will also be assessed.

Material and Methods: Ten left sided DIBH patients were selected. Four separate plans were created for each patient. The treatment techniques used were: conventional tangents comprising of open wedged fields (two to four beams), forward planned segmentation (two beams), hybrid inverse planned intensity modulated radiation therapy (IMRT) (four beams) and volumetric modulated arc therapy (VMAT) (two partial arcs). All plans were optimised to the departmental breast protocols. Plans were then delivered on a Varian 21iX linear accelerator (Varian Medical Systems, CA, USA) using Millennium 120 leaf MLC. The maximum dose rate was 600 monitor units per minute. Each plan was delivered three times with the beam on time recorded for each beam. Patients were replanned for forward planned segmentation and inverse planned IMRT using flattening filter free (FFF)

beams. Each plan was delivered three times with the beam on time recorded for each beam. The maximum dose rate was 1400 monitor units per minute.

Results: When comparing dosimetric endpoints four treatment techniques without the inclusion of FFF, IMRT performed statistically better 2cc PTV maximum, 2cc body maximum and homogeneity index for the PTV compared to all other techniques. In general Organs at Risk (OAR) constraints were comparable between the conventional tangents, Field in field and hybrid IMRT techniques. VMAT performed statistically worse in several endpoints including both the point maximum and mean dose for the contralateral breast, Volume receiving 10Gy (V10) and 5Gy (V5) for the heart, ipsilateral and contralateral lung V5 and mean dose as well as the mean dose for combined lung compared to all other techniques planned.

There was no statistical difference for the V20 for the ipsilateral lung and combined lung for all techniques. When looking at the beam on time Hybrid IMRT(10.21s) had the quickest and VMAT(48.76s) the longest.

When comparing dosimetric endpoints four treatment techniques with the inclusion of FFF hybrid IMRT and FFF Hybrid IMRT performed statistically better for PTV2cc max, PTV homogeneity index, total body max and 2cc max. For all other OAR parameters tested in the investigated modulated techniques, treatment planning with FFF beams resulted in plans of equal quality compared with flattened beams. No significant differences were found. When looking at the beam on time FFF Hybrid IMRT(7.45s) had the quickest compared to current tangential delivery times (20.59s).

Conclusion: The inclusion of FFF beams and modulated techniques can significantly reduce treatment delivery times for left sided breast patients who are receiving (DIBH)

EP-2084

Risk assessment of secondary cancer after craniospinal radiotherapy in childhood medulloblastoma

F.M. Giugliano¹, M. Mascarin², L. Iadanza³, E. Coassin², A. Drigo⁴, M.G. Trovò²

¹EmiCenter, Radioterapia, Casavatore, Italy

²Centro di Riferimento Oncologico, Radioterapia Pediatrica, Aviano PN, Italy

³Istituto Tumori- Fondazione "G. Pascale", Dipartimento Fisica Medica, Napoli, Italy

⁴Centro di Riferimento Oncologico, Dipartimento di Fisica Medica, Aviano PN, Italy

Purpose or Objective: Primary central nervous system tumors represent the second most common neoplasms in childhood. The late effects, after radiation treatment (RT), develop gradually over several years, including neurocognitive deficiencies, cardiac toxicity, endocrinological problems, and secondary malignancies (SMNs). The incidence of SMNs is around 10-20%, 30 years after treatment. Predicting SMN risk, from the newer RT techniques is difficult due to absence of epidemiological data, but mathematical models can be used. The aim of this paper is to determine possible dose-response relationships between radiotherapy dose and specific organs SMNs comparing conventional technique (3D-CRT) with IMRT delivered with Helical Tomotherapy (HT).

Material and Methods: In this work a dose-response relationship for malignant tumors is derived based on: the epidemiological data on cancer induction after Hodgkin's disease; from the data about cancer induction of the A-bomb survivor data ("the linear-no-threshold model"). The data from two young patients, affected by medulloblastoma "standard risk" (female age 7y, male age 8y) treated at the National Cancer Institute in Aviano (Italy), were retrospectively analyzed using the Schneider's dose-response model for solid cancers induction (Theoretical Biology and Medical Modelling 2011). We calculated the impact of the different techniques on SMN induction risk, using organ equivalent dose (OED) calculated for a group of different dose-response models including a full model and linear

model. The excess absolute risk (EAR/10000 pts-year) was considered for different organs at risk(OAR).

Results: The results demonstrated that the the linear model fits best colon, cervix and skin. Instead the full model fits all other organs, indicating that the repopulation/repair ability of tissue is neither 0 nor 100% but somewhere in between. We noted that soft tissue sarcoma fitted well by all the models and in the low dose range beyond 1 Gy the risk is negligible, but for increasing dose, sarcoma risk increases rapidly and reaches a plateau at around 25-30 Gy. From the analysis of the EAR breasts, we observed values of 11.5 in 3DCRT plan and of 43.9 in HT plan, respectively. This difference in EAR may be results due to missing of delineation of breast as OAR in pre-planning. The table n. 1 showed the EARK for each OAR in specific dose ranges, calculated for both treatment plans.

SITE	EAR 0-5 Gy		EAR 5-20 Gy		EAR 20-26 Gy	
	3DCRT	TOMO	3DCRT	TOMO	3DCRT	TOMO
Soft tissue	0,0012	0,003	0,57	0,5	2,3	2,2
Thyroid	5,7	9,02	11,5	11,2	0	0
Bladder	2,9	1,7	0	0	0	0
Lung	3,4	9,5	29,4	21,5	38,3	38,4
Bone	0,00083	0,0035	0,47	0,26	0,78	0,79
Small Bowel	6,7	4,3	1,54	1,34	1,3	0
Skin *	0,5	1,9	15,6	10,4	24,2	25,1
Skin **	0,4	1,9	15,6	10,7	24,2	24,4

Conclusion: In this work OED for various OAR was calculated using different models and compared in two plans, in combination with epidemiological obtained absolute risk data. The models have taken into account also the age, important parameters in pediatric population. We think that, in the field of radiation therapy, estimated excess risk it may be interesting to know the advantage of different treatment techniques, in reference to the same organ and the same patient (sex, age, exposure and expected years of life).

EP-2085

Breast irradiation: Is the Isocenter fix ? Results of a Quality Control study.

I. Lvovich¹, S. Daniel¹, A. Dror-Bakalo¹, R. Ben Yosef¹, E. Sabah¹, I. Atnilov¹

¹Rambam Health Care Campus, Oncology/Radiotherapy, Haifa, Israel

Purpose or Objective: The accuracy and reproducibility of tangential fields in breast cancer irradiation is crucial in the sense of tumor control. Small deviation in patient positioning can lead to geometrical miss and low doses in parts of the target as well as exposing OAR (i.e heart and lung) to high doses. Although portal imaging verification can reduce such errors, it is time consuming and could affect machine occupancy. Once the setup is performed in the first treatment it is possible to achieve reproducibility in the AP direction through SSD or couch vertical reading. The aim of this work was to test which of the two should be used in order to achieve better reproducibility through the treatment and whether the Isocenter is truly fixed during the treatment course.

Material and Methods: The study included 30 patients, treated between November 2014 and May 2015 at the ages 34 to 85, with an average age of 60. Total 634 portal images

were taken (18 to 25 per patient). Initially, the patient Set-Up, we performed portal imaging with anatomy comparison to DRRs. We compared lung, heart and breast volumes. The treatment technique was 3D Conformal Radiotherapy. The breast fields were tangential. A Couch Vertical value was determined for each patient at the Set-Up process, and all treatment sessions were performed at that Couch Vertical value. Throughout the course of radiation treatment, daily readings were taken. This included readings of the actual Anterior SSD, as well as portal images taken, to compare anatomical matching to the DRRs. At the end of each patient's treatment course, we performed a comparison of all SSD readings, calculating the differences between planned and actual Anterior SSD readings.

Results: Average difference between the planned and actual Anterior SSD reading was 0.5cm for all treatments (with max 1.15cm and min 0 cm for single patient). For 10 patients (30% of all patients) the mean was above 0.7cm. An upward trend was seen in the average difference along the treatment course. 70% of the patients who had a mean of over 0.7 cm - were over the age of 60. There is also an upward trend of mean depending on age (average of 0.4 cm under the age of 60 and an average of 0.55 cm over 60 ($p=0.058$)). Mean growth with the elapsed time between surgery and treatment (50 to 347 days, average of 150 days) ≥ 100 days: average 0.32 cm, ≤ 100 days: average 0.64 cm ($p<0.001$)

Conclusion: In this study we showed that the difference between the planned and actual Anterior SSD is significant. To get the accuracy and reproducibility in breast cancer irradiation and the increasing use of IMRT (field in field), we recommend to consider re-planning for some patients, or to treating according to a fixed Couch-Vertical value, set during the initial patient Set-Up. Continue further work to examine the deviations in dosimetry based on the change in IsoCenter. A greater number of measurements will enable us to learn whether age and the elapsed time from surgery are significant factors

EP-2086

Advantages of deep inspiration breath-hold (DIBH) in left sided breast cancer using 3D-CRT

A. Kalmár¹, N. Mészáros¹, G. Stelczer¹, C. Polgár¹

¹National Institute of Oncology, Radiotherapy, Budapest, Hungary

Purpose or Objective: Irradiation of the left breast or chest wall was associated with an increased cardiac mortality and morbidity. The relative risk for ischaemic heart disease increased by 7.4 % with every 1 Gray (Gy) increase in mean heart dose. The dose to the heart and left lung can be reduced with deep inspiration breath hold (DIBH) techniques. The aim of this study was to investigate the reduction of organs at risk (OAR) doses with DIBH compared to free breathing (FB) in patients receiving left sided radiation therapy with three dimensional conformal techniques.

Material and Methods: Between September and October 2015, a total of 20 patients with left-sided breast cancer underwent two different computed tomography (CT) scans with 3 mm slice thickness, both FB and DIBH. The breast, lung, and OAR contours were done according to the RTOG breast cancer contouring atlas. The prescribed dose was 25 x 2 Gy, and the radiotherapy plans were made by using 2-4 opposing tangential fields with 6 MV and 18 MV photons. For statistical analysis Wilcoxon matched pair test was used.

Results: Similar target coverage was achieved with both techniques. The mean MHD was reduced from 4.4 Gy (range: 1.3-8.3 Gy) with FB to 2.7 Gy (1.4-4.2 Gy) with DIBH ($p<0.05$), resulting a mean dose reduction of 1.7 Gy (39%) favouring DIBH. The average MLD was 6.7 Gy (3.3-11.7 Gy) at FB compared to 5.7 Gy (2.1-10.7 Gy) at DIBH ($p<0.05$), resulting mean 1 Gy (15%) dose reduction with DIBH. The V_5 heart and V_{20} heart were also significantly lower, 49.3% (7-79%) and 5.8% (0.03-15.9%) with FB and 36% (12-70%) and 1.5% (0-5.9%) with DIBH ($p<0.05$). The V_{20} lung for the group

was reduced slightly at FB from 14.9% (5.2-27.8%) to 12.7% (3.5-24.6%), however this was not statistically significant ($p=0.056$). The V_{30} lung was 12.5% (3.8-23.8%) with FB and 10.2% (2.4-21.8%) with DIBH ($p<0.05$).

Conclusion: A significantly lower dose to clinically important organs at risk (heart and lung). Using simple 3D radiotherapy techniques DIBH can reduce dose to the heart and lung without compromising target coverage be achieved using the DIBH technique compared to FB.

EP-2087

Simultaneous Integrated Boost Bilateral breast cancer RT with Helical IMRT: How to manage it?

J.L. Soares Rodrigues¹

¹Centre Hospitalier Universitaire Vaudois, Department of Radiation Oncology, Lausanne Vaud, Switzerland

Purpose or Objective: The objective of the present case study was to investigate the potential role and the feasibility of Helical intensity modulated radiotherapy, (Tomotherapy, Accuray), for bilateral breast tumor patients, with a simultaneous integrated boost (SIB) strategy.

Material and Methods: Four target volumes were defined by the radiation oncologist: PTV breast (right and left) and PTV boost (right and left). Dose prescription in a SIB scheme was: 50.4 Gy (1.8 Gy/fraction) to PTV breast (right and left), 61.6 Gy (2.2 Gy/fraction) to PTV boost right side and 59.36 Gy (2.12 Gy/fraction) for PTV boost left side. Objectives were: for PTVs $V_{95\%}>95\%$; Mean lung dose $MLD<15$ Gy, $V_{20\text{Gy}}<20\%$, $V_5\text{Gy}$ as low as possible; for the heart a Mean dose < 7 Gy. The plan was generated with Tomotherapy planning station 5.0.5.18 (Volo, Accuray), with a field width of 2.5 cm, pitch of 0.287 and a modulation factor of 3.8. Specific optimization volumes were created by the dosimetrist to avoid high integral dose and to achieve a very conformal and homogeneous dose distribution. Treatment time will be measured.

Results: For PTV breast right and PTV breast left, $V_{95\%}$ was 95.05%. For PTV boost right and PTV boost left the $V_{95\%}$ was 97.9% and 96.8%, respectively. Mean lung dose was 8.6 Gy for each lung. $V_{20\text{Gy}}$ for both lungs combine was 13.8 %, and $V_5\text{Gy}$ was 35.6 %. Mean heart dose was 3.8 Gy with a maximum dose of 37 Gy. The irradiation treatment time is around 7 minutes.

Conclusion: This case show a very promising and feasible role of Helical IMRT, for bilateral breast tumor patients, with a simultaneous integrated boost (SIB) strategy. A good treatment planning strategy is fundamental to achieve the dose volume histogram (DVH) for the organs at risk (OAR) presented here

CT and MRI fusion to minimize contouring uncertainties in Stereotactic Radiosurgery (SRS) planning

I. Pavanova¹, R. Georgiev², R. Lazarov¹, Z. Spasova¹, V. Ivanov³, L. Iliev¹, P. Tsenov¹, A. Antonova¹, T. Georgieva¹, S. Georgieva¹, D. Avgerinova¹

¹Tokuda Hospital, Radiotherapy, Sofia, Bulgaria

²BSBMPE, Biomedical Engineering, Sofia, Bulgaria

³Tokuda Hospital, Imaging diagnostic, Sofia, Bulgaria

Purpose or Objective: To improve image registration accuracy by using markers on patients for head SRS treatment planning. Contour shifts were compared after image matching based on anatomy correspondence and markers superposition.

Material and Methods: Ten patients with head localisations planned for radiosurgery were studied. Scanning procedures using skin markers were done on CT - GELightSpeed RT16, with 1.25mm slice thickness and MRI - GESigna 1,5T following

AxT2 FRFSE, AxT1 and T2FLAIR, MRPerf Ax Dynamic SI C+ and Ax 3D T1 FSPGR. Image fusion of data sets was applied after anatomic landmark matching before target contouring. Alternatively image matching was also implemented by marker superposition. Translation and rotation corrections were calculated from markers' displacement and applied in the matching procedure. Target anatomy contours obtained from both procedures were compared and contour shifts measured. These shifts were analyzed to find how the type of matching procedure would affect target contour displacement.

Results: Coordinates of markers showed geometrical displacements (0.15cm-0.35cm) in transverse direction and rotation angles (1.5o-2.0o). These values were used for compensation in the image matching procedure, achieving visual correspondence of target anatomy after image fusion. Target contour displacement after applying both procedures were found to be within the range of 0-0.3cm.

Conclusion: The precise positioning and method using markers is essential to achieve good quality in the image matching, as well as the accuracy in the SRS. It could be improved with more than 1mm for the target and organs at risk, which makes the SRS treatment procedure itself more effective.

EP-2089

Comparison of target volumes for lower gastro-intestinal tumours using PET-CT and PET-MR images

J. Heywood¹, M. Chiu¹, I. Kayani², L. Allington¹, R. Bodey¹, G. Blackman¹

¹University College London Hospital, Radiotherapy, London, United Kingdom

²University College London Hospital, Nuclear Medicine, London, United Kingdom

Purpose or Objective: The use of PET-CT in radiotherapy planning is emerging as a modality to aid target volume delineation in lower GI tumours. MRI provides superior soft tissue definition compared with CT which may offer further benefit in radiotherapy planning (Wang et al, 2011).

Since 2008, PET-CT has been used for radiotherapy planning within the department and, to date, we have scanned over 170 patients across a range of tumour sites. To explore the role of MRI in lower gastro-intestinal planning, 9 patients were dual scanned as part of a feasibility study to compare target volume delineation using PET-CT and PET-MR images.

Material and Methods: All lower GI tumours requiring a PET-CT for planning purposes were considered eligible for the study. For each patient a PET-CT and PET-MR scan was acquired in the treatment position following a single F18-FDG radioisotope injection. The patients were allocated with 50% having the initial planning scan in PET CT and 50% in PET-MR. Duration time post injection was recorded for each scan.

Prior to volume delineation both data sets were anonymised. Each clinician was provided with the relevant anonymised diagnostic imaging and tumour histopathology reports. On both datasets a Nuclear Medicine Radiologist delineated the BTV and a Clinical Oncologist delineated the gross tumour volume (GTV) and clinical target volume (CTV). Volumes for each patient were delineated on separate occasions for each imaging modality.

Volume sizes for both data sets were compared and a similarity index calculated.

Results: Nine patients were entered into the study, 6 rectal carcinomas and 3 anal canal carcinomas.

									AC	mean	2.8	51.54		
										sd	12.12	104.86		
									Rectum	mean	-2.19	-11.08		
										sd	72.39	26.68		

When compared with volumes delineated using CT data, overall, the GTV of the rectal volumes were smaller when delineated on MRI. Due to the small number of anal canal tumours, it is difficult to draw any conclusion.

The similarity index between volumes will also be presented.

Conclusion: This initial evaluation indicates that, overall, MR delineated volumes for rectal tumours are smaller than those created using CT data. This has the potential to impact treatment planning and reduce toxicity. The study highlighted the challenges of using MR data for nodal volume delineation, indicating that a combined modality approach may be optimal. It is acknowledged that extension of this study to a larger population would allow firmer conclusions to be drawn.

EP-2090

Accurate and stable immobilisation with Lorca Marin masks for head and neck IMRT treatment

A. Ilundain¹, I. Prieto¹, E. Márquez¹, D. Esteban¹, W. Vázquez¹, A. Pérez¹

¹Hospital Universitario Fundación Jimenez Díaz, Radiation Oncology, Madrid, Spain

Purpose or Objective: The aim of this work is to analyze the setup accuracy and stability resulting from the use of the Lorca Marin thermoplastic masks during the complete course in head and neck cancer treatment with intensity modulated techniques.

Material and Methods: 50 consecutive head and neck cancer treatments with intensity modulated radiotherapy (IMRT) were analyzed. Lorca Marin customized masks named Nature were used to immobilize head and neck. These 2-oxepanone polymer thermoplastic masks are 3-points immobilization with frontal and mental reinforcement and 3.2 mm thickness. 3-standard references were marked on the surface of the mask and on the middle chest of the patient for accurate positioning every day. Cone-beam computed tomography scan to verify online the position was performed during 5 consecutive days and after, weekly cone-beam until the end of the treatment. After weekly matching process using automated soft-tissue registration, translational movements along the three axes (x, y, z) were collected and the average for each treatment and each axis was calculated. Displacement's mean of the 50 averages and the standard deviations were analyzed.

Results: The resulting displacement average after analyzing 50 treatments was less than 1 mm along the three axes: x = (0.62±0.51) mm, y = (0.83±0.63) mm, z = (0.65±0.59) mm. These setup displacements have remained under than 3 mm in 100% of treatments. These results achieve the International Commission on Radiation Units and Measurements (ICRU) recommendations regarding the setup margin to compensate the immobilization and positioning errors.

Conclusion: The type of patient immobilization devices and their contribution in the setup errors must be taken into account for IMRT. Additionally, the use of different image-guidance systems can significantly alter the size of the

required margins. Lorca Marin thermoplastics masks show enough accuracy and stability during complete course of treatment with intensity modulated techniques in head and neck cancer patients.

EP-2091

Establishment of dose reference levels (DRLs) for CT of the head and neck in radiation therapy

C. Clerkin¹, S. Brennan², L. Mullaney¹

¹*Discipline of Radiation Therapy- School of Medicine- Trinity College Dublin, Radiation Therapy, Dublin, Ireland Republic of*

²*St Luke's Radiation Oncology Network at St Luke's Hospital- Dublin 6., Department of Radiation Oncology-, Dublin, Ireland Republic of*

Purpose or Objective: Computed tomography (CT) has become an indispensable tool in oncological imaging. Ionising radiation is cumulative and carries a stochastic risk of malignancy. The implementation of dose reference levels (DRLs) for imaging procedures using ionising radiation is mandated by European Commission directive 97/43 EURATOM. There are currently no dose guidelines for radiation therapy CT of the head and neck (H&N) region. The propose of this research is to establish if variation exists in dose delivered by Irish centres; establish a national DRL for H&N CT scanning in radiation therapy and compare the national DRL with a European sample.

Material and Methods: All radiation therapy centres in Ireland and a selection of European centres were invited to complete a dose audit survey for 10 average-sized H&N patients undergoing a CT localisation scan. Data on CTDIvol, DLP, mAs, tube voltage, number of scan phases and scan length was collected.

Results: Surveys were returned by five Irish centres, representing a 42% response rate and one European centre. Significant variation was found in the mean DLP, CTDIvol and scan lengths. Based on the rounded 75th percentile of the mean DLP and CTDIvol, the proposed Irish DRL is 1025.41mGy cm and 20.97mGy, respectively. Based on the European survey the DRLs for DLP and CTDIvol were 680.12mGy cm and 21.85mGy, respectively.

Conclusion: Variation exists in dose used for H&N CT in radiation therapy. DRLs have been proposed with the aim of dose optimisation for this procedure.

EP-2092

Impact of treatment volumes in loco-regional failure of oral cancer in patients treated with IMRT

D. Delishaj¹, S. Ursino¹, E. Lombardo¹, L.R. Fatigante¹, M. Cantarella¹, G. Coraggio¹, F. Matteucci¹, S. Montrone¹, M.G. Fabrini¹

¹*Azienda Ospedaliero Universitaria Pisana, Radiotherapy, Pisa, Italy*

Purpose or Objective: The aim of the study was to analyze the impact of radiation therapy (RT) or concomitant radiochemotherapy (RT-CT) on locoregional control (LRC) in patients affected by oral cancer.

Material and Methods: Materials and methods : In this study were enrolled 48 patients with oral cancer diagnoses underwent postoperative RT or exclusive RT-CT treatment. The RT was performed with intensity-modulated radiotherapy (IMRT) technique and LINAC DHX of Varian System. All patients were treated at the department of Radiotherapy, University of Pisa. In patients non treated surgically or operated with major risk factors (positive margins, Extracapsular extension) RT treatment was performed in combination with chemotherapy (CT) or molecular-target therapy. Again patients operated with presence of minor risk factors (positive lymph nodes, lymphatic vascular invasion, perineural invasion) underwent only RT treatment. The volumes were defined as follows: PTV high risk: 66Gy (2.2Gy /fraction) or 63Gy (2.1Gy / fraction) respectively for

exclusive RTCT treatment and adjuvant RTCT or RT treatment PTV intermediate risk: 60 Gy (2.0Gy /fraction) PTV low risk: 54Gy (1.8Gy /fraction)

Results: From January 2011 to July 2015, 48 patients (mean age 60.9 years; range 33-87) with histologically confirmed diagnosis of oral cancer were treated. At analysis 30 patients (62.5%) underwent surgically treatment and 18 (37.5 %) performed exclusive RTCT treatment. Twentyfour patients were treated with radiochemotherapy or radiotherapy plus molecular-target therapy; in 20 patients (83%) was administered CDDP; in 4 patients (17%) in combination with RT was administered Erbitux. Relapses were divided into local (on T), regional (on N) and locoregional (if the recurrences were on T and N) and classified, after the merger of radiological imaging with radiation therapy planning; in "in field" (within the PTV high risk) and "out field" (without PTV high risk) After a median follow-up of 19.8 months (range 3-62 months), six patients (12.5%) developed local recurrence "in field" and two patients (4.2%) reported locoregional relapse on field. There were not "out field" recurrences. Of six patients relapsed 2 (33.3%) underwent salvage surgery and subsequent CT; 3 (33.3%) underwent second line CT according to Extreme schedule and 1 patient (2%) didn't any systemic treatment but only support care due to comorbidities and scarce performance status. At the date of abstract submission 3/6 patients died while the others are still alive; overall 5/48 patients (10.4 %) died and only 2 died for cancer-related causes and three for comorbidities.

Conclusion: The results of our study confirm the data reported in literature regarding the locoregional recurrences of oral cancer treated with radiotherapy. In field locoregional relapse seems to be the main cause of IMRT treatment failure regardless the patient underwent at surgery treatment or not.

EP-2093

Drinking instructions does not significantly influence inter-fraction bladder volume stability

M. Berg¹, K. Thellesen¹, H. Jensen¹, L.M. Nielsen², H. Wasilevska³, L. Wee¹

¹*Vejle Hospital, Department of Medical Physics, Vejle, Denmark*

²*Vejle Hospital, Radiation Therapy Department, Vejle, Denmark*

³*Vejle Hospital, Department of Oncology, Vejle, Denmark*

Purpose or Objective: Bladder preparatory protocols are used in prostate cancer (PCa) radiotherapy (RT) prior to simulation (Sim) imaging, and thereafter prior to each fraction of RT. Patients are asked to drink, and hold without voiding, a constant volume of water. Distension of the bladder reduces the volume of the bladder irradiated to high doses. A study of online image-guided radiotherapy (IGRT) in bladder cancer showed that inter- and intra-fraction reproducibility was mostly insensitive to degree of bladder filling. Radiographer students were asked to test the analogous hypothesis for inter-fraction reproducibility in bladder volume over 7 weeks of PCa IGRT.

Material and Methods: An audit of PCa IGRT found 96 cases within 1 year of study commencement. 56/96 were locally advanced PCa homogeneously treated with bladder preparation instructions, daily online cone-beam CT (CBCT) verification and 28Gy sequential boost to gland only following 50Gy to gland plus seminal vesicles by normo-fractionated IMRT. 42 were complete cases in which bladders had been consistently outlined at Sim and 7 CBCTs weekly. 30/42 men agreed to hold 300mL of water each session, but in practice only 26/42 were able to comply throughout treatment. 12/42 men declined the drinking instructions outright.

Results: Sim and weekly CBCT volumes were tested for non-normality and leverage. 4 men had Sim volumes that were well in excess of 500mL, and by mid-course, had greatly reduced. The extreme cases exerted strong leverage. In 38 men, bladder volumes were log-normally distributed. Compliant men had bladder volumes (162 mL) statistically significantly larger ($p < 0.01$) than men refusing (83 mL). The random inter-fraction variation was the same in both groups (33%). Compliant men had a mean systematic increase in bladder volume of 12% (95%CI = 4.8-21%, $p < 0.01$) relative to Sim, compared to 32% (95%CI = 12%-55%, $p < 0.01$) in the refusing group.

Conclusion: Systematic and random changes in bladder volume during PCa IGRT are relatively insensitive to bladder filling in PCa IGRT, provided the Sim volume is not excessive ($> 500\text{mL}$). Volumes at Sim are statistically significantly different between groups, so there may be implications for dose planning. We have proposed a follow-on project to measure the effect of changing the drinking instructions, so men are advised to drink and practice holding as much water as they can comfortably tolerate without voiding for 1 hour.

EP-2094

Can Radiation Oncologist delegate to Therapist the kV setup control in patients with pelvic cancers?

V. Frascino¹, M. Ferro¹, A. Alitto¹, A. Castelluccia¹, A. Petrone¹, G. Nicolini¹, S. Teodoli¹, G. Mattiucci¹, G. Mantini¹, M. Gambacorta¹, S. Chiesa¹, F. Deodato², L. Azario¹, S. Luzi¹, V. Valentini¹, M. Balducci¹

¹Università Cattolica del Sacro Cuore - Policlinico A. Gemelli, Radiation Oncology Department - Gemelli-ART, Rome, Italy

²Università Cattolica del S. Cuore - Fondazione di Ricerca e Cura "Giovanni Paolo II", Radiation Oncology Department, Campobasso, Italy

Purpose or Objective: Check of patients' set-up is mandatory in modern radiation therapy. The aim of this preliminary analysis is to investigate the possibility to delegate to Radiation Therapists (RT) the evaluation of two-dimensional orthogonal kV/kV imaging of pelvic cancers.

Material and Methods: Paired orthogonal kV images of patients who underwent pelvic irradiation were independently evaluated by a trained RT (on-line control) and a Radiation Oncologist (RO, off-line control). If a displacement of the isocenter larger than 5 mm was observed, the RT had to call the RO to verify and confirm such displacement. The difference of measures and the agreement between RO and RT decisions were calculated. Results are presented as mean values, and population systematic (Σ) and random (σ) errors. SPSS software was used for the statistical analysis.

Results: From March 2015 to September 2015, 904 images' pairs were obtained from 40 patients (10 prostate, 15 rectal, and 15 gynaecological cancers). A difference ≥ 3 mm was recorded in 766/904 (85%) paired images. A difference between 3 and 5 mm was recorded in 94/904 (10%) paired images. Forty-two/904 (4%) checks required on-line evaluation by the RO. In anteroposterior (AP), craniocaudal (CC) and mediolateral (ML) directions, systematic errors were 0.7, 0.4 and 0.8 mm, and random error were 0.2, 0.1 and 0.1 mm, respectively. Mean radial displacement was 2.6 mm (range 0-16 mm). CTV to PTV margins calculated by van Herk's formula were 3.3, 2.3 and 3.0mm (AP, CC and ML directions, respectively).

Conclusion: These data suggest that inter-observer variability between RT and RO is within few mm, therefore on-line kV/kV images' evaluation could be delegated to RT after an adequate training period. Such kind of quantitative analysis can be used to define a proper action level to call for RO intervention. Similar study is currently ongoing to assess inter-observer variability for CBCT evaluation.

EP-2095

A retrospective evaluation of the feasibility of automatic prostate matching in IGRT

Z. Campbell¹, B. O'Neill², L. O'Sullivan², M. Keaveney², L. Mullaney¹

¹Discipline of Radiation Therapy- School of Medicine- Trinity Centre Dublin, Radiation Therapy, Dublin, Ireland Republic of

²St Luke's Radiation Oncology Network- Beaumont Hospital, Radiation Therapy Department, Dublin, Ireland Republic of

Purpose or Objective: The current practice for prostate localisation in some centres is an automatic match to the bony anatomy of the pelvis. The prostate moves independently of bone and so its true motion may not be accounted with this method. An automatic match to the prostate may be more accurate. The purpose of this research is to identify if automatic prostate matching is more accurate than automatic bony matching and assess the impact on CTV-PTV planning margins.

Material and Methods: A retrospective review of CBCT data for 30 consented prostate patients was undertaken (9 CBCT each, $n=270$). All patients followed a bladder filling and rectal emptying protocol. Using Varian's On-Board Imager® software, the random; systematic and population mean translational shifts was calculated based on 3 different registration techniques: automatic bone matching; automatic bone matching followed by an automatic volume of interest (VOI) match using CTV and an expert manual CTV match (gold standard). A comparison was made of the CTV-PTV margins required for the two automatic registration methods.

Results: No significant difference in the mean translational shifts was reported between the automatic bone match and gold standard match. A significant difference was seen between the population mean shift of the gold standard match and the automatic prostate match in the anteroposterior direction only ($p=0.007$). A larger CTV-PTV margin was required for the automatic prostate match when compared with the automatic bone match.

Table 1: Population mean (and standard deviation) displacements (cm) in the anteroposterior (AP), superoinferior (SI) and left-right (LR) are shown based on the three different matching techniques: automatic bone match; an automatic volume of interest (VOI) match using CTV and an expert manual CTV match (gold standard). Negative values indicate posterior, inferior and left displacements.

	Matching Technique		
	Automatic Bone Match	Automatic VOI Match	Gold Standard Match
AP	-0.04 (0.18)	-0.12 (0.21)*	-0.05 (0.17)*
SI	0.04 (0.12)	0 (0.14)	0.01 (0.17)
RL	-0.05 (0.15)	-0.05 (0.16)	0.01 (0.16)

*Significant difference ($p < 0.05$) when compared with the control group statistics.

Conclusion: Automatic bone matching is comparable to expert manual matching in this patient group. Automatic prostate matching is not as accurate in the anteroposterior direction and does not allow for a reduction in planning margins.

EP-2096

Risk of rectal bleeding in patients with prostate cancer treated with RT on anticoagulant therapy

B. Shima¹, M.T. Martinetti¹, M. Carnevale¹, D. Musio¹, R. Lisi¹, V. Tombolini¹

¹Policlinico Umberto I - "Sapienza" Università di Roma, Dipartimento di Scienze Radiologiche Oncologiche e Anatomo-Patologiche, Roma, Italy

Purpose or Objective: The aim of the study is to evaluate the risk of late rectal bleeding and its association with anticoagulants and/or antiaggregants use in patients receiving radiation therapy for prostate cancer.

Material and Methods: We analyzed 187 patients, age between 50-84, with prostate cancer who were managed from 2009 to 2011 at our institution. They were treated with curative intent intensity-modulated radiation therapy (IMRT 76 Gy/38 fractions) at the level of the prostate and seminal vesicles. The doses delivered to the rectum was evaluated in a manner consistent with ICRU 50-62-83. Dose constraint

evaluation was performed according to RTOG recommendation for IMRT. Patients were placed in two main categories: no anticoagulants and/or antiaggregants use category during RT and anticoagulants and/or antiaggregants one. Rectal toxicity was evaluated using the Common Toxicity Criteria Adverse Effect (CTCAE v. 4.03) All patients had assumed the anticoagulant and/or antiaggregant therapy before radiation therapy, during treatment as well as during the follow up.

Results: 20 of the 73 patients treated with anticoagulant and/or antiaggregant therapy, presented rectal bleeding; while in the group of patients not taking anticoagulants and/or antiaggregants this even occurred in 10 patients of 114 ($p < 0.001$). Of the 20 patients who have received anticoagulant and/or antiaggregant agent who presented rectal bleeding, 8 developed G1 toxicity, 10 had G2 toxicity and 2 patients had G3 toxicity. Of the 10 patients who did not receive anticoagulant and antiaggregant therapy and presented rectal bleeding, 5 patients had G1 toxicity, 4 present G2 toxicity and G3 toxicity only 1 patient.

Conclusion: The results of our study found that patients taking anticoagulant and/or antiaggregants therapy undergoing curative radiotherapy for prostate adenocarcinoma have a higher risk of developing rectal bleeding.

EP-2097

Patient friendly compression-belt settings in liver stereotactic radiotherapy

A.S. Bouwhuis-Scholten¹, E.B. Van Dieren¹, S. Koch¹, H. Piersma¹, D. Woutersen¹

¹Medisch Spectrum Twente, Radiotherapy, Enschede, The Netherlands

Purpose or Objective: Stereotactic radiotherapy of liver metastases is challenging: breathing motion, and the flexibility of the abdominal organs, in particular remaining liver, may be large. This may render a priori imaging for position verification virtually useless. Hence, "decision to treat" may be difficult and stressful.

Abdominal compression may be used to reduce movement and flexibility, but maximum compression is highly uncomfortable and probably intolerable for patients during the entire session (20-30 min). Our institution has chosen to limit compression so that patients can endure it easily during the entire session. This study investigates whether this type of abdominal compression is effective.

Material and Methods: In short, a diagnostic 2 phase CT scan was used to locate tumor positions. Belt pressure and marking position (Orfit Industries), were reproduced for each treatment fraction. Each fraction, cone beam CTs (CBCT) were recorded before and immediately afterwards. Scans were matched offline, using deformable image registration (Varian Smart Adapt V13), resulting in "CBCT liver contours". These were checked and adjusted, if necessary. Each CBCT liver contour was compared to original CT contour using absolute volume, center of mass shift (CMS) and dice coefficient (DC). To assess effectiveness of compression, data were averaged for each of the three computed parameters.

Results: Until this date, a total of 6 patients were treated using this technique. All 6 tolerated the applied abdominal compression easily during the sessions. Therapists, trained in >> 100 brain or lung stereotactic treatments, reported no exceptional difficulties in fixation, CBCT, and matching. Data from 4 patients, and a total of 24 CBCTs, were eligible for analyses. Liver CBCT volumes appeared to be very similar to CT contours: the average is only 18 cc less, with a maximum of 116 cc. The average CMS in X, Y, Z are 0.14cm (max 0.41cm), 0.05cm (max 0.33cm) and 0cm (max 0.23cm), respectively. Average DC is 0.94, with a range of [0.89 0.99].

Conclusion: Difference in volume, center of mass, and even shape are well within the range of standard uncertainties in

stereotactic abdominal radiotherapy. This corroborates with the reported feasibility by therapists treating these patients. In short, the patient comfortable setting of the compression-belt is reproducible and safe to correctly deliver the dose in stereotactic radiotherapy of the liver.

EP-2098

Use of a bladder minimum contour for prostate treatment planning to increase comfort and efficiency

C. Evans¹, E. Crees¹, G. Kidane¹, M. Brown¹, M. Campbell², S. Gibbs³, K. Tarver³, G. Ghebremariam¹

¹Queen's Hospital, Department of Medical Physics, Romford, United Kingdom

²Queen's Hospital, Radiotherapy Department, Romford, United Kingdom

³Queen's Hospital, Oncology, Romford, United Kingdom

Purpose or Objective: Prostate cancer patients often find it difficult to maintain a full bladder throughout the course of their radiotherapy treatment. These bladder filling problems can result in patients being taken out of the treatment room in order to increase bladder filling, leading to treatment delays. The aim of this study was to provide a range of acceptable bladder sizes without compromising the bladder dose constraints.

Material and Methods: An audit was carried out with ten patients who attended for IMRT radiotherapy planning for prostate cancer. A minimum bladder volume (bladder min) in each patient was defined by cropping the planning CT (pCT) bladder volume to around 150cc. This new volume was then used in addition to the pCT bladder volume in the IMRT plan optimisation to fulfil the bladder dose constraints. The patients had their bladder volume assessed prior to treatment using a standard CBCT imaging protocol. Retrospective dose calculations were undertaken using the daily CBCT images, and bladder doses were plotted against bladder volume to demonstrate that dose constraints were still being met at the reduced bladder volume. The tolerance doses used are taken from the CHHiP trial protocol.

Results: The bladder min contour is used by the treatment radiographers as a visual guide on the CBCT scan taken before each treatment in order to assess whether the patient's bladder is an acceptable size to continue with treatment without compromising bladder tolerance doses.

The volume of the bladder min contour is adjusted to meet the constraints for each individual patient as necessary. The need for patients to be taken out of the treatment room to re-fill the bladder has been reduced and this has resulted in better workflow on the treatment floor. The use of the bladder min contour for prostate IMRT treatment planning is now standard practice in our clinic.

Conclusion: The use of the bladder min contour has improved patient comfort without compromising the therapeutic ratio and has aided the radiographers in online review of treatment images.

The implementation of the above has led to a reduction in treatment delays due to the bladder volume obtained at planning CT not being maintained throughout treatment. This has improved the clinic workflow. Patient discomfort is kept to a minimum and repeat CBCT scans have been reduced.

EP-2099

Influence of anxiety on reproducibility of cancer patients (pts) repositioning during pelvic RT

E. Sierko¹, R. Maksim¹, J. Czauderna¹, T. Filipowski¹, M. Wojtukiewicz²

¹Białostockie Centrum Onkologii, Departament of Radiation Therapy, Białystok, Poland

²Medical University in Białystok, Departament of Oncology, Białystok, Poland

Purpose or Objective: The aim of the study was an analysis of an influence of type and intensity of pts anxiety on pts repositioning during planning and delivery of RT to the pelvic area in relation to pts gender, immobilization device, and

assessments: subjective of QoL and objective -of pts repositioning during RT.

Material and Methods: 57 pts(28 gynecological cancer females and 29 prostatic cancer males) underwent radical RT to the pelvic area in Radiation Therapy Department of Contemporary Cancer Center in Bialystok, Poland. Pts were immobilized with an AIO SOLUTION by Orfit™ set or kneefix plus headrest. Demographic questionnaire one was filled once. Second questionnaire using VAS scale evaluated subjective sensation of anxiety via 20 questions describing events influencing areas: biological social, psychological and somatic. It was filled 3 times: before: localization CT, 1st and 11th fraction (fr) of RT. Heart rate (indicating objective pts anxiety) examination was performed before each evaluation. Reproducibility of pts positioning in relation to X, Y, Z-axes was verified under Elekta accelerator using X-ray volume imaging (XVI).

Results: Most of pts exhibit highly increased anxiety before CT. It was decreasing in time but still was significant at the end of RT. Contrary to men, female pts experienced higher anxiety specially in somatic, and biological areas before CT. Males developed the sensation before 1st fr. In pts positioned with hands on their chest significantly worse Y-axis position reproducibility (PR) before 1st fr and significantly higher anxiety ($p=0,007$) was observed before 11th fr of RT ($p=0,03$) comparing to those localized with hands along the body. Higher psychological anxiety was associated with significantly worse average PR in all axes ($p=0.03$, $R=0,3$). Average heartbeat was highest before the 1st while lowest - before 11th fr of RT. Intensity of anxiety was not associated with social situation, experience with cancer among relatives, and the time between diagnosis and start of RT.

Conclusion: Since anxiety influences pts repositioning during RT, more attention should be paid by RTT to decrease this emotional status of the pts. Educational events should be organized for RTT to help them overcome the problem of pts anxiety during RT.

EP-2100

Effectiveness of the manual correction during positioning patients with prostate cancer

T. Piotrowski¹, K. Kaczmarek², A. Jodda³, B. Bąk¹, A. Ryczkowski³

¹Poznan University of Medical Sciences, Electroradiology, Poznan, Poland

²Greater Poland Cancer Centre, 2nd Radiotherapy Ward, Poznan, Poland

³Greater Poland Cancer Centre, Medical Physics, Poznan, Poland

Purpose or Objective: Total shift (TS) in each of the directions along the x, y or z-axis is a sum of shifts resulting from automatic registration (AR) and manual correction (MC) and is described by formula: $TS=AR+MC$. Unfortunately, MC is burdened by error resulting from inter-observer variability. The aim of this study was to find the level of MC, above which the use of MC during positioning of the patients with prostate cancer on the helical tomotherapy will be reasonable.

Material and Methods: This retrospective study based on the image guidance data gathered from 30 consecutive patients with prostate cancer treated on helical tomotherapy in 2013. The planned dose for each patient was 74 Gy delivered to the prostate or to the prostate and to the basis of the seminal vesicles. The treatment was realized in 37 fractions. Daily MVCT imaging covered whole irradiated region expanded by 10 mm in cranio-caudal direction. The data from each fraction and for every patient (daily MVCT and planned kVCT) were re-registered by five independent observers.

The MCs established by observers were averaged for each fraction and for every patient, respectively. The level of MC, above which usage of MC is reasonable, was recognized on the level of averaged MC higher than 1 mm.

Results: 1110 registrations were re-registered by each observer.

Using the condition of the average MC higher than 1 mm, we established that the reasonable MC that should be applied during registrations are respectively: higher than 2 mm in medio-lateral and cranio-caudal directions; and higher than 2.5 mm in antero-posterior direction.

Figure 1 shows averaged manual corrections in the medio-lateral and cranio-caudal directions.

Conclusion: Manual correction effectively increase the accuracy of the registrations when the value of the corrections are higher than 2 mm in medio-lateral and cranio-caudal directions and higher than 2.5 mm in antero-posterior direction. Lower values of manual corrections are burdened by error resulting from inter-observer variability and can not be applied to the total shift during registration process.

EP-2101

Inverting a teaching practice

D. Montgomerie¹, B. Mudie¹

¹University Of Otago, Radiation Therapy, Wellington, New Zealand

Purpose or Objective: Introduction: The first year radiation therapy (RT) planning paper in the Bachelor of Radiation Therapy, University of Otago, New Zealand covers all of the basic concepts required to be able to plan radiation treatments. As the students' progress through the three years of the programme the concepts remain the same but the application of them becomes more complex. Planning concepts were taught one by one, with the students gaining knowledge and comprehension on each concept. Towards the end of the paper the aim was to be able to apply, analyse and evaluate all of these concepts together to produce a radiation therapy plan. However, students were indicating that although they understood each of the concepts individually they struggled to apply them together and felt underprepared for the clinical placement - the acquisition of knowledge had not led to critical thinking.

Objectives: In response to this feedback major changes were instituted to the structure of the paper delivery by essentially reversing the approach. The students' now began by creating and critiquing plans then unpacking and exploring the concepts. The authors wanted to assess the impact this new approach had on the students in their clinical placement.

Material and Methods: Method: To assess the preparedness of the students for clinical placement a comparison of the original method of delivery (group A) to the new approach (group B) was undertaken. Six students from group A were invited to participate in a focus group using a semi-structured

interview technique with an independent interviewer. The focus group was conducted shortly after the completion of the first clinical placement. The themes that came from this were then used to create a survey for group B. This was also completed shortly after their first clinical placement. Additionally this survey was also undertaken by supervising qualified RTs from the clinical placements.

Results: Results: The results from the focus group A showed that the students did not fully grasp how the concepts applied to the final plan and this left them feeling very underprepared for their clinical placement and that this was reflected back to them by supervising qualified staff. Group B however, felt themselves to be much better prepared and reasonably confident to undertake clinical placement a view which was supported by the supervising radiation therapists.

Conclusion: Conclusion: The alteration of the teaching delivery had allowed the students to start the paper by thinking critically about a plan and then supporting this thinking with new knowledge. Although this was a very steep learning curve for the students at the beginning of the paper the final assessment and course evaluations also indicated that they had a much better overall grasp by the end.

EP-2102

"We're all here for the patient": exploring the process of interprofessional learning

K. Coleman¹, B. Darlow², E. McKinlay², L. Beckingsale³, S. Donovan⁴, P. Gallagher⁴, B. Gray², H. Nesar¹, M. Perry⁵, S. Pullon²

¹University of Otago- Wellington, Department of Radiation Therapy, Wellington, New Zealand

²University of Otago- Wellington, Department of Primary Health Care and General Practice, Wellington, New Zealand

³University of Otago- Wellington, Department of Human Nutrition, Wellington, New Zealand

⁴University of Otago- Wellington, Medical Education Unit, Wellington, New Zealand

⁵University of Otago- Wellington, School of Physiotherapy, Wellington, New Zealand

Purpose or Objective: This qualitative study aimed to explore student perceptions and experiences of the Interprofessional Education (IPE) programme focused on long-term condition management. (1) A secondary aim was to explore the experiences of radiation therapy students who recently joined the programme.

Material and Methods: Three focus groups were conducted. All 41 students who participated in the IPE programme (dietetics; n=4, medicine; n=18, physiotherapy; n=6, radiation therapy; n=13) were invited to attend one of the two interdisciplinary focus groups. Students from radiation therapy were also invited to attend a unidisciplinary focus group. Focus groups were audio-recorded and transcribed verbatim. Data were independently analysed by two researchers within the framework of Thematic Analysis. (2) Themes were determined following parallel coding and research team verification.

Results: Thirty-four students participated in the interprofessional focus groups and 13 radiation therapy students participated in their unidisciplinary focus group. Three key themes emerged related to i) learning ii) perceived long-term professional benefits and iii) the structure and content of the programme. An additional theme emerged from the radiation therapy focus group related to how they perceived, and considered they were perceived by, the medical students.

Conclusion: Participants considered the programme to be a valuable learning opportunity which had direct relevance to their clinical careers. Listening to the insights of students is an important means of discovering what, for them, constitutes a meaningful and positive learning experience. Providing students with an opportunity to learn about each

other should be prioritised within IPE programmes in order to allow them to effectively learn with and from each other.

EP-2103

Margin assessment for feline and canine radiotherapy using a custom cranial immobilisation device

J. Sharpe¹, A. Tini¹, I. Minneken¹, C. Winter¹, V. Meier², C. Rohrer Bley²

¹University Hospital Zürich, Radio-Onkologie, Zurich, Switzerland

²Vetsuisse Faculty University of Zurich, Division of Radiation Oncology, Zurich, Switzerland

Purpose or Objective: The purpose of this study was to observe the daily positioning correction errors in feline and canine radiotherapy, using a custom cranial immobilization device and KV onboard imaging. Then further assess the data for margin definition in the event of an unguided approach (without the possibility of daily imaging) for treatment use with the identical positioning device.

Material and Methods: Canine and feline patients with cranial tumors were treated using a custom made cranial immobilization device, consisting of: a plastic plate which is fixed to the couch, a detachable custom molded bite block, and a custom fitted vacuum foam cushion supporting the neck, thorax and body. The patients were imaged daily before treatment, thereby correcting all positioning errors in lateral, vertical and longitudinal directions. The shift values were then saved to a data base for later analysis.

Results: 8 patients (3 feline, 5 canine) and a total of 93 post-imaging corrections were observed in 3 directions (lateral, vertical, and longitudinal). Upon assessment of the data, the formula:

$PTV\ Margin = 2\sigma + 0.7\sigma$ (van Herk et al.)

was used to calculate margin for the unguided approach. A result of 3mm x 2mm x 3mm (lateral, vertical, longitudinal) was found.

Conclusion: Based on the results, the margin of an unguided approach using the custom positioning system, would need to be extended from 2mm (margin used for image guided treatment planning) to 3mm in the lateral and longitudinal directions, while vertical would remain at 2mm.

Waiting times for IMRT as a Quality Indicator: A study from a Tertiary Hospital in Saudi Arabia

Z. Mulla¹, M.E. El Sayed^{1,2}, S.M. Soaida^{1,3}, A. AlHebshi¹, M. Bayoumy¹, A.H. Mohammed Khasim⁴

¹King Faisal Specialist Hospital & Research Centre-Jeddah, Oncology, Jeddah, Saudi Arabia

²National Cancer Institute, Radiotherapy and Nuclear Medicine Department- Cairo University, Cairo, Egypt

³Cairo University, Clinical Oncology Department- Faculty of Medicine, Cairo, Egypt

⁴King Abdulaziz University Hospital, Radiology Department, Jeddah, Saudi Arabia

Purpose or Objective: To assess the compliance of our protocol of ≤ 10 working days (WD) for IMRT.

Material and Methods: A retrospective analysis of all cases treated between October 2010 and December 2014. Waiting

times from the date of the request to the start of treatment (REQ-ST), from the request to CT Simulation (REQ-CT) and from CT simulation to the start of treatment (CT-ST) were computed. To assess the compliance of our performance with the protocol, we calculated two indicators: mean waiting times and compliance rates. The cut-off of compliance for CT-ST ≤10 WD is defined by our protocol. Using this value, the two other cut-offs were respectively calculated using a linear equation of REQ-ST and REQ-CT as a function of CT-ST, giving a REQ-CT=9 and REQ-ST=26 week days (WKD). To assess the evolution in time of all studied parameters, we divided the study into 4 periods: 1) from Oct 2010 to Dec 2011, 2) from Jan to Dec 2012, 3) from Jan to Dec 2013 and 4) from Jan to Dec 2014. In addition, we analyzed the impact of the indication of IMRT on the waiting-times by comparing the indicators across the tumor localizations. Statistical analysis was performed using SPSS. Mean waiting times were compared using ONEWAY ANOVA and compliance rates were compared using Pearson's Chi-square test.

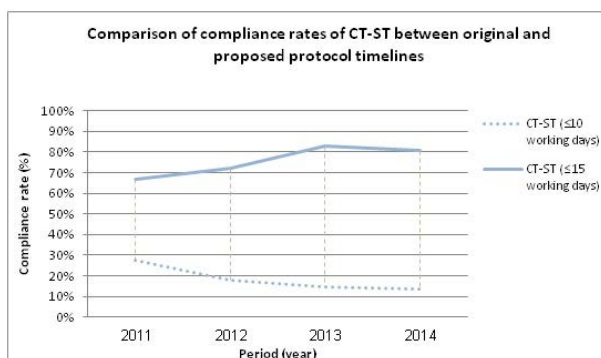

Results: A total 245 IMRT cases were included. Mean CT-ST was 13.80 ± 5.07 days, without significant difference across the study periods (p=0.254). The compliance rate of CT-ST with the protocol ≤10 WD, was 16%, without significant difference across the periods (p=0.257). Regarding REQ-ST, total mean was 30 ± 10 WKD, with a compliance rate at 33%. Regarding REQ-CT, total mean was 11.26 ± 8.33 WKD, with a compliance rate at 49%. There was a significant difference across the periods in both REQ-ST and REQ-CT, with the best performance for period 1, followed by period 4. See Table below.

Evolution in time of the number of cases, indications and waiting times of IMRT
(Z. Mulla et al. "Waiting times for IMRT as a Quality Indicator: A study from a Tertiary Hospital in Saudi Arabia", 2015)

Year (Period)	2011 (1)	2012 (2)	2013 (3)	2014 (4)	2010-2014

Skin	0 (0%)	1 (2%)	0 (0%)	2 (2.7%)	3 (1.2%)
Lung	0 (0%)	0 (0%)	1 (1%)	2 (2.7%)	3 (1.2%)
Ophthalmic	1 (5.6%)	0 (0%)	0 (0%)	0 (0%)	1 (0.4%)
Quality indicators					
REQ-CT(week days)	8.61 ± 7.58	14.28 ± 10.64	11.01 ± 7.86	10.21 ± 6.86	11.26 ± 8.33
CT-ST(working days)	14.27 ± 5.31	15.02 ± 7.10	13.41 ± 4.81	13.41 ± 3.41	13.80 ± 5.07
REQ-ST(week days)	27.66 ± 10.95	34.28 ± 10.16	29.42 ± 10.63	29.64 ± 9.23	30.35 ± 10.30
Compliance					
REQ-CTs ≤ 9 (p<0.00*)	66.7%	38.0%	51.9%	54.8%	49.6%
CT-STs ≤ 10 (p=0.257)	27.8%	18.0%	14.4%	13.7%	15.9%
REQ-STs ≤ 26 (p=0.34*)	50.0%	20.0%	39.4%	28.9%	33.1%
Compliance Rate**					
REQ-CTs ≤ 12 (p=0.66)	83.3%	56.0%	66.3%	75.3%	68.2%
CT-STs ≤ 15 (p=0.4%)	66.7%	22.0%	62.8%	80.8%	78.8%
Rate(2)	61.1%	44.0%	69.2%	60.3%	60.8%

* Statistically significant results (p<0.05). **Compliance Rate = percentage of observations complying with the timeline; compliance rate 1: timelines according to initial protocol; compliance rate 2: timelines according to newly proposed protocol.

Regarding these unsatisfying results, we proposed to update our protocol with a new set of more feasible timelines: CT-ST ≤ 15 WD; REQ-CT ≤ 12 WKD; REQ-ST ≤ 31 WKD. See compliance rates in graph below.

Furthermore, there was significant variations in the REQ-CT waiting times across tumor sites with worst performance for Head & Neck (compliance rate = 40%), while the Abdomen and pelvis had the best performance (compliance rate = 66%). No statistically significant difference was found between tumor sites for CT-ST and REQ-ST.

Conclusion: There is a definitive need to amend our protocol to ≤15 WD for CT-ST, as an intermediate step to improve our performance.

EP-2105

The helpful rays a children's book about cancer and radiotherapy explained in a non-intimidating way
K. Farstad¹

¹Ålesund Hospital, Radiotherapy, Ålesund, Norway

Purpose or Objective:

«Now I'm gonna tell you a story about your body, and some strong and helpful rays, which can help you if you get sick.....» This is how my book for children, about radiotherapy begins. I started as a RTT 10 years ago, and have always felt that our department needed aid to explain cancer and radiotherapy to children in a comprehensible way. I couldn't find any information that caters for children, so I wrote "The Helpful Rays". Small children can sense differences in behavior and atmosphere in the family when someone gets sick. To help children understand, they need explanation. My purpose with this book is to explain cancer, radiotherapy and side-effects to children in a non-intimidating way. The word cancer can be frightening to children as well as adults. My goal is to provide this book as a tool to talk about cancer with children.

Material and Methods: I wrote this book in cooperation with an illustrator, a publisher and our national cancer society. I have used radiotherapists and doctors as proofreaders. And I used my own children (3,5 and 5 years) to make sure the book was understandable and gripping enough.

It can be difficult to find the right words to describe what a mother, father, or relative is going through. Why do they need radiotherapy? Why do they feel nauseous? Why do they lose their hair? The "answers" are in this book. It can be difficult for young children to grasp the complicated cell biology and radiation physics involved, so, the side-effects are explained with use of imagination. For example when rays are burning the hair cells, the hair cells jump out of the skin, and may never come back. Simple explanations that children can understand, regardless if it's according to reality or not.

I have presented the various health personnel that a cancer patient will meet in a hospital. Ex: Radiographer, bioengineer, doctor, nurse and radiotherapist. Also I have presented the most common examinations the patients have to go through. Ex. Blood samples, MRI, CT and biopsy. In that way, children can be prepared for whom they might meet and why, which examinations they must go through and why.

Results: The book is currently being published in Norway, where hospitals, nurses, radiotherapy departments, doctors, schools and kindergartens are using the book in contact with children who have cancer themselves, or their mom, dad, siblings, grand-parents, classmates or other people they are close to that got diagnosed with cancer. The response has been overwhelming. Since June this year approx. 1500 books have been handed out. And we are soon out-of-stock.

Conclusion: There are few or none books written for children about radiotherapy. In my country the book got welcomed as a much needed book, and I think it can be helpful in cancer departments in other countries as well, when adjustments to

the book are made in order to fit a country's own cancer treatment program.

EP-2106

Structuring a database to evaluate haematological toxicity in post-prostatectomy IMRT patients

V. Sacco¹, G. Salvadori¹, A. Sbalchiero¹, A. Viale¹, A. Soccio¹, M. Martulano¹, R. Bin¹, S. Selli¹, A. De Leonardis¹, D. Parutto¹, A. Capelli¹, A. Tavilla¹, L. Longoni¹, L. Palumbo¹, F. Baratto¹, N. Barricella¹, C. Fiordelisi¹, C. Cozzarini¹, N. Di Muzio¹
¹IRCCS San Raffaele Scientific Institute, Radiotherapy, Milano, Italy

Purpose or Objective: Haematological toxicity (HT) in post-prostatectomy patients (WPRT) treated with whole pelvis radiotherapy represents a problem due to the irradiation of a large fraction of the bone marrow (BM). HT is under evaluation in our Institute according to an observational prospective study aiming to explore a dose-effect correlation. Therefore, clinical and dosimetric data have to be collected. This study reports (quantify) the complexity and workload of the clinical data collection were to evaluate its feasibility in the routine clinical practice.

Material and Methods: A database for the enrolled WPRT patients (pts) was created, collecting the following data: clinical features (age, surgery, diabetes, hormonal therapy, results from blood samples at several time points); intent (adjuvant, salvage); technique (step and shot IMRT, Rapid Arc, Helical Tomotherapy); dose-volume histogram (DVH) of BM structures; The time required to fill in database was also evaluated.

Results: To date 238 pts were included in the database. The average age is 66 years (range 48 - 84). Conventionally fractionated (1.8 - 2Gy/fraction, 139 pts) and moderately hypofractionated (2.35-2.65 Gy/fraction, 99 pts), step-and-shoot IMRT (SS-IMRT, n=18), Volumetric Arc (RA IMRT, n=111) or helical tomotherapy (HTT, n=99) EBRT. Adjuvant n = 159 pts, salvage n = 79 pts. The workload to fill in the database was 40 min/pt.

Conclusion: The availability of clinical/dosimetric data was crucial for the dose effect analysis, being HT not negligible. In our experience, the implementation of the database in the routine setting is feasible provided a dedicated operator, such as a radiotherapy technologist (RT), after a simple learning curve to lead the RT to reach the proper expertise.

EP-2107

Work satisfaction and motivation of radiation therapists. A qualitative study

P.G. Kup¹, J.A. Rubin², I.A. Adamietz¹, K. Fakhrian¹
¹Marien Hospital Herne- Ruhr university Bochum, Radiation Oncology, Herne, Germany
²University of Bremen, Psychology, Bremen, Germany

Purpose or Objective: For more than 120 years radiation therapists (RTT) treat oncology patients in radiation oncology facilities. However, influencing factors on motivation, work performance and work satisfaction of RTTs is still not studied. The aim of this trial was to detect factors influencing work satisfaction and motivation of MTRAs in radiation oncology. Leadership solution approaches will be discussed.

Material and Methods: In a qualitative interview study with seven RTTs at a university clinic we investigated determinants influencing motivation, work and work satisfaction based on the individual experiences of our participants. An inductive thematic content analysis framework was applied to the transcripts.

Results: The interviews were conducted with seven RTTs in our radiation oncology unit. The interview lasted between 40- 60 minutes (mean 52 minutes). All participants were of female sex. Mean age was 46 years (range 30-59 years). Mean work experience in radiation oncology was 19 years (range 3-

37 years). All but 2 RTTs were employed fulltime. Three participants have professional experience in diagnostic radiology. All participants declared an interdisciplinary lack of communication between physicians, physicists and RTTs as one of the influencing factors on their work motivation. Furthermore, RTTs receive negative feedback about treatment failures and death of the patients more frequently than results of therapy success. This fact has considerable impact on the motivation of the majority of interviewed RTTs. Additionally, the lack of positive feedback influences the willingness of further education, self-improvement and motivation to recommend the employment as RTTs.

Conclusion: Frequent negative feedback weakens RTTs motivation and work satisfaction. Improved communication about therapy results, especially therapy success, may increase RTTs work motivation. Stabilized motivation may have positive effects on trainee recruitment in radiation oncology.

EP-2108

Gaps in Radiotherapy: What can we do to improve it?

R. Jimenez¹, N. Becerra¹, N. Rodriguez¹, M. Algara¹
¹Hospital de la Esperança. Parc de Salut Mar, Oncologia Radioterapica, Barcelona, Spain

Purpose or Objective: We want to determine if having a liberated late shift of patients and incorporating hypofractionation protocols in different pathologies makes decreasing the number of lost sessions caused by breakdown and scheduled reviews of treatment units in a 30%, because we can only act on them.

Material and Methods: We compare the data obtained in a management program of treatments (GestRdt) with Excel 2010 software, between the first nine months of 2013 and 2015, because during 2014, hypofractionation new protocols were implemented and a late shift unit treatment was closed. We analyzed the total number of sessions, the total number of patients, the number of sessions per patient, sessions missed by stop-treatment unit and sessions missed by patients in absolute numbers and percentages.

Results: In the year 2013, 1104 sessions (10.11%) were lost and in 2015 were 547 (6.68%). Missed sessions related with the patient and their environment (toxicity, patient-derived and other) was 6.17% in 2013 and 4.79% in 2015, which means a decrease of 22.35%. The percentage of sessions missed by failures and planned outages was 3.94% in 2013 and 1.88% in 2015, representing a decrease of 52.13%. Decreasing of one session per patient in 2015 has generated 768 sessions or free holes in treatment units.

Conclusion: Hypofractionation new techniques and the provision of a free shift of patients have allowed that the reduction of missed sessions related to the treatment units is greater than 50%.

Electronic Poster: RTT track: Position verification

EP-2109

Novel verification technique for craniospinal irradiation with an image plate in the supine position

S.K. Ahn¹, S.K. Lee¹, J.H. Cho¹, C.O. Suh¹
¹Yonsei Cancer Center, Yonsei University Health System-Seoul- Korea, Seoul, Korea Republic of

Purpose or Objective: It has not yet been possible to confirm the junction of the treated fields for craniospinal irradiation treated in the supine position; the intention of this study was to improve the accuracy of radiation therapy through a technique using an image plate.

Material and Methods: The subjects of this study were 20 medulloblastoma patients who were treated in the supine position in three parts from the brain to the sacrum spinal canal. A half beam was used for the cranial field, and the

collimator was rotated with the isocenter set to C-spine level 2. The divergence of the upper spinal field was aligned with the junction of the cranial field; the couch was rotated 270° and the gantry was rotated to align the divergence of the lower spinal field with the inferior border of the upper spinal field. To confirm the junction of the treated field: 1) an image plate (14x17 inches) was placed vertically on the couch so that the junction of the cranial field and the upper spinal field would be included in the plate; 2) the cranial field was irradiated to check it; 3) the lateral lock of the couch was released and the isocenter was moved to the image plate before irradiation to check the upper spinal field; and 4) the junction of the cranial field and the upper spinal field was analyzed with a computed radiography reader (CAPSULA XLII, Fujifilm, Japan). The field junction was photographed three times to confirm its accuracy and reproducibility. Two-millimeter or smaller gaps or overlaps were considered setup error. If a 2 mm or greater error was specifically reproduced, the center was moved again through 2D simulation.

Results: The junction of two fields could be confirmed regardless of the degree of enlargement according to the distance between the cranial isocenter and the image plate, with the cranial field as the half beam. The verification images of the 20 patients were measured with a computed radiography reader. Eighteen patients showed a setup error that was smaller than 2 mm, and the center was moved again for two patients who showed the specific reproduction of a gap or overlap of 2 mm or more at the junction. Since the divergences of the upper spinal field and lower spinal field were aligned at the body of the patient and the bottom of the couch, the junction was confirmed by the naked eye by attaching paper to the bottom of the couch.

Conclusion: For craniospinal irradiation patients, treatment in the supine position rather than in the prone position is advantageous for setup stability and airway security. The proposed technique can maintain the homogeneity of the dose because it can accurately confirm the junction of the fields using an image plate.

EP-2110

A study of prostatic calculi: in patients receiving radical radiotherapy for prostate cancer

A. O'Neill^{1,2}, C.A. Lyons^{1,3}, S. Jain^{1,3}, A.R. Hounsell^{1,4}, J.M. O'Sullivan^{1,3}

¹Queens University Belfast, Centre for Cancer Research & Cell Biology, Belfast, United Kingdom

²Belfast Health & Social Care Trust, Radiotherapy, Belfast, United Kingdom

³Belfast Health & Social Care Trust, Clinical Oncology, Belfast, United Kingdom

⁴Belfast Health & Social Care Trust, Medical Physics, Belfast, United Kingdom

Purpose or Objective: Image guided Radiotherapy (IGRT) for prostate cancer (PCA) frequently employs surgically implanted fiducial markers. It is estimated that up to 35% of prostate radiotherapy patient have prostatic calculi (PC) visible on treatment cone beam CT (CBCT). Prostatic calculi present a potential alternative to implanted fiducials. The purpose of this study was to establish the incidence and location of PC in a contemporary population of prostate radiotherapy patients.

Material and Methods: A retrospective single-observer analysis of images from patients with PCA who received RT at our centre was undertaken to identify PCs within the prostate. The Prostate Imaging and Reporting Data System (PI-RADS) graphical schema was used to record the position of PC. Available images from Trans-rectal Ultra-sound (TRUS) brachytherapy volume study scans, CT scans and CBCT scans were analysed from 242 patients.

Results: In total, 394 scan sets from 242 patients were analysed. 57 out of 62 (91%) TRUS images and 153 of 180 (85%) CT planning scans had visible PC. Of the 153 patients

with PC visible on CT, 136 also had CBCT scans. All but 1 had corresponding PC on CBCT. 16 TRUS scans had corresponding PCs visible on CT scans but seed artefact obscured visibility in most cases. PC were most frequently observed in sections 3p and 9p (poster of mid gland and apex) of the PI-RADS schema and least often observed in 8a, 12a & 13a (anterior base and apex).

Conclusion: In our series, a significant majority of the prostate radiotherapy patient population have PC detectable on pre-radiotherapy imaging. A prospective clinical trial will commence shortly investigating the feasibility of using PC as an alternative to FMs.

EP-2111

Inter-observer variability in stereotactic IGRT with CBCT: is a CTV-PTV margin needed?

M. Massaccesi¹, V. Masiello¹, M. Ferro¹, V. Frascino¹, S. Manfrida¹, M. Antonelli¹, S. Chiesa¹, A. Martino¹, F. Greco², B. Fionda¹, A. Fidanzio², G. Mattiucci¹, L. Azario², S. Luzi¹, V. Valentini¹, M. Balducci¹

¹Policlinico Universitario Agostino Gemelli- Catholic University, Radiation Oncology Department - Gemelli ART, Roma, Italy

²Policlinico Universitario Agostino Gemelli- Catholic University, Physics Institute, Roma, Italy

Purpose or Objective: Use of image guided radiotherapy (IGRT) allows to reduce uncertainty margin from clinical to planning target volume due to better geometric accuracy. Geometric accuracy of Linac-based stereotactic IGRT is reported to be within 2-3 mm and Kilo-voltage cone beam computed tomography (Kv-CBCT) is generally considered as the gold standard for treatment verification. However inter/intra-observer variability in image evaluation may exist. Aim of this report was to conduct a preliminary analysis to quantitatively determine the magnitudes of such inter-observer variations

Material and Methods: Kv-CBCT images were obtained for all patients who underwent stereotactic radiotherapy treatments. They were analyzed both on-line (before treatment delivery) and off-line by two different Radiation Oncologists (RO, M.M. and V.M.) with at least one year of experience in CBCT images verification. Translational displacements in anteroposterior (z), mediolateral (x), and craniocaudal (y) directions were recorded for all verifications and discrepancies between the two RO were calculated. Based on the discrepancies in x, y, and z directions, systematic and random differences were calculated and three-dimensional radial displacement vector was determined. Systematic and random differences were used to derive CTV to PTV margin. Time spent for on-line image verification was also recorded. Results are reported as mean values. The T test was used to assess differences between groups

Results: From January to September 2015, 189 CBCT scans of 48 patients submitted to intracranial (39 scans) or extracranial (150 scans) Linac-based stereotactic radiotherapy were analyzed. An inter-observer discrepancy of ± 3 mm on at least one direction was observed in 37 CBCT scans (19.6%). Mean radial discrepancy was 1.82 mm (range 0-11.1 mm). In AP, CC and ML directions, systematic differences were 0.89, 1.87, and 0.67 mm and random discrepancies were 0.43, 0.55, and 0.50 mm, respectively. By van Herk's formula CTV-PTV margins needed to account for such inter-observer variability were 2.5, 5.0 and 2.0 mm in AP, CC and ML directions, respectively. Inter-observer discrepancies were smaller for intracranial than extracranial stereotactic treatment (mean radial discrepancy 1.2 versus 1.9 mm, respectively p=0.01). On-line verification of CBCT took a mean time of 4 minute and 14 seconds (range 58 sec - 12 min 25 sec). No significant difference in magnitudes of inter-observer variability was observed according to time spent for verification

Conclusion: When using KV-CBCT for set-up verification in stereotactic treatment a large inter-observer variability can be seen in a significant proportion of scans, particularly in extracranial treatment. Such a difference may have an impact on target coverage or organ at risk irradiation, thus requiring a proper margin. Further evaluation is needed, particularly focusing on methods to decrease such inter-observer variability

EP-2112

Intrafraction setup errors in single fraction stereotactic radiosurgery with Elekta Fraxion system

W. Vázquez Rivas¹, J. Luna Tirado¹, M. Rincón Pérez², D. Esteban Moreno¹, A. Ilundain Idoate¹, A. Pérez Casas¹, M. García-Castejón², J. Olivera Vegas¹, I. Prieto Muñoz¹, J. Vara Santos¹

¹Hospital Universitario Fundación Jiménez Díaz, Oncología Radioterápica, Madrid, Spain

²Hospital Universitario Fundación Jiménez Díaz, Radiophysics, Madrid, Spain

Purpose or Objective: Frame-based stereotactic radiosurgery (SRS) using rigid immobilization with head ring continues to be the standard treatment when it comes to intracranial SRS. We wanted to assess setup accuracy and intrafraction errors of patients treated with single fraction intracranial stereotactic radiosurgery using the Elekta Fraxion® immobilization system (Frameless SRS) and HexaPOD positioning platform (translational and rotational set up error).

Material and Methods: 5 patients with a diagnosis of brain metastasis were treated with single fraction frameless stereotactic radiosurgery (SRS) at our institution between April 2015 and September 2015. Patients were initially immobilized using Fraxion® immobilization system (Fraxion comprises a head frame with a mouth-bite, thermoplastic mask and vacuum occipital cushions) and HexaPOD couch platform (HexaPOD™ is a robotic patient positioning platform providing six degrees of positioning freedom). Cone-Beam computed tomography (CBCT) were acquired before and after treatment to assess for intrafraction set up errors. Translational and rotational set up errors were obtained in Right/Left (R.L.), Postero/Anterior (P.A.), Inferior/Superior (I.S.) directions. Means and one standard deviation of the intrafractional errors in all six directions were analyzed.

Results: A total of 10 images were analyzed. A summary of the means and one standard deviation of the intrafractional errors (in mm for translation and degrees for rotation) were 0.01 ± 0.10 (RL), 0.00 ± 0.20 (PA), 0.04 ± 0.10 (IS), -0.76 ± 0.80 (RL rot.), -0.02 ± 0.81 (PA rot), 0.58 ± 0.97 (IS rot) All of the patients were within the intrafractional errors described as for frame-based SRS.

Conclusion: Single fraction intracranial stereotactic radiosurgery utilizing frameless immobilization system like Elekta Fraxion® and HexaPOD® Platform it's a secure, precise and reproducible technique. Comparable results with Frame-based SRS were obtained, keeping between 1 mm and 1 degree margin range.

EP-2113

Clinical implementation of an optical surface monitoring system (OSMS®, Varian) in breast irradiation

A. Tini¹, I. Pytko¹, S. Lang¹, C. Winter¹, M. Guckenberger¹, C. Linsenmeier¹

¹University Hospital Zürich, Department of Radiation Oncology, Zurich, Switzerland

Purpose or Objective: The optical surface monitoring system (OSMS®) was implemented in our clinic to improve our daily radiation therapy workflow, to avoid frequent repositioning and unnecessary skin marks on breast cancer patients.

Material and Methods: 6 breast cancer patients were positioned with OSMS® and the set-up was then compared with MV imaging. The patients were treated using 3D

tangential fields with free breathing and were positioned on the breast board. The OSMS cameras acquired the patient's positioning in 2D and a computer algorithm reconstructed the image in 3D. Prior to that, the patient's reference surface was imported from the planning CT scan and the region of interest within the treated area was selected. For the positioning with OSMS® the breast, hips and part of the upper arm on the treated side were used as a region of interest (ROI). After aligning the patient, MV imaging and bone match on the chest wall was used to correct for positioning error. 2 patients were aligned according to the CT skin reference marks previous to positioning with OSMS®. The other 4 patients were directly set up with OSMS. We compared this data with previously collected data on the difference between positioning, based on the skin marks of the patient using a laser system and MV imaging.

Results: The most suitable ROI was found to be the irradiated breast itself, excluding the shoulder and clavicular region, but including a 2 cm margin of chest wall surrounding the breast. Positioning based on OSMS® was in good agreement with the positioning based on MV imaging. The mean deviation between the two techniques was 1.3 ± 1.6 mm, 1.3 ± 1.8 mm and 0.8 ± 0.8 mm in vertical, longitudinal and lateral directions for the all 6 patients. This was superior to positioning based on patient skin marks alone (1.4 ± 1.4 , 1.8 ± 2.8 and 1.7 ± 1.1 mm). The corrections of patient rotations were difficult to perform with OSMS®. Out of 112 treated fractions, 15 fractions showed on the MV image a rotation which was out of clinical tolerance and the patients had to be repositioned.

Conclusion: According to our preliminary data-patient positioning based on OSMS® is easy, time efficient and reproducible. Additionally, patient skin marks can be avoided. More data will be collected to confirm these findings. In the future we plan to use the OSMS® system for deep inspiration breath hold techniques and the set-up of extremities and bolus.

EP-2114

3D-Transabdominal Ultrasound and ConeBeam-CT: comparison of prostate positioning

A. Boschetti¹, S. Bartoncini¹, C. Fiandra¹, A. Guarneri², C. Cavallin¹, F. Arcadipane¹, E. Trino¹, M. Levis¹, R. Ragona¹, U. Ricardi¹

¹Università di Torino, oncology, Torino, Italy

²Città della salute e della scienza, Radiotherapy, Torino, Italy

Purpose or Objective: External beam radiotherapy (EBRT) is a mainstay therapeutic option for prostate cancer and hypofractionated schedules were proposed as a suitable approach. Image guidance procedures are strongly needed to provide adequate accuracy precision, minimize geometric uncertainties and further diminishing unintended normal tissue irradiation. The Elekta Clarity™ platform allows the acquisition of three-dimensional ultrasound scans (3DUS) of the pelvic regions to perform image-guided radiotherapy. In our department, 3DUS is the reference IGRT modality and is used into daily clinical practice for prostate cancer radiotherapy (since from 2009) with optimal clinical results in terms of biochemical control and a good toxicity profile on 160 patients. Moreover 3DUS is a non invasive method with avoidance of extra radiation. In this study 3DUS was compared to grey-based positioning in kilovoltage Cone-Beam Computed Tomography (CBCT) during radiotherapy sessions.

Material and Methods: 10 patients affected with organ-confined prostate cancer were included. All patients should have a reliable ultrasound visualization of the prostate gland within the Clarity Platform. All patients received 61.1 Gy/26 fractions to the prostate gland and seminal vesicles and 70.2 Gy/26 fractions to the only prostate gland. The prostate positioning was controlled by 3DUS and CBCT. Patients were aligned to skin marks before all of the 260 treatment sessions. Control of the remaining inter-fractional setup error by 3DUS was successfully employed 147 times. During the

remainder of fractions, insufficient bladder filling and patient movement were the most frequent obstacles to 3DUS. In total, 210 3DUS scans were compared to CBCT.

Results: The average differences in the anterior-posterior (AP), superior-inferior (SI) and lateral (LL) directions from CBCT were 0.25 ± 0.53 cm, -0.08 ± 0.52 cm, -0.16 ± 0.57 cm for 3DUS. Student's t-test was used to test the difference between this US modality against CBCT and the distribution of the differences is reported in Figure 1.

Conclusion: Based on the obtained results, significant differences with CBCT were found in all directions. However the average value of the differences is always less than 3 mm in all directions. Differences greater than 1 cm were observed in the AP direction (5%) showing that CBCT imaging modality is not safely interchangeable with 3DUS.

EP-2115

Breast radiotherapy: comparison of set up error using All In One system and dedicated breast board

V. Manestar¹, V. Karadza¹

¹*Clinical Hospital Center Zagreb Rebro Hospital, Clinic for Oncology and Radiotherapy, Zagreb, Croatia*

Purpose or Objective: The aim of this study was to determine whether proper selection of fixation equipment has positive effect on the reduction of setup error for breast radiotherapy.

Material and Methods: The study has been performed on 10 breast cancer patients positioned on All In One system, and 10 patients treated using dedicated breast board. Selected patients represent average breast cancer patients. Patients with special setup needed, were excluded. (eg. patients with reduced arm mobility, patients with large contra lateral breast etc.). On both fixation systems the same setup protocol was used. Imaging and setup correction were performed on fractions 1, 2, 3, 8, 13, and every 5th further fraction. All the correction data were written in specially prepared forms. All the data collected were entered in excel worksheet, and further analyzed.

Results: The results showed that All In One system had standard deviation of set up error 0.31 cm in sagittal axis, 0.3 cm in longitudinal axis, and 0.36 cm in coronal axis. Compare to that, standard deviations of setup error for dedicated breast board were: 0.28 cm in sagittal axis, 0.24 cm in longitudinal axis, and 0.24 cm in coronal axis.

Conclusion: The result showed that usage of dedicated breast board offers better setup precision, especially in coronal axis. This can be due to more rigid construction of dedicated breast board, compare to foamy structure of All In One system. However, this difference is not so big to completely exclude usage of All In One system, especially in situations where his comparative advantages makes him a fixation of choice. Also, this was relatively small sample of patients, so further study should be performed.

EP-2116

Optimization of whole breast irradiation setup: comparison between two different positioning systems

E. Sanfilippo¹, C. Galeotti¹, P. Cornacchione², Y. Wandael¹, A. Nacca², M. Morroni¹, B. Onorati², D. Greto¹, P. Bonomo¹, N. Groccia¹, R. D'Angelillo², S. Ramella², I. Meattini¹, L. Livi¹

¹*University of Florence, Scienze Biomediche Sperimentali e Cliniche, Florence, Italy*

²*Università Campus Bio-Medico, Radiation Oncology Unit, Rome, Italy*

Purpose or Objective: A precise and reproducible patients' setup, within established thresholds, may lead to a reduction of time spending in breast radiotherapy treatment positioning, and highly precision in targets irradiation, sparing organs at risk (OAR). The aim of this study is to compare two different breast positioning systems.

Material and Methods: Overall 278 portal images film were analyzed with EPID system, for a total of 40 female patients treated with tangential fields breast RT. EPID acquisitions were made in two different Italian University Centers. Twenty patients were treated with a supine positioning on a 12.5 degrees inclined breast board, while 20 patients were treated with supine positioning using a wing board. Each EPID imaging couple were acquired weekly using medial and lateral tangential fields. Images were newly acquired in case of 5 mm error shift. The EPID images were subsequently compared to the referring DRR, using the three spatial axes: X (lateral), Y (longitudinal), and Z (vertical). The systematic and random errors of the two different studied groups were then calculated.

Results: Breast board system showed a systematic error of $\Sigma=1.41$ mm on the X, 2.23 mm on the Y, and 1.69 mm on the Z axis; the median random error was 0.3 mm, 0.46 mm and 0.36 mm, respectively. Concerning the wing board system, the systematic errors were $\Sigma=3.34$ mm on the X, 3.12 mm on the Y, and 2.68 mm on the Z axis; with random errors of 0.63 mm, 0.6 mm, and 0.53 mm, respectively.

Assuming as acceptable the shift with a maximum threshold of 5 mm, it was possible to calculate the probability of setup accuracy. It was 99% on the X, 94% on the Y, and 97% on the Z axis, using the breast board setup; while it was 91%, 86%, and 88% using the wing board system.

Conclusion: Since the small sample series, these data should be interpret with caution. Preliminary results of our analyses showed an high accuracy sensitivity for both setup approach. However a better accuracy in favor of the breast board positioning system was shown.

EP-2117

Is Rotational shifts necessary in SBRT? A geometric analysis using a 6-degree of freedom(6-DoF)couch

A.R. Alitto¹, S. Chiesa¹, S. Menna², L. Azario², M. Massaccesi¹, F. Greco², M. Ferro¹, V. Frascino¹, M. Balducci¹, V. Valentini¹

¹*Università Cattolica del Sacro Cuore, Radiation Oncology Department- Gemelli-ART, Rome, Italy*

²*Università Cattolica del Sacro Cuore, Physics Institute & Operative Unit of Medical Physics, Rome, Italy*

Purpose or Objective: To study the relevance of rotational shifts using 6DoF robotic couch in patients treated with stereotactic body radiation therapy(SBRT)to improve setup accuracy.

Material and Methods: Patients affected by primary or metastatic lung tumours with a diameter until 5 cm were enrolled to SBRT. Breast board(CIVCO support system) was used for set-up of supine patient in all phases of treatment. Gross target volume was defined by a radiation oncologist on 4D TC scan. Treatment planning was carried out with Eclipse™ Treatment Planning Systems (Varian Medical System®, Palo Alto, CA) and Volumetric arc therapy was used. Total dose was prescribed on the basis of tumours position and dimensions: 42 Gy in three fractions, for lesions with diameter smaller than 3 cm, or 50 Gy in five fractions, for lesions between 3 and 5 cm. Daily Cone Beam Computed Tomography(CBCT) was performed before dose delivery. Then images were compared with CT scan for radiotherapy planning(automatic and manual 3D-3D match) in order to determine the magnitude of set-up error and organ motion: translational(Lateral, Vertical and Longitudinal) and rotational(Pitch, Yaw and Roll) shifts were identified(Varian 6D Online Review System). The collected shifts were applied

on the Protura TM Robotic couch 6DOF to obtain a more accurate alignment. Mean translational and rotational shifts were calculated.

Results: From July to September 2015, 13 patients were enrolled (10 with primary lung tumours and 3 with metastatic lung lesions) with a median age of 74 yrs (range 58-86). Fifty-two CBCT were performed and compared to CT images. The mean (\pm SD) interfraction displacements in all DoF are reported in Table 1.

	Lat (cm)	Vrt (cm)	Lng (cm)	Roll (deg)	Pitch (deg)	Yaw (deg)
MEAN	0,04	-0,11	0,00	0,16	0,04	-0,28
ST.DEV.	0,40	0,39	0,57	1,21	1,21	1,31
MAX	0,95	1,12	1,64	3,00	3,00	2,60
MIN	-0,84	-0,79	-1,50	-3,70	-2,00	-3,40

The mean (\pm SD) 3D vector of displacement was 0.7 ± 0.4 cm. The maximal translation setup shift was 1.1 cm vertically, 1.6 cm longitudinally and 1 cm laterally, with 77% of the shifts < 3 mm. The maximal rotation error was $+3^\circ$ for Pitch, -3.7° for Roll and -3.4° for Yaw, with 22% of the rotations $>1^\circ$ and 5% of rotations $>2^\circ$. No correlation was observed between the magnitude of translational and rotational shift. A Kruskal-Wallis test showed that there was no statistically significant difference between the 3 rotation groups ($p>0.05$).

Conclusion: This work confirms that a 6-DoF robotic couch could be useful to improve accuracy in IGRT era, especially in SBRT. No correlation was found between translational and rotational errors, but it could revealed important outliers and corrected. Geometric and dosimetric analysis on other regions are on going.

EP-2118

CBCT in stereotactic body radiation therapy for lung tumors: manual matching versus auto-matching

M. Orlando¹, Y. Wandael¹, P. Bonomo¹, C. Galeotti¹, F. Cascino¹, L. Cecconi², D. Greto¹, I. Meattini¹, S. Pallotta³, L. Livi³

¹A.O.U. Careggi, Radiotherapy, Florence, Italy

²University of Florence, Statistics department, Florence, Italy

³University of Florence, Department of biomedical-experimental and clinical sciences "Mario Serio", Florence, Italy

Purpose or Objective: To correlate manual matches performed by radiation therapy technologists (RTTs) with two modality of automatic matching ("Bone match" and "Grey value match"). The manual alignment is taken as the gold standard mode and the purpose is to check the deviation between the values of translation and rotation obtained by this alignment and the values detected with the two types of automatic matching.

Material and Methods: This study included 10 central lung lesions treated with three sessions of SBRT, 18 Gy per fraction. 4DCT was used. The gross tumor volume (GTV) was defined on average reconstruction (AVG) and the internal target volume (ITV) was obtained modelling the GTV on the secondary images (MIP: maximum intensity projection). Planning Target Volume (PTV) was obtained adding 0.5 cm of margin to the ITV. For each session values of translation and rotation along the three axes (x, y, z) were collected off line by performing three different registrations: manual match only on the target, bone match and grey value match using a clip box containing a vertebral body and closest bone structures. Values of manual alignment were collected by three RTTs for a total of 9 images comparisons for each patient and a mean manual alignment was assessed and compared to the values of the automatic alignments. Table 1 shows an example of collected data related to one of the patients.

Table 1

PATIENT 1	CBCT BONE (TR)			CBCT GREY VALUE (TR)			TECHNICIAN 1			TECHNICIAN 2			TECHNICIAN 3		
	X	Y	Z	X	Y	Z	X	Y	Z	X	Y	Z	X	Y	Z
Session 1	0.19	-0.30	-0.26	0.31	-0.37	-0.20	0.27	-0.35	-0.20	0.40	-0.30	-0.30	0.33	-0.50	-0.27
Range	0.0	359.2	0.0	359.9	0.2	359.6	0.0	0.0	359.0	359.0	0.0	0.0	359.0	0.0	0.0
Session 2	0.61	-0.40	0.40	0.68	-0.43	0.40	0.64	-0.47	0.33	0.60	-0.40	0.20	0.43	-0.40	0.60
Range	0.0	359.5	0.0	0.0	359.5	359.9	0.0	359.5	359.0	0.0	359.0	0.0	0.0	0.0	0.0
Session 3	0.07	0.05	-0.16	0.14	-0.02	0.35	0.10	0.13	-0.13	0.00	0.00	0.40	0.10	0.10	-0.30
Range	359.5	359.9	0.5	358.9	359.5	359.7	359.0	359.0	359.9	0.0	0.0	0.0	0.0	0.0	0.0

Results: The results are summarized in the table 2. About translations: gray value matching fails in all sessions of subject 5 (affected by pleural effusion), bone matching fails in the second session of the subject 4 and both have errors slightly high in the subject 8. About rotations: gray value matching fails in all sessions of subject 5 and in the first session of the subject 2. The bone shows difficulty in subjects 4, 9 and 10.

Table 2

Conclusion: The study shows that in some particular pathological cases, such as pleural effusion and atelectasis, automatic method could be not accurate. In these it was found that the bone matching values are the closest to the gold standard values. In particular in four cases there was a significant difference between the manual and the automatic alignments, it could result in a not tolerable location of the target before and during the treatment. The results could be conducted to the difference in the breathing in the different sessions, a larger PTV in some selected patients could guarantee an higher precision in treatment delivery.

EP-2119

A clinical investigation of optimal CBCT image matching for non-SABR radical lung cancer patients

L. Malaspina¹, A. Baker¹, C. Baker², A. Pope¹, M. Warren³

¹Clatterbridge Cancer Centre, Radiotherapy, Bebington, United Kingdom

²Clatterbridge Cancer Centre, Physics Department, Bebington, United Kingdom

³The University of Liverpool, School of Health Sciences, Liverpool, United Kingdom

Purpose or Objective: Spine-based image registration has traditionally been used for patient setup for non-SABR radical lung cancer radiotherapy. Enhanced visualisation of soft tissue structures through volumetric imaging has led to research of various landmarks that may offer target localisation of increased accuracy compared to spine-based registration. The objectives of this project were to answer the following: Can using carina or tumour as registration landmarks for IGRT offer superior target coverage compared to spine registration? Does the position of tumour affect which registration landmark offers superior target coverage? What are the implications of carina or tumour registration on spinal cord safety?

Material and Methods: Ten patients with central tumours and ten patients with peripheral tumours were selected. A clinical expert assessed a sample of CBCTs from each patient and selected which thoracic landmark (spine, carina, or tumour) produced the the optimal match. CBCTs from each patient (238 CBCTs in total) were matched using the spine and the optimal match and translational displacements were recorded. The difference between the spine-match displacements and optimal-match displacements were

calculated. The shortest distance between the spinal cord and tolerance isodose was measured for each patient.

Results: Carina- and tumour-matching produced target localisation of increased accuracy compared to spine-matching. The average bone-to-optimal 3D vector displacement was 0.4 cm. The 2D vector (vertical and lateral) displacements were more relevant for spinal cord safety because longitudinal displacements did not affect the spinal cord-to-tolerance isodose distance in this sample. The 90th percentile of the 2D vector bone-to-optimal displacements were 0.6 cm and 0.5cm for the central and peripheral groups, respectively.

Conclusion: For central and peripheral tumours, carina- and tumour-matching produced the most optimal target coverage, respectively. The spinal cord-to-tolerance isodose distance is important, as any deviation from spine-matching could result in spinal cord tolerance being exceeded. Using a threshold spinal cord-to-tolerance isodose distance, based on the 90th percentile 2D vector bone-to-optimal displacement, is a measurable method of indicating if carina or tumour match introduces a risk of exceeding spinal cord tolerance dose.
