Lung: Volume dependent mechanisms of lung toxicities were observed, where high volumes with low dose limiting early vascular/inflammatory responses inducing pulmonary hypertension and consequential cardiac problems, whereas low volumes displayed high or even no dose limiting late fibrotic response. Moreover, inclusion of the heart in the irradiation field strongly enhanced early lung responses.

In summary, using high-precision proton irradiation of rat organs we elucidated several mechanisms and critical targets for normal tissue damage. In general we found that, rather than dose to the organ, the development of toxicity strongly related to dose to functional sub-structures within the organ or even in other organs. In general, in more parallel organized tissues it seems that a high dose to a small volume

is better than a low dose to a large volume. Maintaining or enhancing the regenerating potential of the normal tissue seems warranted to further optimize radiation therapy.

Symposium: New insights in treating vertebral metastases

SP-0613

Recent progresses in interventional radiology

P. Bize¹

¹Centre Hospitalier Universitaire Vaudois, Department of Diagnostic and Interventional Radiology, Lausanne Vaud, Switzerland

Treatment of vertebral metastasis can be complex, involving medical treatment, radiotherapy, surgery or newer techniques such as thermal ablation and vertebroplasty. The purpose of vertebral metastasis treatment is to rapidly improve the quality of life of the patients and to restore the mechanical properties of the spinal column and to a lesser extent to prevent local tumor growth.

Minimally invasive treatment, such as vertebroplasty, combined or not, with thermal ablation fulfill all these purposes with minimal impact on the patient's quality of life. Vertebroplasty is efficient in controlling the patient's pain in 89.7% at 1 month and 86.9% at 6 months (ref 1).

Restoration of the mechanical properties of the spinal column is obtained in 100% of cases after successful vertebroplasty (ref 2)

When combined with thermal ablation (RFA or Cryoablation) the local recurrence rate is very low (ref 3)

While radiation therapy remains the mainstay in the treatment of vertebral metastasis, it does not improve the stability of the vertebral column. A complementary surgery is often necessary to ensure stability of the treated vertebra. Minimally invasive procedures such as thermal ablation combined with vertebroplasty do offer immediate pain control in addition to local tumor control and restoration of mechanical stability with a minimal impact on the patient's quality of life.

SP-0615

How to optimise the potential of SBRT

P. Ost¹

¹University Hospital Ghent, Ghent, Belgium

Radiotherapy is a well-established treatment for painful vertebral metastases. Multiple prospective studies report pain response rates of 50 to 90%. Based on randomized studies, 8 Gy in a single fraction is the standard of care for painful uncomplicated bone metastases. Despite the lack of a dose response relationship for pain control, there is good rationale for dose escalation with the aim to improve upon existing rates of local tumour control and pain control. Stereotactic body radiotherapy is ideally suited to safely escalate the dose and improve tumour control. In order to optimize the potential of SBRT, adequate patient selection and specific technical considerations should be taken into account.

PATIENT SELECTION

Several considerations should be taken into account before delivering SBRT for vertebral metastases. A first consideration is the life expectancy of the patient, which should be evaluated with validated scoring systems (e.g. NRF score, Recursive partitioning analysis index, PRISM). Patients with a short life expectancy in need for palliative radiotherapy should be managed with short effective radiotherapy courses. In patients with longer life expectancy local control might be an important end point potentially

requiring a higher radiotherapy dose. A second consideration is the characteristic of the vertebral metastasis and divides the metastases into uncomplicated or complicated. A systematic review suggested the following working definition for uncomplicated bone metastases: those unassociated with impending or existing pathologic fracture or existing spinal cord compression or cauda equina compression. Although this definition looks straightforward it is still variable to interpretation and might be incomplete. The Spinal Instability Neoplastic Score (SINS) might help us estimate the risk of vertebral fracture limiting SBRT to stable and potentially unstable metastases. Different definitions of spinal cord compression are available with the minimum evidence for cord compression being indentation of the thecal sac at the level of clinical features. Finally, other aspects such as, primary tumour type, other metastases, symptoms, practical considerations, current systemic treatment and previous radiotherapy... should be taken into TECHNICAL CONSIDERATIONS

For treatment simulation several options are available for patient immobilization. Independent of the system used, the patient must be positioned in a stable position capable for reproducibility of positioning, allowing the patient to feel as comfortable as possible. A typical CT scan length should extend at least 10 cm superior and inferior beyond the treatment field borders (slice thickness of 2.5 - 3 mm). CT contrast will help visualize the soft tissue and adjacent normal tissues. The International Spine Radiosurgery consortium developed a consensus guideline for target volume definition. MRI images are mandatory for delineation. Axial volumetric T1 and T2 sequences without gadolinium are a standard with ≤ 3 mm slice thickness. Contouring of normal tissue should be standardized for example: start contouring at 10 cm above the target volume to 10 cm below the target (RTOG 0631). Different fractionation schedules exist with variable total doses. None of the proposed schedules is proven to be superior to another. In case of single fraction, the doses vary between 16 and 24 Gy, with a strong trend for increasing pain relief with higher radiation doses, particularly with doses ≥ 16 Gy. In case of fractionated radiotherapy, doses vary between 7-10 Gy for a 3 fraction schedule and between 5-6 Gy for a 5 fraction schedule. Most centers prescribe the dose (Dpr) to a % volume of the PTV. A PTV dose coverage of $< 80\%$ of the Dpr should be avoided (RTOG 0631). This Dpr. should be prescribed to the isocenter or periphery of target. To minimize the risk for toxicity it is advised to strictly adhere to the published dose-constraints keeping in mind that they are mostly unvalidated. Control and correction of the patient and tumor position should be done with volumetric or stereoscopic X-ray imaging at least before each treatment fraction. Extensive recommendations and guidelines for a stereotactic or high precision QA program, supplementing the QA program for linear accelerators can be found in literature and should be followed (e.g. AAPM TG 101 report).

OUTCOME

The International Bone Metastases Consensus Working Party developed guidelines for the assessment of endpoints of palliative radiotherapy of bone metastases. It is recommended to follow the proposed definitions of pain assessment and pain response. Toxicity should be evaluated at follow up visits using standardized criteria such as the National Cancer Institute (NCI) Common Terminology Criteria for Adverse Events (CTCAE) v.4.0.

Symposium: IMRT, the new standard in treatment of gynaecological, lung and breast cancers?

SP-0616

Organ motion: is it an obstacle to the use of IMRT as a standard technique for gynecological cancers?

J. Barillot¹

¹Hôpital Bretonneau, Tours, France

Intensity-modulated radiotherapy (IMRT) has been introduced in a number of disease sites in the late nineties for treating complex treatment volumes and avoiding close proximity

organs at risk (OAR) that may be dose limiting. Fifteen years later, in many countries, IMRT is still not considered as a standard technique for treating gynaecological cancers. It is well accepted that, if reducing acute and chronic toxicity are the main endpoints, IMRT may be considered as the ideal technique. By contrast, if disease-related outcomes are considered, there are still insufficient data to recommend IMRT over three-dimensional conformal radiotherapy. Moreover, with the increased accuracy of treatment delivery comes the need for greater accuracy in incorporation of organ motion to prevent geographical misses.

Uterus significantly moves according to the bladder and rectal filling. The majority of motion occurs in the anterior-posterior and superior-inferior directions, with mean interfraction movements of 4-7 mm, but very large displacements up to more than 2 cm may occur with the inherent risk of poor coverage of the posterior part of the cervix or of the uterine fundus. Similarly, during post-operative irradiation, the vaginal CTV changes its position with standard deviation of 2.3 cm into the anterior or posterior direction, 1.8 cm to left or right and 1.5 cm towards the cranial. According to the majority of studies a uniform CTV planning treatment volume margin of 15 mm would fail to encompass the CTV in 5% of fractions in post-op. It rises up to 32%, when the CTV includes the entire uterus. For intact cervical cancer, where gross disease is present, the significant shrinkage in tumour volume of 62% in mean, also contributes to potential unintended doses to normal tissues, but the risk is rather low.

How to deal with motion uncertainties?

It can be helpful to attempt to control rectum and bladder filling, although the compliance with instructions for bladder filling and for rectal emptying does not always result in adequate reproducibility. The construction of an ITV from CT images acquired with empty and full bladder is also another way to account for interfraction motion of the CTV. The implementation of IGRT on a daily basis is essential for judging the effectiveness of the measures previously outlined. However, one must never forget that the cervix or vaginal cuff and surrounding tissues are mobile relative to the bony pelvis, while the pelvic lymph nodes which are also part of the target are relatively fixed. Thus, the shifts to account for motion of the mobile target may move the pelvic lymph nodes out of the PTV. Consequently, care should be taken when shifting to ensure that nodal targets are still within PTV, but keeping CTV to PTV margins to 10-15 mm helps to find a good compromise without jeopardizing the OAR's sparing. The risk of geographical misses does exist, but its level must be appreciated in the light of the dose contribution brought by the additional brachytherapy. Brachytherapy still plays a major role in the treatment of cervix carcinomas. The important dose gradient and the absence of target movements in relation to the inserted radioactive sources allow for dose escalation and 3D image guided adaptive procedure allows for accurate definition of target volumes with definition of dose volume parameters. Consequently a moderate under dosage of a part of CTV during IMRT may be compensated by the high dose delivered by brachytherapy.

The concept of adaptive IMRT seems to be applicable for the management of the complex deformable target motion that occurs during radiation of gynecological cancers. The cervix-uterus shape and position can be predicted by bladder volume, using a patient-specific prediction model derived from pre-treatment variable bladder filling CTscans. Based on that, a strategy called "plan of the day" has been elaborated and is under investigation.

In conclusion, organ motion is not an obstacle to the use of IMRT as standard technique for gynecological cancer, especially when combined with brachytherapy, provided that PTV margins are not reduced and IGRT is adequately used. The participation to prospective studies and/or the registration of patients in database are strongly encouraged.

SP-0617

IMRT for lung cancer: current status and future developments

C. Faivre-Finn¹

¹The Christie NHS Foundation Trust, Institute of Cancer Sciences - Radiation Oncology, Manchester, United Kingdom

IMRT is a technique that adds fluence modulation to beam shaping, which improves radiotherapy dose conformity around the tumour and spares surrounding normal structures. Treatment with IMRT is becoming more widely available for the treatment of lung cancer, despite the paucity of high level evidence supporting the routine use of this more resource intense and complex technique [Chan. *J Thor Oncol* 2014]. It allows the treatment of patients with large volume disease, close to critical organs at risk with curative doses.

Very few prospective trials have reported on the use of IMRT. RTOG 0617 was a 2 x 2 factorial design study, in which patients with stage III NSCLC were randomized to receive high dose (74 Gy in 37 fractions) or standard dose (60 Gy in 30 fractions) RT concurrently with weekly paclitaxel/carboplatin with or without cetuximab [Bradley. *Lancet Oncol* 2015]. The radiotherapy technique (3D conformal RT vs IMRT) was a stratification factor. Disappointingly, there was a significant increase in the risk of death in the high-dose arms (median survival, 19.5 months vs 28.7 months; $p=0.0007$), and a 37% increase in the risk of local failure in the high-dose arms (hazard ratio, 1.37; $p=0.0319$). It should be noted that just under half of the patients in this study were treated with IMRT (46.5%). Although patients were stratified by treatment delivery technique and the proportions of patients treated with IMRT were balanced between treatment groups (46.1% in 60 Gy arms and 47.1% in 74 Gy arms), the delivery of 74 Gy was probably challenging, particularly in patients treated without IMRT, given the gross tumour volume (GTV) (mean 124.7 in 60 Gy arms and 128.5 cc in 74 Gy arms).

A subsequent analysis on patient reported outcome demonstrated a significantly worse quality of life on the 74 Gy arms at 3 months after treatment [Mosvas *JAMA* 1015]. Interestingly, despite minimal differences in clinician-reported side-effects between treatment arms, the decline in quality of life was significantly reduced with the use of IMRT compared to 3DCRT suggesting that the use of improved radiotherapy treatment techniques may be beneficial. Furthermore, baseline QOL was an independent prognostic factor for survival. A further analysis of RTOG0617 compared the outcome of patients treated with 3D-conformal and intensity modulated radiotherapy [Chun. *ASTRO* 2015]. Survival was the same in both groups in spite of the larger proportion of patients with stage IIb vs IIIa and larger Planning Target Volume in the IMRT cohort. Moreover the use of IMRT reduced severe pneumonitis, dose delivered to the heart and more patients received chemotherapy in the IMRT cohort.

Population-based studies have not shown any significant difference in overall survival, toxicity or time spent hospitalized following treatment between 3DCRT and IMRT [Harris. *Int J Radiat Oncol Biol Phys* 2014; Chen. *J Thorac Oncol* 2014]. The need remains to develop clinical trials that will demonstrate the benefit of IMRT in terms of toxicity, local control, survival or quality of life.

A number of clinical trials are currently recruiting patients. Some are evaluating personalized dose escalation based on dose delivered to organs at risk (NCT01836692, NCT01166204) and others an increase dose to selected parts within the tumour, defined by functional imaging (Dose Painting) (NCT01024829, NCT01507428).

SP-0618

Are there early and late benefits of breast IMRT for improving dose distribution homogeneity?

J.P. Pignol¹

¹Erasmus MC Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands

In countries with active mammography screening programs, the majority of breast cancers are diagnosed at an early

stage. Those patients are treated with breast conserving surgery followed by adjuvant radiotherapy, which is equivalent to mastectomy in term of survival. The objective of the radio-surgical association is hence primarily cosmetic. Since those patients have excellent outcomes, it is logical to minimise any detrimental effects of the treatment, in term of acute and delayed side effects.

Intensity Modulated Radiation Therapy (IMRT) is a radiation technique where the photon beam intensity is modulated across multiple irradiation fields to achieve a pre-determined goal for the dose distribution, using try and error methods. The goal can be to improve the conformality of the dose distribution or, as it is often the case for the breast, its homogeneity.

There are many cohort studies and randomised clinical trials reporting on the clinical benefit for BIMRT used to improve the dose distribution homogeneity in the breast. A multicentre randomised controlled trial from Canada has demonstrated a large and significant reduction of acute skin toxicity, notably the moist desquamation occurring on the infra-mammary fold. This benefit was not present for large breasted patients. Moist desquamation was significantly associated with a severe pain and a reduction of Health Related Quality of Life (HRQoL). There are several studies reporting significant associations between the occurrence of moist desquamation and delayed side effects like telangiectasia and induration. Several randomised trials have also evaluated the impact of BIMRT on long-term side effect, and two studies from the UK using hypofractionated regimen showed a small but significant improvement of the cosmetic outcome at 5 years. It is important to note that no cosmetic improvement was found at 8 years in the Canadian study using conventional fractionation of 50 Gy in 25 treatments. In the Cambridge and Canadian studies there was no impact of the radiation technique on the long-term HRQoL. In the Canadian study there was a highly significant correlation between the initial pain experience at time of radiotherapy and the occurrence of chronic pain and a reduction in HRQoL at 8 years. Also the occurrence of moist desquamation at the time of radiation treatment was significantly correlated with the occurrence of telangiectasia, fibrosis and a poorer cosmetic outcome on self-evaluation questionnaire. Those studies suggest a complex interplay between the breast volume, the dose-fractionation schedule and the radiation technique. More recently, a study from Ghent demonstrated that for large breasted patients hypofractionated prone BIMRT significantly reduces moist desquamation compared to hypofractionated supine BIMRT.

In summary, there are solid evidences to suggest that BIMRT reduces the occurrence of acute skin toxicity, including moist desquamation and pain. For large breasted women, the use of a prone technique BIMRT appears to significantly reduce moist desquamation. In regards to long-term side effect it seems that BIMRT could improve the cosmetic outcome when using hypofractionation, but its role is less clear when using a standard dose-fractionation regimen. A painful experience of moist desquamation during the initial radiation treatment is significantly associated with chronic pain and poorer HRQoL. Since BIMRT is a technique relatively simple to implement at no cost, outside the USA, it should be used as standard for adjuvant breast radiotherapy.

Symposium with Proffered Papers: Plan of the day (PotD): current status

PotD external beam: overview of current practice

J. Penninkhof¹, S. Heijkoop¹, S. Quint¹, A.P. Kanis¹, A. Akhiat², R. Langerak¹, J.W. Mens¹, B.J.M. Heijmen¹, M.S. Hoogeman¹

¹Erasmus MC Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands

²Elekta AB, Research Physics, Stockholm, Sweden

Most image guidance strategies today aim at minimizing random and/or systematic geometrical uncertainties by offline or online correction protocols based on either

surrogates or the actual tumor position. Corrections are usually limited to translations, and rotational errors, shape change and intra-fractional changes are not corrected for. For targets with a large day-to-day shape variation, or in case of multiple targets with differential motion, generous safety margins have to be used that partly undo the healthy tissue sparing properties of modern radiation techniques such as IMRT and VMAT. Adaptive radiotherapy (ART), e.g. with a Plan-of-the-Day (PotD) strategy has been proposed to overcome this problem. Guidelines for proper selection of patients that need a replanning (e.g. lung, rectum), or implementation of a more labour-intensive PotD workflow for groups of patients (e.g. cervix, bladder) have been major research topics in recent years.

In this presentation, an overview will be given of current clinical implementations of PotD strategies in literature. The library-based PotD procedure as implemented at Erasmus MC for cervical cancer patients will be discussed in more detail. For these patients, a plan library contains 2 or 3 VMAT plans adequate for target shapes and positions corresponding to smaller and larger bladder volumes. Every treatment day, the best fitting plan is selected based on an in-room acquired cone beam CT scan, showing internal anatomy and markers implanted around the primary tumor. The recent PotD implementation in our record & verify system has pathed the way for a more wide-spread application of safe and efficient delivery of library-based PotD strategies, and for more advanced library-based approaches including dynamic plan-library updates.

In-room MR image-guided plan of the day

R. Kashani¹, J. Olsen¹, O. Green¹, P. Parikh¹, C. Robinson¹, J. Michalski¹, S. Matic¹

¹Washington University School of Medicine, Radiation Oncology, St. Louis, USA

The clinical implementation of magnetic resonance image-guided radiation therapy (MR-IGRT) has enabled the daily visualization of internal soft-tissue anatomy with the patient in the treatment position. The information provided by the daily MR, which may not be available in some other online imaging modalities such as cone-beam CT, has allowed us to evaluate the impact of geometric variations in the patient on the planned versus delivered dose on a day to day basis. The availability of daily volumetric MR images, in combination with software tools integrated into the MR-IGRT system, and independent quality assurance tools for online patient-specific QA, has allowed for clinical use of online adaptive MR-IGRT since September 2014.

We report on the first year of clinical experience with online treatment adaptation for over 45 patients treated to various sites including abdomen, pelvis, and thorax, having received more than a total of 150 adapted fractions. Here we describe the clinical implementation and workflow for online adaptive MR-IGRT, provide details on decision criteria for daily plan adaptation, and discuss and compare an online plan adaptation approach to a plan library approach where the plan of the day is selected from a group of plans based on previous patient anatomy. We also discuss limitations of current techniques and future improvements.

OC-0621

A population based library of plans for rectal cancer: design and prospects for margin reduction

L. Hartgring¹, J. Nijkamp¹, S. Van Kranen¹, S. Van Beek¹, B. Van Triest¹, P. Reameijer¹

¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiotherapy, Amsterdam, The Netherlands

Purpose or Objective: The clinical target volume (CTV) in rectal cancer is subject to considerable shape deformations due to rectal and bladder filling changes, which require large planning target volume (PTV) margins when conventional correction strategies based on bony anatomy are used.

To mitigate errors introduced by shape variations, the library of plans (LoP) approach has been successfully applied for cervical and bladder cancer. For those sites, libraries were

created by interpolation of structures of interest defined on CT scans in the full and empty bladder state. However, for rectal patients this approach is not feasible, as a major source of uncertainty is not bladder, but rectal filling. The purpose of this study was therefore to develop an alternative method for generating structures for a LoP for rectal cancer and to investigate its potential for PTV margin reduction.

Material and Methods: The method proposed is based on 3D population statistics of the shape variation of the rectum CTV, rather than patient specific data derived from several CT scans, allowing the use of only a single planning CT scan for structure generation. The population statistics were derived from shape variation data of thirty three short course radiotherapy (SCRT) patients with daily repeat scans on which the rectum CTV was delineated. Shape variations were defined as standard deviations of (local) perpendicular displacements of the CTV surface, using each patient's planning CT scan as reference.

The LoP CTVs were created by expanding or contracting the planning CTV perpendicular to its surface, proportional to the local statistics of shape variation of the population and a global scaling factor. The scaling factor was tuned such that the largest distance between CTVs was 1 cm. Five CTVs were created; the original CTV, two smaller (max -1, -2 cm) and two larger CTVs (max +1, +2 cm).

To determine the potential of this method, residual errors were calculated by using the most optimal CTV from the library as a reference in computing the shape variation statistics, rather than the original planning CTV. Subsequently, margins were computed for both the conventional and LoP strategy, using a modified version of the van Herk recipe.

Results: An example of the constructed CTV structures is depicted in figure 1a. The original CTV is the middle one; two larger and two smaller CTVs were created using population statistics. Figures 1c and 1d show the required PTV margin for a conventional and a LoP approach, respectively. The difference between the two methods is shown in Figure 1b. The largest reduction was found in the upper anterior part of the CTV: 1.5 cm (\approx 40%).

Conclusion: We have successfully developed a LoP strategy for rectum patients that uses population statistics and scalable expansions, thereby only requiring a single CT scan, as opposed to the current methods for cervix and bladder. Analysis of the residual errors has shown that a potential margin reduction of 40% is possible with this approach.

Figure 1. Example of generated LOP structures on a sagittal CT slice (A). Figures B to D depict anterior views of 3D representations of the (average) CTV. Figures C and D present the required margins in the case of bony anatomy based corrections and when using our LoP approach, respectively. Figure B shows the difference between the two methods. All measurements are in cm.

Debate: We don't need better dose calculation, it's doing more bad than good

SP-0622

For the motion

E. Sterpin¹

¹Katholieke Universiteit Leuven, Oncology, Leuven, Belgium

Advanced dose calculation algorithms have demonstrated excellent performance against measurements for complex treatments and heterogeneous phantoms. Thus, it is natural to consider those as the best candidates for treatment planning. Because the dose calculation is more accurate, so will be the treatment and its outcome improved. This seems intuitively obvious.

However, a broader view on our clinical practice may temper this conclusion. In our clinical practice, we are using dose prescriptions from past experience that was typically based on less accurate dose calculation algorithms. Also, we are using safety margins for geometrical uncertainties that are based on hypothesis that simplify considerably the physics of dose deposition, but yet seem to provide adequate coverage and safety for the majority of the patients.

We will show during this debate that changing the dose calculation algorithm considering our present practice will not necessary have a positive impact for the patients. Therefore, the introduction of such algorithms in clinics should be made cautiously.

Debate: Are we precisely inaccurate in our adaption?

SP-0624

For the motion

M. Leech¹, M. Kamphuis²

¹TCD Division of Radiation Therapy, Radiation Therapy, Dublin, Ireland Republic of

²Academic Medical Centre, Radiotherapy, Amsterdam, The Netherlands

This debate will critically discuss recent developments in adaptive radiotherapy (ART). Adaptive radiotherapy is being introduced in many departments nowadays and one of the main questions is if there is sufficient evidence to safely do so?

In the debate, the inaccuracies of the process will be discussed profoundly. What is the accuracy of the process as a whole? Do delineation errors and dose calculation errors still make ART really worth the effort? Or can these errors safely be corrected for?

Another aspect that will be discussed is risk management. Procedures are often not supported by software released for this purpose. In case of e.g. plan selection, different manual steps are made which are probably prone to human errors. What is the impact of these human errors? On the other hand, do we really have to wait for optimal software to be released and keep patients treated in a sub-optimal manner?

Last but not least is the lack of sufficient knowledge on tumor spread e.g. in the case of gynecological tumors. If we reduce the treatment area, aren't we going to miss our target? Will this in the end increase local relapse rates instead of reducing toxicity? From a different point of view it can be argued that we will never get knowledge of the exact tumor location if we keep treating patients with a (too) large safety margin.

Debate: Moving away from 2 Gray: are we ready for a paradigm shift?

SP-0626

This house believes that larger fraction sizes will be the standard-of-care for the majority of curative treatments by 2025

J.R. Yarnold¹

¹The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Radiotherapy & Imaging Department, Sutton, United Kingdom

A significant proportion of curative schedules still use fraction sizes ≤ 2.0 Gy, mostly on a once-daily basis five times per week. These practices are likely to diminish further over the next 10 years, driven independently by advances in biology and physics. Although randomised trials in the 1980s and '90s confirmed squamous carcinomas of the head and neck and bronchus to be relatively insensitive to fraction size compared to the dose-limiting late-reacting normal tissues, it is now well established that adenocarcinomas of the breast and prostate share comparable, or perhaps greater, sensitivity to fraction size than the dose-limiting late normal tissues. Hypofractionation is increasingly adopted as a standard of care for women with breast cancer, and practices are changing for men with prostate cancer too, diseases account for 28% and 17%, respectively, of all UK radiotherapy courses. High dose brachytherapy and novel external beam techniques exclude adjacent normal tissues from the high dose zone so effectively that prescribed dose is limited mainly, if not exclusively, by tissues in the paths of entry and exit beams. The impact of stereotactic radiotherapy in common cancers remains to be established, but early results for early stage lung cancer look encouraging, particularly when the benefits of acceleration are factored in. There is therefore ample justification to support a prediction that accelerated hypofractionation will be a standard of care for the majority of curative treatments well before 2025.

SP-0627

SP-0628

For the motion (rebuttal): It is the *small* fraction sizes that need special pleading, not the large ones.

A. Nahum

Fractionation is a very odd business. The question ought really to be "Why should we deliver curative radiotherapy in a large number of small doses, thereby prolonging the number of treatment days, increasing both patient inconvenience, and overall treatment costs?" Given the significant reduction in doses to non-target tissues achievable by modern conformal external-beam therapy (including intensity modulated photons and spot-scanned protons), and the recent findings for breast tumours, and probably also for prostate, that the α/β for the clonogens is of the same order as that for late normal-tissue complications, there are not many tumour sites where hyperfractionation is justified. In the latter category are only relatively large lung tumours, close to the mediastinum, and those tumours in the head & neck region where 'serial' normal tissues (e.g. spinal cord) are dose-limiting. Otherwise the onus is on the 'hyper-fractionators' to justify, to both administrators and patients, the vast number of daily visits they wish to impose on patients. One can go further - fraction size/number should be tailored to each patient according to the maxim "Deliver the minimum number of fractions compatible with a high rate of local control and a low rate of complications". Software such as 'BioSuite' exists to do exactly this; there are no good excuses for not using it.

Outcomes of induction chemotherapy for head and neck cancer patients

S.Y. Wu¹, L. Kuan-Chou², C. Tsung-Ming³, L. Fei-Peng³¹Taipei Medical University Hospital, No.111- Section 3, Taipei, Chinese Taipei²Wan Fang Hospital- Taipei Medical University- Taipei-Taiwan, Department of Oral and Maxillofacial Surgery, Taipei, Taiwan³Wan Fang Hospital- Taipei Medical University- Taipei-Taiwan, Department of Otorhinolaryngology, Taipei, Taiwan

Purpose or Objective: To the present, the role of induction chemotherapy has remained a subject of controversy. In this study, we directly compared the survival of patients receiving induction chemotherapy using docetaxel or platinum given before concomitant chemoradiotherapy (CCRT) with upfront chemoradiotherapy alone.

Material and Methods: The National Health Insurance claims database and cancer registry databases from The Collaboration Center of Health Information Application in Taiwan were linked for the analysis. Head and neck cancer patients from January 1, 2002 to December 31, 2011 were included in the study. The follow-up duration was from the index day to December 31, 2013. The inclusion criteria were having a head and neck cancer (identified according to the International Classification of Diseases, Ninth Revision, Clinical Modification [ICD-9-CM] codes 140.0-148.9), being aged > 20 years, being at American Joint Committee on Cancer (AJCC) clinical cancer stage III or IV, and having undergone induction chemotherapy or platinum-based CCRT. Exclusion criteria were having been diagnosed with cancer before the head and neck cancer was confirmed, having distant metastasis, being at AJCC clinical cancer stages I or II, having platinum and docetaxel combined use before radiotherapy (RT), being younger than 20 years, one's gender being unknown, and having docetaxel use during or after RT, induction chemotherapy beyond 8 weeks before RT, only one course of induction chemotherapy before RT, cetuximab use, adjuvant chemotherapy within 90 days after completion of RT, <7000 cGy dose of RT, curative head and neck cancer surgery before RT, nasopharyngeal cancer, carcinoma in situ, a sarcoma, and head and neck cancer recurrence. The total number of enrolled head and neck cancer patients was 30,990 persons.

Results: In total, 10,721 stage III or IV head and neck cancer patients without distant metastasis were included in the study, and the median follow-up duration was 4.18 (interquartile range, 3.25) years. There were 7968 patients in the CCRT group (arm 1); 503 patients in the induction chemotherapy with docetaxel group of arm 2, and 2232 patients in the induction chemotherapy with platinum group of arm 3. We used the CCRT arm as the control arm to investigate the risk of death after induction chemotherapy. After adjusting for age, gender, clinical stage, and comorbidities, the adjusted hazard ratios (HRs) of overall deaths were 1.37 (95% confidence interval [CI], 1.22-1.53) in arm 2 and 1.44 (95% CI, 1.36-1.52) in arm 3. In a disease-specific survival rate analysis, the adjusted HRs of head and neck cancers deaths were 1.29 (95% CI, 1.14-1.46) in arm 2 and 1.47 (95% CI, 1.38-1.56) in arm 3.

Conclusion: Our cohort study showed that induction chemotherapy with docetaxel or platinum did not improve survival and also resulted in more all-causes death and head and neck cancer death risks compared to CCRT.

PO-0631

The prognostication of tumour volume and lower neck lymph nodes in laryngeal cancer treated with IMRT

S.H. Huang¹, J. Su², J. Waldron¹, J. Kim¹, A. Bayley¹, S. Bratman¹, J. Cho¹, A. Hope¹, M. Giuliani¹, J. Ringash¹, A. Hansen³, J. De Almeida⁴, L. Tong¹, W. Xu², B. O'Sullivan¹¹Princess Margaret Cancer Centre/University of Toronto, Department of Radiation Oncology, Toronto, Canada²Princess Margaret Cancer Centre/University of Toronto, Department of Biostatistics, Toronto, Canada³Princess Margaret Cancer Centre/University of Toronto, Division of Medical Oncology, Toronto, Canada⁴Princess Margaret Cancer Centre/University of Toronto, Department of Otolaryngology - Head and Neck Surgery, Toronto, Canada

Purpose or Objective: Evidence suggests that gross tumor volume (GTV) is a prognostic factor (PF) for laryngeal cancer beyond TNM staging. Lower neck lymph nodes (LWLN-LNs) have been linked to increased risk of distant metastasis (DM) although are generally evident when upper neck disease also exists. We hypothesized that primary GTV (GTV-T) and total lymph node (LN) GTV (GTV-N) may differentially impact overall survival (OS) and DM, and that LWLN-LN may lack independent effect.

Material and Methods: All newly diagnosed laryngeal cancers treated with definitive intensity modulated radiotherapy (IMRT) +/- chemotherapy in 2005-2012 were included. GTV-T and GTV-N were delineated for IMRT treatment (confirmed with staging CT/MRI) and peer-reviewed at quality assurance meetings. Levels IV or Vb LNs were considered LWLN-LNs. GTV-N was the summed LN volume receiving full-prescribed dose (lower doses were occasionally used to spare brachial plexus). OS and distant control (DC) were compared between larger/smaller GTV-T, GTV-N (both dichotomized at median value), and presence/absence of LWLN-LN. Multivariate analysis (MVA) identified PFs for OS and DM.

Results: A total of 635 cases [456 (72%) glottic, 164 (26%) supra- and 15 (2%) sub-glottic cancers] were included. TNM stages were I: 215 (34%), II: 161 (25%), III: 129 (20%), and IV 130 (20%). Gross LNs were present in 131 (21%) patients. LWLN-LNs were present in 55/131 (42%) cases, all of which also had overt LNs in the upper neck (levels 2 +/- 3). Median GTV-T was 4 cc (range: 0.1-234.0) and GTV-N was 8 cc (range: 0.9-178.0). Systemic agents were used in 81 (13%) patients. Larger GTV-T (>=4 cc vs <4 cc) or GTV-N (>8 cc vs <=8 cc), or presence of LWLN-LN had inferior 3-year OS (GTV-T: 65% vs 89%; GTV-N: 37% vs 75%; LWLN-LN: 41% vs 65%, all p<0.001) and DC (GTV-T: 87% vs 97%; GTV-N: 71% vs 87%; LWLN-LN: 72% vs 84%, all p<0.001). MVA (adjusted for treatment) confirmed that TNM stage was the strongest PF for OS [III/IV vs I/II: HR 2.52 (1.78-3.56), p<0.001] and DM [HR 6.24 (2.67-14.57), p<0.001]. GTV-T (per 10 cc increment) was also a PF for OS [HR 1.15 (1.07-1.23), p<0.001] and DM [HR 1.18 (1.03-1.36), p=0.015]. GTV-N was a PF for OS [HR 1.13 (1.07-1.20), p<0.001] but not for DM (p=0.22). LWLN-LN was not a PF for OS (p=0.18) nor for DM (p=0.67) although it became significant for OS [HR 1.97 (1.32-2.93), p<0.001] when GTV-T and GTV-N were excluded from the MVA model.

Conclusion: The TNM classification remains the strongest PF for OS and DM. GTV-T is also a PF for OS and DM in addition to TNM. GTV-N is a PF for OS but not for DM. Presence of LWLN-LN is always associated with upper neck LN involvement (likely a surrogate for lymph node burden), and seems to lack independent impact on DM and OS if controlling for GTV-T and GTV-N.

PO-0632

A multivariate model predicting grade ≥ 2 neck fibrosis at 6 months after radio(chemo)therapy

D. Nevens¹, A. Laenen², F. Duprez³, J. Daisne⁴, W. De Neve³, S. Nuyts¹¹KU Leuven-University of Leuven- University Hospitals Leuven, Radiation Oncology Department, Leuven, Belgium²KU Leuven-University of Leuven, Leuven Biostatistics and Statistical Bioinformatics Centre, Leuven, Belgium³Ghent University Hospital, Radiation Oncology Department, Ghent, Belgium⁴Clinique & Maternité Ste-Elisabeth, Radiation Oncology Department, Namur, Belgium

Purpose or Objective: Neck fibrosis is an important complication following radio(chemo-)therapy (R(C)T) for head and neck cancer (HNC). The purpose of this study was to find a parameter that could predict late neck fibrosis and to make a multivariate model to predict neck fibrosis grade (fibrosis RTOG2-4) at 6 months following R(C)T for HNC.

Material and Methods: We prospectively included 193 patients in 5 different RT centers for a randomized controlled trial. On this patient-population we tested age, sex, T/N stage, tumor site, concomitant chemotherapy, upfront neck dissection, neo-adjuvant chemotherapy, accelerated RT, smoking (never-former-current), alcohol abuse (never-former-current), the dose prescribed to the elective neck and erythema at the end of treatment for their potential to predict neck fibrosis RTOG2-4 6 months after the end of treatment. Fisher's exact test and Mann-Whitney U test were used for testing the association between fibrosis grade 0-1 versus fibrosis grade 2-4 with categorical or continuous variables, respectively. A stepwise selection procedure was made to determine the best combination of predictor variables for fibrosis RTOG2-4 at 6 months. The area under the ROC curve (AUC) was determined for the selected model. Additionally a bootstrap-corrected AUC value was calculated. This AUC value corrects for over optimism resulting from the fact that model construction and model validation were performed on the same data set. All tests are two-sided; a 5% significance level is considered for all tests.

Results: Upfront neck dissection ($p < 0.01$), erythema at the end of R(C)T \geq grade 3 ($p < 0.01$), increasing N stage ($p < 0.01$) and cancer of unknown primary ($p = 0.02$) are significantly associated with the incidence of fibrosis RTOG2-4 at 6 months in our patient population in univariate analysis. Upfront neck dissection and erythema grade ≥ 3 at the end of R(C)T were identified for our model using a stepwise selection procedure. Additionally, increasing N stage was selected as an independent predictor variable (Table 1).

Parameter	OR	P-value
Neck dissection vs No neck dissection	159.06 (19.158;1320.7)	<.0001
Acute erythema grade3 vs grade 0-2	129.18 (15.930;1047.6)	<.0001
N-stage (+1 level)	1.446 (1.012;2.068)	0.0430

Table 1: Final model

CI: confidence interval

OR > (<) 1 means higher (lower) risk for first category.

OR > (<) 1 means higher (lower) risk for higher level.

The AUC for this model containing upfront neck dissection, erythema at the end of treatment and smoking status was 0.92; the bootstrap-corrected AUC was 0.90. The risk for fibrosis RTOG2-4 at 6 months can be calculated using the following formula:

$$\text{risk for fibrosis RTOG2 - 4 at 6 months} = \frac{e^{\mu}}{1 + e^{\mu}}$$

$$\begin{aligned} \mu = & -5.3225 + 5.0693 \text{ (only when upfront neck dissection was performed)} \\ & + 4.8612 \text{ (when grade } \geq 3 \text{ erythema is present at the end of treatment)} \\ & + 0.3691 \text{ (Nstage: N0 = 0; N1 = 1; N2a = 2; N2b = 3; N2c = 4; N3 = 5)} \end{aligned}$$

Conclusion: A model for the prediction of fibrosis RTOG₂₋₄ following R(C)T for head and neck cancer is presented with an AUC of 0.92. Erythema at the end of R(C)T is associated with RTOG₂₋₄ fibrosis at 6 months.

PO-0633

Dissection of submandibular glands increases the risk of xerostomia after postoperative radiotherapy

H.P. Van der Laan¹, H.P. Bijl¹, A. Van der Schaaf¹, J.G.M. Vemer-van den Hoek¹, J.A. Langendijk¹, R.J.H.M. Steenbakkers¹

¹University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands

Purpose or Objective: To determine if the remaining submandibular gland volume after surgery is a prognostic factor for late xerostomia after postoperative radiotherapy (PORT) for head and neck cancer (HNC).

Material and Methods: This prospective cohort study consisted of 198 HNC patients who received PORT. The primary endpoint was CTCAE v4.0 grade 2 or higher physician rated xerostomia at 6 months after completing PORT (XERM6). From a set of factors deemed relevant in relation to the endpoint (patient characteristics, treatment details, surgical data, dosimetric data of major and minor salivary glands and oral cavity) a subset of candidate factors was selected, using expert knowledge and model exploration. Manual stepwise logistic regression was performed with the aim to build a strong and valid parsimonious prediction model for XERM6.

Results: XERM6 was observed in 54 patients (27.3%). The number of remaining submandibular glands was 2 (n=42, average remaining volume: 18.7 cm³); 1 (n=105, average remaining volume: 9.0 cm³); or 0 (n=51). Patients underwent surgery in the oral region (n=154) or in the hypopharyngeal / laryngeal region (n=44). The multivariable analysis revealed the following independent prognostic factors for the final model: baseline xerostomia grade 1 (OR: 2.978, 95%CI: 1.363-6.504); ipsilateral parotid mean dose (OR: 1.035 per Gy, 95%CI: 1.007-1.065); contralateral parotid mean dose (OR: 1.019 per Gy, 95%CI: 0.984-1.056); and the remaining total submandibular gland volume (OR: 0.908 per cm³, 95%CI: 0.855-0.964). This model calibrated well with the observed data (Hosmer & Lemeshow test: p = 0.798) and had a good performance (Nagelkerke adjusted R²: 0.223, and ROC-AUC: 0.758). Effect sizes and performance measures were not significantly different after internal validation using cross-validation.

Conclusion: With a similar dose in the parotid glands, the risk of late xerostomia increased significantly with less remaining submandibular gland volume after surgery. This effect is not accounted for in existing models for late xerostomia. The proposed model is the first model specifically valuable for predicting late xerostomia in HNC patients receiving PORT.

PO-0634

Body image in irradiated head and neck cancer patients

H. Chiu¹, T.M. Hung², J.T.C. Chang²

¹Chang Gung Memorial Hospital, Radiation Oncology, Taoyuan, Taiwan

²Chang Gung Memorial Hospital, Radiation Oncology, Taoyuan, Taiwan

Purpose or Objective: To investigate the body image in head and neck cancer patients treated with radiotherapy.

Material and Methods: A cross-sectional survey of 150 patients with head and neck cancer, 60 patients were nasopharyngeal cancer (NPC) treated by definite radiotherapy without surgery, and 90 patients were oral cavity cancer (OCC) treated by radical surgery plus adjuvant radiotherapy. All participants completed a 10-item Body Image Scale (BIS) to assess the body image dissatisfaction. In all patients, the clinical and socio-demographic variables were cancer type, age, gender, partnership, education, and employment. In OCC patients, the socio-demographic variables were the same, and clinical variables were facial skin sacrificed, mouth angle sacrificed, glossectomy, maxillectomy, and mandibulectomy. ANOVA, t-test, and multiple regression were used to evaluate the relationships between these variables and BIS.

Results: In all patients, the cancer type (NPC vs. OCC) was the strongest independent predictor of BIS. The non-surgically treated NPC patients had significantly better body

image outcome than the surgically treated OCC patients. Education was also an independent factor for BIS. In OCC patients, facial skin sacrificed, mouth angle sacrificed, maxillectomy, and mandibulectomy were significantly associated with BIS. Using multivariate analysis, inferior maxillectomy and segmental mandibulectomy were the independent poor prognosticators of body image outcome in OCC patients.

Conclusion: The radical surgery for head and neck cancer patients has a significant impact on body image, especially those with facial bone destruction. These findings could be used to guide psychosocial interventions targeting body image disturbance for patients with head and neck cancer.

PO-0635

Dose to the masseter muscle and risk of trismus after chemoradiation for advanced head & neck cancer

S. Verheijen¹, O. Hamming-Vrieze¹, M. Jonker¹, E. Lamers¹, S.A.C. Kraaijenga², L. Van der Molen², J.B. Van de Kamer¹, M.W.M. Van den Brekel², W.D. Heemsbergen¹

¹Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands

²Netherlands Cancer Institute, Head and Neck Oncology & Surgery, Amsterdam, The Netherlands

Purpose or Objective: Head and neck cancer patients treated with chemoradiation are at risk for developing trismus (reduced mouth opening). Trismus is often a persisting side-effect and difficult to manage. It impairs eating, speech and oral hygiene, affecting quality of life. Although several studies identified the masseter muscle (MM) as one of the main organs at risk, currently this structure is rarely considered during treatment planning. Prospective studies for chemoradiation are lacking. The aim of our study was to quantify the relationship between radiation dose to the MM and development of radiation-induced trismus in an IMRT-VMAT population.

Material and Methods: The 93 patients in this study participated in a prospective preventive exercise program to preserve oral functioning between 2006-2013. All received concomitant high-dose chemotherapy during VMAT- or IMRT-radiotherapy (70 Gy in 35 fractions). Tumor locations were mainly oropharynx (37%) and hypopharynx (33%). Maximum interincisor mouth opening was measured before and approximately 10 weeks after the end of treatment. Bilateral delineations of the MM were available from 2 retrospective studies. Patients were excluded if trismus was present at baseline, or if gross tumor infiltration of the MM was present on CT evaluation. Evaluated outcomes were trismus (mouth opening \leq 35 mm) and decrease in mouth opening. Logistic regression (using maximum likelihood) was performed.

Results: At the first evaluation, 6-12 weeks post-treatment, fourteen patients had developed radiation-induced trismus (15%). On average, mouth opening decreased with 4.1 mm, or 8.2 % relative to baseline. Mean dose to the ipsilateral MM was a stronger predictor for trismus than mean dose to the contralateral MM, as indicated by the lowest -2 log likelihood (Table 1). Figure 1A shows the correlation between the ipsilateral mean masseter dose and the relative decrease in mouth opening, with trismus cases indicated in red. No trismus cases were observed in 33 patients (35%) with a mean dose to the ipsilateral MM < 20 Gy. The risk of trismus in the other 60 patients (65%) increased with higher mean doses to the ipsilateral MM. Figure 1B shows the fitted NTCP curve as a function of the mean dose, with a TD50 of 55 Gy. The actual incidence (with 1 SE) of trismus cases within 5 dose bins is indicated as well, showing a good correspondence with the NTCP fit with a relatively large uncertainty in the dose area > 50 Gy. Patients with tumors located in the oropharynx were at highest risk.

Conclusion: The risk of trismus can be established with the mean dose to the ipsilateral masseter muscle. The majority of head and neck cancer patients could benefit from dose reduction to the masseter muscles to prevent trismus,

especially patients with a mean dose to the ipsilateral masseter > 20 Gy. Further development of a NTCP model could identify dose objectives to guide treatment planning.

Table 1. Results of univariate logistic regression analysis.

Dose parameter	RR per		
	-2 LLH	10 units	p value
<i>Ipsilateral Masseter</i>			
Volume > 20 Gy (%)	66.5	1.5	0.004
Volume > 40 Gy (%)	69.8	1.4	0.004
Mean dose (Gy)	65.3	2.3	0.001
<i>Contralateral Masseter</i>			
Volume > 20 Gy (%)	66.5	1.4	0.002
Volume > 40 Gy (%)	70.6	1.5	0.007
Mean dose (Gy)	68.2	2.2	0.003

Figure 1. % decrease in mouth opening (A), NTCP for trismus & actual incidence with 1 SE (B), both as function of mean dose to the ipsilateral masseter muscle.

PO-0636

Safety profile support efficacy of gingival clonidine tablet to prevent severe oral mucositis in HNC

¹²Onxeo, Clinical Department, Paris, France

¹³Onxeo, Clinical Dept, Paris, France

¹⁴Universitätsklinikum Freiburg Klinik f. Strahlentherapie, Section Head Clinical Studies, Freiburg-, Germany

Purpose or Objective: Oral mucositis (OM) is the most frequent and severe acute toxicity of chemoradiotherapy (CRT) in head and neck cancer (HNC) patients. In preclinical

studies, topical clonidine shown activity in reducing NF- κ B activation and incidence of severe OM (SOM). In a randomized double blind, placebo-controlled study, a novel mucoadhesive buccal tablet (MBT) containing clonidine reduced the incidence of SOM in HNC patients being treated with CRT. We now report overall survival (OS), tolerability and systemic exposure of clonidine of study subjects.

Material and Methods: Clonidine MBT 50 μ g (n=56), 100 μ g (n=65) or matching placebo (n=62) were applied to the gum once daily 1-3 days prior to RT and then daily until the end of CRT (1.8-2.2 Gy/d, 5 times/week combined with a platinum based CT). AEs, vital signs and gingival tolerance by Silness-Loe index (global score from 0 to 9) were assessed twice a week; xerostomia and sedation (visual scale from 0 to 10) were evaluated once a week. Blood and saliva samples for clonidine levels were collected Q2 weeks. OS data will be collected until 2 years after last patient last visit. Patients received a median cumulative radiation dose of 66 Gy [min: 4; max: 78]. SOM was reported in 60% [95%CI: 47%; 72%] of placebo patients, 43% [95%CI: 29%; 57%] in clonidine 50 μ g MBT (p=0.063) and 48% [95%CI: 35%; 61%] in clonidine 100 μ g MBT (p=0.169).

Results: All grade AE incidence was 91% in clonidine MBT groups and 98% in placebo group (p<0.10). No difference in heart rate and blood pressure was reported between groups. Reversible hypotension AEs were reported in 7% clonidine MBT 50 μ g patients, 6% clonidine MBT 100 μ g and 2% placebo-treated patients (p=ns). Sedation score slightly increased in all groups between week 1 and week 6 (overall from 1.5 \pm 2.3 to 3.0 \pm 2.3) and was similar between groups (p=ns). Xerostomia grade \geq 2 increased to 41% in clonidine MBT 50 μ g, 31% in clonidine MBT 100 μ g and 42% in placebo patients (p=ns). The mean plasma/saliva concentrations of clonidine were 0.087/154.2ng/mL in clonidine MBT 50 μ g and 0.134/301.1 ng/mL in clonidine MBT 100 μ g. With a median follow-up of 15 months, the median 1year-OS of 89.3% [95%CI: 73.9; 95.8] placebo and 89.7% [95%CI: 80.4; 94.8] clonidine MBT.

Conclusion: Clonidine MBT daily applied to the gum throughout CRT reduced the incidence of SOM and was well tolerated in HNC patients undergoing postoperative CRT. No significant systemic effects of clonidine were reported in the phase 2 study probably due to its low systemic levels.

PO-0637

RCT pilot study of Therabite vs wooden spatula in amelioration of trismus in H&N cancer patients

R. Lee¹, S.N. Rogers², A.L. Caress³, A. Molassiotis⁴, R. Edwards⁵, D. Ryder¹, P. Sanghera⁶, C. Lunt¹, T. Yeo⁵, N. Slevin⁷

¹The Christie, Research and Development, Manchester, United Kingdom

²University Hospital Aintree, Maxillofacial Unit Directorate, Liverpool, United Kingdom

³University of Manchester, School of Nursing and Midwifery, Manchester, United Kingdom

⁴The Hong Kong Polytechnic University, Cancer & Supportive Care, Hong Kong, China

⁵Bangor University, The Bangor Health Economics Unit, Bangor, United Kingdom

⁶University of Birmingham, Clinical Oncology, Birmingham, United Kingdom

⁷The Christie, Clinical Oncology, Manchester, United Kingdom

Purpose or Objective: Specific objectives of the study were (i) to assess whether prophylactic exercise intervention prevented the worsening of jaw tightening that would be expected following radiotherapy (ii) to assess whether the Therabite® or wooden spatulas intervention improved patients' QOL as measured using validated questionnaires; (iii) to assess issues around power for sample size calculations, compliance and practical aspects of running a full RCT in this group of patients and (iv) whether the intervention reduced the level of post-treatment clinical

management/health care utilisation required by mouth cancer patients

Material and Methods: All patients had some sense of subjective jaw tightening prior to study entry. Measurements of jaw opening and QOLs were taken pre and post radiotherapy 3 and 6 months. Patients were instructed to follow the 5-5-30 regimen daily, for 6 months. (5stretches, 5times, 30 second hold).

Results: 37 patients with stage 3/4 oral/oropharyngeal cancers were randomised to receive the therabite device and 34 the wooden spatulas for jaw exercises. The study has shown that mouth openings had increased on average in both groups following the exercise intervention. There was no statistically significant difference between the two interventions. There were problems with compliance. Lessons learnt from the semi structured telephone interviews, (15 patients) which would aid compliance included: (1) Allow patients to have more of a say in the exercise regimen ie reduce to 3 times a day. (2) Allow patients to take a variable break (up to 6 weeks) from the exercises when side effects of radiotherapy are at their worst. Mucositis, soreness and pain in mouth being reported during last few weeks and 4 weeks post radiotherapy. (3) More regular contact with the patients for encouragement and support. The study was designed to give an indication about the benefits of exercises and to inform feasibility to conduct a larger study

Conclusion: Prophylactic exercises during and after radiotherapy treatment can ameliorate trismus for stage 3 and 4 oral/oropharyngeal cancers. **Keyword:** Trismus, Radiotherapy This abstract presents independent research funded by the National Institute for Health Research (NIHR) under its Research for Patient Benefit (RfPB) Programme (Grant Ref No: PB-PG-0610-22317). Adaptive dose painting by numbers for head and neck cancer: interim analysis of a randomised trial

F. Duprez¹, J. Daisne², D. Berwouts³, W. De Gerssem¹, I. Goethals³, A. Olteanu¹, J. Schatteman³, T. Vercauteren¹, W. De Neve¹

¹Universitair Ziekenhuis Gent, Radiotherapy, Gent, Belgium

²Clinique et Maternité Sainte-Elisabeth Namur, Radiotherapy, Namur, Belgium

³Universitair Ziekenhuis Gent, Nuclear Medicine, Gent, Belgium

Purpose or Objective: A prospective randomized multi-centre phase II trial comparing standard IMRT (S-IMRT) to 3-phase adaptive dose painting by numbers (DPBN) for head and neck cancer (HNC) is currently recruiting patients. Unlike the fact that the initial dose prescription was derived from a phase I trial, we observed an unacceptable rate of late mucosal ulceration using this dose prescription in the DPBN group. This made us change the dose prescription in two steps. This interim analysis reports on acute and late toxicity and local (LC), regional (RC) and distant control (DC) in almost half of the patients to be included.

Material and Methods: From 2011, Q3 to 2015, Q3 53 patients received primary radio(chemo)therapy for HNC. We report on 45 patients who have ended therapy for 3 or 6 months. Patient, tumor and treatment characteristics can be found in Table 1

	3-phase adaptive DPBN (n = 21)	Standard IMRT (n = 24)	p-value

Fig. 1 demonstrates dose prescription protocols (DPP) of the DPBN- and S-IMRT group

Results: As previously reported (ESTRO 2015) we unexpectedly observed late grade (G)3 and 4 mucosal ulcers in 1/7 and 3/7 DPBN-patients in DPP1, respectively, that healed spontaneously (n = 1), after surgical intervention (n = 2) and is still persisting (n = 1) at 42 months. In order to avoid G4 mucosal late toxicity (LT) the DPBN-DPP has been adapted in 2 steps (Fig. 1): DPP1 used a median dose prescription that can result in increased doses in a GTV with > 50% voxels of low-uptake. This median dose prescription was abandoned in DPP2. In DPP2 the very-high dose region is limited to an absolute volume of 1.75 cc. In DPP3, 1/2 had G3 mucosal LT that healed spontaneously. In DPP3, 2/11 and 1/11 had G3 and G4 mucosal LT, respectively. In S-IMRT, there was no G3-4 mucosal LT (n = 20). Late G3 dysphagia was seen in 2/18 and 3/20 DPBN and S-IMRT patients at month 3, respectively. After 6 months, 6/15 and 2/13 patients had G2 dysphagia (p = 0.22) and PEG-tube was needed in 5/15 and 3/13 patients in DPBN and S-IMRT, respectively. G2 xerostomia was present in 6/13 and 7/13 patients in DPBN and S-IMRT, respectively. Median follow-up is 12 (3-45) months. Nine patients deceased: 5 DPBN-patients (metastases in 3, complications

after neck dissection for regional recurrence in 1 and unknown cause in 1) and 4 S-IMRT patients (2 metastases, 1 aspiration pneumonia and 1 cardiac event). Local failure was seen in 1/21 (5%) and 4/24 (17%) in DPBN and S-IMRT, respectively. Regional failure was seen in 2/21 (10%) and 2/24 (8%) in DPBN and S-IMRT, respectively. Metastases were seen in 4/21 (19%) and 5/24 (21%) in DPBN and S-IMRT, respectively. At 1 year actuarial LC was 92% and 76% (p = 0.22), RC 86% and 87% (p = 0.9), DC 76% and 86% (p = 0.9) and OS 68% and 90% (p = 0.6) in DPBN and S-IMRT, respectively.

Conclusion: At short term, we did not observe significant differences yet in LC, RC, DC or OS in the first 45 patients. Due to mucosal LT, the DPBN-DPP has been adapted. Since then, G4 mucosal LT was observed in 1/12 patients. Strict follow-up of LT is being performed.

PO-0639

Graves ophthalmopathy: a network meta-analysis of treatments

M.P. Shaikh¹, F. Alite¹, M. Wu², J. Welsh¹, B. Emami¹, E. Melian¹, M.M. Harkenrider¹

¹Stritch School of Medicine- Loyola University Chicago, Radiation Oncology, Chicago, USA

²Loyola University Chicago, Research Methodology, Chicago, USA

Purpose or Objective: Although several treatments have been evaluated in randomized clinical trials (RCTs) for Graves Ophthalmopathy (GO), many of these treatments have not been directly compared against each other and thus the relative efficacy among them is unclear. We conducted a network meta-analysis (NMA) to compare all regimens simultaneously.

Material and Methods: A systematic review was performed through MEDLINE, Cochrane Central Register of Controlled Trials and meeting abstracts to identify RCTs involving treatments for GO. Treatments included: Radiation 10 Gy in 10 fractions (RT10) or 20 Gy in 10 fraction (RT20), with oral glucocorticoid (RT20POGC), with intravenous glucocorticoid (RT20IVGC), with retrobulbar glucocorticoid injections (RT20RBGC); oral glucocorticoid (POGC); intravenous glucocorticoid (IVGC); surgical decompression (Decomp); somatostatin analogs i.e., Octreotide or Lanreotide (SSanlg); Cyclosporin alone (Cysprn), with oral glucocorticoid (CysprnPOGC); Ciamezone (Ciamez); rituximab (Ritux); peribulbar orbital glucocorticoid injection (BGCI) or no treatment/placebo/sham radiation (NoTx). Success of treatment was determined from overall clinical response, which was provided by most studies. If this was absent, then it was estimated from proportion of patient not needing further treatment, improvement in clinical activity score (CAS), ophthalmopathy index (OI) or proptosis was used in that order. Odds Ratio (OR) was calculated either directly or via standardized mean difference (SMD) in measures. A frequentist NMA was used to compare treatments. Fixed or random effect model was used based on any significant variation among ORs.

Results: 27 studies involving 1216 patients were identified, with 15 distinct treatments including NoTx. Fixed effect model was used, as there was no significant variation among ORs. RT20IVGC was significantly better than BGCI (OR 31.4 [5.1, 195.7]), Ciamez (OR 6.8 [1.4, 33.1]), Cysprn (OR 64.9 [10.6, 398.5]), Decomp (OR 25.8 [1.7, 392.8]), IVGC (OR 4.1 [1.5, 11.6]), NoTx (OR 18.9 [5.69, 62.6]), POGC (OR 11.8 [4.0, 34.6]), RT10 (OR 10.1 [1.9, 52.2]), RT20 (OR 8.4 [2.7, 25.9]), RT20POGC (OR 4.2 [1.3, 12.9]), RT20RBGC (OR 3.5 [1.2, 10.2]) and SSanlg (OR 11.1 [3.0, 40.4]), but did not reach significance compared to CysprnPOGC (OR 3.7 [0.8, 17.8]) or Ritux (OR 5.0 [0.9, 28.9]). IVGC was found to be significantly better than BGCI (OR 7.6), Cysprn (OR 15.7), NoTx (OR 4.6) and POGC (OR 2.9). Also, CysprnPOGC was significantly better than BGCI (OR 8.6), Cysprn (OR 17.7), NoTx (OR 5.1) and POGC (OR 3.2). RT20, RT20POGC and RT20RBGC were all significantly better than Cysprn (ORs 7.7, 15.6 & 18.6 respectively). RT20 and RT20RBGC were better

than NoTx (ORs 2.3 & 5.4 respectively). Also, SSanlg was better than NoTx (OR 1.7).

Conclusion: RT20IVGC is the best treatment followed by IVGC and CysprnPOGC per this NMA. Also, RT20RBGCI and SSanlg were better than NoTx.

Table: Odds ratios of pair-wise comparisons of treatments for thyroid eye disease synthesized using network meta-analysis

Prognostic factors in definitive salvage RT for recurrent Head and Neck cancer

O. Suzuki¹, R. Oh², K. Ogawa³

¹Osaka University Graduate School of Medicine, Carbon Ion Radiotherapy, Suita, Japan

²Miyakojima iGRT Clinic, Radiation Oncology, Osaka, Japan

³Osaka University Graduate School of Medicine, Radiation Oncology, Suita, Japan

Purpose or Objective: Recurrent head and neck cancer (HNC) after radiotherapy or surgery has many problems about salvage treatment options such as surgery, chemotherapy and radiation therapy. Stereotactic radiotherapy is one of the treatment options for inoperable patients. However, in many cases, salvage radiation (SRT) is considered as a re-irradiation, and the treatment results of salvage radiation with a definitive dose for recurrent HNC are still insufficient. This analysis was done to reveal the treatment results and prognostic factors in SRT for both of locoregional and distant recurrences, with definitive treatment dose.

Material and Methods: One hundred and three patients with 43 local, 23 regional and 36 distant recurrences were treated with stereotactic radiotherapy for definitive treatment purpose. Treatment period was between May 1998 and July 2014. Eighteen to 70 Gy were delivered in 3 to 20 fractions. Treatments were delivered with CyberKnife or Novalis

treatment system. There were 59 patients with squamous cell carcinoma, 8 with adenoid cystic carcinoma, 7 with papillary adenocarcinoma and 26 patients with other histological type.

Results: Median follow up period of survivors was 17 months (range 0-103), and the median survival time of all patients was 23 months. At 3 years, actuarial overall survival rate (OS) was 37%, 33% and 23%, and median survival time was 30, 26 and 20 months for local, regional and distant recurrence, respectively (p =0.638). OS was significantly better in the patients with oligo-recurrence (p<0.001) or to whom SRT were done for a lesion previously untreated by surgery (p=0.001). Cox regression analysis indicated that factors of oligo-recurrence and histology except for squamous carcinoma had significant influence on OS. The favorable group having both of the two factors (n=23) showed excellent 5 year survival as 73 % compared with 15% of unfavorable group.

Conclusion: This study showed that SRT with definitive dose achieved equivalent survival regardless of recurrent site and revealed two prognostic factors of oligo-recurrence and non-squamous carcinoma in the SRT for recurrent HNC.

PO-0641

Radiosurgery for intracranial meningioma. A systematic review and meta-analysis

V. Pinzi¹, E. Biagioli², A. Roberto², F. Galli², F. Chiappa², I. Floriani², L. Fariselli¹

¹IRCCS Istituto C. Besta, Neurosurgery Radiotherapy Unit, Milan, Italy

²IRCCS-Istituto di Ricerche Farmacologiche Mario Negri, Laboratory of Clinical Research Department of Oncology, Milan, Italy

Purpose or Objective: Single session radiosurgery (SRS) and staged radiosurgery (sSRS) have been performed in primary and adjuvant settings for intracranial meningioma. Although, different aspects of SRS and sSRS are still controversial above all regarding timing, prescription doses and fractionation of delivery. So far there are no definitive data about treatment-related symptom control and toxicity and categorization. The aim of this systematic review is to summarize the data on the long-term efficacy and safety of SRS and sSRS for meningioma patients.

Material and Methods: Medline and Embase databases were searched for relevant studies published until April 2015. Experimental and observational studies focused on SRS and sSRS for intracranial WHO grade I and II meningioma were included. Studies enrolling a number of patients inferior to five for each arm (for comparative studies) or overall (for non-comparative studies) were excluded. Studies including patients with malignant meningioma (WHO grade III), radio-induced meningioma or patients who had previously undergone brain radiation therapy were excluded from our review. Studies including both benign and malignant meningiomas were considered eligible, provided that results were reported separately, according to histo-pathological subtype. The primary outcomes were disease control and progression-free-survival. The secondary outcomes were symptom control and radiation-induced toxicity.

Results: Thirty-four studies fulfilled eligibility criteria. Only two studies were about sSRS. The estimate of disease control rate ranged from 87.0% to 100.0% at 5 years and from 67.0% to 100.0% at 10 years. The PFS rate ranged from 78.0% to 98.9% and from 53.1% to 97.2% at 5 and 10 years, respectively. No meta-analysis could be performed. We meta-analyzed symptom control and toxicity data. The overall frequency of symptom control was 92.3% (95% CI:88.4-95.6%), the overall toxicity was 8.1% (95% CI:5.2-11.5%). The overall relative frequency of patients with toxicity of 8.1% (95% CI:

5.2-11.5%), again with high heterogeneity (I2=81.0%) among studies.

Conclusion: All included studies have shown some limitations: most of them were retrospective and all were non-comparative; many of them were carried out in absence of a rigorous methodology and only few reported a measure of variability for the primary endpoint. Despite these limitations, we can conclude that SRS appears safe and effective treatment for intracranial meningioma.

PO-0642

Radiosurgery without whole brain radiotherapy in brain metastases from non-small cell lung cancer

P. Anselmo¹, L. Chirico¹, M. Muti¹, M. Basagni¹, F. Trippa¹, R. Rossi¹, L. Draghini¹, F. Arcidiacono¹, M. Italiani¹, M. Casale¹, S. Fabiani¹, C. Giorgi², E. Maranzano¹

¹"S. Maria" Hospital- Terni, Radiation Oncology Centre, Oncology Department, Terni, Italy

²"S. Maria" Hospital- Terni, Oncology Department, Terni, Italy

Purpose or Objective: patients (pts) with 1-4 brain metastases (BM) from non-small cell lung cancer (NSCLC) submitted to radiosurgery (SRS) alone were retrospectively evaluated.

Material and Methods: 130 pts with 207 BM were identified. Pts were treated with a 5-MV linear accelerator fitted with a commercial dynamic μ MLC. Doses were prescribed to isocentre so that at least the 90% isodose line encompassed the target volume. Doses were chosen according to maximum diameter of the tumor as suggested by RTOG Protocol 90-05. Male/female ratio was 90/40, median age was 64 years (range, 31-86). Median KPS was 100% (range, 70-100). 42/130 (32%) pts had extracranial metastases, 83 (64%) pts had a controlled systemic disease, and 47 (36%) progressive disease. Neurologic functional score was generally good (NFS = 0), and only 15 (11.5%) pts had an NFS = 3 or 4. Relapse was defined "in-field" when more than 95% of the recurrence volume was within the original 50% isodose, and "out-field" in the other cases.

Results: In 82 (63%) pts there was only one BM, in remaining 48 (37%) 2-4 BM with a median volume of 0.8cc (range, 0.09-25) Median prescribed dose was 23 Gy (range, 12-25). At a median follow-up of 67 months (range, 24-110), 123 (95%) pts with 197 (95%) BM were evaluable. Local control, evaluated 3 months after SRS, was obtained in 95% of lesions: there were complete remission in 50 (25%), partial remission in 77 (39%), stable disease in 62 (31%), and progression in 13 (5%) BM. During follow up, 63 (51%) pts had no brain progression of disease, 11 (9%) had in-field relapse, 40 (33%) out-field relapse, and 9 (7%) in- and out-field relapse. Of 60 (49%) relapsing pts, 37 (62%) were retreated: 19 with SRS, 15 with whole brain radiotherapy (WBRT), 2 with fractionated stereotactic radiotherapy, and 1 with surgery and WBRT. No SRS-induced late toxicity was registered. At the time of analysis, 119/123 patients (97%) had died, 40 (34%) for brain progression, 72 (60%) for systemic progression and 7 (6%) for non-oncological causes. The median overall survival was 13 months, deaths from brain progression occurred after a median time of 51 months, while from systemic progression after 19 months.

Conclusion: SRS without upfront WBRT is an effective treatment of BM from NSCLC. Since that our results are similar to the best published data on SRS plus WBRT, SRS alone could be considered the treatment of choice in this setting.

PO-0643

Stereotactic hypofractionation in combination with radiosurgery in the treatment of brain metastases

P. Ivanov¹, I. Zubatkina¹, G. Andreev¹

¹International Institute of Biological Systems, Radiosurgery, Saint-Petersburg, Russian Federation

Purpose or Objective: To estimate the clinical results of hypofractionated stereotactic radiotherapy (HSR) alone or in combination with stereotactic radiosurgery (SRS) for the treatment of brain metastases using different radiation devices, which provide precise delivery of a high radiation dose to the target.

Material and Methods: Between November 2010 and July 2015, 257 patients with brain metastases were treated by HSR alone or simultaneous application of two stereotactic radiation techniques (SRS plus HSR) at the Radiosurgical Centre of IIBS (Saint Petersburg, Russia). Radiation treatment was performed with Gamma Knife 4C and Perfexion (Elekta AB, Stockholm, Sweden), Cyber Knife (Accuray, Sunnyvale, CA, USA) and linear accelerator TrueBeam STX (Varian Medical Systems, Palo Alto, CA) equipped with the BrainLAB Exac Trac system. The indications for HSR were determined by the presence of large volume lesions or proximity to critical brain structures. Patients with multiple brain metastases were subjected to a combination of HSR and SRS. Radiation schemes were selected depending on the number of metastases, size, location, proximity to critical brain structures, histological type of primary cancer and the patient's general condition. SRS was performed with the marginal dose of 18 - 24 Gy at 40 - 90 % isodose and HSR was performed with the total dose of 24, 27 or 30 Gy in 3 fractions. Following treatment the patients underwent control MRI examination with standard protocols (2 mm T2 and 1 mm T1 with double contrast enhancement) at 8 weeks and then every 3 months. The median follow-up period was 6 months.

Results: The study revealed that the application of hypofractionated stereotactic radiotherapy for the treatment of large volume or critically located brain metastases provides a high level of local control (12-month local control rate was 83 %). Complications in the form of radiation necrosis occurred in 15 % of patients at a median of 6 months after treatment. The median overall survival for the entire patient cohort was 9 months. There was no statistically significant difference in the median survival of the patients receiving HSR alone and those receiving HSR plus SRS. The best results were obtained in patients belonging to the first RPA-class who achieved two-year survival in 70 % of the cases. The advantage of combining SRS and HSR is the possibility to deliver high radiation doses to large volume lesions, without exceeding the brain's tolerance. HSR allows one to achieve a rapid shrinkage of large volume tumors, which considerably improves the patient's neurological condition.

Conclusion: High-dose stereotactic radiation is a safe and effective method for controlling brain metastases. A combined application of SRS and HSR is a viable treatment strategy for patients with multiple brain metastases who have at least one large lesion or a lesion located in/near critical brain structures.

PO-0644

Hippocampal sparing brain radiotherapy using VMAT to the primary brain tumour

K.S. Kim¹, C.W. Wee¹, J.Y. Seok², J. Hong², J.B. Chung², K.Y. Eom², J.S. Kim², I.A. Kim²

¹Seoul National University College of Medicine, Radiation Oncology, Seoul, Korea Republic of

²Seoul National University Bundang Hospital, Radiation Oncology, Seongnam-si, Korea Republic of

Purpose or Objective: We hypothesized that hippocampal-sparing radiotherapy using volumetric modulated arc therapy (VMAT) could preserve cognitive function of the patients with primary brain tumor treated with brain radiotherapy.

Material and Methods: We prospectively collected patients who were diagnosed with primary brain tumor and treated with brain radiotherapy from March 2014 to April 2015. Brain radiotherapy was delivered using VMAT planning technique with inclined head position. Optimization criteria for the

hippocampus dose was Dmax less than 17Gy without compromising the coverage of planning target volume (PTV) and other organs at risk were prioritized over hippocampal constraint. The mini-mental state examination (MMSE) and Seoul verbal learning test for total recall, delayed recall and recognition (SVLT-TR, DR, R) were performed at baseline and at 7 and 13 or 16 months after radiotherapy.

Results: A total of 41 patients were accrued. Median age was 48 years (range 26-76) and 51.2 % of the patients were male. Eighteen patients (43.9%) had WHO grade I or II tumor whereas 23 patients (56.1%) had grade III or IV tumor. Median volume of PTV was 192.8 cc (range 33.4-522.6) and median prescribed dose was 60Gy (range 46-66). Concurrent chemotherapy was given to 18 patients (43.9%). Median D100% and Dmax to the contralateral hippocampus were 7.7Gy (range 0.6-24.8) and 16.6 Gy (range 3.56-60.4) respectively. Mean dose to contralateral hippocampus could be spared to less than 21 Gy in 39 patients with median value of 11.6 Gy (range 0.3-37.3) which was lower compared to previous documentation. Median value of maximal dose to lenses and eyeballs were 4.3 Gy (0.4-8.1) and 13.7 Gy (0.5-46.6) respectively. At median follow up of 7.8 months (range 0-14.8), median progression-free survival and overall survival were not reached. Cognitive function tests at 7 months were analyzable in 12 patients. For these patients, MMSE, SVLT-TR, SVLT-DR and SVLT-R at 7 months showed improved results compared to the baseline with 2.0% (95% CI, -0.8% to 4.7%), 11.0% (95% CI, 3.3% to 18.8%), 20.1% (-5.5% to 45.8%) and -0.6% (95% CI, -6.6% to 8.2%) increase respectively. No grade 4 or 5 toxicity was reported.

Conclusion: Hippocampus could be spared effectively in radiotherapy to primary brain tumors using VMAT. Despite limited follow up data, cognitive function tests of the patients showed promising results. Further follow up data would clarify the effect of hippocampal sparing on the cognitive function of the patients treated with radiotherapy for primary brain tumor.

PO-0645

18F-FET PET and MRI for treatment planning in glioblastoma

M. Harat¹, B. Malkowski², Z. Okońska³, R. Makarewicz⁴

¹The Franciszek Lukaszczyk Oncology Centre, Radiotherapy, Bydgoszcz, Poland

²The Franciszek Lukaszczyk Oncology Centre, Nuclear Medicine, Bydgoszcz, Poland

³The Franciszek Lukaszczyk Oncology Centre, Medical Physics, Bydgoszcz, Poland

⁴The Franciszek Lukaszczyk Oncology Centre, Oncology and Brachytherapy, Bydgoszcz, Poland

Purpose or Objective: To analyze pre-treatment MRI- and 18F-fluoroethylthiosine-PET- (FET-PET) based target volumes and patterns of failure following radiotherapy (RT) with concurrent temozolomide (TMZ) for primary glioblastoma multiforme (GBM).

Material and Methods: Thirty-four patients with primary GBM were treated using MRI based treatment volumes (GTV_{rm}). Before treatment patients underwent FET PET/CT scans and biological tumor volume (GTV_{pet}) were contoured but not used for target definition. Progression were defined according to RANO criteria. Tumor progression and pre-treatment MRI and PET scans were co-registered to the radiation dose map. Failures were classified based on location of primary GTVs and dose delivered at the site of failure. We investigated volumetric size and uniformity of MRI- vs. FET-PET/CT-derived GTVs and progression patterns assessed by means of FET PET/CT and MRI.

Results: FET-PET based GTVs measured 10 minutes after radionuclide injection (a.r.i.) (median 37.3 cm³) were larger than GTVs measured 60 minutes a.r.i. (median 27,7 cm³). GTV_{pet} were significantly larger than corresponding MRI based GTVs (median 19,3 cm³). The congruence of MRI and FET signals for the identification of glioblastoma GTVs is poor

with mean uniformity index of 0.4 (p=0,0). 74% of failures were located inside primary GTV_{pet}. 68% of failures occurred within the 95% isodose line, and 9% within 60 Gy isodose.

Conclusion: The size and geometrical location of GTVs differed in a majority of patients. The volume of GTV_{pet} depends on time a.r.i. Tumor progression were mostly inside FET-PET volumes. FET PET better defined failure site than MRI. Finally dose inhomogeneity inside GTV_{pet} and GTV_{rm} and favourable tumor control within 60Gy isodose advocates further studies with PET-MR based high-dose radiation therapy of GBM.

PO-0646

Temozolomide during radiotherapy of glioblastoma multiforme: daily administration improves survival
S. Nachbichler¹, G. Schupp¹, H. Ballhausen¹, M. Niyazi¹, C. Belka¹

¹Klinikum der Universität München, Klinik und Poliklinik für Strahlentherapie und Radioonkologie, München, Germany

Purpose or Objective: Temozolomide (TMZ) based chemoradiotherapy defines the current gold standard for the treatment of newly diagnosed glioblastoma. Data regarding the influence of TMZ dose density during chemoradiotherapy are currently not available. We retrospectively compared outcomes in patients receiving no TMZ, patients receiving TMZ during radiotherapy on radiotherapy days only (5/7) and patients receiving TMZ constantly 7 days a week (7/7).

Material and Methods:

From 2002 to 2012 a total of 432 patients with newly diagnosed glioblastoma received radiotherapy in our department. 118 patients had radiotherapy alone, 210 had chemoradiotherapy with temozolomide (75 mg/m² daily (7/7 days a week) and 104 chemoradiotherapy with temozolomide only on radiotherapy days (5/7 days a week, Monday till Friday). Radiotherapy was applied in 30 fractions to a total dose of 60 Gy.

Results: Median survival after radiotherapy alone was 9.1 months, compared to 12.6 months with temozolomide 5/7 and to 15.7 months with temozolomide 7/7. The 1 year survival was 33% in the radiotherapy only group, 52% in the 5/7 group and 64% in the 7/7 group. Kaplan Meier analysis showed a significant improvement of temozolomide 7/7 vs. 5/7 (p=0.01 by the log-rank test), while temozolomide 5/7 was still superior to no temozolomide at all (p=0.02).

Conclusion: Our results confirm the findings of the EORTC/NCIC-trial by Stupp et al., establishing the daily temozolomide chemoradiotherapy as standard therapy for glioblastoma. Also a reduced temozolomide scheme can at first prolong the survival of glioblastoma patients, but not as much as the daily application.

PO-0647

Subventricular zones: new key targets for glioblastoma treatment

J. Khalifa¹, F. Tensaouti², A. Lusque³, B. Plas⁴, J.A. Lotterie², E. Uro-Coste⁵, V. Lubrano⁴, E. Cohen-Jonathan Moyal¹

¹Institut Universitaire du Cancer de Toulouse - Oncopole, Radiation Oncology, Toulouse Cedex 09, France

²INSERM, U825, Toulouse, France

³Institut Universitaire du Cancer de Toulouse - Oncopole, Biostatistics, Toulouse Cedex 09, France

⁴CHU Purpan, Neurosurgery, Toulouse, France

⁵Institut Universitaire du Cancer de Toulouse - Oncopole, Pathology, Toulouse Cedex 09, France

Purpose or Objective: We aimed to identify subventricular zone (SVZ)-related prognostic factors of survival and patterns of relapse among patients with glioblastoma.

Material and Methods: Forty-three patients with primary diagnosed glioblastoma treated in our Cancer Center between 2006 and 2010 were identified. All patients received surgical resection, followed by temozolomide-based

chemoradiation (60 Gy, 2 Gy per fraction). Ipsilateral (iSVZ), contralateral (cSVZ), and bilateral (bSVZ) SVZs were retrospectively segmented following two delineation methods: with (TH+) and without (TH-) temporal horns. Dose-volume histograms were retrospectively generated on the original plans. Progression was defined according to the RANO criteria. Multivariate analysis using the Cox proportional hazards model including significant covariates in univariate analysis was assessed to examine the relationship between prognostic factors and time to progression (TTP).

Results: Median age was 59 years (range: 25-85). Median follow-up, OS and TTP were 52.8 months (95% CI 43.4-61.1), 26.2 months (95% CI 20.3-34.2) and 6.4 months (95% CI 4.4-9.3), respectively. On univariate analysis, initial contact to SVZ was a poor prognostic factor for OS (20.5 vs 56.4 months, $p = 0.011$) and TTP (4.6 vs 12.9 months, $p = 0.002$). With TH-method, patients receiving mean dose to bSVZ greater than 40 Gy had a significantly improved TTP, as well as patients whose V20 Gy to bSVZ was greater than 84% (17.7 months vs 5.2 months, $p = 0.017$). On multivariate analysis, initial contact to SVZ and V20 Gy to bSVZ lesser than 84% remained poor prognostic factors for TTP (HR = 3.07, $p = 0.012$ and HR 2.67, $p = 0.047$, respectively).

Conclusion: Our results suggest that contact to SVZ, as well as insufficient bSVZ coverage such as a V20 Gy lower than 84%, are independent poor prognostic factors for TTP. Therefore, targeting SVZ is of crucial interest for optimizing glioblastoma treatment.

PO-0648

Pilot study in the assessment of contouring variability in stereotactic radiosurgery

H. Sandstrom¹, C. Chung², J. Gårding³, I. Toma-Dasu¹

¹Stockholm University and Karolinska Institutet, Medical Radiation Physics, Stockholm, Sweden

²University of Toronto and University Health Network-Princess Margaret Cancer Centre, Department of Radiation Oncology, Toronto, Canada

³Elekta Instrument AB, Research & Physics- Neuroscience, Stockholm, Sweden

Purpose or Objective: The accuracy in contouring the target is one of the key factors for the success of stereotactic radiosurgery (SRS). This is particularly important when delivering one large fraction of radiation with small or no margins, since the consequence of not defining the correct clinical target volume can be that intended treatment results are not achieved. Furthermore, accurate contouring of the relevant Organs-at-Risk (OARs) is essential to minimize any normal tissue toxicity. The aim of this study was to analyze and quantify the variability of target and OAR contouring for two lesions in the brain.

Material and Methods: A multicenter analysis of the variability in contouring the target and the OARs for two typical cases of brain disorders, a cavernous sinus meningioma and a vestibular schwannoma was performed. Twelve Gamma Knife centers from around the world have participated in the study by contouring the targets and the OARs. The resulting treatment plans were analyzed with respect to the agreement in target and OARs contouring. The 50 %-agreement volume, AV50, and the common volume, AV100, together with the encompassing volume, AV100/N, were determined based on a binary analysis method. A novel metric for the variability in delineation defined as the Agreement-Volume-Index was introduced and additionally calculated. The variability of the contoured structures was also analyzed with respect to the position of their centers of mass (COMs).

Results: Substantial disagreement in target delineation was observed with an Agreement-Volume-Index of 0.22 for the meningioma case and 0.50 for the vestibular schwannoma case, respectively. Very high disagreement was also observed for the delineation as OARs of the optic apparatus and cochlea with an Agreement-Volume-Index ranging from 0 to

0.13. The disagreement was observed with respect to the shape, size and position of the contoured volumes. The resulting disagreement in target volumes was highest for the meningioma (range 5.29-7.80 cm³) while a lower disparity was observed for the schwannoma (range 3.56-4.48 cm³). The majority of structures analyzed displayed the highest disagreement of the COM in longitudinal direction. An illustration of the displacement of the COMs together with the common volume and encompassing volume is shown in Figure 1 for the cavernous sinus meningioma case.

Figure 1. Illustration of the displacement of the COMs (red dots) together with the common volume (blue) and encompassing volume (green) for the cavernous sinus meningioma case.

Conclusion: Differences in target and OARs contouring expressed using different parameters, including a novel metric, emphasize the importance of further investigating and standardizing the contouring in SRS. Therefore, clinically significant differences in target and OARs delineation might lead to the need of better contouring tools, education and standardized protocols in SRS.

PO-0649

Evaluation of distant brain failure among patients undergoing SRS for lung cancer brain metastases

G. Bhattal¹, A. Keller¹, J. Dajac¹, Z. Pavlovic¹, R. Ismail¹, S. Kailas¹, J. Babb¹, T. Buntinx-Krieg¹, T. Do¹, E. Kim¹, A. Sarparast¹, N. Ramakrishna²

¹University of Central Florida, College of Medicine, Orlando, USA

²UF Health Cancer Center-Orlando Health, Dept. of Radiation Oncology, Orlando, USA

Purpose or Objective: The latency, overall extent, and rate, of distant brain failure for non-small cell lung cancer patients undergoing SRS for brain metastases is not well characterized. We evaluated the impact of multiple pre-treatment parameters including age, KPS, extracranial disease status (ECD), initial number of metastases, initial aggregate tumor volume, and histological/molecular subtypes, on distant brain failure. We also evaluated the impact of WBRT performed before, combined with, or after SRS.

Material and Methods: The retrospective study population included 118 NSCLC patients with brain metastases treated with SRS between 11/2008 and 01/2014. The distant brain metastasis-free survival (DBMFS) was defined as latency in months from initial SRS to first subsequent radiographic evidence of new brain metastasis. The extent of overall distant brain failure (ODBF) was defined as the total number of new metastases that developed following initial SRS treatment. The distant brain failure rate (DBFR) was defined as the ODBF/RFI where RFI was defined as the maximum radiographic follow-up interval in months. Kaplan Meir analysis was used to evaluate DBMFS and Log Rank test was used to determine the significance (p -value <0.05 was considered significant). For ODBF and DBFR, Independent

sample t-test and one way ANOVA were used for statistical evaluation.

Results: The median overall DBMFS was 12.9 months. A significant difference in median DBMFS was observed for patients with squamous cell vs. adenocarcinoma primary histology (4.57 months vs. 15.9 months, respectively, $p < 0.015$). The initial number of metastases, total initial metastasis volume, ECD status, KPS scores, EGFR mutation status, or ALK gene rearrangement status, made no significant difference on DBMFS. None of the analyzed parameters displayed significant impact on ODBF. WBRT had no significant effect on DBMFS or ODBF in the study population, but patients with history of WBRT prior to SRS had an increased DBFR (0.396 vs. 0.089) which was borderline significant ($p=0.05$). There was an insufficient number of patients receiving combined WBRT with SRS to determine an effect on distant brain failure vs. SRS alone.

Conclusion: Characterization of the risk of distant brain failure is important to treatment selection, prognosis and follow-up. Among lung cancer patients with brain metastases treated with SRS, our study found no impact from age, initial number/volume of metastases, EGFR/ALK status, or ECD status, on distant brain failure. However, this study did reveal a significantly shorter latency to appearance (DBMFS) of distant brain metastatic disease for patients with squamous vs. adenocarcinoma histology. The clinical prognostic significance of this histologic subtype-dependent difference on distant brain failure is the subject of further study.

PO-0650

Prognostic value of minimal time to peak in dynamic 18F-FET-PET for high-grade glioma re-irradiation

D.F. Fleischmann^{1,3}, M. Unterrainer², P. Bartenstein², C. Belka¹, N.L. Albert², M. Niyazi¹

¹University Hospital of Munich, Radiation Oncology, Munich, Germany

²University Hospital of Munich, Nuclear Medicine, Munich, Germany

³German Cancer Consortium (DKTK), German Cancer Research Center (DKFZ), Heidelberg, Germany

Purpose or Objective: Most high-grade gliomas recur after initial multimodal therapy and re-irradiation has been shown to be a valuable re-treatment option in selected patients. We present the prognostic value of dynamic O-(2-18F-fluoroethyl)-l-tyrosine ([18F]-FET) PET for patients treated with re-irradiation ± concomitant bevacizumab. Dynamic [18F]-FET-PET provides useful information to individualize treatment decisions and personalize risk stratification of patients with high-grade glioma recurrence.

Material and Methods: We retrospectively analyzed 72 patients suffering from recurrent high-grade glioma. Static and dynamic [18F]-FET-PET was performed prior to re-irradiation. PET analysis revealed information about the maximal standardized uptake value (SUVmax) of the tumor corrected for the mean background (BG) (SUVmax/BG), the biologic tumor volume (BTV) and the mean tracer uptake within the BTV (SUVmean/BG). Dynamic parameters such as time-activity-curves (TACs) and minimal time-to-peak (TTPmin) were analyzed. Additional analysis was performed for gender, age, KPS, MGMT methylation status, IDH1 mutational status, WHO grading, concomitant bevacizumab therapy and the number of foci. The influence of PET derived and clinical parameters on post-recurrence survival (PRS) was investigated.

Results: TTPmin had a significant impact on PRS both on univariate ($p=0.027$) and multivariate analysis ($p=0.008$). Shorter TTPmin was related to shorter PRS after re-irradiation with 6 months for TTPmin <12.5 min, 7 months for TTPmin 12.5 - 25 min and 11 months for TTPmin >25 min ($p=0.027$). Other factors significantly related to PRS were number of foci ($p=0.025$), TAC classifications ($p=0.019$; G1-2 vs G3-5), and gender ($p=0.028$).

Conclusion: Dynamic [18F]-FET-PET with TTPmin is of high prognostic value for recurrent high-grade glioma and might help to personalize re-irradiation treatment regimens in future either through PET-guided dose escalation or by combination therapy with targeted agents.

PO-0651

Pattern of failure in glioblastoma patients after FET-PET and MRI-guided chemo-radiotherapy

M. Lundemann Jensen^{1,2}, J. Cardoso Costa^{1,3}, I. Law³, A. Muhic⁴, S.A. Engelholm¹, P. Munck af Rosenschöld^{1,2}

¹Rigshospitalet, Department of Oncology- Section for Radiotherapy, København Ø, Denmark

²University of Copenhagen, Department of Science- Niels Bohr Institute, København Ø, Denmark

³Rigshospitalet, Department of Clinical Physiology- Nuclear Medicine and PET, København Ø, Denmark

⁴Rigshospitalet, Department of Oncology, København Ø, Denmark

Purpose or Objective: The aim of this work is to investigate the pattern of failure for patients with glioblastoma, after FET-PET- and MRI-planned volumetric-modulated arc therapy (VMAT) with concomitant and adjuvant temozolomide (TMZ). Our hypothesis; FET-PET volume will better predict the pattern of failure and the inclusion of FET-PET in the radiation therapy target leads to a decrease in marginal failures.

Material and Methods: We analysed the first 66 consecutive patients with histologically confirmed glioblastoma (WHO grade IV), scanned with FET-PET and MRI for post-surgical radiotherapy planning. Residual tumor volume including the resection cavity, denoted GTV(MR), was manually contoured on contrast-enhanced T1-weighted MRI (cT1). Metabolic tumor volume (GTV(PET)) was semi-automatically delineated by including tissue with uptake exceeding 1.6 times the uptake in normal appearing grey matter and subsequently edited to exclude non-tumor tissue. The CTV was created by adding a uniform margin of up to 2 cm to GTV(MR) and if necessary modified to include GTV(PET) and exclude natural boundaries such as the skull. A dose of 60 Gy was prescribed to the PTV (CTV plus 0.2 cm) in 2 Gy fractions, five days a week, using VMAT. TMZ was administered daily with radiotherapy (75 mg/m²) and subsequently in 6 cycles in a 5 days schedule every 28 days (150-200 mg/m²). The recurrence volume (RV) was evaluated radiologically on follow-up cT1 according to the RANO-criteria. Patterns of failure were classified as central, in-field or marginal if >95%, 80-95% or 20-80% of the RV was located within the 95% isodose (D95%). In case of the appearance of any new lesion outside the D95% or if <20% of the RV was within D95%, the failure was defined as distant. The treatment failure overlap (TFO) for three pre-treatment tumor volumes; GTV(MR), GTV(PET) and the union of the two, denoted GTV(MRPET), were calculated as the intersection of each GTV and RV divided by RV. Differences were assessed using Willcoxon signed rank test.

Results: Sixteen patients were excluded due to; no follow-up imaging (n=6), incomplete RT (n=3), whole-brain irradiation (n=1), clinical deterioration but no sign of radiological progression (n=2) and four patients were progression-free at the time of analysis (median follow-up 38.5 months). All patients were FET-positive. The pattern of failure was central, in-field, marginal and distant in 82%, 10%, 2% and 6%, respectively. The TFO were in median 0.73, 0.34 and 0.87 for GTV(MR), GTV(PET) and GTV(MRPET), respectively. All TFO were significantly different ($p < 0.001$).

Conclusion: The inclusion of FET in radiotherapy planning leads to fewer marginal failures compared to previously reported studies. FET-PET alone is not better than MRI to predict the pattern of failure in glioblastoma patients. However, the combination of the two appears better than either of the modalities alone.

PO-0652

SFRT of the resection cavity in patients with one to three brain metastases

A. Bilger¹, H. Lorenz¹, D. Milanovic¹, O. Oehlke¹, A.L. Grosu¹
¹University Medical Center Freiburg, Department of Radiation Oncology, Freiburg, Germany

Purpose or Objective: In patients undergoing surgical resection of brain metastasis local recurrence is about 60%. Whole brain Radiation Therapy (WBRT) can significantly reduce the risk of local relapse but fails to improve overall survival. The most important side effects of WBRT are neurocognitive deficits, which can reduce quality of life. The goal of this study is to evaluate the role of stereotactic fractionated radiotherapy (SFRT) in patients with one to three brain metastases after surgical resection.

Material and Methods: We performed a retrospective single-institutional study in 60 patients undergoing SFRT of surgical cavity after resection of ≤ 3 brain metastases (November 2009 - August 2013). The total irradiation dose was 30 Gy (5Gy/d, BED 45 Gy) after complete macroscopical resection and 35 Gy (5Gy/d, BED 52.5 Gy) in patients with macroscopic residual tumour after surgery. Macroscopic residual tumour was defined as contrast enhancement next to the resection cavity on the postoperative T1-MRI. We investigated local control (LC) as a primary endpoint. Intracranial distant intracranial tumour control (DC), overall survival (OS) and side effects were secondary endpoints.

Results: The median follow-up for 52 patients was 8 months (1 to 32 months). 8 patients were lost to follow-up, due to mortality or morbidity. There were 6 (11.5%) local failures and 29 (55.8%) distant failures. Local control was correlated with age ($p=0.046$). Thirty-seven of 60 (61.7%) patients died during follow-up. Median overall survival was 15 months. Cox regression for survival was significant for KPS score $\leq 70\%$ and size of PTV. No severe side effects were seen. Patients undergoing whole brain radiation therapy (WBRT) as salvage therapy in case of progression had no severe side effects.

Conclusion: SFRT could be an alternative to WBRT after surgical resection of brain metastasis. We had an encouraging rate of local control. Due to the high rate of distant intracranial failure regular follow-up with MRI is mandatory. No Grade 3, 4 or 5 adverse events were reported in patients undergoing WBRT or additional Stereotactic Radiotherapy as salvage therapy in case of intracranial progression. Prospective studies are warranted.

PO-0653

Surgical interventions after previous SBRT of the spine - increased risk for complications?

J. Roesch¹, J. Cho², D.K. Fahim³, J.C. Flickinger⁴, P.C. Gerszten⁵, I.S. Grills³, M.S. Jawad³, R. Kersh⁶, D. Letourneau⁷, F. Mantel⁸, A. Sahgal⁹, J.H. Shin¹⁰, B. Winey¹¹, M. Guckenberger¹

⁹Sunnybrook Health Sciences Centre, Department of Radiation Oncology, Toronto, Canada

¹⁰Massachusetts General Hospital, Department of Neurosurgery, Boston- Massachusetts, USA

¹¹Massachusetts General Hospital, Department of Radiation Oncology, Boston- Massachusetts, USA

Purpose or Objective: Stereotactic body radiotherapy (SBRT) of vertebral metastases has emerged as a promising methodology, offering high rates of symptom relief and local control combined with low risk of toxicity. Nonetheless, local failure or spinal instability may occur, generating the need for subsequent surgery in the irradiated region. This study evaluated whether there is an increased incidence of intra- and post-surgical complications after high-dose radiotherapy.

Material and Methods: Based on a retrospective international database of 704 cases of SBRT for vertebral metastases, 42 patients treated at 7 different institutions were identified who underwent surgery in a previously stereotactic irradiated region. Data regarding surgical characteristics and complications were available for 38 patients.

Results: Twenty women, 13 men, median age 59 years (range 27 to 84 years) underwent SBRT for vertebral metastases followed by surgery. In 18 cases, conventional radiotherapy had been delivered prior to SBRT at a median dose of 30 Gy in median 10 fractions. SBRT was most frequently administered in 1 fraction with a mean prescription dose of 20,9 Gy (mean EQD2/10 = 45,3Gy). The median time until the surgical intervention was performed was 7.5 months after SBRT. The most frequent reason for surgery was progressive pain (n=35) followed by progressive neurological deterioration (N=20) or fracture of the vertebral body (n=16). Therefore, open surgical decompression (n=29) and/or stabilization (n=22) were the most frequently performed surgical procedures. Increased fibrosis complicating the operation was explicitly stated in the surgical report in 5 cases. In 3 patients a durotomy occurred which could be sufficiently sealed during the operation in two cases and required surgical revision in 1 case. Median blood loss was 425 ml, but 5 patients had a blood loss of $>1l$ during the procedure. After the operation, 2 patients suffered from an increased neurological deficit which could be explained by an epidural hematoma in one case. Delayed wound healing was reported in 4 cases. In one patient this lasted for 5 months after surgery until death. One patient died shortly after the surgical procedure due to unknown causes.

Conclusion: In this largest series of surgical interventions following spine SBRT, the overall complication rate was 45%. This appears to be higher when compared to primary surgery without previous SBRT. Therefore, spine surgery after SBRT is technically feasible. However, the decision to perform surgical procedures in these highly complex cases should be made by a multidisciplinary team and their performance in an experienced center may be beneficial.

PO-0654

Hypofractionated Stereotactic RS for patients with brain metastases. Outcome evaluation and toxicity

P. Navarria¹, A. Ascolese¹, G. D'agostino¹, E. Villa¹, E. Clerici¹, A. Tozzi¹, C. Iftode¹, F. De Rose¹, L. Liardo¹, T. Comito¹, C. Franzese¹, D. Franceschini¹, F. Pessina², M. Riva², L. Bello², G. Reggioni¹, M. Scorsetti¹

¹Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

²Istituto Clinico Humanitas, Neurosurgery, Rozzano Milan, Italy

Purpose or Objective: Hypofractionated Stereotactic radiosurgery (HSRS) delivered in few fractions, up to 5, has been employed in patients with large brain metastases (BM), alone or after surgical resection on tumor bed, as an alternative to whole brain radiotherapy or to single fraction SRS with the aim to reduce late radiation-induced toxicity while maintaining high local control rate. The aim of this study was to evaluate the outcome and toxicity of patients treated for large brain metastases using HSRS, in terms of local control, incidence of distant brain metastases (DBM) and toxicity

Material and Methods: Between July 2001 and July 2015, 138 patients, 66 men and 72 women, with large brain metastases from different solid tumors have been treated with HSRT, using Volumetric Modulated Arc Therapy Rapid-Arc (VMAT-RA) in flattening filter-free (FFF) beams mode. The total doses prescribed were 30 Gy in 3 fractions or 30 Gy in 5 fractions in relation to the size and site of BM or 30 Gy in 3 fractions on tumor bed in patients underwent surgical resection.

Results: At a median follow-up time of 10.6 months (range 2-53 months) 6 (4%) patients had local relapse at a median time of 8 months (range 2-53 months) and 45 (32%) patients distant brain progression at a median time of 8 months (range 2-26 months). The 1- and 2-year local control rates were 90% and 87% respectively. The 1- and 2-year survival rates were 72% and 42% respectively. At the last observation time 99 (71.7%) patients were alive and 39 (28.3%) dead. Eighty-five percent of patients succumbed to their extracranial disease and 15% died of progressive intracranial disease. During HSRS no increases of corticosteroid or AED have been needed. No symptomatic radionecrosis was observed. Factors recorded as influencing local failure and worse survival were the presence of metastases at diagnosis, NSCLC histology and impossibility to surgical resection

Conclusion: HSRS is a safe and effective treatment option for patients with large brain metastases. In our series better local control was recorded in case of metachronous BM, breast cancer histology and patients suitable for surgical resection followed by HSRT.

PO-0655

Targeted therapy and stereotactic radiotherapy in brain metastases from renal cell carcinoma

P. Anselmo¹, C. Caserta², M. Casale¹, F. Trippa¹, F. Arcidiacono¹, L. Draghini¹, F. Roila², E. Maranzano¹

¹Ospedale Santa Maria, Radiotherapy Oncology Centre, Terni, Italy

²Ospedale Santa Maria, Medical Oncology Centre, Terni, Italy

Purpose or Objective: To retrospectively evaluate safety and brain control (BC) in patients (pts) with 1-4 brain metastases (BM) from renal cell carcinoma (RCC) submitted to radiosurgery (RS) or fractionated stereotactic radiotherapy (FSRT) with or without target therapies (TTs).

Material and Methods: 46 pts with 74 BM were treated. Male/female ratio was 31/15, median age was 62y (range, 29-76). Median KPS was 100% (range, 50-100), 14 (37%), 27 (59%) and 2 (4%) pts were in RPA class 1, 2 and 3, respectively, and 37 (80%) pts had extracranial metastases. Disease was controlled in 28 (61%) and in progression in 18 (39%) pts. Neurologic functional score was generally good (NFS=0-2) having only 5 (11%) NFS=3. Relapse was defined "in-field" when more than 95% of the recurrence volume was within the original 50% isodose, and "out-field" in the other cases. Median number of irradiated BM per patient was 1 (range, 1-4). 37 (80%) pts with 63 BM (85%) received RS at a median dose of 20Gy (range, 15-25). Remaining 9 (20%) with 11 lesions (15%) were underwent FSRT at a dose of 5x6-7Gy. 21 (46%) pts did not receive TTs, 19 (46%) received concomitant and 6 (8%) post-irradiation TTs (sunitinib, sorafenib, pazopanib, mTOR inhibitors, bevacizumab).

Results: At a median follow-up of 19 months (range, 1-51), 41 (89%) pts with 66 (89%) BM were evaluable. Local control was obtained in 96% of BM: there were complete remission in 29 (44%), partial remission in 25 (38%), stable disease in 9 (14%), and progression in 3 (4%) BM. During follow up, 21 (51%) pts had no brain progression, 4 (10%) had in-field relapse, 15 (37%) out-field relapse, and 1 (2%) in- and out-field relapse. Of 20 (49%) relapsing pts, 14 (70%) were retreated with RS, surgery, WBRT and FSRT (8, 3, 2 and 1, respectively). In-field relapse occurred after a median time of 21.5, out-field relapse after a median time of 8 months. At the time of analysis, 39/41 pts (95%) had died, 9 (22%) for brain progression, 30 (73%) for systemic progression. Global

median duration of BC was 22 months (range, 3-51) and global median OS from irradiation was 19 months (range, 4-53). No difference in outcome and toxicity was registered comparing pts receiving or not TTs. Deaths due to brain or systemic progression occurred after a median time of 12 and 20 months, respectively.

Conclusion: Effectiveness of RS and FSRT in RCC BM was confirmed. The addition of concomitant TTs, though safety, does not seem to improve outcomes.

PO-0656

Radiosurgery in brain metastases: a mono-institutional experience

E. Pelle¹, E. Trino¹, M. Levis¹, C. Mantovani¹, U. Ricardi¹

¹University of Turin, Radiotherapy, Turin, Italy

Purpose or Objective: to evaluate the local control and survival in patients with brain metastases treated with stereotactic radiosurgery (SRS) as primary treatment approach and to identify predictors of distant brain failure (DBF)

Material and Methods: from 2010 to 2014 three hundred and eleven brain metastases in 204 consecutive patients were treated with SRS at University of Turin. Patients eligible for SRS had one to five brain lesions, metastases size ≥ 3 cm, Karnofsky performance status ≥ 70 and life expectancy ≥ 3 months. A total of 172 patients with 266 brain metastases were analysed. Doses ranged from 18-24 Gy in single fraction related to lesion size. Local control (LC), overall survival (OS) and distant brain failure were estimated using the Kaplan-Meier method. Univariate and multivariate analysis were performed to determine the prognostic factors for treatment outcomes and DBF

Results: the median follow-up was 24.9 months. The 6- and 12- month local control rates were 88.5% and 75.1% respectively. 46 patients recurred locally after SRS on 55 brain metastases, with a median time to local failure of 12.1 months. The median overall survival was 12.8 months, with 6- and 12- months OS rates of 74.5% and 53.8% respectively. On multivariate analysis, no significant prognostic factors were associated with local control and survival outcome, even if RPA class (I versus II) and metastases diameter showed a trend of significance for OS ($p=0.11$ e $p=0.10$ respectively). A distant brain failure was observed in 88 patients (43.2%), with a median time to DBF of 5.5 months. 60.8% of these patients maintained an oligometastatic intracranial disease (≤ 5 brain lesions), while 39.2% of patients developed multiple brain metastases. Salvage therapy was delivered in 46.5% of DBF patients, consisting of WBRT in 28.4% of cases and SRS on metastases of new onset in 18.1% of patients. However, more than half of patients with DBF (53.5%) did not require any salvage treatment. Prognostic factors significantly associated with prolonged DBF-free survival on multivariate analysis included the number of brain metastases < 2 ($p=0.000$) and breast primary ($p=0.026$). Tumor size ≤ 10 mm, stable extracranial disease and oligometastatic brain failure were significant predictive factors for survival after DBF.

Conclusion: stereotactic radiosurgery is an effective and well-tolerated treatment option in patients with oligometastatic disease. SRS might also represent a valid salvage strategy in patients relapsing in order to delay or completely avoid WBRT.

PO-0657

Does Radiomics have prognostic value in glioblastoma?

I. Compter¹, R.T.H. Leijenaar¹, D.B.P. Eekers¹, J.D. Zindler¹, A. Hoeben², B. Küsters³, J. Beckervordersandforth³, L. Ackermans⁴, O.E.M.G. Schijns⁴, M. Anten⁵, A.A. Postma⁶, P. Lambin¹

¹MAASTRO clinic, Dept. of Radiation Oncology, Maastricht, The Netherlands

²Maastricht University Medical Centre, Dept. of Medical Oncology, Maastricht, The Netherlands

³Maastricht University Medical Centre, Dept. of Pathology, Maastricht, The Netherlands
⁴Maastricht University Medical Centre, Dept. of Neurosurgery, Maastricht, The Netherlands
⁵Maastricht University Medical Centre, Dept. of Neurology, Maastricht, The Netherlands
⁶Maastricht University Medical Centre, Dept. of Radiology, Maastricht, The Netherlands

Purpose or Objective: Radiomics is the high-throughput extraction of large amounts of features from radiographic images and allows to capture intra-tumoral heterogeneity in a non-invasive way. It can therefore have an important role in predicting clinical outcome and has the potential to support personalized medicine for the treatment of different types of cancer. The value of Radiomics has already been shown for head-and-neck- and non-small cell lung cancer. In this study we assess the prognostic value of CT Radiomics in glioblastoma (GBM) patients.

Material and Methods: Clinical data were obtained from 125 patients with a GBM, diagnosed with a biopsy only and treated with radiotherapy +/- TMZ between 2004 and 2015 at our institute. Patients underwent pre-treatment CT imaging and the tumor volume was manually delineated for treatment planning purposes. Pretreatment images from 74 patients were available for analysis. In total, 161 Radiomic features were extracted, comprising: a) first-order statistics, b) shape, and c) (multiscale) texture. Multivariable Cox proportional hazards (Cox PH) regression was performed using least absolute shrinkage and selection operator (LASSO) model selection (100 times 10-fold cross-validated). First, a Cox PH model consisting of only clinical features was fitted. A second model consisted of both clinical and Radiomic features, for which the Radiomic feature space was first reduced by selecting cluster medoids after hierarchical cluster analysis using correlation ($\rho > 0.9$) as a distance measure. Harrell's concordance index (C-index; 500 times bootstrapped) and time dependent AUC curves were used to assess model performance.

Results: At a median follow up of 7.4 months, 8 (11%) of the patients were still alive at time of analysis. Mean age was 64 years (20 - 86). WHO performance status was <2 for 82%. Sixty-six percent of patients was concurrently treated with TMZ. Median overall survival was 6.5 months after treatment. The time-dependent AUC curves for the clinical model (C-index: 0.65) and the model including Radiomics (C-index: 0.71) are shown in Figure 1, Table 1. Incorporation of Radiomic features resulted in an overall higher time-dependent AUC curve and significantly higher C-index.

Conclusion: Radiomics has the potential to predict outcome using the pre-treatment CT and possibly identify clinical subgroups which can support personalized treatment for GBM. Additionally the dataset will be expanded to MR imaging, the leading imaging modality in GBM.

PO-0658
Linear accelerator radiosurgery for arteriovenous malformations: a single institution experience
 S. Yahya¹, G. Heyes¹, P. Nightingale², S. Lamin², G. Cruickshank², I. Geh¹, D. Spooner¹, P. Sanghera¹
¹Hall-Edwards Radiotherapy Research Group- Queen Elizabeth Hospital, Cancer Center, Birmingham, United Kingdom
²Queen Elizabeth Hospital, University Hospitals Birmingham, Birmingham, United Kingdom

Purpose or Objective: Arteriovenous malformations (AVMs) are the leading causing of intra-cerebral haemorrhage. Stereotactic radiosurgery (SRS) is an established treatment for arteriovenous malformations (AVM) and commonly delivered using Gamma Knife. Linear accelerator (LINAC) SRS is often more widely available however there is debate over whether it offer equivalent outcomes. The aim of this project is to evaluate the outcomes using LINAC SRS for AVMs within a large UK neurosciences unit.

Material and Methods: Fifty sequentially treated patients with an AVM were identified from a prospective SRS database at a tertiary university hospital with a neurosciences unit. Planning was performed using BrainLab's BrainScan 5.3.1 treatment planning system, utilising a rigid fixed headframe and radiographic localisation box to determine target coordinates. Treatment was performed using multiple co-planar arcs delivered with a Varian600C linear accelerator at 6MV fitted with the BrainLab external stereotactic collimator system (fixed cones 10-35mm diameter). A review of all imaging was undertaken by a neurovascular radiologist to confirm obliteration and post SRS necrosis. A retrospective review of case notes was undertaken to confirm toxicity which was recorded using CTCAE Version 4. All outcomes were correlated prospectively recorded dose metrics.

Results: Forty six patients data analysed with median follow up of 5 years (1-14 years). Median age at first SRS treatment was 37.5 years (15-71 years) with 24 male and 22 female patients. Median lesion volume treated was 1.97cm³ (mean 2.81cm³ range 0.11-19.50). The median radiosurgery dose was 19.9Gy (range 13.0 - 28.7). The median normal brain volume V12Gy was 5.86cm³ and the median gradient index was 4.4 (2-9.9). Overall obliteration rate at 3 years was 71.7%. The overall incidence of CTCAE v 4 grade 3 or 4 toxicity was 6.5%. One patient presented with cognitive and mobility decline 3 years after treatment and was diagnosed with hydrocephalus. One patient had recurrent bi-frontal headaches with nausea and vomiting (MRI showed necrosis). One patient had refractory epilepsy (parietal AVM) although no imaging features present to support necrosis.

Conclusion: LINAC based SRS offers similar outcomes in terms of obliteration and toxicity to other platforms. Recent

developments in imaging and technology may further improve the therapeutic index.

PO-0659

Impact of 68Ga-Dotatoc-PET on tumor delineation and outcome in patients with meningioma

H. Fischer¹, K. Kessel^{1,2}, T. Pyka³, M. Devečka¹, M. Schwaiger³, S.E. Combs^{1,2}

¹Technische Universität München TUM, Department of Radiation Oncology, München, Germany

²Institute of Innovative Radiotherapy IRT, Helmholtz Zentrum München, München, Germany

³Technische Universität München TUM, Department of Nuclear Medicine, München, Germany

Purpose or Objective: Surgery represents the treatment of choice for meningiomas. However, complete resection is often not possible, and recurrence is common. Radiation therapy (RT) can be prescribed as an alternative treatment to surgery for low-grade meningiomas, or in the recurrent/adjuvant setting. Differentiation between normal tissue, i.e. meninges, post-operative changes and residual viable tumor can be difficult using MR and CT imaging alone. We evaluated the impact of 68Ga-Dotatoc-PET imaging on treatment planning including potential benefit in terms of outcome.

Material and Methods: We analyzed 15 patients with WHO I meningiomas of different localizations. All patients were treated with fractionated stereotactic radiotherapy (FSRT) with a total dose of 54 Gy and a single dose of 1.8 Gy. An advanced radiation oncologist delineated gross tumor volume (GTV) independently once based on diagnostic CT and MRI only (GTV_MR/CT), and a second time complemented by data of diagnostic 68Ga-Dotatoc-PET (GTV_PET). For image fusion and target definition BrainLab iPlan RT® software (Munich, Germany) was used. The intersection and union volumes of both GTVs (GTV_inter, GTV_union), were calculated.

Results: In 11 of 15 patients (73%) the additional data gained by 68Ga-Dotatoc-PET led to a larger GTV. In four patients (27%) GTV_PET was smaller than GTV_MR/CT. The mean intersection of both GTVs was 58.6%. Hence, 41.4% of the GTV_PET was contributed only due to information from 68Ga-Dotatoc-PET. About 22.6% of the GTV_MR/CT was not delineated in the GTV_PET volume because no increased tracer enhancement could be detected in these parts. Our first analyses of overall and progression free survival showed no significance in patients with a 68Ga-Dotatoc-PET for tumor delineation during treatment planning.

Conclusion: 68Ga-Dotatoc-PET improves the detection of residual or recurrent tumor cells especially in patients with meningioma of the skull base and the sphenoorbital region. In addition it helps to spare normal tissue in patients with large tissue defects after operation. However, the interobserver variability must be taken into account. The data will now be correlated with OS and further analyzed concerning the standard uptake values (SUV) of the PET-images to assess if a threshold value can be recommended for meningioma detection and delineation.

PO-0660

Evaluation of distant brain failure among patients undergoing SRS for melanoma brain metastases

S. Kailas¹, E. Kim¹, A. Sarparast¹, P. Adedoyin¹, A. Keller¹, G. Bhattal¹, R. Ismail¹, J. Babb¹, T. Buntinx-Krieg¹, J. Dajac¹, T. Do¹, Z. Pavlovic¹, N. Ramakrishna²

¹University of Central Florida, College of Medicine, Orlando, USA

²UF Health Cancer Center-Orlando Health, Dept. of Radiation Oncology, Orlando, USA

Purpose or Objective: The latency, overall extent, and rate, of distant brain failure for patients undergoing SRS for melanoma brain metastases is not well characterized. We evaluated the impact of multiple pre-treatment parameters including age, KPS, gender, extracranial disease status (ECD),

initial number of metastases, initial aggregate tumor volume, and B-raf V600E status, on distant brain failure. We also evaluated the impact of WBRT performed before, combined with, or after SRS.

Material and Methods: The retrospective study population included 54 melanoma patients with brain metastases treated with SRS between 11/2008 and 01/2014. The distant brain metastasis-free survival (DBMFS) was defined as latency in months from initial SRS to first subsequent radiographic evidence of new brain metastasis. The extent of overall distant brain failure (ODBF) was defined as the total number of new metastases that developed following initial SRS treatment. The distant brain failure rate (DBFR) was defined as the ODBF/RFI, where RFI was defined as the maximum radiographic follow-up interval in months. Kaplan Meir analysis was used to evaluate DBMFS and Log Rank test was used to determine the significance (p-value <0.05 was considered significant). For ODBF and DBFR, Independent sample t-test and one-way ANOVA were used for statistical evaluation.

Results: The median overall DBMFS was 5.69 months. A significant difference in median DBMFS was observed for patients with KPS<70 vs KPS >70 (2.24 vs. 10.44 months, p <0.022). Females had significantly worse DBMFS than males (5.96 vs. 17.96 months, p<0.009). The initial number of metastases, total initial metastasis volume, ECD status, and B-raf V600E mutation status, were associated with no significant difference in DBMFS. The ODBF was also worse for females than males (P<0.002). The DBFR was worse for females (p<0.049), and those with c-kit mutation (P<0.024). WBRT had no significant effect on DBMFS, ODBF or DBFR in the study population.

Conclusion: Characterization of the risk of distant brain failure is important to treatment selection, prognosis and follow-up. Among patients with melanoma brain metastases treated with SRS, our study found that female gender and a KPS<70 was associated with a significantly decreased latency to distant brain failure. In addition, female gender was associated with greater overall number of distant brain metastases and rate of distant brain failure. Mutations in c-kit but not b-raf were found to be associated with increased distant brain failure. Further study is underway to examine the overall clinical prognostic relevance of these findings.

PO-0661

Gliosarcoma: prognostic and therapeutics factors

¹¹Centre Paul Strauss, Radiotherapy, Strasbourg, France

¹²Centre Eugène Marquis, Oncology, Rennes Cedex, France

Purpose or Objective: In concern gliosarcoma management, the aims of this multicentre retrospective study were to identify prognostic or therapeutic factors impacting on overall survival.

Material and Methods: The analysis included all the patients treated for gliosarcoma between 1998 and 2014 in seven French academic centres.

Results: Seventy-five patients with a median age of 60 years (range from 23 to 79 years) were treated with a combination of surgery (n=66), radiotherapy (adjuvant for 64 patients and exclusive for 8 patients) and temozolomide based chemotherapy (n=58). Median follow-up was 12 months (range from 2 to 71 months). Two-year overall survival (OS) and disease free survival rates were 12% (95% CI: 4-20%) and 2% (95% IC: 0-6%), respectively. The median OS was 13 months. Treatment at recurrence consisted of chemotherapy (n=38) (bevacizumab for 18 patients, resumed temozolomide for 10 patients), salvage surgery (n=8) and radiochemotherapy (n=1). In univariate analysis, younger age, high total dose of radiotherapy, long time to recurrence and treatment at recurrence increased significantly OS. In multivariate analysis, high total dose of radiotherapy (HR = 0.97, p=0.007) and treatment at recurrence (HR=0.28 p<0.001) were favourable prognostic factor of OS.

Conclusion: High dose of radiotherapy and salvage surgery increase OS of gliosarcoma.

¹⁰Nara Medical School Hospital, Radiation Oncology, Nara, Japan

¹¹Cancer Institute Hospital JFCR, Radiation Oncology, Tokyo, Japan

Purpose or Objective: JCOG0211 study demonstrated that the 5-year local control, 5-y OS and 5-y PFS of patients treated with RT-DeVIC were 94, 70 and 63%, respectively. NKEA project (UMIN000015491) conducted a multi-institutional retrospective study to clarify the changing current practice of the treatment for Extranodal natural killer(NK)/T-cell lymphoma nasal type(ENKL) over the first decade of this century in Japan, reviewing detailed information on treatment, clinical features and prognosis of patients with ENKL. The aim of this sub-study is to investigate the relationship between local failure patterns and radiation therapy before and after JCOG0211 study.

Material and Methods: Selection criteria of NKEA survey are newly pathologically diagnosed ENKL, any stage, and any type of treatment and treated from 2000 to 2013. From 32 institutions, more than 384 data of patients with ENKL have been registering in the NKEA project database. Of them, radiation therapy (RT) data, focusing on CTV setting, of 233 patients with localized nasal ENKL were evaluated with the JROSG-lymphoma committee.

Results: The baseline patients characteristics were followings, median age was 58 years old (range 18-88), male dominant (2:1), stage I/II=162/66(2.4:1). The median dose of RT was 50 Gy (range 9-60), delivering median 25 (range 3-33) fractionation over 37 (range 9-106) days. The 3D-CRT (CT

based RT planning) was applied in 88% of patients and IMRT in 3%, using shrinking technique; 70%. RT was interrupted with 15% of patients due to hematological and mucosal toxicities. After JCOG0211 study, 49% of RT was designed according to JCOG0211 RT protocol, while 80% or more were not compliant RT protocol before/during JCOG0211. The local control was 74% for all population, 88% of local control rate was observed in patients treated with RT compliant with JCOG0211 RT protocol (extended RT), while 70% in patients not compliant with JCOG RT protocol (small field/limited RT). Based on the results of RT-QA review; we would like proposed the CTV guideline for IMRT/VMAT.

Conclusion: A multi-institutional retrospective survey after prospective clinical trial is important to review how the results of trial influence on the community standard practice of the treatment for rare lymphoma, and observance of radiation therapy guidance. The extended RT had higher local control rate than small limited RT.

PO-0663

Treatment result of primary thyroid lymphoma; a single institute experience

N. Yoshikawa¹, T. Shimbo¹, H. Yoshioka¹, K. Yoshida¹, Y. Uesugi¹, Y. Narumi¹

¹Osaka Medical College, Radiology, Takatsuki, Japan

Purpose or Objective: Primary thyroid lymphoma (PTL) is a relatively rare entity of extra-nodal lymphoma. There was no randomized clinical trial and the optimal treatment is not established. The purpose of this retrospective study is to verify the effectiveness and safety of our treatment protocol with long term follow-up.

Material and Methods: The stage IE - IIE PTL patients treated with combined treatment including radiotherapy and followed up at least three years were eligible for this retrospective study. We used CHOP or CHOP-like regimens with or without rituximab. Chemotherapy was not administered to the patients who were IEA MALToma treated in or after 2007 or have a contraindication to it. Acute and late toxicities were graded by CTCAE v4.0.

Results: Seventy-two PTL patients were analyzed and median follow-up period was 91 months (37 - 238 m). The doses of radiotherapy were 36 - 61.2 Gy (median 41.4Gy). Seven-year overall survival and cause specific survival were 98.6 % and 92.2 %, respectively. Recurrences were observed in 7 patients; five of them were retreated (chemotherapy +/- radiotherapy) and four patients achieved complete remission. Three patients died during follow-up; 2 of them due to malignant lymphoma, one due to breast cancer. Grade 3 dermatitis, mucositis and pneumonitis were observed in 11 patients (15.2 %), 4 patients (5.5 %) and 3 patients (4.2 %), respectively. Two patients experienced grade 3 late toxicities (dyspnea and laryngeal edema), but we judged they were less relevant to the treatment. Laryngeal carcinomas which located in field of radiotherapy were appeared in two patients.

Conclusion: Effectiveness and safety of our treatment protocol were excellent. Because PTL patients are expected to have long term survival, we should optimize our treatment strategy to minimize acute and late toxicities and patients' quality of life.

PO-0664

Outcome of radiotherapy for stage I and II follicular lymphoma in patients staged by 18 FDG PET-CT

J.L. Brady^{1,2}, S.F. Barrington³, V. Warbey⁴, N.G. Mikhaeel^{1,2}

¹Guy's and St. Thomas' NHS Foundation Trust, Department of Clinical Oncology, London, United Kingdom

²King's Health Partners, Academic Health Sciences Centre, London, United Kingdom

³King's College, PET Imaging Centre at St Thomas' Hospital-Division of Imaging Sciences and Biomedical Engineering, London, United Kingdom

⁴King's College, PET Imaging Centre at St Thomas' Hospital-Division of Imaging Sciences and Biomedical Engineering, London, United Kingdom

Purpose or Objective: The majority of patients with follicular lymphoma (FL) present with advanced disease and are considered incurable. For patients with localised stage I or contiguous stage II, radiotherapy (RT) may be curative, but a significant proportion will relapse, usually at distant sites. Historical series report progression free survival (PFS) rates at 5 & 10 years post RT of 50-60% and 40-50% respectively. PET-CT using Fluorodeoxyglucose (FDG) is superior to CT for staging of FL, with upstaging reported in 10-60% of patients. PET-CT has recently been recommended as the standard imaging modality for staging of FL.

By measuring outcomes in patients who underwent radical RT for stage I/II FL staged by PET-CT, this study aims to test the hypothesis that more accurate staging improves selection for localised RT and consequent patient outcome.

Material and Methods: A retrospective review was undertaken of all patients who underwent radical RT for stage I and II FL (grade 1, 2, 3a) at our institution from 2006-2014 staged by PET-CT. Patients were newly diagnosed and had not received any prior systemic or radiation therapy. Sex, age, PET-CT stage, LDH level, FLIPI score were recorded and whether a bone marrow trephine (BMT) was performed. RT site and dose were documented. Outcomes included relapse within the radiation field, distant relapse and PFS.

Results: Between July 2006 and November 2014, twenty-seven patients received radical involved field RT for stage I or contiguous stage II FL. 11 were male and 16 female. Median age (range) at RT was 59 years (32-84). 11 patients had grade 1 FL, 5 grade 1-2, 7 grade 2 and 5 grade 3a. 23 of 27 (85.2%) had Ann Arbor stage I disease by PET-CT. 23/27 (85.2%) had a BMT prior to treatment. In 3 cases BMT was not performed and in 1 the sample was inadequate. FLIPI score was 0-1 in all cases. The radiation dose was 24Gy/12# or 30.6Gy/17#, with the majority receiving 30.6Gy (23/27, 85.2%).

With a median follow up of 59.6 months (10.6-104), 23/27 (85.2%) remain free of relapse either within or outside the radiation field. There have been no in-field recurrences. 4 patients (14.8%) have relapsed at distant nodal sites. The 4 relapses occurred at 3, 3, 9 and 25 months post treatment. 5 year PFS estimate was 84.75% (95% CI 71.01- 98.59) (see figure 1). For patients with stage 1 by PET-CT, 5 year PFS estimate was 90.87% (95% CI 68.2-97.9) and for those with stage 2, 50% (95% CI 6.6-.84.2). All patients were alive at completion of the study.

Conclusion: PFS after local RT for stage I/II FL staged by PET-CT appears to be better than for those historically staged by CT. Longer follow up and more patients are needed to confirm our findings, but this study suggests that earlier series from the pre-PET-CT era may have underestimated the efficacy of RT as a curative treatment for truly localised FL.

PO-0665

Compliance with ILROG guidelines in the treatment of extranodal lymphomas: an internal plans review

C. Furlan¹, P. Bulian², M. Michieli², M. Trovo¹, A. Ermacora³, M. Spina⁴, U. Tirelli⁴, F. Franchin¹

¹Centro di Riferimento Oncologico, Radiation Oncology, Aviano, Italy

²Centro di Riferimento Oncologico, Hematology, Aviano, Italy

³Azienda Ospedaliera Santa Maria degli Angeli, Hematology, Pordenone, Italy

⁴Centro di Riferimento Oncologico, Medical Oncology, Aviano, Italy

Purpose or Objective: In 2015 the International Lymphoma Radiation Oncology Group (ILROG) has published guidelines on field and dose for modern radiotherapy in extranodal lymphomas. Involved site radiation therapy (ISRT) is recommended, and for most cases, ISRT results in smaller radiation fields than the involved-field radiation (IFRT) used previously. We analyzed our treatment plans to determine the compliance to ILROG guidelines in extranodal lymphomas.

Material and Methods: This retrospective study is based on the medical records of 62 patients with extranodal lymphoma, who were treated with definitive radiotherapy at our institute between 2011 and 2014. The patients characteristics are shown in Table 1. After evaluating the compliance to ILROG guidelines for each RT plan, Fisher's exact test was performed to determine factors associated with non-standard treatment including tumor site, histology, and radiation technique (IMRT vs. conventional technique). We calculated the progression free survival (PFS) by site and histology, and compared our findings to reference data retrieved from the IELSG trials.

Table 1. Clinical characteristics of patients and treatment modality

Patients	62
Age (range)	65 years (33-86 years)
Sex	
Male	26 (58%)
Female	26 (42%)
Histology	
DL BCL	34 (55%)
T cell anaplastic large cell	2 (8%)
T cell N/K	1 (2%)
MZL	8 (13%)
FL	9 (14%)
Mucosis Fungoides	5 (8%)
Stage	
I-II	47 (76%)
III-IV	15 (24%)
IP1	
0-1	48 (78%)
>1	14 (22%)
Site	
Skin	21 (34%)
Pharynx	7 (11%)
Perianasal Sinuses	3 (5%)
Testis	3 (8%)
Brain	5 (8%)
Bone	4 (6%)
Stomach	4 (6%)
Salivary gland	3 (5%)
Breast	3 (5%)
Orbital	3 (5%)
Soft tissue	3 (5%)
Thyroid	1 (2%)
Comorbidity index (ACE27)	
1	43 (70%)
2-3	19 (30%)
E COG performance status	
0-1	57 (92%)
2	5 (8%)
Prior chemotherapy	
Yes	34 (56%)
No	28 (44%)
Median radiation dose (range)	30 Gy (24 - 46 Gy)
IFRT	
Yes	19 (30%)
NO	43 (70%)

Results: Forty-four (71%) patients were treated according to ILROG guidelines, and eighteen did not receive a standard treatment, either due to non standard treatment volume (n=13) or due to radiation dose (n=5). The major deviations from ILROG guidelines were observed in patients affected by pharynx lymphoma and orbital lymphoma. All patients with pharynx lymphoma underwent whole-Waldeyer ring RT instead of ISRT, while all patients with orbital lymphoma underwent partial-orbital RT instead of recommended whole-orbital RT. The majority (61%) of patients managed with nonstandard treatment were treated with IMRT technique. PFS by site and histology were similar to those reported in the IELSG trials.

Conclusion: This plans review process resulted in a high compliance to ILROG guidelines (71%). We identified a subset of patients which did not receive a standard treatment, therefore we are revising our treatment policy for pharynx lymphoma and orbital lymphoma.

PO-0666

Comparing the efficacy of low-dose radiotherapy in patients with aggressive and indolent lymphomas

C. Furlan¹, P. Bulian², M. Michieli², M. Spina³, A. Ermacora⁴, M. Trovo¹, U. Tirelli³, G. Franchin¹

¹Centro di Riferimento Oncologico, Radiation Oncology, Aviano, Italy

²Centro di Riferimento Oncologico, Hematology, Aviano, Italy

³Centro di Riferimento Oncologico, Medical Oncology, Aviano, Italy

⁴Azienda Ospedaliera Santa Maria degli Angeli, Hematology, Pordenone, Italy

Purpose or Objective: Low-dose radiotherapy (LDRT) is a highly effective treatment in indolent non-Hodgkin lymphomas (NHLs). However, a reduced efficacy in aggressive lymphomas has never been demonstrated. We aimed to assess the effect of histologic type on disease response to LDRT.

Material and Methods: Data from a clinical phase-II trial using LDRT for palliation in diffuse large B-cell lymphoma (DLBCL) patients were compared with clinical outcome of patients with follicular lymphoma (FL), marginal zone lymphoma (MZ), and mycosis fungoides (MF) which were treated with LDRT at our Institution in the same period. LDRT consisted of 4 Gy in 2 fractions on symptomatic areas only for both DLBCL and indolent NHLs. Bulky disease was defined as > 5 cm in maximum diameter. Chemoresistance was defined as the failure of chemo to achieve a complete or partial response, or as disease relapse after a complete response. Clinical response was assessed 21 days after LDRT, and was defined as reduction > 50% of maximum diameter of the radiated lesions. Response evaluation was performed with CT-scan or clinical exam for palpable lesion. Toxicity was scored using the CTCAE v3.0.

Results: In all, 35 patients were evaluated. Sixteen were male; histologies were 17 DLBCL, 8 FL, 6 MZ, and 4 MF. Characteristics were generally balanced between the two groups. However, DLBCL patients were more likely to have bulky disease and chemoresistance. Median follow up was 7 months (range, 1 - 49 months). No significant difference was noted concerning overall response rate between DLBCL and indolent NHLs (overall response rate was 70% (12/17) and 83% (15/18) for patients with aggressive and indolent forms, respectively; $p = 0.39$), but indolent forms were associated with a higher rate of complete response (complete response rate was 61% (11/18) and 35% (6/17) for patients with indolent and aggressive NHL, respectively; $p = 0.09$). Only 1 case of toxicity was noted (grade 2 nausea). The median duration of response was 7 months (range, 1 - 35 months). Among responders, only 2 patients progressed within the radiated field at the time of last follow-up visit.

Conclusion: Efficacy of LDRT for DLBCL and indolent NHL patients resulted comparable in terms of overall response rate. Complete response rate was higher in the indolent NHL population than in the subset of DLBCL patients included in the phase II trial.

PO-0667

Second malignancies after TBI in AHCT for relapsed follicular lymphoma

S. Tisseverasinghe¹, R. Samant¹, M. Sabloff², Y. Xu³, C. Bredeson², L. Huebsch², P. Genest¹, P. Cross¹

¹University of Ottawa and The Ottawa Hospital, Radiation Oncology, Ottawa, Canada

²University of Ottawa and The Ottawa Hospital, Haematology, Ottawa, Canada

³Ottawa Hospital Research Institute, Epidemiology, Ottawa, Canada

Purpose or Objective: Follicular lymphoma (FL) is an indolent disease with a progressive relapsing course. Autologous hematopoietic cell transplantation (AHCT) has been proven to be effective in treating recurrences. At The Ottawa Hospital (TOH), AHCT utilizing total body irradiation

(TBI) has been used to treat FL patients, who have progressed after at least one course of chemotherapy, for over 20 years. There are concerns in the literature regarding the use of TBI due to the potential for radiation-induced second malignancies. However, we hypothesize that TBI based conditioning regimens should not lead to excessive second cancers. We undertook a review of our large single-institution AHCT experience in order to assess patient outcomes and rates of second malignancy.

Material and Methods: We retrospectively reviewed consecutive patients undergoing AHCT for relapsed FL from July 1991 to February 2013. All patients received treatment at TOH, a regional tertiary center. The most common pre-AHCT conditioning regimen was Etoposide 60 mg/kg / Melphalan 140 mg/m² / TBI. Patients received TBI on a linear accelerator using high energy photons (10MV or 18MV) and utilizing a translating bed technique. 92% received 5 Gy / 1fraction / 1day, the rest received 12 Gy / 6 fractions / 3 days. Lung attenuators were used for all patients to maintain a homogeneous dose. Patient information was stored in our bone marrow transplant registry database. This includes baseline characteristics, demographics, outcomes, types and dates of second cancers. Descriptive statistics were calculated for all relevant demographic variables. Overall survival of the cohort was estimated using the Kaplan-Meier method. Cumulative incidence of second malignancy was calculated; death was a competing risk.

Results: Overall, we evaluated 174 patients with a median age of 50 years at transplant. There were 106 men and 68 women included, and median follow-up was 6.0 years after AHCT. Overall survival at 1, 5, 10 and 15 years was 93%, 73%, 57% and 47% respectively. The median follow-up among survivors was 8.3 years. Eighteen of 174 patients (10.3%) developed a second malignancy. Of these, 11 (6.3%) had solid tumors, 2 (1.1%) had AML and 5 (2.9%) developed myelodysplastic syndrome. Median time to second malignancy was 7.2 years, with cumulative incidences of developing second cancer at approximately 4.5% and 8.2% at 5 and 10 years. Solid tumors included breast (2), prostate (3), endometrial (1), skin (4) and lung cancers (1). Furthermore, 82% of patients who developed solid tumors were alive at last follow-up.

Conclusion: Our results with AHCT utilizing TBI in the management of relapsed FL patients have been very good. Indeed, most patients survive more than 10 years after treatment. The risk of second cancers is acceptable and compares favorably with the published literature. Moreover, we suspect screening, particularly for solid tumors post-treatment, may help detect early treatable second malignancies.

PO-0668

Outcome of low and intermediate dose radiotherapy in head and neck MALT lymphoma

F. Rahman¹, J. Brady¹, S. Galli¹, N.G. Mikhaeel¹

¹Guy's and St Thomas' NHS Foundation Trust and King's Health Partners Academic Health Sciences Centre, Department of Clinical Oncology, London, United Kingdom

Purpose or Objective: Mucosa-associated lymphoid tissue (MALT) lymphoma can present in several sites in the head and neck and is often treated with radiotherapy. MALT lymphoma of the salivary and lacrimal glands is >300 fold more common in patients with Sjogren's syndrome (SS) than in the rest of the population and tends to be a multifocal process. The optimal dose of radiotherapy is not established. The aim of this study is to analyse the outcome of radiotherapy for head and neck MALT lymphoma in patients with and without SS.

Material and Methods: A retrospective review of departmental records identified 26 patients with head & neck MALT lymphoma treated with radiotherapy between 2003-2013. Inclusion criteria were histologically proven MALT lymphoma and complete radiotherapy record. The primary end-points were objective response rate and response

duration. Median age was 61 years (range 30-83). Fourteen patients had confirmed SS. Eighteen patients were female (12 with SS) and 8 were male (2 with SS). Stage of disease includes: stage 1 (17 patients) stage 2 (7), stage 3 (1) and stage 4 (1). Patients with SS were treated with 4Gy and patients without SS were treated with 25.2Gy, unless they had advanced stage. Sites treated include: parotid (13 patients), orbit or conjunctiva (6), thyroid (1), tongue (1), palate (4) & spine (1) Indications for treatment included pain, recurrent inflammation or unsightly mass. 17 patients received 4 Gy in 2 fractions (13 with SS) and 9 patients received 25.2 Gy in 14 fractions (1 with SS).

Results: The objective response rate (ORR= CR + PR, assessed 6 weeks after RT) was 100%. Twenty-two patients (84.6%) remain progression-free at the time of writing with median FU of 89 months (range 22 - 144). Two males (1 with SS) and one female had disease progression in the treated area at 3, 36 and 19 months respectively. All 3 relapses occurred in 4Gy dose group. Two patients were subsequently retreated with further 4Gy/2# and 20Gy/5# and achieved further progression-free survival of 36 and 60 months respectively. One female patient (4Gy/2#) underwent transformation to diffuse large B-cell lymphoma at 36 months. The distribution of relapses is summarised in table 1. Radiotherapy was well tolerated in all patients, with the most common long-term side effect being dry mouth in 3 patients (11.5%), cataract in 1 patient and watery eye in 1 patient. All three patients who reported dry mouth were known to have SS.

Conclusion: Radiotherapy is a very effective treatment for head and neck MALT lymphoma resulting in high response rate, durable local control and minimal toxicity. There were no relapses after 25.2Gy and only few relapses (3/17) after 4Gy, 2 of which had durable remission following re-treatment.

Table 1: distribution of relapses

	SS (no of relapses)	No SS (no of relapses)	Total
4Gy	13 (2)	4 (1, *1)	17
25.2Gy	1	8	9
Total	14	12	26

* transformation to DLBCL

PO-0669

Risk of second malignant neoplasms among long-term survivors of extranodal NK/T-cell lymphoma

B. Chen¹, Y.X. Li¹, W.H. Wang¹, J. Jin¹, S.L. Wang¹, Y.P. Liu¹, Y.W. Song¹, H. Fang¹, H. Ren¹, Q.F. Liu¹, R.Y. Wu¹, Y. Yang¹, X.F. Liu¹, Z.H. Yu¹

¹Cancer Hospital- Chinese Academy of Medical Sciences & Peking Union Medical College, Department of Radiation Oncology, Beijing, China

Purpose or Objective: The purpose of this study was to estimate risk and incidence of second malignant neoplasms (SMN) among long-term survivors of early stage extranodal nasal-type natural killer/T-cell lymphoma (NKTCL).

Material and Methods: Between January 1983 and December 2007, 174 patients with stage IE and IIE NKTCL survived 3 or more years after treatment. Of them, 50 patients were treated with radiotherapy alone, 120 patients with combined modality therapy, and 4 patients with chemotherapy alone. The China 2010 population census data and Segi's world population data were used for calculating the age-standardized cancer incidence rates.

Results: Median follow-up time was 8.3 years (range, 3.1 - 35.6 years) for all patients. Nine (5.2%) SMNs were recorded. The median time to SMN was 12.6 years (range, 0.9 - 18.5 years) from diagnosis of NKTCL. Seven patients had solid tumors, and 2 had other type of malignant lymphomas. The cumulative incidence rates at 5-year, 10-year and 15-year were 1.2%, 2.4%, and 13.7% (Figure), respectively. The crude incidence was 531.6/105 person-years, the age-standardized rates by Chinese standard population (ASR China) and by world standard population (ASR world) were 294.5/105 and

243.7/105, and the cumulative incidence rate (0-74 age years old) was 22.4%. All of them were higher than the cancer incidence rates for general population in China in 2010.

Conclusion: A frequency of SMN in patients with NKTCL is higher than expected in the general population. The patients have more risk for SMN during 10 to 15 years after diagnosis of NKTCL. Patients with long-term survivor are at higher risk of SMN and should be carefully follow-up.

PO-0670

Efficacy of low dose radiotherapy in relapsed or refractory high grade non Hodgkin lymphoma

J.L. Brady^{1,2}, H. Attallah³, N.G. Mikhael^{1,2}

¹Guy's and St.Thomas' Hospital NHS Foundation Trust, Department of Clinical Oncology, London, United Kingdom

²King's Health Partners, Academic Health Sciences Centre, London, United Kingdom

³Maadi Military Hospital, Department of Clinical Oncology and Radiotherapy, Cairo, Egypt

Purpose or Objective: Low dose radiotherapy (LDRT) provides effective palliation and local disease control in patients with low grade non Hodgkin lymphoma (LGNHL). Its role in high grade NHL (HGNHL) remains unclear.

The purpose of this study was to evaluate the efficacy of LDRT in relapsed/refractory (RR) HGNHL.

Material and Methods: We performed a retrospective review of all patients undergoing LDRT for RR HGNHL at our institution. LDRT was defined as a total dose of 8Gy or less in 1 or more fractions.

Sex, age, histological type, time from diagnosis to LDRT and number of prior systemic therapies were recorded, along with radiotherapy dose and site treated.

Outcomes included overall response rate (ORR), in field recurrence, time to progression (TTP) and overall survival from completion of RT. Toxicity was also recorded. Analysis was performed by site and by patient as a number of patients had more than 1 site treated at different times.

Results: Between August 2004 and September 2015 15 patients received LDRT for HGNHL. 5 patients had >1 site treated, with LDRT being given to 37 sites in total. Most patients (12/15) had a diagnosis of diffuse large B cell lymphoma, which accounted for 32/37 (86.5%) of all sites. Patient and treatment characteristics are shown in table 1.

Table 1. Patient and treatment characteristics

Patient characteristics	
Total number of patients	15
Total number of sites	37
Sex	
Male	9
Female	6
Median age at treatment in years (range)	73 (54-88)
Histological subtype	
Diffuse large B cell lymphoma	12 (32 sites)
Mantle cell lymphoma	3 (6 sites)
Median time from diagnosis to LDRT in months (range)	11.8 (0.23-195.1)
Median number of prior systemic therapies (range)	2 (1-7)
Treatment characteristics	
Site treated (n=37)	
Nodal	6
Extra-nodal (parotid, stomach, brain, orbit and oropharynx)	7
Skin	19
Bone	5
Radiotherapy dose/number of fractions	
4Gy/1	1
4Gy/2	15
6Gy/1	1
8Gy/1	2
8Gy/2	16
8Gy/4	2

Overall response rate (ORR) for all sites was 89.2% (33/37 sites). 17 sites (45.9%) achieved a complete response (CR) and 16 sites (43.2%) a partial response. 4 sites (10.8%) did not respond to LDRT. Considering ORR by patient, 11/15 patients (73.3%) had a response to LDRT at all sites, 3/15 (20%) did not respond and 1 patient responded at 2 sites but not the 3rd.

Skin was the most commonly treated site (19/37, 51.4%) and skin sites had the highest ORR at 100%, with 73.7% (14/19) CR. This was statistically significant when compared to all other sites ($p=0.046$). ORR for nodal sites was 83.3% (5/6) and extra-nodal sites was 85.7% (6/7). Bone sites had the lowest ORR at 60% (3/5 cases) with no CR.

16 sites received a total dose of 4Gy in 1 or 2 fractions. 21 sites received either 6 or 8Gy in total. ORR in both groups was similar (87.5% versus 90.5%, $p=1$). Toxicity from LDRT was minimal, with no toxicity recorded above grade 2.

Of the 33 initially responding sites there have been 4 infield recurrences (12.1%). Median TTP was 4.8 months (3.1-11.8). 2 sites were retreated with further symptomatic benefit. Median duration of response was 3.6 months (0.5-126.7). 6 sites (2 patients) had responses lasting >30 months. The majority of patients died without documented local recurrence, with median overall survival from LDRT of 2.4 months (0.03-126.7).

Conclusion: LDRT is an effective palliative treatment for patients with RR HG NHL and anticipated short survival, achieving high response rates and excellent local control, with minimal toxicity and inconvenience. A small subgroup of patients with slowly relapsing disease derived durable remissions with LDRT.

PO-0671

Risk of cardiac damage after mediastinal radiotherapy for Hodgkin's disease

M. Buglione¹, F. Trevisan¹, L. Baushi¹, M. Triggiani², N. Pasinetti¹, A. Alghisi¹, D. Greco¹, A. Papa¹, L. Spiazzi³, P. Borghetti¹, S. Nodari², S. Magrini¹

¹University and Spedali Civili di Brescia, Radiotherapy Unit, Brescia, Italy

²University and Spedali Civili di Brescia, Cardiology Unit, Brescia, Italy

³Spedali Civili di Brescia, Medical Physics, Brescia, Italy

Purpose or Objective: Hodgkin lymphoma (HL) has become a highly curable lymphoid malignancy. The improved prognosis of HL has been accompanied by increasing incidence of adverse late effects. Mediastinal radiotherapy (RT) and cardiotoxic chemotherapy (CT) with anthracyclines are

routinely used to treat HL, but they could be associated with a variety of cardiovascular complications in long-term HL survivors. The aim of this study is to evaluate the late cardiovascular toxicity of a series of 202 patients treated from 1995 to 2012.

Material and Methods: 420 patients (pts) were treated for HL with RT +/- CT at our institution from 1995 to 2012. All the alive patients were contacted and invited to participate to the study. A detailed medical history of the 202 pts who accepted and subscribed informed consent was obtained, collecting events occurred after treatment; they had medical examination, ECG, Echocardiogram TT and blood tests. Treatment features were extracted from medical records. The entire group was divided in two groups: 157 pts received mediastinal RT (cases) and 45 pts did not (controls). The cardiac events were categorized using CTCAE ver. 4.0. A preliminary descriptive statistic using SPSS® software (x2 test) has been performed and here presented. The contouring of the different cardiac structures for dosimetric evaluation is ongoing.

Results: The patients and therapeutic characteristics of the patients are summarized in Table 1. After a median follow-up of 8 years (range 2-20 years) 144 pts (71,3%) manifested cardiac alterations: 1,0% arrhythmia, 2,5% ischemia, 1,5% heart failure and 66,3% valvular fibrosis without statistical differences between cases and controls. Most patients (75,4%) had asymptomatic grade I-II valvular fibrosis; only one had grade III valvular fibrosis. After treatment, with a median follow up time of 11,2 years, (range 4,1-17,8 years), acute myocardial infarction occurred in 5 pts, all in the group of cases.

Ten years experience of breast reconstruction after mastectomy in previously irradiated patients

A. Di Donato¹, E. Ippolito¹, R.M. D'Angelillo¹, A. Sicilia¹, E. Molfese¹, P. Trecca¹, S. Ramella¹, L. Trodella¹, B. Cagli², M. Barone²

¹Campus Bio-Medico University, Radiotherapy, Roma, Italy

²Campus Bio-Medico University, Plastic and Reconstructive Surgery, Roma, Italy

Purpose or Objective: To evaluate the rate of complications and the aesthetic outcome in previously irradiated patients who underwent mastectomy and subsequent prosthetic reconstruction in 2 times.

Material and Methods: Eighty-three patients who underwent immediate postmastectomy reconstruction with tissue expander between January of 2003 and June of 2012 at the Campus Bio-Medico University Hospital in Rome were retrospectively divided into two groups: Group A (study group) included 30 patients with previous quadrantectomy and radiotherapy who underwent salvage mastectomy after local recurrence and Group B (control group) included 53 patients submitted to primary radical mastectomy. Patients and disease characteristics were analysed and complications were correlated to treatment group.

Results: The median follow-up time for the whole group was 36 months (range= 12-144 months). Between group A and group B, there were no significant differences in terms of age, body mass index, comorbidities, pathological stage, treatments data (p=NS). In Group A 25/30 patients (83.33%) completed heterologous reconstruction. In 5 patients (16.67%) a conversion to combined or solely autologous reconstruction was needed. In Group B, 52/53 patients (98.11%) completed heterologous reconstruction. In 1 case (1.88%) the expander was removed due to infection and an autologous reconstruction was performed. Revision surgery was needed in 5 patients (9.4%). Autologous salvage reconstruction was more frequent for Group A patients (relative risk 10.4, p=0.02). The overall rate of complications was not different between the two groups (66.6% vs 58.5%; p=0.49) even if major complications (vast necrosis of mastectomy flaps with or without partial implant exposure, with or without implant removal, all III and IV-degree capsular contractures, either requiring or not requiring further surgery) were non significantly higher in the irradiated group (53.3% vs 32.0%; p= 0.07). However, analysing capsular contracture, a significantly higher risk of grade III-IV were recorded in Group A (40% vs 15%; relative risk 3.75, p=0.02). In Group A the median time from RT to reconstruction was 24 months (range= 9-192 months) and the incidence of major complications was not related to time from RT to reconstruction (p=0.313).

Conclusion: Heterologous reconstruction after salvage mastectomy in previously irradiated patients, is still possible with satisfactory results.

PO-0673

Common European mitochondrial haplogroups in the risk of RT-induced breast fibrosis

L. Deantonio¹, S. Terrazzino², S. Cargnin², L. Donis¹, C. Pisani¹, L. Masini¹, G. Gambaro¹, P. Canonico², A. Genazzani², M. Krengli¹

¹University Hospital Maggiore della Carità, Radiotherapy, Novara, Italy

²University of Piemonte Orientale, Department of Pharmaceutical Sciences, Novara, Italy

Purpose or Objective: Germline polymorphisms in oxidative stress response genes have been postulated to be involved in

the development of late normal tissue complications following radiotherapy. Despite the key role of mitochondria in the production of reactive oxygen species, the contribution of mitochondrial DNA variations to clinical radiosensitivity is still largely unknown. In the present study, we evaluated the association between mitochondrial DNA haplogroups and the risk of radiation-induced subcutaneous fibrosis after postoperative radiotherapy in breast cancer patients.

Material and Methods: Subcutaneous fibrosis was scored according to the Late Effects of Normal Tissue-Subjective Objective Management Analytical (LENT-SOMA) scale in 286 Italian breast cancer patients who received radiotherapy after breast conserving surgery. Eight mitochondrial DNA (mtDNA) SNPs that define the nine major haplogroups in the European population were determined by PCR-RFLP analysis on genomic DNA extracted from peripheral blood.

Results: In a Kaplan-Meier analysis evaluated by the log-rank test, carriers of haplogroup H were found at lower risk of grade ≥2 subcutaneous fibrosis (P=0.018). In the multivariate Cox regression analysis adjusted for clinical factors (BMI, breast diameter, adjuvant treatment, dose per fraction, radiation type and acute skin toxicity), the haplogroup H emerged as significant protective factor for moderate to severe radiation-induced fibrosis (HR: 0.50, 95% CI 0.27-0.92, P=0.027).

Conclusion: Our results support a protective role of the mitochondrial haplogroup H in the development of radiation-induced fibrosis in breast cancer patients. Further prospective studies with larger sample size and different populations are nevertheless warranted to corroborate the possible influence of mitochondrial haplogroups on late normal tissue radiosensitivity.

PO-0674

Factors influencing patient reported cosmetic outcome: results of the Young Boost Trial

P. Brouwers¹, E. Van Werkhoven², J. Van Loon¹, P. Poortmans³, H. Bartelink², L. Boersma¹

¹MAASTRO clinic, Department of Radiation Oncology, Maastricht, The Netherlands

²The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

³Radboud University Medical Center, Department of Radiation Oncology, Nijmegen, The Netherlands

Purpose or Objective: The Young Boost trial (YBT), a multicenter RCT (NCT00212121), investigates whether a higher boost dose leads to a lower recurrence rate in young patients treated with breast conserving therapy. Cosmetic outcome is the secondary objective. The aim of the current analysis is to investigate the factors influencing the patients' opinion about cosmesis.

Material and Methods: From 2004-2011, 2421 breast cancer patients ≤ 50 yrs were included in The Netherlands, France, and Germany. All patients were treated with lumpectomy, followed by 50 Gy whole breast irradiation. Patients were randomized to receive a standard 16 Gy (n=1211) or a high 26 Gy boost (n=1210) to the tumour bed. Cosmetic outcome data at 4 years of 807 patients were used for the current analysis according to the following two scoring systems:

1. BCCT.core: Digital photographs were analyzed using a software program to extract an overall cosmetic score: excellent, good, fair or poor. This score is based on symmetry, skin color and scar visibility. The 7 features of symmetry in the BCCT.core program are: nipple position (pBRA), level of lower breast contour (pLBC), level of nipple (pUNR), distance from nipple to inframammary fold (pBCE), length of breast contour (pBCD), area of the breast (pBAD) and non-overlapping area between left and right breast (pBOD). 2. Patients' score using a validated patient's questionnaire about the breast appearance, including an overall score: very satisfied, satisfied, not dissatisfied, dissatisfied or very dissatisfied. First, we analyzed the 7 features of BCCT.core in a proportional odds model, to

investigate which parameters were related to the patients' opinion about cosmesis. In addition, we analyzed whether firmness, presence of rib pain or quality of life (QoL) aspects (EORTC QLQ C-30 questionnaire) at 4 years were related to the patients' opinion on cosmetic outcome.

Results: Of the 7 BCCT.core parameters, pBCE and pBCD were significantly related to patients' score at 4 years. Patients with any difference in firmness rated their cosmesis worse than patients without any difference, even when the objective score (i.e. BCCT.core) was similar. This effect was larger by increasing difference. Worse perception of cosmetic outcome was also independently related to lower global QoL, lower emotional functioning and higher scores in the depression scale. The presence of rib pain had no influence.

Conclusion: The patients' opinion on cosmetic outcome was significantly related to objective parameters like distance from nipple to inframammary fold (pBCE) and length of breast contour (pBCD), but also to subjective factors, i.e. severity of firmness, depressive feelings, global QoL and emotional functioning.

PO-0675

Radical radiotherapy in oligometastatic breast cancer patients

M. Trovo¹, C. Furlan¹, M. Berretta², L. Militello², S. Spazzapan², J. Polesel³, A. Del Conte⁴, S. Arcangeli⁵, A. Fiorentino⁶, G. Franchin¹

¹Centro di Riferimento Oncologico, Radiation Oncology, Aviano, Italy

²Centro di Riferimento Oncologico, Medical Oncology, Aviano, Italy

³Centro di Riferimento Oncologico, Epidemiology, Aviano, Italy

⁴Pordenone General Hospital, Medical Oncology, Pordenone, Italy

⁵San Camillo Hospital, Radiation Oncology, Rome, Italy

⁶Sacro Cuore - Negrar, Radiation Oncology, Negrar, Italy

Purpose or Objective: The primary endpoint of this phase II study was to determine the progression-free survival (PFS) of oligometastatic breast cancer patients treated with radical radiotherapy to all metastatic sites.

Material and Methods: Patients affected by oligometastatic breast cancer were enrolled in this phase II trial. Inclusion criteria were the following: 1) histologically confirmed diagnosis of breast cancer, 2) 5 or fewer metastatic lesions, 3) no brain metastases, 4) primary tumor controlled. Radiotherapeutic treatment was SBRT (30-45 Gy in 3 fractions) or fractionated IMRT (40-60 Gy in 15-25 fractions). Primary endpoint was PFS; secondary endpoints were local-control (LC), overall survival (OS), and toxicity, which was assessed using the CTCAE v4.0 scale.

Results: The analysis was conducted on 37 patients. The median age was 55 years. Twenty-five (68%) had oligometastatic disease at diagnosis, and 12 (32%) had the oligometastatic status induced by systemic treatment. Sixteen (43%) patients had a single metastasis, and 21 (47%) had 2 or more lesions. Thirty-one (84%) patients were treated with SBRT and 6 (16%) with fractionated IMRT. With a median follow-up of 18 months, 1-year and 2-year PFS was 74% and 44%, respectively. No differences were seen in PFS between patients with only 1 metastases vs. those with ≥ 2 metastases, or between patients treated with SBRT vs. fractionated IMRT. Only two patients experienced local failure. One of these two patients had an isolated local failure for a spinal lesion that was treated with a minimum dose of 17 Gy in 3 fractions (being the spinal cord constraint prior on the PTV coverage). Two-year LC was 96%. Two patients died of disease, and 2-year OS was 96%. The proposed treatment was well tolerated; no Grade 3 toxicity was documented. Two patients experienced Grade 2 pain, 4 Grade 1 pain, and 2 developed Grade 2 fatigue.

Conclusion: Radical radiotherapy delivered to all the metastatic sites in oligometastatic breast cancer patients led to promising results in terms of local control and progression-free survival. Treatment was well tolerated. The results of this study may motivate for conducting phase III trials.

PO-0676

Impact of IMN irradiation on the right coronary artery and OAR in right-sided post-mastectomy patients

K. Rock¹, A. Barry¹, M. Rahman¹, M. Pintilie¹, C.A. Koch¹

¹Princess Margaret Cancer Centre, Department of Radiation Oncology, Toronto, Canada

Purpose or Objective: Previous studies have shown an increased risk of ischemic heart disease in breast cancer patients treated with radiotherapy (RT). It has recently been reported that the risk of major coronary events increases per gray of mean radiation dose delivered to the heart for patients undergoing either left- or right-sided breast RT. However, the anatomy of cardiovascular damage related to right-sided breast RT has not been well-described, specifically for radiation dose delivered to the right coronary artery (RCA). This may be of particular relevance for regional nodal irradiation that includes the internal mammary nodes (IMNs). In this prospective planning study, the impact of IMN irradiation on the RCA and organs at risk (OAR) in patients undergoing right-sided post-mastectomy RT (PMRT) was assessed.

Material and Methods: CT simulation scans of 60 right-sided post-mastectomy patients were identified from an institutional database. In 30 cases, the IMNs were contoured from the 1st to 3rd intercostal space with a PTV of 5 mm. The RCA, heart, lungs and contralateral breast were delineated as OARs. A four-field modified wide tangent photon plan was created encompassing the chestwall, IMNs, supraclavicular fossa and axilla. For the remaining 30 patients (control group), a four-field plan that excluded the IMNs was generated. All patients were planned to receive 50 Gy in 25 fractions over 5 weeks. Doses were compared between the two groups utilizing the Mann-Whitney test to determine whether there was a statistically significant difference in dose to OARs between these groups.

Results: In the group with IMN treatment, 95% of prescribed dose to the IMN PTV covered a median volume of 99% (range 90-100). There was a significant increase in dose to the RCA in the IMN treated group compared to the control group. The maximum dose to the RCA (3.33 Gy vs 2.35 Gy, $p < 0.0001$) and mean RCA dose (2.41 Gy vs 1.69 Gy, $p < 0.0001$) were both increased. Similarly, the mean heart dose (MHD) was increased (1.3 Gy vs 1.09 Gy, $p < 0.022$). Inclusion of the IMNs increased lung V20 (18 Gy vs 15 Gy, $p < 0.00021$) and mean lung dose (9.1 Gy vs 8.09 Gy, $p < 0.00051$). There was a significant increase in the volume of contralateral breast receiving 3 Gy in the group requiring IMN treatment (3.75 Gy vs 0 Gy, $p < 0.0001$).

Conclusion: Inclusion of the IMNs in patients undergoing PMRT significantly increases radiation dose to the RCA and MHD. An acceptable dose to the RCA has not been well-established but should be as low as is reasonably achievable. The dose and clinical implications of radiation to the RCA needs further evaluation in prospective studies utilizing techniques to minimize cardiac exposure.

PO-0677

Comparing detailed cardiac structure dose-volume metrics in supine versus prone breast irradiation

C. Luo¹, J. Otton^{1,2}, V. Batumalai^{1,3,4}, E.M. Pogson^{3,4,5}, K. Dundas^{3,4,5}, L. Holloway^{1,3,4,5,6}, W. Xuan⁴, G.P. Delaney^{1,3,4}, L. Thomas^{1,2}, D.H. Tran², G. Liney^{1,3,4,5}, E.S. Koh^{1,3,4}

²Liverpool Hospital, Department of Cardiology, Sydney, Australia

³Liverpool Hospital, Cancer Therapy Centre, Sydney, Australia

⁴Ingham Institute for Applied Medical Research, Ingham Institute, Sydney, Australia

⁵University of Wollongong, Centre for Medical Radiation Physics, Wollongong, Australia

⁶University of Sydney, Institute of Medical Physics, Sydney, Australia

Purpose or Objective: To compare radiation dosimetry of various cardiac structures and other thoracic tissue, such as lung fields and non-treated breast, associated with breast irradiation (left versus right-sided) in supine versus prone treatment positions.

Material and Methods: Twenty-four post-lumpectomy patients (8 left-sided, 16 right-sided) underwent non-contrast 2mm slice thickness radiotherapy (RT) planning CT scans in the supine and prone positions. Optimized tangential breast RT plans were generated. In all cases, prescribed RT dose was 50Gy in 2Gy daily fractions. Twenty specific structures (whole heart, atria and ventricles, major vessels, cardiac valves, epicardial coronary arteries including left anterior descending (LAD), ipsilateral/contralateral lung and non-treated breast) were contoured on each CT dataset based on a published reference atlas. Maximum, minimum, mean doses and volume (cm³) were compared for all structures in both supine and prone positions. Whole heart V5, V25 and V30 as well as lung V20 were evaluated. The independent two-sample t-test was used to determine the impact of treatment laterality and the paired t-test for the treatment positioning on RT dosimetry respectively, with $p < 0.05$ considered significant.

Results: Left compared to right-sided breast irradiation significantly increased maximum ($p < 0.001$) and mean ($p < 0.001$) whole heart dose, as well as doses to individual cardiac structures, in both prone and supine positions.

Prone versus supine positioning significantly increased maximum whole heart dose 25.8Gy versus 19.2Gy ($p = 0.007$) and mean LAD artery 8.4Gy vs. 5.0Gy respectively ($p = 0.03$). Whole heart V5 (3.9 vs. 2.5%), V25 (1.4 vs. 0.8%), and V30 (1.1 vs. 0.7%), did not differ significantly between prone and supine positions. Table 1 illustrates comparisons of other individual cardiac structures. As anticipated, maximum dose (48.5 vs. 50.3Gy), mean dose (3.3 vs. 6.5Gy) and V20 (5.3% vs. 11.5%) to the ipsilateral lung ($p < 0.001$ for all comparisons) were reduced when patients were treated in the prone versus supine position.

Table 1: Comparison of radiation doses to selected cardiac structures in patients planned for supine (n=24) versus prone (n=24) treatment

	Supine Treatment (n=24)	Prone Treatment (n=24)	p-value (* indicates significant values)
Right Ventricle			
Maximum (Gy)	12.5	16.8	0.03*
Minimum (Gy)	0.6	0.6	0.09
Mean (Gy)	1.6	2.5	0.01*
Right Atrium			
Maximum (Gy)	2.9	5.9	0.03*
Minimum (Gy)	0.5	0.6	0.06
Mean (Gy)	1.3	1.6	0.001*
Aortic Valve			
Maximum (Gy)	1.5	1.8	0.001*
Minimum (Gy)	0.7	0.8	0.02*
Mean (Gy)	1.0	1.2	0.006*
Tricuspid Valve			
Maximum (Gy)	2.2	2.3	0.6
Minimum (Gy)	0.9	1.1	0.05
Mean (Gy)	1.4	1.5	0.1
Left Anterior Descending Artery			
Maximum (Gy)	14.2	16.2	0.08
Minimum (Gy)	0.9	0.8	0.43
Mean (Gy)	5.0	8.4	0.03
Left Coronary Artery			
Maximum (Gy)	1.1	1.1	0.9
Minimum (Gy)	0.7	0.7	0.4
Mean (Gy)	0.9	0.8	0.7
Right Coronary Artery			
Maximum (Gy)	2.7	3.2	0.009*
Minimum (Gy)	1.3	1.6	0.001*
Mean (Gy)	2.0	2.4	0.001*

Conclusion: A statistically higher radiation dose was seen to the whole heart and various cardiac structures, including atria, ventricles and LAD artery, for left compared to right-sided breast cancer patients. Furthermore, prone positioning

increased maximum whole heart and LAD artery doses, despite its known benefit in reducing dose-volume effects to lung tissue. This is one of few studies to assess differential radiation doses to individual cardiac structures.

PO-0678

Do blood-biomarkers enhance clinical models for NSCLC patients treated with radical radiotherapy?

S. Carvalho¹, E.G.C. Troost², J. Bons³, P. Menheere³, P. Lambin¹, C. Oberije¹

¹GROW - School for Oncology and Developmental Biology-Maastricht University Medical Centre MUMC+, Department of Radiation Oncology - MAASTRO, Maastricht, The Netherlands

²Institute of Radiooncology, Helmholtz-Zentrum, Dresden-Rossendorf, Germany

³Maastricht University Medical Centre MUMC+, Laboratory for Immunodiagnostics- Central Diagnostic Laboratory, Maastricht, The Netherlands

Purpose or Objective: A prognostic model for non-small cell lung cancer (NSCLC) patients with validated clinical variables [gender, World Health Organization performance status, forced expiratory volume in 1 second, number of positive lymph node stations, and total gross tumor volume], and blood-biomarkers related to hypoxia [osteopontin (OPN) and carbonic anhydrase IX (CA-IX)], inflammation [interleukin-6 (IL-6), IL-8, and C-reactive protein (CRP)], and tumor load [carcinoembryonic antigen (CEA), and cytokeratin fragment 21-1 (Cyfra 21-1)] was developed and validated. Finally, the model was extended with alpha-2-macroglobulin ($\alpha 2M$), serum interleukin-2 receptor (sIL2r), toll-like receptor 4 (TLR4), and vascular endothelial growth factor (VEGF).

Material and Methods: The model was developed and validated on respectively 182 and 181 inoperable stage I-IIIb NSCLC patients treated radically with (chemo)radiotherapy. It included the mentioned clinical features, and blood-biomarkers were selected by least absolute shrinkage and selection operator (LASSO). Discrimination was reported by means of internal 10-fold cross-validated (CV) and external concordance index (c-index).

Results: The inclusion of OPN and Cyfra 21-1 (hazard ratios of 3.3 and 1.7) in this clinical model significantly increased the c-index from 0.66 to 0.70 (10-fold CV=0.64 and 0.67; c-index external =0.62 and 0.66). The calibration slope of the prognostic index in the validation cohort was 0.66 ($p < 0.01$), therefore requiring re-calibration. Further extension of the model by selecting from the 4 additional blood biomarkers yielded a c-index of 0.67 (10-fold CV = 0.66), TLR4 was left unincluded, and resulted in a better fitting model (likelihood ratio test: $p = 0.01$; Table 1). Hypoxia is known to be present in NSCLC adversely affecting disease progression and response to radiation treatment. Likewise, tumor load is often associated with disease development and prognosis. The value of hypoxia and tumor load associated markers OPN and Cyfra 21-1, was confirmed in this study. Extension of the model included $\alpha 2M$, sIL2r, and VEGF, with higher concentrations of these new markers being associated with a worse prognosis. $\alpha 2M$, a previously identified candidate predictor for radiation pneumonitis was found to be a prognostic factor in NSCLC. IL-2 was already identified as an independent prognostic marker in patients with advanced NSCLC. The correlation of IL-2 with shorter survival was confirmed in these cohorts and may be of relevance for patients receiving IL-2 immunotherapy. Finally, VEGF, the angiogenesis factor found in a variety of solid tumors including NSCLC, was found to be of added value in the extended model.

Table 1 - Multivariable Cox PH regression of the clinical variables and blood-biomarkers fitted on the validation dataset, after a feature selection made by LASSO, by including the offset of the re-calibrated linear predictor and allowing for a selection among the new blood-biomarkers. Performance of the model expressed in terms of internal Harrell's c-index, corrected for optimism by a 10-fold CV (between brackets).

Feature	Hazard Ratio	95% CI HR	p-value	c-index
Calibrated PI	2.4	1.7-3.5	<0.01	
α 2M	4.6	1.3-16	<0.01	0.67
sIL2R	3.1	1.1-9.2	<0.01	(0.66)
VEGF	1.4	0.8-2.4	0.3	

Conclusion: In conclusion, we improved and validated a clinical model with inclusion of hypoxia and tumor-load related blood-biomarkers. New immunological markers were associated with overall survival. Currently we are aiming to extend these models to include imaging information (Radiomics).

PO-0679

Comparison of toxicity and outcome in stage III NSCLC patients treated with IMRT or VMAT

R. Wijsman¹, F. Dankers¹, E.G.C. Troost², A.L. Hoffmann², J. Bussink¹

¹Radboud University Medical Center, Radiation Oncology, Nijmegen, The Netherlands

²Institute of Radiooncology, Helmholtz-Zentrum Dresden Rossendorf, Dresden, Germany

Purpose or Objective: Intensity-modulated radiation therapy (IMRT) and volumetric-modulated arc therapy (VMAT) are widely used in the treatment of advanced stage non-small cell lung cancer (NSCLC). These techniques deliver conformal dose distributions at the cost of increased target dose heterogeneity (particularly IMRT) and larger volumes of surrounding healthy tissues receiving low doses (particularly VMAT). We evaluated whether these dosimetric differences between IMRT and VMAT are of influence on treatment toxicity and outcome.

Material and Methods: We retrospectively assessed a cohort of 189 consecutive patients with stage III NSCLC having undergone radical (chemo-)radiotherapy using IMRT (until 2011) or VMAT (starting in 2011). Most patients (n=182) received 66 Gy in 33 (once-daily) fractions to the primary tumour and involved hilar/mediastinal lymph nodes based on FDG-PET/CT. Concurrent chemoradiation (CCR; n=122) consisted of 2 courses of etoposide cisplatin, whereas sequential treatment (n=56) consisted of 3 courses of gemcitabine cisplatin. Acute and late toxicity were assessed using the RTOG radiation morbidity scoring criteria for esophageal and pulmonary toxicity. Follow-up visits were planned every 3 months (first 2 years), biannually thereafter. Median overall survival (OS) was calculated using Kaplan-Meier survival analysis. Differences between the groups receiving IMRT and VMAT were statistically tested using the Mann-Whitney-U or Chi-square test, where appropriate.

Results: Gender, age, performance score, clinical (tumour and nodal) stage and radiation dose did not significantly differ between the IMRT (n=93) and VMAT (n=96) groups. Patients undergoing IMRT, however, received less concurrent chemotherapy compared to patients treated with VMAT (n=51 vs n=71; p= 0.007). Incidences of grade 2 and \geq 3 acute

esophageal toxicity (AET) were significantly lower for IMRT compared to VMAT (28 vs 57 patients, p<0.001; and 6 vs 17 patients, p=0.025, respectively). Maximum grade acute and late pulmonary toxicity did not differ between groups (p=0.57 and p=0.14, respectively). Grade \geq 3 late esophageal toxicity was scored in 1 and 3 patients after IMRT and VMAT, respectively. Median follow-up for the patients alive was 32 months (range 2.4-82.1 months). Median OS was 23.9 months (95% CI 19.6-28.1), without a significant difference between the groups (23.9 and 24.9 months for IMRT and VMAT, respectively; p=0.70).

Conclusion: Patients treated with VMAT showed significantly higher incidence of Grade \geq 2 and \geq 3 AET, which may be due to a higher percentage of patients receiving CCR in the VMAT-group. Median OS did not differ between groups. Currently the target volumes and dosimetric data are evaluated for differences between the groups, for we hypothesized that VMAT enables treatment of larger tumour volumes, leading to increased AET.

PO-0680

Predictive models of the extent and CT appearance of radiation induced lung injury for NSCLC

U. Bernchou¹, R. Christiansen¹, J. Asmussen², T. Schytte³, O. Hansen³, C. Brink¹

¹Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

²Odense University Hospital, Department of Radiology, Odense, Denmark

³Odense University Hospital, Department of Oncology, Odense, Denmark

Purpose or Objective: The purpose of the present study was to investigate the extent and appearance of early radiologic injury in the lung after radiotherapy (RT) for non-small cell lung cancer (NSCLC). Furthermore, the ability of planned mean lung dose to predict the risk of a radiologic response was explored.

Material and Methods: Eligible follow-up computed tomography (CT) scans acquired within 6 months after commencement of radiotherapy were retrospectively evaluated for radiologic injuries in a cohort of 213 NSCLC patients treated to 60 or 66 Gy in 2 Gy fractions at a single institution from 2007 to 2013. Radiologic injuries were divided in two categories based on CT appearance. Category 1 represented ground-glass opacity (GGO) and interstitial changes. Both are characterized by moderately increased densities in the lung parenchyma, but where GGO appears diffuse, amorphous, and with poorly defined vessel structures, interstitial changes are identified by more pronounced vessels and borders. Category 2 indicated patchy or confluent consolidation in the lung. The volume fraction of injured lung corresponding to either category was estimated in each scan. To investigate the relationship between the volume fraction of injured lung and mean lung dose, a logistic regression analysis was performed. Four different cut-points were chosen to define radiologic injury response. These were volume fractions of injured lung larger than 5%, 10%, 15%, or 20%. Both individual and combined categories were investigated.

Results: Radiologic injuries of category 1 and 2 were found in follow-up scans for 81% and 42% of the patients, respectively. The mean volume fraction of injured lung was 6.5% (range 0-95%) and 1.7% (range 0-22%) for category 1 and 2, respectively, and 8.2% (range 0-95%) when the categories were combined. The logistic normal tissue complication probability (NTCP) models are shown in the figure for the combined categories of lung appearance. The risk of radiologic response was found to be significantly associated with mean lung dose. The mean lung dose resulting in 50% risk of radiologic response (D50) increased from 17 to 29 Gy as the cut-point used for dichotomization increased from 5 to 20% of volume fraction of affected lung (see table). A logistic relationship between radiologic response and mean lung dose was also found for the individual categories of lung

appearance (see table). In these cases, increased D50 values were found since the frequency of response was reduced.

Fraction of lung affected [%]	Category 1 and 2 combined		Category 1		Category 2	
	D ₅₀ [Gy]	γ ₅₀	D ₅₀ [Gy]	γ ₅₀	D ₅₀ [Gy]	γ ₅₀
>5	17 (15-20)	0.6 (0.3-0.8)	21 (15-26)	0.7 (0.4-1.0)	31 (25-59)	1.1 (0.7-1.9)
>10	22 (21-26)	1.2 (0.8-1.7)	24 (21-29)	1.3 (0.9-2.0)	29 (25-49)	2.5 (1.4-8.0)
>15	25 (23-30)	1.4 (1.0-2.0)	28 (23-39)	1.6 (1.1-2.5)	NA	NA
>20	29 (25-42)	1.5 (1.0-2.5)	30 (25-45)	1.7 (1.1-2.9)	NA	NA

γ₅₀ is the relative gradient at D₅₀. 95% confidence intervals are given in the parentheses.

Conclusion: Radiologic injuries were frequently found in follow-up CT scans after RT for NSCLC patients. Logistic relationships between the risk of a radiologic response and increasing mean lung dose were observed both when categorizing the lung injuries in terms of appearance and when combining the categories.

PO-0681

Randomized phase II study of Erlotinib with radiotherapy in irresectable non small cell lung cancer

E. Martinez¹, M. Rico Osés¹, F. Casas², N. Viñolas², J. Minguez³, A. Paredes⁴, A. Pérez Casas⁴, E. Domine⁴

¹Complejo Hospitalario de Navarra, Department of Radiation Oncology, Pamplona, Spain

²Hospital Clinic i Provincial, Radiation Oncology, Barcelona, Spain

³Hospital Donostia, Radiation Oncology, San Sebastian, Spain

⁴Fundación Jiménez Díaz, Radiation Oncology, Madrid, Spain

Purpose or Objective: Although many studies have confirmed the synergic effects of combining chemotherapy and radiotherapy (RT), clinical data evaluating safety and efficacy of erlotinib in combination with RT in locally advanced non-small-cell lung carcinoma (NSCLC) are limited. This is the first study to determine the feasibility, tolerability, and efficacy of the concurrent addition of erlotinib to the standard conformal thoracic RT in patients with unresectable or locally advanced NSCLC who are not candidates for receiving standard CT by any cause.

Material and Methods: 90 patients (p) with irresectable NSCLC (I-IIIB stage), ECOG < 2 and measurable disease for criteria RECIST were randomized. P assigned to the arm A received RT 3D (66 Gy/33 fractions) and P in the arm B received the same RT with erlotinib 150 mg/d p.o. concurrent up to a maximum of 6 months. The principal aim

was the G 3-4 toxicity the secondary aims: OS, PFS, cause-specific survival (CSS), and objective response rate (ORR).

Results: 90 p were included (30 in arm A, 60 in B), 89 were valid for safety analysis and 81 of efficacy. Responses: CR A/B (%): 21,4/ 41,5 (p <0,05). Median of follow-up 17,1 m. OS: 15,3/ 12,9 m (p: NS). CSS: 17,7/ 21,4 m (p: NS). G 3-4 toxicities: A/B (%): pneumonitis: 10,6/3,3; radiodermatitis: 3/3,3; esofagitis: 0/0; pulmonary fibrosis: 0/3,3; cardiopathy: 3,4/1,6; rash: 0/13,3; diarrhea: 3,4/6,7; fatigue: 0/8,3. Erlotinib did not increase the toxicity produced by the RT.

Conclusion: The combination of erlotinib with RT produces a scarce clinical benefit in this group of patients, limited to complete responses and longer CSS rate compared with RT alone. Increased toxicity events were associated with combined therapy, mainly cutaneous toxicity. Further studies in molecularly unselected lung cancer patients treated with EGFR TKIs and radiotherapy are not indicated. Use of predictive biomarkers to identify patients most likely to benefit are mandatory

PO-0682

Prognostic factors and patterns of failure after post-op radiotherapy for epithelial thymic tumors

F. Belkhir¹, A. Levy¹, A. Suissa¹, N. Grellier-Adedjouma¹, P. Xu¹, E. Fadel², C. Le Péchoux¹

¹Institut Gustave Roussy, Radiation Oncology Department, Villejuif, France

²Centre Chirurgical Marie-Lannelongue, Surgery, Le Plessis-Robinson, France

Purpose or Objective: To evaluate the sites of relapse and prognostic factors of outcome in a retrospective series of patients with epithelial thymic tumors (ETT) treated consecutively with surgery and post operative RT.

Material and Methods: Data from 134 ETT patients who were operated according to guidelines in different centres and received RT in Gustave Roussy from 1990 to 2011 was retrospectively analysed. Before 1998, patients had radiotherapy to the thymic region as well as elective nodal radiotherapy (ENRT) to the mediastinum and both supra-clavicular regions. From 1999 on, patients had conformal RT limited to the thymic tumour bed. A 3D-conformal radiotherapy (CRT) with CT-based treatment planning was used from 1995, and Intensity Modulated Radiotherapy has been gradually implemented since 2010

Results: Median follow-up was 8.8 years. Quality of resection was R0 in 75%, R1 in 22%, and R2 in 3% of patients. 16% had neoadjuvant chemotherapy. Classification according to Masaoka-Koga was: stage I/IIA in 17%, IIB in 22%, III in 28%, and IV in 33%. 28 patients (21%) had thymic carcinoma according to WHO classification. The mean (median) delivered dose of RT was 54 Gy (42-66) and 53% patients an ENRT at a dose of 45-50 Gy median dose different between ENI and CRT. Late toxicities were observed in 16% of patients (11 pneumonitis, 9 pericarditis and 6 coronaropathy) but no related toxic-death was reported. Considering patterns of relapse, there were 26 local relapses which could be considered in-field (46% pleura, 27% mediastinum, and 27% to both locations) and 42 regional relapses (88% pleura, 5% mediastinum, and 7% lung) resulting in a locoregional control (LRC) rate of 67%49% at 5/10 years. Distant control rate was 91% at 10 years. ENI (HR: 2.3) and Masaoka-Koga classification > stage IIB (HR: 3.2) were associated with a decreased LRC in the multivariate analysis (MVA). Gender, age, WHO classification, PS, score, R0 status, CRT dose, and boost CRT Were not correlated with LRR in the MVA. The cause specific and overall survivals (OS) at 5 and 10 years were 72% and 63%, respectively (add 5 year results). PS>0 (HR: 2.6), and Masaoka-Koga stage IV (HR: 2.1) correlated with a lower OS in the MVA.

Conclusion: Masaoka-Koga was the main prognostic factor of OS and LRC in this analysis. Indications of RT should be

discussed within a multidisciplinary board. When adjuvant RT is indicated, conformal RT should be used. Patients should be followed up as late recurrences may occur

PO-0683

Multiple training interventions improve PET/CT based target volume delineation in NSCLC RTP

T. Konert¹, W. Vogel¹, M. MacManus², S. Everitt², D. Thorwarth³, J. Sonke⁴, D. Paez⁵, E. Fidarova⁵, G. Hanna⁶

¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Nuclear Medicine, Amsterdam, The Netherlands

²Peter MacCallum Cancer Centre, Radiation Oncology, Melbourne, Australia

³University Hospital Tübingen, Radiation Oncology, Tübingen, Germany

⁴Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiation Oncology, Amsterdam, The Netherlands

⁵International Atomic Energy Agency, Nuclear Sciences and Application, Vienna, Austria

⁶Centre for Cancer Research and Cell Biology, Radiation Oncology, Belfast, United Kingdom

Purpose or Objective: PET/CT based radiotherapy planning (RTP) has been shown to improve the consistency of target volume delineation (TVD) in lung cancer radiotherapy, hopefully leading to improved local control. This study assesses the impact of a standardized delineation protocol and multiple training interventions on PET/CT based TVD in NSCLC.

Material and Methods: Over a one year period, nuclear medicine physicians (NMP) and radiation oncologists (RO) with limited experience in PET/CT based TVD from nine different countries participated in a multicenter study. The first training intervention included a three-day training course, consisting of three contouring assignments which formed the basis of a teaching discussion with the aim of identifying and correcting misinterpretations of practical guidelines, and various lectures on PET/CT based RTP. The second training event contained detailed individual feedback reports about previous performed contouring assignments and a webinar on PET/CT based TVD in NSCLC. Eleven teams consisting of a RO and NMP performed joint gross tumor volume (GTV) delineation of the primary tumor as per a standardized delineation protocol. In-house developed software called Big Brother recorded any user-software interaction, consequently allowing visual inspection of delineation strategies. Six delineation cases were performed before, during and after the training program and were compared with agreed expert contours (GTVexp) to assess delineation performance.

Results: Following the three-day training course overall concordance indices for 3 repetitive cases increased from 0.57±0.11 (SD) to 0.66±0.10. Observer volumes were larger after the training and miss of GTVexp was significantly reduced from 79.01±52.35 cc (SD) to 42.86±38.08 cc. Results are summarized in table 1. After further feedback and the webinar overall concordance indices for another 3 repetitive cases increased from 0.64±0.10 (SD) to 0.80±0.08. A reduction of GTVexp miss from 78.89±44.51 cc (SD) to 30.87±20.26 cc was observed.

Table 1. Comparison of results from contouring the GTV before and after the first training event, and before and after a complete training in the use of a standardized delineation protocol. C_{expert} = median concordance index between the observers' GTV and expert GTV.

	Expert Volume (cc)	Median Group Volume (cc ± SD)	Miss (cc ± SD)	C_{expert} (± SD)
<i>Contours before and after the three-day training course</i>				
Before	388.38	282.75 ± 46.28	127.32 ± 42.43	0.67 ± 0.10
After		409.48 ± 115.12	59.94 ± 48.94	0.70 ± 0.07
			(p=0.03)	(p=0.34)
Before	50.86	30.58 ± 6.99	20.43 ± 6.09	0.59 ± 0.11
After		51.35 ± 20.94	8.88 ± 9.34	0.65 ± 0.10
			(p=0.03)	(p=0.06)
Before	164.46	84.93 ± 11.67	84.26 ± 11.66	0.49 ± 0.07
After		108.49 ± 41.23	62.18 ± 23.14	0.58 ± 0.12
			(p=0.05)	(p=0.08)
<i>Contours before and after the complete training program</i>				
Before	377.99	280.39 ± 92.41	115.45 ± 52.16	0.68 ± 0.11
After		370.78 ± 37.06	26.73 ± 18.34	0.85 ± 0.03
			(p=0.01)	(p=0.01)
Before	254.68	157.99 ± 80.15	103.70 ± 43.86	0.59 ± 0.10
After		220.24 ± 81.53	39.72 ± 25.87	0.82 ± 0.10
			(p=0.04)	(p=0.05)
Before	134.07	83.77 ± 15.95	50.66 ± 10.13	0.61 ± 0.06
After		117.52 ± 30.95	23.32 ± 10.12	0.80 ± 0.07
			(p=0.01)	(p=0.01)

Conclusion: Following a training intervention, PET/CT based TVD in NSCLC RTP using a standardized delineation protocol led to significant improvement in delineation performance. A greater improvement in TVD with the use of multiple training events as compared to a single training event was observed.

PO-0684

Does the dose to heart affect survival in NSCLC patient treated with definitive Radiotherapy?

T. Schytte¹, T.B. Nielsen², T. Stolberg-Rohr², C. Brink², O. Hansen¹

¹Odense University Hospital, Department of Oncology, Odense, Denmark

²Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

Purpose or Objective: High radiotherapy dose to the heart increase the risk of cardiac morbidity and death in early stage breast cancer and lymphoma. Recent reports (1,2) have indicated that an association between overall survival and dose to heart (e.g. V5 for the heart) are observable after radiotherapy of NSCLC patients as well. The objective of this study was to evaluate if overall survival was affected by high V5 to the heart in NSCLC patients treated with definitive radiotherapy (RT).

1) Bradley et al, *Lancet Oncology* 2015 Feb;16(2):187-99. 2) Belderbos et al, *WCLC2015 mini33.03*

Material and Methods: In a single institution, 297 NSCLC patients were treated consecutively with definitive RT from 2001-2007 with at least 60 Gy. Concomitant chemotherapy was not part of the standard treatment initially but became a treatment option later in the study period (weekly docetaxel). RT was delivered as 3D RT without elective nodal irradiation. No constraint on dose to the heart was applied during treatment planning. The heart was delineated retrospectively and heart doses were extracted from the treatment planning system (mean heart dose (MHD) and V5). Patients were stratified in two groups depending on their heart dose being above or below the median value. Survival test was performed using Kaplan Meyer and log-rank test. All patients were followed to death.

Results: Patient and treatment characteristics are summarized in table 1. Median follow-up was 127 months. The overall median survival was 19.1 months with 1, 2 and 5 year survival of 69%, 41%, and 17%, respectively. Median V5 for the heart was 49%. No association between survival and heart dose were observed (p=0.29 see Fig 1). The same was true when including smoking, gender, and concomitant chemotherapy as strata in the analyses. Median MHD was 14 Gy. Survival for patients with MHD ≥14 Gy or <14 Gy was 17% and 21%, respectively (p=0.83).

Table 1	Median	Range	SD
Age (year)	67	34-88	9.29
Heart V ₅ (%)	49	0-100	1.83
Mean heart dose (Gy)	14	0.1-47.5	11.4

	80	12	4
Concomitant chemotherapy		34	12

* Current or ex-smoker within 10 yr. † Never or ex-smoker at least for 10 yr.

Conclusion: This study did not show that heart V5 or MHD had a negative effect on survival for NSCLC patients treated with definitive radiotherapy. This study differs from recently reports by having a longer follow-up. On the other hand, concomitant chemotherapy was only used in 12% of the patients in this study. The main goal for NSCLC patients is still to achieve better loco-regional control. However, if dose escalation is performed with doses significant above those in the present study, strict dose constraints to the heart might still be advisable based on experience from patients with breast cancer.

PO-0685

Is PET imaging a reliable target for dose painting by numbers in lung cancer?

D. Di Perri¹, J. Lee¹, A. Bol¹, S. Differding¹, G. Janssens¹, D. Labar¹, A. Robert², F. Hanin¹, X. Geets¹

¹Université Catholique de Louvain, Institut de Recherche Expérimentale et Clinique IREC - Center of Molecular Imaging Radiotherapy & Oncology MIRO, Brussels, Belgium

²Université Catholique de Louvain, Institut de Recherche Expérimentale et Clinique IREC - Epidemiology and Biostatistics EPID, Brussels, Belgium

Purpose or Objective: Since many years, PET has been foreseen as a promising candidate for dose painting. However, the lack of biological specificity of tracers together with the low spatial resolution could call PET into question as a reliable target for voxel-based dose prescription.

To address this issue, we analysed FDG (tumor burden) and FAZA (hypoxia) PET uptake distributions in lung tumours in terms of biological specificity, spatial resolution, and spatiotemporal evolution.

Material and Methods: Twelve patients with locally advanced lung carcinomas treated by concomitant chemo-radiation were prospectively included. These patients underwent 4D PET/CT (FDG and FAZA) with audio coaching at 3 time-points: prior to radiotherapy, and in the second and the third weeks of treatment. All images were reconstructed in their time-weighted mid-position (MidP).

At each time-point, CT-based rigid registration was performed between FDG and FAZA MidP PET/CT while CT-based deformable registration was performed between per- and pre-treatment images.

In order to be compared with native FDG images, simulated PET images (PETsim) were created. To this end, tumours were segmented on FDG images (GTVFDG) using a gradient-based method relying on watershed and clustering. Subsequently, binary images were generated (uniform activity inside and null activity outside GTVFDG) and blurred using a Gaussian kernel of 8-mm FWHM.

PET SUV within the GTV were pairwise compared on a voxel-by-voxel basis using Spearman's correlation (rs) between:

- FDG and FAZA images, to assess their respective specificity
- FDG and PETsim images, to assess to which extent the blurring effect linked to the limited spatial resolution impacts the observed tracer distribution)
- per- and pre-treatment images, to assess the spatiotemporal evolution of the uptake distribution during radiation therapy

Results: At each time point, FDG and FAZA SUVpeak showed high correlation ($r = 0.78$) (Fig. 1A). FDG and FAZA voxel-by-voxel comparison showed high correlation ($r_s = 0.75 \pm 0.13$). This correlation was even higher when the 50% more hypoxic tumours were considered (FAZA SUVpeak = 1.83 ± 0.32 ; $r_s = 0.80 \pm 0.05$), compared to the 50% less hypoxic (FAZA SUVpeak = 1.17 ± 0.22 ; $r_s = 0.69 \pm 0.16$) (Fig. 1B).

Similarly, high correlation was found between FDG and PETsim images ($r_s = 0.78 \pm 0.14$).

Finally, the uptake distribution was spatially stable through imaging sessions for both tracers (FDG: $r_s = 0.86 \pm 0.09$; FAZA: $r_s = 0.82 \pm 0.11$).

All results were significant ($p < 0.01$).

Fig 1a. Comparison between FDG and FAZA SUV_{peak}: FDG and FAZA SUV_{peak} showed high correlation ($r = 0.78$).

Fig 1b. Voxel-based comparison between FDG and FAZA SUV: FDG and FAZA voxel-by-voxel comparison showed high correlation ($r_s = 0.75 \pm 0.13$). The correlation was higher for the 50% more hypoxic tumors ($r_s = 0.80 \pm 0.05$) than for the 50% less hypoxic ($r_s = 0.69 \pm 0.16$).

Conclusion: FDG and FAZA PET images share similar uptake patterns, even more for hypoxic tumours. In addition, FDG and FAZA uptake distribution were stable over treatment time. Blurring caused by the limited spatial resolution seems to be the main driver of the observed uptake distributions, as

suggested by the comparison between real and simulated images.

These results question the use of PET imaging as a target for dose painting by numbers in lung cancer.

PO-0686

Locoregional failure in locally advanced non-small cell lung cancer after definitive radiotherapy

E. Jouglar¹, V. Isnardi², D. Goulon³, C. Ségura-Ferlay⁴, M. Ayadi⁵, C. Dupuy⁶, M.A. Mahé¹, L. Claude⁷

¹Institut de Cancerologie de L'Ouest Centre René Gauducheau -Site Hospitalier Nor, Radiation Oncology, Saint-Herblain, France

²Centre Léon Bérard, Nuclear Medicine, Lyon, France

³Institut de Cancerologie de L'Ouest Centre René Gauducheau -Site Hospitalier Nor, Nuclear Medicine, Saint-Herblain, France

⁴Centre Léon Bérard, Biostatistics Unit- DRCl, Lyon, France

⁵Centre Léon Bérard, Medical Physics, Lyon, France

⁶Institut de Cancerologie de L'Ouest Centre René Gauducheau -Site Hospitalier Nor, Medical Physics, Saint-Herblain, France

⁷Centre Léon Bérard, Radiation Oncology, Lyon, France

Purpose or Objective: To determine the patterns of locoregional failure (LRF) in patients with locally advanced non-small cell lung cancer treated with definitive radiotherapy (RT).

Material and Methods: One hundred and fifty-four patients from the Gating 2006 prospective randomized trial (NCT00349102) were treated with conformal RT with or without respiratory motion management. All patients had a PET-CT with 18FDG in the two months leading up to study inclusion. The recommended protocol prescription was 66 Gy in daily 2-Gy fractions, five days a week. IMRT was not permitted. Patients with a LRF as first event were included. Treatment plannings with simulation CT, pre-treatment 18FDG PET-CT and post-treatment images demonstrating recurrence were registered and analyzed. Measurable LRF was contoured (rGTV) and classified as in-field (if 95% of rGTV volume was within the 95% isodose), marginal (if 20 to 95% of rGTV volume was within the 95% isodose), or out-of-field (if less than 20% of rGTV volume was within the 95% isodose).

Results: Median follow-up was 27.8 months. Forty-eight patients presented LRF. One-year and 2-year locoregional disease-free survival were 77% (95% CI 70-83) and 72% (95% CI 64-79) respectively. Age was the only independent LRF prognostic factor. The median age for patients in LRF was 67 years vs 60 years for the group not in LRF ($p=0.009$). 79% of the patients with LRF as first event relapsed within the RT field. 32% of patients with LRF had a marginal LRF component. Isolated out-of-field failure occurred in only 3% of all patients. The regions of highest FDG-uptake on pre-treatment PET-CT were located within the recurrence in 91% of patients with in-field LRF.

Conclusion: In-field failure was the most common pattern of failure. Escalated dose RT with high-dose fractions guided by PET parameters warrants further investigation.

Machine learning method for biomarkers identification in lung cancer patients

B.D. Delgado-León¹, J. Moreno², J. Cacicado³, M. Perez⁴, A. Moreno⁵, F.J. Núñez², L. Delgado⁴, S. Pérez⁴, J.M. Praena-Fernandez⁵, E. Montero¹, J.M. Nieto¹, C. Parra², M.J. Ortiz-Gordillo¹, J.L. López-Guerra¹

¹University Hospital Virgen del Rocío, Radiation Oncology, Sevilla, Spain

²University Hospital Virgen del Rocío, Group of Technological Innovation, Sevilla, Spain

³Cruces University Hospital, Radiation Oncology, Bilbao, Spain

⁴Instituto de Biomedicina de Sevilla, IBIS/HUVR/CSIC/Universidad de Sevilla-, Sevilla, Spain

⁵University Hospital Virgen del Rocío, Methodology Unit-Fundación Pública Andaluza para la Gestión de la Investigación en Salud de Sevilla- Sevilla- Spain, Sevilla, Spain

Purpose or Objective: Treatment of lung cancer (LC) with radiotherapy (RT) is often accompanied by the development of relapse. The significance of biologic markers for predicting recurrence has been increasingly emphasized by recent studies. Highly accurate and reliable machine-learning approaches can drive the success of biomarkers identification in clinical care. We developed a prospective platform to incorporate translational research into the clinical decision making process in LC patients.

Material and Methods: Prospective data from 138 consecutive LC patients with indication of radio(chemo)therapy and diagnosis from January 2013 to August 2014 were available to enable the development of a prediction model. Median age was 62.5 years-old (range, 35-88) and the Karnofsky performance status (KPS) was 70-80 except for 129 cases. The most common histology for non-small cell LC patients (77.5%) was squamous cell carcinoma (52.3%). 73.1 percent of patients had Stage III disease (9 cases were a mediastinum recurrence) and 91 % received platinum-based chemotherapy. Median total dose prescribed was 61.2 Gy. 20 cases also underwent surgery. Data from translational research included genotypes of 4 single nucleotide polymorphisms (SNPs) of the transforming growth factor (TGFB1) gene (rs4803455, rs1800468, rs8179181, and rs8110090) and 3 SNPs of the heat shock protein (HSPB1) gene (rs2868370, rs2868371, and rs7459185).

Results: In univariate analysis, the CA genotype (N=92; 64 relapses [70%]) of TGFB1 rs4803455 was associated with a statistically significantly higher risk of recurrence (OR = 2.09; $P = 0.045$) compared with the CC genotype (N=46; 24 relapses [52%]). This effect was virtually unchanged after multivariate analysis (OR = 2.31; 95% CI, 1.08- 4.95; $P = 0.031$). In addition, we performed an ROC curve analysis to determine the strength of the above identified biomarker in predicting relapse. Age was the most important predictor, with an AUC of 0.62. By adding the TGFB1 rs4803455 SNP, the predictive power of the recurrence risk model improved, enhancing the AUC to 0.67 (95% CI, 0.57- 0.76; $P = 0.001$).

Conclusion: The prediction model for recurrence of patients with LC highlights the importance of combining patient, clinical, treatment, and translational variables. Our results showed that the CA genotype of TGFB1 rs4803455 SNP was associated with a higher risk of relapse in patients with LC treated with radio(chemo)therapy and thus may be used for guiding therapy intensity or as a selection criteria for a clinical trial, which would further the goal of individualized therapy. This tool could be used as a first building block for a decision support system.

PO-0688

Patterns of LR for stage III N2 NSCLC patients after chemotherapy and surgery: implications for PORT

C. Billiet¹, D. De Ruysscher¹, S. Peeters¹, H. Decaluwé², J. Vansteenkiste³, C. Doooms³, C.M. Deroose⁴, M. Hendriks⁵, J. Mebis⁶

¹University Hospitals Leuven, Radiation Oncology, Leuven, Belgium

²University Hospitals Leuven, Thoracic Surgery, Leuven, Belgium

³University Hospitals Leuven, Respiratory Oncology, Leuven, Belgium

⁴University Hospitals Leuven, Imaging and Pathology- Nuclear Medicine, Leuven, Belgium

⁵University of Hasselt, Cardiothoracic Surgery, Hasselt, Belgium

⁶University of Hasselt, Medical Oncology, Hasselt, Belgium

Purpose or Objective: To evaluate loco-regional patterns of failure after induction chemotherapy and surgical resection for stage III N2 non-small-cell lung cancer (NSCLC).

Material and Methods: This retrospective study included 151 patients with pathological confirmed diagnosis of stage III-N2 NSCLC from 1998 to 2012, at the University Hospitals Leuven and the Oncologic Center Limburg. All patients were treated with induction chemotherapy and surgical resection. Postoperative radiotherapy (PORT) was only performed in case of incomplete resection (R1/R2) or persistent nodal disease (ypN2). For the non-PORT group, we created a virtual PTV, consisting of the initially involved lymph node stations, N7, the ipsilateral hilum and bronchial stump. All patients were staged with FDG PET-CT and brain imaging. Disease recurrence at the primary affected lobe of the lung, ipsilateral hilum, and/or initially involved mediastinal nodes was considered loco-regional (LR). R2 resections were also seen as LR. Follow-up occurred at 3-month intervals for the first 2 years, every 6 months for the next 3 years, and then annually and included physical examination, blood test and CT scan of thorax and upper abdomen each 6 months.

	2R	2L	3	4R	4L	5,6	7	8,9	10R	10L	Surgical margin	Sites of relapse
PORT group (n=27)	5	1	2	6	3	5	10	2	13	6	7	N=60
	19%	4%	7%	22%	11%	19%	37%	7%	48%	22%	26%	
Non-PORT group (n=32)	9	3	0	19	7	7	20	3	17	7	6	N=98
	28%	9%	0%	59%	22%	22%	63%	9%	53%	22%	19%	

Results: After a mean follow-up of 46 months, disease recurrence occurred in 96/151 patients. Cumulative LR and distant metastases (DM) were seen in 39% (59/151) and 57% (86/151), respectively. Forty-eight patients (32%) had a LR as first event. PORT was performed in 76 patients. Considering the patients with cumulative LR (n=59), patients who underwent PORT (n=27) had a total of 60 relapse sites (2.2 sites/patient), whereas in the non-PORT group (n=32) a total of 98 sites were documented (3.1 sites/patient) (p<0.05).

In the PORT-group, the most common site of failure was the hilum, followed by station 7, the bronchial stump, 4R, 2R, 5-6, 4L, 2L, 3 and 8-9. In the non-PORT group, the most common site of failure was station 7, followed by station 4R, the hilum, 2R, 4L, 5-6, the bronchial stump, 8-9 and 2L (table).

In the PORT group, 33% of patients relapsed inside the planning target volume (PTV), 33% had a local relapse both within and outside the PTV. Another 18% of patients had a LR outside the PTV. In the non-PORT group, 66% of patients relapsed inside the virtual PTV, 31% both within and outside the PTV, and only 3% had a LR outside the PTV.

Conclusion: Patients receiving PORT had less sites of LR compared to the non-PORT group. In the non-PORT group, significantly more relapses were seen in nodal station 7, 4R and 4L, which are in the majority of cases irradiated in the PORT group. These data indicate the potential benefit of PORT in stage III N2 NSCLC treated with induction chemotherapy and surgery.

PO-0689

Outcome predictors for moderate hypofractionated tomotherapy in Malignant Pleural Mesothelioma

A. Fodor¹, S. Broggi², I. Dell'Oca¹, M. Picchio³, C. Fiorino², E. Incerti³, M. Pasetti¹, G. Cattaneo², L. Gianolli³, R. Calandrino², N. Di Muzio¹

¹San Raffaele Scientific Institute, Department of Radiotherapy, Milan, Italy

²San Raffaele Scientific Institute, Medical Physics, Milan, Italy

³San Raffaele Scientific Institute, Department of Nuclear Medicine, Milan, Italy

Purpose or Objective: Malignant pleural mesothelioma (MPM) has an aggressive course, high mortality rate and no standard of care. The role of radiotherapy has not been established. In a dose escalation study of moderate hypofractionated tomotherapy (HTT) we obtained statistically

significant better local control adding a simultaneous integrated boost (SIB) on FDG-PET positive areas (BTV) (Fodor et al, Strahlenther Onkol 2011). Here we evaluate factors influencing outcome in MPM patients(pts) treated with HTT.

Material and Methods: From May 2006 to April 2014 54 pts with MPM, progressive after previous treatments (surgery + chemotherapy) were treated with salvage HTT. Patient characteristics are presented in the table below. Median survival was 10.2 (1.18-70) months, 4 patients, all treated with SIB, were alive at the last follow up. A univariate analysis was performed to identify which of these factors: BTV boost, volume of BTV, type of surgery, histology, stage, chemotherapy yes/no and volume of PTV influence Overall Survival(OS), Local Relapse(LR) and Distant and Local Relapse(R).

Sex	Men: women = 44:10
Median age	69 years (39-82)
Median follow up	10.2 months (1.18-70)
Histology	Biphasic /sarcomatous:epithelial= 8:46
Location	Right pleura: Left pleura= 29:25
Initial Stage	I:II:III:IV= 10:15:22:7
Induction CT	Yes:no= 48:6
Surgery	Extrapleural pneumonectomy(EPP) vs Pleurectomy (P) vs Biopsy/Talc Pleurodesis= 2 vs 19 vs 33
Boost on BTV	Yes:No= 40:14
Treated volumes	Median PTV= Median BTV= 3166.7 cc: 196.65 cc

Results: Median survival for initial stage I vs II vs III vs IV was: 10.2: 22.07:9.97:5.72 (p=0.006). Only stage (I-II vs III-IV) was statistically significant in predicting OS: 13.11 vs 8.23 months(mts) (p=0.04) and only surgery yes(EPP/P) vs Biopsy/Talc Pleurodesis (TP) for LR(p=0.009). SIB on BTV has an impact on survival for stage III-IV (p=0.05), but not for stage I-II (p=0.7). A BTV volume of 353.2 cc was found to be the best cut-off having a statistically significant impact on OS (p= 0.0003). Median OS was 5.84 vs 7.8 vs 11.54 (p=0.04) for pts without SIB vs pts with SIB and BTV volume > cut off vs pts with BTV < cut-off. BTV volume< 353.2 cc significantly influences OS in stage III-IV (p=0.03). In stage III-IV SIB has a role in BTV< 353.2 cc, and pts with higher BTV treated with SIB have similar OS to pts without boost: 11.54 vs 6 vs 4.85 mts (p=0.04). In stages III-IV, type of surgery was significant for OS: EPP vs P vs TP= 1.61: 10.1:8.23 (p=0.001). For pts with TP BTV volume <353.2 cc is a significant predictor of survival (p=0.001) and these pts have a better OS than pts with larger BTV treated with SIB or without SIB: 13.11 vs 7.8 vs 7.74(p=0.04).

Conclusion: The BTV cut off volume <353.2 cc significantly influences OS in stage III-IV pts, even in those treated with palliative surgery, but irradiated with SIB and can help in patient selection for salvage SIB HTT.

PO-0690

Patient weight loss predicts worse overall survival for stage I lung cancer treated with SABR

G. Cook¹, Y. Xu², P. Cross¹, O. Holmes¹, R. Macrae¹, J. Pantarotto¹

¹The Ottawa Hospital Regional Cancer Centre, Radiation Oncology, Ottawa, Canada

²The Ottawa Hospital Research Institute, Radiation Oncology, Ottawa, Canada

Purpose or Objective: As per published guidelines, SABR is the recommended curative treatment option for those stage I non-small cell lung cancer patients (NSCLC) who either cannot or will not have surgery. This study investigates whether patient reported weight loss at presentation is a prognostic factor in a retrospective cohort of biopsy-proven stage I NSCLC patients who received SABR at one institution.

Material and Methods: Between January 2009 and December 2013, 314 consecutive patients with histologically proven T1 or T2a N0 NSCLC treated with SABR were entered in a research ethics board approved database. All patients were reviewed for potential surgical resection by a thoracic surgeon and all had FDG-PET/CT staging. Overall survival (OS) by weight loss was evaluated by Kaplan-Meier and log-rank test. Univariate and multivariate of weight loss was performed using a Cox proportional hazard model; adjustment of potential confounders included age, gender, performance status, histology, T-stage, tumor location, SUV max, smoking status and Charlson Comorbidity Index (CCI).. Weight loss was self-reported by patients on a standard intake form prior to oncology consultations under 5%, 5-10% or greater than 10%.

Results: 292 patients (92.9%) in the database had self-reported weight loss. 26 (8.9%) and 27 (9.2%) patients self-reported weight loss of 5-10% or greater than 10%, respectively. Survival differences were significant between weight loss groups especially in those patients with greater than 10% cohort. On univariate analyses, hazard ratio (HR) were 0.86 (95%CI 0.41-1.80) and 2.77 (95%CI 1.61-4.79) for patients with 5-10% and greater than 10% weight loss, respectively. The increased risk of death in patients with greater than 10% weight loss remained significant after adjustment for all confounders HR= 2.52 (95% CI 1.43-4.45). Weight loss overall was a significant risk factor for overall survival (P=0.0059).

Conclusion: Patient reported weight loss is a symptom that predicts shorter survival even in early stage NSCLC treated with SABR.

PO-0691

SABR for central lung tumors: plan quality and long-term clinical outcomes

H. Tekatli¹, S. Senan¹, M. Dahele¹, B.J. Slotman¹, W. Verbakel¹

¹VU University Medical Center, Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: The role of stereotactic ablative radiotherapy (SABR) for central tumors is less well established due to toxicity concerns. Volumetric modulated arc therapy (VMAT) has been used at our center since 2008 to deliver risk-adapted SABR for central tumors. We evaluated plan quality and clinical outcomes for patients with a central tumor.

Material and Methods: We identified 80 consecutive patients with primary NSCLC located within 2 cm from the proximal bronchial tree (PBT) and treated using RapidArc™ between 2008-2013. Patients with prior radiotherapy or lung surgery were excluded. RTOG definitions were used to contour organs at risk (OARs). Compliance to departmental, RTOG 0813 and LungTech criteria was assessed for PTV coverage, high/low dose spillage and doses delivered to OARs. Long-term toxicity results were analysed and overall survival (OS) was compared

with 252 peripheral tumors (same exclusion criteria) treated with 3 or 5 fractions during the same period.

Results: PTV V95 was 60Gy in 96% of patients. Median PTV was 66 cm³ (range 9-286). Dmax was ≥60Gy in 40% of patients for PBT, 26.3% for aorta, 55% for heart, and 1.3% for trachea. Esophageal maximum Dmax was 58Gy. Mean total lung V5Gy was 21% and mean total lung V20Gy was 8%. Mean contralateral V5Gy was 6.3%. 54 patients (68%) exceeded RTOG0813 Dmax for organ-at-risk (OAR), with 27 exceeding PBT Dmax. LungTech OARs dose limits were exceeded in 48 patients (60%). 5 of 78 patients (6.4%) with adequate follow-up information had grade 3 toxicity. Grade 4 toxicity was not observed. Treatment-related death was considered possible (n=3) or likely (n=3) in 6 patients (7.5%). With a median follow-up of 47 months, 3-year survival was 53%, compared with 57% for 252 peripheral tumors treated with 3 or 5 fractions SABR in the same period (p=0.369).

Conclusion: Although a substantial proportion of moderately central SABR patients received ≥60Gy to OARs, the 3-year survival was similar to patients with peripheral tumors. OARs tolerance doses continue to be refined and patients should be informed of the potential risks and benefits of central lung SABR. In the meantime, it appears reasonable to limit Dmax in OARs (including inside PTV) and lung doses (e.g. V5), using IMRT/VMAT. It is finally important to note that the outcomes in the present analysis should not be extrapolated to very central tumors, where the toxicity risks may be higher.

PO-0692

A novel endoscopically injected liquid-gel marker for image guided radiotherapy of thoracic tumours

S.R. Mortensen¹, J. Scherman-Rydhög², K.R. Larsen³, P.F. Clementsen⁴, G.F. Persson¹, M. Aznar², M. Josipovic², P.M. Rosenschöld², R.I. Jøck^{5,6}, T.L. Andresen⁵, L. Specht¹

¹Copenhagen University Hospital- Rigshospitalet, Dept. of Oncology- Section for Radiotherapy, Copenhagen, Denmark

²Copenhagen University Hospital- Rigshospitalet/University of Copenhagen, Dept. of Oncology- Section for Radiotherapy/Niels Bohr Institute of physics, Copenhagen, Denmark

³Bispebjerg Hospital, Dept. of Pulmonary Medicine, Copenhagen, Denmark

⁴Gentofte Hospital, Dept of Pulmonary Medicine, Gentofte, Denmark

⁵Technical University of Denmark- DTU Nanotech, Dept. of Micro and Nanotechnology- Center for Nanomedicine and Theranostics, Kgs Lyngby, Denmark

⁶Nanovi Radiotherapy A/S, Kgs Lyngby, Denmark

Purpose or Objective: A novel liquid gel fiducial marker (BioXmark®) was developed for use in image guided radiotherapy (IGRT).

The injectable marker is based on three components; sucrose acetate isobutyrate (SAIB), x-SAIB (electron dense SAIB analogue) and ethanol. After injection, the liquid gel matrix rapidly increases viscosity forming a rigid hydrophobic gel with minimal degradation over months (animal studies). The marker was developed as an alternative to solid metal fiducial markers, providing a simpler injection procedure and potentially lowering the risk of complications/displacement/marker loss while remaining visible on ultrasound, 2D kV X-ray/CT and MRI images.

In this study, we investigated the safety and feasibility of endoscopic (bronchial) ultrasound (EUS/EBUS) guided injection of the liquid marker into patients with stage III non-small cell lung cancer (NSCLC), and the visibility of the marker throughout the radiotherapy (RT) course.

Material and Methods: Patients with stage III NSCLC referred for concomitant chemo-RT (66 Gy in 33 fractions) were eligible.

Marker injection was done by experienced pulmonologists as an outpatient procedure. Standard EUS and EBUS equipment with a 22G aspiration needle was used for injection.

Marker deposits were injected in the primary tumour (if possible) and affected mediastinal lymph nodes. The

injection was monitored on real-time ultrasound using the probe on the endoscope. Patients were monitored for two hours before discharge.

Daily cone beam CT (CBCT) images and 2D kV fluoroscopy (FS) images at fractions 2, 16 and 30 were acquired for setup and evaluation of marker visibility.

Safety visits were planned twice during the RT course.

Results: 15 patients were included. A total of 35 markers were injected, 1-3 markers per patient, 0.10-0.30 mL per injection.

The marker injections were performed 9-27 days before start of RT

No pneumothorax, haemorrhage or other serious complications to the marker injection were observed during or after the procedure.

29 of 35 placed markers were available for evaluation; 2 markers disappeared and one dispersed into a tumour cavity.

Another three markers were injected in two patients who subsequently did not receive RT; one patient died (not related to the marker) and one patient developed metastatic disease prior to start of RT.

All 29 examined markers remained stable in position relative to original injection site (based on visual assessment) and were visible on planning CT, CBCT and FS images throughout the treatment course (fig.1).

27 of 29 markers were usable for image registration between planning CT and CBCT.

No marker related adverse events were seen during the RT period.

Fig 1. CBCT images of patient 1 at fraction 2 (left) and fraction 32 (right). Marker indicated by arrow.

Conclusion: The liquid fiducial marker is a safe and clinically useful alternative to solid metal fiducial markers for IGRT of patients with NSCLC and may also be a good alternative for use in IGRT of other solid tumours.

PO-0693

Primary tumor response of locally advanced NSCLC in PET/CTs during radiochemotherapy

T. Schimek-Jasch¹, S. Adebahr^{1,2}, M. Mix³, A.L. Grosu^{1,2}, U. Nestle^{1,2}

¹University Medical Center Freiburg, Department of Radiation Oncology, Freiburg, Germany

²German Cancer Consortium DKTK, Partner Site Freiburg, Heidelberg, Germany

³University Medical Center Freiburg, Department of Nuclear Medicine, Freiburg, Germany

Purpose or Objective: Standard of care for patients with inoperable, locally advanced non-small-cell lung cancer (NSCLC) consists in combined radiochemotherapy (RCT) with curative intent. Ideally, radiotherapy planning will be performed based on F18-FDG-PET/CT. Additionally, there is great interest in using the biological signal from PET/CT for assessment of treatment response and outcome prediction. Hypothetically, PET/CT may serve as basis for treatment modification such as dose escalation of radiotherapy for poor responders to RCT. The objective of the presented work was the evaluation of the early primary tumor (PT) response during RCT by means of response (R)-PET/CTs during and shortly after radiotherapy and its correlation with survival.

Material and Methods: Between 2011 - 2015, 39 patients with locally advanced NSCLC undergoing conventionally fractionated (2 Gy/day) RCT were prospectively scheduled for three whole-body PET/CT-scans (a radiotherapy planning (RP) PET/CT, a first response PET/CT (1R-PET/CT) 2 weeks after start of RCT and a second response PET/CT (2R-PET/CT) within one week after end of RCT. FDG-uptake of the PT was measured semiquantitatively by means of the maximum standardized uptake value (SUVmax). SUVmax measurements were compared using PERCIST 1.0 criteria*. Here, a response to treatment is defined by a decline of SUVmax of at least 30% (partial metabolic response, PMR). * *Wahl RL, et al.: From RECIST to PERCIST: Evolving Considerations for PET Response Criteria in Solid Tumors, JNM, Vol. 50, No. 5 (Suppl), May 2009*

Results: 39 patients (33% female, 67% male) with a NSCLC (59% SCC, 31% adenocarcinoma and 10% other NSCLC) in UICC-stage IIa (5%), IIIa (51%) und IIIb (44%) received an average total dose of median 68 (58-76) Gy during a median duration of 49 (39-66) irradiation days. Median GTV size was 58 (15-923) ml. SUVmax was median 14 (5.5-28.3) in the RP-PET/CT median 15 (2-37) days before start of irradiation. 33 patients had a 1R-PET/CT median 15 (13-29) days after start of irradiation and at median 22 (16-40) Gy, with a SUVmax of median 10.5 (3.4-23.7)). 36 patients had a 2R-PET/CT median 4.5 (4 days before, 15) days after end of irradiation, with a SUVmax of median 5.45 (1.4-14.3). A PMR was seen in 14/33 (42%) patients in the 1R-PET/CT (PMR1) (compared to the RP-PET/CT), and in 22/30 (73%) patients in the 2R-PET/CT (PMR2) (compared to the 1R-PET/CT). 9/29 (31%) patients reached both a PMR1 and a PMR2 (double PMR), none of these patients experienced a PT-progression during a median follow up of 18 (1.4-53) months after end of irradiation. The 2-year-overall survival rate was 75% as opposed to 54% without a double PMR.

Conclusion: These preliminary data imply that a double PMR measured in response PET/CTs scheduled during and at the end of RCT for NSCLC is associated with a prolonged overall survival rate.

PO-0694

Lung toxicity modelling in thoracic post-operative RT for NSCLC and pleural mesothelioma

A. Botticella¹, G. Defraene¹, C. Billiet¹, C. Draulans¹, K. Nackaerts², C. Deroose³, J. Coolen⁴, P. Naftoux⁵, S. Peeters¹, D. De Ruyscher¹

¹KU Leuven - University of Leuven- University Hospitals Leuven, Laboratory of Experimental Radiotherapy- Oncology Department, Leuven, Belgium

²KU Leuven - University of Leuven- University Hospitals Leuven, Respiratory Diseases/Respiratory Oncology Unit, Leuven, Belgium

³KU Leuven - University of Leuven- University Hospitals Leuven, Department Imaging and Pathology- Nuclear Medicine and Molecular Imaging, Leuven, Belgium

⁴KU Leuven - University of Leuven- University Hospitals Leuven, Radiology Department, Leuven, Belgium

⁵KU Leuven - University of Leuven- University Hospitals Leuven, Department of Thoracic Surgery, Leuven, Belgium

Purpose or Objective: Our hypothesis is that NSCLC patients and malignant pleural mesothelioma (MPM) patients treated with thoracic post-operative RT (PORT) are more prone to develop lung toxicity compared to non-surgical NSCLC RT patients. Main objectives are: 1) To quantify the differences in terms of CT lung density changes after PORT for NSCLC and MPM vs. non-surgical RT patients; and 2) To evaluate the correlation between CT lung density changes, dosimetric factors and clinical symptoms (dyspnea).

Material and Methods: Two groups of patients were analyzed: a) SURGICAL GROUP (n=27): stage I-III resectable MPM treated with extrapleural pneumonectomy (EPP) and PORT (n=22) and stage I-III NSCLC treated with pneumonectomy and PORT (n=5); b) NON-SURGICAL GROUP (n=35): stage I-IV NSCLC treated with chemo-radiotherapy.

Patients were treated consecutively in the University Hospitals of Leuven between 2005 and 2014 and their data were retrospectively retrieved. PORT MPM patients were treated with RT doses up to 64 Gy in 2-Gy fractions. PORT NSCLC were treated with RT doses up to 60 Gy in 2-Gy fractions. Non-surgical patients were treated with RT doses up to 66 Gy in 2.75 Gy sequentially with chemotherapy or up to 70 Gy in 2 Gy fractions concurrently with chemotherapy. Dyspnea scores (CTCAE 4.03) before and after RT were retrieved and delta dyspnea was calculated as the difference between the dyspnea after RT (worse at any time point) and before RT. For every patient, 2 CT scans were retrieved: 1) CT0: a free breathing planning CT scan; 2) CT3M: deep inspiration breath-hold diagnostic follow up CT scan 3-6 months after the end of RT. CT0 and CT3M were non-rigidly co-registered in MIM. Differences in Hounsfield Unit (delta HU=HU3M-HU0) were represented as the slope of the dose-dependent delta HU between 0 and 20 Gy (expressed in delta HU/Gy). Primary endpoint was delta dyspnea ≥ 2 . Univariate and multivariate logistic regression analysis were performed in order to identify significant predictors of delta dyspnea ≥ 2 . A p-value of < 0.05 was considered statistically significant.

Results: Delta dyspnea ≥ 2 was observed in 10/27 patients (37%) in the surgical group and in 7/35 patients (20%) in the non-surgical group (chi-square test 3.38, $p=0.06$). Mean delta HU/Gy was higher in the surgical group (1.63 vs. 0.67, t-test: $p=0.04$) (see Figure 1). Outcomes of univariate and multivariate analysis are showed in Table 1. The model with MLD, mean delta HU/Gy and mean heart dose appears to better predict a delta dyspnea ≥ 2 both in the surgical and non-surgical group (although not significant).

Independent variables	Non-surgical group		Surgical group	
	Logistic regression		Logistic regression	
	C-statistics	P value	C-statistics	P value
Mean delta HU/Gy	0.71	NS	0.62	NS
MLD	0.66	NS	0.55	NS
Mean heart dose	0.64	NS	0.62	NS
MLD - Mean delta HU/Gy	0.73	NS	0.73	NS
MLD - Mean delta HU/Gy - mean heart dose	0.76	0.08	0.75	0.07

Conclusion: Surgical patients after PORT are at higher risk of developing clinically relevant dyspnea (with a delta ≥ 2) and have a higher increase in lung density (a surrogate of lung damage) compared with non-surgical patients. To strengthen this hypothesis, we will investigate radiation toxicity after more limited surgery (lobectomy) in NSCLC patients. Results will be available by the time of the congress.

PO-0695

Lobectomy vs Stereotactic Ablative Radiotherapy in NSCLC: a multicentric series in four centers

V. Scotti¹, A. Bruni², G. Simontacchi¹, I.F. Furfaro³, M. Loi¹, D. Scartoni¹, A. Gonfiotti⁴, D. Viggiano⁴, C. De Luca Cardillo¹, B. Agresti¹, L. Poggesi¹, E. Olmetto¹, K. Ferrari⁵, M. Perna¹, P. Bastiani³, L. Paoletti³, L. Lastrucci⁶, P. Pernici⁶, G. Carta¹, S. Borghesi², S. Bertocci¹, P. Giacobazzi², L. Voltolini⁴, L. Livi¹

¹Azienda Ospedaliera Universitaria Careggi, Oncology, Firenze, Italy

²Radiation Oncology, Oncology and Respiratory Disease, Modena, Italy

³Radiation Oncology, Oncology- Ospedale Santa Maria Annunziata, Florence, Italy

⁴Thoracic Surgery, Cardiovascular Department, Florence, Italy

⁵II Pneumology, Cardiovascular Department, Florence, Italy

⁶Radiation Oncology, Ospedale San Donato, Arezzo, Italy

Purpose or Objective: Purpose Data from prospective randomized clinical trials are lacking in the comparison between lobectomy (LOB) and stereotactic ablative Radiotherapy (SABR) in operable patients (pts) and on-going trials have troubles in recruiting. In inoperable pts SABR achieves a local control of 64-95% in retrospective and 92-98% in prospective trials particularly when over 100 Gy Biological Equivalent Dose (BED) is delivered.

Material and Methods: From 2010 to 2014, 187 pts with stage I-II NSCLC were treated: 133 were male, 54 female. Mean age was 72 years. Cyto-histological prove of NSCLC was available in 167/187 (89.3%): 111 pts had adenocarcinoma, 51 squamous cell carcinoma and 3 other histologies. 133 pts had stage T1 NSCLC, and 54 (29.9%) stage II NSCLC. Ninety-three (49.8%) pts underwent SABR, while ninety-four (50.2%) were submitted to LOB. Pts who underwent SABR received to 9-20 Gy/die for 3-7 fractions; BED was superior than 100 Gy for all treatments. Response to SABR was evaluated according to RECIST criteria and toxicity according to CTCAE 4.0 scale. To compare LOB vs SABR, we analyzed outcomes in terms of Local Control (LC), Tumor-Specific Survival (TSS), Metastasis Free Survival (MFS) and Overall Survival (OS) using Kaplan-Meier method and log rank tests to evaluate differences in time-to-event outcomes between LOB and SABR.

Results: At a mean follow up of 23 months (range 6-67), LOB showed a better OS ($p < 0.014$) with a 2- and 5-yr OS of $67.6 \pm 5.9\%$ and $34.6 \pm 15.7\%$ for SABR and $84.1 \pm 4.8\%$ and $73.4 \pm 6.6\%$ for LOB. SABR achieved the same results in terms of LC with a 2 and a 5 years LC of $92 \pm 3.2\%$ and $80.8 \pm 7.9\%$ respectively with a $p < 0.07$. Neither significant difference in frequency of distant metastasis nor in TSS was observed between the two treatment groups (respectively $p < 0.41$ and $p < 0.50$). In SABR group only 3 G3 lung toxicities were found. No other G3 or G4 acute/late toxicity was found. Toxicity was minor in SABR group (1 fatigue G1,1 dyspnoea G1,1 hemoptysis G1); in surgery group we have recorded 7 atrial fibrillation, 2 bleeding, 1 with death, e 6 prolonged air leak.

Conclusion: SABR using high doses (BED>100) shows similar LC than LOB. Very encouraging results in terms of MFS and TSS with very few toxicity and no excess of tumor-related deaths are obtained with SABR compared with LOB. OS is better in LOB group, apparently being strongly influenced by the selection of pts addressed to surgery.

Poster: Clinical track: Upper GI (oesophagus, stomach, pancreas, liver)

PO-0696

Prognostic impact of celiac/supraclavicular node metastasis in locally advanced oesophageal cancer

W.K. Cho¹, D. Oh¹, Y.C. Ahn¹, H. Lee², Y.M. Shim³, J.I. Zo³, J.M. Sun⁴, M.J. Ahn⁴, K. Park⁴

¹Samsung Medical Center, Radiation Oncology, Seoul, Korea Republic of

²Kangbuk Samsung Hospital, Radiation Oncology, Seoul, Korea Republic of

³Samsung Medical Center, Thoracic and Cardiovascular Surgery, Seoul, Korea Republic of

⁴Samsung Medical Center, Medicine, Seoul, Korea Republic of

Purpose or Objective: Most of trials which established the standard treatment of locally advanced oesophageal cancer included M0 stage according to the 6th edition of the AJCC staging system. Now in the 7th edition of AJCC staging system, supraclavicular and celiac lymph node (LN) metastasis are no more classified into M1, but considered same as other regional LNs. We aimed to evaluate the treatment outcomes of NACRT followed by surgery in thoracic

esophageal squamous cell carcinoma (ESCC) patients including this group of tumors that had been excluded in the previous randomized studies.

Material and Methods: A total of 202 patients who were diagnosed with stage II-III thoracic ESCC initiated NACRT between January 2003 and July 2014. Among them, 9 patients refused further treatment during the course of NACRT and finally 200 patients were analyzed. For clinical staging, endoscopic ultrasonography was performed in 116 (58.0%) and FDG PET/CT in all patients. 75 patients (37.5%) had supraclavicular or celiac LN metastasis, which staged as M1a (N=54, 27.0%) or M1b (N=21, 10.5%) according to the 6th edition of AJCC staging. 168 patients (84.0%) completed both NACRT and surgery, 79 (47.0%) of whom underwent 2 field LN dissection while 89 (53.0%) received 3 field LN dissection. Prognostic factors for survival were assessed using Cox regression.

Results: After the median 17.8 months' follow-up, patients (%) experienced disease progression and (%) died. In all patients, the 2-year locoregional control (LRC), disease free survival (DFS), and overall survival (OS) rates were %, 47.8%, and 67.9%, respectively. Following surgery, the pathologic complete response was achieved in 44 (26.2%) patients. In multivariate analysis, 3 field LN dissection ($p=0.0439$), ypT0 ($p=0.0380$), ypN0 ($p=0.0024$), and negative surgical margin ($p=0.0037$) were favorable prognostic factors for DFS and negative surgical margin ($p<0.0001$) and age < 60 years ($p=0.0411$) were favorable factors for OS. The metastasis to supraclavicular and/or celiac LN was not significant factor for and DFS ($p=0.5584$) and OS ($p=0.5874$).

Conclusion: Celiac and/or supraclavicular LN metastasis did not compromise treatment outcomes significantly following NACRT and surgery in selected patients who tolerates the trimodality treatment.

PO-0697

Neoadjuvant vs. adjuvant treatment of gastroesophageal junction cancer: a retrospective analysis

A. Stessin¹, J. Miccio², O. Oladeru², S. Ryu¹

¹*Stony Brook University Hospital, Department of Radiation Oncology, Stony Brook, USA*

²*Stony Brook University Hospital, Stony Brook University School Of Medicine, Stony Brook, USA*

Purpose or Objective: Cancer of the gastroesophageal junction (GEJ) has been rising in incidence in recent years. The role of radiation therapy (RT) in the treatment of GEJ cancer remains unclear, as the largest prospective trials advocating for either adjuvant or neoadjuvant chemoradiotherapy (CRT) combine GEJ cancer with either gastric or esophageal cancer. The aim of the present study is to examine the effect of neoadjuvant versus adjuvant treatment on overall and disease-specific survival for patients with surgically resected cancer of the true GEJ (Siewert type II).

Material and Methods: The Surveillance, Epidemiology, and End Results (SEER) registry database (2001-2011) was queried for cases of surgically resected Siewert type II gastroesophageal junction cancer. The variables obtained for each case include patient demographics (race/ethnicity, sex, age at presentation, year of diagnosis), disease characteristics (histologic grade, surgical stage/extent of disease, nodal status of the disease, presence of distant metastases), and treatment modalities (radiation sequence relative to surgery, type of surgery performed, and type of radiation administered). Patients with metastatic disease, no surgical intervention, and missing data were excluded from the cohort. 1497 patients with resectable GEJ cancer were identified, with 746 receiving adjuvant RT and 751 receiving neoadjuvant RT. Retrospective analysis was performed with the endpoints of overall and disease-specific survival.

Results: Using cox regression and controlling for independent covariates (age, sex, race, stage, grade, histology, and year

of diagnosis), we showed that adjuvant RT resulted in significantly lower death risk (hazard ratio [HR], 0.84; 95% confidence interval 0.73-0.97; p -value=0.0168) and significantly lower disease-specific death risk (HR, 0.84; 95% confidence interval, 0.72-0.97; p -value=0.0211)

Conclusion: This analysis of SEER data showed a survival benefit for the use of adjuvant RT over neoadjuvant RT for the treatment of Siewert type II GEJ cancer. We suggest future prospective studies to compare outcomes of adjuvant versus neoadjuvant treatment for true GEJ cancer.

PO-0698

Integration of radiotherapy to chemotherapy for abdominal lymph node recurrence in gastric cancer

J. Lee¹, S.Y. Rha², W.J. Hyung³, Y.C. Lee², J.S. Lim⁴, H.S. Kim², W.S. Koom¹

¹*Yonsei University College of Medicine, Radiation Oncology, Seoul, Korea Republic of*

²*Yonsei University College of Medicine, Internal Medicine, Seoul, Korea Republic of*

³*Yonsei University College of Medicine, Surgery, Seoul, Korea Republic of*

⁴*Yonsei University College of Medicine, Radiology, Seoul, Korea Republic of*

Purpose or Objective: We hypothesized that selected cases among patients with localized ALN recurrence in gastric cancer (GC) might be salvaged by integration of radiotherapy (RT) in the multimodal treatment.

Material and Methods: We retrospectively identified patients with isolated ALN recurrence from GC between 2005 and 2013. We categorized patients into two groups by treatment approach after diagnosis of ALN recurrence: those who treated with integration of RT to chemotherapy (RCT group) vs. those who received systemic chemotherapy only (CT group).

Results: Of 53 patients with ALN recurrence from GC, 31 patients were classified as RCT group and 22 as CT group. The isolated distant failure (DF; 11/31, 35.5%) was dominant pattern of failure (POF) in the RCT group (median DF-free, 26 months). While local progression (LP) followed by DF (7/22, 31.8%) was dominant POF in the CT group, in which LP (median LP-free, 8 months) occurred earlier than DF (median DF-free, 18 months). RCT group had significantly prolonged median PFS compared with CT group (25 vs. 8 months, $p = 0.021$). In multivariate analysis, the treatment group was identified as independent prognostic factor related to PFS ($p = 0.013$). There was a borderline significance in OS between RCT group and CT group (29 vs. 20 months, $p = 0.095$).

Conclusion: Integration of RT and chemotherapy influenced the pattern of failure, and significantly improved PFS with isolated ALN recurrence in recurrent GC. RT may be considered in the treatment course of isolated ALN recurrence.

PO-0699

Treatment of metachronous esophageal cancer after head and neck cancer

K.H. Fan¹, Y.K. Chao², H.M. Wang³, C.Y. Lin¹, T.C. Chang¹, C.T. Liao⁴, C.H. Hsieh³

¹*Chang Gung Memorial Hospital, Radiation Oncology, Taoyuan, Taiwan*

²*Chang Gung Memorial Hospital, Thoracic Surgery, Taoyuan, Taiwan*

³*Chang Gung Memorial Hospital, Medical Oncology, Taoyuan, Taiwan*

⁴*Chang Gung Memorial Hospital, Otorhinolaryngology- Head and Neck Surgery, Taoyuan, Taiwan*

Purpose or Objective: To review the treatment result of metachronous esophageal cancer (ESC) after head and neck cancer (HNC).

Material and Methods: This study reviewed cancer registry data of our hospital from 2004 to 2012 with following inclusion criteria: ESC were found at least 90 days after HNC in the same patient, and both were diagnosed with pathology of invasive cancer. Patients would be excluded with following criteria: ESC was an extension of HNC or vice versa, and no available information of treatment could be retrieved. Treatment was composed by combinations of radiotherapy, chemotherapy, and surgery depending on disease status and performance status of the patient. The primary end point was overall survival (OS), and the second endpoint was progression-free survival (PFS).

Results: 77 patients were eligible. The median time from HNC to ESC was 32 months (4 - 147 months). Fifty-three patients (60%) were stage III/IV and 15 patients received best supportive care only after diagnosis of ESC. After excluding the BSC group, the 2-year OS were 34.9%. Fifteen patients were alive and one of them still had ESC. Thirty-five, 10, and 2 patients died from ESC, treatment related complications, and other disease, respectively. Univariate analysis revealed that ECOG > 1, tube feeding, anemia, and no esophagectomy correlated with poor OS ($p < 0.05$). Multivariate analysis showed that lower hemoglobin level, habit of smoking, ECOG score = 2, and no esophagectomy were independent poor prognostic factors ($p < 0.05$). The 2-year PFS rate for all patients was 30.7%. In the univariate analysis, ECOG > 1, tube feeding, body weight loss > 5%, anemia, no esophagectomy, and ESCstage III/IV were significantly correlated with poor PFS ($p < 0.05$). In the multivariate analysis, anemia and no esophagectomy were independently correlated with tumor recurrence ($p < 0.05$). Treatment outcome of patients who received esophagectomy were similar to ESC patients without prior history of HNC. The 2-year OS and PFS were 63.9% and 50.6%, respectively. Both were significantly higher than patients who did not receive esophagectomy (11.8% and 9.9%, $p < 0.01$).

Conclusion: the treatment result of metachronous ESC after HNC varied with disease and patient status. If esophagectomy was possible, the treatment outcome was not inferior to esophageal cancer without prior head and neck cancer history. But the treatment outcome was poor in patients with unresectable disease or poor performance status. A screening program for metachronous ESC should be considered for high risk patients to detect resectable ESC and improve treatment outcome.

PO-0700

Salvage radiotherapy in the patients with supraclavicular lymph node metastases after esophagectomy

Z.G. Zhou¹, C.J. Zhen¹, P. Zhang¹, X.Y. Qiao¹, J.L. Liang¹, W.W. Bai¹

¹Fourth Hospital of Hebei Medical University, Department of Radiation Oncology, Sijiazhuang- Hebei, China

Purpose or Objective: Evaluate the salvage radiotherapy outcome in patients with supraclavicular lymph node metastases (SCLN) after esophagectomy.

Material and Methods: A total of 117 patients with esophageal squamous cell carcinoma after initial esophagectomy (R0 resection) were retrospectively analyzed and they were diagnosed supraclavicular lymph node metastases during follow-up time. All patients were divided into salvage radiotherapy group (SR, n=89) and no salvage radiotherapy group (NSR, n=27).

Results: The 1,3,5-year overall survival rates were 81.6%, 31.4%, 8.6%, respectively. In all patients the 1,3-year survival time after SCLN metastasis (ASMS) rates were 40.2%, 14.5%, and the median ASMS time was 10 months. The 1, 3-year ASMS rates were 48.1%, 18.9% in SR group and 12.0%, 0% in NSR group, respectively ($P < 0.001$). In SR group, the 1, 3-year ASMS rates in the patients with combined radiochemotherapy and single radiotherapy were 62.6%, 33.4% and 41.9%, 16.5% ($P < 0.001$). In the subgroup analysis,

in combining visceral metastases group (CVM), the 1,3-year ASMS rates were 35.5%, 0%, and 42.3%, 21.5% in no combining visceral metastases group (NCVM) ($P = 0.004$). The 3-year ASMS rate with the patients in no combining mediastinal failure group (NCMF) (22.2%) was higher than those in combining mediastinal failure group (CMF) (7.0%) ($p=0.041$). According to the salvage radiation dose, the 1,3-year ASMS rates were 56.5%, 23.4% in ≥ 60 Gy group and 29.2%, 7.5% in < 60 Gy group ($p < 0.001$). Multivariate factor analysis revealed that combining visceral metastases, combining mediastinal failure, salvage radiotherapy, salvage radiation dose and salvage treatment model may be considered favourable prognostic factors.

Conclusion: Salvage radiotherapy may improve survival of patients with supraclavicular lymph node metastases after esophagectomy. Combined radiochemotherapy and no combining visceral metastases and a salvage radiation dose ≥ 60 Gy were associated with a better prognosis for those patients.

PO-0701

Dose-response relationship for locoregional control in esophageal cancer treated with curative CRT

H.J. Kim¹, Y.G. Suh¹, W.S. Koom¹, Y.B. Kim¹, C.G. Lee¹

¹Yonsei University, Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: To evaluate the correlation between radiation dose and locoregional control (LRC) for patients with stage II-III esophageal cancer treated with definitive concurrent chemo-radiotherapy (CCRT).

Material and Methods: The medical records of 236 patients with clinical stage II and III esophageal cancer treated with definitive CCRT at the Yonsei Cancer Center between Feb 1994 and May 2013 were retrospectively reviewed. Among these patients, 120 received a radiation dose of < 60 Gy (standard-dose group), while 116 received a radiation dose of ≥ 60 Gy (high-dose group). The median dose of radiation in the standard and high dose groups was 50.4 Gy (range, 45.0-59.4 Gy) and 63 Gy (range, 60.0-66.6 Gy). Concurrent 5-FU/cisplatin (FP) chemotherapy (CHT) was performed in 82.2 % of patients.

Results: The patient characteristics had no differences in age, sex, pathology, grade, tumor length, and clinical stage between the two groups. Patients with high Karnofsky performance status scale and lower thoracic esophageal tumor were included more in standard dose group ($p = 0.017$ and 0.038). Maintenance CHT was performed more in standard dose group (45% versus 30.2%, $p = 0.037$) and FP CHT was more frequently used in high dose group (76.7% vs. 87.9%, $p = 0.019$). The median follow-up time for all patients was 19.2 months (range, 2.2-164.7). Of all patients, 2-yr and 5-yr LRC rate were 60.0% and 48.4%. The median progression-free survival (PFS) and overall survival (OS) were 13.2 months and 26.2 months, respectively. Patients in the high-dose group had a significantly better LRC (2-yr LRC rate, 50.3% vs. 69.1%, $p = 0.002$), PFS (median, 11.7 vs. 16.7 months, $p = 0.029$) and OS (median, 22.3 vs. 35.1 months, $p = 0.043$). The complete clinical response (CR) rate was significantly higher in the high-dose group (44.2% vs. 62.1%, $p = 0.007$). The treatment-related toxicities did not show a significant difference between the both groups ($p = 0.936$), although it was difficult to assess due to a retrospective fashion. On multivariate analysis, sex (female), radiation dose ≥ 60 Gy) and use of maintenance CHT were independent predictors for improved LRC, and sex (female), clinical stage (stage II vs. III), radiation dose ≥ 60 Gy) and use of maintenance CHT were significant predictive factors for OS.

Conclusion: A higher radiation dose of > 60 Gy is associated with increased LRC, PFS and OS for patients with stage II-III esophageal cancer treated with definitive CCRT.

PO-0702

The use of pet texture analysis to predict lymph node metastases in patients with oesophageal cancer

K. Foley¹, B. Berthon², C. Marshall², E. Spezi³

¹Cardiff University, Institute of Cancer & Genetics, Cardiff, United Kingdom

²Cardiff University, Wales Research & Diagnostic PET Imaging Centre, Cardiff, United Kingdom

³Cardiff University, School of Engineering, Cardiff, United Kingdom

Purpose or Objective: The prognosis of oesophageal cancer (OC) is poor, with overall 5-year survival approximately 15%. The presence of lymph node metastases (LNMs) is a major prognostic indicator and the ability to identify LNMs is important. Texture analysis of medical images enables additional information to be extracted from routine staging investigations and quantifies intra-tumoural characteristics via non-invasive methods. The aim of the study is to obtain preliminary data investigating the association of texture variables and LNMs.

Material and Methods: A prospectively maintained database including clinical, radiological and pathological details of consecutive OC patients with biopsy proven adenocarcinoma in South East Wales from October 2010 to August 2013 was retrospectively analysed. All patients underwent PET/CT staging. Consecutive patients were grouped into those with and without LNMs on endoscopic ultrasound (EUS), considered the superior staging investigation for loco-regional assessment. Texture analysis of the primary tumour was carried out on the PET images using PET-STAT, software developed and written in the Matlab-based open source software CERR. The tumour was outlined with ATLAAS, a learning algorithm for optimised automatic segmentation developed at Cardiff University. Seventeen variables including SUVmax, metabolic tumour volume (MTV), total lesion glycolysis (TLG) and intensity variability (IV) were calculated. Table 1 details all variables calculated. Patients with primary tumour volume less than 5 ml and distant metastatic disease were excluded. Independent T-tests were used to identify promising texture variables for future study. A p-value <0.05 was considered significant. Primary outcome was LNMs on EUS.

Results: Eighty-one patients underwent staging with PET/CT and EUS [male 67, median age 66 (range 42-82)]. Forty patients were staged as N0 on EUS, with 41 having evidence of regional lymph node metastases. Independent T-tests demonstrated significant differences between patients with and without LNMs for MTV [mean 38.45 v 21.71; $t(56.03)=-2.449$, $p=0.017$], TLG [mean 328.72 v 208.66; $t(74.721)=-2.023$, $p=0.047$], Coarseness [mean 0.010 v 0.013; $t(79)=3.107$, $p=0.003$], Entropy [mean 6.15 v 5.91; $t(79)=-2.075$, $p=0.041$] and IV [mean 21.09 v 13.45; $t(64.366)=-2.458$, $p=0.017$].

Conclusion: Preliminary results have shown a number of texture variables that have the potential to predict LNMs. On-going work at our institution is investigating the added benefit of texture analysis when developing robust clinical predictive models.

²UMC Utrecht, Surgery, Utrecht, The Netherlands

Purpose or Objective: Perioperative chemotherapy (pCT) and neoadjuvant chemoradiotherapy (nCRT) are well-established therapies to improve survival for resectable non-metastatic esophageal carcinoma. However, the optimal type of treatment for esophageal adenocarcinoma is currently under debate. Until now, limited evidence is available to determine whether pCT or nCRT is most beneficial with

regard to toxicity, pathologic outcome and survival. Therefore, the aim of this study was to compare toxicity, pathologic outcome and survival after pCT versus nCRT and surgery in patients with esophageal adenocarcinoma.

Material and Methods: Consecutive patients who underwent pCT or nCRT followed by esophagectomy for cancer between October 2006 and September 2015 in a single institution were analyzed. The pCT regimen consisted of intravenous administration of epirubicin, cisplatin and capecitabine, whereas nCRT consisted of paclitaxel and carboplatin with concurrent radiotherapy. Toxicity of grade 3 or higher was scored according to the National Cancer Institute Common Terminology Criteria for Adverse Events. Data on surgical procedures, complications and follow-up were collected from a prospectively maintained database. Full propensity score-matching was applied to generate matched sets of cases based on pretreatment covariates in order to create comparable groups. Univariable analysis was performed to determine differences between the two groups. Disease-free survival (DFS) and overall survival (OS) were assessed using the Kaplan-Meier method and log-rank test.

Results: A total of 189 eligible patients were identified of whom 19 were discarded after propensity matching; 86 underwent pCT and 84 received nCRT. During preoperative therapy, thromboembolic events occurred more frequently in the pCT group (18% vs. 0%, $p<0.001$), while leukopenia occurred more frequently in the nCRT group (25 vs. 11%, $p=0.013$). Complete resection with no tumor within 1 mm of the resection margins (R0) was achieved in 90% of patients in the pCT group, as opposed to 96% in the nCRT group ($p=0.103$). Pathologic tumor regression was more frequently observed in patients who underwent nCRT compared to pCT ($p<0.001$). There was no significant difference between the groups with regard to risk of surgical complications, length of hospital stay or in-hospital mortality. Both treatments resulted in comparable 3-year DFS (49% vs. 53% for pCT and nCRT, respectively, log-rank $p=0.774$) and OS rates (48% vs. 51%, log-rank $p=0.842$) (Figure 1).

Conclusion: Perioperative chemotherapy (MAGIC) and neoadjuvant chemoradiotherapy (CROSS) were associated with comparable toxicity and postoperative morbidity. Although neoadjuvant chemoradiotherapy was associated with improved tumor regression compared to perioperative chemotherapy, this finding did not translate into improved R0 resection or 3-year survival rates.

PO-0704

Patterns of rebase in stage III thoracic esophageal squamous cell carcinoma patients after surgery

Y.X. Wang¹, Q. Yang^{1,2}, M. He³, J.F. Yao³, J. Li¹, S.C. Zhu¹, X.Y. Qiao¹, Z. Qi³

¹*the fourth Hospital of Hebe Medical University, Department of Radiation Oncology, Shijiazhuang, China*

²*Handan Central Hospital, Department of Radiation Oncology, Handan, China*

³*The fourth Hospital of Hebe Medical University, Department of Thoracic Surgery, Shijiazhuang, China*

Purpose or Objective: To evaluate the patterns of recurrence and its value in target delineation for postoperative radiotherapy(PORT) in patients with stage III thoracic esophageal squamous cell carcinoma(ESCC) after esophagectomy.

Material and Methods: 395 patients with stage III thoracic ESCC treated with radical esophagectomy from Jan, 2008 to Dec, 2011 were enrolled in this study. No patients had accepted preoperative adjuvant therapy. There were 302 males and 93 females; median ages was 60 years old (range 33-83). There were 33 patients located in upper-, 273 in middle- and 89 in low-segment. 375 patents has operated with two-field and 22 with three-field esophagectomy. The median number of dissected lymph nodes were 10 per case (range 1-34). There were 244 with stage IIIA, 106 with IIIB and 45 with IIIC. There were 97 patients received with surgery alone, 212 with postoperative chemotherapy(POCT), 86 with PORT(30 with POCT and PORT). Diagnosis of recurrence was primarily based on CT images, some of which were biopsy-confirmed. The location and time of tumor recurrences were analyzed.

Results: The overall failure rates was 75.7%(299/395). Locoregional recurrence(LR) was found in 48.4% of patients, distant metastasis(DM) in 16.2%, and LR plus DM in 4.3%; the total rate of LR and DM were 52.7% and 20.5%, respectively. There were 208 patients recurred with LR, 26.9%(56) recurred in supraclavicular/neck(51 in supraclavicular), 69.7% (145) in mediastinum, and 19.7% (41) in upper abdomen (38 in para-aortic lymph node). 92.8% of LR involved locoregional lymph nodes; the rate of anastomotic recurrence was 5.1% (20/395). Further analysis showed that upper-mediastinal recurrence accounted for 88.7% of mediastinal recurrence. The estimated 1-, 3-, and 5-year accumulated LR rates for all patients were 32.2%, 55.1% and 60.1%. Multivariate COX and logistic regression analysis showed that TNM stage and adjuvant therapy were independent factor for LR ($p<0.05$); PORT could reduce LR, especially in patients with middle-thoracic segment, IIIA and IIIB disease, two-field esophagectomy, less than 6 dissected lymph node or severe adhesion at surgery ($p<0.05$); but POCT did not decrease LR.

Conclusion: The recurrence rate was very high in stage III thoracic ESCC patients, LR was the main pattern of failure; TNM stage was one of the most important factor for LR. PORT could reduce LR but POCT could not. Upper-mediastinum was the most common site of recurrence, followed by supraclavicular and para-aortic regions; these areas should be considered the key target of PORT.

PO-0705

Clinical outcomes for inoperable HCC treated with SBRT: results on 71 patients and 102 lesions.

T. Comito¹, C. Franzese¹, E. Clerici¹, F. De Rose¹, A. Tozzi¹, G. D'Agostino¹, P. Navarra¹, C. Iftode¹, E. Villa¹, A.M. Ascolese¹, D. Franceschini¹, R.L.E. Liardo¹, L. Cozzi¹, A. Fogliata¹, A. Stravato¹, F. Zucconi¹, G. Reggiori¹, S. Tomatis¹, M. Scorsetti¹

¹*Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy*

Purpose or Objective: Aim of this study is the evaluation of feasibility and efficacy of SBRT in the treatment of unresectable hepatocellular carcinoma (HCC).

Material and Methods: Patients with 1-3 inoperable HCC lesions with diameter ≤ 6 cm were treated by SBRT. Prescription dose was 36-75Gy in 3-6 fractions. SBRT was delivered using the volumetric modulated arc therapy technique with flattening filter free photon beams. The

primary end points of this study were in-field local control (LC) and toxicity. Secondary end points were overall survival (OS) and progression free survival (PFS).

Results: From February 2011 and April 2015, 71 patients with 102 HCC lesions were irradiated. All patients had Child-Turcotte-Pugh class A or B disease. Median follow-up was 9 months (range 5-43 months). Actuarial LC at 1 and 2-years was 92% and 81%. An Equivalent Dose >100 Gy was a significant prognostic factor for LC in univariate analysis, with a 1-2 years LC rates of 99%-94% for a subgroup of lesions treated with a $BED \geq 100$ Gy and 58% -29% for lesions treated with a $BED < 100$ Gy ($p<0.001$). Median OS was 25 months. Actuarial OS at 1 and 2 years was 70% and 60%, respectively. Univariate analysis showed that OS is correlated with LC ($p<0.02$), $BED > 100$ ($p<0.05$) and Cumulative GTV <5 cm ($p<0.04$). Median PFS was 9 months. Grade 3 toxicity was observed in 7 patients (18%). No classic RILD was observed.

Conclusion: Our study shows that SBRT is a safe and effective treatment for selected patients with inoperable HCC. Local control rates and toxicity profile were encouraging.

PO-0706

Supraclavicular lymphnode disease is not an independent prognostic factor in esophageal cancer

P. Jeene¹, M.C.C.M. Hulshof¹, E. Versteijne¹, M.I. Van Berge Henegouwen², J.J.G.H.M. Bergmann³, E.D. Geijsen¹, H.W.M. Van Laarhoven⁴

¹*Academic Medical Center, Academic Radiotherapy, Amsterdam, The Netherlands*

²*Academic Medical Center, Academic Upper GI Surgery, Amsterdam, The Netherlands*

³*Academic Medical Center, Academic Gastroenterology, Amsterdam, The Netherlands*

⁴*Academic Medical Center, Academic Medical Oncology, Amsterdam, The Netherlands*

Purpose or Objective: In the TNM 7 staging, supraclavicular lymph nodes (SCN) are considered distant metastasis and thus prognostically unfavourable. This is one of the reasons for a generally accepted policy to treat these patients with supraclavicular disease spread and without further distant metastases with definitive chemoradiation (dCRT), irrespective of N stage. However, the worse prognostic value of a supraclavicular disease may be questioned. We analysed the prognostic value of supraclavicular disease in dCRT for esophageal cancer.

Material and Methods: We retrospectively analyzed 207 patients treated between 2003 and 2013 with a standardized protocol of definitive chemoradiation (dCRT) for esophageal cancer to identify the prognostic value of metastasis in the supraclavicular lymphnodes on treatment failure and survival, with special attention to the relation between supraclavicular disease and N stage. All patients were treated with external beam radiotherapy (50.4 Gy in 28 fractions) combined with weekly concurrent paclitaxel 50 mg/m² and carboplatin AUC2.

Results: Median follow up time for patients alive was 43.3 months. The median overall survival (OS) for all patients was 17.5 months. OS at 1, 3 and 5 year was 67%, 36.1% and 21.3% respectively. For patients with a metastasis in a supraclavicular lymph node, overall survival was 23.6 months compared to 17.1 months for patients without a metastasis in the SCN ($p=0.51$). In multivariate analyses, higher cT status, cN status and tumor length were found prognostically unfavorable, but a positive supraclavicular lymph node was not of independent prognostic value for survival ($p=0.67$). The relationship between SCN involvement and N stage was analyzed separately. Median OS for tumors with SCN involvement and N0/1 disease was 49.0 months (15.4-82.6) compared to 17.4 months in patients with N2/3 disease (95%CI 99-24.8 $p=0.097$). Median disease-free survival (DFS) for tumors with SCN involvement and N0/1 disease was 51.6 months (95%CI 0-108.5) compared to 8.2 months in the N2/3 group (95%CI 6.2-10.1 $p=0.028$). No significant difference in

toxicity was seen between patients with SCN involvement and those without, irrespective of the location of the primary tumor.

Conclusion: In esophageal cancer treated with definitive chemoradiation, number of affected lymph nodes is an important prognostic factor, while involvement of a supraclavicular lymph node is not. The supraclavicular lymph node should be considered a regional lymph node and treated with curative intent if the total number of involved lymph nodes is limited, irrespective of the site of the primary tumor.

¹²S. Raffaele Scientific Institute, Department of Oncology, Milan, Italy

Purpose or Objective: To define the role of radiation dose on overall survival (OS) in pancreatic adenocarcinoma (PAC) patients treated with adjuvant chemoradiotherapy (CRT).

Material and Methods: A total of 518 patients from different centers, completely resected with macroscopically negative margins (R0-1) for PAC (T1-3; N0-1; M0) and treated with adjuvant CRT, were retrospectively reviewed. Patients with metastatic or unresectable disease at surgery, macroscopic residual disease (R2), treated with intraoperative radiotherapy (IORT), dead within 60 days of surgery and without a histological diagnosis of ductal carcinoma were excluded. Only 142 patients received adjuvant chemotherapy.

Results: With 35 months of median follow-up, median OS was 23.0 months after adjuvant CRT with dose 45 Gy versus 13.0 months with dose < 45 Gy ($p < 0.001$); 5-year OS was 21.9% versus 3.8%, respectively. Among prognostic factors, higher Ca19-9 levels (>90 ; $p < 0.001$), higher tumor grade (G3-4, $p = 0.017$), R1 resection ($p = 0.003$), higher pT stage ($p = 0.002$) and positive nodes ($p < 0.001$) can be identified as negative. Multivariate analysis (HR: 0.52, 0.34-0.77; $p = 0.001$) proved the positive impact of higher dose.

Conclusion: A significant impact of CRT dose on OS was pointed out by the results of this analysis. The randomized trials on adjuvant CRT in PAC, in which a relatively low-dose

of radiation (40 Gy, split course) was used, may have had conflicting results due to this bias.

PO-0708

Advanced age is no contraindication for chemoradiotherapy with curative intent in oesophageal cancer

F. Voncken¹, R. Van der Kaaij², K. Sikorska³, E. Van Werkhoven³, J. Van Dieren⁴, C. Grootsholten⁴, P. Snaebjornsson⁵, J. Van Sandick², B. Aleman¹

¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Radiation Oncology, Amsterdam, The Netherlands

²Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Surgery, Amsterdam, The Netherlands

³Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Biometrics, Amsterdam, The Netherlands

⁴Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Gastrointestinal Oncology, Amsterdam, The Netherlands

⁵Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Pathology, Amsterdam, The Netherlands

Purpose or Objective: To compare long-term outcomes of chemoradiotherapy between young and elderly (≥ 70 years) oesophageal cancer patients treated with curative intent.

Material and Methods: Oesophageal cancer patients treated between 1998 and 2013 in our institute with neoadjuvant (nCRT) or definitive (dCRT) chemoradiotherapy were retrospectively analysed. nCRT consisted of 36-50Gy with concurrent 5-fluorouracil/cisplatin or 41.4Gy with concurrent carboplatin/paclitaxel. dCRT consisted of 50Gy with concurrent fluorouracil/cisplatin or 50.4Gy with concurrent carboplatin/paclitaxel. Overall survival (OS), disease-free survival (DFS) and locoregional control (LRC) were compared between older (>70 years) and younger patients (< 70 years). Cox models were used to obtain adjusted hazard ratios (HR) and 95% confidence intervals (CI).

Results: The cohort consisted of 253 patients with a median follow up of 4.3 years. A group of 182 patients (72%) was < 70 years (median age 60). The remaining 71 patients were >70 years (median age 75). The two age groups (younger vs. older) differed significantly regarding smoking (59% vs. 31%; $p < 0.001$), alcohol abuse (64% vs. 46%; $p = 0.007$), Charlson comorbidity index (median 0 vs. 1; $p = 0.001$) and weight loss prior to CRT (median 4 vs. 3 kgs; $p = 0.038$). Most patients had stage IIA-IIIa disease (82%). Distribution of tumour stages was similar in the two age groups (stage IIA: 27% vs. 24%, stage IIB: 4% vs. 4%, stage IIIA: 51% vs. 55%).

Initial treatment was nCRT with the intent to proceed to surgery in 169 patients, whereas 84 patients were planned for dCRT. Although surgery was the intent, 15% of the younger nCRT patients were not operated versus 35% of the older nCRT patients ($p = 0.01$). Reasons to withhold surgery in the younger versus older patients were tumour progression (10% vs. 14%), toxicity (2% vs. 11%) or patient's own choice (3% vs. 11%), $p = 0.01$. At baseline, there was a significant difference in the distribution of the final treatment given (nCRT + surgery, dCRT or nCRT without surgery; $p < 0.001$).

For the entire study population, OS at 3-years was 42%. In the multivariable analysis, no difference was found in OS between the two age groups (old vs. young; HR 0.72, 95% CI 0.49-1.07, $p = 0.10$). In the older age group, DFS (HR 0.66, 95% CI 0.45-0.98, $p = 0.04$) and LRC (HR 0.43, 95% CI 0.23-0.82, $p = 0.01$) were significantly better than in the younger age group.

Conclusion: Elderly oesophageal cancer patients (>70 years) treated with neoadjuvant chemoradiotherapy followed by surgery or definitive chemoradiotherapy had long-term outcomes which did not differ from the outcomes of their younger counterparts. For oesophageal cancer patients, advanced age alone should not be a contraindication for chemoradiotherapy as a part of treatment with curative intent.

PO-0709

Interobserver variation of CT and FDG-PET based GTV for oesophageal cancer: a Dutch nationwide study

M.E. Nowee¹, F.E. Voncken¹, A.N. Kotte², L. Goense³, P.S.N. Van Rossum³, A.L.H.M.W. Van Lier², B.M. Aleman¹, M. Van Vulpen², G.J. Meijer², I.M. Lips²

¹The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

²University Medical Center Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands

³University Medical Center Utrecht, Department of Radiation Oncology and Surgery, Utrecht, The Netherlands

Purpose or Objective: Interobserver variation in target definition is a major contributor to geometric uncertainty in radiotherapy and consistent GTV delineation is crucial in dose escalation studies for oesophageal cancer. The routine use of FDG-PET for target delineation in oesophageal cancer patients treated with chemoradiation is debated in the literature. The aims of this study were to evaluate the interobserver variation of GTV delineation in The Netherlands and the impact of adding FDG-PET to CT images on interobserver variability in patients with oesophageal carcinoma.

Material and Methods: Six cases were included from a prospective database of oesophageal carcinoma patients. All cases underwent a planning FDG-PET/CT scan in treatment position. Twenty upper gastro-intestinal dedicated radiation oncologists from 14 institutes in The Netherlands independently delineated the GTV first on CT, using additional clinical and diagnostic information. Secondly, they adjusted this GTV after CT and FDG-PET images were fused. As general metrics for interobserver variability, volumes and generalized conformity indices were calculated. For visual comparison of interobserver variation observer count maps were generated for each case, i.e. maps of voxels showing the number of enclosing observer delineations. To quantify the interobserver variation at the cranial and caudal border, the distance along the z-axis that contains 5-95% of the observers was used.

Results: Significant differences in delineated GTV volumes were observed in 4 out of 6 cases after addition of FDG-PET to CT (Table 1). In 3 cases there was a significant volume reduction, whereas in one case a significant volume increase was found by PET, caused by unsuspected continuation of the tumour in the stomach. Generalized conformity indices were comparable for CT and FDG-PET/CT (Table 1). Count maps revealed that interobserver variation was mainly located at the cranial and caudal border (Figure 1A). The median observer variation was 26 mm (range 6-36 mm) at the cranial border and 18 mm (range 3-30 mm) at the caudal border (Figure 1B). Even after addition of PET interobserver variation remained more than 20 mm in 4 out of 6 cases (Figure 1B). In 2 cases a reduced interobserver variation was seen with PET/CT at the cranial border and in another 2 cases only at the caudal border. An increased variation was seen with PET/CT compared with CT at the caudal border for the case with the unsuspected FDG uptake in the stomach.

Figure 1A. Observer variation of CT based delineations of 20 observers in case 5, displayed as observer count map overlay on CT. Axial and sagittal view. **1B.** Interobserver variation at the cranial and caudal border of CT based and of FDG-PET/CT based delineations. Interobserver variation was defined as the distance along the z-axis that contains 5-95% of the observers.

Table 1. Comparison of CT and PET/CT based delineations in 6 oesophageal cancer patients

Case	Mean volume in cm ³ (SD)		CIgen [#]	
	CT	PET/CT	CT	PET/CT
1	51.0 (12.3)	53.1 (11.4)	0.67	0.69
2	54.2 (9.4)	49.2 (8.7)*	0.76	0.77
3	65.8 (7.6)	76.7 (12.1)*	0.66	0.69
4	52.0 (13.6)	45.0 (12.7)*	0.62	0.65
5	28.3 (7.5)	26.8 (7.5)	0.58	0.56
6	13.3 (2.3)	12.4 (2.0)*	0.75	0.76

* p<0.05, pairwiset-test

CIgen = generalized conformity index [Kouwenhoven et al. 2009]

Conclusion: This nationwide Dutch contouring study in oesophageal cancer demonstrated that in daily clinical practice considerable GTV delineation variation is present, with variations up to 36 and 30 mm at the cranial and caudal border, respectively. Although FDG-PET significantly impacted the delineated volume in two-thirds of the patients, the addition of PET did not translate into an observer variation below 20 mm in 4 out of 6 cases.

PO-0710

Large interobserver variation of delineated target volumes of pancreatic cancer in the Netherlands

⁴Maastricht Clinics, Radiation Oncology, Maastricht, The Netherlands

⁵Maastricht Clinics, Radiation Oncology, Maastricht, The Netherlands

⁶Catharina Hospital, Radiation Oncology, Eindhoven, The Netherlands

⁷University Medical Center Leiden, Radiation Oncology, Leiden, The Netherlands

⁸University of Manchester, Institute of Cancer Sciences, Manchester, United Kingdom

Purpose or Objective: In pancreatic cancer, the delineation of target volumes on a CT scan can be difficult due to poor contrast between tumour and surrounding tissues. This study quantifies, for pancreatic cancer in the Netherlands, the interobserver variation of delineated gross tumour volume (GTV) and the internal GTV (iGTV: the volume encompassing GTV in all ten phases of the respiratory cycle) on three-dimensional CT (3DCT) and four-dimensional-CT (4DCT), respectively.

Material and Methods: Seven radiation oncologists from six institutions, with an average of 5 irradiated pancreatic patients per year (range: 3-10), delineated pancreatic tumours in four patients with (borderline) resectable pancreatic cancer. First, the GTV was delineated on a contrast-enhanced 3DCT under guidance of an arterial and venous contrast-enhanced diagnostic scan. This contrast-enhanced 3DCT scan was obtained during free breathing, using a GE LightSpeed RT16 scanner. The GTV was expanded with a fixed margin of 5 mm to create the CTV. In the same session, a 4DCT scan, without contrast enhancement, was obtained, during which the respiratory motion of the patient was monitored to reconstruct 10 respiratory phase scans. Second, the iGTV was delineated on the 4DCT, under guidance of the diagnostic CT and expanded with a fixed margin of 5 mm to create an iCTV. Also, a questionnaire concerning experience of the participating radiation oncologists was filled out. We calculated median volumes, encompassing volumes and common volumes of the GTV, iGTV, CTV and iCTV. In addition, the generalized conformity index (CI_{gen}) and overall observer variation were calculated (value of 1 representing full agreement; 0 no agreement). Interobserver variation of 3DCT and 4DCT delineations were analysed and compared.

Results: For all delineated and created volumes, the results of the mean median volumes, encompassing volumes, common volumes and CI_{gen} over all four patients are presented in Table 1. The mean overall standard deviation (SD) (averaged over 4 patients) was 0.54 cm and 0.58 cm on 3DCT and 4DCT, respectively. The CI_{gen} was smaller for 4DCT, indicating larger variations in delineation on 4DCT. Typical differences in delineations between the seven observers are presented in Fig. 1. The radiation oncologists experienced the GTV and iGTV delineations in this study as difficult.

Table 1: The volumes and generalized conformity index CI_{gen} averaged over all 4 patients.

	3DCT GTV	3DCT CTV	4DCT iGTV	4DCT iCTV
Median Volume (cm ³)	20.8	52.2	19.6	48.7
Mean SD (cm)	0.48	0.58	0.42	0.54
Encompassing volume (cm ³)	65.5	129.7	93.9	178.7
Common volume (cm ³)	7.3	22.0	6.1	19.6
CI _{gen}	0.36	0.46	0.27	0.35

Figure 1: Typical delineations of all seven observers of the GTV and iGTV in two patients projected on the average scan

Conclusion: A considerable interobserver variation in delineation of pancreatic tumours was found, with a mean CI_{gen} of 0.46 for 3DCT (GTV) and 0.35 for 4DCT (iGTV). This indicates a large variation in interpretation of diagnostic CT images and 4DCT images. The limited experience of the observers with delineation as well as the poor contrast between pancreatic cancer and surrounding tissues on CT imaging may have contributed to these results. This should be improved, perhaps by using additional imaging.

PO-0711

Relating CT image heterogeneity to patient outcome in the SCOPE 1 oesophageal cancer trial

R. Carrington¹, E. Spezi², S. Gwynne³, J. Staffurth⁴, T. Crosby⁵

¹Velindre Cancer Centre, Medical Physics, Cardiff, United Kingdom

²Cardiff University, School of Engineering, Cardiff, United Kingdom

³Singleton Hospital, Clinical Oncology, Swansea, United Kingdom

⁴Cardiff University, Institute of Cancer and Genetics, Cardiff, United Kingdom

⁵Velindre Cancer Centre, Clinical Oncology, Cardiff, United Kingdom

Purpose or Objective: Heterogeneity is a well recognised feature of malignancy that has been associated with adverse tumour biology (1). There is also initial evidence that it may be a potential prognostic biomarker for oesophageal cancer (2). Using texture analysis, the purpose of this study is to investigate the relationship between CT image heterogeneity and patient outcome in the SCOPE 1 UK wide multi-centre clinical trial on oesophageal cancer.

References	
1	Ganeshan B, Miles KA. Quantifying tumour heterogeneity with CT. <i>Cancer Imaging</i> . 2013;13(1):140-9.
2	Yip C, Landau D, Kozarski R, Ganeshan B, Thomas R, Michaelidou A, et al. Primary oesophageal cancer: Heterogeneity as potential prognostic biomarker in patients treated with definitive chemotherapy and radiation therapy. <i>Radiology</i> . 2014;270(1):141-8.

Material and Methods: The planning CT images of 215 patients from the SCOPE 1 clinical trial were uploaded to the TexRAD texture analysis software package. The original GTV outlines from the trial were imported on to the relevant DICOM CT images for each patient. Outcome data from the trial (Overall survival (OS) and progression free survival (PFS)) was included for analysis. Texture analysis of the area within

the GTV was undertaken on the images to quantify entropy, uniformity, mean grey-level intensity, kurtosis, standard deviation of histogram and skewness for fine to coarse textures (filters: 0.0-6.0).

Results: To date, 23 patients from 21 centres entered in the trial have been analysed. Mean Grey Level <399.745, Skewness >2.215, Kurtosis >0.6 were associated with improved PFS ($p=0.0227$, $p=0.0218$, $p=0.0460$ respectively) for medium filter 3.0. For filter 4.0, improved PFS was associated with Mean Grey Level <454.055 ($p=0.0227$) and Skewness >0.840 ($p=0.0371$). Mean Grey Levels of <565.535 ($p=0.0251$) and <542.5 ($p=0.0251$) were associated with improved PFS for filters 5.0 and 6.0 respectively. For OS, mean grey levels of <34.845 ($p=0.0182$), <399.745 ($p=0.0381$) and <454.055 ($p=0.0371$) were associated with improved survival for filters 0.0, 3.0 and 4.0 respectively. An entropy level <5.6 was also found to be significant ($p=0.0428$) for improved overall survival using filter 2.0.

Conclusion : Normal 0 false false EN-GB JA X-NONE
We have shown using a 10% sample of the overall database available that CTimage heterogeneity factors are associated with PFS and OS for patients from multiple centres. Preliminary results therefore suggest that in the future it may be possible to make clinical treatment decisions based on the CT image heterogeneity of a tumour volume. This will be confirmed by completing analysis on the whole SCOPE 1 database.

PO-0712

Stereotactic body radiotherapy in the treatment of inoperable hepatocellular carcinoma

P. Franco¹, A. Guarneri¹, E. Trino¹, M. Levis¹, F. Giglioli¹, A.R. Filippi¹, R. Ragona¹, U. Ricardi¹

¹Ospedale Molinette University of Turin A.O.U. San Giovanni Battista di Torino, Department of Oncology - Radiation Oncology, Torino, Italy

Purpose or Objective: To evaluate the feasibility and clinical results of stereotactic body radiation therapy (SBRT) in the treatment of hepatocellular carcinoma (HCC) in patients unsuitable or failing to standard loco-regional therapies.

Material and Methods: Patients with < 3 inoperable HCC lesions with < 6 cm diameter were treated with SBRT. Prescription dose was adapted according to tumor size and global liver function and comprised 48-36 Gy in 3 fractions or 40 Gy in 5 fractions (prescribed on 80 % isodose). Primary endpoint included in-field (LC) local control and toxicity. Secondary endpoints were overall (OS), cancer-specific (CSS) and progression-free survival (PFS).

Results: 82 patients with 120 HCC lesions were treated. Median age was 70 (range 44-90). Most of the patients had Child-Pugh A5-A6 cirrhosis (80.4%), Barcelona Clinic Liver Cancer classification 0-A-B (93%). Median lesion size was 22 mm (range 7-120 mm). Most lesions were in the left lobe (65%). In most patients SBRT was the first local treatment (82%). Up to 7% of patients had portal vein thrombosis. Median observation time was 14 months. Actuarial 1-year LC, PFS, CSS and OS were 76.7% (95%CI:40-92.5%), 13.5% (95%CI:4.9-26.4), 92.1% (95%CI:81.8-96.7%) and 78% (95%CI:66.4-86%), respectively. Up to 18 patients (22%) experienced G3-G4 acute toxicity and 1 case of G5 toxicity was reported. Four cases of classical Radiation-induced liver disease (RILD) were reported, while 21 patients experienced a modification of Child-Pugh classification (25%), mostly of 2-3 points. On multivariate analysis, no factors were predictive for LC while initial Child-Pugh class and > 2 points Child-Pugh classification modification predicted for OS and CSS.

Conclusion: SBRT is a safe and effective treatment option for inoperable HCC, with acceptable LC rate and toxicity profile. Limiting toxic events may have prognostic significance.

PO-0713

Conformity analysis of target-volume definition for margin-directed boost in pancreatic cancer SBRT

D. Holyoake¹, M. Robinson², D. Grose³, D. McIntosh³, D. Sebag-Montefiore⁴, G. Radhakrishna⁴, N. Patel⁵, S. Mukherjee², M. Hawkins¹

¹University of Oxford, CRUK/MRC Oxford Institute for Radiation Oncology, Oxford, United Kingdom

²Oxford University Hospitals NHS Foundation Trust, Department of Clinical Oncology, Oxford, United Kingdom

³The Beatson West of Scotland Cancer Centre, Department of Clinical Oncology, Glasgow, United Kingdom

⁴St James's University Hospital, The St James's Institute of Oncology, Leeds, United Kingdom

⁵Oxford University Hospitals NHS Foundation Trust, Department of Radiology, Oxford, United Kingdom

Purpose or Objective: Margin-directed neoadjuvant pancreatic cancer radiotherapy aims to improve rates of surgical resection with clear margins. The target volume encompasses adjacent/infiltrated vasculature but methods used in its definition have varied and in some cases lacked reproducibility. SPARC (UKCRN ID: 18496) is a CRUK-funded [grant number C43735/A18787] phase 1 study of pre-operative Margin-Intense Stereotactic Radiotherapy for patients with Borderline-Resectable Pancreatic Cancer (BRPC) and incorporates a comprehensive Radiotherapy Quality Assurance protocol to ensure consistency in target definition and radiotherapy delivery.

Material and Methods: On a BRPC test case 'Gold-Standard' structures were defined by two clinical oncologists and one radiologist. A detailed method was specified for derivation of GTV_M, the target structure for the margin-directed boost. GTV_T was contoured to define gross tumour. Conformity analysis metrics were generated to compare structures produced independently by six clinical oncologist investigators with the Gold-Standard.

Figure. Absolute volumes of investigator and gold standard structures

Results: Gold-Standard and median investigator volumes for GTV_T were 2.1cc and 5.35cc (IQR 4.1-6.7) respectively, and 1.1cc and 1.3cc (IQR 0.9-1.5) for CTV_M. Median distance between centre of mass of Gold-Standard and investigator volumes was 0.32cm (0.19-0.47cm) for GTV_T and 0.24cm (0.09-0.36cm) for CTV_M. Median DICE conformity coefficients for GTV_T and CTV_M were 0.51 (0.40-0.60) and 0.68 (0.60-0.75), median discordance indices (measurement of over-inclusive contouring) for GTV_T and CTV_M were 0.64 (0.54-0.74) and 0.39 (0.19-0.44).

Conclusion: The investigator CTV_M structures showed less inter-observer variance in volume and less deviation from the Gold-Standard compared with the investigator GTV_T structures. The method of CTV_M definition appears consistently reproducible but accurate delineation of pancreatic malignancies remains difficult and oncologists should have expert radiology support in this task.

PO-0714

Proposal for the delineation of the clinical target volume in biliary tract cancer radiotherapy

J. Socha¹, M. Michalak², G. Wołakiewicz³, L. Kępką³

¹Regional Oncology Centre Częstochowa, Radiotherapy, Częstochowa, Poland

²Independent Public Care Facility of the Ministry of the Interior and Warmian & Mazurian Oncology Center, Diagnostic Imaging, Olsztyn, Poland

³Independent Public Care Facility of the Ministry of the Interior and Warmian & Mazurian Oncology Center, Radiotherapy, Olsztyn, Poland

Purpose or Objective: Adjuvant radiotherapy (RT) is frequently used in the treatment of biliary tract cancer (BTC). Accurate target volume delineation is crucial for tumor control and avoiding unnecessary damages. However, there is no consensus on delineation of clinical target volume (CTV) in BTC. The aim of our study is to review the published details of the CTV contouring practice and to propose criteria for the CTV delineation in the adjuvant RT of BTC.

Material and Methods: A comprehensive literature search was performed using the "PubMed" and "Google Scholar" databases, and articles on BTC radiotherapy that provided descriptions of the CTV contouring were selected. The descriptions were thoroughly reviewed and compared to identify the areas of strong consensus on their inclusion in the CTV among different authors and the areas with more variability that require individual decisions when creating the CTV. Nodal CTV was considered as well as the microscopic tumor spread (MTS) into the liver and along the bile-duct system. Three types of BTC were considered: intrahepatic cholangiocarcinoma (IHC), extrahepatic cholangiocarcinoma (EHC) and gall bladder cancer (GBC). Based on the analyzed data on contouring practice, we proposed a set of guidelines for the CTV delineation.

Results: Out of 52 studies that reported the use of adjuvant RT in BTC, 17 were finally included: one prospective, 13 retrospective and 3 reviews. 1. EHC and GBC (14 relevant studies): the porta hepatic and celiac lymph nodes (LN) were always included into the CTV (100% accordance), the pancreaticoduodenal LN were included in all but one study (93%), whereas for paraaortic LN no agreement exists: four authors (28.5%) mentioned them to be included. Additionally, one author (7%) included the superior mesentery artery nodes for ampullary location. Some data regarding the MTS was reported in three studies: tumor bed was encompassed with 1 cm, 1-1.5 cm and 2-3 cm margin, respectively. One author mentioned 2-4 cm margin to account for MTS along the bile duct. 2. IHC (3 studies): a strong consensus (100% accordance) exists on including the porta hepatic, celiac and pancreaticoduodenal LN into the CTV. Only one author mentioned the para-aortic LNs to be included. Regarding the MTS: two authors used 1 cm margin to cover the tumor bed and resection margin of liver and one author mentioned 2-4 cm margin to account for MTS along the bile duct.

Conclusion:

This is the first proposal of the CTV contouring guidelines for adjuvant RT for BTC. We recommend the coverage of porta hepatic, celiac and pancreaticoduodenal LN in all cases of BTC. Para-aortic LN coverage should be considered especially in EHC and GBC, and its use should be individualized. Tumor bed and resection margin of liver should be encompassed

with at least 1cm margin. In view of considerable variability between different authors, there is an obvious need for the international consensus guidelines.

Poster: Clinical track: Lower GI (colon, rectum, anus)

⁸Bellaria Hospital, Radiotherapy Department, Bologna, Italy

Purpose or Objective: Aim of this clinical study was to evaluate resectability and pathological response after preoperative concurrent chemotherapy with 2 different drugs and radiation therapy (RT) intensified with concomitant boost.

Material and Methods: A clinical trial based on two-stage Simon's design was planned. The trial included a first phase with enrolment of 9 patients. If 0/9 patients had complete pathologic response (pCR) the study had to be closed. In case of $\geq 1/9$ patients with pCR it was planned to enrol other 8 patients. RT was performed with 3D-conformal technique. The dose to mesorectum and pelvic lymph nodes was 45 Gy (1.8 Gy/fraction). A concomitant boost was delivered to GTV + 2 cm margin with a total dose of 55 Gy (2.2 Gy/fraction). The following concurrent chemotherapy was administered: Raltitrexed (3 mg/m²) and Oxaliplatin (130 mg/m²) on days 1, 17, 35 of RT. Acute and late toxicities were evaluated according to CTC-AE v.3.0 criteria.

Results: All 9 patients enrolled in the 1st phase underwent radical surgical resection, with 4/9 pCR. Then, 9 additional patients were enrolled for a total of 18 patients (F: 8, M: 10; median age 64.5, range: 45-80; clinical stage: 2 local recurrences, 16 cT4, 6 cN0, 4 cN1, 7 cN2, 1 cN3). Seventeen patients underwent surgical resection (7 anterior resections and 9 abdominal-perineal amputation) while 2 patients did not undergo surgery for early metastatic progression (1) or surgery refusal (1). R0 resection was achieved in all patients who underwent surgery. Overall, 5 patients had pCR and 2 patients showed only microscopic residual disease (pT0-Tmic: 7/17 = 41.2%). Acute grade ≥ 3 toxicity was: 1 leucopenia - neutropenia, 1 liver toxicity, 5 gastro-intestinal toxicities, with an overall incidence of 7/18 patients (38.9%). The actuarial analysis showed the following 2-year results: local control 100%, metastasis-free survival 93.7%, overall survival 92.3%.

Conclusion: The regimen used in this study allowed to achieve complete and near-complete response rate higher than 40%, despite the advanced stage of disease. However, severe acute toxicity was reported in more than 1/3 of patients.

⁹Bellaria Hospital, Radiotherapy Department, Bologna, Italy

Purpose or Objective: Aim of this analysis was to describe the results of a phase II study based on the use of VMAT in preoperative combined treatment of locally advanced rectal cancer.

Material and Methods: A clinical trial based on two-stage Simon's design was planned. The trial includes a 1st phase enrolment of 9 patients. If 0/9 patients had complete pathologic response (pCR) the study had to be closed. In the case of $\geq 1/9$ patients with pCR it was scheduled to enrol other 8 patients. Radiation therapy was performed using VMAT-SIB technique. The dose to mesorectum and pelvic lymph nodes was 45 Gy (1.8 Gy/fraction). A concomitant boost was delivered on GTV + 2 cm margin with a total dose of 57.5 Gy (2.3 Gy/fraction). The following concomitant chemotherapy was administered: Capecitabine (825 mg/m² twice daily, 5 days/week) and Oxaliplatin (130 mg/m² on days 1, 17, 35). Acute and late toxicities were evaluated according to CTC-AE v. 3.0 criteria.

Results: All 9 patients enrolled in the 1st phase underwent radical surgical resection, with 4/9 pCR. Then 9 additional patients were enrolled for a total of 18 patients (F: 7, M: 11; median age 62, range: 39-79); clinical stage: 4 local recurrences, 6 cT4, 5 cT3, 3 cT2, 2 cN0, 7 cN1, 9 cN2). Sixteen patients underwent surgical resection (9 anterior resection) while 2 patients did not undergo surgery for early metastatic progression (1) or death from acute pulmonary oedema prior to surgery (1). R0 resection was achieved in all patients who underwent surgery. Overall, 4 patients had a pCR and 7 patients only a microscopic residual of disease (pT0-Tmic: 11/18 = 61.1%). Acute grade 3 toxicity was: 1 leukopenia-neutropenia, 1 skin toxicity, 1 genitourinary toxicity and 5 gastrointestinal toxicities, with an overall incidence (considering the patient who died after radio chemotherapy) of 7/18 patients (38.9%). The actuarial analysis reported the following 2-year results: local control 80%, metastasis-free survival 93.7%, overall survival 88.9%.

Conclusion: The regimen used in this study showed excellent results in terms of pathologic responses (pT0-Tmic: 61.1%). However, despite the use of VMAT technique, more than 1/3 of patients had severe acute toxicity.

PO-0717

Serum miR-345-5p predicts pathological response to chemoradiotherapy in local advanced rectal cancer

J. Yu¹, N. Li¹, J. Jin¹

¹Cancer Hospital- CAMS, Radiation Oncology, Beijing, China

Purpose or Objective: Neoadjuvant chemoradiation(nCRT) has been represented as the standard treatment for locally advanced rectal cancer(LARC). Tumor pathological responses and radiotherapeutic sensitivity alter variously. We aimed to explore the predict value of serum circulating miRNAs, which have already been certificated as potential therapeutic predictors in many cancers for the pathological responses and radiosensitivity after nCRT in LARC patients.

Material and Methods: Six fresh tumor biopsy samples of T3-4/N+ rectal cancer patients were collected before any treatments and these samples were classified as radiation sensitive and resistant groups according to the postoperative pathological analysis assessed by Mandard TRG scale(3 samples of TRG1 vs 3 samples of TRG4). The two groups were strictly matched by clinical features. miRNAs expression profile of the two groups were analyzed by microarray. Predictive value of radiotherapeutic sensitivity of the candidated miRNAs was further validated by 160 serum samples of LARC patients.

Results: 19 miRNAs were identified to have different expression profile between radiation sensitive and resistant groups by microarray analysis ($p<0.05$). Among these miRNAs, nine miRNAs were down-regulated and ten were up-regulated in radiation sensitive group. miR-345-5p was identified significantly correlated with radiation resistant to nCRT and appeared highly discrepant expression between the two groups (fold change>2). Low expression of miR-345-5p in serum predicted superior pathological responses to radiosensitivity after nCRT (TRG1/2) (AUC=0.69, $p<0.001$) and favorable LRFS ($p=0.02$).

Fig 1. A: Comparison of miR-345-5p expression levels between radiation sensitive and resistant groups. Statistical significance was determined by the Mann-Whitney U test; B: Predictive value of pathological responses by miR-345-5p was determined by a ROC curve test; C: Low expression of miR-345-5p was correlated with superior of LRFS.

Conclusion: Serum level of miR-345-5p is associated with favorable pathological responses to neoadjuvant chemoradiotherapy and local-regional control ratio in LARC patients. It presents as a promising biomarker to predict the radiotherapy sensitivity and prognosis.

PO-0718

The significance of postop CEA after preoperative CRT followed by TME in advanced rectal cancer

⁹Dongsan Medical Center- Keimyung University School of Medicine, Radiation Oncology, Daegu, Korea Republic of

¹⁰Gyeongsang National University School of Medicine, Radiation Oncology, Jinju, Korea Republic of

Purpose or Objective: To evaluate the significance of postoperative carcinoembryonic antigen (CEA) level as a predictor for tumor recurrence and as a prognostic factor for survival in locally advanced rectal cancer patients treated with preoperative concurrent chemoradiation followed by curative surgery

Material and Methods: Total 1559 rectal cancer patients staged with cT3-4N0-2M0 received pelvic preoperative chemoradiotherapy (CRT) 50.4 Gy in 28 fractions followed by total mesorectal excision (TME). CEA levels were measured before CRT and after surgery. Clinicopathologic factors which could be associated with tumor recurrence and survival were analyzed.

Results: The cumulative probability of the tumor recurrence showed a steep increase with a cutoff value of 2.5 ng/mL for postoperative CEA, and the gradient decreased as postoperative CEA levels increased above 2.5 ng/mL. After median follow-up time of 46.7 months, patients with postoperative CEA level of > 2.5 ng/mL had significantly lower relapse-free survival (75.6% vs. 65.2%, $p<0.001$) and overall survival (88.3% vs. 78.1%, $p<0.001$) at 5 years than patients with CEA level of ≤ 2.5 ng/mL. In the multivariate analysis, postoperative CEA level is the only significant prognostic factors of relapse free survival (HR=1.561 and 95% CI=1.221-1.996, $p<0.001$) and overall survival (HR=2.073 and 95% CI=1.498-2.869, $p<0.001$). Increased pre-CRT CEA level is not a significant prognostic factor with consideration of postoperative CEA in multivariate analysis. The postoperative CEA level above 2.5 ng/ml is a significant predictor for distant recurrence (OR=1.689 and 95% CI=1.188-2.402, $p=0.004$), but not for local recurrence (OR=0.776 and 95% CI=0.389-1.549, $p=0.472$).

Conclusion: Postoperative CEA level above 2.5 ng/ml is a predictor for tumor recurrence and a negative prognostic factor for survival in rectal cancer patients who received preoperative CRT and curative surgery. Physician can consider intense surveillance after curative resection in these patient.

PO-0719

Target delineation of anal cancer based on MR or PET - an inter-observer, inter-modality study

E. Rusten^{1,2}, B.L. Rekdal¹, C. Undseth³, G. Al-Haidari³, B. Hanekamp⁴, E. Hernes⁵, T.P. Hellebust¹, E. Malinen^{1,2}, M. Guren³

¹Oslo University Hospital, Dept of Medical Physics, Oslo, Norway

²University of Oslo, Biophysics and medical physics, Oslo, Norway

³Oslo University Hospital, Dept of Oncology, Oslo, Norway

⁴Oslo University Hospital, Dept of Radiology, Oslo, Norway

⁵Oslo University Hospital, Dept of Radiology and Nuclear Medicine, Oslo, Norway

Purpose or Objective: Anal cancers are treated by definitive chemoradiotherapy of the primary tumor and pelvic nodes. Although survival is high (5y 75%), locoregional recurrence occurs in 24% of patients. Patients are mostly treated with IMRT and VMAT, and therefore precise dose delivery is important. For target volume delineation typically either PET or MRI is used together with planning CT, but practice varies between institutions. In the current work, we aim to investigate the variability between imaging modalities and oncologists with respect to target volume delineation based on either PET/CT or MRI/CT information.

Material and Methods: Twenty patients with anal cancer referred to chemoradiotherapy were prospectively included. Written informed consent was obtained from all patients and the regional ethics committee approved the study. Prior to therapy, patients underwent a planning CT scan, a PET/CT scan with 18FDG and T2 and diffusion weighted MRI scans at a 3T scanner. At the treatment planning station (Varian Eclipse), all images were co-registered to the planning CT scan. Three oncologists delineated the Gross tumor volume (GTV) independently of each other twice for each patient, once with medical records and images blinded for MRI information, and once blinded for PET information. The CT image information was always available. A randomization scheme of the order of the anonymized patients was used during delineation to minimize intra-observer bias. All volumes were exported from the treatment planning system, analyzed by calculating the DICE coefficients and compared with the Wilcoxon Signed-rank test.

Results: The median volume of the GTV was respectively 27.5 cm³ and 31.0 cm³ for PET and MRI, and there was a high correlation ($r=0.94$) between the volumes. The DICE coefficient (minimum, median, maximum) was 0.43, 0.81, 0.93 and 0.50, 0.75, 0.89 for PET and MRI. These DICE distributions were significantly different ($P=0.03$). Half of the patients with low DICE (<0.7) for PET, also gave low DICE for MRI, this indicated difficulties with delineation irrespective of imaging modality. For inter-modality comparison (PET to MRI for same observer), the DICE coefficient was 0.31, 0.75, 0.92, with a significant difference in distribution relative to the inter-observer distribution.

Conclusion: PET and MRI produced similar GTV volumes for radiotherapy planning of anal cancer. However, PET has a significantly lower inter-observer variability in terms of the DICE coefficients. Still, the deviations between PET and MRI were not substantial and may not translate into clinically meaningful differences. This is also supported by the relatively high inter-modality DICE coefficients. Thus, radiotherapy target delineation for anal cancer is performed quite consistently among observers and is not strongly dependent on whether PET or MRI is used.

PO-0720

High tumour glycine concentration - an adverse prognostic factor in locally advanced rectal cancer

K. Redalen¹, B. Sitter², T. Bathen³, K. Grøholt⁴, K. Hole⁵, S. Dueland⁶, K. Flatmark⁷, A. Ree¹, T. Seierstad⁵

¹Akershus University Hospital, Department of Oncology, Lørenskog, Norway

²Sør-Trøndelag University College, Department of Health Science, Trondheim, Norway

³Norwegian University of Science and Technology, Department of Circulation and Medical Imaging, Trondheim, Norway

⁴Oslo University Hospital, Department of Pathology, Oslo, Norway

⁵Oslo University Hospital, Department of Radiology and Nuclear Medicine, Oslo, Norway

⁶Oslo University Hospital, Department of Oncology, Oslo, Norway

⁷Oslo University Hospital, Department of Gastroenterological Surgery, Oslo, Norway

Purpose or Objective: In locally advanced rectal cancer (LARC), further advances in individualised treatment approaches require identification of robust biomarkers. Although metabolic reprogramming has been regarded essential for cancer cell proliferation, the systematic characterisation of activated metabolic pathways in aggressive cancer is scarce. Hence, by recognising the link between altered tumour metabolism and disease aggressiveness, we aimed to identify associations between pretreatment tumour metabolic profiles and therapeutic outcome in LARC.

Material and Methods: Tumour metabolic profiles were acquired from 54 LARC patients, receiving induction neoadjuvant chemotherapy followed by long-course chemoradiotherapy and surgery, by using high-resolution magic angle spinning magnetic resonance spectroscopy. Metabolite concentrations were correlated to TNM and presence of disseminated tumour cells (DTC) at time of diagnosis, and to ypTN and tumour regression grade (TRG) following the neoadjuvant treatment. All patients had either reached 5 years of follow-up or were scored with a progression-free survival (PFS) event at time of analysis. The performance of metabolite concentrations in prediction of PFS was assessed by receiver operating characteristic curves. Univariate Cox regression assessed associations between selected variables and PFS; those being significant were entered into multivariate analysis. Survival differences were assessed by the Kaplan-Meier method.

Results: Pretreatment tumour metabolite concentrations showed no significant associations to TNM, DTC, ypTN or TRG. In univariate regression analysis, high concentrations of glycine, creatine and myo-inositol were significantly associated to poor PFS, with distant metastasis to the lung and/or liver being the main PFS event (87.5% of events). When separating patients above and below the identified cut-off concentrations the respective estimated 5-year PFS were 85% and 50% for glycine, 74% and 29% for creatine and 81% and 50% for myo-inositol. In multivariate analysis, high glycine concentration remained most significantly associated to poor PFS (hazard ratio = 4.4, 95% confidence interval = 1.4-14.3, $p = 0.008$).

Conclusion: High tumour glycine concentration was identified as adverse prognostic factor for PFS in LARC. In a patient population treated with curative intent but with metastatic disease as main PFS event these results motivate further investigations of glycine as early predictor of metastatic progression and as potential therapeutic target.

PO-0721

Impact of sentinel lymph-node biopsy on staging and treatment in patients with anal cancer

N. Slim¹, C. Gumina¹, P. De Nardi², A. Tamburini², C. Canevari³, M. Ronzoni⁴, G. Bordogna⁴, V. Ricci¹, C. Fiorino⁵, R. Rosati², N. Di Muzio¹, P. Passoni¹

¹*Ospedale San Raffaele IRCCS, Radiation Oncology, Milan, Italy*

²*Ospedale San Raffaele IRCCS, Surgery, Milan, Italy*

³*Ospedale San Raffaele IRCCS, Nuclear medicine, Milan, Italy*

⁴*Ospedale San Raffaele IRCCS, Medical Oncology, Milan, Italy*

⁵*Ospedale San Raffaele IRCCS, Medical Physics, Milan, Italy*

Purpose or Objective: The prophylactic inguinal lymph-nodes (LNs) radiotherapy (RT) is considered the standard treatment, however it implies more toxicity. Moreover, inguinal recurrence occurs in 0%-12% of T1-T2, and 19%-30% of T3-T4 patients (pts) who did not receive prophylactic inguinal RT. So, 70%-81% of T3-T4 pts are uselessly irradiated, and 0%-12% of T1-T2 pts should be treated. An improvement of staging is mandatory. Aim of this study is to evaluate the role of sentinel lymph-node biopsy (SLNB) in staging and treatment of pts with anal cancer.

Material and Methods: Patients with squamous cell carcinoma of anal canal were staged with physical examination, endoscopy, chest and abdomen CT, pelvic MR, and simulation FDG-PET. Pts without gross inguinal LN metastasis were candidate for the lymphoscintigraphy with ^{99m}Tc nanocolloid. The CTV included the GTV (primary tumour and positive LNs), mesorectum, internal and common iliac LNs. As the inguinal RT was considered standard, the radiation oncologists were left free to decide whether irradiate this region independently from the clinical stage and the SLNB histological results. PTV1 and PTV2 corresponded to GTV and CTV, respectively, with a margin of 0.5 cm. Prescribed dose was 50.4Gy in 28 F to the PTV2, and 64.8Gy in 36 F, as sequential boost, to the PTV1. IMRT or Volumetric Modulated Arc Therapy (VMAT) were used. Concomitant chemotherapy consisted of 2 cycles of Mito-C 10 mg/m², and continuous infusion 5-FU 1000 mg/m²/day for 4 consecutive days.

Results: From 3/2008 to 2/2014, 48 consecutive pts were treated (T1=9, T2=15, T3=16, T4=8). PET was performed in 42 out of the 48 pts, and 27 out of these 42 pts underwent lymphoscintigraphy. Pathologic inguinal uptake was shown in 15/42 (36%) pts. Lymphoscintigraphy was performed in 9 out of these 15 pts. Histological examination was performed in 8 pts (SLN not found in 1 pt) and confirmed inguinal metastasis in 3/8 pts (37.5%) but did not confirmed metastasis in 5 pts (62.5%). PET did not show pathologic uptake in 27/42 pts (64%). Lymphoscintigraphy was performed in 18 out of these 27 pts: SLN was not found in 1 pt. Histological examination found metastasis in 2/17 (12%) and confirmed the absence of metastasis in 15 pts (88%). Thirty-one pts received prophylactic or curative RT to the groins, the "Groin group", and 17 pts did not, the "No groin group". All the 17 pts of the "No groin group" underwent SLNB procedure: 16 pts had SLNB histologically negative, 1 pt had lymphoscintigraphy negative (SLN not found) and PET negative; two pts with PET positive in right inguinal LN but ipsilateral SLNB negative were not irradiated. No pt in both groups had inguinal relapse or progression. Of note, median follow up duration in the "No groin group" was 41 months (19.2-90.7 months).

Conclusion: SLNB can further improve the PET based staging and select the "true negative" patients for which the inguinal LN irradiation could be avoided.

PO-0722

Stereotactic ablative radiotherapy for lung oligometastatic patients with colorectal cancer

L. Agolli¹, V. Maurizio², N. Luca², D.S. Vitaliana², O. Mattia F²

¹*Azienda Ospedaliera Sant' Andrea, Department of Radiation Oncology, Rome, Italy*

²*Sant'Andrea Hospital, Radiation Oncology, Rome, Italy*

Purpose or Objective: to evaluate efficacy and tolerability of stereotactic ablative radiotherapy (SABR) in the treatment

of patients with colorectal cancer with exclusive oligometastases to the lung.

Material and Methods: we treated 62 lung metastases in 38 patients with oligometastatic colorectal cancer. Inclusion criteria were: primary tumor controlled, ≤ 5 lung metastases, no other active sites of disease at the time of the SABR. Dose prescription was: 23Gy/1 fr per central lesion <30 cc (18 lesions), 30Gy/1fr for peripheral metastases <30 cc (35 lesions), 45Gy/3fr for peripheral lesion >30cc (9 lesions). Twenty patients had 1 metastasis (53%), 14 patients had 2 metastases (37%) and 4 patients three-to-four metastases (10%). Median BED was 120 Gy. OS, PFS, MFS, local control and toxicity were evaluated.

Results: median follow-up was 24 months (ranged 3-76 mo). Median actuarial survival was 34 months (c.i. 20-47 months). Overall survival (OS) at 1-, 2- and 5-years was 80%, 50.7% and 26.9% respectively. Complete response (CR) was achieved in 22/62 lesions (35.4%). Median disease-free survival (DFS) was 24 months (ranged 13-34 months). DFS at 1-, 2- and 5-years was 79.8% and 40.4% and 22%, respectively. Complete response (CR) was the only prognostic factor significantly correlated with OS, PFS and metastasis-free survival (MFS) (p= 0.001 in each case). Patients with CR had 1-,2- and 5-years OS of 100%, 90.9% and 67.3%, while patients with partial response (PR) and stable disease (SD) had respectively 69.2, 34.6% and 0% and 63.5% at 1 and 2-years and 15.9% at 5-years. Acute G1-2 lung toxicity, according to the CTCAE-V4.0, was 10%, G3 lung toxicity was 1.6%. Late G1-2 toxicity rate was 25%. No late G3 toxicity was found.

Conclusion: SABR has a high rate of local control in the lung metastasis from colorectal cancer and also affect survival. CR statistically correlated with OS, PFS and MFS, even at long-term. There is a need of prospective trials to confirm these data and to identify the right selection criteria and the best timing with systemic therapies.

Poster: Clinical track: Gynaecological (endometrium, cervix, vagina, vulva)

PO-0723

Short time interval between radiation and hyperthermia improves treatment outcome in cervical cancer

C.M. Van Leeuwen¹, A.L. Oei¹, K.W.T.K. Chin¹, L.J.A. Stalpers¹, A. Bel¹, J. Crezee¹, N.A.P. Franken¹, H.P. Kok¹

¹*Academic Medical Center, Radiation Oncology, Amsterdam, The Netherlands*

Purpose or Objective: To determine the effect of the time interval between external beam radiotherapy (EBRT) and hyperthermia (HT) treatments on locoregional recurrence and overall survival of patients with cervical cancer.

Material and Methods: This retrospective study included 59 women with locally advanced (stage IB2-IVA) cervical cancer, all treated with radiotherapy and HT. Additional treatment with chemotherapy was reason for exclusion.

Patients received four to five weekly HT treatments concurrent with 23-28 fractions (1.8-2.0 Gy) EBRT and a brachytherapy boost (20-24Gy). On HT treatment days, HT was given after EBRT. The mean time interval between the EBRT and HT treatments that were delivered on the same day was used to characterize the typical time interval for that patient. The median thereof (79.2 minutes) was used to split the cohort in a 'short' and 'long' time-interval group. Median time intervals were 65.8 minutes (range 33.8-79.2) and 91.7 minutes (range 80.0-125.2) for the short and long time-interval group, respectively.

Locoregional recurrence and overall survival were estimated using Kaplan-Meier analysis, and compared by a log-rank test. To correct for any potential confounding factors, a stepwise Cox regression analysis using backward elimination was used with time-interval group, age, FIGO stage, number of HT treatments, tumour temperature during HT treatment (T90), lymph node status and smoking as covariates.

Results: Locoregional recurrence was significantly lower in the short time-interval group (Fig. 1). Recurrence rate at 2 years was 11% (95%CI 3-36%) in the short time-interval group compared to 49% (95%CI 30-73%) in the long time-interval group. The stepwise Cox regression identified time-interval (a short interval is better), T90 (higher temperatures are beneficial) and age (younger age is unfavourable) as significant prognostic factors, and shows a favourable trend for lower FIGO stage (Table 1).

Overall survival was also significantly better in the short time-interval group (Fig. 1). Overall survival at 2 years was 60% (95%CI 39-75%) in the short group compared to 39% (95%CI 21-56%) in the long time-interval group. The stepwise Cox regression identifies a short time-interval and higher T90 as significant factors for a favourable outcome (Table 1).

Fig. 1. Kaplan-Meier curves for locoregional recurrence (left) and overall survival (right) after EBRT and HT for advanced cervical cancer, grouped by time-interval between EBRT and HT.

Table 1 Results of the Cox multivariable analysis of locoregional recurrence and survival after radiotherapy and hyperthermia for advanced cervical cancer.

Outcome	Factor	Hazard ratio (95%CI)	P-value
Recurrence	Time-interval	6.7 (1.6-28)	0.008
	T90	0.31 (0.13-0.72)	0.007
	Age	0.93 (0.89-0.97)	0.002
	Stage	4.5 (0.96-21)	0.057
Overall survival	Time-interval	2.2 (1.2-4.2)	0.014
	T90	0.57 (0.38-0.86)	0.008

Conclusion: A short time interval between EBRT and HT results in a significantly lower recurrence and better overall survival for locally advanced cervical cancer patients. Furthermore, a higher tumour temperature during HT is associated with lower locoregional recurrence and better overall survival, stressing the importance of HT quality assurance.

PO-0724

Adjuvant SIB-VMAT in endometrial cancer: a dose escalation study

G. Macchia¹, S. Cilla², F. Deodato¹, M. Nuzzo¹, A. Ianiro², M. Marucci¹, G. Perrella¹, C. Digesù¹, V. Valentini³, M. Ferioli⁴, F. Bertini⁴, A. Galuppi⁴, M. Perrone⁵, P. De Iaco⁵, S. Cammelli⁴, G. Frezza⁶, A.G. Morganti⁴

⁴S. Orsola-Malpighi Hospital- University of Bologna, Radiation Oncology Center- Department of Experimental- Diagnostic and Specialty Medicine - DIMES, Bologna, Italy

⁵Sant'Orsola-Malpighi Hospital, Gynecologic Oncology Unit, Bologna, Italy

⁶Bellarìa Hospital, Radiation Department, Bologna, Italy

Purpose or Objective: To define the recommended dose in high-intermediate risk endometrial cancer (HIR-EC) patients postoperatively irradiated by simultaneous integrated boost volumetric modulated arc therapy (SIB-VMAT).

Material and Methods: A radiation dose of 45 Gy over 5 weeks, 1.8 Gy/fraction, was delivered to the vagina and the lymphatic drainage (planning target volume, PTV2). Radiation dose was escalated to the upper two thirds of vagina (PTV1) with the SIB-VMAT strategy, after 1 year follow up of the first 15 patients. Two dose levels were planned: Level 1 (PTV2: 45/1.8 Gy; PTV1: 55/2.2 Gy), and Level 2 (PTV2: 45/1.8 Gy; PTV1: 60/2.4 Gy). All treatments were delivered in 25 fractions. Patients were treated according to a Phase I-II dose-escalation study. Toxicity was scored by CTC-AE v. 3.0 scale.

Results: Sixty-six HIR-EC patients were enrolled. The Level 1 group included 38 patients while Level 2 group included 28 patients. Clinico-pathological characteristics of the two groups are reported in Table 1. All patients completed radiation treatment without interruption. No differences were found between the 2 groups in terms of skin, gastrointestinal and genitourinary toxicities.

Table 1: Patients characteristics and toxicity (CTC v 3.0); number in brackets are percentages

	Level 1	Level 2	p
N° Patients (%)	38 (57.5)	28 (42.5)	ns

2	4 (10.5)	9 (32.2)	
3	0 (0)	1 (3.5)	
4	0 (0)	0 (0)	

BMI= Body Mass Index; CT= chemotherapy; RT: radiotherapy.

With a median follow up of 20 months (range 3-48 months), no dose limiting toxicity was reported, therefore Level 2 was considered as the recommended dose. Three vaginal recurrences were documented at 8, 14 and 19 months after SIB-VMAT in Level 1 group. At two-years local control was 90.4% (Level 1), versus 100% (Level 2), while disease free survival was 85.6% (Level 1) versus 93.3% (Level 2); overall survival was 96.2% (Level 1) versus 100% (Level 2), respectively.

Conclusion: To date, according with this phase I-II study clinical results, SIB-VMAT strategy represents the standard adjuvant treatment in HIR-EC at our Institution. We established the dose of 45Gy/1.8 Gy to pelvic nodes and 60 Gy/2.4 Gy to the upper two thirds of vagina as the recommended doses for further evaluation of SIB-VMAT approaches in this setting.

PO-0725

Pelvic organ motion during radiotherapy for cervical cancer and impact on target coverage

G. Eminowicz¹, J. Motlib¹, S. Khan¹, C. Perna¹, M. McCormack¹

¹University College London Hospital, Radiotherapy Department, London, United Kingdom

Purpose or Objective: Minimisation of internal organ motion during pelvic radiotherapy (RT) is necessary to ensure accurate reproducible treatment. We analysed bladder and rectal filling during pelvic RT and their impact on CTV coverage.

Material and Methods: Cone beam Computed Tomography scans (CBCTs) taken twice weekly during 3D conformal RT were retrospectively analysed for 10 cervical cancer patients. All patients followed the departmental guidelines; empty bladder then drink 4 cups of water 40 minutes before

scanning/RT; laxatives taken to ensure bowels opening daily, ideally Bristol stool chart type 5. Bladder, rectum and primary CTV were outlined on each CBCT by 2 independent clinicians. Effects of time through RT, chemotherapy administration, and drinking time on bladder and rectal volume were analysed. Volume variation impact on CTV coverage was also investigated using fixed effect logistic regression modelling.

Results: 10 planning scans and 109 CBCTs were reviewed. Bladder volume was 45-578cc during radiotherapy and 73-664cc at planning. Bladder volume increased (approx. 4cc/minute) with waiting time, decreased (average 4cc/day) through RT and was larger (approx. 50cc average) on chemotherapy days. All bladder volumes that deviated >130cc from planning led to CTV being out of PTV. The odds of CTV remaining within PTV reduced by 1.9% for every cc deviation from planning volume, predominantly affecting uterus. Large planning bladder volumes (>300cc) were not reproducible during RT. Rectal anterior-posterior (AP) diameter correlates with rectal volume and displays no pattern through treatment. AP diameter ranged from 2.9-5.3cc at planning and 1.6-8.7cc during RT. The odds of CTV remaining in PTV reduced by 5.8% with every mm deviation from planning rectal AP diameter, predominantly affecting cervix.

Conclusion: Bladder volume changes during RT and with chemotherapy increase the risk of CTV being outside of PTV, especially the uterus. Rectal size changes increase the risk of CTV being outside of PTV, predominantly affecting the cervix. Increasing rectal size correlates with decreasing bladder volume, possibly due to dehydration. We therefore recommend an ideal bladder planning volume of 150-300cc, a shorter waiting time on chemotherapy days and adequate hydration throughout RT. We also recommend regular laxatives to ensure smaller rectal sizes through RT. Even with these recommendations, regular imaging is vital to monitor organ motion when implementing advanced RT techniques for gynaecological cancers.

PO-0726

Stereotactic body radiotherapy for mediastinal and sub-diaphragmatic nodal relapse of ovarian cancer

L. Draghini¹, F. Trippa¹, F. Arcidiacono¹, P. Anselmo¹, M. Casale¹, M. Italiani¹, M. Muti¹, M.L. Basagni¹, L. Chirico¹, R. Rossi¹, E. Maranzano¹

¹Radiation Oncology Centre, Oncology Department "S.Maria" Hospital Terni, Terni, Italy

Purpose or Objective: To retrospectively evaluate the effectiveness and toxicity of stereotactic body radiotherapy (SBRT) for localized nodal relapse (NR) of ovarian cancer.

Material and Methods: Between August 2008 and March 2015, eleven patients were treated with SBRT on 16 NR of previous ovarian cancer. All patients at the time of ovarian cancer diagnosis were submitted to surgery and at least 1 line of chemotherapy (range, 1-3). Median age was 64 years (range, 49-74), and primitive histology was sero-papillar and endometrioid carcinoma in 8 (72%) and 3 (28%) patients, respectively. Median interval time between first diagnosis and NR was 83 months (range, 22-148). NR was documented with PET-CT as the only site of disease. Response was evaluated with PERCIST criteria.

Results: Median follow-up was 11 months (range, 2-47), median GTV 5.4 cc (range, 1.8-18.3), median PTV -obtained adding an isotropic margin of 5 mm to the GTV- 16.5 cc (range, 4.2-85.7). There were 11/16 (69%) sub-diaphragmatic, 5/16 (31%) mediastinal NR. Fractionation schemes were: 5 x 8Gy in 10 (62%), 5 x 7Gy in 1 (6%), 5 x 6Gy in 1 (6%) and 5 x 5Gy in 5 (26%) NR. Outcome, evaluated with PET-CT 3 months after SBRT, showed a complete response in all treated NR, with a median duration of response of 17 months (range, 2-47). Six (54%) patients had a subsequent "out-field" progression, 1 nodal and 4 peritoneal progression in sub-diaphragmatic region, 1 nodal progression in

mediastinal region. The two cases with nodal progression received another SBRT, while the others chemotherapy. No acute or late toxicity was registered after SBRT. At the time of last follow-up, 9 patients were alive 6 of whom without evidence of disease.

Conclusion: All ovarian cancer patients submitted to SBRT for NR had a durable complete response without toxicity. However, outcome seems less satisfying in patients with sub-diaphragmatic disease because of peritoneal progression in absence of in-field relapse.

PO-0727

Prognostic impact of 18F-FDG PET-CT in patients with locally advanced cervical carcinoma

S. Cima¹, A. Galuppi², P. De Iaco³, M. Perrone³, S. Fanti⁴, G. Compagnone⁵, M.C. Valli¹, A. Richetti¹, G. Macchia⁶, M. Nuzzo⁶, F. Deodato⁶, G. Ferrandina⁷, F. Bertini², A. Farioli⁸, S. Cammelli², G. Frezza⁹, A.G. Morganti²

⁴Nuclear Medicine Unit- S.Orsola-Malpighi Hospital-University of Bologna, Department of Experimental-Diagnostic and Specialty Medicine, Bologna, Italy

⁵S.Orsola-Malpighi University Hospital, Department of Medical Physics, Bologna, Italy

⁶Fondazione di Ricerca e Cura "Giovanni Paolo II" - Catholic University of Sacred Heart, Radiotherapy Unit, Campobasso, Italy

⁷Policlinico Universitario "A. Gemelli"- Catholic University of Sacred Heart, Department of Gynecologic Oncology, Roma, Italy

⁸S.Orsola-Malpighi Hospital - University of Bologna, Department of Medical and Surgical Sciences- DIMEC, Bologna, Italy

⁹Ospedale Bellaria, Radiotherapy Department, Bologna, Italy

Purpose or Objective: The primary objective of this study was to evaluate the prognostic value of pretreatment 18-F-FDG PET-CT in patients with locally advanced cervical cancer.

Material and Methods: At pre-treatment staging, 92 patients with histological diagnosis of cervical cancer, underwent 18-F-FDG PET-TC in addition to routine protocol including International Federation of Obstetrics and Gynecology (FIGO) staging and MRI. Patients were treated with concurrent chemoradiation followed by brachytherapy boost.

Results: 18-F-FDG PET-CT identified the presence of para-aortic lymph node metastases in 17 patients (18%). These patients were treated with extended field irradiation (including para-aortic nodes). The results of multivariate analysis showed that 18-F-FDG PET-CT positive para-aortic lymph nodes and advanced FIGO stage were predictive of worse disease-free survival (p=0.01; p=0.001, respectively), and high T SUV max had a negative impact on local control, disease-free survival and overall survival (p=0.02; p=0.01; p=0.01, respectively).

Figure 1. Actuarial local control, Disease free survival and Overall survival for T SUVMAX

Conclusion: High T SUV (max) showed a strong prognostic impact in these patients. Furthermore, staging 18-F-FDG PET-

CT modified radiotherapy planning in a significant percentage of patients.

PO-0728

Stereotactic Body Radiation Therapy for oligometastatic patients with ovarian cancer

A. Tozzi¹, C.S. Iftote¹, T. Comito¹, C. Franzese¹, F. De Rose¹, E. Villa¹, P. Navarria¹, A.M. Ascolese¹, D. Franceschini¹, R.L.E. Liardo¹, E. Clerici¹, G.R. D'Agostino¹, V. Palumbo¹, M. Scorsetti¹

¹Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

Purpose or Objective: Ovarian cancer is a gynecological malignancy characterized by a dismal outcome for its tendency to metastasize despite aggressive systemic therapies, commonly carboplatin and paclitaxel. Among recurrent ovarian cancer, patients with oligometastatic disease are supposed to have a better prognosis since they could benefit from local approaches besides chemotherapy, considering also the limited alternative regimens of systemic therapy. The aim of our study is to evaluate the role of stereotactic body radiotherapy (SBRT) in terms of LC and toxicity in a setting of patients with oligometastatic recurrent ovarian cancer.

Material and Methods: Between January 2011 and February 2015, 15 patients (20 lesions) with recurrent oligometastatic ovarian carcinoma of any histology underwent SBRT. Toxicity and tumor response was scored using Radiation Therapy Oncology Group/European Organization for Research and Treatment of Cancer Scale. Tumor response was evaluated by CT/ PET, according to Response Evaluation Criteria in Solid Tumors.

Results: Median age at treatment was 60 years and median follow-up was 21 months. The sites of disease were abdomino-pelvic lymphnodes (13 lesions), liver metastasis (4 lesions), lung metastasis (2 lesions) and para-vaginal mass (1 lesion). The SBRT doses were prescribed based on dimensions of target volumes and organs at risk constraints as follow: for lymphnodal lesions the dose prescription was 36-45 Gy in 6 fractions and only one case treated with 40 Gy in 4 fr; for hepatic lesions 61.89 -75 Gy in 3 fractions, for the pulmonary lesions both cases received 48 Gy in 4 fractions meanwhile in the para vaginal recurrence dose prescription was 36 Gy in 6 fractions. None of the patients had grade 3 /4 acute or late Gu or Gi toxicity. At a median follow-up of 21 months local control was observed in 85%. Complete radiologic response, partial response and progressive disease were observed in 12 (60%), 5 (25%) and respectively 3 cases (15%).

Conclusion: SBRT is a feasible and well tolerated treatment approach in oligo-metastatic ovarian patients, offering a good local control. Certainly, additional patients and longer follow-up are necessary to confirm the impact of local treatment as SBRT in ovarian cancer therapy.

PO-0729

Hematological toxicity of Rth-Chth for cervical cancer: Rth technique and dose given to bone marrow

K. Białas¹, M. Agnieszka Stefanowicz¹, M. Karolina Osowiecka¹, P. Katarzyna Pawłó - Pyrk¹, P. Lucyna Kępa¹
¹SP ZOZ MSW Warmia@Mazury Oncology Centre, Radiation Oncology, Olsztyn, Poland

Purpose or Objective: This is a concern about hematological toxicity (HT) of intensity-modulated radiation therapy (IMRT) technique combined with chemotherapy used in the treatment of gynecological malignancies due to the high volume of low radiotherapy doses given to bone marrow. We aimed to determine if pelvic IMRT increased HT and which dosimetric parameters were predictors of this toxicity.

Material and Methods: Ninety-nine consecutive cervical cancer patients treated with radio-chemotherapy (45-50,4Gy with Cisplatin 40mg/m2/week) between IX2011 and V2015

were included. Fifty patients received three-dimensional conformal radiotherapy (3D-CRT) (4-6 fields) and 49 IMRT with RapidArc. Target volumes were contoured in accordance with RTOG Atlas guidelines. Pelvic bone marrow was defined using a computed tomography density-based autocontouring algorithm. HT was graded by Common Terminology Criteria for Adverse Events, version 4.0 criteria weekly during treatment. The rate of occurrence of grade III-IV HT (overall, anemia, thrombocytopenia, neutropenia, leucopenia) were evaluated in relation with radiotherapy technique, PTV, age, mean dose to bone marrow, volumes of bone marrow receiving 5, 10, 20, 30, and 40 Gy (V5, V10, V20, V30, and V40). The Chi2 test was used to compare HT for each studied parameter dichotomized at the median. Differences between IMRT and 3D-CRT technique were compared with U-Mann-Whitney test.

Results: Patients treated with IMRT had significantly lower V20, V30, V40, mean bone marrow dose, and PTV volume than 3D-CRT patients ($p < .00001$ for each). The both techniques did not differ significantly in age of patients, number of chemotherapy cycles given, V5 and V10. Grade III-IV HT of any kind occurred in 52% of 3D-CRT patients and 30% of IMRT patients, $p = 0.03$. Each evaluated threshold of dose given to bone marrow predicted significantly occurrence of HT. Larger PTV was not predictor of higher HT.

Conclusion: Pelvic IMRT decreased HT of radio-chemotherapy for cervical cancer in comparison with 3D-CRT by reduction of volume of doses >20 Gy given to bone marrow. Even though a precise dose threshold for bone marrow was not determined, limitation of bone marrow volume defined automatically as bone in patients treated with radio-chemotherapy is warranted.

PO-0730

QOL after postoperative IMRT for cervical cancer: results from matched pair analysis with 3DCRT

S. Chopra¹, S. Mohanty¹, U. Mahantshetty², S. Kannan¹, R. Engineer², S. Mechanery¹, R. Phurailatpam¹, J. Ghosh¹, S. Gupta¹, S. Shrivastava²

¹Advanced Centre for Treatment- Research and Education in Cancer- Mumbai, Radiation Oncology, Mumbai, India

²Tata Memorial Hospital- Tata Memorial Centre, Radiation Oncology, Mumbai, India

Purpose or Objective: Adjuvant intensity modulated radiotherapy (IMRT) for cervical cancer is associated with reduced late gastrointestinal toxicity (GI) however its impact on quality of life (QOL) is not known. The present matched pair analysis was performed to compare QOL between three-dimensional conformal radiation (3DCRT) and IMRT.

Material and Methods: From Jan,2011- Dec,2013 patients undergoing adjuvant or salvage radiation with 3DCRT or IMRT (with or without concurrent chemotherapy) and vaginal brachytherapy were included. Those who received systemic chemotherapy or extended field radiation were excluded. The study inclusion criteria also necessitated at least 1 year of follow up with QOL assessment at at least 2 time points. At follow up toxicity was documented using CTCAE version 3.0 and QOL was measured with EORTC QLQC-30 and Cx-24 module. The baseline characteristics of two cohorts were compared using chi-square test. Raw scores were converted into final scores using EORTC recommended conversion and linear mixed model was used to evaluate impact of time trends and treatment technique on QOL. A 10-point difference in QOL score and $p < 0.05$ was considered relevant and statistically significant. All data were analyzed using SPSS, version 20.0 and Graph pad Instat.

Results: A total of 64 patients were eligible. Postoperative IMRT and 3DCRT was used in 40 and 24 patients respectively. The baseline socioeconomic, disease and treatment related characteristics were well balanced in both groups rendering cohorts eligible for a matched pair analysis. At one year there was recovery in most of the QOL domains in both cohorts with objective scores reaching baseline levels. The

recovery in QOL scores over time was deemed statistically significant ($p < 0.0001$). A clinically and statistically significant improvement in physical (78.7 vs. 87.7, $p = 0.05$), emotional (66.5 vs. 78.5, $p = 0.05$) and social functioning (61.5 vs. 82.2) was observed in IMRT cohort. The patients treated with IMRT had fewer patients having symptoms of appetite loss (30.4 vs. 12.1, $p = 0.01$) and diarrhea (24 vs. 9; $p = 0.04$). The use of IMRT was also associated with reduced lymphedema (15.2 vs 3.2; $p = 0.05$). However no difference was observed in sexual and global QOL.

Conclusion: Early results show improved functional scales and reduced symptom scales with use of postoperative IMRT when compared to 3DCRT. Further long term follow up is needed to clearly define the impact of IMRT on patient reported outcomes.

PO-0731

Quality of life of women after endometrial cancer: the role of the vaginal dilator

R. Foerster¹, L. Schnetzke¹, T. Bruckner², H. Rief¹, J. Debus¹, K. Lindel¹

¹University Hospital Heidelberg, Department of Radiation Oncology, Heidelberg, Germany

²University Hospital Heidelberg, Department of Medical Biometry, Heidelberg, Germany

Purpose or Objective: Pelvic radiotherapy (RT) provides good local control in women with endometrial cancer (EC), but may also cause substantial acute and chronic adverse effects, which in turn may reduce patients' (pts) quality of life (QoL).

Material and Methods: 293 pts who were treated with adjuvant pelvic RT for EC at our department between 2004 and 2012 were asked to fill in questionnaires regarding their QoL (EORTC QLQ-C30, EN24). Median follow-up was 6 years. 112 pts agreed to participate. 42 (38%) used the vaginal dilator (VD; group A) as prescribed, 62 (55%) did not use the VD (group B), 8 (7%) preferred not to answer this question. The values of the function and symptom scales of the pts were statistically analyzed and compared between the two groups as well as compared with reported values of normal populations.

Results: The values of the function and symptom scales are generally lower in our pts compared to an age adapted normal population (NP). Pts reported statistically better values for sexual interest and sexual activity compared to NP ($p < 0.0001$), while sexual enjoyment was significantly reduced ($p < 0.0001$). Vaginal dryness and pain during intercourse ($p < 0.0001$) were the leading complaints. Sexual interest and activity increased with age ($p < 0.0005$) in contrast to NP. Pts in group A were younger than in group B ($p = 0.016$). Group A reported significantly less pain in the back and pelvis ($p = 0.005$) as well as less muscular pain ($p = 0.013$). Pts using VD > 1 year had better values for sexual interest ($p = 0.022$) and sexual activity ($p = 0.013$) compared to < 1 year. Pts with vaginal brachytherapy (IVB) only had a better global health status compared to pts with additional external beam RT, while IMRT was better than 3D-conformal RT ($p < 0.0017$). Pts with higher acute GI toxicity reported more chronic GI symptoms ($p = 0.002$) with diarrhea ($p = 0.009$), nausea/vomiting ($p = 0.032$) as well as poorer social functioning ($p = 0.036$). Pts with higher acute GU toxicity reported more pain during intercourse ($p = 0.044$).

Conclusion: Pelvic RT substantially affects QoL even years after treatment. Women participating in our study were more sexually active than the normal population. Therefore sexuality is important for QoL in women after endometrial cancer, even at higher age. The vaginal dilator is capable of improving chronic pelvic pain, sexual interest and sexual activity when used longer than one year. Pts with higher acute toxicities also exhibit more chronic problems. IMRT seems to be beneficial for long-term QoL.

PO-0732

Predictive factors for inter-fraction uterine motion in definitive radiotherapy for cervical cancer

H. Maemoto¹, T.T. Takafumi Toita¹, S.H. Seiji Hashimoto¹, T.A. Takuro Ariga¹, Y.K. Yasumasa Kakinohana¹, J.H. Joichi Heianna¹, S.M. Sadayuki Murayama¹

¹University of Ryukyus, Radiology, Okinawa, Japan

Purpose or Objective: Uterine motion is a challenging issue in applying intensity-modulated radiotherapy (IMRT) for patients with cervical cancer. In this study we quantified the inter-fraction uterus movement during a course of definitive radiotherapy (RT) to determine the predictive factors affecting uterine motion.

Material and Methods: A total of 343 cone-beam CT (CBCT) scans from 43 patients who underwent definitive RT were analyzed retrospectively. The median age of the patients was 58 years (range, 34-85 years). The FIGO stages were as follows: IB1, 9; IB2, 6; IIA, 1; IIB, 12; IIIB, 10; and IVA, 5. Cervical and corpus movement (mm) were measured for each direction (cranial [C], anterior [A], left [L] and right [R] for the uterine corpus; and A, posterior [P], L, and R for the cervix) by comparing planning CT and CBCT. The mean movement of each patient was analyzed according to the following factors: age; tumor stage; BMI; area of visceral fat in the umbilical plane, as assessed by CT; circumference of abdominal girth; history of abdominal surgery; uterine orientation (anteverted or retroverted); size of the uterus; tumor diameter; and tumor invasion to the corpus.

Results: The mean movement of the corpus was as follows: C, 5.8 mm (range, 0-29.0 mm); A, 5.2 mm (range, 0.3-37.7 mm); L, 2.4 mm (range, 0-10.6 mm); and R, 2.5 mm (range, 0-9.2 mm). The mean movement of the cervix was as follows: A, 3.2 mm (range, 0-11.4 mm); P, 2.4 mm (range, 0-12.5 mm); L, 1.5 mm (range, 0-9.2 mm); and R, 1.6 mm (range, 0-7.3 mm). There was a significant correlation between abdominal girth and anterior movement of the corpus ($r = -3.6$ and $p = 0.029$). Tumor invasion to the corpus had a negative correlation with posterior movement of the cervix with marginal statistical significance ($p = 0.05$).

Conclusion: The study demonstrated that abdominal girth and tumor invasion to the corpus were predictive factors of uterine motion during definitive RT for patients with cervical cancer.

PO-0733

Treatment response evaluation with ADCmean in cervical cancer patient treated with chemoradiotherapy

C. Onal¹, G. Erbay², O.C. Guler¹

¹Baskent Universitesi Tip Fakultesi- Adana Hastanes, Department of Radiation Oncology, Adana, Turkey

²Baskent University Faculty of Medicine, Department of Radiology, Ankara, Turkey

Purpose or Objective: The aim of this study is to investigate the ADCmean of the primary tumor to evaluate their correlations with the recurrence and survival rates in patients with primary cervical cancer before and after definitive CRT.

Material and Methods: The data of 44 patients with histologically proven squamous cell carcinoma of cervix was retrospectively evaluated. All patients had multi-parametric pelvic MR imaging (CE-MRI and DW-MRI) and 18F-FDG PET/CT for initial staging prior to treatment and also multi-parametric pelvic MR imaging after treatment at our Institution between February 2009 and May 2014. ADC response was measured by the proportion of ADC changes between pretreatment and posttreatment ADC measured in DW-MRI. The patients were divided into groups based on the pretreatment and posttreatment ADCmean of the primary tumor cutoff values derived from the ROC curves. Disease-

free survival (DFS) and OS rates were calculated using the Kaplan-Meier method. Multivariate analyses were performed using the Cox proportional hazards model.

Results: The median follow-up for all patients and surviving patients was 25 months (range, 3-75 months) and 28 months (range, 15-75 months), respectively. Post-treatment MRI images were taken within a median of 3.2 months (range, 2.8-4.1 months) after the completion of CRT. At post-treatment MRI, 41 patients (93%) exhibited a complete response. The mean pretreatment and posttreatment ADCmean were $0.882 \pm 0.096 \times 10^{-3}$ mm²/sec, $1.159 \pm 0.168 \times 10^{-3}$ mm²/sec, respectively. Median percent ADC change was 33.7% (5.0 - 70.0%). The analyses identified pretreatment ADCmean of the primary tumor cutoff values of 0.878×10^{-3} mm²/sec for recurrence (area under the curve [AUC] = 0.818, $p < 0.001$; 95% CI, 0.690-0.946, sensitivity 86.4%, specificity 72.7%), posttreatment ADCmean of the primary tumor cutoff values of 1.132×10^{-3} mm²/sec for recurrence (AUC = 0.810, $p < 0.001$; 95% CI, 0.684-0.936, sensitivity 77.3%, specificity 72.7%), ADC change cutoff values of 32.8% for recurrence (AUC = 0.810, $p < 0.001$; 95% CI, 0.683-0.937, sensitivity 77.3%, specificity 68.2%). In a multivariate analysis, pelvic lymph node metastasis and pretreatment ADCmean were significant prognostic factors for both OS and DFS. Additionally, ADC change between pretreatment and posttreatment DW-MRI was significant factor for OS.

Conclusion: Our findings provide evidence that posttreatment low ADCmean of the primary tumor is a useful clinical prognostic biomarker for recurrence and survival in patients with cervical cancer.

PO-0734

Justgin in the prevention of radio-induced vaginal mucositis

F. Piccolo¹, A. Romano¹, A. Rese¹, E. D'Ippolito¹, F. Pastore¹, P. Romanelli¹, L. Faraci¹, E. Toska¹, V. De Chiara¹, A. Farella¹, R. Solla^{1,2}, M. Conson^{1,2}, R. Liuzzi^{1,2}, L. Cella^{1,2}, R. Pacelli^{1,2}

¹Az. Ospedaliera Universitaria Federico II, Dipartimento di Scienze Biomediche Avanzate, Napoli, Italy

²C.N.R. Istituto di Biostrutture e Bioimmagini, Napoli, Italy

Purpose or Objective: Radiation therapy on the pelvic region in women may induce disturbing vaginal irritation impacting on patients quality of life. We tested a hyaluronic acid based vaginal washing (Justgin) in the prevention of vaginal mucositis in patients treated with external beam radiation therapy for pelvic neoplasms.

Material and Methods: Fifty eight female patients affected by uterine tumors and undergoing radiation therapy on the pelvic region were considered for the study. Median age was 58. Twenty eight patients were affected by endometrial cancer, while 30 were affected by cervical cancer. Radiation therapy was delivered by 6 MV X ray of a linear accelerator with 4 fields 3D conformal radiation therapy with a dose of 45-50.4 Gy in 25-28 daily 1.8 Gy fractions. Group A (28 patients) used Justgin every other day, and 30 patients (group B) did not use any prophylactic therapy. Patients were visited and interviewed about vaginal discomfort or symptoms every week.

Results: At the end of radiation therapy 13/28 patients of group A and 27/30 of group B, developed vaginal toxicity of any grade ($p = 0.0005$). Overall, however the toxicity was mild or moderate in all patients.

Conclusion: Our study suggests that a vaginal washing with hyaluronic acid (Justgin) can reduce the incidence of the vaginal acute symptoms induced by external beam irradiation in women affected by uterine cancer.

PO-0735

Prognostic value of microRNA-205 in endometrial cancer patients treated with adjuvant radiotherapy.

M. Wilczynski², J. Danielska¹, J. Fijuth³, A. Malinowski²

¹Medical University of Lodz, Radiotherapy Department, Lodz, Poland

²Polish Mother's Memorial Hospital Research Institute, Department of Surgical- Endoscopic and Oncologic Gynecology, Lodz, Poland

³Medical University of Lodz, Radiotherapy Department, Lodz, Poland

Purpose or Objective: Endometrial cancer (EC) is the leading malignant tumour occurring in the female genital tract. miRNAs are small non-coding RNAs that have a broad impact on cancer progression. The aim of our study was to define tissue miRNA-205 expression levels, which could potentially serve as a prognostic marker in EC. We investigated miRNA-205 profiles in regard to clinicopathological characteristics of patients treated with adjuvant radiotherapy from 2002 until 2014.

Material and Methods: Expression profiling of miRNA-205 was performed in EC tissues from patients who were submitted to adjuvant radiotherapy after hysterectomy, according to the International Federation of Gynecology and Obstetrics (FIGO) guidelines. 90 patients were included in the study. The median follow-up period was 46 months (min.2 months;max.119 months). We analyzed the paraffin-embedded tissue samples and identified the areas of EC. We extracted total RNA from 90 EC samples. The reference group was constituted by 10 paraffin-embedded healthy endometrial tissue samples. Spectrophotometric assessment of the total RNA concentration was performed. cDNA was synthesized from total RNA with high capacity cDNA synthesis kit and miRNA-specific primers (miR-205 and internal control RNU6b). The expression of the miRNA-205 was determined using real-time quantitative PCR. The expression level of miRNA-205 was calculated $\Delta\Delta CT$ values based on the internal control and plotted as relative value (RV).

Results: Our results indicate that the expression of miRNA-205 was significantly higher in EC samples ($p = 0.000158$). The expression of miRNA-205 was differentiated considering different grading levels. The lowest miRNA-205 expression was observed in grade 3 ($p = 0.02$). There was no correlation between FIGO stages of EC and miRNA-205 expression ($p = 0.23$). When we divided patients into two subgroups: advanced EC (III, IV FIGO) and non-advanced EC (I,II FIGO) it turned out that the expression levels of miRNA-205 were significantly lower in the advanced EC patients group ($p < 0.045$). The miRNA-205 expression was lower when there was over 50% invasion of the myometrium ($p < 0.038$). Kaplan-Meier survival curves were generated to examine the relationship between the expression levels of miRNA-205 and patient's survival rate. Its analysis revealed that high levels of miRNA-205 are associated with longer survival (fig.1).

Conclusion: Increased miRNA-205 expression is a positive prognostic factor. Lower levels of miRNA-205 are characteristic of more advanced stages of EC.

⁴Universidad Europea, Department of Research, Madrid, Spain

⁵Universidad Europea, School of Medicine, Madrid, Spain

⁶Hospital Quiron, Medical Physics, Madrid, Spain

⁷Hospital Quiron, Pathology, Madrid, Spain

⁸Hospital Quiron, Urology, Madrid, Spain

⁹Hospital Quiron, Clinical Oncology, Madrid, Spain

¹⁰Hospital Quiron, Assistant manager, Madrid, Spain

Purpose or Objective: To assess and validate the incorporation of the multiparametric magnetic resonance imaging (mpMRI) tumor stage (mT-stage) to the conventional clinical tumor stage (cT-stage), in order to guide the radiotherapy (RT) treatment decisions in prostate cancer. In addition, to identify the clinical factors associated to the technique reliability.

Material and Methods: mpMRI was performed in 274 prostate cancer patients in order to refine the treatment decisions according to PSA, Gleason Score (GS) and cT-stage. Comparisons between the cT and mT-stage were performed, as well as the impact on the RT treatment prescription (target volume, doses and hormonal therapy [HT]) independently if it was finally performed. Changes in HT indication for intermediate risk with unfavourable factors were also analyzed. Until 2014, the unfavourable factors according to the initial criteria were a GS of 7 (4+3), or three unfavourable intermediate risk factors (T2b+PSA 10-20 ng/mL + GS 3+4), or T2c by digital rectal exam (DRE)/transrectal ultrasound (TRUS); more recently, unfavourable risk factors have been established according to Memorial Sloan Kettering Cancer Center (MSKCC) criteria: GS 4+3, or at least two intermediate-risk factors, or at least one intermediate-risk factor and a positive prostate biopsies (ppb) percentage greater than 50%. mpMRI validation was performed with pathological staging (n=90 patients finally decided to join surgery). To analyse the relationship between the reliability of mpMRI and the clinical variables, a univariate and multivariate logistic regression analysis was performed.

Results: The mpMRI upstaging range was 86-94% for any PSA value or GS. Following mpMRI, 32.8% of the patients (90/274) were assigned to a different risk group. Compared to cT-stage, mpMRI identified more intermediate-risk (46.4% vs. 59.5%) and high-risk (19.0% vs. 28.8%) prostate cancer patients. This resulted in a higher indication (p<0.05) of seminal vesicle irradiation (63.5% vs. 70.1%), inclusion of any extracapsular disease (T3-T4) within the target volume (1.8% vs. 18.2%), higher doses (65.3% vs. 88.3%) and more indication of HT associated to RT (45.6% vs. 62.4%), Table 1. Finally, decisions concerning RT were changed in 43.8% (initial criteria) or 52.5% (MSKCC criteria) of the patients, depending on the criteria applied to indicate HT in intermediate-risk patients. Global reliability of T-staging with DRE/TRUS was 8.8% (8/90), while it was 71.1% (64/90) for mpMRI. cT-stage was associated to a greater occurrence (p<0.05) of indication of inadequate RT treatments. mpMRI reliability was independent of PSA or GS or ppb percentage.

Table 1. Impact of mpMRI tumor staging on RT treatment prescription (target volume, doses and hormonal therapy).

Characteristics	DRE/TRUS n (%)	mpMRI n (%)	p value

VVS seminal vesicles, DRE/TRUS digital rectal exam/transrectal ultrasound

Conclusion: mpMRI tumor staging significantly improved the RT treatment decisions in all prostate cancer risk groups. The magnitude of the impact on final RT treatment decisions will depend on the institution's clinical protocol for prostate cancer management.

PO-0737

Predictors of PSA relapse in patients with intermediate risk prostate cancer treated with SBRT

T. Kole¹, S. Guleria¹, H. Koneru¹, O. Obayomi-Davies¹, T. Yung¹, S. Lei¹, B. Collins¹, S. Suy¹, A. Dritschilo¹, S. Collins¹
¹Georgetown University Hospital, Radiation Medicine, Washington, USA

Purpose or Objective: SBRT has demonstrated favorable outcomes in selected patients with early stage localized prostate cancer. Treatment of patients with intermediate risk disease remains cautionary due to the heterogeneity within this population with respect to risk for occult extraprostatic disease. Here we report an analysis of PSA outcomes following SBRT for intermediate risk prostate cancer and identify disease specific risk factors for biochemical failure.

Material and Methods: Patients treated with SBRT at Georgetown University Hospital for intermediate risk prostate adenocarcinoma, with or without the use of androgen deprivation therapy (ADT), were included in this retrospective analysis. Treatment was delivered using CyberKnife® SBRT with doses of 35 Gy or 36.25 Gy in 5 fractions. PSA failure was defined as a rise > 2 ng/ml above nadir (ASTRO Phoenix definition) and analyzed using the Kaplan Meier method. A Cox proportional hazards model was generated using disease related covariates including T stage, primary gleason pattern, pretreatment PSA, number of positive cores, percent positive cores, maximum single core involvement in order to identify potential predictors of PSA relapse after SBRT. A logrank test was also used to compare patients classified as having favorable vs. unfavorable intermediate risk disease by previously reported criteria of primary gleason pattern 4, 50% cores involved, or ≥2 intermediate risk factors.

Results: Three hundred and fifty three patients at a median age of 70 years (range, 46 to 90) received SBRT. ADT was initiated prior to SBRT in 16% of patients and the median pre-

treatment PSA was 7.2 ng/ml (range, 0.8 to 19.9). The overall 3-year biochemical relapse free survival (bRFS) was 93.9%. Cox regression identified primary gleason pattern as the only significant predictor of PSA relapse with a HR of 5.84 (1.92 to 17.8, 95% CI) for primary gleason pattern 4 vs. 3. There was no significant difference in bRFS between patients classified as having favorable vs. unfavorable intermediate risk disease, HR 0.39 (0.11 to 1.41, 95% CI). There were no significant benefits observed with respect to ADT in any subgroup.

Conclusion: Early PSA responses after SBRT for intermediate risk prostate adenocarcinoma compare favorably to those reported using other radiation therapy modalities. Primary gleason pattern 4 is predictive of less favorable bRFS, however early rates of PSA control are excellent compared to historical controls. The role of ADT in these patients is still unclear. The current evidence supports SBRT as a standard therapeutic option in intermediate risk disease.

PO-0738

Hydrogel injection prevents long-term rectal toxicity after radiotherapy for prostate cancer

M. Pinkawa¹, V. Schmitt¹, V. Djukic¹, J. Klotz¹, L. König¹, D. Frank¹, B. Krenkel¹, M. Eble¹
¹Uniklinikum RWTH Aachen, Radiation Oncology Department, Aachen, Germany

Purpose or Objective: The aim of the study was to compare health-related quality of life (QoL) after external beam radiotherapy (RT) for prostate cancer with and without a hydrogel spacer.

Material and Methods: A group of 202 patients with the indication for treatment of the prostate +/- base of seminal vesicles without pelvic lymph nodes was treated in a single institution in the years 2010-2013. Depending on the patient's and responsible radiation oncologist's preference, 108 patients were selected for a hydrogel injection before the beginning of RT. The injection of 10 ml hydrogel was performed under transrectal ultrasound (TRUS) guidance after dissecting the space between prostate and rectum with a saline/lidocaine solution under local anaesthesia. Treatment was performed with a five-field IMRT or VMAT technique with daily ultrasound based image guidance. Only for patients with a spacer the prescription dose was increased from 76Gy to 78Gy, subsequently 80Gy. Patients were surveyed prospectively before RT (time A), at the last day of RT (time B), a median time of two months (time C) and seventeen months after RT (time D) using a validated questionnaire (Expanded Prostate Cancer Index Composite; comprising 50 items concerning urinary, bowel, sexual and hormonal domains). The multi-item scale scores were transformed lineary to a 0-100 scale, with higher scores representing better QoL. Baseline QoL assessment was available from 101 / 66 patients with / without a spacer. Responses to both the baseline and last (time D) questionnaire were available in 94 / 57 cases with / without a spacer.

Results: Apart from higher prescription doses in the spacer group, baseline patient characteristics were well balanced between patients with vs. without a spacer (Table). In particular, baseline QoL was comparable. Acute toxicity (corresponding to QoL changes at times B and C relative to baseline levels) did not differ significantly, with only a tendency for better scores in the spacer group. However, mean bowel bother scores >1 year after RT in comparison to baseline did not change for patients with a spacer (mean change of 0 points) in contrast to patients without a spacer (mean decrease of 7 points). Long-term mean urinary bother scores did not decrease in both groups. At time D, statistically significant differences were found in the function items "bloody stools", "painful bowel movements" and "frequency of bowel movements". Focusing on patients with no problem with bowel symptoms initially, 0% vs. 12% with vs. without a spacer reported a moderate/big problem with bowel symptoms >1 year after RT (p<0.01).

	with spacer	without spacer	
patient age (years); median (range)	72 (49-82)	73 (53-85)	
PTV (cm ³); median (range)	127 (37-335)	123 (36-300)	
prescription dose to PTV ≤76Gy / 78Gy / 80Gy; %	64* / 26* / 10*	100* / 0* / 0*	
PSA (ng/ml); median (range)	7.6 (2.3-83)	7.3 (1.8-94)	
low/intermediate/high risk patients; %	33 / 37 / 30	33 / 42 / 26	
urinary bother score; mean	before RT	84	79
	decrease at time B/C/D	18 / 14 / -1	21 / 17 / -2
bowel bother score; mean	before RT	94	93
	decrease at time B/C/D	14 / 3 / 0*	18 / 6 / 7*
sexual bother score; mean	before RT	66	66
	decrease at time B/C/D	6 / 12 / 12	9 / 19 / 17

*p<0.01 (significant differences between groups)

negative decrease corresponds to quality of life improvement

Conclusion: Though acute rectal symptoms are still reported, spacer injection is associated with a significant long-term benefit for patients after prostate cancer RT.

PO-0739

IMRT versus 3D conformal radiotherapy when used in combination with I-125 prostate brachytherapy

A. Yorozu¹, T. Tanaka¹, R. Kota¹, Y. Takagawa¹, Y. Shiraishi¹, K. Toya¹, S. Saito²

¹Tokyo Medical Centre- NHO, Department of Radiation Oncology, Tokyo, Japan

²Tokyo Medical Centre- NHO, Department of Urology, Tokyo, Japan

Purpose or Objective: To compare biochemical outcomes and toxicity of intensity modulated radiotherapy (IMRT) and three-dimensional conformal radiotherapy (3D-CRT) when used in combination with I-125 brachytherapy (BT) for the treatment of unfavorable-risk prostate cancer.

Material and Methods: A retrospective review was performed on 839 patients with localized prostate cancer who received external-beam radiotherapy (EBRT) following BT between 2003 and 2012. Patients were categorized into National Comprehensive Cancer Network risk groups: 616 were unfavorable intermediate-risk (Gleason score 4+3, or Gleason score 3+4 with positive biopsy core rate >1/3), and 223 were high-risk. Treatment begins with BT, followed 6 weeks later by 45 Gy/25 fractions of EBRT. EBRT was delivered via 3D-CRT in 616 men at first and via IMRT technique for 223 men after 2010. The prescription dose for I-125 was 100 Gy, up to 110 Gy after 2009. All patients underwent a CT scan for postplan dosimetry at day 30. The rectal volumes receiving doses higher than 30 Gy, 35 Gy, and 40Gy should be kept under 35%, 25%, and 15%, respectively. Neoadjuvant androgen deprivation therapy was given to 45% of patients. Biochemical failure was defined with the Phoenix criteria, and toxicity was graded according to the National Cancer Institute's Common Terminology Criteria for Adverse Events, prospectively collected. The median (range) follow-up was 7 (2-12) years for the entire cohort; 8.3 years for 3D-CRT, and 4.3 years for IMRT. The biological effective dose (BED) was calculated using an α/β of 2 Gy and the D90 values of the prostate on a day-30 CT scan. Comparisons were made by chi-square test and log-rank test.

Results: The total BED value of the prostate was higher in the IMRT group than in the 3D-CRT group (219 Gy2 vs. 209 Gy2, p <0.001). The 5-year actuarial freedom from biochemical failure for the IMRT group vs. the 3D-CRT group were 92.7% vs. 92.6% (p=0.825) for all; 95.4% vs. 95.1% for intermediate-risk, and 88.0% vs. 84.8% for high-risk group (p=0.788), respectively. Acute gastrointestinal (GI) grade 2+ toxicities occurred in 0.5% of the IMRT group and 2.7% of the 3D-CRT

group ($p = 0.056$), and the 5-year actuarial grade 2+ GI toxicity rate was lower in the IMRT group than in the 3D-CRT group (5.0% vs. 12.1%, $p < 0.01$). A lower incidence of acute genitourinary (GU) grade 2+ toxicities occurred in the IMRT group than in the 3D-CRT group (7.1% vs. 16.4%, $p = 0.001$). The 5-year actuarial grade 2+ GU toxicity rate for the IMRT vs. the 3D-CRT group was 16.3% vs. 21.7% ($p = 0.103$), respectively.

Conclusion: IMRT combined with I-125 brachytherapy in prostate cancer patients found a lower incidence of toxicities than 3D-CRT combination, without compromise of biochemical outcomes.

PO-0740

Nodal clearance rate and efficacy of individualised SN-based pelvic IMRT for prostate cancer

A. Müller¹, F. Eckert¹, F. Paulsen¹, D. Zips¹, A. Stenzl², D. Schilling², M. Alber³, R. Bares⁴, P. Martus⁵, D. Weckermann⁶, C. Belka⁷, U. Ganswindt⁸

⁶Klinikum Augsburg, Urology, Augsburg, Germany

⁷University Hospital Munich- Ludwig-Maximilians-University, Radiation Oncology, Munich, Germany

⁸University Hospital Munich- Ludwig-Maximilians-University, Radiation Oncology, Munich, Germany

Purpose or Objective: Studies on extended or sentinel node (SN) pelvic lymph node dissection (PLND) have shown a higher detection rate compared to standard PLND in high risk prostate cancer (HRPC). In accordance with these findings, we previously demonstrated that ~30% of SNs in HRPC-patients were detected outside of the radiotherapy volume for elective lymph node irradiation. The aim of this study was to assess efficacy of individually SN-guided pelvic intensity modulated radiotherapy (IMRT) by determining nodal clearance rate $\{(n \text{ expected nodal involvement} - n \text{ observed regional recurrences}) / n \text{ expected nodal involvement}\}$ in comparison to surgically staged patients.

Material and Methods: Data on 475 HRPC patients were examined. Sixty-one consecutive patients received pelvic SN-based IMRT (5x1.8Gy/week to 50.4Gy (pelvic nodes+individual SN) and an integrated boost with 5x2.0Gy/week to 70.0Gy to prostate + (base of) seminal vesicles) and neo-/adjuvant long-term androgen deprivation therapy; 414 patients after SN-PLND were used to calculate the expected nodal involvement rate for the radiotherapy sample. Biochemical control and overall survival (OS) were estimated for the SN-IMRT patients using the Kaplan-Meier method. The expected frequency of nodal involvement in the radiotherapy group was estimated by imputing frequencies of node-positive patients in the surgical sample to the pattern of Gleason, PSA, and T-category in the radiotherapy sample.

Results: After a median follow-up of 61 months, five year OS after SN-guided IMRT reached 84.4%. Biochemical control according to the Phoenix definition was 73.8%. The nodal clearance rate of SN-IMRT reached 94%. The estimated nodal involvement in the SN-IMRT group was 28.6% (95%-CI:19.3%-37.7%). Retrospective follow-up evaluation is the main limitation.

Conclusion: Radiation treatment of pelvic nodes individualized by inclusion of SN is an effective regional treatment modality in HRPC patients. The pattern of relapse indicates that the SN-based target volume concept correctly covers individual pelvic nodes. Thus, this SN-based approach

justifies further evaluation including current dose-escalation strategies to the prostate in a larger prospective series.

PO-0741

Even high-dose radiotherapy requires long-term androgen ablation for high-risk prostate cancer

T.K. Nam¹, D.D. Kwon², J.W. Jeong¹, Y.H. Kim¹, M.S. Yoon¹, J.Y. Song¹, S.J. Ahn¹, W.K. Chung¹

¹Chonnam National University Medical School, Radiation Oncology, Gwangju Metropolitan, Korea Republic of

²Chonnam National University Medical School, Urology, Gwangju Metropolitan, Korea Republic of

Purpose or Objective: Whether the benefit of androgen ablation therapy (AAT) remains currently unclear in the era of dose escalation and the recent radiation therapy oncology group trials regarding this issue are still under accrual. We tried to evaluate the role of long-term adjuvant AAT for more than 12 months after completion of high-dose intensity modulated radiotherapy (IMRT) for high-risk prostate cancer patients at the single institution retrospectively.

Material and Methods: Between 2005 and 2013, there were 177 high-risk patients treated with radical IMRT. From 2005 to 2009, 25 patients were treated by LINAC-IMRT, and since 2010, remaining 152 patients were treated by helical tomotherapy. High-risk was defined as having one or more among three factors such as pretreatment prostate specific antigen (pPSA) levels > 20 ng/ml, or Gleason score (GS) > 7 , or clinical stage \geq T3a. Ninety-four patients (53.1%) had pPSA levels > 20 ng/ml, and 91 patients (51.4%) had GS > 7 . Clinical stage T3 or 4 was diagnosed in 143 patients (80.8%) and 21 (11.9%) had pelvic lymph node metastasis initially. Among all patients, 95.5% received neoadjuvant/concurrent and 91.1% had adjuvant AAT. Median fraction size was 2.2 Gy for prostate plus proximal seminal vesicles with simultaneously integrated boost during whole pelvic irradiation of 1.8 Gy fraction. Most patients (88.1%) received whole pelvic irradiation of a median of 45.0 Gy. Median total nominal dose was 72.6 Gy (66.0 - 78.0) which was equivalent to a median of 81.4 Gy α/β 1.5 (74.2 - 86.3) in biologically effective dose of 1.8 Gy fraction. Biochemical failure (BCF) was defined as nadir plus 2 ng/ml.

Results: Follow-up period was ranged from 6 to 117 months (median: 37). Eighteen patients (10.2%) developed BCF and 5-year BCF-free survival rate (BCFFS) was 83.1%. Six out of 18 BCF patients eventually developed clinical failure and 5-year clinical failure-free survival (CFFS) was 93.7%. 5-year cause-specific survival (CSS) and overall survival (OS) was 99.1% and 95.8%, respectively. Several potential prognostic factors were analyzed for each survival endpoints by multivariate analysis. Whether adjuvant AAT or not ($p=0.000$) and N stage ($p=0.016$) were significant factors affecting BCFFS but no factors were significant for CFFS, CSS, or OS. Biologically effective dose according to 1.8 Gy α/β 1.5 vs. > 80.0 Gy α/β 1.5) was not a significant factor in all survival endpoints. There was only one patient who suffered urethral stricture of grade 3 late toxicity. No patient suffered grade 3+ in gastrointestinal or grade 4+ in genitourinary late toxicity. s 2 ng/ml.

Conclusion: Based on BCF end point, even high-dose IMRT was an insufficient treatment for high-risk prostate cancer patients if adjuvant AAT was not added. The addition of adjuvant AAT significantly reduced the BCF, although longer follow-up is needed to determine if the combined treatment impacts significantly on other survivals

PO-0742

Image-guided IMRT reduces late toxicity compared to 3D-CRT for prostate cancer

R. Wortel¹, L. Incrocci¹, F. Pos², U. Van der Heide², J. Lebesque², S. Aluwini¹, M. Witte², W. Heemsbergen²

¹Erasmus MC Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands

²Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: Image-guided intensity modulated radiotherapy (IG-IMRT) reduces dose to organs at risk (OARs) compared to 3D-conformal radiotherapy (3D-CRT). Currently it is not known to what extent this reduces late toxicity in prostate cancer patients. We previously reported on significant reductions in dose to OARs and acute toxicity. The aim of this study was to assess the therapeutic gain with IG-IMRT in terms of long-term toxicity reductions, and to establish to what extent acute toxicity was associated with late side effects. For that purpose we used prospective data of two randomized trials.

Material and Methods: A total of 242 IG-IMRT patients from a hypofractionation trial (2007-2010) and 189 3D-CRT patients from a dose escalation trial (1997-2003) with ≥ 2 completed questionnaires were selected. All patients received 78 Gy in 2 Gy fractions. Applied margins were 10 mm for 3D-CRT and 5-8 mm for IG-IMRT, all with 0 mm margin towards the rectum for the 10 Gy boost. The mean dose to the anorectum was 34.4 Gy vs. 47.3 Gy, 23.6 Gy vs. 44.6 Gy for the anal canal and 33.1 Gy vs. 43.2 Gy for the bladder (all significantly reduced with IG-IMRT). Late toxicity was scored using identical questionnaires and case report forms according to RTOG/EORTC scoring criteria. Study endpoints were grade ≥ 2 ($G_{\geq 2}$) gastrointestinal (GI) and genitourinary (GU) toxicity. Cumulative incidences of $G_{\geq 2}$ endpoints were calculated. Cox regression was used to determine Relative Risks (RR) for IG-IMRT, adjusted for baseline factors. RRs of acute toxicity as a predictor for late $G_{\geq 2}$ endpoints were also calculated.

Results: Median follow-up was 60 months. The five-year (5y) cumulative incidence of late $G_{\geq 2}$ GI toxicity was 25.4% for IG-IMRT compared to 36.4% for 3D-CRT (RR=0.62, $p=0.009$) (Figure 1). This resulted from significantly lower incidences of increased stool frequency ≥ 6 /day (4.3% vs 16.5%, RR=0.24, $p<0.001$) and non-significant lower incidences of $G_{\geq 2}$ (needing medical intervention) rectal bleeding (RR=0.67, $p=0.4$), rectal pain/cramps (RR=0.59, $p=0.13$), and proctitis (RR=0.38, $p=0.05$). $G_{\geq 2}$ anal incontinence (with use of pads) was not reduced (RR=1.02, $p=0.9$). With regard to GU toxicity, a non-significant increase was observed with IG-IMRT with 5y incidences of 46.9% vs. 37.1% for 3D-CRT (RR=1.3, $p=0.12$). Acute toxicity levels $G_{\geq 2}$ (mainly proctitis) were 29% vs. 51% ($p<0.01$). Acute $G_{\geq 2}$ toxicity was predictive for late $G_{\geq 2}$ toxicity (RR=2.9 for IG-IMRT, 2.5 for 3D-CRT, both $p<0.01$), especially for rectal discomfort (RR=7.2, $p<0.001$) in IG-IMRT, and rectal incontinence (RR=3.5, $p<0.01$) in both groups. IG-IMRT patients with acute GU $G_{\geq 2}$ complaints had a 1.81 fold ($p=0.002$) increased risk of late GU $G_{\geq 2}$ toxicity, compared to 2.37 ($p=0.001$) for 3D-CRT.

Figure 1. Grade 2+ gastrointestinal toxicity

Conclusion: IG-IMRT for prostate cancer was beneficial since it significantly reduced the incidence of long-term GI toxicity, as a result of lower doses to OARs and reduced acute toxicity levels. GU toxicity was not reduced despite significant reductions in bladder dose.

PO-0743

Stereotactic body radiotherapy in recurrent lymph nodes metastases from prostate cancer

F. Trippa¹, E. Maranzano¹, E. Ponti², A. Carosi², F. Arcidiacono¹, L. Draghini¹, L. Di Murro², A. Lancia², P. Anselmo¹, R. Santoni², G. Ingrosso²

¹Radiation Oncology Centre, Oncology- "S.Maria"- Hospital, Terni, Italy

²Radiation Oncology Centre, Diagnostic Imaging- Molecular Imaging- Interventional Radiology and Radiotherapy- Tor vergata- Hospital, Rome, Italy

Purpose or Objective: To assess outcome and toxicity of stereotactic body radiotherapy (SBRT) in prostate cancer patients (pts) with recurrent isolated lymph node metastases (LNM).

Material and Methods: Between September 2008 and December 2014, 40 prostate cancer pts with 47 recurrent isolated LNM, were treated with SBRT. Median age was 74 yrs (range, 58-83), median Gleason score at the primary diagnosis was 7 (range, 5-10). Median and mean time from primary treatment to SBRT were 37.45 and 62.6 m, respectively (range 11.16-216.03). Diagnosis was performed with choline (ch) PET/CT, and the mean and median PSA values before SBRT were 5.6 and 4.2 ng/ml, respectively. Six (15%) pts were treated in different sessions for metachronous metastases, and one (2%) underwent SBRT for two synchronous metastases. 21 (52.5%) pts underwent only SBRT, remaining 19 (47.5%) received also androgen deprivation therapy (ADT). Gross tumor volume (GTV) was delineated using choline uptake and planning target volume (PTV) was defined as the GTV plus a 5-8 mm isotropic margin. Mean and median volume of GTV and PTV were 6.63 cc and 3 cc and 25.03 and 15.03 cc, respectively. In 90% of cases 5 fractions of 6-8 Gy were delivered. Response was assessed with PSA evaluation scheduled every 3 m during the first year and then every 6 m. Pts with a reduction or a stability of PSA level were considered responders. Being evaluation of response with ch-PET-CT not mandatory, it was done in 23 (57.5%) pts.

Results: Mean and median follow-up were 30.18 and 23.8 m, respectively (range 3.73-79.8). Mean time of biochemical progression from the end of SBRT was 15.54 m (range 1.16 - 48.86), and the 2-years biochemical progression free survival (b-PFS) was 44%. We registered a complete concordance between PSA increase and progression of disease shown at ch-PET/CT. Sixteen (40%) of the pts experienced no disease recurrence after SBRT. Of 21 no-ADT pts, 16 (76%) were still free from ADT (mean 26.18 m), whereas remaining 5 (24%) had a mean deferment time of ADT of 13.58 m. At univariate analysis, Gleason score >7 is related with a worse b-PFS ($p=0.02$). Acute grade 2 diarrhea was registered in 1 (2.5%) case. Grade 3 small bowel late toxicity was observed in only one (2.5%) case 11.76 m after the end of SBRT.

Conclusion: SBRT resulted effective and generally well tolerated by pts. PSA level is a valid tool for response evaluation and ch-PET/CT can be useful for pts with documented biochemical progression.

PO-0744

Effects of IMRT or radical prostatectomy (RP) on serum testosterone in patients with prostate cancer

A. Giraldo Marin¹, X. Maldonado¹, J. Planas², M. Hermida³, M.J. Mañas¹, S. Mico¹, J. Morote², J. Giralt¹

¹Hospital Universitario Vall d'Hebron, Radiotherapy Department, Barcelona, Spain

²Hospital Universitario Vall d'Hebron, Urology Department, Barcelona, Spain

³Hospital Universitario Vall d'Hebron, Radiation Physics Department, Barcelona, Spain

Purpose or Objective: Subtle changes in serum testosterone have been noted in prostate cancer patients, without androgen blockade, treated with radiotherapy as well as radical prostatectomy (RP). The significance of these changes

remains unanswered. The aim of the study was to retrospectively review the changes in total testosterone in low risk prostate cancer patients treated with IMRT alone, in comparison with a RP cohort and to assess the correlation between dosimetric parameters for the testes and changes in the level of testosterone.

Material and Methods: From 2009-2012 we studied 115 men in this cross-sectional study. 92 patients underwent RP and 23 patients were treated with IMRT exclusively. The patients were treated with IMRT to the prostate and seminal vesicles for a total dose of 76 Gy (2 Gy/d, 5d/w) with 6 MV photons. We measured serum levels of total testosterone, at baseline and at 3, 12 and 24 months (m) after treatment. We calculated the mean and maximum dose in the testes and the distance between PTV-testes. T-test and Pearson correlation index (PI) were used for statistical purposes.

Results: Patients undergoing RP were younger with IMRT (64.3 vs 72 years, $p < 0.0001$). No differences regarding serum hormonal levels were found at baseline between the two groups. At 3 months the testosterone levels were significantly lower in IMRT group (360,3 vs 414,83 ng/dl) in comparison with RP group ($p < 0,039$). At 12 months testosterone levels remained significantly lower (339,89 vs 402,39 ng/dl, $p 0,03$) in the IMRT group.

In the IMRT group the mean and maximum testes doses (\pm SD) were 0.472Gy (± 0.195) and 0.896 Gy (± 0.382) respectively. At 3 months, the mean testosterone reduction was 29.4 ng/dl (± 111.3), without correlation among the mean and maximum dose to the testes ($p=0.2$). At 12 months, 60% (12/20) of the patients had recovered their basal testosterone levels as well as 61% (11/18) at 24 months. The PI didn't show any statistical significance related with testosterone kinetics and dosimetric parameters at 12 and 24 months. In the multivariate analyses, we didn't find any significant relationship regarding: scattered doses in testes; total dose to the prostate; distance between PTV-testes or age, with testosterone recovery.

Conclusion: Despite IMRT for localized prostate cancer leading to low doses to the testes, we observed a decline in total testosterone higher than RP. Nevertheless, it doesn't seem to correlate with either dosimetric parameters or the scattered dose in testes. More studies are needed to elucidate the role that the prostate may play as an endocrine organ itself.

PO-0745

Significant correlation between prostate volume and obstructive voiding symptom in hypofractionation

S. Pérez Echagüen¹, C.J. Sanz Freire², G.A. Ossola Lentati¹

¹Center for Biomedical Research of La Rioja, Radiation Oncology, Logrono, Spain

²Center for Biomedical Research of La Rioja, Medical Physics, Logrono, Spain

Purpose or Objective: To investigate the correlation between initial prostate volume and the probability of developing acute Obstructive Voiding Symptoms (OVS) during the course of moderate hypofractionated (HF) prostate RT.

Material and Methods: Data from patients ($n=181$) undergoing IMRT delivered, daily Cone Beam CT guided, HF RT were retrospectively analyzed. Two treatment schedules were considered: HF1 (2.6 Gy/fr, 27 fr; $n=107$) and HF2 (3.15 Gy/fr, 20 fr, 4 days a week; $n=74$). Patients verifying: 1. previous OVS score 3 or greater according the International Prostatic Symptoms Score (IPSS), 2. CTVs encompassing volume outside the prostatic capsule (*i.e.* margin for extracapsular extension or seminal vesicles invasion), 3. presence of central calcification masses or 4. altered RT schedules for reasons other than OVS, were excluded. Measured HF1 and HF2 median prostate volumes as contoured in the simulation CT image were 61.0 cc [18.6, 157.7] and 53.6 cc [18.5, 114.8], respectively. OVS was assessed according the RTOG/CTC v3.0 scale. Development of OVS G2 or greater during treatment was considered as binary end-

point. Volume-effect correlation was evaluated by logit analysis, assuming a log-normal distribution.

Results: OVS G2 or greater was found in HF1 ($n=11$) and HF2 ($n=10$) patients. A few patients HF1 ($n=1$) and HF2 ($n=5$) needed urethral catheterization. Some patients ($n=12$) had their course of treatment modified due to OVS: temporary interruption of treatment ($n=6$), modified fractionation ($n=5$), urinary catheterization at treatment delivery ($n=1$). Logit analysis showed that prostate volume did not correlate with OVS for HF1 patients ($p > 0.05$) but proved to be significantly predictive of OVS for HF2 patients ($p = 0.0002$). For this second arm, normalized gradient of the volume-effect regression curve was found to be $\gamma_{50}=7.8$ [3.2-14.7] and $ED_{50\%} = 95.7$ cc [84.7-117.8] (see Figure). The Receiver Operating Characteristics analysis (ROC) showed excellent predictive capabilities of the model, with Area Under the Curve $AUC=0.94$. Based on these findings, a volume cutoff value of 80 cc, corresponding to an acceptable 20% risk of OVS G2 or greater was selected.

Conclusion: Depending on the HF scheme, patients with larger prostate volume will face an increasing risk of OVS. This may compromise their quality of life and alter the RT treatment schedule. In this work, we successfully correlated OVS to prostate volume. This predictive model can be exploited for decision-making prior to treatment. In our Institution, patients with prostate volume larger than 80 cc will be preferably addressed to the HF1 schedule due to the risk of OVS.

PO-0746

Spanish validation of Charlson Index applied to prostate cancer

F. Casas i Duran¹, F. Ferrer², A. Herreros³, J. Saez⁴, C. Camacho⁴

¹Hospital Clinic, Radiation Oncology, Barcelona, Spain

²Hospital Duran I Reynals, Radiation Oncology, Hospitalet del Llobregat, Spain

³Hospital Clinic, Radiation Oncology Physics, Barcelona, Spain

⁴Hospital Clinic, Radiation Oncology Physics, Barcelona, Spain

Purpose or Objective: Comorbidity assessment is essential to triage of care for men with prostate cancer. Specially in these with an expectative of life less of ten years. We made a Spanish validation of comorbid revised Charlson index (RCI) applied to prostate cancer.

Material and Methods: A group of 619 consecutive patients of Prostate Cancer diagnosed between 1994- 2007 were send for clinical assessment at Radiation Oncology Department of Hospital Clinic of Bacerlona.

A long the period of follow-up (till November 2014) 69 patients deceased for Prostate Cancer and were excluded in this study in order to determine the risks of mortality associated with comorbidities measured by the RCI.

RCI was classified in three categories 0 to 2, 3 to 4 and 5 and higher. For this purpose we used Kaplan-Meier method and Cox proportional hazards modeling

Results: Finally 550 patients with prostate cancer were included, with median age of 70 years old (47-85), Mean follow-up time was 136.8 months, between 5,6 and 245,8 months. D'Amico risk classification distribution was for low risk, medium and high 20.4%, 36,5% and 43,1% respectively. RCI distribution categories was as follows 61,5%, 21,8 and 16,7%. Survival analysis showed significant differences ($p < 0.001$) between RCI groups at 5 and 10 years. Survival probability was 98,2 and 88,5% ; 95% and 79,6% ; and 52,2% and 8,9% was respectively for each RCI category.

Conclusion: RCI allowed for more accurate identification of men at highest risk for other cause mortality.

Our results are in concordance with original RCI. This revised index may be used to aid medical decision making and personalized medicine for men with prostate cancer.

PO-0747

Revisiting guidelines for target definition after prostatectomy when taking MRI study into account

G. Sancho Pardo¹, D. Hernandez², D. Gimenez¹, N. Jornet³, M. Menso², E. Umbrurescu¹, F. Benítez¹, G. Gómez de Segura¹, J. Craven-Bartle¹

¹Hospital de la Santa Creu i Sant Pau, Radiation Oncology, Barcelona, Spain

²Hospital de la Santa Creu i Sant Pau, Radiology, Barcelona, Spain

³Hospital de la Santa Creu i Sant Pau, Medical Physics, Barcelona, Spain

Purpose or Objective: The definition of the clinical target volume (CTV) for salvage radiotherapy after prostatectomy is based on clinical and pathologic variables of the tumor and consensus guidelines. Multiparametric-MRI is recommended to evaluate pelvic recurrences after radical prostatectomy when the PSA is low (0.2-2 ng/ml) but the benefit of planning individualised radiation treatment based on the results of MRI is unknown. We analysed whether all suspicious lesions detected with pelvic multiparametric MRI were included in the clinical target volume defined according to four current guidelines and we determined the percentage of missing target if this radiological information was lost.

Material and Methods: We retrospectively reviewed the clinical records and multiparametric MRI studies of 70 patients with PSA recurrence after radical prostatectomy. Salvage radiotherapy of at least the prostate bed was indicated in all cases. On the simulation CT scan of 33 patients who had visible tumor recurrence in the MRI study, we delineated four different CTV according to RTOG, EORTC, PMH and FROGG consensus guidelines for postoperative prostate bed irradiation. We delineated a relapse CTV which included the radiological tumor recurrence plus 5 mm. For the PTV, we added a 5 mm margin. We compared volume size of the CTV and determined the percentage of geographically missed target (relapse PTV not included / relapse PTV).

Results: Multiparametric-MRI was positive in 33/70 patients. Local recurrence occurred in 27 patients, mainly in the perianastomotic area (19). Multiparametric-MRI detected positive lymph nodes in 7 patients, mostly in the external iliac region. The mean size of the lymph nodes was 10 mm (range 8-16 mm). The mean volumes of the CTV delineated according to the EORTC, RTOG, PMH and FROGG consensus were 81.5, 100.7, 109.3 and 99.7 cc, respectively. In 2 out of 33 cases, the recurrence depicted in the pelvic MRI was not totally enclosed in the CTV, independently of the consensus guidelines used. The missed recurrences were located in the left retrovesical region (patient 1) and at the level of the penile bulb (patient 2). The volumes of the relapsed PTV were 23.4 and 14.9 cc, respectively. The percentages of relapse PTV out of the PTV created according to each guideline were 41%, 59%, 44 and 44% in patient 1 and 44%, 39%, 39% and 41% in patient 2. In 7 out of 70 patients (10%),

lymph node recurrence would have been missed if we had only considered salvage prostate bed irradiation.

Conclusion: Using current guidelines for CTV definition for salvage radiotherapy after prostatectomy, we found that the local recurrences depicted in the pelvic multiparametric MRI were totally covered in most patients. Multiparametric-MRI may help tailor local and lymph node CTV and identify lesions to treat with a higher dose

PO-0748

Escalated-dose IMRT for prostate cancer: long-term toxicity and biochemical outcomes

H. Bettina¹, D. Strauß¹

¹Südharz- Krankenhaus Nordhausen gGmbH- Germany, Department of Radiation Oncology and Radiotherapy, Nordhausen, Germany

Purpose or Objective: To report the toxicity and preliminary biochemical outcomes with high-dose intensity-modulated radiation therapy (IMRT) to a dose of 82.8Gy in patients prostate cancer.

Material and Methods: Between April 2002 and December 2013, 757 patients with biopsy proven prostate cancer were treated with high-dose IMRT. While 398 patients received a 7 or 8- field -IMRT -sliding window- technique up to a median total dose to the prostate of 77.4 Gy/1.8Gy, 359 patients were treated with a 2 arc-Volumetric Modulated ArcTherapy (VMAT) plans up to a median total dose to the prostate of 82.0Gy/ 1.8Gy. In 264 high-risk prostate cancer patients the pelvic node region was treated to incorporate the nodes at risk. Total doses of 50.4Gy were prescribed to the pelvis. In 29 % of SW patients and 23% of VMAT patients an additional boost of 5 to 16Gy was administered in cases of MRI-staged lymph node metastases. Acute and late toxicities were prospectively scored by the RTOG/ LENT SOMA morbidity grading scales (until 2009) and a modified CTCAEv3.0 score (since 2009), respectively. Biochemical failure was defined according to the Phoenix definition of nadir + 2ng/ml. The median follow- up time was 65 months (range,12-151 months).

Results: The IMRT dose distribution provided excellent PTV coverage and satisfying protection of all the organs at risk, with less than 2% of all patients experiencing grade (G) 3 toxicities, G4 toxicities were not observed at all. In total 40.3 / 11 / 1.1% of patients developed acute G1/ 2/ 3 genitourinary (GU) toxicities. 28% / 3.1% of patients experienced acute G1/ 2 gastrointestinal (GI) side effects, no patient developed acute > G2 gastrointestinal symptoms. Late GU- and GI toxicity was mild with > 85% of the patients free from any GU/GI toxicity during follow-up and no time trend to increased rates or to higher grade of GU/GI-toxicity. Maximum late GU toxicities were G1/ 2/ 3 for 10/ 2.5/ 1.6% of patients, respectively. Maximum late GI toxicities were G1/2 for 4.9 / 0.4% of patients. The 5-year freedom from biochemical failure (FFBF) was 87.8% for all patients and 95, 79.9 and 83.4% for low-, intermediate-, and high-risk disease.

Conclusion: These data demonstrate that escalated -dose IMRT is a well tolerated technique in prostate cancer patients and the preliminary excellent biochemical control rates are encouraging.

PO-0749

Factors predicting late severe urinary incontinence after postprostatectomy RT: a longitudinal study

B. Noris Chiorda¹, C. Sini², C. Fiorino², F. Badenchini³, A. Briganti⁴, A. Chiara¹, C.L. Deantoni¹, N. Slim¹, N. Suardi⁵, F. Montorsi⁴, N. Di Muzio¹, C. Cozzarini¹

¹San Raffaele Scientific Institute, Department of Radiation Oncology, Milan, Italy

²San Raffaele Scientific Institute, Department of Medical Physics, Milan, Italy

³Istituto Nazionale Tumori - San Raffaele Scientific Institute, Department of Radiation Oncology, Milan, Italy

⁴Vita-Salute San Raffaele University - San Raffaele Scientific Institute, Department of Urology, Milan, Italy

⁵San Raffaele Scientific Institute, Department of Urology, Milan, Italy

Purpose or Objective: The fear of radiotherapy-induced urinary incontinence (URINC) often contraindicates post-prostatectomy RT (POPRT), despite the lack of accurate data about its real incidence and severity. The purpose of this analysis was to analyze clinico-dosimetric factors predicting severe, self-reported URINC 1 and 2 years after POPRT.

Material and Methods: In 2012 a longitudinal, observational study aimed at assessing URINC from POPRT including prophylactic whole-pelvis irradiation (WPRT) was activated at our Institute. For the evaluation of urinary toxicity, 2 validated questionnaires, IPSS and ICIQ-SF, are to be filled-in by pts at baseline, at RT mid-point and end, at 3 and 6 months after RT conclusion, and every 6 months thereafter. This analysis pertains to the first 101 pts correctly filling the questionnaires at baseline and at 12 months (60 also at 2 years). Fifty-four and 47 pts were treated with adjuvant (ADV) and salvage (SALV) intent after a median of 4 and 38 months, respectively, from radical prostatectomy (RP), with either conventional (n=42) or moderately hypofractionated (n=59) regimens, at a median 2-Gy equivalent dose (EQD2) to the prostatic bed of 70 and 74 Gy in ADV and SALV cohort, respectively, and a median EQD2 dose of WPRT of 50 Gy.

Results: The mean baseline ICIQ scores were 7.8 and 4.8 in ADV and SALV cohorts, respectively (p=0.009). The corresponding values at 1 and 2 years were 7.4 vs 7.3 and 8.5 vs 7.9, respectively. Severe URINC (≥ 13 points) was recorded in 23% and 19% at 1 year, and in 37% and 21% of pts treated with ADV and SALV intent, respectively ($p=0.20$). The 75th quartiles of ICIQ at 12 (ICIQ12) and 24 (ICIQ24) months (12 and 13 points, respectively), were set as end-points for regression logistic analysis. Several clinico-dosimetric factors, including age, diabetes, hypertension, pT and pN stage, # of removed LNs, RT intent, time from RP to RT, fractionation, EQD2, adjuvant androgen deprivation (AAD), IQI and IPSS baseline values were analyzed. Variables with a p-value <0.20 at univariable analysis were entered into a backward stepwise multivariable model indicating baseline ICIQ and nocturia (IPSS item #7) and AAD as predictors of ICIQ12 (AUC 94%), while baseline ICIQ and EQD2 predicted ICIQ24 (AUC 89%).

Conclusion: The risk of long-term severe URINC 1 and 2 years after POPRT is strongly modulated by baseline URINC, and by AAD and higher EQD2, respectively (Figure 1).

PO-0750

Conventionally-fractionated VMAT vs. SBRT in prostate cancer: PSA kinetics, toxicity, quality of life

M. Tambas¹, F. Agaoglu¹, A. Iribas¹, M. Guveli¹, Y. Dizdar¹, M. Okutan², D. Ozkan³, N. Tenekeci³, E. Darendeliler¹

¹Istanbul University Institute of Oncology, Radiation Oncology, Istanbul, Turkey

²Istanbul University Institute of Oncology, Medical Physics, Istanbul, Turkey

³Istanbul University Institute of Oncology, Radiology, Istanbul, Turkey

Purpose or Objective: In the present study, conventionally fractionated volumetric arc therapy (VMAT) and hypofractionated stereotactic body radiotherapy (SBRT) modalities were aimed to compare in terms of side effects and quality of life (QOL) in patients with localized prostate cancer.

Material and Methods: Patients who admitted to I.U. Institute of Oncology with a diagnosis of localized prostate cancer during the period from March 2010 to December 2013 were included into the study. Patients received radical RT with dose schedules of either 33.5 Gy/5 fr for SBRT or 75.6 Gy/35 fr for VMAT. Acute and late side effects of treatment were evaluated according to CTCAE version 4. IPSS and EORTC QOL-PR25 forms were used to assess QOL at baseline, end of treatment and during follow-up.

Results: Of the 48 patients (28 SBRT, 20 VMAT) who were included into the study, 40 (20 SBRT, 20 VMAT) were evaluated for their QOL status. All demographic and pathological features including median age of the patients, clinical manifestations, and the risk groups were found to be similar between treatment groups. PSA control rates were %100 in both arms during the follow up with a median of 23 months. PSA nadir values were detected to be 0.5 ng/dl in both arms. PSA bounce was observed in 43% and 50% of patients in SBRT and VMAT arms, respectively. The magnitude of PSA bounce value was significantly higher in SBRT arm compared with VMAT (0.8 ng/dl vs. 0.1 ng/dl, p=0.01). PSA decline rate in VMAT arm was found to be significantly higher than in SBRT arm (p = 0.028). Grade 3 rectal toxicity was not observed in any of the treatment arms. Although Grade 3 urinary side effects were not seen in patients treated with VMAT technique, 3 patients (10.7%) in SBRT arm with a history of TURP before RT experienced Grade 3 urinary toxicity. No significant difference was observed between the two arms concerning sexual activity functioning and sexual functioning scores whereas the scores at 10.5 and 13.5 months were found to be significantly decreased compared with baseline in both treatment arms. SBRT and VMAT arms did not differ significantly regarding urinary, incontinence, bowel symptom scores and IPSS obstruction scores. The magnitude of increase in IPSS scores at the end of the treatment compared with baseline were detected to be significantly higher in VMAT arm than SBRT arm (p=0.046). The decrease in hormonal symptom scores at 4.5, 10.5 and 13.5 months compared with baseline was detected to be significantly higher in VMAT arm than SBRT arm (p=0.007, p=0.027, and p=0.021, respectively).

Table 1. Comparison of SBRT and VMAT arms in terms of amount of changes over time relative to baseline EORTC-PR25 functioning (sexual activity and sexual) and symptom (urinary, incontinence aid, bowel and hormonal) scores

Purpose or Objective: The aim of this work is to develop an algorithm to predict recurrence in prostate cancer patients treated with radical radiotherapy, getting up to a prognostic power higher than traditional D'Amico risk classification.

Material and Methods: 2493 men belonging to the EUREKA-2 retrospective multi-centric database on prostate cancer and treated with external-beam radiotherapy (3D-CRT and/or IMRT) as primary treatment comprised the study population. A Cox regression time to PSA failure analysis was performed in univariate and multivariate settings, evaluating the predictive ability of age, pre-treatment PSA, clinical-radiological staging, Gleason score and percentage of positive cores at biopsy (%PC). The accuracy of this model was checked with bootstrapping statistics. Subgroups for all the variables' combinations were combined to classify patients into five different "Candiolo" risk-classes for biochemical Progression Free Survival (bPFS); thereafter, they were also applied to clinical PFS (cPFS), systemic PFS (sPFS) and Prostate Cancer Specific Survival (PCSS), and compared to D'Amico risk grouping performances.

Results: the Candiolo classifier splits patients in 5 risk-groups with the following 10-years bPFS, cPFS, sPFS and PCSS: for very-low-risk 90%, 94%, 100% and 100%; for low-risk 74%, 88%, 94% and 98%; for intermediate-risk 60%, 82%, 91% and 92%; for high-risk 43%, 55%, 80% and 89% and for very-high-risk 14%, 38%, 56% and 70%. Our classifier outperforms D'Amico risk classes for all the end-points evaluated, with concordance indexes of 71.5%, 75.5%, 80% and 80.5% versus 63%, 65.5%, 69.5% and 69%, respectively.

Conclusion: Our classification tool, combining five clinical and easily available parameters, seems to better stratify patients in predicting prostate cancer recurrence after radiotherapy compared to the traditional D'Amico risk classes. This classifier must be validate by another prostate cancer series.

Outcome of prostate cancer patients treated with 3DCRT: impact of rectal/bladder preparation

A. Maggio¹, E. Garibaldi², D. Gabriele³, S. Bresciani¹, E. Delmastro², A. Di Dia¹, A. Miranti¹, M. Poli¹, P. Gabriele², M. Stasi¹

¹Candiolo Cancer Institute - FPO-IRCCS, Medical Physics, Candiolo, Italy

²Candiolo Cancer Institute - FPO-IRCCS, Radiotherapy, Candiolo, Italy

³University of Torino, Neuroscience Department- Physiology Unit, Turin, Italy

Purpose or Objective: To test the hypothesis that rectal/bladder preparation is associated with an increase in Cancer Specific Overall Survival (CSOS), in Clinical Disease Free (CDFs) and Biochemical Disease free Survival (BDFS)

Material and Methods: From October 1999 to March 2012, 1080 prostate cancer patients (PCa) were treated with 3DCRT. 761 patients (pts) were treated with empty rectum and comfortable full bladder while for 319 pts no rectal/bladder preparation (NRBP) protocol was adopted. The mean age was 69.2±5.6 years. The mean prescribed dose was 76±2 Gy. The mean followup was 81±39 months. Survival analysis was performed by Kaplan Meier method. Comparison between groups were made with the log-rank test. A Cox proportional hazards model was applied for univariate (UVA) and multivariate analysis (MVA). Hazard Ratio (HR) was used to measure how rapidly an event occurs.

Results: Pts with rectal/bladder preparation (RBP) have significantly lower biochemical and clinical failures rates and lower risk of dying of PCa respect to NRBP pts (log-rank p<0.0001). At 140 months for RBP and NRBP, the CSOS was 95% vs 85%, the CDFs was 81% vs 71%, the BDFS was 64% vs 48 %, respectively. Table 1 shows UVA and MVA results. In MVA, for CSOS the Gleason Score (GS) and RBP predicted for death from PCa, while for CDSF and BDFS the GS, D'Amico Risk Classification, PSA, dose>75 Gy, clinical stage and RBP

predicted for clinical and biochemical failures. MVA indicates that RBP is an independent risk factor for biochemical failure (p=0.003, HR=0.6) while it is the strongest risk factor for clinical failures and PCa deaths (p<0.0001, HR<0.5, regression coefficient b<-0.5). No statistical significant difference in rectal volume between RBP (mean volume 62.4±24.5 cc) and NRPB (mean volume 63.4±27 cc) was observed (chi square p value equal to 0.52)

Dose>75 Gy	0.006	-0.61	0.54	-0.500	0.0200	0.60

Figure 1: Univariate and multivariate Cox regression analysis

Conclusion: We found strong evidence that rectal/bladder preparation significantly decreased (HR<0.6, b<-0.5) the probability of death from PCa, biochemical and clinical failures in patients who were treated with 3DCRT for PCa without daily image-guided prostate localization, presumably because pts with RBP are able to maintain a reproducible empty rectum and comfortable full bladder for all the treatment. These results also emphasize the routinely need of image-guided radiotherapy to improve outcome in prostate cancer patients

³Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology, Milan, Italy

⁴San Raffaele Scientific Institute, Medical Physics, Milan, Italy

⁵Fondazione IRCCS Istituto Nazionale dei Tumori, Prostate Program- Radiation Oncology, Milan, Italy

Purpose or Objective: The aim of the study is to prospectively evaluate urinary symptoms using the International Prostate Symptom Score (IPSS) in patients with localized prostate cancer (CaP) treated with radical (RRT) or postprostatectomy (PRT) radiotherapy delivered with conventional (CONV) or moderately hypofractionated (HYPO) fractionation.

Material and Methods: We considered patients enrolled in the two multicentric prospective observational studies DUE01 (RRT, CONV and HYPO) and IHU WPRT TOX (RRT and PRT, including irradiation of the pelvic lymphnodal area, CONV and HYPO). The IPSS questionnaire, evaluating 7 symptoms

(IPSS1-IPSS7) and a quality of life (IPSS8), is filled in before and at the end of RT, then 3 and 6 after treatment end and every 6 months thereafter up to 5 years after the end of treatment. In this preliminary analysis only data relative to first year will be analyzed. Longitudinal trends were assessed by analysis of variance (anova).

Results: The analysis pertains to 146 RRT CONV pts, 104 RRT HYPO pts, 74 PRT CONV pts and 94 PRT HYPO. The median age in the 2 studies was 71 (RRT) and 66 (PRT) years (p = 0.0001). Overall, urinary function was always better in the RRT CONV cohort. Statistically significant differences among the 4 groups have emerged with respect to urinary frequency, urgency, effort, nocturia. When comparing RRT vs PRT, frequency (p = 0.007) and stress (p = 0.01) were significantly more present in PRT, while only a borderline difference in terms of urgency (p = 0.07) was evident. The last item of IPSS shows a significant difference of quality of life between groups, especially at 12 month where RRT cohort, especially CONV, shows a better score than PRT patients. Figure 1 shows the comparison of each group for all IPSS items (incomplete emptying, urinary frequency, intermittence, urgency, urinary stream, obstruction, nocturia, QoL), evaluating the mean response in the first five time of compilation (Rt start, RT end, 3m, 6m, 12m).

Conclusion: These preliminary results seem to suggest that RRT would result in less deterioration of urinary symptoms over time than PRT, especially RRT with conventional fractionation. Further analyses are ongoing in order to study the effect of baseline urinary situation, age, doses to the bladder and the impact of each urinary symptoms on quality of life.

⁵Fondazione IRCCS Istituto Nazionale dei Tumori Via, Prostate Cancer Program, Milan, Italy

⁶University of Leicester, Medical Genetics, Leicester, United Kingdom

Purpose or Objective: Although intensity modulated radiotherapy (IMRT) permits the delivery of a highly conformal dose to target volumes while sparing dose to identified organs at risk, it results in a higher whole body integral dose due to irradiation of a larger volume of tissue at lower doses. A randomized clinical trial in head and neck cancer comparing IMRT with 3-D conformal radiotherapy, demonstrated higher acute fatigue in the IMRT cohort, raising the possibility of an association with higher integral dose. We hypothesized that a higher integral whole body dose is associated with worsening fatigue and an adverse functional outcome in patients with localized prostate cancer treated with intensity modulated external beam radiotherapy.

Material and Methods: 26 patients with localized adenocarcinoma of prostate treated with intensity modulated external beam radiotherapy were included in this analysis. The integral dose was calculated as the product of mean body dose and body volume and the study cohort was dichotomized using the median integral dose as the cut-off value. The fatigue, physical functioning and role functioning domains of the EORTC QLQ-C30 questionnaire prior to radiotherapy and upon completion of radiotherapy were assessed. The outcome measure was defined as worsening in any of these three domains.

Results: The median integral dose was 119.7 litre-Gy (range 90.5 - 168.1). In the whole population 17/26 (65%) had worsening of fatigue, physical or role functioning. A significantly higher proportion of patients with an integral dose above median had worsening fatigue, physical and role functioning compared with patients with an integral dose below median. (6/13 versus 11/13; z test for proportions p=0.04).

Conclusion: To our knowledge, this is the first study linking acute worsening of fatigue and functional outcome with whole body integral dose. Further validation in a larger cohort and in different tumour sites is necessary and the relationship between integral dose and toxicity merits further investigation.

Purpose or Objective: To prospectively evaluate acute intestinal toxicity (AIT) from RT including whole-pelvis irradiation (WPRT) for prostate cancer by means of a validated questionnaire (IBDQ, Intestinal Bowel Disease Questionnaire), and to investigate the intestinal symptoms that most affect patient quality of life (QoL).

Material and Methods: In 2014 a multicentric, observational trial aimed at assessing IT from RT including WPRT was activated. Prior to study activation, a pilot feasibility study was started in the coordinating Institute. For the study's purpose, the IBDQ is to be filled in by pts at baseline, RT mid-point and end, 3 and 6 months, and thereafter every 6 months up to 5 years. The questionnaire comprises 32 items investigating bowel symptoms (10 items), emotional health (12), systemic symptoms (5) and social function (5). The responses are scored on a seven-point scale in which 7 corresponds to the best function and 1 to the worst. Average per item scores can be calculated for each of the 4 domains. This analysis pertains to the first 144 pts (8 Institutes) with complete data available at baseline, RT mid-point and end. Initially, only pts treated with post-prostatectomy RT with either adjuvant (ADV, n= 71) or salvage (SALV, n=73) intent were enrolled. Pts were treated with static-field IMRT (n=31), Tomotherapy (n=42) and VMAT (n=71), with conventional (1.8-2 Gy/fr, n=78) or moderate hypofractionation (2.15-2.65 Gy/fr, median 2.35, n=66). The median EQD2 dose to the prostatic bed and pelvic lymph-nodal area was 71.2 and 50 Gy, respectively. 58 pts received concomitant androgen deprivation.

Results: Overall, self-perceived intestinal toxicity from WPRT was mild: mean scores for bowel symptoms at baseline, RT mid-point and end were in fact 6.58, 6.09, 5.90 (repeated measures Anova, p<0.0001), for emotional health 5.94, 5.79, 5.69 (0.0003), for social function 6.20, 5.83, 5.65 (p<0.0001) and for systemic symptoms 5.95, 5.55, 5.40 (p<0.0001), respectively. For the evaluation of acute toxicity, the worst variation (delta) between baseline and RT mid-point or end was considered. With respect to the bowel symptoms, the median score decrease (worsening) was 2 points for only one item (frequent bowel movements), 1 point for loose bowel movements, gas passage, abdominal bloating and urge to defecate, and 0 for abdominal pains and cramps, rectal bleeding, accidental soiling and nausea. Nevertheless, abdominal pain and urge to defecate were the two items with higher predictive power (AUC 72-79% at ROC curve analysis) with respect to a worsening of ³1 point (25th percentile) of either emotional or systemic or social domains, as well as gas passage, urge to defecate and nausea (AUC 72-73%) for emotional.

Conclusion: The self assessed AIT from WPRT delivered by means of modern IMRT technique is negligible. Abdominal pain and urge to defecate are the 2 symptoms mostly correlated with a worsening of patient's QoL.

PO-0756

Choline PET/CT and Stereotactic Body Radiotherapy in oligometastatic prostate cancer patients

Purpose or Objective: A new entity of patients with recurrent prostate cancer limited to a small number of active metastatic lesions is having growing interest: the oligometastatic patients. Patients with oligometastatic disease could eventually be managed by treating all the active lesions with local therapy, i.e. either surgery or ablative stereotactic body radiotherapy. This study aims to assess the impact of [18F]Choline ([18F]FMCH) PET/CT and the use stereotactic body radiotherapy (SBRT) in patients (pts) with oligometastatic prostate cancer (PCa).

Material and Methods: Twenty-nine pts with oligometastatic PCa ≤ 3 synchronous active lesions detected with [18F]FMCHPET/CT) were treated with repeated salvage SBRT until disease progression (development of > three active synchronous metastases). Primary endpoint was systemic therapy-free survival measured from the baseline [18F]FMCHPET/CT.

Results: A total of 45 lesions were treated with SBRT. After a median follow-up of 11.5 months (range 3-40 months), 20 pts were still in the study and did not receive any systemic therapy. Nine pts started systemic therapy, and the median time of the primary endpoint was 39.7 months (CI 12.20-62.14 months). No grade 3 or 4 toxicity was recorded.

Conclusion: Repeated salvage [18F]FMCHPET/CT-guided SBRT is well tolerated and could defer the beginning of systemic therapy in selected patients with oligometastatic PCa.

⁴Hospital Provincial de Zamora, Radiation Oncology, Zamora, Spain

⁵Hospital Clínico Universitario de Salamanca, Urology, Salamanca, Spain

⁶Hospital Clínico Universitario de Salamanca, Radiology, Salamanca, Spain

Purpose or Objective: 5-fraction SBRT using CyberKnife is a well-established safe alternative treatment for selected low-risk (LR) and intermediate-risk (IR) prostate cancer. The aim of this study is to determine prospectively the morbidity (CTCAE) and QOL (auto-administered IPSS) of an 8-fraction scheme for high-risk (HR), IR and LR using tomotherapy.

Material and Methods: Exclusion criteria were T3b-4, GS 9-10, PSA ≥ 50 , IPSS ≥ 20 .

Since 2012 eighty-two patients were treated: 41 HR (23/41 with GS ≥ 8 or PSA >20 or T3a, and 18/41 with ≥ 2 intermediate risk factors), 17 IR (GS 7 or PSA 10-20 or T2b-c), and 24 LR.

57/82 patients received 6-month hormonal therapy (HT).

8 fractions of 5.65 Gy for HR-IR, and 5.48 Gy for LR patients were delivered every other day over about 2.5 weeks. EQD2 is 92.3 Gy (HR, IR) or 87.4 Gy (LR) for prostate cancer (a/b 1.5), and 78.2 or 74.3 Gy for late-responding tissues (a/b 3), respectively.

Results: Median follow-up was 13.7 months (0.3-40.1). No acute/late grade ≥ 3 events were observed. Late GU or GI grade 2 toxicities were far below 10% (see Table). We observed a slight urinary flare at 18 months.

		During/following SBRT (N=81)	1 month (N=80)	6 months (N=66)	12 months (N=50)	18 months (N=35)	24 months (N=27)
GU toxicity	Grade 1	41 50.6%	17 21.2%	11 16.7%	9 18%	3 8.6%	2 7.4%
	Grade 2	17 21%	3 3.8%	0 0%	0 0%	2 5.7%	0 0%
GI toxicity	Grade 1	26 32.1%	8 10%	6 9.1%	9 18%	7 20%	1 3.7%
	Grade 2	10 12.4%	0 0%	1 1.5%	1 2%	1 2.9%	2 7.4%
GU / GI toxicity	Grade 3+	0 0%	0 0%	0 0%	0 0%	0 0%	0 0%

IPSS scores (Q1-7) and patient satisfaction (Q8) returned to baseline at 6 months (p=0.21), after they significantly worsened at the last fraction (p=0.00), especially the IPSS-obstructive component (see Figure).

Without HT, PSA nadir has not been reached yet. Mean value at 24 months was 0.66 ng/mL.

With HT, PSA nadir was reached between 1-6 months and then raised up to 0.37 ng/mL average at 18 months (mean testosterone 291 ng/dL), to remain steady afterwards.

No biochemical (nadir+2) /clinical failure was found. One unrelated cancer/treatment death occurred during SBRT.

Conclusion: To our knowledge this is the first communication of SBRT using helical tomotherapy for localized prostate cancer.

The 8-fraction scheme is being well tolerated, with no moderate-severe toxicity, suggesting that this approach is safe.

Longer follow-up is needed to find out whether the delivery of equivalent doses near the plateau of the dose-response curve (>90 Gy) results in better tumour control in this cohort of patients (mostly HR and IR tumours).

PO-0758

Adjuvant or Salvage? 10-y results of the AIRO Group on Prostate cancer multicentre prospective trial

F. Maurizi¹, P. Antognoni¹, S. Barra¹, F. Bertoni¹, A. Bonetta¹, G. Bortolus¹, A. Colombo¹, G. Frezza¹, O. Gabriele¹, C. Iotti¹, F. Mattana¹, S. Meregalli¹, G. Moro¹, M. Signor¹, G. Malinverni¹

¹AIRO, AIRO National Working Group on Prostate Radiotherapy, Italy, Italy

Purpose or Objective: The use of postoperative radiotherapy (RT) in patients (pts) at risk for local recurrence is well established for many tumours. The postoperative subgroup of the AIRO Working Group on Prostate RT carried out a multi-institutional prospective study to evaluate the impact of Adjuvant RT (PORT) and Salvage RT (SART) on biochemical outcomes in prostate cancer pts.

Material and Methods: Between January 2002 and December 2003, data of 440 pts (mean age: 65 years, range 42-81) treated with radical prostatectomy (RP) were collected by 14 Italian RT Departments. Of the 411 pts available for the 10 year analysis (median follow up: 111 months), 284 (69.1%) received PORT (started <6 months after RP) and 127 underwent SART because of increasing PSA level after having been undetectable or persistently elevated PSA (> 6 months after RP). Gleason Score (GS) > 7 and positive surgical margins (SM+) have been shown by 69% pts and 74.5% respectively; 76.5% presented locally advanced disease (pT3-4), 27 (6.7%) positive pelvic nodes; 163 pts (40.2%) revealed seminal vesicles invasion (SVI). All pts received RT to the prostatic fossa (mean dose of 67.8 Gy, range: 60-76). Pelvic RT was delivered to 111 pts (27%). Androgen deprivation (AD) was prescribed to 47,3% pts. Among 127 SART pts, pre-RT PSA level was 1 ng/mL or less in 56 pts (44,1%).

Results: Ten year analysis shows that 259 pts are disease free and 331 are still alive. 10 year (10-y) overall survival and biochemical control (BC) rate are 75.9% and 57.8% respectively. On univariate analysis, PORT versus SART, SVI and GS > 7 significantly influenced 10-y BC rate: 62.7% in PORT group versus 45.6% SART one (p = 0.003), 56.9% in pts with SVI versus 65.6% pts without SVI (p < 0.001), 52.5% if GS > 7 and 69.8% if GS < 7 (p= 0.003). SM+, pathological T and N stages, AD or pelvic RT had no impact on biochemical recurrence rate. SVI and PORT versus SART were variables associated with BC on multivariate analysis. Only pre-RT PSA level significantly influenced disease free survival in SART setting: when the pre-RT PSA was 1 ng/mL or less, 59.8% pts were disease free at 10-y compared with 33.5% of those treated at PSA levels greater than 1 ng/mL (p= 0.017).

Conclusion: Pts in PORT group, pts without SVI and with GS < 7 show better BC rates. Postoperative RT delivered in high risk prostate cancer patients can reduce the impact of other common unfavourable prognostic factors (pT stage, positive surgical margins). Early referral for SART offers better disease control after radical prostatectomy. This prospective multicenter study confirms outcomes of other series.

PO-0759

Results of radical radiotherapy with a tumour boost for bladder cancer in patients unfit for surgery

L.J. Lutkenhaus¹, R.M. Van Os¹, A. Bel¹, M.C.C.M. Hulshof¹

¹Academic Medical Center, Radiotherapy, Amsterdam, The Netherlands

Purpose or Objective: A bladder-preserving strategy, combining transurethral resection of the bladder tumor (TUR-B) with radiochemotherapy, results in a long-term overall survival comparable to cystectomy. However, such a strategy is mostly applied to elderly or unfit patients, but their medical status regularly contraindicates chemotherapy. This leaves the combination of TUR-B and radical radiotherapy as the only treatment option. For this vulnerable patient group, reduction of toxicity is of additional importance, which could

be obtained by more conformal treatment plans. It was our aim to retrospectively analyze the treatment outcome and associated toxicity of both conformal and intensity-modulated radiotherapy (IMRT) using a tumor boost, for locally advanced bladder cancer in patients not suitable for cystectomy.

Material and Methods: 119 patients with T1-4 N0-1 M0 bladder cancer were analyzed retrospectively. Median age was 80 years. Patient and treatment characteristics can be found in Table 1. Treatment consisted of either a conformal box technique or IMRT. Patients were treated with 40 Gy in 20 fractions to the elective treatment volumes, and a daily boost of 0.75 Gy to the tumor. This resulted in a tumor boost of either 55 Gy or 60 Gy, the latter in case expected toxicity allowed delivery of two additional 2.5 Gy fractions to the tumor. Cystoscopic placement of fiducial markers aided in tumor delineation. To evaluate response, a cystoscopy was performed two months after treatment and thereafter every six months. To assess toxicity, patients were seen by their oncologist every week during the treatment course, and thereafter with 1-12 month intervals until up to 5 years after treatment. Toxicity was scored according to the CTCAE version 4, with acute toxicity defined as occurring during treatment or within the first three months thereafter. The Kaplan-Meier method was used to estimate survival and locoregional control. Possible predictors for survival were examined in univariate Cox proportional hazard regression analyses. Differences in toxicity between IMRT or conformal radiotherapy were tested using x2 tests.

Table 1: Patient and treatment characteristics

Characteristics	Patients n	(%)
Sex		
Female	28	(24)
Male	91	(76)
Tumor stage		
1	2	(2)
2	37	(31)
3	70	(59)
4	10	(8)
Clinical lymph node involvement		
No	110	(92)
Yes	9	(8)
Tumor size		
2-4 cm	37	(31)
4-6 cm	59	(50)
≥ 6 cm	22	(18)
Unknown	1	(1)
Planned radiotherapy dose		
55 Gy	62	(52)
60 Gy	57	(48)
Elective treatment volume		
Bladder	24	(20)
Bladder and lymph nodes	95	(80)
Boost delivery		
Concomitant	101	(85)
Simultaneously integrated	18	(15)
Radiotherapy technique		
3D-conformal	68	(57)
IMRT	51	(43)

Results: At 3 months, a complete response was seen in 87% of patients. 3-year overall survival was 44%, with a locoregional control rate of 72% at three years (Figure 1). Including pelvic lymph nodes in the elective field increased survival significantly (hazard ratio: 0.58, p = 0.04). Late toxicity was low, with urinary and intestinal toxicity grades ≥ 2 of 14% and 5%, respectively. IMRT reduced late intestinal toxicity grade ≥ 1 from 24% to 7% (p=0.04), as well as acute intestinal toxicity grade ≥ 2 (from 36% to 12%, p = 0.03).

Figure 1: A: Overall survival. B: Locoregional control. Dashed lines indicate the 95% confidence intervals.

Conclusion: Radical radiotherapy is feasible and effective for elderly or unfit patients. Three-year locoregional control after radical radiotherapy using a boost technique was 72%, with low rates for late urinary and intestinal toxicity. Early and late toxicity rates were reduced by using IMRT.

PO-0760

3D Radiotherapy with concurrent weekly Gemcitabine and Cisplatin for bladder carcinoma

A. Varveris¹, J. Stratakis², M. Mazonakis², A. Spanakis¹, C. Varveris¹

¹University Hospital of Heraklion, Radiotherapy, Heraklion, Greece

²University of Crete, Medical Physics, Heraklion, Greece

Purpose or Objective: We conducted a phase I trial of Gemcitabine (GEM) with concomitant 3D-Conformal Radiotherapy (3D-CRT) and Cisplatin (CDDP) in patients with muscle-invasive bladder cancer who were ineligible for surgery or refused organ loss.

Material and Methods: 28 patients with transitional cell carcinoma, cT2(n=14), cT3(n=8), T4a(n=6), cN0-1, M0, median age 70.5 years were included after maximal transurethral resection. 3D-CRT was administered with a 18MV Linac, 1.8Gy/Fr, 5d/week up to 64.80Gy. The GEM starting dose of 40mg/m²/week was increased by 40mg/m² increments to 2 levels (80 and 120mg/m²/week) in cohorts of 6 patients. The standard dose of CDDP was 25mg/m²/week given 2 days after GEM infusion. Both drugs were given 30 to 60min before irradiation

Results: All patients were evaluated for toxicity which was evaluated according to the Common Toxicity Criteria and the RTOG/EORTC Score. The DLTs (Dose Limiting Toxicities) were defined as hematologic grade >3 or Non-hematologic grade 3 events, as Abdominal pain/Diarrhea (Proctitis), Dysuria/Urinary frequency (Cystitis), Fatigue/Asthenia, not resolving to grade 1/2 within 2 days or necessitating the interruption of RT for >1 week, in more than 3 of 6 patients in each cohort. The GEM dose immediately before the level at which the DLT was observed was defined as the Maximum Tolerated Dose (MTD). In 6 patients accrued to GEM dose 40mg/m²/week no grade 3 toxicities were seen. From 6 patients given 80mg/m²/week of GEM, 2 had episodes of grade 3 bladder toxicity, 3 General Weakness and 2 presented with grade 3 hematological sequelae. From 6 patients accrued to GEM dose 120mg/m²/week, 4 had episodes of grade 3 neutropenia and/or thrombocytopenia and 3 showed grade 3 fatigue/malaise. In 4 patients treatment was interrupted for more than 1 week. The 2-year locoregional failure rate was 28% (8/28). 12 of 28 (42%) patients are alive with no evidence of disease progression, 8 patients developed M1 disease and 5 died from this.

Conclusion: GEM given synchronously with 3D-CRT is well tolerated as a bladder preservation schema. The MTD was defined at 80mg/m²/week combined to CDDP and merits evaluation in phase II/III trials.

Radiation therapy for angiosarcoma of the scalp: total scalp irradiation with X-rays and electrons

M. Hata¹, H. Wada², I. Ogino¹, M. Omura¹, I. Koike¹, Y. Tayama¹, K. Odagiri¹, T. Kasuya¹, M. Aihara², T. Inoue¹

¹Yokohama City University Graduate School of Medicine, Department of Radiology, Yokohama, Japan

²Yokohama City University Graduate School of Medicine, Department of Dermatology, Yokohama, Japan

Purpose or Objective: Wide surgical excision is the standard treatment for angiosarcoma of the scalp, but it is often difficult to completely excise because of the invasive nature and typical multifocal spread of the tumor. Furthermore, many patients are medically inoperable because of old age or coexisting disease. Therefore, we investigated the outcome of radiation therapy with total scalp irradiation for angiosarcoma of the scalp.

Material and Methods: Seventeen patients with angiosarcoma of the scalp underwent radiation therapy with total scalp irradiation with curative intent. Their median age at the time of irradiation was 77 (range, 57-89) years. Four of the 17 patients had tumor invasion into the deep organs, including the skull in three and the temporal muscle in one. Four patients had cervical lymph node metastases, but none had distant metastases. A median initial dose of 50 Gy in 25 fractions was delivered to the entire scalp. Two pairs of lateral X-ray and electron fields were used for total scalp irradiation: 4-6 MV X-rays were delivered through bilaterally opposed ports to the central scalp from the frontal eminence to the suboccipital region, to a depth of 10 mm inside the skull, and 5-9 MeV electrons were delivered through single ports to the bilateral temporal scalp. Subsequently, local radiation boost to the tumor sites achieved a median total dose of 70 Gy in 35 fractions.

Results: All irradiated tumors disappeared or were markedly reduced after radiation therapy; the objective response rate was 100%. However, 14 of the 17 patients developed recurrences during the median follow-up period of 14 months after radiation therapy; seven had recurrences in the scalp, including primary tumor progression in two patients and new disease in five, and 12 patients developed distant metastases. The two patients with primary tumor progression originally had tumor invasion into the skull and temporal muscle, and received a total radiation dose of 70 Gy in 35 fractions. The primary progression-free, scalp relapse-free,

and distant metastasis-free rates were 86%, 67%, and 38% at 1 year and 86%, 38%, and 16% at 3 years, respectively. Thirteen patients died; the cause of death was tumor progression in 10 patients, infectious pneumonia in two, and old age in one. The overall and cause-specific survival rates were both 73% at 1 year and 23% and 44% at 3 years, respectively. The median survival time was 16 months. Although all 17 patients developed grade 1-2 radiation dermatitis, there were no therapy-related toxicities of grade ≥ 3 .

Conclusion: Total scalp irradiation with X-rays and electrons is safe and effective for local tumor control of angiosarcoma of the scalp, but a prophylactic dose of 50 Gy in conventional fractions may be insufficient to eradicate microscopic disease. For gross tumors, a total dose of 70 Gy, and >70 Gy for tumors with deep invasion, is recommended.

PO-0762

Dose-volume predictors of radio-induced effects after SRS for uveal melanoma

C.R. Gigliotti¹, M. Di Nicola², L.A. Perna¹, C. Fiorino¹, G. Modorati², P. Mortini³, A. Franzin³, A. Bolognesi⁴, A. Del Vecchio¹, R. Calandrino¹

¹IRCCS San Raffaele Scientific Institute, Medical Physics, Milano, Italy

²IRCCS San Raffaele Scientific Institute, Ophthalmology, Milano, Italy

³IRCCS SAN Raffaele Scientific Institute, Neurosurgery, Milano, Italy

⁴IRCCS SAN Raffaele Scientific Institute, Radiotherapy, Milano, Italy

Purpose or Objective: Uveal melanoma (UM) is a life threatening intraocular malignant tumor in adults. Gamma Knife Stereotactic Radiosurgery (GKSRS) is a well assessed strategy for conservative treatment of UM providing satisfactory results in terms of survival, local control and eye preservation. Despite severe side effects following GKSRS have been reported, literature studies designed to investigate dose effect relationship of critical structures are rather poor. The aim of this work is to develop predictive models for radio induced effects in UM patients (pts) treated with GKSRS.

Material and Methods: In our institute 149 pts were treated with exclusive GKSRS for UM between 1994 and 2014. Prospectively collected clinical data are available. For 66/149 pts, 3D dosimetry data of involved critical structures could be recovered: optic nerve (ON), eyeball and posterior part of bulb. For this cohort of pts the median follow up of 2years (6 months-6 years) is available. Cox's analyses were used to identify selected clinical and dosimetric variables as independent risk factor of main side effects: cataract, radiation vasculopathy (RV), radiation papillopathy (RP) and neovascular glaucoma (NVG), visual acuity (VA) reduction > 20% of basal value (VA20%) and complete loss of basal VA (VA100%). ROC curve analysis allowed predicting cut off value of significant variables.

Results: The 2 years incidences from our data were: cataract 39%, RV 10%, RP 12%, NVG 14%, VA20% 59% and VA100% 27%. Age and sex did not result significant. Concerning cataract the volume of whole bulb receiving more than 30Gy (p=0.0004) and tumor thickness (p=0.002) resulted highly predictive; best cut off were respectively 82.2mm³ and 6.6mm. A clear relationship with maximum dose (Dmax) to ON was found for RP (p=0.009 cut off: 14.9Gy) and RV (p=0.0009 cut off: 23.8Gy). For RV, also tumor in the anterior to equator position was predictive (p=0.008). The volume of the posterior bulb receiving more than 20Gy (p=0.0003, cut off: 413.7mm³) and tumor thickness (p=0.0009 cut off: 8.7mm) were predictive for NVG. Multivariate analyses resulted in two variables predictive model both for VA20% (AUC=0.79) and for VA100% (AUC=0.83), including the tumor longest basal diameter and Dmax to the ON. The best cut off values for the tumor longest basal diameter were 11.6mm for VA20% (p=0.02) and 8.98mm for VA100% (p=0.007); the best

cut off values for Dmax to the ON were 7.8Gy (p=0.045) for VA20% and 13.2Gy (p=0.002) for VA100%. A summary of the main results are reported in Figure.

	Cataract	Neo Vascular Glaucoma	Radiation Vasculopathy	Radiation Papillopathy	20% Visual Acuity Reduction (Model AUC=0.79)	100% Visual Acuity Reduction (Model AUC=0.83)
V30 Whole Bulb	p=0.0004 HR=1.007 95%CI: 1.003-1.011 cut-off: 82.2mm ³ AUC=0.71					
Dmax Optic Nerve			p=0.0009 HR=1.2 95%CI: 1.07-1.32 cut-off: 23.8Gy AUC=0.86	p=0.009 HR=1.14 95%CI: 1.052-1.258 cut-off: 14.9Gy AUC=0.83	p=0.045 HR=1.04 95%CI: 1.00-1.08 cut-off: 7.8Gy	p=0.002 HR=1.12 95%CI: 1.04-1.21 cut-off: 13.2Gy
V20 Posterior Bulb		p=0.0003 HR=1.12 95%CI: 1.05-1.19 cut-off: 413.7mm ³ AUC=0.83				
Position: anterior to equator			p=0.008 HR=0.14 95%CI: 0.04-0.60			
Tumor Longest Basal Diameter					p=0.02 HR=1.15 95%CI: 1.02-1.30 cut-off: 11.6mm	p=0.007 HR=1.26 95%CI: 1.09-1.69 cut-off: 8.98mm
Tumor Thickness	p=0.002 HR=1.35 95%CI: 1.12-1.62 cut-off: 6.6mm AUC=0.64	p=0.0009 HR=2.01 95%CI: 1.53-2.62 cut-off: 8.7mm AUC=0.83				

Conclusion: We found clinical and dosimetric variables to clearly predict the risk of the main side effects after GKSRS for UM. These results may provide new dose constraints to critical structures, that once implemented during treatment planning, could reduce radiation toxicities. Further investigation to create bulb dose surface maps highlighting any specific regions more radiosensitive are now under implementation.

PO-0763

Ruthenium-106 brachytherapy for choroidal melanoma: high efficacy with improved visual outcome.

F.P. Peters¹, M. Marinkovic², N. Horeweg¹, L. Sommers¹, M. Fiocco³, J.C. Bleeker², M. Ketelaars¹, G.P.M. Luyten², C.L. Creutzberg¹

¹Leiden University Medical Center, Department of Radiation Oncology, Leiden, The Netherlands

²Leiden University Medical Center, Department of Ophthalmology and Melanoma Center, Leiden, The Netherlands

³Leiden University Medical Center, Department of Biostatistics, Leiden, The Netherlands

Purpose or Objective: Choroidal melanoma is the most frequent malignant tumour of the eye. Eye-conserving treatment with Ruthenium-106 brachytherapy (RuBT) is a standard treatment for patients with small to intermediate size melanomas. The present study was done to evaluate

efficacy and visual outcomes of a large series of patients with choroidal melanoma (CM) treated with RuBT, and compare the results to those of the preceding protocol in which RuBT was combined with transpupillary thermotherapy (Ru/TTT).

Material and Methods: Outcomes of 449 consecutive CM patients with tumour prominence <8 mm and basal diameter <16 mm treated with RuBT from 2004 to 2011 were analysed. 253 (56.3%) were treated according to the current RuBT protocol (from 2008 onwards) with 130 Gy specified at the tumour apex and minimum and maximum doses to the scleral surface of 300 Gy and 1000 Gy, respectively. 196 (43.6%) were treated using the preceding Ru/TTT protocol with either 400 or 600 Gy to the scleral surface followed by TTT, or 600-800 Gy without TTT for peripheral tumour location. The brachytherapy dose was standardized to a dose rate of 100 Gy per 24 h using a correction factor (2-10% dose correction). Local failure was defined as residual prominence with signs of activity on fluorescence angiography, or regrowth after complete remission.

Results: Median follow-up was 40.1 months; 25.9 months for RuBT and 67.5 months for Ru/TTT; hence 3-year results were analysed. Patients treated with RuBT had smaller and less centrally located tumours and better median visual acuity (VA). VA deteriorated more rapidly in Ru/TTT patients; at 1 year the loss of vision relative to the VA before treatment was -0.1 for RuBT patients vs -0.25 for Ru/TTT, while at 3 years the relative VA decline was similar (-0.30 vs. -0.28). Local failure was detected within 3 years in 4.3% of RuBT patients compared to 11.2% of Ru/TTT patients, for 3-year cumulative incidence rates of 6.4% vs 11.2% (p=0.09). Treatment for local failure consisted of repeated RuBT; TTT; or enucleation. Enucleation was performed in 2.4% of RuBT patients vs. 10.2% of Ru/TTT; of these, 1.6% vs 6.1% were done for recurrence and 0.8 vs 4.1% for complications. Three-year cumulative incidence of distant metastases was 4.8% vs 6.6% for RuBT vs Ru/TTT (p=0.37), and of death 0.5 vs 3.7%. In univariate analyses, most important risk factors for local recurrence and metastases were tumour prominence, tumour diameter and stage, while in multivariate analysis only diameter remained significant for local recurrence. In view of the short follow-up of RuBT, updated results will be presented.

Conclusion: Both protocols for eye-conserving treatment of patients with choroidal melanoma provided excellent rates of local tumour control and eye preservation, with the RuBT protocol confirmed to be best standard of care with 97% eye preservation and significantly longer preservation of visual acuity.

⁴Fondazione di Ricerca e Cura "Giovanni Paolo II"- Catholic University of Sacred Heart, Radiotherapy Unit, Campobasso, Italy

⁵Ospedale Bellaria, Radiotherapy Department, Bologna, Italy

Purpose or Objective: The standard primary treatment for soft tissue sarcoma (STS) is radical surgical resection, preceded or followed by radiotherapy. The purpose of this retrospective study was to assess the efficacy and safety of

perioperative brachytherapy (BT) plus postoperative external beam radiation therapy (EBRT) +/- chemotherapy (CT).

Material and Methods: The primary aim of the study was evaluating local control (LC) and overall survival (OS) in a large patients population of treated with combined modality therapy. Secondary objectives were to identify prognostic factors for local recurrence (LR). BT was delivered with Pulsed Dose Rate. Total dose was 20 Gy (0.80 Gy/pulse). EBRT was delivered with 3D-technique by using multiple beams technique. The prescribed dose was 46 Gy (2Gy/fraction). Neoadjuvant and adjuvant chemotherapy was prescribed to patients with potentially chemo-sensitive histological subtypes. Univariate analysis was performed with the log-rank test and multivariate analysis with Cox's proportional hazard model.

Results: From 2000 to 2011, 107 patients (median age 54 years; range 13-85) with high grade primary or recurrent STS were treated with surgery, perioperative BT and adjuvant EBRT +/- CT. Five year LC and OS were 82.2% and 87.8%, respectively. A higher LC was recorded in patients treated for primary tumor, lower limbs, and negative margins STS.

Conclusion: The combination of BT and EBRT was able to achieve high LC and OS rates. A particular risk factor recorded was the disease site. These results warrant further prospective studies to define the role of BT boost in adjuvant therapy of resected STS.

PO-0765

Management of primary cardiac and great vessel sarcomas, The RMH experience 2000-2015.

R. Rieu¹, C. Benson¹, A. Dunlop¹, K. Khabra¹, O. Al-Muderis¹, R. Jones¹, W. Van der Graaf¹, C. Fisher¹, K. Thway¹, C. Messiou¹, I. Judson¹, A. Miah¹, S. Zaidi¹

¹The Royal Marsden, Sarcoma Unit, London, United Kingdom

Purpose or Objective: Primary cardiac and great vessel sarcomas are a challenging group of cancers with poor prognosis. No consensus management guidelines exist and definitive treatment favours surgery, reserving adjuvant radiotherapy (RT)/chemotherapy (CT) for high-risk patients.

Material and Methods: Retrospective analysis of patients identified from a prospectively collected database Sarcoma Unit, 2000-2014.

Results: 33 patients (19 males) were identified with either primary cardiac (73%) or great vessel sarcomas; median age of 46.9 (range 13-83). Presenting symptoms included dyspnoea (55%), pain (21%), cough/haemoptysis (11%), heart failure (24%), emboli (18%) or pulmonary HTN (12%). Diagnosis was on biopsy (42%) or following resection (58%). Atrial tumours accounted for 58% of cases. Surgery was performed in 66%, with R0 (12%), R1 (24%), R2 (24%), or unknown (6%) margins. High grade tumours were seen in 17 (52%) cases. Commonest histological subtypes were angiosarcoma (32%), and spindle cell (17%). Localised disease was observed in 18 (55%) cases. Median follow-up was 379 days.

Group A, Radiotherapy: 15 patients received RT (6 males), 10 had operable tumours. 8 patients also received CT. Median time to first treatment was 57.9 days. Patients received 60 Gy/30#(n=4), 59.4 Gy/33#(n=3), 58 Gy/30#(n=1), 50.4 Gy/28#(n=3), 45 Gy/25#(n=1), 35 Gy/15#(n=1), or 20 Gy/5#(n=1). 85% reported toxicity (oesophagitis, cough or fatigue). 8 (53%) patients developed a local recurrence (LR) and 13 patients developed metastatic disease (DM). 2 were long term survivors. Median time to DM for right sided lesions was 116 days, left sided, 1226 days. Overall survival was 2.1 years (R side) and 3.4 years (L side). Median OS was 803 days.

Group B, Chemotherapy: 13 patients received CT (10 males), 7 had operable tumours. Median time to first treatment was 44 days. Regimens were mainly alkylating/anthracycline/taxane based. 3 patients stopped early (toxicity). 10 patients had LR (77%) and 10 patients developed DM. 2 were long term survivors. Median OS was 296 days.

Group C, Surgery:

5 patients, 1 died 3 days after diagnosis. 4 patients had surgery, 3 developed DM and 1 is a long-term survivor. Median OS was 68 days.

Conclusion: These rare sarcomas have variable clinical presentations. Surgery is the central component for successful treatment but complete resection is not always possible. RT may reduce LR (reduced from 77%, group B, to 53%, group A) and chemotherapy is offered if high risk (inoperable, R2 margins, or DM). We still need to define the optimum management.

PO-0766

Is dose de-escalation possible in sarcoma patients treated with extended limb sparing resection?

A. Levy¹, S. Bonvalot², P. Terrier³, A. Le Cesne⁴, C. Le Pêcheux⁵

¹Institut Gustave Roussy, Radiation Oncology department, Villejuif, France

²Curie, Surgery, Paris, France

³Gustave Roussy, Pathology, Villejuif, France

⁴Gustave Roussy, Medicine, Villejuif, France

⁵Gustave Roussy, radiation Oncology, Villejuif, France

Purpose or Objective: To evaluate the impact of a dose escalation > 50 Gy in a large series of resected limbs soft tissue sarcomas (STS)

Material and Methods: Data were retrospectively analyzed from 414 consecutive localized limbs STS patients who received irradiation and enlarged surgery at Gustave Roussy from 05/1993 to 05/2012. RT dose level were decided in multidisciplinary staff and depended upon the quality of surgery and margins size.

Results: The median age was 52 years, the median tumor size was 89 mm, most patients had proximal locations (72%), and G-2-3 tumors (79%). Available histologic analyses after surgery retrieved 84% unifocal tumors and free-tumor margins >1 mm in 69% of cases. Radiotherapy (RT) was delivered prior (13%) or after (87%) surgery. Seven patients (2%) had pre- and a postoperative RT boost. Median delivered RT dose was 50 Gy (36-70 Gy), and 40% received >50Gy. At a median follow-up of 5.5 years, the 5-year local relapse rates (LRRs) were 7%, 4%, and 13% in the general population, in patients receiving <50Gy and in those who had >50 Gy (p<0.001), respectively. Despite this may be due to confounding factors, a dose >50 Gy (HR: 2.6; p=0.04) remained associated with higher LRRs in the multivariate analysis (MVA), as well as histological subtypes (HR: 3.7; p=0.002), and surgical margins<1mm (HR: 3.2; p=0.008). Grade, age, and tumour size were not associated with LRRs in the MVA.

Conclusion: In this retrospective analysis of patients having enlarged and surgery and RT dose escalation did not allow offsetting local relapse in high-risk patients. This should be evaluated in a larger set of patients all having enlarged surgery. A Prospective study allowing dose refinement in this setting is required.

PO-0767

Does fluid collection have an impact on radiotherapy outcomes after excision of soft tissue sarcoma?

N. Choi¹, J.Y. Kim¹, T. Yu¹, H.S. Kim², H.J. Kim¹, I.H. Kim¹

¹Seoul National University College of Medicine, Department of Radiation Oncology, Seoul, Korea Republic of

²Seoul National University College of Medicine, Department of Orthopaedic Surgery, Seoul, Korea Republic of

Purpose or Objective: Fluid collection of lymph or blood may accumulate at the site of excision after surgery for soft tissue sarcoma, with reported incidence rates from 10-36%. Though small fluid collections have a high probability of being completely covered within the postoperative radiotherapy (PORT) field, large fluid collections may require a more extensive expansion of CTVs. This study is an unprecedented analysis of fluid collection in relation to radiotherapy outcomes after wide excision of soft tissue sarcoma (STS).

Material and Methods: Medical records of 151 patients with STS treated with wide excision followed by adjuvant PORT between 2004 and 2014 were retrospectively reviewed. Only non-recurrent and non-metastatic patients were included. After evaluation of CT and MR images taken at the time of PORT planning, fluid collection was detected in 46 patients (30.5%). Because fluid collection developed more commonly in lower extremity (p<0.001) and higher grade tumors (p=0.095), only these patients were included in further analyses (n=76). Fluid collection was present in 35 (46.1%) patients, of which 74.3% and 25.7% had, respectively, either complete or partial coverage in planning target volumes (PTVs) throughout the entire course of PORT.

Results: After a median follow-up of 41 months, patients with and without fluid collection demonstrated local failure rates of 14.3% and 9.8%, and 5-year local control (LC) rates of 83.1% and 86.8%, respectively. The presence of fluid collection had no statistical impact on the clinical outcomes of PORT. Partial coverage of fluid collection showed a low 5-year LC rate of 77.8% compared with 85.5% and 86.8% for patients that had complete PTV coverage or absence of fluid collection, respectively, without statistical significance. Post-PORT complications developed in 5 (6.6%) patients, of which 4 had fluid collection. Wound complication developed in 3 (8.6%) of 35 patients with fluid collection and in 1 (2.4%) of 41 patients without fluid collection.

Conclusion: Fluid collection demonstrated lower LC rates after wide excision and PORT for STS, but with a reasonable wound complication rate of 8.6% when compared with rates of previous studies ranging from 5-17%. Furthermore, partial coverage of fluid collections in PTVs had worse LC rates, thus recommending complete coverage. Future evaluation with a larger number of cases will be needed for statistical support of our findings.

PO-0768

Evaluation of RT practice for limb soft tissue sarcomas and its impact on prognosis and toxicity

¹¹Hopital Trousseau, Radiation Oncology, Tours, France

¹²Institut Paoli-Calmette, Radiation Oncology, Marseille, France

Purpose or Objective: If radiotherapy (RT) combined with extended resection is part of the standard treatment of high risk extremity soft tissue sarcomas (ESTS), the evidence regarding the optimal target volume of RT ensuring local control (LC) is not very robust. But it is well known that toxicity is directly related to the RT volume and the delivered dose. The development of image-guided radiotherapy and implementation of better target volume conformation could reduce toxicity without compromising outcome. Here we evaluate the definition of RT volume according to clinical, surgical and histological factors.

Material and Methods: Between the 1st January 2008 and the 31st Decembre 2009, 173 patients from eleven centers with ESTS were retrospectively evaluated, all patients having had resection with pre- or post-operative RT. Primary endpoint was to evaluate the target volume and RT dose and their impact on LC and patterns of local relapse (LR). Secondary endpoints were: impact of surgery's quality on LC, patterns of relapse and RT volume. Impact of RT dose on LC and patterns of LR. Impact of histological type on LC and on recurrent pattern. Impact of RT volume on toxicity (CTC V.04).

Results: Median age was 60 years [19-91]. 32% of patients had upper limb and 68% lower limb STS. Median tumor size was 75mm [17-270]. RT was preoperative in 12% and postoperative in 88% of cases. Quality of surgery was R0 in 62%; R0 after second surgery in 11% and R1 in 27% patients. Intraoperative tumor fragmentation rate was 6% in expert centers and 16% in non-expert centers. Most frequent histologic types were liposarcoma (31%) and myxofibrosarcoma (13%). Median dose was 54 Gy [36-70]. Median PTV1 and PTV2 volumes were 864cc [25-5122] and 443cc [20-1613] respectively. LR rate was 11.20% (n=20); 45% within PTV1, 28% in the PTV2, 18% at the edge of the RT volume and 9% outside. 21.4% of patients had a metastatic failure. Regarding toxicity, we observed 19.6% and 15.2% of G1 and G2 fibrosis, 19.6% and 12.5% of G1 and G2 edema, 12.6% and 4.5% G1 and G2 pain, 3.4% and 6.9% of G1 and G2 joint stiffness, 5.2% and 6.9% G1 and G2 neuropathy. Bone fracture occurred in 3.2% of cases. After univariate analysis, intraoperative tumor fragmentation was related to a higher risk of LR (22% vs 8% p=0,004) and distant metastasis (50% vs 17% p= 0,0029). Including scar drainage in the RT field was correlated to a lower LR rate (9% vs 29% p= 0,015). Upper limb location was correlated with higher risk of neuropathy (p=0,049) and lower limb location was correlated with edema (p=0,024). Dose > 60 Gy did not impact on LC but was correlated with pain (p=0,021). No significant correlation with fibrosis could be identified.

Conclusion: As in other studies, the quality of surgery is the most important prognostic factor predicting outcome. Most of LR were within the PTV field translating a correct target volume definition. Toxicity was acceptable. A prospective evaluation is warranted.

¹²VU Medisch Centrum, Pediatrics, Amsterdam, Germany

¹³Georg-August-Universität, Pediatric Hematology and Oncology, Goettingen, Germany

Purpose or Objective: Radiotherapy remains the cornerstone of treatment for patients with DIPG. Nevertheless, median overall survival of patients initially responding to radiotherapy is poor. The role of chemotherapy as second-line treatment remains elusive. Purpose of this study is to analyze the benefit and toxicity of re-irradiation at the time of disease progression.

Material and Methods: At the time of disease progression 27 children, aged 2 to 16, underwent re-irradiation (10 fractions of 1.8, 2.0 or 3.0 Gy) alone (N=21) or combined with systemic therapy (N=6). At first diagnosis, all patients had symptoms for ≤3 months, ≥2 signs of the neurological triad (cranial nerve deficit, ataxia, long tract signs), characteristic features of DIPG on magnetic resonance imaging or biopsy proven high-grade glioma. An interval of ≥3 months after first-line radiotherapy was required before re-irradiation. A group of 39 patients fulfilling the same diagnostic criteria receiving radiotherapy at primary diagnosis, followed by best supportive care (N=10) or systemic therapy (N=19), were eligible for a matched-cohort analysis.

Results: Median overall survival for patients undergoing re-irradiation was 15.9 months. For a similar median time to first progression (8.1 vs. 7.7 months; P=.22), a significant benefit in median overall survival (15.9 [95% CI 13.0-20.0] vs. 10.3 [95% CI 9.4-12.5] months; P=<.01) was observed in favor of patients undergoing re-irradiation compared to no re-irradiation. The median overall survival benefit of re-irradiation versus no re-irradiation was most pronounced in patients with a longer interval between end-of-radiotherapy and first progression (3-6 months: 11.1 vs. 8.7; P=<.01; 6-12 months: 19.4 vs. 13.8; P=.02). On multivariable analysis corrected for age and systemic therapy, re-irradiation remained prognostic for overall survival (HR 0.43 [0.13-81]; P=<.01). Clinical improvement after re-irradiation was observed in 15/20 (75%) patients. No grade 4 or 5 acute or late toxicity was diagnosed.

Conclusion: The majority of patients with DIPG, responding to first-line radiotherapy, do benefit of re-irradiation. A prospective data collection, supported by the SIOP-E-HGG/DIPG working group, will start for patients fulfilling the criteria of re-irradiation.

Purpose or Objective: The risk of colorectal adenomas (CRAs) in childhood cancer survivors (CCS) is unknown. In the general population and in individuals with cancer susceptibility syndromes, CRAs are associated with colorectal carcinoma (CRC) risk and this knowledge is the basis for colorectal cancer screening. To support recommendations for or against CRC screening among asymptomatic CCS, we aim to estimate the risk of histologically confirmed CRAs in a large cohort of 5-year CCS and to quantify the contribution of associated treatment-related factors.

Material and Methods: The Dutch Childhood Oncology Group-Late Effects After Childhood Cancer (DCOG LATER) cohort includes 6,168 five-year CCS treated between 1/1/1963 and 12/31/2001 in one of the seven Dutch pediatric oncology/hematology centers before age 18. Detailed information on prior cancer diagnosis and treatment was collected, including information on radiotherapy (RT) dose, field, and fractionation schedule and chemotherapy (CT) dose per drug. Subsequent CRAs were identified by linkage with the population-based Dutch Pathology Registry (PALGA) for follow-up years 1990-2014, a unique resource for case ascertainment without selection bias from self-reporting. Among patients with CRA we also ascertained the occurrence of CRC based on cancer registry linkage.

Results: At a median follow-up of 23 years (range: 5-52) since childhood cancer diagnosis and a median attained age of 30 years, we identified 60 patients with at least one histologically confirmed CRA, of which 37 had >1 CRA. Most common CRA histology was tubular adenoma, followed by tubulovillous adenoma. Median age at first CRA diagnosis was 39 years and median time from childhood cancer diagnosis to CRA diagnosis was 28 years. Most CRA patients had been treated for leukemia (23.3%) or lymphomas (20.0%). Eight CRA patients also developed a CRC. Preliminary univariate analyses showed an increased risk of CRA associated with abdominal/pelvic RT (odds ratio=2.7; 95% CI: 1.5-4.9).

Conclusion: This study shows a fairly high incidence of histologically confirmed CRAs in a relatively young population. However, these exploratory analyses need further in-depth medical file review to ascertain the

potential for surveillance bias. More detailed analyses with multivariable risk models including RT dose and specific CT agents and the role of cancer susceptibility syndromes will be presented during the meeting. Also this study provides the baseline for a longitudinal assessment of CRA and CRC risk, as this population ages.

Purpose or Objective: Pediatric cancer treatment, including radiotherapy (RT) achieves high cure rates, but can cause late health problems. We aim to describe temporal trends of pediatric RT use in the Netherlands based on treatment experience in the DCOG-LATER cohort of five-yr childhood cancer survivors (CCS).

Material and Methods: The Dutch Childhood Oncology Group - Late effects after childhood cancer (DCOG-LATER) is a collaborative effort of all 7 academic paediatric oncology/hematology centres in the Netherlands for optimal patient care and research. The DCOG-LATER cohort includes 6168 five-yr CCS diagnosed 1963-2001 prior to age 18 yrs. Most children were treated according to (inter) national study protocols. Trained data-managers obtained *individual* medical file information on prior cancer diagnosis and treatment including prescribed RT dose, field(s), fractionation schedule, machine and RT technique from data were coded and stored in a web-based database using study coding manuals. Here we summarize trends in RT use by calendar period (1963-1979 vs 1980-2001) and diagnosis group.

Results: In all, 2426 (39%) CCS received external beam RT (EBRT) for a primary tumor or recurrence, most often photons, or, <1989, Cobalt-60. Use of orthovoltage and electrons was limited. Brachytherapy (2%) and radio isotopes (2%) were given, mainly during 1990-2001. RT use decreased substantially for all cancer types; most dramatic changes were seen among CCS of acute lymphoblastic leukemia, Non-Hodgkin lymphoma, neuroblastoma, and nephroblastoma, for whom RT-use declined from 92%, 79%, 59% and 76% (1963-1979), to 15%, 8%, 8%, and 27% (1990-2001), respectively, but also for bone tumors (75%-32%), retinoblastoma (57%-16%), and CNS tumors (82%-47%). Modest declines were seen for CCS of Hodgkin lymphoma (74%-50%), soft tissue sarcomas (57%-36%), and germ-cell tumors (43%-26%). Among 2094 leukemia survivors, 773 had any RT, directed to the cranium (56%), total body (22%), cranio-spinal axis (12%), and testes (4%). Formal trend analyses by childhood cancer type, body compartment, and RT dose will be presented.

Conclusion: The use of RT declined over time for all pediatric cancer types, likely related to improved diagnostic techniques (CT/MRI/pathology) and the introduction of multimodal chemotherapy and enhanced surgical techniques. Temporal changes in treatment exposures document the magnitude of changes, illustrate the heterogeneity of treatment exposures and can be correlated with trends in health outcomes.

⁵S. Orsola-Malpighi Hospital- University of Bologna, Department of Medical Physics, Bologna, Italy

⁶Policlinico Universitario "A. Gemelli"- Catholic University of Sacred Heart, Department of Radiotherapy, Roma, Italy

Purpose or Objective: To verify the adequacy of dose volume constraints in stereotactic radiotherapy and radiosurgery of abdominal area considering that dose constraints reported in literature are not still validated. This study is based on toxicity recorded in organs at risk (OARs) of patients enrolled in dose-escalation trials and treated in Our Institution.

Material and Methods: Treatment plans of 51 patients (Table 1) who underwent SBRT (30 patients) or SBRS (21 patients) on abdominal neoplasms from March 2007 to May 2014 were retrospectively evaluated. All patients were treated using V-MAT technique. SBRT treatment was delivered in 25-40 Gy in 5 fractions, and 16-30 Gy in single fraction in SBRS treatment. Small intestine and duodenum were the main OARs whose irradiation was virtually limited to 30 Gy in SBRT treatments and 12 Gy in SBRS treatments. Dosimetric data were compared with clinical results in terms of early and late toxicity.

Table 1: Patients' characteristics

		SBRT (N, %)	SBRS (N, %)
N°		30 (59)	21 (41)
M/F		8/22	9/12
Age (range; average)		31-82; 64	39-85; 67
Primary tumor			
	Endometrium	6 (20)	0 (0.0)
	Ovary	5 (16.7)	1 (4.8)
	Cervix	5 (16.7)	1 (4.8)
	Vagina	2 (6.7)	0 (0.0)
	Breast	0 (0.0)	3 (14.3)
	Pancreas	4 (13.3)	1 (4.8)
	Prostate	3 (10)	5 (23.8)
	Colon	3 (10)	3 (14.3)
	Rectum	1 (3.3)	2 (9.5)
	Stomach	1 (3.3)	0 (0.0)
	Other	0 (0.0)	5 (23.8)
Treated lesion			
	Primary tumor	4 (13.5)	3 (14.2)
	Nodal metastases	22 (73)	7 (33.3)
	Distant metastases	4 (13.5)	12 (57.1)

Results: SBRT treatment: maximum small bowel and duodenum dose-volume constraints were exceeded in 5/30 (16.7%) and 2/30 (6.7%), respectively. Dose to OARs was: small bowel: Dmax 31.5-40.5 Gy, V30 0.2-13.4 cc; duodenum: Dmax 35.7-36.6 Gy, V30 2.1-3.7 cc.

SBRS treatment: maximum small bowel and duodenum dose-volume constraints were exceeded in 2/21 patients (9.5%) and 1/21 patient (4.7%), respectively. Dose to OARs was: small bowel: Dmax 15.6-16.3 Gy, V12 1.7-8.5 cc; duodenum Dmax 16.0 Gy, V12 0.1 cc.

With a median follow up of 24 months after SBRT and 18 months after SBRS, no early or late severe toxicity was observed in patients in whom constraints were not respected.

Conclusion: Patients irradiated on small bowel and duodenum did not develop severe toxicity although the administered doses were above constraints proposed in literature. A prolonged follow-up and a larger population are needed to confirm the safety of dose-volume constraints other than those reported in literature about SBRT and SBRS on abdominal area.

Purpose or Objective: To define the maximum tolerated dose (MTD) of extra-cranial stereotactic treatment (SBRT) in previously irradiated patients.

Material and Methods: In a dose escalation (Phase I) study, previously irradiated patients were enrolled in two different arms depending on treatment site and previous dose: 1) retreatment with previous dose > 60 Gy or retreatment of pancreatic and pelvic tumors, 2) retreatment with previous dose < 60 Gy. SBRT was delivered in 5 fractions with static 3D technique (4 non-coplanar beams) or dynamic arc (VMAT). The dose was prescribed at the isocenter. The Planning Target Volume (PTV) was defined as the GTV + 5-15 mm margin. According to the study arm, the first cohort of 6

patients received a dose of 20 or 25 Gy, and subsequent cohorts of patients received doses up to 40 Gy. The dose limiting toxicity (DLT) was defined as any acute and late toxicity Grade ≥ 3. The MTD was defined as the dose level with 2/6 or 4/12 DLT.

Results: From September 2004 to December 2014, 51 patients (M/F: 27/24; median age 65, range 44-87), previously irradiated with doses of 30 to 87 Gy (median dose 50 Gy) were enrolled, after 4-228 months from the first treatment (median 11 months). Sixty-six lesions were treated (23 primary lesions or relapses, 43 lymphadenopathies) mainly from gynecological tumors (30%), followed by gastrointestinal tumors (26%) and prostatic tumors (17%). Nineteen of the 66 lesions were in the neck or chest, 22 in the abdomen and 25 in the pelvis. With a median follow-up of 19 months (3-104), an overall response rate of 81% (Complete Response: 55%, Partial Response: 26%), with only 3% of disease progression was recorded. At 40 Gy dose-level, only 1 patient showed DLT (cutaneous fistula in the sacral region). Two-year local control was 75% and 2-year metastasis-free survival was 30%.

Conclusion: SBRT treatment in 5 fractions up to a dose of 40 Gy is well tolerated in previously irradiated patients. This dose escalation protocol is still ongoing (Table 1).

Level	n° pts	Retreatment	
		previous dose ≤ 60 Gy (pancreas e pelvis); previous dose > 60 Gy	previous dose ≤ 60 Gy
1	6 §	20 Gy	25 Gy
2	6 §	25 Gy	30 Gy
3	6 §	30 Gy*	35 Gy
4	6 §	35 Gy	<u>40 Gy</u>
5	6 §	40 Gy	45 Gy
6	6 §	<u>45 Gy</u>	50 Gy

⁶S. Orsola-Malpighi Hospital- University of Bologna, Department of Medical Physics, Bologna, Italy

⁷Bellaria Hospital, Radiotherapy Department, Bologna, Italy

Purpose or Objective: To define the maximum tolerated dose (MTD) of stereotactic extracranial radiosurgery performed in a single session (SBRS) in different clinical settings.

Material and Methods: Based on a Dose Escalation study (Phase I), oligometastatic patients were enrolled in 4 different arms depending on site and treatment purpose: 1) liver metastases, 2) lung metastases, 3) lymph node metastases or liver or lung metastases with a prolonged local control purpose, 4) bone metastases (non-vertebral). Dose was prescribed according to the Rosel protocol (V100 >95%, V90 >99% and Dmax <140% of the prescription) with dynamic

volumetric intensity modulated arc technique (VMAT). The Planning Target Volume (PTV) was defined as the GTV plus a personalized Internal Margin and a 3 mm Set-up Margin. Based on the study arm, the first cohort of 6 patients received a dose of 12-26 Gy, and the subsequent cohorts of patients received doses up to 30 Gy. The dose limiting toxicity (DLT) was defined as any acute and > Grade 3 late toxicity (CTC-AE v. 4.03). In case of 2/6 or 4/12 DLT in the analyzed cohort, this dose was considered as MTD.

Results: From August 2010 to April 2015 92 patients were enrolled (M/F: 50/42; median age: 67 years (40-93); range: 40-93) and 142 lesions were treated (bone: 47, lung: 39, nodes: 33, and liver: 23) mainly from prostatic (28%), gastrointestinal (25%), breast (21%), and gynecological (8%) tumors. With a median follow-up of 11 months (2-58), overall response rate was 70% (CR: 47%, PR: 23%), with 15% stable disease and only 4% of progressive disease (15 lesions (11%) not evaluable for response at the time of the analysis). No DLT was recorded. Two-year local control at was 77% and 2-year metastases-free survival was 34%. Two-year overall survival was 78%.

Conclusion: SBRS is well tolerated up to a dose of 30 Gy. The dose escalation protocol is ongoing (Table).

Table: Destroy -2: study arms and dose levels

Dose level	Lung	Liver	Bone	Other
1	26 Gy	26 Gy	12 Gy	16 Gy
2	28 Gy	<u>28 Gy</u>	14 Gy	18 Gy
3	<u>30 Gy</u>	30 Gy	16 Gy	20 Gy
4	32 Gy	32 Gy	18 Gy	22 Gy
5	34 Gy		20 Gy	<u>24 Gy</u>
6			22 Gy	
7			<u>24 Gy</u>

PO-0775

Risk stratification of vertebral compression fracture after palliative RT for spinal metastases

T. Yu¹, J.H. Kim¹, K. Kim¹, K. Hak Jae¹, E.K. Chie¹, K.H. Shin¹, H.G. Wu¹, I.H. Kim¹

¹Seoul National University College of Medicine, Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: Vertebral compression fracture (VCF) by involvement of metastatic tumor significantly compromises in quality of life of patients. Spinal Instability Neoplastic Score (SINS) is the classification system to predict VCF, but lacks clinical validation. The purpose of this study was to develop a novel simple method predicting the risk of VCF and compare its effectiveness with SINS.

Material and Methods: A total of 225 vertebral segments in 154 patients treated with palliative radiotherapy from Sep 2011 to Aug 2013 were included for analysis. VCF was defined as occurrence or progression of collapse deformity within treated vertebral segments. Each segment was scored by SINS. In addition to 6 SINS components, we also evaluated the impact of paraspinal tumor extension, epidural extension, tumor origin, performance status, and radiotherapy-related factors on VCF risk. Recursive partitioning analyses (RPA) was used to identify optimal classification of risk groups.

Results: The median follow-up was 8.5 months. The 6-month and 12-month VCF-free probability was 83.3% and 77.3%, and median survival was 10 months. Multivariate analysis identified paraspinal tumor extension ($P=0.03$) and baseline vertebral body collapse ($P<0.001$) were independent

predictors for VCF. All SINS criteria except body collapse were not significant for VCF. The RPA defined 3 risk groups. The lowest risk group (n=96) were vertebrae with less than 50% body involved by tumor and no collapse. The intermediate risk group (n=90) were vertebrae with more than 50% body involved and no collapse, or vertebrae with body collapse and no paraspinal tumor extension. The highest risk group (n=39) were vertebrae with body collapse and paraspinal extension. The 6-month VCF-free probability for each groups were 93.5%, 84.9%, and 53.7%, respectively ($P<0.001$). According to the SINS classification, the 6-month VCF-free probabilities were 91.9% (stable group, n=78), 81.9% (potentially unstable group, n=122), and 62.8% (unstable group, n=25) ($P<0.001$).

Conclusion: Not all the components of SINS were significant predictors of VCF. It is feasible to estimate VCF by the simpler RPA stratification.

PO-0776

Radiotherapy for painful bone metastases: clinical predictors of efficacy

N. Bychkova¹, E. Khmelevsky¹, A. Kaprin¹

¹Gertzen Moscow Research Oncological Institute, Radiotherapy Department, Moscow, Russian Federation

Purpose or Objective: The purpose of this randomized clinical trial was to estimate prognostic factors predicting symptom control after radiotherapy in patients with painful bone metastases.

Material and Methods: 640 cases of symptomatic bone metastases treated with EBRT were analyzed. The primary tumor sites were breast (419), prostate (52), lung (50), renal (37), colon (13), melanoma (8), sarcomas (7) and others including bladder, thyroid, uterus, carcinoid (54). The lesions of spine and pelvis predominated (48% and 30% correspondingly). Pathological fractures in treatment area were observed in 72,3% for spinal metastases and in 22,2% for long bones lesions. The average pain intensity was 2,2 by the four-point verbal scale and proved significantly lower for carcinoid tumors. Treatment schedules included 2, 3 and 4 fractions of 6,5 Gy and standard treatment schedule with 23 fractions of 2 Gy.

Results: The average follow-up period was 70 months. Overall effectiveness of EBRT - 96,1%. Complete response rate (CRR) - 59,1%. The pain relapse rate - 8,7%. CRR for standard treatment schedule was 77,4% and significantly decreased from 64,4% to 47,9% and 43,6% for 2, 3 and 4 fractions of 6,5 Gy correspondingly ($p<0,05$). There was no correlation between treatment schedules and pain relapse rate. CRR in patients with low initial pain intensity was 87,3%, with moderate pain - 59,8% and intense pain - 42% ($p<0,01$). CRR for spine and pelvis lesions was 63,4% and 59,3%, for long bones metastases - 48,3% and significantly decreased for sacrum isolated metastases - 27,8% ($p<0,01$). The frequency of pathological fractures in treatment area detected no correlation with CRR. High radiosensitivity was revealed for bone metastases of carcinoid with CRR 100%, melanoma - 75%, breast cancer - 64%, prostate cancer - 59,6% and sarcomas - 57,1%. Bone metastases of lung, colon, and renal cancer turned to be radioresistance (44%, 30,1% and 27% correspondingly). Analysis of variance (ANOVA) revealed several factors affecting CRR: tumor primary site ($p<0,001$), total dose ($p<0,001$), initial pain intensity ($p<0,001$), localization of metastases in skeleton ($p<0,02$). In the multifactorial analysis MANOVA tumor primary site and pain intensity before radiotherapy were the only independent prognostic factors of CRR.

Conclusion: Tumor primary site, initial pain intensity, total dose, localization of metastases in skeleton are clinical predictors of radiosensitivity of bone metastases, they significantly affect the CRR.

PO-0777

Evaluation of spinal stability in relation to pain response after radiotherapy for spinal metastases

A.S. Gerlich¹, J.M. Van der Velden¹, A.L. Versteeg², H.M. Verkooijen¹, C.G. Fisher³, F.C. Oner², M. Van Vulpen¹, L. Weir⁴, J.J. Verlaan²

¹University Medical Center Utrecht, Radiation Oncology, Utrecht, The Netherlands

²University Medical Center Utrecht, Orthopedic Surgery, Utrecht, The Netherlands

³University of British Columbia, Orthopedic Surgery, Vancouver, Canada

⁴University of British Columbia, Medicine, Vancouver, Canada

Purpose or Objective: A substantial number of patients with painful spinal metastases experience no effect of palliative radiotherapy. Besides tumor-induced pain, mechanical spinal instability due to metastatic disease, could be associated with failed pain control following conventional radiotherapy. Early identification of patients who will not benefit from radiotherapy is important, since these patients might benefit more from a surgical approach. This study aims to prospectively investigate the relation between spinal instability, as defined by the Spinal Instability Neoplastic Score (SINS), and the pain response to conventional palliative radiotherapy in patients with symptomatic spinal metastases.

Material and Methods: From two academic centers, data of 155 patients with thoracic, lumbar or lumbosacral metastases was prospectively collected. In all patients, SINS was calculated by a spine surgeon, specialized in spine oncology and blinded for treatment outcome. Images from radiotherapy planning computed tomography (CT) scans were used. The highest SINS was recorded in case more than one lesion was irradiated. Patients who died within four weeks after radiotherapy (n=13, 8%) or had an otherwise unknown pain response (n=18, 12%) were excluded. Pain response, determined using the International Bone Metastases Consensus Working Party, was recorded between 4 to 8 weeks after treatment in 124 patients. Multivariable logistic regression analysis was used to estimate the association between SINS and pain response in patients with spinal metastases.

Results: In total, 81 (65%) patients experienced a pain response. Of the patients who died within four weeks after radiotherapy (n=13), 6 patients had SINS of 7 or higher. Except for Karnofsky performance score, no significant differences in patients and disease characteristics were found between responders and non-responders within the cohort. Median SINS was not significantly different between responding and non-responding patients. In multivariate analysis, SINS was not associated with pain response (adjusted odds-ratio 0.94; 95% confidence interval 0.81-1.10; p = 0.449) (Table). SINS improved the prediction of response in addition to other clinical variables only marginally: the area under the receiver operating curve improved from 0.68 (0.60-0.79) to 0.70 (0.60-0.80) (Figure).

Table Association between SINS and response status

SINS	Response (n=81)	No response (n=43)	Odds ratio (95% CI)			
			Unadjusted	p-value	Adjusted*	p-value
Continuous SINS*			0.91 (0.80-1.04)	0.186	0.94 (0.81-1.10)	0.449
Median (range)	7 (2-15)	8 (2-15)				
Mean ±SD	7.8±2.9	8.6±2.9				
Categorized SINS						
Stable, n (%)	29 (36%)	12 (28%)	1.00		1.00	
Impending unstable, n (%)	46 (57%)	27 (63%)	0.71 (0.31-1.61)	0.405	0.91 (0.37-2.27)	0.841
Unstable, n (%)	8 (9%)	4 (7%)	0.62 (0.15-2.60)	0.514	0.71 (0.15-3.27)	0.708

SINS, spinal instability neoplastic score; CI, confidence interval; SD, standard deviation

* adjusted for gender, tumor, and performance status

* SINS modeled as continuous variable ranging from 0 to 18

Conclusion: In this study no significant relationship between mechanical spinal instability, as reflected by the SINS score, and pain response to conventional radiotherapy could be demonstrated. SINS was developed as a referral tool in

patients with spinal metastases, and is not useful as a predictive tool for pain response.

PO-0778

Limited short-term effect of radiotherapy on bone density in metastatic femoral bone

F. Eggermont¹, L.C. Derikx¹, N. Verdonshot¹, G. Hannink¹, R.S.J.P. Kaatee², E. Tanck¹, Y.M. Van der Linden³

¹Radboud University Medical Center- Radboud Institute for Health Sciences, Orthopaedic Research Laboratory, Nijmegen, The Netherlands

²Radiotherapeutic Institute Friesland, Leeuwarden, The Netherlands

³Leiden University Medical Center, Department of Radiotherapy, Leiden, The Netherlands

Purpose or Objective: Bone metastases are frequently treated with radiotherapy (RT) for pain, which also may have a beneficial effect on bone density, and thus bone strength. So far, only one study (Koswig *et al.*, *Strahlenther Onkol*, 1999) compared single fraction (SF) and multiple fraction (MF) RT in terms of remineralization and found a larger response after MF RT. However, they only studied lytic lesions in mostly vertebrae. Although a pathological fracture results in major problems for mobility and self-care, femoral lesions have been studied limitedly for remineralization. Furthermore, little is known about the effect of RT on bone tissue surrounding the lesions. Therefore, the aim of this study was to determine the effect of SF and MF RT on bone density over time in proximal femora and in lytic, blastic and mixed lesions.

Material and Methods: In this prospective cohort study, 42 patients with 47 femora irradiated for 52 metastatic lesions were included from three RT centers in the Netherlands. All patients received SF (1x8Gy) or MF (5 or 6x4Gy) RT, according to Dutch clinical guidelines. Quantitative computed tomography (QCT) scans were obtained before RT and 4 and 10 weeks after RT. MF patients additionally underwent QCT on the final day of RT (after 1 week). Mean bone densities were determined at each time point for each proximal femur and for each lesion (expanded by 6 mm to account for obscure edges). For proper comparison over time, proximal femora and lesions were registered using an automated, objective and accurate registration method. Linear mixed models were used for statistical analysis.

Results: No significant differences in bone density were found between SF and MF RT over all time points (Figure 1A). Blastic, lytic and mixed lesions responded differently to RT over time (Figure 1B). No difference in bone density was found for lytic lesions, whereas bone density in mixed and blastic lesions increased up to 105% (SD 10%) and 121% (SD 17%) after 10 weeks, respectively. Comparably, bone density of the proximal femora with blastic lesions increased to 109% (SD 10%), while proximal femora with lytic and mixed lesions showed no difference in bone density over time.

Figure 1: Bone densities (percentage relative to baseline QCT) of the lesions over time, average \pm SD; (A) SF vs. MF RT; (B) each lesion type. Symbols indicate significant differences within lesions (*blastic, † mixed), or between lesion types at ten weeks (**).

Conclusion: In general, 10 weeks after RT in patients with femoral metastases a significant increase in bone density was seen in blastic and mixed lesions, but not in lytic lesions. However, the subsequent effect of these changes on femoral bone strength remains unknown. Since higher total doses did not lead to significantly higher bone densities, the clinical relevance of MF over SF for stabilizing femoral bone with metastases can be questioned.

PO-0779

Multicenter study of palliative pelvic radiation for symptomatic primary and recurrent rectal cancer

M. Cameron¹, C. Kersten¹, I. Vistad², R. Van Helvoirt¹, K. Weyde³, C. Undseth⁴, I. Mjaaland⁵, E. Skovlund⁶, S. Fosså⁴, M. Guren⁴

¹Sørlandet Hospital, Department of Oncology, Kristiansand, Norway

²Sørlandet Hospital, Department of Obstetrics and Gynecology, Kristiansand, Norway

³Innlandet Hospital, Department of Oncology, Gjøvik, Norway

⁴Oslo University Hospital, Department of Oncology, Oslo, Norway

⁵Stavanger University Hospital, Department of Oncology, Stavanger, Norway

⁶Norwegian University of Science and Technology, Department of Public Health and General Practice, Trondheim, Norway

Purpose or Objective: Advanced primary and recurrent rectal cancers (RC) may cause significant pelvic morbidity including pain, dysfunction and hematochezia. Palliative pelvic radiotherapy (PPRT) is often used but symptomatic effects and toxicities are poorly documented and optimal treatment schedules remain undefined. Aims of this prospective multicenter phase-II study were to evaluate changes in symptom severity and explore quality of life (QOL) and toxicity after PPRT of RC using a common palliative radiotherapy regimen.

Material and Methods: Patients with symptomatic pelvic RC (primary or recurrent) prescribed PPRT with 30-39 Gy in 3 Gy fractions were eligible. Treatment volume included primary tumor or recurrence and enlarged pelvic lymph nodes, if indicated. Subjects identified a target symptom (TS) as their principal pelvic complaint requiring palliation. Primary outcome was self-reported TS severity relative to baseline 12 weeks after PPRT. Pelvic symptom burden including toxicity and QOL (EORTC QLQ C30) were assessed before, at the end of, and six and 12 weeks after PPRT.

Results: From Q4/2009-Q3/2015, 51 patients were included at 8/9 Norwegian radiotherapy centers. Thirty-three patients were evaluable 12 weeks after PPRT, and 16 (31%) did not complete the study due to progressive cancer (n=6) and death (n=10). Albumin < 36 g/L (OR=1.31 (95% CI 1.11-1.54)) and age \geq 79 yrs (OR=4.79 (95% CI 0.97 -23.65)) were independent predictors of study drop-out. Median delivered dose was 36 Gy (6-39). Pain (n=24), rectal dysfunction (n=16), and hematochezia (n=9) were the most common TS. 28/33 (85%) evaluable patients reported that their TS had either resolved or improved 12 weeks after PPRT. 4/33 (12%) reported unchanged TS severity, while one patient had worsening TS severity at the 12-week follow-up. Forty-two of the 51 included patients (82%) reported complete resolution or improvement of the TS at at least one of the three follow-up visits. Hematochezia responded most rapidly and consistently with all evaluable patients reporting improvement or resolution. The time course of pain and rectal dysfunction severity was variable. Twelve weeks after PPRT, 10/13 (77%) and 9/10 (90%) of evaluable patients who had identified TS pain and rectal dysfunction, respectively, reported improvement or resolution. Non-target pelvic symptom severity decreased during the study. Median global QOL scores remained stable at follow-up visits. There was no grade 4 toxicity reported. Median survival after PPRT was 9 months (0-51).

Target symptom response and HRQOL compared to baseline

Proportion of evaluable patients reporting target symptom improved or resolved (95% CI)				
Number of patients with target symptom at Baseline		End of radiotherapy	6 week follow-up	12 week follow-up
Pelvic pain	n=24	14/21 67% (0.46-0.88)	14/18 78% (0.58-0.98)	10/13 77% (0.54-1.0)
Rectal dysfunction ^f	n=16	4/15 27% (0.04-0.50)	10/12 83% (0.63-1.0)	9/10 90% (0.71-1.0)
Hematochezia	n=9	9/9 100%	100%	100%
Other ^g	n=2	1/2 50% (0-1.0)	2/2 100%	1/2 50% (0-1.0)

Proportion of the evaluable patients (95% CI)				
Global QOL compared to baseline:		End of radiotherapy	6 week follow-up	12 week follow-up
Clinically significant improvement*		17/45 38% (0.24-0.52)	14/35 40% (0.24-0.56)	10/25 40% (0.21-0.59)
Stable**		18/45 40% (0.26-0.54)	10/35 29% (0.14-0.44)	7/25 28% (0.13-0.43)
Clinically significant deterioration***		10/45 22% (0.10-0.24)	11/35 31% (0.16-0.46)	8/25 32% (0.14-0.50)

HRQOL: Global health status score Median (IQR); p-value ^h				
Global QOL score	Baseline	End of radiotherapy	6 week follow-up	12 week follow-up
	50 (37.5-67) n=49	60 (50-67) n=45 p=0.146	50 (33-63) n=35 p=0.837	67 (50-83) n=25 p=0.569

CI= confidence interval; HRQOL= health-related quality of life; IQR= interquartile range. ^f includes rectal obstruction (n=6), diarrhea (n=2), incontinence (n=6), mucous production (n=2); * = increase ≥ 10 points; ** = values within 9 points of baseline score; *** = decrease ≥ 10 points; ^g = Edema, urinary incontinence; ^h = Score compared to baseline.

Conclusion: In the majority of patients with symptomatic primary or recurrent RC, PPRT with 30-39 Gy contributes to relief of pain, rectal dysfunction, hematochezia, and other pelvic symptoms, with little toxicity. A large proportion of patients prescribed PPRT of RC have very limited life expectancy and future studies should investigate patient selection and further simplification of PPRT.

PO-0780

An analysis of elderly patients compliance and disease distribution treated with radiation therapy

S.H. Lee¹, L. Seung Heon¹, S. KiHoon¹, C. Young Eun¹, L. Kyu Chan¹, K. Kwang Pil²

¹Gil Medical Center- Gachon University of Medicine and Science, Department of Radiation Oncology, Incheon, Korea Republic of

²Gachon University of Medicine and Science, Department of Preventive Medicine, Incheon, Korea Republic of

Purpose or Objective: In this study, we investigated the disease distribution and analyzed treatment compliance for the elderly patients received radiation therapy (RT).

Material and Methods: Among the patients underwent RT from January 2005 to May 2014 in this hospital, the 670 patients aged over 75 were retrospectively analyzed in this study. We classified the patients for each disease and analyzed the RT compliance for each disease. The RT compliance was determined whether or not the scheduled RT plan was completed. The Chi-squared test and multiple logistic regression analysis were used for the factors (region, economic status, age, gender, disease type, treatment aim, ECOG score) influencing the RT compliance.

Results: The mean age of the patients was 78 years (range; 75-99 years). The disease distribution was as follows; Lung cancer in 127 patients (19.0%), metastasis in 123 patients (18.4%), gastrointestinal (GI) cancer in 116 patients (17.3%), gynecologic cancer in 110 patients (16.4%), head and neck cancer in 53 patients (7.9%), genitourinary cancer in 44 patients (6.6%), breast cancer in 30 patients (4.5%), hematologic cancer in 22 patients (3.3%), skin cancer in 17 patients (2.5%), brain tumor in 9 patients (1.3%), and others in 19 patients (2.8%). The RT compliance in total 670 patients was 82.6%. The 116 patients of all patients could not complete their course of scheduled treatment. According to x2 test analysis, the factors found to be related to the RT compliance were; gender(p=0.001), disease type(p=0.014), and patient's ECOG score(p<0.001). Multiple logistic analysis showed that gender(p=0.016) and patient's ECOG score(p<0.001) were related to RT compliance.

Conclusion: Based on these preliminary results, more than 80% of elderly patients received RT for lung cancer, metastatic cancer, GI cancer, gynecologic cancer, head and neck cancer, and genitourinary cancer. This study showed that the most significant factor related to RT compliance was the patient's functional status. Further comparative studies with younger patients are also needed.

PO-0781

Hypofractionated or conventional radiotherapy for early glottis cancer. Does age influence?

L. Gutierrez Bayard¹, M. Salas Buzón¹, E. Porras Alonso², L. De Ingunza Barón¹, S. Garduño Sánchez¹, I. Villanago Beltrán¹, V. Díaz Díaz¹, E. González Calvo¹, L. Díaz Gómez¹

¹Hospital Universitario Puerta del Mar, Radiation Oncology, Cadiz, Spain

²Hospital Universitario Puerto Real, Otorrinolaringology, Puerto Real, Spain

Purpose or Objective: To evaluate the effect of shortening overall treatment time by hypofractionated radiotherapy for cT1-T2N0M0 glottic carcinomas. Results for local control, survival and toxicity were calculated and compared to cT1-

T2N0M0 tumors those received conventionally dose fraction schedule, by age group, less than 65 years old or greater.

Material and Methods: Between 2005 and 2008, 72 patients with cT1N0M0 and 47 with cT2N0M0 glottic cancer were treated with radical conventional radiotherapy (2Gy/fraction, 5 days per week total dose 70Gy and 72 Gy: group 1), 87/119 over 65 years old. Between 2009 and 2013, 34 patients with cT1N0M0 and 31 with cT2N0M0 glottic cancer were treated with radical hypofractionated radiotherapy (2.75Gy/fraction, 5 days per week, total dose 55Gy and 57.75Gy: group 2), 52/65 over 65 years old. Toxicity was evaluated according to RTOG toxicities scale.

Results: The 5-year local control was in group 1 was 86% for T1 and 78% for T2, in group 2 was 90% for T1 and 88% for T2, whereas the 5- year overall survival was in group 1: 72% for T1 and 67.7% for T2 ; in group 2: 73.8% for T1 and 70.7% for T2. The treatment was well tolerated. No significant statistical difference was found between the two groups, or by age group. Only grades 1 and 2 acute skin and dysphonia toxicity with good voice quality were observed and no evidence of severe late toxicity.

Conclusion: Hypofractionated radiotherapy proved beneficial for T1-T2 glottic carcinoma with no increase of toxicity and a good local control, well tolerated in older patients, over 65 years.

PO-0782

Stereotactic body radiation therapy for primary lung cancer in the elderly

L. Larrea¹, E. López¹, P. Antonini¹, V. González¹, M. Baños¹, J. Bea¹

¹Hospital NISA Virgen del Consuelo, Radiation Oncology Department, Valencia, Spain

Purpose or Objective: To evaluate stereotactic body radiation therapy (SBRT) for primary lung tumors in patients over 75 years old.

Material and Methods: Between 2002 and 2015, 62 elderly patients with 65 lung primary tumors (T1-T2N0M0) were treated using SBRT at our institution. SBRT procedure involved: Slow-scan computed tomography (CT) simulation with immobilization devices, contouring the target volume in 3 sets of CTs, superimposing the volumes in the planning system to represent the internal target volume and dose calculation using heterogeneity correction. Radiation delivery with multiple static planar or non-coplanar beams and arc therapy assured conformal dose distribution and steep fall-off of the radiation. The prescribed dose was 3 fractions of 15 Gy each (90%) over 6 to 10 days or a single 30-Gy fraction (10%). Dosimetric constraints were set for surrounding organs at risk. Repeated cone-beam CT (2 previous and 1 after radiation administration) were used to verify and adjust daily positioning. Toxicity and radiologic response were assessed in follow-up visits, using standardized criteria (RTOG and RECIST) and analyzed retrospectively. Survival rates and toxicities were calculated by the Kaplan-Meier method.

Results: Median patient age was 81 years (75-88). All patients had good performance status at the moment of treatment (ECOG PS 0-1). Because of patient's comorbidities or preferences, none were surgical candidates. The FEV1 was over 30 % of predicted in all cases. 7 % of all patients also received systemic treatment before or after SBRT. 83 % of the patients had 18-FDG PET-CT previous to SBRT. Histology included: epidermoid (48 %), adenocarcinoma (14 %), undifferentiated NSCLC (19 %), microcytic/neuroendocrine (4 %) and PET positive tumors without histology (15%). Mean tumor volume was 28.4 cm³ (1.2-143). Transient grade 1 or 2 acute toxicities (cutaneous erythema, esophagitis or respiratory symptoms) occurred in 18.4% of all cases. No grade > 3 acute or any chronic toxicities were identified. The median follow-up was 24 months (3-65). The overall and cancer-specific survivals were: 80 and 85 % at 1 year and 64 % and 70 % at 2 years. Control in the irradiated volume is 98 %,

the only relapse occurring in a patient with neuroendocrine histology.

Conclusion: SBRT is an excellent treatment option for lung tumors in elderly patients in whom other treatment options might be limited. Our encouraging results are in line with those reported in recent literature for younger patients.

Implementation of a trial outpatient clinic to improve participation and data collection in trials

J. Paulissen¹, C. Offermann¹, R. Houben¹, E. Van Erp¹, M. Brouns¹, H. Backes¹, L. Boersma¹, G. Vreuls¹, R. Lemmen¹, A. Dekker¹, P. Lambin¹, M. Jacobs¹, K. Smits¹

¹MAASTRO clinic, Radiation Oncology MAASTRO Clinic, Maastricht, The Netherlands

Purpose or Objective: Participation of patients in trials and quality of trial data collection are important factors hampering successful execution of clinical trials. Our aim was to design a system to increase patient participation in clinical radiotherapy trials and to install a process that would lead to a higher quality of data collection during treatment and follow-up.

Material and Methods: In 2013 we implemented a Trial Outpatient Clinic (TOC) for prospective screening of all patients referred to our radiotherapy institute, in order to identify potential trial candidates and to support radiation oncologists during the informed consent procedure and the work-up phase before the patients' treatment within the trial. During treatment and follow-up, dedicated TOC consultations facilitate a rearrangement in trial data collection from radiation oncologists to trial (physician) assistants of the TOC.

Patient inclusion in trials was measured in relation to the total number of radiotherapy treatments in our institute per year from 2005 to 2014. Quality of data collection was subjectively analysed based on completeness of CRF's and consistency of data. In addition, a questionnaire was provided to a random subset of seventeen trial participants to evaluate their satisfaction with the TOC. Interviews with seven radiation oncologists were performed to evaluate their experience with the TOC.

Results: The percentage of trial patients as compared to the total number of treatments declined between 2005 and 2008 from 6.6% to 3.8%. After implementing the TOC, this number increased to 5.3%. In 2014 we observed an increase to 9.3% despite a decline in the number of trials open for inclusion in the last two years. CRF's were found to be more consistent and complete. The participants' questionnaire showed that 82% was very satisfied having one contact person for trial related issues and 71 % thought that the existence of the TOC had added value. Participants did not think it bothersome having additional consultations and experienced an extra benefit by becoming more familiar with TOC personnel. Radiation oncologists were satisfied about the TOC as rearrangement of data recording was beneficial to them and less laborious.

Conclusion: The implementation of our TOC model has led to a higher inclusion in trials, an improved data collection and a higher satisfaction of patients and radiation oncologists involved in clinical trials. The TOC model has led to an optimal infrastructure for well-performed, high-quality clinical trials.

PO-0784

Targeting general practitioners: prospective outcomes of a nationwide GP education programme

L. Morris¹, S. Turner¹, P. Gorayski²

¹*Crown Princess Mary Cancer Centre, Department of Radiation Oncology, Sydney, Australia*

²*Radiation Oncology Queensland, Toowoomba, Queensland, Australia*

Purpose or Objective: To report the learning outcomes of a standardised national multicentre education program aimed at improving General Practitioner (GP) knowledge about radiation therapy (RT) and referral pathways to radiation oncologists (RO).

Material and Methods: In 2014, a GP education session was developed through the 'Targeting Cancer: Radiation Oncology' campaign (an initiative of RANZCR, Faculty of Radiation Oncology). The content and structure was developed by a committee of ROs with skills in training and education. The sessions are designed to be held within an RT department and consist of RO-led interactive teaching around two common patient scenarios, followed by a physical tour of the RT department with demonstrations of set up and treatment. Pre- and immediate post-session custom surveys were administered on consented GPs. Four key domains were assessed:

1. Objective and subjective knowledge about RT.
2. Satisfaction regarding referral pathways to ROs.
3. Self-reported referral behaviours.
4. Feedback on quality of the educational session.

A 6 question follow up survey was sent 6-8 months after the session to assess the usefulness of the knowledge gained in the clinical care of cancer patients and ongoing referral behaviours.

Results: 120 GPs attended a total 10 sessions held in RT departments across Australia between October 2014 and 2015. Pre-session, 96% of GPs reported their knowledge of radiation therapy required significant or some improvement. Post-session, 91% rated their knowledge as "excellent", "above average" or "competent". In concordance with this, the proportion of GPs correctly answering objective knowledge questions rose from 50% to 82%. Over one third of GPs did not know the location of their nearest RT department and 80% wanted improved referral pathways to ROs. Despite this 92% have had patients in their practice who might benefit from palliative RT. However nearly half the GPs indicated they were not comfortable referring directly to a RO. Following the session this rose to 92%. All 120 respondents felt the session improved their understanding of RT and would recommend the session to colleagues. Early data from the 6 month follow up survey shows 100% of GPs felt the knowledge gained at the education session has improved their ability to care for cancer patients and increased their confidence to refer directly to ROs.

Conclusion: A national standardized GP education program can significantly improve GP knowledge of the core RT concepts and likely influence patient referrals for RT.

PO-0785

Improvement strategies and performance enhancement in Healthcare: the reorganisation of Radiotherapy

M. Altini¹, D. Gallegati², L. Solinas², C. Zani¹, I. Massa³,

A. Romeo⁴, V. Turri¹

¹*IRCCS - Istituto Scientifico Romagnolo per la Cura e lo Studio dei Tumori, Healthcare Department, Meldola, Italy*

²*IRCCS - Istituto Scientifico Romagnolo per la Cura e lo Studio dei Tumori, Planning and Business Management, Meldola, Italy*

³*IRCCS - Istituto Scientifico Romagnolo per la Cura e lo Studio dei Tumori, Biostatistic and Clinical Trial Unit, Meldola, Italy*

⁴*IRCCS - Istituto Scientifico Romagnolo per la Cura e lo Studio dei Tumori, Radiotherapy Unit, Meldola, Italy*

Purpose or Objective: Population ageing, changes in epidemiological trends and the development of new treatments are putting strain on National Health Systems, which need to implement performance measurement systems to minimize the impact of expenditure reduction on service quality and to drive value creation for the whole population. We developed a model of healthcare performance evaluation for oncology care whose main focuses are: - specific types of cancers and value for citizens of a catchment area served. The model synthesizes into a single index the value of a service - outcome and costs for the population - building upon the Italian NHS principles. We applied the model to a Radiotherapy Service before and after IRST IRCCS took over its management in January 2014

Material and Methods: We measured value produced by Radiotherapy Services for the Ravenna district (393,184 inhabitants) before 2013 and after the technological investment in 2014. We considered three performance dimensions:

- clinical outcomes;
- appropriateness;
- accessibility and geographic proximity of services.

An expert panel selected variables, indicators and weights such as waiting times for treatments, % advanced treatment (IMRT, V-MAT), passive migration cases to other areas, average access to treatment. Per-capita cost was computed as direct costs of radiotherapy minus reimbursement for "active" patient migration, plus costs for "passive" patient migration; total costs were divided by age-adjusted population. A composite indicator was computed, whose nominator synthesizes quality indicators and whose denominator accounts for costs. 2013 IRST performance in Forlì-Cesena district was used as benchmark

Results: Value assessed in Ravenna district was lower than that of Forlì-Cesena in 2013 (0.35 and 0.78, respectively), translating into a higher per-capita cost (12 euro vs. 9 euro) and lower service level (4.2 vs. 7.0 quality points). In 2014, performance of Ravenna Radiotherapy Service significantly improved (0.47; +34%): quality points went up from 4.2 to 5.1 as a result of better clinical outcome, improved accessibility and shorter wait times Fig1.

Per-capita costs decreased from 12 Euro to 10.8 Euro thanks to a reduction in "passive" patient migration, efficiency gain (fewer radiotherapy sessions for specific regimens) and economies of scale. A return on investment and financial stability were guaranteed by efficiency gain (lower emerging compared to savings from reduced "passive" patient migration) and by increased attractiveness (increased "active" patient migration) Fig2.

Fig.1 Populational Performance

Populational Performance: Unit of Effectiveness / Per capita Cancer Cost

Fig.2 Indicator results

Indicators	2013 Ravenna	2014 Ravenna	2013 Forlì Cesena
Waiting times for treatments (Performance Index to 30 days)	35%	76.9%	31%
% Advanced treatment (V-MAT - IM RT)	23%	48%	53%
Passive migration to other areas	55%	41%	14%
Average access to treatment	19	15	14

Conclusion: Investments in technological upgrades in public services can result in increased efficiency and productivity levels, while improving service quality, decreasing costs and reducing service duplication and overlapping. Our preliminary findings suggest the applicability of our model to the full cancer care pathway

PO-0786

Could a 3-tier teleradiotherapy network provide a cost-effective radiotherapy care in LMICs?

N.R. Datta¹, M. Heuser¹, M. Samiei², S. Bodis¹

¹Kantonsspital Aarau, Radio-Onkologie, Aarau, Switzerland

²International Atomic Energy Agency IAEA, Senior Consultant, Vienna, Austria

Purpose or Objective: Information and communication technologies (ICTs) have enabled cost-effective eHealth programmes gain wider acceptance in a range of health disciplines. However, this is yet to be evaluated in radiotherapy (RT), especially in low- and middle income countries (LMICs). We explored the use of ICTs to create a 3-tier network of teleradiotherapy centres (RTC), namely - primary (PRTC) with 1 teletherapy (TRT) unit; secondary (SRTC) with 2 TRT units and brachytherapy (BRT); and tertiary RT centre (TRTC) with state-of-the-art RT facilities. The cost-effectiveness of this network was evaluated for 10 adjoining countries in middle and east Africa.

Material and Methods: Seven of the 10 countries (Gabon, Congo Republic, Congo DR, Central African Republic, South Sudan, Rwanda and Burundi) have no RT facilities for their 123.6 million inhabitants. Remaining 3 countries (Uganda, Kenya and Tanzania) have in total 11 TRT and 6 BRT units. Thus, presently, only 2.3% of 262.2 million people have RT access in these 10 countries. Based on the regional population density and location of current centres, 6 PRTCs, 2 upgraded PRTCs (with BRT), 6 SRTCs and upgradation of an existing centre to SRTC are proposed. These could be networked to share the available resources. With DICOM RT compatible data sets, ICTs could facilitate an easy exchange of patient information between centres. Consequently, patients at PRTC with a standalone TRT unit could deliver RT based on treatment plans derived at SRTC. Similarly patients treated at PRTC could receive brachytherapy at SRTC. TRTC could cater to specialized RT techniques not feasible either at PRTC or SRTC. Thus, patients within the 3-tier network would have access to state-of-the-art technology in a shared step-wise manner.

Results: The total cost of the infrastructure, networking, maintenance and incidentals is estimated around US\$ 66.25

million. With a total of 32 TRT and 15 BRT units provided in this network, the RT accessibility would enhance from 2.3% to 30.7% (9.2%-76.9%). The mean cost of this investment for the 262.2 million inhabitants would be around US\$ 0.69 per inhabitant (US\$ 0.12-2.22) while the average cost in terms of individual patients receiving RT is estimated to be US\$ 374 (US\$ 71.67-508.33). Capacity building could be undertaken through telementoring by linking to regional or international centres of excellence and professional societies through multisectoral collaborative efforts.

Conclusion: The 3 tier-teletherapy network with ICTs could provide cost-effective comprehensive RT care by overcoming the geographical barriers by optimizing resource sharing, pedagogical telementoring and capacity building. This could lead to scalable, equitable, affordable and improved RT access to patients of the region. The approach could be explored for other underserved LMICs and executed with the help of respective national and international stakeholders.

PO-0787

Abstract withdrawn

PO-0788

Predicted patient demand for MRI Linac

B. Sanderson¹, A. McWilliam², C. Favier-Finn¹, A. Choudhury¹, T. Mee³

¹The Christie NHS Foundation Trust, Department of Clinical Oncology, Manchester, United Kingdom

²The Christie NHS Foundation Trust, Department of Medical Physics and Engineering, Manchester, United Kingdom

³University of Manchester, Institute of Cancer Sciences, Manchester, United Kingdom

Purpose or Objective: MRI offers superior soft tissue delineation compared to CT. When incorporated in to a linear accelerator (MRI Linac), it could improve temporal resolution and dynamic visualisation of the target during treatment allowing for motion compensation and real-time adaptive planning. This study investigated the predicted patient demand for radiotherapy delivered via a MRI Linac for prostate and lung cancer at a large comprehensive cancer centre to ensure that any clinical research will be achievable.

Material and Methods: Local stage data was sourced from hospital databases and the UK NHS CASCADE system. Indications for MRI Linac were obtained by consulting with the specialist clinical leads for prostate and lung cancers. Locally advanced patients where soft tissue definition would be clinically advantageous were identified (T3/4 prostate, stage 2/3 non-small cell lung cancer [NSCLC] including superior sulcus tumours and limited stage small cell lung cancer [SCLC] with good performance status). The Malthus programme was used to estimate the demand for MRI Linac. The Malthus programme is an evidence based, predictive mathematical model, based on regional population and incidence data, mapping around 2,000 clinical decisions relating to radiotherapy for 23 different cancer sites.

Results: The catchment area of the comprehensive cancer centre in the study is approximately 3.2 million people. For prostate, the total projected incidence for 2015 was 1,983 cases, of which 436 high risk patients were predicted to be eligible for MRI Linac. For lung, the total projected incidence for 2015 is 2,634 cases. Of these, a total of 360 patients were identified as suitable for MRI Linac (table 1). Approximately 92 of the NSCLC's were considered superior sulcus tumours.

Table 1. Estimated number of patients eligible for MRI Linac according to stage and type of lung cancer.

Disease & Stage	Estimated number for MRI Linac
NSCLC	
Stage 2	94
Stage 3a	169
Stage 3b	45
SCLC	
Limited	52
Total	360

Conclusion: The potential cohort is estimated at 796 eligible patients for MRI Linac in lung and prostate cancer. In the context of lung and prostate cancer, we estimate during the initial research phase that we will treat around 180 patients per year on one machine. Therefore, the estimated number of eligible patients far exceeds the estimated throughput for a single MRI Linac machine. This has positive implications for its use as a research tool. Even after accounting for patients who will inevitably decline entry to clinical trials, the estimated eligible patient population is such that trials should still have sufficient recruitment; this is especially important for rare indications such as superior sulcus tumours.

PO-0789

Treatment time in breast irradiation: a trade-off between positioning and complexity.

C. Monten¹, L. Veldeman¹, Y. Lievens¹

¹University Hospital Ghent, Radiotherapy, Ghent, Belgium

Purpose or Objective: In whole breast irradiation (WBI), different approaches are used to spare the organs at risk, including intensity modulation and altered positioning. These may however come at the cost of longer treatment times, which in turn may slow down adoption in daily clinical practice. To document the impact of different approaches, time measurements were performed, following a strict protocol.

Material and Methods: A time-and-motion study was carried out using a ‘continuous timing’ method (running chronometer with defined intervals), according to the following protocol:

- Positioning time: Patient in bunker - Start Cone Beam CT (CBCT)
- CBCT recording time: Start CBCT - Stop CBCT
- Adaptations: Stop CBCT - Beam on
- Irradiation time: Beam on - Beam off
- Patient recovery time: Beam off - Patient exits bunker

Time measurements were categorized per position, technique and target. Positioning time is reported over all patients, irradiation time per category, in absolute time and, to correct for dose and volume differences, in Irradiation Time per 100MU’s (ITcMU). Statistical analysis was performed using parametric testing, i.e. the One Way Anova.

Results: Registration was performed in 86 patients, of which 47 in prone and 39 in supine position. Positioning time was measured in 74 patients, and irradiation time in 86. Results are listed in table 1.

00:46:46		01:12:45		01:09:45		01:09:45		

Abbreviations: WBI = Whole breast irradiation; SIB = Simultaneous integrated boost; IMRT = Intensity modulated radiotherapy; VMAT = Volumetric modulated arc therapy; ITcMU = irradiation time per 100 monitor units.

Positioning time per session was on average 1’11” longer for prone than for supine. This difference is confirmed in “WBI only”, simultaneous integrated boost (SIB) and tumor bed irradiation, all three predominantly performed in prone, in contrast to two purely supine positions: thoracic wall and “lymph node included” irradiation.

ITcMU was 17” faster for supine versus prone positioning. Looking into hypofractionated WBI only, no difference was observed in ITcMU, but irradiation time per fraction was 1’40” longer for supine versus prone position. The mean number of gantry positions for prone and supine position was respectively 2 and 5, signifying less complex planning in prone to obtain equivalent dosimetric results.

Single-arc Volumetric Modulated Arc Therapy (VMAT) resulted in less than half of the irradiation time needed compared to IMRT or normal VMAT used for similar target or position.

Conclusion: Prone position comes at the cost of longer positioning time, but reduces irradiation time as a result of less need for complex planning, especially for WBI and sequential boosting. Although fraction time increases when using acceleration, overall irradiation time decreases, which compensates for potentially higher time demands of more complex treatment techniques. Single-arc VMAT reduces longer fraction times. These data will be used for balancing the costs and effects of the different approaches.

Radiation-induced mesothelioma among solid cancer survivors: an analysis of the seer cohort

A. Farioli¹, L. Ronchi², M. Ferioli², F. Busi², G. Compagnone³, S. Cammelli², M. Ferro⁴, F. Labropoulos⁴, M. Nuzzo⁴, G. Macchia⁴, F. Deodato⁴, G. Frezza⁵, A.G. Morganti², F.S. Violante¹

¹Sant'Orsola-Malpighi Hospital- University of Bologna, Department of Medical and Surgical Sciences DIMEC, Bologna, Italy

²Sant'Orsola-Malpighi Hospital- University of Bologna, Radiation Oncology Center- Department of Experimental-Diagnostic and Specialty Medicine - DIMES, Bologna, Italy

³Sant'Orsola-Malpighi Hospital- University of Bologna, Department of Medical Physics, Bologna, Italy

⁴Fondazione di Ricerca e Cura "Giovanni Paolo II"- Catholic University of Sacred Heart, Radiotherapy Unit, Campobasso, Italy

⁵Ospedale Bellaria, Radiotherapy Department, Bologna, Italy

Purpose or Objective: To investigate the association between external beam radiotherapy (EBRT) and pleural and peritoneal mesothelioma among long-term (>5 years) solid cancer survivors.

Material and Methods: We analysed data from the US Surveillance, Epidemiology, and End Results (SEER) program (1973-2012). We fitted survival models adjusted by age, gender, race, year, surgery, and relative risk of primary mesothelioma in the county of residence (proxy for individual asbestos exposure). We estimated hazard ratios [HR] with reference to non-irradiated patients. We distinguished between scattered and direct irradiation to study the dose-response.

Results: We observed 300 mesotheliomas (264 pleural; 32 peritoneal; 4 others) among 913,873 patients. EBRT increased the risk of mesothelioma (any site; HR 1.36, 95%CI 1.05-1.76). We observed an increased risk of pleural mesothelioma (HR for EBRT 1.35, 95%CI 1.02-1.78), but we did not find signs of a dose-response relationship (HR for scattered irradiation 1.35; HR for direct irradiation 1.36). On the opposite, only direct peritoneal irradiation was associated with peritoneal mesothelioma (HR 2.13, 95%CI 0.96-4.74), particularly for latencies ≥ 10 years (HR 3.19, 95%CI 1.11-9.18). A competing risks analysis revealed that the clinical impact of radiation-induced mesothelioma was limited by the high frequency of competing events. The cumulative incidence function of mesothelioma after 40 years of observation was very low (non-irradiated patients: 0.00031, irradiated patients: 0.00056).

Conclusion: EBRT is a determinant of mesothelioma. Longer latency periods are associated with higher risks, while the dose-response seems non-linear. The clinical impact of mesothelioma after EBRT for primary solid cancers is very limited.

PO-0791

Motion management and Vero dynamic tracking for SBRT in oligometastatic disease: a prospective trial

R. Van den Begijn¹, B. Engels¹, M. Boussaer¹, J. Dhont¹, M. Burghelée¹, C. Collen¹, T. Gevaert¹, D. Verellen¹, G. Storme¹, M. De Ridder¹

¹Universitair Ziekenhuis Brussel, Department of Radiotherapy, Brussels, Belgium

Purpose or Objective: To evaluate the clinical efficacy and toxicity of stereotactic body radiotherapy (SBRT) with respiratory motion management in patients with oligometastatic cancer.

Material and Methods: Patients with five or less metastases were eligible for this prospective trial. A four-dimensional

respiration-correlated CT (4D-CT) was obtained for planning. In metastases with significant motion, a fiducial marker was implanted for dynamic tracking using the gimbaled Vero SBRT system, otherwise an internal target volume (ITV) was defined to encompass the tumor trajectory. ITV-targets were also treated on Vero, unless numbering 4 or more, in which case tomotherapy was used. A dose of 50 Gy in 10 fractions of 5 Gy was prescribed on the 80% isodose line, covering the planning target volume.

Results: We treated 87 metastases in 44 patients, with colorectal cancer as the most common primary origin (65.9%). Metastatic sites were mainly lung (n=62) and liver (n=17). Twenty-seven metastases, of which 12 in lung, 14 in liver and 1 in a kidney, were treated with dynamic tracking, the remaining 60 using the ITV-concept. Three patients (7%) experienced grade ≥ 3 toxicity, of which one with a liver metastasis invading the major bile ducts with grade 5 cholangitis due to bile duct stenosis. After a median follow-up of 12 months, we report an actuarial one-year local control (LC) of 89% for the whole group (95% CI 77-95%), with corresponding values of 90% and 88% for the metastases irradiated with the ITV-approach and dynamic tracking, respectively. Median progression-free survival reached 6.5 months, one-year overall survival 97%.

Conclusion: This first clinical trial on Vero dynamic tracking shows favorable efficacy. SBRT with respiratory motion management resulted in a high LC and acceptable toxicity profile in oligometastatic cancer patients.

Direct dose measurements in contrast enhanced radiotherapy with iodine and gadolinium

A.A. Cherepanov¹, A.A. Lipengolts², E.S. Vorobyeva³, V.A. Klimanov³, V.N. Kulakov¹, E.Y. Grigorieva²

¹Burnasyan Federal Medical Biophysical Centre, Department of radiation technologies, Moscow, Russian Federation

²Russian Cancer Research Center, Institute of Clinical and Experimental Radiology, Moscow, Russian Federation

³National Research Nuclear University, Department of Experimental and Theoretical Physics, Moscow, Russian Federation

Purpose or Objective: Contrast enhanced radiotherapy (CERT) has already been shown to be a promising antitumor modality capable to overcome some limitation inherent to conventional beam radiotherapy. Depth dose distribution in CERT is characterized by local dose increase in a volume, which incorporates certain amount of a high atomic number element. Photoabsorption of external X-ray radiation by high atomic number elements (such as iodine, gadolinium, gold etc.) leads to absorbed dose enhancement exactly in the region of the element location. Dose increase is caused by emission of short range secondary radiation such as characteristic X-rays, photoelectrons and Auger electrons. Dose enhancement in CERT for particular high atomic number element is strongly dependent on energy spectrum of external radiation. Calculations of many researchers show that significant part of absorbed dose is caused by Auger-electrons especially in the close vicinity (about 1 μm) of emitting atom. Because of their extremely short range in water Auger-electrons are not detectable by most dosimetric tools such as ionizing chambers, radiochromic films etc. However ferrosulfate based dosimeters (Fricke dosimeters) can be used to measure total absorbed dose caused by photoabsorption of external X-ray radiation by high atomic number elements.

Material and Methods: Direct dose enhancement was measured for iodine in the chemical form of iopromide (Ultravist 370, Bayer) and gadolinium in the form of gadolinium sulfate (Sigma-Aldrich). Fricke dosimeter solution was prepared by standard procedure described elsewhere.

Iopromide and gadolinium sulfate solutions were introduced into standard Fricke dosimeter solution for final concentrations of iodine from 2.5 mg l/ml to 50 mg l/ml and gadolinium from 5 mg Gd/ml to 10 mg Gd/ml. Detection of iron (III) ions was performed with spectrophotometer Varian Cary 50. For measurement of iron (III) ions concentration in the presence of iopromide ammonium tiocianate (Panreac) was used as an indicator because optical spectrum of iopromide interfere with optical spectrum of iron (III) ions. Irradiation of Fricke solutions was performed with 110 kVp X-rays through 3.5 mm Al filter at 0.7 Gy/min dose rate.

Results: Dose enhancement in presence of iodine and gadolinium was expressed as dose enhancement factor (DEF), which is the ratio of absorbed dose value in Fricke water solution containing iodine or gadolinium and in pure Fricke water solution. Measured DEF values and corresponded iodine and gadolinium concentrations are presented in Table.

High atomic number element	Concentration, mg/ml	DEF
Gadolinium	5	1.3±0.1
	10	1.5±0.1
Iodine	2.5	1.2±0.1
	5	1.3±0.1
	10	1.7±0.2
	50	4.8±0.5

Dose enhancement is proportional to concentration of the element used. DEF value for iodine varies from 1.2±0.1 to 4.8±0.5 for concentration of iodine from 2.5 mg l/ml to 50 mg l/ml respectively.

Conclusion: A new approach for measuring dose enhancement in CERT was proposed. This method can be used as a routing procedure in experimental and clinical practice of CERT dose measurements.

PO-0793

The Advanced Markus ionization chamber is useable for measurements at ultra high dose rates

K. Petersson¹, M. Jaccard¹, T. Buchillier¹, C. Bailat¹, J. Germond¹, M. Vozenin², J. Bourhis², F. Bochud¹

¹Lausanne University Hospital - CHUV, Institute of Radiation Physics - IRA, Lausanne, Switzerland

²Lausanne University Hospital - CHUV, Department of Radiation Oncology, Lausanne, Switzerland

Purpose or Objective: The Advanced Markus ionization chamber from PTW (PTW-Freiburg GmbH, Freiburg, Germany) saturates at high dose rates (\dot{D}) and/or at a high dose-per-pulse (DPP). According to PTW, the ion collection efficiency is $\geq 99\%$ at continuous $\dot{D} < 375$ Gy/s and at DPP < 5.56 mGy. At a source-to-surface distance (SSD) of 50 cm, our prototype linac produces a mean \dot{D} of ≈ 500 Gy/s, an instantaneous \dot{D} of ≈ 2.5 MGy/s, and a DPP of ≈ 5 Gy (far above the chamber datasheet range). In order to use the Advanced Markus chamber for determining the absorbed dose in these intense radiation conditions, we needed to establish a model of its saturation as the \dot{D}/DPP increases.

Material and Methods: Two independent methods were used to determine the chamber saturation curve. 1) Measurements in a water phantom at different \dot{D}/DPP by varying the SSD and the linac gun grid tension (pulse amplitude). The hypothesis was that if the linac output varies with grid tension in a reproducible way and if the grid tension was varied by the same factor for every SSD then the relative change in chamber response with grid tension should be the same for all SSD if not for the chamber saturation. 2) Simultaneous measurements of chamber and \dot{D}/DPP independent radiochromic film (Gafchromic™ EBT3, Ashland

Inc., Covington, USA), in a solid water phantom (RW3 slabs, PTW) at various \dot{D}/DPP .

Results: The results show how the chamber saturation increases (the ion collection efficiency decreases) as the DPP increases (Figure). These results also show that the chamber saturation is much more dependent on the DPP than the instantaneous \dot{D} , as the ion collection efficiency curves for the different pulse widths (= DPP/instantaneous \dot{D}) are only slightly separated when plotted against DPP.

A mathematical model of the saturation curves was established by fitting a logistic function (dependent on DPP) to the data points:

$$\frac{1}{k_s} = \frac{1}{\left(1 + \left(\frac{0.3}{DPP}\right)^{-2}\right)^a} \Leftrightarrow k_s = \left(1 + \left(\frac{DPP}{0.3}\right)^2\right)^a$$

Where k_s is the saturation (ion recombination) correction factor and where a takes a slightly different value for different instantaneous \dot{D} ($a = 0.197, 0.192,$ and 0.184 for pulse widths of 0.5, 1.0, and 1.8 μ s, respectively).

Figure: The Advanced Markus ionization chamber's ion collection efficiency ($1/k_s$) as a function of the dose-per-pulse for the water phantom measurements (unfilled data points), the logistic function model (Eq. 1, lines), and for the simultaneous film and chamber measurements (filled data points). Above: a linear dose-per-pulse axis, below: a logarithmic axis. Pulse widths are given in μ s.

Results from subsequent dose measurements at various \dot{D}/DPP verified that chamber dose values (corrected by the saturation model) were compatible with film and TLD dose values.

Conclusion: We present a saturation model for the Advanced Markus ionization chamber, which was based on dose measurements performed in a water phantom as well as simultaneous film and chamber measurements in a solid water phantom, at various \dot{D}/DPP . Chamber dose measurements corrected by the saturation model were compared to independent film and TLD dose measurements. These measurements verified that the Advanced Markus ionization chamber does not completely saturate up to DPP values of 10 Gy and can consequently be used for accurate dose measurements (within 5%) in ultra high \dot{D}/DPP irradiation conditions, if the chamber saturation model is applied.

First proton irradiation experiments with a deformable radiochromic 3D dosimeter

E.M. Høyve¹, P.S. Skyt¹, P. Balling², L.P. Muren¹, J. Swakoń³, G. Mierzwińska³, M. Rydygier³, V. Taasti¹, J.B.B. Petersen¹

¹Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark

²Aarhus University, Department of Physics and Astronomy, Aarhus, Denmark

³Polish Academy of Sciences, Institute of Nuclear Physics, Kraków, Poland

Purpose or Objective: In proton therapy, anatomical changes may cause considerable deterioration of the delivered dose distributions. Transmission-based treatment verification is generally not possible, making three-dimensional (3D) dosimetry a promising tool for verification of the delivered dose. However, solid state 3D detectors have significant problems related to linear-energy-transfer dependent quenching in particle beams - an under-response of the signal in the Bragg peak. A new deformable, silicone-based, radiochromic 3D dosimeter has recently been developed by our group. The aim of this study was to perform the first proton beam experiments with this detector. Special attention was given to the quenching and dose-rate dependencies in general, relating these effects to the chemical composition of the dosimeter.

Material and Methods: Dosimeters (1 x 1 x 4.5 cm³) of varying chemical compositions were produced. They contained leuco-malachite green (LMG) dye as the active component, chloroform and silicone elastomer.

Twelve different batches were irradiated with 60 MeV proton beams, using a 40 mm circular collimator, to different doses (0 - 30 Gy). Irradiations were performed with both a low and a high dose rate (0.23 and 0.55 Gy/s). For comparison, depth-dose distributions were measured in water with a Markus-type plane-parallel ionizing chamber. Simultaneously, dosimeters from the same batches were irradiated with 6 MV photon beams in a 10 cm square field on a linear accelerator. All dosimeters were read out before irradiation and four hours after, at a wavelength of 635 nm. The read-out was performed with a home-built 1D-scanner with a depth resolution of 0.2 mm for the proton irradiated dosimeters, while a spectrophotometer was used for the photon read-out. The dose-rate dependency was compared for proton and photon irradiations. The ratio of Bragg-peak to plateau response (at 1 cm) was compared between batches.

Results: The effect of lowering the dose rate was similar for proton and photon beams, although the beam qualities were different. The dose response was higher at a low dose rate, but at increasing dye concentration the effect was reduced. Significant under-response was observed in the Bragg peak. The peak-to-plateau ratio was improved from (2.5 ± 0.1) to (3.0 ± 0.04) by increasing the dye concentration from 0.1 to 0.3 % (w/w). By increasing the curing-agent concentration from 5 to 9 % (w/w), the ratio further improved to (3.7 ± 0.4) and (3.5 ± 0.1) for the same respective dye concentrations.

The dose response (change in optical density (ΔOD) vs. dose) for protons has been plotted for the plateau at 1 cm depth (blue squares) and for the Bragg peak (red circles). The lower sensitivity in the Bragg peak is clearly observed. The dose response is linear in both cases; 0.011 cm⁻¹ Gy⁻¹ at the plateau and 0.006 cm⁻¹ Gy⁻¹ at the Bragg peak. The inset shows one example of a measured proton depth-dose profile (blue full line), which has been normalized to the ion chamber measurement (black dashed line) at a depth of 13.1 mm. The example given here is from a batch irradiated with protons at 0.23 Gy/s, where the dosimeters contained 0.23 % (w/w) dye, 1.5 % (w/w) chloroform and 5.0 % (w/w) curing agent.

Conclusion: The 3D radiochromic silicone based dosimeter has for the first time been investigated in proton beams, and it was demonstrated that chemical modifications could influence the dosimeter response.

PO-0795

Dose verification of fast and continuous scanning in proton therapy

G. Klimpki¹, S. Psoroulas¹, M. Eichin¹, C. Bula¹, D.C. Weber^{1,2}, D. Meer¹, A. Lomax¹

¹Paul Scherrer Institute, Center for Proton Therapy, Villigen PSI, Switzerland

²University of Zurich, University Hospital, Zurich, Switzerland

Purpose or Objective: Out of all techniques proposed to mitigate intra-fractional motion in particle therapy, rescanning appears to be the easiest to realize: One simply needs to apply the same field multiple times with proportionally reduced dose to average out interplay patterns (Phillips *et al.* 1992). However, dead times (e.g. energy changes, spot transitions) accumulate which lengthens the overall treatment time. Thus, efficient rescanning - possibly combined with gating and/or breath-hold - requires fast energy changes (~ 100 ms) and fast lateral scanning. The former is already established at Gantry 2 (Safai *et al.* 2012). For the latter, we pursue implementing a faster delivery technique called line scanning, in which we scan the beam continuously along a straight line while quickly modulating the speed and/or current (Schätti *et al.* 2014). In this presentation, we would like to report on the dose verification concept of line scanning.

Material and Methods: With beam current changes in less than 1 ms (Schippers *et al.* 2010) and lateral scanning speeds of up to 2 cm/ms (Pedroni *et al.* 2004), the frequency of speed and current modulation along a line can be exceptionally high. This calls for a verification system that can intervene (almost) in real-time to fulfill current safety standards. Thus, we decided to monitor the beam current and position continuously during the delivery of a single element, since errors in those two parameters directly impair the homogeneity of the delivered dose distribution. In addition to these real-time verification measures, we implemented a final, redundant verification step, in which the overall dose profile of the delivered line is validated.

Results: We investigated time-resolved signals from (a) two planar ionization chambers in the gantry nozzle to monitor the beam current and (b) two Hall probes in the sweeper magnets to verify the lateral beam position. Tolerance bands define acceptable fluctuations of all signals. We

implemented the readout in detector-specific firmware, running at a sampling rate of 100 kHz. This allows us to initiate interlocks in a few ms whenever limits are exceeded. Figure 1 shows the Hall probe signal during the application of a corrupt line. We simulated two position errors of ± 1 mm at iso-center during its application; both clearly visible (peak downwards, peak upwards). In the redundant verification step, we compared the dose profile of each line, measured with a strip chamber in the nozzle, to a forward-calculated expectation.

Figure 1: Measured Hall probe signal during the application of a corrupt line. Both delivery errors in position (± 1 mm at iso-center) push the signal outside of the pre-defined tolerance band (here at $t_1 = 25$ ms and $t_2 = 65$ ms). Short reaction times in initiating interlocks prevent clinically unacceptable distortions of the delivered dose distribution. The curved signal shape originates from a non-linear correlation between the magnetic field of the sweeper and the actual beam position.

Conclusion: Line scanning is a fast scanning technique; well-suited to rescanning, because it can deliver entire low-dose fields within a few seconds. The combination of real-time verification and dose profile validation ensures safe beam delivery. Interlocks can be initiated quickly during the application of a line if continuously monitored signals exceed pre-defined tolerance limits.

PO-0796

Dose rate dependence of the PTW 60019 microDiamond detector in high dose-per-pulse pulsed beams

J. Pardo-Montero¹, L. Brualla-González², F. Gómez³, M. Pombar¹

¹Clinical University Hospital, Medical Physics, Santiago de Compostela, Spain

²Hospital General Universitario-ERESA, Medical Physics, Valencia, Spain

³Universidade de Santiago, Particle Physics, Santiago de Compostela, Spain

Purpose or Objective: Recombination can affect detectors used for the dosimetry of radiotherapy fields, and should be corrected for. The introduction of FFF accelerators increases the typical dose-per-pulse (DPP) used in radiotherapy, which leads to more important recombination effects.

Diamond detectors provide a good solution for the dosimetry of small fields, due to their low energy dependence and small volume. The group of Università di Roma Tor Vergata has developed a synthetic diamond detector, commercialized by PTW as microDiamond. In this work we present an experimental characterization of the collection efficiency of the this detector, focusing on high-DPP, FFF beams.

Material and Methods: Measurements were performed in a Truebeam linac (Varian) with FF and FFF modalities. The microDiamond chamber was placed in a cubic PMMA phantom

at 10 cm depth, the detector axis perpendicular to the beam axis. The source-to-detector distance was varied between 70 cm and 150 cm to change the DPP. The detector was irradiated with different modalities (6MV-FFF, 10MV-FFF, and 10 MV for reference) and monitor unit rates. The detector was pre-irradiated with -15 Gy, enough to achieve signal stability. Leakage current was measured before and after each irradiation, and was always found to be <0.1 pA. We also performed measurements with a CC13 air ionization chamber (IBA, Belgium) for reference. Collection efficiencies for the microDiamond detector can qualitatively be obtained from ratios of detector readings.

Results: The collection efficiency decreases with DPP, down to 0.978 at 2.2 mGy/pulse. The effect is within 1.1% in the range 0.1-2.2 mGy/pulse, referred to 0.5 mGy/pulse. This dependence is similar to the value reported in the user manual in a narrower dose-per-pulse range (0.05-0.8 mGy). The collection efficiency versus DPP curve does not show the typical linear dependence observed in the near saturation region for ionization chambers, but an equation based on the Fowler-Attix model provides a good fit. Such different behaviour is not surprising: recombination in diamond detectors is a more complex physical process than it is in ionization chambers, with impurities playing a significant role.

On the other hand, we have found no significant dependence of the collection efficiency on pulse repetition frequency.

Conclusion: The dose rate dependence of the microDiamond is within 1.1% in the range 0.1-2.2 mGy/pulse referred to 0.5 mGy/pulse. The dependence, though moderate, can cause some systematic discrepancies when measuring FFF beams with different DPP values and should probably be considered.

Figure. MicroDiamond collection efficiencies versus DPP: 10 MV (triangles), 6MV-FFF (boxes) and 10MV-FFF beams (circles). Best fits to a linear dependence on the dose-per-pulse (dashed line), an equation with a square root dependence (thin solid line), and the Fowler-Attix expression (thick solid line), are showed.

PO-0797

Advanced Radiation Dosimetry System (ARDOS) - A novel breathing phantom for radiation therapy

N. Kostiukhina¹, A. Sipaj¹, S. Rollet¹, E. Steiner^{2,3}, P. Kuess^{2,3}, H. Furtado^{3,4}, D. Georg^{2,3}

¹AIT Austrian Institute of Technology GmbH, Health & Environment Department- Biomedical Systems, Vienna, Austria

²Medical University of Vienna / AKH Vienna, Division Medical Radiation Physics- Department of Radiation Oncology, Vienna, Austria

³Medical University of Vienna, Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

⁴Medical University of Vienna, Center for Medical Physics and Biomedical Engineering, Vienna, Austria

Purpose or Objective: Nowadays an increasing number of techniques that account and compensate for 4D tumor motion are proposed, investigated and implemented into

clinical practice for imaging, treatment planning and dose delivery. Consequently, it is necessary to verify such techniques and/or investigate the related dosimetric improvements under conditions as close as possible to the clinical situation. For this purpose a respiratory motion phantom, i.e. the Advanced Radiation Dosimetry System (ARDOS), was developed and a prototype was realized. This phantom can be used in clinical practice and research to verify dose delivery and image quality of lung cancer patients on a quantitative and reproducible basis.

Material and Methods: The phantom represents an average human torso with a movable tumor insert and comprises a chest wall, ribs, and lungs (Figure 1a). These parts consist of tissue-equivalent materials. Different types of dosimeters can be inserted at the position of the tumor. The phantom's movement is based on an ARDUINO microcontroller and dedicated software allowing to program independent motions: translational motion for all the parts individually, while the tumor additionally can be rotated. Some basic motion types like sinusoidal and quadratic are preprogrammed with the possibility of changing their parameters. Moreover, complex or irregular motions (e.g., patient-specific breathing cycles) can be reproduced.

Figure 1: (a) Phantom setup. (b) Tumor motion (blue) tracking in comparison with annotated motion (black) along cranio-caudal direction

Results: To demonstrate the versatility of the phantom first a dosimetric investigation was performed using a clinical stereotactic photon beam treatment plan. The dosimetric study was based on ionization chamber, EBT3 film, and TL dosimetry. The obtained results showed differences (among the dosimeters) in the delivered dose between static and chest-wall-only or ribs-only motion of up to 1.2%. This value increased to 4.3% for tumor-only- and all-of-the-parts motion modes. In the second step real-time 2D/3D image registration software was verified using kV images with the moving tumor, chest wall and ribs in the phantom. Figure 1b shows results obtained from this tumor motion tracking sub-study.

Conclusion: In this pilot study, the anthropomorphic phantom with its specific characteristics (mimicking a tumor, rib cage, and lungs), flexibility, and possibility to offer close-

to-real conditions was found to be easily applicable for state-of-the-art research and QA purposes for advanced clinical practice. In the next steps of the project the evaluation of scanned ion beam radiotherapy for a moving target, as well as the development of a 4D QA workflow protocols, and the comparison of measurement data with numerical simulations are envisaged.

PO-0798

Validation of Monte Carlo calculated correction factors for MRI-linac reference dosimetry

D.J. O'Brien¹, D.A. Roberts², S. Towe², G. Ibbott¹, G.O. Sawakuchi¹

¹The University of Texas MD Anderson Cancer Center, Radiation Physics, Houston, USA

²Elekta Limited, Linac Platforms, Crawley- West Sussex, United Kingdom

Purpose or Objective: MRI-guided radiotherapy is an emerging field of considerable interest and has prompted the development of specialized treatment units which integrate MR-imaging systems with radiation sources. Such devices require patients and dosimetry equipment to be immersed in a magnetic (B-)field. Consequently the B-field influences the trajectory of charged particles via the Lorentz force which affects the dose-distribution in water and, critically, the response of the ionization chambers (IC) that are needed for reference dosimetry. To accurately calibrate MRI-RT units it is necessary to correct the chamber readings for these effects. The purpose of this study was to validate Monte Carlo (MC) calculations of IC correction factors against measurements with and without a 1.5 T B-field in an MRI-RT unit.

Material and Methods: Measurements were performed using an Elekta 1.5 T MR-linac located at The University of Texas MD Anderson Cancer Center with and without the B-field. An NE2571 Farmer chamber was placed at isocenter at depths of 10 and 20 cm in a water-equivalent plastic phantom. Three orientations were examined: i) the chamber's long-axis parallel to the B-field; ii) the long-axis rotated 90° clockwise w.r.t. the B-field; and iii) the long-axis rotated 90° anticlockwise w.r.t. the B-field. The long-axis was always perpendicular to the beam. Measured charge readings were corrected for temperature, pressure, polarity and ion recombination using the TG-51 protocol. The ratios of the corrected readings with and without the B-field were compared with those predicted by a Geant4 MC model of the chamber with the energy spectrum from an Elekta MR-linac used as a source.

Results: The measurements indicate that the change in chamber signal due to the B-field ranges from 1.4-2.5% and depends on the chamber orientation which compares to the range of 1.7-3.3% predicted by MC. The ratio of the signal with and without the B-field was within 0.3% of the MC values except for the clockwise perpendicular orientation in which a larger discrepancy of 2.5% was found. However, the two perpendicular orientations differed from each other in both the measured and MC data.

Conclusion: Our MC calculations accurately predict the response of the NE2571 Farmer chamber in the 1.5 T MR-linac beam. Measurements performed in the parallel orientation are the least affected by the B-field and can be accurately corrected. Larger uncertainties exist for perpendicular orientations which are possibly due to uncertainties in the MC chamber geometry.

PO-0799

Beam quality specifiers for an integrated MRI-linac

D.J. O'Brien¹, D.A. Roberts², S. Towe², G. Ibbott¹, G.O. Sawakuchi¹

¹The University of Texas MD Anderson Cancer Center, Radiation Physics, Houston, USA

²Elekta Limited, Linac Platforms, Crawley- West Sussex, United Kingdom

Purpose or Objective: The emergence of MRI-guided radiotherapy has led to the development of new radiotherapy treatment machines with integrated MR-imaging systems. Several designs have emerged such as the 60Co ViewRay system and the different MRI-linac systems developed independently by Utrecht/Elekta, the Cross Cancer Institute in Canada and the Ingham Research Institute in Australia. Magnetic (B-)fields do not alter the photon energy fluence of the beam but they do change the dose distribution in water. Therefore the quantity that is used to specify the beam quality of an MRI-RT device must ideally be insensitive to these changes. The purpose of this study was to investigate the sensitivity of the two most standard beam quality specifiers (%dd(10)x and TPR20,10) to the presence of the B-field.

Material and Methods: Depth dose curves and tissue phantom ratio at depths of 20 and 10 cm (TPR20,10) values with and without a 1.5 T B-field were calculated using the Geant4 Monte Carlo toolkit with the energy spectrum from an Elekta MRI-linac used as a source. For comparison, TPR20,10 values were also measured with a NE2571 Farmer chamber in a water-equivalent plastic phantom on an Elekta MRI-linac with and without the 1.5 T B-field.

Results: The measured and calculated TPR20,10 values agreed within 0.3%. The Lorentz force acts perpendicularly to the direction of motion of the secondary electrons causing them to move in spirals which shortens their range. This reduces the depth of the build-up region and enhances the dose per primary photon at the depth of maximum dose (dmax). On the other hand, the dose at depths where transient charged particle equilibrium (CPE) exist are relatively unaffected by the B-field. Consequently, the photon component of the percentage depth dose at 10 cm depth, %dd(10)x, changes by 2.4% when the B-field is applied because this value is normalized to dmax. However, the calculated and measured values of the TPR20,10 changed by only 0.1% and 0.3% respectively due to the fact that both depths (10 and 20 cm) are in regions of transient CPE.

Figure 1: Depth dose curves per primary photon with and without a 1.5 T magnetic field.

$ \vec{B} $	MC PDD Data		$TPR_{20,10}$	
	%dd(10)	%dd(10) _x	MC	Measured
0	70.4	71.2	0.694	0.695
1.5 T	69.3	69.5	0.695	0.697
% diff	1.6%	2.4%	0.1%	0.3%

Table 1: Measured and calculated TPR20,10 values as well as calculated percentage depth dose data with and without a 1.5 T magnetic field. %dd(10)x is the photon component of the percentage depth dose at 10 cm water depth. %dd(10) contains electron contamination.

Conclusion: The TPR20,10 beam quality specifier is more consistent in the presence of B-fields than the %dd(10)x specifier.

PO-0800
Fricke-type dosimetry for “real-time” 3D dose measurements using MR-guided RT: a feasibility study
 H.J. Lee¹, M. Alqathami¹, J. Wang¹, A. Blencowe², G. Ibbott¹
¹The University of Texas MD Anderson Cancer Center, Radiation Physics, Houston, USA
²The University of South Australia, Health Sciences, Adelaide, Australia

Purpose or Objective: To investigate the feasibility of using 3D Fricke-type gel dosimeters for “real-time” dose observations using the combined 1.5 T MRI - 6 MV linear accelerator system (MRL).

Material and Methods: Fricke-type dosimeters were prepared in 97% w/w Milli-Q water with 3% w/w gelatin (300 Bloom), 1 mM ferrous ion, 0.05 mM xylenol orange, 50 mM sulfuric acid, and 1 mM sodium chloride. The dosimeters were stored at 4 °C prior to irradiation and imaging. For this preliminary study, the dosimeters were irradiated in air, with a part of each dosimeter outside the treatment field to act as a reference. MR imaging was performed with the MRL to observe the change in paramagnetic properties pre and post irradiation using a T1-weighted sequence of TR = 500 ms and TE = 20 ms. MRI during irradiation was done in the MRL using a fast sequence of TR = 5 ms and TE = 1.7 ms.

Results: When exposed to ionizing radiation, ferrous ions are oxidized to ferric ions forming a 1:1 xylenol orange - ferric complex in radiochromic Fricke dosimeters. The corresponding changes in paramagnetic properties can be measured using an MRI. The paramagnetic spin changes, which are dependent on the concentrations of ferrous and ferric ion species, were observable on T1-weighted images due to changes in the spin-lattice relaxation rate ($R1 = 1/T1$). We observed a mean increase in pixel value of 53% from un-irradiated to irradiated regions of about 20 Gy. The increase in pixel value and corresponding dose was also visible during irradiation using a fast MR sequence with four snapshots included in the figure (in RGB color scale to emphasize the irradiated region). Visibly, the dosimeter underwent a color change from yellow to purple with the formation of the xylenol orange - ferric complex.

Conclusion: Our Fricke-type dosimeters displayed visible ferric complex formation with xylenol orange after irradiation using the 6 MV linear accelerator component of

the MRL, as well as measurable paramagnetic changes observed using the 1.5 T MRI component of the MRL during and after irradiation. To our knowledge, this is the first time the dose accumulation inside a 3D dosimeter has been visualized in real-time during irradiation using the MRL. The results of this study warrant further investigations into the use of 3D dosimeters for the verification of patient specific radiation therapy treatment plans for the MRL.

Large area 2D polycrystalline CVD diamond dosimeter under intensity modulated beams

C. Talamonti^{1,2}, A. Baldi³, M. Scaringella⁴, M. Zani¹, D. Pasquini⁴, E. Pace⁵, L. Livi¹, S. Pallotta^{1,2}, M. Bruzzi^{2,5}

¹University of Florence, Dip Scienze Biomediche Sperimentali e Cliniche, Firenze, Italy

²Istituto Nazionale di Fisica Nucleare, Sezione di Firenze, Firenze, Italy

³University of Florence, Dip. di Ingegneria Industriale, Firenze, Italy

⁴University of Florence, Dip. di Ingegneria dell'Informazione, Firenze, Italy

⁵University of Florence, Dip. di Fisica e Astronomia, Firenze, Italy

Purpose or Objective: In radiotherapy, the development of bidimensional detectors with the suitable dosimetric features for pretreatment quality assurance of the new advanced treatment techniques is of interest. Diamond is a valid candidate as real-time dosimeter since, contrary to silicon, it is an almost tissue equivalent material showing in principle no energy dependence. Furthermore, it is possible to produce large-area polycrystalline diamond wafers with suitable electronic properties. In this study we describe the performance of DIPIX, a large area dosimeter used for pretreatment verification of intensity modulated treatment plans.

Material and Methods: The dosimeter is made of two detector-grade adjacent 2.5x2.5cm² polycrystalline Chemical Vapour Deposited (pCVD) diamond samples, each equipped with a 12x12 matrix of 144 contacts with a pitch of 2mm, connected to a custom-made electronic read-out system. Tests of the pCVD diamond dosimeter have been performed by means of an Elekta Synergy LINAC, with conventional photon beams, with clinical IMRT fields, from prostate and breast cancer, and with a VMAT lung treatments. The dosimeter was placed at the isocenter and sandwiched inside a phantom of water equivalent material. First set of measurements under a conventional radiotherapy beam aimed to verify the correct behavior of the whole matrix under a flat field and to obtain a flatness correction factor for each pixel were performed. Afterwards dosimetric maps were acquired. Since the area of the prototype under study is smaller respect to a typical IMRT field, the dosimeter was firstly positioned at the isocenter and then shifted in the Latero-Lateral direction. QA plans were computed on the phantom using the Treatment Planning System (TPS) Monaco v3.2., which uses a MonteCarlo algorithm to compute the dose distribution, with a dose grid of 2 mm, and Pinnacle v9.2 which uses a collapsed cone convolution respectively for the VMAT and IMRT plan.

Results: A comparison between the measured maps and the ones predicted by the TPS was performed. As an example, in fig 1 is reported the map collected of lung VMAT plan and the comparison between the measured profiles of some pixels and the ones calculated by Monaco TPS. Dose differences with TPS are in general within 5%, apart in the penumbra region where the dose gradient is high and where the distance-to-agreement is within 3mm.

Conclusion: Dose profiles compare favorably with TPS both for IMRT and VMAT. These results demonstrate that the pCVD diamond device is a suitable detector for dosimetric pretreatment verification analysis in modulated radiation therapy and for conformal beams. This allows for the development of a large area monolithic device with high spatial resolution. In a next future, three samples will be put together in order to realize a matrix with 432 pixels with a total area of 7.5x2.5 cm².

This work has been supported by the experiments INFN CSN5 DIPIX and IRPT/MIUR.

Monte-Carlo based validation of accelerator beam base data measurements

M. Alber¹, M. Söhn², M. Sikora³

¹Aarhus University, Department of Clinical Medicine - Department of Oncology, Aarhus, Denmark

²University of Munich, Radiation Oncology, Munich, Germany

³Haukeland University Hospital, Medical Physics, Bergen, Norway

Purpose or Objective: The quality of beam base data (BBD) is crucial for the accuracy of dose computation, because every measurement error translates into a systematic dose computation error. Despite elaborate guidelines and recommendations, the quality of BBD measurements cannot be verified directly. This constitutes a gap in the clinical QA chain. We present a Monte-Carlo (MC) based method to validate the self-consistency and overall quality of typical BBD measurements.

Material and Methods: BBD are naturally not independent; therefore, self-consistency is a sensitive indicator. Ideally, a full MC simulation, starting with the primary electron beam, would allow benchmarking of individual measurements. This requires that the electron beam properties are known, which can in turn only be determined indirectly from measurements of the photon fields, resulting in a circular problem; not to mention that full linac simulations with a final uncertainty fit for this purpose still require a long time. Thus, we propose: for each accelerator type, a number of electron beam tunes are simulated with BEAMnrc and the phase spaces recorded. The phase spaces are then decomposed into 5 sources and each source is described by a parametric model. The model parameters are naturally highly correlated and yield a unique parameter fingerprint of the beam tune. Given that the photon dose distribution of each source is known, the model parameters of a BBD set can be derived by a fitting process. If a parameter fingerprint of a measurement does not follow

the previously established correlation patterns, the measurement can be considered problematic, and the most probable parameter fingerprint can be determined by mixing the base fingerprints.

Results: Parameter fingerprints for the most frequent energies of Varian and Elekta linacs were generated and used to validate BBD. The method is very sensitive to problems with depth-dose curves (DDC), e.g. incorrect placement of the sensitive volume of the detector, spectral dependencies of the detector for large fields/large depths, partial-volume-, cable- and scatter-effects. Due to the virtually absent scatter in small fields, MC is the ideal method to augment and validate the self-consistency of small field dosimetry. The precision of error detection is in the range of 0.1 mm detector position shifts and 0.3% dose error, for DDC from 5x5 mm² to 400x400 mm². Output factor variations can be detected with a sensitivity of 0.2%, MLC positioning uncertainty with a sensitivity of 0.1 mm. Typical issues with detector types and accelerator models can be identified.

Conclusion: Monte-Carlo derived phase space abstractions can be used to validate the self-consistency and overall quality of base data measurements and thereby fill a gap in the quality assurance chain. Base data can be validated with an accuracy of 0.3%, being one order of magnitude better than potential experimental errors.

Validation of a pre-treatment delivery quality assurance method for the CyberKnife Synchrony System

E. Mastella¹, S. Vigorito², E. Rondi², G. Piperno³, A. Ferrari³, E. Strata³, D. Rozza³, B.A. Jereczek-Fossa³, F. Cattani²

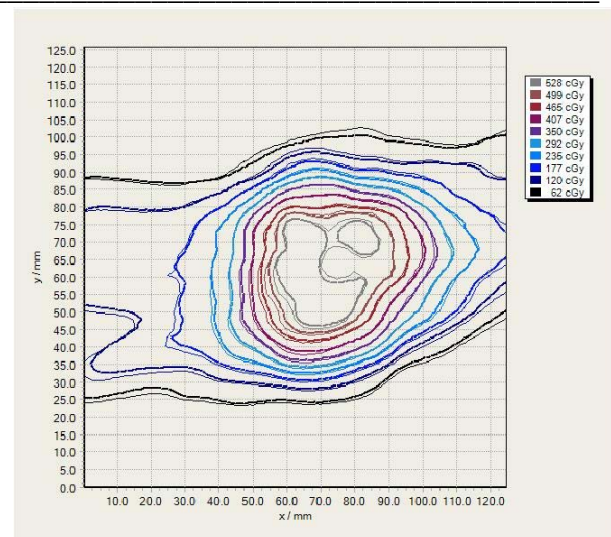

¹Fondazione CNAO, Medical Physics Unit, Pavia, Italy

²IEO - European Institute of Oncology, Medical Physics Unit, Milano, Italy

³IEO - European Institute of Oncology, Department of Radiation Oncology, Milano, Italy

Purpose or Objective: To evaluate the accuracy of the CyberKnife Synchrony Respiratory Tracking System (RTS) and to validate a method for pre-treatment patient-specific delivery quality assurance (DQA).

Material and Methods: An EasyCube Phantom (Sun Nuclear), consisting of RW3 slabs, was mounted on the ExacTrac (ET) Gating Phantom (Brainlab), which can move along the superior-inferior axis of the patient to simulate a moving target. Eight fiducial markers were implanted in the EasyCube for the treatment set-up and for the tracking. A Gafchromic EBT3 film (Ashland) was positioned between two slabs of the EasyCube, while a PinPoint ionization chamber (PTW) was placed in an appropriate insert. The EBT3 films were calibrated with a 6MV beam (Trilogy, Varian) from 0 to 15 Gy and analysed with the multichannel film dosimetry performed by the FilmQA Pro software (Ashland). Our evaluation was performed in two steps: 1) the films were irradiated with single fields perpendicular to the EasyCube for several collimators (3 fixed collimators: 15, 30, 60mm; 3 IRIS openings: 20, 30 and 40mm) and in different dynamic conditions (e.g. motion amplitude of the ET Phantom from 8 to 28 mm). The delivered and planned dose distributions were compared with the gamma (γ) analysis method. The local γ passing rates (GP) were evaluated using 3 acceptance criteria, varying the local dose difference (LDD), the distance-to-agreement (DTA) and the dose threshold (TH): 3%/3mm TH=10%, 2%/2mm TH=30% and 3%/1mm TH=50%. Dynamic cases were also delivered with purposefully simulated errors (RTS switched off or low coverage of the respiratory correlation model). 2) The DQA plans of 6 clinical patients were delivered in different dynamic conditions, for a total of 19 cases. The measured and planned dose distributions were evaluated with the same γ -index criteria of step 1 and the measured PinPoint doses were compared with the planned mean doses in the sensitive volume of the chamber.

The test was considered passed if the 3 γ analysis criteria yielded a GP>90% or at least 2 criteria yielded a GP>90% and the PinPoint dose difference (Δ D) was <5.0%.

Results: The γ analysis of the collimators showed the need to use more γ -index criteria to detect the simulated errors. Only the stricter DTA criterion drastically failed the test, with GP<70%. All of the DQA plans passed the tests, both in static and dynamic conditions. The mean GP (\pm) were 95.5 \pm 5.2% (3%/3mm), 98.6 \pm 1.4% (2%/2mm) and 97.8 \pm 2.2% (3%/1mm). The mean Δ D was 2.9 \pm 1.8%. No significant differences were found between the static and the dynamic cases.

Conclusion: The presented method confirms the ability of the RTS, if used properly, to treat a moving target with great precision. Our pre-treatment patient-specific DQA method was robust, combining PinPoint dose measurements and an evaluation of dose distributions with EBT3 films. However, we found the need of a detailed study of each case, especially when one acceptance criterion does not satisfy the tolerance level.

PO-0804

Clinical applications of a Monte Carlo tool of a proton pencil beam scanning delivery system

F. Fracchiolla^{1,2}, M. Schwarz¹

¹Azienda Provinciale per i Servizi Sanitari, Protonterapia, Trento, Italy

²Università di Roma "La Sapienza", Post Graduate School of Medical Physics, Roma, Italy

Purpose or Objective: Apply a validated Monte Carlo (MC) tool for independent dose calculation in proton PBS to 'patient specific' quality assurance (QA) tasks

Material and Methods: We had developed and validated a MC tool for independent dose calculation[1]. In this work we use this code for:

- Recalculation of a clinically approved plan from the TPS, to evaluate the quality of our TPS semi-analytical dose calculation algorithm at the level of the individual patient
- Recalculation of a treatment session using the Log File coming from the Therapy Control System (TCS), to evaluate differences in 3D dose distribution in patient anatomy taking into account the characteristics of spots (energy, position, MU etc.) as actually delivered by the machine
- Simulation of a 2D patient specific QA (2DQA).

This is a retrospective study on 10 patients done to evaluate the possibility of substituting our actual 2DQA measurement process with a completely automatic and reliable MC based workflow. For each 2DQA TPS and MC dose distributions recalculated in water equivalent material, at different depths, were compared with measurements performed with an array of 1020 ionization chambers

(IC)detector making use of gamma analysis (3%,3mm): measurement and simulation times were compared too.

Results: The table shows a comparison of clinically significant DVH points from TPS dose distribution, MC simulation of the nominal plan and of TCS log file.

ROIs - DVH points	DVH values		
	TPS	MC - Nominal	MC - Log File
PTV - D95	52,63	55,97	52,16
Brainstem - D1	53,37	54,71	53,46
Coclea dx - D1	46,42	46,11	50,67
GTV - D95	53,74	54,88	54,14
GTV - Mean dose	54,46	55,69	55,50
Cerebral Tissue - V33	38,67%	34,82%	35,21%

Table: DVH points comparison between TPS dose distribution, MC recalculated dose from nominal plan and MC dose calculation from TCS log files.

In figure a comparison of TPS and MC planar dose distribution with 2DQA measurements is shown. In our protocol, if the passing rate (PR) is above 95% the field is accepted. If it is between 95 and 90% a justification must be added to the QA report to flag the field as accepted. A passing rate below 90% makes the field unacceptable. In the graph 27 fields belonging to 10 patients are analysed. MC has a PR always greater than 95% for every depth showing a good agreement with measurements. TPS results are always in the "grey" area between 90 and 95%. The execution time of a 2DQA with an array of ICs takes almost 1 hour and half; simulations, that can be performed in parallel, take 11 minutes on average.

Figure: gamma PR (3%,3mm). Comparison at different depths between TPS (diamonds) and MC (squares) dose distribution with measurements of 27 fields belonging to 10 patients.

Conclusion: We realized a system to verify with an independent calculation algorithm both the nominal plan and the delivered one with the TPS dose distribution. This lets the user to estimate the effects on the dose distribution due to a different algorithm and due to delivery uncertainties of the machine. We proposed a method to drastically reduce 2DQA verification time. Our suggestion is to substitute measurements with simulation that showed a very high accordance in terms of gamma PR (always above 95%); one field per patient may be measured at single depth as an additional safety check.

Proton radiography for the clinical commissioning of the new Gantry2 head support at PSI

L. Placidi¹, S. König², R. Van der Meer², F. Gagnon-Moisan², A.J. Lomax¹, D.C. Weber³, A. Bolsi¹

¹Paul Scherrer Institute PSI- Center for Proton Therapy, Medical physics, Villigen PSI, Switzerland

²Paul Scherrer Institute PSI- Center for Proton Therapy, Facility Management, Villigen PSI, Switzerland

³Paul Scherrer Institute PSI- Center for Proton Therapy, Radiation oncology, Villigen PSI, Switzerland

Purpose or Objective: The treatment couches for Gantry2 will support new head pieces for head and neck treatments, the BoS HeadframeTM. Thanks to their geometry and composition (a sandwich of thin carbon layers and light

foam), they will increase the flexibility of planning, as they should only minimally disturb proton beams passing through it. Therefore there will be no restrictions in the deliverable gantry angles; posterior targets will be treated in supine position, thus increasing patient comfort, safety (especially for children under anesthesia) and the position accuracy (bite block will be used more often). We describe here the measurement of their Water Equivalent Range (WER) and homogeneity.

Material and Methods: Mono-energetic scanned proton layers (12x20cm²) of 129 MeV up to 145 MeV were delivered through the head support, with the proton dose on exit being measured using a scintillating screen/CCD camera device approach. A reference set of measurements were first performed without the head support with 1 MeV discrete energy steps. The measurements were then repeated for three different positions (head, neck and shoulder) of the head support. A second set of measurements were performed with an energy step of 0.2 MeV for energies between 133-139 MeV, to increase the measurement accuracy. For each acquisition, a 2D map of the maximum values among all the layers was generated, from which the WER of the head support in the different positions could be calculated by subtracting the measurements with and without the frame. WER homogeneity was calculated as the standard deviation of sub-regions of the 2D difference maximum value maps. CT images of the head supports were also imported in the TPS and converted to WER (via HU-Relative Proton Stopping Power calibration curve), to estimate if the planned WER corresponded to the measured values (with no need of synthetic CTs).

Results: WER was found to be between 2.4mm and 7.2mm with an accuracy of 1.0mm or 0.5mm, depending on the measurements energy steps (respectively 1.0 MeV and 0.2 MeV) (Fig). In the three different positions, WER inhomogeneity was lower than 1.0mm (respectively 0.36mm, 0.99mm and 0.40mm). The differences of WER between measured and TPS values were also below 0.5 mm (0.2 MeV step) and 1.4 mm (1 MeV step).

Conclusion: The described method was accurate, fast and reproducible. The results on the thickness and homogeneity of the head frame show that it can be safely and accurately used in clinical operation and the first patients have already been treated.

PO-0806

Optimisation and assessment of the MLC model in the Raystation treatment planning system

A. Savini¹, F. Bartolucci¹, C. Fidanza¹, F. Rosica¹, G. Orlandi¹

¹AUSL 4 Teramo, Medical Physics Department, Teramo, Italy

Purpose or Objective: Accurate modeling of the MLC is necessary to achieve a clinically acceptable agreement between dose calculations and measurements in IMRT/VMAT treatment plans. The RayStation TPS uses several parameters to model a MLC but no specific procedure exists on how to perform measurements to optimize them. The aim of this work is to present a fast procedure to optimize the MLC parameters in RayStation v.4.5 and to assess the obtained MLC model.

Material and Methods: A proper set of MLC-collimated fields was designed on a Varian Trilogy linear accelerator equipped with a Millennium 120 MLC. Dose profile scans of those fields

were taken in a motorized water phantom using small detectors (Razor stereotactic diode and PFD, IBA Dosimetry). In addition, MLC transmission was measured using a Farmer ion chamber. MLC model parameters (transmission, offset, leaf tip width, tongue-and-groove) were optimized to maximize the agreement between measurements and calculations. Model assessment was performed using a set of highly intensity-modulated MLC geometrical patterns, designed to enhance tongue-and-groove, transmission and offset/leaf-tip effects. For those fields, planar dosimetry was carried out with GafChromic EBT3 films. Clinical validation was performed evaluating TG-119 cases along with 25 DMLC and 10 VMAT clinical plans. Plan-specific quality assurance was performed with a 2D-array (MatriXX, IBA Dosimetry) and gamma-index metric was used to assess the agreement between planned and measured dose distributions. A 2%/2mm criterion was used with both local (LN) and global (GN) normalization.

Results: Optimized MLC parameters were: transmission 0.018, position-offset 0.04cm, tongue-and-groove 0.05cm, leaf tip width 0.3cm. Average and standard deviation (SD) values of gamma index pass-rates were: for geometrical patterns: 92.8%, SD=5.1%(LN); 95.5%, SD=2.5%(GN). For TG-119 plans: 97.1%, SD=4.4%(LN); 99.7%, SD=0.7%(GN). For DMLC clinical plans: 97.0%, SD=3.7% (LN); 98.8%, SD=2.6%(GN). For VMAT plans 90.1%, SD=4.0% (LN); 96.5%, SD=2.1% (GN). Critical regions dominated by tongue-and-groove and rounded-leaf-tip effect showed a very good agreement between measurements and calculations (see Fig.1).

Fig.1

Conclusion: Results demonstrate the followed procedure leads to a proper optimization of the MLC model in RayStation, leading to clinically acceptable gamma index pass-rates. The needed additional measurements can be easily integrated as a subset of the standard measurements required for the commissioning of the RayStation TPS.

PO-0807

3D and 4D dose calculations for tumour-tracking irradiation of lung/liver tumours using gimbaled linac

Y. Iizuka¹, N. Ueki², Y. Matsuo¹, Y. Ishihara¹, K. Takayama³, M. Nakamura¹, T. Mizowaki¹, M. Kokubo³, M. Hiraoka¹

¹Kyoto University, Department of Radiation Oncology and Image-Applied therapy, Kyoto, Japan

²Hyogo Prefectural Amagasaki General Medical Center, Department of Radiation Oncology, Amagasaki, Japan

³Institute of Biomedical Research and Innovation, Division of Radiation Oncology- Department of Image-based Medicine, Kobe, Japan

Purpose or Objective: To compare dose-volume metrics calculated with the four-dimensional (4D) Monte Carlo (MC) and three-dimensional (3D) dose evaluation systems in dynamic tumor tracking (DTT) irradiation for lung or liver tumors.

Material and Methods: Twenty patients with lung tumors and 15 patients with liver tumors who underwent DTT irradiation using a gimbal-mounted linac were enrolled in this study. During computed tomography (CT) simulation, 4DCT under free breathing and exhale breath-hold CT were performed. Planning target volume (PTV) for DTT was calculated using the gross tumor volume (GTV) delineated on a reference CT scan (exhale phase in the 4DCT or exhale breath-hold CT) by adding asymmetric margins to compensate for possible errors due to the DTT. The 6 to 9 non-coplanar ports of the 6-MV X-ray were set to each PTV. Doses were calculated for the reference CT using a commercially available treatment planning system (TPS). At the same time, 4DMC dose evaluation was performed for 10 respiratory phases of 4DCT using an in-house dose calculation system based on the MC algorithm, considering the gimbal rotation. The doses calculated for 10 phases were accumulated using deformable image registration software for the lung tumor patients, whereas mean values of the dose-volume metrics were evaluated for the liver tumor patients. The difference between the doses calculated with 4DMC (4D doses) and those calculated for the reference CT scan with TPS (3D doses) were investigated for the following dose-volume metrics: the percentage of dose that covers 95% of the GTV (GTV D95), the max dose received by the spinal cord (Cord max), the percentage of lung volume that received more than 20 Gy and 5 Gy irradiation (Lung V20 and Lung V5, respectively) in patients with lung tumors, and the mean dose and percentage of liver volume that received more than 20 Gy irradiation (Liver mean and Liver V20, respectively) in patients with liver tumors.

Results: The mean values of the dose-volume metrics for the 4D doses were as follows: 94.1% (range, 83.8-99.7%) GTV D95, 9.7 Gy (range, 1.8-22.0 Gy) Cord max, 4.9% (range, 1.9-13.7%) Lung V20, 19.2% (range, 7.2-30.7%) Lung V5, 10.0 Gy (range, 5.2-15.2) Liver mean, 15.5% (range, 8.2-27.7%) Liver V20. The mean differences in the dose-volume metrics for the 3D and the 4D doses were as follows: 0.5% (range, -7.4-4.8%) GTV D95, 0.1 Gy (range, -2.5-1.8 Gy) Cord max, 0.1% (range, -0.8-1.4%) Lung V20, 0.3% (range, -1.6-2.1%) Lung V5, 0.1 Gy (range, -1.6-1.1 Gy) Liver mean, and -1.0% (range, -1.7-3.1%) Liver V20. There were no statistical significant differences in these dose-volume metrics evaluated by paired t-test.

Conclusion: The 3D doses calculated with TPS for the target tumor and organs at risk were almost equal to those calculated with 4DMC. 3D dose could be used as a substitution for 4DMC calculation. However, the dose to the spinal cord was underestimated by a maximum of 2.5 Gy.

PO-0808

Validation of a clinical peripheral photon dose model: prostate IMRT irradiation of Alderson phantom

B. Sanchez-Nieto¹, L. Irazola², M. Romero-Expósito³, J. Terrón⁴, F. Sánchez-Doblado⁵

¹Pontificia U-dad Católica de Chile, Institute of Physics, Santiago, Chile

²Universidad de Sevilla, Departamento de Fisiología Médica y Biofísica- Universidad de Sevilla- Spain, Sevilla, Spain

³Universitat Autònoma de Barcelona, Departamento de Física, Barcelona, Spain

⁴Hospital Universitario Virgen Macarena, Servicio de Radiofísica, Sevilla, Spain

⁵Universidad de Sevilla, Departamento de Fisiología Médica y Biofísica, Sevilla, Spain

Purpose or Objective : Unwanted peripheral doses (PD) from external beam radiotherapy (RT) are associated with increased incidence of second cancers. PD estimations after RT are becoming highly relevant due to the larger cancer incidence as well as survival rates. Additionally, an accurate knowledge of out-of-field doses is of importance when treating children, pregnant patients and those with implantable electronic devices [1]. Our group has developed a novel peripheral photon dose (PPD) model [2] which includes intensity modulated treatments. This model estimates out-of-field doses (i.e., beyond the commercial TPS limits -around 10 cm from the field edge) received by individual patients undergoing any RT isocentric technique. The aim of this work was the experimental validation of the model in a number of points inside the Alderson Radiation Therapy phantom (ART) irradiated with an IMRT prostate plan. This exercise is part of the process toward the implementation of the model onto a commercial TPS.

Material and Methods: A Siemens Primus linac was used to deliver a 6 MV prostate IMRT treatment (896 MU and 7 incidences, equivalent to 2 fractions of the treatment). TLD-100 pairs of dosimeters were inserted at phantom holders, placed outside the 1% isodose as shown in the coronal plane of the figure. Positions were selected as being representative of cancer-at-risk organs. TLD-100 readings were converted into doses, through a calibration factor which considers the spectral condition outside the field, and then compared to PPD model estimates [2]. Measured leakage outside the field resulted 4 μ Gy/MU. Peripheral photon equivalent dose (PPED) to organs was also computed using PERIPHOCAL [2] (a MATLAB® GUI piece of software which considers a basic patient model with scaled dimensions from Cristy phantom [3]).

Results: Plot at the figure depicts the estimated and measured photon equivalent doses (mSv) at 11 points for studied case (identified on the coronal plane of the phantom). Uncertainty Range (UR) corresponds to ± 2 mSv and the error bars represent the ± 6 % global uncertainty estimated for the TLDs in the out-of-field area.

Figure.

Conclusion: Validation of a PPD calculation model [2] has been carried out in an Alderson phantom for an IMRT prostate treatment using TLD-100 detectors. Very good agreement has been found between the model and the experimental measurements. However, bigger differences have been found between dose to points and PPED to organs, which might suggest that the mathematical phantom and/or the escalation model used for estimating organ location/dimensions are not properly mimicking the anatomy of the Alderson phantom. This issue deserves further investigation before implementing the dose-to-organ model onto a commercial TPS.

³Hôpital Riviera Chablais, Radiation Oncology Dept, Vevey, Switzerland

⁴Kaiser Franz Josef Spital, Radio-Oncology Dept., Vienna, Austria

Purpose or Objective: Flattening filter free (FFF) beams generated by medical linacs are today clinically used for stereotactical treatments, thanks to their very high dose rate (up to four times the dose rate of the common flattened beams). Such beams differ from the standard flattened beams (FF) in the profile shape, that is strongly peaked on the beam central axis. However, FFF beams are not standard in terms of the parameters describing the field characteristics. Definitions of new parameters as *unflatness* and *slope* for FFF beams have been proposed, based on a renormalization factor for FFF profiles. With those factors the FFF dose fall-off at the field edge is superimposed with the corresponding (in nominal energy) flattened profile commonly normalized to 100% at the beam central axis. The present study aims to provide the renormalization factors for FFF beams of 6 and 10 MV generated by Varian TrueBeam and by Elekta Versa HD linacs. Estimation of the values of the new parameters (unflatness and slope) for the two units are also given.

Material and Methods: Dosimetric data from two Varian TrueBeam and two Elekta Versa HD linacs, all with 6 and 10 MV nominal accelerating potentials, FF and FFF modes have been collected. Renormalization factors were estimated according to Fogliata et al. procedure (Med.Phys. 2012,39) with the third derivative method, and parameters of $RenormFactor = (a+b*FS+c*depth)/(1+d*FS+e*depth)$ have been fitted for FFF beams of both units and energies. Unflatness and slope parameters were computed. Dosimetric differences as beam penetration and surface dose were also assessed.

Results: Renormalization factors are summarized in the graphs here presented.

Once the FFF profiles have been renormalized, the unflatness and slope were computed. As an example of the unflatness parameter, for a 20x20 cm² field, it was estimated in the range (from dmax to 30 cm depth) of 1.248-1.317, and 1.304-

1.371 for the 6MV beams, TrueBeam and Versa HD, respectively. The same figure for the 10MV beams were 1.484-1.524, and 1.501-1.543. Concerning beam penetration, TPR_{20,10} for 6 and 10 flattened and FFF TrueBeam beams were: 0.665, 0.629 (6MV) and 0.738, 0.703 (10MV), while for Versa HD beams are: 0.684, 0.678 (6MV) and 0.734, 0.721 (10MV).

Conclusion: Renormalization factor and unflatness parameters proved to be efficient to describe the FFF beam characteristics. Renormalization factors here presented could be used for all TrueBeam and Versa HD beams, without the need of recalculate them for the site specific conditions.

PO-0810

Implementation of Normalised Dose Difference method for evaluation of VMAT Monte Carlo QA

R.O. Cronholm¹, P. Andersson², M. Krantz², R. Chakarova^{2,3}

¹Skåne University Hospital, Radiation Physics, Lund, Sweden

²Sahlgrenska University Hospital, Department of Medical Physics and Biomedical Engineering, Gothenburg, Sweden

³Sahlgrenska Academy at the University of Gothenburg, Department of Radiation Physics, Gothenburg, Sweden

Purpose or Objective: Monte Carlo calculations are increasingly applied as an independent QA tool for pre-treatment verification of patient plans for complex treatment delivery techniques such as VMAT. The dose obtained is usually imported to the treatment planning system for further analysis. The analysis can encompass visual comparison of dose distributions as well as qualitative and/or quantitative comparison of Dose Volume Histograms for specific structures. More sophisticated quantitative comparison in 3D includes gamma analysis combining dose difference and distance-to-agreement evaluation generating pass/fail maps. The normalized dose difference (NDD) method is considered to be an extension of the gamma-index concept including locally defined, spatially varying normalization factors. The NDD is reported to be insensitive to the dose grid size. Also, it shows which dose distribution has a higher value at the comparison point (has a sign). The objective of the work is to test the applicability of the NDD method in the Monte Carlo pre-treatment QA procedure, as well as to develop a stand-alone module which will include visual and quantitative analysis.

Material and Methods: Monte Carlo simulations were performed using the EGSnrc/BEAMnrc code system with modifications, capable to compute dose distributions due to a continuously moving gantry, dynamic multileaf collimator and variable dose rate (I.A. Popescu and J. Lobo, Radiother. Onc.2007). A Monte Carlo model of a Varian Clinac iX accelerator was used. Patient treatment plans were generated by Eclipse treatment planning system (Varian Medical Systems, USA) and calculated by the AAA algorithm. NDD formalism has been applied in Matlab (Mathworks®) as described in (Jiang SB, et al. Phys Med Biol 2006).

Results: Dose distributions for patients in different anatomical regions have been obtained; pelvic and head and neck. Example of NDD analysis for a prostate cancer is shown in the figure.

A 3%, 3 mm tolerance criteria is used. The colour scale varies from $\pm 3\%$, i.e. the region of acceptance. Negative values indicate that the Eclipse dose (AAA) is lower than the Monte Carlo calculated dose. The Monte Carlo simulations include the air surrounding the patient. Therefore the NDD values outside the patient are negative. All the NDD values are

within tolerance on the left transversal slice, i.e. there is agreement between Monte Carlo and AAA. On the right transversal slice, the AAA shows higher target dose in small ventral regions and lower dose at some points in the risk organ (rectum). In general the pass-rate observed is $> 95\%$. A slight dominance of the Monte Carlo dose has been observed in the NDD statistics expressed as a shift of the maximum in the NDD distribution.

Conclusion: The NDD method can give important information for pre-treatment verification of VMAT plans, which is complementary to the dose analysis in the treatment planning system.

PO-0811

Patients in vivo skin dosimetry using the Exradin W1 plastic scintillator for proton therapy

F. Alsanea¹, L. Wootton¹, N. Sahoo¹, S. Beddar¹

¹U.T. M.D. Anderson Cancer Center, Radiation Physics, Houston- TX, USA

Purpose or Objective: To evaluate the usefulness and accuracy of a commercially available plastic scintillator (Exradin W1) for use in *in vivo* proton therapy skin dosimetry.

Material and Methods: Six patients undergoing passive scatter proton therapy for prostate cancer were enrolled in an IRB approved protocol. The Exradin W1 plastic scintillator was used to measure *in vivo* skin dose by attaching the detector to the patient's skin at the central axis of each treatment field (2 laterally opposed treatment fields). Measurements were acquired once per week for the entire treatment course resulting in a total of 93 measurements. The detector was first calibrated on a Cobalt-60 unit, and phantom measurements in the proton beam with the W1 and a calibrated parallel plane ion chamber were used to account for the under-response due to ionization quenching. The average dose difference between the Exradin W1 *in vivo* dose and parallel plane ion chamber in phantom dose over all measurement and per-patient was computed, as well as standard deviations. Furthermore, dose extracted from the treatment planning system was compared to the parallel plane ion chamber. Finally, baseline stability measurements in the cobalt unit were performed weekly for the duration of the study.

Results: The calibrated detector exhibited a 7% under-response for 225 MeV proton beams. The temperature under-response was 4% when used at 37° C (relative to the response at the calibration temperature of 20° C). The detector exhibited a stable response and was within 1% for the duration of the study (144 days). The average dose difference between the Exradin W1 and parallel plane ion chamber over all patient measurements was $0.27 \pm 0.67\%$ after applying the temperature and quenching correction factors. The dose difference between the Exradin W1 *in vivo* measurements and parallel plane ion chamber for all six patients treatment fields throughout the study were all within $\pm 2\%$ with a standard deviation of 0.67% (see figure 1).

Figure 1 Dose difference between Exradin W1 *in vivo* dose and parallel plane ion chamber dose for every patient during the study.

Conclusion: The Exradin W1 exhibited a high level of accuracy for *in vivo* skin dosimetry measurements in passively scattered proton beams. The quenching correction and temperature corrections are easy parameters to extract. The detector will be useful as a verification tool for proton therapy patients because plastic scintillators are water equivalent, very small detectors (2mm diameter), accurate, and durable.

PO-0812

Dosimetric accuracy of TPS algorithms for actively scanned proton beams and small target volumes

G. Magro¹, S. Molinelli², A. Mairani², A. Mirandola², D.

Panizza², S. Russo², E. Mastella², F. Valvo³, M. Ciocca²

¹University of Pavia, Physics Department, Pavia, Italy

²Fondazione CNAO, Medical Physics Unit, Pavia, Italy

³Fondazione CNAO, Clinical Directorate, Pavia, Italy

Purpose or Objective: To evaluate the accuracy of different lateral proton beam spreading models of two commercially available treatment planning systems (TPS) in optimizing proton pencil beam dose distributions for small targets located at increasing depths in water.

Material and Methods: The TPSs analytical algorithms were benchmarked against experimental data and the FLUKA Monte Carlo (MC) code, previously validated for the selected beam-line. We tested the Siemens Syngo and the RaySearch RayStation TPS plan optimization modules for water cubes, by fixing the configurable parameters at clinical standards, with homogeneous target coverage to a 2 Gy (RBE) (Relative Biological Effectiveness) dose prescription as unique goal. An RBE of 1.1 has been used. For shallower targets requiring a range shifter, two different approaches were adopted with Syngo: A) the passive absorber was numerically accounted for its water equivalent thickness only and a single Gaussian approximation was considered for the lateral evolution of the beam; B) the passive absorber was contoured as a body included in the TPS calculation volume, where a double Gaussian modeling for the beam lateral spread is applied. Case B served to directly compare Syngo with the RayStation strategy of accounting the range shifter as a part of patient geometry during pencil beam tracing. Transversal and longitudinal profiles, acquired across target centers, were compared and a γ -analysis was performed within each volume between TPS and MC. Optimized plans were delivered and the dose at each volume center was measured in water with a calibrated PTW Advanced Markus chambers. An EBT3 film was also positioned at the phantom entrance surface for the acquisition of 2D dose maps.

Results: Discrepancies between TPS calculated and MC simulated values were mainly due to the different lateral spread modeling and resulted to be related to the field-to-spot size ratio. Severe limitations were found for Syngo configuration A (clinical scenario), when planning on very small and shallower cubes. The high level of agreement shown between MC and Syngo configuration B and RayStation, regarding these challenging targets, supported the hypothesis that the use of a single Gaussian beam model is one of the main sources of dose deviations for superficial volumes. No major discrepancies were registered in all cases analyzed, either at the volume center or in the penumbra region.

Conclusion: The accuracy of the TPSs was proved to be clinically acceptable in all cases but very small and shallow volumes, when a poor beam lateral spreading model is used (single Gaussian). Satisfactory dose calculation accuracy could be achieved by using either a double Gaussian parameterization or the RayStation version of this algorithm, separately handling the nuclear halo effect, for range shifter modeling in the TPS. In this contest, the use of MC to validate experimental results proved to be a reliable procedure for pre-treatment plan verifications.

PO-0813

Assessing the quality of proton PBS delivery: log file analysis of every treatment at PSI Gantry 2

D. Scandurra¹, F. Albertini¹, R. Van der Meer¹, G. Meier¹, D. Weber¹, A. Bolsi¹, A. Lomax¹

¹Paul Scherrer Institute, Center for Proton Therapy, Villigen PSI, Switzerland

Purpose or Objective: Pencil beam scanning (PBS) proton therapy requires the delivery of many thousand proton beams, each modulated for position, energy and dose, to provide a highly conformal patient treatment. The quality of the treatment is dependent on the delivery accuracy of each beam and at each fraction. In this work we describe the use of treatment log files, which are a record of the machine parameters for a given field delivery on a given fraction, to investigate the integrity of treatment delivery compared to the nominal planned dose, for all clinical patients treated at Paul Scherrer Institute on Gantry 2.

Material and Methods: The dosimetry-relevant log file parameters are used to reconstruct the 3D dose distribution on the patient anatomy, using a TPS-independent dose calculation system developed at our institute and experimentally validated previously. The analysis was performed for all clinical treatments, both for individual fields and per series, and delivery quality was assessed by comparing the log file dose to the TPS dose, in particular by determining the percentage of voxels within +/- 1% of the nominal dose, as well as gamma index using 1% and 2mm criteria.

Results: The mean +/-1% pass rate on the series-level is 96.4%, though individual fields showed larger variations in pass rate. Furthermore, this work establishes a correlation between the delivery quality of a field and the beam position accuracy. This correlation is evident for all delivered fields regardless of individual patient or plan characteristics. We have also detailed further implementation of log file analysis within our clinical workflow, including the clinical evaluation of patient delivered dose from a problematic fraction delivery, the discovery and diagnosis of systematic issues in treatment planning or delivery workflow, extra TPS quality assurance, and the trending of machine performance following repairs or upgrades.

Conclusion: We have demonstrated the usefulness of treatment log files in PBS proton therapy, particularly in regard to assessing the quality of daily treatment delivery by calculating 3D dose distributions on the patient anatomy and comparing it to the nominal TPS dose. We have presented the results of this analysis for every patient field and series delivered thus far on Gantry 2. Additionally, we have shown that the integrity of treatment delivery is highly correlated with the accuracy of spot position and believe this will be useful for driving machine performance improvements in the PBS field.

PO-0814

Beam quality and perturbation factors of Farmer chambers in magnetic fields

C.K. Spindeldreier¹, O. Schrenk¹, S. Greulich¹, C. Karger¹, A. Pfaffenberger¹

¹German Cancer Research Center, Medical Physics in Radiation Oncology, Heidelberg, Germany

Purpose or Objective: Hybrid MR-Radiotherapy devices combine radiation treatment and excellent soft tissue contrast imaging, which does not deliver any additional radiation dose to the patient. The permanent magnetic field of the MRI is known to deflect the electrons during irradiation, influencing the dose response of ionization chambers [Meijsing 2009]. This work investigates the effect of the magnetic field on the beam quality and the perturbation factors for six customized Farmer chambers with different sensitive volumes.

Material and Methods: Six ionization chambers, essentially identical in design but varying in radius of the sensitive volume from 0.1 cm to 0.6 cm, were modelled using the C++ class library *egspp* of the Monte Carlo code *EGSnrc* [Kawrakow 2009]. In order to calculate the beam quality factors, Monte Carlo simulations were performed placing the chamber models into a water phantom at 10 cm depth using a Siemens PRIMUS phase space [Pena 2007] and at 5 cm water depth using a ^{60}Co -spectrum [Rogers 1987]. The perturbation factors were determined following the process described by [Wulff 2008]. For the calculations, magnetic field strengths from 0.0 T to 3.0 T were used.

Results: The beam quality factors of all chambers differ from the values without magnetic field with a maximum of $\pm 3\%$ depending on the magnetic field strength. The highest influence on the beam quality factor can be found for the replacement and the central electrode perturbation factor. Moreover, these two factors show the highest dependency on the magnetic field strength.

Conclusion: Magnetic field specific perturbation and beam quality factors of six different Farmer chambers were calculated. The results indicate that chambers with a small sensitive volume show less influence of the magnetic field. In order to measure dose with ionization chambers in a magnetic field correctly, beam quality factors have to be determined for every individual chamber and every magnetic field strength.

Acknowledgements: We thank Dr. Iwan Kawrakow (ViewRay) for providing the magnetic field macro for the *EGSnrc* code system. Detailed information on the geometry of the Farmer chambers given by Dr. Edmund Schüle (PTW) are gratefully acknowledged.

PO-0815

Impact of digitizer response and time averaging de-noising in radiochromic film dosimetry

J.A. Vera Sánchez¹, C. Ruiz Morales², A. Gonzalez Lopez³

¹Hospital Universitari Sant Joan de Reus, física mèdica, Reus, Spain

²Hospital IMED- Elche, Radioterapia, Elche, Spain

³Hospital Clínico Universitario Virgen de la Arrixaca, Radioprotección, Murcia, Spain

Purpose or Objective: To study how noise and digitizer response affect radiochromic film dosimetry. The variations introduced because of these factors in gamma scores is determined.

Material and Methods: Five VMAT treatment plans were analyzed in this work. Two dose planes (coronal and saggital) were verified for every treatment plan, they were irradiated in a MULTICUBE phantom (IBA, dosimetry), measured with the Matrixx chamber array (IBA, Dosimetry) and analyzed with the Omnipro l'm RT (IBA, Dosimetry). Once the plans were accepted for clinical treatment, the analysis of the same dose planes was carried out with radiochromic films and two different algorithms: the multichannel protocol of Mayer et al (MC), that corrects the lateral effect of the digitizer and minimize the amount of noise, and the efficient protocol of Lewis et al (EP), that keeps the corrections included in the multichannel protocol and corrects the digitizer variability with a two point recalibration. Radiochromic film dosimetry is affected by known factors as digitizer lateral effect, noise and variability in digitizer response. These factors affect the gamma scores. In particular, when the dose plan obtained from the film is used as the reference distribution in the gamma analysis, the amount of noise and changes in digitizer response may give rise to wrong gamma evaluations. Every film was digitized with three different resolutions (72, 96 and 150 ppp), and twenty digitalizations were obtained for every resolution. For every single digitized image a dose map was obtained with the two mentioned algorithms and, in addition, dose maps from averaged images were analyzed (dose maps 21 to 25) and averaged dose maps were also analyzed (dose maps 26 to 30)

Results: In the figure, results of the passing rate of a prostate VMAT coronal dose plane evaluated with radiochromic film are shown for the 2mm, 2% criteria.

Conclusion: The multichannel protocol is not able to compensate variability in digitizer response, and this is a central issue for radiochromic film dosimetry. The efficient protocol compensates variations of digitizer response, so parameters of the gamma analysis become more stable. The compensation of variability in digitizer response by the efficient protocol may be used for de-noising by time averaging and gamma analysis results may be improved for all resolutions.

PO-0816

Sensitivity and reproducibility of the portal imaging panel for routine FFF QC measurements

A. Willett¹, D. Kelly¹, M. Gilmore¹, C. Rowbottom¹

¹The Clatterbridge Cancer Centre - Wirral NHS Foundation Trust, Physics, Bebington- Wirral, United Kingdom

Purpose or Objective: The purpose of this work was to see if the EPID is a viable alternative to other QA devices for routine FFF QA measurements.

Material and Methods: Sensitivity measurements were made to assess response to small changes in field size, beam steering, and energy. A series of QA plans were created where field size was varied from baseline values in small increments. Field size: (5-5.5cm, 20-20.5cm) 1mm increments. Beam steering was adjusted by manually altering values in service mode. Beam steering: (Symmetry 0-3%) 1% increments. Symmetry was defined using the maximum variation method (Dx-D-x)max. Energy was varied by placing small quantities of Perspex into the beam path (0-6cm), 2cm blocks. These plans were then measured using the portal imager (aS1200 DMI panel), QA3 (Sun Nuclear), and Starcheck Maxi (PTW). EPID beam data was taken from the Portal Dosimetry module in ARIA and exported into Excel for processing; FFF beam parameters as stated in Fogliata et al [1] were calculated. Starcheck data was also exported to allow for similar analysis. The increment measured by each of the devices was compared to the known increment set by looking at the differences between the baseline (no increment) measurement and the incremented one.

Constancy measurements were then taken on an ad-hoc basis over a period of 5 weeks using all 3 QC devices to measure a MLC defined 20x20cm field and the results were recorded.

Results: Overall the EPID and the Starcheck performed better at detecting changes in field size (Average difference from set offset: EPID = 0.28mm, Starcheck = 0.33mm, QA3 = 0.88mm), with the QA3 performing better when detecting changes in beam symmetry (Average difference from set offset: EPID = 0.10%, Starcheck = 0.20%, QA3 = 0.07%). Energy changes were looked at using the slope parameter (EPID - range 0.295-0.309 %/mm for 0-6cm of Perspex), (Starcheck - range 0.31-0.315 %/mm) or the Energy parameter (QA3 - range 104.7-109.1%).

Daily measurements were examined for consistency and again the EPID and Starcheck performed similarly, with comparable standard deviations, as shown in Table 1.

Date	Transverse symmetry (%)			Field size X(cm)			Slope (%/mm) / Energy (%)		
	EPID	Starcheck	QA3	EPID	Starcheck	QA3	EPID	Starcheck	QA3
15/09/2015	0.5	-	0.04	19.92	-	20.01	0.29	-	107.2
18/09/2015	0.24	-	0.04	19.91	-	20.06	0.29	-	105.9
21/09/2015	0.46	-	0.21	19.91	-	20.01	0.29	-	106.6
24/09/2015	0.36	0.39	0.44	19.91	19.91	20.02	0.29	0.3	106.3
25/09/2015	0.42	0.32	0.33	19.93	19.87	20.05	0.29	0.3	106.6
29/09/2015	0.57	0.33	0.11	19.91	19.94	20.01	0.29	0.3	105.7
08/10/2015	0.42	0.34	0.09	19.91	19.92	20.24	0.29	0.3	104.7
12/10/2015	0.42	0.37	0.09	19.91	19.93	20.24	0.29	0.3	105.4
Std Deviation	0.097	0.029	0.147	0.007	0.027	0.101	0.000	0.000	0.791

Table 1 – Table showing the daily measurements and calculated standard deviations for all three devices taken for Symmetry, Fields size and Energy.

Conclusion: Our results show that for FFF QA measurements such as field size and symmetry, using the EPID is a viable alternative to other QA devices. The EPID performs particularly well on geometric measurements, as it is able to detect small changes in position (-1mm) with good consistency. This is to be expected due to its high resolution when compared to the other QA devices used (EPID 0.34mm, Starcheck 3mm, QA3 5mm). Therefore the EPID could potentially be used for a wider range of QC measurements with a focus on geometric accuracy, such as MLC positional QA.

PO-0817

Characteristics and performance of the first commercial MLC for a robotic delivery system

P. Prins¹, C. Fürweger², H. Coskan¹, J.P.A. Marijnissen¹, B.J.M. Heijmen¹

¹Erasmus Medical Center Cancer Institute, Department of Radiation Oncology, Rotterdam, The Netherlands

²European Cyberknife Center, Munich, Germany

Purpose or Objective: To assess characteristics and performance of the "InciseTM" MLC (41 leaf pairs, 2.5mm width, FFF linac) mounted on the robotic SRS/SBRT platform "Cyberknife M6TM" in a pre-clinical 5 months test period and to ensure quality of clinical treatments.

Material and Methods: Beam properties were measured with unshielded diodes and EBT3 film. Bayouth tests for leaf / bank position accuracy were performed in standard (A/P) and clinically relevant non-standard positions, before and after exercising the MLC for 10+ minutes. Total system accuracy was assessed in End-to-End tests. Delivered dose was verified with EBT3 film for exemplary and clinical plans. Stability over time was evaluated in Picket-Fence- and adapted Winston-Lutz-tests (AQA) for different collimator angles.

Results: Penumbrae (80-20%, with 100%=2*dose at inflection point; SAD 80cm; 15mm depth) parallel/perpendicular to leaf motion ranged from 2.7/2.2mm for the smallest (0.76x0.75cm²) to 3.7/3.6mm for larger (8.26x8.25cm²) square fields. MLC penumbrae are slightly wider than penumbrae fixed cones (2.1 to 2.8mm for 5 to 60 mm cones). Interleaf leakage was <0.5%. Average leaf position offsets were ≤0.2mm in 14 standard A/P Bayouth tests and ≤0.6mm in 8 non-standard direction tests. Pre-test MLC exercise slightly increased jaggedness (range +/-0.3mm vs. +/-0.5mm) and allowed to identify one malfunctioning leaf motor. Total system accuracy with MLC was 0.39 +/-0.06mm in 6 End-to-End tests. Delivered dose showed good agreement with calculated dose (typically Gamma(3%,3mm)<1 for >95% of pixels with D > 0.1 Dmax). Picket-Fence and AQA showed no adverse trends (> 1 yr).

Conclusion: The InciseTM MLC for CyberKnife M6TM displays high mechanical stability and accurate dose delivery. The specific CK geometry and performance after exercise demand dedicated QA measures.

Purpose or Objective: Small field dosimetry standardization is fundamental to ensure that different institutions deliver comparable and consistent radiation doses to their patients. The current study presents a multicenter small field evaluation including: Tissue Phantom Ratio (TPR), dose profiles FWHM and penumbra, and output factors (OF), for the two major linear accelerator manufacturers and different X-ray energies.

Material and Methods: The project enrolled 31 Italian centers, 15 equipped with Elekta Linacs and 16 with Varian Linacs. Each center performed TPR measurement, in-plane and cross-plane dose profile of 0.8x0.8cm² field and OFs measurements for field sizes ranging from 0.6x0.6 cm² to 10x10 cm² defined by both secondary jaws and MLC. Set-up conditions were: 10cm depth in water phantom at SSD 90cm. Measurements were performed using the new Exradin W1 plastic scintillator detector (Standard Imaging). The two canals SuperMAX electrometer (Standard Imaging) to automatically correct for Cherenkov radiation was used. Two identical W1 were used to speed up the data collection.

Results: The analysis included 13 Varian and 13 Elekta centers; 7 centers were excluded due to a condenser problem in an electrometer. As reported in Table 1 for the two most representative linac models, TPR measurements showed standard deviations (SD)=0.6%; penumbra values of dose profiles showed SD=0.5mm, while FWHM measurements showed a greater variability. As illustrated in Figure 1, OF measurements showed standard deviations within 1.5% for field size greater than 2x2 cm²; for field size less than 2x2 cm² measurements' variability increases with decreasing field size. OF values show no dependence from the effective field size.

Table 1. TPR, FWHM and penumbra values measured with W1 PSD for the two most representative linacs of the multicenter study

Manufacturer	Model	Energy	TPR	FWHM (mm)	Penumbra (mm)
Varian	Clinac 2100	6	0.670±0.003	8.1±0.4	7.9±0.5
Elekta	Agility	6	0.688±0.004	9.3±0.4	7.9±0.5

Fig. 1. OF values measured with W1 PSD for the two most representative linacs of the multicenter study

Conclusion: High TPR and penumbra values consistency were obtained over the centers. FWHM and OF showed greater variability, also considering Linac with the same model of the head. Measurements confirm W1 PSD as a good candidate for small field clinical radiation dosimetry in advanced radiation therapy techniques.

PO-0819

Analysis of liquid embolic agents on flattening filter free dose deposition with Monte Carlo method

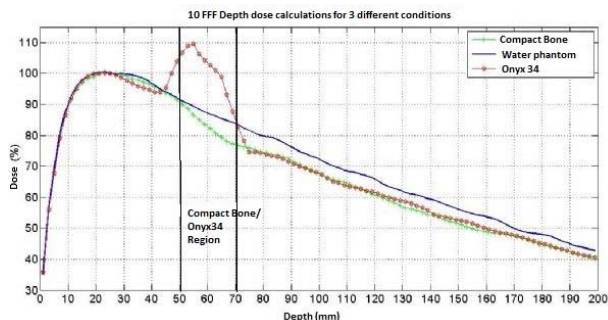

D. Akcay¹

¹Dokuz Eylul University Medical Faculty, Radiation Oncology, IZMIR, Turkey

Purpose or Objective: Brain Arteriovenous mal-formation (AVM), in some cases, is treated with Onyx34 liquid embolic system (LES) containing tantalum. Moreover, stereotactic radiosurgery (SRS) may be required when total obliteration is not achieved after embolization. Presence of tantalum in radiation field not only generates artefacts in computed tomography (CT) images but also it could arise dose distribution perturbations. Goal in this study was to analyze the perturbation effect of Onyx34 in flattening filter free (FFF) photon beams using GAMOS Monte Carlo (MC). Artefact cause analysis was also included in the study.

Material and Methods: GAMOS simulations for 6 FFF and 10 FFF photons were done in three different conditions: a) depth dose simulations in a water phantom containing 2x2x2 cm³ Onyx34 (inc. %35wt/vol Ta) medium at 5 cm depth, b) depth dose simulations in the same condition with compact bone instead of Onyx34, c) simulations in homogenous water phantom. Dose and photon flux scorers were used at central beam axis with 5x5x2 mm³ grid sizes. For comparison purposes, photon fluxes were also scored with broad photon beam with single photon energy of 80 keV. All of MC calculations were done with 1.5% and 0.5% statistical noise respectively.

Results: In 80 keV photon simulations, photon flux decreased around 50% at post Onyx34 region relative to homogeneous water simulations. However, for compact bone falloff was around 10% at the same geometry. Also, there was a remarkable flux reduction in pre-Onyx34 region which is not as much as post Onyx34 region. For both 6 and 10 FFF photon beams, around 5% of decrease was seen in photon flux and depth dose after Onyx34 and compact bone inhomogenities. Pre-Onyx34 region doses were increased by 15% for 6 FFF and 10% for 10 FFF.

Conclusion: Photon flux calculations for 80 keV beam, showed a considerable photon attenuation and lateral

scattering due to presence of Onyx34. As a result, photon starvation causes black-white streak artefacts in CT images. In conclusion, in AVM SRS planning the presence of LES can be taken into account by defining high density artefact region as a compact bone. However in vicinity of critical structures, the possible dose peaks must be considered at pre-Onyx regions which might not be calculated in treatment planning systems.

PO-0820

Volumetric quality assurance of RapidArc plans for multiple intracranial targets using gel dosimetry

N. Khater¹, C. El Khoury¹, M. Sarraf², J. Barouky¹, D. Nehme Nasr¹, F. Azoury¹, T. Felefly¹, R. Sayah¹, N. Farah¹, S. Achkar¹, E. Nasr¹

¹Hotel Dieu de France - University of Saint Joseph, Radiation Oncology, Achrafieh, Lebanon

²Clinatec-Cea-Grenoble, University of Joseph Fourier - University of Saint Joseph, Grenoble, France

Purpose or Objective: Given the unlimited spatial arrangements of multiple intracranial tumors, an evaluation of a planar sampling for end-to-end test is insufficient as it could provide no information about one or more tumors. Hence, a volumetric approach is needed. Here, we evaluate polymer gel dosimetry for three-dimensional (3D) patient-specific quality assurance (QA) in multiple brain lesions stereotactic radiosurgery (SRS) plans using volumetric modulated arc therapy (VMAT) technique.

Material and Methods: End-to-end test using polymer gel dosimeters was performed for an intracranial SRS case involving two lesions treated with VMAT - single isocenter approach. The following was performed: (1) BANG-3 polymer gel was prepared for two opaque spherical glass phantoms, one for patient plan QA and one for calibration; (2) the patient plan was delivered to the patient phantom and a simple non-modulated plan with predetermined doses was given to the calibration phantom; (3) 1.5T MRI was performed on both phantoms; (4) an in-house program was used to determine the relaxation rate maps (R2) from proton density and T2-weighted images; (5) CT scans were acquired with markers triangulating the isocenter of irradiation setups; (6) CTs were imported into Eclipse treatment planning system for dose computation in corresponding gel phantoms; (7) CTs and MRs were registered in Eclipse and registration transformations used to resample the R2 maps in corresponding CT positions using MATLAB. Then, data analysis was performed using an in-house visual-C++ code which took as input all 3D images, 3D dose, patients' structures exported from Eclipse and performed the following: (8) A calibration was extracted from the calibration gel and used in the patient gel QA; (9) the patients' structures were registered with the patients' gel using CT isocenter marks on the gel phantom and through the isocenter on the patients' plan; and (10) compared measured versus planned 3D isodose, dose volume histogram (DVH) analyses, and multi-slice 2D gamma evaluation.

Results: The measured isodose lines and surfaces were well visualized and qualitatively reproduced the calculated dose distribution (Figure 1). Gamma analysis between the dose matrices were carried out using gamma criteria 3% 3mm and 5% 5mm, % dose difference - distance to agreement combination within the volume enclosed by the 50% and the 80% isodose surface, respectively. Representative transverse slices yielded gamma pass rates of greater than 90%. Measured and planned DVH analyses showed agreement for planning target volume and organs at risk.

Conclusion: Polymer gel dosimetry shows promise for volumetric patient-specific QA of IMRS dose distributions. It does not present limitations when treatments involve couch rotation and gives a complete 3D assurance. However, it is labor intensive to be applicable in daily clinical practice. Nevertheless, the gel method has an important role during safe implementation of a SRS program.

PO-0821

A comparison between different patient QA devices for IMRT treatments on VERO system

A. Bazani¹, F. Pansini¹, C. Garibaldi¹, S. Comi¹, E. Rondi¹, G. Piperno², A. Ferrari², B.A. Jereczek-Fossa^{2,3}, F. Cattani¹

¹European Institute of Oncology, Medical Physics, Milan, Italy

²European Institute of Oncology, Radiation Oncology, Milan, Italy

³University of Milan, Radiation Oncology, Milan, Italy

Purpose or Objective: The purpose of this study was to compare the ability of OCTAVIUS® 4D phantom with 1000 SRS array (PTW) and ArcCHECK® system (SunNuclear) in detecting geometric and dosimetric errors intentionally introduced into the IMRT step-and-shoot treatments delivered with VERO® system (Mitsubishi Heavy Industries and BrainLAB). Moreover, the impact of these errors on the DVH of PTVs and OARs was investigated.

Material and Methods: The treatment plans of 3 clinical cases were considered (prostate, partial breast irradiation PBI and splenic lesion). From each of the original plans, 4 verification plans were created, containing one intentional error per plan: gantry rotation of +3°, ring rotation of +5°, 2% increased number of monitor units and isocenter translation of 3 mm (caudal direction). All the plans were calculated with iPlan 4.5.3 (BrainLAB) with a calculation grid of 2 mm on a mathematical phantom, for OCTAVIUS® 4D system, and on the CT images (plug inserted), for ArcCHECK®. The analysis was executed applying the 3D γ evaluation method (3% local dose-3mm and 2% local dose-2mm, 10% dose threshold), comparing the original calculated distributions with the measured ones (with errors) using the related software (VeriSoft® Patient Plan Verification Software for OCTAVIUS 4D®, coronal projection, and SNC Patient™ Software for ArcCHECK®). The tolerance level considered was 5% for the gamma failure rate (an error was considered detected when the gamma failure rate was higher than 5%). The impact of the errors introduced was evaluated by considering the DVH of PTVs (D98%, D2% and Dmean), rectum (D50% and D5%), ipsilateral lung (D40% and D10%) and spinal cord PRV (Dmax) respectively. The Pearson's correlation coefficient between the variation of the gamma passing rate and the variations of the DVHs points for the PTVs and the OARs considered was also calculated.

Results: The results of the 3D γ evaluation are reported in the figure, both for 3%-3 mm and 2%-2 mm criteria, for the

original plans and for the modified ones. Using McNemar's test, the total detection rate detected by ArcCHECK® was higher than that of OCTAVIUS® 4D (p= 0.045), with 3%-3 mm criteria, while it was comparable with 2%-2 mm criteria (p= 0.480).

The Pearson's correlation coefficient calculated between the variation of the gamma passing rate and the variations of the constraints for the OARs considered are shown in the table.

OCTAVIUS® 4D + PTW 1000SRS					
r	PTV			OAR	
	D98%	D2%	Dmean	Rectum D50%	Rectum D5%
Prostate					
3%-3 mm	0.848	0.236	0.408	-0.689	-0.994
2%-2 mm	0.587	-0.170	0.019	-0.840	-0.936
PBI					
3%-3 mm	0.899	0.543	0.294	Lung D40%	Lung D10%
2%-2 mm	0.691	0.057	-0.213	-0.048	-0.472
Spleen					
3%-3 mm	-0.131	0.135	0.248	PRV Dmax	-0.624
2%-2 mm	0.249	0.578	0.378	-0.777	

ArchCHECK®					
r	PTV			OAR	
	D98%	D2%	Dmean	Rectum D50%	Rectum D5%
Prostate					
3%-3 mm	0.059	0.651	0.609	0.900	0.502
2%-2 mm	0.283	0.779	0.773	0.806	0.294
PBI					
3%-3 mm	0.092	0.813	0.949	Lung D40%	Lung D10%
2%-2 mm	0.238	0.892	0.987	0.628	-0.332
Spleen					
3%-3 mm	0.576	0.414	0.874	0.649	-0.427
2%-2 mm	0.767	0.687	0.983	0.519	0.323

Conclusion: The results showed a different sensitivity to errors for the two systems, in particular in the case of ring and gantry rotations. This variation can be related to the different dose reconstruction methods applied: ArcCHECK® uses both the entry and exit dose, while OCTAVIUS® system the planar dose measured by the inserted detector and the PDD of the beam. Furthermore, no significant correlation was found between the results of the 3D γ analysis and the DVHs variations due to the intentional errors, as shown in literature.

PO-0822

Tumor margin estimation by multiple Bragg peak detection in carbon ion therapy

M.F. Ferraz Dias¹, C.A. Collins Fekete², G. Baroni¹, J. Seco³, M. Riboldi¹

¹Politecnico di Milano University, Dipartimento di Elettronica- Informazione e Bioingegneria - DEIB, Milano, Italy

²Université Laval, Département de Physique- de Génie Physique et d'Optique et Centre de Recherche sur le Cancer, Québec, Canada

³Massachusetts General Hospital MGH, Department of Radiation Oncology, Boston, USA

Purpose or Objective: Carbon ion therapy is very sensitive to tissue density variations along the beam path. Within the lung region, due to the high-density difference between tumor and lung tissue, these variations are further emphasized, leading to miss the tumor or high-dose deposition in critical structures. Hence, it is crucial to have correct knowledge of tumor margin. If one shoots these structures with a carbon beam with energy high enough to cross the patient and detects their residual range using a range detector, multiple peaks will be present in the acquired signal. This is caused by the fact that carbons from the same beam cross different structures. The purpose of this work is to show that using information from these multiple peaks, it is possible to measure the interface position using just a few irradiation spots, thus minimizing the imaging dose.

Material and Methods: Two approaches are proposed: the single shot approach is a theoretical model, which provides a relationship between the peaks intensity and distance from the interface; such approach only requires one shot around the interface to predict its position. The second approach (inflection point) entails irradiating the interface at two different positions and through an exponential fit compute the exact interface location. Both methods are validated using Monte-Carlo simulations with different interface configurations. A Carbon Digitally Reconstructed Radiography (CDDR) method is implemented in order to assess both methods in two lung tumor cases. Positional shifts to a water density tumor are implemented and the accuracy of the proposed methods is tested.

Results: Results show that both approaches exhibit an error <1mm in determining where the interface is positioned with respect to the beam. The inflection point method showed to be the most reliable, since it allows the determination of the interface when more than two peaks are detected using prior-knowledge information. Both methods offer a low dose approach, which will potentially allow adjustment of the irradiation beam position when a tumor shift occurs.

Conclusion: By measuring the difference between the two generated peaks at an interface, it is possible to determine its exact position with 1mm accuracy. Currently tumor margin positioning/delimitation is being accessed using multiple angle approaches and considering breathing motion effects. Future work will consider applying the same methods to other tumor areas and structures which can be used for patient positioning.

PO-0823

Five-year results of treatment quality assurance using in vivo dosimetry in ocular proton therapy

A. Carnicer Caceres¹, V. Letellier², G. Angellier¹, V. Floquet¹, W. Sauerwein³, J. Thariat¹, J. Hérault¹

¹Centre Antoine Lacassagne, Physics, Nice, France

²MedAustron, MedAustron, Wiener Neustadt, Austria

³Universitätsklinikum Essen, Universitätsklinikum Essen, Essen, Germany

Purpose or Objective: An in-house in vivo dosimetry system based on the measurement of gamma-prompt radiation emission during irradiation was implemented for quality assurance of ocular proton therapy treatments at the Centre Antoine Lacassagne (CAL) in 2011. Based on the last five years results we report the performance and limitations of the system.

Material and Methods: Gamma-prompt radiation is emitted during proton therapy irradiation by collision of protons with beam modifiers all along the optical bench. A correlation was established at CAL between gamma-prompt radiation and the

accessories conforming the clinical SOBP (range shifter and modulating wheel), by measuring, for a large set of treatment sessions, the charge cumulated (Q) at a large volume ionization chamber located inside the treatment room at 3 m from the optical bench. A power function was used to fit the dose rate D/MU and Q/D data points, where D is the dose delivered to the patient. The function was introduced to an in-house Visual Basic code to automatically retrieve the differences (d) between calculated and expected D/MU. A tolerance of 5% was established, out-of-tolerance cases requiring systematic SOBP accessories checking. Out-of-tolerance rate was calculated from more than 4000 treatment sessions performed from May 2011 to September 2015. Out-of-tolerance causes were analysed by assessing uncertainties on the ionization chamber measurement acquisition (repeatability test performed in reference treatment conditions (10 s irradiation, 13 Gy and 1.37 cGy/UM)), correlations of d with D, D/MU and Q and the impact of the customized patient accessories located just before the eye (collimators, filters and compensators).

Results: The relative differences were normally distributed and centered on 0.004% with a σ of 3%. 12% of cases were out-of-tolerance, only 2% being larger than 7%. Out-of-tolerance cases were never related to an error on SOBP accessories. More than 60% cases with differences larger than 7% were related to low dose treatments (<7 Gy). Relative differences were not correlated to the use of filters or to the collimator area. Treatments performed with compensator yielded higher differences (doses are below 7 Gy for these treatments). The uncertainty on Q acquisition was estimated to 0.8%. Cumulating Q beyond the treatment time (40 s) increased the relative difference by 2%.

Conclusion: The system is independent of the customized patient accessories located right before the eye. The precision is consistent with in-vivo dosimetry systems and yields results within or very near tolerance limits for most standard treatments performed at CAL (13 Gy). Out-of-tolerance cases could be minimized by limiting the ionization chamber measurement acquisition time. The method perfectly fulfills the goal of SOBP accessories verification, and could be further improved by reviewing the default for low dose treatments.

PO-0824

Treatment couch modeling in Elekta Monaco treatment planning system

C. Huertas¹, C. Ferrer¹, C. Hueriga¹, I. Mas¹, A. Serrada¹

¹H.U. La Paz, Radiofísica y Protección Radiológica, Madrid, Spain

Purpose or Objective: This study describes the modeling of the treatment couch in Elekta Monaco treatment planning system (v. 3.30.01), and the measurements made to validate it for attenuated and skin dose calculation, and 6MV energy beams.

Material and Methods: The iBEAM evo carbon fiber couch has a sandwich design. It consists of a narrow outer layer of electron density $\rho_E=1.7\text{gr/cm}^3$ and a foam core of lower density $\rho_E=0.3\text{gr/cm}^3$.

First modeling was composed of a single contour. CT images were acquired and the couch contoured in each slice. The dimensions were according to vendor specification. The best agreement between experimental and computed dose attenuation was using an effective density of $\rho_E=0.13\text{gr/cm}^3$. However, the comparison failed at the edges of the couch. Therefore, a second contour has been added with the thick of the edges and the density of carbon fiber $\rho_E=1.7\text{gr/cm}^3$. That way, calculations vary slightly with grid size and don't depend on the order of ROIs.

A cylindrical phantom with an ionization chamber CC13 placed in the central insert was used to measure the attenuated dose. The phantom was centered laterally on the couch and the chamber position coincides with linac isocenter. Dose measurements were performed for an open 10x10 field at multiple gantry angles, $M\theta$, 100 Monitor Units

(MU) were delivered at each angle: The reference dose without couch attenuation is the average dose at 0°, 90° and 270°. Gantry angles ranging from 235° to 223° in 1° increments are used to measure the edge attenuated dose. And gantry angles ranging from 220° to 180° in 10° increments to measure the dose attenuation of the central region of the couch.

Skin dose was measured with radiochromic films and FilmQA Pro. Several films were placed between RW3 slabs in different depths. The center of RW3 phantom coincides with linac isocenter.

First, films were located at the surface, 0.5cm and 1.5cm from the surface, and in the center of the RW3 phantom. Then 200MU were delivered with an open 10x10 field and with zero gantry angle. The irradiated films were removed and other films were placed under the phantom, 0.5cm and 1.5cm from the couch and in the center. The opposite beam was delivered, so we measure the effect of the couch to the dose distribution in the buildup region.

Results: Table 1A Comparison results between measured and calculated relative transmitted dose (T%), with and without the couch. Table 1B Evaluation of skin dose increment and comparison results between scanned and calculated increment of skin dose.

TABLE 1A									
Angle	Monaco						Measurements

average difference %			3.3	average difference %			0.4		

TABLE 1B				
	Monaco		Radiochromics	
	Dose (cGy)	percentage of Dmax	Dose (cGy)	percentage of Dmax
AP 10x10 SSD=91cm, 200MU without couch				
Over 18cm of RW3 (at the surface)	56.5	23.7	49.8	20.9
0.5cm from the surface	213	89	205	86
1.5cm from the surface	239	100	238	100
Iso. at 9cm depth	174	73	166	69.8
PA 10x10 SSD=91cm, 200MU with couch				
under the phantom, 18cm of RW3	228	93.8	221	92
0.5cm from the couch	241	99.4	239	99.5
1.5cm from the couch	243	100	240	100
Iso. at 9cm of depth	158	65	163	67.7
Increment of skin dose	3.96		4.4	

Conclusion: The couch model improves the discrepancy between measured and computed attenuated dose. If we take into account the couch in treatment planning calculations, this average difference decreases from 3.3% to 0.4%. The couch increases 4 times the skin dose and the couch model provides an accurate calculated dose in the buildup region.

PO-0825

Characterization of a commercial EPID 3d software for in vivo dosimetry.

M. Esposito¹, P. Bastiani², A. Bruschi¹, A. Ghirelli¹, S. Pini¹, G. Zatelli¹, S. Russo¹

¹Azienda Sanitaria Firenze, Fisica Sanitaria, Firenze, Italy

²Azienda Sanitaria Firenze, Radioterapia, Firenze, Italy

Purpose or Objective: Dosimetry Check (DC) is a commercial software that allows reconstruction of 3d dose distributions

using transit and through-air EPID images. DC is composite of two parts: a deconvolution kernel that converts EPID images to fluence, and a pencil beam algorithm to calculate the dose. It can be used for pre treatment QA verification and for in vivo dosimetry. In this work we evaluated the suitability of DC software for in vivo dosimetry of VMAT treatments.

Material and Methods: DC (v4.10) was used along with Elekta Synergy® Linac (6 and 10 MV beams) equipped with a-Si Electronic Portal Imaging Device (EPID) Iview-GT. Twenty VMAT (5 prostate, 5 whole pelvis, 5 lung, 5 head and neck), elaborated by treatment planning system (TPS) Elekta Monaco® 5.0 were measured. Through-air (EPID T-A) and transit EPID images were used for three dimensional dose maps reconstruction in homogeneous phantoms. Octavius 4D with 729 2D array was used as reference. Gamma analysis at 3% local dose /3mm DTA was performed. Doses from through-air measurements were also reconstructed in the planning CT (T-A in plan TC) and compared with the treatment planning dose maps. Gamma pass rate of DC dose maps were compared with those of 729 in the Octavius 4D.

Results:

Anatomical Site	Energy	Octavius 4d	EPID T-A	EPID Transit	T-A in plan TC
Prostate1	X10	97.7	92.6	92.5	92.9
Prostate2	X10	95.4	83.3	87.1	81.3
Prostate3	X10	96	91.8	92.5	94.8
Prostate4	X10	96	90.5	89.9	90.2
Prostate5	X10	98.8	94.8	95.4	95.9
Whole Pelvis1	X10	92.5	94.4	95.9	94.5
Whole Pelvis2	X10	88.9	95.2	85.9	93.5
Whole Pelvis3	X10	88.9	91.8	83.6	91.8
Whole Pelvis4	X10	88.1	90.2	84.6	86.3
Whole Pelvis5	X10	89.3	95.5	92.34	95.6
Lung1	X6	97.7	92.0	96.8	89.2
Lung2	X6	98.0	96.8	97.8	85.8
Lung3	X6	96.0	97.5	99.4	79
Lung4	X6	97.2	93.4	98.7	72.8
Lung5	X6	97.0	96.8	97.4	96.3
Head and Nek1	X6	90.3	81.9	72.4	89.7
Head and Nek2	X6	91.2	70.1	73.8	90.6
Head and Nek3	X6	92.9	75.9	73.4	90.7
Head and Nek4	X6	92.5	80.1	83.3	94.5
Head and Nek5	X6	92.6	79.5	86.4	89.8

Table1 Gamma pass rate. EPID T-A are computed in the synthetic Octavius 4D phantom, EPID transit is measured and computed in the homogeneous Octavius II phantom.

Figure1: Results of a whole pelvis SIB treatment. In the upper part comparison of profiles for Octavius 4D (A), T-A EPID (B) and Transit EPID (C). In yellow the TPS profile. The lower part of the image contains central coronal map of gamma>1 points. In D the comparison of DVH measured by DC in plan CT (solid) versus TPS (dotted lines) is shown.

Gamma pass rates are shown in the table1. The assessment of VMAT plans shows a mean of 93.9% points with gamma<1 for Octavius 4d (3.5% SD), 89.2% and 7.9%SD for EPID T-A, 89% and 8.5% SD for EPID Transit and 89.8% and 6.1%SD for T-A in plan CT. Transit and through-air EPID acquisitions produced similar gamma pass rates. Through-air EPID images computed by DC in the planning CT showed gamma pass rate in agreement with those of Octavius 4d in the prostate, whole

pelvis and head and neck, in lung instead, gamma pass rates were lower in 4/5 cases.

Conclusion: DC is a suitable tool for VMAT in vivo dosimetry. The pencil beam algorithm can be inaccurate in the presence of low-density inhomogeneities.

PO-0826

Benchmarking computed IDD curves for four proton treatment planning systems against measured data

J. Alshaihi^{1,2}, D. D'Souza², C.G. Ainsley³, I. Rosenberg², G. Royle¹, R.A. Amos²

¹University College London, Medical Physics & Biomedical Engineering, London, United Kingdom

²University College London Hospitals, Radiotherapy Physics, London, United Kingdom

³University of Pennsylvania, Roberts Proton Therapy Center, Philadelphia, USA

Purpose or Objective: Accurate beam modelling is an essential function of a treatment planning system (TPS) to ensure that plans can be calculated that are deliverable within clinically acceptable tolerances. The purpose of this work is to evaluate the computed integral depth dose (IDD) curves of four commercially available proton TPSs, benchmarked against measured data. The four TPSs (EclipseTM, XiO®, Pinnacle3, RayStation®) were commissioned using pencil beam scanning data from the University of Pennsylvania (UPenn) facility.

Material and Methods: A water cube phantom (40cm³) was created in each TPS for calculation of IDD curves. Calculation grid size set to 1mm in all TPSs. Individual IDDs for 27 nominal energies, ranging from 100 to 226.7MeV, were calculated by integrating the calculated depth dose distributions. These were all benchmarked against measured data from UPenn, comparing the clinical range at 80% distal dose (D80), Bragg peak width between distal and proximal 80% (D80-P80), range at 0.5% (R0.5), and distal penumbra between D80 and R0.5. Gamma-index analysis with pass criteria of 1mm/1% was also used to compare computed and measured IDDs.

Results: Mean percentage of IDDs with >95% pass rate for 1mm/1% criteria were 96.7% (SD 4.9) for XiO®, 94.1% (SD 8.9) for EclipseTM, 95.4% (SD 8.6) for RayStation®, and 49.2 (SD 26.0) for Pinnacle3. Maximum differences between computed and measured IDD data are shown below. No correlation with nominal energy was observed.

	Maximum differences [mm]			
	Range 80% (D80)	Peak width (D80-P80)	Distal penumbra (D80-R0.5)	Range 0.5% (R0.5)
XiO®	0.1	0.1	0.2	0.2
Eclipse™	0.8	0.6	1.1	1.2
RayStation®	0.3	0.4	0.8	0.8
Pinnacle ³	0.4	0.6	0.9	1.3

Conclusion: Characteristics of computed IDDs were compared to measured data for four commercially available TPSs. All were within clinically acceptable tolerances, with XiO showing the closest agreement. Differences observed were attributed to TPS specific beam modelling. Further investigation will assess the cumulative impact of these discrepancies on verified clinical treatment plans.

PO-0827

Principal component analysis for deviation detection in 3D in vivo EPID dosimetry

R.A. Rozendaal¹, B. Mijnheer¹, I. Olaciregui-Ruiz¹, P. Gonzalez¹, J.J. Sonke¹, A. Mans¹

¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Department of Radiotherapy Physics, Amsterdam, The Netherlands

Purpose or Objective: One of the clinical issues our institute faces regarding in vivo EPID dosimetry is the number of raised alerts. For example, alerts are raised for 49% of the treatments in case of head-and-neck (H&N) VMAT treatments; an alert is raised when dosimetry results are

found deviating according to statistics derived from the histogram of 3D γ -analysis results. These alerts are mostly found to be patient-related or attributable to limitations of our back-projection and dose calculation algorithm. After inspection, an intervention is considered for only 0.3% of the treatments. The purpose of this study is to develop a principal component analysis (PCA) based classification method to improve the specificity of our EPID dosimetry system. In particular, in contrast to our current classification method, PCA allows for the spatial distribution of γ -values to be taken into account for deviation detection.

Material and Methods: The input for PCA consisted of 3D γ -distributions (3%/3mm), one per treatment arc per fraction. In total, 2024 3D γ -distributions from 499 H&N VMAT treatment-plans were included. As an initial choice, components describing at least 1% of the variance were selected. The distribution of variances over the components was inspected to validate this choice. Using these components, new 3D γ -distributions were created by projecting each input 3D γ -distribution on only these components and then projecting the result to the original coordinate system of the 3D γ -distributions. If the selected components describe the original γ -distribution well, the new and original γ -distributions will be similar. This similarity was quantified by the root mean square (RMS) of the difference between the two γ -distributions; a γ -distribution was marked as deviating when d exceeded a threshold. All true positive γ -distributions ($n = 2$) in the dataset, as identified by experienced medical physicists, were used to determine this threshold for identification of alerts.

Results: The first 16 components were each found to describe at least 1% of the variance; cumulatively, they account for 83% of the variance in the dataset. Figure 1 shows the cumulative variance accounted for as a function of selected components and indicates that the choice for selecting components is reasonable. After finding and applying the appropriate threshold for detecting the identified true positives, a drop in alert rate from 49% to 11% was observed, corresponding to an increase in specificity from 0.51 to 0.89.

Conclusion: The PCA-based classification method presented in this study enhances the specificity of deviation detection in 3D in vivo EPID dosimetry of H&N VMAT from 0.51 to 0.89, compared to our current clinical γ -histogram based method. Before clinical implementation, a rigorous validation is required.

PO-0828

Dosimetric assessment of a second generation Multi-Leaf Collimator for robotic radiotherapy

P.H. Mackeprang¹, D. Schmidhalter¹, D. Henzen¹, M. Malthaner¹, D.M. Aebbersold¹, P. Manser¹, M.K. Fix¹

¹Division of Medical Radiation Physics and Department of Radiation Oncology Inselspital, Bern University Hospital, and University of Bern, Switzerland

Purpose or Objective: Recently, a second generation Multi-Leaf Collimator (InCise 2™) was released for the CyberKnife® M6™ robotic radiotherapy system. As part of the evaluation and initial characterization, physical, dosimetric and planning parameters were recorded. Further, planning studies on phantoms were performed to compare the InCise 2 to the Iris™ collimator system.

Material and Methods: As part of the InCise 2 validation, leakage, TG-50 picket fence, Bayouth fence and automated quality assurance measurements were performed using radiochromic film. End to end delivery tests were performed for skull-, fiducial-, x-sight spine-, x-sight lung- and synchrony tracking. Ten treatment plans and five QA plans were delivered to phantoms using the InCise 2. Ionization chamber measurements as well as film measurements were compared with dose calculated by the treatment planning system. For dosimetric assessment, treatment plans to water phantoms were generated using the IRIS collimator system and the InCise 2 MLC. On a cylindrical water phantom of a diameter of 20 cm, spherical target volumes of diameters from 5 to 80 mm were drawn. Firstly, the dose optimization algorithm using the MLC was assessed using a simple Optimize Minimum Dose (OMI) objective. Secondly, shell volumes were generated around the target volumes and their coverage was optimized (OCI). 1000 cGy were prescribed to the 80% isodose. Dose distributions, Nakamura's new Conformity Index (nCI) as well as optimization and estimated treatment times were analyzed.

Results: All validation tests were passed within tolerances. Maximum leakage was recorded as 0.44% for all MLC orientations. Mean leaf positioning errors in Bayouth fence tests ranged from -0.043 mm to 0.006 mm, without any individual leaves exceeding the tolerance of ± 0.27 mm. All phantom plans were delivered successfully, with recorded dose for QA plans differing 1.94% $\pm 1.03\%$ from calculated dose and gamma analysis (3% / 1mm, 20% dose threshold) showing > 97% agreement. Total end to end tracking errors were below 0.95 mm for all tested tracking methods. Testing the optimization algorithm revealed nCI values for plans optimized based on target volume shells between 1.02 and 1.50 for plans using the InCise 2 and 1.05 and 1.43 for IRIS. MLC optimization times increased as a function of both target size and optimization steps, ranging from 12 s for the 5 mm PTV OMI plan to 7 h for the 80 mm PTV shell based optimization. Estimated treatment times including setup times for the synthetic plans were reduced by a mean of 19.1% when choosing the InCise 2 over the IRIS.

Conclusion: The InCise 2 MLC system passed initial physics evaluation at our site and showed dose distributions comparable to the CyberKnife IRIS collimator system for spherical targets. Estimated MLC treatment times are about 20% lower compared to the IRIS collimator system.

PO-0829

Determining the mechanical properties of a radiochromic deformable silicone-based 3D dosimeter

L.P. Kaplan¹, E.M. Høye², P. Balling¹, L.P. Muren², J.B.B. Petersen², P.R. Poulsen², E.S. Yates², P.S. Skyt²

¹Aarhus University, Dept. of Physics and Astronomy, Aarhus C, Denmark

²Aarhus University/Aarhus University Hospital, Dept. of Oncology, Aarhus C, Denmark

Purpose or Objective: Recently emerged radiotherapy methods such as intensity-modulated or image-guided radiotherapy are capable of delivering very conformal dose distributions to patients, but their accuracy can be greatly compromised by e.g. the deformation of organs in the patient. The accuracy of deformable registration algorithms developed to correct for this is not well known due to the challenging nature of deformation measurements. A new type of deformable radiochromic 3D dosimeter consisting of a silicone matrix has recently been developed in our group. This dosimeter makes direct dose measurements in deformed geometries possible. The aim of this study was to investigate

its mechanical properties in terms of tensile stress and compression.

Material and Methods: The dosimeter contained the SYLGARD® 184 Silicone Elastomer kit (Dow Corning), Leuco-Malachite Green (LMG) dye as the active component and chloroform as solvent and sensitizer. To determine the shape of the dosimeter's stress-strain curve and Young's modulus (Y), tensile stress was imposed on rod shaped samples along their central axis and the resulting strain was observed using a camera. To define Y a linear approximation was made for small strains. This was done at varying times after production, for varying curing agent concentrations and for both irradiated and non-irradiated dosimeters. 10×10 cm² photon fields with beam quality 6 MV were used to deliver a dose of 60 Gy at 600 MU/min. To investigate whether the density of the material is conserved under compression, dosimeters were CT-scanned while placed in a wooden clamp to impose varying degrees of compressive stress. Finally, dosimeters were also partially irradiated while subject to tensile stress to see if the irradiated areas would return to the original geometry once the stress was removed after irradiation.

Results: The measured stress-strain curves did not show hysteresis or plastic deformation, even after multiple deformations. Y was found to be 0.08-0.2 MPa 48 hours after production depending on the amount of curing agent (see figure), and it increased at an exponentially decreasing rate for up to several weeks afterwards due to further hardening. Irradiation prior to imposing tensile stress did not affect the mechanical properties immediately, but it slowed the hardening process in the following days. The volume was found to be conserved during compressive stress of up to 60%. Multiple tests showed that dosimeters irradiated partially under tensile stress returned completely to their original geometries after removing the stress (see table).

Figure 1: Stress-strain curve for dosimeters with varying curing agent concentrations 48 hours after production. The un-filled markers indicate measurements taken while loading, while the filled markers show measurements taken while unloading. Notice that these coincide well with the un-filled markers, indicating the absence of hysteresis. Linear fits are included for strains smaller than 0.5. Error bars are not included, as they are smaller than the markers.

Table 1.1: Dosimeters irradiated under tensile strain. All dosimeters were irradiated with a field 0.5 cm wide.

Original length of irradiated area (no strain) ¹ (cm)	Length after irradiation(cm)
0.5	0.5
0.44	0.48
0.41	0.41
0.38	0.39
0.34	0.34
0.31	0.32
0.28	0.28
0.25	0.27
0.19	0.21

¹ Due to the setup there was an uncertainty of $\approx \pm 0.05$ cm in determining the original length of the areas to be irradiated.

Conclusion: The dosimeter's deformable properties are not altered significantly by repeated strain or irradiation, its volume is conserved under compression and it displays predictable behavior when being irradiated under strain. These properties makes the dosimeter a very strong candidate for direct dose measurement in deformed geometries.

PO-0830

Correlation of MLC positions detected using log-files with MLC positions detected using the EPID

W. Lechner^{1,2}, A. Moser^{1,2}, A. Altendorfer^{1,2}, D. Georg^{1,2}

¹Medical University of Vienna, Department of Radiation Oncology, Vienna, Austria

²Medical University of Vienna, Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria

Purpose or Objective: The Purpose of this work was to investigate the long term correlation between leaf positioning errors determined using LINAC log-files with an independent method.

Material and Methods: A picket fence pattern was irradiated on four different LINACs with simultaneous EPID measurement and log-file recording. Measurements were performed on two VersaHD and two Synergy LINACs (Elekta AB, Stockholm, Sweden) over a period of six months on a weekly basis. The picket fence pattern consisted of 5 bands with a width of 2 cm. The positions of bands' centers were -11 cm, -2 cm, 0 cm, 2 cm and 11cm. An in-house developed software was employed to calculate the deviation of the actual leaf positions according to the log-file data from the planned position. The simultaneously acquired EPID images were analyzed using MLCSoft-EPID (PTW, Freiburg, Germany) and provided reference data. The sensitivity of all measurement methods was evaluated by means of implementing leaf errors in the picket fence pattern. The sensitivity of both methods was investigated by artificially introducing leaf positioning errors of 0.5 mm, 1 mm and 2 mm. In order to investigate the correlation between log-file and EPID data, Pearson's correlation coefficient was calculated considering all leaves as unity of each LINAC over the measurement period (henceforth denoted as total correlation coefficient p_{tot}). Additionally, Pearson's correlation coefficient was calculated for each leaf separately (p_L). The percentage of the absolute value of p_L exceeding 0.6 was reported.

Results: The artificially introduced errors were detected by both measurement systems. The total correlation coefficients for LINAC 1, LINAC 2, LINAC 3 and LINAC 4 were 0.44, 0.06, 0.61 and -0.19, respectively. In contrast to that, only 0%, 2.04%, 6% and 0% of the absolute values of correlation coefficients calculated for each leaf separately exceeded a value of 0.6. These results are summarized in Table 1. In Figure 2 depicts an example of a scatter plot of the data acquired for LINAC 2.

Fig 1: Scatter plot of all simultaneously measured leaf deviations of LINAC 2. The blue line represents a linear fit of the data. The correlation coefficient for this LINAC was 0.06

Table 1:

	LINAC 1 Synergy	LINAC 2 VersaHD	LINAC 3 Synergy	LINAC 4 VersaHD
p_{tot}	0.44	0.06	0.61	-0.19
$abs(p_L) > 0.6$ (%)	0	2.04	6	0

Conclusion: When investigating the correlation of MLC positioning errors detected with different methods, it is not sufficient to consider correlation coefficients based on sets of leaves, since a bias could be introduced. Such correlations must be investigated for each single leaf separately. This investigation revealed a poor correlation between log-file detected leaf positioning errors with EPID detected leaf positioning errors. However, deviations from planned leaf positions can potentially be detected using log-files, provided that a rigorous MLC quality assurance procedure using an independent system is performed on a regular basis.

PO-0831

Does a single MLC characterization guarantee a high accuracy of RapidArc delivered dose?

A. Scaggion¹, N. Pivato¹, A. Roggio¹, M. Paiusco¹

¹Instituto Oncologico Veneto IOV-IRCCS, Medical Physics, Padova, Italy

Purpose or Objective: In order to improve the accuracy of RapidArc delivered doses, users of Eclipse TPS commonly are forced to tailor the values of dosimetric leaf gap (DLG) and MLC transmission factor (TF). The aim of this work is to propose a methodology to improve the agreement between planned and delivered dose identifying a suitable group of (DLG,TF) couples.

Material and Methods: The 2D variation of DLG and TF has been measured for a Varian Unique Linac equipped with a Millennium 120 MLC. Using the 2D maps of DLG and TF an optimal couple (DLG,TF) has been computed for 50 treatment plans including H&N, chest and pelvis. A clinical couple (DLG,TF) has been computed as the mean over each optimal couple for the entire group of plans and for subgroups. Pre-treatment QA has been performed using a cylindrical diodes array and analyzed using both gamma index and DVH-oriented metric. QA results of any calculated plan has been correlated with the distance between the clinical couple and the optimal one. Finally a sensitivity analysis has been performed to assess a relation between the results of pre-

treatment QA and the minimum number of clinical couples (DLG,TF) needed to ensure the acceptance of all plans.

Results: The optimal couple of (DLG,TF) was found to vary with MLC motion complexity: as the MLC apertures became smaller and more irregular DLG and TF increase. As a consequence the optimal value of (DLG,TF) vary with district from (2mm,1.7%) for prostate plans to (2.35mm,1.9%) for H&N ones. Despite this rough classification, some differences within the same district can arise when target volumes are significantly different from typical values. Because of this differences the use of a single couple (DLG,TF) can lead to mean dose deviations as large as 5% between planned and delivered dose. In our case three different (DLG,TF) couples were found to be enough to ensure a local gamma (3%,3mm) passing rate larger than 95% for each plan. Once a significant database has been collected the optimal couple (DLG,TF) to be used for a new plan can be a priori decided considering the anatomical district. The choice can be then confirmed after a single optimization process computing the optimal couple for that plan and evaluating the distance from the clinical couple to foresee the expected degree of dosimetric agreement.

Conclusion: Our work shows that a single optimal couple (DLG,TF) can not be found for all possible clinical plans, but three MLC configurations can be enough to ensure the accuracy of delivered dose. A method to identify the group of MLC configurations is proposed together with indications about how to identify the appropriate couple to be used for any plan.

PO-0832

Preliminary scanning water phantom data for beam characterisation of a hybrid MRI-Linac

S. Woodings¹, H. Van Zijp¹, T. Van Soest¹, P. Woodhead², M. Duglio², N. Marinos², S. Pencea², D.A. Roberts², J. Kok¹, J.W.H. Wolthaus¹, B.W. Raaymakers¹

¹University Medical Center Utrecht, Radiotherapy, Utrecht, The Netherlands

²Elekta Limited, Linac House, Crawley, United Kingdom

Purpose or Objective: An Elekta MR-Linac (MRL) prototype has been installed at the author's institute, combining 1.5 T magnetic resonance imaging (Philips) with linear accelerator treatment (Elekta). A novel method for alignment and use of a scanning water phantom has been established. The first data of sufficient precision and quantity to characterize the beam has been acquired in a 1.5 T magnetic field for the purposes of beam modelling and/or beam verification.

Material and Methods: The isocentre is located at 143.5 cm from the linac target and is within an enclosed MRI-like bore which affects the use of a water phantom. A prototype MR-compatible water phantom (PTW) was used to acquire percentage depth doses, inline and crossline scans, relative output factors and collimator scatter factors with a CC04 ion chamber (IBA) and a micro-diamond detector (PTW). An exit PDD showing the electron return effect was also acquired. Position and orientation of the phantom was established using radio-opaque markers and a gantry-mounted electronic portal imaging device.

Linac-specific parameters such as gantry tilt, EPID rotation and isocentre location were independently checked using the water phantom.

Results: The beam energy is consistent with a nominal 7.3 MV photon beam (TPR 0.702), however the depth of maximum dose is 13 mm, closer to the surface than in a standard field due to the 1.5 T magnetic field. Inline profiles are generally consistent with those of a standard flattening-filter-free beam, however the crossline profiles are clearly distinct with an off-axis shift and asymmetric penumbral shoulders and feet due to the Lorentz force of the magnetic field on the secondary electrons. Small field data were acquired taking into account the dose-shift due to the magnetic field.

The relative output factors are consistent with those from a standard FFF beam, with no evidence of abnormal variation for small fields.

Final results will be presented.

Conclusion: Practical use of a scanning water tank has been established in an MRL. The data presented here comprises the first substantial collection of MRL data that can be used for beam characterization. The dataset is suitable for calculating relative doses and testing planning system model performance in a 1.5 T magnetic field.

Measured neutron spectra & dose: craniospinal irradiation on single-room passively scattered proton

R. Howell¹, E.A. Burgett², D. Isaccs², S.G. Price Hedrick³, M.P. Reilly³, L.J. Rankine³, K.K. Grantham³, S. Perkins³, E.E. Klein³

¹UT MD Anderson Cancer Center Radiation Physics, Radiation Physics, Houston- TX, USA

²Idaho State University, Nuclear Engineering, Pocatello, USA

³Washington University, Radiation Oncology, St. Louis, USA

Purpose or Objective: Secondary neutron dose is of particular concern in proton craniospinal irradiation (CSI) as this treatment is primarily used to treat children and adolescents, who are at significant risk of developing radiation-related late effects. While Monte Carlo techniques have been used to calculate such data for proton CSI, doses that are based on spectra measurements are lacking in the literature. Furthermore, the existing data are only reported for one of the proton beamline manufacturers. Given that doses from externally generated neutrons are highly dependent on the design of the proton therapy machine itself and treatment-specific devices within the beamline, there is a need to report doses for all beamlines used to treat proton CSI. Single-room compact proton systems are particularly noteworthy as many units are currently operational and more are being commissioned and installed. Therefore, the objectives of the present study, for a typical passively scattered proton CSI treatment, were to measure the secondary neutron spectra and calculate dose equivalents for neutrons delivered via a single-room compact system.

Material and Methods: Secondary neutron spectra were measured using extended-range Bonner spheres for three different clinical CSI proton fields, including their respective brass apertures: whole brain, upper spine, and lower spine. For each field, measurements were repeated with an active scintillator and 18 different moderating. Measurements were performed with a water phantom at isocenter and the detector located at 50 cm from the isocenter along the patient plane. For each set of measurements, neutron spectra were determined by mathematical deconvolution of detector count rates. Ambient dose equivalents [H*(10)] were calculated using ICRP-74 conversion coefficients to the fluence spectra.

Results: The measured neutron spectral fluence and H*(10) for each field are shown in Figure 1a and 1b, respectively. The energy distributions for each of the fluence spectra were similar, with a high-energy direct neutron peak, an evaporation peak, a thermal peak, and an intermediate continuum between the evaporation and thermal peaks. Neutrons in the evaporation peak made the largest contribution to the dose equivalent. The, H*(10) in mSv per proton Gy to isocenter were 3.94, 2.79, and 2.71 respectively, for the brain, upper spine, and lower spine fields. Neutron fluence and H*(10) were approximately 1.6 times higher for the brain field than for the spine fields, which is attributed to the greater range and modulation for the brain field than for the spine fields.

Conclusion: We measured neutron spectra and calculated neutron dose equivalents for a clinical treatment for a single gantry proton system, whose use and planned installations have recently increased. Data reported here are consistent with dose equivalents reported for CSI carried out with other proton therapy beamlines.

Calibrating absolute malignant induction probabilities into life-time attributable risk

A. Madkhali^{1,2}, C. Timlin³, M. Partridge¹

¹University of Oxford, CRUK/MRC Oxford Institute for Radiation Oncology, Oxford, United Kingdom

²King Saud University, College of Medicine - Department of Medicine, Riyadh, Saudi Arabia

³University of Oxford, PTCRI, Oxford, United Kingdom

Purpose or Objective: More than half of cancer patients receive radiotherapy for radical or palliative purposes. Increasing survival rates in cancer patients make it important to study late side-effects, including secondary radiation-induced cancers. Although a number of predictive models exist, the absolute accuracy of these models in the radiotherapy dose range is limited partly due to scarcity of data and partly by extrapolation beyond historical data bounds. The aim of this work is to investigate conversion of malignant induction probabilities, which provide useful relative risk estimates, into absolute life time attributable risk estimates (LAR) and excess absolute risk (EAR) by calibrating and benchmarking our models using published outcome data.

Material and Methods: An in-house modelling tool, which calculates voxelwise risk estimates from patient-specific 3D dose distributions, was modified to generate linear-no-threshold (LNT) model-based risk estimates for the whole body and per organ using organ-equivalent dose. Second cancer risk was calculated for uniform whole-body exposure of 0.1 Gy for comparison with tabulated BEIR VII data. Model parameters initially used were taken from existing published reports for the relevant models. The calculated LAR was then compared to the BEIR VII results and the linear coefficient, λ , was adjusted to make the model prediction better match the BEIR VII result. A similar calibration of parameters was then performed for the linear quadratic (LQ) and linear model

(LIN) malignant induction coefficients. EAR was calculated for a dose range to compare results with published data.

Results: After calibration, calculations of LAR for single uniform exposure of 0.1 Gy produced a value of 837 cases per 100,000 for an exposure at age of 40, in comparison to 824 according to BEIR VII report. Averaging over ages at exposure of 20 to 80 produced a value within 5% of the BEIR VII report. Calculations of EAR for a dose range relevant to RT of 1-6 Gy using the LIN model were always within the range of uncertainty due to differences in RBE neutron value in the independent published Hodgkin Lymphoma data (Schneider et al, 2008).

LAR for 0.1 Gy single exposure - after calibration (LIN)

LAR for 0.1 Gy single exposure - after calibration (LIN)

Conclusion: These results show that our models can produce absolute LAR estimates for secondary cancer which are consistent with the values reported in the BEIR VII report for uniform irradiation to 0.1Gy. The comparison of our results of EAR using LIN model to published data showed agreement with independent published data of HL.

PO-0835

A system for measuring and calculating neutron doses in paediatric proton patients

R. Schulte¹, S.D. Clarke², E. Pryser², B.M. Wieger², M. Norsworthy², S.A. Pozzi², R. Hälgl³, A. Lomax³, V. Smyth⁴, A. Ottolenghi⁴

¹Loma Linda University, Division of Radiation Research, Loma Linda, USA

²University of Michigan, Nuclear Engineering and Radiological Sciences-, Ann Arbor, USA

³Paul Scherrer Institut, Center for Proton Therapy-, Villigen, Switzerland

⁴University of Pavia, Physics, Pavia, Italy

Purpose or Objective: There is increased use of proton therapy in paediatric cancer patients. In treatment planning, neutrons produced in the treatment delivery system and the patient are usually ignored and not documented. The goal of this ongoing project is to develop and establish a system for measuring and simulating 3D neutron and gamma radiation fields of passively scattered and actively scanned proton beams using representative clinical proton fields impinging on tissue-equivalent phantom materials. Eventually this should lead to a standardized approach for calculating organ neutron doses in paediatric proton patients.

Material and Methods: The neutron dosimetry consists of neutron and gamma fluence measurements with an array of three organic scintillators positioned 70-80 cm lateral to blocks of tissue equivalent materials (soft tissue and compact

bone, CIRS) which are at isocenter and irradiated with therapeutic proton beams. The tissue equivalence of the irradiated materials for neutron doses (per incident proton) and energy spectra has previously been established with Geant4 simulations. Pulse shape discrimination is used to classify each detected pulse as either a neutron or a gamma ray, which allows selective analysis of the neutron and gamma ray spectra. Data are acquired using a digital measurement system based on a CAEN DT5720 waveform digitizer (12 bit, 250 MHz). The response of the scintillators is also simulated using a detection post-processor distributed with a modified version of MCNPX (PoliMi code). To validate the code, the total simulated neutron pulse height distributions scaled to the absolute fluence recorded during the measurements is compared with the measured distributions from the scintillators.

Results: There was good agreement (within 10%) of neutron dose and energy spectra for investigated tissue equivalent materials when compared to ICRP human tissues. So far measurements have been performed at three different proton treatment centers and measurements at two additional centers are planned, thus testing the system on a range of contemporary proton beam accelerators and beam delivery systems. Good agreement was found between the detector responses and Monte Carlo simulations. Using MCNPX, it was shown that the secondary neutron field can be separated into two distinct components; an isotropic, low-energy component and a forward-directed, high-energy component.

Conclusion: The neutron dosimetry system is applicable to any proton facility and will be valuable for prospective data collection of neutron doses and second cancer risk evaluation, thus establishing the dosimetric basis for a prospective clinical data base for paediatric proton patients.

PO-0836

Low dose out-of-field radiation: calculation, measurement and radiobiological impact on cells

M. Kruszyna¹, S. Adamczyk¹, A. Skrobala², M. Skorska¹, W. Suchorska³, K. Zaleska³, A. Konefal⁴, A. Kowalik¹, W. Jackowiak⁵, J. Malicki²

¹Greater Poland Cancer Centre, Medical Physics Department, Poznan, Poland

²Medical Science University, Electroradiology Department, Poznan, Poland

³Greater Poland Cancer Centre, Medical Physics Department-Radiobiology Laboratories, Poznan, Poland

⁴Silesian University, Department of Nuclear Physics and its Applications- Institute of Physics, Katowice, Poland

⁵Greater Poland Cancer Centre, 1st Radiotherapy Department, Poznan, Poland

Purpose or Objective: The study presented here is three-part work whose primary aims were to determine a) the properties of the scattered radiation responsible for out-of-field doses b) the out-of-field radiation doses at varying distances from the primary beam, and c) the impact of these doses to biological response of in-vitro cells.

Material and Methods: We developed a purpose-designed water phantom to study out-of-field radiation. The phantom consists of seven dual-purpose inserts that can be used to measure doses and to assess radiobiological effects at the same measuring points. The photon (6 MV) energy spectra were calculated at 5 unique positions (at depths of 0.5, 1.6, 4, 6, 8, and 10 cm) along the central beam axis (CAX) and at six different off-axis distances. To gain a better understanding of out-of-field doses, we measure the individual contribution of photons and neutrons to the total out-of-field dose for 6 MV and 20MV photons at open beam. Radiation doses were measured at 6 separate points in the phantom with TLD 100, TLD 600, TLD 700, and Gafchromic EBT films. Cells from the human breast cancer line MDA-MB-231 were inserted in a water phantom and irradiated at CAX and off-axis distance, at varying doses (1.5, 2.0, 2.5, 3.0 Gy). Survival fraction, number of DNA double strand-breaks (DNA

DSBs), and cleaved PARP levels were determined by clonogenic assay and flow cytometry.

Results: Measured Monte Carlo simulations showed that mean radiation energy levels drop rapidly beyond the edge of the 6 MV photon beam field (Table 1). Simulations showed that the energy level actually increased slightly in some cases as the distance from the field edge increased. At a prescribed dose of 75 Gy to the isocentre, the measured photon dose level in the close-to-field area could reach up to 2.0-2.5Gy for 6MV and 1.5-2.0Gy for 20MV. Although the dose decreased rapidly as the distance from the CAX increased, even distant doses could reach several cGy when photons were used (Fig. 1). The neutron dose for 20 MV photons at a distance of 25 cm from the isocentre was 3.5 mSv/Gy. A slight non-significant decrease of 3-5% in cell SF was observed in cells irradiated outside the primary field.

Table 1. The mean photon energy at depths of 0.5, 1.6, 8 and 10 cm on the central axis (0 cm) and at 10, 15, 20, 25, 30 and 35 cm from the CAX at open (10x10 cm) beam.

Depth [cm]	Mean energy [MeV]						
	Distance from beam central axis [cm]						
	0	10	15	20	25	30	35
0.5	1.514	0.296	0.248	0.295	0.275	0.214	0.279
1.6	1.456	0.319	0.205	0.252	0.221	0.250	0.234
8.0	1.181	0.239	0.241	0.174	0.201	0.204	0.225
10.0	1.178	0.278	0.245	0.186	0.204	0.213	0.247

Figure 1. Dose measurements outside the field of radiation for 20 MV photon energy.

Conclusion: The dose levels measured in this study strongly suggest that out-of-field doses (especially for 20 MV) should be taken in consideration to obtain radiation protection of patients, as these dose levels could increase second cancer risk. Scattered irradiation appears to induce an in vitro biological response on out-of-field cells.

³Odense University Hospital, Department of Oncology, Odense, Denmark

Purpose or Objective: Treatment plans for head and neck (H&N) cancer are highly complex due to multiple dose prescription levels and numerous organs at risk (OAR) close to the target. The plan quality is inter-planner dependent since it is dependent on the skills and experience of the dosimetrist. This study presents a blinded clinical comparison

of automatic (AU) and manual (MA) generated H&N VMAT plans created for clinical use.

Material and Methods: All patients (n=30) referred to curative H&N radiotherapy in August and September 2015 were planned with a MA and AU VMAT plan in Pinnacle version 9.10. Half of the tumours were located in the pharynx (15) and the rest were mixed between larynx (4), oral cavity (3), salivary glands (2), thyroid gland and unknown primary (4). The plans followed national guidelines, and planning techniques were blinded before clinical evaluation of senior oncologists. The MA plans were optimized according to standard clinical practice. The AU plans were created by the Autoplan software available in the Pinnacle planning system. After AU optimisation, slight manual fine-tuning of the plans was performed. To supplement the clinical evaluation the operator time for the dosimetrist was recorded along with DVH parameters and the global detector pass rate (3% and 3mm) of the delivered plans on an ArcCheck phantom. All statistical analyses were performed with a paired Wilcoxon-signed rank test.

Results: In 29/30 plans, the AU plan was chosen for clinical application ($p < 0.001$). In terms of DVH parameters similar target coverage was obtained between the two planning methods. As seen in the table, mean OAR doses were significantly reduced in the AU plans for all organs. The mean reduction ranged from 0.5 Gy for the entire patient to 6.5 Gy for the contralateral submandibular gland. Differences in DVH showed significant AU superiority in the dose range 10 Gy to 45 Gy for all organs (Mean DVH example shown in figure). The only manual plan selected for clinical use was a thyroid cancer plan involving level VII lymph nodes and therefore included a large volume of the lung, which had a lower lung dose in the manual plan. The AU plans were more modulated as illustrated by the increase in MUs, which might cause the reduced, but still clinically acceptable, pass rate of 97.7% in ArcCheck measurements. The increased beam-on time of 4 sec is clinically unimportant. Mean operator time spent on MA plans was more than twice that of AU plans. The target homogeneity, conformity and dose fall off were all superior in the AU plans.

Mean Target dose	Unit	Autoplan		Manual		P
		Mean	SD	Mean	SD	
PTV68	Gy	67.9	0.3	67.6	0.6	0.06
PTV66	Gy	65.9	0.8	65.5	0.8	<0.001
Mean OAR dose						
Spinal cord	Gy	20.2	6.9	22.9	5.8	<0.001
Brainstem	Gy	3.5	4.0	5.1	4.7	<0.001
Oral cavity	Gy	31.6	13.3	34.3	12.8	<0.001
Libs of mouth	Gy	12.3	7.7	15.2	6.8	<0.001
Parotid Ipsi	Gy	23.4	16.4	25.5	15.7	<0.001
Parotid Contra	Gy	18.5	8.1	20.5	8.8	0.004
Submand Ipsi	Gy	53.2	11.4	56.0	7.7	0.014
Submand Contra	Gy	34.0	19.2	40.5	18.9	<0.001
Mandible	Gy	30.2	9.4	32.3	8.9	<0.001
Thyroid	Gy	34.6	13.3	37.1	11.2	<0.001
Larynx	Gy	39.1	9.4	44.8	8.7	<0.001
Body	Gy	9.3	3.0	9.8	2.9	<0.001
Delivery						
MU	MU	435	79	360	56	<0.001
Operator time	Min	64	31	32	26	<0.001
Beam on time	Sec	113.8	22.3	110.1	24.0	0.017
Pass rate (3%,3mm)	%	97.7	1.7	98.4	1.7	0.0011

Conclusion: All AU and MA plans were of acceptable clinical quality, however, AU plans resulted in reduced doses to all OAR and required less operator time in the planning process. AU plans were almost consistently preferred by senior head and neck cancer specialists. The dosimetric superiority of the AU plans was evident.

Impact of dosimetric outliers on the performance of a knowledge-based planning system

A. Delaney¹, J. Tol¹, M. Dahele¹, J. Cuijpers¹, B. Slotman¹, W. Verbakel¹

¹VUMC, Radiotherapy, Amsterdam, The Netherlands

Purpose or Objective: RapidPlan (Varian Medical Systems) is a knowledge-based planning solution based on a model derived from a library of previous treatment plans. The model utilizes the geometric features and associated dosimetry of these plans to predict a range of achievable dose volume histograms (DVHs) for each organ at risk (OAR) of a new patient. RapidPlan (RP) drives the VMAT or IMRT optimization process by placing a line of optimization objectives along the lower boundary of the DVH prediction range. Planning inconsistencies may lead to sub-optimal plans in the model, which can be identified as dosimetric outliers. Outlier cleaning is advised, however this is time consuming and often subjective. We examined the effect of model cleaning and increasing numbers of dosimetric outliers in a model library, on RP plan quality.

Material and Methods: 70 head and neck cancer treatment plans (planned consistently using the same departmental objective priorities) were used to populate uncleaned ModelUC. Statistical metrics provided by RP were used to identify geometric/dosimetric outliers in ModelUC which were then visually assessed and, if appropriate, removed to create cleaned ModelC. The last 5-40 patients (increments of 5) of ModelC were then re-planned with no attempt to spare the salivary glands, and afterward re-introduced to ModelC, creating Model5-40. All models were used to create plans for a 10 patient evaluation group. Although RP can generate OAR objective priorities, for this study, the same standard priorities were used as for the plans in ModelUC. Plans were compared on the basis of generated prediction ranges, boost/elective target volume homogeneity index (HIB/HIE), mean dose to the oral cavity (OC) and to composite structures comprising the salivary glands (compsal) and swallowing structures (compswal).

Results: On average, outlier cleaning (ModelUC vs ModelC) had minimal impact on HIB/HIE and OAR sparing, although in 1/10 patients, outlier removal resulted in substantial deteriorations to the sparing of two swallowing OAR (>10Gy increase). Adding 5/10 outliers to the model marginally improved average compsal while increasing the number of outliers to 40 led to a 3.9Gy increase in compsal (Table). The increase in OAR dose, even with 40 outlier plans added to the model, was modest compared to the average increase of 14.9Gy in compsal, in the outlier plans themselves. This is due to the placement of optimization objectives along the lower boundary of the DVH prediction range, which progressively widened with the addition of outliers.

Knowledge Based Plan	HI _B (%)	HI _E (%)	Oral Cavity (Gy)	Comp _{sal} (Gy)	Comp _{swal} (Gy)
Model _{UC}	9.4 ± 1.5	14.7 ± 1.5	20.5 ± 8.4	21.4 ± 4.7	27.9 ± 6.0
Model _C	9.4 ± 1.3	14.3 ± 1.1	20.6 ± 9.0	21.3 ± 4.6	28.3 ± 6.0
Model ₁₀	9.6 ± 1.6	14.6 ± 1.6	21.1 ± 9.7	20.7 ± 5.0*	27.9 ± 6.0
Model ₂₀	9.4 ± 1.3	14.6 ± 1.4	20.0 ± 8.5	22.2 ± 5.8	27.6 ± 6.2
Model ₃₀	8.9 ± 1.3	14.1 ± 1.3	19.6 ± 8.4	23.8 ± 5.8*	27.5 ± 6.0*
Model ₄₀	9.1 ± 1.2	13.5 ± 1.4*	19.6 ± 8.2	25.2 ± 6.9*	27.4 ± 6.3

Rapidplan results, averaged over the 10 patient evaluation group, using the uncleaned model(Model_{UC}), cleaned model(Model_C) and outlier models(Model₁₀₋₄₀). Mean OAR doses are reported. * Indicates a statistically different (p<0.05) value from Model_C plan.

Conclusion: This study reveals that extensive outlier cleaning from this large model comprising 70 consistently made plans had limited impact on the performance of RP. Furthermore, the replacement of >20 plans with those in which the salivary glands were not spared only modestly deteriorated RP performance. In summary, RP demonstrated robustness for moderate proportions of salivary gland dosimetric outliers.

PO-0839

Clinical simulation of nodal boosting in cervix cancer using reduced margin and coverage probability

A. Ramlov¹, M.S. Assenholt¹, M.F. Jensen¹, C. Grønberg¹, R. Nout², L. Fokdal¹, M. Alber¹, K. Tanderup¹, J.C. Lindegaard¹
¹Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark
²Leiden University Medical Center, Department of Radiation Oncology, Leiden, The Netherlands

Purpose or Objective: We examined the feasibility of reducing PTV margin when using a simultaneous integrated boost (SIB) of pathological lymph nodes in locally advanced cervical cancer. Additionally the clinical performance of a coverage probability (CovP) planning strategy was investigated.

Material and Methods: 25 previously treated patients with regional lymph node metastases were included. All patients were treated with whole pelvic EBRT (45 Gy/25 fx) using IMRT or VMAT. Nodal GTV contouring was based on MRI in supine treatment position. A CTV-N was constructed based on the combined (fused) nodal GTV-N contoured on MRI and PET-CT. Treatment planning was performed in Eclipse with three margin strategies for the SIB: 1) 10 mm GTV-PTV margin (ICRU PTV10mm plan), 2) 5 mm CTV-PTV (ICRU PTV5mm plan) and 3) 5 mm CTV-PTV margin using CovP (CovP plan). Constraints for the ICRU plans (1+2): PTV coverage of 95-107% of prescribed dose. Running a number of CovP plans in the research dose planning software Hyperion developed dose constraints for CovP planning in Eclipse. CovP dose constraints: PTV5mm D98 >90%, CTV D98 > 100% and a soft constraint of CTV D50 > 101.5% of prescribed dose (Figure 1). Dose prescription for SIB was 55 Gy/25 fx in the true pelvis and 57.5 Gy/25 fx above true pelvis. Daily image-guidance with cone beam CT (CBCT) and couch correction based on

bony fusion was used systematically. GTV-N was contoured on every second or third CBCT scan and the contour transferred to the planning CT. The accumulated dose for each node was determined in terms of D98 and Dmax. Finally, the volumes of body, bones and bowel receiving >50 Gy (V50) were calculated directly from organs at risk (OAR) contours on the planning CT.

Results: In total 47 lymph nodes were boosted of which 41 (87%) were visible on CBCT. Median number of nodes per patient was 2 (range 1-4). Median GTV D98 and Dmax (%) are listed in Table 1. All nodes treated with ICRU plans had a D98 above 98% and no difference was found between the ICRU plans with regard to target coverage. For CovP the D98 was significantly lower but Dmax significantly higher when compared to the two ICRU plans. Only one node positioned in the true pelvis had a D98 below 95% using CovP. In this patient, bladder filling varied during EBRT, which resulted in large shifts of GTV-N. V50 of body, bones and bowel were significantly lower (p<0.001) with the 5mm margin strategy. A further significant reduction was seen with the use of CovP (p<0.001).

	ICRU PTV _{10mm}	ICRU PTV _{5mm}	CovP
PTV volume (cm ³)	19.9 (9.2-98.5)	8.4 (2.9-62.7)	-
GTV D98 (%)	100 (98 - 102)	100 (99 - 102)	99 (93 - 101)
GTV Dmax (%)	102 (101 - 104)	102 (99 - 103)	104(101 - 107)
Body volume > 50 Gy (cm ³)	75 (32 - 315)	48 (16 - 209)	27 (12 - 122)
Bones volume > 50 Gy (cm ³)	7(0-50)	2 (0-25)	1 (0-8)
Bowel volume > 50 Gy (cm ³)	4 (0-106)	2 (0-68)	1 (0-35)

Conclusion: Pathological nodes are visible on CBCT in the majority of patients with locally advanced cervical cancer. Sequential analysis of CBCT taken during EBRT shows that nodal boosting by use of SIB and CovP is clinically feasible providing an increased central dose in the nodes, full target coverage and a significant reduction in near by OAR volumes treated to high doses. CovP based SIB using the above planning aims are now standard at our institution for nodal boosting and will be implemented in the forthcoming Embrace II study.

PO-0840

Voxel-based Δ TCP distribution: a tool to study the impact of dose distributions in tumour outcome

D. Fabri¹, B. Sánchez-Nieto¹, A. Gago¹, I. Espinoza¹, A. López-Medina²

¹Pontificia Udad Católica de Chile, PHYSICS, Santiago, Chile

²Galaria-Hospital do Meixoeiro-Complexo Hospitalario Universitario de Vigo, Medical Physics Department and Radiological Protection, Vigo, Spain

Purpose or Objective: The aim of this study is to create a tool to evaluate the effect of radiosensitivity parameterization and dose distributions on the local Tumour Control Probability (TCP). This tool will be an extension of the Δ TCP method by Sánchez-Nieto and Nahum¹ without missing the spatial information associated to the dose volume histograms (DVH)

Material and Methods: In ref [1] it was shown, that the use of a voxel control probability (VCP) distribution is not a correct approach to discretize the effect on TCP of dose inhomogeneity throughout the tumour. Alternatively, the concept of the Δ TCP using the information of the bins of the DVH was proposed and proved to be a better solution.

Based on this concept and due to the advances made on the last 15 years in terms of computational calculation time, access to individual patient information regarding radiosensitivity and 3D dose distribution maps, we propose a Δ TCP voxel-based model.

The first step for generating the mentioned distribution map is to identify, by means of functional images, three regions with different oxygenation status (normoxic, hypoxic and necrotic regions) to which oxygenation histograms [2] are assigned. Secondly, a radiosensitivity value α is initially assigned to the system and modified for every voxel taking into account the oxygen parametrization (α'). Moreover, patient-to-patient variabilities are considered using a σ around the initial value so that the final distribution of effective radiosensitivity values (i.e., including the oxygen status) produce a response curve with a clinically meaningful steepness. Then, VCPs are calculated for the planned dose distribution according to the expression in [1]. A second set of VCPs are calculated for a different reference dose distribution (e.g., a completely homogeneous dose through the tumour or an optimized one after a dose painting approach).

Finally, the Δ TCP for every (i,j,k) voxel, representing the impact on the final TCP of that voxel having a tested dose (D_t) instead the reference one (D_r) is computed as:

$$\Delta TCP_{ijk} = \sum_x TCP(\alpha'x) [1 - VCP_{ijk}(\alpha'x, D_r)] / VCP_{ijk}(\alpha'x, D_t)$$

Where $\alpha'x$ the oxygen-corrected initial α value and $TCP(\alpha'x)$ is calculated as the multiplication of all the VCPs for $\alpha'x$, for the tested dose distribution.

Results: The tool was tested using a H&N patient from Artfibio project[3]. As a result the Δ TCP distribution shown on the image was obtained. A dose distribution chosen to have a low local control (to highlight the tool functionality) and as reference an homogeneous 2 Gy dose per fraction to the GTV for 32 fractions were used.

Conclusion: It was shown that this could be a useful tool. As expected due to the small influence of single voxel dose variabilities on the total TCP, it is necessary to think on a future steps using megavoxels define within a certain threshold of oxygen level, dose and any relevant parameter.

Cranial stereotactic trajectory optimization via patient-specific overlap atlas

L. MacDonald¹, J.L. Robar^{1,2,3}, C. Thomas^{1,2,3}

¹Dalhousie University, Medical Physics, Halifax, Canada

²Nova Scotia Cancer Centre, Medical Physics, Halifax- Nova Scotia, Canada

³Dalhousie University, Radiation Oncology, Halifax, Canada

Purpose or Objective: This study examines potential dosimetric improvements in cranial stereotactic radiotherapy plan quality by using a geometric optimization approach to reduce dose to organs-at-risk.

Material and Methods: Using previously delivered cranial stereotactic radiotherapy plans treated at the Nova Scotia Cancer Centre (NSCC), we have redesigned the treatment geometry to find an optimal couch rotation position based on a two-step process involving novel algorithms which reduce the presence of dose in surrounding organs at risk of exposure (OARs). Maintaining the gantry start/stop orientation from the conventionally designed treatment, the couch position is optimized based on a cost function analysis of accumulation of overlap score from an equation developed by Yang et al. [2] and refined by MacDonald et al. [1]. The score equations are used to generate 2D patient overlap atlases that are inform trajectory design. The algorithm incorporates factors for depth of both organs at risk (OAR) of exposure and target (PTV) volumes, and radiation dose sensitivities of each OAR. A further step is then implemented to focus on an individual OAR in need of further reduction after initial optimization. This algorithm applies an urgent sparing factor to the specified OAR, whose purpose is to maximize dose gradient between OAR and PTV, while minimally affecting the dose reduction effects to others.

Results: The optimization was conducted recursively on twenty plans for previously treated acoustic neuroma patients. Maximum and mean doses to the OARs were reduced by 37.03% \pm 2.48% and 42.25% \pm 1.62% respectively

with application of the optimization technique when compared to the clinical treatment plans. Secondary optimization of the brainstem with the urgent sparing factor was able to increase further sparing to the brainstem by up to 9.8%, with a subtle effect on the sparing of the remaining of the structures. In addition, PTV coverage was maintained to the same degree as the delivered treatment.

Conclusion: The geometric optimization method allows enhancement of the existing arc geometries, resulting in significant improvements in OAR sparing, without increase to required treatment planning or delivery time.

PO-0842

Non-coplanar volumetric-modulated arc therapy for craniopharyngiomas reduces doses to hippocampus

M. Uto¹, T. Mizowaki¹, K. Ogura¹, M. Hiraoka¹
¹Kyoto University Graduate School of Medicine, Radiation Oncology and Image-applied Therapy, Kyoto, Japan

Purpose or Objective: As patients with craniopharyngiomas make good prognoses and as pediatric patients seem to be more sensitive to radiation than adults, irradiation of normal tissue should be minimized. Recent studies suggest that radiation-induced injuries to the hippocampus play important roles in compromising neurocognitive functioning for patients with brain tumors and it could be important to spare the hippocampus using modern planning methods for patients with craniopharyngiomas. In terms of radiation techniques, 3D conformal external beam radiotherapy delivered using dynamic conformal arc therapy (DCAT) and volumetric-modulated arc therapy (VMAT) are clinically employed to treat for patients with craniopharyngiomas. While the use of non-coplanar beams in VMAT of malignant intracranial tumors has recently been reported, no dosimetric comparison has yet been made between VMAT using non-coplanar arcs (ncVMAT) and VMAT employing only coplanar arcs (coVMAT) among patients with craniopharyngiomas. We performed a planning study comparing dose distributions to the planning target volume (PTV), hippocampus, and other organs at risk (OAR) of DCAT, coVMAT, and ncVMAT.

Material and Methods: DCAT, coVMAT, and ncVMAT plans were created for 10 patients with craniopharyngiomas. The prescription dose was 52.2 Gy in 29 fractions, and 99% of each PTV was covered by 90% of the prescribed dose. The maximum dose was held below 107% of the prescribed dose. CoVMAT and ncVMAT plans were formulated to satisfy the following criteria: the doses to the hippocampus were minimized, and the doses to the OAR were similar to or lower than those of DCAT.

Results: The mean equivalent doses in 2-Gy fractions to 40% of the volumes of the bilateral hippocampus [EQD2(40%hippos)] were 15.4/10.8/6.5 Gy for DCAT/coVMAT/ncVMAT, respectively. The EQD2(40%hippos) for ncVMAT were <7.3 Gy, which is the threshold predicting cognitive impairment, as defined by Gondi et al.. The mean doses to normal brain tissue and the conformity indices were similar for the three plans, and the homogeneity indices were significantly better for coVMAT and ncVMAT compared with DCAT.

Figure.

Coronal plains of dose distributions in a representative case and a comparison of the normalized doses covering 40% of the volume of the bilateral hippocampus using DCAT, coVMAT, and ncVMAT.

The yellow line shows the contour of the bilateral hippocampus. The normalized value of D40%_{hippo} indicates that the dose covering 40% of the volume of the bilateral hippocampus was significantly reduced in the following order: ncVMAT, coVMAT, and DCAT (ncVMAT 0.4, coVMAT 0.7, and DCAT 1).

DCAT=dynamic conformal arc therapy, coVMAT=coplanar volumetric-modulated arc therapy, ncVMAT=non-coplanar volumetric-modulated arc therapy, NV_D40%_{hippo}=normalized value of D40%_{hippo}

Table.

Summary of doses delivered to the bilateral hippocampus and the normal brain and the dose indices, in Gy.

Structure Index	DCAT	coVMAT	ncVMAT	P-value (ANOVA)	P-value (DCAT vs. coVMAT)	P-value (DCAT vs. ncVMAT)	P-value (coVMAT vs. ncVMAT)
	(Mean±SD)						
Bilateral Hippo							
Maximum dose	42.3±9.8	36.2±11.2	30.5±15.0	0.121			
Mean dose	20.7±7.6	15.4±8.1	10.7±8.2	<0.05	0.515	<0.05	0.530
D40% _{hippo}	21.7±8.4	16.2±7.6	10.3±7.9	<0.05	0.406	<0.05	0.326
EQD ₂ (40% _{hippo})	15.5±7.9	10.8±6.3	6.5±6.0	<0.05	0.41	<0.05	0.51
NV_D40% _{hippo}	1	0.7±0.2	0.4±0.2	<0.05	<0.05	<0.05	<0.05
Normal brain							
Mean dose	6.8±1.7	6.2±1.5	6.8±1.4	0.563			

If a significant difference was evident when data from the entire cohort were compared via two-way analysis of variance (ANOVA), the Bonferroni post hoc test was performed to compare pairs of modalities.

DCAT=dynamic conformal arc therapy, coVMAT=coplanar volumetric-modulated arc therapy, ncVMAT=non-coplanar volumetric-modulated arc therapy, SD= standard deviation, Hippo=hippocampus.

D40%_{hippo}=dose to 40% of the volume of the bilateral hippocampus.

EQD₂(40%_{hippo})=equivalent dose in 2-Gy fractions (assuming α/β=2) to 40% of volume of the bilateral hippocampus.

NV_D40%_{hippo}=normalized value of D40%_{hippo} (the DCAT value was set to unity). The normalized values for coVMAT and ncVMAT were calculated as D40%_{hippo}(coVMAT)/D40%_{hippo}(DCAT) and D40%_{hippo}(ncVMAT)/D40%_{hippo}(DCAT), respectively.

Conclusion: NcVMAT is more appropriate than DCAT and coVMAT for patients with craniopharyngiomas. NcVMAT significantly reduces radiation doses to the bilateral hippocampus (to 50% that of the DCAT) without increasing the doses to normal brain tissue and other OAR.

PO-0843

Dosimetric evaluation of 10 years of treatment planning improvements in head and neck cancer

J. Tol¹, P. Doornaert¹, M. Dahele¹, B. Slotman¹, W. Verbakel¹
¹VU University Medical Center, Radiotherapy, Amsterdam, The Netherlands

Purpose or Objective: Advances in delivery techniques like intensity modulated radiotherapy (IMRT) and volumetric modulated arc therapy (VMAT) facilitated increased treatment plan complexity, leading to the inclusion of more organs-at-risk (OARs) for sparing. Initial treatment planning

studies typically evaluate whether extra sparing affects boost/elective planning target volume (PTVB/PTVE) dose coverage or homogeneity, sparing of previously included OARs or dose conformity. However, once novel techniques are introduced in routine clinical practice, predicted changes are rarely retrospectively evaluated or confirmed. We therefore analyzed longitudinal changes in plan quality for head and neck cancer (HNC) patients treated at our department from 2005-2015 following the introduction of new technologies and planning techniques.

Material and Methods: 4x30 plans of oropharynx patients were selected from 4 distinct periods (P). P1: 7-field static IMRT plans with parotid gland sparing. P2: Dual arc VMAT plans including submandibular gland sparing. P3: VMAT with swallowing muscle sparing and further attempts to reduce parotid gland / oral cavity doses through manual interactivity during optimization. P4: VMAT with the same OARs as P3, but automatically optimized using in-house developed software. PTV prescribed doses were 54.25-57.75Gy in P1/P2, and 54.25Gy in P3/P4. 70Gy was prescribed to PTVB for all patients, delivered in 35 fractions as a simultaneous integrated boost. Plans were compared using mean dose to composite salivary glands (Dsal), swallowing muscles (Dswal) and oral cavity (Doc), PTVB/PTVE dose coverage (V95) and homogeneity indices (HI), and V5Gy (volume receiving 5Gy), V30Gy, V50Gy and mean dose to the body contour with PTV subtracted.

Results: The Figure shows mean salivary gland, swallowing muscle and oral cavity DVHs for each period and the Table summarizes the mean dosimetric results. OAR sparing, swallowing muscle sparing in particular (P1=55.0Gy to P4=38.6Gy), gradually improved throughout the periods without compromising PTV dose coverage, homogeneity or conformity indexes. In addition, P3 improved Dsal/Doc over P2 by 6.3/7.5Gy, illustrative of gains facilitated by improved planner experience and planning technique used. Automatically optimized plans (P4) achieved similar OAR sparing, Body-PTV doses and PTV V95/HI values as P3 plans. Although depending on the degree of OAR-PTV overlap, individual OAR sparing could vary between the periods, such differences are inherent to this type of study.

	Period	1- Parotid gland sparing IMRT	2- Salivary gland sparing VMAT	3- Swallowing muscle sparing VMAT	4- Automatically optimized VMAT
PTVB	V95 (%)	98.1 ± 1.6	98.8 ± 0.9	99.0 ± 0.5 *	98.9 ± 0.2 *
	HI (%)	9.8 ± 1.0	10.0 ± 1.4	10.4 ± 1.1 *	9.7 ± 0.9 #
PTVE	V95 (%)	98.5 ± 1.0	98.2 ± 1.0	97.7 ± 1.2 *	98.2 ± 0.6 #
	HI (%)	13.3 ± 2.1	13.6 ± 2.1	15.8 ± 2.2 * †	13.2 ± 1.4 #
Mean Dose (Gy)	Salivary Glands	41.1 ± 7.1	37.3 ± 7.7	31.0 ± 5.0 * †	31.3 ± 6.4 * †
	Swallowing muscles	55.0 ± 5.7	56.0 ± 8.0	40.8 ± 7.3 * †	38.6 ± 7.9 * †
	Oral cavity	35.3 ± 7.2	36.8 ± 8.2	29.3 ± 7.8 * †	27.5 ± 8.2 * †
Body-PTV	Mean Dose (Gy)	20.5 ± 2.1	20.6 ± 1.9	18.7 ± 1.2 * †	18.9 ± 1.6 * †
	V5Gy (%)	73.8 ± 5.9	79.1 ± 3.1 *	74.5 ± 3.8 †	73.5 ± 4.7 †
	V30Gy (%)	29.7 ± 4.8	29.6 ± 4.9	27.2 ± 2.8 * †	27.2 ± 3.6 * †
	V50Gy (%)	7.4 ± 2.4	7.0 ± 2.4	4.5 ± 0.8 * †	5.3 ± 1.5 * † #

* , † , # : Statistically significant differences (p<0.05) with respect to period 1, 2 and 3, respectively ANOVA with post-hoc Bonferroni analysis

Conclusion: Successive improvements in radiotherapy technologies and planning techniques substantially improved HNC plan quality. Swallowing muscle sparing did not compromise sparing of other OARs, PTV dose coverage and homogeneity or dose deposition in the remainder of the body. On the contrary, salivary gland doses, HIB/HIE and Body-PTV doses generally decreased in P3/P4 compared to earlier periods.

PO-0844

Dosimetrical advantages of 4D mid-vent: should every LA NSCLC patient be treated this way?

S. Philippi¹, N. Barthelemy¹, M. Devillers¹, P. Nguyen¹, P. Coucke¹, A. Gulyban¹

¹C.H.U. - Sart Tilman, Radiotherapy Department, Liège, Belgium

Purpose or Objective: In this study, we aimed to compare the effect of 4D mid-ventilation vs. free breathing 3D CT technique on target volume differences and corresponding dosimetrical changes using intensity modulated radiation therapy (IMRT) for patients with locally advanced non small cell lung cancer (NSCLC). Furthermore, additional investigation was performed to evaluate the possible dosimetrical improvement by using volumetric modulated arctherapy (VMAT) instead of IMRT.

Material and Methods: Twenty-three patients with locally advanced NSCLC were scanned with 4D-CT acquisition for treatment planning purpose. The different breathing phases were analyzed to obtain the tumor motion (direction and amplitude) and to determine which dataset better represents the mid-ventilation phase. Based on the gross tumor volume, two planning target volumes were generated for each patient: One using 15 mm margin in all three directions (PTV-3D) and the other with 12 mm with the margin of 1/4 of the movement (= mid-ventilation approach, PTV-4D). For objective comparison, IMRT plans (3D-IMRT, 4D-IMRT) were made by using Pinnacle v9.0 (Philips, Eindhoven, the Netherlands) with identical optimization parameters. For the 4D mid-vent, additional VMAT plan was generated. All DVH were collected using the VODCA package (Medical Software Solutions, Hagendorn, Switzerland). For the evaluation, the following dosimetric parameters were used: for corresponding PTV coverage using V95%, for lungs-PTV4D (for objective comparison of healthy lung volume) V20Gy and Dmean, for spinal cord Dmax, for oesophagus Dmean, while for heart V35Gy. All 4D plans were verified at the treatment machine following the institutions QA procedure. Differences were tested using the pairwise t-tests with the significance level of p<0.05.

Results: Based on the 4D-CT analysis, the average (range) tumor motions were 3.1 (0-11.2) mm for cranio-caudal, 1.7 (0-4.6) mm for antero-posterior and 1.9 (0-4.0) mm for lateral direction. The average PTV volumes were reduced on average with 14% (Table 1).

Mean (SD)	3DCT (IMRT)	4DCT (IMRT)	3D vs. 4DCT (IMRT)	4DCT (VMAT)	IMRT vs. VMAT (4DCT)
cc, % or Gy					
PTV volume	618 (333)	518 (296)	p<0.01		
PTV V95%	95.2 (3.4)	97.1 (2.7)	p<0.01	97.1 (2.1)	p=0.83
PTV V107%	0.5 (0.5)	0.1 (0.1)	p<0.01	0.2 (0.3)	p=0.06
Lungs-GTV V20Gy	25.6 (5.4)	24.3 (5.5)	p<0.01	22.8 (4.7)	p<0.01
Lungs- PTV4D V20Gy	21.8 (5.3)	20.5 (5.3)	p<0.01		p<0.01
Oesophagus Dmean	21.6 (8.0)	20.9 (8.2)	p=0.02	19.8 (8)	p=0.04
Heart V35Gy	11.8 (10.7)	11.1 (10.2)	p<0.01	8.6 (8.6)	p<0.01

All treatment plans were met the clinically acceptable goals. The 4D-IMRT showed a statistically significant improvement ($p<0.05$) compared to 3D-IMRT in all relevant parameters. The 4D-VMAT plans further reduced all OAR parameters significantly ($p<0.05$), while maintaining identical target coverage. Phantom measurements confirmed that both techniques (IMRT and VMAT) can be safely administered.

Conclusion: By using the 4D-CT acquisition and mid-ventilation target delineation approach, significant PTV volume reduction was obtained. This method is improving PTV coverage and OAR doses using the same technique (IMRT). VMAT technique might further gain additional dosimetric benefits for patients with NSCLC.

PO-0845

Evaluating dosimetric indices in lung SBRT for establishing treatment plan quality guidelines

R. Yaparalvi¹, M. Garg¹, J. Shen¹, W. Bodner¹, D. Mynamapati¹, H.C. Kuo¹, P.G. Scipes¹, A. Basavatia¹, N. Ohri¹, W.A. Tome¹, S. Kalnicki¹

¹Montefiore Medical Center, Radiation Oncology, Bronx- New York, USA

Purpose or Objective: We applied a variety of published conventional and stereotactic plan quality dosimetric indices to describe and discern clinically achieved target dose distributions in Lung SBRT.

Material and Methods: Treatment plans of 100 Lung SBRT patients treated were retrospectively reviewed. The targets ($n=102$) were evenly distributed - right lung (53) and left lung (49). Patients were prescribed to a total dose of 50-60 Gy in 3-5 fractions. Dose optimizations were accomplished with 6 MV using either 2-5 arcs VMAT (90); 8-14 IMRT fields (6) or 10-16 static fields (6). Dose calculations were performed using AAA algorithm with heterogeneity correction. A literature review on dosimetric indices recommended for qualitative analyses of conventional and stereotactic dose distributions in target coverage, homogeneity, conformity and gradient categories was performed. From each patient treatment plan, the necessary parameters for calculating various indices were quantified.

Results: For the study, the mean (\pm SD) values for indices were: coverage (96.4 (\pm 2.4) %); homogeneity (1.27 (\pm 0.07)); Conformity (1.04 (\pm 0.08)) and Gradient 1.27(\pm 0.30) cm. Geometric conformity (g) strongly correlated with the conformity index (defined by van't Riet /Paddick)($p<0.0001$). All Gradient measures strongly correlated with PTV ($p<0.0001$). Evaluating High Dose Spillage, the average cumulative volume of all tissue outside the PTV receiving a dose of > 105% of prescription dose was 0.94 (\pm 1.64) %. Considering Low Dose Spillage, the maximum % of prescription dose to any point at 2 cm distance in any direction from PTV was 56.0 (\pm 11.4) %. The lung volume (total lung volume - GTV) receiving doses of 20 Gy and 5 Gy (V20 and V5) were mean 4.9 % (\pm 3.1) and 16.9 % (\pm 9.0). The RTOG lung SBRT protocol advocated conformity guidelines for prescribed dose in all dosimetric evaluation categories were met in \geq 94% of cases.

Conclusion: The high-rate of adherence to RTOG protocol dose conformity guidelines in our study validates that indices derived from our SBRT lung plan dose distributions are a tool for establishing plan metrics in clinical trials, for scoring competing plans and as well as for comparing inter-institutional lung SBRT plan dosimetric data. However, these indices should only be used as an additional tool to grade plan quality once a satisfactory treatment plan has been achieved judged on the basis of clinical expertise, acceptable dose distributions and dose gradients, while respecting critical organ and normal structure doses.

PO-0846

The impact of anatomical changes on the accumulated carbon ion dose in pancreatic cancer patients

A.C. Houweling¹, K. Fukata², Y. Kubota², H. Shimada², C.R.N. Rasch¹, T. Ohno², A. Bel¹, A. Van der Horst¹

¹Academic Medical Center, Department of Radiation Oncology, Amsterdam, The Netherlands

²Gunma University, Gunma University Heavy Ion Medical Center, Maebashi, Japan

Purpose or Objective: Improvements in overall survival of pancreatic cancer patients after carbon ion radiotherapy have been reported from Japanese clinical trials. Due to the sharp distal dose fall-off, a high dose can be delivered to the tumor, while sparing the nearby healthy organs. However, changes in gastrointestinal gas volumes can greatly influence the carbon ion range.

We evaluated the robustness of carbon ion therapy for pancreatic cancer patients by investigating the impact of interfractional anatomical changes on the accumulated dose when using bony anatomy- and fiducial marker-based position verification.

Material and Methods: Nine pancreatic cancer patients, treated with photon radiotherapy in free breathing, were included in this retrospective planning study. The internal gross tumor volume (iGTV), internal clinical target volume (iCTV), duodenum, stomach, liver, spinal cord and kidneys were delineated on the (average) 4D-CT scan. Intratumoral gold fiducial markers were implanted in all patients to enable position verification using cone beam CT (CBCT).

Treatment plans were created using a 4-beam passive scattering technique. A smearing technique was used to account for patient setup errors; a safety margin of 3 mm was applied to compensate for range uncertainties. Plans were generated to deliver at least 95% of the prescribed dose (36GyE in 12 fractions) to 99% of the iCTV.

To enable dose calculations on the daily CBCTs, the planning CT was deformably registered to each CBCT. The gastrointestinal gas volume visible on each CBCT was copied to the deformed CTs. Next, fraction doses were calculated by aligning the treatment plan according to a bony anatomy- and a fiducial marker-based registration. For both registration methods the resulting fraction doses were rigidly summed to acquire the accumulated dose.

We compared both accumulated doses to the planned dose using dose-volume histograms (DVHs) and calculated DVH parameters for the iGTV and iCTV (Dmean, D2%, D98%) and organs at risk (Dmean, D2cc).

Results: The D98% of the target volumes showed the largest differences (Figure). For the bony anatomy-based registration, D98% reduced significantly from 99.6% \pm 0.2% (iGTV; mean \pm standard deviation) and 98.6% \pm 0.5% (iCTV) as planned to 92.3% \pm 3.8% and 81.9% \pm 7.7% for the accumulated dose, respectively. For the marker-based registration, this was slightly improved to 95.1% \pm 4.0% (iGTV) and 88.6% \pm 4.0% (iCTV), which was still significantly different from planned.

For the duodenum, severe deviations were observed in the DVHs between the planned and accumulated dose. Both the direction and magnitude of the deviations differed considerably between patients. The other organs showed minor changes.

Figure Example of the dose distributions of planned dose (a) and accumulated dose for bony anatomy-based (b) and marker-based registration (c). iCTV (white), duodenum (purple), stomach (green), spinal cord (red), liver (blue) and kidneys (yellow) are shown.

Conclusion: Severe reductions in target dose coverage were observed as an effect of interfractional anatomical changes. The difference between the position verification methods was a lesser issue compared to the effect of the anatomical changes.

PO-0847

Implementing the new ESTRO guideline for elective breast radiotherapy with the humeral head as PRV

K. Surmann¹, J. Van der Leer¹, T. Branje¹, M. Van der Sangen¹, M. Van Lieshout¹, C.W. Hurkmans¹

¹Catharina Hospital, Radiation Oncology, Eindhoven, The Netherlands

Purpose or Objective: The new ESTRO consensus guideline for target delineation for elective breast radiotherapy (Offerens Radiother Oncol. 2015) establish the humeral head and connective tissues 10 mm around it as Planning Risk Volume (PRV). The objective was to implement these guidelines for sparing the humeral head in elective breast radiotherapy with level 1 and 2 (L1/L2) lymph nodes by comparing three different planning techniques.

Material and Methods: Ten patients with left-sided breast cancer were enrolled in a planning study performed in Pinnacle3 v9.8 (Philips). All patients were planned with 16 x 2.66Gy on the breast (PTVp) and the elective L1/L2 lymph nodes (PTVn). We compared three techniques: IMRT with high tangential field (HTF), 6-field IMRT and VMAT. The humeral head PRV (hh+10) was included with an objective of V40Gy < 1cc for all three techniques. Treatment plans were obtained with the inverse planning tool and optimization was achieved by decreasing the dose to the organs at risk (OARs; lungs, heart and right breast) as low as possible while maintaining a PTVp V95% of 97% and PTVn V90% of 95%.

For the high tangential fields, the cranial border of the fields was extended to include PTVn. The leaves of the 5 mm multi leaf collimator were then closed to exclude hh+10 to reduce the dose to the humeral head and the surrounding tissue. This technique is currently used in our clinic. The 6-field IMRT technique consisted of tangential fields and four additional fields (at 330, 20, 80 and 170 degrees) to ensure proper coverage of the cranial part of the breast and the lymph nodes. The cranial border of the tangential fields and caudal border of the four additional fields was set 1cm below the attachment of the clavicle at the sternum. The third technique was a VMAT dualarc from 305 to 180 degrees.

Results: HTF resulted in an average PTVp V95% of 97.2% and an average PTVn V90% of 90.4% (see Table 1). With the additional fields of the 6-field IMRT technique, the coverage of the lymph nodes increased significantly to on average 98.0% ($p = 0.01$) while PTVp did not vary significantly ($p = 0.92$). The doses to the OAR were comparable between the HTF and IMRT technique. The coverage of PTVn increased

when using VMAT to an average of 99.5% ($p < 0.01$ compared to HTF and $p = 0.19$ compared to IMRT). The dose to the OAR increased as well. The mean dose to the contralateral breast increased significantly from 0.6Gy with HTF and IMRT to 2.3Gy with VMAT ($p < 0.01$ for both).

Table 1: Dosimetric parameters for the planning target volumes (PTVp and PTVn), planning risk volume (humeral head + 10 mm) and the organs at risk for high tangential fields (HTF), 6-field IMRT and VMAT.

The parameters are given as average (min - max).

	HTF	IMRT	VMAT
PTVp V95% (%)	97.2 (91.8 - 99.5)	97.1 (96.8 - 97.3)	97.0 (96.6 - 97.4)
PTVn V90% (%)	90.4 (73.7 - 98.7)	98.0 (89.5 - 99.9)	99.5 (98.2 - 99.9)
hh+10 V40Gy (cc)	0.45 (0 - 1.02)	0.67 (0 - 1.83)	0.70 (0 - 1.35)
Lungs Dmean (Gy)	4.7 (3.9 - 6.1)	4.8 (3.8 - 5.9)	5.2 (4.2 - 6.8)
Heart Dmean (Gy)	3.3 (1.6 - 6.1)	2.9 (1.6 - 5.7)	3.6 (2.0 - 5.7)
Right breast Dmean (Gy)	0.6 (0.3 - 0.9)	0.6 (0.3 - 0.7)	2.3 (0.6 - 4.2)

Conclusion: The humeral head and surrounding tissues as defined in the new ESTRO guideline can be spared with the 6-field IMRT or VMAT technique. It is not possible through high tangential fields without reducing PTVn coverage.

A 6-field IMRT technique including tangential fields and four additional fields to cover the lymph nodes and the cranial part of the breast leads to adequate coverage of the primary target and the lymph nodes without increasing the dose to the other OARs.

PO-0848

Simultaneous integrated protection (SIP): a new concept for high precision radiation therapy

T. Brunner¹, S. Adebahr¹, E. Gkika¹, A. Zipfel¹, R. Wiehle¹, U. Nestle¹, A. Grosu¹

¹Universitätsklinik Freiburg, Department of Radiation Oncology, Freiburg, Germany

Purpose or Objective: Stereotactic radiotherapy near critical serial organs at risk (OAR) requires specific caution to avoid severe toxicity. Current strategies are to (1) to rule out SBRT as a treatment option, (2) to use full dose SBRT and expose patients to higher risks, (3) to homogeneously underdose the entire planning target volume (PTV), or (4) to trim PTV margins individually and non-quantifiably. We here describe a novel IMRT prescription method termed simultaneous integrated protection (SIP) for quantifiable and comparable dose prescription to targets very close to dose limiting structures. This work will be focussed on the planning of SBRT.

Material and Methods: For patients with infringement of dose constraints to at least one serial OAR, e.g. central airways, bowel, we defined a planning risk volume (PRV). The intersection volume of the PRV with the total planning target volume (PTV_Σ) was defined as the protection PTV_{SIP} and the vast non-intersecting majority of PTV_Σ as the dominant PTV (PTV_{dom}). Radiotherapy treatment planning was performed using IMRT. Dose was prescribed to PTV_{dom} according to ICRU in 3, 5, 8 or 12 fractions. If in doubt, preference to a higher number of fractions was given as a function of the size of PTV_{SIP}. D_{max} was allowed to be up to 130% of the prescribed dose. No specific dose was prescribed to the PTV_{SIP} but dose was required to stay just within the constraints for the respective OAR. Dose-volume-histogram (DVH) analysis was based on absolute volumes of OARs, not on PRVs.

Results: This method led to a fall off region within PTV_{SIP} between the PTV_{dom} and the OAR. We here demonstrate this approach for six patients. Two had lesions in the chest, one in the liver, two in the pancreas and one in the left kidney (Figure 1). Size of the PTVs (PTV_Σ) ranged from 14.5 to 84.9 mL (median 49.2 mL, mean 49.7 mL; Figure 2). Sizes of PTV protection subvolumes (PTV_{SIP}) ranged from 1.8 - 3.9 mL (median and mean 2.8 mL). Relative PTV_{SIP} ranged from 2.9% - 13.4% of the size of PTV_Σ (median 7.4%). Noteworthy, the largest ratio, 13.4%, was an absolute volume of 2 mL, only. D_{min} of the PTV_{SIP} was significantly lower in patients

1, 2 and 6 due to air within the PTV_SIP volumes compared with the other patients. Safety of the plans was analysed from the absolute volume DVHs (dose to mL). The steepness of dose fall off could be read off by the comparing the doses to the PRVs with those to the OARs. The constraints were respected for the corresponding OARs. All patients had local control at a median follow-up of 9 months and toxicity was low.

Conclusion: SIP-IMRT is shown to result in a median dose of $\geq 100\%$ to PTV_Σ, to achieve high local control and low toxicity. Longer follow-up is required for verification of these results and a prospective clinical trial is currently testing this new approach in chest and abdomen SBRT.

Figure 2
Dose to planning target volumes (PTV) in six patients planned with the SIP concept. For each patient from left to right the non-protection PTV (PTV_{dom}), total PTV_Σ and protection PTV (PTV_{SIP}) are shown with minimal, maximal and mean (open circles) relative doses. In plans 1 and 4 maximal doses were asked to be $\leq 130\%$. Sizes of PTV_{dom} and PTV_{SIP} volumes are shown. Abbreviations: OAR: organ at risk, mL: millilitre, SIP: simultaneous integrated protection.

PO-0849

Heart structures sparing through volumetric modulated arc therapy in mediastinal Hodgkin lymphoma

A.R. Filippi¹, M. Levis¹, A. Girardi¹, C. Fiandra¹, F. Cadoni¹, V. Papurello¹, C. Piva¹, I. Donegani², R. Ragona¹, U. Ricardi¹
¹Università di Torino, Radiation Oncology Department, Torino, Italy
²Università di Torino, School of Medicine, Torino, Italy

Purpose or Objective: Within the frame of further implementing a precise dose delivery in young patients with mediastinal Hodgkin lymphoma, heart sparing appears a crucial endpoint. Recent studies demonstrated a correlation between the occurrence of various late events (e.g. heart failure, myocardial infarction, valve disease) and the dose received by different cardiac substructures, giving insights into a complex mechanism of radiation-induced toxicity. The purpose of this study was to compare the dose received by these substructures either using an optimized multi-arcs volumetric arc therapy (VMAT) or classical 3D-CRT.

Material and Methods: We analyzed the plans of 14 patients (3 males and 11 females) with stage I-IIA mediastinal disease without axillary involvement, treated with involved site radiotherapy; 11 had a bulky presentation at diagnosis. In every patient, a deformable fusion was performed with a dedicated software (Velocity™, Varian) between the planning CT scan and the pre-radiotherapy contrast enhanced CT scan. The following structures were delineated: whole heart; left main, left descending, circumflex and right coronary arteries; aortic, pulmonary, mitral and tricuspid valves; right and left atria; right ventricle, left ventricle and inter-ventricular septum; left ventricular apex, mid cavity, base and lateral wall. Two experienced radiation oncologists contoured target volumes (CTV) and heart structures, after a training session with a cardiologist and a heart radiologist. 3DCRT was planned as AP-PA, while the VMAT approach consisted of multi non-coplanar arcs (the so-called butterfly technique). Mean and max dose received by the single substructures were compared by Student's T test.

Results: Mean and max doses for the different cardiac structures, according to the technique used, are reported in table 1. Maximum dose resulted similar for almost all the

structures except for the whole heart and the right ventricle, where VMAT gave higher doses (probably due to small hotspots in the PTV areas adherent to heart segments, mainly located in the lower anterior mediastinum). Conversely, a lower mean dose was delivered by using VMAT to all structures, reaching a strong significant difference for whole heart (p = 0.025), aortic valve (p<0.0001), mitral valve (p=0.049) and left atrium (p<0.0001). Most significant findings are illustrated in figure 1.

Structure	Dosimetric parameter	VMAT	3D-CRT	p-value
Apex	Maximum Dose (Gy)	3.5	5.0	0.444
	Mean Dose (Gy)	0.9	1.6	0.222
Right Atrium	Maximum Dose (Gy)	25.8	24.8	0.406
	Mean Dose (Gy)	9.4	10.9	0.146
Left Atrium	Maximum Dose (Gy)	25.5	27.3	0.135
	Mean Dose (Gy)	10.2	14.7	< 0.0001
Basal Cavity	Maximum Dose (Gy)	23.6	24.0	0.653
	Mean Dose (Gy)	7.2	8.6	0.358
Circumflex Artery	Maximum Dose (Gy)	20.6	20.4	0.614
	Mean Dose (Gy)	12.1	14.4	0.062
Right Coronary	Maximum Dose (Gy)	23.0	21.8	0.428
	Mean Dose (Gy)	13.1	13.9	0.345
Heart	Maximum Dose (Gy)	30.3	28.7	0.031
	Mean Dose (Gy)	6.1	7.7	0.025
Left Descending	Maximum Dose (Gy)	25.0	25.2	0.181
	Mean Dose (Gy)	14.9	15.4	0.892
Mid Cavity	Maximum Dose (Gy)	9.3	8.5	0.544
	Mean Dose (Gy)	2.2	3.6	0.305
Lateral Wall	Maximum Dose (Gy)	17.2	15.6	0.290
	Mean Dose (Gy)	2.9	4.0	0.374
Interventricular Septum	Maximum Dose (Gy)	24.0	23.1	0.071
	Mean Dose (Gy)	4.1	4.5	0.584
Left Main Trunk	Maximum Dose (Gy)	26.1	25.7	0.947
	Mean Dose (Gy)	20.8	Unassessable	/
Aortic Valve	Maximum Dose (Gy)	24.4	26.8	0.094
	Mean Dose (Gy)	14.8	21.9	0.0001
Mitral Valve	Maximum Dose (Gy)	17.1	14.7	0.678
	Mean Dose (Gy)	7.1	10.0	0.049
Pulmonary Valve	Maximum Dose (Gy)	27.2	26.5	0.174
	Mean Dose (Gy)	23.7	23.1	0.845
Tricuspid Valve	Maximum Dose (Gy)	14.7	15.1	0.824
	Mean Dose (Gy)	8.5	10.8	0.101
Right Ventricle	Maximum Dose (Gy)	27.3	26.0	0.025
	Mean Dose (Gy)	4.8	5.3	0.296
Left Ventricle	Maximum Dose (Gy)	24.0	24.1	0.958
	Mean Dose (Gy)	3.5	4.8	0.238

Conclusion: In this preliminary dosimetric comparison, optimized multi arcs VMAT was able to significantly reduce the mean dose to crucial heart substructures such as aortic valve, with a generalized reduction in mean doses received

by other substructures. The potential clinical benefits still need to be demonstrated in expanded cohorts, with prolonged life-long follow-up.

PO-0850

Interplay effect quantification of PBS lung tumour proton therapy with various fractionation schemes

Y. Zhang¹, I. Huth², M. Wegner², D. Weber¹, A. Lomax¹

¹Paul Scherrer Institut, Center for Proton Therapy, Villigen PSI, Switzerland

²Varian Medical Systems, Particle Therapy, Troisdorf, Germany

Purpose or Objective: This study aims to investigate how much fractionation, and the different delivery dynamics of higher dose-per-fraction deliveries, can influence the impact of interplay effects for PBS-based lung tumour treatments.

Material and Methods: For two example lung tumour cases (I and II), three-field 3D plans were calculated on a patient specific range-adapted ITV (rITV) using a spot spacing of 4mm orthogonal to the beam directions. 4D dose calculations were performed, simulating three different fractionation treatments with schemes of (A)2.5Gyx35fx, (B)5Gyx10fx and (C)13.5Gyx3fx, based on machine and delivery parameters of the Varian ProBeam system (lateral scanning speed of 5/20 mm/ms and energy switching time of 700 ms with layer-wise optimized dose rates). 1x- to 10x- layered and volumetric rescanning was simulated to mitigate residual motion effects. The final dose distributions for fractionated treatments were obtained by superposition and normalization of the 4D dose distributions of each field and each fraction with random starting phases sampled from 4DCT (10 different phases with 100 random starts). We used homogeneity index (HI:D5-D95) in the CTV to quantify the resultant 4D dose distributions within the target, while for the normal lung (both lungs minus CTV), V20, mean lung dose (MLD) and D2 were compared.

Results: For single fraction only delivery (shown by error bars in figure a), the normalized HIs are similar for the different fraction doses for both patients, with HI being typically 14/15% higher than the static for case I and II respectively. For the full treatments (solid markers), the normalized HIs of plans under scheme A and B are equal or better than for the static plan, with only $\pm 1.2\%$ variations as a function of starting phase. In addition, whereas for scheme C, HI is $2.5 \pm 2.6/4.8 \pm 2.3\%$ (Case I/II) higher than the static case, this also reaches comparable homogeneity as the static case once combined with moderate rescanning ($<5x$). Variability is also reduced to within 1%, independent of the rescanning technique used. Concerning treatment time, for single fractions, nearly no difference can be seen among the different schemes when no rescanning is applied, due to the layer-wise optimized dose rate used by the ProBeam system. For 5x LS or VS, treatment time is increased by 100% and 37% respectively for scheme C in comparison to scheme A, although the absolute treatment time for LS is always less than half that of VS for all schemes. For the whole treatment, more than 75% reduction of time cost can be obtained once fractionation scheme (C) is used.

Conclusion: For PBS-based lung tumour proton therapy, fractionation can lead to an improved target homogeneity, and variability as a function of starting phase is only obvious when large fraction doses are used and can be reduced with moderate ($<5x$) rescanning is applied.

PO-0851

Development of a postoperative image-based treatment planning system for breast IOERT

H.R. Baghani¹, M.E. Akbar², S.R. Mahdavi³, S.M.R. Aghamiri⁴, H.R. Mirzaei², M. Robatjazi⁵, N. Naffisi²

¹Hakim Sabzevari university, Applied Physics, Sabzevar, Ireland Republic of

³Iran University of Medical Science, Medical Physics, Tehran, Iran Islamic Republic of

⁴Shahid Beheshti University, Radiation Medicine, Tehran, Iran Islamic Republic of

⁵Tehran University of Medical Science, Medical Physics, Tehran, Iran Islamic Republic of

Purpose or Objective: One of the major limitations of IOERT is the lack of a postoperative image based treatment planning, in order to optimize the radiotherapy procedure. The aim of this study is to develop and introduce a postoperative image based treatment planning system for breast cancer IOERT.

Material and Methods; to obtain a postoperative image based treatment planning software, it is necessary to have a postoperative image which includes the anatomical modifications of the tumor bed after the surgery. To this end, a C-arm fluoroscopy system (Zeihm Vision-8000) was employed to obtain a series of 2D images which include the tumor bed together with the IOERT applicator and protection disk. In addition to the postoperative images, it is mandatory to have the complete isodose distributions for different combinations of applicator size/energy. To obtain this data, Monte Carlo simulation was employed. The LIAC IOERT accelerator was simulated by MCNPX code and then, isodose distributions were extracted using mesh tally inside a water phantom. To develop a graphical treatment planning software, a graphical user interface (GUI) was prepared by an in house program written with MATLAB. At first, the postoperative image is imported to the program. Then, the corresponding isodose distribution file is loaded to the program. Then, the user will specify the applicator edge and program registers the isodose curves to the postoperative image. In order to evaluate the performance accuracy of the implemented postoperative image based treatment plans and delivered dose to the patient, in vivo dosimetry was used. To this end, the delivered dose to the surface of tumor bed was measured by Gafchromic EBT2 film.

Results: The result of intraoperative imaging and corresponding treatment planning is shown in Fig. 1.

As it can be seen, the developed treatment planning system is able to clearly show the variations of isodose levels at the site of tumor bed. Therefore, treatment team can precisely determine the interested isodose level for the dose prescription. The results of in vivo dosimetry at the surface of tumor bed showed there is no meaningful difference between the measured and expected dose at the surface of tumor bed (P -value=0.92).

Conclusion: The feasibility of intraoperative imaging and development of a postoperative image based treatment planning system during breast cancer IOERT was investigated in this study. The results of in vivo dosimetry confirm the validity of the developed treatment planning system for clinical applications.

PO-0852

The dose in marrow of iliac plates during radiotherapy of cervical and endometrial cancer

A. Jodda¹, T. Piotrowski², B. Urbański³, A. Roszak³, J. Malicki²
¹Greater Poland Cancer Centre, Medical Physics, Poznan, Poland

²Poznan University of Medical Sciences, Electroradiology, Poznan, Poland

³Greater Poland Cancer Centre, Gynaecological Radiotherapy Ward, Poznan, Poland

Purpose or Objective: To compare the differences between average doses cumulated in the marrow of iliac plates (PBM), obtained for five different radiotherapy strategies of cervical and endometrial cancer.

Material and Methods: A total of 150 treatment plans were calculated retrospectively for 30 patients with cervical and endometrial cancer.

For each case, 3 different dose delivery techniques were used. It were respectively: (i) 4-field, X15MV, 3DCRT; (ii) 7-field, X6MV, IMRT; and (iii) 2-arc, X6MV, VMAT. Two strategies were used during preparation of the IMRT and VMAT plans. The first take into account (+) PBM during optimization of the dose distribution and the second, do not take it into account (-).

All plans were normalized on the median dose in PTV. The same calculation algorithm (AAA) was used for calculation of the dose for each of plan. The total dose was 50.4 Gy (1.8 Gy in 28 fractions).

Average doses cumulated in PTV, PBM, bladder, rectum, bowels and femoral heads obtained from the evaluated plans were compared. In addition, the doses accumulated in PBM were analyzed in the light of the volume of PTV and/or PBM. The statistical analysis were performed by Friedman ANOVA with Nemenyi's procedures used as post-hoc tests. In order to find the relationship between doses in PBM and volume of PTV and/or PBM, the Spearman correlation was used. All tests were performed on the significance level equal to 0.05.

Results: Table 1 shows the result of the comparison of the average dose in the light of the generated plans.

Technique	PTV	PBM	Bladder	Rectum	Bowels	FHR	FHL
Average Dose (Standard Deviation) [Gy]							
3DCRT	50.4 (0.1)	33.3 (1.7)	49.9 (0.4)	47.7 (1.6)	37.6 (2.4)	38.2 (1.2)	38.3 (2.8)
IMRT(-)	50.4 (0.1)	29.9 (1.5)	35.4 (1.7)	36.2 (3.0)	32.6 (1.3)	25.4 (1.3)	27.7 (1.6)
VMAT(-)	50.4 (0.1)	29.4 (2.0)	34.6 (2.4)	35.7 (2.6)	33.2 (1.1)	26.3 (1.8)	28.7 (1.7)
IMRT(+)	50.5 (0.1)	27.7 (1.5)	35.5 (2.9)	36.3 (2.8)	32.6 (1.3)	23.9 (1.4)	24.4 (2.2)
VMAT(+)	50.4 (0.1)	26.4 (1.7)	34.6 (2.8)	35.7 (2.9)	32.9 (1.1)	24.1 (1.2)	25.0 (2.0)

VMAT(+)	A	C	B	B	B	C	C

PTV - Planning Target Volume; PBM - The bone marrow in the iliac plates; FHR - right femoral head; FHL - left femoral head

The average dose in PTV for evaluated plans was similar. The worst doses in organs at risk were obtained for 3DCRT. Using the PBM during optimization of IMRT and VMAT reduces the average dose in organs at risk without increasing the doses in bladder, rectum and bowels. Differences between doses in PBM for IMRT and VMAT plans, where PBM was used during optimization, were not statistically significant. The correlation between mean dose in PBM and the volume ratio of PBM and PTV was found for each technique (Figure 1).

Conclusion: Using the PBM during optimization of the IMRT and VMAT plans effectively reduces the dose in PBM without increasing the dose in bladder, rectum and bowels. The doses, obtained in PBM for IMRT and VMAT are not statistically different. Decreasing the PBM volume in relation to PTV increases the mean dose in PBM.

Impact of CT modality used for treatment planning of lung SBRT

A. Vicedo-Gonzalez¹, T. Garcia-Hernandez¹, L. Brualla-González¹, A. Hernandez-Machancoses², D. Granero-Cabañero¹, J. Roselló-Ferrando¹

¹Eresa Valencia, Medical Physics, Valencia, Spain

²Eresa Valencia, Radiotherapy, Valencia, Spain

Purpose or Objective: The introduction of lung stereotactic body radiation therapy (SBRT) requires images that allow a more precise delineation of the tumor and its movement. The free breathing CT does not contain information on the variable electron density over time. The objective of this study is to analyze the CT mode that provides the best estimation of the tumor movement and the most appropriate image set for the calculation of the dose distribution image.

Material and Methods: 10 patients were retrospectively investigated. For each patient, a retrospective 4DCT was acquired using a Brilliance 16-slice scanner. From the 4DCT study, 10 respiratory phases, an average CT and a maximum intensity projection (MIP) were reconstructed. The gross tumor volumes (GTV) were delineated in each image set of the 4DCT using a MIM® 6.4 software. Three internal target volumes (ITV) were obtained, one from the union of GTVs delineated in each phase, another from the average CT and the last from the MIP reconstruction. Special care was taken with the window level selection when contouring. The size of the three ITVs was compared. The planning target volume

(PTV) was created adding a margin of 5 mm to the ITV. The dose distribution was optimized on the average CT prescribing a dose of 20 Gy per fraction delivering a total dose of 60 Gy to the PTV. The plans were calculated in a Phillips Pinnacle 9.10 planning system using conformal 3DRT and heterogeneity correction. The parameters obtained in the average CT optimized plan, were copied to the different image sets with identical monitor units to analyze the differences.

Results: The average GTV volume was 1.6 ± 1.1 cc. The ITV size is twice the lesion size in most of the cases except in those with higher breathing amplitude. The ITVs outlined in the average CT were smaller than those outlined in the 4DCT ranging from 0.1 cc, where there hardly was lesion movement, to 0.6 cc. The differences between the volumes were usually found in the cranio-caudal direction due to the higher movement of the lesion in this direction. The ITVs outlined in the MIP CT were equivalent to the 4DCT except in the cases where there was a higher density organ in the vicinity of the tumor. Respect to dose distribution, the dose of the organs at risk shows no significant differences in the different image sets. The V100 of the ITV presents significant variations up to 15% due to the variation in electron densities depending on the CT mode chosen. The V100 of the GTV calculated in each phase is greater than 97%.

Conclusion: We recommend using the ten phases of the 4DCT study for proper delineation of ITV. If the institution does not have the technology the CT average (low pitch CT) could be used selecting the appropriate window level and increasing margins. There is no significant difference in dose to organs at risk between the images modalities studied. Optimized planning in the average CT provides adequate coverage of GTV at different breathing phases.

Evaluation of a dedicated brain metastases treatment planning optimization for radiosurgery
T. Gevaert¹, F. Steenbeke¹, L. Pellegrini², B. Engels¹, N. Christian², M.T. Hoornaert², C. Mitine², D. Verellen¹, M. De Ridder¹

¹Universitair Ziekenhuis Brussel, Radiotherapy, Brussels, Belgium

²Centre Hospitalier Jolimont, Radiotherapy, Jolimont, Belgium

Purpose or Objective: Stereotactic radiosurgery alone has become a popular treatment option in the management of patients with brain metastases. Multi- or single-isocenter dynamic conformal arcs (DCA) and volumetric modulated arc therapy (VMAT) are two common used delivery techniques. Recently, a dedicated inverse optimized brain metastases treatment planning solution using single isocenter multiple DCA (SIDCA) has been developed, with intend to carefully balance normal tissue protection, target coverage and treatment speed. The purpose of the current study was to investigate the feasibility of this novel software and to benchmark it against well-established multi-isocenter DCA and single isocenter VMAT approaches.

Material and Methods: Ten previously treated patients were selected representing a variable number of lesions (1-8), range of target sizes and shapes most frequently observed in the practice of SRS for brain metastases. The original multi-isocenter DCA (MIDCA) were replanned with both single-isocenter VMAT approach and the novel brain metastases tool

(Elements, Brainlab AG, Germany). The treatment dose was 20 Gy at the 80% prescription isodose. For all the plans, the dose to the surrounding healthy brain tissue (brainstem, cochlea, optical nerve, eyes and lens) was optimized to minimize normal tissue complications. The plans were evaluated by calculation of Paddick conformity and gradient index, and the volume receiving 10 and 12 Gy indicating risk of radionecrosis.

Results: All plans were judged clinically acceptable, but differences were observed in the dosimetric parameters. The mean conformity of the automated single-isocenter planning tool (SIDCA) compared similarly to the established MIDCA and VMAT treatment techniques (CISIDCA= 0.65 ± 0.08 , CIMIDCA= 0.66 ± 0.07 and CIVMAT= 0.67 ± 0.16). Comparable mean dose fall off was observed between SIDCA and MIDCA (GISIDCA= 3.9 ± 1.4 and GIMIDCA= 4.5 ± 1.6). On the other hand, the GI of the VMAT plans (GIVMAT= 7.1 ± 3.1) were significantly higher compared to the SIDCA. The V10 and V12 were significantly higher for VMAT plans (V10VMAT= 67.9 ± 55.9 cc, V12VMAT= 46.3 ± 35.9 cc) ($p < 0.05$) compared to MIDCA (V10MIDCA= 49.0 ± 38.1 cc, V12MIDCA= 35.6 ± 26.4 cc) and SIDCA (V10= 48.5 ± 35.9 cc, V12= 36.3 ± 27.1 cc).

Conclusion: The automated brain metastases treatment planning element, based on an inversely-optimized SIDCA approach, revealed comparable results to the general accepted MIDCA approach. By reducing the time on planning, patient and treatment setup, this software tool improves the planning and delivery efficiency while preserving the plan quality of the MIDCA technique and lowering low dose spread of the VMAT approach, suggesting that this novel software offers the best of both worlds (i.e. efficient single-isocenter DCA delivery).

PO-0855

Flattening Filter Free VMAT for extreme hypofractionation of prostate cancer

M. Ahlström¹, H. Benedek², P. Nilsson², T. Knöös², C. Ceberg¹
¹Lund University, Department of Medical Radiation Physics-Clinical Sciences, Lund, Sweden

²Skåne University Hospital and Lund University, Department of Oncology and Radiation Physics, Lund, Sweden

Purpose or Objective: To examine the feasibility of flattening filter free (FFF) volumetric modulated arc therapy (VMAT) for extreme hypofractionation of prostate cancer and investigate the potential decrease in treatment time per fraction while preserving or improving the treatment quality. To investigate the impact of intrafractional prostatic displacement.

Material and Methods: Single arc treatment plans with photon beam qualities 10 MV with flattening filter (FF), 6 MV FFF and 10 MV FFF were created for nine patients treated with conventional fractionation (78 Gy, 2 Gy/fraction) and hypofractionation (42.7 Gy, 6.1 Gy/fraction), respectively. Dose-volume histograms (DVH) for all beam qualities were statistically evaluated using a paired sample Student's t-test. Treatment delivery was evaluated through measurements on a Varian TrueBeam™ using a Delta4 PT system (ScandiDos AB). The beam-on time for each plan was recorded. A motion study, including one FF and one FFF hypofractionated treatment plan, was also performed using the HexaMotion (ScandiDos AB) and with trajectory data from six authentic prostate movement patterns.

Results: All treatment plans were approved by a senior radiation oncologist. Evaluating the DVHs, no significant differences between beam qualities or between fractionation schedules were observed. All objectives were met for all plans. At the treatment delivery all plans passed the gamma criterion 3%, 2 mm with a pass rate of 98.8% or higher. The beam-on time for all conventional treatment plans was 1.0 minute. The mean beam-on time was 2.3 minutes for the hypofractionated 10 MV FF plan, 1.3 minutes for the 6 MV FFF and 1.0 minute for the 10 MV FFF. In the motion study, no or little effect was observed on the pass rate for displacements

≤ 1 mm. The shorter treatment delivery was superior for three patterns, while the longer treatment was preferred in the case of temporal displacement of the prostate.

Conclusion: The treatment time for extreme hypofractionation of prostate cancer is reduced to less than half the time per fraction by combining FFF-technique with VMAT. The treatment plan quality was preserved for the FFF beams. Finally, a shorter beam-on time also seems advantageous for the majority of prostate motion patterns investigated.

PO-0856

Clinical and dosimetric issues of VMAT craniospinal irradiation for paediatric medulloblastoma

S. Meroni¹, T. Giandini¹, B. Diletto², E. Pecori², C. Chiruzzi², V. Biassoni³, E. Schiavello³, F. Sreafico³, M. Massimino³, E. Pignoli¹, L. Gandola²

¹Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics, Milan, Italy

²Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology- Paediatric Radiotherapy Unit, Milan, Italy

³Fondazione IRCCS Istituto Nazionale dei Tumori, Paediatric Oncology, Milan, Italy

Purpose or Objective: With increased 5 years survival of children with medulloblastoma, optimization of radiotherapy treatment to avoid iatrogenic sequelae has become a primary issue. Clinical and dosimetric characteristics of VMAT Craniospinal Irradiation (CSI) were studied and compared with the 3DCRT technique in use since 1997 at our institution with excellent clinical results. The impact of a setup error on dose distribution was also studied.

Material and Methods: CT images of 8 pts that received CSI at our institution (23.4 Gy in 13 fractions) were used for the dosimetric study. For each patient, a standard 3DCRT treatment and a VMAT were planned. PTV dosimetric objectives for treatment planning were: D95% >95%, D100% >90%, D5% <107%. The resulting DVHs were analyzed considering: conformity index (CI) and homogeneity index (HI) for PTV, mean dose (Dmean) and D2% for OARs (small bowel, kidneys, heart, liver, stomach, lenses, thyroid, lungs) and V2Gy of non target tissues as an integral dose index. The data were then compared using paired Student's t test. The dependence of dose indexes on patient size was evaluated. A 3 mm longitudinal error in patient setup was simulated for both techniques to evaluate dosimetric impact in the junction region.

Results: Dosimetric objectives were always met. All VMAT treatment plans had better HI and CI independently of patient size. Dmean and D2% of heart and thyroid were significantly lower with VMAT. On average, for heart Dmean was 9.8 ± 3.4 Gy and 6.3 ± 1.0 Gy, and D2% was 20.3 ± 4.1 Gy and 10.4 ± 1.7 Gy, for 3DCRT and VMAT respectively, while for thyroid Dmean was 18.2 ± 1.2 Gy and 13.8 ± 1.8 Gy, and D2% was 20.4 ± 1.2 Gy and 17.4 ± 2.0 Gy, for 3DCRT and VMAT respectively. On the contrary, lung dose was higher with VMAT: on average Dmean was 1.8 ± 0.9 Gy for 3DCRT and 3.5 ± 0.8 Gy for VMAT. A 3 mm gap at field junction level resulted in an underdosage of about 20% for VMAT and 50% for 3DCRT, while a 3 mm overlap gave rise to a hotspot on the spine up to 30% for VMAT and 70% for 3DCRT. V2Gy was about 3 times higher for VMAT.

Conclusion: VMAT allowed to achieve a more conformal and homogeneous dose distribution, with greater sparing of most OARs. Considering the risk of iatrogenic cardiopathy, hypothyroidism or secondary tumors to the thyroid, the dose reduction obtained with VMAT was significant. The clinical effect of the increased lung dose is not yet predictable, since absolute dose values were extremely low. VMAT implies a higher MU value for the delivery of the prescribed dose, possibly increasing the risk of secondary tumors. This is an important factor when dealing with pediatric pts. In VMAT, overdosage areas are greatly reduced with respect to 3DCRT, particularly in the junction region. The analysis of simulated

gaps and overlaps shows that field junctions are less critical for VMAT, nevertheless junction moving is still mandatory to avoid potentially dangerous hot or cold spots. Partially supported by Associazione Italiana per la Ricerca sul Cancro (AIRC)

GTV-based prescription and Monte Carlo treatment planning in Cyberknife treatments for lung lesions

A. Vai^{1,2}, P. Bonfanti¹, M. Invernizzi¹, A. Martinotti¹, I. Redaelli¹, F. Ria^{1,3}, R. Beltramo¹, L.C. Bianchi¹, I. Bossi Zanetti¹, A. Bergantin¹

¹Centro Diagnostico Italiano, Cyberknife Department, Milan, Italy

²ProgettoDiventerò Grantee, Fondazione Bracco, Milan, Italy

³ProgettoDiventerò Alumnus, Fondazione Bracco, Milan, Italy

Purpose or Objective: GTV-based prescription has been proposed as a possible recipe for Monte Carlo treatment planning in Cyberknife SBRT treatments for lung lesions (Lacornerie et al., 2014, [1]). The feasibility of this approach was investigated comparing Ray-Tracing algorithm (Effective Path Length method, EPL) and Monte Carlo (MC) dose calculation.

Material and Methods: A group of 40 consecutive patients from July to October 2015, treated with Cyberknife SBRT using an advanced target tracking system (Lung Optimized Treatment, LOT) was considered. Primary lung cancers and metastatic pulmonary lesions, different tumor size (small: $V < 14$ cc, large: $V > 65$ cc) and locations (totally air-surrounded, partially air-surrounded), prescription dose and fractionation schemes were included in the group. Treatment plans were optimized using RT algorithm (RT plans), with prescription isodose line of 80% providing 95% PTV coverage ($PTV = GTV + 5$ mm), and re-calculated with MC algorithm ($1 \times 1 \times 1$ mm³ dose grid, uncertainty=1%), using the same beam angles and monitor units (MCrecalc plans). Dose parameters for RT and MCrecalc plans were evaluated for both GTV, PTV and OARs, in relation to tumor size and position. On a subset of 5 patients, MCrecalc plans were normalized to the isodose line encompassing the 95% of the GTV volume (MCnorm plans) and compared to MC-optimized plans, with dose prescribed to the same isodose line (MCopt plans).

Results: Difference between RT and MCrecalc plans in average percentage volume covered by the prescribed dose for GTV and PTV is 13.5% (RT: 99.6%, MC: 86.1%) and 41.8% (RT: 96.8%, MC: 55.0%) respectively. Dose parameters referred to GTV (Dmean, D50, D98, D2) have a lower variation compared with PTV parameters: excluding D2, D50 shows the lowest variability for the analyzed group. Concerning OARs, difference in V20, V10, V5 for lungs (ipsilateral and contralateral) is 0.6%, 1.4% and 3.4%, respectively.

Table 1

Average difference RT - MC _{recalc}					
GTV	V _{DosePrescCovered}	D _{mean}	D ₅₀	D ₉₈	D ₂
all	13.5%	8.2%	7.9%	13.9%	5.1%

large	11.8%	4.2%	3.9%	6.6%	2.2%
air-surrounded					
totally	14.2%	3.2%	3.0%	7.5%	0.8%
partially	12.8%	9.6%	9.3%	15.4%	6.5%
PTV					
V _{DosePrescCovered}	D _{mean}	D ₅₀	D ₉₈	D ₂	
all	41.8%	12.9%	12.5%	24.6%	5.3%
small	50.8%	16.1%	15.9%	30.3%	6.1%
medium	26.4%	7.2%	6.6%	14.3%	4.2%
large	14.9%	4.0%	3.3%	10.2%	1.7%
air-surrounded					
totally	39.1%	6.6%	6.0%	18.2%	0.9%
partially	41.4%	14.4%	14.0%	26.1%	6.7%
Lungs					
V ₂₀	V ₁₀	V ₅			
average	0.6%	1.4%	3.4%		
max	1.5%	7.2%	22.7%		
Average difference RT, MC _{recalc} , MC _{norm} , MC _{opt}					
MC _{recalc} -RT		MC _{norm} -RT		MC _{opt} -RT	
D ₅₀	D _{mean}	D ₅₀	D _{mean}	D ₅₀	D _{mean}
-12.8%	-13.7%	0.4%	-0.5%	9.3%	8.3%

MC_{norm} and MC_{opt} have a value of GTV D50 and D_{mean} comparable to the RT plan and higher than the MC_{recalc} plan. At the same time, MC_{norm} plans could not always be accepted referring to OARs dose constraints respect and target dose conformity (see Fig.1). Results are reported in Table 1.

Figure 1. MC_{opt} (up) and MC_{norm} (down) plans for a lung lesion near the heart. GTV and PTV are contoured as a green and purple lines, respectively. Although volume coverage is obtained, dose constraint on the heart (D_{1cc} < 22Gy) is not respected in MC_{norm} plan.

Conclusion: Lower variation of GTV dose parameters compared with PTV, when both RT and MC_{recalc} treatment plans are evaluated, suggests that GTV should be used for dose normalization and reporting instead of PTV. According to van der Voort van Zyp et al. (2010, [2]), a different prescription dose could be adopted, depending on lesion size and location. Moreover, MC_{opt} plans need to be implemented, adopting a different prescription dose based on GTV D50 and D_{mean} values [1], as MC_{norm} plans could not guarantee appropriate target coverage and OARs sparing. Further multivariate analysis is mandatory to determine if there are correlations between the variables (size and location of the lesions, type of tracking adopted) considered for plan comparisons.

PO-0858

Development of dysphagia optimised IMRT for head and neck cancer treatment in the DARS trial

J. Tyler¹, D. Bernstein¹, K. Rooney², C. Nutting³

¹Royal Marsden NHS Foundation Trust, Physics, London, United Kingdom

²Belfast Health and Social Care Trust, Radiotherapy, Belfast, United Kingdom

³Royal Marsden NHS Foundation Trust, Radiotherapy, London, United Kingdom

Purpose or Objective: To develop a dysphagia optimised IMRT (Do-IMRT) technique comparing fixed-field IMRT with VMAT for treatment of head and neck cancer in the DARS clinical trial (CRUK/14/014), which is a phase III randomised multicentre study of Do-IMRT versus standard IMRT (S-IMRT).

Material and Methods: Six oropharynx cases were outlined and planned according to the DARS trial QA guidelines. CTVs were outlined using a volumetric approach with a 10mm GTV-CTV expansion. Pharyngeal constrictor muscles (PCM) were also delineated. The dose levels prescribed were 65 Gy to the primary site and involved nodes and 54 Gy to the elective volume in 30 fractions. Plans were produced according to both arms of the trial using both fixed-field IMRT and VMAT (RapidArc) with an Eclipse treatment planning system (version 11). In the experimental Do-IMRT arm, the aim was to achieve a mean dose of less than 50 Gy to the superior and middle PCMs, excluding the CTV receiving 65 Gy (PlanSMPCM), and less than 20 Gy to the similarly edited inferior PCM (PlanIPCM). These constraints were prioritised over coverage of the PTV receiving 54 Gy (PTV_5400) but not the PTV receiving 65 Gy (PTV_6500). In the S-IMRT arm no attempt was made to reduce PCM doses. Plans were assessed for their clinical acceptability and DVH statistics compared.

Results: Using fixed-field IMRT for Do-IMRT, it was not possible to achieve clinically acceptable plans in terms of both PTV_5400 95% isodose coverage and homogeneity whilst achieving the PCM constraints. However, using VMAT for Do-IMRT a PlanSMPCM mean dose of less than 50 Gy was achieved in all cases, reduced by 8 Gy on average compared to S-IMRT. PlanIPCM mean doses of less than 20 Gy were achieved in the majority of cases, reduced by 30 Gy on average compared to S-IMRT. Do-IMRT plans had decreased but acceptable dose homogeneity and 95% isodose coverage was maintained, only compromising in the region where PCMs and PTV_5400 overlap (as shown in the example in figure 1). Other OAR (spinal cord, brainstem and parotids) doses were increased for Do-IMRT but critical OAR constraints were still achieved in all cases. The results are summarised in table 1.

Figure 1: Dose distribution (colour wash displays 95-107% of 54 Gy) of transverse slice showing PTV_5400 (blue) coverage using S-IMRT (left) compared to Do-IMRT (right), where

coverage is compromised in the region of PlanSMPCM (yellow).

Table 1: Comparison of VMAT S-IMRT and Do-IMRT plan dose-volume statistics for PlanPTVs (edited 5mm from body surface and excluding PlanPTV_6500 from PlanPTV_5400), spinal cord, brainstem, contralateral (CL) and ipsilateral (IL) parotids, PlanSMPCM and PlanIPCM.

Dose-volume statistics	Case 1		Case 2		Case 3		Case 4		Case 5		Case 6		Paired t-test
	S-IMRT	Do-IMRT	S-IMRT	Do-IMRT	S-IMRT	Do-IMRT	S-IMRT	Do-IMRT	S-IMRT	Do-IMRT	S-IMRT	Do-IMRT	
PlanPTV_6500 D95 (%)	96.3	95.5	96.2	96.0	97.4	96.4	97.4	96.3	95.9	96.7	96.3	96.3	0.004
PlanPTV_5400 D5 (%)	101.8	102.2	102.4	102.6	101.7	102.0	101.6	102.3	102.0	101.3	101.6	101.9	0.001
PlanPTV_5400 D95 (%)	80.1	74.4	80.0	68.2	85.1	71.2	80.0	66.3	79.9	72.9	79.5	75.8	0.001
SpinalCord max dose (Gy)	44.2	44.5	40.0	42.8	35.2	42.3	37.9	42.6	38.9	38.5	42.5	41.2	0.080
Brainstem max dose (Gy)	45.2	41.2	42.0	42.4	44.1	46.0	38.6	44.1	40.0	39.5	36.4	38.6	0.235
Parotid_CL mean dose (Gy)	23.7	27.3	24.6	26.7	24.2	26.6	25.8	32.0	29.3	29.4	28.3	29.5	0.015
Parotid_IL mean dose (Gy)	24.0	28.3	35.2	36.1	32.1	38.2	37.0	46.0	35.2	29.6	29.6	30.6	0.131
PlanSMPCM mean dose (Gy)	57.9	49.2	56.3	45.6	57.5	48.6	58.3	49.3	56.1	49.6	56.7	50.0	0.000
PlanIPCM mean dose (Gy)	53.6	38.6	50.3	20.0	51.5	19.3	52.6	29.9	45.3	39.9	56.2	29.9	0.000

Conclusion: Do-IMRT can be achieved using VMAT for the DARS trial. Fixed-field IMRT may also be used to reduce constrictor dose, however is unlikely to produce plans acceptable within the DARS trial QA guidelines.

PO-0859

Quantifying and categorizing plan rejections as a part of the clinical process improvement

C. Speirs¹, J. LaBrash¹, S. Mutic¹, Y. Rao¹, S. Rehman¹, M.C. Roach¹, J.M. Michalski¹, S.M. Perkins¹

¹Washington University Medical Center, Radiation Oncology, St. Louis, USA

Purpose or Objective: RT plan rejections are defects that cause suboptimal or erroneous treatments if undetected and should be a focus of improvement. Applying the DMAIIC (Define, Measure, Analyze, Improve, Implement, and Control) formalism to clinic workflow provides actionable parameters for feedback and process correction. In our clinic, a web-based treatment planning board shows the real-time workflow and compiles causes of plan rejection, which can be categorized and quantified for subsequent process improvement efforts.

Material and Methods: Data was collected from July 2014-September 2015. 341 (of 673) entries associated with plan rejection were categorized as changes in one of the following: (1) tumor anatomy/patient setup; (2) dose/volume; (3) tumor/OAR constraints; (4) treatment planning modification generated during plan review; and (5) external (patient-, disease-, or hospital/equipment-generated) causes. Each entry was initiated by the physician, physicist, or dosimetrist involved in planning. Analyzed time intervals included the following: (1) dosimetry contours; (2) MD contour approval; (3) dosimetry plan computed; (4) physics plan precheck; (5) MD plan approval; and (6) total time for planning from simulation/planning board entry until MD plan approval (TMD). The data was analyzed with Two-way ANOVA, Student T-test, and Pearson correlation.

Results: The mean TMD time was 85 hrs (+/- 45). With breakdown by interval, the mean dosimetry contour (16 hrs), MD contour approval (27 hrs), dosimetry planning (12 hrs), physics precheck (4 hrs), and MD approval (11 hrs) times were calculated. The planning modification category was a significant source of variation in planning time (p<0.0001). Treatment planning modifications presented the predominant (50%) source of planning delay, followed by constraint (26%), dose/volume (18%), external (4%), and tumor anatomy/patient setup changes (2%). Those with tumor anatomy/patient setup or dose/volume changes resulted in the longest TMD, dosimetry contour, dosimetry plan computing, and MD plan approval intervals. 27% of plan modifications were initiated by physicians, 70% by physicists, and 3% by dosimetrists. Entries initiated by physicians on the planning board were associated with shorter TMD times than when physicists initiated plan rejection (p=0.016).

Conclusion: We report a novel process for quantification of clinical RT plan rejections. In this analysis, tumor anatomy/patient setup or dose/volume changes resulted in the longest treatment TMD times. Physician-initiated plan modification entries were associated with shorter TMD times,

which may denote early, proactive involvement—an optimal approach with complicated or aggressive disease. Though planning delays may depend on department infrastructure and patient population, our method provides a comprehensive census to optimize planning throughput and can be applied as a part of broader process improvement.

PO-0860

Is there a “best technique” available for reducing acute toxicities in craniospinal Irradiation?

M. Devecka¹, M.N. Duma^{1,2}, S. Kampf^{1,3}, C. Hugo¹, K.M. Hofmann¹, B.S. Müller^{1,3}, C. Heinrich¹, J.J. Wilkens^{1,2,3}, S.E. Combs^{1,2}

¹Klinikum rechts der Isar- Technische Universität München, Department of Radiation Oncology, Munich, Germany

²Institute of Innovative Radiotherapy IRT, Department of Radiation Sciences- Helmholtz Zentrum München, Munich, Germany

³Technische Universität München, Physik-Department, Munich, Germany

Purpose or Objective: Craniospinal irradiation is performed rarely in a palliative intention due to concerns of acute toxicities (mostly dysphagia and bone marrow suppression). Therefore the purpose of this study was to evaluate the dosimetric parameters responsible for the acute toxicity in patients with leptomeningeal metastasis of a solid cancer treated with craniospinal irradiation (CSI) by helical tomotherapy (HT), 3D conformal radiotherapy (3D-CRT) and Protons.

Material and Methods: Data of five adult patients previously treated with HT CSI were evaluated. For each patient the initial tomotherapy plan (inHT) was compared to a 3D conformal plan (3D-CRT), a scanning proton beam plan (p-CSI) as well as to a specifically optimized bone marrow (BM) sparing tomotherapy plan (BM-HT). The BM-HT was also optimized to reduce the acute dysphagia. The prescribed dose was 36 Gy. All active bone marrow compartments were delineated separately according to Campbell et al. To analyse the impact of different bone marrow compartments weighted bone marrow exposure (WBME) was used. $WBME_{Dmean} = \sum(\text{proportion}(\%) \text{ of functional bone marrow according to anatomical site} \times D_{mean} \text{ to anatomical site})$ $WBME_{V20} = \sum(\text{proportion}(\%) \text{ of functional bone marrow according to anatomical site} \times V20 \text{ to anatomical site})$ This calculation was also performed for V30.

Further, the following organ at risks (OARs) were delineated: left and right submandibular glands, the parotid glands, the eyes, the cochlea, the oral cavity, the pharynx, the thyroid gland, the esophagus, the heart, both lungs, both kidneys, the liver, the bowel, and the pancreas. For all of these structures the Dmean in all four treatment plans were analyzed. Descriptive statistics were used to analyze the results.

Results: p-CSI results in the best sparing of the organs at risk (OARs) including the active bone marrow compartments. BM-HT achieved better results as inHT and 3D-CRT regarding bone marrow sparing (see Figure 1.). Dose to the crucial OARs responsible for dysphagia was also reduced with BM-HT. The trade off for this was a slightly increased lung and kidney dose.

Figure 1. Total bone marrow and weighted bone marrow dosimetry (presented are averages and 95% confidence intervals).

Conclusion: With the use of the novel techniques such as p-CSI and BM-HT quality of life impairing acute side effects such as cytopenias and dysphagia can be reduced. We propose WBME to better assess the impact on active bone marrow.

PO-0861

Whole lung irradiation using VMAT - dosimetric and NTCP benefits vs. second cancer risks

P. Clarke¹, S. Padmanaban¹, M. Partridge², T. Foord³, D. Cutter³

¹Oxford Cancer Center, Radiotherapy Physics, Oxford, United Kingdom

²CRUK/MRC Oxford Institute for Radiation Oncology, Gray Laboratories- University of Oxford, Oxford, United Kingdom

³Oxford Cancer Center, Clinical Oncology, Oxford, United Kingdom

Purpose or Objective: Whole lung irradiation (WLI) of 12 to 18 Gy is used as treatment for lung metastases in patients with Ewing sarcoma and Wilms tumour. This results in irradiation of normal tissues including heart and breast. Conventionally this treatment has been delivered with standard AP-PA fields. To minimise cardiac radiation dose and reduce the risk of subsequent late complications, we validated the use of VMAT to deliver WLI without increasing the predicted risks of secondary breast cancers compared to AP-PA fields.

Material and Methods: Five female patient datasets (ages ranging from 3 to 18 years) were used for this retrospective study. The planning target volume (PTV) included total lung volume with a 1 cm margin (and adjacent vertebrae for three patients). Organs at risks included were heart, breast bud/tissue, liver and thyroid. 6 MV AP-PA (with segments) and RapidArc (2 or 3 full arcs) plans were created using the Eclipse treatment planning system (Version 11). Plans were calculated using the anisotropic analytical algorithm (AAA). The prescribed dose was either 15 Gy in 10 fractions or 18 Gy in 12 fractions based on the patient's age. PTV D2%, D98% and D50% and mean and maximum doses for heart and breast were obtained. The absolute excess risk (AER) of cardiac mortality at 15 years post treatment was calculated for each plan based on an age-at-exposure adjusted relative risk per Gy obtained from published data (1,2,3,4) combined with contemporary UK population-based absolute risks. The risk of breast cancer induction was calculated using the model proposed by Schneider et al. (2011) (5).

Results: The VMAT plans resulted in a similar minimum PTV coverage when compared to the AP-PA plans whilst reducing the PTV D2% by an average of 6.1% (4.1 - 9.1). The use of VMAT reduced the heart and breast mean dose by an average of 19.1% (11.7 - 30.5) and 16.2% (-2.2 - 30.4) respectively when compared to the AP-PA plans. The difference in AER of cardiac mortality at 15 years was lower for the VMAT plans by an average of 0.48% (0.11 - 0.98). The average excess absolute risk (EAR) for breast cancer induction across all plans decreased by 2.9% (-0.8 - 6.8) when compared to the conformal plans (assuming $\alpha/\beta = 3$ Gy, $\alpha = 0.067$ Gy⁻¹, $R = 0.62$, $\mu = 4.8/10000$ PY/Gy).

Table: Calculated mean dose, AER and EAR per patient.

Patient	Age	Dose [Gy]	Heart			
			Mean Dose [Gy]		AER [%]	
			AP-PA	VMAT	AP-PA	VMAT
1	17	18	18.6	12.9	3.19	2.21
2	18	18	18.5	13.7	3.29	2.43
3	13	15	15.5	13.1	2.07	1.75
4	3	15	15.4	13.6	0.98	0.87
5	3	15	15.4	13.6	0.98	0.87

Patient	Age	Dose [Gy]	Breast			
			Mean Dose [Gy]		EAR [#10k/yr]	
			AP-PA	VMAT	AP-PA	VMAT
1	17	18	18.2	14.2	26.5	24.7
2	18	18	13.5	10.4	22.0	22.1
3	13	15	12.5	8.7	21.8	20.4
4	3	15	14.3	13.1	24.9	24.2
5	3	15	13.6	13.9	24.6	24.7

Conclusion: VMAT achieved highly conformal plans and reduced cardiac late normal tissue complication probability whilst also reducing (or achieving similar) predicted risk of second cancer induction in breast tissue.

PO-0862

Comparison of Monte-Carlo computed 50 kV X-rays radiation therapy and EBRT for rectal cancer.

M. Vidal¹, M. Gautier¹, O. Croce², J.P. Gerard¹, K. Benezery¹

¹Centre Antoine Lacassagne, Radiotherapy, Nice, France

²Institute for Research on Cancer and Aging of Nice IRCAN, INSERM U1081 - CNRS UMR 7284 - UNS, Nice, France

Purpose or Objective: Traditionally, patients with rectal cancer (T2 anterior low rectum, T3-T4 N0-N+) are treated with preoperative radiotherapy or chemoradiation (CAP 50 regimen). 3D Conformal Radiation Therapy is conventionally delivered: 44 Gy more 6 Gy as a sequential boost to the high risk target volume (total dose 50 Gy). Another strategy would be to use the Contact Therapy technique [1] using 50 kV X-rays (CXRT) to deliver higher dose (30 Gy) to the high risk target volume in addition to 44 Gy. The present study first describes CXRT dose computation with Monte-Carlo simulations and then compares the resulting dose (EBRT+CXRT) with the conventional treatment (EBRT only).

Material and Methods: The CXRT machine Papillon 50™ installed in Centre Antoine Lacassagne (Nice, France) delivers a 50 kV X-ray beam with a dose rate close to 15 Gy/min, allowing treatment delivery more comfortable for the patients [2]. The system is currently used for treating skin and rectal cancers. The detailed geometry of the Papillon 50™ machine [3] was fully generated in Monte-Carlo code PenEasy based on PENELOPE [4] and the resulting simulations were validated against measurements in water (depth dose curves and transverse dose profiles) for all applicators used for rectum cancer. For 10 patients with T2-T3 nodes smaller than 3 cm, dose distributions were calculated to irradiate the high risk target volume. For each patient, 30 Gy CXRT dose was computed with Monte-Carlo simulation in 3DCT patient data acquired in a position close to the rectal cancer CXRT position (genupectoral position). 6 Gy EBRT treatment was computed with the commercial TPS Isogray (Dosisoft) in the 3DCT scan acquired in supine position. Both dose distributions were compared in terms of dosimetric indices computed for target volumes (conformity and homogeneity indices) and dose to organs at risk.

Results: Monte-Carlo penEasy simulations are in good agreement with the Papillon50™ measurements in water for

all rectum applicators. Simulations in patients 3DCT scan allowed us to evaluate CXRT dose to organs at risk and to the target volume. The comparison of dosimetric indices of EBRT and CXRT treatment delivery for the high risk target volume showed that the CXRT technique delivers higher dose to the target volume for the same dose, or even less for some cases, to the organs at risk.

Conclusion: Monte-Carlo simulations are useful to compute accurate dose distributions in 3DCT patient data for the CXRT treatment delivery. Moreover, this comparative study between the EBRT and CXRT techniques confirms the role of CXRT in curative treatment with organ preservation for early rectal cancers.

PO-0863

Localizing the benefit of a hydrogel rectum spacer for prostate IMRT within the ano-rectal wall

B.G.L. Vanneste¹, F. Buettner², M. Pinkawa³, P. Lambin¹, A.L. Hoffmann⁴

¹MAASTRO clinic, Radiation Oncology, Maastricht, The Netherlands

²European Bioinformatics Institute, European Molecular Biology Laboratory, Hinxton- Cambridge, United Kingdom

³Radiation Oncology, RWTH Aachen University, Aachen, Germany

⁴University Hospital Carl Gustav Carus at the Technische Universität Dresden, Radiotherapy, Dresden, Germany

Purpose or Objective: In previous studies the dosimetric impact of an implanted rectum spacer (IRS) in prostate cancer patients undergoing intensity-modulated radiation therapy (IMRT) has been assessed by dose-volume histograms (DVHs) and dose-surface histograms (DSHs) obtained from 3D dose distributions of the ano-rectal wall (ARW). Unfortunately, spatial information is lost when analyzing DVHs or DSHs. This hampers to study the correlation between the shape and location of the ARW dose distribution and clinical outcome. Dose-surface maps (DSMs) have been suggested as a valuable tool for taking the spatial-dosimetric information into account. The purpose of this study is to assess spatio-dosimetric differences in DSMs obtained from planned ARW dose distributions in patients receiving IMRT with and without IRS (IMRT+IRS; IMRT-IRS, respectively).

Material and Methods: In 26 patients with localized prostate cancer a hydrogel rectum spacer (SpaceOAR®, Augmenix) was injected under transrectal ultrasound guidance in Denonvilliers' space between the prostate and the rectal wall. Per patient, two IMRT treatment plans (78 Gy in 39 fractions) were designed, based on CT scans acquired before and after hydrogel injection. DSMs of the ARW were generated from the planned 3D dose distributions by virtual unfolding the rectum contour as described in Buettner et al. (Fig. 1a-b).

Figure 1a
Rectal wall DSM (in Gy) without IRS (left) and with IRS (right). Vertical axis corresponds to superior-inferior direction. Horizontal axis represents circumferential direction: P, posterior; L, left; A, anterior; R, right.

Figure 1b
Anal wall DSM (in Gy) without IRS (left) and with IRS (right).

Various shape-based dose measures were extracted from the DSMs. First, dose clusters were generated by thresholding the DSMs at 38 dose levels ranging from 5-79 Gy. Then, for each dose level an ellipse was fitted to the largest dose cluster. Lateral (posterior-anterior-posterior) and longitudinal (superior-inferior) extents were quantified by projecting the major and minor axes of this ellipse to the main axes of the DSMs. The non-circularity of the dose clusters was described by the eccentricity of the ellipse. The contiguity of the ARW dose distribution was assessed by the contiguous-DSH (cDSH), reflecting the single largest contiguous ARW area fraction as function of the dose threshold at the given level. Statistical differences were assessed with a one-sided paired Wilcoxon signed rank test.

Results: Lateral extent, longitudinal extent as well as cDSH were significantly lower in IMRT+IRS than for IMRT-IRS at high-dose levels. Largest significant differences were observed for cDSH at dose levels >50Gy, followed by lateral extent at doses >57Gy, and longitudinal extent. For these three features, no significant differences were observed for low to medium dose levels. For eccentricity no significant differences were found, independent of the dose level.

Conclusion: Significant spatio-dosimetric differences in ARW DSMs exist between prostate cancer patients undergoing IMRT with and without IRS. The IRS particularly reduces the lateral and longitudinal extent of high-dose areas (>50 Gy) in anterior and superior-inferior directions.

PO-0864

A planning study investigating different planning techniques for SBRT of NSCLC.

C. Moustakis¹, I. Ernst¹, F. Ebrahimi Tazeh Mahalleh¹, U. Haverkamp¹, H.T. Eich¹, M. Guckenberger²

¹University Muenster, Radiation Oncology, Münster, Germany

²University Zurich, Radiation Oncology, Zürich, Switzerland

Purpose or Objective: SBRT is a novel treatment procedure, which is used for the particular localization of the tumor to deliver targeted high doses with greatly precise fields. Different irradiation techniques provide a wide spectrum of therapy options. The aim of this work was to evaluate the clinical benefits and potential dosimetric of different planning methods against each other for the treatment of NSCLC.

Material and Methods: In this study, three diagnosed patients with NSCLC metastasis, were chosen. One had a peripheral metastasis in the left lung, the other had a metastasis in the right lung, and the last one had a central metastasis located near to vertebral body. The delineated structures (PTV and OARs) on CT were shared among 22 clinics with the request to generate an irradiation plan with their own internal criteria. Three fractions of 15 Gy were prescribed to the PTV-enclosing 65%. All together it was

assembled 78 treatment plans, that they were generated, 36 IMAT, 18 3DCRT, 3 IMRT, 9 helical irradiation and 12 robotic radiosurgery. All gathered data were finally imported into one treatment planning system for evaluating different planning strategies.

Results: In all plans, the dosimetric coverage of the target volume and the dose to OARs were within clinical limits. The coverage of the PTV were disclosed: CICRU =1.0(0.9-1.1); CI65 =0.7(0.4-1.0); HI=0.3(-0.3-0.5); Dmin/Dmax=0.6(0.5-0.7); D2%, =64.6(47.5-71.3)Gy; D98%=47.2(39.5-68.6)Gy; Dmiddle=57.8(47.3-65.8)Gy.

In the 3DCRT Plans, the mean dose in the PTV was on average, 3 Gy higher than dynamic techniques; MU and irradiation time were by the factor of 2-3 higher in the dynamic techniques. Dose to the OARs for the 1st and 2nd patient is as follows: Dmedi, ipsilat. lung = 4.9 (3.2-8.8)Gy; Dmax, esophagus =7.7(0.4-16.1)Gy. V35Gy, ribs =10(0.6-43.7). For the 3rd one: Dmedi., ipsilat. lung = 8.3(6.8-10)Gy; Dmedi., contralat. lung = 2.3(1.4-4.7)Gy Dmax, esophagus=20.7(11.3-27.7)Gy.

Picture shows the Dmax for the spinal cord.

Conclusion: All irradiation techniques were applicable for clinical use, the resulting dose distribution were quite similar. By comparison, the statistically significant differences between the users were greater than the differences between the techniques. This demonstrate that strict constrains and works like the DEGRO reference paper (Guckenberger et al) are necessary to homogenize the SBRT planning at a national level.

This study reports the results of the irradiation planning for the treatment of NSCLC with SBRT depends largely on the user.

PO-0865

Developing sciatic nerve-sparing stereotactic radiotherapy for re-irradiating the pelvic sidewall

M. Llewelyn¹, E. Wells², A. Taylor¹

¹Royal Marsden NHS Foundation Trust, Department of Gynaecology, London, United Kingdom

²Royal Marsden NHS Foundation Trust, Department of Radiotherapy, London, United Kingdom

Purpose or Objective: Management of pelvic sidewall recurrence in gynaecological cancers is a challenging clinical scenario. Sciatic nerve involvement may exclude surgery and cause intractable symptoms that are difficult to palliate. In the context of re-irradiation, high doses of radiation without consideration of the sciatic nerve can cause irreversible

nerve damage, yet this has not traditionally been included as an OAR.

The aims of this study were to develop dose target constraints for re-irradiation of the sciatic nerve, and to assess the impact of nerve-sparing optimisation on target volume coverage and OAR sparing with stereotactic radiotherapy techniques.

Material and Methods: Cumulative dose constraints for re-irradiation were derived assuming prior pelvic radiotherapy of 50Gy (EQD2) and allowing nerve recovery values of 50% and 100%. Treatment plans were produced for 10 patients with recurrent gynaecological cancer delivering 30 Gy in 5 fractions. Two normalisation methods were assessed: ICRU 83 type normalisation and prescription (ICRU); and stereotactic radiotherapy convention of prescribing to the isodose covering 95% PTV allowing maximum doses of ~125% (SRS). For each method, plans were optimised with and without sciatic nerve sparing targets. Sciatic nerve roots were contoured from sacral foramina until the nerve exits the pelvis. Nerve sparing plans were optimised to minimize dose to nerve PRV while maintaining PTV coverage. Doses to GTV, PTV, OAR and sciatic nerve were compared.

Results: All 40 plans met the PTV targets with >95% PTV coverage by the specified isodose. The sciatic nerve was involved in 3 patients, close proximity (<5 mm) in 4 patients and more than 5 mm distant from PTV in 3 patients. The dose targets were Dmax 32 Gy when there was nerve involvement and 21.9 Gy when the nerve was distant from tumour. For all patients, the sciatic nerve dose was reduced with each technique: median Dmax with ICRU from 28.8 Gy to 22.3 Gy and with SRS from 28.7 Gy to 19.9 Gy. For patients with overt nerve involvement, median Dmax was reduced from 34.9 Gy to 32.1 Gy with SRS. Nerve sparing was achieved without significantly decreasing GTV mean doses or increasing bowel doses.

Conclusion: The sciatic nerve should be an OAR for re-irradiation of sidewall recurrence. Optimisation using a sciatic nerve PRV can significantly reduce dose to nerve by up 40% (EQD2-2) while having minimal effect on GTV coverage or bowel doses. Feasible dose targets depend on proximity of nerve to GTV and clinical scenario.

PO-0866

Evaluation of three planning RT techniques for boost phase in pediatric medulloblastomas

A.R. Figueira¹, A.R. Lago¹, A. Monteiro¹, D. Monteiro², D. Inácio¹, L. Osório¹, M.J. Fontes¹, P. Varzim¹, G. Pinto¹

¹Hospital de São João, Radiotherapy, Porto, Portugal

²University of Lleida, Medicine, Lleida, Spain

Purpose or Objective: Over the last half century we have seen remarkable improvements in the survival of pediatric cancer patients. Therefore, the impact of cancer and its treatment must be assessed. Furthermore, the radiotherapy technique must be well selected in order to minimize the secondary effects. Since hearing loss is a common late effect of radiotherapy, the purpose of this study was to compare three different treatment techniques and to evaluate the dose to the cochleas and supretentorial brain, in children treated with radiotherapy for medulloblastoma.

Material and Methods: A total of 121 children were treated in our department with radiotherapy for CNS tumors, between January 2000 and December 2014. Those who were diagnosed with medulloblastoma were included. A total of 29 children fulfilled these criteria. The adopted treatment plan consisted of a first phase with three-dimensional conformal radiotherapy (3D-CRT) to the craniospinal region (prescribed doses from 23.4 to 36.0 Gy) followed with a boost to the PTV (posterior fossa/tumor bed) with prescribed doses of 18.0 or 31.6 Gy depending on the clinical risk-group, high or standard risk respectively. For each child, three different treatment plans were prepared for the boost phase: one with conventional 2 parallel opposed fields (CRT), one more complex with 3D conformal radiotherapy (3D-CRT) and

another with IMRT. The original plans delivered to the patients were not considered in this study because treatment techniques have been changing since 2000 and were not uniform within the selected group. All plans assured PTV coverage according to ICRU 83 criteria. Cochleas and supratentorial brain mean doses, as organs, were analyzed using QUANTEC values and compared for each plan.

Results: Among 29 children, 22 were males. The median age at diagnosis was 8.66 years. At the beginning of treatment, their age range from 3.26 to 15.47 years old. The average mean dose to the OAR analyzed are presented in Table 1.

Table 1: Average Mean Doses to OARs

Mean Dose (Gy)	High Risk			Standard Risk		
	CRT	3D-CRT	IMRT	CRT	3D-CRT	IMRT
Right Cochlea	17,6	11,0	10,0	29,3	18,0	16,4
Left Cochlea	17,4	11,0	9,0	29,0	19,0	15,0
Supratentorial Brain	6,0	4,5	4,9	10,0	7,5	8,2

Conclusion: The plans for the CRT technique, with 2 parallel opposed fields, produced worst results for both OARs. The IMRT technique was slightly superior to the 3D-CRT in terms of mean dose of cochleas but conducted, in average, to higher dose values to the supratentorial brain. Based on these results we decided to adopt the 3D-CRT technique for the boost phase in high-risk group and IMRT for the standard-risk group, considering the higher potential impact in the cochleas mean doses in this risk-group.

PO-0867

Treatment planning study for spatially fractionated mini-beam radiotherapy

A. Alexander¹, C. Crewson¹, W. Davis², M. Mayer³, G. Cranmer-Sargison¹, V. Kundapur⁴

¹Saskatchewan Cancer Agency - Saskatoon Cancer Centre, Medical Physics, Saskatoon, Canada

²University of Saskatchewan, Physics and Engineering Physics, Saskatoon, Canada

³University of Saskatchewan, Small Animal Clinical Sciences, Saskatoon, Canada

⁴Saskatchewan Cancer Agency - Saskatoon Cancer Centre, Radiation Oncology, Saskatoon, Canada

Purpose or Objective: This work is to present the treatment planning workflow and delivery technique for the first application of linac based spatially fractionated mini-beam radiotherapy within a clinical trial of canine brain tumor treatments. The motivation for this investigation originates from work performed using synchrotron generated micro-beams (MRT) which have shown promising results in preserving brain architecture while killing tumor cells. Spatial fractionation of radiation using arrays of parallel micro-planar beams is a developing technique with many unknowns and limitations. To further research this technique and to potentially enable MRT for human treatments, a mini-beam collimator has been designed for use with a linac and a Monte Carlo (MC) beam model has been commissioned for clinical treatment planning.

Material and Methods: Patient population was selected from client-owned canines with spontaneously occurring brain tumors. Patients were placed under general anesthesia and positioned prone within stereotactic immobilization equipment during imaging and treatment delivery. CT and MRI images were used for contouring. The planning technique utilized an arrangements of static mini-beams. Beam angles were chosen such that the treatment depth was within 20% for each beam to minimize beam broadening with depth and blurring of the peak and valley doses. Beam apertures were defined with the MLC leaves set 3 mm back from the PTV. The mini-beam collimated dose distributions were calculated to a statistical uncertainty of $\pm 1.0\%$ within a voxel size of 0.5 mm. Beam weighting was equalized and the plan normalized such that the prescription dose was delivered to an ICRU dose

reference point within the PTV. Deliver quality assurance (DQA) was performed by measuring the absolute dose from each beam using an ion chamber within a solid water phantom.

Results: Contouring and beam arrangement, which included MLC placement, was performed within the clinical treatment planning system (TPS). The DICOM plan was then exported to the MC treatment planning system for mini-beam dose calculation. The distribution was reviewed and DVHs assessed for normal tissue tolerances. The final step was to transcribe the calculated MUs back to the original TPS. Planning turnaround time was 2 days. The MC calculations were initiated overnight at the end of day 1. Day 2 was spent reviewing the plan, generating the DQA plan, and finalizing the treatment parameters into the record-and-verify system (RVS). DQA output measurements of the treatment fields agreed with the calculated dose to within 1.5%. An image of the patient dose distribution and setup is shown in figure 1.

Figure 1: Colorwash display of mini-beam dose distribution (top), photo of patient setup with mini-beam collimator (bottom)

Conclusion: A workflow for mini-beam treatments that includes the planning technique, MC dose calculation method, DQA process, and data integration into a RVS has been established. This clinical dataset represents the first treatment planning study of linac based mini-beam patients.

PO-0868

A method to define isodose-based structures in Dose Painting treatment of GBM in Tomotherapy.

M. Orlandi¹, A. Botti¹, E. Cagni¹, L. Orsingher¹, R. Sghedoni¹, P. Ciammella², C. Iotti², M. Iori¹

¹Arcispedale S. Maria Nuova, Fisica Medica, Reggio Emilia, Italy

²Arcispedale S. Maria Nuova, Radioterapia, Reggio Emilia, Italy

Purpose or Objective: The aim of this study is to investigate different strategies in choosing, in a mathematical way, the structure set that best fit a Dose Painting (DP) distribution, based on ADC maps, to be submitted to the optimization process within the TomoTherapy TPS.

Material and Methods: Hypofractionated Stereotactic Radiation Therapy plans in 5 fractions of intracranial GBM for six patients were retrospectively realized.

A non-uniform Dose Painting By Numbers Dose Distribution (DPBN) was obtained from an ADC map of each patient registered with the planning CT scan. The pixels values within the CTV of the registered ADC maps were converted to dose values through the function of Eq. 1, where $D_{min} = 25$ Gy, $D_{max} = 50$ Gy, $I_{min} = 500$ mm²/s e $I_{max} = 1500$ mm²/s. According to Deveau et al., (Acta Oncol. 2010) 9 isodose levels of the DPBN should be converted into structures in order to restrict the number of planning structures in the TPS optimization step. Four different methods to select the isodose levels were implemented.

IsoDose Method (IDM). The dose interval prescription is divided in 9 equal sub-intervals (Fig. 1.a). In this way the sub-intervals are dependent on the dose prescription interval only.

IsoVol Method (IVD). The volume of the CTV structure is divided in 9 equal subvolumes (Fig. 1.b). The absolute DVH of the DPBN of the CTV allows to associate to each volume value (cm³) a dose value. These are used as the isolevels to be converted in structures.

IsoVD Method (IVDM). An arbitrary function, indicated as ΔDV , was defined in Eq. 2 where D_{min} and D_{max} are the minimum and maximum prescribed dose, V_{max} is the total volume of the CTV, D_i and V_i are the dose and the volume at the point i in the DVH line. Dividing the $\Delta DV(D_i)$ function in 9 equi-spaced interval, as in Fig. 1.c, the corresponding dose values, from which derive the sub-structure for the optimization, were found.

minQF Method (mQM). Starting from a structure set of 9 isolevels obtained from DPBN, it is possible to calculate a Dose Painting By Contours Dose Distribution (DPBC), assigning to each voxel pertaining to the isolevels k a uniform dose of value D_k . This method imposes that the Quality Factor (QF), in Eq. 3-4 (Vanderstraeten et al., Phys. Med. Biol. 2006), between the DPBN and the DPBC be as close as possible to zero, using a genetic minimization algorithm (Matlab).

In order to estimate which method returns the DPBC more consistent with the DPBN, the QF and the QVH were computed for each method.

$$D(I) = \begin{cases} D_{max} & I < I_{min} \\ D_{min} + \frac{I - I_{min}}{I_{max} - I_{min}} \cdot (D_{max} - D_{min}) & I_{min} < I < I_{max} \\ D_{min} & I > I_{max} \end{cases} \text{ Eq. 1}$$

$$\Delta DV(D_i, V_i) = (D_i - D_{min}) \cdot (V_{max} - V_i) \text{ Eq. 2}$$

$D_i \in [D_{min}, D_{max}]$

$$V_i \in [0, V_{max}]$$

$$QF = \frac{1}{n} \sum_i |Q_i - 1| \text{ Eq. 3}$$

$$Q_i = \frac{DPBC_i}{DPBN_i} \text{ Eq. 4}$$

Results

Comparing the four methods, the results in Table 1 show that the mQM provides QF values closest to zero for six patients and that only in one patient the IVD is better than the mQM only of about 1 %. Also QVHs show lines more about to 1 for the mQM.

Method		Pz1	Pz2	Pz3	Pz4	Pz5	Pz6
IsoDose	(IDM)	0.0236	0.0309	0.0150	0.0362	0.0328	0.0181
IsoVol	(IVM)	0.0230	0.0330	0.0144	0.0432	0.0322	0.0209
IsoVxD	(IVDM)	0.0279	0.0398	0.0238	0.0509	0.0410	0.0259
minQF	(mQM)	0.0226	0.0283	0.0145	0.0310	0.0317	0.0161

Table 1

Conclusion: A robust and mathematical method in order to select the structure set that better fit a Dose Painting distribution was found in the mQM method. This method could be employed regardless the way used to obtained the Dose Painting distribution.

PO-0869

Comparing Varian EDGE and Gamma Knife for brain metastases radiosurgery. Preliminary results

S. Tomatis¹, P. Navarra², D. Franceschini², L. Cozzi², P. Mancosu¹, F. Lobefalo¹, G. Reggiori¹, A.M. Ascolese², A. Stravato¹, F. Zucconi¹, G. Maggi², M. Scorsetti²

¹Istituto Clinico Humanitas, Medical Physics Service of Radiotherapy- Radiotherapy and Radiosurgery Department, Rozzano Milan, Italy

²Istituto Clinico Humanitas, Radiotherapy and Radiosurgery Department, Rozzano Milan, Italy

Purpose or Objective: Brain metastases occur in 20-40 % of patients affected by primary solid tumors. Radiosurgery (SRS) was demonstrated to be safe and efficient for the brain metastases control. SRS can be delivered with dedicated equipment, like GammaKnife, or with conventional LINAC. Few comparative studies have been conducted. In our institution we designed a phase III randomized trial to evaluate cerebral side effects following SRS delivered by Gamma Knife Perfexion and Linac EDGE

Material and Methods: Patients with 1 to 4 brain metastases, from any primary except for small cell lung cancer (SCLC) or Lymphoproliferative disease, suitable for SRS were randomized to receive the treatment with GammaKnife or Linac. Primary end point was the symptomatic radionecrosis incidence; brain LC, DFS and OS were secondary end points. Planning parameters, including target coverage for accepted surface dose levels, paddick conformity index (PCI), gradient index (GI), homogeneity index (HI), maximum and minimum dose to the target were determined. Beam on time (BOT) was also recorded

Results: Until now, 26 patients with 39 metastases (range 1-3) were enrolled in this phase III trial (12 GK, 14 Linac-EDGE). Median prescribed dose was 24 Gy (range 21-24 Gy). Most common primary cancers were breast and melanoma. At the time of analysis 3 patients died. Follow up evaluation was available in 12 cases. No local progression was observed, 4 patients had a further intracranial progression. Until now, no radionecrosis was recorded. PCI was better for linac-based plans (0.93 vs 0.82), in contrast, a better GI for gamma knife was observed (2.5 vs 3.5). Due to the specific characteristics of the two delivery systems, HI was lower for linac (0.14 vs 0.80). BOT was lower for linacs (within 2 min for each target vs 35 min). In our center, linac based immobilization was made by an open mask setup (qfix); CBCT-based IGRT was applied; patients were monitored by optical surface monitoring system (OSMS) during the delivery. Gamma knife immobilization was performed by the traditional stereotactic head frame by Elekta. For this reason, no specific online imaging or tracking device was required

Conclusion: These are very preliminary results of a randomized phase III trial recently started in our institution. No significant clinical data can be provided yet, because of the short follow up time and the small number of enrolled patients. On the dosimetry side, the two systems have different characteristics and markedly different ways to prescribe dose. For linacs, a better dose distribution was obtained on the target rather than for normal tissues, even though no specific side effects were reported. In addition,

data suggested a better comfort for the patient for linac-based therapy, due to the shorter treatment time and the non-invasive immobilization system. Dosimetric data for the patients treated according to this protocol suggest a substantial balance between Gamma Knife and Linac EDGE treatments

¹⁰Medical University of Vienna - Vienna General Hospital, Department of Urology, Wien, Austria

¹¹San Raffaele Scientific Institute, Department of Oncology/Unit of Urology, Milano, Italy

Purpose or Objective: By pooling data of five large prospective studies/Institutional series, a large data base of pT2-pT3, pN0 patients treated either in the adjuvant or in the salvage setting with conventionally fractionated (1.8-2.0 Gy/fr) 3DCRT post-prostatectomy radiotherapy (RT) was available. The aim of the study was to fit individual data of biochemical-recurrence-free survival (bRFS) with a comprehensive Poisson-based TCP model.

Material and Methods: Considering pre-RT PSA as a surrogate of the number of clonogens, 5-year bRFS was expressed as a function of the dose depending on radiosensitivity (α_{eff}), number of clonogens for pre-RT PSA=1ng/mL (C) and the fraction of patients that relapses due to clonogens outside the treated volume, assumed to linearly depend on pre-RT PSA ($K=1-B \times PSA$), according to:

$$bRFS = (1 - B \times PSA) \times [1 - \exp(-\alpha_{eff} D)]^C \times PSA$$

In addition, the impact of Gleason score (GS) was included by performing separate fits for different sub-groups, depending on GS (<7, =7, >7). In total, complete data regarding bRFS, dose, pre-RT PSA (between 0.01 and 2.0 ng/ml) and GS of 894 hormone-naïve patients treated with adjuvant (n=331) or salvage (n=563) intent with a minimum follow-up of 3 years were available. Patients with GS<7, =7 and >7 were 392, 383, and 119 respectively. Best-fit procedures were performed with the sequential quadratic programming, using the sum of the squared residuals error as loss function (SPSS v.17, SPSS Inc., Chicago, IL). The 95% CI of the parameter's best-fit values were calculated by bootstrap. The performance of the resulting model was assessed by calibration plot.

Results: The median follow-up was 72 months; median pre-RT PSA and dose were 0.25 ng/mL (inter-quartile range: 0.1-0.5) and 66.6Gy (range:59.4-77.4Gy) respectively. The fit converged in all situations: depending on GS, best-fit values were in the range 0.20-0.22 Gy⁻¹ and 10⁶ for α_{eff} and C respectively; the maximum obtainable bRFS was reduced by 1.7, 4.9 and 5.6% for each 0.1ng/ml PSA increment for GS<7, =7 and >7 respectively. The calibration plot showed an

excellent agreement between predicted and expected values ($R^2=0.96$) and the AUC was 0.69 (95% CI: 0.66-0.73). The bRFS curves as estimated by the model vs prescribed dose for different pre-RT PSA (between 0.1 and 1.0 ng/ml) and for the three GS groups are plotted in the figure.

Conclusion: Long-term bRFS data of a large multi-centric data base of post-prostatectomy patients could be fitted by a radiobiologically consistent TCP model, showing a dose-effect critically depending on pre-RT PSA and GS. The model suggests that most relapses occur in patients with clonogens outside the treated volume, indirectly supporting lymph-nodal irradiation and/or systemic therapy for specific risk groups, depending on pre-RT PSA and GS. Early RT is preferred over delayed RT as the detrimental effect due to a PSA increase can never be compensated by increasing the dose, more dramatically evident for patients with GS ≥7.

⁵S. Camillo-Forlanini Hospital, Department of Radiation Oncology, Rome, Italy

⁶Memorial Sloan Kettering Cancer Center, Department of Medical Physics, New York, USA

Purpose or Objective: Traditional normal tissue complication probability (NTCP) models rely on dose-volume histogram (DVH) analysis, which disregards any spatial dose distribution information and possible inhomogeneity in regional organ radio-sensitivity. We propose a voxel-based (VB) approach to correlate local lung dose and radiation-induced lung damage (RILD).

Material and Methods: An inter-institutional database of 115 Hodgkin lymphoma survivors treated with sequential chemoradiotherapy (with 18 RILD cases after treatment) were included in the study. Sixteen patients were excluded due to an inadequate CT coverage of the lungs.

Each patient dataset was first normalized to a common template. Pre-registration steps were based on a binary mask extrapolated from the organ at risk segmentations of the treatment plan. For each patient, the mask, computed as the union and dilation (spherical structuring element of radius 30 mm) of heart and lung structures, was used to crop the field-of-view, allowing a coarse alignment of the structures of interest. CT images were masked accordingly in order to hide some anatomical inter-individual differences, and allowed the registration algorithm to work more efficiently on tissue contrast inside the chest. The median lung-volume patient was chosen as reference image in the non-rigid registration and a log-diffeomorphic approach [1] was used. The obtained deformation fields were then used to map the dose of each patient to the common coordinate system of the reference patient.

A voxel-wise two-sample t-test was then performed on the normalized dose maps and statistical significance of the differences between groups was displayed as p-value map.

Results: The robustness of co-registration process was assessed both by visual inspection (Fig. 1a-b) and by Dice scores for the lungs (Fig. 1c). On the whole population, the median Dice value was 0.94 (range: [0.87; 0.95]). As shown in

Fig. 1d-f, a significantly ($p < 0.01$) higher dose was delivered to RILD patients nearby the basal portion of the right lung and the submantellar region of the left lung. The average dose delivered to this volume (9.4% of the lungs) was of 5.3 Gy in RILD patients and 2.6 Gy in non-RILD patients.

Figure 1. a) Average of the pre-registration CTs. b) Average of the post-registration CTs. c) Lung Dice scores distribution. d) 3D anteroposterior volume rendering of the mean RILD patients' dose (gray scale) with in red the p -value map (masked for $p < 0.01$). e) Coronal view of the mean RILD patients' dose (gray scale) with in red the p -value map (masked for $p < 0.01$). f) Axial view of the mean RILD patients' dose (gray scale) with in red the p -value map (masked for $p < 0.01$).

Conclusion: By a VB approach we were able to highlight local dose-RILD relationship in the lungs. Interestingly, a significantly different dose was delivered in the low-dose (~ 5 Gy) parenchymal regions, in agreement with previous DVH analyses showing that the volume exceeding 5 Gy is consistently more predictive than other dosimetric variables. In order to obtain more powerful insights on local lung radiosensitivity, this preliminary results should be enriched by applying the VB approach to larger databases evaluating RILD in heterogeneously treated lungs.

PO-0872

The variability of the RBE in proton therapy: can we base it on empirical clinical data?

A. Lühr^{1,2,3}, C. Von Neubeck^{1,2,3}, M. Baumann^{1,2,3,4,5}, M. Krause^{1,2,3,4,5}

¹German Cancer Consortium DKTK, Partner Site Dresden, Dresden, Germany

²OncoRay - National Center for Radiation Research in Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden- Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

³German Cancer Research Center DKFZ, Heidelberg, Germany

⁴University Hospital Carl Gustav Carus- Technische Universität Dresden, Department of Radiation Oncology, Dresden, Germany

⁵Helmholtz-Zentrum Dresden - Rossendorf, Institute of Radiooncology, Dresden, Germany

Purpose or Objective: Particle therapy has the potential to improve radiotherapy due to the increase in dose conformity and RBE. The RBE depends on multiple factors including cell type, dose, particle type and energy. Accordingly, a variable RBE is clinically applied for carbon ion therapy, in contrast to a prescribed constant RBE = 1.1 in proton therapy

jeopardizing part of its accuracy. Therefore, it is the aim to enhance proton therapy by translating a more realistic RBE description into the clinic directly based on clinical (and preclinical) experience gained with photons and heavier ions such as helium and carbon ions.

Material and Methods: The RBE is considered to depend on a) the dose response of the biological endpoint and b) the heterogeneity of the dose distribution on the cellular level (similar to the local effect model). The heterogeneity is determined by the clinically accessible (prescribed) dose D and the beam quality $Q = Z^2/E$ (varying within the patient), where Z and E are the ion charge and kinetic energy, respectively. We propose an approach to obtain proton RBE by interpolating between the biological effectiveness of a homogeneous dose distribution for photons and an increasingly heterogeneous distribution for heavier and slower ions. Based on the linear-quadratic (LQ) model and the dose heterogeneity an analytical description of the radiobiological effect was derived. It suggests a linear increase of the LQ parameter for particle irradiation αP with beam quality Q . *In vitro* RBE data from the literature for different ion types, cell lines, and within clinically relevant LET ranges (below the RBE maximum) were analyzed.

Results: The considered RBE data seem to depend directly on beam quality Q (Figure 1a). In contrast, particle type together with LET appear as a surrogate for beam quality Q (Figure 1b). In accordance with the derived description, the LQ parameter αP increases linearly with Q (Figure 1c) and the RBE (Figure 1d) as well as αP could be approximated for all considered ions and cell lines with a simple formula depending on Q , D , and the photon LQ parameters αX and βX . The deviations between prediction and experiment are mostly within 10 - 20% and therefore on the order of uncertainties often associated with RBE experiments. The variation of BP with Q was much weaker and less conclusive.

Figure 1: Biological effectiveness for different beam qualities, beam energies, and ion types: green: proton; red: helium; black: carbon; cyan: neon. The same *in vitro* RBE data for human salivary gland tumor (HSG) cells as a function of a) beam quality $Q = Z^2/E$ and b) LET. c) Linear LQ parameter as function of Q for HSG cells. d) Modeled compared to measured RBE values for about 125 different combinations of cells, ion types and energies. The dashed lines visualize a 20% spread around the solid identity line. All lines are just to guide the eye.

Conclusion: As long as cells “experience” a comparable microscopic dose distribution they cannot distinguish between different ion beams confirming that RBE variability also exists in proton therapy. More realistic RBE values for proton therapy may be directly obtained from available empirical RBE data for heavier ions considering the same beam quality Q and endpoint or, alternatively, by interpolating between empirical data from photon irradiation and heavier ions. Experimental preclinical (and clinical) data should be gathered in order to validate the proposed strategy to enhance proton therapy.

PO-0873

Modelling severe late rectal bleeding in a large pooled population of prostate cancer patients

⁴University of Newcastle, School of Medicine and Public Health, New South Wales, Australia

⁵Cliniche Humanitas-Gavazzeni, Radiotherapy, Bergamo, Italy

⁶Ospedale Santa Chiara, Radiotherapy, Trento, Italy

Purpose or Objective: To develop a model for grade 3 (G3) late rectal bleeding (LRB) after radical radiotherapy (RT) for prostate cancer, in a pooled population from two large prospective trials.

Material and Methods: The trials included patients (pts) treated with a conventional fractionated 3DCRT at 66-80Gy. Planning data were available for all pts. G3 LRB was prospectively scored using the LENT/SOMA questionnaire, with a minimum follow-up of 36 months. Rectal dose-volume histograms were reduced to an Equivalent Uniform Dose (EUD) distribution calculated with volume-effect parameter, n, derived by 3 studies: n=0.018 (Defraene IJROBP2011), n=0.05 (Rancati RO2011) and n=0.06 (Rancati RO2004). EUD was inserted into a multivariable logistic (MVL) regression together with clinical and treatment features. Irradiation of seminal vesicles (SV), irradiation of pelvic nodes, hormonal therapy, hypertension, previous abdominal surgery (SURG), use of anticoagulants, diabetes, cardiovascular diseases and presence of acute toxicity were considered as potential dose-modifying factors. Goodness of fit was evaluated with Hosmer Lemeshow test (HL), calibration through fitting slope, while the AUC was used for the discrimination power.

Results: A total of 1337 pts were available: 708 from first trial and 669 from the second one. G3 LRB was scored in 95 pts (7.1%): 62 and 33 in the first and second trial, respectively. EUD calculated with the volume parameter n=0.06 was the best dosimetric predictor for G3 LRB. A 4-variable MVL model was fitted including EUD (OR=1.07 p=0.02), SV (OR=4.75 p=0.01), SURG (OR=2.30 p=0.02) and cardiovascular disease (OR=1.42 p=0.18). This model had an AUC=0.63, a calibration slope=0.99 (R²=0.89) and a p for HL=0.43.

Figure 1 shows dose response relationship (model vs observed toxicity rates) as a function of SV irradiation, cardiovascular disease and abdominal surgery.

Inclusion of acute toxicity (OR=2.34 p<0.001) slightly improved AUC (0.65), confirming a possible role of consequential injury.

Variables	Coefficient	Standard Error	P> z	Odds Ratio
Cardiovascular disease	0.35	0.26	0.18	1.42
Previous abdominal surgery	0.83	0.36	0.02	2.3
Irradiation of seminal vesicles	1.55	0.6	0.01	4.7
EUD with n=0.06	0.07	0.028	0.02	1.07

Conclusion: EUD with n=0.06 was predictive of G3 LRB in this pooled population, confirming the importance of sparing the rectum from high doses. Irradiation of seminal vesicles together with the presence of cardiovascular disease and previous abdominal surgery were relevant dose-modifying factors highly impacting the incidence of G3 LRB.

PO-0874

Dose prescription in carbon ion radiotherapy: how to compare different RBE-weighted dose systems.

S. Molinelli¹, G. Magro², A. Mairani¹, A. Mirandola¹, N. Matsufuji³, N. Kanematsu³, A. Hasegawa³, S. Yamada³, T. Kamada³, H. Tsujii³, F. Valvo¹, M. Ciocca¹, P. Fossati⁴, R. Orecchia⁵

¹Fondazione CNAO, Medical Physics, Pavia, Italy

²Università degli studi di Pavia, Fisica, Pavia, Italy

³National Institute of Radiological Science, Research Center for Charged Particle Radiotherapy, Chiba, Japan

⁴Fondazione CNAO, Radiotherapy, Pavia, Italy

⁵Istituto Europeo di Oncologia, Radiotherapy, Milan, Italy

Purpose or Objective: In carbon ion radiotherapy (CIRT), mainly two calculation models are adopted to define relative biological effectiveness (RBE)-weighted doses (DRBE): the Japanese Kanai model and the Local Effect Model (LEM). Taken the Japanese longest-term clinical data as a reference, the use of a different RBE model, with no correction for the Gy (RBE) scale, leads to deviations in target absorbed dose (Dabs) with a potentially significant impact on tumor control probability. In this study we validate a conversion method linking the two DRBE systems, confirming DRBE prescription dose values adopted in our LEM-based protocols.

Material and Methods: The NIRS beamline was simulated with a Monte Carlo (MC) code, according to design information about elements position, size and composition. Validation went through comparison between simulated and measured pristine and Spread Out Bragg Peaks, ridge filter based, in water. CT scan, structure set, plan and dose files of 10 treatment fields delivered at NIRS were exported in DICOM format, for prostate (3.6 Gy (RBE) per 16 fractions), Head & Neck (4 Gy (RBE) per 16 fractions) and pancreas (4.6 Gy (RBE) per 12 fractions) patients. Patient specific passive system geometries (range shifter, MLC, compensator, collimator) were implemented, for each field, to simulate delivered Dabs distributions. The MC code was then interfaced with LEM to calculate DRBE resulting from the application of a different RBE model to NIRS physical dose. MC and TPS calculated Dabs and DRBE were compared in terms of dose profiles and target median dose. Patient CT and structure sets were also imported in a LEM-based commercial TPS where plans were optimized prescribing the non-converted and converted DRBE values, respectively.

Results: The agreement between MC and measured depth dose profiles in water demonstrated beamline model accuracy. Patient dose distributions were correctly reproduced by MC in the target region, with an overall target median dose difference < 2%. MC median DRBE resulted 16% higher than NIRS reference, for the lower prostate dose level,

10% for head and neck and 4.5% for pancreas, in agreement with respective LEM-based prescription doses, adopted in our protocols. Deviations are expected to be close to zero around a prescription $DRBE = 5 \text{ Gy (RBE)}$. Target under-dosage was shown in LEM-based optimized plans, when uncorrected $DRBE$ were prescribed.

Conclusion: The delivery of a voxel by voxel iso-effective plan, if different RBE models are employed, is not feasible; it is however possible to minimize differences in dose deposited in the target. Dose prescription is a clinical task which ultimately depends only on the radiation oncologist clinical decision; in this study we made an attempt to avoid systematic errors which could potentially compromise tumor control. Initial clinical data on local control of adenoid cystic carcinoma treated in our facility confirms the validity of this approach.

¹⁶Istituto Nazionale dei Tumori IRCCS, Prostate Cancer Program and Radiation Oncology 1, Milan, Italy

Purpose or Objective: To assess clinical and dose factors affecting the incidence of urinary symptoms between 6 and 24 months after therapy completion in patients treated with radical RT for prostate cancer.

Material and Methods: This study examined the dataset of a prospective study with patients treated with conventional (74-80 Gy at 1.8-2 Gy/fr) or moderately hypofractionated RT (65-75.2 Gy at 2.2-2.7 Gy/fr) in 5 fractions per week. Clinical factors were collected for each patient: comorbidities, drugs, hormone therapies, previous surgeries, smoking, alcohol, age, and body mass index. Bladder DVHs were corrected with $\alpha/\beta=3\text{Gy}$. Urinary symptoms were evaluated through the IPSS (International Prostate Symptom Score) and ICIQ (International Consultation on Incontinence Modular Questionnaire short form) questionnaires filled in by the patients at start/end of RT and every 6 months until 5 years of follow up. We considered the sum of the 7 IPSS questions and the sum of questions 3-4 of ICIQ for the two endpoints: 1) $IPSS \geq 15$ and 2) $ICIQ_{34} \geq 4$ at least once between 6 and 24 months after RT. The best predictors to be included in the logistic regression model were identified through backward feature selections on 1000 bootstrap resamplings (the reported NArea identifies the weighted occurrences of the

variables at the leading positions); then multivariate regressions on 1000 bootstrap resamplings were employed to compute the odds ratio distributions of the selected variables.

Results: 539 patients were enrolled: dose parameters and toxicity data at baseline and between 6-24 months were available for 195 (IPSS) and 197 (ICIQ) patients. 158/195 (81%) and 150/158 (95%) patients did not show toxicity at baseline ($IPSS \leq 12$ and $ICIQ_3=0$, respectively). At 6-24 months, the incidence of $IPSS \geq 15$ was 42/158 (27%) and of $ICIQ_{34} \geq 4$ was 34/150 (23%). A 6-variable model ($AUC=0.86$) was considered for IPSS: basal IPSS ($NArea=0.72$, $OR=1.51$) and the change of IPSS at RT end ($\Delta IPSS$) ($NArea=0.74$, $OR=1.16$) were the leading risk factors. V62Gy was also a risk factor ($NArea=0.36$, $OR=1.04$), while the analogues and antiandrogens in hormone therapies were found protective ($NArea=0.34$, $OR=0.38$) and risk parameters ($NArea=0.29$, $OR=2.57$), respectively. For ICIQ, a backward feature selection was employed: antiaggregants ($OR=2.16$, $p=0.11$), antiandrogens ($OR=2.03$, $p=0.08$) and age ($OR=1.09$, $p=0.04$) were found as risk factors, whereas none dose parameter was found correlated with toxicity.

	Coefficient	Median OR (5 th perc - 95 th perc)	Narea
IPSS ≥ 15 (basal IPSS ≤ 12)			
AUC 0.86 (0.79 - 0.93)			
Delta IPSS	0,15	1,16 (1,09-1,25)	0,74
Basal IPSS	0,41	1,51 (1,32 - 1,8)	0,72
Lymph node irradiation	1,15	3,17 (1,38 - 6,9)	0,58
Volume receiving 62 Gy (%)	0,04	1,04 (1,01 - 1,07)	0,36
Hormone therapy with analogues	-0,97	0,38 (0,14 - 0,8)	0,34
Hormone therapy with antiandrogens	0,94	2,57 (1,23 - 6,02)	0,29
constant	-6,05		

Conclusion: The analysis shows an important correlation of urinary toxicities at 6-24 months with the patient urinary condition at baseline and, also, with the acute worsening of symptoms. Interestingly, hormone therapies with analogues (protective) and antiandrogens (risk) showed an opposite behaviour for late toxicities. The absence of correlation of incontinence with dose might be due to the very low number of severe toxicities registered.

PO-0876

Voxel-by-voxel NTCP model for lung density changes after IMRT

M. Avanzo¹, S. Barbiero¹, M. Trovo², J. Stancanello³, C. Furlan², C. Cappelletto¹, E. Capra¹

¹Centro di Riferimento Oncologico, Medical Physics Unit, Aviano, Italy

²Centro di Riferimento Oncologico, Radiation Oncology Department, Aviano, Italy

³General Electric, MRI Applications and Workflow, Buc, France

Purpose or Objective: Differential diagnosis between benign changes on follow-up CT from progression or recurrence is a difficult task in highly conformal RT because areas of dense consolidation usually develop around the treated tumor. The

prediction of radiation-induced changes in lung density on follow-up CT can be of help with differential diagnosis. The goal of this work was to develop a Normal Tissue Complication Probability (NTCP) model for voxel by voxel prediction of changes in lung density on CT scans of patients treated with IMRT.

Material and Methods: 20 patients were treated with fractionated IMRT (60 Gy/25 fractions) or SBRT with Helical Tomotherapy (40-52 Gy in 5-10 fractions) for lung tumors. Follow-up CT scans were acquired at 6 months after the end of RT and were registered with pre-treatment scans using rigid (6 degrees of freedom) followed by a b-spline (> 27 degrees of freedom) deformable registration performed using the 3D Slicer freeware software suite. Registration accuracy was assessed by comparing the calculated displacement at bifurcation points with the displacement measured on unregistered images. Registration was repeated when the difference was more than 1 cm. Voxels Hounsfield units were converted into relative electron density (RED) using in-phantom measured CT-RED curves. The change in RED between the two images was calculated for each voxel within the healthy lung tissue, defined as combined lungs after subtraction of PTV, among all the patients. Voxels RED changes versus absolute dose were fitted among all patients using a function similar to Lyman NTCP model. Model parameters were $DO.5$, the dose giving 0.5 increase in relative electron density and m , the slope of the dose-response curve. No correction was used for fractionation of the treatments. Predictive power of model was assessed by a test of correlation of measured and predicted RED changes.

Results: The dose giving an increase of 0.5 RED estimated from fitting of lung density changes was $DO.5 = 99.5$ Gy (95%CI = 84.0-114.9 Gy). Slope of dose response, m , was 0.338 (95%CI = 0.296-0.380). The correlation test shows that predicted and measured RED changes were statistically strongly correlated ($p < 0.001$).

Conclusion: The model describes well the change in RED in follow-up CT scans of IMRT patients and can be used to generate maps of predicted RED to be visualized on follow-up CT scans, as a support for differential diagnosis between benign changes from progression or recurrence.

PO-0877

Baseline CT image and isodose shape features improve prognostic models for dyspnea after RT in NSCLC

G. Defraene¹, W. Van Elmpt², D. De Ruyscher³

¹KU Leuven - University of Leuven, Experimental Radiation Oncology, Leuven, Belgium

²Maastricht University Medical Centre, Department of Radiation Oncology Maastricht-Clinic, Maastricht, The Netherlands

³University Hospitals Leuven, Department of Radiation Oncology, Leuven, Belgium

Purpose or Objective: Lung toxicity prediction models currently rely on dosimetric factors as mean lung dose (MLD) or V20 (volume of lung receiving more than 20 Gy), and clinical factors (e.g. age, smoking history). With a consistently reported area under the curve (AUC) around 0.6 these models are limited in discriminating between low- and high-risk patients before treatment. The present study aims at designing a better prognostic model by broadening the search for prognostic factors using a radiomics approach both on the imaging and dosimetric level. For this, CT image features of lung tissue and isodose shape measures were explored to predict the endpoint of dyspnea.

Material and Methods: 80 stage I-IV non-small cell lung cancer patients were included. Prescription dose was 66Gy, in fractions of 2.75 Gy sequentially or 2 Gy concurrent with chemotherapy. Maximal increase in CTCAE 4.0 dyspnea score in the first 6 months after the end of radiotherapy was retrospectively recorded with respect to baseline status.

30 lung image features were extracted from the baseline free-breathing planning CT: 10 intensity-based features

(derived from the histogram of intensities), and the mean value and standard deviation of 10 texture features (from the co-occurrence matrix, neighbourhood gray tone difference matrix (NGTDM) and neighbouring gray level dependence matrix (NGLDM) categories). All features were calculated within each of the isodose volumes V5, V20 and V40 of the lung excluding the GTV structure. Additionally 15 shape and location features of these isodose volumes were collected: volume, bounding box dimensions, centroid coordinates and compactness. Other features included age, smoking status, chemotherapy regimen, treatment modulation, heart Dmax and Dmean.

All combinations of the 5 most significant features resulting from a univariate logistic regression analysis were tested in multivariate setting (likelihood ratio test between nested models).

Results: Dyspnea increase grade ≥ 2 was present in 13.8% of patients. For an increase of at least 1 grade, this was 38.8%. In univariate modeling, several image and isodose shape features performed significantly better than MLD for both endpoints (Table 1). The resulting classifier for dyspnea increase grade ≥ 1 was based on the texture feature 'small number emphasis' and the V40 isodose antero-posterior dimension (AUC=0.71). The dyspnea increase grade ≥ 2 classifier was based on mean heart dose and antero-posterior dimension of the V20 isodose (AUC=0.71).

Feature	AUC
Dyspnea increase grade ≥ 1	
Texture small number emphasis (NGLDM): mean in V20*	0.66
Texture small number emphasis (NGLDM): SD in V20	0.66
Texture Deviation: mean in V20	0.63
Shape: V40 bounding box relative antero-posterior dimension*	0.62
Intensity histogram in V20: 75 th quantile	0.60
Mean Lung Dose	0.51
Dyspnea increase grade ≥ 2	
Texture Strength (NGTDM): mean in V40	0.70
Texture Coarseness (NGTDM): mean in V20	0.69
Texture Complexity (NGTDM): mean in V20	0.67
Mean heart dose*	0.66
Shape: V20 bounding box absolute antero-posterior dimension*	0.65
Mean Lung Dose	0.57

*selected as covariate in the best multivariate model

Table 1 Area under the curve (AUC) of univariate logistic regression models for the 5 most prognostic features. A mean lung dose-based model performance is given as reference.

Conclusion: A radiomics analysis with image and isodose features yielded promising prognostic models for dyspnea compared to the classical MLD-based model. Validation on a recently available large multicentric database will be performed by the time of the congress, which will allow the selection of the most robust model.

This project has received funding from the European Union's Seventh Framework Programme under grant agreement no 601826 (REQUIRE).

Poster: Physics track: Intra-fraction motion management

PO-0878

The effect of rectal retractor on intra-fraction motion of prostate

A. Vanhanen^{1,2}, M. Kapanen^{1,2}

¹Tampere University Hospital, Department of Oncology, Tampere, Finland

²Medical Imaging Center and Hospital Pharmacy, Medical Physics, Tampere, Finland

Purpose or Objective: Intra-fraction motion of the prostate is a known phenomenon that degrades the delivered dose to

the target. Rectal retractor (RF) which main purpose is to separate the rectum from the prostate in order to decrease the rectal dose is commonly suggested to fixate the prostate [1]. In the current study the effect of RF on intra-fraction motion of the prostate was investigated using real-time electromagnetic tracking system.

Material and Methods: A total of 22 conventionally fractionated (39 x 2 Gy) or moderately hypofractionated (20 x 3 Gy) prostate cancer patients were investigated. RF (RectafixTM, Scanflex Medical AB, Sweden) was used in 15/39 and 10/20 first fractions to study its effect on prostate motion. In the RF method the rectum-prostate separation is achieved by rectal rod that is inserted into the rectum and manually pushed posteriorly. Intra-fraction motion of the prostate was recorded with electromagnetic tracking system RayPilot (Micropos Medical AB, Sweden). The system consists of a transmitter implanted into the prostate and a receiver plate positioned on the treatment couch. The system provides transmitter 3D position in real-time. Intra-fractional prostate motion of a total of 260 RF fractions and 351 non-RF fractions were tracked and analyzed. Absolute prostate displacement after image guidance was calculated in all directions. Unidirectional and 3D motion distributions within 10 min treatment time were evaluated by the means of percentage time at displacement $\geq 1, 2, 3, 4, 5$ and 6 mm. Motion patterns between the RF and non-RF fractions were compared individually and over the whole patient population.

Figure 1. Average percentage time of lat, lng, vrt and 3D prostate displacements

Results: The average percentage time was larger in RF data compared to non-RF data in every direction (fig 1). The greatest increase in motion was seen in superior, inferior and posterior directions (table 1). Differences between the datasets in these directions, as well as 3D motion, were statistically significant ($p < 0.03$). Individually, the 3D motion of the prostate was significantly larger ($p < 0.05$) with RF than without it for 13 patients. For two patients significant ($p \leq 0.04$) stabilizing effect with the RF was observed.

Table 1. Average percentage time of unidirectional and 3D prostate displacements $\geq 1, 2, 3, 4, 5$ and 6 mm

		≥ 1	≥ 2	≥ 3	≥ 4	≥ 5	≥ 6
3D	RF	69,6	32,8	15,3	7,5	3,8	2,2
	non-RF	44,8	16,0	6,4	2,9	1,4	0,5
Left	RF	9,4	3,5	1,6	0,4	0,0	0,0
	non-RF	7,5	1,8	0,5	0,2	0,0	0,0
Right	RF	9,7	2,4	0,3	0,1	0,0	0,0
	non-RF	6,0	0,9	0,1	0,0	0,0	0,0
Superior	RF	6,0	2,4	1,1	0,3	0,1	0,0
	non-RF	3,8	1,5	0,6	0,1	0,0	0,0
Inferior	RF	35,0	10,3	4,4	2,0	1,0	0,8
	non-RF	9,4	1,4	0,3	0,0	0,0	0,0
Anterior	RF	8,6	4,1	2,1	0,9	0,2	0,1
	non-RF	9,3	3,6	1,5	0,8	0,4	0,2
Posterior	RF	30,5	9,1	3,8	2,3	1,3	0,9
	non-RF	17,5	5,6	2,2	0,4	0,1	0,0

Conclusion: The use of RF increased the intra-fraction motion of the prostate on average and for most of the patients. The reason for larger motion could be increased muscular tension due to uncomfortableness of the RF and the anatomical changes that the retraction creates at the prostate-rectum surface. Our results indicate that the use of RF requires larger treatment margins or application of real-time tracking and dose gating. As the RF increases the prostate motion its use is questionable and should be evaluated against desired rectum dose sparing.

Real-time prostate tracking in prostate cancer radiotherapy using autoscanner transperineal ultrasound
 X. Qi¹, X.S. Gao¹, H. Yu¹, S.B. Qin¹, H.Z. Li¹
¹Peking University First Hospital, Radiation Oncology, Beijing, China

Purpose or Objective: More recently, noninvasive 4D transperineal ultrasound (4D-TPUS) has been introduced in tracking interfraction, as well as intrafraction prostate motion in radiotherapy. Compared to other tracking method, the ultrasound has its own advantage in precise identification of soft tissue without invasive procedure or extra radiation dose. Several studies have reported the tracking data that confirming its accuracy in monitoring prostate motion and 4D-TPUS is nowadays gradually accepted as a monitoring option in prostate cancer radiotherapy. However, rare experience of this new technology with Asia populations has been reported. In this study, we report our clinical experience and tracking data using 4D-TPUS to monitor both inter- and intra-fraction prostate motion.

Material and Methods: Fifteen prostate cancer patients were enrolled in a prospective study and treated to a total dose of 76Gy in 38 fractions using IMRT. For each patient, before treatment delivery, prostates were localized using US and CBCT respectively to determine setup offsets relative to the patient skin tattoos. In the treatment protocol, adjustment of couch was guided by CBCT images. During the treatment, real-time ultrasound images were acquired and data was collected for direct monitoring of 3D motion of the prostate.

Results: A total of 221 fractions were evaluated. The means (μ) and standard deviations (SD) of inter-fraction prostate motion, as evaluated using CBCT and US, averaged from all patients and fractions, were [μ US = (4.62, 4.75, 4.37) mm, SD US = (4.21, 5.17, 5.52) mm], and [μ CBCT = (2.49, 2.26, 3.27) mm, SD CBCT = (2.15, 1.83, 2.89) mm] in the left-right, superior-inferior and anterior-posterior directions, respectively. The median (5% to 95% percentile) of 221 intra-fraction prostate motions in the L-/R+, S+/I- and A+/P- were

0.1 mm (-1.13 to 1.64 mm), -0.1 mm (-1.89 to 1.90 mm), and -0.3mm (-2.88 to 1.25 mm). There were 70/221 (32%) fractions with deviation exceeded 2 mm in any direction, with an average duration of 26% of treatment time. While, there were 19/221 (8.6%) fractions with deviation exceeded 3 mm in any direction with an average duration of 6.3% of treatment time.

Conclusion: 4D-TPUS provides an accurate and noninvasive method for real-time tracking of prostate in radiation treatment. We reported the first tracking data from Asia populations. These data can help to understand the intrafraction motion of the prostate, and may allow a reduction of treatment margin.

Clinical implementation of 5DCT workflow

D. Low¹, D. Thomas¹, T. Dou¹, P. Lee¹, J. Lewis¹, D. O'Connell¹

¹UCLA Medical Center, Department of Medical Physics, Los Angeles, USA

Purpose or Objective: To implement a quantitative clinical breathing motion characterization technique that employs a 5D motion model.

Material and Methods: We have employed a research breathing motion model and CT acquisition technique into clinical service, supporting lung cancer radiation therapy. The workflow employs 25 fast helical CT scans that are acquired using low mA, fast rotation (0.28s) and a pitch of 1.2 to scan the lungs in approximately 1 s, acquired alternately head to foot and foot to head. A breathing surrogate device, consisting of a hollow sealed bellows-shaped tube, is stretched around the abdomen. The air pressure in the tube is measured using a pressure transducer and the transducer voltage is used as the surrogate. Each slice is assigned a breathing phase according to the breathing surrogate measured at the point in time the scan was acquired. The breathing amplitude and the breathing rate define the breathing phase, allowing the model to explicitly manage breathing amplitude variations as well as breathing hysteresis. The scans are deformably registered to the first scan, arbitrarily assigned as the reference scan. The deformation vectors along with the breathing phases are coupled with a breathing motion model that linearly relates breathing motion to the amplitude and rate of breathing. The 25 scans are averaged at the reference phase geometry to reduce image noise, and the averaged scan deformed to user-defined breathing phases. For the first clinical implementation, we provide 8 static images at breathing phases corresponding to equally spaced breathing amplitude percentiles from the 5th percentile to the 95th percentile and back in equally spaced steps. The model is used to reconstruct the original 25 scans and compare the reconstructed to original scans using deformable image registration, providing a measure of model error. The clinician is provided not only the phase images for planning but estimates of the motion model error presented as colormaps of the model discrepancy.

Results: The protocol provides artifact-free images for contouring and previous research studies have shown that the overall accuracy of the proposed workflow is approximately 2 mm, with severely irregularly breathing patients having only slightly reduced accuracy. The protocol allows the clinician, for the first time, to access quantitatively validated breathing gated CT scans that are related to the overall breathing pattern statistics and that come with accuracy estimates.

Conclusion: While the clinical 5D protocol increases the quantitation available to clinicians, it is only the first step in the next generation of breathing motion modeling and breathing motion mitigation strategies made possible by the quantitative nature of the protocol. Further automation will enable the clinic to greatly increase the efficiency and

efficacy of selecting and evaluating competing motion mitigation strategies.

PO-0881

Patient selection for DIBH technique for left sided breast cancers: Impact of chest wall shape

S. Chilukuri¹, D. Adulkar¹, S. Subramaniam¹, N. Mohammed¹, A. Gandhi¹, M. Kathirvel¹, T. Swamy¹, K. Kiran Kumar¹, N. Yadala¹

¹Yashoda Cancer Institute, Department of Radiation Oncology, Hyderabad, India

Purpose or Objective: Deep inspiratory breath hold (DIBH) technique delivers less dose to heart and left lung during radiotherapy for left sided breast cancers. But the benefit is not uniform in all patients. We analyzed the impact of shape of the chest wall (CW) in predicting benefit with DIBH technique.

Material and Methods: All patients of left sided breast cancer undergoing radiotherapy at our centre in the last one year were analyzed. All the patients underwent 2 sets of planning scans-one in DIBH phase and the other in free breathing (FB) phase. DIBH patients were monitored in prospective mode with the help of Varian real time position management system system. For patients who underwent mastectomy, the shape of the CW was assessed on visual inspection and confirmed on the FB planning CT (pCT). For patients with intact breast, the CW excluding the breast was contoured on the FB pCT to evaluate the shape. CW angle (CWA)-angle measured at mid chest level and is made by the tangent to the most curved portion of chest wall with any line parallel to the couch was computed.

Results: 36 patients were found to have curved CW and 17 (32%) were found to have flat CW. All the 17 patients with flat CW had CWA<30 and all with curved CW had CWA>30. In patients with curved CW mean left lung V20 (V20), mean heart dose (MHD) and mean left anterior descending artery (LAD) dose were significantly less with DIBH technique compared to FB plans, (12% vs. 19%, p=0.001, 1.2Gy vs. 5.5Gy, p<0.000, 16.6Gy vs. 29.1Gy, p<0.000 respectively). In patients with flat CW, there was no benefit seen with DIBH scans compared to FB scans with respect to V20, MHD and mean LAD {21% vs. 22.3% (p=0.78), 5.9Gy vs. 6.5Gy (p=0.19) and 29.1Gy vs. 28.9Gy (p=0.9)} respectively. In patients with curved CW, the NTCP for cardiac mortality was less compared to FB plans (0.25% vs. 4.5%, p<0.001) which was not the case in flat CW patients (4.2%, p=0.86)

Conclusion: Patients with curved CW had a significant benefit with DIBH technique compared to flat CW. CW shape, which is easy to determine, is an effective tool to identify patients suitable for DIBH technique. For patients with flat CW other techniques should be explored to address cardiac doses.

PO-0882

Abdominal organ motion during breath-hold measured in volunteers on MRI: inhale and exhale compared

E. Lens¹, O.J. Gurney-Champion^{1,2}, A. Van der Horst¹, D.R. Tekelenburg¹, Z. Van Kesteren¹, M.J. Parkes³, G. Van Tienhoven¹, A.J. Nederveen², A. Bel¹

¹AMC Amsterdam, Radiation Oncology, Amsterdam, The Netherlands

²AMC Amsterdam, Radiology, Amsterdam, The Netherlands

³University of Birmingham, School of Sport- Exercise & Rehabilitation Sciences, Birmingham, United Kingdom

Purpose or Objective: Breath-hold (BH) techniques, used to eliminate respiratory-induced tumor motion, are in radiotherapy often implemented without clear feedback and characterization of the residual geometric uncertainties. We measured the motion of the pancreatic head and of the diaphragm during four different 1-minute BHs (2 inhale and 2 exhale) in healthy volunteers using MRI. The aim was to investigate which BH type produced the most stable anatomy

and to establish whether the diaphragm could be used as a surrogate for pancreatic motion.

Material and Methods: We studied 12 healthy volunteers (4 males), with a mean age of 33 y, mean height of 172 cm, mean weight of 63 kg and a mean vital capacity of 3.2 L. Each attempted to perform three 1-minute BHs in end-inhale (completely inflated lungs), deep-inhale (lung volume of ~70%), deep-exhale (lung volume of ~30%) and end-exhale (completely deflated lungs). During BH, we used a 3T MRI to dynamically (1.7 Hz) acquire a thick (8 mm) high resolution (0.9×0.9 mm²) 2D coronal slice including both the pancreatic head and the diaphragm.

For each BH, the motion (i.e. displacement in all successive images relative to the first image) of the pancreatic head and of the diaphragm in the inferior-superior (IS) direction was determined using a 2D image correlation algorithm. The Wilcoxon signed-rank test was used to test the differences in maximum displacement during BH between the different BH types. To investigate the correlation between the intra-BH motion of the pancreas and of the diaphragm, we determined the Pearson correlation coefficient (*r*). As the achieved BH duration varied, only the data acquired during the first 30 seconds of each BH were included in our analysis.

Results: We observed substantial motion in the IS direction in the form of drifts of the pancreatic head and of the diaphragm during all BH types (Figure and Table). We observed significantly larger maximum displacements for the pancreatic head during deep-inhale compared with deep-exhale (*P*=0.012) and end-exhale (*P*=0.045). For the diaphragm, we observed a significant difference in maximum displacement between each of the inhale BHs compared with each of the exhale BHs (0.019), the mean displacement was always larger during the inhale BHs than during the exhale BHs.

A strong correlation (≥ 0.8) between the motion of the pancreas and of the diaphragm was observed in only 60 out of the 141 analyzed BHs and a moderate correlation (≥ 0.6 < 0.8) in 34 BHs. Both strong and moderate correlations were found most often for the deep-inhale BHs (Table).

Conclusion: We observed substantial intra-BH motion in IS of the pancreatic head and of the diaphragm. Exhale BH seems more stable and might therefore be preferred for radiotherapy. The diaphragm is not a suitable surrogate for pancreatic motion during BH, especially when the observed motion is small. The intra-BH displacements could have a high clinical impact if not taken into account during radiotherapy under BH conditions.

Figure: Boxplots of the intra-breath-hold (intra-BH) motion magnitudes of pancreatic head and diaphragm in the IS direction for the different breath-holds. Significance: * *P*<0.05 and ** *P*<0.01. The boxes indicate the median value and upper and lower quartiles, whiskers give the lowest and highest data point within 1.5× inter quartile range and the dots show the outliers.

Table: Intra-breath-hold motion in the IS direction during 4 different breath-holds in 12 volunteers.

	End-inhale	Deep-inhale	Deep-exhale	End-exhale
Pancreatic head motion				
Mean (mm)	5.5	5.1	3.4	3.4
Range (mm)	1.0–19.7	1.2–10.8	1.0–6.4	1.1–8.5
Standard deviation (mm)	3.4	2.5	1.0	1.4
Diaphragm motion				
Mean (mm)	8.7	8.2	4.4	3.6
Range (mm)	1.2–26.4	1.7–19.7	1.3–8.1	1.0–9.5
Standard deviation (mm)	4.8	4.6	1.5	1.8
# <i>r</i> ≥ 0.8 / # breath-holds [†]	19/36	23/36	3/36	15/33
# 0.6 ≤ <i>r</i> < 0.8 / # breath-holds [‡]	26/36	31/36	12/36	25/33
Mean breath-hold duration (s)	60	59	59	51

[†]Number of times a strong (*r* ≥ 0.8) correlation between pancreatic and diaphragm motion was observed out of the total number of analyzed breath-holds.

[‡]Number of times a moderate (0.6 ≤ *r* < 0.8) correlation between pancreatic and diaphragm motion was observed out of the total number of analyzed breath-holds.

PO-0883

Quantification of Duodenum motion: analysis from respiratory phase guided radiotherapy planning scan

T. Basu¹, T. Kataria¹, D. Gupta¹, S.S. Bisht¹, A. Abhishek¹, S. Goyal¹, S. Krishnan², K. KP¹, K. Narang¹, S. Sambasivam¹, S. Banerjee¹

¹Medanta The Medicity, Radiation Oncology, Gurgaon, India

²Medanta The Medicity, Radiology, Gurgaon, India

Purpose or Objective: In the era of stereotactic body radiotherapy (SBRT) radiation induced changes in duodenum (D) is an important concern. The tortuous and curvy anatomy often indistinguishable from adjoining organs led to the publication of RTOG upper abdominal normal structure contouring guidelines. The current study assesses the impact of respiration (expiration, inspiration and free breathing) on D and its parts with quantification of planning organ at risk (PRV) volume from respiratory phase guided radiotherapy planning CT scans (RPRTCP).

Material and Methods: Ten cases of liver tumors (eight: primary hepatocellular, two: liver metastasis) were selected for RPRTCP. After breath hold training in end expiration (E) and end inspiration (I), 1mm slice thickness RPRTCP along with free breathing (FB) contrast scans were obtained. Three image sets per patient were imported in contouring workstation (Focal Sim) with E as primary. D as a whole structure was contoured by single radiation oncologist in E, I and FB phases of respiration. Following the RTOG and our D

contouring guidelines the first (D1), second (D2), third and fourth (D3) parts were contoured separately in E, I and FB phases creating twelve image sets per patient. Motion variation for each structure was calculated by the difference in all three (XYZ) co-ordinates. Mean variations in position of D, D1, D2 and D3 with respect to E, I and FB phases were noted. The difference between E/I, E/FB and I/FB for D, D1, D2 and D3 were analyzed. Final data had 36 sets of values for mean and standard deviation per patient.

Results: Mean variations (cm) of D motion between E and I in XYZ co-ordinates were: $0.38(\pm 0.53)$, $0.61(\pm 0.56)$, $0.53(\pm 0.72)$; between E and FB: $0.47(\pm 0.53)$, $0.49(\pm 0.52)$, $0.49(\pm 0.74)$; between I and FB $0.35(\pm 0.49)$, $0.62(\pm 0.39)$, $0.61(\pm 0.81)$. The next step was the motion calculation for different parts of D in XYZ co-ordinates. For D1: between E and I $0.31(\pm 0.25)$, $0.65(\pm 0.71)$, $0.44(\pm 0.38)$, between E and FB: $0.31(\pm 0.17)$, $1.0(\pm 1.35)$, $0.66(\pm 0.84)$; between I and FB $0.22(\pm 0.15)$, $1.05(\pm 1.39)$, $0.66(\pm 0.88)$. For D2: between E and I: $1.18(\pm 1.26)$, $2.4(\pm 2.65)$, $0.55(\pm 0.76)$; between E and FB $1.01(\pm 1.07)$, $2.28(\pm 2.29)$, $0.45(\pm 0.6)$, between I and FB: $0.29(\pm 0.22)$, $0.46(\pm 0.44)$, $0.18(\pm 0.16)$. Similarly for D3 between E and I: $0.77(\pm 1.01)$, $1.5(\pm 2.13)$, $0.52(\pm 0.65)$, between E and FB: $0.48(\pm 0.41)$, $1.48(\pm 2.76)$, $0.2(\pm 0.16)$ and between I and FB: $0.9(\pm 1.11)$, $2.4(\pm 2.99)$, $0.62(\pm 0.83)$.

Conclusion: D moves maximally in cranio-caudal (CC) direction and minimally in lateral direction in different phases of respiration. Relatively fixed D1 moves maximally in antero-posterior (AP) direction (range: 0.1-2.3 cm), while mobile parts D2 and D3 in CC directions (range: 0.5-4 cm) between E and I. Keeping in mind the precision of SBRT, a PRV for duodenum 3mm radial and 5 mm CC with respiratory phase guidance will cover the range of motion. Differential margin for D1-D3 with validated delineation guideline should be evaluated in a larger cohort.

PO-0884

Respiratory motion models from Cone-Beam CT for lung tumour tracking

A. Fassi¹, E. Tagliabue¹, M. Tirindelli¹, D. Sarrut², M. Riboldi¹, G. Baroni¹

¹Politecnico di Milano, Dipartimento di Elettronica Informazione e Bioingegneria, Milano, Italy

²Centre Léon Bérard, Department of Radiotherapy - CREATIS, Lyon, France

Purpose or Objective: To develop and evaluate a patient-specific respiratory motion model obtained from time-resolved Cone-Beam CT (CBCT) and driven by a surrogate breathing signal. The motion model is proposed for the real-time tracking of lung tumors, accounting for interfraction motion variations.

Material and Methods: The motion-compensated CBCT reconstruction algorithm [1] was used to derive a time-resolved CBCT scan sorted into ten breathing phases. Tumor position was identified on each CBCT phase volume by non-rigidly propagating the GTV contours defined on the planning CT scan. GTV coordinates associated to each CBCT volume were linearly interpolated to obtain the patient-specific motion model, describing the 3D tumor position over the mean respiratory cycle of the CBCT scan. The phase parameter given as input to the respiratory model was estimated from diaphragm motion computed from CBCT projections. The proposed motion model was tested on a clinical database of six lung cancer patients, including two CBCT scans acquired per patient before and after setup correction. The first CBCT scan was used to build the motion model, which was tested on the second scan after correcting model coordinates for the applied setup shifts. Tumor positions estimated in 3D with the motion model were projected at the corresponding angle and compared to the real target position identified on CBCT projections by using a semi-automatic contrast-enhanced algorithm [2].

Figure 1. Comparison between real and estimated tumor trajectories obtained for patient P4. Only CBCT projections in which lung tumor was detectable are represented in the Figure.

Table 1. Absolute tracking errors between tumor trajectories estimated from CBCT motion model and real tumor motion identified on CBCT projections along the superior-inferior and transverse directions. Results are expressed as median value [25th - 75th percentiles].

Patient	Superior-inferior tracking error (mm)	Transverse tracking error (mm)
P1	1.0 [0.4 - 1.8]	1.2 [0.8 - 2.8]
P2	1.2 [0.4 - 2.0]	2.4 [1.2 - 3.6]
P3	1.2 [0.4 - 2.0]	2.8 [1.2 - 4.0]
P4	1.2 [0.8 - 2.0]	2.0 [0.8 - 4.0]
P5	2.0 [1.2 - 2.8]	2.4 [1.2 - 3.6]
P6	2.0 [0.8 - 2.8]	1.6 [0.8 - 2.4]

Results: Twenty-five seconds of CBCT scan, corresponding to about 135 CBCT projections, were analyzed on average for each patient. Figure 1 depicts exemplifying results of tumor trajectories along the vertical image direction, which corresponds to the projection of the superior-inferior tumor motion, and along the horizontal image direction, which represents the combination of antero-posterior and medio-lateral tumor motion. A significance correlation (p-value < 0.05) was found between real and estimated tumor trajectories, with Spearman correlation coefficients of 0.71 and 0.68 on average for superior-inferior and transverse directions, respectively. As reported in Table 1, the median value of absolute tracking errors did not exceed 2.0 mm for the single direction of tumor motion.

Conclusion: A novel approach for intrafraction tracking of lung tumors was investigated, exploiting a patient-specific respiratory motion model derived from time-resolved CBCT images. Compared to CT-based motion models, the proposed method does not need to compensate for interfraction motion variations that can occur between planning and treatment phases. An external breathing surrogate obtained from non-invasive optical surface imaging is envisaged to be used to drive the motion model during treatment.

Brain motion induced artefacts in microbeam radiation therapy: a Monte Carlo study

M. Donzelli¹, E. Braeuer-Krisch¹, U. Oelfke²¹European Synchrotron Radiation Facility, Biomedical Beamline ID17, Grenoble, France²The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Joint Department of Physics, London, United Kingdom

Purpose or Objective: Microbeam Radiation Therapy (MRT) is a relatively new approach in radiation oncology exploiting the dose-volume effect by using orthovoltage X-rays on a microscopic scale [1]. Arrays of plane parallel beams of typically 50 μm width with spacings of a few hundred μm show extraordinary normal tissue sparing, while still being capable to ablate tumours in preclinical research [2].

Organ motion has not been an issue in MRT, as long as preclinical research was carried out in small samples, such as cell cultures and rodents. The possible future treatment of human brain tumours using microbeam radiation however may be affected by cardio-synchronous tissue pulsation. This pulsation, with amplitudes in the order of 100 μm [3], induces translational movements of the brain tissue causing a blurring of the planned plane-parallel dose pattern of microbeams in case of extended exposure times.

Material and Methods: A Monte Carlo study to quantify these effects was performed using the Geant4 toolkit. Dose was scored in a homogeneous cubic water phantom of 15 cm size on a grid with 5 μm resolution perpendicular to the beam. The sensitive volume was chosen to have an extension of 1 mm along the beam direction in 20 mm depth from the surface, which corresponds to the reference dosimetry conditions in MRT. The relative statistical uncertainty of the dose (1 standard deviation) per voxel was between 1% and 1.5% in the peak region and between 6% and 9% in the dose valley, depending on the evaluated beam configuration and could be further reduced by appropriate binning of the raw data.

Results: Monte Carlo calculations for different geometrical microbeam configurations and employed dose rates revealed significant changes of the planned dose patterns when compared to the static case. The chosen quality indicators of our study like peak dose, peak-to-valley dose ratio (PVDR), microbeam width, spacing, and penumbra were observed to be highly degraded, e.g. the PVDR being reduced by up to 35%.

Conclusion: We have demonstrated that the effect of even small organ motions occurring at heart rate frequencies in the brain can only be tolerated at high dose rates of approx. 10 Gy/s. For example, a dose rate of 12.3 kGy/s can be given as a threshold value if one wants to apply a high peak entrance dose of 300 Gy in 3 mm depth for 50 μm wide microbeams and a primary beam size of 500 μm perpendicular to the scan direction. For lower dose rates the observed deterioration of the microbeam dose patterns is likely to destroy the intended dose sparing effect for healthy tissues.

For interlaced microbeam geometries an appropriate gating technique could be applied in the future based on the phase of the cardiac cycle.

PO-0886

Does lung capacity influence the geometrical reproducibility in DIBH radiotherapy of NSCLC patients?

P. Sibolt^{1,2}, W. Ottosson², C.F. Behrens², D. Sjöström²¹Technical University of Denmark, Radiation Physics- Center for Nuclear Technologies, Roskilde, Denmark²Herlev Hospital, Radiotherapy Research Unit- Department of Oncology, Herlev, Denmark

Purpose or Objective: Deep-inspiration breath-hold (DIBH) mitigates the breathing motion, and thereby reduces the treated volume. This yields less dose to adjacent organs-at-risk, and enables dose escalated radiotherapy of locally advanced non-small cell lung cancer (NSCLC) patients. However, DIBH can potentially introduce an extra uncertainty as reproducibility of DIBH can be affected by e.g. arching or unwanted motion during inspiration. This study was designed to investigate the feasibility and geometrical reproducibility of the anatomy, when utilizing DIBH in radiotherapy of locally advanced NSCLC patients.

Material and Methods: Seventeen NSCLC patients scheduled for curative radiotherapy were enrolled. One 4DCT in free-breathing (FB) and one 3DCT in DIBH, both with intravenous contrast, were acquired prior to (pre), in the middle of (mid), and after (post) the course of treatment. Furthermore, cone-beam CTs (CBCTs) both in FB and DIBH were acquired weekly throughout the course of treatment. A marker-based optical breathing signal (RPM, Varian Medical Systems, CA, USA) was utilized both for phase sorting into 10 phases during 4DCT and for visual guidance in DIBH 3DCT/CBCT. Changes in relative lung volumes (DIBH over FB) and in gross tumor volumes (GTVs) over the course of treatment were analyzed. Furthermore, the feasibility of DIBH for locally advanced NSCLC patients was analyzed based on the average breath-hold times and average number of breath-holds required to complete a CBCT acquisition.

Results: Compared to FB, the total lung volume increased in DIBH by, on average, a factor of 1.84, 1.81 and 1.86 for the pre, mid and post treatment scans, respectively. A correlation between relative total lung volume (DIBH/FB) and mean amplitude during DIBH CT was observed (Figure 1). No statistically significant changes in lung volume during the courses of treatment were discovered. In the middle of the treatment course the GTV had decreased with 34 % and 26 %, while at the end of treatment the decrease from the original GTV was 42 % and 43 % for DIBH and FB, respectively. On average 2.1 breath-holds, with an average breath-hold time of 43 seconds, were required for a patient to complete a DIBH CBCT acquisition. However, among the patients this varied between 1 to 11 breath-holds with breath-hold times ranging from 4 to 74 seconds. For each patient, no statistically significant changes in breath-hold times or

number of breath-holds required were observed during the courses of treatment.

Figure 1. Relative total lung volume (DIBH/FB) as a function of average breath-hold amplitude during CT; pre (circles), mid (crosses) and post (triangles) course of treatment.

Conclusion: Breath-hold capabilities are highly individual and generally not observed to be changing during the course of treatment. The ratio between DIBH and FB total lung volume was observed to be stable during the course of treatment, while systematic decreases in GTV were observed both in DIBH and FB. DIBH radiotherapy of locally advanced NSCLC patients is considered to be feasible with geometrical reproducibility.

PO-0887

Latency characterisation of gated radiotherapy treatment beams using a PIN Diode circuit

M. Lempart¹, M. Kügele^{1,2}, F. Nordström¹, L. Ambolt¹, B. Blad¹
¹Skåne University Hospital, Department of Oncology and Radiation Physics, Lund, Sweden

²Lund University, Department of Medical Radiation Physics, Lund, Sweden

Purpose or Objective: The aim of radiotherapy is accurate delivery of dose to target volumes within a patient, while minimizing dose to the surrounding healthy tissue. Respiratory motion is still a significant problem in many radiotherapy treatments. Recent developments in the treatment of breast cancer have focused on “gating” the delivery of the treatment beams. With this technique, the effect of patient motion during treatment is reduced and the separation between the target volume and organs at risk (OAR) increased. Rapidly switching the treatment beam on or off, depending on the patient breathing cycle is the basic principle of gating. It is therefore important that the characteristics of gated treatments such as latency are known.

Material and Methods: For this study, an in-house built electrical PIN diode circuit was designed to function as a tool for quality assurance (QA). Beam latency timing properties were measured on a TrueBeam™ (Varian, Palo Alto) linear accelerator and its internal gating system. Pulses of radiation, triggered within a predefined gating window, were measured with the PIN diode and the results compared to measurements of current through the linac target. A phantom consisting of the electrical circuit coupled to a moving stage was used to simulate a binary pattern to produce fast beam triggering. Processing of the beam pulses and calculation of the latency timings was performed by an Atmega328P microcontroller (MCU). All measurements were performed with photon energies 6MV and 10MV and a dose rate of 600MU/min (equivalent to a reference dose in water of 6 Gy/min). For every measurement, a total of 50 data points were collected and the results compared by calculating the arithmetic mean value and the standard deviation.

Results: The results of the beam latency measurements are shown in the table below.

Energy	Beam on latency (ms)		Beam off latency (ms)	
	Target I	PIN diode	Target I	PIN diode
6 MV	2.13 ±1.15	2.11 ±1.05	57.33 ±10.01	57.69 ±9.59
10 MV	2.15 ±1.06	2.12 ±1.09	56.01 ±10.10	57.73 ±10.06

Conclusion: Measuring beam gating latencies of a linear accelerator via beam pulse analyses with the help of a PIN diode and the in-house built electrical circuit is a useful method in good agreement with measurements from the accelerator target current signal. The PIN diode circuit provided a good response when using different beam energies and can be a useful tool to perform QA on different types of linear accelerators and gating systems. This could potentially lead to improvements in the gated radiotherapy treatments.

PO-0888

The influence of breathing motion on the precision of delivered dose to breast cancer patients

S. Agergaard¹, A. Bertelsen¹, E.L. Lorenzen^{1,2}, K.L. Gottlieb¹, C. Brink^{1,2}

¹Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

²University of Southern Denmark, Institute of Clinical Research, Odense, Denmark

Purpose or Objective: Respiration motion during radiotherapy of breast cancer patients will perturb the delivered dose. The accuracy of the delivered dose can be measured by *in vivo* EPID dosimetry. The respiration motion can be reduced by use of the Active Breathing Coordinator (ABC) produced by Elekta. This study investigates whether a difference in EPID measured acceptance pass rate is associated to the use of ABC and whether the residual breathing variation while using the ABC system is associated to the measured pass rate.

Material and Methods: 15 ABC and 10 non-ABC breast cancer patients were monitored by EPID dosimetry for up to five fractions during the treatment. In total 185 and 82 tangential fields were available for analysis for ABC and non-ABC groups, respectively. The *in vivo* EPID dosimetry system (Wendling et al. Med Phys 2006) back projects the dose to a plane parallel to the EPID panel that includes the prescription point. The dose is compared to the planned distribution using a gamma analysis (3%, 3mm) and defines the pass rate as the fraction of gamma values less than one. Since pass rates are not normally distributed comparison between the ABC and non-ABC group was performed by a Mann-Whitney U test. The ABC system measured the amount of actual inhaled air at each treatment session and during the treatment planning CT. At breath-holds during treatment, deviation in inhaled air

(Vol_dif = Vol_treatment - Vol_CT) could potentially influence the pass rate negatively. Association between Vol_dif and gamma pass rates was analysed by linear regression between the gamma pass rates and Vol_dif squared. In order to adjust at least partially for the residual setup uncertainty, the regression was performed including the fraction number as predictor variable since fields within a fraction are assumed to have the same setup uncertainty.

Results: Difference between pass rates for the ABC and non-ABC group was highly statistically significant ($p < 0.001$), with median pass rates of 84.7% and 76.1%, respectively (see figure). However, within the ABC group no significant association was observed between pass rates and deviation of inhaled air relative to the reference from the planning CT. EPID images were used to evaluate patient positioning prior to treatment and only accepted if deviations were less than 5 mm. Thus, it seems likely that the residual positioning uncertainty is the dominant uncertainty relative to the uncertainty in breath-hold volume when using ABC.

Conclusion: Breast cancer patients treated with the use of ABC showed an improved EPID dosimetry pass rate, reflecting an improved accuracy of dose delivery. However, a potential patient selection bias exists since no randomization between groups was performed. No significant association was observed between Vol_dif and pass rate within the ABC group. The ABC system therefore performs as intended and errors in breath-hold volumes are not of concern given the residual setup uncertainties.

PO-0889

Intra-fraction re-setup with Triggered Imaging allows for margin reduction in prostate treatments

L. Van der Weide¹, M.A. Admiraal¹, T.S. Rosario¹

¹VU University Medical Center, Department of Radiotherapy, Amsterdam, The Netherlands

Purpose or Objective: Intra-fraction motion of the prostate during irradiation requires large PTV margins. The recently released imaging application Triggered Imaging (TI), Varian Medical Systems, Palo Alto CA) allows to generate 2D kV images at predefined intervals during irradiation. The application can automatically detect implanted fiducial markers and initiate beam interrupt. Our previous work shows that re-setup was justified for almost half of the beam interrupts based on a 6mm tolerance. This study describes how applying TI and re-setup in the clinical workflow resulted in the reduction of the PTV margin.

Material and Methods: A total of 96 prostate cancer patients with implanted gold seeds were treated on the Truebeam with two RapidArc beams (Software version 2.0, Varian Medical Systems, Palo Alto, CA). For patient setup, the gold seeds are lined up using two orthogonal 2D kV images. After

the setup procedure, TI is applied during both beams at an interval of 3 seconds, resulting in 41 images per fraction. In the planning CT, the center of gravity of each seed is defined as a Marker. During treatment, each seed is automatically detected on each acquired Triggered Image and its center of gravity is marked with a cross. A circular overlay centered at the Marker position is projected on each Triggered Image. The radius of this circle indicates the maximum allowed seed deviation and is referred to as the TI limit. A color coding is used to indicate whether the seed is in or outside the TI limit (Fig 1). If one or more gold seeds exceed the limit for more than 6 seconds the beam is manually paused, while TI continues at the same gantry angle. If the deviation persists for another 6 seconds, the beam is interrupted and re-setup is performed using two orthogonal 2D kV images. For a first group of patients (n=27) TI was used, with the TI limit set to 6mm which corresponds to the PTV margin. For a second group of patients (n=32) the TI limit is set to 5mm, with an unchanged PTV margin of 6mm. For a third group (n=37) the PTV margin was reduced to 5mm, along with a TI limit of 5mm.

Figure 1. In this figure the auto-detection shows three coloured circles. Green indicates the gold seed is projected within the TI limit, red indicates the gold seed is outside the TI limit.

Results: For the total of 1434 fractions, 134 fractions showed excessive intra-fraction motion of one or more gold seeds leading to 173 beam interruptions and re-setups. Translations applied in re-setup were on average: 3mm, 3mm and 1mm in ventrodorsal, longitudinal and lateral directions, respectively. Overall, the average shift magnitude was 5mm (SD: 2.2mm) with a maximum of 13mm. Shift magnitudes exceeding the PTV margin were considered justified. Table 1 shows that a TI limit that equals the PTV margin leads to about 45% of justified interruptions.

Group (PTV margin/TI limit), n=96	Fractions	Interruptions	Average Shift magnitude (max)	Justified interruptions
Group 1 (6mm/6mm), n=27	305	4.3 %	5 (10) mm	46.2 %
Group 2 (6mm/5mm), n=32	615	14.0 %	5 (12) mm	27.5 %
Group 3 (5mm/5mm), n=37	514	14.4 %	5 (13) mm	42.5 %
Total	1434			

Table 1: Overview of the interrupts and shifts resulting from intra-fraction monitoring with TI.

Conclusion: Triggered Imaging in combination with auto-detection provides a powerful tool to monitor tumor motion during treatment for patients with implanted fiducial markers. We have developed a strategy for intra-fraction re-setup allowing for PTV margin reduction with limited increase in workload.

PO-0890

Homogeneous versus inhomogeneous dose prescription in liver SBRT: effect on delivered CTV-dose

A.T. Hansen¹, P.R. Poulsen¹, E.S. Worm¹, M. Hoyer¹

¹Region Midtjylland, Medicinsk Fysik, Aarhus N, Denmark

Purpose or Objective: In SBRT it is typical to prescribe a lower dose to an isodose-line encompassing the PTV rim rather than prescribing a uniform PTV dose. This strategy may allow for a higher central tumor dose than achievable by conventional homogenous dose prescription while maintaining an acceptable risk of normal tissue toxicity. However, the tumor dose may deteriorate because of intra-fraction motion. The aim of this study was to determine an optimal dose prescription strategy when explicitly considering the effects of intra-treatment motion in liver SBRT.

Material and Methods: Six patients received liver SBRT in 3 fractions. The PTV was generated from the CTV by adding margins of 5mm (LR,AP) and 10mm (CC). The 3-D motion of an implanted gold marker was monitored throughout each fraction by fluoroscopic kV and MV imaging. Later, five VMAT treatment plans with different PTV dose coverage were

produced for each patient. All plans had a mean CTV dose of 18.75 Gy per fraction (=100% dose) and 95% minimum CTV dose coverage. The PTV was covered by 50%, 67%_S, 67% (our standard), 80%, and 95% of the prescribed dose, respectively. The 67%_S plan was an alternative to the standard 67% plan made with maximum conformity, i.e. as steep as possible dose gradient from 95% to 67% outside the CTV. The 50%, 67%_S, 80%, and 95% plans were renormalized to be isotoxic with the standard 67% plan, i.e. to give the same risk of radiation induced liver disease (RILD) according to the NTCP-model of Dawson *et al.* (Acta Oncol., 2006). For each patient and plan, the dosimetric effects of the observed intrafraction motion were investigated by calculating the delivered dose by an in-house developed method for motion-including dose reconstruction.

Results: The figure shows the CTV mean dose and D99 for each plan type and each patient as planned (start of each arrow) and as delivered with the known tumor motion (end of each arrow). The mean values over all patients are presented in Table 1. The planned CTV dose decreased markedly from 63.3Gy to 47.0Gy (average mean dose) and from 60.5Gy to 44.9Gy (average D99) as the prescription level to the PTV rim was increased from 50% to 95%. Although intrafraction motion reduced this CTV dose difference the CTV dose of plans with high PTV prescription levels remained inferior to isotoxic plans with low PTV prescription levels even when motion was included in the dose calculations, see Table 1. The absolute dose delivered to the liver was almost unaffected by intrafraction motion as seen in Table 1.

Figure 1
Mean dose (horizontal axis) and D99 (vertical axis) for CTV for each plan type for each patient as planned (start of each arrow) and as delivered with the known tumor motion (end of each arrow). Each color represent a plan type.

Conclusion: The dose level at the PTV rim has a large effect on the risk of RILD. Using a low dose at the PTV rim, where the probability of CTV presence during treatment was low, allowed for higher CTV dose for iso-toxic conditions in 50% and 67%_S plans. Although these plans were less robust to intra-fraction motion, their CTV dose remained superior to the 80% and 95% plans when motion effects were included.

Table 1

PTV prescription dose	Planned mean CTV dose (Gy)	Delivered mean CTV dose (Gy)	Planned mean CTV D ₉₉ dose (Gy)	Delivered mean CTV D ₉₉ dose (Gy)	Planned mean liver dose (Gy)	Delivered mean liver dose (Gy)
50%	63.3	58.0	60.5	47.8	10.91	10.53
67% _S	57.7	54.2	54.7	44.7	11.03	10.80
67%	56.3	52.9	54.3	45.5	10.97	10.66
80%	52.0	49.7	50.2	43.0	11.05	10.72
95%	47.0	45.5	44.9	39.8	11.13	10.93

PO-0891

Clinical implementation and experience with real-time anatomy tracking and gating during MR-IGRT

O. Green¹, L. Rankine², L. Santanam¹, R. Kashani¹, C. Robinson¹, P. Parikh¹, J. Bradley¹, J. Olsen¹, S. Mucic¹

¹Washington University School of Medicine, Radiation Oncology, St. Louis, USA

²University of North Carolina, Radiation Oncology, Chapel Hill, USA

Purpose or Objective: To describe the commissioning process and initial experience using real-anatomy, real-time tracking and gating with MRI-guided radiation therapy.

Material and Methods: An MR-IGRT system was commissioned to enable real-time anatomy tracking and gating. The imaging rate is 4 frames per second; the radiation shuts off when the anatomy of interest is automatically detected outside a pre-defined treatment region. The specific commissioning tests were driven by the goal of compensating for the inherent system latency such that there would not be an increase in treatment margins (i.e., GTV to PTV expansion). Dosimetric and geometric accuracy was evaluated by using both a commercial and an in-house motion phantoms with film and ionization chamber dosimetry. Clinical procedures were developed to maintain the established accuracy during actual patient treatments.

Results: Since initial clinical implementation, 51 patients have been treated using the gating and tracking capability of the MR-IGRT system (out of a total of 193). Based on system characteristics established during commissioning tests, the standard-of-care GTV to PTV expansion was maintained (e.g., 5 mm for abdominal tumors). Dosimetric accuracy was established via ionization chamber measurements that showed a 1.28%±1.7% average difference when comparing gated (with motion) vs. non-gated (without motion) delivery for typical IMRT and open field plans. Spatial accuracy was established via film dosimetric measurements and spatial integrity measurements to be on the order of 2 mm. This level of accuracy is maintained during patient delivery by using the following procedure: setting up to an exhale breath-hold position and using a gating boundary around the region of interest that's 2 mm less than the PTV of interest (e.g., 3 mm expansion of the GTV if a 5-mm expansion to PTV). Depending on the location of the tumor (or other anatomy of interest), duty cycles so far have ranged from about 50% (especially for tumors close to diaphragm) to about 80% (for pancreatic lesions and other abdominal sites excluding liver). Examples are shown in figure below.

Conclusion: We have clinically demonstrated the practicality of real-time, real-anatomy tracking and have shown that clinical parameters can be selected which allow efficient treatment delivery. This work will be used as a foundation for evaluating options for treatment volume reduction.

PO-0892

Assessment of respiratory and cardiac motion to supplement MRI based tracking of hilar lymph nodes

L.P.W. Canjels¹, M.E.P. Philipens¹, T. Bruijnen¹, B. Stemkens¹, D.C.P. Cobben¹, S. Sharouni¹, J.J.W. Lagendijk¹, A.L.H.M.W. Van Lier¹, R.H.N. Tjissen¹

¹UMC Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands

Purpose or Objective: In current radiotherapy for hilar or mediastinal lymph node metastases large treatment margins are used. Online MRI guidance will offer direct visualization of the lymph nodes, allowing highly conformal treatments using gating or tracking techniques. However, both respiratory and cardiac induced motion are expected to cause significant displacements. In this study we have assessed the relative contributions of the heart and respiration to the motion of hilar lymph nodes in order to find the optimal motion compensation strategy on the MR-Linac.

Material and Methods: Five healthy subjects were imaged during free-breathing using cine-MRI on a 1.5T MRI scanner. Sagittal and coronal scans, positioned through the center of the hilar lymph nodes, were acquired interleaved using a balanced Steady-State Free-Precession (bSSFP) sequence, providing T2/T1 contrast; Tacq = 1:08 min, TE/TR = 1.92/0.96 ms, 1.38 x 1.38 mm², 7 mm slices, at a rate of 4 frames/sec. The motion in the region of the hilar lymph nodes was estimated using an optical flow algorithm [1]. As the cardiac induced motion manifests as a modulation of the respiratory motion waveform, power spectra were calculated to assess the relative contribution of each source of motion. The respiratory-to-cardiac power ratios were determined from the power spectrum by dividing the respiratory peak by the cardiac peak.

Results: Typical results of optical flow analysis on sagittal and coronal slices in Figs. 1A-B. Cardiac motion is shown to have significant contributions in left-right (LR) and anterior-posterior (AP) directions as shown by the power spectra (Fig. 1C). The mean lymph node displacements and respiratory-to-cardiac power ratios are listed in Table 1. The mean displacement was largest in CC direction. The respiratory-to-cardiac power ratio was largest in CC direction, while in LR direction the lowest values are observed. This implies that cardiac induced motion contributes most in LR direction, whereas respiratory induced motion dominates most in CC direction.

Conclusion: These preliminary results in five volunteers showed that cardiac motion has a significant contribution on the motion of hilar structures. This indicates that the cardiac

component cannot be ignored when implementing motion compensation strategies. Soon, this study will start with the inclusion of lung cancer patients with lymph nodes metastases. The power spectra will be used to separate the cardiac from the respiratory signal to determine the exact cardiac induced displacement.

Table 1: Motion characteristics

	Cranio-caudal direction		Left-Right direction		Anterior-posterior direction	
	Mean lymph node displacement (mm)*	respiratory-to-cardiac power ratio**	Mean lymph node displacement (mm)*	respiratory-to-cardiac power ratio**	Mean lymph node displacement (mm)*	respiratory-to-cardiac power ratio**
Subject 1	3.2	32	2.1	3.1	2.4	9.2
Subject 2	5.9	4.1	1.0	1.5	1.8	3.0
Subject 3	4.8	7.9	1.5	1.2	1.3	2.3
Subject 4	8.2	50	1.8	3.4	3.3	5.5
Subject 5	3.9	21	1.6	1.2	0.9	4.4
Average	5.2	33	1.8	1.8	1.9	4.4

* The mean lymph node displacement was calculated using a 95% confidence interval to exclude outliers

** The respiratory-to-cardiac power ratios were determined from the power spectrum by dividing the respiratory peak by the cardiac peak.

Figure 1: A: Displacement vectors of the hilar lymph node region in a sagittal slice and B: in a coronal slice. C: Power spectra in LR (blue), AP (red) and CC (yellow) directions in one subject. D: Single power spectrum in which the peaks used for the peak-to-peak ratio are indicated.

PO-0893

Direct comparison of electromagnetic guided couch and MLC tracking on a TrueBeam accelerator

R. Hansen¹, T. Ravkilde¹, E.S. Worm¹, J. Toftegaard², C. Grau², K. Macek³, P.R. Poulsen²

¹Aarhus University Hospital, Department of Medical Physics, Aarhus C, Denmark

²Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

³Varian Medical Systems, Imaging Laboratory, Baden, Switzerland

Purpose or Objective: Couch and MLC tracking are promising methods for real-time motion compensation for moving targets during radiation therapy. Couch and MLC tracking experiments have mainly been performed by different research groups, and no direct comparison of couch and MLC tracking of VMAT plans has been published. Varian TrueBeam 2.0 includes a prototype tracking system with selectable couch or MLC compensation. This study provides a direct comparison of the two tracking types with an otherwise identical setup.

Material and Methods: Several experiments were performed to characterize the geometric and dosimetric performance of electromagnetic guided couch and MLC tracking on a TrueBeam linear accelerator. The tracking system latency was determined without motion prediction as the time lag between sinusoidal target motion and the compensating motion of the couch or MLC as recorded by continuous MV portal imaging. The geometric and dosimetric tracking accuracy was measured in tracking experiments with motion phantoms that reproduced four prostate and four lung tumor trajectories. A Kalman filter was used for prediction in these experiments. The geometric tracking error in beam's eye view was determined as the distance between an embedded gold marker embedded and the circular MLC aperture in continuous MV images. The dosimetric tracking error was quantified as the Delta4-measured 2%/2mm gamma failure rate of a low and a high modulation VMAT plan delivered with the eight motion trajectories and using the static dose distribution as reference.

Results: The mean MLC tracking latency was consistently around 146ms while the couch tracking latency increased from 187ms to 246ms with decreasing sinusoidal period length due to limitations in the couch acceleration. The mean root-mean-square geometric error was 1.26mm (couch tracking) and 0.67mm (MLC tracking) parallel to the MLC leaves and 0.84mm (couch) and 1.74mm (MLC) perpendicular to the leaves. The motion-induced mean gamma failure rate was in mean 30.4% (no tracking), 0.1% (couch tracking), and 8.1% (MLC tracking) for prostate motion and 41.2% (no tracking), 2.9% (couch), and 2.4% (MLC) for lung tumor motion. The dose errors with tracking were largest for high modulation VMAT (see figure). The errors were mainly caused by fast lung tumor motion for couch tracking and by inadequate leaf fitting to prostate motion perpendicular to the MLC leaves for MLC tracking.

Conclusion: Both MLC and couch tracking markedly improved the geometric and dosimetric treatment accuracy. However, the two tracking types have different strengths and weaknesses. While couch tracking can correct perfectly for slowly moving targets such as prostate, MLC tracking has limitations when adapting to motion perpendicular to the MLC leaves. Advantages of MLC tracking include faster dynamics with better adaptation to fast moving targets, the avoidance of moving the patient, and the potential to track target rotations and deformations.

Poster: Physics track: Inter-fraction motion management (excl. adaptive radiotherapy)

PO-0894

Evaluation of daily setup errors in VMAT for craniospinal irradiation of paediatric patients

C. Constantinescu¹, Y. Bahadur², R. Al-Wassia², M. Hussain¹, V. Josephjohn²

¹King Faisal Specialist Hospital, Bio-Medical Physics, Jeddah, Saudi Arabia

²King Abdulaziz University Hospital, Radiology, Jeddah, Saudi Arabia

Purpose or Objective: To retrospectively evaluate setup errors in craniospinal irradiation (CSI) with volumetric-modulated-arc-therapy (VMAT) for paediatric patients using daily cone-beam-computed-tomography (CBCT), and assess adequate planning-target-volume (PTV) margins.

Material and Methods: Ten paediatric patients with median age 10 years (range 3-14 years) undergoing CSI by VMAT were included in this study. All patients were immobilized by five-point thermoplastic mask with shoulder fixation and Vac-Lock cushions and treated in supine position, using 6 MV photons and 2 longitudinally aligned isocenters. Radiation beams were covering the brain and upper spine, and the lower spine respectively. The dose distribution at their virtual junction was optimized by inverse planning. Three patients (age ≤ 6 years) received general anesthesia and 1 patient was sedated during positioning and treatment procedures. Daily kV CBCTs were acquired before treatment for both the upper and lower

segments of craniospinal axis. CBCT scans were registered to the planning CT using bony anatomy and setup shifts were determined. Inter-fraction shifts were retrospectively evaluated as systematic (Σ) and random (σ) errors in the antero-posterior (AP), lateral (LR), cranio-caudal (CC) and directions. PTV margins were calculated for a minimum CTV dose of 95% for 90% of patients. Setup errors of upper and lower craniospinal axis were compared by a 2-tailed t-test and a p value <0.5 was considered significant.

Results: A total of 376 CBCT image registrations were assessed.

Table 1. Summary of setup errors for upper and lower segments of craniospinal axis for all patients.

	Upper segment			Lower segment		
	AP	LR	CC	AP	LR	CC
M (mm)	0.2	-0.2	0.8	1.4	-0.7	0.1
Min (mm)	-5.	-9.	-5.	-10.	-14.	-6.
Max (mm)	11.	8.	15.	10.	8.	9.
Σ (mm)	0.9	0.6	1.	1.6	2.8	0.8
σ (mm)	2.1	4.5	4.9	4.1	5.2	4.3
Margin (mm)	3.7	4.7	5.9	6.9	10.6	5.1

The largest setup error occurred in the CC and LR direction, for the upper and lower segment of craniospinal axis, respectively. Statistical significant difference was found between upper and lower segment of craniospinal axis in CC (p=0.032) and LR (p=0.009) directions, due to different immobilization devices.

Fig. 1. Distribution of setup errors in all directions, for upper and lower segment of craniospinal axis.

Conclusion: For paediatric patients undergoing CSI by VMAT, the main setup variation occurs in the CC and LR direction, for the upper and lower segment of craniospinal axis, respectively. Despite of specific immobilization methods, large PTV margins are required to reduce the setup

uncertainty. Our data recommend daily kV CBCT imaging and setup corrections for this group of patients.

PO-0895

Intraprostatic calcifications as IGRT fiducial markers: analysis of 646 CBCT images in 35 patients
 P. Antognoni¹, D.P. Doino¹, L. Pozzi², S. Gottardo¹, P. Stucchi², C. Bianchi², M. Monciardini², L. Cerizza¹, M. Molteni¹, R. Novario²

¹Ospedale di Circolo Fondazione Macchi, Department of Radiotherapy, Varese, Italy

²Ospedale di Circolo Fondazione Macchi, Department of Medical Physics, Varese, Italy

Purpose or Objective: To review CBCT images of 35 pts receiving radical irradiation for localized prostate cancer, according to an IGRT protocol based on the use of intraprostatic calcifications as natural fiducial markers for the evaluation of inter-fraction organ motion.

Material and Methods: Between 2013 and 2014, 646 KVCBCT images of 35 pts radically irradiated with moderately hypofractionated VMAT (2.5 Gy/fract.- 70 Gy in 28 fract.) for localized prostate cancer were acquired according to an IGRT protocol aimed at evaluating the role of intraprostatic calcifications as natural fiducial markers. All the evaluated pts presented at least 3 calcifications of >2 mm located inside or at the borders of the CTV and contoured on high resolution CT-simulation scans and on each CBCT (mean: 18 CBCT/patient). In order to assess the internal stability of the calcifications the distances between them were measured for each patient on both CT-simulation scans and each CBCT, then mean \pm SD of differences between distances was calculated. Distances between calcifications and the center of mass of CTV were also calculated in 21 patients by drawing CTV on 360 CBCT images, contoured by a same physician. The center of CTV mass spatial coordinates (X, Y, Z) was determined for each CTV and finally the distances between the center of the CTV and the center of each calcification were measured. Stability of calcifications in respect of CTV was assessed by calculating mean values \pm SD of measured distances.

Results: The mean value of differences in distances between calcifications was -0.04 mm \pm 1.54 SD, with 95% of values contained inside 3 mm ($\mu \pm 2SD$). The mean value of differences in distances between calcifications and center of mass of CTV (Fig. 1) was -0.03 mm \pm 1.55 SD, with 95% of values contained inside 3 mm ($\mu \pm 2SD$).

Fig.1: Frequency distribution of differences in distances (cm) between calcifications and center of mass of CTV

Conclusion: Our results derived from the analysis of a large data set of CBCT images confirm that intraprostatic calcifications, when >2 mm and present at least Nr.=3, properly selected and contoured, can be used as very reliable natural fiducials, with potential reduction of iatrogenic risks and costs associated with the implantation of fiducial markers for prostate cancer IGRT.

PO-0896

The effect of bladder volume on bowel dose in the treatment of anal cancer using IMRT

K. McDonald¹, L. Wells¹, H. Phillips¹, C. McLean¹, L. Carruthers¹, W. Nailon¹

¹Edinburgh Cancer Centre, Radiotherapy Physics, Edinburgh, United Kingdom

Purpose or Objective: Bony anatomy is used to match anal cancer patients treated using volumetric modulated arc therapy (VMAT). Only extreme volume changes due to bladder, rectum or bowel filling are currently highlighted to the responsible clinician. This study aims to determine the impact that changes in bladder volume has on the dose to the small bowel over the course of the treatment by comparing the dose to volumes outlined on cone-beam CT (CBCT) to the initial planned dose statistics. A more representative value of accrued dose to the small bowel over the course of treatment can also be gained.

Material and Methods: Ten patients who were treated with VMAT for anal cancer were selected for this study. Weekly cone beam CT images were acquired to monitor extreme changes in bladder and rectum filling. Patients were asked at both planning CT and treatment to have a comfortably full bladder. The bladder and small bowel (contained within the scan) were outlined on three CBCTs by one clinician; week one, mid treatment and final week. The bladder volumes were compared over the course of the treatment and the maximum small bowel dose, amount of small bowel receiving 30Gy (V30Gy) and 40Gy (V40Gy) were recorded.

Results: The results in Table 1 show the variation in bladder volume. The V40Gy bowel volume was plotted against the difference between the bladder volume at CBCT and the initial planning scan with the intercept for the linear trends set to the planning CT volume for each patient (see Fig. 1). A similar trend was found for the V30Gy measurement. There was less impact on maximum dose to small bowel with changing bladder size.

Table 1 - Bladder Volumes

Patient	1	2	3	4	5	6	7	8	9	10
Planning CT bladder volumes	579	196	278	140	157	170	182	247	239	161
[Range from CBCT5] (cm3)	[426- 618]	[75- 628]	[146- 225]	[57- 248]	[31- 70]	[80- 232]	[146- 215]	[65- 227]	[79- 154]	[81- 191]

Conclusion: In eight cases a smaller bladder at CBCT resulted in a greater volume of small bowel receiving clinically relevant doses compared to the initial planning CT. There were two patients where the trend indicated that a larger bladder increased small bowel dose. Limitations of this study

include poor visibility of the small bowel on the CBCTs, smaller field of view meaning less volume and variation between initial planning clinician and clinician outlining CBCTs. CBCT is now widely used for adaptive planning techniques and in this case has provided evidence for implementing a stricter bladder filling protocol to improve the accuracy of bowel dose statistics at planning.

PO-0897

Comparison of hippocampus sparing extent according to the tilt of a patient head during WBRT

S. Moon¹, M. Yoon¹, M. Chung², W. Chung², D. Kim²

¹Korea University, Department of Bio-convergence Engineering, Seoul, Korea Republic of

²Kyung Hee University Hospital at Gangdong, Department of Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: We report the results of our investigation into whole brain radiotherapy using linear accelerator-based intensity-modulated radiation therapy and volumetric-modulated arc therapy in cancer patients with a high risk of metastasis to the brain. Concretely, we assessed the absorbed dose and the rate of adverse effects for several organs at risk according to the tilt of a patient's head.

Material and Methods: From data regarding patients who had previously received WBRT, we arbitrarily selected five cases where measurements were made with the patients' heads tilted forward and five cases without such tilt. We set the entire brain as the planning target volume, and the hippocampi, the lenses, the eyes, and the cochleae as the main OAR, and formulated new plans for IMRT (coplanar, non-coplanar) and VMAT (coplanar, non-coplanar). Using the dose-volume histogram obtained from the treatment plans, we calculated and compared the effective uniform dose and normal tissue complication probability of the OAR. In order to compare the extent of hippocampal sparing, we also analyzed the mean and the maximum doses.

Results: When a patient received coplanar IMRT with the head tilted forward, the EUD and NTCP values for the hippocampus decreased by 13% and 81%, and the mean dose and maximum dose decreased by 8% and 7%, respectively. When the patient received non-coplanar treatment, the hippocampal EUD and NTCP values decreased by 2% and 15%, and the mean dose and maximum dose decreased by 2% and 4%, respectively. For coplanar VMAT treatment, the EUD values decreased by 20%, the NTCP values decreased by 92%, and the mean dose and the maximum dose decreased by 10% and 13%, respectively. For non-coplanar treatment as well, the EUD values decreased by 14%, the NTCP values decreased by 81%, and the mean dose and the maximum dose decreased by 14% and 10%.

			CVI	CI	HI
IMRT	Coplanar	Tilt	0.98 ± 0.01	0.91 ± 0.02	0.09 ± 0.02
		Non-tilt	0.99 ± 0.00	0.90 ± 0.02	0.07 ± 0.01
	Noncoplanar	Tilt	0.99 ± 0.01	0.91 ± 0.01	0.08 ± 0.02
		Non-tilt	0.99 ± 0.01	0.90 ± 0.02	0.07 ± 0.01
VMAT	Coplanar	Tilt	0.98 ± 0.01	0.90 ± 0.01	0.09 ± 0.01
		Non-tilt	0.98 ± 0.01	0.90 ± 0.02	0.09 ± 0.02
	Noncoplanar	Tilt	0.98 ± 0.01	0.90 ± 0.01	0.10 ± 0.01
		Non-tilt	0.98 ± 0.01	0.90 ± 0.01	0.10 ± 0.01

Conclusion: If the patient tilted the head forward when receiving the Linac-based treatment, for the same treatment effect in the PTV, we confirmed that a lower dose entered the OAR, such as the hippocampus, eye, lens, and cochlea. Also, the damage to the hippocampus was expected to be the least when receiving coplanar VMAT with the head tilted forward, and we showed that damage to OAR, including the hippocampus, was the least overall when the head was tilted forward. Accordingly, if patients tilt their heads forward when undergoing Linac-based WBRT, we anticipate that a smaller dose would be transmitted to the OAR, resulting in better quality of life following treatment.

PO-0898

Inter-fraction position of the tongue in postoperative radiotherapy of tongue cancer

E. Dale¹, C. Salamonsen¹, K. Angelvik², S. Gjørlme², B. Bø²

¹Oslo University Hospital - Radium, Department of Oncology, Oslo, Norway

²Oslo and Akershus University College of Applied Sciences, Department of Life Sciences and Health, Oslo, Norway

Purpose or Objective: Postoperative radiotherapy (PORT) of tongue cancer is associated with side-effects such as acute mucositis. Our department previously used intraoral stents to depress the tongue to minimize the dose to the palate. However, the stents were not always very well tolerated and there were also reproducibility issues. Therefore, the intraoral stents were omitted. In order to still ensure target coverage, we have included the air gap (if present) above the tongue in the target volume (CTV tongue including the surgical bed) on the planning CT. We wanted to investigate whether the air gap is a systematic phenomenon over all treatment fractions, so that the size of the CTV could be reduced avoiding irradiating the palate.

Material and Methods: We have so far included 10 patients with T1-T2 N0 M0 squamous cell carcinoma of the tongue referred to PORT. Nine patients were treated with 50 Gy in 2 Gy fractions, and one patients with 60 Gy in 2 Gy fractions with concurrent chemotherapy (cisplatin) because of positive surgical margins. All patients underwent daily kV cone-beam CT (CBCT). From each CBCT we obtained three distance measures from the sagittal images: The caudo-cranial air gap from the cranial border of the tongue to the palate on the 1) lateral left, 2) midline and 3) lateral right side.

Results: Two of 10 patients had air gaps between the tongue and palate systematically present over the treatment period (Figure, mean air gaps 6 mm and 8 mm) indicating that a caudo-cranial reduction of the CTV for these individuals could be safe. However, for the remaining 8 patients the tongue was mostly located cranially towards the palate. It was not possible to identify a relationship between the size of the air gap and clinical parameters such as resected volume, tumor size, infiltration depth, patient age or gender.

Conclusion: PORT for tongue cancer without intraoral stent is best planned with the target volume extending towards the palate to allow for inter-fractional movement of the tongue.

PO-0899

Robustness of fractionated photon RT for pancreatic cancer: Dosimetric effects of anatomical changes

A. Van der Horst¹, A.C. Houweling¹, J. Visser¹, G. Van Tienhoven¹, A. Bel¹

¹Academic Medical Center, Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: Anatomical changes taking place over the course of radiation therapy (RT) result in a difference between planned and delivered dose. For pancreatic cancer, we investigated the robustness of clinical treatment plans by quantifying the dosimetric effects of changes in gas volumes, body contour and interfractional target displacement. In addition, we compared the dosimetric effect of anatomical changes between use of bony anatomy and use of intratumoral fiducial markers for patient positioning.

Material and Methods: Nine pancreatic cancer patients were included who had intratumoral markers for daily cone-beam CT (CBCT)-based position verification. The clinical plans (10 MV; 1 arc VMAT; internal CTV (iCTV) to PTV margin = 10 mm) were used for dose calculation. To enable fraction dose calculations on CBCT, the planning CT was deformably registered to each CBCT (13-15 CBCTs per patient); air volumes visible on the CBCT were copied to the deformed CT.

Calculations were done for marker-based registration (as clinically used) and for bony anatomy-based registration. For both methods, doses were rigidly summed to yield the accumulated doses on the planning CT. For each patient, all DVHs were normalized to yield for the planned dose to the PTV: V98% = 95% (100% = 36 Gy).

To evaluate target coverage, we defined an iCTV+5mm volume, i.e. the iCTV expanded with a 5 mm margin to account for remaining uncertainties including delineation. We analysed D98%, Dmean and D2% for iCTV+5mm and iCTV and examined DVH differences for duodenum and stomach, the organs at risk closest to the iCTV.

Results: For the iCTV+5mm, D98% changed from mean 96.3% (range 95.5-97.8%) for the planned dose to 96.7% (96.4-97.0%) for marker-based accumulated dose (Table 1).

Table 1. Target dose for the 9 patients.

		Planned	Marker-based	Bony anatomy-based
		mean (range) [%]	mean (range) [%]	mean (range) [%]
iCTV+5mm	D98%	96.3 (95.5-97.8)	96.7 (96.4-97.0)	95.3 (85.8-97.9)*
	Dmean	98.7 (97.8-101.1)	99.0 (98.2-100.0)	98.8 (96.7-100.1)
	D2%	100.9 (99.2-104.5)	101.2 (99.7-103.3)	100.6 (98.8-102.4)
iCTV	D98%	96.3 (95.5-98.0)	96.7 (96.4-97.1)	97.1 (93.6-98.6)*
	Dmean	98.6 (97.8-101.1)	99.0 (98.1-100.0)	99.0 (97.6-100.2)
	D2%	100.7 (99.1-104.5)	101.0 (99.7-103.2)	100.5 (98.8-102.2)

* Doses <95% in bold.

For each patient, the DVH of the PTV of the planned dose distribution was normalized to D98% = 95%; all other DVHs of planned and accumulated doses were scaled accordingly. For the group, this yielded a PTV D2% of mean 100.8% (range 99.3-104.3%).

These relatively small differences indicate a limited dosimetric effect from changes in gas and body contour, even though the amount of gas visible on CBCT showed large variations (avg. 166 ml, SD 145 ml).

In contrast, D98% decreased to 95.3% (85.8-97.9%) for bony anatomy registration, due to systematic errors inherently associated with bony-anatomy patient positioning. Changes for stomach and duodenum depended strongly on the direction of these errors, with large increases in D2% for

some (error in direction of organ) and large decreases for others. Differences were largest for the stomach (e.g. D2% from 72.7% (planned) to 82.4% (bony anatomy-based accumulated)). For marker-based positioning, the dosimetric effects for stomach and duodenum were limited (<0.5 Gy in 8 out of 9 patients).

Conclusion: Photon irradiation of pancreatic tumours is robust to variations in body contour and gastrointestinal gas, with dose coverage only mildly affected by these anatomical changes. However, when using bony anatomy for patient positioning, dose coverage declines due to interfractional tumour position variations. Therefore, the use of fiducial marker-based daily position verification is essential in RT for pancreatic cancer.

PO-0900

Dosimetric analysis of organ deformation during prostate IMAT with cone beam CT imaging

D. Foley¹, B. McClean², P. McBride²

¹UCD, School of Physics, Dublin, Ireland Republic of

²St. Luke's Radiation Oncology Network, Physics, Dublin, Ireland Republic of

Purpose or Objective: Patients undergoing prostate intensity modulated arc therapy (IMAT) were retrospectively investigated using the CBCT images acquired for setup purposes to determine the volumetric variability of the target and organs at risk and the dosimetric implications of these changes.

Material and Methods: IMAT plans from 11 patients were designed to deliver 74 Gy in 37 fractions to the target. The CTV consisted of the prostate and seminal vesicles, while the PTV was the CTV plus a margin of 10 mm in all directions except posteriorly, where a 5 mm margin was used. For between 9 and 14 of the 37 fractions, the patients were scanned using an on-board CBCT imager to verify the setup. These images were retrospectively registered to the planning CT using an in-house registration algorithm to determine the transformations between the images. The calculated transformation vector field was used to deform the planning CT so that the plan could be recalculated with the original MU on this new adapted CT. This allowed the determination of the dosimetric impact of the change in anatomical information from the time of acquisition of the planning CT to immediately prior to a given treatment fraction. The imaged fractions were treated as though they were representative of the entire treatment and were weighted equally for dose accumulation purposes.

Results: Over the course of the patients' treatments, the changes in CTV volume compared to the plan were from a decrease of 25% up to a maximum increase of 6%. Their bladder volumes ranged from -10% to 10% of their respective volumes on the planning CT. The rectal volume decreased for all patients, with 5% less than the planning volume the smallest reduction and 34% being the largest volume shrinkage.

The dosimetric impact of these anatomical changes varied for each structure. The minimum dose received by the CTV varied by less than 1% for all patients, with full coverage of the CTV achieved in all fractions.

The mean dose delivered to the bladder averaged over each patients treatment resulted in variation of between -4% and 17% of their respective planned mean doses. This did not result in a break of the dose-volume constraints (DVCs) for the bladder at any fraction, for any patient.

The rectum received a higher mean dose than the planned value for all patients. This ranged from an increase of 7% up to 38%. It was found that the rectum frequently broke multiple DVCs, resulting in the rectum being overdosed in 79% of the fractions examined.

Conclusion: Analysis of the anatomical condition of the patient on the day of treatment can give an indication of how suitable the original plan for their treatment is. For these patients, although the variability in the anatomy did not

result in any significant under-dosing of the target, the observed differences showed that the rectum broke our institutional DVCs during treatment. This is important data required to evaluate the robustness of institutional procedures for the planning and delivery of patients' treatments.

PO-0901

Investigation of a fast CBCT protocol for supine accelerated whole breast Irradiation

E. Bogaert¹, C. Monten¹, C. De Wagter¹, W. De Neve¹

¹Ghent University Hospital, Radiotherapy, Ghent, Belgium

Purpose or Objective: Acceleration in breast cancer treatment might become the new standard. As fraction dose rises, the importance of correct positioning increases. CBCT is time consuming and uses (low dose) radiation. Increasing interval between positioning and actual treatment reduces precision. We therefore investigated a CBCT technique with lower dose and faster acquisition.

Material and Methods: Both standard and fast pre-treatment CBCT imaging (STAND and FAST) were performed on XVI Elekta® in a 5-fractions supine and whole breast irradiation scheme (5 x 5.7 Gy). The main difference between protocols was gantry speed (Table 1). Central dose was measured with PTW equipment in a CTDI32 phantom. High resolution (HR) and contrast were measured on a Catphan Phantom. Breast contour appearance was assessed on a polystyrene breast phantom. Fifteen clinical CBCT-images for three patients to which FAST or STAND was randomly assigned, were blindly scored by a skilled oncologist. A three-level answer had to be formulated regarding visibility of 1) all clips, 2) entire breast contour, 3) lung/thorax wall edge and 4) excision cavity. Answers were decoded: 0: Not at all; 1: Yes, but only with guidance of reference CT; 2; Yes clearly, without reference CT.

Results: FAST operated at only 53% and 61 % of dose and time of STAND. A low HR (3 lp/mm) was the same for FAST and STAND. Contrast was assessed for STAND through visibility of the largest (15mm) 1% contrast nodule. For FAST, no nodules could be distinguished. There was excess-tissue on cranial and caudal CBCT breast phantom slices, but to the same extent in STAND and FAST. In mid position, breast edge was sharp and coincided with reference CT.

The Patient study reflected a difference in the overall low soft tissue contrast for the two protocols. The excision cavity was never scored 2, more 1 for STAND and more 0 for FAST and was less visible with higher breast density (patient 3). Breast contours showed step-wise artifacts near inframammary and axillary folds for both protocols. Lung/thorax wall edges were scored 2 and 1 but the dependency was larger for patient anatomy than for scan protocol. All clips were visible: the rather poor HR is however sufficient. Streak artifacts due to beam hardening and undersampling were apparent in both protocols (Figure 1). Even though the noisy and artifact-rich appearance of the images, effect on clinical decision making for registration is minimal. The stepwise artifacts appear very localized and are easily corrected for in the observer's mind. Additional information by outer breast contour and lung-thoracic wall edge compensates for this. Distinction between real artifacts and excision cavity can be done by comparison with reference CT. Clips are always visible and of special importance in high density and/or voluminous breasts.

Figure 1: a) STAND CBCT image with step-wise artifacts (arrow 1); b-c) STAND mid and caudal breast phantom image sets (green-purple representation), tissue excess (arrow 2); d) STAND CBCT image with streak artifacts (arrow 3) and clip (arrow 4); e-f) FAST CBCT and reference CT image of the same patient with boost CTV volume (red) where visibility of excision cavity was scored 1.

Table 1: Standard and fast pre-treatment CBCT imaging protocols

Protocol parameters*	STAND		FAST	
	left	right	left	right
Acquisition angle [degrees]	205	200	205	200
gantry speed [degrees/min]	180	180	360	360
N° of frames	376	367	188	183
Dose and Time measurements				
Dose Length Product [†] [mGy.cm]	30.7	35.1	16.1	19.0
CBCT-acquisition time [s]	79	76	49	45

* all: 120kV; mA/frame=20; ms/frame=32; 5.5 frames/s

[†] Dose Length Product: dose measured over 30 cm long pencil chamber @ central hole of CTDI32 phantom

Conclusion: FAST allows the oncologist to register breast CBCT. However, with high density or voluminous breasts, clips are recommended with the use of FAST.

PO-0902

Improving frameless intracranial stereotactic setup with 6DOF couch using two pre-treatment CBCTs

J. Gagne¹, A. Mestrovic¹, S. Zavgorodni¹

¹BC Cancer Agency - Vancouver Island Cancer Centre, Medical Physics, Victoria, Canada

Purpose or Objective: The primary goal of this study was to evaluate the residual inter-fraction positioning errors of our intra-cranial frameless stereotactic treatment following a six-degree of freedom (6DOF) correction based on automatic bone anatomy matching. A secondary goal was to evaluate the intra-fraction motion.

Material and Methods: Since the implementation of the stereotactic program at our centre, 13 patients were treated with frameless intra-cranial fractionated radiotherapy on a Varian TrueBeam STx linear accelerator. All patients had a planning CT scan with an immobilization system that comprised of a CIVCO head cup, customizable pillow and thermoplastic shell. To guide setup, nose to forehead pitch was calculated using CT information and reproduced at treatment using a digital level. Roll was measured as the difference in height at the level of the anterior ear notch and reproduced at treatment using the in-room lasers. Two pre-treatment CBCTs were acquired; the first to correct using 6DOF bone anatomy matching the initial inter-fraction positioning error and the second to assess the residual inter-fraction error post 6DOF correction. Since our initial experience with the first 3 patients, revealed residual inter-fraction setup errors greater than 1mm, the residual inter-fraction setup error post 6DOF correction was measured and corrected prior each treatment for all remaining 10 patients. Due to the technical limitations of Varian's 6DOF couch (i.e. maximum 3 degrees pitch and roll), the correction of the residual inter-fraction error was carried out using 4DOF automatic bony anatomy matching (i.e. excluding pitch and roll due to 3degree limitation). A post-treatment CBCT was acquired to determine the intra-fraction motion using 6DOF bone anatomy matching.

Results: Datasets from 10 patients were obtained for a total of 705 CBCT scans - the first 3 patients were excluded from the study due to changes in methodology partly through treatment. The mean 3D vector of residual setup error post first correction (6DOF) was 0.7 ± 0.4 mm (mean \pm SD) and the maximum 3D vector was 2.2mm. The mean 3D vector of residual setup error post second correction (4DOF) was 0.2 ± 0.1 mm and the maximum 3D vector was 0.8mm. The mean 3D vector of intra-fraction motion was 0.4 ± 0.2 mm and the maximum 3D vector was 1.3mm.

Conclusion: Incorporating a second correction pre-treatment significantly reduced the residual inter-fraction setup error from 0.7 ± 0.4 mm to 0.2 ± 0.1 mm. The intra-fraction motion for this cohort of patients was twice as large as the residual inter-fraction setup error. Efforts are currently underway to reduce this intra-fraction motion by focusing on improvements to the immobilization system.

PO-0903

IGRT for a highly conformal VMAT-technique for simultaneous treatment of the breast and lymph nodes

B. Houben-Haring¹, M. Admiraal¹

¹VU University Medical Center, Department of Radiotherapy, Amsterdam, The Netherlands

Purpose or Objective: Recently we introduced an improved hybrid treatment planning technique for breast with simultaneous irradiation of axillary and supraclavicular lymph nodes (level I-IV). This technique combines tangential open fields with VMAT (RapidArc®, Varian Medical Systems) and results in a highly conformal coverage of the lymph node region, with a steep dose fall-off towards esophagus and thyroid. The purpose of this study is to evaluate the validity of this conformal planning technique, with the required setup and image guidance.

Material and Methods: Ten patients were included, of which 8 were treated in Free Breathing and 2 were treated in Deep Inspiration Breathhold. Fractionation was 16 x 267 cGy for both elective breast and lymph node regions. PTV-margin of level I-IV lymph nodes is 5 mm to the medial direction and 8mm for all other directions (image 1). Daily online setup was performed on bony anatomy with 2 orthogonal kV-images and subsequent verified with medio-lateral MV field imaging. At the level of the PTVnodes setup deviation up to 3mm was allowed in lateral direction, in all other directions and for the humeral head 5mm was allowed. At the first 3 fractions and weekly a CBCT was acquired for verification of the PTV-coverage of the lymph nodes. All CBCT's were used offline for analysis of the reproducibility of level I-II nodes, level III-IV nodes, humeral head and bony anatomy. All 160 fractions were used for evaluation of the efficiency of the setup and imaging procedure.

Image 1: 95% dosewash: CTV_{nodes level I-IV} (green) PTV_{nodes level I-IV} (thick red) and PTV_{total} (thin red)

Results: A t-test showed a significant relation between the position of the humeral head and all the nodes in cranio-caudal direction ($p < 0.001$) and for level III-IV also in lateral direction ($p = 0.01$). Repositioning was required in 31 fractions (19%). This was reduced to 19 fractions (12%) by excluding 1 patient with positioning problems. Based on the CBCT's, we found that only in 2% of all cases, an off-set of the humeral

head less than 8mm lead to a deviation of the nodal PTV of more than 5mm. Analysis of the CBCT's also showed that the remaining average setup error for level I-II nodes and level III-IV nodes was less than 2mm in all directions with SD of max 1.6mm in AP direction (Table 1).

Table 1: Residual setup error of the lymph nodes and humeral head after bony anatomy match on 2 orthogonal kV-images

	Level I-II lymph nodes				Level III-IV lymph nodes				Humeral head			
	vr(mm)	lg(mm)	lat(mm)	Rot(dgr)	vr(mm)	lg(mm)	lat(mm)	Rot(dgr)	vr(mm)	lg(mm)	lat(mm)	Rot(dgr)
MEAN	0,19	0,14	0,14	0,8	0,17	0,15	0,13	0,6	0,31	0,23	0,22	1,8
SD	0,16	0,13	0,09	0,6	0,15	0,15	0,09	0,5	0,32	0,15	0,19	1,9
MIN	0,02	0,00	0,01	0,1	0,01	0,00	0,01	0,0	0,31	0,23	0,22	1,8
MAX	1,26	0,90	0,52	3,8	0,82	0,74	0,38	2,3	1,77	0,66	0,88	8,3

Conclusion: The positioning of the lymph nodes level I-IV can be well addressed by the position of the surrounding bony anatomy and the humeral head. For the adequate treatment of both the lymph node regions and the breast, two orthogonal kV-images and MV field imaging are sufficient.

Bladder changes assessment using daily cone-beam computed tomography

O. Casares-Magaz¹, V. Moiseenko², A. Hopper², N. Pettersson², M. Thor³, L. Cerviño², R. Knopp², M. Corneli², J.O. Deasy³, L.P. Muren¹, J. Einck²

²University of California San Diego, Department of Radiation Medicine and Applied Sciences, San Diego, USA

³Memorial Sloan Kettering Cancer Center, Department of Medical Physics, New York, USA

Purpose or Objective: Late genitourinary (GU) and gastrointestinal (GI) toxicities are the main dose limiting factors prostate radiotherapy plans. However, no predictive models, and consequently, no consensus guidelines have been reported for GU toxicity. One possible explanation is that the plan dose-volume histogram (DVH) is not representative of the accumulated bladder dose throughout the treatment given variability in bladder filling status, motion and set-up uncertainties. Modern image guidance techniques, in particular the use of cone beam computed tomography (CBCT), facilitates reconstruction of the accumulated dose. The aim of the study was to compare planned with accumulated dose and volume data for the bladder with the latter assessed from daily CBCT imaging and deformable image registration (DIR).

Material and Methods: Eight subjects presenting with RTOG GU Grade 2+toxicity were selected from a cohort of 287 patients treated for prostate cancer in 2006-2013. Prescribed dose was 81Gy in 45 fractions. The 8 subjects were each matched to 3 patients without GU toxicity by the following criteria: pretreatment GU symptoms (IPSS score), age \pm 5y, risk group (low, intermediate, high), whole pelvis vs. prostate, and use of neoadjuvant ADT. Treatment required adherence to a full bladder and empty rectum protocol. Daily CBCT was used for patient realignment and to assess bladder and rectal filling status. Dose from planning CT was rigidly registered to CBCT using recorded daily shifts followed by bladder contour propagation from plan CT to the first day CBCT and then to the remaining CBCTs using an intensity-based deformable image registration (DIR) algorithm. Bladder contours were corrected manually and the accumulated D10 and D20 (defined as the highest dose received by a volume up to 10 and 20 cm³ of the bladder, respectively) were compared to corresponding values from the planned DVH. All registrations and DVHs computations were done using MIM Maestro 6.4.4 (Mim Software Inc. Cleveland, OH, US).

Results: In the analyzed patients, the bladder volumes in the daily CBCTs were found to vary between 62% and 256% of that from the planning CT, with a mean difference in volume ranging from 63% to 20%. Differences in the compared DVH were also observed where D10 was $\pm 2.7\%$, and D20 $\pm 11.2\%$ of the corresponding planned metrics.

Figure 1. Bladder DVH's for the plan CT and for the daily CBCTs throughout the treatment course, and obtained after the image registration and contour correction.

Conclusion: We found considerable variation in bladder dose and volumes throughout the treatment course. Inclusion of inter-fractional bladder deformations should, therefore, likely be considered in future dose-response modeling of GU toxicity.

Preparation for the first in man on the MR-Linac: virtual couch shift and on line plan adaptation

I.H. Kiekebosch¹, E.N. De Groot¹, C.N. Nomden¹, G.H. Bol¹, B. Van Asselen¹, G.G. Sikkens¹, L.T.C. Meijers¹, A.N.T.J. Kotte¹, B.W. Raaymakers¹

¹University Medical Center Utrecht, Radiation Oncology, Utrecht, The Netherlands

Purpose or Objective: The MR-Linac (MRL) combines a linear accelerator and a 1.5T MRI scanner, which provides the possibility for on line adaptation on the current anatomy. In the current workflow, compensation for discrepancies between pre-treatment and daily treatment geometry is performed using couch translations. On the MRL it is not possible to shift the couch in left-right and anterior-posterior direction. Instead a Virtual Couch Shift (VCS) is applied: the pre-treatment dose distribution is shifted to cover the target volume by moving the MLC aperture. After VCS, it is also possible to perform Segment Weight Optimization (SWO) and Segment Shape Optimization (SSO). The first in man on the MRL will be a patient with vertebral metastases. The purpose of this study was to assess the accuracy and usability of VCS and possibly subsequent optimization for palliative treatment of patients with vertebral metastases.

Material and Methods: Three patients with repeated CT scans of the thoracic spine were included. A CTV of one thoracic vertebra was delineated, a PTV was created with an isotropic margin of 5 mm around the CTV. A clinical reference plan with a prescription dose of 800cGy (single fraction) was created in a research version of Monaco (Elekta)(figure 1). The second CT scan was used to mimic daily imaging at the MRL. The second CT was shifted in left-right and superior-inferior direction from -5 to 5 cm and in the anterior-posterior direction from -1 to 1 cm. VCS plans were created for each shift resulting in 60 plans. These were further optimised by SWO (60 plans) and by both, SWO and SSO (60 plans).

To determine the accuracy of all 180 plans, the dose distributions and DVH's were evaluated and compared with

the reference plan. Plans were acceptable if $V_{107} < 2\text{cm}^3$, the V_{99} decreased less than 2%, the V_{95} decreased less than 1% and the Dmean differed maximal 1% from the reference plan. Also time was evaluated to determine the usability in an online situation at the MRL.

Figure 1: Treatment plans for a patient with vertebral metastases, using a 3-field IMRT technique with the isocenter at the center of the patient and a collimator rotation of 90°.

Results: In total, 52% of the VCS plans were acceptable. Left-right shifts resulted mainly in an unacceptable V_{107} . Superior-inferior shifts resulted mainly in lower coverage. With SWO, 63% of the plans were accepted, the unaccepted plans had a $V_{107} > 2\text{cm}^3$. With SWO+SSO, 98% of the plans were accepted. The last 2% failed due to minimal hotspots in the PTV. The average calculation time to create a reference plan was 205 sec. The mean calculation time of a VCS plan, SWO plan and SWO+SSO plan was 125 sec, 9 sec and 507 sec, respectively.

Conclusion: VCS seems to work well for half of the cases, further optimization results in acceptable plans. The time to create VCS plans and SWO plans is compatible with an online setting. SWO+SSO results in stable plans. However, this takes long time in comparison with creating a new plan. To determine for what extent of shifts, acceptable plans can be created, more plans will be made. Then a trade of can be made when to create a VCS/SWO(+SSO) plan or start a new plan.

NTCP differences between planned and delivered dose in treatment for head and neck cancer

J. Heukelom¹, C. Fuller², M. Kantor², K. Kauwelo², C. Rasch³, J.J. Sonke¹

¹The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

²MD Anderson Cancer Center, Radiation Oncology, Houston, USA

³Academic Medical Center, Department of Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: During the 7 weeks of radiation therapy, the anatomy of head and neck cancer patients changes, resulting in a difference between planned and delivered dose. Currently, the allocation of adaptive radiotherapy (ART) is often based on visual inspection on repeated imaging or dosimetric criteria and thus only implicitly on changes in treatment outcome. Normal Tissue Complication Probability (NTCP) is a metric that translates the treatment dose distribution to treatment outcome. The goal of this study was to assess the impact of anatomical changes over the course of radiation therapy and the consequential difference in NTCP.

Material and Methods: For 36 squamous cell head and neck cancer patients treated in a single tertiary cancer center, daily in room CT scans were made in treatment position using CT on rails. In post-treatment analysis, the original beam set up was used to calculate dose of the day. Additionally, the daily CT was deformably registered to the planning CT (pCT). These daily doses were propagated to the pCT and

accumulated to estimate the delivered dose after which the dose-volume histograms were calculated on the pCT using the original contours. Treatment plan adaptations applied in clinical practice were ignored in this analysis, assuming that ART does not affect anatomic changes. NTCP calculations were done based on the LKB model for both planned and delivered dose, using input parameters based on work by Burman et al. and Emami et al. (1,2) OAR were contoured if deemed at risk and subsequently peer-reviewed by a team of experienced head and neck radiation oncologists. The overall NTCP per patient was calculated by multiplication of the chance of no toxicity i.e.

$$1 - \prod_{n=1}^N (1 - NTCP_n)$$

, for both the planned and delivered dose.

Results: On average, 6 OAR per patient were contoured. In 8 patients (22%), the difference in overall NTCP between planned and delivered dose was >3%. In half of them, NTCP of delivered dose was lower than planned. The largest difference in overall NTCP was 14% (Figure 1). The patients with the largest differences in overall NTCP could not be identified based on largest absolute dose differences for the OAR. Of the 8 patients that received ART clinically, 3 had an overall NTCP difference >3%.

Figure 1. Difference in overall NTCP between delivered and planned dose. A value > 0 means delivered dose NTCP was higher than planned dose NTCP.

Conclusion: Differences >3% in overall NTCP between planned and delivered dose occur in about 1/4th of the head and neck cancer patients. Both increases and decreases in NTCP were observed, stressing the need for ART to either reduce NTCP or allow dose escalation. Expert opinion does not identify the same patients for ART as NTCP calculations do. A model to select patients for ART, however, should not only be based on changes in NTCP but should also include possible changes in TCP. Thus, further research is warranted to timely identify patients in which these differences occur, and on how to optimize the allocation of ART.

Effect of weight loss in head and neck patients in the presence of a magnetic field

A. McWilliam^{1,2}, M. Culley², M. Van Herk¹

¹Institute of Cancer Sciences, University of Manchester, Manchester, United Kingdom

²The Christie NHS Foundation Trust, Christie Medical Physics and Engineering, Manchester, United Kingdom

Purpose or Objective: Head and neck patients experience weight loss in a predictable pattern during treatment. CTV volumes typically reduce in volume by a third, as do the parotid glands. Adaptive methods for these patients focus on an offline protocol where the patient is rescanned and planned at two-to-three weeks through treatment, resulting in significant reduction in parotid doses. The MR linac (Elekta, AB, Stockholm, Sweden) will provide excellent soft tissue contrast which may be desirable for this group of

patients, e.g., for tumour response monitoring. The presence of the magnetic field results in the Lorentz force causing electrons exiting the patient to spiral and be incident on the exit surface. This may potentially result in an increased dose to superficial tissues, i.e. the parotid glands. This effect can be controlled in plan optimisation. It is unknown, however, whether the presence of the magnetic field makes it necessary to adapt the plan at an earlier stage or more frequently during treatment. It is therefore the purpose of this paper to evaluate the effect of the magnetic field on need for adaptive radiotherapy in the head and neck.

Material and Methods: Five patients were selected from the clinical archive that had shown significant weight loss during treatment and required a repeat CT. Both the initial planning CT and the repeat CT were fully contoured including spinal cord, brainstem, left and right parotids. An initial plan was created for the planning CT using Monaco, Elekta AB Stockholm, Sweden, which met the departmental constraints for OAR dose. This plan was optimised with the B field set to 1.5T and then re-calculated at 0T, allowing the segmentation to remain constant. Plans were calculated with a 1% statistical uncertainty with the GPUMCD algorithm. The plans were transferred onto the re-scan CT and re-calculated. The magnitude of the change in dose to the OARs due to weight loss was compared between the 0T and 1.5T plans.

Results: Table one shows the results of the analysis for the five initial patients investigated. Spinal cord, brainstem and parotid glands are included in the table. Entries in red show that the magnitude of change in the OAR dose is greater, resulting in a larger dose to that OAR compared to the complementary plan. The spinal cord and brainstem do not show a trend, with the 0T and 1.5T plans showing increase dose in an equal number of plans. However, for the parotid glands the magnitude of the change in dose is greater with the 1.5T field present with the majority of plans showing an increase.

	PT1		PT2		PT3		PT4		PT5	
	0T	1.5T	0T	1.5T	0T	1.5T	0T	1.5T	0T	1.5T
BS PRV Max	-113	33	340	66	47	250	-494	-616	1126	1557
Dose to 1cc	-233	-23	524	244	241	295	-663	-806	1039	1355
SC PRV Max	33	140	1105	814	103	204	2084	1882	92	-374
Dose to 1cc	-97	72	1060	742	174	141	1766	1409	-77	-498
LT PAROTID Mean	85	309	143	301	462	564	-437	-644	-160	-184
RT PAROTID Mean	-	-	-636	-431	67	133	2143	2255	-73	49

Table 1. Increase in cGy for each OAR when the plan optimised for the original planning scan is delivered onto the scan displaying weight loss, entries in red show that the magnitude of change to dose is greater than the complementary plan.

Conclusion: The results from these patients indicate that weight loss in head and neck patients results in a greater increase in dose to the parotid glands when treated in a magnetic field. Adaptive protocols for these patients therefore require more frequent adaption than the current mid-treatment approach.

PO-0908

Inter-fraction OAR dose variation in pancreatic SBRT using contrast-enhanced in-room diagnostic CT

C. Papalazarou¹, M.S. Hoogeman¹, V. Gupta¹, B.J.M. Heijmen¹, J.J.M.E. Nuyttens¹

¹Erasmus Medical Center Rotterdam Daniel den Hoed Cancer Center, Radiotherapy, Rotterdam, The Netherlands

Purpose or Objective: In SBRT for Locally Advanced Pancreatic Carcinoma (LAPC), the nearby organs of the GI tract are dose limiting. Given the daily positional variation of those OARs, the planning approach is conservative, often leading to concessions in the PTV coverage. The purpose of this study is to evaluate the daily variation in abdominal organ dose.

Material and Methods: For this study, 5 patients were treated for LAPC with SBRT on a Cyberknife to a prescribed dose of 40 Gy in 5 fractions. During treatment, respiratory tracking was applied using implanted fiducials for real-time alignment of the treatment beams to the target. Planning constraints for the OARs included a maximum of 5 cc to

receive a dose above 35 Gy for the stomach, bowel and duodenum, and 15 Gy for the kidneys. For each patient, CT scans with intravenous contrast were obtained prior to the first three fractions using a sliding-gantry in-room CT. Directly after imaging, the patient was automatically transported by the robotic manipulator of the treatment couch to the treatment location in no more than 45 seconds. Each of the daily CTs was matched to the planning CT using automatic deformable image registration that allowed the fast (<1 min) adaptation of OAR contours to match daily anatomy. The OAR contours were manually adjusted by a radiation oncologist. To evaluate the dose to the OARs, each daily CT was matched to the planning CT using a combination of spine and fiducial matching, as performed at treatment. The same transformation was applied to the planned dose distribution, and the dose was evaluated on the new OAR contours.

Results: For the stomach, duodenum and small bowel, we evaluated the maximum dose, as well as the volume exceeding 35 Gy. The Dmax is shown in Figure 1. In all 15 (3x5) imaged fractions, the Dmax to at least one of these OARs was higher than the planned Dmax. The volume above 35 Gy was between 0 and 0.3 cc at planning, and increased or remained constant during treatment. For two patients, a clinically significant increase was observed, i.e. to 4.7 cc for bowel and 4.4 cc for duodenum, respectively. However, the clinical constraint of 5 cc was not violated. Dose to the kidneys remained well within constraints. The PTV volume receiving 95% of prescribed dose was 99% for 3 of the 5 patients. For two patients with high OAR dose at planning (Pt3 & Pt4), the planned coverage was 83% and 66%, resp, demonstrating the current limitations imposed by OAR constraints.

Figure 1 - Dmax for stomach, duodenum, and small bowel for the 5 patients. Note that for patient 5, duodenum is absent due to surgical resection.

Conclusion: In this study, we have employed in-room CT, combined with fast deformable image registration, to evaluate OAR dose constraints on a daily basis. We have observed clinically significant differences in the maximum dose to critical OARs, due to anatomical variations. This observation, even in this small patient group, demonstrates the need for further research on developing adaptive strategies to improve CTV coverage while keeping OAR dose within the clinical constraints.

PO-0909

Merging proton radiographies with treatment planning CT for adaptive radiation therapy

C. Gianoli¹, G. Dedes², S. Meyer², L. Magallanes², G. Landry², R. Nijhuis³, U. Ganswindt³, C. Thieke³, C. Belka³, K. Parodi²

¹Ludwig Maximilian University of Munich, Department of Experimental Physics - Medical Physics- Department of Radiation Oncology, Garching bei Munchen, Germany

²Ludwig Maximilian University of Munich, Department of Experimental Physics - Medical Physics, Garching bei Munchen, Germany

³Ludwig Maximilian University of Munich, Department of Radiation Oncology, Munich, Germany

Purpose or Objective: Ion CT imaging (iCT), as obtained from tomographic reconstruction of ion radiographies, can be considered an emerging modality for adaptive radiation therapy (ART) in ion beam therapy due to accurate characterization of the in-room/in-beam anatomy in terms of tissue ion stopping power. The purpose of this work is to

investigate ART feasibility, by limiting the number of low-dose scanned beam proton radiographies obtained in the treatment room, for different detection configurations of list mode and integration mode, in combination with high resolution anatomical information from the initial treatment planning X-ray CT.

Material and Methods: Proton radiographies obtained from Monte Carlo simulations (MCRs) are calculated based on patient CT images. For each pencil beam, 100 primary protons are delivered and the energy at the detector plane is converted to Water Equivalent Thickness (WET) relying on the *Bethe-Bloch* formula. List mode is reproduced by tracking each proton according to the Maximum Likelihood Path (MLP) and assigning each WET value along the estimated trajectory, while in integration mode only the most probable WET value of the raster point is assigned to a straight trajectory. To simulate inter-fractional anatomical changes, the patient CT, which is assumed to represent the in-room/in-beam scenario, is warped according to three-dimensional (3D) rigid and/or Gaussian deformation fields in head-neck and thoracic-abdominal sites, thus leading to a modified CT (mCT), which provides a theoretical representation of the treatment planning CT. Digitally Reconstructed Radiographs of mCT (mDRRs) are generated and two-dimensional (2D) deformable and/or rigid image registration is applied between corresponding mDRR and MCR in projection domain. By means of dedicated tomographic reconstruction algorithms, which rely on estimating the deformation in projection domain, high resolution anatomical information from mDRR is merged with accurate tissue stopping power from MCR, thus leading to combined iCT-CT. In this study, the DRRs of CT are used as the gold standard for 2D geometrical quantification. The methodological framework is reported in Fig. 1.

Fig. 1. Methodological framework depicted for one proton radiography.

Results: Performance for list mode was slightly better than integration mode but for both configurations difference were always <35 Hounsfield Unit (HU), translating into maximum 8% error in Relative Stopping Power (RSP), according to the approximate HU-RSP calibration curve. The comparison between list mode and integration mode as a function of different number of primaries will be presented, considering different inter-fractional anatomical changes. Quantification in image domain of combined iCT-CT will be performed as a function of different numbers of radiographies.

Conclusion: Both configurations enable accurate image registration for ART purpose. Conclusions about achievable dose reduction for acceptable quality of iCT-CT will be drawn.

PO-0910

Potential increase in dose delivered on a fraction by fraction basis by adapting to daily OAR DVCS

D. Foley¹, B. McClean², P. McBride²

¹UCD, School of Physics, Dublin, Ireland Republic of

²St. Luke's Radiation Oncology Network, Physics, Dublin, Ireland Republic of

Purpose or Objective: The feasibility of a technique using analysis of on-board CBCT images to adapt the dose to the target on a fraction by fraction basis was investigated. The new approach involves using the dose volume constraints (DVCs) as the objective to be met at each fraction. The dose to be delivered could be adapted such that dose to the target is maximised each day without any organ at risk (OAR) DVCs being broken.

Material and Methods: An in-house registration algorithm based on phase correlation was used to register CBCT images to the planning CT to determine the transformations and deformations in the patients' anatomy. This allowed the original plan to be recalculated on the registered CT image that provided the position of the target and organs at risk (OARs) for that fraction. With this new dose distribution, the DVHs and dose volume constraints (DVCs) values were determined for each fraction and accumulated by tracking throughout the treatment.

To determine how the dose could be changed, the DVCs were used as limits such that the dose that could be delivered would result in the tightest constraint being just met. Therefore, the dose was increased until that point or, if a DVC was already broken for a given fraction, the dose could be reduced by the minimum amount required to ensure that the DVC was within tolerance.

11 patients who underwent prostate treatment were retrospectively investigated for this feasibility study. IMAT plans consisting of 2 arcs were designed to deliver 74 Gy in 37 fractions of 2 Gy each to the target. The patients were imaged prior to treatment with an on board CBCT imager for between 9 and 14 fractions (121 in total). The relevant DVCs can be found in Table 1.

OAR	Bladder	Rectum
V _{50 Gy}	-	60 %
V _{60 Gy}	-	50 %
V _{65 Gy}	50 %	30 %
V _{70 Gy}	35 %	20 %
V _{75 Gy}	25 %	15 %
V _{80 Gy}	15 %	-

Results: Three of the patients investigated could have received higher doses during their treatment without breaking their OAR DVCs. In the remaining 8 patients, for only 3 fractions (out of 88) could an increase in dose been given while staying below the DVC limits.

The largest individual increase possible for all the imaged fractions was of 0.560 Gy. If all changes were made, the accumulated increase in dose possible for the three patients

were 3.98 Gy, 6.89 Gy, and 7.70 Gy, weighting all fractions equally and assuming the imaged fractions were representative of the patients' entire treatment.

Conclusion: Analysis of the anatomical condition of the patient on the day of treatment can give an indication of how suitable the original plan for their treatment is. Adapting the dose to be delivered to the patient on a fraction by fraction basis has the potential to allow for significant dose escalation while staying within institutional DVCs. This could be particularly useful in the hypofractionation of treatments. Although it is unlikely that in the clinic the dose level would be reduced below 2 Gy per fraction, it was also included in the calculations here to see how it could theoretically impact the treatment.

⁶Shandong Cancer Hospital, Department of Radiation Oncology, Jinan, China

⁷Southeast University, Laboratory of Image Science and Technology, Nanjing, China

Purpose or Objective: In the context of head and neck cancer (HNC) adaptive radiation therapy (ART), this study aimed to quantify the dosimetric benefit of various replanning frequencies and timings with regard to sparing the parotid glands (PG).

Material and Methods: Fifteen locally-advanced HNC patients had one planning then six weekly computed tomography (CT) scans during the seven weeks of IMRT. Weekly doses were recalculated without replanning or with replanning to spare the PGs as at the planning. A total of 63 ART scenarios were simulated by considering all the combinations of numbers and timings of replanning. The cumulated doses corresponding to "standard" IMRT (no replanning) and ART scenarios were estimated using deformable image registration. Finally, these doses were compared to each other and the planned dose by using a Wilcoxon Signed-Rank-Test.

Results: The median PG overdose using "standard" IMRT, compared to the planned dose, was 1.24 Gy, with a maximum of 9.45 Gy.

The table represents the best scenario for each number of replannings, the corresponding mean (min - max) cumulated dose, the difference between the planned and the cumulated delivered dose. Each ART scenario is better than the planned or delivered dose ($p < 0.05$).

Number of replanning	Best week(s) for replanning	Cumulated dose (Gy) Mean (Min-max)	P value
0	NC	32.00 (8.83 - 57.63)	NC
1	w ₁	29.39 (6.14 - 50.58)	$p < 0.05$
2	w ₁ , w ₂	28.59 (4.93 - 50.58)	$p < 0.05$
3	w ₁ , w ₂ , w ₃	27.73 (4.57 - 50.58)	$p < 0.05$
4	w ₁ , w ₂ , w ₅ , w ₆	27.34 (4.57 - 50.58)	$p < 0.05$
5	w ₁ , w ₂ , w ₄ , w ₅ , w ₆	27.11 (4.50 - 50.58)	$p < 0.05$
6	w ₁ , w ₂ , w ₃ , w ₄ , w ₅ , w ₆	27.06 (4.48 - 50.58)	$p < 0.05$

Table : Best scenario by number of replannings. The mean PG planning dose was 30.94 Gy (9.26 - 54.64)

Comparing with the standard IMRT scenario, the most effective ART scenario was the one with six replannings, leading to a decrease of 4.94 Gy (12.22Gy max.) 86 % of this benefit was obtained with 3 replannings only (at week 1-2-5). If only one replanning should be applied, it should be done at the first week.

Conclusion: Each supplementary replanning leads to a decrease of the mean PG dose.

Early replanning proved the most beneficial for sparing the PG. Considering the maximum benefit obtained with six replannings, almost 90% of this benefit was obtained with only three replannings (Weeks 1-2-5), thus representing an attractive combination for ART in locally-advanced HNC.

MRI-only based RT: adopting HU conversion technique for pseudo-CT construction in various body parts

J. Korhonen¹, L. Koivula¹, T. Seppälä¹, M. Kapanen¹, M. Tenhunen¹

¹Helsinki University Central Hospital, HUCH Cancer Center, Helsinki, Finland

Purpose or Objective: MRI is increasingly applied for radiotherapy target delineation. Recent studies have demonstrated a possibility to omit CT imaging from the radiotherapy treatment planning workflow by developing methods enabling the entire process by relying on MRI only. The HU conversion technique has been shown to construct heterogeneous CT-representative (pseudo-CT) images for prostate cancer patients by transforming the intensity values of an in-phase MR image into HUs with separate conversion models for soft and bony tissues. The technique has been implemented into a routine MRI-only based radiotherapy treatment planning workflow in our clinic. This study aims to investigate whether the pseudo-CT construction technique could be adopted for different patient groups, also in different body sites in addition to the male pelvis.

Material and Methods: The examinations were conducted by investigating the correspondence between the MR image intensity values and CT image HUs for different tissues. The data were applied to develop HU conversion models to transform the MR image intensities into appropriate HUs. In the absence of air cavities, the method was applied as a dual model HU conversion technique with separate conversion models within and outside of a bone segment obtained by atlas and threshold -based segmentation methods. An additional air segment was constructed in the presence of air cavities. An ultra-short echo-time sequence was applied to recognize boundaries between air and bone cortex with an intensity threshold. The constructed HU conversion models were employed with a medical image processing software, and applied for head (10 patients), pelvis (10), abdomen (2), and limbs (2). The obtained pseudo-CT images were tested by comparisons against standard CT images. The tests included evaluation of HU uncertainty and photon dose calculation accuracy.

Results: The HU conversion technique enabled construction of heterogeneous pseudo-CT images for various body sites. The duration of MR image intensity value transformation into HUs was roughly 30 seconds for each image series. Figure 1 shows examples of the resulted pseudo-CT images with the original MR images. Table 1 presents the local HU differences between those in pseudo-CT images and those in standard CT images. The target volume mean dose differences between those in pseudo-CT images and those in standard CT images were within 1% in all cases.

Table 1. Local HU differences between those in pseudo-CT images and those in standard CT images as mean±SD

Site	Bony tissues	Soft tissues
Pelvis	-10±139	-1±13
Abdomen	-173±195	-2±35
Limbs	-3±37	-4±16
Head	31±109	6±20

Conclusion: The HU conversion technique can be adopted for various body sites to enable construction of heterogeneous pseudo-CT images for MRI-only based radiotherapy treatment planning. The conversion models should be adjusted for each site separately to improve pseudo-CT image quality; e.g. for abdomen. Further examinations are ongoing.

PO-0913

Clinically applicable T2-weighted 4D Magnetic Resonance Imaging with good abdominal contrast

D. Tekelenburg¹, O. Gurney-Champion¹, E. Lens¹, A. Van der Horst¹, A. Nederveen², A.K. Biegun³, A. Bel¹, Z. Van Kesteren¹

¹Academic Medical Center, Department of Radiation Oncology, Amsterdam, The Netherlands

²Academic Medical Center, Department of Radiology, Amsterdam, The Netherlands

³University of Groningen, KVI-Center for Advanced Radiation Technology, Groningen, The Netherlands

Purpose or Objective: The main drawback of CT is poor soft tissue contrast. This research aims to develop an accurate respiratory-correlated four-dimensional MRI (4D MRI) method analogous to 4D CT with a clinically relevant acquisition time and superior contrast for abdominal structures.

Material and Methods: We developed a 4D MRI method by alternating a fast (0.6 seconds per 2D slice) T2-weighted turbo spin echo image acquisition (resolution: 1.3 x 1.6 mm²; 5 mm thickness) with a 1D navigator acquisition. The navigator obtained the diaphragm position prior to each slice acquisition. The total acquisition was done continuously during free breathing for 6 minutes, covering multiple respiratory cycles and yielding 60 image frames per slice over a volume of 11 slices.

After acquisition, each image was coupled to a navigator signal and assigned to a respiratory bin with either phase or amplitude binning. A complete 4D MRI consisted of 110 assigned image states (10 bins, 11 slices).

For phase binning, bins are determined by dividing each end-exhale peak to peak position into evenly distributed bins. For amplitude binning, bins were determined according to the navigator based breathing amplitude range. The range was defined per volunteer and divided into bins. The minima and maxima were the mean values of end-inhale and end-exhale amplitudes, respectively.

The two strategies were used to reconstruct 4D MRI images for 5 volunteers (4 female, mean age 30 years) obtained on a 3T scanner. The position and superior-inferior (SI) motion of the diaphragm were quantified by registering the diaphragm to the begin-inhale image of a series (bin 1). Sorting images into respiratory bins often resulted in multiple images assigned to the same state. From this set, the image with the median diaphragm position was selected for 4D MRI reconstruction. Sometimes, when no images could be assigned to a state, an incomplete 4D MRI resulted.

The 4DMRIs were evaluated on data completeness (filled states of 4D MRI data set) and intra-bin variation of diaphragm position (mean standard deviation (SD) and maximum SD). The variation was calculated over all bins from 3 central slices covering the largest diaphragm motion.

Results: 4D MRI data sets were acquired using a T2-weighted sequence, facilitating abdominal tissue contrast. Figure 1 shows for one volunteer the SI position of the diaphragm for all bins for one central slice, the selected median showing a representation of the respiratory motion. Table 1 summarizes mean and maximum SD of the intra-bin variation as well as data completeness. Phase binning resulted in a more complete (6.9%) dataset, whereas amplitude binning had lower variation (difference of 1.6 (3.5) mm for mean (max) SD).

Figure 1: The intra bin variation and inter bin diaphragm (SI) motion is shown for amplitude and phase binning for a representative slice (volunteer 3). Bin 1, 6 and 10 represent data from begin-inhale, begin-exhale and end-exhale respectively.

Table 1: Data completeness (D.C.) and intra bin variation for all volunteers. Mean SD and maximum (Max) SD were calculated over all bins for 3 central slices.

Volunteer	Amplitude Binning			Phase Binning		
	DC (%)	Mean SD (mm)	Max SD (mm)	DC (%)	Mean SD (mm)	Max SD (mm)
1	96.4	0.6	1.6	100	0.9	2.1
2	90.9	0.9	1.9	100	4.6	13.7
3	90.9	0.4	5.0	100	1.3	2.2
4	90.0	0.8	1.7	98.2	2.0	5.0
5	95.5	0.8	1.3	100	2.5	6.2
Mean	92.7	0.7	2.3	99.6	2.3	5.8

Conclusion: We demonstrated the feasibility of 4D MRI as an alternative for 4D CT by creating fast T2-weighted 4D volumetric images. The more accurate amplitude binning can lead to 4D MRI that can be implemented in the clinical workflow.

PO-0914

Adjustment of CT calibration in presence of titanium implants by pencil beam proton radiography

R. Righetto¹, A. Meijers², F. Vander Stappen², P. Farace¹
¹Centro di Protonterapia, Proton therapy, Trento, Italy

²Ion Beam Applications IBA, IBA, Louvain-la-Neuve, Belgium

Purpose or Objective: To implement an adjustment method for conversion of CT numbers to stopping power ratio (SPR) for proton therapy planning in presence of titanium implants, using pencil beam proton radiography (PR) that is acquired by utilizing a multilayer ionization chamber (MLIC).

Material and Methods: A head phantom containing a titanium implant in the cervical region was used. Lateral PR was obtained by delivering spots uniformly positioned at 5.0mm distance in a square of 11x11 spots and collecting the exit dose by MLIC. Spot by spot, the integral depth dose (IDD) measured by MLIC was compared with the reference IDD in air (i.e. without the phantom in the beam path) to assess the corresponding water equivalent thickness (WETMLIC). CT scan of the head phantom was acquired, based on which SPR map was determined (through mass density), to compute the corresponding WET along the beam path (WETCT), assuming a Gaussian spot with uniform size of about 3 mm along the path. CT numbers to mass density conversion was conventionally obtained by scanning a number of tissue equivalent materials (TEM) of known properties. To this multilayer curve, an additional extrapolated point and one titanium point were added. Mass density to SPR conversion was performed by published relationships (Fippel and Soukup, Med Phys 2004;31:2263-73) tuned on human tissue properties. Since the titanium caused CT image to be saturated, an artificial mass density was initially assigned to the maximum value supported by the CT scanner, so that the corresponding SPR is equal to the SPR of titanium. The mass density of this point in the calibration curve was varied and the corresponding WETCT computed. The optimal calibration was selected by comparing the corresponding WETCT with the measured WETMLIC.

Results: The values of the initial and the optimal calibrations are reported in Table. The corresponding differential WET maps (WETMLIC-WETCT) are shown in figure. By the initial calibration (fig.B) the WET of the implant was overestimated. The WET error was around 6-8 mm in the thicker portion of the implant along the lateral direction. On the contrary, the optimized CT calibration showed small difference on the differential WET map (fig.C). In fig.A a maximum intensity projection of the CT scan was computed to show the box where the PR was acquired.

CT numbers to mass density calibration curves

	CT numbers (HU)	Mass density (g/cc)
air	-1024	0.001
Lung (inhale)	-823	0.20
Lung (exhale)	-497	0.50
Adipose	-76	0.96
Breast	-24	0.99
Muscle	48	1.06
Liver	56	1.07
Trabecular bone	212	1.16
Dense bone	919	1.53
Extrapolated	1817	2.00
Titanium	3071	4.10* 2.70**

* initial value; **optimized value

Conclusion: It has been previously reported that the size of the titanium implants can be overestimated on CT scans (Huang et al, Phys Med Biol 2015;60:1047). This can produce range overshooting in phantoms (Farace et al, Phys Med Biol 2015;60:N357-67). In patients, it can cause considerable errors when the proton beam crosses through the implants before stopping close to an organ at risk. With the described method, the potential errors were compensated by an optimized calibration so that a more accurate range can be computed in treatment planning.

PO-0915

Evaluation of a metal artifact reduction algorithm for radiotherapy CT scans

L. Rechner¹, D. Kovacs¹, A. Bangsgaard¹, A. Berthelsen¹, M. Aznar¹

¹Rigshospitalet, Department of Oncology, Copenhagen, Denmark

Purpose or Objective: The purpose of this study was to investigate the appropriateness of a new commercial iterative metal artifact reduction reconstruction (MAR) algorithm (iMAR, Siemens Healthcare) for use in radiotherapy (RT) CT scans in our clinic.

Material and Methods: A combination of phantom and patient scans were used for analysis. Phantom scans were performed with and without metal and MAR reconstruction. Phantoms used included an electron density phantom and home-made phantoms with removable metal and low contrast objects. The HU values and geometric accuracy of low contrast objects were evaluated. The artifact index (AI) was calculated as the ratio of artifact pixels to total pixels, where artifact pixels were defined as greater than noise after subtracting a no artifact scan from an artifact scan. Differences in dose calculation were also determined in one phantom scan (hip) and for 10 patient scans with metal implants (2 bilateral hips, 1 unilateral hip, 2 shoulder, 1 dental, 4 spine).

Results: HU values were found to be improved with MAR relative to no MAR, and the accuracy of low contrast object next to the metal implant that was previously obscured by artifact was within 1 mm with MAR. In a phantom scan with a hip prosthesis, the use of MAR reduced the AI from 0.62 to 0.35 and the median error of artifact pixels from 155 to 41 HU. The difference in dose between calculation on the MAR phantom scan and the scan with no metal was 0.3%. For the patient scans, the mean difference in dose calculated on the MAR scan and the original scan with HU override of artifacts was 0.06% (range -0.47 to 0.92%) (figure 1). However, when the MAR algorithm was incorrectly applied (e.g. "dental" MAR setting applied to a spine implant) it was observed that new artifacts can be introduced, including new streaking or loss of image contrast near metal. These induced artifacts could potentially cause inaccuracies in the dose calculation or contouring.

Conclusion: The MAR algorithm tested was found to be suitable for use in RT CT scans and has been implemented in our clinic. It increases our confidence in contouring near metal artifacts and reduces the time required during contouring for manual correction of HU values. However, due

to the possibility of induced artifacts or loss of information that we observed, a visual comparison of each MAR scan with the original scan is performed, and the HU values in the artifact-reduced area are spot checked for reasonability relative to known tissue HU values. Future studies will investigate the impact of this type of MAR on contouring variability and accuracy.

Figure 1: Example of a plan for a patient with bladder cancer and double hip prostheses without (top) and with (bottom) MAR, where the PTV identical in both images (colorwash 15-68 Gy). In the top image, the dose was calculated after manual override of artifact to 0 HU. The mean dose to the PTV was 63.8 Gy and 64.0 Gy, respectively.

PO-0916

MR-based treatment planning for intracranial glioma patients

M.A. Palacios¹, M. Bennis¹

¹VU University Medical Center, Radiation Oncology Department, Amsterdam, The Netherlands

Purpose or Objective: To assess the dosimetric accuracy of CT-substitute attenuation correction (AC) maps generated from existent clinical MR data for radiation treatment planning in glioma patients.

Material and Methods: CT substitute AC maps were obtained with Statistical Parametric Software (SPM) software applied on 3D T1-weighted Inversion Recovery scans (IT 650 ms; TR/TE 4.6/2.0 ms). Three probability maps (PM) were obtained: air, tissue and bone. To derive corresponding AC maps, air-PM was multiplied by -1000, tissue-PM by 30 and bone-PM by 1000 and 300 when the probability for bone tissue was >0.8 and <0.8, respectively. A composite AC map (MR-based CT) was obtained by summing up all the PM multiplied by the aforementioned values. Difference in bone between clinical CT and MR-based CT was quantified with the Dice Similarity Coefficient (DSC).

MR-based CT were read into Eclipse Treatment Planning System (Varian Medical Systems, Palo Alto CA) and clinical Volumetric Modulated Arc Therapy (VMAT) plans were recalculated with a 0.1 cm dose calculation grid size for 10 patients. All plans were calculated with Accuros XB dose calculation algorithm for a prescription dose of 60 Gy and consisted of two arcs with a different collimator angle to minimize tongue and groove effect.

Differences between both plans were assessed according to the D2%, D98%, Dmean and γ -index (3%/3mm) for the relevant structures: CTV, PTV, brainstem and optical system.

Results: MR-based CTs were generated for 10 patients using SPM software and current clinical MR examinations without the need of adding extra sequences to the clinical protocol. Bone segmentation exhibited an average DSC of 0.81 ± 0.07 (SD) between clinical CT and MR-based CT segmentation, detecting SPM software less bone than in the clinical CT. Recalculated VMAT plans on the MR-based CTs exhibited a very good agreement with the clinical plans. Average Dmean, D2% and D98% for CTV and PTV differed less than 0.5%. Difference in D2% for brainstem and optical system between the clinical plans and recalculated plans using an MR-based CT were 0.4% and 1.1%, respectively. All metrics were found not significantly different ($p > 0.05$) from the clinically approved plans.

3D-dose distributions for the CTV and PTV in MR-based plans resulted in γ -passing rates higher than 0.99 ± 0.01 for both structures. Average γ -value for CTV and PTV was 0.16 ± 0.08 and 0.23 ± 0.16 , respectively.

Average DVH of PTV for CT (blue) and MR-based (red) planning for 10 glioma patients. Shaded blue and red areas highlight standard deviations in the DVHs for CT and MR-based plans, respectively.

Conclusion: MR-based CTs were generated using SPM software on 3D MR T1-weighted Inversion Recovery scans with more than 80% agreement for bone segmentation. MR-based VMAT plans exhibited a very good agreement with the clinical plans based on a standard CT as measured by the D2%, D98%, Dmean and γ -index metrics for all relevant structures.

It is feasible a clinical workflow for radiation treatment planning purposes for glioma patients based only on MR without the need of CT or adding additional MR sequences to the clinical protocol for bone segmentation.

PO-0917

The impact of irregular respiratory patterns on tumour volumes in 4DCT

E. Huizing¹, E.B. Van Dieren², R. Bruggink¹, D. Woutersen², C.H. Slump³

¹University of Twente, Biomedical Engineering and Technical Medical MIRA, Enschede, The Netherlands

²Medisch Spectrum Twente, Radiotherapy, Enschede, The Netherlands

³University of Twente, Robotics and Mechatronics, Enschede, The Netherlands

Purpose or Objective: Current clinical practise in radiotherapy CT scanning of lung tumours takes into account movement due to breathing. However, the accuracy of used scan protocols is usually validated for phantoms with fairly regular movements, and the effects of breathing irregularity are unclear. Aim of this study is to establish the impact of clinically occurring irregularities on delineated treatment volumes determined using 4DCT images.

Material and Methods: Respiratory patterns, as recorded during CT scanning, were (anonymously) obtained for 50 lung

ca. patients treated in our institution. First, pattern statistics were compared to population data in literature to establish validity of the data used for testing. Second, patterns representing highest irregularity were selected: variance in amplitude (1), periodicity (2), and a pattern with a baseline drift (3). A periodical computer generated sinusoid (4) was used for comparison.

Patterns were fed into a QUASAR™ Respiratory Motion Phantom (Modus Medical), with “lung tumour insert” (cork/polystyrene). Each pattern was scanned 5 times using a 16 slice lightspeed RT series scanner (General Electric). “Lung tumour” contours were extracted using auto segmentation of average (AVE) and MIP CT data. Contour volumes were compared using Dice coefficients (DC) and to expected volumes.

Results: The average breathing amplitude in our patient population was 8.70 ± 3.0 mm. The average period was 3.99 ± 1.0 seconds per breath. Both compared well with literature values.

Based on repeat CT data, DC was ≥ 0.90 for group (1) and (3) and (4). However, DC for group 2 (“irregular periodicity”), was only 0.83, which is significantly lower ($p=0.002$). Computed volumes were nearer to expected volumes using AVE CT, but using AVE CT always leads to underestimation. Volumes computed in MIP CT reconstructions cover the expected volumes better, but there is a chance of overestimation of up to 20% in volume.

Conclusion: Even though 4D CT scanning has been around quite some time, this is one of the first studies to address the effects of clinically found breathing irregularities. The selected test data seem to be adequate for lung ca. patients, and selected types of irregularities are commonly seen by therapists operating CT scanner and linac.

The study indicates that irregular respiratory patterns introduce the element of “chance” in the position and size of delineated tumour volumes, depending on amount and type of irregularity. Therefore, it is recommended to always take into account effect of breathing pattern irregularity in scanning and treatment planning for lung tumours.

Since 4D imaging typically consists of scanning while tracking a marker position, the recommendation probably holds for every CT scanner used in radiotherapy, and possibly also for PET and MRI scanners.

PO-0918

Validation of freeware-based mid-ventilation CT calculation for upper abdominal cancer patients

S. Vieira¹, J. Stroom¹, K. Anderle², B. Salas¹, N. Pimentel¹, C. Greco¹

¹Fundação Champalimaud, Radiotherapy, Lisboa, Portugal

²GSI Helmholtz, Center for Heavy Ion Research, Darmstadt, Germany

Purpose or Objective: Most institutes use the ITV approach to account for breathing motion into treatment planning, generally yielding too large treatment volumes. Recent publications showed that use of a mid-ventilation CT (midV-CT, representing the mean breathing phase) and treating remaining breathing motions as a random error, led to high tumor control and overall survival for hypo-fractionated treatments. However, the midV-CT is not available commercially yet. In this work we perform a marker-based validation of our open-source software to generate a midV-CT for upper abdomen cancer patients.

Material and Methods: Planning data from 12 upper abdominal cancer patients (8 liver- and 4 pancreatic patients) were used for this study. These patients were treated with the ITV approach using hypo-fractionated schemes (ranging from 5x7.5 Gy to 1x24 Gy). Each patient had a gold marker implanted close to the CTV center of mass (COM). 4DCT data consisted of 10 amplitude-based breathing phases (CT Brilliance™, Phillips). In our planning system (Eclipse™, Varian), the position of the marker was measured by hand for each breathing phase and patient. In the open-source medical imaging 3DSlicer, B-spline deformable

registration was used to register the plan CT and the different phases of the 4DCT. The resulting transformation matrices were then used by our 3DSlicer modules to automatically generate the midV-CT and the COM motions of any planning volume or marker. Subsequently, the marker position in the midV-CT was compared to the average marker position in Eclipse. Furthermore, the Eclipse marker motion curves and amplitudes were compared with the marker and CTV motions from 3DSlicer. Additionally, treatments plans were generated for one patient using the midV-CT and compared with our ITV-based clinical plan.

Results: The mean CTV volume was 24.7 ± 22.0 cc (1SD) and the mean marker to CTV COM distance was 12.7 ± 6.2 mm (1SD). The midV CTs are generated by 3DSlicer within 30 minutes using a PC. Motion validation results are shown in Table 1. Differences in the mean COM of the marker in Eclipse and in midV-CT are within 1 mm, indicating an accurate midV-CT generation by our software. Average amplitude differences are within 1 mm but Eclipse motions tend to be slightly larger, possibly due to the uncertainty of manually finding the marker in the 4D phases. Correspondingly, RMS differences between motion curves of Eclipse and 3DSlicer were therefore 0.2-0.6 mm, whereas the RMS differences between marker and CTV motion in 3DSlicer only 0.1-0.2 mm (Fig 1a). The latter suggests that well-placed markers can estimate CTV motions. Fig 1b shows differences in dose volume histograms between the ITV and the midV-CT approach.

	LR(mm)		AP(mm)		IS(mm)	
	mean	SD	mean	SD	mean	SD
Δ marker(midV-Eclipse)	-0.1	0.4	-0.2	0.6	-0.4	0.9
AMPLITUDE						
Marker Eclipse (ME)	1.4	1.1	2.4	1.1	5.6	2.8
Marker Slicer (MS)	1.2	0.9	1.9	1.1	5.2	2.7
CTV Slicer (CS)	1.2	1.1	1.8	1.0	5.0	2.7
Δ (ME-MS)	0.2	1.0	0.5	0.8	0.4	1.4
Δ (ME-CS)	0.2	1.3	0.6	0.7	0.6	1.3
MOTION CURVES RMS						
Δ (ME-MS)	0.4	0.3	0.4	0.2	0.6	0.4
Δ (ME-CS)	0.4	0.2	0.4	0.2	0.6	0.3
Δ (MS-CS)	0.1	0.1	0.1	0.1	0.2	0.2

Table 1. Mean and variation of breathing motion data of all patients for the marker and CTV position as measured in 3DSlicer (MS and CS, respectively), compared to marker motions as measured in Eclipse (ME).

Figure 1. (a) Breathing motion curves of marker and CTV for Eclipse (E) and 3DSlicer (S) for patient 6. (b) Dose volume histograms using midV CT and the ITV-based irradiated plans for patient 1. Although asymmetric ITV margins can compensate for a planning CT in an extreme phase, OARs might truly get a different dose than expected based on the planning DVHs (esophagus). The solid line refers to the irradiated plan with clinical contours; the dashed line to the calculated midV CT plan using clinical contours; the dotted line to the irradiated plan with midV CT contours; and the dashed dotted line to the midV CT-based plan with midV CT contours.

Conclusion: Accurate midV-CT can be generated using freeware. This opens the prospect for its use in our clinical practice, allowing treatments in the upper abdomen with more adequate CTV-to-PTV margins. For lung cancer patients the approach should work even better due to the higher contrast images.

Optimal respiratory gated FDG-PET for characterizing intra-tumour heterogeneity in lung cancer

J. Bussink¹, W. Grootjans², F. Tixier³, C. Van der Vos², D. Vriens⁴, C. Cheze Le Rest⁵, W. Oyen², L.F. De Geus-Oet⁴, D. Visvikis⁶, E. Visser²

¹Radboud University Medical Center, Radiation Oncology, Nijmegen, The Netherlands

²Radboud University Medical Center, Department of Radiology and Nuclear Medicine, Nijmegen, The Netherlands

³University Hospital Poitiers-, Department of Nuclear Medicine-, Poitiers, France

⁴Leiden University Medical Center, Department of Radiology and Nuclear Medicine, Leiden, The Netherlands

⁵University Hospital Poitiers-, Department of Nuclear Medicine, Poitiers, France

⁶University of Brest, INSERM-UMR1101- LaTIM, Brest, France

Purpose or Objective: Radiotracer uptake patterns in FDG-PET through computation of textural features vcan be used to improve characterization of lung cancer lesions for disease prognostication and response monitoring and tumor delineation purposes. Respiratory motion artefacts cause lesion blurring resulting in loss of intra-tumour heterogeneity. We have investigated the effect of respiratory gating on the recovery of intra-tumour heterogeneity.

Material and Methods: FDG-PET/CT imaging was performed in 70 lung cancer patients. Amplitude-based optimal respiratory gating (ORG) was performed on bed positions covering the thorax. The duty cycle (percentage of the total PET data) used for image reconstruction of ORG images was 35%. Non-gated images were reconstructed using 126 seconds of PET data, yielding similar noise characteristics as ORG. Lesion segmentation was performed using the fuzzy locally adaptive Bayesian (FLAB) algorithm. Four heterogeneity parameters (entropy, dissimilarity, zone percentage (ZP), and high energy emphasis (HIE)), which have previously shown to be robust and associated with survival in lung cancer, were calculated in non-gated and ORG images.

Results: Respiratory gating did not result in statistically significant differences in the heterogeneity parameters. Sub-group analysis revealed a significant effect of ORG on the heterogeneity parameters of lesions in the lower lobes. The mean increase for entropy, dissimilarity, ZP and HIE, considering lesions in the lower lobes was $1.3 \pm 1.5\%$ ($p=0.02$), $11.6 \pm 11.8\%$ ($p=0.006$), $2.3 \pm 2.2\%$ ($p=0.002$), and $16.8 \pm 17.2\%$ ($p=0.006$) respectively. For the centrally located lesions, the mean increase for entropy, dissimilarity, ZP and HIE was $0.58 \pm 3.7\%$ ($p=0.6$), $5.0 \pm 19.0\%$ ($p=0.4$), $0.59 \pm 4.0\%$ ($p=0.9$), and $4.4 \pm 27.8\%$ ($p=0.4$), respectively. Lesions in the upper lobes showed a mean increase of $-0.35 \pm 1.8\%$ ($p=0.3$), $-1.0 \pm 7.7\%$ ($p=0.3$), $-0.4 \pm 2.7\%$ ($p=0.5$), $-1.7 \pm 13.2\%$ ($p=0.4$), for entropy, dissimilarity, ZP and HIE, respectively. There was no significant correlation between lesion volume and the change in parameters between non-gated and ORG images.

Conclusion: Results from this study indicate that ORG significantly impacts characterisation of intra-tumour heterogeneity, particularly for lesions in the lower lung lobes. This suggests that adequate management of respiratory motion artefacts is important for improving characterisation of intra-tumour heterogeneity in PET.

Early prediction of individual response in neo-adjuvant adaptive Radiochemotherapy for rectal cancer

R. Raso¹, P. Passoni², A. Palmisano³, C. Fiorino¹, G.M. Cattaneo¹, F. De Cobelli³, A. Esposito³, P. Mangili¹, N. Slim², N.G. Di Muzio², R. Calandrino¹

¹San Raffaele Scientific Institute, Medical Physics, Milano, Italy

²San Raffaele Scientific Institute, Radiotherapy, Milano, Italy

³San Raffaele Scientific Institute, Radiology, Milano, Italy

Purpose or Objective: Developing a radiobiologically consistent model predicting individual outcome for rectal cancer patients (RCPs) treated with an adaptive boost approach during neo-adjuvant radiochemotherapy (RCH).

Material and Methods: Forty-two RCPs were treated within a prospective observational study. CH consisted of oxaliplatin (on days: -14, 0, 14) and 5-fluorouracil (from day -14 to end) being day 0 the start of RT. All patients were treated with Helical Tomotherapy (18x2.3Gy) with an adaptive concomitant boost technique delivering 3Gy/fr on the residual gross tumor volume (GTV) in the last 6 fractions (fr), based on MRI imaging taken at fr 9. GTVs were contoured by a single radiologist on axial T2 MRI images acquired for initial planning (V_PRE), at fr 9 for the adaptive planning (V_MID) and before surgery, after a median time of 8.9 weeks after the end of RCH (V_POST). Based on a Poisson-like tumor regression model and neglecting repopulation and inter-patient variability of the removal kinetics of killed cells, the parameter $(1-\Delta V(D))^{V_PRE}$ was taken as a surrogate of tumor control probability (TCP), where $\Delta V(D)=V_MID/V_PRE$ or V_POST/V_PRE , considering D at fr 9 (TCP_MID) or at the end of RCH (TCP_POST). The discriminative power of TCP_MID/POST in predicting the pathological complete remission (pCR, n=14) was assessed by the AUC of the corresponding ROC curves. Then, two-variables logistic (LOG) models including V_PRE and $\Delta V(D)$ as covariates were also considered and the ROC curves of the four models (TCP_MID, TCP_POST, LOG_MID, LOG_POST) were compared. In addition, an estimate of the residual cells at surgery (V_S) was robustly taken as the product of the pathologically assessed fraction of viable cells and V_POST. Spearman correlation rank test was used to evaluate the correlation between the models and V_S.

Results: All models showed a high discriminative power in predicting pCR (p -value<0.0001). AUCs for TCP_MID was 0.87 (specificity: 71.4%, sensitivity: 96.4%, best cut-off: 5.85), higher than TCP_POST (0.82), although the difference did not reach significance ($p=0.18$). TCP_MID/TCP_POST were also highly correlated with V_S ($R=0.77$ and $0.74, p<0.0001$). Similar performances were found for LOG_MID/LOG_POST with AUC=0.90/0.87 and $R=0.79/0.77$. No significant differences were found when comparing TCP models against the corresponding LOG models.

Conclusion: A radiobiologically consistent model including early regression (TCP_MID) measured on T2-MRI images well predicts pCR and is strongly correlated with the estimated residual cells number after adaptive RCH; similar performances were obtained with a logistic model including V_PRE and V_MID/V_PRE. The corresponding models using V_POST showed a slightly, statistically not significant, worse

discriminative power. The results showed that MRI volumes measured before and during RCH have a great potential to better individualize adaptive RCH.

⁷Liverpool and Macarthur Cancer Therapy Centre, Radiation Oncology, Liverpool, Australia

⁸University of Sydney, Institute of Medical Physics, Sydney, Australia

Purpose or Objective: Dynamic contrast enhanced (DCE) MRI is becoming an increasingly important tool for assessing tumour response in Radiotherapy (RT). Important characteristics are spatial and temporal resolution and in lung this is further complicated by the effects of respiratory motion. A common approach is to acquire fast gradient-echo imaging utilising k-space sharing to provide optimum temporal resolution and to collect data during short 'windows' of breath-holds over the time course. However patient compliance during breath hold manoeuvres can lead to tumour displacement and introduce error in analysis. Radial acquisitions can alleviate motion by oversampling the centre of k-space albeit with reduced temporal resolution. The purpose of this study was to evaluate whether such a 'stack-of-stars' acquisition can be used with high enough resolution for the DCE sequence to provide a complete free breathing RT planning protocol in lung patients.

Material and Methods: Institutional review board approval was obtained. Two patients receiving lung radiotherapy underwent DCE-MRI on our dedicated wide bore 3 Tesla system (Skyra, Siemens) using an 18 channel flexible coil and 32 channel table coil. Patients were positioned as per treatment setup with their hands above their head. Two DCE protocols were examined; a fast gradient-echo sequence employing k-space sharing (TWIST) acquired as 5 breath-hold periods of 20s each with a spatial and temporal resolution of 1.5 mm/3 s; and a completely free breathing scan performed using a radial acquisition (StarVIBE) with a resolution of 1.8 mm and 14 s. The acquisition time was approximately 6 minutes for both sequences. In both cases a rapid pre-contrast measurement of T1 was acquired using the same sequence and two flip angles. Analysis included calculation of T1 map and a two-compartment model fit to the data (Tissue4D, Siemens) to provide pixel-by-pixel maps of the perfusion rate constant.

Results: Figure 1 shows images and analysis taken from both sequences. Viewing DCE data in a cine loop revealed large movement between frames for TWIST compared to StarVIBE. A comparison of signal-time plots shows a typical result where failure to maintain and reproduce breath hold has produce large variation and discontinuities in the dataset. As a result the goodness-of-fit (χ^2) was better for StarVIBE (0.05) than the corresponding value using TWIST (0.16). Although temporal resolution is much poorer with the StarVIBE sequence, it was sufficient to sample the early upslope phase of the contrast agent. General image quality was assessed with radial and motion artefacts scored as being negligible.

Figure1

(A) StarVIBE, (B) TWIST (i) T1 map; (ii), DCE image; (iii), Ktrans; (iv), Time-enhancement curve

Conclusion: These initial results show that use of a radial k-space trajectory as a method of motion compensation provides a DCE scan of sufficient image quality and temporal resolution which can be used as part of a complete free breathing lung protocol.

PO-0922

Are planning CT radiomics and cone-beam CT radiomics interchangeable?

J.E. Van Timmeren¹, R.T.H. Leijenaar¹, W. Van Elmpt¹, P. Lambin¹

¹Maastricht University Medical Centre, GROW-School for Oncology and Developmental Biology - Department of Radiation Oncology - MAASTRO clinic, Maastricht, The Netherlands

Purpose or Objective: Radiomic image features derived from conventional treatment planning CT images have already been shown to have prognostic information. For cone-beam CT (CBCT) imaging during radiotherapy this has not yet been described. Due to the fact that a CBCT image is acquired prior to each fraction it has the potential to monitor response to treatment. The goal of this study was to investigate the stability and the correlation between radiomic features derived from planning CT vs. CBCT and between CBCTs of different fractions.

Material and Methods: A total of 27 stage II-III NSCLC patients who received radiation therapy were included in this study. For each patient a treatment planning CT scan was acquired and CBCT scans were obtained prior to each fraction. The planning CT (CT1), the CBCT of the first (CBCT-FX1) and second fraction (CBCT-FX2) were used in this study. CBCT images were registered to CT1 using automatic rigid registration prior to feature extraction. In total, 149 radiomic image features were extracted of different feature groups: I) tumor intensity, II) texture, III) Laplacian of Gaussian. The third group consists of filtered first order features and the group was subdivided into 10 groups, according to different LoG filter standard deviations ranging from 0.5 mm to 5 mm with a 0.5 mm interval. Since a rigid registration was used, features related to shape and volume were not analyzed. The correlation between features derived from (1) CT1 and CBCT-FX1 and (2) CBCT-FX1 and CBCT-FX2 were analyzed. Correlations were calculated using an intraclass correlation coefficient ICC(2,1). An ICC-value above 0.9 was considered a good agreement.

Results: For 26% of the 149 analyzed radiomics features, the ICC-value was higher than 0.9 for CT1 compared to CBCT-FX1 (Figure). The ICC-value was above 0.9 for 81% of the features when comparing CBCT-FX1 to CBCT-FX2. Specifically for the feature group 'texture', one of the 44 features had an agreement between CT1 and CBCT-FX1 that was higher than 0.9, but 35 out of 44 did show agreement for CBCT-FX1 vs. CBCT-FX2. For 'tumor intensity', 2 out of 15 features showed a large correlation between CT1 and CBCT-FX1 higher than 0.9, whereas 10 out of 15 features showed agreement higher than 0.9 between CBCT-FX1 and CBCT-FX2 (ICC>0.8 for all). All features with ICC above 0.9 for CT1 vs. CBCT-FX1 also showed high correlation between CBCT-FX1 and CBCT-FX2.

Figure: Percentage of features with ICC > 0.9 for CT1 vs. CBCT-1 and CBCT-1 vs. CBCT-2, displayed for each feature group.

Conclusion: For 26% of the radiomics features there is good agreement between CT1 and CBCT. 81% of the image features show high correlation between CBCT-FX1 and CBCT-FX2 where no large differences are expected. In the future, radiomic features derived from CBCT images will be investigated to monitor changes of CBCT features over the course of treatment. One has to be careful with mixing radiomic features derived on planning CT and CBCT scans.

PO-0923

Comparing FMISO and FDG positive tumour sub-volumes for PET-based dose escalation in SCCHN

D. Mönnich¹, S. Leibfarth¹, S. Welz², C. Pfannenbergl³, D. Zips², D. Thorwarth¹

¹Section for Biomedical Physics - Department of Radiation Oncology, University Hospital Tübingen, Tübingen, Germany

²Department of Radiation Oncology, University Hospital Tübingen, Tübingen, Germany

³Department of Diagnostic and Interventional Radiology, University Hospital Tübingen, Tübingen, Germany

Purpose or Objective: Tumour sub-volumes for dose escalation can be defined using different PET tracers. This study compares hypoxic volumes defined by FMISO PET and metabolically active volumes defined by FDG PET for patients with advanced squamous cell carcinomas of the head and neck (SCCHN).

Material and Methods: Imaging data of 14 patients was used, which were included in a phase II FMISO dose escalation study. Pre-therapy FMISO PET/CT images were acquired four hours post tracer injection. FDG PET/CT imaging was performed according to the institutional diagnostic protocol. The planning CT and the GTV of the primary tumour were available. Datasets were deformably co-registered using the CT images. Metabolically active sub-volumes were segmented in FDG PET images based on a source-to-background method with an adaptive threshold. Hypoxic sub-volumes were defined using a tumour-to-muscle threshold of 1.4. Expanding the volumes by an isotropic margin of five millimeters resulted in PTV-prim and potential dose escalation volumes PTV-FMISO and PTV-FDG. We analyzed the overlap between PTV-FMISO and PTV-FDG.

Results: Mean dose escalation volumes were 19.7 cm³ (0.0-57.3 cm³) for PTV-FMISO and 39.3 cm³ (17.5-91.9 cm³) for PTV-FDG. On average PTV-FDG covered 73.5% of PTV-FMISO (4.9-100.0%). Only for two out of fourteen patients (14%) PTV-FMISO was completely covered by PTV-FDG. Vice versa 36.3% of PTV-FDG overlapped with PTV-FMISO (0.0-97.4%). PTV-prim from treatment planning was 111.1 cm³ (57.1-201.2 cm³). Detailed results of the overlap analysis for all patients are given in Table 1.

Patient	Volumes			Overlap PTV _{FDG} and PTV _{FMISO}		
	PTV _{prim} / cm ³	PTV _{FDG} / cm ³	PTV _{FMISO} / cm ³	cm ³	% of PTV _{FDG}	% of PTV _{FMISO}
006	65.8	35.6	10.3	9.5	26.8	92.7
007	118.7	42.4	27.1	7.6	17.8	28.0
008	81.6	43.6	54.0	39.4	90.4	73.0
009	142.8	47.6	0.0	0.0	0.0	
010	106.6	34.5	12.1	9.0	26.0	74.0
011	57.3	36.5	0.0	0.0	0.0	
013	74.9	26.6	22.5	21.4	80.3	95.0
014	69.2	21.2	5.9	5.9	27.8	100.0
015	196.3	91.9	33.5	25.5	27.8	76.2
016	201.2	17.9	16.0	0.8	4.4	4.9
017	166.4	43.4	4.8	4.8	11.0	100.0
018	57.1	17.5	13.8	11.4	65.0	82.5
019	117.0	39.1	57.3	38.0	97.4	66.4
020	100.4	51.7	19.3	17.2	33.2	89.0
Mean	111.1	39.3	19.7	13.6	36.3	73.5
Min	57.1	17.5	0.0	0.0	0.0	4.9
Max	201.2	91.9	57.3	39.4	97.4	100.0

Conclusion: PTV-FDG typically covers PTV-FMISO only partially and is on average two times larger. Therefore, a dose escalation in the metabolically active sub-volume partially misses the hypoxic sub-volume. The large volume difference suggests that a substantially higher dose escalation is feasible in PTV-FMISO than in PTV-FDG. Clinical trials are required to compare the efficacy of both methods.

PO-0924

Histogram analysis of ADCs from DWMRI predicts tumour response and survival for rectal cancer

K. Bakke¹, T. Seierstad², K.H. Hole², S. Dueland³, K. Flatmark⁴, A. Hansen Ree¹, K. Røe Redalen¹

¹Akershus University Hospital, Department of Oncology, Lorenskog, Norway

²Oslo University Hospital, Department of Radiology and Nuclear Medicine, Oslo, Norway

³Oslo University Hospital, Department of Oncology, Oslo, Norway

⁴Oslo University Hospital, Department of Gastroenterological Surgery, Oslo, Norway

Purpose or Objective: Patients with locally advanced rectal cancer (LARC) are commonly treated with neoadjuvant chemoradiotherapy (CRT) followed by radical surgery. However, tumor responses vary considerably and about one third of the patients experience poor disease outcome due to metastatic progression. We aimed to investigate if apparent diffusion coefficients (ADCs) quantified from diffusion-weighted MRI (DWMRI) predicted histologic tumor response to the neoadjuvant treatment and long-term survival. Recognizing the tumor heterogeneity we specifically aimed to explore if histogram analysis of tumor ADC may reveal more useful information than the commonly used mean ADC measure.

Material and Methods: Data from 23 prospectively enrolled patients receiving induction neoadjuvant chemotherapy (NACT) followed by CRT and radical surgery was analyzed. DWMRI was acquired at baseline and after NACT. Tumor volumes contoured in T2-weighted MR images were transferred to tumor ADC maps calculated with b-values 300 and 900 s/mm², before ADCs were extracted from all tumor voxels and presented as histograms. The predictive information contained in the histograms was evaluated using receiver operating characteristic (ROC) curve analysis of each percentile from 1-100. Study endpoints were histologic tumor regression grade (TRG) and 5-year progression-free survival (PFS).

Results: Using the change in tumor ADC from baseline to NACT completion, we identified a histogram area below median (20th-40th percentiles) to be associated with both TRG and PFS. By using the 20th percentile, an increase in

ADC predicted poor histologic tumor response (TRG3-5 versus TRG1-2) with 91% sensitivity and 83% specificity (area under curve (AUC)=0.89, 95% confidence interval (CI)=0.74-1.0, $p=0.001$). Using the 30th percentile, an increase in ADC predicted poor PFS with 89% sensitivity and 71% specificity (AUC=0.75, 95% CI=0.54-0.95, $p=0.051$). Univariate regression analysis also revealed that the ADC increase was significantly associated to poor PFS (hazard ratio=9.7, 95% CI=1.21-78.30, $p=0.033$).

Conclusion: By ADC histogram analysis of DWMRI acquired during NACT of LARC we identified low histogram percentiles as predictive of histologic tumor response in particular, but also long-term survival. The results require validation in larger, independent cohorts, but are promising for identification of patients that may benefit from individualized treatment approaches for improved disease outcome.

PO-0925

Simulation of FMISO diffusion-retention in a three-dimensional tumor model

L.J. Wack¹, A. Menegakis², R. Winter¹, S. Böke², D. Mönnich¹, D. Zips², D. Thorwarth¹

¹University Hospital Tübingen, Department of Radiation Oncology- Section for Biomedical Physics, Tübingen, Germany

²University Hospital Tübingen, Department of Radiation Oncology, Tübingen, Germany

Purpose or Objective: Tumor hypoxia is prognostic for poor outcome after radiotherapy (RT). A method for non-invasive assessment of hypoxia is PET using hypoxia radiotracers such as FMISO. The goal of this study was to develop and evaluate a tool to simulate 3D oxygen distribution and the resulting FMISO accumulation on realistic vessel architectures, which can be compared to measured PET activities in small animal experiments.

Material and Methods: Two FaDu tumors (human HNSCC) were grown on the right hind leg of nude mice. Imaging was performed after a growth phase of about 5 weeks. FMISO was injected into the tail vein of the anesthetized mice with an activity of ~12MBq for dynamic PET/MRI. ROIs inside the left ventricle and in the tumor were chosen to determine blood and tumor time activity curves (TACs). After image acquisition tumors were excised, snap frozen and cut into consecutive sections (20µm). Sections were stained with immunofluorescence-labeled antibodies for endothelial marker CD31 and scanned with a Zeiss Axioplan 2 fluorescence microscope. Obtained immunofluorescence images were rigidly registered, manually adjusted and thresholded to create a binary 3D vessel map. These maps were used to simulate 3D oxygen distributions based on a Michaelis-Menten relation. Using the oxygen distribution and the dynamic activity in the left ventricle as input, FMISO retention was simulated on the same vessel maps. A tumor ROI was selected and its average activity at different time points post-injection (p.i.) compared against the measured activity in the same region on the PET scan (tumor TAC). To compare 3D and 2D simulations, the simulation were repeated in 2D on the individual sections, and 2D-based oxygen histograms and TACs were determined.

Results: O₂ histograms showed a large difference between 2D and 3D simulations, with much lower values for 2D simulations than for 3D (5.94 mmHg vs 26.57 mmHg). Mean values were closer together (8.9 mmHg vs 13.2 mmHg). This is due to the large amount of anoxic voxels ($pO_2 < 1$ mmHg) in the 2D simulation, which made up 17.5% of all simulated voxels in 2d, but less than 1% in the 3D simulations (see Table 1). Visually, the 3D simulations result in a TAC with a similar overall shape compared to the TAC measured with small animal PET, but with a 20.7% overestimation of activity. However, the 2D simulations severely overestimated the total activity by 99.2% (2D) when compared against measured activity in the tumor after 90min as determined by PET.

	2D simulation	3D simulation	Small animal PET image
Tumor 1			
Median oxygen content (mmHg)	2.11	26.03	n.a.
Mean oxygen content (mmHg)	12.28	15.65	n.a.
Anoxic fraction (<1mmHg)	14.1%	0.0%	n.a.
FMISO activity at 90 min p.i. (kBq/ml)	535.2	460.2	425.3
Tumor 2			
Median oxygen content (mmHg)	9.78	27.79	n.a.
Mean oxygen content (mmHg)	14.14	26.57	n.a.
Anoxic fraction (<1mmHg)	20.9%	1.0%	n.a.
FMISO activity at 90min p.i. (kBq/ml)	1339.0	653.7	491.2

Conclusion: 3D simulations based on real 3D vessel architecture is feasible. Our FMISO simulations showed large discrepancies between 2D and 3D simulation approaches, with the 3D values being closer to the PET measurements. Verification of 3D tracer accumulation patterns in additional tumors against pimonidazole stainings is still necessary to validate and calibrate the method, with PET scans in the same test subject to confirm observed activity.

PO-0926

Voxel-based PSMA-PET/histopathology analysis in patients with primary prostate cancer

C. Zamboglou¹, F. Schiller², T. Fechter¹, V. Drendel³, C.A. Jilg⁴, P.T. Meyer², M. Mix², A.L. Grosu¹

¹Universitätsklinik Freiburg, Klinik für Strahlenheilkunde, Freiburg, Germany

²Universitätsklinik Freiburg, Klinik für Nuklearmedizin, Freiburg, Germany

³Universitätsklinik Freiburg, Institut für Pathologie, Freiburg, Germany

⁴Universitätsklinik Freiburg, Klinik für Urologie, Freiburg, Germany

Purpose or Objective: Tumor control of primary prostate cancer (PC) is dose dependent. Dominant index lesions (DIL) within the prostatic gland are responsible for local and distant failure. Radionuclide-labelled inhibitors of prostate-specific membrane antigen (PSMA-PET) showed promising preclinical and clinical results in detection of primary prostate cancer. We correlated PET/histopathology using a new coregistration approach, which allows pixel-wise evaluation of the tracers performance in prostatic tissue. Aim of this work is to evaluate the diagnostic accuracy of 68Ga-PSMA-PET/CT and to determine potential SUV-thresholds enabling a focal dose escalation on DIL delineated by PET.

Material and Methods: 10 patients with primary PC and 68Ga-PSMA-PET/CT were enrolled. After prostatectomy, thorough histopathological preparation and anatomical-based coregistration between in-vivo and ex-vivo material was performed. Simulated PET-images were generated out of blurred 3D histopathological tumor distribution (histoPET). The coregistration was further optimized by matching histoPET information with the in-vivo PET signal. The tracer performance was evaluated by coefficient of determination (R^2) between histoPET/PSMA-PET patterns and SUV-values within different tissue types.

Results: 1 patient was excluded due to imprecise pathological preparation. Mean R^2 value was 60 % (\pm SD 15.2, range: 42.5-81.6). SUVmax of PSMA-PET was located in non resolution adapted / resolution adapted PC-tissue in 80%/90% of patients. Mean SUVmean in non resolution adapted PC and non-PC tissue was 6.1 (range: 2 - 21) and 2.7 (range: 1.3 - 8.2), respectively. The ratio between SUVmean in PC / non-PC was 2.2 (SD \pm 0.6).

Conclusion: Using a sophisticated approach for PET/histopathology coregistration PSMA-PET/CT yielded high R^2 -values which can be translated in excellent overlap with PCa. Furthermore, we were able to provide SUV-guidance values for PSMA-PET/CT which opens the opportunity for SUV-based GTV-delineation techniques using PSMA-PET as a base for focal dose escalation on DIL.

PO-0927

Bone texture analysis as predictive of bone radiation damage in patients undergoing pelvic RT.

V. Nardone¹, M. Biondi², P. Tini¹, L. Sebaste¹, E. Vanzi², G. Battaglia¹, P. Pastina¹, L.N. Mazzoni², F. Banci Buonamici², L. Pirtoli¹

¹Azienda Ospedaliera Universitaria Senese, U.O.C. Radioterapia, Siena, Italy

²Azienda Ospedaliera Universitaria Senese, U.O.C. Fisica Sanitaria, Siena, Italy

Purpose or Objective: To assess the potential role for a CT-based, bone texture analysis as a predictive factor of bone radiation damage in patients undergoing radiotherapy (RT) for pelvic malignancies.

Material and Methods: We performed a retrospective analysis of suitable patients treated with RT for pelvic malignancies from January 2010 to December 2014. The DICOM CT data acquired for RT planning were collected, and used for a homemade ImageJ macro analysis. Two region of interest (ROI) were selected: the L5 vertebral body and the femoral heads. Typical texture analysis (TA) parameters were retrospectively evaluated: mean (M), standard deviation (SD), skewness (SK), kurtosis (K), entropy (E) and uniformity (U). The patients who developed bone RT-related damages (i.e.: pelvic bone stress fracture, radiation osteitis, insufficiency fractures) during the follow-up constitute the study patients (SP) group. The TA data were collected for a comparative analysis also in a control group of patients (CP: 2:1 ratio, with respect to SP) not developing bone damages. The CPs were matched taking into account: age, sex, type of tumor, intent of postoperative treatment, comparable doses to the considered organs-at-risk. As for the statistical comparisons, we performed a univariate analysis (Pearson correlation) and a multivariate analysis (logistic regression) using the SPSS software 17.0.

Results: Twenty-four SPs and 48 CPs are the subject of this report. Out of SPs, postoperative RT was delivered for cancer: of the digestive tract (anal or rectal) in thirteen patients (54%); of the female reproductive organs (endometrial or cervical) in 9 (37%); and of the excretory apparatus (prostate or bladder) in 3 patients (9%). In the comparison between SP and CP groups, the univariate analysis showed a significant correlation of the ROI parameters of L5: SD (p: 0,012); K (p<0,001), E (p: 0.001); U (p: 0,008), and of the femoral head: M (p<0,001); SD (p<0,001), with the development of bone damage. The logistic regression highlighted a significant correlation with the ROI parameters of L5: E (p:0.004); U (p:0,014), and femoral head M (p:0,022); and -SD (p:0,042), with an Overall Model Nagelkerke R Square of 0,590.

Conclusion: These results (with the limit of a small series) and those reported in previous related studies deserve some interest, since the knowledge of predictive factors of bone radiation damage might help in patients' selection for pelvic RT, and in identifying suitable dose constraints for the bony pelvis in RT planning for patients at risk.

PO-0928

Impact of fuzzy-thresholding of 18F-FDG PET images for cervical cancer recurrence prediction

G. Roman Jimenez¹, A. Devillers², J. Leseur², J.D. Ospina³, H. Der Sarkissian⁴, O. Acosta¹, R. De Crevoisier²

¹Laboratoire Traitement du Signal et de l'Image - INSERM U642, Université de Rennes 1, Rennes, France

²Centre Eugène marquis, Department of Radiotherapy, Rennes, France

³Escuela de Estadística, Universidad Nacional de Colombia, Medellín, Colombia

⁴Keosys medical imaging, Department of medical imaging, Saint-Herblain, France

Purpose or Objective: In case of cervix cancer irradiation, parameters extracted from initial 18F-FDG-PET images can be used to predict recurrence. FDG PET parameters are classically computed among voxels binary selected in the segmentation step. We proposed the use of fuzzy-threshold, providing tumor membership probability map, and present a generalization of the computation of FDG PET parameters by weighting each PET voxel by its tumor membership probability. The goal of the study was to evaluate the relevance of fuzzy-threshold based weighted parameters in prediction of tumor recurrence, in comparison with a "standard" fixed or hard threshold based parameters.

Material and Methods: This study included 53 patients treated for locally advanced cervical cancer by external beam radiation therapy with concurrent chemotherapy, followed by brachytherapy and \pm surgery. All patient underwent 18F-FDG PET/CT exam before the treatment. Different tumor membership probability maps were extracted from 18F-FDG PET images using fuzzy-thresholding defined by a threshold Th and a level of fuzziness ΔTh (both expressed in % of the maximum uptake value) using a Zadeh's standard function. Fuzzy-thresholding were tested with $Th=41\%$, 50% and 70% and ΔTh from 0% to 40% ($\Delta Th=0\%$ corresponding to hard-thresholding). Using the fuzzy-thresholding, we computed weighted analogs of four standard 18F-FDG PET parameters; the maximum uptake averaged by its 26 neighbors (SUVpeak), the average SUV inside the tumor region (SUVmean), the metabolic tumor volume (MTV) and the total lesion glycolysis (TLG). The recurrence was defined based on clinical examination, MRI and PET imaging. Median follow-up was 49 months [range: 7-83]. A total of 16 patients developed disease recurrence. The predictive capability of the PET parameters to predict 3 year overall recurrence were evaluated using the area under the receiver operating characteristic curve (AUC) and the p-value of the logistic regression model.

Results: The figure shows the predictive values (AUC and p values) of the weighted parameters depending on the threshold Th and the fuzzy-level Δth used. SUVpeak and SUVmean were not predictive for any of the segmentations tested. TLG and MTV extracted through hard-thresholding ($\Delta Th=0\%$) were highly predictive with $Th=41\%$ (AUC=0.74, p=0.012) and $Th=50\%$ (AUC=0.77, p=0.006) but not with $Th=70\%$. Weighted parameters were discriminative (p<0.05) at $Th=41\%$ with $\Delta th = [0\% - 22\%]$, at $Th=50\%$ with $\Delta th = [0\% - 32\%]$ and at $Th=70\%$ with $\Delta th = [0\% - 32\%]$ indicating a lower sensitivity to the choice of threshold.

Conclusion: PET weighted parameters including voxels tumor membership probability can be used to predict tumor

recurrence in cervical cancer. Weighted PET parameters were less sensitive to the choice of threshold than standard parameters computed through hard-thresholding, all tested threshold TLG and MTV parameters becoming statistically predictive.

PO-0929

Dual Energy CT imaging of tumour vasculature in NSCLC: an intra-patient comparison with DCE-CT

A.J.G. Even¹, M. Das², B. Reymen¹, P. Lambin¹, W. Van Elmpt¹
¹Maastricht University Medical Centre, GROW - School for Oncology and Developmental Biology - Department of Radiation Oncology - MAASTRO clinic, Maastricht, The Netherlands

²Maastricht University Medical Centre, Department of Radiology, Maastricht, The Netherlands

Purpose or Objective: Quantification of vasculature is frequently performed by dynamic contrast enhanced CT (DCE-CT) or MRI imaging. However, there are some limitations to this technique: DCE-CT requires a detailed kinetic fitting procedure, a prolonged acquisition time with increased dose to the patient, has a limited FOV and is not easy to implement in clinical routine. Dual Energy CT is an evolving field in CT image analysis that allows quantification of contrast material uptake using a single acquisition, making it easily implementable in a clinical workflow. Therefore we investigated the correlation between the DCE-CT derived vasculature parameters, blood flow and blood volume, with iodine related attenuation measured on a Dual Energy CT acquisition for non-small cell lung cancer patients.

Material and Methods: The same imaging protocol was followed for 13 patients on a Dual Energy CT scanner (Siemens Definition Flash). The protocol consisted of a Dual Energy CT scan (either 80/140kVp or 100/140kVp; 70 ml of iodine 300 mg/ml) of the entire thorax and a DCE-CT acquisition (65 ml of iodine 300 mg/ml; 33 frames @ 1.5sec for a total of 50 sec) in a 13 cm FOV centred around the primary tumour. Kinetic analysis was performed using commercial software (Siemens VPCT body) allowing the assessment of blood flow (unit: ml/100ml/min) and blood volume (unit: ml/100ml) in every voxel. Dual Energy CT images were analysed using in-house developed software for iodine contrast quantification. Iodine related attenuation was calculated by subtracting the Hounsfield units of the CT scan acquired at high energy from the scan acquired at low energy. A comparison was performed on 1) the entire tumour and 2) on a sub-volume level, defined by the upper 50% of the volume-of-interest. Correlation on tumour level was assessed by the Pearson correlation coefficient; overlap of sub-volumes with a DICE coefficient.

Results: There was a significant positive correlation between average contrast enhancement on Dual Energy CT and blood flow ($r=0.615$, $p=0.025$) and blood volume (average $r=0.742$, $p=0.004$) on a patient (i.e. tumour) level. Furthermore, the volumes defined by the highest 50% contrast enhanced uptake and 50% elevated perfusion coincided well (see Figure), with DICE scores of 0.72 ± 0.10 (range 0.58-0.87) and 0.71 ± 0.13 (range 0.50-0.91), for the blood flow and volume, respectively.

Figure: Example of a patient showing a heterogeneous vasculature; the DICE coefficients for this patient, between

the Dual Energy CT iodine enhancement and DCE-CT blood flow and blood volume, were respectively 0.87 and 0.91.

Conclusion: We observed high agreement between Dual Energy CT derived iodine enhancement and DCE-CT derived kinetic parameters, both on a tumour and sub-volume level. This may allow wider implementation of vasculature imaging of tumours using the simplified Dual Energy CT acquisition protocol.

PET based response assessment of lung toxicity - assessment of two approaches for dose response

A. Abravan¹, I. Skjei Knudtsen¹, H. Eide², A. Helland², P. Van Luijk³, E. Malinen¹

¹University of Oslo, Department of Physics, Oslo, Norway

²Oslo University Hospital, Department of Oncology, Oslo, Norway

³University Medical Center Groningen- University of Groningen, Department of Radiation Oncology, Groningen, The Netherlands

Purpose or Objective: Patients with lung cancer given external radiotherapy are at risk of radiation induced lung toxicity (RILT). In many studies, mean density changes from CT (in Hounsfield units) have been used as a surrogate for radiation-induced alterations in the lung. However, a combination of mean density changes from CT scans with corresponding standard deviations has been shown to be a more sensitive method. In the current work, we explore whether such a combined approach is feasible for 18F-FDG PET data as well.

Material and Methods: 13 patients with advanced non-small cell lung cancer, participating in a phase II trial on combined radiation and erlotinib therapy, were included. The patients were examined by 18F-FDG-PET/CT at three sessions; prior to, one week into, and six weeks after fractionated radiotherapy (3 Gy \times 10). For each patient, lung was delineated in the planning CT images. The RT dose matrix was co-registered with the PET image series. For each PET image series, mean (μ) and standard deviation (σ) map were calculated based on cubes in the lung (3 \times 3 \times 3 voxels) and were further used to quantify local structure (S). The spread in μ and σ was characterized by a local covariance ellipse (in pre-therapy PET series) in a sub-volume of 3 \times 3 \times 3 cubes. The distance of individual cube values to the origin of the ellipse is then calculated using Mahalanobis distance method to form S maps. ΔS and $\Delta \mu$ maps are derived by subtracting pre-therapy maps from maps of mid- and post-therapy. A detection threshold was calculated based on three patients with two sets of pre-therapy PET scans who were not included in the study.

Results: The structure difference maps (ΔS) identified new areas of interest in the lungs of individual patients compared to the mean difference maps ($\Delta \mu$) (Figure 1 A). On a population level, both ΔS and $\Delta \mu$ were significantly different ($P < 0.05$) from the respective threshold level, irrespective of dose (Figure 1 B). The inter-patient relative variation in ΔS and $\Delta \mu$ were 57% and 88%, respectively, indicating that the ΔS approach yielded less heterogeneous results. 18F-FDG dose response was analyzed up to total dose of 15 Gy by first order linear regression. The relative slopes of the regression lines were 0.036, 0.018, 0.052, and 0.061 for $\Delta \mu$ (mid-pre), ΔS (mid-pre), $\Delta \mu$ (mid-pre), and ΔS (post-pre), respectively. A significant dose response was only seen for the ΔS taken between post and pre-therapy PET.

Conclusion: The new method based on local structures in 18F-FDG PET images was a feasible approach. This method is more sensitive in terms of providing a clearer 18FDG uptake dose response six weeks after initiation of treatment compared to standard image subtraction, and may be valuable in future studies addressing RILT.

PO-0931

Onset and recovery of neuronal injury following proton radiotherapy

C.L. Teng¹, M. Mix¹, B.K.K. Kevin¹, C. Ainsley¹, W. Sumei², K. Manoj², H. Poptani², R. Wolf², L. Sloan¹, T. Brown¹, N. Thorne¹, S. Avery¹, Z. Tochner¹, C. Hill-Keyser¹, S. Mohan², T. Solberg¹, C. Armstrong³, M. Alonson-Basanta¹

¹University of Pennsylvania, Radiation Oncology, Philadelphia, USA

²University of Pennsylvania, Radiology, Philadelphia, USA

³The Children's Hospital of Philadelphia, Neuron-Oncology, Philadelphia, USA

Purpose or Objective: To quantify the time course and the extent of radiation-induced neuronal changes following skull base (cohort I) or brain (cohort II) proton radiation therapy (PRT).

Material and Methods: We analyzed 4 cohort I and 4 cohort II patients, who completed 2 year follow-up magnetic resonance imaging (MRI) and neurocognitive (NC) study. Apparent diffusion coefficient (ADC) and fractional anisotropy (FA) from diffusion tensor imaging were used to evaluate neuronal and white matter injury at 1.5, 6, 12 and 24 m following PRT. All MR images for each patient were co-registered to the planning CT using rigid image registration, enabling patient-specific contours (ROIs) to be transferred. Each ROI thus encoded time-dependent MR parameters. The biologically effective doses to GTV ranged from 52 to 70 Gy. Dose-related neuronal changes were compared between the two cohorts as well as within each patient. Cohort I typically received a left-right symmetric PRT with higher dose to the temporal lobes and brainstem, and cohort II a unilateral PRT with a significant higher dose to only hemisphere. ROIs were hippocampus, cerebellum, corpus callosum, temporal lobes, GTV, brainstem and the whole brain. NC testing used 8 memory indices that are radiation-sensitive and insensitive, based on prior series of studies: visual or verbal, semantic or

perceptual memory (encoding, retrieval, and reaction time to recognize).

Results: ADC is an inverse measure of cellular density. After PRT, average ADC first increased and then decreased; the peaks of the average ADC were detected at 1.5 m and 12 m after PRT for cohort I and II patients. Further, variations in the ADCs were correlated with the mean doses. This dose dependence had different temporal course between the two cohorts. For cohort I, the dose relationship disappeared 12 m after RT. For cohort II, the dose relationship was the strongest at 12 m after RT. $\Delta\text{ADC}/\text{ADC} (\%/Gy) = [0.16, 0.15, 0, -0.06]$ and $[0.16, 0.19, 0.37, 0.09]$ at 1.5, 6, 12 and 24 m after PRT for cohort I and II. FA is a measure of neural connectivity in the brain. On average, no consistent changes in FA were observed for ROIs receiving a mean dose < 40 Gy. In ROIs that received > 40 Gy mean dose, FA decreased consistently. The largest reduction of FA was observed at 1.5 m following PRT. $-\Delta\text{FA}/\text{FA} (\%) = [-7.5, -5.3, 2.9, -1.4]$ at 1.5, 6, 12 and 24 m after PRT for both cohorts. Among NC tests, only changes in verbal and visual semantic retrieval were significant. Decline occurred 1.5 m after PRT (visual semantic reaction time: $p < 0.005$; verbal semantic retrieval: $p < 0.000$). Recovery occurred 6 m after PRT, and reached baseline at 24 m.

Conclusion: ADC and FA are sensitive measures to quantify radiation-induced neuronal injury following PRT. Both ADC and FA showed changes at 1.5 m and a recovery similar to the time course of changes in NC functions.

Preliminary clinical study to evaluate an interactive system to segment OARs in thoracic oncology

J. Dolz^{1,2}, H.A. Kirisli¹, T. Fechter³, S. Karnitzki³, U. Nestle³, M. Vermandel², L. Massoptier¹

¹AQUILAB Parc Eurasante Lille Metropole, Research, Loos, France

²Univ. Lille, Inserm- CHU Lille- U1189 - ONCO-THAI - Image Assisted Laser Therapy for Oncology, Lille, France

³University Medical Center of Freiburg, Department of Radiation Oncology, Freiburg, Germany

Purpose or Objective: Radiotherapy aims at delivering the highest possible dose to the tumor while minimizing the irradiation of surrounding healthy tissue, and especially to the organs at risk (OARs). Therefore, accurate delineation of OARs is required for radiation treatment planning (RTP). In thoracic oncology, delineation of some OARs remains manual, making the task time consuming and prone to inter observer variability. Various (semi-) automatic approaches have been proposed to segment OARs on CT but the task still remains challenging. Here, a system to interactively segment OARs in thoracic oncology on CT images is presented and its clinical acceptability evaluated.

Material and Methods: The proposed framework has been implemented using MITK platform. User interaction lies in the easy definition of few manual seeds for the OARs and background using a 'paintbrush' tool, which can be interactively added in any view (axial, sagittal or coronal), and is subsequently propagated within the whole volume. Once the user is content with the seeds placement, the system automatically performs the segmentation. If the outcome is not satisfying, the user can modify the seeds, which involves adding and/or removing existing seeds, and perform again the automatic segmentation. Number of tries has been limited to five in the current study. If after the five modifications the segmentation result is not sufficient to be usable in the RTP, the user shall reject it; otherwise, he shall accept it. A hybrid approach combining watershed transformation and graph cuts is used for the segmentation task.

Results: The system was evaluated on multivendor CT datasets of 10 patients presenting from early stage to locally advanced NSCLC or pulmonary metastases. OARs taken into consideration in this study were: heart, lungs, oesophagus, proximal bronchus tree, spinal canal and trachea. Interactive contours were generated by a physician using the proposed system. Delineation of the OARs obtained with the presented system was approved to be usable for RTP in more than 90% of the cases, excluding the oesophagus, which segmentation was never approved (Fig 1). On the accepted reported cases, more than 90% of the interactive contours reached a Dice Similarity Coefficient higher than 0.7 with respect to manual segmentations (Fig 2). Therefore, our interactive delineation approach allows users to generate contours of sufficient quality to be used in RTP up to three times faster than manually.

Figure 1. Dice Similarity Coefficients (DSC) of semi-automatic OARs segmentation.

Figure 2. Acceptance rate for the semi-automatic segmentations

Conclusion: An interactive, accurate and easy-to-use computer-assisted system for OARs segmentation in thoracic oncology was presented and clinically evaluated. The introduction of the proposed approach in clinical routine might offer a valuable new option to radiation therapists (RTTs) in performing OARs delineation task. Consequently, further experiments will be carried out on larger databases and with the participation of additional RTTs to investigate its potential use in daily clinical practice.

PO-0933

Towards standardisation of PET auto-segmentation with the ATLAAS machine learning algorithm

B. Berthon¹, C. Marshall², E. Spezi³

¹Cardiff University, Wales Research and Diagnostic PET Imaging Centre, Cardiff, United Kingdom

²Cardiff University, Wales Research & Diagnostic PET Imaging Centre, Cardiff, United Kingdom

³Cardiff University, School of Engineering, Cardiff, United Kingdom

Purpose or Objective: Positron Emission Tomography (PET)-based -auto-segmentation (PET-AS) methods have been recommended for accurate and reproducible delineation of tumours. However, there is currently no consensus on the best method to use, as different methods have shown better accuracy for different tumour types. This work aims to

evaluate the accuracy of a single segmentation model trained for optimal segmentation on a variety of different tumour corresponding to different anatomical sites.

Material and Methods: ATLAAS, an Automatic decision-Tree based Learning Algorithm for Advanced Segmentation was developed and validated in previous work. ATLAAS (patent pending PCT/GB2015/052981) is a predictive segmentation model, trained with machine learning to automatically select and apply the best PET-AS method, according to the tumour characteristics. The ATLAAS model was trained on 500 simulated PET images with known true contour. The PET-AS used in the model included adaptive iterative thresholding, region growing, watershed-based segmentation, deformable contours, and clustering with K-means, fuzzy C-means and Gaussian Mixture Models, applied to the detection of 2 to 8 clusters. In this work, ATLAAS was applied to the segmentation of PET images containing synthetic tumours generated using the fast PETSTEP simulator. The data included 5 Head and Neck (H&N), 5 lung, 5 abdominal and 5 brain tumours. The contours obtained with ATLAAS were compared to the true tumour outline using the Dice Similarity Coefficient (DSC). DSC results for ATLAAS were compared with results obtained for thresholding at 42% (RT42) and 50% (RT50) of the maximum intensity.

Results: ATLAAS contours were closer to the true contour for all cases. The DSCs obtained with ATLAAS were 5.3% to 123% higher across cases than DSCs obtained for RT50 and 4.1% to 74% higher than for RT42. The largest differences between ATLAAS and relative thresholding were obtained for lung images, the smallest differences for H&N and Brain tumours. The minimum conformity of ATLAAS contours on the whole dataset was 0.81 DSC compared to 0.38 and 0.47 for RT50 and RT42 respectively.

Conclusion: Our results show that ATLAAS is capable of providing highly accurate segmentation for different tumour sites, largely outperforming single-value thresholding methods. The ATLAAS machine learning algorithm represents a standardized approach to PET auto-segmentation. The robustness and adaptability of ATLAAS makes it a very promising tool for PET segmentation in radiotherapy treatment planning.

PO-0934

Cardio-respiratory motion compensation for 5D thoracic CBCT in IGRT

S. Sauppe¹, A. Hahn¹, M. Brehm², P. Paysan², D. Seghers², M. Kachelrieß¹

¹German Cancer Research Center, Medical Physics in Radiology, Heidelberg, Germany

²Varian Medical Systems, Imaging Laboratory, Baden-Dättwil, Switzerland

Purpose or Objective: Accurate information about patient motion is essential for precise radiation therapy, in particular for thoracic and abdominal cases. Patient motion assessment based on daily on-board CBCT images immediately before treatment potentially allows accounting for organ motion during the treatment. Especially for patients with tumors close to organs at risk, the organ positions need to be precisely known as a function of time. In case of the heart 5D

CBCT images are required. Since simple double gating yields severe sparseness artifacts we propose a 5D motion compensation (MoCo) algorithm dedicated to cardio-respiratory CBCT in IGRT.

Material and Methods: Clinical patient data acquired with the TrueBeam™ CBCT system (Varian Medical Systems, Palo Alto, CA) have been used for our study. For the intrinsic respiratory and cardiac motion signal detection, about hundred overlapping regions of interests are automatically evaluated in projection space, thus yielding a robust approach independent on the anatomy shown in the projection images. In addition to respiratory gating (4D CBCT) cardiac gating is applied to obtain initial volumes. We compensate respiratory and cardiac motion in a two-step procedure. First, respiratory motion is estimated and compensated using respiratory phase binning only. Then, cardiac motion estimation is performed using respiratory-compensated images with cardiac gating. The motion estimation algorithm is based on a deformable intensity-based 3D-3D image registration method. Combining the obtained motion vector fields for respiratory and cardiac motion allows us to compensate motion for any arbitrary respiratory and cardiac target phases.

Results: Either 5D double-gated or respiratory-compensated plus cardiac-gated images both contain strong streak artifacts and high noise levels. Our 5D MoCo algorithm is able to significantly improve the image quality while maintaining the same high temporal resolution for respiratory and cardiac motion as achieved with simple double gating. Because all sparse projection streak artifacts are removed, small structures can be delineated even in areas where motion is high. The noise level of patient data is the same as that of 3D CBCT due to making use of 100 % of the projection data for each reconstructed frame.

Conclusion: This work presents a reconstruction method for true 5D imaging in IGRT. Our patient data demonstrate that good image quality is achievable at identical x-ray dose levels and at acquisition times as for today's 3D CBCT. Treatments of regions close to the heart should be able to benefit from our approach.

PO-0935

Correcting diffusion weighted MR images for signal pile-up and distortions near gas pockets

L.D. Van Buuren¹, D. Polders¹, M. Milder¹, F.J. Pos¹, S.W. Heijmink¹, B. Van Triest¹, U.A. Van der Heide¹

¹The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: Diffusion weighted (DW) MRI is used in RT to improve tumor delineation and monitor treatment response. To minimize scan time, echo-planar imaging (EPI) is employed, but variations in the magnetic field (B0) distort

EPI images due to a low pixel bandwidth in the phase-encoding (PE) direction. Geometric distortions can be corrected using a measured B0 map or by combining EPI images obtained with opposite gradients (ref. 1). However, near gas pockets B0 varies strongly. Here signal pile-up can occur, when signals from distinct, possibly non-neighboring, voxel locations are reconstructed into the same voxel. Our objective is to fully correct DW-EPI images using a combination of the above methods.

Material and Methods: On a 3T MRI (Philips Achieva), we acquired EPI images with opposite PE gradients and a dual gradient echo sequence to map B0. Both EPI images are corrected for geometric distortions by the standard correction method using the B0 map. For the new correction method, the B0 map also identifies voxels containing signal pile-up. The distortion-corrected images are averaged into a single image rejecting voxels with signal pile-up. These voxels contain data from only one EPI image. We demonstrated the correction method in a water phantom including an air cavity. The PE gradients had bandwidths ranging from 6 to 17 Hz/mm, comparable to clinical protocols. The corrected image was compared to raw EPI images and images corrected with the standard method. In a region-of-interest containing only pure water and signal pile-up, improvement was quantified as signal homogeneity using the coefficient of variation (CoV defined as standard deviation divided by signal mean). We applied the same method in two patients (prostate and rectal cancer), who underwent an MRI exam before radiotherapy and compared the raw images with the results of the standard correction and our full correction.

Results: With the standard correction method, distortions and intensity variations were removed in the EPI phantom images, but signal pile-up and signal loss were still visible. These were strongly reduced in our method, which was confirmed by the change in CoV in regions with signal pile-up. Here, the coefficient was 0.34 and 0.35 for the raw EPI image and B0 corrected image, respectively, and decreased to 0.12 after applying the proposed correction. Patient data are shown in the figure below. Here, rectal gas was present causing distortions and clear signal pile-up in the EPI images. After applying the correction, the signal pile-up was removed resulting in improved images.

Figure: Images of 2 patients with rectum cancer (top row) and with prostate cancer (bottom row). Gas pockets are clearly visible on the high-resolution T2w images and cause variations in B0. Resulting signal pile-up in the EPI images is indicated by arrows. The black regions on the corrected EPI images result from an amplitude threshold on the B0 signal to mask out regions where B0 is unknown.

Conclusion: Our method has shown improvements in correcting EPI images, both in phantom and clinical data. It does not only correct for geometric distortions, but also for possible signal pile-up near gas pockets. Corrected DW-EPI images can improve tumor delineation and response monitoring near these regions.

Evolved Grow-cut: A PET based segmentation algorithm for heterogeneous tumors

H.M.T. Thevarthundiyil¹, D. Devakumar², Danie Kingslin Heck², Sasidharan Balu Krishna³, I. Rabi Raja Singh³, Regi Oommen², E. James Jebaseelan Samuel¹

¹VIT University, Photonics Nuclear and Medical Physics Division School of Advanced Sciences, Vellore, India

²Christian Medical College, Department of Nuclear Medicine, Vellore, India

³Christian Medical College, Department of Radiation Oncology, Vellore, India

Purpose or Objective: The purpose of the study was to evaluate the consistency, accuracy and timesaving of a grow-cut segmentation algorithm for heterogeneous tumor volumes.

Material and Methods: We present a new PET segmentation method, which is developed as a combination algorithm of Otsu and the Grow-cut segmentation algorithms and henceforth referred to as Otsu_GC. An initial contour of the tumor was defined using Otsu algorithm, which sets the threshold to minimize the intra-class variance of the tumor and its background. A concentric 3D shell was defined around the initial tumor contour at a distance of twice the slice thickness and extends up to four times the slice thickness. The space between the initial tumor contour and the inner edge of the shell ensured that the background voxels did not include the spill over voxels. The segmentation then employs the Grow-cut algorithm with the initial tumor contour and the 3D shell as the foreground and background seed respectively. The images underwent preprocessing, which included resampling to thinner slices with smaller in-plane voxel sizes that equal the CT slices. Edge preservation and contrast enhancement was achieved by convolution of high boost filter kernel in spatial domain and denoising with Gaussian blur ($\sigma = 1$ pixel) filter. The implementation of preprocessing was in MATLAB and the segmentation was with SlicerRT and Grow-cut modules from 3D Slicer. The algorithm was tested on 11 heterogeneous NSCLC tumors (coefficient of variance: mean 0.35 ± 0.04) from 9 retrospective patient data. The manual contour of the PET uptake by the treating clinician was used as the ground truth for validation using Dice Similarity coefficient (DSC) and absolute volume difference as the evaluation metrics. The true contours were also compared to adaptive threshold (*Tadaptive*) and 40% SUVmax threshold (*T40*) based isocontours. The PET(*Otsu-GC*) contours were also provided as the initial contour that was edited for final gross tumor volume (GTV) definition, which included composite information from CT and PET. The time taken for manual GTV contouring versus the time to edit the PET(*Otsu-GC*) contours was assessed as a measure of efficiency in this approach.

Results: Otsu_GC segmentation produced consistent contours, which were comparable to those delineated by the clinician (DSC: mean+ Std: 0.82 ± 0.062); while *Tadaptive* performed reasonably well (0.80 ± 0.137) and *T40* fared poorly (0.61 ± 0.197). Compared with manual volumes Otsu_GC volumes showed an overall overestimation (mean+ Std: 2.05 ± 4.51 cc); volumes with *Tadaptive* had slight underestimation (-1.17 ± 7.33 cc) and large underestimated volumes were seen with *T40* (mean -14.49 ± 13.42 cc). The mean time of 5.72 minutes for manual GTV definition was reduced to 2.8 minutes (35%) with Otsu_GC.

Conclusion: The proposed cellular automata based algorithm show promising results, robust enough to handle complex shaped tumor volumes with inhomogeneous tracer uptake.

PO-0937

Sound speed reconstruction in full wave ultrasound computer tomography for breast cancer detection
M. Perez-Liva¹, J.L. Herraiz¹, E. Miller², B.T. Cox³, B.E. Treeby³, J.M. Udías¹

¹Universidad Complutense de Madrid, Física Atómica-Molecular y Nuclear, Madrid, Spain

²Tufts University, Electrical & Computer Engineering, Medford-MA, USA

³University College London, Medical Physics and Biomedical Engineering, London, United Kingdom

Purpose or Objective: Ultrasound computer tomography (USCT) is an emerging medical imaging modality in which the acoustical properties of the tissues in the body are studied. Among these properties, the speed of sound has a close correlation with the tissue density [1], providing similar structural information to X-ray mammograms. Therefore, the sound speed maps could be employed to detect breast tumors, avoiding the use of compression and radiation. The potential of these systems as a main diagnostic tool is currently limited by the large computational cost required for image reconstruction, especially when full-wave inversion (FWI), the method that provides the best image quality, is employed [2]. In this work, we present a code based in FWI to reconstruct sound speed maps for USCT.

Material and Methods: The implemented code is based on the Adjoint Method [3] which allows finding the expression of the functional gradient of the global error norm between experimental and simulated data (Eq 1):

$$\nabla_{F\epsilon}(r) = \frac{1}{c_o^2} \int_0^T \frac{\partial p(r,t)}{\partial t} \frac{\partial p^*(r,t)}{\partial t} dt \quad (1)$$

$$n(r) = n^j(r) - \alpha_j \nabla_{F\epsilon}^j(r) \quad (2)$$

Here p and p^* are the direct and adjoint pressure fields respectively. The functional gradient of the error is used to update the speed of sound distribution Eq 2.

The code was implemented in C++ and a CUDA version of the software k-wave [4] was employed to perform the forward and backward wave propagation. Noisy simulated data were employed to test the algorithm (Fig 1D). A reconstruction with bent-rays was used as initial guess. The simulated setup was a circular ring of detectors of 256 point elements with a field of view of 128 mm and 500 kHz of central frequency. A 2-dimensional numerical phantom representing a coronal slice of breast with 4 different tissues (fat, fibroglandular tissue, benign and malignant tumors) was studied.

Results: The reconstruction took around 9 minutes using 2 iterations with 15 subsets in an Intel Xeon 16-CPU @2.4GHz with Nvidia GeForce GTX 660. We obtained adequate recovery of the shape and values of the several structures included in the phantom and very good quality parameters in general.

Fig. 1 A) Actual numerical breast phantom. B) Reconstructed image C) Profiles comparison D) Example of noisy reference signal.

Conclusion: A full wave code was implemented in time domain for USCT. The obtained images employed simulated data and present adequate quality parameters. The calculation time was around 9 minutes which is very fast for this modality. These results are encouraging and we are currently working on the reconstruction of real data and other acoustical properties to validate and improve the applicability of the code.

PO-0938

Estimation of system-related geometric distortion in 7T MRI using a 3D anthropomorphic head phantom

J. Peerlings¹

¹Maastricht Radiation Oncology MAASTRO GROW - School for Oncology and Developme, Radiation Oncology, Maastricht, The Netherlands

Purpose or Objective: Morphological 7 Tesla (7T) MRI is a high-resolution imaging modality offering excellent soft-tissue contrast and promising visualization of micro-vascularization. It shows potential value to be used for improved target volume definition in radiation therapy planning of glioblastoma (GBM) over 1.5T and 3T MRI. However, system- and object-related geometric distortion (GD) of 7T MRI could compromise the spatial accuracy required for high-precision image-guided radiotherapy (IGRT) of GBM. Hence, quantitative evaluation of GD for 7T MRI is mandatory before integration into IGRT. A phantom study was performed to measure system-related GD in clinically relevant 7T MR pulse sequences.

Material and Methods: To assess the GD, a new anthropomorphic head-phantom (CIRS Model 603A) with a rigid 3D grid (3mm rods, spaced 15mm apart) was used. Images were acquired with a Siemens Magnetom 7T whole-body scanner in combination with a Nova Medical 32-channel head coil. Scan protocols with clinically relevant T2-GRE and MP2RAGE pulse sequences were used with and without automatic GD correction. For both sequences, 436 points of interests (POIs) were defined by manual reconstruction of the 3D grid points in the respective images. A global and a local measure of GD were estimated: MAD_{global} is the mean absolute difference (MAD) between the measured and the true Euclidian distances of all unique combinations of POIs, whereas MAD_{local} is the MAD between the measured and the true Euclidian distances of all POIs relative to the magnetic field isocenter.

Results: MAD_{global} and MAD_{local} ranges from 0.88-1.72 mm and from 0.28-1.76 mm in uncorrected GRE images, respectively. For uncorrected MP2RAGE images, MAD_{global} and MAD_{local} ranges from 0.83-1.62 mm and from 0.26-2.04 mm, respectively. Overall GD (MAD_{global}) is present in both uncorrected images and is shown to be sequence-independent. Larger values for MAD_{local} are observed with increasing distance from the magnetic field isocenter, with a maximum of 2.04 mm in uncorrected MP2RAGE near the edges of the phantom (Figure 1). At equal distance from the isocenter, GD was found to be anisotropic with the principal component in the superior-inferior direction (MAD_{local} = 1.38 mm in uncorrected MP2RAGE). In corrected images, MAD_{global} is respectively lower in both sequences as B0 inhomogeneity was corrected for. MAD_{local} for GRE and MP2RAGE ranges from 0.22-0.91 mm and 0.21-0.97 mm, respectively. This means that most GD could be reduced within clinically acceptable limits (≤1mm) by the automatic GD correction method.

Conclusion: With 7T MRI, the system-related geometrical uncertainty of GD-corrected GRE and MP2RAGE pulse sequences is less than 1 mm and may thus render integration of 7T MRI for IGRT of GBM feasible. The next step will be to quantify and correct object-related GD for clinical implementation.

The dosimetric consequences of delineation variation for cervical external beam radiotherapy

G. Eminowicz¹, V. Rompokos¹, C. Stacey¹, M. McCormack¹

¹University College London Hospital, Radiotherapy Department, London, United Kingdom

Purpose or Objective: Target volume delineation variation is of emerging importance with more advanced conformal radiotherapy delivery such as Intensity Modulated Radiotherapy (IMRT). We investigate delineation variation and consequent dosimetric variation for external beam cervical radiotherapy.

Material and Methods: Two INTERLACE trial test cases were outlined by 21 different UK centres. A gold standard clinical target volume (GSCTV) was created by consensus agreement and validated using the STAPLE algorithm. Volume, Jaccard conformity index (JCI) and anatomical areas included (compared with protocol recommendations) were analysed for each centre's CTVs. Individual RapidArc plans were created for each centre's planning target volumes (PTVs). For each centre a gold standard PTV (GSPTV) was created by applying the margins used by that centre to the GSCTV. Comparisons were made with GSPTV dose volume histograms (DVH) parameters including D98%, D95%, D2% (dose delivered to 98%, 95% and 2% volume) and V95% (percentage volume receiving 95% dose). A qualitative review was also performed.

Results: Combined primary and nodal CTV volume varied by up to 1.99 fold. JCI ranged from 0.51 to 0.81 overall. No CTVs demonstrated poor concordance (JCI<0.5). 13% and 32% achieved good concordance (JCI≥0.7). The largest variation in anatomical areas included within CTV was seen in obturator, pudendal and pre-sacral nodal regions. Up to 4cm variation was seen in the superior slice delineated (aortic bifurcation) and up to 3.5cm variation in inferior slice (mid-vagina). Acceptable coverage was achieved for all centres' PTVs but no plans achieved acceptable GSPTV coverage. GSPTV V95%>95% prescribed dose was not achieved for all plans. GSPTV V95%>90% prescribed dose was not achieved in 67% of plans and V95%>80% was not achieved in 9% of plans. GSPTV V95% is on average 10-15% lower than planned and D95% is 10

to 20% lower than planned. Most common anatomical areas not receiving 95% dose were vagina, obturator and external iliac nodes for both cases and superior nodal aspect for case 1. The DVH below shows the gold standard PTV coverage for each centre's RapidArc plan.

Conclusion: This quality assurance exercise demonstrates that, using IMRT, CTV delineation variation leads to potentially clinically important PTV dosimetric variations. Therefore, as IMRT use increases, the importance of accurate target volume delineation also increases.

PO-0940

The problems found within the on-site dosimetry audits of radiotherapy centres in the Czech Republic

J. Koniarova¹, I. Horakova¹, V. Dufek¹

¹National Radiation Protection Institute, Department of Radiotherapy and X-ray Laboratory, Praha, Czech Republic

Purpose or Objective: The aim of the study is to report the most important problems found within the on-site dosimetry audits of radiotherapy centres. On-site audits of therapeutic units are performed by our institute after commissioning and acceptance test for each external radiotherapy and brachytherapy unit in the Czech Republic since 1997. They are performed with the same dosimetry equipment by the same persons to reduce the uncertainty in the results. The system of on-site audits includes the basic audit aimed at the verification of selected mechanical and dosimetric parameters, advanced audit to verify selected functions of TPS, and end-to-end audit to check the whole radiotherapy chain from planning to delivery. When high deviation is found (not only exceeding tolerance level), the auditors always try to find the reason, rectify the problem on-site, or give appropriate recommendations to the particular centre. The results of the audits are reported to the national regulatory body.

Material and Methods: The results from on-site basic, advanced, and end-to-end audits have been reviewed and analysed. Statistical process control (SPC) has been performed where appropriate.

Results: We report important errors that might lead to the radiological accident if not revealed by the on-site audit. In early years, the main typical errors were caused by incorrect input data in the TPS after the acceptance test. Of the main importance were: incorrect determination of dose rate for 60Co unit; incorrect output factors or wedge factors; using ionisation data instead of dose data measured with ion chamber for electron beams; incorrect SSD for measurement; incorrect detector; not taking into account couch attenuation etc. These types of errors are not so frequent but still observable nowadays, regardless the high quantity of published recommendations and literature on that topic. Currently, with new algorithms implemented in the TPS, various errors were found due to the lack of training, in particular for Monte Carlo (MC) algorithms. The TPSs were not commissioned i.e. with MC input data used in clinical practice but with data calculated for highest accuracy to comply with the measurements. End-to-end audit enabled to reveal insufficient patient QA, inaccuracy in TPS calculations for non-reference material, incorrect CT numbers to RED

calibration curves, not following the ICRU and other international reports.

Conclusion: All the examples can serve as a learning system. In early years, the main cause of errors was a lack of time for measurements evaluation and verification. More recently, the other cause of the errors is a lack of time to get familiar with new equipment, especially with the software (TPS). In all cases, the errors were found at centres with a lack of clinical medical physicists with sufficient continual professional development. This work was supported by the project No. TB04SUJB001.

PO-0941

3D printed bolus for chestwall radiation therapy

J. Robar¹, J. Allan², R.L. Macdonald³, R. Rutledge¹, T. Joseph⁴, J. Clancey², K. Moran⁴

¹Dalhousie University, Radiation Oncology, Halifax, Canada

²Nova Scotia Health Authority, Medical Physics, Halifax, Canada

³Dalhousie University, Physics and Atmospheric Science, Halifax, Canada

⁴Nova Scotia Health Authority, Radiation Therapy, Halifax, Canada

Purpose or Objective: 3D printing technology introduces the potential for improved accuracy of bolus in conforming to patients and may provide efficiency gains through automation of production based on planning CT data. The objectives of this study are i) to compare build-up depth dose characteristics of solid and flexible 3D printed bolus material to both Solid Water and standard sheet bolus material, ii) to assess the fit of 3D printed bolus to chestwall anatomy based on CT imaging compared to sheet bolus, and iii) to examine dosimetric accuracy of the treatment plan compared to OSLD measurements with 3D printed bolus.

Material and Methods: Depth dose measurements were performed with a Markus parallel plate chamber for polylactic acid (PLA) and flexible (Ninjaflex) 3D printing materials, and results were compared to both standard sheet bolus (Superflab) and Solid Water. For three chestwall patients, ballistics gel molds of the chestwall were fabricated to produce spatially realistic phantoms with plasticity similar to that of tissue. 5 mm thick, 3D printed chestwall boluses were fabricated for these phantoms based on CT data. CT imaging was then used to assess conformity to the surface and presence of air cavities. Optically Stimulated Luminescent Dosimetry (OSLD) was used to measure dose under both 3D printed and sheet bolus at nine locations on the chestwall surface for typical field-in-field treatment deliveries.

Results: In the build-up region, PLA and Ninjaflex bolus material exhibit similar depth dose characteristics. Both types of 3D bolus yield a greater dose compared to Solid Water, however differences remain below 5%. CT imaging of gel phantoms show an improved fitting of 3D printed bolus, with air cavities below the bolus reduced by 9% to 321% compared to standard sheet bolus. Treatment planning studies show better uniformity of skin dose for 3D printed bolus compared to sheet bolus, with the former giving a standard deviation of 1.8% compared to 4.2%. On average, the agreement of OSLD-measured to planned dose was similar between sheet bolus and 3D printed bolus, however standard sheet bolus shows greater variability in the measured-to-planned dose ratio (15% range for sheet bolus compared to 6% for 3D printed bolus).

3D bolus reduced total air gap volume by 9% to 321% compared to conventional sheet bolus.

Depth dose characteristics for solid (PLA) and flexible (NinjaFlex) 3D bolus compared to sheet bolus (SuperFlab) and Solid Water.

Conclusion: Rigid (PLA) and flexible (Ninjaflex) bolus materials provide build-up characteristics within 5% of Solid Water. When incorporated into treatment planning calculations, planned dose for 3D bolus agrees with OSLD measured dose to within 2% on average, and 3D printed bolus gives lower variability in the agreement of the delivered to planned dose. In summary, 3D printed chestwall bolus may be produced in an automated fashion and gives improved consistency of delivered dose accuracy compared to standard sheet bolus.

PO-0942

VMAT planning and treatment preparation process adapted for failure mode and effect analysis

N. Khater¹, F. Azoury¹, D. Nehme Nasr¹, N. Farah¹, T. Felefly¹, J. Barouky¹, C. El Khoury¹, R. Sayah¹, E. Nasr¹
¹Hotel Dieu de France Hospital - Saint Joseph University, Radiation Oncology, Beirut, Lebanon

Purpose or Objective: Mitigating risks in radiotherapy is paramount for patient safety. A volumetric modulated arc therapy (VMAT) adapted to failure mode and effect analysis (FMEA) and implemented through workflow-integrated checklists is presented. This work is in line with efforts done by organizations to integrate a culture of patient safety into radiotherapy processes.

Material and Methods: VMAT is currently being offered to our patients using RapidArc®, Eclipse® 11, Aria-11®, and TrueBeam™; all by Varian Medical Systems (Palo Alto, CA). All systems went clinical in February 2013. Three months into the VMAT program, we realized our operation may be optimized by using the new Workflow feature introduced in Aria® version 11. Consequently, a workgroup consisting of 2 physicists, 3 radiation oncologists, one radiation therapist and one IT was created to identify modes-of-failure in our VMAT planning and preparation process; and to implement a workflow that mitigates their risks. A process-centered risk analysis for VMAT employing FMEA was performed. Risk priority numbers (RPN) for occurrence, severity and detection, were assigned for identified modes of failure based on a simplified model of the AAPM TG100 scoring. FMEA for one task in our VMAT process (Figure 1) is presented as example in Table 1. Mitigation actions were implemented into Aria-11® Workflow via integrated checklists where e-signatures are enforced. Risk mitigation strategies employing redundancy, implementation of related policies-and-procedures, documentation, and peer-review were hardwired into the VMAT process.

Results: A VMAT workflow (Figure 1) was designed and included 114 potential-modes-of-failure distributed into 4 groups: (1) 59 modes recurring redundantly, (2) 3 decision-type modes forcing re-planning, (3) 33 recurring modes aimed

for enhancing communication, and (4) 19 modes occurring only once; some with residual RPN's necessitating implementation of policies-and-procedures. In the 18 months period leading up to this study, more than 600 VMAT planning and preparation processes were delivered conforming to the workflow in Figure 1. No aberrations in treatments occurred. Shortcomings in e-chart preparations were virtually eliminated.

Conclusion: An adaptation of the VMAT planning and preparation process to FMEA using the Aria-11® workflow was presented. Risk analysis was performed, and risk mitigation was achieved through hardwiring appropriate checklists into the VMAT planning tasks. The adaptation to FMEA resulted in marked improvements in patient safety, process control and process documentation. The presented workflow adaptation to FMEA could serve as a reference or model for clinics offering VMAT.

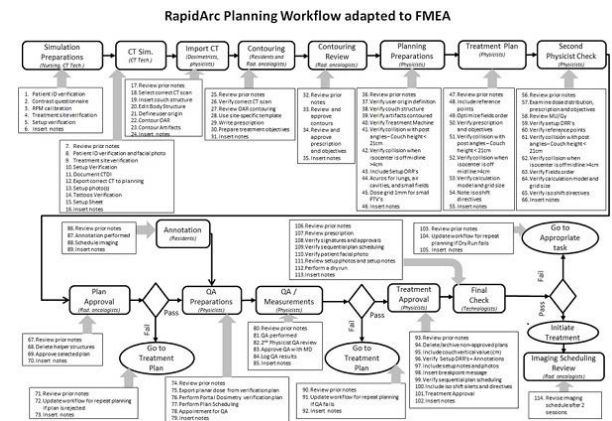

TABLE 1: FMEA for the "Planning Preparation" task (shown with associated check-lists as mitigating actions). The owners usually of this task are physicist and documenters.

Reference Failure Mode (check-list item)	Potential Effect of Failure	Planning Cause of Failure	Planning Failure Mode	Severity	Detection	RPN	Actions/Check-List Mitigation Control(s)	Final Occurrence Prob.	Final Severity Prob.	Final RPN

PO-0943

Dutch national head and neck plan comparison significantly improved treatment planning quality

W. Verbakel¹, C. Raaijmakers², L. Bos³, M. Essers⁴, C. Terhaard², J. Kaanders³, P. Doornaert¹

¹VU University Medical Center, Radiation Oncology Department, Amsterdam, The Netherlands

²University Medical Center Utrecht, Radiation Oncology, Utrecht, The Netherlands

³Medical Center Alkmaar, Radiation Oncology, Alkmaar, The Netherlands

⁴Bernard Verbeeten Instituut, Radiation Oncology, Tilburg, The Netherlands

⁵Radboud University Medical Center, Radiation Oncology, Nijmegen, The Netherlands

Purpose or Objective: The National Platform RT Head and Neck Cancer (HNC, Landelijk Platform Radiotherapie Hoofdhals Tumoren, LPRHHT) is a working party of the Dutch Society of Radiation Oncology, and is engaged in regulating and improving RT for HNC. One of the objectives of the LPRHHT is to evaluate the variation in treatment plan (TP) objectives and possibly improve treatment planning by increased organ at risk (OAR) sparing and reduction of variation between institutes.

Material and Methods: A survey was conducted in all 14 Dutch RT centers treating HNC to identify how a typical TP for oropharynx cancer was generated and judged in terms of PTV coverage, dosimetry requirements and OAR sparing. To this purpose, a CT-scan of an oropharynx cancer patient with delineation of PTVs and OARs was sent to each department. Planning aims were low mean doses of individual salivary glands, swallowing structures and oral cavity, with PTVboost/elective coverage V95%>98%. Prescription dose was 70Gy/35 fractions for the boost, 54.25Gy for PTelective, using a simultaneously integrated boost. Results were presented anonymously, and the 4 centers with lowest OAR doses were asked to share planning tips and tricks with other centers. Centers were asked to undertake a second attempt to lower the OAR dose, using the suggestions of the other centers. In a third step, after evaluating the results, all centers were asked to plan a new case, using their improved planning protocol.

Results: Five different intensity modulated planning systems/techniques were used. Table 1 shows planning aims and averaged plan results. The initial variation in OAR dose was high, with a mean dose range of 20-46 Gy for combined swallowing structures and 18-49 Gy for the submandibular gland. Using the suggestions of best performing departments significantly improved the overall plan quality and reduced the variation in the 2nd phase without loss of PTV coverage. E.g. the submandibular gland mean dose±SD reduced from 35.4±9.3 to 28.0±7.6 Gy. The SD is a measure of variation between institutes. Average combined salivary/swallowing mean doses (±SD) decreased from 30.3±5 / 36.6±8Gy to 26.0±3.3 / 29.0±6.3Gy. The more consistent OAR sparing was confirmed by the reduced variations in the plan comparison for the new patient in the 3rd step.

Table. Planning aims and results averaged for the 14 centers plus variation for step 1 and step 2. Since step 3 involved planning of a different patient, only the variation (SD) is shown here.

	Aim	Step 1, mean ± SD	Step 2, mean ± SD	Step 3, SD
Contralateral parotid	Mean dose ↓	21.8 ± 4.3 Gy	18.5 ± 2.5 Gy	3.1 Gy
Combined salivary glands	Mean dose ↓	30.3 ± 5.0 Gy	26.0 ± 3.3 Gy	2.4 Gy
Combined swallowing muscles	Mean dose ↓	36.6 ± 8.0 Gy	29.0 ± 6.3 Gy	5.0 Gy
PTVboost V95%	V95% > 98%	99.0 ± 0.7 %	98.8 ± 0.6 %	0.5%
PTVboost V107%	V107% < 5%	0.6 ± 1.4 %	0.7 ± 1.4 %	0.6%
PTVelective V95%	V95% > 98%	97.2 ± 2.5 %	97.3 ± 1.8 %	0.9%

Conclusion: Despite many years experience with IMRT for HNC in all centers, treatment plans from all 14 Dutch RT centers showed great variation using the same set of contours. The centers with the highest original OAR doses benefited from the plan evaluation, and the tips and tricks from the best performing centers, resulting in significantly lower OAR dose in subsequent optimizations. Such exercise, initiated by a national radiation oncology working party, can significantly improve plan quality and reduce variation between institutes.

PO-0944

Stability in leaf position of 3 generations of optical digitally controlled Multi Leaf Collimators

A. Bertelsen¹, C.R. Hansen¹, N.K. Olsen¹, C. Brink^{1,2}

¹Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

²University of Southern Denmark, Institute of Clinical Research, Odense, Denmark

Purpose or Objective: To investigate random and systematic uncertainties of MLC-leaf positions for three generations of Elekta MLCs to determine whether highly accurate and precise calibration is possible.

Material and Methods: MLCs of six Elekta accelerators were evaluated; two MLCi, two MLCi2 and two Agility. Details of the heads can be found elsewhere [e.g. Bedford et al J.A.C.M.P, v14, 2013, pp172]. The precision and accuracy

over time of the MLC leaf positions were evaluated using the Electronic Portal Imaging Device, measuring a series of rectangular field with MLC positions moving in steps of 40 mm from -120 mm to 80 mm. Analysis of the images were performed by in-house developed software using steepest gradient analysis and compensating for head rotation inaccuracies.

Random uncertainties were assessed by repeating the above described procedure sequentially five times for each MLC. The random variation was measured as standard deviation of each leaf within a given leaf position, creating a distribution of variances for each MLC. Aggregated random variations for each MLC were calculated as the Root Mean Square of all the individual standard deviations.

Systematic uncertainties or time dependent drift was measured by calculating the average position of the five repeated scans. This average was then subtracted from the similar value measured previously, at the last calibration of the MLC, creating a distribution of drifts between the two time points. The aggregated drift was calculated as the standard deviation of the drift distribution.

Statistical differences of the distributions and differences in median were tested by Kruskal-Wallis tests and differences in the width were assessed by Levenes test.

Results: For all generations of MLC both random and systematic errors are found less than 0.15 mm which is small compared to the EPID pixel size of 0.25 mm and the smallest possible MLC-leaf adjustment of the control systems of 1/12mm (Table and figure).

The systematic difference was measured over a time period shown in the table in which no calibrations was performed on the MLC. Both random and systematic errors are statistically significant improved for each generation of MLC (p<0.001).

For the latest generation, the Agility, the development has resulted in a random error of 0.03 mm. The systematic error for Agility was found to be 0.07 mm when evaluated more than 79 days after calibration.

All measurements are made relative to radiation iso-centre, thus the group median drift (table and figure) is a combination of stability of MLC and radiation iso-centre. The small values in group median reflect high stability of both radiation iso-centre as well as MLC.

Tabel	MLCi	MLC2	Agility
Daily variation			
Random error [mm]	0.06	0.03	0.03
Long Term Error			
Group Median [mm]	0.06	-0.02	0.01
Systematic error [mm]	0.15	0.12	0.07
Minimum days since calibration	88	30	79

Conclusion: All three generations of MLC are found to be highly stable with a significant improvement in stability for each generation. Thus, it is possible to make a highly accurate and precise calibration of the Elekta MLCs if an adequate calibration procedure is available.

PO-0945

Modeling and simulation of simultaneous using of two superficial hyperthermia antennas

A. Di Dia¹, S. Depalma², S. Bresciani¹, A. Maggio¹, A. Miranti¹, M. Poli¹, P. Gabriele³, E. Garibaldi³, M. Stasi¹

¹Istituto di Candiolo- IRCCS, Medical Physics, Candiolo, Italy

²Politecnico di Torino, Dipartimento di Elettronica e telecomunicazioni, torino, Italy

³Istituto di Candiolo- IRCCS, Radiotherapy Department, Candiolo, Italy

Purpose or Objective: Hyperthermia is a powerful radiosensitizer for treatment of superficial tumors. The purpose of this study is the 3D-modeling and simulation of the simultaneous using of two antennas of our equipment. In particular, geometric and functional characterization of the antennas as a function of various tissues characteristics (skin, fat and muscle) were investigated.

Material and Methods: The hyperthermia device is equipped with double arms, operating at a radiofrequency of 434 MHz, with a water automatic superficial cooling device. For temperature measures, it is equipped with an integrated Multichannel thermometer. The antennas are designed to cover areas from 7.2×19.7 cm² up to 20.7×28.7 cm². The applicators geometry have been reproduced in the CAD environment with a professional software based on the FDTD processing methods. In order to identify the distribution of specific absorption power rate in different types of tissues, several simulations have been performed, varying the relative thicknesses of a model consisting of skin, fat and muscle. Working incident power has been set equal to 100 watt. Waterbolus temperature is assumed to be equal to 38 °C

Results: The numerical model of the applicator has been coupled to various models of tissue, the incident maximum power of 100W for 60 minutes, with a thickness of waterbolus equal to 10 mm. In particular, as the fat thickness is gradually increased, muscle layer temperatures decrease of about 0.04 °C per mm of fat layer. Setting the skin thickness, as the fat thickness increases, the maximum temperature and the penetration depth reached in the muscle decrease; increasing skin thickness, if the fat thickness increases, consequently the maximum temperatures reached in the muscle and the depth of penetration decrease. In particular, increasing the fat thickness, temperatures in the underlying muscles were gradually reduced (approximately 0.2 °C for 5 mm fat raise). In the underlying muscle layer, maps were more homogeneous, with an approximately uniform power intensity decrease on the section plane. By varying waterbolus thickness, from 10 to 20 mm, the adaptation of the applicator coupled to tissue model undergoes small changes of the reflected power and, at the operating frequency, the model with thickness 17.5 mm showed to have the best reflection coefficient (-31.35 dB). The simultaneous use of the two antennas showed that only the 10% isoSAR are overlapping, and it demonstrates that it is possible to use both antennas in safety without possibility of hot spots in the tissue, varying also the thickness of the bolus.

Conclusion: The numerical simulation allows to know in detail the temperature distribution to different levels of depth, in particular it demonstrate that it is possible the simultaneous using of two antennas to treat more lesion in the same hyperthermia treatment session without hot spot in the tissue.

PO-0946

A new liquid fiducial marker formulation for image-guided pencil beam scanning proton radiotherapy

J. Scherman Rydhög¹, R. Perrin², R. Irming Jøelck³, T. Lomax², F. Gagnon-Moisan², K. Richter Larsen⁴, S. Riisgaard Mortensen¹, G. Fredberg Persson¹, D. Weber², T. Andresen³, P. Munck af Rosenschöld¹

¹Rigshospitalet, Oncology, Copenhagen, Denmark

²Paul Scherrer Institut, Center for Proton Therapy, Villigen, Switzerland

³DTU Nanotech, Dept of Micro and Nanotechnology, Copenhagen, Denmark

⁴Rigshospitalet, Department of Pulmonary Medicine, Copenhagen, Denmark

Purpose or Objective: The purpose of this work was to test the dosimetric impact of using a novel liquid fiducial marker (BioXmark®) in a proton spot scanned system.

Material and Methods: In order to test the clinical applicability of the new fiducial marker for proton therapy we measured the relative proton stopping power (RSP) of the liquid fiducial marker. Second, we measured the dose perturbation of a clinical pencil beam scanning proton beam of the liquid fiducial marker and three other commercially available solid markers for comparison by introducing them in a gelatin phantom. Dose perturbation was measured for several proton energies between 90 and 101 MeV at several distances after the markers in order to evaluate potential dose perturbation directly behind the markers, in the Bragg peak and after the Bragg Peak. Finally, we created proton therapy plans on five patients with locally advanced lung cancer and with the liquid fiducial marker implanted. Each treatment plans had 3-4 intensity modulated proton (IMPT) beams. We examined the markers impact on the dose distribution caused by the fiducial markers. This was done by first calculating the dose with no marker correction, secondly by matching the RSP of the fiducial marker with the experimental results, and subsequently with the RSP matching soft tissue and comparing changes in the dose distributions.

Results: The RSP of the liquid fiducial marker was determined to be 1.164 and 1.174 experimentally and theoretically, respectively. The dose perturbation of the liquid fiducial marker showed no effect directly after the marker itself and only had an effect on the proton range (Figure 1). By introducing the fiducial markers, we estimated a median range deviation of 1.2 (range: 0.7-1.9 mm) of the proton beam as compared to soft tissue. On the clinical lung cancer IMPT plans with the correct RSP manually introduced, the spinal cord max dose, lung V20, PTV V95, CTV V95 and GTV V95 were all modified by less than 1% by introducing the markers.

Conclusion: The experimentally determined RSP of the liquid fiducial marker was in good agreement (within 1%) of the theoretical calculation. The investigated liquid fiducial marker introduced smaller dose perturbation than the solid fiducial markers. The liquid fiducial marker shows promise for use in image-guided proton therapy of locally advanced lung cancer, as the risk of altering the clinical dose distribution is minimal.

PO-0947

VMAT-based grid for spatially fractionated radiation therapy

S. Gholami¹, M. Severgnini², H.A. Nedaie³, F. Longo⁴, A. S.Meigooni⁵

¹Tehran University of Medical Sciences, Department of Medical Physics and Biomedical Engineering, Tehran, Iran Islamic Republic of

²A.O.U. Ospedali Riuniti, Department of Medical Physics, Trieste, Italy

³Tehran University of Medical Sciences, Radiation Oncology Department- Cancer institute, Tehran, Iran Islamic Republic of

⁴University of Trieste and INFN Trieste, Department of Physics, Trieste, Italy

⁵Comprehensive Cancer Centers of Nevada, Las Vegas-Nevada, USA

Purpose or Objective: The purpose of this study is to investigate about feasibility of using volumetric modulated arc therapy (VMAT) technique to provide a Grid dose distribution with the therapeutic ratio (TR) advantage similar to the block-based Grid.

Material and Methods: A series of cylinders with hole diameters of 1.3 cm and 1 cm height was created in a phantom as the boost volume within a larger volume target. The Monaco® 5 treatment planning system was used to plan the phantom. Four arcs, with collimator angles at 00 and 180 0 were used. The cost functions were defined to deliver 17 Gy dose to the boost volume and 6 Gy dose to the target volume. A dose profile from treatment plan was utilized to calculate TR for the VMAT-based Grid. In addition, for an available Grid block in our department the TR value was calculated from dose profile using EBT Gafchromic film. The Hug-Kellerer (H-K) radiobiological model (Equation 1) which is more appropriate at doses higher than 12 Gy was used to calculate survival fraction of cell lines under a single hole of the both Grids. The values of α/β ratios for tumor cells and normal cells were considered to be 10 Gy and 2.5 Gy, respectively.

Equation 1:

$$\left\{ \begin{aligned} SF &= \sum V_i e^{(-k_1 D_i + k_2 (1 - \exp(-k_3 D_i)))} \\ \alpha &= k_1 - k_2 \cdot k_3 \quad \beta = k_2 \cdot k_3^2 \cdot (\ln(2) - 1 / 2) / (\ln(2))^2 \end{aligned} \right.$$

Where the V_i represents the relative cell numbers receiving the same dose ranging from D_i and D_i+1 . The therapeutic advantage of the Grid irradiation was considered in terms of the normal tissue cell survival ratio (Grid/open field ratio) for the same tumor cell survival. The therapeutic ratio (TR) was calculated for both VMAT-based and block-based Grids.

Results: Figure 1 shows a 2D dose distribution of VMAT-based and block-based Grids at the center of the phantom. The VMAT plan generated a highly spatially modulated dose distribution in the volumes. D95% and D50% for the cylinders and the target in Gy were 16.5, 17 and 6, 10 respectively. The valley to peak ratio of the VMAT-based and block-based Grid was 19% and 22% respectively. The Therapeutic ratio for VMAT-based and block-based Grid was obtained 1.25 and 1.38 respectively.

Figure 1-The beam profile for (a) the VMAT-based Grid and (b) the block-based Grid. Dose distributions of (c) VMAT-based Grid from treatment plan and (d) block-based Grid from EBT Gafchromic film.

Conclusion: The therapeutic ratio value obtained for VMAT-based Grid demonstrated the feasibility of volume arc therapy to deliver spatially fractionated radiation therapy technique which can help the treatment time with the additional potential advantage of reducing dose to the normal tissues.

PO-0948

A comprehensive evaluation of intracranial SRS treatment accuracy

T.A. Van de Water¹, P. Remeijer¹, F. Wittkämper¹, C. Schneider¹, M. Frantzen-Steneker¹, E. Damen¹, C. Panneman¹, J. Geuze¹, J. Kaas¹, R. Van Schie¹, A.M. Van Mourik¹

¹The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: This study provides a comprehensive overview of our geometric accuracy of frameless, linac-based intracranial SRS treatments. It is currently used to evaluate and further improve SRS treatment accuracy at our institute. Moreover, for other institutes, the overview may be used as reference material to supplement the more coarsely defined tolerance limits available in guidelines. To our knowledge, this is the first study that presents an overview of MRI/CT-to-RT treatment accuracies in such detail, combining regular QA data with clinical data, for a specific treatment.

Material and Methods: Our intracranial SRS treatments are based on a non-coplanar dual arc VMAT technique (table 0° and ±90°), in combination with an extensive online IGRT protocol with table correction verification and a post treatment CBCT. We systematically evaluated precision of the main elements of this SRS chain. We gathered patient set up data and image registration data, evaluated the imaging, treatment planning and QA protocols that were used, measured small fields (≤3 cm²) and compared this data with the TPS beam fit, and analysed QA data of the last couple of

years, including EPID-based Winston Lutz tests, table rotation inaccuracy measurements, leaf and jaw position accuracies and kV-MV isocenter measurements.

Results: Table 1 summarizes the precision of the separate elements in our intracranial SRS treatment chain. The largest inaccuracies of about a mm are found for imaging, delineation and treatment planning. Image registration, machine QA and patient setup show high sub mm accuracy. Resulting accuracies are in compliance with the SRS tolerances as mentioned in international and national guidelines (AAPM TG 142, NCS 22 and 24). The TPS dose grid will be adjusted to 2 mm (recommendation by AAPM TG 101). Furthermore, setup and image registration data are in good agreement with literature [1]. In addition to the upper tolerance limits from guidelines, this table provides detailed reference material regarding realistic machine and treatment accuracies for frameless, linac-based intracranial SRS.

	Accuracy [mm]					Type	Effect	Data based on			
	LR	CC	AP	SD _{LR}	SD _{CC}				SD _{AP}	estimated tolerance measured	shift blur

Table 1. Precision of the separate elements in our intracranial SRS chain. 'Effect' specifies whether the inaccuracy results in a shift or blur of the delivered dose distribution. It is important to note that the summed value of these separate inaccuracies does not correctly represent the total uncertainty in treatment delivery, but will give an overestimation (as values are correlated or maximum values and in the total treatment chain errors can compensate one another).

Conclusion: This method to comprehensively map and evaluate SRS treatment accuracy has allowed us to identify the most relevant sources of treatment delivery uncertainties and indicate items that require further investigation. Currently, relevant treatment uncertainties are further investigated and an end-to-end test is developed to further define and improve our accuracy. This approach can be extended to other stereotactic sites and techniques as well as to other institutes. We believe that comparing this kind of comprehensive data over institutes will also help to improve evaluation of treatment outcome as the actually delivered dose highly depends on the treatment accuracy.

PO-0949

Automated approval of a pre trial benchmark RTQA case. The ARISTOTLE experience.

L.N. Sweeney¹, E. Spezi², N. Cole¹, D. Sebag-Montifiore³, R.A. Adams¹

¹Velindre Cancer Centre, Clinical Oncology, Cardiff, United Kingdom

²Velindre Cancer Centre, Medical Physics, Cardiff, United Kingdom

³St James Institute of Oncology, Clinical Oncology, Leeds, United Kingdom

Purpose or Objective: To demonstrate the feasibility of using a statistical algorithm, MDC-OVER-UNDER, as an automated assessment tool of a test case for radiotherapy outlining. If feasible, this efficient technique could be used to screen submissions for significant errors in outlining a radiotherapy quality assurance (RTQA) pre-trial test case.

Material and Methods: UK centres submitted a neoadjuvant radiotherapy rectal cancer test case, prior to recruitment to the phase III ARISTOTLE trial. CERR (a computational environment for radiotherapy research) software platform was used for assessment. Previous pilot work using conformity indices to evaluate target volume delineation (TV) in this trial had limitations. An MDC value of +/- 0.2mm from a single line reference volume calculated from ROC curve analysis, gave high sensitivity and specificity for slices which were over/under outlined. We were unable to satisfactorily validate this system owing to areas of "accepted" discrepancy from the reference standard (RS). In this work, a RS (non-margin generated) CTV with a minimum and maximum extent was created by two clinicians involved in the RTQA process (fig 1). This was based on previous single line RS and iterative review of submissions from several centres. MDC-OVER-UNDER on a slice by slice basis, was applied to the individual institution submitted CTV. For any slice of the volume to pass the automated assessment, both following criteria had to be met. NB. An outline difference of 0.1mm is visually perfect.

- 1) For CTV MAX extent: MDC Over (mm) - 0.1mm ≤ 0mm
- 2) For CTV MIN extent: MDC Under (mm) + 0.1mm ≥ 0mm.

Results: We analysed 16 submissions from 10 centres. Data was saved in CERR format with uniform naming convention. The RS CTV ranged from maximum extent slices 30-53 (24 slices); minimum extent slices 31-52 (22 slices). Assessment of a submission was complete within seconds. The algorithm identified and quantified deviation for every outlined slice as expected. There was a quantifiable improvement in TV delineation in 75% of centres who had more than one submission, post feedback. Extra/missing slices were always associated with an MDC value greater than +/- 0.5mm respectively. Superior and inferior portions of the volume showed most discordance as reflected in the MDC values, with a tendency to over outline superiorly. Data was simply presented in Excel (see table) for review by centre and reviewer, highlighting and quantifying slices for revision.

Centre A - CTVB Assessment			Centre B - CTVB Assessment			Centre A 20/24 submitted slices were acceptable. Over outlining was evident on slices 46-49 incl. We recommend you review these and resubmit the case.
CT Slice #	MDC OVER	MDC Under	CT Slice #	MDC OVER	MDC Under	
27	1.5039		27	0.2052		Centre B 0/25 submitted slices were acceptable. There was evidence of outlining extra slices superiorly. There was also evidence of both significant under and over outlining throughout the remaining volume. Please see our individualised comments.

49			49	0.6243	-1.8762	
50			50	0.2052	-1.6206	
51			51	0.2052	-1.6206	
52			52	0.2052	-1.6206	

Conclusion: The MDC-OVER-UNDER analysis as an assessment tool, has the potential to reduce labour, reduce inter/intra observer variability and provide rapid quantified feedback. Consistently failing volumes would trigger protocol review in the first instance. Wider application in an RTTQA or educational setting requires a consensus min/max extent volume for several operator defined volumes by the TMG from the outset, supported by the STAPLE algorithm. ⁸GZA Sint-Augustinus, Radiotherapy, Wilrijk, Belgium

⁹University Hospital Zürich, Department of Radiation Oncology, Zürich, Switzerland

¹⁰University Hospital Gasthuisberg, Radiation Oncology, Leuven, Belgium

Purpose or Objective: The TRENDY trial is an international multi-center phase II study in which patients with hepatocellular carcinoma (HCC) are randomized between transarterial chemoembolization in the standard arm and stereotactic body radiation therapy (SBRT) in the experimental arm. SBRT is delivered in six fractions with a total target dose of 48-54 Gy. Since the treatment is technologically challenging, an extensive quality assurance (QA) program has been established. The main goal is to ensure high quality treatments in order to achieve an optimal clinical outcome.

Material and Methods: QA guidelines and recommendations are outlined in a separate QA protocol, which also defines minor and major protocol deviations. Treatment is not allowed with a major deviation. If possible minor deviations must be avoided. Centers can only start entering patients with a successfully completed external dosimetry audit. Prior to patient inclusion, a QA questionnaire should be filled out with regards to imaging modalities, treatment planning, patient setup, margins, breathing-motion management and treatment delivery. Besides that, centers are requested to complete a dummy run, including contouring and treatment planning. Contours are evaluated by comparison with golden contours, based on consensus within an expert panel. Treatment plans are evaluated using the constraints and objectives outlined in the treatment protocol, including an NTCP for the healthy liver. During patient accrual, the QA protocol accommodates prospective feedback for the first patients from each center.

Results: Ten participating institutes completed and submitted the dummy-run. All contours were considered acceptable, although variation in both liver and GTV contours was substantial as shown in the figure below. Both individual feedback and general recommendations regarding delineations have been provided. The results of the treatment planning round are summarized in the table below. Two centers (III and VII) did not meet the NTCP constraint

initially and re-planned the dummy-run patient after feedback had been provided. Dose homogeneity and conformity vary substantially, with some institutes aiming at a high target dose allowing for large dose gradients in the GTV-PTV margin, and others optimizing for a smoother, more homogeneous, dose distribution.

Item	Protocol	I	II	III	III*	IV	V	VI	VII	VII*	VIII	IX	X

⁷University of Sydney, Radiation Physics Laboratory- School of Medicine, Sydney, Australia

⁸Illawarra Cancer Care Centre, Medical Physics, Wollongong, Australia

⁹University of Sydney, Institute of Medical Physics, Sydney, Australia

Purpose or Objective: To develop and assess methodologies necessary for baseline alignment and dosimetry measurements for a fixed horizontal radiation beam as may occur in heavy ion and proton facilities and is the case for the Australian MRI-linac program (AMP)

Material and Methods: The AMP utilises a fixed horizontal beam which is parallel to the magnetic field. To maximise flexibility the entire linac system (a linatron and independent millennium MLC system, Varian Inc) can be moved on a rail

system towards or away from the isocentre position, which is defined by the isocentre of the MRI scanner. The rail system enables the linatron to be placed at 8 different positions from the linatron ranging from a SSD of 190-336cm. To verify alignment of the radiation beam for the different linac rail positions, radiation profiles were acquired in air at different distances from the target. From the profiles the central axis position (CAX) was used to establish the alignment of the radiation beam. To verify MLC alignment to the CAX without the ability to rotate the collimator, a series of half blocked fields were used, with abutting fields and picket fence tests used to verify positional accuracy. Standard scanning water tank systems can not be used within the MRI scanner due to both ferromagnetic components and lack of physical space. To enable a comparison of baseline data once the magnet is installed, water dosimetry measurements were compared with measurements within an adjustable solid water phantom.

Results: CAX measurements were successfully used to establish the alignment of the radiation beam for different linac positions. The reproducibility of the central position of the radiation beam was within 2 mm for all positions and the radiation beam alignment for all positions was within 0.5 degrees, demonstrating that the radiation beam was horizontal and not misaligned within that plane. MLC alignment was within 0.5mm of the CAX beam position at a source to surface distance (SSD) of 100cm and within 6.5mm at a SSD of 277cm. The solid water phantom set-up achieved comparable dosimetry with the water tank set-up, enabling future measurements to be undertaken safely within the confines of the MRI scanner.

Conclusion: We have developed a generalised methodology appropriate for the commissioning a fixed radiation therapy beam line. We have taken baseline (no magnetic field) alignment and dosimetry measurements for the AMP beamline, demonstrating that the rail system and MLC alignment are within tolerance. We have also demonstrated the equivalency of a solid water approach with a conventional water tank enabling future dosimetry measurements within the MRI scanner.

²Europe Hospitals, Department of Radiation Oncology, Brussels, Belgium

³European Society for Radiation and Oncology, ESTRO, Brussels, Belgium

⁴Institut Gustave Roussy, Department of Radiation Oncology, Paris, France

⁵Odense University hospital, Department of Oncology, Odense, Denmark

⁶RadOnc, eLearning Center- Inc., Fremont- CA, USA

⁷Catholic University, Department of Radiation Oncology, Rome, Italy

Purpose or Objective: Interobserver contouring variability is one of the most important sources of uncertainty in radiotherapy. Blended learning techniques are formal educational programs in which students learn, at least in part, through delivery of content and instruction via digital and online media with some element of student control over time, place, path, or pace. In 2009, ESTRO launched the FALCON (Fellowship in Anatomic deLineation and CONtouring) project. This web-based project aims at the improvement of the skills and homogeneity in contouring among professionals and/or trainees in the field of radiation oncology by organizing live and online contouring workshops. This study

reports the first results of interactive teaching during live workshops.

Material and Methods: We analyzed the contours of 66 participants to 2 live FALCON workshops and covering 2 clinical situations: the contouring of prostate cancer (35 participants) and the contouring of some Organs At Risks (OARs - brachial plexus, esophagus, trachea and proximal bronchial tree, 31 participants). In all the analysed workshops, delineations were done before and after interactive teaching. Variability of clinical target volumes (CTVs) contoured by participants and the impact of teaching courses was evaluated using the DICE indexes. Moreover, for the prostate case, 3 sub-regions were retrospectively identified and analyzed separately: the prostate base (upper 5 slices, total length: 1 cm), the mid-prostate (following 15 consecutive slices) and the prostate apex (five lower slices, total length: 1 cm).

Results: Table 1 summarizes data of the 2 workshops. Mean CTV DICE indices for the workshops ranged overall from 15% to 84.1% before the teaching lecture, and from 23.4% to 86.1% after teaching, but with large interobserver variations. Usually, a significant improvement in delineation was observed on DICE indices among participants compared to experts' delineations after the teaching lecture (two-tailed t-test P value ranging between 0.04 and <0.001). An improvement was also noted at a more qualitative analysis, with the contours being much more homogeneous amongst participants after teaching.

STRUCTURE	AVERAGE	AVERAGE	AVERAGE	P-VALUE
	PRE TEACHING DICE (%)	POST-TEACHING DICE (%)	DIFFERENCE (%)	
WHOLE PROSTATE	84.1	86.1	+2	<0.0001
PROSTATE BASE	57.3	68.9	+11.6	<0.0001
MID-PROSTATE	88.3	89.3	+1%	0.01
PROSTATE APEX	48.5	50.3	+1.8	0.35
TRACHEA AND PROXIMAL BRONCHIAL TREE	73.3	76.4	+2.1	0.33
OE SOPHAGUS	65.1	77.1	+12	0.1
BRACHIAL PLEXUS	15	23.4	+8.4	0.03

Conclusion: Evaluation of the immediate impact of teaching contouring is feasible and FALCON teaching methods reduce interobserver variability in CTV delineation at workshops. ESTRO is strongly committed in the further development of the current and of the future live and online FALCON workshops. The long-term impact of the FALCON workshops will be further evaluated in the context of well designed ad hoc research projects.

Intraoperative multicatheter implant for APBI or boost in conservative surgery of breast cancer

M. Cambeiro¹, F. Regueira², N. Rodriguez-Spiteri², B. Olartecoechea³, J. Idoate⁴, L. Pina⁵, R. Martinez-Monge¹

¹Clinica Universitaria de Navarra, Radiation Oncology, Pamplona, Spain

²Clinica Universitaria de Navarra, General Surgery, Pamplona, Spain

³Clinica Universitaria de Navarra, Gynecology, Pamplona, Spain

⁴*Clinica Universitaria de Navarra, Pathologist, Pamplona, Spain*

⁵*Clinica Universitaria de Navarra, Radiologist, Pamplona, Spain*

Purpose or Objective: To assess the safety, feasibility and efficacy of free-hand intra-operative multi-catheter breast implant and peri-operative high-dose rate brachytherapy (FHIOMBI-PHDRBT program) in early breast cancer treated by breast conservative surgery (BCS).

Material and Methods: Patients with early breast cancer who were candidates for BCS and potential accelerated partial breast irradiation (APBI) were prospectively enrolled for the FHIOMBI-PHDRBT program. Patients suitable for APBI received PHDRBT (3.4 Gy BID for 10 in five days). Patients not suitable for APBI received PHDRBT as anticipatory boost (3.4 Gy BID for 4 in two days) followed by whole breast irradiation (WBI).

Results: From November 2008 to January 2015, a total of 119 patients were treated and 122 FHIOMBI procedures were performed. Median duration of FHIOMBI was 25 minutes. A median of 8 catheters (range 4-14) were employed. No intraoperative complications were observed. Severe early postoperative complications (bleeding) were documented in 2 patients (1.6%), wound healing complications in 3 (2.4%), and infection (mastitis or abscess) in 2 (1.6%). Late mammogram follow-up revealed oil cysts in 56% of patients but symptomatic fat necrosis in only 2 patients (1.6%). PHDRBT was delivered as APBI in 88 patients (74%) and as a boost in 31 (26%). The median CTV-T was 40.8 cc (range 12.3-160.5), median D90 of 3.32 Gy (range 3.11-3.85), median DHI 0.72 (range 0.48-0.82) median D10 in high-risk skin zone 1.94 Gy (range 0.92-3.37). With a median follow-up of 35 months (range 5.9-80.9) in the whole group and 37.7 months (range 7.6-80.9) in APBI patients, no local, elsewhere or regional failures were observed, only one distant failure in PHDRBT boost was documented. Cosmetic outcomes were evaluated in APBI patients as excellent (42.0%), very good (46.0%), fair (10.0%) or poor (2.0%).

Conclusion: The FHIOMBI-PHDRBT program does not add complications to conservative surgery, it adapts to breast size and location of the tumor, fulfilling at the same time prescription requirements and constraints. It allows an exquisite selection of APBI patients and offers excellent results in disease control and cosmetics. It also offers logistic advantages as it dramatically shortens the time of local treatment and avoids further invasive procedures.

²³*Phoenix Baptist Hospital, Department of Surgery, Phoenix, USA*

Purpose or Objective: To describe early observations of a multi-center study utilizing a single fraction of intra-operative radiation therapy (IORT) using the Xofter® Axxent® Electronic Brachytherapy System® (eBx®) immediately following surgical resection of early stage breast cancer.

Material and Methods: 727 subjects have been treated at 25 hospitals. Upon meeting entry criteria, patients underwent partial mastectomy. While in the operating room a balloon applicator was placed in the lumpectomy cavity and inflated with saline (30-75 cc). The skin was closed over the balloon, a balloon surface-to-skin distance of >1.0 cm was confirmed, and a single fraction of IORT was delivered to the lumpectomy cavity. The prescribed dose was 20 Gy at the balloon applicator surface; the mean treatment time was 10.3 minutes. After treatment, the balloon was deflated and removed, and skin sutured.

Results: 726 subjects received the prescribed dose of 20 Gy; one received 21 Gy. 56 are removed from the primary analysis post-IORT due to subsequent whole breast irradiation (N=37), positive lymph nodes (N=7), positive surgical margins (N=4), re-excision (N=4), inadequate skin bridge (N=2), inadequate balloon conformance (N=1), and other (N=4). These subjects will be followed for the duration of the study. An additional 60 subjects have withdrawn, leaving 667 active subjects. The mean patient age is 65 years (44-88). 148 subjects (20%) had ductal carcinoma in situ, 550 (75%) had invasive ductal carcinoma, 28 (5%) were unknown. DCIS nuclear grade was high (N=55), intermediate (N=64) and low (N=27); 2 were unknown. Invasive cancer was Grade 1-2 in 465/550 cases. 93% (N=676) had T1 lesions, 7% (N=51) had T2 lesions. Mean tumor size is 10.53 mm ± 8.3 mm. Mean follow-up is 336 days (4-1096). Only 125/926 (13.5%) of the reported adverse events were Grade 2 or higher. The most frequent AEs are seroma (15.4%), breast pain (14.1%), erythema (10.7%), and induration (8.5%). Cosmesis was excellent-to-good in over half (65%) of the cases. There have been six (6) deaths (aortic aneurysm; heart attack; pneumonia; liver cancer; 2 unknown causes) and only one (1) recurrence reported to-date.

Conclusion: IORT using the Xofter System as part of the conservative treatment of breast cancer is safe, with low morbidity. Early results from this multi-center trial demonstrate this short, convenient course of radiation therapy for select patients with early stage breast cancer has excellent-to-good cosmetic results and a low rate of low-grade adverse events.

PO-0955

PBI with interstitial HDR brachytherapy: acute and late toxicities & cosmetic results.

V. Carboneschi¹, M. Mignogna², S. Linsalata³, M. Mignogna¹

¹*Ospedale San Luca, Radioterapia, Lucca, Italy*

²*Student Of Medicine, University, Pisa, Italy*

³*Ospedale San Luca, Fisica Sanitaria, Lucca, Italy*

Purpose or Objective: Purpose: The study we report is for early stage breast cancer and is a multicentre clinical investigation of PBI achieved by interstitial HDR brachytherapy with intraoperative placement of catheters.

The aim of this study is to evaluate feasibility, acute and late toxicities and cosmetic results with a long follow-up.

Material and Methods: Methods and materials: From January 2005 to December 2013 a total of 445 patients were enrolled in the study, implanted during surgery and treated using a microSelectron-HDR brachytherapy Unit. The median age of the patients was 65 years (range 48-88 years). All those enrolled had an infiltrating ductal carcinoma in the absence of an extensive intraductal component and with clear surgical margins. Sentinel node biopsy was positive in 19,9% of patients and the 76,7% of patients have had estrogen therapy, 15,9% have had adjuvant chemotherapy. In the 95.75 of patient the histology was ductal infiltrating carcinoma, in the 51% of cases the stage was T1b, in the 35% was T1c. Adjuvant chemotherapy was given to 15,9% of patients and hormone therapy to 76,7% of patients. The reference dose is taken as 85% of the mean basal dose. A reference dose of 35 Gy (3.5 Gy in two fractions per day) was delivered to 17% and a dose of 32 Gy (4 Gy in two fractions per day) to 83%. The average time of overall treatment was five days (76,8% in 4-5 days and 23,2% in 6-7 day); the difference is due to festivity and hospital provenience. Catheters were implanted (average of 14) guided by templates in most cases with distance between holes of 16 mm, in a double or triple-plane arrangement in 99% of patients. The mean volume surrounded by the prescription-isodose was 69,2 cc (range 13-129 cc). The treatment plans were evaluated in terms of skin dose, natural dose-histogram, quality (mean 2,15 - range 1-3.04) and uniformity (mean 2.53 and range 1-3.54) index.

Results: Results: The average overall treatment time is five/six days starting from implant commencement. The incidence of acute and late toxicities are given in Table I. Cosmetic results were excellent/good in 81% of patients. In a follow-up of 96 months we observed a local control of 7,7% and in 1,5% metastatic disease.

Table II. Acute and late toxicities.

toxicity	acute	late
Erythema, grade III	4,1	
Dehiscence	4,4	
Reversible oedema	4,1	
Infection	2,7	
Sieroma	3,4	
Fever	3,1	
Highly pigmented skin		8,4
Telangiectasia		5,6
Moderate fibrosis		8
Medium fibrosis		2
Scarring Keloids		0,4
Fat necrosis		1,7

Conclusion: Conclusions: The initial data demonstrates that an interstitial perioperative brachytherapy implant is a feasible method of treatment with good tolerance and good cosmetic results.

PO-0956

Audit of 100 consecutive cervical cancer patients treated with HDR CT guided brachytherapy

M. Zahra¹, L. White¹, L. Bleakley¹, W. Keough²

¹Western General Hospital- Edinburgh Cancer Centre, Clinical Oncology, Edinburgh, United Kingdom

²Western General Hospital- Edinburgh Cancer Centre, Medical physics, Edinburgh, United Kingdom

Purpose or Objective: To assess the outcome of patients treated with CT guided HDR brachytherapy for cervical cancer

Material and Methods: The records for 100 consecutive patients treated in our centre were reviewed. All patients prior to treatment had a biopsy for diagnosis, and a staging pelvic MRI and whole body PET scan. Treatment comprised of EBRT to a dose of 45Gy in 25 fractions given to the pelvis ± para-aortics with concurrent cisplatin chemotherapy. The brachytherapy was delivered in 3 fractions using a ring and tandem applicator with CT planning of each individual fraction and using information from a pre-implant planning MRI. The aim is to achieve HRCTV d90 of >80Gy whilst staying within the published parameters for the OARs. The outcomes in terms of survival and pattern of relapse were recorded and correlated with the HRCTV d90 and volume, and the dose to the OARs. The unpaired t-test and pearson correlation coefficient were used with 2-tailed significance testing level of 0.05.

Results: The median follow up was 32 months with a median age at time of treatment of 44 years (21 - 85 years). Most patients were diagnosed with squamous cell carcinoma (77) or adenocarcinoma (17), 3 patients had an adenosquamous carcinoma and there were 4 cases with unusual histological findings of small cell, serous papillary (2) or neuroendocrine carcinomas. At the time of follow up 78 patients are alive, 21 died from disease and 1 died from unrelated causes. The median time to relapse was 8 months (range 1-23 months). There were 2 cases of isolated pelvic central recurrences, 11 cases of pelvic and distant metastases and 8 cases with only distant disease. The median d90 was 83.9Gy and the mean HRCTV volume was 32.3cm³ (range 9.0 - 83.9cm³). There was a statistically significant difference in d90 between patients with relapse v.s. no relapse (t= 2.49, p=0.019) and there was a strong negative correlation between the HRCTV volume and the d90 (r= -0.48, p<0.0001). The median doses to the OARs: rectum 60.3Gy (46.8 - 74.1Gy), sigmoid 66.9Gy (46 - 76.5Gy), small bowel 59.1Gy (43.7 - 75Gy) and bladder 75Gy (51.4 - 93.9Gy). There were 3 cases with grade 3-4 toxicity that could be related to the brachytherapy: 1 vesico-vaginal fistula, 1 recto-vaginal fistula, and 1 post treatment hydronephrosis.

Conclusion: CT guided cervical brachytherapy allows the delivery of adequate radiation doses to the HRCTV as shown by our acceptable local control and toxicity rates. The pattern of distant disease in the majority of relapses indicates that despite optimal staging investigations and adequate radiation doses to the HRCTV, distant undetected microscopic disease will still determine the outcome in a proportion of cases.

PO-0957

Focal boost to GTV in interstitial and intracavitary cervical brachytherapy - a feasibility study

N. Groom¹, N. Thiruthaneeswaran², G. Lowe¹, P. Hoskin²

¹Mount Vernon Hospital, Radiotherapy Physics, Northwood Middlesex, United Kingdom

²Mount Vernon Hospital, Cancer Centre, Northwood Middlesex, United Kingdom

Purpose or Objective: Image guided plan optimisation with MRI and CT for interstitial and intracavitary brachytherapy is an established technique in treating cervical cancer. The purpose of this current study is to assess the feasibility of boosting the dose to GTV(BT) to 140% of the HRCTV prescription dose, while keeping critical structure dose volume histograms within tolerance.

Material and Methods: 14 MRI/CT guided treatment plans were analysed in this study. Patients were treated using either Vienna-style ring applicator or Fletcher-style applicator, with or without interstitial catheters. The median age of the patients was 51.5 years (range 25-80.2 years). One patient had FIGO Stage IB cancer, 10 had stage IIB cancer and 3 had stage IIIB cancer. All received IMRT external beam

radiotherapy (50.2Gy/27#, 50Gy/25# or 45Gy/25#) followed by brachytherapy (26Gy/4# or 28Gy/4# to HRCTV). In the current study the original treatment plans were re-optimised, using Brachyvision Version 11. The aim was to escalate the GTV(BT) dose to 140% of the original HRCTV prescription dose (8.4Gy and 9.8Gy/# respectively), keeping the HRCTV coverage and organ at risk DVH values within the tolerance which had been accepted for the original clinical plans. GTV (BT) and HRCTV were drawn according to GEC-ESTRO recommendations. The relationship between the volumes can be defined by the following equation. HRCTV2 = HRCTV1 - GTV(BT) The quality of the re-optimised plans was quantified by using dose volume histogram parameters.

Results: Table 1 shows a comparison of the original and the re-optimised plan parameters. In 10 out of the 14 cases (71.4%) more than 90% of the GTV(BT) was covered by the 140% isodose after re-optimisation. The HRCTV1 V100% was reduced for the re-optimised plans by an average of 2.95% (range 0.7-6.01%). Average coverage of HRCTV2 with the prescription isodose was 94.5% for the 6Gy plans, and 81.7% for the 7Gy plans. In 12 out of the 14 cases (85.7%) the treatment time was reduced with the boost plan.

14	Needles in close proximity to GTV(BT)	1	87.0	42.7	95.5

Table 1: Reporting parameters for the standard and re-optimised GTV (BT) boost plan

Conclusion: It is possible to boost the prescription dose to the GTV(BT) to 140% for treatment plans with interstitial catheters and IU within the GTV(BT) volume. Plans without both interstitial catheters and IU in the GTV(BT) are most likely to be suboptimal. This planning study demonstrates that dose escalation to the GTV(BT) is feasible if clinically indicated, and further work into clinical application and outcome should be considered.

PO-0958

Locally advanced cervical cancer treated with IGABT: impact of the D90 HR-CTV on patterns of relapse

C. Chargari¹, R. Mazon¹, P. Maroun¹, I. Dumas¹, F. Martinetti¹, A. Tafo-Guemie¹, E. Deutsch², P. Morice³, C. Haie-Meder¹

¹Institut Gustave Roussy, brachytherapy, Villejuif, France

²Institut Gustave Roussy, Radiotherapy, Villejuif, France

³Institut Gustave Roussy, Surgical Oncology, Villejuif, France

Purpose or Objective: Locally advanced cervical cancer patients with a bulky high-risk clinical target volume (HR-CTV) get the largest benefit of dose escalation in terms of local control. But the expected survival benefit could be lessened by a higher metastatic risk. We examined the patterns of relapse according to the HR-CTV and to the ability to reach the target dose.

Material and Methods: Pts treated with chemoradiation between 04/2007 and 02/2012 were included if they had a disease limited to the pelvis after an exhaustive primary staging (PET/CT plus primary laparoscopic para-aortic lymphadenectomy) and if they had received concurrent chemotherapy. Pts received pelvic irradiation (45 Gy) then a PDR brachytherapy boost +/- a pelvic sequential boost for PET positive pelvic lymph nodes. First sites of relapse were examined.

Results: 109 pts were included, with median follow-up of 39 months. Median D90 HR-CTV was 73.5 Gy in case of HR-CTV ≥ 30 cm³ (n = 28) versus 86.4 Gy in case of HR-CTV < 30 cm³ (p < 0.001). Pts with a not-bulky HR-CTV (< 30 cm³) experienced local failure in 5/81 (6.2%), versus in 6/28 (21.4%) in case of bulky HR-CTV (p = 0.03), but the HR-CTV volume did not correlate with the risk of local failures as only events. Pts with a bulky HR-CTV volume had a higher risk of distant failures: 10/28 (35.8%) versus 7/81 (8.6%) in case of not-bulky HR-CTV (p = 0.002). Local failures were seen in 3/47 (6.4%) for pts with a D90 HR-CTV ≥ 85 Gy and in 8/62 (12.9%) for pts with a D90 HR-CTV < 85 Gy, respectively (p=0.055). Distant failures were seen in 1/47 (2.1%) and in 16/62 (25.8%), respectively (p<0.001). This higher frequency of distant events in pts with a D90 HR-CTV < 85 Gy remained significant after exclusion of local failures: 0/44 (0%) versus 11/54 (20.4%), respectively (p < 0.001).

Conclusion: The inability to reach the target dose seems correlated with a higher propensity to metastases. Strategies integrating the metastatic risk are mandatory for maximizing the benefit of dose escalation.

PO-0959

Dosimetric outcome and perioperative toxicity using Utrecht applicator in cervical brachytherapy

F.J. Celada Alvarez¹, J. Burgos², S. Roldán², R. Chicas², D. Farga², M. Pérez², I. Paredero³, J. Pérez-Calatayud⁴, A. Tormo²

¹Universidad de Valencia, Programa de Doctorado de Medicina, Valencia, Spain

²Hospital Universitari i Politecnic La Fe, Oncología Radioterápica, Valencia, Spain

³Hospital Doctor Peset, Oncología Médica, Valencia, Spain

⁴Hospital Universitari i Politecnic La Fe, Radiofísica, Valencia, Spain

Purpose or Objective: GEC-ESTRO recommendations for IGRT in brachytherapy, the incorporation of MRI in the planning and new MRI-compatible applicators have improved our treatments. But, in big tumours, intrauterine applicators don't seem enough in order to reach a good coverage. Interstitial CT-MRI Utrecht (Elekta®) applicator with plastic needles lets improve HR-CTV and IR-CTV coverage sparing organs at risk. However, a further complication using interstitial applicators may be gynaecological bleeding during the withdrawal of the applicator.

The purpose of this study is to review perioperative toxicity and dosimetry in patients with cervix tumours using interstitial CT-MRI Utrecht applicator.

Material and Methods: Retrospective review of the records of 122 cervical cancer patients treated in our institution from

February '10 to September '15. To be included in the study, the treatment had to fulfill the criteria: (1) include a previous treatment of at least 45Gy of EBRT to the pelvis concomitant with cisplatin; (2) the BT boost consisted in insertion of interstitial Utrecht applicator under spinal anesthesia and individualized MRI planning. Each treatment was composed of 2 applications (7 days apart), with 2 separated fractions (in 24 hours) of nominal 7 Gy (the aim is to obtain the HR-CTV and IR-CTV D90 higher than 85 and 65 Gy EQD2 respectively keeping the OAR doses as low as possible with limits of D2cc of rectum and sigmoid lower than 70 Gy EQD2 and 85 Gy EQD2 in case of bladder). Applicator withdrawal was performed at the surgical theatre. Toxicity score (gynaecological bleeding) were defined by CTCAE v4.0.

Results: 110/122 (90.16%) patients were IIB stage or bigger, and in 68% of patients 6 needles were inserted in both applications. Median tumour volume at diagnoses was 39.8 cc (8.79-205) and median HR-CTV volume at first application was 18.01 cc (7.36-116.59). The final median biologically equivalent doses (EQD2) were D90 HR-CTV = 89.75 Gy10 (78.50-94.00) and D90 IR-CTV = 67.90 Gy10 (58.60-77.40).

For the first application, needles were used in all patients, and 4 (3.2%) patients required vaginal tamponade and/or stitch (Grade 2 CTCAE v4.0), and 2 (1.6%) patients required transfusion and/or endoscopic intervention (Grade 3 CTCAE v4.0).

For the second application, needles were used in 114 patients, and 5 (4.3%) patients required vaginal tamponade and/or stitch (Grade 2 CTCAE v4.0) without bigger toxicities.

Conclusion: Our results suggest that interstitial IGBT as recommended by the GEC-ESTRO, is a safe option without life-threatening consequences due to bleeding, and dosimetric results compare favorably with the traditional technique.

PO-0960

Making MR-guided cervix cancer brachytherapy efficient: Are plan adaptation & daily planning needed?

J. Skliarenko¹, M. Carlone², K. Han¹, A. Beiki-Ardakani², J. Borg², J. Croke¹, R. Ujaimi¹, W. Levin¹, A. Rink², J. Xie¹, A. Fyles¹, M. Milosevic¹

¹Princess Margaret Cancer Centre, Radiation Oncology, Toronto, Canada

²Princess Margaret Cancer Centre, Radiation Physics, Toronto, Canada

Purpose or Objective: MR-guided brachytherapy (MRgBT) improves local control and survival in patients with cervical cancer. It is expected that MRgBT will be standard of care within 5 years. MRgBT is more demanding of resources and optimized processes will be of great importance in assuring its widespread availability. Our aim was to determine the value of imaging and adaptive replanning prior to each MRgBT fraction compared to a less resource intensive approach tailored to specific technique considerations.

Material and Methods: A total of 20 patients with cervical cancer who received external beam radiotherapy (EBRT: 45-50.4 Gy in 1.8-2 Gy fractions) and high dose rate MRgBT (28 Gy in 4 fractions using 2 insertions) were included in this study. A tandem/ring applicator (TR) was used in 9 patients, and a TR with interstitial needles in 4 patients for all 4 fractions. In 3 of these 4 patients, further plan adaptation with increase in number of needles was performed for fractions 3 and 4. In the remaining 7 patients, a TR alone was used for fractions 1 and 2 and a TR plus needles for fractions 3 and 4 to improve target coverage or OAR sparing. All patients underwent MR imaging, contouring and planning prior to each fraction. To simulate a more efficient approach with only one plan per insertion, optimized fraction 1 plan was applied to fraction 2 anatomy, and optimized fraction 3 plan was applied to the fraction 4 anatomy. To assess value of plan adaptation, projected total dose from first insertion was compared to the final total dose following plan adaptation.

Results: There was no systematic change in the high-risk clinical target volume (HRCTV) across fractions (mean range 41-44 cm³). Mean cumulative HRCTVD90 with daily plan optimization was 92 Gy10, and the mean rectal, sigmoid and bladder D2cc doses were 67, 65 and 83 Gy3 respectively. There were no clinically significant changes in the mean HRCTV or OAR D2cc doses with only two plans prior to fractions 1 and 3. The GEC-ESTRO HRCTV target dose >85 Gy10 was achieved in 16/20 patients with either daily plan optimization or planning only twice. All GEC-ESTRO OAR target doses (rectum <75 Gy3, sigmoid <75 Gy3, bladder <90 Gy3) were achieved in 14/20 patients with optimized daily replanning, and this was maintained when only two plans were used. Plan adaptation with addition of interstitial needles for second insertion resulted in improved HRCTVD90 dosimetry in 6/10 cases and in improved OAR dosimetry in 4/10 cases.

Conclusion: MRgBT can potentially improve outcomes of cervical cancer patients but is more resource intensive. This study suggests that improvements in efficiency can be achieved through process analysis and optimization. While adaptive MR-based replanning is fundamental to achieving the benefits of MRgBT, replanning at strategic intervals may be as effective as daily replanning with considerable savings in resources.

PO-0961

Retrospective dosimetric comparison of TG43 and a commercially MBDCA for gynecological brachytherapy

S. Pinto¹, A. Pereira¹, T. Viterbo¹

¹Instituto Português de Oncologia do Porto Dr. Francisco Gentil Porto, Medical Physics, Porto, Portugal

Purpose or Objective: To compare dosimetric plans using a commercially model based dose calculation algorithm (MBDCA) following TG186 recommendations, and the conventional TG43 method in an 192Ir high dose rate (HDR) gynaecological brachytherapy (BT) procedures using two types of cylindrical applicators.

Material and Methods: We analyzed the data of six patients with cervical carcinoma, receiving a 192Ir HDR brachytherapy treatment. The dose was delivered with a micro-Selectron afterloader. A treatment plan was performed using both the TG43 and TG186 dose calculation methods of the Oncentra Brachy v4.5 treatment planning system (TPS). Two cylindrical applicators, of 30 mm and 35 mm diameter were used: the Vaginal Applicator Set and the Shielded Cylindrical Applicator Set, by Nucletron. The treatment dose is prescribed at 0.5 cm distance from the cylinder wall (prescription point), with a treated extension of 3 cm. Analysis included dose volume histograms (DVH) for bladder and rectum and prescription point, according to American Brachytherapy Society (ABS) consensus guidelines (2012). The TG186 results were obtained using the standard accuracy level option of model-based algorithm (Oncentra Brachy-Advanced Collapsed cone Engine (ACE), Elekta), resulting in calculation times on the order of 40 s.

Figure 1 - Mean (point), maximum (triangle) and minimum (square) value and standard deviation (line) of the difference between TG43 and TG186 results, for the dose points, bladder and rectum.

Results: In all cases, the obtained dose following the TG186 method was lower than that obtained with the TG43 recommendations. Moreover, differences were found between the two described applicators (that had never been noticed with the TG43). The prescribed dose and the dose to 2cc of the bladder and rectum varied as follows (figure 1): between 0.4% and 2.7% for the prescribed dose, between 0.6% and 2.5% for the bladder and between 0.9% and 2.7% for the rectum.

Conclusion: Differences were found between the dosimetry plans obtained with the TG43 and our model based dose calculation algorithm following TG186 recommendations. A deeper knowledge of this new algorithm and its applications in a more accurate dose calculation will be the future of this work.

PO-0962

Adjuvant brachytherapy as a part of a multimodal treatment for high-grade uterine sarcoma

P. Annède¹, P. Maroun¹, C. Petit¹, R. Mazon¹, I. Dumas¹, C. Genestie², P. Pautier³, C. Chargari¹, C. Haie-Meder¹

¹Gustave Roussy, Radiation Oncology, Villejuif, France

²Gustave Roussy, Pathology, Villejuif, France

³Gustave Roussy, Gynecology, Villejuif, France

Purpose or Objective: To assess the loco-regional efficacy and toxicity of a multimodal strategy including brachytherapy (BT) as part of the adjuvant treatment of localized high-grade uterine sarcoma.

Material and Methods: A single center retrospective analysis of patients (pts) treated from 1985 to 2015 was conducted. 104 pts with high-grade uterine sarcoma were identified. 80 pts had leiomyosarcomas, 17 undifferentiated sarcomas, 3 rhabdomyosarcomas and 1 high grade adenocarcinoma. 10 pts had a microscopic (n = 8) or macroscopic (n = 2) positive surgical margins.

Results: The median follow-up time was 5.4 years. 57 pts underwent perioperative chemotherapy. 102 pts underwent postoperative external beam radiation therapy (EBRT) followed by a BT boost, and 2 pts received BT without EBRT. The median pelvic EBRT dose was 45 Gy (range 25-50.4). 69 pts were treated with HDR BT (median dose = 10Gy), 33 with LDR (median dose = 15Gy), and 2 with PDR without EBRT (median dose = 60Gy). The 5-year local-regional failure-free survival and overall survival rates were 93% (CI 95% = 87-99%), and 73% (CI 95% = 0.63-0.84%) respectively. Only 5 vaginal recurrences were identified. 2 pts presented grade 3 late toxicity, all other side effects were grade 2 or less.

Conclusion: Adjuvant BT included in a multimodal treatment was associated with a high loco-regional control rate and acceptable acute and late toxicity in patient with localized high-grade uterine sarcoma.

PO-0963

Effectiveness of week 5 MRI virtual preplanning for Image-Guided Brachytherapy for cervical cancers

A. Chang¹, F. Cheung², T. Wong², E. Wong³, F. Cho³, C. Yip¹, I. Soong¹, A. Law¹, M. Lee², R. Yeung¹

¹Pamela Youde Nethersole Eastern Hospital, Clinical Oncology, Hong Kong, Hong Kong SAR China

²Pamela Youde Nethersole Eastern Hospital, Medical Physics, Hong Kong, Hong Kong SAR China

³Pamela Youde Nethersole Eastern Hospital, Radiology, Hong Kong, Hong Kong SAR China

Purpose or Objective: This study aims to demonstrate effective and non-invasive virtual pre-planning using week 5 MRI without the need of applicator in-situ for image-guided cervix brachytherapy.

Material and Methods: 15 patients with stage IB2-IVA cervical cancers were treated at our institution in January to October 2015 using chemoradiation and brachytherapy. All patients received whole pelvic radiotherapy 45Gy in 25 fractions over 5 weeks, with concurrent weekly cisplatin 40mg/m² for up to 6 cycles, followed by additional parametrial boosting 10-16G in 5-8 fractions over 1-2 weeks. HDR brachytherapy using Ir-192 was performed in all patients at week 6 and 7, using Vienna schedule³ of 2 weekly insertions with 2 consecutive fractions per week, and first insertion was approximately 4-7 days after completion of whole pelvic radiotherapy. Treatment aim was 7Gy to HRCTV D90 each for 4 fractions. Week 5 MRI was performed in all patients, and HRCTV_{wk5} was contoured. Virtual preplanning was done with proposed applicators according to pre-brachytherapy clinical assessment of dedicated oncologist. An estimated D90 for HRCTV (D90_{wk5}) was then compared with the actual D90 HRCTV at week 6 and week 7. Maximum diameter for HRCTV at week 6 were measured, and plans with suboptimal coverage after brachytherapy was regarded as having cumulative D90 HRCTV \leq 83.9Gy.

Results: All 15 patients completed chemoradiation with schedule indicated. The choice of applicators was dependent on geometry of tumor (tandem and ovoids or ring or cylinder). Five patients were noted to have suboptimal tumor coverage, with cumulative D90 HRCTV dose ranging from 40.7 to 70.7 Gy. The corresponding maximum diameter of week 6 HRCTV was found to have significant correlation with cumulative HRCTV D90, and a cut-off value of tumor diameter 4.63cm could predict cumulative dose of 83.9 Gy. Based on the initial results, 2.5cm tumor radius from midline was decided to be the cut-off for using interstitial needles to improve dosimetry. With the implementation of interstitial needles in September 2015, one patient received needle insertion based on virtual preplanning with estimated needle position and depth of insertion from week 5 MRI. Estimated HRCTV D90_{wk5} tumor radius from midline was 3.6cm. Improvement of HRCTV D90_{wk5} from 4.9Gy and 8.33 Gy was noted before and after virtual needle insertion. The subsequent week 6 and 7 brachytherapy using the preplanning information showed excellent correlation in terms of HRCTV D90 dosimetry, with cumulative HRCTV_{actual} 89.2Gy (dose per fraction was 7.8, 7.5, 8.6 and 8.6Gy respectively).

Conclusion: This study demonstrates the effectiveness of a non-invasive method using week 5 MRI for virtual pre-planning, with accurate estimation of HRCTV, that can guide needle insertion diligently. Tumor radius of 2.5cm was proven to be a good reference to select patients for interstitial needle insertion.

High-dose-rate interstitial brachytherapy as monotherapy for locally limited mobile tongue cancer

K. Yoshida¹, H. Yamazaki², T. Takenaka³, T. Kotsuma⁴, K. Masui², H. Akiyama⁵, Y. Uesugi¹, T. Shimbo¹, N. Yoshikawa¹, H. Yoshioka¹, E. Tanaka⁴, Y. Narumi¹¹Osaka Medical College, Radiology, Takatsuki, Japan²Kyoto Prefectural University of Medicine, Radiology, Kyoto, Japan³National Hospital Organization Himeji Medical Center, Radiology, Himeji, Japan⁴National Hospital Organization Osaka National Hospital, Radiation Oncology, Osaka, Japan⁵Osaka Dental University, Oral radiology, Osaka, Japan

Purpose or Objective: In order to evaluate the usefulness of high-dose-rate interstitial brachytherapy (HDR-ISBT) as monotherapy for locally limited mobile tongue cancer, we analyzed our clinical experience.

Material and Methods: We investigated 29 locally limited mobile tongue cancer treated by HDR-ISBT as monotherapy at National Hospital Organization Osaka National Hospital between February 2001 and August 2012. The median age of the patients was 60 years (range: 34-84 years). All patients had histologically confirmed squamous cell carcinoma. According to the UICC classification of 2007, 3 T1, 18 T2 and 8 T3 were classified, respectively. The median tumor thickness of the patients was 10 mm (range: 2-45 mm). Ten (34%) medically poor risk patients (more than 80 years of age or severe intercurrent disease) were included. One patient had previous irradiation history. All but one patients received 54 Gy in 9 fractions. The other patient reduced his treatment doses (48 Gy in 8 fractions) because of previous irradiation history. We used three-dimensional planning for later 7 patients and delivered the prescribed doses to CTV (clinical target volume). Gross tumor volume (GTV) was defined with metal markers positions, applicator positions, intraoral ultrasonography and CT image. The GTV was equal to the CTV.

Results: The median follow-up time was 47 months (range; 10-171 months). The median V100(CTV) were 100%prescribed dose (range; 99.6-100%) for 7 evaluable patients. The 4-year local control rates were 100%, 73% and 88% for T1, T2 and T3. The 4-year overall survival rates were 67%, 66% and 31% for T1, T2 and T3. The 4-year local control rates were 88%, 83% and 60% for tumor thickness of <10 mm (12 patients), 10-19 mm (12 patients) and ≥20 mm (5 patients). The 4-year overall survival rates were 63%, 67% and 40% for tumor thickness of <10 mm, 10-19 mm and ≥20 mm. Four (14%) patients showed moderate to severe radiation ulcer.

Conclusion: Our treatment result of HDR-ISBT as monotherapy showed good local control result although there were many medically poor risk patients. Overall survival rate was worse for patients who had T3 tumor or tumor thickness of ≥20 mm.

PO-0965

125I seeds implantation under ultrasound guidance for local recurrent tumor of head and neck

P. Jiang¹, J. Wang¹, W. Ran², Y. Jiang¹, S. Tian¹, H. Sun¹¹Peking University Third Hospital, Radiation Oncology Department, Beijing, China²Peking University Third Hospital, Ultrasound Department, Beijing, China

Purpose or Objective: To evaluate the efficacy and safety of interstitial permanent low dose rate 125I seeds implantation under ultrasound guidance for local recurrent tumor of head and neck.

Material and Methods: A total of 70 patients (median age, 60years; range, 4-94 years) with malignant mass in head and neck were retrospective -y studied (from Jan. 2004 to Oct. 2014). 6 were lost to follow-up, and 64 met the inclusion criteria. 81 lesions in head and neck implanted 125I seeds were evaluated. And 54 of 81 lesions were diagnosed cervical lymph node recurrence and another 27 lesions were local recurrence of primary or residual after first management. All the patient underwent 125I seed implantation guided by ultrasonography (Color Doppler Ultrasound with high frequency probe and guiding stabilization devices, Alokaα-10, Figure 1) with adequate local anesthesia. Postoperative dosimetry was routinely performed by TPS (3D treatment planning system; Beijing Fei Tian Industries, Inc.) for all patients. The actuarial D90 of the implanted 125 I seeds ranged from 100Gy to 160Gy (median:130Gy). The activity of 125 I seeds ranged from 0.3mCi to 0.8mCi (median: 0.69mCi). The total number of seeds implanted ranged from 3 to 89 (median: 20). The follow-up period ranged from1 to103.5 months (median: 14months).The survival and local control probabilities were calculated by the Kaplan-Meier method (SPSS 16.0).

Results: Among all the 81 lesions, totally response rate was 80.2% , 22 lesions had complete remission CR (27%) and 43 had partial remission PR (53%) . The 1- ,3-and 5-year tumor control rates were all 75.2% , 73% and 69.1%respectively. The results of cervical lymph node recurrence shows better than the recurrence or residue of primary head and neck neoplasm, with the local control of 5 year was 72.7% and 39.9% respectively. As of the date of follow-up, 22 of 64 patients still alive , The 1- and 3-,5-year overall survival rates were 57.4% , 31% , 26.6% respectively, with a median survival of 20 months. Grade 4 side effects of skin ulceration was seen in 2 patient; grade 1 or 2 skin reactions were seen in 11 patients (17%) who had received external beam radiation therapy before. Other severe complications were not seen.

(A) Local control curve of 81 lesions, (B) Local control curve of 54 cervical lymph node recurrences, (C) Local control curve of 27 recurrence or residue of primary, (D) Cancer specific survival curve of 64 patients

Conclusion: Interstitial permanent implantation of 125 I seeds under ultrasound guidance is feasible, efficacious and safe for refractory head and neck metastasis or recurrence.

PO-0966

Dose planning of intraluminal brachytherapy for esophageal cancer using MR imaging

R. Rezi¹, D. Föörvik¹, L. Lundgren¹¹Skåne University Hospital, Radiation Physics, Lund, Sweden

Purpose or Objective: A new methodology using magnetic resonance (MR) imaging for brachytherapy dose planning of esophageal cancer has been developed. The main objective

have been to determine an MR sequence capable of visualising the tumour and finding a suitable esophageal applicator that can be visualised on the MR images.

Material and Methods: A total of six patients were included in this study. Each patient was scanned with one of two T2-weighted sequences, inversion recovery fast spin echo (IR FSE) or fast recovery fast spin echo (FRFSE). To reduce the motion artefacts in the images, the scanning was only triggered when the diaphragm was at the end-exhale position. The imaging was performed on a 3.0 T MR (GE Healthcare). Dose planning on the obtained MR images was performed using two different methods 1) dose was prescribed at 10 mm from the applicator's centre, which is the method currently used at Skåne University Hospital for treatment based on 2D images 2) dose planning was performed by manual optimisation, i.e. the dwell times were manually adjusted until adequate tumour coverage was reached. To our knowledge, an MR-safe esophageal applicator could not be found at the time of this study. Instead a modified duodenal tube was used. Different contrast agents were studied with the purpose to render the tube's visibility on the MR images.

Results: The esophageal tumour was successfully visualised and delineated on T2-weighted images with the FRFSE sequences, whereas the tumour in the MR images from the IR FSE sequences was difficult to visualise due to poor image quality. Furthermore, improved dose coverage to the tumour was observed when the dose planning was manually optimised to the tumour volume, where V100% to the tumour was increased from 70% to 95% and D90% was increased by 34%. Moreover, the esophageal applicator (duodenal tube) was filled with a saline solution, which was successfully visualised on the MR images.

Conclusion: Brachytherapy dose planning for esophageal cancer with MR imaging enhances tumour visibility and the ability to optimise the dose to the tumour volume and organs at risk.

PO-0967

Current practice in quality assurance of the Papillon50 contact X-ray brachytherapy system in the UK

L. Humbert-Vidan¹, T. Sander², C. Clark^{3,4}

¹Guy's & St Thomas' NHS Foundation Trust, Radiotherapy Physics, London, United Kingdom

²National Physical Laboratory, Radiotherapy Physics, Teddington, United Kingdom

³National Physical Laboratory, Radiotherapy Physics, Teddington, United Kingdom

⁴Royal Surrey County Hospital, Radiotherapy Physics, Guildford, United Kingdom

Purpose or Objective; Papillon50 contact brachytherapy has been used for early rectal cancer treatment in the UK since 1993. Currently there are four centres treating and a few more are in the process of implementation. The National Institute for Health and Care Excellence has issued guidance on safety and efficacy from a clinical perspective. However, there is currently no guidance on quality assurance (QA) testing. This review assessed any significant differences in machine QA practice between the current UK Papillon50 users. This is the first step towards standardising QA tests, tolerances and procedures in order to ensure that the accuracy of this technique is maintained at a high level across the UK.

Material and Methods: Each centre provided in-depth information regarding their QA programme. Details on machine-specific design characteristics were also taken into account. An inter-departmental comparison was made with regards to the QA tests performed, the frequency of each test, the accepted accuracy of the results with respect to the set baselines, the setup for each test and the equipment used.

Results: Significant differences were seen between centres in the QA tests in terms of types of test, frequency and acceptable accuracy. A tolerance variation of 10% versus 2% in the beam quality check and a difference of 2 mm versus 0.5 mm in the radiation field size check were observed. The manufacturer provides a calibration jig with which all four centres carry out radiation output measurements. However, each centre uses its own HVL jig design. There are significant design differences between these jigs with respect to the source-to-detector distance (SDD), the narrow beam geometry achieved and the backscatter conditions. All centres use the 1996 IPEMB CoP for the determination of absorbed dose for x-rays below 300 kV generating potential and its Addendum (2005) as a reference for the determination of the radiation output. However, the reference conditions stated in the CoP were generally not met due to the inherent design of the calibration jig used.

Conclusion: Significant differences exist between centres in the level of accuracy and extent of the QA programme. The very-low energy and short SDD in the Papillon50 system result in a very rapid dose fall-off. Differences in the design of the HVL jig may play an important role in the definition of the beam quality in such conditions. An extension of the CoP Addendum may be needed to include the achievable Papillon50 measurement conditions. This review highlights the need to carry out an independent audit in order to assess whether the inter-departmental variations observed could result in differences in the treatment received by patients.

PO-0968

Development of a fluorescent screen based QA system for dose verification of afterloading HDR unit

T.L. Chiu¹, B. Yang¹, H. Geng¹, W.W. Lam¹, C.W. Kong¹, K.Y. Cheung¹, S.K. Yu¹

¹Hong Kong Sanatorium & Hospital, Medical Physics & Research Department, Happy Valley, Hong Kong SAR China

Purpose or Objective: To develop and assess the feasibility of an in-house developed fluorescent screen based system on dose distribution verification of HDR brachytherapy treatment delivery.

Material and Methods: The QA system consisted of a solid water block with various thicknesses on top of a fluorescent screen (Kodak, Lanex regular screen) and a PMMA block below the screen. The fluorescent signal light was reflected by a mirror below the transparent PMMA to a CCD camera. The whole system was contained in a light tight box. Dose linearity was examined in a previous experiment. In measurement, an Ir-192 source was loaded to an applicator positioned on top of the solid water block. Single source dose distribution without entrance dose effect was first acquired to help obtain a universal light deconvolution kernel. It will then be used in subsequent image processing. Two source dwell positions were placed in each measurement with equal weighting. Source intervals were 5 mm and 10 mm. Four different measurement distances were selected, ranging from 5 mm to 30 mm away from the applicator. Various dwell times ranging from 0.8s to 8s were assigned at different depth to produce the optimal light output. Captured images were then processed by applying a median-filter and the deconvolution kernel to remove radiation induced noise and deconvolute the acquired image, respectively. After the image processing, images were normalized and a region of interest (ROI) (16 cm²) was selected. Gamma index comparisons were performed between acquired dose distributions and the respective depth calculated by TPS (Elekta, Oncentra). Two profiles which cross the central line of the source dwell positions were obtained.

Results: The system can obtain a dose distribution with resolution 0.257 mm per pixel. Gamma index comparisons, (3% dose difference/1 mm DTA) were performed on all 8 conditions. Results were tabulated in Table 1.

Measurement distances (Dwell time for 5 mm interval, Dwell time for 10 mm interval)	5 mm source interval	10 mm source interval
5 mm(0.8s, 1s)	96.20%	97.40%
10 mm(2s, 2s)	100.00%	98.60%
20 mm(4s, 4s)	99.90%	99.80%
30 mm(8s, 8s)	99.50%	99.00%

Table 1 Gamma index passing rate for various distances away from the applicator.

All gamma indexes have passing rate above 95%. At measurement distances 10 mm to 30 mm, areas which failed to meet the gamma index criteria were, mostly, on the peripheral of the ROI. Gamma index near the source dwell position is well below 1. At measurement distance 5 mm away from source, the discrepancy between measurement and TPS calculation is the most severe. Both cases have points fail to meet the gamma criteria on the entrance path of the source. In particular, for 10 mm source separation, while assigning equal weighting for both dwell positions, measured data has two uneven signal peaks, as shown in Fig. 1 (d)-(f).

Figure 1 Measurement at 5 mm distance.

Conclusion: The system measured dose distributions agreed closely with TPS calculations, gamma index (3% dose difference/1 mm DTA) passing rates are all above 95% despite a high dose gradient near the source. Hence, this system can serve as a dose verification tool in afterloading brachytherapy. Besides, transit dose is detectable by this system but insignificant in a brachytherapy treatment.

PO-0969

Development of dose measurements close to brachytherapy sources in the German standard DIN 6803 F. Hensley¹, N. Chofor², A. Schönfeld², D. Harder³

¹previously University Hospital Heidelberg, Department of Radiation Oncology, Dossenheim, Germany

²Medical Campus of the Carl-von-Ossietzky University of Oldenburg, Clinic of Radiotherapy and Radiation Oncology - University Clinic of Medical Radiation Physics- Pius-Hospital, Oldenburg, Germany

³Georg-August University Goettingen, Prof. em.- Medical Physics and Biophysics, Göttingen, Germany

Purpose or Objective: Due to the steep dose gradients close to a radiation source and the properties of the changing photon spectra, dose measurements in Brachytherapy usually have large uncertainties and are therefore scarcely performed in clinical routine. On the other hand,

recommendations for experimental measurements are traditionally part of dosimetry protocols which in Germany are formulated in DIN standards. Within the revision of the outdated DIN standard for clinical brachytherapy dosimetry a working group (DIN 6803-3) was charged to formulate recommendations for brachytherapy dosimetry incorporating recent developments in brachytherapy in the description of radiation fields as well as new detectors and phantom materials. The Goal is to prepare methods and instruments e.g. to verify the emerging new dose calculation algorithms, for clinical dose verification and for in-vivo dosimetry.

Material and Methods: After an analysis of the distance dependent spectral changes of the radiation field surrounding a brachytherapy source, the energy dependent response of a number of typical brachytherapy detectors was examined with Monte Carlo simulations. A dosimetric formalism was developed which allows the correction of the energy dependence as a function of the source distance for a Co-60 calibrated detector. A number of phantom materials were examined with Monte Carlo calculations for their specific influence on the brachytherapy photon spectrum and on their water equivalence.

Results: A simple description of the energy dependence of a detector in the vicinity of a brachytherapy source was found by defining an energy correction factor k_Q for brachytherapy in the same manner as in existing dosimetry protocols. The factor can be calculated as a polynomial of the distance from the source. Volume averaging and radiation field distortion by the detector are incorporated into k_Q. Materials for solid phantoms were identified which allow precise positioning of a detector close to a source together with small correctable deviations from absorbed dose to water. Recommendations for the selection of detectors and phantom materials are being developed for different measurements in brachytherapy.

Conclusion: The introduction of an energy correction factor k_Q for brachytherapy sources may allow more systematic and comparable dose measurements. In principle, the corrections can be verified or even determined by measurement in a water phantom and comparison with dose distributions calculated using the TG43 dosimetry formalism.

PO-0970

On the water equivalence of thirteen commercially available phantom materials in 192Ir brachytherapy

A. Schoenfeld¹, D. Harder², B. Poppe¹, N. Chofor¹

¹Carl von Ossietzky Universität Oldenburg, Medizinische Strahlenphysik, Oldenburg, Germany

²Georg-August University Goettingen, Medical Physics and Biophysics, Goettingen, Germany

Purpose or Objective: Thirteen commercially available phantom materials have been tested by Monte Carlo simulations of a typical 192Ir therapy source with regard to their suitability as water substitutes in high energy brachytherapy.

Material and Methods: The radial dose-to-water profiles in differently sized cylindrical water substitute phantoms surrounding a centric and coaxially arranged Varian GammaMed afterloading 192Ir brachytherapy source were compared to the corresponding dose-to-water profiles in equally sized water phantoms in order to evaluate the water equivalence of each phantom material within the clinically relevant source center distances up to 10 cm in the transversal plane. Monte Carlo simulations were performed in EGSnrc. The studied phantom materials are RW1, RW3 (both PTW, Germany), Plastic Water (as of 1995), Original Plastic Water (as of 2015), Plastic Water DT, Plastic Water LR (all CIRS, USA), Solid Water, HE Solid Water (both Gammex, USA), Virtual Water (Med-Cal, USA), Blue Water (Standard Imaging, USA), polyethylene, polystyrene and PMMA.

Phantom sizes were varied between diameters and heights of 10 cm and 60 cm to study the effect on the dose contribution by scattered photons. The radial variations of the total

spectral photon fluence and of the fluence contributions by scattered and primary photons were evaluated. The effects of phantom material composition, especially of the organic polymer density and of the amount of inorganic additives, were also studied in terms of the resulting linear attenuation coefficient μ .

Results: Significant differences were seen in the degree of water equivalence between the phantom materials covered by this study. While RW1, RW3, Solid Water, HE Solid Water, Virtual Water, Plastic Water DT and Plastic Water LR phantoms show dose deviations of less than 1.4% in all phantom sizes, Original Plastic Water (2015), Plastic Water (1995), Blue Water, polyethylene and polystyrene produce deviations up to 8.1%. The role of PMMA is unique, showing deviations up to 4.3% in phantoms with radii below 10 cm, but below 1% in larger phantoms. Scattered photons with energies reaching down into the 25 keV region dominate the photon fluence at source distances exceeding 3.5 cm. The degree of water equivalence of a phantom material is correlated with the equivalence of its linear attenuation coefficient μ with that of water over a large energy range.

Conclusion: The key feature of a suitable water substitute material is the agreement of its linear attenuation coefficient μ with that of water over a large range of photon energies. This precondition provides water equivalence with regard to the attenuation of the primary photons, the release of low-energy photons by Compton scattering and their attenuation by a combination of the photoelectric and Compton effects. The instrument to achieve this goal is a balanced content of inorganic additives in a plastic phantom material.

PO-0971

Production of Gd-153 as a source isotope for use in rotating shield high dose rate brachytherapy

G. Famulari¹, A. Armstrong², T. Ulrich³, S. Enger¹

¹McGill University, Medical Physics Unit, Montreal, Canada

²McMaster University, McMaster Nuclear Reactor, Hamilton, Canada

³McMaster University, Medical Physics & Applied Radiation Sciences, Hamilton, Canada

Purpose or Objective: Brachytherapy (BT) can be administered by low ($E < 50$ keV), intermediate ($50 \text{ keV} < E < 200$ keV) or high ($E > 200$ keV) energy sources. For the lower energy sources, the photoelectric effect dominates the energy deposition and the dose distribution decreases rapidly as the inverse of the distance from the source. For the intermediate and high energy sources, Compton scattering is the dominant photon interaction. The attenuation in tissue is compensated by the photon scatter build-up of the dose. Radiation sources used in high dose rate (HDR) BT have conventionally provided near-isotropic or radially symmetric dose distributions, delivering very high doses to tumours but often with poor tumour dose conformity due to the asymmetric shape of the tumours. Rotating shield brachytherapy (RSBT), is a HDR BT technique delivered through shielded, rotating catheters, providing unprecedented control over radiation dose distributions. However, its application in clinical practice has been limited due to lack of an appropriate radiation source. In this work, gadolinium-153 (¹⁵³Gd) was produced as source isotope for use in RSBT.

Material and Methods: A sample of isotopically enriched ¹⁵²Gd with precisely known mass was irradiated in the reactor core at McMaster Nuclear Reactor (MNR) site. The radioactive ¹⁵³Gd formed was counted on a high purity germanium detector to determine the effective neutron capture cross-section of ¹⁵²Gd. A sample of natural gadolinium oxide powder was heated at 1000 °C in a muffle furnace to make it more compact. Radioactive gadolinium with known activity was loaded on a series of solid substrates and the remaining activity in the substrate was measured to determine the loading capacity for each sorbent. The maximum specific activity of ¹⁵³Gd produced from enriched ¹⁵²Gd at MNR was predicted by modelling studies. Finally, a

prototype of the ¹⁵³Gd source was encapsulated in a titanium casing.

Results: The effective thermal neutron capture cross-section was determined to be 500 b. The maximum density of gadolinium oxide after heating was 2.2 g/cm³, significantly lower than the literature value of 7.4 g/cm³, which refers to the metal oxide state. Dowex 50x6 resin was found to have the greatest loading capacity for gadolinium at 219.6 mg/g sorbent. ¹⁵³Gd could be produced with a maximum achievable specific activity of 150 Ci/g of ¹⁵²Gd at MNR after 3 months of continuous irradiation. ¹⁵³Gd emits 40-100 keV photons with a dose distribution similar to that of iridium-192 (¹⁹²Ir) due to its intermediate energy, but with much lower shielding requirements (TVL of 3.7 mm in platinum).

Conclusion: We have developed a means of immobilizing and encapsulating a ¹⁵³Gd source for potential use in brachytherapy. A ¹⁵³Gd BT source can be used in combination with a shielding system to deliver RSBT.

PO-0972

Clinical application and validation of a collapsed cone based algorithm for brachytherapy

A. Guemnie Tafo^{1,2}, I. Dumas¹, S. Koren³, C. Tata-Zafarifety¹, C. Petit¹, C. Haie-Meder¹, C. Chargari¹, R. Mazon¹, F. Monnot¹, D. Lefkopoulou¹

¹Gustave Roussy, Radiotherapy, Villejuif, France

²INSERM, U1030, Villejuif, France

³Rabin Medical Center, Radiation Oncology, Petach Tikva, Israel

Purpose or Objective: In this study we evaluated the Advance Collapsed cone Engine (ACE) algorithm for clinical application to Brachytherapy. To this purpose, we followed 3 main objectives: 1) commission the ACE algorithm, 2) Validate this algorithm as compared to measurement and Monte Carlo simulation and 3) quantify the dosimetric differences observed as compared to TG43 for 3 common clinical indications.

Material and Methods: We followed the AAPM TG186 guidelines for MBDCS commissioning. This task group recommends to commission the dose calculation algorithm by 1) performing calculation in simple geometry 2) verifying dose calculation with hand calculation 3) comparing dose calculation results in complex geometries with a MC based algorithm. We developed a dedicated 6 source positions phantom allowing homogeneous dose distribution at the point of measurement in order to perform dose calculation and measurements in air and liquid water with or without heterogeneities introduced (Air, PMMA, Lead, Cortical Bone). Based on this phantom, we performed measurement using 3 different detectors, a A1SL detector, a Farmer chamber and TLD measurements. Measurements have been compared to dose calculated using ACE, TG43 and validated MC (MCNPX and Fluka). Finally ACE algorithm has been used on 19 Gynecologic, 11 Lips and 21 Penis patients where clinical common indicators (V250%, V100%, D2cc, V100%CTV ...) have been compared to TG43 and MC calculated dose distribution.

Results: Simple geometries with a uniform phantom have shown agreement within 0.3% between ACE and TG43 for both point and line sources. Using dedicated phantom, TG43 vs ACE in air and in water measurements with lead heterogeneity showed up to 95% difference and 86% respectively. ACE vs measurements showed an agreement within 3% in air and 0.3% in liquid water using several heterogeneity media (Table1).

	D ₅₀ (Gy)	D _m (Gy)	D _{95%} (Gy)	D _{95%} (Gy)	D _{95%}/D_m}	D _{95%}/D₅₀}	D _{50}/D_m}
Without Heterogeneities	1,024	1,018	1,000	1,018	0,02%	0,61%	0,63%
PMMA	0,999	0,996	1,000	0,998	0,25%	0,06%	0,31%
Air	1,123	1,155	1,000	1,152	-0,29%	-2,52%	-2,80%
Lead	0,291	0,298	1,000	0,231	-22,40%	25,87%	-2,33%

Comparison between dose calculation with TG43 and TG186 and dose measurement with Ionisation chamber and TLD using Equal ESTRO phantom setup

For clinical cases, few differences have been observed between ACE and TG 43 in Gynecologic cases (up to 2.75% differences on the CTV and up to 1%,2% and 6% for D_{2cc} of sigmoid, rectum and bladder respectively). For Penis cases large differences in glans volume covered by the 200% isodose up to 70% have been observed, and up to 10% for the 100% isodose volume in lips cases.

Conclusion: We have demonstrated that the use of an advance algorithm for Brachytherapy dose calculation is clinically and physically feasible. It shows good agreements with measured data. The use of such algorithms opens questions regarding the prescription and tolerances allowed in clinical use.

PO-0973

A novel approach to locating source dwell positions in HDR brachytherapy gynaecological applicators

R. Franich¹, M. Hanlon¹, R.L. Smith^{1,2}, C. Demsey³, J.L. Millar^{1,2}

¹RMIT University, School of Applied Science, Melbourne, Australia

²The Alfred Hospital, Alfred Health Radiation Oncology, Melbourne, Australia

³Calvary Mater Newcastle Hospital, Department of Radiation Oncology, Newcastle, Australia

Purpose or Objective: Accurately locating the source dwell positions within HDR brachytherapy applicators is essential to ensure accurate reconstruction of the radioactive source path within the applicator for commissioning. Traditional approaches using radiochromic film are inefficient and limited to one or few dwell positions per film. The aim of this study was to develop a filmless procedure using a flat panel detector (FPD) source tracking system to accurately determine every dwell position and to correlate these with radio-opaque markers.

Material and Methods: The method was applied to two gynaecological HDR treatment applicators, incorporating interuterine tube/ovoids and an interuterine tube/ring combination. The disassembled applicators were fixed to the FPD. Auto-radiographs were captured by the FPD while the HDR source was dwelled at each available position. The location of the source was determined from these images. Using an external x-ray source, a radiograph was also captured, acquiring a combined exposure image. A subtraction method was then used to visualise the physical source in the applicator channel. Radiographs were also acquired with radio-opaque markers installed. Results of this new method were compared to traditional radiochromic film methods for distal dwell positions to compare commissioning approaches.

Results: The double-exposure image subtraction technique provided a method for visualising the active source and accurately determining its true location for all available dwell positions in each applicator channel (see Figure 1). Furthermore, determining the source dwell positions from

the radiograph alone agreed with this projection-subtraction technique to < 1.0 mm for 34 out of the 35 available dwells of the ring channel (as an example). One position differed by 1.4 mm having been influenced by a high contrast feature in the radiograph. Distance to coincidence between the actual source positions and three positions identified by radio-opaque markers in the ring (dwells 1, 16, and 30) were measured and shown to differ by 0.7 mm, 1.0 mm and 0.7 mm respectively.

Figure 1: (a) Autoradiograph (source radiation) captured by the FPD. (b) Simultaneous external x-ray exposure and source

autoradiograph. (c) The subtracted image clearly showing the physical position of the source in the applicator and path of the drive cable through the applicator lumen.

Conclusion: We have demonstrated a filmless approach to determining actual source positions corresponding to each dwell position in each channel of two gynaecological HDR brachytherapy applicators. Accuracy is generally sub-millimetre and can also be used to quantify the accuracy of using marker-wire defined positions for reconstructing applicators in planning. The flat panel detector method is efficient and provides additional information not possible with radiochromic film.

Urethral and bladder dose of total and focal salvage brachytherapy: toxicity and dose constraints

M. Peters¹, J.R.N. Van der Voort van Zyp¹, C.J. Hoekstra², H. Westendorp², S. Van de Pol², M.A. Moerland¹, M. Maenhout¹, R. Kattevilder², M. Van Vulpen¹

¹UMC Utrecht, Radiation Oncology Department, Utrecht, The Netherlands

²Radiotherapiegroep, Radiation Oncology Department, Deventer, The Netherlands

Purpose or Objective: Salvage Iodine-125 brachytherapy (I-125-BT) constitutes a curative treatment approach for patients with organ-confined recurrent prostate cancer after primary radiotherapy. Currently, focal salvage (FS) instead of whole-gland or total salvage (TS) is being investigated, to reduce severe toxicity associated with cumulative radiation dose. Differences in urethral and bladder dosimetry and constraints to reduce late (>90 days) genitourinary (GU) toxicity are presented here.

Material and Methods: Dosimetry on intraoperative ultrasound (US) of 20 FS and 28 TS patients was compared. The prostate, bladder, urethra (figure 1) and bulbomembranous (BM) urethra were delineated. Toxicity was assessed using the CTCAE version 4.0. Dose constraints to reduce toxicity in TS patients were evaluated with receiver operating characteristic (ROC) analysis.

Figure. 1. Urethral (= yellow) D10 difference for TS (A) compared FS (B). The urethral D10 in A was 270 Gy versus 100 Gy in B.

Results: FS I-125 BT significantly reduces bladder and urethral dose compared to TS. Grade 3 GU toxicity occurred once in the FS group. For TS patients late severe \geq grade 3) GU toxicity was frequent (38% in the total 61 patients and 56% in the 27 analyzed patients). TS patients with \geq grade 3 GU toxicity showed higher bladder D2cc than TS patients without toxicity (median 43 Gy) ($p = 0.02$). The urethral V100 was significantly higher in TS patients with several toxicity profiles: \geq grade 3 urethral strictures, \geq grade 2 urinary retention and multiple \geq grade 2 GU toxicity events. Dose to the BM urethra did not show a relation with stricture formation. ROC-analysis indicated a bladder D2cc <70 Gy to prevent \geq grade 3 GU toxicity (AUC 0.76, 95%CI: 0.56-0.96, $p = 0.02$). A urethral V100 <0.40 cc (AUC from 0.73-0.91, $p = 0.003-0.05$) could prevent other late GU toxicity.

Conclusion: FS I-125 BT reduces urethral and bladder dose significantly compared to TS. With TS, there is an increased risk of cumulative dose and severe GU toxicity. Based on these findings, bladder D2cc should be below 70 Gy and urethral V100 below 0.40 cc.

PO-0975

External beam radiotherapy with HDR brachytherapy boost in prostate cancer: 5- and 8-year results

R. Soumarova^{1,2,3}, T. Blažek¹, L. Homola¹

¹Hospital Nový Jičín a.s., Department of radiation and clinical oncology, Nový Jičín, Czech Republic

²Agel Research and Educational Institute- o.p.s. - Nový Jičín Branch- Nový Jičín Hospital a.s., Oncology Department, Nový Jičín, Czech Republic

³Medical Faculty- Ostrava University, Department of Internal Medicine, Ostrava, Czech Republic

Purpose or Objective: To report 5 and 8-year clinical outcomes, early and late complications in 226 patients with prostate cancer treated with high-dose-rate brachytherapy (HDR-BT) in combination with external-beam radiotherapy (EBRT).

Material and Methods: Between 2004 and 2010, 226 patients underwent HDR-BT in combination with EBRT as a treatment for their low, intermediate or high risk prostate cancer. The HDR-BT procedure was performed using ultrasound-based transperineal implantation. The total HDR-BT dose was 16 - 18Gy in 2. The EBRT technique used by treatment was 3D-CRT (70.3%) or IGRT/IMRT (29.7%) with daily correction of set up errors. Total dose of EBRT for low risk patients was 45Gy in 25 fractions of 1.8Gy within 5 weeks. For intermediate and high-risk patients the dose was 50.4Gy in 28 of 1.8Gy within 5 weeks. Patients were stratified by risk factors in to risk groups - 67 (29.5%) low, 87 (38.5%) intermediate and 72 (32.0%) high risk patients. Neoadjuvant hormonal therapy was applied in patient of intermediate or high risk of recurrence. High risk patients received adjuvant hormonal therapy.

Results: 5-year results after a mean follow-up of 70 months of the 226 patients the freedom from biochemical failure was 92.5%. 17 patients (7.5%) showed prostate specific antigen progression according to the Phoenix definition. In 9 patients clinical progression (bone or lymph node metastases) was documented. 8-year results after a mean follow up of 96 months of the 130 patients the freedom from biochemical failure was 82%. 23 patients (18.0%) showed prostate specific antigen progression. In 11 patients clinical progression was documented. Cancer specific survival during 5-year and 8-year follow up was 99.1% and 96.8% respectively. Toxicity was scored using the EORTC/RTOG score system. During follow up we haven't observed any consequential toxicity or relationship between acute and late toxicity respectively. Higher incidence of GU and GIT toxicity was observed in patients treated by 3D-CRT technique. Acute and late gastrointestinal toxicity (GIT) was very low. Toxicity grade 2 was observed in 1.3%. No grade 3 or 4 GIT toxicity was observed. Acute GU toxicity in most cases was grade 1 (40.2%) or grade 2 (10.6%). Late GU toxicity was also in most cases grade 1 (32.7%) or grade 2 (10.1%). Grade 3 toxicity was observed only in 2.2%. Grade 4 toxicity didn't occurred. We have detected a trend that higher grade late GU toxicity was observed after longer period of treatment than lower grade. Mean time of occurrence for grade 3 and 2 was 64 and 23 months respectively, compared to mean time 12 months for grade 1.

Conclusion: Combination of external beam radiotherapy with high-dose-rate interstitial brachytherapy boost is safety and effective option in treatment localized prostate cancer. Our results show a low incidence of acute and late complications with favorable oncologic outcome after 5 and 8 year follow up.

PO-0976

HDR prostate brachytherapy: 3-D planned simultaneous integrated boost to the peripheral zone

R. Hepp¹, L. Herberholz¹, A. Petry², T. Eggert³, L. Piotrowski², C. Morgenstern¹, G. Schabl¹, R. Galalae¹

¹Evangelische Kliniken Gelsenkirchen, Klinik für Radioonkologie und Strahlentherapie, Gelsenkirchen, Germany

²Gemeinschaftspraxis Urologie Gelsenkirchen, Urologie, Gelsenkirchen, Germany

³Urologische Praxis, Urologie, Haltern am See, Germany

Purpose or Objective: Radiotherapy (RT) is one of the most important curative options for treating localized prostate cancer (PC). At low α/β ratio of prostate tumors, HDR-brachytherapy (HDR-BT) represents a way to perform an absolute and radiobiologic dose escalation. When using 3-D real-time planning systems it is possible to optimize treatment plans generating dose distributions with an integrated boost (SIB) to peripheral zone (PZ) without substantially increasing the dose to the organs at risk (OAR), especially the urethra.

Aim: to analyze the dosimetric parameters (DP) and the acute toxicity of 30 consecutive patients (pts) treated with HDR-BT and a SIB to the PZ.

Material and Methods: From January 2014 to September 2015, 20 pts with intermediate/high risk PC were treated with combined external beam RT (EBRT 50 Gy/25 f) and HDR-BT (2 x 9 Gy in the 2nd and 4th week of the EBRT). In the same period, 10 pts with low risk PC were treated with HDR-BT monotherapy (3 x 11.5 Gy, every 2nd week). In all implants a SIB of 20% (EBRT+HDR-BT) or 15% (HDR-BT monotherapy) to the PZ was planned. Equivalent dose at 2 Gy / fraction (EQD2), using α/β of 1.5 for target volumes and 3 for OAR, were calculated.

Results: Median age was 68 years (range 56-76). DP are presented in table 1. In 33/40 implants in pts with EBRT+HDR-BT dose-escalation to the PZ was reached (range 6 -44% of the prescribed dose). The median V100 for the prostate was 94.5% (CI $\pm 1.6\%$). In 26/30 of the implants in pts with HDR-BT monotherapy the intended dose-escalation was reached (range 6 - 40% of the prescribed dose). The median V100 for the prostate was 92.8% (CI $\pm 2.2\%$). No grade toxicity was observed. Grade 2 toxicity was 13% and resolved within 1 month in 90% of the pts.

Table 1. Dose distribution parameters

Dose distribution parameters	Median	95 CI (%)	Dose distribution parameters	Median	95 CI (%)
D90 Prostate (Gy)	9.8	0.2	D90 Prostate (Gy)	11.8	0.4
D90 Boost (Gy)	12.0	0.3	D90 Boost (Gy)	14.0	0.3
Boost Factor (%)	123.9	3.6	Boost Factor (%)	119.1	3.6
D2cc Rectum (Gy)	6.6	0.4	D2cc Rectum (Gy)	7.6	0.6
D2cc Bladder (Gy)	5.4	0.4	D2cc Bladder (Gy)	6.5	0.6
D0.1cc Urethra (Gy)	11.5	0.4	D0.1cc Urethra (Gy)	14.9	0.4
EQD2 Prostate (Gy α/β 1.5)	112.1	2.1	EQD2 Prostate (Gy α/β 1.5)	135.6	6.4
EQD2 Boost (Gy α/β 1.5)	141.2	3.6	EQD2 Boost (Gy α/β 1.5)	185.4	6.2
EQD2 Rectum 2 cc (Gy α/β 3)	75.1	2.1	EQD2 Rectum 2 cc (Gy α/β 3)	51.3	4.9
EQD2 Bladder 2 cc (Gy α/β 3)	67.6	2.4	EQD2 Bladder 2 cc (Gy α/β 3)	39.4	5.0
EQD2 Urethra 0.1 cc (Gy α/β 3)	117.2	3.1	EQD2 Urethra 0.1 cc (Gy α/β 3)	154.9	6.0

Combined EBRT + HDR-BT (n: 20 pts, 40 implants)

HDR-BT monotherapy (n: 10 pts, 30 implants)

Conclusion: HDR-BT with SIB to the PZ is feasible in both combined and monotherapy settings. Acute toxicity was mild. Local control and late toxicity profile should be investigated prospectively.

PO-0977

Ten year patient reported Quality of Life following I-125 prostate brachytherapy monotherapy

A. Henry¹, B. Sethugavalar¹, T. Witteveen¹, B. Al-Qaisieh¹, P. Bownes¹, J. Smith¹, B. Carey¹, K. Franks¹, D. Mitchell¹, D. Bottomley¹

¹St James Institute of Oncology, Clinical Oncology, Leeds, United Kingdom

Purpose or Objective: This prospective longitudinal study quantifies patient reported Quality of Life (QoL) pre-treatment and up to ten years following permanent I-125 prostate brachytherapy delivered as monotherapy in a single institution

Material and Methods: 120 patients were asked to complete the Expanded Prostate Cancer Index Composite (EPIC) questionnaire, a comprehensive validated QoL tool designed to evaluate patient function and bother after prostate cancer treatment. Men completed the EPIC questionnaire before brachytherapy and at 8 time points after treatment (6 weeks; 6,10 and 18 months; 2,3,5, and 10 years). At each time point clinically relevant small, moderate and severe declines in QoL were defined as 0.2-0.5 times SD, 0.5-0.8 times SD and > 0.8 times SD of baseline function for each of urinary, bowel and sexual domains respectively.

Results: Response rates in the first two years were >90% but thereafter dropped to 75% at 5 years and 48% at 10 years. 50 patients (41.6%) responded at all stages. Maximal deterioration in mean urinary and sexual summary scores was noted 6 weeks after implant with severe urinary symptoms and moderate bowel/sexual symptoms at that point. At 6 months urinary and bowel QoL had improved to mild impairment which then fully resolved by 10 months. Sexual QoL remained mildly impaired throughout the 10 years. At 10 years new mild impairment of urinary and bowel QoL was also found.

Conclusion: Clinically mild changes in urinary, bowel and sexual QoL are found 10 years after I-125 monotherapy. The impairment in sexual function persists from treatment but urinary and bowel symptoms are new at 10 years and may be either a late effect of brachytherapy or due to increasing age.

PO-0978

Image-guided impact on the brachytherapy prostate treatment quality.

V. Carboneschi¹, V. Ravaglia², M. Paoluzzi³, M. Mignogna⁴, M. Mignogna¹

¹Ospedale San Luca, Radioterapia, Lucca, Italy

²Ospedale San Luca, Fisica Sanitaria, Lucca, Italy

³Ospedale San Luca, Urologia, Lucca, Italy

⁴Student, University, Pisa, Italy

Purpose or Objective: Purpose: to evaluate the impact of the "image-guided" technology evolution on the implant quality in the interstitial brachytherapy with 125I seeds in the treatment of the prostate cancer.

Material and Methods: Methods and materials: from April 2004 until May 2014 we treated 306 patients with prostate cancer with permanent brachytherapy implants of radioactive 125I seeds with a prescription dose of 145 Gy. The technology is changed during the years and we identify 4 groups relative to each different image-guided method. Group 1: 107 implants from April 2004 until January 2007 using ultrasound guide in the transverse plane, fluoroscopic check and planning with 3D Prowess TPS; Group 2: 76 patients until October 2008 with Variseed 8.0 TPS and ultrasound both for transverse and longitudinal guide; Group 3: 43 patients until February 2010 with a "real-time" ultrasound guide both for transverse and longitudinal guide; Group 4: 80 patients with a new delivery system to assembly seed trains (Quicklink, BARD). For each group we calculate the mean D90 in the "postplanning" (evaluated on CT images after 60 days) and the difference between planning and postplanning in terms of D90 and V100 (dose fall-off). In the last group we evaluate also the difference, in terms of D90, V100 and maximum urethra dose between the theoretical planning and the effective implant, evaluated in the operating room on the ultrasound images at the end of the surgery.

Results: Results: in the 4 groups the results in terms of D90 are respectively $123\pm 32\text{Gy}$, $146\pm 28\text{Gy}$, $153\pm 23\text{Gy}$, $166\pm 17\text{Gy}$, as shown in Figure 1. The dose fall-off in terms of D90 is respectively 58Gy, 43Gy, 37Gy, 21Gy (as shown in Figure 2) and in terms of V100 17%, 10%, 8%, 4%. In the last group the mean theoretical D90 and V100 are 187Gy and 99%, against a real implant evaluation of 186Gy and 99% and the maximum urethra dose is 210Gy in the planning and 219Gy at the end of the implant. In the 30% of the patients of the "real-time" group we changed the number of seeds or needles composition during the implant, to reach the desired constraints and PTV coverage.

Conclusion: Conclusion: our work shows the impact of the "image-guided" technology evolution on the dose fall-off both in terms of D90 and V100. Moreover, we show how the "real-time" method allows to change the "theoretical" plan during the implant, to reach the recommended constraints and PTV coverage [1].

PO-0979

LTB control and toxicity for Favorable and Intmed Risk pts using real time IO-PSI prostate BT alone

A. Raben¹, A. Sarkar¹, A. Hanton², H.C. Chen¹, F. Mourtada¹, A. Glick³, M. Lobis³, S. Terranova³, T. Desperito³, D. Cozzolino³

¹Helen F. Graham Cancer Center, Radiation Oncology, Newark- DE, USA

²University of Pennsylvania, Department of Nursing, Philadelphia, USA

³Brandywine Urology Consultants, Urology, Newark, USA

Purpose or Objective: We initially reported biochemical control rate of 97% at 4 years of followup (Brachytherapy, 2009), which highlighted our methodology of limiting needle trauma, relying on Intra-operative, Real-Time computer assisted IO (Inverse Optimization) to reduce the number of sources and total activity without compromising dosimetric quality. This update was performed to confirm our earlier favorable BFFS outcomes.

Material and Methods: Between 2001 and 2013, 491 patients underwent real-time IO-PSI. Only patients with a minimum of 2 years of follow-up treated without supplemental IMRT were the subject of this analysis (N=315). Our dose objectives and constraints for real-time IO-PSI have previously been published and remain unchanged. The main dose objective intra-operatively was to achieve a V100 > 95% (Volume receiving > 95% of the prescribed dose). Patients were implanted with either ¹²⁵I (PD=145 Gy) or ¹⁰³Pd (PD =120 Gy). Toxicity was prospectively scored using the Radiation Oncology Group Toxicity scale and the International Prostate Symptom Score questionnaire. Biochemical control was determined using the nadir+2 ng/ml definition.

Results: The mean and median followup was 58 and 54 months respectively (range: 24-110 months). The NCCN risk classification for FR and IR patients were used. ¹²⁵I sources were used for 93% of the implants, and ¹⁰³Pd for 7%. 89% of patients presented with FR disease while 10% presented with IR, and in 2 cases HR. (1%). The median number of sources and total activity implanted were 65 and 999MBq, respectively. The median prostate volume implanted was 36

cc. The median V100 was 95%. Absolute BNED was 97%. The 10 year actuarial probability of biochemical control rate for all patients was 95%, with no difference observed between FR or IR patients (97% and 95% respectively) Late Gu and GI Grade 2 and higher toxicity was very low. With a minimum follow-up for 2 years, the late Grade 2 and Grade 3 GU toxicity was 19% and 1% respectively. The late Grade 2 and 3 rectal bleeding rate was 1% and 0% respectively, with no Grade 4 toxicity observed.

Conclusion: With extended follow-up of 10 years, real-time IO-PSI demonstrated excellent biochemical control rates with low incidence of toxicity confirming the validity of our original hypothesis and methodology of Inverse planning in real time for PSI, and comparing favorably to other alternatives at lower cost in the USA.

Inhibition of STAT3 enhances the radiosensitising effect of Temozolomide in Glioblastoma model

I.A. Kim¹, T. Han², B. Cho³, E. Choi³, S. Song², S. Paek⁴

¹Seoul National Univ. Bundang Hospital, Radiation Oncology, Seongnam- Gyeonggi-Do, Korea Republic of

²Seoul National University, Graduate School of Medicine, Seoul, Korea Republic of

³Seoul National Univ. Bundang Hospital, Medical Science Research Institute, Seongnam- Gyeonggi-Do, Korea Republic of

⁴Seoul National University Hospital, Neurosurgery, Seoul, Korea Republic of

Purpose or Objective: Despite aggressive treatment with radiation therapy plus temozolomide (TMZ), the prognosis for glioblastoma remains poor. We investigated the potential of targeting signal transducer and activator of transcription-3 (STAT3) to improve the therapeutic outcome of glioblastoma.

Material and Methods: We evaluated the preclinical potential of a STAT3 inhibitor, Cpd188 combined with temozolomide and radiation in vitro assays using two established glioblastoma cell lines (U251, U87) and two patients-derived glioblastoma cell lines (GBL12, GBL28) and in vivo studies using nude mice bearing intracranial U251 xenografts.

Results: Cpd188 potentiated the radiosensitizing effect of TMZ in U251 cell which has high levels of p-STAT3 expression. Increased radiosensitizing effects of TMZ were associated with impaired DNA damage repair, apoptosis and the reversion of epithelial-mesenchymal transition (EMT). Cpd188 delayed in vivo tumor growth both alone and in combination

with radiation and TMZ. We also confirmed the radiosensitizing effect of Cpd188 of GBL28 cell which was originated from a patient with high level of STAT3 expression and unmethylated MGMT.

Conclusion: Targeting STAT3 using Cpd188 could be a viable therapeutic approach to improve the outcome of current standard therapy for glioblastoma patients having high p-STAT3 expression regardless of MGMT methylation status. Work supported by the grant (#2013R1A1A2074531) from the Ministry of Science, ICT & Future Planning to In Ah Kim.

PO-0981

Activation of immune cells and enhanced efficacy of radiotherapy by anti-TIP1 antibodies in cancer
D. Hallahan¹, V. Kapoor², D. Thotala², H. Yan²

¹Washington University School of Medicine, Radiation Oncology, St. Louis, USA

²Washington University, Radiation Oncology, St. Louis, USA

Purpose or Objective: Purpose: Stress responses in cancer cells are exaggerated over that of normal tissues include signal transduction pathways such as GRP78, PKC, PLC, Rho and others. Many of these regulators of cell viability translocate of the cell membrane during the stress response. Mechanisms of protein transport include motor and scaffold proteins such as Tax Interacting protein-1 (TIP-1), which translocates to the surface of the cell membrane of cancer cells following exposure to ionizing radiation. TIP1 is a scaffold protein that moves proteins to and from the cell membrane. It is over expressed in poor prognosis cancers.

Material and Methods: Methods: We studied radiation induction of TIP1 by western immunoblot and flow cytometry. We used siRNA to knock down TIP1 in human GBM and NSCLC cell lines. We utilized Anti-TIP1 antibodies administered IV to mouse models of human cancer xenografts. We measured tumor growth delay. To assess the ability of mouse NK cells to target and kill anti-TIP1 antibody-opsionized lung cancers, we cultured H460, or LLC cells in 96-well plates at 37°C. After 40 hr., cells were irradiated with 3 Gy (or shield) to induce TIP1 expression. Cells were continued in culture for 4 hr. 10 µg/ml 2C6F3, NMIgG, or media were added and incubated for an additional 2 hr. Murine NK cells were added and incubated for 16 hr. Cytotoxicity was then determined by cancer cells cytolysis. anti-TIP1 antibodies (Ab) that bind to the PDZ domain of this protein were administered IV to mice bearing irradiated human cancers.

Results: Results: Membrane protein western blots showed a significant increase in the expression of TIP-1 protein at 4 and 24 hrs following irradiation with 3 Gy as compared to 0 Gy untreated control tumors. Significant levels of the TIP-1 membrane protein were also present in the irradiated tumors, but not in untreated controls, as demonstrated by immunohistochemistry. Near-infrared imaging studies showed significant targeting and binding of anti-TIP-1 Ab to irradiated tumors compared to untreated tumors and IgG controls at 72 hrs. Knockdown of TIP1 and blocking Abs that bind to the PDZ domain of TIP1 enhance cytotoxicity in cancer but not normal tissues. Anti-PDZ-domain Abs significantly enhanced cytotoxicity in D54, H1299, H460 and A549 human cancer cells. We studied the mechanisms by which the Abs enhance cytotoxicity and improve tumor control. Abs activate caspases 2, 3/7 in irradiated cancers. Moreover, Anti-TIP1 antibodies bound to the surface of cancer cells activated immune effector cells. In mouse models of human cancers, Anti-TIP1 Abs enhanced tumor growth delay after radiotherapy when administered IV to mouse models of human cancer.

Conclusion: Conclusion: Anti-TIP1 antibodies activate immune effector cells and enhance the efficacy of radiotherapy specifically in cancer without enhancing the response in normal tissues. TIP1 is a molecular target for the development of novel radiation sensitizing agents.

PO-0982

Therapeutic potential of the YB-1/Notch-3 interaction in prostate cancer

N. McDermott¹, A. Meunier¹, C. Haynes², A. Flores², A. O'Callaghan¹, L. Marignol¹

¹Division of Radiation Therapy- School of Medicine, Radiation Therapy, Dublin, Ireland Republic of

²Mount Sinai School of Medicine, International Health, New York, USA

Purpose or Objective: YB-1, a protein increasingly associated with tumour progression and treatment resistance in prostate cancer, is the only known ligand of the Notch-3 receptor. The Notch pathway is an evolutionarily conserved signaling system whose inhibition is under scrutiny as a novel therapeutic approach. We have previously identified elevated Notch-3 mRNA expression in high grade prostate cancer. This study investigated the anti-tumour properties of the YB-1 inhibitor Fisetin, a dietary flavonoid, in an isogenic model of radioresistant prostate cancer cells *in vitro*.

Material and Methods: An isogenic model of radioresistance was generated in 22Rv1 prostate cancer cells through exposure to 30 x 2-Gy dose fractions. YB-1 and Notch-3 expression were determined by western blotting in parent, aged-matched and radioresistant cells following irradiation (5Gy) and/or 60µM Fisetin treatment (24hrs). Patterns of expression were related to modification in cell cycle distribution through analysis of PI staining by flow cytometry and clonogenic survival. The anti-tumour effects of fisetin were compared to those of two notch inhibitors DAPT and Batimastat.

Results: Following a cumulative total dose of 60Gy, the resulting subline RR22Rv1 was associated with a significant increase in clonogenic survival (1.3 fold increase in survival after 2Gy and 2.2 fold increase after 10Gy) when compared to both parent 22Rv1 and aged-matched controls. YB-1 was detected in the cytoplasm of all three lines. Expression levels were elevated following irradiation (4Gy) in RR22Rv1. Radiation (5Gy) inhibited activation and nuclear translocation of Notch-3. Fisetin treatment led to a loss of Notch-3 cytoplasmic expression in RR22Rv1 cells. DAPT and Batimastat did not affect clonogenic survival of 22Rv1 and RR22Rv1 cells. Fisetin induced G2 cell cycle arrest and significantly reduced clonogenic survival in untreated and 5-Gy irradiated parent and RR22Rv1 cells.

Conclusion: This study identifies potential role of the YB-1-Notch-3 interaction in the radioresistance of prostate cancer cells, and highlights fisetin as a novel therapeutic agent for the management of prostate cancer.

PO-0983

Nanoparticle mediated tumor vascular disruption: A novel strategy in radiation therapy

S. Kunjachan¹, A. Detappe², R. Kumar³, S. Sridhar³, G.M. Makrigiorgos², R. Berbeco²

¹Harvard Medical School- Brigham and Women's Hospital- Dana-Farber Cancer Institute, Department of Radiation Oncology- BWH/DFCI/HMS, Boston, USA

²Harvard Medical School- Brigham and Women's Hospital- Dana-Farber Cancer Institute, Radiation Oncology- BWH/DFCI/HMS, Boston, USA

³Nanomedicine Science and Technology Center- Northeastern University, Department of Physics, Boston, USA

Purpose or Objective: More than 50% all cancer patients receive radiation therapy. Despite recent innovations, clinical delivery of curative radiation doses is strictly restricted by the proximal healthy tissues. Chemical/biological agents to augment the radiosensitization of cancer cells are limited by severe off-target toxicity concerns. We propose a dual-targeting strategy using tumor vascular-targeted gold nanoparticles (which amplify radiosensitization) combined with the conformal image-guided radiation therapy to induce tumor vascular disruption. This is a unique concept with a clear translational path.

Material and Methods: Chemically synthesized, RGD-/PEG-functionalized gold nanoparticles (RGD:AuNP; $\approx 2-3$ nm) were characterized using STEM, TEM, and LIBS imaging. Following clonogenic assay, radiation damage was induced in Panc1 xenografts with 10 Gy and 220 kVp (Xtrahl, Inc). γ -H2AX, 3D-(confocal) vessel imaging and IHC were performed.

Results: Tumor vessel-targeted gold nanoparticles were subjected to conformal image-guided irradiation in Panc-1 tumor xenograft to induce tumor vascular disruption. By specifically targeting the early angiogenic tumor endothelium, RGD:AuNP circumvent the dense stromal diffusion pathways that often limits the penetration and permeation of anti-cancer drugs/ nanoparticles to the cancer cells - a limitation of current radiosensitization approaches. *In vitro* testing in HUVEC displayed a 3-fold difference ($***P < 0.0001$) in radiation damage in the +RGD:AuNP/+IR compared to the controls. More to it, the sub-millimeter accuracy of image-guided radiation therapy facilitated improved therapeutic efficacy (95%-100% tumor dose distribution) and less off-target toxicities. Quantification of the DNA-strand breaks (by γ H2AX) showed ≈ 3 -fold increase ($P < 0.001$) in the radiation specific DNA damage in the 'nanoparticle-radiation' cohort (+RGD:AuNP/+IR: 57%) compared to the 'radiation' group (-RGD:AuNP/+IR: 19%) and almost ≈ 10 -fold difference ($P < 0.001$) compared to (+RGD:AuNP/-IR: 6% and -RGD:AuNP/-IR: 6%).

Conclusion: This dual-targeting strategy holds great translational potential in radiation oncology. The resulting vascular disruption substantially improved the therapeutic outcome and subsidized the radiation/ nanoparticle toxicity, extending its utility to intransigent/ non-resectable tumors that barely respond to standard therapies. This abstract presents the first in-depth experimental investigation of tumor vascular disruption with nanoparticles, a novel strategy in radiation therapy.

PO-0984

Combined inhibition of Chk1 and Wee1 kinases for cancer treatment

S. Hauge¹, G. Hasvold¹, M. Joel¹, C. Naucke¹, G.E. Rødland¹, R.G. Syljuåsen¹

¹DNR - Norwegian Radium Hospital, Department of Radiation Biology, Oslo, Norway

Purpose or Objective: Inhibition of checkpoint kinases Wee1 or Chk1 causes G2-checkpoint abrogation and mitotic catastrophe, particularly in p53 defective tumors. Based on this, Wee1 and Chk1 inhibitors are currently in clinical trials, combined with radiation or chemo-therapy. However, our previous work has shown that inhibition of Wee1 or Chk1 also causes DNA breakage in S-phase, largely due to high Cyclin-Dependent-Kinase (CDK)-activity followed by unscheduled replication initiation. Furthermore, recent work by others has shown synergistic anti-cancer effects after combined Wee1 and Chk1 inhibition. The aim of this study was to investigate whether S-phase DNA damage may contribute to the synergistic effects after combined Chk1/Wee1 inhibition.

Material and Methods: Osteosarcoma U2OS and lung cancer A549, H460 and H1975 cells were exposed to the Wee1 inhibitor MK1775 and/or the Chk1 inhibitors AZD7762, LY2606368, MK8776 and UCN01. The DNA damage marker γ H2AX was analyzed in S-phase cells by flow cytometry. DNA damage signaling and inhibitory phosphorylation of CDK1 and CDK2 were examined by immunoblotting, and cell survival by clonogenic survival assays. CDK activity was measured in S-phase cells by a novel flow cytometry barcoding method. In this method, CDK-dependent phosphorylations (antibodies to phospho-BRCA2 S3291, phospho-bMyb T487 and phospho-Mpm2) versus DNA content (Hoechst staining) were examined in individual cells. Barcoding with Pacific Blue was included to reduce sample-to-sample variations. Loading of the replication initiation factor CDC45 was measured by a similar flow cytometry method and by immunoblotting after removal of unbound proteins by extraction with salt and detergent.

Results: We observed a strong synergy in induction of S-phase damage after combined Wee1 and Chk1 inhibition. Also, clonogenic survival was strongly decreased after the combined treatment. Surprisingly, this synergy could not be explained by increased CDK-activity, as S-phase CDK-activity did not correlate with induction of DNA damage after Wee1 and Chk1 inhibition. Wee1 inhibition caused a bigger increase in CDK-activity than Chk1 inhibition. However, Chk1 inhibition caused more S-phase damage and loading of the replication factor CDC45. The combination of Wee1 and Chk1 inhibitors further increased the CDC45 loading, and the extent of CDC45 loading correlated with DNA damage induction.

Conclusion: We have shown for the first time that combined Wee1 and Chk1 inhibition causes synergistic S-phase DNA damage, due to distinct effects of Wee1 and Chk1 kinases in regulation of CDK activity and CDC45 loading, respectively. This synergy can explain the synergistic anti-cancer effects obtained by simultaneous Chk1/Wee1 inhibition. We propose that combined Chk1/Wee1 inhibition may be useful together with radiation therapy to eliminate radioresistant S-phase cells.

PO-0985

Anti-GRP 78 antibodies bind specifically to cancers enhance efficacy of radiotherapy in cancer

D. Dadey¹, V. Kapoor¹, D. Thotala¹, D. Hallahan¹

¹Washington University, Radiation Oncology, St. Louis, USA

Purpose or Objective: Purpose: Glioblastoma demonstrates progression of disease within the high dose region of radiotherapy, in nearly all cases. The physiologic response within glioblastoma to radiation is in part dependent upon a pro-survival signaling. GRP78 was first described to regulate cellular stresses, including hypoglycemia, hypoxia and the ER stress response. GRP78 is an important regulator of cell stress, and binds to several pro-survival proteins. Antagonists to GRP78 include Kringle-5 and PAR4 which induce apoptosis in tumor vasculature endothelium and cancer cells. The molecular events that result from the ER stress response can enhance cell viability. GRP78 is overexpressed in poor prognosis cancers and is a molecular therapeutic target in poorly differentiated cancers.

Material and Methods: Methods: We studied radiation induction of GRP78 by western immunoblot and flow cytometry. We used siRNA to knock down GRP78 in human GBM and NSCLC cell lines. In order to study the potential relationship between radiation dose and induction of ATF6 activity, we treated D54 cells with 3 Gy and 6 Gy and analyzed GRP78 protein expression 48h after irradiation. We utilized Anti-GRP78 antibodies administered IV to mouse models of human cancer xenografts. We measured tumor growth delay using subcutaneous implants of human cancer xenografts.

Results: Results: We found that radiation induces the expression of GRP78 in glioblastoma. Antibodies to GRP78 enhanced radiation-induced cytotoxicity in glioblastoma but not normal cells. We found that radiation induced GRP78 expression is regulated through the ER stress response, and that ATF6 is responsible for the transcriptional induction of GRP78. Knockdown of ATF6 abrogates GRP78 induction and enhanced cytotoxicity from radiation. Moreover interruption of GRP78 signaling enhances therapeutic effects of radiation. GRP78 antibodies enhanced cytotoxicity from radiation in human glioblastoma and NSCLC cell lines. We found that the levels of GRP78 protein were elevated at the 48 and 72h time points. Knockdown of ATF6 was sufficient to abrogate GRP78 induction. We observed dose dependent increases in GRP78 levels, which were reproducible when the experiment was repeated with LN827 cells. Similar changes were observed in GRP78 mRNA levels 48h after IR, where a 75% and 100% increase was observed in D54. Anti-GRP-78 antibodies bind specifically to irradiated cancers enhanced the efficacy of

radiotherapy in human cancer models in vitro and in mouse xenografts.

Conclusion: GRP78 is a molecular target for the development of novel radiation sensitizing agents. Anti-GRP78 antibodies enhance the efficacy of radiotherapy when administered IV to mouse models of human cancer.

MiR-143 inhibits tumour progression by targeting STAT3 in esophageal squamous cell carcinoma

B. Li¹, S.C.H.&.I. Jia liu¹, S.C.H.&.I. Yu Mao¹

¹Shandong Cancer Hospital and Institute, Departments of Radiation Oncology Chest Section- Shandong Cancer Hospital and Institute, Jinan, China

Purpose or Objective: The objective of this study was to investigate the biological role of miR-143 in esophageal squamous cell carcinoma (ESCC) progression and its underlying mechanism.

Material and Methods: Surgical tumor tissue samples were obtained from 40 patients. MiR-143 and STAT3 protein expression levels in these clinical samples and three ESCC cell lines were determined by quantitative RT-PCR and western blot. The relationship between expression level of miR-143 and clinical parameters were explored by one-way ANOVA. The specific targeting site of miR-143 in the 3'-UTR of STAT3 was identified using dual-luciferase reporter assays. Then, the effects of ectopic miR-143 or STAT3 expression on proliferation, cell cycle distribution, migration and invasion were determined in colony-forming assay, flow cytometry and transwell assay. The effect of miR-432 on tumor progression in vivo was determined by performing tumor formation assay in nude mice. The role miR-143 in regulating cell cycle signaling, epithelial-mesenchymal transition and MMP up-regulation through repressing STAT3 was explored by analyzing the expression level of the downstream proteins.

Results: MiR-143 expression was downregulated in 90% of the ESCC clinical samples and its expression level was associated with the lymph node metastasis(LNM), invasion and TNM stage in ESCC patients. Functional experiments showed that ectopic expression of miR-143 could inhibit tumor cell proliferation, migration and invasion by suppressing STAT3 in vitro. Animal experiments showed that the size of subcutaneous tumors derived from miR-143 overexpressing cells were significantly smaller than that of empty vector expressing cells. Further studies verified that miR-143 might regulate cell cycle, EMT and MMP up-regulation by targeting STAT3 and hence, lead to the suppression of ESCC cell proliferation, migration and invasion.

Conclusion: Our study showed that miR-143 could act as a tumor suppressor through the inhibition of proliferation, migration and invasion by directly targeting STAT3 and subsequently mediates the downstream proteins. Thus, miR-143 has significant value in clinical and may serve as a prognostic marker and therapeutic target in the future.

MiR-432 inhibits tumor progression by targeting IGSF3 in esophageal squamous cell carcinoma

J. Liu¹, Y. Mao¹, B. Li¹

¹Shandong Cancer Hospital and Institute, Department of Radiation Oncology- Shandong Cancer Hospital and Institute, Jinan, China

Purpose or Objective: The objective of this study was to investigate the biological role of miR-432 in esophageal squamous cell carcinoma (ESCC) progression and its underlying mechanism.

Material and Methods: Surgical tumor specimens and adjacent tissue samples were obtained from 40 patients. Pearson correlation coefficients and linear regression model were used to explore the bivariate correlations between miR-432 and IGSF3 expression levels and one-way ANOVA were used to estimate the relationship between expression level of miR-432 and clinical parameters. Then the effects of ectopic miR-432 or IGSF3 expression on proliferation and apoptosis were determined using miR-432 over-expression or knockdown cells in colony-forming assay and flow cytometry, and the effects on cell migration and invasion were determined using a transwell assay. On the other hand, bioinformatic analysis were performed to assess the relationship between IGSF3 and miR-432, and this relationship was identified using a dual-luciferase reporter assay. Finally, the biological consequences of miR-432-mediated suppression of IGSF3 expression in ESCC cell lines were also determined by performing colony-forming assay, flow cytometry and transwell assay.

Results: MiR-432 expression was downregulated in 93% (37/40) of the ESCC clinical samples and its expression level was associated with LNM and TNM stage in ESCC patients. Functional experiments showed that over-expression of miR-432 induced an inhibition of cell proliferation, promotion of apoptosis and suppression of cell migration and invasion in vitro by targeting IGSF3.

Conclusion: In conclusion, our results established a functional link between miR-432 and IGSF3 expression in esophageal cancer, demonstrating that IGSF3 was directly repressed by miR-432, which subsequently effects the tumor biological process. Collectively, this finding not only helped us understand the molecular mechanism of esophageal carcinogenesis, but also gave us a strong rationale to further investigate miR-432 as a potential biomarker and therapeutic target for esophageal cancer.

PO-0988

Combined treatment strategies for microtubule interfering agent-resistant tumors

A. Broggin-Tenzer¹, A. Sharma¹, S. Bender¹, K. Nytko-Karouzakis¹, M. Pruschy¹

¹University Hospital Zürich, Department of Radiation Oncology, Zurich, Switzerland

Purpose or Objective: Tumor cells are the major targets for classic anticancer treatment modalities. At the same time other cell types within the tumor microenvironment are also targeted and co-determine the treatment response. Resistances to specific treatment modalities are therefore not only linked to the mutated genetic background of the tumor cells but also to the interaction of tumor cells with the tumor microenvironment. Thus targeting of important elements of the microenvironment is a promising strategy to overcome treatment resistances in solid tumors. Here we mechanistically investigate in different clinically relevant microtubule-stabilizing agent (MSA)-refractory tumor models the potency of combined treatment modalities of MSAs, inhibitors of angiogenesis and ionizing radiation to overcome MSA-resistance.

Material and Methods: Rationally designed single and combined treatment regimens of ionizing radiation, microtubule stabilizing (taxane, epothilone) and destabilizing agents and anti-angiogenics compounds were investigated in genetically defined MSA-sensitive and MSA-resistant lung and colon adenocarcinoma cell lines in vitro and in the corresponding tumor xenografts in vivo.

Results: While MSAs potently inhibited A549wt and endothelial cell proliferation, no anti-proliferative effect was observed in the corresponding mutated MSA-resistant tumor cells. Importantly, MSAs did not block anymore pro-survival auto- and paracrine signaling from resistant tumor cells by downregulation of HIF1-alpha transcriptional activity and subsequent secretions of HIF-1alpha-mediated growth factors and cytokines like VEGF. Thereby continuous pro-survival

signaling from these resistant tumor cells resulted in an additional level of treatment resistance towards the combined treatment modality of MSAs and ionizing radiation in vivo. However, combined treatment of MSAs with clinically relevant mTOR-signaling- or VEGF-antagonists strongly re-sensitized MSA-resistant tumors (lung and colon carcinoma models) to the corresponding MSA. Interestingly, a novel clinically relevant microtubule-stabilizing agent, which is still active in MSA-resistant tumors, successfully overcame MSA-resistance in the lung and colon carcinoma models, downregulated the HIF1-alpha related aggressive tumor phenotype and strongly sensitized for ionizing radiation (bolus and metronomic scheduling).

Conclusion: These data demonstrate that the interaction between the tumor cell compartment and the tumor microenvironment strongly determines the tumor response to the combined treatment modality of ionizing radiation and microtubule interfering agents. A combined treatment modality of microtubule interfering agents with antiangiogenic agents is potent to overcome tumor cell-linked MSA-resistance and should be considered as clinical strategy for MSA-refractory tumor entities alone and in combination with radiotherapy.

PO-0989

Hypoxic and perfusion effects of Trastuzumab in a HER2+ oesophageal adenocarcinoma xenograft model

C. Yip^{1,2}, A. Weeks¹, G. Cook¹, D. Landau¹, V. Goh¹

¹King's College London, Department of Cancer Imaging-Division of Imaging Sciences & Biomedical Engineering, London, United Kingdom

²National Cancer Centre Singapore, Department of Radiation Oncology, Singapore, Singapore

Purpose or Objective: We aimed to evaluate the pathological hypoxic and perfusion effects of Trastuzumab (T) and/or Cisplatin (C) in HER2+ oesophageal adenocarcinoma xenograft (OE19) which may potentially direct future clinical adjunctive therapy.

Material and Methods: SCID mice (n=17) bearing subcutaneous OE19 tumours were treated with either (i) Cisplatin 4mg/kg once a week, (ii) Trastuzumab 20mg/kg twice a week or (iii) Cisplatin and Trastuzumab for 2 weeks. Intraperitoneal Pimonidazole (Pm), an exogenous hypoxic marker, and intravenous Hoechst 33342 (Ho), a perfusion marker, were injected 2 hours and 1 minute prior to tumour excision, respectively. Tumours were immediately snap-frozen and 10µm frozen sections were obtained for immunofluorescence study. Following fixation, non-specific binding was blocked using 10% normal goat serum. The sections were then incubated overnight at 4°C with primary Pimonidazole FITC labelled mouse monoclonal antibody at 1:25 concentration. Propidium iodide (PI) was used as a counterstain to highlight morphology. Tumour sections were scanned using different filters for Pm (green), Ho (blue) and PI (red) on a fluorescence microscope at x100 magnification (Figure 1).

Image analysis was performed using the ImageJ software. Percentage areas stained with Pm (hypoxic fraction/HF) and Ho (perfusion fraction/PF) were derived and mean (%) ± SD are presented. Difference in the HF and PF between Trastuzumab (T) and non-Trastuzumab (NT) treated animals were analysed.

Results: Overall, tumour periphery was better perfused in most tumours but there was no consistent hypoxic intratumoral spatial localisation. There was an inverse spatial relationship between Pm and Ho fluorescence in 10/17 tumours, colocalisation in 3/17 and no relationship found in 4 tumours. Trastuzumab-treated tumours (HF 38%±17) were less hypoxic compared to the NT group (HF 50%±13) and these tumours were also better perfused (PF: T 46%±25, NT 39%±16). Cisplatin-treated tumours had the highest HF (50%±13) and lowest PF (39%±16) compared to Trastuzumab (HF 34%±13, PF 48%±26) and combination therapy (HF 41%±21, PF 45%±27).

Conclusion: Trastuzumab appeared to exert the predominant proangiogenic effect with improved perfusion and reduced intratumoral hypoxia, although these effects were diminished with combination therapy. These data suggest that the addition of hypoxia-modifying agents might be tested as an adjunctive therapy, particularly in those not eligible or fit for Trastuzumab therapy.

Impact of Ramipril on rat spinal cord after high- and low-LET irradiation

M. Saager¹, E.W. Hahn², P. Peschke³, S. Brons⁴, P.E. Huber³, J. Debus⁵, C.P. Karger¹

¹DKFZ, Medical Physics in Radiation Oncology, Heidelberg, Germany

²The University of Texas- Southwestern Medical Center, Department of Radiology, Dallas- Texas, USA

³DKFZ, Clinical Cooperation Unit Molecular Radiooncology, Heidelberg, Germany

⁴Heidelberg Ion Beam Therapy Center, HIT, Heidelberg, Germany

⁵Heidelberg University Hospital, Department of Clinical Radiology, Heidelberg, Germany

Purpose or Objective: In radiotherapy of head and neck cancer the central nervous system is the dose limiting factor. Late side effects may occur which severely impair the patient's quality of life. Thus, to improve the therapeutic ratio, radioprotective drugs receive increasing interest. In the optimal case, they could protect the normal central nervous system without influencing the tumor response to irradiation. A lot of studies using various approaches with e.g. melatonin, pentoxifylline, growth factors, Amifostine or Angiotensin converting enzymes inhibitors (ACEi) were performed focusing on mitigation or, ideally, on protection from late side effect in central nervous system (brain, optic nerve or spinal cord).

Material and Methods: Within our study the impact of ACEi Ramipril on prevention from the late side effect radiation-induced myelopathy (forelimb paresis grade II) was tested. The cervical spinal cord of female Sprague Dawley rats was irradiated with either 6 MeV photons or carbon ions (12C-ion) (a linear energy transfer (LET) of 45 keV/μm and a 6 cm spread-out Bragg Peak was used). Immediately after irradiation (RT) Ramipril (2 mg/kg/day) was given via the drinking water for 300 days. A total of four groups were used: (1) photon RT + Ramipril (n = 24), (2) photon RT only (n = 20), (3) 12C-ion RT + Ramipril (n = 20) and (4) 12C-ion RT only (n = 20). For each group a complete dose-response curve after single dose irradiation was established and TD50-values (dose at 50% complication probability) were determined for the development of paresis grade II within 300 days.

Results: Preliminary analysis of the data shows no marked shift of the TD50-values related to administration of Ramipril after 12C-ion or photon RT, however, a prolongation of latency time for both irradiation modalities was found. At a dose level of 21 Gy the minimum latency time after 12C-ion RT was 160 d compared to 191 d after 12C-ion RT + Ramipril administration. Whereas, at a dose level of 26 Gy the minimum latency time after photon RT was 191 d compared to 225 d after photon RT + Ramipril administration. Overall the latency time after 12C-ion RT was shorter compared to photon RT.

Conclusion: Ramipril administration after 12C-ion or photon RT exhibits a prolonged latency time. However, to find an ideal radiomitigator further examinations of the underlying pathological mechanisms leading to radiation-induced myelopathy are necessary. Additionally, since it is unclear how Ramipril interferes the pathological mechanism(s) of radiation-induced damage, it is important to understand the underlying mechanism. Thereby it would be possible to compensate potential weak points in inhibition by combination with other compounds.

PO-0991

p53 and in vitro radiation response of fibroblasts from RT-sensitive and -resistant patients

C. Herskind¹, O. Nuta², N. Somaiah³, S. Boyle³, M.L.K. Chua⁴, L. Gothard³, K. Rothkamm⁵, J. Yarnold³

¹Universitaetsmedizin Mannheim- Medical Faculty Mannheim-Heidelberg University, Department of Radiation Oncology, Mannheim, Germany

²Public Health England, Centre for Radiation- Chemical and Environmental Hazards, Chilton, United Kingdom

³Institute of Cancer Research, Division of Radiotherapy and Imaging, Sutton, United Kingdom

⁴National Cancer Centre- Duke-NUS Graduate Medical School, Division of Radiation Oncology, Singapore, Singapore

⁵Department of Radiotherapy and Radiation Oncology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Purpose or Objective: To test the association between the molecular and functional radiation response of fibroblasts *in vitro* and breast cancer patients' risk of late reaction after radiotherapy.

Material and Methods: Fibroblast cultures were established by outgrowth from biopsies taken with informed consent from

selected breast cancer patients with minimal (RT-resistant, n=15) or marked breast changes (RT-sensitive, n=19) after breast conserving therapy. The clinical risk of RT-sensitive patients was further ranked according to severity relative to external risk factors. Early-passage cultures were irradiated *in vitro* with 4Gy or sham irradiated. Molecular markers p53, p21/CDKN1A, p16/CDKN2A, α-sma, and Ki-67, were detected by immunofluorescence microscopy at 2h, 2 and 6 days after irradiation (IR). Plating efficiency (PE) and surviving fraction after 4 Gy (SF4) were determined by the colony formation assay. Non-parametric analysis of differences between fibroblasts from RT-sensitive and RT-resistant patients was performed with the Wilcoxon/Mann-Whitney test, and correlations using the Spearman's ρ rank correlation test.

Results: The basal level of p53 without irradiation was significantly higher in fibroblast cultures from RT-sensitive relative to RT-resistant patients (P=0.02). p53 was upregulated 2h - 2 days after IR in all cells but decayed more slowly on day 6 in fibroblasts from RT-sensitive patients. Further, explorative analysis showed strong early upregulation of p53 2h after irradiation in fibroblasts from high-risk patients (P=0.002). RT sensitivity showed no significant correlation with p21/CDKN1A, p16/CDKN2A, α-sma, and Ki-67, or functional endpoints, PE and SF4. However, proliferation activity (Ki-67 index) appeared to have a confounding influence on the effect of p53. Thus risk was correlated with basal levels of p53 (P<0.001) in unirradiated cultures with lower Ki-67 whereas it correlated with early upregulation at 2h (P<0.001) in cultures with higher Ki-67. Furthermore, correlations of p21/CDKN1A with p53 or p16/CDKN2A were markedly different in fibroblasts from RT sensitive and RT-resistant patients.

Conclusion: In this cohort, patient selection was performed to enhance the contrast between RT-resistant and RT-sensitive patients, including rare patients with severe late reaction. p53 levels in fibroblast cultures *in vitro* were significantly correlated with the risk of developing late breast changes after radiotherapy, and high-risk patients' fibroblasts showed strong early upregulation of p53 after irradiation which depended on the proliferation index. We suggest that a relation between p53 and the risk of late reaction exists in a subgroup of RT-sensitive patients, possibly via enhanced genetic instability and partial dysregulation of the DNA damage response.

PO-0992

The role of HIF-1 in the neo-vascularization of the rectal mucosa after radiation therapy.

L. Eusebi¹, I. Kurelac², A. Guido³, A. Farioli¹, L. Giaccherini³, L. Frazzoni¹, G. Gasparre², F. Bazzoli¹, A. Morganti³, L. Fuccio⁴

¹S.Orsola-Malpighi Hospital- University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy

²S.Orsola-Malpighi Hospital- University of Bologna, Medical Genetics Unit, Bologna, Italy

³S.Orsola-Malpighi Hospital- University of Bologna, Division of Radiation Oncology, Bologna, Italy

⁴S.Orsola-Malpighi Hospital- University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy

Purpose or Objective: Rectal bleeding after radiation therapy (RT) for prostate cancer has been observed in up to 40% of patients and it is mainly due to multiple rectal angiectasias developed after RT. Soon after the beginning of RT, there is an acute mucosal reaction that can evolve into a more severe condition with prominent vascular involvement, evidence of vasculitis, arteriolar thrombosis and subsequent ischemia and angiogenesis. Recently, attention to the role of hypoxia has contributed to the understanding of radiation-induced late normal tissue response. Under hypoxic conditions, the diverse hypoxia-driven genes (e.g., VEGF) are regulated by a transcriptional factor, hypoxia-inducible factor-1 (HIF-1). *In vivo* and *in vitro* studies have shown that the HIF-1 expression increased soon after irradiation, reaching the highest level after 30 days and preceding the expression of VEGF.

Aim of this prospective study is to evaluate the expression of HIF-1 after RT and correlate it with the development of rectal mucosal angiectasias and bleeding.

Material and Methods: Patients with histological proof of prostate cancer without distant metastases, undergoing a standard course of external beam radiation therapy (3D-RT), were considered eligible. Each patient underwent a rectosigmoidoscopy with bioptic sampling prior to and one month and one year after RT. The development of rectal mucosal angiectasias was graded according to the Vienna Rectoscopy Score (VRS). HIF-1 was evaluated by immunohistochemistry and western blot analysis; the mean number of blood vessels per field was also assessed. Radiation-induced side effects (e.g. rectal bleeding) were recorded during follow-up visits.

Results: Thirty-one patients were enrolled (median age 72 years, IQR 67-75). After the end of a median follow-up of 19.8 months (IQR 18.4-20.9), 10 patients (32.3%) developed rectal bleeding needing intervention. All these patients presented a grade II or III VRS ($p=0.03$). The difference in the mean number of blood vessels between bleeders and not bleeders was not significantly different ($p=0.47$). The expression of HIF1 in bleeding patients was down regulated in 2 cases, unchanged in 3 and up regulated in 4 cases ($p>0.99$); in one case it was not feasible to determine the expression. There was no correlation between the expression of HIF1 and the VRS.

Conclusion: The expression of HIF1 does not correlate with the development of rectal mucosal angiectasias and bleeding in patients irradiated for prostate cancer.

Genetic profiles of glioblastoma in proximity to the subventricular zone receiving chemoradiation

S. Adeberg¹, C. Koelsche², D. Kehle¹, S.B. Harrabi¹, A. Unterberg³, A. Von Deimling², J. Debus¹, S. Rieken¹

¹University Hospital Heidelberg, Department of Radiation Oncology- Im Neuenheimer Feld 400, Heidelberg, Germany

²University Hospital Heidelberg, Department of Neuropathology- Im Neuenheimer Feld 224, Heidelberg, Germany

³University Hospital Heidelberg, Department of Neurosurgery- Im Neuenheimer Feld 400, Heidelberg, Germany

Purpose or Objective: Subventricular zone-infiltrating (SVZ-infiltrating) glioblastomas (GBMs) with subependymal spreads along ventricle walls are associated with decreased patient survival. The heterogeneity in patient survival and recurrence patterns of GBM with SVZ infiltration might be related to neuronal therapy resistant stem cells, located in the SVZ. It has not been systematically investigated if specific molecular genetic patterns of SVZ-infiltrating GBMs exist, and therefore are responsible for the unfavorable course after chemoradiation.

Material and Methods: The current study assessed the molecularbiologic profile of 55 primary GBM cases that underwent chemoradiation. GBMs with SVZ infiltration and subependymal tumor spread ($n = 24$; 43.6 %) and peripherally located GBMs ($n = 31$; 56.4 %) were included. Genome methylation patterns were determined and copy number profiling was performed using an Illumina Infinium HumanMethylation450K (450K) Array, and the prognostic influence on progression and survival was evaluated.

Results: The majority of patients showed the characteristics of a "classic" GBM subtype, independent of the tumor localization in regard of the SVZ, demonstrating a chromosome 7 gain and chromosome 10 loss, as well as deletion of Cyclin-Dependent Kinase Inhibitor 2A (CDKN2A)

and amplification of Epidermal Growth Factor Receptor (EGFR). Second, RTK I subtype, showing Platelet-Derived Growth Factor Receptor Alpha (PDGFRA) amplifications, could be detected equally in both groups. However, SVZ-infiltrating GBMs with subependymal spreading showed a decreased overall survival (OS) compared to their peripheral counterparts.

Figure: Genome wide copy number profiling of a classic primary glioblastoma with chromosome 7 gain and chromosome 10 loss

Conclusion: Genome methylation patterns were distributed independently of tumor localization in regard of the SVZ, suggesting that the biological entities in both GBM groups are identical. However, survival rates of GBMs with proximity to the SVZ were inferior and therefore the central localization seems to be responsible for the poor clinical courses.

PO-0994

Assessment of [11C]-metformin PET for identification of patients suitable for metformin treatment

A. Iversen¹, M. Vendelbo², L. Gormsen², N. Jessen³, M. Horsman¹, M. Busk¹

¹Aarhus University Hospital, Department of Experimental Clinical Oncology, Aarhus C, Denmark

²Aarhus University Hospital, PET Centre, Aarhus C, Denmark

³Aarhus University Hospital, The Department of Molecular Medicine, Aarhus C, Denmark

Purpose or Objective: Evidence to support a role for the antidiabetic drug metformin in the prevention and treatment of cancer has emerged over the last decade. In particular, recent studies demonstrate that metformin enhances tumor response to radiation in experimental models. Metformin may therefore be of utility for nondiabetic cancer patients treated with radiation therapy. Despite being in clinical use for almost 60 years, the underlying mechanisms for metformins action remain elusive. We have therefore applied a novel PET-tracer, [11C]-metformin, to determine the uptake mechanism and elimination of the drug *in vitro* and *in vivo*.

Material and Methods: To verify transporter-mediated uptake of metformin in tumor cells, a selection of cell lines were incubated with [11C]-metformin in the absence or presence of blocking unlabelled metformin. Two tumor models A549 (lung) and SiHa (cervix) was chosen for *in vivo* experiments. Mice bearing subcutaneous tumors in the lower back were administered ~10 MBq [11C]-metformin and dynamically PET scanned for 90 minutes. As a "proof of principle" experiments using PET/CT with [11C]-metformin organ specific uptake of [11C]-metformin was determined in healthy humans. Dynamic whole-body PET was performed on four healthy volunteers (2 male). Two minutes before scan start, a bolus injection of ~200 MBq [11C]-metformin was injected and five consecutive whole-body scans with increasing frame durations were obtained: 1, 1.5, 2, 2.5 and 3 minutes per bed position. Time intervals for the PET scans were 2-8, 9-18, 19-32, 33-48 and 49-67 minutes (see figure 1). Source organs for the dosimetry calculations were the liver, kidneys, salivary glands and the bladder.

Results: *In vitro* metformin uptake varied widely but a high and inhibitable uptake was observed in A549 and SiHa cells.

Imaging with [¹¹C]-metformin in tumor bearing mice showed a large uptake in the kidneys and excretion through the bladder, as expected for metformin. An uptake of [¹¹C]-metformin was seen in both A549 (lung) and SiHa (cervix) tumors and autoradiography supported this finding. Biodistribution of metformin in humans is shown in figure 1 with visible uptake in liver, kidney and the salivary glands, but no detectable uptake in brain, muscle or adipose tissue.

Conclusion: It is possible to visualize distribution of [¹¹C]-metformin *in vivo*. In xenograft models uptake in tumor was seen. It will be of great interest to investigate whether it is possible to visualize an uptake in human tumors, which will be done in a planned study in prostate cancer patients.

Figure 1: Tissue distribution of [¹¹C]-metformin. Healthy subjects given 200 MBq [¹¹C]-metformin i.v. Time denotes min after injection.

Conclusion: RT increased the levels of OPN expression in GBM tumour cells. This may be a direct effect or related to RT-induced changes in the hypoxic tumour microenvironment that were not detectable on a DCE-MRI or by Glut-1 expression. Although RT significantly increases overall survival compared with surgery alone, particularly when combined with temozolomide, it may promote the cancer stem cell-like phenotype of residual GBM cells. Enhanced OPN/CD44 signalling in the perivascular niche is associated with resistance to therapy and blockade of this signalling pathway may prove of clinical benefit. The relative lack of induction of OPN expression in rectum cancer may explain the success of short course pre-operative RT in this tumour type.

Osteopontin expression in glioblastoma - a promoter of the cancer stem cell-like phenotype?

S. Rogers¹, R. Grobholz², J. Berberat³, A.R. Fathi⁴, S. Bodis¹

¹Kantonsspital Aarau, Radiation Oncology, Aarau, Switzerland

²Kantonsspital Aarau, Pathology, Aarau, Switzerland

³Kantonsspital Aarau, Neuroimaging, Aarau, Switzerland

⁴Kantonsspital Aarau, Neurosurgery, Aarau, Switzerland

Purpose or Objective: A high level of circulating osteopontin (OPN) at the end of radiotherapy (RT) is an adverse prognostic factor in patients with glioblastoma (GBM) and other tumours including rectum cancer. Recent mechanistic studies demonstrated HIF2 α -mediated OPN/CD44 promotion of the glioma stem cell-like phenotype in a mouse model. Using unique paired tumour samples from patients with GBM, we investigated changes in levels of OPN protein expression following RT and compared these with rectum cancers from patients irradiated with the same pre-operative fractionation.

Material and Methods: 3 patients with histologically confirmed GBM received pre-operative RT in an ethics-approved Phase I trial. 2.5 Gy b.d. was delivered using IMRT over 5 days. Maximal safe tumour resection was performed at 3, 5 and 10 days post RT in patients 1, 2 and 3 respectively. Immunohistochemistry was performed on the paired diagnostic biopsy and irradiated resection specimen using validated antibodies (rabbit polyclonal antibody to OPN: clone PA1-38332, Thermo Fisher Scientific) and an automated immunostainer. The staining was scored by a board-certified pathologist.

Results: Levels of OPN in GBM tumour cells were high at baseline as compared with rectum adenocarcinoma. There was marked increase in OPN expression in response to RT in all three GBM tumours (Fig 1). Expression of Glut-1, a marker of intrinsic hypoxia and a target of HIF-2 α , was not induced. Ki67 levels were reduced although levels of cyclin D1 expression were unchanged. A dynamic contrast-enhanced (DCE) MRI performed on the last day of RT did not detect any change in tumour perfusion in any of the GBMs. Resection specimens from 3 rectum cancer patients irradiated preoperatively with the same schedule showed very low level induction of OPN.

PO-0996

Distinct radiation responses after mtDNA depletion are potentially related to oxidative stress

M.W. Van Gisbergen¹, A.M. Voets², R. Biemans¹, G.R.M.M. Haenen³, M.J. Driittij-Reijnders³, R.F. Hoffmann⁴, I.H. Heijink⁴, H.J.M. Smeets², K.M.A. Rouschop¹, L. Dubois¹, P. Lambin¹

¹Maastricht University, Radiation Oncology, Maastricht, The Netherlands

²Maastricht University, Genetics and Cell Biology, Maastricht, The Netherlands

³Maastricht University, Toxicology, Maastricht, The Netherlands

⁴University of Groningen, Pathology and Medical Biology, Groningen, The Netherlands

Purpose or Objective: In process like reactive oxygen production and apoptosis mitochondria play an important role and both processes play also a significant role in radiotherapy (RT) response. Repair of RT induced damage is dependent on mitochondrial energy supply suggesting a role for mitochondrial DNA (mtDNA) in RT. mtDNA variations, such as mutations or depletion, might therefore influence RT response, as for example found in cisplatin-treated patients. Therefore carefully elucidating the effect of these processes in radiation response might be important. Hence, we hypothesize that reduced mitochondrial function enhances the radiation response as a consequence of reduced ATP production and increased cellular ROS exposure (Fig.1).

Fig 1. We hypothesize that reduced mitochondrial function caused by mtDNA variations, such as mtDNA depletion, enhances the radiation response as a consequence of reduced ATP production and increased cellular ROS exposure. Oxidative phosphorylation complexes that are encoded by the mtDNA are indicated by the orange stars. Through disruption of these complexes and thereby interfering with free radical and ATP production, radiation responses could potentially be altered. Lightning signs indicate processes that are also involved in radiotherapy.

Material and Methods: Three cell lines were depleted from their mtDNA by ethidium bromide. BEAS-2B immortalized bronchial epithelial, A549 lung adenocarcinoma and 143B osteosarcoma cell lines and their mtDNA depleted counterparts (p0) were metabolically characterized using the XF96 Seahorse. Changes in radiosensitivity were assessed by clonogenic survival (0, 2, 4, 6 and 8Gy). ROS production (by dihydrorhodamine FACS analysis), ATP (Cell-TiterGlo Luminescent cell viability test) and glutathione levels (in cell lysate) as well as γ H2AX immunostainings were assessed 24 hours post irradiation.

Results: mtDNA depletion resulted in a significant ($p < 0.05$) decreased proliferation ($64 \pm 7\%$) for all cell lines. Compared to their respective controls, increased clonogenic survival was observed for the BEAS-2B p0 cells ($p = 0.004$) after irradiation, while both tumor p0 lines were more radiation sensitive ($p = 0.013$), mainly at higher irradiation doses. ROS formation at baseline (0Gy) was similar ($p = 0.878$) for BEAS-2B parental and p0, while reduced for A549 and 143B p0 ($p = 0.021$) cells, compared to their parental counterparts. 24 hours after irradiation ROS levels were significantly ($p < 0.05$) increased for all parental cell lines, while levels for the p0 cells remained equal. Glutathione levels were lower for the A549 and 143B p0 cell lines compared to the parental lines under any experimental condition but no changes were found for the BEAS-2B cells. In agreement, increased residual DNA damage was observed upon mtDNA depletion for A549 and 143B cells. Depletion of mtDNA reduced cellular ATP levels only for the BEAS-2B cell line ($p = 0.046$), but not for the A549 and 143B cell lines in high glucose culture medium.

Conclusion: The observed differences in dependence on mitochondrial function for radioresponsiveness appear to be associated with the balance in ROS levels and the antioxidant status of the cells. Currently, the levels of MnSOD and GPX1 and the effect of ROS scavenging on radiotherapy response are investigated in our lab.

PO-0997

Interferon response genes in breast cancer resistance to endocrine treatment and radiotherapy

A.E.M. Post^{1,2}, A.P. Nagelkerke^{1,2}, J.W.M. Martens³, J. Bussink¹, C.G.J. Sweep², P.N. Span¹

¹Radboud University Medical Center, Radiation Oncology, Nijmegen, The Netherlands

²Radboud University Medical Center, Laboratory Medicine, Nijmegen, The Netherlands

³Erasmus MC Cancer Institute, Medical Oncology and Cancer Genomics Netherlands, Rotterdam, The Netherlands

Purpose or Objective: We have previously shown that lysosome-associated membrane protein-3 (LAMP3), a protein involved in the unfolded protein response pathway, is involved in resistance to both endocrine (tamoxifen) treatment and radiotherapy in breast cancer patients. We have created subclones of the MCF7 breast cancer cell line that are resistant to either treatment. In these subclones, we investigated common mechanisms between tamoxifen- and radioresistance, and the possible role of LAMP3 therein.

Material and Methods: The estrogen receptor positive breast cancer cell line MCF7 was grown to tamoxifen resistance (MCF7TAM) by culturing with gradually increasing concentrations of 4-OH-tamoxifen up to $10 \mu\text{M}$. Additionally, MCF7 cells were exposed to multiple fractions of 2 or 4 Gy irradiation, adding up to a total dose of at least 50 Gy (MCF7RT). Changes in expression profiles in MCF7TAM and MCF7RT cells compared to parental MCF7 cells were investigated by RNA sequencing. Pathway analysis software was used to find pathways involved in tamoxifen- and radioresistance. QPCR was used to confirm the RNA sequencing data, and to investigate the changes in genes of interest after tamoxifen treatment and irradiation. The role of LAMP3 in these treatment resistance pathways is being elucidated by performing LAMP3 gene silencing by siRNA and CRISPR-Cas mediated gene knockout.

Results: The MCF7TAM cells were completely resistant to treatment with $10 \mu\text{M}$ 4-OH-tamoxifen. Remarkably, these cells had also become resistant to irradiation, with a surviving fraction at 4 Gy (SF4) of 19.7%, compared to 8.3% for the parental MCF7 cells. MCF7RT cells were less sensitive to irradiation with a SF4 of 9.6% compared to 3.9% for the parental cells. RNA sequencing of MCF7TAM and MCF7RT cells revealed an increase of genes involved in the antiviral response, including classic interferon response genes such as IFI6 (shown in figure, left), IFI27, STAT1, OAS1 and DDX60. These genes were increased in parental cells following 4 Gy irradiation (figure, right) or tamoxifen treatment as well.

Conclusion: MCF7 cells resistant to tamoxifen treatment are also less sensitive to irradiation, suggesting a common mechanism in the resistance to these diverse types of treatment. Using an unbiased approach, we here show that interferon response genes are increased in both MCF7TAM and MCF7RT cells. Interestingly, others have shown LAMP3 to be a regulator for this pathway. We are currently investigating the role of LAMP3 in our treatment resistant breast cancer clones.

PO-0998

The Robo1-receptor is involved in the migration of irradiated glioblastoma cells

H. Bühler¹, P. Nguemgo-Kouam¹, A. Kochanek¹, H. Hermani¹, K. Fakhrian¹, I.A. Adamietz¹

¹Marienhospital Herne- Ruhr-Univers., Klinik für Strahlentherapie und Radio-Onkologie, Herne 1, Germany

Purpose or Objective: The brain tumor glioblastoma multiforme (GBM) is highly malignant with a very short OS due to rapid recurrences adjacent to the primary tumor. Even radio-chemotherapy extends the survival only for a few months. In this project we tested whether or not the Slit2/Robo1 axon guidance system might be involved in the migration of metastatic GBM cells and whether irradiation with photons might modify this putative effect.

Material and Methods: The experiments were performed with 2 human GBM cell lines (U87 and U373) and in parallel after irradiation with 0.5, 2, or 8 Gy photons. The motility/migration of the cells was analyzed by time-laps videography. Travelling cells were tracked and the parameters accumulated distance and Euclidean distance were determined. The expression of Slit2, Robo1, and FAK (focal adhesion kinase) was tested by Western blot and qRT-PCR. In addition, the cells were transfected either with a Robo1 expression-vector or with a siRNA construct and analyzed similarly.

Results: Irradiation with low doses enhanced the motility of the cells. Slit2 as well as Robo1 was extremely low expressed in the cell line with higher motility (U87). Irradiation reduced the expression even more. On the other hand, a stable overexpression of Robo1 decreased significantly the migration of the cells and suppressed the increase in motility observed after irradiation. In contrast, the siRNA mediated knockdown of Robo1 increased the migratory potential of the cells. The analysis of FAK, a key player in cellular migration, revealed a decreased expression in Robo1-overexpressing cells.

Conclusion: Our data indicate a role for Robo1 in the migration of malignant GBM cells. The expression of Robo1 reduced the migration of these cells and was also able to impede the increase in motility observed after irradiation with photons.

²Klinikum Rechts der Isar- Technische Universitaet Muenchen, Radiooncology, Muenchen, Germany

³Universität der Bundeswehr, Institut für Angewandte Physik und Messtechnik, Neubiberg, Germany

Purpose or Objective: Proton minibeam radiotherapy aims to minimize normal tissue damage in the entrance channel while keeping tumor control through a homogeneous tumor dose due to channel widening with increasing track length. Side effects of proton minibeam irradiation were examined in an in-vivo mouse model to account for immune system, vasculature and higher complexity. Here, we report on our comparative study of minibeam and broad beam irradiation in the ear of Balb/c mice, to prove this hypothesis of reduced adverse effects in normal tissue.

Material and Methods: At the ion microprobe SNAKE, 20 MeV protons were administered to the right ear of 2-3 months old, female Balb/c mice, using an average dose of 60 Gy in a field of 7.2 x 7.2 mm² in the central part of the ear, in two irradiation modes, homogeneous and minibeam. The 4 x 4 minibeam of 180 x 180 µm² size were set in a distance of 1.8 mm, resulting in a dose of 6000 Gy in the channels, but with negligible dose in between. Inflammatory response, i.e. ear swelling and skin reactions were monitored for 90 days following irradiation, as well as genetic damage and release of inflammatory proteins.

Results: No ear swelling or other skin reaction was detected after the minibeam irradiations, while significant ear swelling (up to 4-fold), erythema and desquamation (crust formation) developed in homogeneously irradiated ears 3-4 weeks after irradiation. Loss of hair follicles was only detected in the homogeneously irradiated fields after 4-5 weeks.

Conclusion: Our results prove that proton minibeam radiotherapy leads to reduced side effects compared to conventional broad beam irradiation and could become an option in clinical proton and/or heavy ion therapy. Supported by the DFG Cluster of Excellence: Munich-Centre for Advanced Photonics.

Effect of X-rays and carbon ions on cell survival and expression of Hh pathway genes in cancer cells

K. Konings¹, M. Moreels¹, A. Suetens¹, A. Gonnissen², S. Isebaert², K. Haustermans², S. Baatout¹

¹SCK-CEN, Radiobiology, Mol, Belgium

²KU Leuven, Laboratory of Experimental Radiotherapy, Leuven, Belgium

Purpose or Objective: Metastasis is an important cause of mortality in cancer patients and evidence shows that irradiation could actually increase the formation of metastasizing cells. An important pathway implicated in the process of metastasis is the Hedgehog (Hh) signaling pathway. Recent studies demonstrated that activation of this pathway can lead to radioresistance. So far, the impact of high-LET radiation on the Hh pathway is still unknown. In the present study the impact of different radiation qualities (e.g. X-rays and carbon ions) on Hh gene expression was investigated in prostate cancer cells (PC3) and medulloblastoma cells (DAOY).

Material and Methods: *In vitro* models used for prostate cancer and medulloblastoma were PC3 and DAOY, respectively. Colony survival assays were performed to analyze the effect of radiation on cell survival. The impact of radiation on the expression of the different Hh signaling pathway components (SHH, PTCH, SMO, GLI1, GLI2, GLI3 and SUFU) was investigated by means of RT-qPCR. Experiments with X-rays were performed at SCK-CEN (Mol, Belgium) whereas carbon ion irradiation (LET = 33.7 KeV/µm) experiments were performed at the Grand Accélérateur National d'Ions Lourds (GANIL) (Caen, France).

Results: Colony survival assays showed that DAOY cells were more radioresistant than PC3 cells (respectively D10=5.3 Gy and D10=4.2 Gy). Evaluation of the Hh signaling pathway showed that basal gene expression is present in both PC3 and DAOY, although very low. However, basal gene expression of the Hh components differed between both cell lines. Moreover, the more radioresistant cell line DAOY had higher expression levels of Gli1 compared to the PC3 cells. Preliminary RT-qPCR results show that different radiation qualities induce different changes in the expression of the Hh signaling components.

Conclusion: In conclusion, radiation exposure can induce changes in the Hh pathway. Future experiments will address whether modulation of the Hh pathway also affects the radio-responsiveness of cancer cells.

⁴Princess Margaret Hospital, Clinical Oncology, Hong Kong, Hong Kong SAR China

⁵Prince of Wales Hospital, Clinical Oncology, Hong Kong, Hong Kong SAR China

⁶Pamela Youde Nethersole Eastern Hospital, Clinical Oncology, Hong Kong, Hong Kong SAR China

Purpose or Objective: This retrospective study aimed to compare and determine the potential dosimetric benefits of intensity-modulated radiotherapy (IMRT) treatment plans with (FF) and without flattening filter (FFF) as well as to explore the dosimetric differences in 6MV FFF and 10MV FFF plans for non-small-cell lung carcinoma (NSCLC).

Material and Methods: Ten cases of CT data were selected from NSCLC patients. 4 sets of 5-field-IMRT plans were computed with FFF beams (X6FFF, X10FFF) and flattened beams (X6FF, X10FF) with the prescription of total 60Gy in 30 fractions. Planning constraints were based on the Radiation

Therapy Oncology Group (RTOG) protocol 1306. Determination of isocentre, beam arrangement and dose constraints were kept constant in each case. All plans were computed using Varian Eclipse version 11.0 treatment planning system. The plans were then evaluated based on the target coverage, homogeneity, conformity, number of monitor units (MU) to be delivered and dose-volume constraints for various organs at risk (OARs).

Results: All plans exhibited comparable PTV homogeneity ($HI \leq 7.5$) and conformity ($CI > 96\%$) with a steep dose fall-off outside the PTVs but at the expense of increased MUs by 39.4% ($p=0.007$) and 44.7% ($p=0.005$) for FFF beams at 6 MV and 10 MV respectively. FFF beams offered better dose sparing of OARs than flattened beams. Spinal cord+5mm and volume of 'whole lung (WL) - Gross tumour volume (GTV)' (WL-GTV) that received 20Gy (V20) were reduced by 2% ($p=0.017$) and 2.8% ($p=0.016$) respectively in X10FFF plans when compared with X10FF plans. There was also a 16.4 % dose reduction to brachial plexus in X10FFF plans than X6FFF plans.

Conclusion: The application of FFF IMRT for NSCLC yielded quantitatively comparable dosimetric distribution with better sparing of the OARs including 'spinal cord+5mm', V20 of 'WL-GTV' and brachial plexus than using FF beams.

PO-1002

A comparison of outcomes using VMAT and 3DCRT in treatment of esophageal cancer

E. Jimenez-Jimenez¹, J. Font², P. Mateos², F. Romero², J. Pardo¹, N. Aymar³, I. Ortiz³, M. Vidal³, S. Sabater⁴

¹Hospital Universitari Son Espases, Radiation Oncology Department, Research Group IDISPA, Palma de Mallorca, Spain

²Hospital Universitari Son Espases, Medical Physics Department, Palma de Mallorca, Spain

³Hospital Universitari Son Espases, Radiation Oncology Department, Palma de Mallorca, Spain

⁴Complejo Hospitalario Universitario de Albacete, Radiation Oncology Department, Albacete, Spain

Purpose or Objective: There are few studies comparing 3-dimensional conformal radiation therapy (3DCRT) and volumetric modulated arc therapy (VMAT) in treatment of esophageal cancer. These studies often compare 3DCRT unsophisticated, with few treatment beams, which is not common in clinical practice.

Our aim was to compare a modern 3DCRT plan with VMAT using dose volume histograms (DVH) and evaluate the dosimetric profile.

Material and Methods: We evaluate 7 patients with esophageal cancer (4 medium, 2 distal and 1 upper neoplasms). All were contoured using PET-CT and treated with radio-chemotherapy. Target volumes for primary lesions (50-50,4 Gy) and electively treated regions (45 Gy) were contoured.

Every patient had 2 dose-plans, one with 3DCRT (8-10 beams) and other with VMAT (2 arcs) techniques. For each technique, we evaluate the coverage target, homogeneity index of PTV (HI), conformity index (CI), monitor units and DVH metrics of lungs, heart and spinal cord.

Results: VMAT plans reduced total lung volume treated above 20 Gy (V20) and mean lung dose (MLD), but volume treated above 5 Gy (V5) were higher than 3DCRT. VMAT improved total heart volume treated above 20 Gy and 40 Gy (V20, V40) and maximum dose to cord.

Monitor units (MU) were higher with the 3DCRT. HI and CI are better with VMAT technique. Coverage target was very high with both schemes. Statistically meaningful differences were observed (Table 1).

Conclusion: Our results suggest that VMAT for radical treatment of esophageal cancer is useful for decreasing dose in organs at risk. It can play a more important role in some locations, such as cervical cancer. Nevertheless, VMAT

increases low-doses in lung and this may contribute increase pulmonary complications.

A complex multibeam technique -3DCRT preserves constraint of organs at risk with high conformity and homogeneity of the target.

Target	Coverage (%)	3DCRT	VMAT	p-value
		HI	98,1 ± 1,4	95,4 ± 1,1
Lung	CI	0,083 ± 0,016	0,047 ± 0,006	< 0,05
	V5 (%)	1,62 ± 0,15	1,00 ± 0,03	< 0,05
	V20 (%)	80,5 ± 11,0	83,9 ± 12,0	< 0,05
Heart	MLD (Gy)	24,5 ± 4,9	14,5 ± 10,0	< 0,05
	V20 (%)	15,03 ± 2,13	12,78 ± 2,72	< 0,05
	V40 (%)	48,8 ± 23,2	28,2 ± 22,6	< 0,05
Spinal cord	Maximum dose (Gy)	16,4 ± 15,8	3,7 ± 4,1	< 0,05
	1 cm ³ dose (Gy)	40,2 ± 3,7	33,0 ± 4,1	< 0,05
Monitor units		36,3 ± 4,6	30,1 ± 3,6	< 0,05
		588 ± 98	558 ± 127	0,499

PO-1003

Does level of DIBH amplitude correlate to reduction in cardiac dose in left breast cancer patients?

D. Ledsom¹, A. Reilly², H. Probst³

¹Clatterbridge Cancer Centre, Radiotherapy, Bebington, United Kingdom

²Clatterbridge Cancer Centre, Physics, Bebington, United Kingdom

³Sheffield Hallam University, Faculty of Health and Wellbeing, Sheffield, United Kingdom

Purpose or Objective: The aim was to investigate whether the amplitude level achieved during DIBH impacted on the mean cardiac dose and V30 reduction in 30 women treated for a left sided breast cancer during radiotherapy.

Material and Methods: Patients were dual scanned in free breathing and DIBH. Varian Real-time Position Management (RPM) was used to record and monitor breathing. Plans were virtually simulated with field borders following IMPORT high guidelines. Pinnacle treatment planning software was used for dosimetric calculation; all plans conformed to ICRU 62. Spearman's Rank correlation and statistical analysis was performed using SPSS v22. All patient data was anonymised. To improve reliability and assess validity of the researcher, 10 of the 30 patients were chosen at random, re-outlined and re-planned to confirm consistency and intra-rater reliability. The heart was also re-contoured for one patient 5 times to calculate the error in heart contouring.

Results: All patients achieved decreased cardiac V30 and mean cardiac dose reduction using DIBH technique. Moderate positive correlation between DIBH amplitude and cardiac V30 reduction was statistically significant ($p=0.007$, $R=0.48$). Ratio increase from free breathing to DIBH and cardiac V30 reduction was also positively correlated and statistically significant ($p=0.04$, $R=0.38$). Twenty seven percent of patients achieved full cardiac V30 reduction and 73% of patients achieved over 90% reduction. Ratio of amplitude increase from free breathing to DIBH ranged from 4-27 times with ratios of at least 15 times free breathing all achieving 100% cardiac V30 reduction. However 100% cardiac V30 reduction was observed with amplitude of ratio increase as low as 6.25 times free breathing.

Positive correlation between DIBH amplitude and mean cardiac dose reduction was statistically significant ($p=0.003$, $R=0.523$). Seventy seven percent of patients achieved over 50% mean cardiac dose reduction with DIBH amplitudes of 1.04-5.46cm. Correlation of ratio of amplitude increase from free breathing to DIBH and mean cardiac dose reduction was not statistically significant ($p=0.316$, $R=0.189$).

Conclusion: A 100% reduction in cardiac V30 can be achieved with a DIBH amplitude increase 15 times free breathing, yet full reduction can also be achieved at much lower levels (6.25 times free breathing in the current study) suggesting patients unable to achieve a large amplitude increase may

still be able to achieve 100% reduction. DIBH amplitudes of 1-5cm reduce cardiac mean dose by at least 50%.

PO-1004

Optimising breast dosimetry: improving homogeneity through the application of angled IMRT fields

M. Squires¹, S. Cheers¹

¹Radiation Oncology Centres, Gosford, Gosford, Australia

Purpose or Objective: Studies have demonstrated significant side effects associated with dose inhomogeneity and low dose integral splay. Several techniques seek to maximise dose uniformity whilst minimising regions of low dose. The angled segment technique offers two additional options, each allowing for control over homogeneity (HI) and low dose conformity (CI).

Material and Methods: Tangent fields of twenty previously optimised plans were copied. Two re-optimisation methods were applied. Firstly, a single medially angled off inversely planned (I-IMRT) beam was appended to the existing beamset. The plans were further optimised and normalised (PTV V47.5 = 99.00%). Secondly, an additional acutely laterally angled off I-IMRT beam was added, reoptimised, and normalised.

Results: The addition of the single I-IMRT beam resulted in a statistically similar average absolute maximum dose (Dmax 54.55Gy vs. 54.71Gy, p=0.33) but a markedly reduced V107% (14.71cc vs. 23.17cc, p<0.01). Low dose (V1) integral splay was maintained (6410.04cc vs. 6402.45cc, p=0.44), but was reduced marginally contralaterally (V1 splay over midline 6.60cm vs. 6.80cm, p=0.04). Dose to the ipsilateral lung was slightly reduced (5.23Gy vs. 5.33Gy, p=0.04). The additional dual angled off I-IMRT fields reduced the average maximum dose (Dmax 53.79Gy vs. 54.71Gy, p=0.03) and the V107% size substantially (1.90cc vs. 23.17cc, p<0.01). Homogeneity was improved (HI= 0.11 vs. 0.13, p=0.03), whilst the ipsilateral mean lung dose was unaffected (5.33Gy vs. 5.33Gy, p=0.48). The volume of the low dose (V1) integral splay increased by an average of 1.5% (6501.14cc vs. 6402.45cc, p=0.04), and appeared further contralaterally (8.40cm vs. 6.80cm over midline, p=0.02).

Conclusion: The application of additional acutely angled fields provides scope to reduce regions of high dose and improve breast homogeneity while controlling integral dose splay.

PO-1005

Dosimetric effect of US versus CT delineation on postplanning I-125 treatment

J. Van der Klein¹, M. Mast¹, P. Koper¹, P. Rietveld¹, J. Van Wingerden¹, H. De Jager¹

¹Haaglanden Medical Centre Location Westeinde Hosp, Radiotherapy Centre West, Den Haag, The Netherlands

Purpose or Objective: Since 2000 we have been treating low- and intermediate-risk prostate cancer patients with permanent Iodine-125 implants. After 6 weeks postimplant dosimetry (PID) was performed using the Pro-Qura technique (Allen et al, 2008). In a previously performed study in our institute (cohort of 394 patients), we found that the dosimetric quantifier V100 was not correlated with biochemical relapse. Therefore, we examined the PID method to obtain more detailed information on the quality of the PID parameters. From the literature it appeared that in PID many uncertainties affect the quantifiers: delineation, source identification and imaging modalities (De Brabandere et al, 2012). In 2014 we started working with an automated seed reconstruction system (Elekta) to eliminate uncertainties in source identification. However, the other uncertainties still remained. Furthermore, the craniocaudally length of the Ultrasound (US) prostate contour was distally more extended compared to the contour on the postplan CT-scan. This could be explained by the deformation of prostate by the US probe. The main purpose of this study was to

determine the differences in PID based on US- or CT-contours.

Material and Methods: For 71 patients in supine position an axial CT-scan (1 mm slice thickness) was made of the prostate. One radiation therapist (RTT) performed the PID using the US prostate contour fused with the postplan CT-scan. The apex area was defined as the volume derived from a quarter of the base-apex distance. We analyzed the V100 of the apex area and selected the patients with a coverage of less than 67%. Thereafter, we randomly selected 2 groups of patients: Group A: 5 patients with an optimal postplan implantation in the apex area conform Pro-Qura. Group B: 5 patients with an inferior implantation result in the apex area, a coverage of less than 67%. For each patient, one radiation oncologist delineated the prostate on the CT-scan, trying to ignore the seeds. With that new delineated prostate the RTT performed a PID and these CT-based results were compared to the original results. To see the difference in length of the prostate on both modalities, we defined the last slice of the visible apex on both US and CT.

Results: Between the US- and CT-scan volume an absolute difference was found of 12% (SD 2%). In both groups we found, in four out of five patients, that the apex on CT was positioned less caudally compared to the US-scan, figure. This was 4 and 10mm for group A and B respectively.

Figure: Delineated prostate volumes. Red: US; Yellow: CT. For all patients, we found in both groups a significantly higher V100 using the prostate contours of the CT-scan.

Conclusion: The volume of the prostate depends on the image modality. Consequently, the PID results differ as a function of image modality. This needs to be studied in a larger cohort of patients and could help to define on which modality the delineation and the PID needs to be performed.

PO-1006

A breath-hold friendly, hybrid 3DCRT/IMRT technique for locoregional breast irradiation

K. Hunnegro¹, D. Martens¹, D. Steeneveld¹, A. Dijkhuizen¹, L. McDermott¹, F. Gescher¹, G. Speijer¹

¹HagaZiekenhuis, Radiotherapy, The Hague, The Netherlands

Purpose or Objective: IMRT optimises not only the planned dose, but also the clinical preparation and treatment delivery. Until recently, our hospital used a standard 3DCRT for the breast, thoracic wall and lymph nodes ranging from level I to IV, including the parasternum. This usually leads to inconsistent OAR sparing, PTV coverage and conformity, abutting region from multiple fields and long treatment times due to many, high-MU fields. The objective of this study was to develop a hybrid 3DCRT-IMRT technique for locoregional breast irradiation, which is also "breath-hold friendly" i.e. fewer MUs and fields. This technique should optimise planning and treatment times, maintain or reduce dose to OAR, improve PTV homogeneity, avoid the use of wedges and minimise the number of abutting beams.

Material and Methods: 25 Patients were included, with regional nodes level I-IV. Twelve were left-sided with breath-hold treatments. All were planned with both original 3DCRT and a new hybrid 3DCRT-IMRT techniques. Delineations were made according to ESTRO guidelines. Comparison was based on DVH parameters for OARs, namely lung, heart, oesophagus, contra-breast (eg V20, Dmean) and the PTV (V95%, D2%, D98%, conformity). Analysis was performed using SPSS. Further analysis focussed on the efficacy for breath-hold treatments and efficiency in planning and delivery.

Results: The hybrid plan required extra structures to help avoid hotspots, which is especially important for heart-sparing breath-hold treatments. In general, hybrid plans were superior to 3DCRT plans. An exception was the slightly higher, but acceptable, average dose to selected OAR. Resulting clinical recommendations are as follows: for level I/II, where the delineation of lymph nodes in the cranial direction are limited to lateral side, an optimal plan may be created from 2-3 3DCRT open fields and 2-4 IMRT fields. For level I-IV (also with parasternal lymph node involvement), plan as for level I/II above, with an abutment involving no more than 2 fields. Previously 3DCRT treatments required 10-12 fields, hybrid plans require at most 7 fields (each 3 segments) and only half of the MUs.

Conclusion: Hybrid 3DCRT-IMRT plans are a major improvement on the current 3DCRT technique, with fewer hotspots and more control over the dose to OARs and the target. Planning objectives were achieved, with fewer fields, MUs and field abutments, without the need for wedges. In addition, the treatment length has been reduced, making this hybrid technique more suitable for breath-hold delivery.

PO-1007

Optimizing the overlap sector for patients undergoing cranio-spinal irradiation by VMAT

M. Willemsen - Bosman¹, G.O.R. Janssens¹, E. Seravalli¹

¹UMC Utrecht, Radiation Oncology Department, Utrecht, The Netherlands

Purpose or Objective: Volumetric modulated arc therapy (VMAT) techniques for cranio-spinal irradiation (CSI) allows radiation delivery without any field junction. Junctions are replaced by sectors in which arcs of two consecutive isocenters overlap. The dose contribution from each arc in this sector is automatically accounted for by the treatment plan optimization process. Inaccurate patient positioning during treatment in this area of overlap between arcs belonging to different isocenters, causes regions of over- or underdosages.

The purpose of this analysis is to find an optimal length of overlap between the overlapping arcs, to minimize the dose deviations that can be attributed to patient setup inaccuracies.

Material and Methods: Five (n = 5) patients undergoing CSI were planned using the Monaco 5.1 (Elekta Ltd, Crawley, UK) treatment planning system. Each plan consisted of 2 isocenters, with an overlap sector at the mid-cervical level. For the head a full clockwise-counterclockwise (cw-ccw) arc was used, while for the spine two cw-ccw partial arcs (180-260 ° and 100-181 °).

In order to assess the optimal overlap length, plans were generated for overlap sectors of 4, 6, 8 and 10 cm. Afterwards, plans were recalculated without re-optimization for a superior isocenter shift of +0.5 cm in cranio-caudal direction and a -0.5 cm in the left-right direction, mimicking a potential patient setup error. Dose distributions of the generated plans with isocenter shift were compared to the original plans based on V90%, V95%, V110% of the Planning Target Volume (PTV) and Conformity Index (CI).

Results: The introduction of a shift in the superior isocenter causes a 3% decrease in the V90% of PTV independently of the overlap length (Table1).

Table 1

Average (n=5) relative differences (Δ) of V90%, V95%, V110% and CI of the PTV between the shifted isocenter and the original plans.

Overlap length (cm)	Δ V90 (%)	Δ V95 (%)	Δ V110 (%)	Δ CI (%)
4	-3	-11	-50	-31
6	-3	-10	+39	-25
8	-3	-10	+58	-31
10	-3	-14	+373	-39

A decrease in PTV coverage (V95%) is also observed and the effect is larger for the 10 cm overlap length. The volume receiving $\geq 110\%$ of the prescribed dose increases when the length of the overlap becomes larger than 4 cm. The relative difference of the CI between the shifted and original plan is the smallest for the 6 cm overlap length. The smallest relative dosimetric deviations from the original non shifted plan are obtained for 6 cm overlap length.

Conclusion: To reduce the impact of setup errors during CSI by VMAT, the optimal length of the overlap sector using the Monaco 5.1 treatment planning system, should be around 6 cm.

PO-1008

In silico implementation of MRI-60Co RT. A dosimetrical comparison in cervical cancer (SIMBAD-02)

N. Dinapoli¹, L. Boldrini¹, E. Placidi², L. Azario², G.C. Mattiucci¹, D. Piccari¹, S. Teodoli², M.A. Gambacorta¹, S. Chiesa¹, A. Piermattei², V. Valentini¹

¹Università Cattolica del Sacro Cuore - Policlinico A. Gemelli, Radiation Oncology, Rome, Italy

²Università Cattolica del Sacro Cuore - Policlinico A. Gemelli, Medical Physics, Rome, Italy

Purpose or Objective: The ViewRay MRI-60Co hybrid system (MRIdian) allows MRI based targeting, structure autosegmentation and direct planning for numerous anatomical districts. Our department is implementing this technology and, up to date, we are testing QA planning procedures compared to our clinical standards in order to define which districts could take advantage from the use of the MRI-60Co technology. Aim of this investigation was to assess the impact of the implementation of the ViewRay magnetic resonance imaging (MRI)-guided 60Co radiation therapy system through an in silico planning analysis for cervical cancer treatments.

Material and Methods: Patients affected by cervical cancer (cT3; cN0, cN+) were manually segmented on Eclipse TPS v11. RapidArc (6-15 MV arcs) and 5 beams (6-15 MV) sliding window IMRT treatment plans were calculated according to our usual QA protocols by skilled planners. The PTV1 (CTV1+7/10 mm margin) was represented by the tumor, the PTV2 (CTV2+7 mm margin) by drainage pelvic nodes. The OARs considered for this analysis were the body, the bowel bag and the bladder. The total prescribed dose for PTV2 was 39.6/1.8 Gy and 50.6/2.3 Gy for PTV1 through simultaneous integrated boost. The PTV V95 and OARs QUANTEC dose constraints on the DVHs and Wu's homogeneity indexes (HI) were then analyzed to ensure the dosimetrical reliability of the plans. The structure sets were then uploaded on the MRIdian workstation and a 60Co plan was calculated by beginner planners after a specific training session. The DVHs and HI were then compared to the RapidArc and IMRT gold standard in order to evaluate MRIdian's performances.

Results: We calculated ten sets of three plans (MRI-60Co, RapidArc and 5 beams static IMRT) for ten consecutive patients. The MRI-60Co system showed a better HI when compared to the other techniques for PTV1, while this advantage could not be appreciated for PTV2, even if a better PTV2 V100 (39.6 Gy) was observed. Comparable mean doses for the bladder were registered, while a higher bowel V45 was observed (even if still in the constraints limits). Low dose body V5 was higher for the MRI-60Co system. The results are summarized in table 1.

Mean	MRIdian	RapidArc	IMRT
V95 PTV1 [%]	98.9	95.7	96.0
V105 PTV1 [%]	0.1	0.0	0.1
V95 PTV2 [%]	98.4	98.0	95.4
V100 PTV2 [%]	70.4	52.2	56.1
V105 PTV2 [%]	21.6	10.3	8.8
V5 Body [cc]	14615	12883	12617
V20 Body [cc]	7003	5004	6086
V45 Bowel Bag [cc]	9.5	6.3	6.9
Mean Dose Bladder [Gy]	37.2	36.2	37.0
Homogeneity Index PTV1	1.5	1.9	2.1
Homogeneity Index PTV2	7.8	5.5	6.0

Standard Deviation	MRIdian	RapidArc	IMRT
V95 PTV1 [%]	0.4	1.8	1.3
V105 PTV1 [%]	0.1	0.1	0.3
V95 PTV2 [%]	0.5	1.1	2.0
V100 PTV2 [%]	1.5	11.4	8.4
V105 PTV2 [%]	3.5	6.5	3.6
V5 Body [cc]	3837	3537	3598
V20 Body [cc]	1857	1620	1235
V45 Bowel Bag [cc]	18.1	13.1	14.1
Mean Dose Bladder [Gy]	3.7	1.9	2.5
Homogeneity Index PTV1	0.2	0.7	0.6
Homogeneity Index PTV2	0.4	1.4	1.0

Conclusion: We registered an higher PTV dose coverage between MRIdian's and the RapidArc and IMRT plans for cervical cancer, with a HI advantage for the PTV1. Differences were described for OaRs, especially for low dose areas (V5 Body). The MRIdian's planning platform showed to be user friendly and allowed to reach dosimetric goals comparable to RapidArc and IMRT gold standards. The evaluation of a possible reduction in PTV margins and a proper target coverage by MRI based gating will be analyzed when the system will become operative.

PO-1009

VMAT planning approach to avoid superficial underdosage for accelerated partial breast irradiation

F. Zucconi¹, P. Mancosu¹, G. Reggiori¹, F. Lobefalo¹, A. Stravato¹, A. Gaudino¹, V. Palumbo¹, L. Paganini¹, F. De Rose², S. Tomatis¹, M. Scorsetti²

¹Humanitas Clinical and Research Center- Rozzano- Milan-Italy, Medical Physics Unit of radiation therapy, Rozzano, Italy

²Humanitas Clinical and Research Center- Rozzano- Milan-Italy, Departement of Radiotherapy and Radiosurgery, Rozzano, Italy

Purpose or Objective: Accelerated Partial Breast Irradiation (APBI) is a RT approach that treats only the lumpectomy bed plus a margin, rather than the whole breast. The dose fluence outside the breast contour to account for breathing and residual motions can be manually increased with RapidArc/VMAT. At this aim, a 10 mm virtual expansion of the breast with soft-tissue equivalent HU is usually applied to the CT series (CT_E) and the optimization is performed on the APBI target expanded along the anterior/lateral directions. However, the dose recalculated on the original CT series (CT_O) could underdose the superficial target volume. In this study, a simple technical strategy to increase the target superficial dose is presented.

Material and Methods: Ten patients treated by APBI were randomly selected from the internal database (41 patients since 06/14). PTV_O was defined on CT_O as the tumor bed + 1-2cm, cropping it of 5 mm to the body. Dose prescription was 30 Gy in 5 fractions. Plans were normalized to PTV_O mean dose. PTV_E was defined on CT_E, expanding PTV_O of 10 mm in anterior/lateral directions. PTV_E was subdivided

in three parts: PTV_EI (PTV_E cropped of 7 mm from the CT_O body - internal), PTV_ES (PTV_E cropped 5-7 mm - superficial), PTV_EE (PTV_E minus PTV_EI and PTV_ES - external). Two plans were optimized on the CT_E: (i) prescribing the same dose to the three PTVs, (ii) PTV_EI = 30 Gy, PTV_ES = 32 Gy, PTV_EE = 33 Gy. Final dose calculations for the two optimizations were performed on the CT_O. Plan objectives were: D98% (dose received by 98% of the target volume) > 95% and D2% < 107% for PTV, minimizing the homogeneity index (HI=D2%-D98%); V15Gy (volume of the organ receiving 15Gy) < 50% for breast minus PTV; V10Gy < 20% for ipsilateral lung; V5Gy < 10% for contralateral lung; V3-5Gy < 10% for heart, Dmax < 1-2 Gy for contralateral breast. Plans were compared in terms of dosimetric plan objectives findings.

Results: Figure 1 shows the different dose distribution for the two optimizations on the CT_O and CT_E. Opposite dose distributions outputs were obtained on the two CT series. On the CT_E, D98%, D2%, and HI were favorable to the (i) (respectively, 94.9% vs 94.5%, 103.7% vs 105.9%, 8.8% vs 11.5%). On the CT_O, D98%, D2%, and HI were favorable to the (ii) (respectively, 92.3% vs 94.2%, 104.3% vs 104.2%, 12.1% vs 10.1%). In particular, the superficial volume (i.e. PTV_ES) was the region of highest underdosage (D98%= 85.4 ± 3.3% for the first approach). Regarding the OAR, minimal changes were found between the two approaches.

Conclusion: A virtual overdosage on the superficial part of the APBI target is required to account for involuntary motions. A simple procedure was showed to fully cover the target.

Partial delegation in 2-D match set-up evaluation for H&N IGRT treatment: preliminary results

A.R. Alitto¹, A. Pesce¹, S. Menna¹, M. Massaccesi¹, S. Manfrida¹, A. Pacchiarotti¹, A. Castelluccia¹, F. Micciche¹, N. Dinapoli¹, G.C. Mattiucci¹, R. Autorino¹, F. Catucci¹, L. Azario¹, S. Luzi¹, V. Valentini¹, M. Balducci¹

¹Università Cattolica S Cuore, Radiation Oncology Department- Gemelli-ART, Rome, Italy

Purpose or Objective: Aim of this study was to determine the magnitude of discrepancies between radiation oncologists and radiation therapists to define a partial delegation of verification when 2-D orthogonal kilovoltage (Kv) images are evaluated for daily set-up verification in head and neck cancer patients.

Material and Methods: Daily on-line kV-images of patients with head and neck cancer were evaluated for set-up verification both on-line by one of 7 radiation therapists (RTT) with adequate training, and off-line by a radiation oncologist (RO). All patients were treated by volumetric-modulated arc therapy (VMAT), by a LINAC 6 MV photon beam equipped with Millenium 120 MLC and on-board imaging system (VARIAN Medical System). Manual bone anatomy matching was used to determine translational displacements in all three axes (x, y, z) and discrepancies between RTT and RO were calculated. The concordance of decisions between RTT and RO were calculated, in particular for differences inferior, equal and superior to 3 mm. Results are presented as mean values, population systematic (Σ) and random (σ) errors. ANOVA test was used to test differences between groups. SPSS software was used for the statistical analysis.

Results: In this analysis 33 consecutive patients treated from March to September 2015 were included. Nine hundred ten (910) kV images were obtained and 2730 measures were made by the RO and RTT. A total agreement between RO and RTT was observed in 12.2% of cases. An inter-observer discrepancy of ± 3 mm or less and ± 4 mm or less on at least one direction was recorded respectively in 98.4% and 99.3%

kV images. Mean displacements on all the three axes were about 1mm and 79% of differences in craniocaudal direction, 82% in lateral direction and 81% in ventrodorsal direction were between -1mm and 1mm. ANOVA test shows significant differences between the mean displacements of the samples ($p < 0.05$). In AP, CC and ML directions, systematic discrepancies were 0.33, 0.32, and 0.42 mm and random discrepancies were 1.25, 1.42, 1.21 mm, respectively. Mean radial discrepancy was 1.78 mm (range 1.11-2.88 mm). By van Herk's formula CTV-PTV margins needed to account for such inter-observer variability were 1.70, 1.80 and 1.90 mm in AP, CC and ML directions, respectively.

Conclusion: The study showed a small inter-observer variability between the RO and RTT's observations after an adequate training, which allows a partial delegation of daily kV control, if the displacements were not superior to PTV margins.

Radiotherapy of brain metastases. Relationship with patients age and Karnofsky Index

J.L. Monroy Anton¹, J. Albestain Maria², M. Cuenca Torres³, M. Lopez Muñoz⁴, M. Soler Tortosa⁴

¹Hospital Universitario De La Ribera, Radiation Oncology, Madrid, Spain

²Universidad Catolica De Valencia, School Of Nursing, Alzira, Spain

³Hospital Universitario De La Ribera, Research Department, Alzira, Spain

⁴Hospital Universitario De La Ribera, Radiation Oncology, Alzira, Spain

Purpose or Objective: Brain metastases are common secondary lesions in several types of neoplasms. Survival is poor, so the treatment with external radiotherapy has as main goal to improve the quality of life of patients by decreasing the possible symptoms that may have.

Our objective is to analyze age and general condition of the patients and their possible influence on the response to treatment with radiation therapy in terms of survival.

Material and Methods: We evaluated 84 patients with brain metastases treated with external radiotherapy.

Karnofsky Performance Status (KPS), was the tool to evaluate functional status the first day of treatment. We divided the population in two KPS groups: <70 vs ≥ 70

We also distinguish two age groups: <70 years vs 70 years (elderly population)

Results: Global mean survival: 5,2 months; median: 3 m

Survival <6 months: 27patients (32,1%)

6-12 m: 11pts (13%)

>12 m: 9pts (10,7%)

Karnofsky Performance Status(KPS):

<70 : 28 patients (33,3%) mean survival: 5,4 m; median: 3 m

<6 m: 23 (82,1%)

6-12m: 4 (14,3%)

>12 m: 1 (3,5%)

≥ 70 : 56 pts (66,6%); mean survival: 5,4m; median: 3 m

<6 m: 34 (60,7%)

6-12m: 14 (25%)

>12 m: 8 (14,3%)

Age:

<70 years: 58 patients (69%) mean survival: 5,1 m; median: 3 m

<6 m: 41 (70,7%)

6-12m: 10 (17,2%)

>12 m: 7 (12%)

≥ 70 y: 26 (31%) mean survival: 5,3m; median: 3 m

<6 m: 16 (61,5%)

6-12m: 8 (30,7%)

>12 m: 2 (7,7%)

Conclusion: There are no significant differences in survival (months) depending on the age or the KPS in the analyzed population.

Survival in patients with KPS <70 is poor and less than six months in most cases. Most patients under 70 years have a survival <6 m. Survival >12 m is higher in KPS ≥ 70 .

Survival in elderly patients (> 70 years) is also less than six months. 6-12 months survival is higher in the elderly patients compared to the younger group, although survival >12 m is slightly higher in the group of younger patients (<70 y)

With these results we can consider applying hypofractionated treatment schemes (developed in few sessions) in the group of patients with KPS <70 or ≥ 70 years, where poor survival is expected.

Poster: RTT track: Adaptive treatments in the pelvic region

PO-1012

Can we adequately irradiate bladder cancer without daily on line adaptive treatment?

J. Noordermeer¹, M. Mast¹, J. Egmond van¹, P. Koper¹, E. Kouwenhoven¹, H. Jager de¹

¹MCH Westeinde, RCWEST, Den Haag, The Netherlands

Purpose or Objective: Standard pattern of care for muscle-invasive T2-T3 bladder cancer is surgery. However, some patients are not eligible for surgery because of age, comorbidity or non-resectability of the tumour. These patients are treated with radiation therapy. In the literature a large internal motion of the bladder has been reported. Therefore a portion of the Clinical Target Volume (CTV) can be missed during daily treatments. Our current treatment margins have been adjusted according to the findings of these studies. Reduction of margins is important for sparing the bowel. In the present study we investigated the influence of the bladder size and shape as well as the location of tumour itself on the margins.

Material and Methods: From 2013 to 2015, ten patients with solitary bladder cancer were treated. In five patients the tumour was marked circumferentially around the tumour bed using intravesical lipiodol injection. In the other five patients the tumour was not visible anymore after resection of the tumour and no lipiodol was used. As part of our routine treatment protocol, patients were instructed to have a full bladder during simulation and irradiation. They received instructions to void one hour prior to CT simulation or treatment and drink 250 cm³ of liquid. We acquired ConeBeam CT (CBCT) scans daily in the first week of the treatment and thereafter weekly. The bladder and lipiodol volumes were delineated on the CBCT. A bounding box and the centre of mass (COM) was calculated for the bladder and the tumour volumes on both the reference CT and all CBCT's for further analysis. Finally, a comparison of margins was carried out.

Results: In ten patients 93 CBCT-scans were analysed. Despite the full bladder protocol individual deviations were found in the bladder volume, mean volume 203 (SD 93ml), figure. Of the six anatomical directions the movement in the cranial and anterior direction were the largest and appeared to correlate with the volume of the bladder.

Figure: Boxplot of the bladder volumes for each patient. In the five lipiodol patients we found that the COM of the lipiodol depended on the bladder volume and the location of the lipiodol in the bladder. Based on this correlation we developed a model to predict the position of the lipiodol using the bladder volume. We calculated a margin based on the actual position of the lipiodol, and subsequently we calculated a margin based on the difference between the actual and the predicted position, Table.

	COM lipiodol					
	Actual position			Predicted position		
	LR	AP	CC	LR	AP	CC
	X	Y	Z	X	Y	Z
mean of means	-1.2	5.0	1.2	-0.2	0.1	0.0
stdev mean	3.1	5.2	6.0	0.5	0.5	0.2
mean stdev	2.2	5.2	5.6	2.8	4.2	4.6
Margin	9.2	16.6	18.9	3.2	4.1	3.7

Conclusion: As confirmed in the literature the full bladder protocol does not result in a stable bladder filling, and the displacement in cranial-anterior direction was the largest. Taking the predicted location of the tumour volume into account in preparing the treatment plans of the day, a considerable reduction in margin is achieved. Therefore, we need daily on-line adaptive treatment to adequately treat the bladder.

PO-1013

Adaptive radiotherapy in prostate cancer patients: concepts for Individualized Radiotherapy (iRT)

F. Fuchs¹, G. Habl¹, M. Devečka¹, S. Höfel¹, S. Kampfer¹, S. Combs^{1,2}, K. Kessel^{1,2}

¹Technische Universität München TUM, Department of Radiation Oncology, München, Germany

²Institute of Innovative Radiotherapy iRT, Helmholtz Zentrum München, München, Germany

Purpose or Objective: To evaluate interfraction volume changes and dose variations of organs at risk (OAR) and to develop individualized radiotherapy (iRT) concepts with movement compensation. This work analyzes the potential benefit of adaptive planning in patients with prostate carcinoma.

Material and Methods: We analyzed 16 patients with prostate cancer treated with helical IMRT and daily image guidance. Eight patients received radiation after prostatectomy with a total dose of 68 Gy in 34 fractions (group A), and eight a definitive irradiation with a total dose of 76.5 Gy in 34 fractions (group B). OAR rectum and bladder were delineated on daily Megavoltage (MV)CTs. With the Planned Adaptive software by Tomotherapy® (Accuray Inc., Sunnyvale, CA) we performed dose recalculations on the single fractions CTs and compared the summation dose with the original planned dose. Dose variations were analyzed by means of Dmedian, Dmean, Dmax, Dmin, V30, V40, V60, V70, V75, as well as the OAR volume.

Results: Our evaluation is still ongoing. During treatment, rectum volume ranged from 62-223% (A: 62-157%, B: 63-223%) of its initial volume; bladder from 22-375% (A: 30-311%, B: 22-375%). The mean of the Dmean in the rectum was 30.7 Gy and 37.2 Gy in group A and B, respectively; and for the bladder 26.4 Gy and 40.8 Gy. The dose statistics for the rectum was as follows: V30 22.2-90.2%, V40 14.2-80.5%, V60 0.1-46.9%, only for group A: V70 1.0-22.3% and V75 0-7.2%. The statistics for the bladder are: V30 15.6-100.0%, V40 10.9-100.0%, V60 3.8-89.8%, only for group A: V70 1.6-28.0%, V75 0.5-19.4%.

Conclusion: For patients with prostate cancer, relevant variations in volume of OAR, such as rectum and bladder, can be observed. Hence, corresponding dose variations occur. Adaptive replanning approaches have the potential to reduce the dose to OAR. However, which concept, e.g. "plan of the day" or fast online recalculation, will be the suitable solution

for routine patient treatment needs to be assessed in further evaluations.

PO-1014

Long time follow-up experience after IMRT for anal cancer: clinical outcomes and late toxicities

M. De Meric de Bellefon¹, P. Fenoglio¹, D. Azria¹, C. Llacer-Moscardo¹, O. Riou¹, N. Pirault¹, E. Combettes¹, N. Aillères¹, F. Castan¹, C. Lemanski¹

¹Centre Val d'Aurelle - Paul Lamarque, Hérault, Montpellier, France

Purpose or Objective: To assess outcomes of patients with anal canal cancer treated with Intensity-Modulated Radiation Therapy (IMRT) after a long time follow-up.

Material and Methods: From July 2007 to September 2015, 233 patients were treated by IMRT for anal squamous cell carcinoma. In 2009, Volumetric Modulated Arc Therapy RapidArc (VMAT RA) rapidly became our usual way of radiation for this cancer. Radiotherapy consisted in delivering 45 Gy in 1.8 Gy daily-fractions, 5 days a week, to the primary tumor and the risk area including pelvic and inguinal nodes (PTV1). A second plan of 14.4-20 Gy was administered to the primary tumor (PTV2) in 1.8-2 Gy daily-fractions, also 5 days a week (Image 1), or by pulsed-dose rate interstitial brachytherapy for some T1 and T2. PTV1 and PTV2 were treated continuously without gap and without Simultaneously Integrated Boost (SIB). Concurrent chemotherapy based on 5FU-mitomycin (MMC) or cisplatin was added for locally advanced tumors. Toxicities were evaluated according to the Common Toxicity Criteria for Adverse Events 4.0 scale. The survival estimates and their associated CI95% were calculated using the Kaplan-Meier method. We present here the first 166 patients' outcomes.

Results: Median follow-up was 46,7 months CI95% [41,2-51,6]. 124 women (75%) and 42 men (25%) were analysed. Median age was 61 years (range, 36-92). Tumors were classified as stages I, II, III and IV in 13%, 25%, 57% and 4% of the cohort, respectively. 13 patients were immunocompromised, 10 of those were HIV-positive (6%). Radiochemotherapy (RCT) or radiotherapy alone (RT) was delivered in 132 (80%) and 34 (20%) patients, respectively: 104 (79%) MMC, 25 (19%) cisplatin and 3 (2%) other regimens. 21 patients (13%) had the PTV2 treated by brachytherapy. 162 patients (97,6%) were complete responders. 36 patients (21.7%) had a relapse : 20 local (56%) among which were 3 synchronous metastatic failures, 4 locoregional (11%) and 12 metastatic without any local failure (33%). 33 patients (20%) had a colostomy following radiotherapy : 17 (46%) for local relapse, 12 (32%) for radiation toxicity, 3 (8%) for an uncomplete response, 1 (2,7%) for tumor complications during RCT. Concerning late toxicities: no grade 4 was observed; grade 3 were diarrhea (1 patient), proctitis (11), vaginal stricture (5), hematuria (1), fecal incontinence (4), chronic radiodermatitis (2 patients); 28 cases of grade 2 occurred among those clinical categories. About the hematologic late toxicity, there wasn't any significant difference between the blood count prior to treatment and the recent one (p=0.23). The 3-year overall survival rate was 85.5% CI95% [78.7-90.3], cancer-specific survival 89,0% CI95% [82,5-93,1], disease-free survival 74.6% CI95% [67-80.8],

relapse-free survival 79.6% CI95% [72.1-85.2] and colostomy-free survival 81.2% CI95% [74.0-86.6].

Conclusion: IMRT is emerging as a standard therapy for anal cancer. A dosimetric analysis will be done to complete this study.

PO-1015

Virtual training in patient information sessions prior to external beam radiotherapy

A. Stewart-Lord¹, M. Brown²

¹London South Bank University, School of Health and Social Care, London, United Kingdom

²Barking-Havering & Redbridge University Hospitals NHS Trust, Cancer & Clinical Support Division, London, United Kingdom

Purpose or Objective: The aim of the study was to explore the prostate patients' perceptions of Virtual Environment for Radiotherapy Training (VERT) as an information giving resource prior to radiotherapy delivery.

The objectives were:

- To determine the level of knowledge of those patients who attended (VERT) for a pre-treatment talk
- To explore patients perceptions who utilised (VERT) as an information giving resource prior to radiotherapy treatment
- To identify the benefits and limitations of using VERT as pre-treatment information giving resource

Material and Methods: A survey design was utilised to address the aims and objective of the study. The study was conducted over 2 phases: Phase 1 - participants were invited to attend a (VERT)patient information session four weeks prior to their planning CT scan. Phase 2 - patients were asked to complete a questionnaire two weeks after start of radiotherapy treatment. The questionnaire was designed to collect data on the prostate cancer patient's knowledge attitudes and beliefs regarding pre-treatment information provided prior to their radiotherapy treatment. A total population sample was used for this study. All patients being referred for radical radiotherapy to the prostate were invited to participate, over a five month data collection period (March - August 2015). A total of n=40 patients were included in the sample

Results: Statistical package SPSS (Version 21) was used for data analysis. Descriptive statistics and frequency tables were the first steps in the data analysis. Thereafter, Chi-squared tests were used to analyse the data further. Open ended questions were analysed thematically.

Results are currently being analysed however preliminary results are very positive, a summary of the preliminary results are outlined below (the final presentation will include frequency tables):

- Most patients found the (VERT) session to be very helpful
- Most patients stated that the session helped them to understand the importance of following bowel and bladder instructions prior to treatment and enhanced their knowledge about radiotherapy side effects
- The sessions were highly recommended for other patients and future recommendations included family members and carers to be included.
- Most patients were comfortable being part of a group during the presentation.
- Patients believed the sessions reduced their anxiety and stress about their upcoming treatment.

Conclusion: Patient perceptions on the use of (VERT) as information giving tool prior to radiotherapy treatment were very positive. The sessions enable patients to understand the potential impact of treatment volumes if the internal organ shape and location differed from that originally planned, enabling them to comply with radiotherapy treatment instructions.

PO-1016

Radiotherapy students' perceptions of skills training simulation using a bariatric suit

R.N.M. Khine¹, D. Flinton¹, P. Cherry¹, R. Thorne¹

¹City University London, Radiography, London, United Kingdom

Purpose or Objective:

Aim: The question posed is "Can simulation training improve/enhance student knowledge and skills in dealing with bariatric patients?"

Context: Accurate patient positioning, immobilisation and the delivery of precisely targeted radiation treatment are key stages in the radiotherapy process and bariatric patients present a unique challenge in achieving these stages. Radiotherapy for obese patients is a major challenge, both for the patient and the radiographer. There are practical limitations of radiation therapy equipment such as treatment couch weight limits and computed tomography (CT) scan aperture limits. Daily setup potentially is difficult. In addition, it also impacts on the safe manual handling on both staff and this group of patients.

Material and Methods: As part of their professional practice clinical skills sessions, the Year one undergraduate radiotherapy students (n=32) took part in a simulation session involving a bariatric suit. During each session, the radiotherapy lecturer wore the bariatric suit whilst the students working in pairs were required to position the lecturer (acting as the patient) on the couch.

After each simulation session, students were asked to complete a 10 point Likert scale questionnaire which permitted them to rate their experience of using the bariatric suit. A response rate of 100% was achieved.

They were asked to consider the following 3 areas:

- Whether it aided their learning in positioning patients'
- Whether it increased their awareness to deal with different patient groups
- Whether it increased their knowledge on the importance of accuracy and precision

In addition, they were asked to write a short reflection to identify what they learnt from the session.

Results: Students gave favourable feedback in all 3 areas investigated with a mean score above 4.5 (range -5 to +5)

The written reflective feedback supported the above quantitative scores by acknowledging the benefits of simulated training

Conclusion: The feedback from the students suggests that simulation training using a bariatric suit has had a positive impact on their learning. In addition, the sessions have assisted them in appreciating aspects as such as accuracy, precision, communication and manual handling issues. Most significantly students have acknowledged that the sessions have prepared them for their clinical placements.

PO-1017

Survey of image-guided radiation therapy use in Australia

V. Batumalai^{1,2}, L. Holloway^{1,2,3,4}, S. Kumar^{1,2}, K. Dundas¹, M. Jameson^{1,4}, S. Vinod^{1,2}, G. Delaney^{1,2}

¹Liverpool Cancer Therapy & Ingham Institute, Radiation Oncology, NSW, Australia

²South Western Clinical School, University of New South Wales, NSW, Australia

³Institute of Medical Physics, University of Sydney, NSW, Australia

⁴Centre for Medical Radiation Physics, University of Wollongong, NSW, Australia

Purpose or Objective: Image-guided radiation therapy (IGRT) utilises various imaging modalities for target and organs at risk delineation, tumour localisation, and patient setup. Although there is considerable development in IGRT technologies in Australia, little is known about their current clinical applications. The aim of this survey was to evaluate imaging technologies currently in use for planning and delivery of radiotherapy (RT) in Australia.

Material and Methods: An online survey was developed and sent to all 73 RT departments in Australia in August 2015. The survey inquired about imaging practices during both planning and treatment delivery processes. Respondents were asked about the types of IGRT technologies used, reasons for implementation, current utilisation rates, and future plans for IGRT use in their department.

Results: Responses were received from all states and territories, with a response rate of 71%. All respondents had access to CT simulators and regularly used image registration to fuse or co-register the following scans to the RT planning CT to aid tumour delineation; diagnostic CT (50%), diagnostic MRI (95%), planning MRI (34%), planning PET (26%) and diagnostic PET (97%). All respondents used some type of IGRT for in-room setup/tumour localization. The percentage of respondents using ultrasound, MV planar, kV planar, kV CBCT, and MVCT (Tomotherapy) were 9%, 77%, 89%, 97%, 6%, respectively. For other modalities, the percentage of respondents using spirometer, infrared, optical, and radio-frequency systems were 17%, 31%, 9% and 6%, respectively. Figure 1 displays the cumulative adoption of each IGRT modality based on reported years of adoption. Most centres used a combination of modalities for each tumour site depending on the treatment technique used. Table 1 shows rationale for in-room IGRT implementation. The main reasons or contributing factors for under-utilisation of in-room IGRT use were; lack of equipment capability (53%), insufficient funding (38%), concerns about imaging dose (34%), physicist availability for commissioning (28%), radiation oncologists availability to assess images (28%), and radiation technologists availability for image assessment (25%). The number of departments planning to increase use of IGRT for target delineation and in-room set-up/tumour localisation was 46% and 55%, respectively. No current users planned to decrease or cease use of IGRT.

Reasons for implementation	Percentage of respondents
Use of highly conformal techniques	100
Workflow enhancement	77
Use of hypofractionated regimen	57
To minimize normal tissue toxicities	89
To decrease CTV to PTV margin	63
Use of adaptive radiotherapy	54
Clinical trial requirement	43

Conclusion: This survey provides an insight into the IGRT technologies currently in use in Australia. IGRT is widely used among radiotherapy centres in Australia for both planning and treatment delivery. To our knowledge, this is the first study to assess the overall use of IGRT in Australia.

PO-1018

Increase efficiency and quality? Yes please! Use project management, participation and ownership

P.E. Tødenes¹

¹Ålesund Hospital, Academic Physics, Ålesund, Norway

Purpose or Objective: In Norway about 30,000 Norwegians get cancer each year. Approximately 230,000 Norwegians are living with cancer. The numbers are increasing rapidly. With population growth, longer life expectancy and elderly wave, Norway will have a need to streamline their health care.

Material and Methods: In Norway it has been common that each treatment attendance is set to 15 minutes (one PVE - Patient Visits Equivalent) by default. Normal opening hours are from 08:00 a.m. to 3:30 p.m. In other words 30 PVE per machine per day. Norway has strong union movement and strong culture of cooperation and involvement of employee representatives and employees. From management theories we know that change processes are easier to achieve if the changes are requested by the employees, owned by the employees and that employee representatives are included in the process. Radiation therapists and physicists are concerned with quality. Streamlining should not come at the expense of quality. One must therefore find efficiency measures that both improve quality while offering a more efficient operation. In autumn 2014 began management of the department to look at measures to increase quality and improve operational efficiency. One had thought of several possible ways; extended opening hours, logistics efficiency, LEAN processes, dressing stalls, automatic gantry and field execution, change PVE. We organized the work as a project where we included employee representatives and employees. The group consisted of a total of 4 people. They got a project that consisted of; background, mandate, goals, objectives, organization and budget. Important keywords were; Quality, time and cost. The order was that the group would come with concrete suggestions to increase the quality and efficiency. It was pointed out that efficiency should not compromise on quality. The order was both open and linked to direct questions. The group leaves after a few months forward its proposals. The proposals were discussed in a meeting between management and the group. The group then got feedback on what they could work on and discard. A new meeting was scheduled and we together agreeing on measures. The measures were then presented for all workers at the department. The project was then closed down and implements regular operation.

Results: We increased opening hours by 30 minutes without changing working hours or labor costs. Standard PVE was changed from 15 minutes to 10 minutes. One will thus be able to increase patient meetings with around 60% per treatment machines without increasing staffing levels of radiation therapists and physicists. The increase will be gradual and in close dialogue with employee representatives and employees.

Conclusion: Project management is a good work method to introduce changes. All employees now have ownership of the changes that the department must gradually take over the coming years.

PO-1019

Reflective practice: What is its impact on therapy radiographers practice?

J. Rodgers¹

¹Rodgers John, Academic Physics, Manchester, United Kingdom

Purpose or Objective: Reflective practice is a well-established aspect of professional development within radiotherapy. It is believed to improve patient care by assisting in workplace learning and providing more competent radiotherapy practice. The aim of the study was to investigate how therapy radiographers perceive how engaging in reflective practice impacts upon their work practice

Material and Methods: A closed question format Likert questionnaire formulated to investigate therapy radiographer's opinions on how reflection impacts on their work practice was distributed to therapy radiographers in The Christie NHS Foundation Trust radiotherapy department and its satellites. Focus groups were employed to investigate

questionnaire findings, in order to provide a deeper understanding of the processes involved and allow a separate methodology to either reinforce or reject findings.

Results: Questionnaire response rate was 78%. 81.8% of radiographers who participated agreed that reflection is an essential part of their professional learning.

Of the radiographers who responded 96% said they could recall engaging in informal reflection. Fewer could recall recently practicing formal reflection. When asked if they feel their work practice improved after reflecting informally 89.5% of radiographers agreed. Compared to informal reflection, less agreed that engaging in formal structured reflection had improved their work practice (76.4%).

Focus group data results suggest that radiographers believe informal reflection is an essential element of their professional learning, and that it has a direct beneficial impact on their patient care. There is a lack of consensus on the practice of formal reflection, with many radiographers citing barriers such as lack of time, training and evidence to support its use.

Conclusion: This study has found that therapy radiographers within the Christie NHS Trust believe engaging in reflective practice directly benefits their professional work and, by inference, improves patient care. Informal reflection is considered more effective and easier to employ. It should therefore be acknowledged by educators and professional bodies as the dominant reflective process.

To encourage the adoption of formal reflective practice, researchers and theorists should work on unifying the paradigm around a more simplistic, focused approach. Further research investigating the impact of an appropriate reflective model within the radiotherapy clinical setting using a robust qualitative study design is recommended.

PO-1020

Occurrence of visual phosphenes during radiation therapy of the head

A. Timmers¹, W.J.M. De Kruijf¹, T. Rozema¹

¹Institute Verbeeten, Klinische Fysica & Instrumentatie, Tilburg, The Netherlands

Purpose or Objective: We investigated the occurrence of visual phosphenes during the irradiation of the head. Visual phosphenes may occur because of direct stimulation of the retina by ionising radiation or by the Cerenkov irradiation that is generated in the eyeball. These are 2 different physical processes with their own characteristic visual sensation for the patient. We hypothesise that the direct stimulation of the retina is perceived as flashes of light, whereas the Cerenkov effect is perceived as a coloured light source. These are also the 2 main visual phosphenes that patients report. The first objective of the research is to establish what percentage of patients perceives light flashes or coloured light. The second objective is to determine, if it is perceived, what percentage of treatment fractions the patient perceives light flashes or coloured light. The third objective is to determine whether there is a relation between the perception of light flashes and the dose to the retina, or whether such a relation exists between the perception of coloured light and the dose to the eyeball.

Material and Methods: The inclusion criteria for the study were: treatment on the head, treatment plan with at least 3 fractions, and an informed consent. The patient was asked to complete a survey after each treatment fraction. We specifically ask for the occurrence of flashes of light and/or the occurrence of coloured light. Moreover, we ask for a description of the perception. We distinguish between 6 MV (59 patients) or 10 MV (15 patients) treatment plans. The dose relation has been investigated for a subgroup of 17 patients.

Results: 1) Approximately 60% of the patients with 6 MV plans and about 70% of the patients with 10 MV plans observe light flashes or coloured light at least once during their treatment. Often both light flashes and coloured light are

observed at the same fraction. However, it also occurs that only light flashes are observed or only coloured light is observed. 2) If light flashes or coloured light are perceived this occurs in approximately 70% of all treatment fractions for 6 MV beams, approximately 80% of treatment fractions for light flashes in 10 MV beams and approximately 90% of treatment fractions for coloured light in 10 MV beams. 3) The subgroup is too small to establish a dose relationship. However, below an average dose of 25 cGy on both retinas and both eyeballs almost no phosphenes are observed. For plans with an average dose of more than 150 cGy in one retina and more than 100 cGy in one eyeball, the patients in our subgroup perceive both phenomena at every fraction.

Conclusion: We have characterized the occurrence of visual phosphenes in our clinic. A relatively large number of patients perceives these phenomena. A dose relationship cannot be established but seems to exist.

PO-1021

Implementation and clinical use of a digital log regarding the Traffic Light Protocol in daily IGRT

R. Verhage¹, S. Van Beek¹, A. Smit¹, M. Broekhof¹, P. Remeijer¹

¹The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: With the introduction of a decision protocol for anatomical changes as observed on ConebeamCT (CBCT) images (traffic light protocol (TLP)), data such as, for example, actions in response to certain anatomical changes have been recorded in the open text area of the patient's electronic treatment chart on a daily basis. Recording the data in this way is manageable for keeping track of changes during a treatment, but this method cannot easily be used for retrospective analysis for e.g. research purposes. Therefore, we have introduced a dedicated digital TLP log within the patient's dossier, that enabled a clear and structured overview of the information gathered from the CBCT scans. In a retrospective study, the efficacy of this log was evaluated.

Material and Methods: The TLP digital log was implemented and accommodated in the Mosaik Oncology Information Management System. The log contains a separate format for each of the major target areas on which the TLP is used and does not contain any free text entry fields. For every CBCT acquisition a log entry is created. Within the log the user can register the relevant anatomical changes seen on the CBCT, by using drop down lists with fixed entries (e.g. bladder filling or tumour regression and the action taken (see figure). The actions are categorised by colour: Green (no action), Yellow (notification of the Medical Doctor (MD) optional), Orange (action needed by the MD before next fraction) and Red (immediate action needed from the MD). During the period of data gathering the digital TLP was made available for five target areas: Breast, Sarcoma, Lung, Gynaecology and Urology. The digital log was retrospectively evaluated on 120 patients (40 for urology, 20 for all other target areas) with a CBCT imaging protocol treated from January 2013 to December 2013. The use of the digital log in clinical practice was evaluated using a questionnaire filled in by the RTTs. During the data gathering, a total of 1806 CBCT scans were reviewed and registered in the digital log. All of these scans were assessed with the TLP to determine the course of action. In this period, all action codes were registered and recorded.

Date	10/16/15 3:35 PM	10/16/15 3:35 PM	10/16/15 3:35 PM	10/16/15 3:37 PM	10/16/15 3:38 PM
Diagnosis	Lung, SCLC	Lung, SCLC	Lung, SCLC	Lung, SCLC	Lung, SCLC
Location	Left	Left	Left	Left	Left
CBCCT scan number	16	17	18	19	20
Plan					
Code green	Y				
Colourcode		Yellow	Orange	Orange	Orange
Reduction/growth GTV		Reduction	Reduction	Reduction	Reduction
Tumour shift					
Tumour shift vs Plan					
Other image changes					
Ateleclasis			Beginning	Beginning	Reduction
Pleural effusion			Reduction	Reduction	Reduction
Inflammation					
Difficult to judge					
Exceedance of restriction					
Rotations > protocol					
Clipboard exceedance					
Adjusted Threshold					
Decision MD		No action	See Patient chart	See Patient chart	

Results: Using the digital log, the data concerning the TLP can be stored in a structured way, rather than in open text parts of a patient's dossier. The action codes regarding the anatomical changes that are present in the log showed a clear overview of possible variations during treatment. The RTTs scored an average of 7.8/10 in the questionnaire on the digital log overview. In succession, this overview showed a clear course of action regarding these anatomical changes using the TLP.

Conclusion: The implementation and use of a digital log improves the overview of the anatomical changes observed on CBCT during radiotherapy. Moreover, the data gathered within the log can retrospectively be used for clinical or research questions regarding clinical IGRT decisions for a specific target area.

PO-1022

Robotic radiosurgery for vestibular schwannomas - the early tumor response and treatment tolerance

L. Wzietek¹, A. Namysl-Kaletka¹, A. Napieralska¹, D. Gabrys¹, S. Blamek¹

¹*Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology III Dept, Radiotherapy Department, Gliwice, Poland*

Purpose or Objective: Vestibular schwannomas (acoustic neuromas) are common benign tumors that arise from the Schwann cells of the vestibular nerve. Management options include observation with neuroradiological follow-up, microsurgical resection or stereotactic radiotherapy (SRS). The aim of the study was to evaluate tumor size and treatment tolerance of patients treated with CyberKnife (CK) radiosurgery for vestibular schwannoma (VS).

Material and Methods: Between 2011 and 2014, 96 patients with 100 vestibular schwannomas were treated with SRS using CK. The vestibular schwannomas of 5 patients were associated with type II neurofibromatosis. Twenty patients were operated on before radiosurgery. All patients had more than one year follow-up. The median age at the time of treatment was 59 (range 21-88 years). Median tumor diameter was 18 mm (range 3-48 mm) and the median prescribed dose was 16 Gy (12-21 Gy). In 29 patients, single dose of 12-18 Gy was delivered, in 31 total dose of 12-16 Gy was delivered with two fractions and the remaining 40 patients were treated with 15-21 Gy delivered in 3 fractions baseline. Hearing was classified according to the Gardner Robertson grading scale (48% of patients had serviceable hearing).

Results: At 12 month after SRS we observed that :15% of tumors slightly expanded, in 8% patients slight expansion of tumor followed by regression, 11% of tumors increased in size, but then remained stable, 58% were stable in size and 8% responded to therapy. Overall, tumor swelling was, thus, observed in 34% of patients. At first year no patient required neurosurgical intervention due to tumor progression or brainstem compression symptoms. 77% patients had stable level of hearing after SRS, 9% declared improvement and 14% worsening of hearing. The rate of complications was very low, with most consisting of a transient worsening of

preexisting symptoms. At the last assessment, full facial and trigeminal nerve function was preserved in 95% and 98% of patients, respectively; the only facial deficit (House-Brackmann grade III) occurred in patient who received a single dose of 18 Gy in one fraction early in our experience, the remaining were mild, grade II dysfunctions. None of the patients treated with doses lower than 13 Gy experienced facial or trigeminal neuropathy.

Conclusion: Cyber Knife radiosurgery is a safe and effective treatment for VS characterized by high probability of retaining functional hearing and facial and trigeminal nerve function preservation. In about one third of patients a tumor swelling after treatment is observed but reliable tumor control and persistence of neural dysfunctions assessment requires longer follow-up.

PO-1023

Quality assurance for IMRiS phase II study of IMRT in sarcomas: a survey of limb immobilisation

R. Simões¹, E. Miles¹, F. Le Grange², R. Bhat³, B. Seddon²

¹*Mount Vernon Hospital, RTTQA group- Radiotherapy Physics, London, United Kingdom*

²*University College of London Hospital, Sarcoma Unit, London, United Kingdom*

³*Cancer Research UK, UCL Cancer Trials Centre, London, United Kingdom*

Purpose or Objective: Soft tissue sarcomas are rare malignancies, commonly arising in limbs, with an annual incidence of 3,298 cases in the UK in 2010. Their rarity leads to a lack of published data and experience in limb immobilisation for radiotherapy planning. The IMRiS trial is a phase II study of intensity modulated radiotherapy (IMRT) in primary bone and soft tissue sarcoma, due to open in late 2015. As part of a pre-trial quality assurance (PT QA) programme, we report on the current UK practice of limb soft tissue sarcoma (LSTS) immobilization and the significance for multi-centre trial recruitment.

Material and Methods: A facility questionnaire (FQ) was circulated to 29 IMRiS centres to investigate variation in immobilisation devices (ID), planning techniques, and imaging protocols. A workshop was held to address limb sarcoma immobilisation and patient set up. Robustness of patient setup at each centre was evaluated based on setup audits, frequency of imaging and the number of patients (pts) treated per centre per annum.

Results: 27 questionnaires were returned. Less than 1/3 of the responders routinely treat their pts with IMRT (8/27). The remaining 2/3 have little or no experience with IMRT for LSTS. Vacuum bags are currently the most popular ID (9/27), followed by thermoplastic shells (7/27), limb boards (5/27), other devices (3/27) of which 2 used in-house developed and customisable devices, and 1 used common positioning pads. 2 centres combined the use of vacuum bag and shell. 9 centres had audited their setup. However, only 4 had calculated their setup margins on the basis of systematic and random error. The majority of centres follow the recommendations to perform imaging on days 1 to 5 and then weekly. 6 centres perform daily imaging (all 6 treat LSTS with IMRT). Of 6 centres with a high level of setup robustness, 3 are IMRT centres. On average centres treat 24 pts annually (range 3-53). Currently over half the centres treat less than the calculated average number of pts.

Conclusion: The results from the FQ and workshop demonstrate variations in treatment modality, ID and imaging frequency across the UK. 70% of IMRiS participating centres will be implementing or further developing IMRT in order to treat LSTS in the study. This will require a change in treatment modality (from 3DCRT to IMRT) in 9 centres. Comprehensive PT QA is required to ensure quality in a trial to be run at centres with such different levels of experience.

Robustness of patient setup is important to decrease variability arising from different ID. The PT QA program will encourage centres to assess robustness of setup through audit and calculation of centre specific margins. The majority of centres will need to review treatment verification as daily imaging is mandated for the trial. We anticipate that centres with less robust setup systems may need more support to safely implement IMRIS, and in response to this a discussion group will be created to allow centres to share their experience.

PO-1024

Residual interfraction error after orthogonal kV in stereotactic RT. Analyses from 139 CBCT scans

S. Manfreda¹, A. Castelluccia¹, M. Massaccesi¹, V. Frascino¹, M. Ferro¹, C. La Faenza¹, A. Petrone¹, N. Dinapoli¹, C. Mazzarella¹, M. Vernaleone¹, G. Macchia², G.C. Mattiucci¹, L. Azario¹, S. Luzi¹, V. Valentini¹, M. Balducci¹

¹Gemelli-ART- Università Cattolica S.Cuore, Radiation Oncology Department, Rome, Italy

²Fondazione di Ricerca e Cura "Giovanni Paolo II"- Università Cattolica S.Cuore, Radiation Oncology Unit, Campobasso, Italy

Purpose or Objective: To quantify residual interfraction error after two-dimensional (2D) orthogonal kV set-up correction using cone-beam CT (CBCT) and 6DOF robotic couch for target localization in patients undergoing stereotactic radiotherapy.

Material and Methods: After clinical setup using in-room lasers and skin/cradle marks placed at simulation, patients were imaged and repositioned according to orthogonal kV registration of bony landmarks to digitally reconstructed radiographs from the planning CT. A subsequent CBCT was matched to the planning CT using also soft tissue information and the resultant residual error was measured and corrected before treatment. Absolute averages, statistical means, standard deviations, and root mean square (RMS) values of observed error were calculated.

Results: From June 2014 to October 2015 a total of 45 patients with intracranial (15 pts), intrathoracic (19 pts) and abdominal (11 pts) lesions received 139 fractions of SBRT. 2D kV images revealed a vector mean setup deviations of 0,9 mm (RMS). Table 1 shows residual translational shifts observed with CBCT. Means of pitch, roll and yaw errors were 0,18° , 0,27° and 0,05° , respectively. Pitch, roll, and yaw errors were lower than 1° in 92%, 88% and 82% of images, respectively. According to tumor site, residual setup deviations seemed to be higher for abdominal lesions (RMS 1,4 mm) compared with intrathoracic (RMS 1,1 mm) and intracranial lesions (RMS 1,0 mm).

Overall	Mean	AP (mm)	SI(mm)	ML(mm)
	Mean M	-0,8	-4,0	-0,9
SD	3,3	3,1	3,4	
RMS	5,1	5,1	5,0	
		1,3		
Intracranial lesions	Mean	-0,7	-0,1	-0,7
	Mean M	1,1	1,6	1,7
SD	5,3	5,1	4,9	
RMS		1,0		
Intrathoracic lesions	Mean	-0,8	-0,2	-0,7
	Mean M	5,0	4,2	3,6
SD	5,2	5,0	4,9	
RMS		1,1		
Abdominal lesions	Mean	-0,8	-0,3	-1,2
	Mean M	3,8	3,2	4,8
SD	5,1	5,1	4,9	
RMS		1,4		

Tab. 1: Residual translational shifts detected by CBCT after repositioning according to kV registration.

Abbreviation: AP= anterior-posterior, SI= superior-inferior, ML= medial lateral, Mean M= mean value in magnitude, SD= standard deviation, RMS= root mean square .

Conclusion: These data confirm the importance of CBCT to reduce interfraction errors, especially when high dose per fraction is delivered. Residual interfraction shifts for intracranial lesions is lower than for other tumor sites, probably as consequence of poor relevance of organ motion in this site.

PO-1025

Reproducibility of prone immobilization in breast treatment - a retrospective study

N. Rodrigues¹, A. Francisco¹, S. Vieira¹, J. Stroom¹, M. Coelho², D. Ribeiro¹, C. Greco¹

¹Fundação Champalimaud, Radiotherapy, Lisboa, Portugal

²Mercurius Health, Radiotherapy, Lisboa, Portugal

Purpose or Objective: Many studies have been conducted regarding the dosimetric advantages of prone positioning systems for breast radiotherapy treatments, especially for pendulous breasts. However, there is a shortage of publications considering the reproducibility of such systems. This study performs a retrospective patient set-up analysis of a prone positioning system. An estimation of the required safety margin was also calculated in an attempt to predict if patients undergoing breast irradiation in prone position could be safely treated without an online correction protocol.

Material and Methods: A group of 21 patients with localized breast cancer were treated in prone position (New Horizon™ Prone Breastboard, CIVCO Medical Solutions) with a fractionation scheme of 3.2 Gy x 15 to the boost and simultaneously 2.7 Gy x 15 to the whole breast. An online correction protocol based on CBCT imaging was applied and the initial set-up deviations (i.e. the first registration data for each fraction) were used in this study. The overall mean population error (μ) for each translational direction was calculated, as well as the population systematic (Σ) and random (σ) components. These outcomes were subsequently compared to the results derived from an equally numbered group of patients treated in supine position (C-QUAL™ Breastboard, CIVCO Medical Solutions) with the same fractionation scheme.

In both treatment positioning systems CBCT matching criteria was prioritized according to: 1 - Breast contour; 2 - Boost position; 3 - Chest wall.

The mean number of repositioning for each population was also considered.

Geometrical margins were calculated according to the following margin recipe:

$$M_{Geo} = 2.1\sum + 0.8\sigma$$

Results: Results regarding the evaluated overall mean population error (μ), population systematic (Σ) and random (σ) components and estimated safety margin (M_{Geo}), for both immobilization techniques, are displayed in Table 1.

A 5 mm safety margin is used in our institute and an online protocol is followed. However if an off-line protocol would be applied (50% reduction of systematic errors) the resulting M_{Geo} for the prone positioning, would be of 7,6 mm (SI), 8,2 mm (ML) and 5,6 mm (AP) and the applied margin would be insufficient.

Regarding workload, patients in prone position are, on average, repositioned 4 times during the 15 fractions against 1 repositioning for patients in supine position, which we consider to be acceptable when considering the dosimetric gains for PTV coverage and OAR.

	μ (mm)			Σ (mm)			σ (mm)			M_{Geo} (mm)		
	SI	ML	AP	SI	ML	AP	SI	ML	AP	SI	ML	AP
Prone	1,2	-1,3	-1,1	4	4,8	2,4	4,2	3,9	3,8	10,4	12,2	9,1
Supine	-0,3	-1,5	1,7	2,6	1,9	2,3	2,5	1,9	2,7	8,7	6	7,1

Table 1 - Results for the overall mean population error, systematic and random components and estimated safety margins.

Conclusion: Comparing with supine, prone positioning is more unstable and suffers from larger set-up errors, due to both systematic and random components. Additionally, without an online imaging protocol it requires larger safety margins. However, given the dosimetric advantages of prone immobilization, we conclude that this type of positioning can be safely used as long as an adequate margin is applied and especially if an online imaging protocol is followed.

PO-1026

Setup accuracy of DIBH for breast treatment with a simultaneous integrated boost.

B. Kraan¹, M. Admiraal¹

¹VU medical Center, Radiotherapy, Amsterdam, The Netherlands

Purpose or Objective: This study aimed to quantify the setup accuracy of voluntary Deep Inspiration Breath Hold irradiation of the left breast with a simultaneously integrated boost (SIB). We investigated the additional effort required to achieve the same accuracy as in non-breath hold SIB treatment.

Material and Methods: Thirty patients with breast cancer were selected for retrospective setup analysis, 15 patients were treated in free breathing (FB), and 15 patients were treated with Deep Inspiration Breath Hold (DIBH).

Patients in the breath hold group were trained to perform a voluntary DIBH in advance of CT scanning. Breathing motion was monitored using the Real-time Position Management System (RPM, Varian Medical Systems, Palo Alto CA). An in-house developed visual feedback system was available to display the live RPM signal to the patient, both at CT and at the linac. All patients were treated in 21 fractions, each delivering a dose of 200cGy to the whole breast and a 267cGy boost to the tumor bed. Plan setup was similar for all patients, with two tangential open fields and 4 additional IMRT fields to minimize inhomogeneity and to boost the tumor bed.

Setup at the linac was based on two 2D-kV images (Varian Medical Systems, Palo Alto CA), either in free breathing (FB group) or in breath hold (DIBH group). All images were matched such, that the surgical clips deviated no more than 5mm in all directions, and the ventral bony anatomy was

within 8mm. If these two limits could not be achieved in one match, re-positioning was performed.

We analyzed residual setup error in bony anatomy and clips separately, by re-matching the images twice: focusing either only on the bony anatomy, or only on the clips. We also scored the time between the first setup image and the first treatment field (setup-time).

Results: Deviation of the bony anatomy and clips with respect to the online match were small, and not different between the FB group and the DIBH group (table1).

	ventro-dorsal (cm)	cranial-caudal (cm)	lateral (cm)
FB _{bone}	0.3	0.3	0.2
DIBH _{bone}	0.3	0.2	0.2
Fb _{clips}	0.1	0.1	0.1
DIBH _{clips}	0.1	0.1	0.1

Table 1: average offset with respect to the online match for bone match (top rows) and clip match (bottom rows) for FB group and DIBH group.

The average setup-time was 6 and 8 minutes for the FB group and DIBH group respectively, with re-setup in 8 out of 135 fractions (6%) for the FB group, and 7 out of 55 fractions (13%) for the DIBH group.

Conclusion: In treatment of left sided breast patients with a simultaneous integrated boost the same setup accuracy can be reached in DIBH as in treatment in FB. To reach this accuracy, the DIBH group needs re-positioning more often than the FB group. Consequently, the online setup in DIBH will require additional time.

EP-1027

Re treatment in previously irradiated neck. The different problems of relapsed and second cancers

C. Krzisch¹, E. Ecker¹, S. Gabriel¹, A.R. Henry¹, A. Coutte¹

¹CHU Amiens - Hôpital Sud, Radiation Oncology, Salouel, France

Purpose or Objective: Owing to legitimate fears concerning potentially devastating complications, the treatment of head and neck cancer in previously irradiated patient has been based on surgery for the best cases and chemotherapy for the inoperable ones. We review our series of 84 routinely re-(chemo)irradiated patients since 2000.

Material and Methods: Patients : 84 consecutive patients, mean age 60.47, previously treated by radio(chemo)therapy with a median delay between the the two irradiations of 36.3 months have been treated. 54 patients with relapses and 30 patients presenting second cancers . The mean follow-up is 66.45 months.

Methods : 42 patients were operated upon, (chemo)radiotherapy being used postoperatively for poor prognostic factors. 42 inoperable patients have been treated exclusively by radiochemotherapy. Before 2007, patients were treated by 2D techniques then by IMRT. 44 received concomitant platinum-based chemotherapy, 23 cetuximab and 17 radiotherapy alone.

Results: Results : median overall survival for the entire population is 19.61 months. Specific survival 23 months. Death causes : 40 the cancer itself, 9 patients complications et 11 other causes. Prognostic factors : age, sexe, performance status, Charlson score, location, type of resurgence (local, nodal or both), surgery, chemotherapy antecedents, type of concomitant treatment during the reirradiation, previous disabilities (tracheostomy, nasogastric tube) have been investigated. Only the type of resurgence is discriminant with a median survival time of 16.49 months for patients treated for a relapse and 32 months for those treated for a second cancer (Logrank $p=0.00464$). Complications : 9 deceased : 1 carotid blowout (with evolutive tumor), 3 late pneumoniae (patient NED), 3 tumoral hemorrhages (evolutive tumors) and 2 unknown complications. Late sequelae: 10 radionecrosis (7 osteoradionecrosis), 7 persistent dysphagia, 8 long term fistulas.

Conclusion: Conclusion :The survival in our series restricted to the second cancers is similar to that obtained in not previously irradiated patients and confirm some data of the literature. Thereby it is our belief that, if the acceptance of this strategy of treatment may merit further clinical trials for the relapsing tumor (however the results compare favorably with palliative chemotherapy), it becomes unethical not to give this chance for the second cancers in spite of the risk of severe complication.

EP-1028

The role of adjuvant external beam radiation therapy for advanced papillary thyroid cancer

C.Y. Kim¹, N.K. Lee¹, K.Y. Jung², S.K. Baek²

¹Korea University Anam Hospital, Radiation Oncology, Seoul, Korea Republic of

²Korea University Anam Hospital, Otolaryngology-Head and Neck Surgery, Seoul, Korea Republic of

Purpose or Objective: the purpose of this study was to investigate the prognostic implication of adjuvant external beam radiation therapy on the locoregional control in patients with either locally advanced thyroid papillary carcinoma or cervical lymph node involvement.

Material and Methods: retrospective analysis was performed on 165 patients with locally advanced thyroid papillary

carcinoma (T4) or cervical lymph node involvement (N1b), who were treated between 2002 and 2011. Of these, 32 patients were treated with total thyroidectomy followed by adjuvant external beam radiation therapy and radioactive iodine treatment, and 133 patients were treated with total thyroidectomy followed by radioactive iodine treatment.

Results: The median follow-up time was 223 months (range, 93 to 421 months). The 10-year disease-free survival and locoregional relapse-free survival rates were significantly better than unirradiated controls. 10-year disease-free survival rates for patients in the radiation therapy and no radiation therapy groups were 84.3% and 56.7%, respectively ($p = 0.049$). 10-year locoregional relapse-free survival rates for patients in the radiation therapy and no radiation therapy groups were 83.9% and 60.8%, respectively ($p = 0.037$). The overall survival rate and distant relapse-free survival rate were not different between the two groups. Multivariate analysis showed that adjuvant radiation therapy was an independent prognostic factor for locoregional relapse-free survival ($p = 0.044$).

Conclusion: adjuvant external beam radiation therapy should be considered in patients with either pT4 disease or cervical lymph node involvement.

EP-1029

20 v. 25-35 fractions in Oropharyngeal Carcinoma chemoIMRT: Could fraction number be de-escalated?

B. Cheng¹, H. Benghiat², J. Glaholm², H. Mehanna¹, P. Sanghera¹, A. Hartley¹

¹InHANSE, Radiotherapy Quality Assurance, Birmingham, United Kingdom

²Hall-Edwards Radiotherapy Research Group, Queen Elizabeth Hospital, Birmingham, United Kingdom

Purpose or Objective: Highly conformal dose distributions produced by rotational IMRT reliably delivered with daily IGRT raise the possibility that radical chemoIMRT for oropharyngeal carcinoma could be delivered in fewer fractions (#) for certain subgroups. The purpose of this study was to compare two cohorts of patients with oropharyngeal carcinoma treated within a single centre: the first treated with a 20# (4 weeks(wk)) schedule, the second with 25-35# (5-7wk) schedules.

Material and Methods: Patients undergoing radical chemoIMRT between June 2009 and May 2012 were treated with 55Gy/20# over 25 days to PTV1 with synchronous carboplatin or cetuximab (20# cohort). Similar patients were treated between June 2012 and April 2014 with one of three schedules 64Gy/25# over 32 days, 65Gy/30# over 39 days or 70Gy/35# over 46 days to PTV 1 with synchronous cisplatin or cetuximab (25-35# cohort). The local control (LC) and overall survival (OS) of these two cohorts were compared using the log-rank test.

Results: The minimum time elapsed from treatment in all patients was 18 months. There were 86 patients in the 20# cohort: median age 58 years; p16+ 60 (70%); T4 28 (33%); N2C/N3 16 (19%). There were 77 patients in the 25-35# cohort: median age 59 years; p16+ 54 (70%); T4 24 (32%); N2C/N3 16 (22%). The 18 month local control in the two cohorts respectively was 86% v. 88% ($p=0.69$). The 18 month overall survival was 85% v. 89% ($p=0.41$). If the two cohorts were restricted to those patients who were p 16+ve, T1-3, no neo-adjuvant chemotherapy and platinum agent used synchronously the corresponding figures (n= 26 for 20# cohort v. n=38 for 25-35# cohort) for local control were 92% v. 95% ($p=0.34$) and for overall survival 96% v 100% ($p=0.22$).

Conclusion: Although further follow up and late toxicity data is required, the similarity in results seen between the two cohorts in this study warrant the testing of the 20# schedule with synchronous cisplatin in a randomised setting in good prognosis oropharyngeal patients. This similarity in the endpoints studied is evidence against synchronous chemotherapy acting to reduce accelerated repopulation

during chemoradiation and further models to account for the effect of synchronous chemotherapy should be investigated.

EP-1030

Sentinel lymph node biopsy in clinically N0 laryngeal cancer: validation and application

V. Rudzianskas¹, E. Korobeinikova¹, E. Padervinskis², M. Kaseta², S. Vaitkus², N. Jurkiene³

¹Kaunas Medical University Hospital, Oncology and Hematology, Kaunas, Lithuania

²Kaunas Medical University Hospital, Department of Otorhinolaryngology, Kaunas, Lithuania

³Kaunas Medical University Hospital, Department of Radiology, Kaunas, Lithuania

Purpose or Objective: Cervical lymph node dissection for laryngeal cancer patients without clinical and radiologic evidence of regional metastasis (N0) is controversial. Aim of our study was to validate sentinel lymph node biopsy (SLNB) procedure and evaluate its applicability in early T1-2 N0 laryngeal SCC.

Material and Methods: A prospective study conducted at the Lithuanian University of Health Sciences Hospital, with the permission of institutional review board. Inclusion period 2010 - 2013y. Patients with histologically confirmed laryngeal SCC T1-2, N0 were involved. Two phase design: validation phase - SLNB and selective neck dissection (SND) were performed simultaneously; application phase - SND was performed according to SLNB outcome. The end points for SLNB validation phase: sensitivity, specificity, negative-predictive value (NPV). Patients from both phases were followed-up after treatment and compared for recurrence-free survival (RFS). Sentinel lymph nodes (SLN) were located by ^{99m}Tc lymphoscintigraphy and gamma probe. Pathological evaluation included hematoxylin and eosin staining and immunohistochemistry. Statistical analysis was performed by using SPSS® v20.0, Clinical Calculator 1, ©Richard Lowry 2001-2015. The Pearson X2 was used for categorical data. Significant p-value <0.05. RFS was investigated performing a log-rank test.

Results: Clinicopathological features presented in table 1. In SLNB validation period we involved 16 pts. The mean number of SLNs per patient was 2.3. Four patients had positive SLN, no false positive results found. 12 pts had negative SLN, one of them had positive SND histological findings. The prevalence of positive lymph nodes was 0.31 (95% CI 0.12-0.58), overall sensitivity was 0.8 (95% CI 0.29-0.98), specificity was 1 (95% CI 0.67-1). NPV of SLNB equal to 0.91 (95% CI 0.59-0.99). During whole study period 46 pts were involved. The median of SLN removed per patient was 2.2. The total neck control rate was 87% and did not differ between validation and application groups (p=0.4). In a mean follow up period of 24 months, mean RFS time for validation group was 42 months (95%CI 37.36-48.28) vs 40 months in application group (95%CI 32.02-48.13), with no significant difference (p=0.43).

Conclusion: More comprehensive study with a larger group of patients and longer follow-up is needed in order to confirm SLNB applicability, however preliminary data revealed SLNB as sensitive and specific with no negative influence on recurrence-free survival.

EP-1031

Does oral mucosa OAR dose predict duration of G3 mucositis following IMRT for oropharynx cancer?

S. Yahya¹, H. Benghiat¹, P. Nightingale¹, M. Tiffany¹, P. Sanghera², A. Hartley²

¹Hall-Edwards Radiotherapy Research Group, Queen Elizabeth Hospital, Birmingham, United Kingdom

²InHANSE, University of Birmingham, Birmingham, United Kingdom

Purpose or Objective: Various methods have been described to delineate the oral mucosa organ at risk (OAR). Due to uncertainty in the literature, the purpose of this study was to

examine whether dose delivered to two versions of this OAR correlated to the duration of acute grade 3 mucositis in patients with oropharyngeal carcinoma treated with intensity modulated radiotherapy (IMRT).

Material and Methods: 66 patients previously treated with IMRT (55GY in 20 fractions over 25 days to the high dose volume; 46 in 20 fractions to areas at risk of harbouring microscopic disease) and synchronous carboplatin or cetuximab were included in this study. The duration of CTCAE version (v) 3 grade 3 mucositis (G3M) and the duration of strong opiate use (a surrogate for CTCAE v4 G3M) had been prospectively recorded at the time of treatment. Standard and modified oral mucosa OARs were contoured and the following dose parameters derived: mean dose, V55, V50, V45, V40 and V30.

Spearman's correlation was used to investigate for a relationship between the duration of v3 G3M or strong opiate use and these dose parameters for each OAR and 6 additional patient factors: pre-radiotherapy haemoglobin, weight, age, smoking status, use of neo-adjuvant chemotherapy and synchronous chemotherapy (carboplatin v. cetuximab).

Results: No statistically significant correlation of v3 G3M or duration of strong opiate use was noted with the tested parameters with the exception of a trend towards significance with pre-treatment weight (p=0.053). Duration of opiate use was found to be approximately proportional to pre-treatment weight.

Conclusion: This study failed to show a relationship between dose to the standard or modified oral mucosa OAR and the duration of CTCAE v3 G3M or duration of opiate use in patients undergoing IMRT for oropharyngeal cancer. Further work is required to test these models with particle therapy where lower dose distributions to oral mucosa may be achievable. The utility of CTCAE v4 G3M as an endpoint if confirmed in larger studies to be related to pre-treatment weight is questioned by this study.

EP-1032

Unilateral neck radiotherapy in HPV-related tonsillar carcinomas

K. Thippu Jayaprakash¹, K. Geropantass¹, K. Sisson², T. Roques¹

¹Norfolk and Norwich University Hospitals Foundation Trust, Department of Oncology, Norwich, United Kingdom

²Norfolk and Norwich University Hospitals Foundation Trust, Department of Pathology, Norwich, United Kingdom

Purpose or Objective: Unilateral neck radiotherapy is considered a standard treatment for well-lateralized squamous cell carcinomas of the tonsil related to a HPV infection. Well-lateralized tumours are defined as T0-T2 N0-N2b M0 and not invading the base of tongue nor extending more than 1 cm into the soft palate. We performed a retrospective review aiming to assess the risk of a contralateral neck recurrence in this group of patients with a particular focus on those diagnosed with N2b disease.

Material and Methods: Fifty patients with T0-T3 N0-2b M0 disease (only two had T3 tumours) were treated with unilateral 3DCRT between February 2004 and July 2011. All 50 patients had p16-positive tumours. They all received chemotherapy (concomitant, induction or both) apart from two. Twenty-six patients presented with N2b disease. Median follow-up was 54 months.

Results: Four patients relapsed in the contralateral neck with no evidence of local or ipsilateral regional failure; one with recurrent contralateral retropharyngeal nodes and the rest with contralateral level II-IV nodes. Median time to a contralateral recurrence was 32 months (range, 22-47 months). All 4 patients initially presented with T1 N2b M0 disease. Upon recurrence, 2 of these patients were treated with a salvage neck dissection followed by chemoradiation and 2 with re-irradiation. Both re-irradiation patients developed a further recurrence and one of them died of his

disease. Using the Kaplan-Meier method, the estimated 5-year contralateral recurrence-free survival (CRFS) was 90.7% for the total population and 81.3% for the N2b subgroup ($p=0.038$). There was no statistical difference in overall survival (OS) between the N0-2a and N2b subgroups (91.5% vs 86.9%, $p=0.654$).

Conclusion: In view of the high risk of a contralateral neck recurrence, bilateral neck radiotherapy should be considered for well-lateralized, T0-T2, HPV-related squamous cell carcinomas of the tonsil presenting with N2b disease.

EP-1033

Pattern of radiation induced thyroid changes in NPC patients in first 3 years post-chemoradiotherapy

W.C.V. Wu¹, Z. Lin²

¹Hong Kong Polytechnic University, HTI, Kowloon- Hong Kong-SAR, China

²Shantou University Medical College, Cancer Hospital, Shantou, China

Purpose or Objective: Thyroid gland is often irradiated in radiotherapy (RT) of nasopharyngeal cancer (NPC) patients leading to radiation induced thyroid disorder. This study aimed to evaluate the pattern of thyroid gland changes in the first 3 years after the completion of chemoradiotherapy.

Material and Methods: Adult NPC patients treated by concurrent chemo-RT (Cisplatin and 5 Fluorouracil) between 2007 and 2011 were recruited. A 7-beam intensity modulated radiotherapy (IMRT) plan was delivered using 6 MV photons. 70 and 66 Gy were prescribed to the PTVs of the nasopharynx and neck lymphatics respectively. Mean thyroid dose was obtained from dose volume histogram using the treatment planning system. Before RT, apart from planning CT, baseline thyroid hormone levels of each patient, comprising free T3 (fT3), free T4 (fT4) and TSH were established by extracting 6 ml of blood. Repeated measurements of the fT3, fT4, TSH and CT were taken at 3, 6, 12, 18, 24, 30 and 36 months after completion of RT. Readings of the 3 hormone levels and thyroid volume obtained from CT at each time interval were recorded. Trend lines of each parameter were plotted. The incidence of hypothyroidism was recorded based on the hormonal findings. The association between the mean thyroid dose and hypothyroidism was evaluated.

Results: 21 patients (M = 13, F = 8) completed the 3-year follow up. The mean thyroid dose ranged from 18.3-61.5 Gy (average 42.8±9.6 Gy). The average volume of the thyroid gland decreased from 17.6 cm³ at pre-RT to 12.3 cm³ at 18 months and remained stable afterward. The average level of fT4 decreased rapidly in the first 6 months, then slowed down and remained stable after 24 months (Fig 1). The average TSH level showed a significant rise between 6 to 18 months and became steady afterward. The level of fT3 remained constant throughout the study period. The incidence of hypothyroidism increased from 7.8% at 3 months to 34.4% at 18 months and remained relatively steady thereafter. Significant association was found between mean thyroid dose and incidence of hypothyroidism.

Conclusion: Our study demonstrated that 18-24 months after chemoradiotherapy was a critical time interval where 1) shrinkage of thyroid gland was stabilized; 2) decrease of fT4 and increase of TSH levels became steady; 3) incidence of hypothyroidism started to rise. All the parameters reached a relatively steady state after 36 months. Applying dose constraints to the thyroid gland in RT treatment planning was recommended to reduce the risk of hypothyroidism.

EP-1034

Cachexia induces head and neck changes in locally advanced oropharyngeal carcinoma

R. Mazzola¹, F. Ricchetti¹, A. Fiorentino¹, S. Fersino¹, N. Giaj Levra¹, G. Sicignano¹, R. Ruggieri¹, F. Alongi¹

¹Ospedale Sacro Cuore Don Calabria, Radiation Oncology, Negrar - Verona, Italy

Purpose or Objective: Cancer cachexia is a paraneoplastic syndrome characterized by weight loss (WL) and sarcopenia. Aim of the study was to assess the impact of cachexia on head and neck changes during definitive cisplatin- image-guided volumetric modulated arc radiation therapy (VMAT) in a series of locally advanced oropharyngeal cancer.

Material and Methods: Volume variations of sternocleidomastoid muscle (SCM) were considered as surrogate of muscle changes related to sarcopenia. For the purpose of the study, two head and neck diameters, encompassing the cranial limits of II and III neck nodal levels (here defined as "head-diameter" and "neck-diameter", respectively), were measured. All parameters analyzed were defined retrospectively by means of on-board cone beam computed tomography (kV-CBCT) images at 1th, 8th, 15th, 22th radiotherapy fraction (fx) and at the end of treatment. Cachexia was defined as WL > 5% during treatment. Statistical analysis was conducted correlating the parameters changes with three WL ranges: < 5%, 5-9% and > 10%.

Results: 30 patients, underwent to definitive cisplatin-VMAT, were retrospectively evaluated. A total of 150 contoured SCMs and 300 diameters were collected. Median WL of patients during treatment was 6.5% (range, 0-16%). The most significant SCM shrinkage was recorded at 15th fx (mean reduction of 1.6 cc), in correlation with WL 5-9% and WL > 10% (p 0.001). For "head-diameter" the peak reduction was recorded at the 15th fx (mean reduction of 8 mm), statistically correlated to WL > 10% (p 0.001). The peak reduction of "neck-diameter" was registered at the 22th fx (mean value of 6 mm). "Neck-diameter" gradually reduced until the end of treatment for WL > 5%.

Conclusion: The head and neck volume changes here analyzed showed to be potentially related to cancer cachexia. Present data could provide relevant adaptive radiation therapy implications for further investigations.

EP-1035

Predictors of mucositis in volumetric modulated radiotherapy for oropharyngeal-oral cavity cancer

F. Ricchetti¹, R. Mazzola¹, S. Fersino¹, A. Fiorentino¹, N. Giaj Levra¹, S. Naccarato¹, R. Ruggieri¹, F. Alongi¹

¹Ospedale Sacro Cuore Don Calabria, Radiation Oncology, Negrar - Verona, Italy

Purpose or Objective: to assess predictors of mucositis in oropharyngeal and oral cavity cancer after definitive or adjuvant volumetric modulated arc radiotherapy (VMAT) +/- chemotherapy.

Material and Methods: For the purpose of this retrospective analysis, inclusion criteria were: age \geq 18 years, histologically proven carcinoma of the oropharynx and oral cavity, no dysphagia at baseline, radical and adjuvant treatment with VMAT (RapidArc®, Varian Medical System, Palo Alto, CA, USA). Fifty patients were evaluated. Statistical Analysis was performed for the following parameters as potential predictors of mucositis \geq G2: total oral mucosa (OM) and OM minus target high-low radiation dose regions (PTVs), mean dose (Dmean) and maximum dose (Dmax), chemotherapy, weight loss, dysphagia.

Results: mucositis \geq G2 was related to total OM Dmean \geq 50 Gy (p .02, CI 95%: 0.1-1.3) and Dmax \geq 65Gy (p .04, CI 95%: 0.1-1.3). At logistic regression, for Dmean \geq 50 Gy and Dmax \geq 65 Gy, the risk of mucositis \geq G2 increased around 4 times (p .04). Considering OM minus target PTVs, the following volumetric constraints were related to mucositis \geq G2: V45Gy > 40 % (p .04, CI 95%: 0.9-2.3), V50Gy > 30 % (p .009, CI 95%: 0.6-1.4), V55 Gy > 20 % (p .003, CI 95%: 0.5-1.2). At logistic regression, for OM minus target PTVs V45 > 40, V50 > 30 and V55 > 20 the risk of mucositis \geq G2 increased around 5 times (p .05). A ratio between total OM and OM minus target PTVs > 2.5 is related to G3 mucositis (p .03, CI 95%: 0.8-1.8).

Conclusion: new parameters were found as predictors of moderate-severe mucositis.

EP-1036

Glottic carcinoma stage T1 radiotherapy

G.J. Dickie¹, J. Askeew², L. Tripcony¹, T. Ha¹

¹Royal Brisbane and Women's Hospital - Cancer Care Centre, Department of Radiation Oncology, Brisbane, Australia

²Royal Brisbane and Women's Hospital, ENT, Brisbane, Australia

Purpose or Objective: Retrospective review of results of radiotherapy for stage T1 glottic carcinoma.

Material and Methods: A retrospective review was done of all patients with squamous cell carcinoma of the glottis stage T1 treated with radiotherapy between 1960 and 2012 inclusive. There were 995 patients identified. All patients were treated with wedged lateral or angled anterior oblique technique. The main site of relapse was local and hence the main end point for analysis was local control at 5 years. Survival curves were calculated using Kaplan Meier method and log rank test used to compare differences.

Results: Overall the 5 year freedom from relapse was 88%. The only factor which influenced outcome was time period of radiotherapy with those between 1960 and 1980 had a 84% relapse free rate, significantly worse than the latter time period. Other factors examined included sex, age, substage T1a and T1b, grade, radiation dose, radiation field size and duration of radiation, and none of those factors had a significant effect on outcome. There were 121 relapses, most in the primary alone and most within the first two years.

Conclusion: The overall 5 year freedom from relapse was 88%.

EP-1037

Dysphagia and irradiation of constrictor pharyngeal muscles: a clinical-dosimetric correlation

⁷S. Orsola-Malpighi Hospital- University of Bologna, Unit of Otolaryngology- Department of Specialist Surgery and Anesthesiology, Bologna, Italy

⁸Bellarina Hospital, Radiotherapy Department, Bologna, Italy

Purpose or Objective: To correlate clinical late dysphagia with the dose received by the constrictor pharyngeal muscles in patients receiving induction chemotherapy (ICT) and radiochemotherapy (RT-CT) with SIB-VMAT technique.

Material and Methods: Between July 2010 and January 2015, 51 patients with locally advanced head and neck cancer underwent ICT and subsequent RT-CT with concurrent weekly Cisplatin. The superior, middle, and inferior (S, M, and I) pharyngeal constrictors muscles (CM) were delineated and the correlation between dosimetric parameters and late pharyngeal toxicity was analyzed.

Results: 51 patients [M/F: 41/10, median age 56, range 30-77, stage III: 10 (20%), stage IV: 41 (80 %)] were included in this analysis. The tumor site was: oropharynx in 21 (40%) patients, epipharynx in 10 (20%), oral cavity in 9 (18%), larynx in 5 (10%), and hypopharynx in 6 (12%). ICT in the majority of cases (74%), was based on Cisplatin - 5 -Fluorouracil, with the addition of Docetaxel in 26% of cases. The dose delivered to the primary tumor was 67.5 Gy (in 8 patients, 16 %) and 70.5 Gy (in 43 patients, 84 %); 60 Gy and 55.5 Gy were delivered on high and low risk lymph node levels, in 30 fractions with SIB-VMAT (2 arcs) technique, respectively. With a median follow-up of 11 months (range 3-44), late G1 dysphagia was recorded in 6 patients (12%) and late G2 dysphagia was observed in 2 patients (4%) (CTC-AE v. 4.3). Other late toxicities are reported in the Table 1. G3-4 toxicities were not recorded. In DVH analysis, the median dose received by CM was 66.2 Gy (S: 67.4 Gy, M and I: 67.2 Gy), with V50 being 96.9 % (S: 97.4%, M: 98.3%, and I: 95.9 %), and V60 being 82.4% (S: 86.8%, M: 90.1 %, and I: 73.8%). The median dose received by the larynx was 63.5 Gy (V50: 94.1 %, and V60: 66.2 %). No statistically significant difference between the group of patients with and without late dysphagia was observed.

Table 1: Late toxicity (CTC - AE v. 4.3)

	G0	G1	G2	G3	G4
Hyperpigmentation (%)	0 (0)	9 (18)	1 (2)	0 (0)	0 (0)
Xerostomia (%)	0 (0)	16 (31)	5 (10)	0 (0)	0 (0)
Subcutaneous fibrosis (%)	0 (0)	8 (16)	1 (2)	0 (0)	0 (0)

Conclusion: No statistically significant correlation between dose delivered to the constrictors muscles and late dysphagia was observed in this patients cohort. This result may depend on tolerability of the treatment and then by the small number of recorded adverse events.

⁹Bellarina Hospital, Radiotherapy Department, Bologna, Italy

Purpose or Objective: To evaluate the toxicity of intensity modulated radio-chemotherapy with simultaneous integrated boost technique (SIB) after induction chemotherapy in patients with locally advanced head and neck (H&N) cancer.

Material and Methods: The IRMA studies are described in the table. Patients with stage III-IV H&N cancer, without progressive disease after induction chemotherapy (IC), underwent radio-chemotherapy with weekly Cisplatin 30

mg/m2 (IRMA 1, 2, 3, 5) or Cetuximab 400 mg/m2 (IRMA 4). A dose of 67.5 Gy in 30 fractions (IRMA 1, 2, and 4) or 70.5 Gy in 30 fractions (IRMA 3, 4, and 5) was delivered to primary tumor and involved nodes, 60 Gy were delivered to high risk and 55.5 Gy to low risk lymph node areas. Static (IMRT) or volumetric (VMAT) intensity modulated technique with simultaneous integrated boost was used.

Results: 107 patients (median age 56 years, range 30-78, UICC stage III: n = 18, IV: n = 89) were included in this analysis. IC was performed with Cisplatin + 5-Fluorouracil in 65 (61%) patients and with Docetaxel + Cisplatin + 5-Fluorouracil in 42 (39%) cases. Concomitant Cisplatin and Cetuximab were administered in 84% and in 16% of patients, respectively. 51% (n = 55) of cases were irradiated with step & shoot IMRT-SIB technique (7 beams), while 49% (n = 52) of patients were irradiated with VMAT-SIB (two arcs) technique. During radio-chemotherapy, 23 (21%) patients developed mucositis, 12 (11%) G3 dysphagia and 10 (9.3%) G3 hematological toxicity. Even 1 (0.9%) G4 leukopenia and 3 (2.8%) G5 (2 neutropenia and one fatal myocardial infarction) adverse events were observed. The overall response rate after radio-chemotherapy was 82.2%. Two-year local control and survival were 64.2% and 64.6% (IRMA 1), respectively, 57.8% and 56.2% (IRMA 2), 66.4% and 75.5% (IRMA 3), 70.1% and 66.7% (IRMA 4), and 76.5% and 82.4% (IRMA 5), respectively.

Table IRMA and studies related toxicity

* IRMA : Intensified Radiotherapy by multimodality Association in H&N cancer
CF: Cisplatin + 5Fluorouracil ; C: Cisplatin (30 mg / m2) ; DCF: Docetaxel + Cisplatin + 5Fluorouracil;
Cetuximab (400 mg / m2); ** OR: Overall response; ***LC: Local control; ****OS : Overall survival.

Conclusion: In our experience moderately hypofractionated and accelerated radio-chemotherapy after induction chemotherapy was feasible. Intensive patient monitoring and supportive strategies during chemoradiation are necessary to manage of side effects.

EP-1039

H&N IMRT: correlation of dysphagia/xerostomia to dose/volume parameters of involved OARs

L. Deantonio¹, M. Paolini¹, L. Masini¹, F. Pia², M. Brambilla³, M. Krengli¹

¹University Hospital Maggiore della Carità, Radiotherapy, Novara, Italy

²University Hospital Maggiore della Carità, Otolaryngology, Novara, Italy

³University Hospital Maggiore della Carità, Medical Physics, Novara, Italy

Purpose or Objective: To analyse the frequency and severity of dysphagia and xerostomia in patients affected by nasopharyngeal and oropharyngeal cancers treated by intensity-modulated radiotherapy (IMRT) and the correlation with volumetric variations and dosimetric data of pharyngeal constrictor muscles and parotid glands.

Material and Methods: Fifty patients, who underwent adaptive IMRT for nasopharyngeal and oropharyngeal cancers, were included in the present study. Eighty-four percent of patients (42/50) received concurrent radio-chemotherapy and 92% (44/50) were in locally advanced stage. Dose-volume parameters related to constrictor muscles (superior constrictor muscle, SCM; middle constrictor muscle, MCM; inferior constrictor muscle, ICM and whole pharyngeal

constrictor muscle, CM), and parotid glands were analyzed using dose-volume histograms (DVHs). All patients underwent replanning CT scan after 5 weeks of radiation therapy and the target and OARs were re-contoured on fusion images after co-registration. The volumetric variations of pharyngeal constrictor muscles and parotid glands were measured. Volumetric variations and dose-volume parameters were associated to acute and late dysphagia and xerostomia according to RTOG score, quality of life questionnaires (PSS-H&N e QLQ-H&N35), and oesophageal transit .

Results: Volumetric variations and dose-volume parameters of pharyngeal constrictor muscles and parotid glands are reported in Table 1. Adaptive IMRT achieved a good sparing of parotid glands (mean dose 24.9 Gy) and constrictor muscles (mean dose 51.2 Gy). Acute dysphagia, was scored as grade 0-1 in 18/50 patients (36%) and as grade 2-3 in 32/50 (64%). Acute xerostomia, was scored as grade 0-1 in 21/50 patients (42%) and as grade 2-3 in 29/50 (58%). Volumetric variations and dose-volume parameters of the constrictor muscles and parotid glands did not correlate with acute toxicity (p>0.05). At 2 years median follow-up (range 6-67 months), late dysphagia was scored as grade 0-1 in 40/50 of patients (80%) and as grade 2-3 in 10/50 (20%). Late xerostomia was scored as grade 0-1 in 42/50 of patients (84%) and as grade 2-3 in 8/50 (16%). The analysis of the correlation of volumetric variations and dose-volume parameters with clinical data (RTOG score for late toxicity, quality of life questionnaires and oesophageal transit) is ongoing.

OAR	Median Volume (cc)	Replanning median Volume (cc)	Δ volume (%)	Median maximum dose (Gy)	Median mean dose (Gy)
SCM	6.9	8.5	+20	71.9	62.7
MCM	2.1	2.6	+17	65.2	51.5
ICM	3.1	3.7	+11	60.1	42.9
CM	12.0	14.7	+17	71.9	51.2
Right parotid gland	25.0	17.8	-24		24.9
Left parotid gland	22.6	16.2	-32		24.9

Conclusion: During radiotherapy, pharyngeal constrictor muscles and salivary glands underwent volumetric variations. Volumetric variations and dosimetric findings did not correlate with acute toxicity, probably because of the complexity and multifactorial pathogenesis of acute dysphagia and xerostomia. The ongoing analysis on the correlation of late toxicity data with volumetric variations and dose-volume parameters may help in the optimization of IMRT treatment planning.

EP-1040

Development of a CT-based prognostic model for regional control in head and neck cancer after RT

D. Nevens¹, O. Vantomme¹, A. Laenen², R. Hermans³, S. Nuyts¹

¹KU Leuven-University of Leuven- University Hospitals Leuven, Radiation Oncology Department, Leuven, Belgium

²KU Leuven-University of Leuven, Leuven Biostatistics and Statistical Bioinformatics Centre, Leuven, Belgium

³KU Leuven-University of Leuven- University Hospitals Leuven, Radiology Department, Leuven, Belgium

Purpose or Objective: At our center, the need for neck dissection (ND) after radiotherapy (RT) is determined based on the nodal response on the post-RT Computed Tomography (CT) study 4 months after the end of treatment. We want to report the outcome of this approach and investigate whether characteristics on pre- and post- RT CT studies can predict the necessity of post-RT ND.

Material and Methods: Between 2002 and 2012, 183 consecutive patients with lymph node-positive head and neck cancer (HNC) were treated with RT or concurrent chemoradiotherapy (CRT) without planned ND. CT studies pre- and post-treatment were reviewed for lymph node size and presence of necrosis, extracapsular spread and calcifications. At patient level, data were correlated with 3 year regional control (RC), metastasis free survival (MFS), disease free survival (DFS) and overall survival (OS). At nodal level, data were correlated with relapse of the individual lymph nodes (LNR). A stepwise selection procedure was followed to construct a multivariable prediction model for regional relapse (RR) within 3 years. The area under the ROC curve (AUC) was determined for the selected model. Additionally a bootstrap-corrected AUC value was calculated. This AUC value corrects for overoptimism resulting from the fact that model construction and model validation were performed on the same data set.

Results: The median follow-up was 60 months. 3-year outcome rates were as follows: LC of 84%, RC of 80%, MFS of 74%, DFS of 61%, OS of 63%. Pre-treatment nodal size at patient- and nodal level and presence of necrosis at patient level were associated with a poorer outcome. This was also the case for post-treatment lymph node size and presence of necrosis and extracapsular spread (Table 1). Based on our results we developed a multivariate model for RR prediction. After performing a stepwise selection procedure pre-RT T stage ($p=0.02$), post-RT necrosis ($p=0.03$) and post-RT largest nodal diameter ($p=0.01$) were included in the model. The AUC of this model was 0.78 (95% CI 0.63;0.84); the bootstrap-corrected AUC was 0.74 (95% CI 0.67; 0.89). The risk for RR within 3 years can be calculated using the following formula:

$$RR (\%) = \frac{e^{\mu}}{1 + e^{\mu}}$$

$$\mu = 0.085 \cdot \text{largest axial diameter (mm)} + 0.6749 \cdot (T \text{ stage}) - 4.8482 \\ + (\text{only when necrosis}) 1.1384$$

Table 1: Predictive value of post-treatment CT characteristics for outcome

CT characteristic	Outcome	OR/HR (95% CI)	p-value	
Σ nodal volume	RR	OR 1.262 (1.072;1.486)	0.0051	
	MFS	nonlinear trend		
	DFS	HR 1.051 (1.028;1.074)	<0.0001	
	OS	HR 1.056 (1.035;1.078)	<0.0001	
	MFS	HR 1.152 (1.054;1.259)	0.0018	
Σ nodal volume 2cm ³ vs 1cm ³	MFS	HR 1.152 (1.054;1.259)	0.0018	
	Largest diameter	RR	OR 1.108 (1.047;1.172)	0.0004
		MFS	HR 1.043 (1.014;1.072)	0.0036
		DFS	HR 1.059 (1.035;1.083)	<0.0001
		OS	nonlinear trend	<0.0001
OS		HR 5.764 (2.851;11.651)	<0.0001	
Largest diameter > 31.8 mm	RR	OR 5.960 (2.410;14.738)	0.0001	
	MFS	HR 2.203 (1.186;4.092)	0.0124	
	DFS	HR 2.668 (1.671;4.262)	<0.0001	
	OS	HR 2.406 (1.529;3.785)	0.0001	
	Necrosis	RR	OR 5.960 (2.410;14.738)	0.0001
MFS		HR 2.203 (1.186;4.092)	0.0124	
DFS		HR 2.668 (1.671;4.262)	<0.0001	
OS		HR 2.406 (1.529;3.785)	0.0001	
Calcifications		RR	OR 0.643 (0.167;2.483)	0.5189
	MFS	HR 0.950 (0.373;2.421)	0.9143	
	DFS	HR 0.843 (0.404;1.759)	0.6494	
	OS	HR 0.863 (0.430;1.729)	0.6772	
	ECS	RR	OR 3.451 (1.056;11.283)	0.0404
MFS		HR 2.482 (1.144;5.385)	0.0214	
DFS		HR 2.343 (1.275;4.303)	0.0061	
OS		HR 1.800 (0.971;3.337)	0.0620	

Abbreviations: CT = computed tomography; OR = odds ratio; HR = hazard ratio; CI = confidence interval; Σ = sum; RR = regional recurrence; MFS = metastasis-free survival; DFS = disease-free survival; OS = overall survival; ECS = extracapsular spread.

Conclusion: Characteristics on the post-RT CT study can predict the likelihood of residual lymph node disease and outcome. Characteristics on the pre-therapy CT study seem less useful for this purpose. A CT-based multivariate

prognostic model based on our findings was developed which can aid in predicting RR.

EP-1041

Evaluation of dysphagia in head and neck cancer patients undergoing Intensity Modulated Radiotherapy

J. Bashir¹, K. Bansal¹, K. Chufal¹

¹Batra Hospital and Medical Research Centre, Radiation Oncology, New Delhi, India

Purpose or Objective: With the success of Intensity Modulated Radiotherapy (IMRT) techniques in reducing the severity of xerostomia in head and neck cancer (HNC) patients, efforts should be made to improve swallowing dysfunction, which is potentially even more discomforting and incapacitating side effect and adversely affects the quality of life. This is a clinical dosimetric study to investigate the correlation between radiation doses delivered to organs at risk for radiation induced swallowing dysfunction (SWOARs) and severity of dysphagia following concurrent chemoradiotherapy to HNC patients and evaluate various factors which assume importance in determining the risk of dysphagia/aspiration.

Material and Methods: 60 Head and Neck cancer patients (Oropharynx 28, Hypopharynx 12 and Larynx 20) were enrolled between May 2013 and June 2014 for this prospective longitudinal study after prior approval from the hospital ethics and review committee. Patients were treated with curative intent by radiotherapy using IMRT and concurrent chemotherapy using cisplatin (40 mg/m²) on weekly basis. Delineation of SWOARs was done using RTOG guidelines and following structures were contoured: superior, middle and inferior pharyngeal constrictor, cricopharyngeal muscle, esophageal inlet muscle, cervical esophagus, base of tongue, supraglottic and glottic larynx. Dysphagia endpoints included both patient-reported (EORTC Head and Neck Quality of Life instrument and MD Anderson Dysphagia Inventory) and observer-rated scores (Common Terminology Criteria for Adverse Events- CTCAE v4.0 and RTOG/EORTC Late Radiation Morbidity Scoring). Patients were assessed weekly during radiation and at 1 month and 3 months after completion of treatment. Correlation between dysphagia and radiation doses to SWOARs was assessed.

Results: With an increase in the mean dose to the SWOARs, the grades of dysphagia also increased. After 3 months of completion of treatment, 27% patients had persistent dysphagia of grade 3 or grade 4. Significant correlation was observed between patient reported dysphagia scores and the mean doses to the superior and middle pharyngeal constrictor as well as glottic and supraglottic larynx ($p<0.05$). Observer rated dysphagia scores correlated significantly with mean superior pharyngeal constrictor dose and not with dose to other SWOARs. Two patients of carcinoma hypopharynx developed stricture which correlated significantly with dose to esophageal inlet muscle.

Conclusion: Radiotherapy plans sparing SWOARs should be generated and implemented to prevent the problem of dysphagia. The structures whose damage may cause dysphagia and aspiration are the pharyngeal constrictors and the glottic and supraglottic larynx. Further studies are required to evaluate dose constraints to these SWOARs to reduce the incidence of radiation induced dysphagia and thus further improve the quality of life in HNC patients.

EP-1042

Risk-factors in pT1-2N0M0 squamous cancers of the oral cavity and the role of adjuvant radiotherapy

J. Mallick¹, S. Bhaumik¹, K. Sarkar¹, P. Arun², K. Manikantan², P. Roy³, I. Arun³, D. Dabkara⁴, S. Chatterjee¹

¹Tata Medical Center, Department of Radiation Oncology, Kolkata, India

²Tata Medical Center, Department of Head and Neck Surgery, Kolkata, India

³Tata Medical Center, Department of Pathology, Kolkata, India

⁴Tata Medical Center, Department of Medical Oncology, Kolkata, India

Purpose or Objective: Prognostic factors in early stage resected oral squamous cell cancers (OSCC) are not well understood. The aim of this audit was to identify factors influencing recurrence in pT1-2N0M0 patients with a view to determine the role and indications for adjuvant radiotherapy (adjRT).

Material and Methods: Between Aug 2011 to May 2014, 120 patients were determined to have pT-2N0M0 disease following histopathological examination after primary surgery for oral cancer. Primary sites included oral tongue (66, 55%), buccal mucosa (31, 26%), gingiva (10, 8%), retromolar trigone (9, 7%) and lip (4, 3%). AdjRT was advised to 46 (38%) patients on an individual basis in a multidisciplinary meeting, determined by the presence of one or a combination of known risk factors. Patients with close or positive margins always received chemoradiation. AdjRT was delivered with 3D conformal or intensity modulated techniques to a dose of 60Gy/30Fr/6weeks to the tumor bed and 54-60Gy/30Fr/6weeks to the resected but uninvolved nodal levels. Disease-related outcomes were calculated, and pathological prognostic factors were assessed using univariate and multivariate analyses. The impact of adjRT in reducing disease recurrence was assessed.

Results: The median age was 55 (25-82) years. The median tumor size was 2.2 cm. The median depth of infiltration was 6mm. The incidence of known pathological prognostic factors is listed in Table 1. The median follow up was 23 months (2-44 months). A total of 13 patients had recurrence (local 8; nodal 4, distant 3, including overlapping failures). All locoregional failures were within the RT volumes. The 2yr and 3 year disease-free-survival (DFS) was 89% and 82% respectively. On univariate analysis pT2 tumors, lymphovascular invasion (LVI), perineural invasion (PNI) and depth of invasion ≥ 5 mm were statistically significant prognosticators for DFS (Table 1). Primaries of the oral tongue showed a trend towards shorter DFS. None of these factors were independently prognostic on multivariate analysis. A scoring system using the number of risk-factors was created. Patients were grouped as Low risk (0-1 factor); Intermediate risk (2-3 factors) and High-risk (4-7 factors). There was significant difference in DFS of patients in different risk groups (Fig 1). RT was considered unnecessary in Low risk patients (none of 39 received RT, 3 yr DFS 97.1%). In High risk patients, prognosis was poor despite RT (22/25 received RT, 3 yr DFS 68.5%). In the Intermediate risk group, 24/54 patients received RT, but this made no difference to the risk of disease recurrence (2 local failures each in RT vs. no RT cohorts, 3 yr DFS 85.1% vs 72.1%, $p=0.75$).

Table 1. Incidence and impact of risk factors on disease-free-survival (by univariate analysis)

Factor	n (%)	3 yr DFS	p
Tongue Primary (vs. Others)	66 (55%)	76.0% (vs. 91.7%)	0.1
pT2 (vs. pT1)	67 (56.3%)	72.5% (vs. 95.6%)	0.039
Lymphovascular invasion (vs. absent)	10 (8.3%)	58.3% (vs. 83.6%)	0.024
Perineural invasion (vs. absent)	38 (31.7%)	75.0% (vs. 85.6%)	0.013
Depth of invasion ≥ 5 mm (vs. < 5 mm)	72 (61%)	73.8% (vs. 97.5%)	0.017
Poorly differentiated cancer (vs. moderately or well-differentiated)	10 (8.3%)	88.9% (vs. 81.2%)	0.956
Close or positive margins (vs. clear margins)	7 (5.8%)	83.3% (vs. 80.9%)	0.854

Conclusion: Several pathological risk factors alone and in combination impact disease related outcomes even in pT1-2N0 OSCC. Standard AdjRT did not have a clear effect on reducing recurrence in our cohort in patients with up to 3 risk factors.

EP-1043

Clinical and volumetric prognostic factors in external beam radiotherapy for head and neck cancer

K. Takeda¹, H. Matsushita², T. Ogawa³, S. Dobashi¹, Y. Ishizawa¹, K. Chida¹, N. Kadoya², K. Ito², M. Chiba², M. Kubozono², R. Umezawa², Y. Shirata², Y. Ishikawa², T. Yamamoto², M. Kozumi², T. Tanabe², N. Takahashi², Y. Katagiri², S. Tazaka², K. Takeda², K. Sato¹, Y. Katori³, K. Jingu²

¹Tohoku University School of Medicine, Health Sciences-Course of Radiological Technology, Sendai, Japan

²Tohoku University School of Medicine, Department of Radiation Oncology, Sendai, Japan

³Tohoku University School of Medicine, Department of Otorhinolaryngology-Head and Neck Surgery, Sendai, Japan

Purpose or Objective: To investigate clinical and volumetric prognostic factors in head and neck cancer (HNC) patients (pts) treated with curative external beam radiation therapy (EBRT).

Material and Methods: Sixty-four oropharyngeal squamous cell carcinoma (OSCC) pts and 79 hypopharyngeal squamous cell carcinoma (HSCC) pts treated with curative EBRT were enrolled in this retrospective analysis. No pt had previously undergone surgery for HNC. The median total EBRT dose was 70 Gy (range, 60-72 Gy). For planning EBRT, computed tomography (CT) images were acquired prior to EBRT initiation and at 3-5 weeks after the initiation of EBRT for replanning in each pt. We assessed the gross tumor volume (GTV) reduction rate (GTVRR) on the basis of the results from the initial and replanning CT images. Initial cervical body volume (CBV) was measured from the initial CT images. For induction chemotherapy (IC), seven pts received docetaxel (DOC), cisplatin (CDDP), and 5-fluorouracil (5-FU) (TPF regimen). One course of CDDP plus 5-FU and two courses of TPF regimen were delivered to one pt. In total, 125 pts (87.4%) received concurrent chemotherapy (CC) using the following regimen: TPF in 55 (38.5%) pts; another CDDP-based regimen in 43 (30.1%) pts; another DOC-based regimen in 22 (15.4%) pts; cetuximab in 3 (2.0%) pts; nedaplatin and 5-FU in 1 (0.7%) pt; and S-1 (tegafur, gimeracil, and oteracil) in 1 (0.7%) pt. The disease stage was I in 5 (3.5%) pts, II in 20 (14%) pts, III in 24 (16.8%) pts, and IV in 93 (65%) pts.

Progression-free survival (PFS) and overall survival (OS) were estimated by the Kaplan-Meier method. Cox regression was performed to explore parameters in association with PFS and OS. The potential variables that were examined included age; gender; primary site; UICC stages; serum albumin, C-reactive protein (CRP), albumin-globulin ratio, body weight (BW) and body mass index prior to treatment; initial CBV and GTV; GTVRR during EBRT; IC; and CC.

Results: The median follow-up period was 23 months (range, 2-95 months). The 2-year PFS and OS rates were 51.3% [95% confidence interval (CI), 40.2-55.7] and 71.0% (95% CI, 58.4-72.6), respectively. PFS was associated with age [hazard ratio (HR): 1.029 (95% CI, 1.001-1.058), $p = 0.04$]; stage IV disease [HR: 3.755 (95% CI, 1.810-7.788), $p < 0.001$]; pretreatment CRP [HR: 1.077 (95% CI, 1.008-1.152) $p = 0.029$]; initial GTV [HR: 1.004 (95% CI, 1.000-1.007), $p = 0.026$]; and GTVRR during EBRT [HR: 0.99 (95% CI, 0.982-0.998), $p = 0.016$]. OS was related to stage IV disease [HR: 3.669 (95% CI, 1.667-8.071), $p = 0.001$]; GTVRR during EBRT [HR: 0.986 (95% CI, 0.975-0.997), $p = 0.012$]; and pretreatment BW [HR: 0.927 (95% CI, 0.892-0.963), $p < 0.001$].

Conclusion: This study suggested the prognostic value of clinical and volumetric status. Clinical stage, age, pretreatment CRP and BW, initial GTV, and shrinkage of GTV during treatment appear to be critical in the HNC treatment strategy.

EP-1044

Relations between cancer-related communication and dyadic adjustment in head and neck cancer patient

Y.P. Chen¹, B.S. Huang¹, J.T.C. Chang¹

¹Chang-Gung Memorial Hospital, Radiation Oncology, Taoyuan City, Taiwan

Purpose or Objective: Head and neck cancer patients suffered from swallowing and speaking difficulties, neck pain and stiffness, and cosmetic disfigurement, resulting in interpersonal relationship troubles and social and emotional adaptation issues. Discussing cancer and the quality of communication when facing stress would affect partner's adaptation to cancer and quality of relationship. This study investigated the (Cancer-related) communication pattern, effect of disease characteristics in head and neck cancer. We used dyadic analysis to investigate the impact and process of communication pattern on quality of relationship.

Material and Methods: This study is cross-sectional design, and subject were the male patients who completion of cancer treatment more than 3 months and their partners with head and neck cancer, included 131 patient-partner dyads. Each participant completed the basic information questionnaire, Communication Pattern Questionnaire, Dyadic and Adjustment Scale.

Results: By treatment, there are no difference on cancer-related communication pattern for both patient and partner. Both patient and partner, their perception of mutual constructive communication was associated with more quality of relationship, Demand-withdraw communication and mutual avoidanc was associated with less quality of relationship. Using the Actor-Partner interdependence model (APIM), result revealed that although each person's cancer-related communication pattern is the strongest predictor of their own quality of relationship, partner's perception of communication pattern also play significant role on patient's quality of relationship. According to APIM, only the partner perceived communication pattern could be accounted for by their influence on quality of relationship.

Conclusion: We found that cancer-related communication and interaction of relationship among couples play an important role in the head and neck adjustment process. Thus, except the medical care, clinicians concern with interaction between patient and partner can be enhance their psychological adjustment and illness, particularly the partner's perception of communication pattern, which may

improve the quality of relationship and life adaptation of both couples when they are dealing with head and neck cancer.

EP-1045

Phase I study for evaluation of the safety of high-dose hypofractionated RT in early glottic cancer

T. Yu¹, H.G. Wu¹, K. Jin Ho¹, K. Taek-Gyun²

¹Seoul National University College of Medicine, Radiation Oncology, Seoul, Korea Republic of

²Seoul National University College of Medicine, Otorhinolaryngology, Seoul, Korea Republic of

Purpose or Objective: Reducing overall treatment time has advantages for patient convenience, but also for local control as shown by former studies. Critical organs in the neck causes concern in relation to long-term morbidity and quality of life, but with recent advances with high-precision image-guided and intensity-modulated radiotherapy (IMRT) techniques, avoidance of the organs at risk has become possible. The purpose of this study is to develop an image-guided high-dose hypofractionated vocal cord irradiation technique to treat patients with early stage glottic cancer.

Material and Methods: Eligible patients with early stage glottic cancer provided with informed consent will receive hypofractionated radiotherapy to the larynx with a simultaneous boost to the gross tumor. The fraction size will be stepwise increased from 3.5Gy (total dose 59.4Gy) to 9Gy (total dose 45Gy). To proceed to the next dose level, at least 7 patients should be confirmed that they have no toxicity more than grade 2 after 3 month post-RT. The organs at risk include the larynx, contralateral vocal cord, arytenoids, carotid arteries, inferior pharyngeal constrictor muscle, and spinal cord.

Results: Four patients were enrolled to receive 59.4Gy with 3.5Gy per fraction until July 2015. None of the patients developed toxicity more than grade 2 after 1 month post-RT. The mean equivalent dose in 2Gy fractions (EQD2) to contralateral arytenoid, thyroid gland, inferior pharyngeal constrictor muscle, and larynx were in average 69.5Gy, 12.3Gy, 50.8Gy, and 66.5Gy, respectively. No portion of the carotid arteries were irradiated more than 50 Gy (EQD2) in the IMRT plan. After 3 months of follow-up, all 4 patients demonstrated no more than grade 3 toxicities. Also, all patients showed complete remission by laryngoscopy.

Conclusion: The high-dose hypofractionated IMRT technique provided good sparing of critical structures and resulted in no severe toxicity after a short term follow up. We will continuously perform this phase I clinical trial to stepwise increase the fraction size up to 9Gy.

EP-1046

High dose-low energy intraoperative radiotherapy in the treatment of malignant H&N tumors

B. Emami¹, R. Borrowdale², M. Choi¹, E. Thorpe², A. Sethi¹, B. Chinsky¹, W. Small¹

¹Loyola University Medical Center, Radiation Oncology, Maywood, USA

²Loyola University Medical Center, Otolaryngology, Maywood, USA

Purpose or Objective:

Objective: The aim of this study was to investigate the feasibility of high dose-low energy intraoperative radiation (IORT) therapy using INTRABEAM® (Carl Zeiss Surgical, Oberkochen, Germany) in the treatment of malignant Head & Neck tumors.

Methods and Materials: Between March 2014 and July 2015, 12 patients with head and neck cancers (seven with primary malignant parotid tumors and five patients with previously treated recurrent head and neck cancer) received intraoperative radiation therapy after surgical resection at Loyola University Medical Center (Maywood, IL). The median dose prescription was 6Gy (range, 5-14Gy) prescribed to 5mm

depth in a single fraction delivered with cylindrical shaped flat applicators attached to a 50kV x-ray energy source (INTRABEAM). The flat applicator (sizes 3-6cm) was placed at the high-risk area within the surgical cavity, which was delineated by the surgeon as the area with high likelihood for close or positive margins. The average IORT delivery time was 20 minutes. The single IORT fraction was the sole treatment for all patients with recurrent, previously treated patients and in one patient with parotid tumors, while the remaining six patients with parotid malignancies received additional external beam radiotherapy (EBRT) (median dose 50Gy) four weeks after surgery. Decision for EBRT were based on review of final pathology.

Results: All patients underwent successful completion of intraoperative radiotherapy. With follow up time of 5 to 18 months, there have been no acute side effects or complications related to IORT. All patients with parotid tumors are currently NED; in patients with recurrent tumors, 1 of 5 has re-recurred.

Conclusion: IORT with low kv x-rays appears to be an excellent choice for selected patients with H&N cancers, both primary (parotid) and recurrent disease.

We are now in the process of initiating a prospective trial evaluating the use of IORT as part of primary management of parotid tumors at our institution.

Detailed results will be presented.

Volume, FDG-PET and ADC responses could predict a similar prognostic benefit as HPV status

Z. Gouw¹, M. La Fontaine¹, O. Hamming-Vrieze¹, A. Al-Mamgani¹, P. Van Houdt¹, J.J. Sonke¹

¹Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Department of Radiation Oncology, Amsterdam, The Netherlands

Purpose or Objective: Patients treated with concurrent chemoradiation (CCRT) for head and neck cancer (HNC) with HPV(+) associated tumours have a significantly better prognosis compared to those with HPV(-) tumours. Similarly, better prognosis was associated with changes during-treatment consisting of either a reduction in tumour volume, or FDG-PET SUV, or an increase in ADC. This study investigated a possible association between these imaging biomarkers and HPV status. Our hypothesis was that HPV(+) tumours show a stronger ADC increase and a larger volume and SUV decrease.

Material and Methods: 13 Patients with HNC stadium III-IVA underwent CCRT (11 oropharynx, 1 hypopharynx and 1 oral cavity). HPV status was assessed using P16 staining. Patients received FDG-PET and MRI imaging before the start of the treatment and at the end of the second week. The region of interest consisted of the GTV and was delineated by dedicated radiation-oncologists. The volume and the median SUV and ADC were measured pretreatment and during treatment. Relative responses were calculated by subtracting the pretreatment from the during treatment value, which was then normalized to the pretreatment value. A new variable (pooled response) was computed consisting of the average of the relative SUV and volume decrease and ADC increase. A one tailed independent samples t-test compared the average responses between the HPV(+) and HPV(-) tumours. Voxel-based Pearson correlation coefficients between baseline and response maps were calculated for ADC and FDG-PET. A Fisher's z-transformation was used to compare the correlation coefficients between HPV(+) and HPV(-) tumours.

Results: 7 out of 13 tumours were HPV(+) and 6 HPV(-). Comparing HPV(+) to HPV(-), GTV volume decreased 42% vs

28% (p=0.080), SUV decreased with 32% vs 5% for (p=0.074) and ADC increased 24% vs 7% (p=0.058) (figure 1). The total response was significantly higher for HPV(+) tumours (33% vs 13%, p=0.012). Correlation coefficients between baseline and response maps did not differ significantly for HPV(+) and HPV(-) tumours (PET: z= 1.05 vs 1.08 p=0.85, ADC: z=0.47 vs 0.51, p=0.78).

Conclusion: Volume, ADC and FDG-PET individually showed a trend towards a higher response in the HPV(+) tumours at the end of the second week CCRT. The total response was significantly higher for HPV(+) tumours, demonstrating a significant association between HPV-status and imaging biomarkers. The similar correlation coefficients of the response maps indicate the spatial distribution does not depend on HPV status. This study emphasises the importance of reporting HPV status in imaging response biomarker studies for HNC patients. A validation of the prognostic value of imaging response biomarkers within HPV(+) and (-) cohorts is warranted.

EP-1048

Phase I trial of a novel metalloporphyrin radiosensitiser (MTL005) in head and neck cancer

S. Schipani¹, B. Foran², T. Guerrero Urbano³, H. Jürgens⁴, C. Beattie⁵, J. Caldwell⁵

¹Institute of Cancer Sciences University of Glasgow, Radiation Oncology, Glasgow, United Kingdom

²Clinical Trials Centre, Academic Unit of Clinical Oncology Western Park Hospital, Sheffield, United Kingdom

³Guy's and St Thomas' Hospitals, Radiation Oncology, London, United Kingdom

⁴Tartu University Hospital, Radiation Oncology, Tartu, Estonia

⁵MorEx Development Partners LLP, MorEx, London, United Kingdom

Purpose or Objective: MTL005 is a novel metalloporphyrin that demonstrated efficacy as a radiosensitizer in oxic and hypoxic pre-clinical models, increasing tumour doubling times by 50-90% depending on radiation dose. MTL005 achieved higher concentrations in tumour tissue compared with normal tissues (6:1 ratio), and these higher levels were retained for up to 62 days post administration. We developed a first-in-human phase I, open label, dose escalation, multicenter clinical trial to evaluate the safety and tolerability of single dose MTL005 in combination with radiotherapy (Part 1) and cisplatin chemo-radiotherapy (Part 2) in patients with locally advanced head & neck cancer treated with palliative and curative intent respectively. The results of Part 1 of the study are reported.

Material and Methods: In Part 1 of the study MTL005 was administered 1 week prior to palliative radiotherapy as i.v. injection in 38-76 minutes. Two dose levels were explored (2 and 4 mg/kg). Patients were immobilised in a thermoplastic mask and a contrast enhanced CT scan was used to define the PTV and the organs at risk. Radiotherapy was delivered with IMRT with a total dose of 50Gy to the PTV in 25 consecutive

fractions for 5 days a week. Toxicity was recorded using the CTCAE v4.0 to define a Dose Limiting Toxicity (DLT) and a Maximum Tolerated Dose (MTD) of MTL005.

Results: A total of 8 patients, 7 males (88%) and 1 female (12%), were enrolled, 4 in each of the 2 dose level cohorts. Six patients, all male with median age of 65 (54-77), were dosed with MTL005 successfully, 3 in each cohort. Dosing failures were due to an unexpected severe pain reaction (1 patient) and a technical problem with the infusion line (1 patient). In the 6 evaluable patients the following adverse events were recorded. Grade ≤ 2 oral mucositis and dysphagia were recorded in 3 (50%) and 4 (67%) patients respectively. Grade 1 pain in site of MTL005 injection was assessed in 1 (17%) patient. Grade ≤ 2 other toxicities (anaemia, dysgeusia) occurred in 3 (50%) patients. Grade 3 (dyspnoea, pneumonitis, oral haemorrhage, back pain, hyperuricemia) and Grade 4 toxicity (sepsis) were recorded in 4 (67%) and 1 (17%) cases respectively requiring hospitalisation and being considered as Serious Adverse Events (SAE). None of the SAE was assessed as directly related to MTL005 so DLT/MTD was not defined.

Conclusion: We completed Part 1 of the study and MTL005 DLT/MTD was not defined. Part 2 has been commenced with a MTL005 starting dose of 4mg/kg and is currently ongoing.

EP-1049

Prognostic role of 18F-FDG PET/CT in head and neck cancers treated with radical radio-chemotherapy

L. Sandler¹, P. Castellucci¹, S. Fanti¹, U. Caliceti², R. Frakulli³, A. Milani³, S. Cammelli³, F. Deodato⁴, M. Nuzzo⁴, G. Macchia⁴, G. Frezza⁵, A.G. Morganti³

¹Nuclear Medicine Unit- S.Orsola-Malpighi Hospital-University of Bologna, Department of Experimental-Diagnostic and Specialty Medicine-DIMES, Bologna, Italy

²Unit of Otolaryngology- S.Orsola-Malpighi University Hospital, Department of Specialist Surgery and Anesthesiology, Bologna, Italy

³Radiation Oncology Center- S.Orsola-Malpighi Hospital-University of Bologna, Department of Experimental-Diagnostic and Specialty Medicine-DIMES, Bologna, Italy

⁴Fondazione di Ricerca e Cura "Giovanni Paolo II"- Catholic University of Sacred Heart, Radiotherapy Unit, Campobasso, Italy

⁵Ospedale Bellaria, Radiotherapy Department, Bologna, Italy

Purpose or Objective: To assess the prognostic role of 18F -FDG PET/CT based response evaluation after primary concomitant radio-chemotherapy (RCT) for loco regionally advanced Head and Neck squamous cell carcinoma (HNSCC).

Material and Methods: 150 patients were included in this retrospective study. Mean age was 59 years (107 males and 43 females). The sites of HNSCC were oropharynx (53%), nasopharynx (14%), oral cavity (10%), hypopharynx (7%), larynx (7%), salivary glands (5%) and paranasal sinuses (4%). All patients underwent 18F-FDG PET/CT between 2006 and 2013 to assess treatment response; 62% of patients also had a pre-therapy 18F -FDG PET/CT scan. 18F -FDG PET/CT was performed from 6 to 36 weeks (median 21 weeks) after the end of RCT. Patients were divided in three groups: 18F -FDG PET/CT performed from 6 to 14 weeks after the end of RCT (group I: 30 patients), from 15 to 23 weeks (group II: 89 patients) and from 24 to 36 weeks (group III: 31 patients). 18F -FDG PET/CT scans were performed according to standard procedure, then they were visually analysed by 2 expert physicians and categorized as negative ("score 1"), doubt negative ("score 2"), doubt positive ("score 3") and positive ("score 4"). Patients were followed-up, based on clinic and radiological and/or histological findings. Median follow up was 38 months (range, 12-60 months). At the end of the follow-up 18F-FDG PET/CT were classified as true positive (TP), true negative (TN), false positive (FP) and false negative (FN).

Results: Group I showed "score 1" in 14 patients, "score 4" in 11 patients and therefore 18F-FDG PET/CT sensitivity was

69%, specificity 83%, VPP 82%, VPN 72%, and accuracy 0.76. This group showed 5 doubt scans (16%) as "score 2" that were found out to be 2 negatives and 3 positives. No "score 3" was observed in this group. Group II showed "score 1" in 55 patients, "score 4" in 27 patients and therefore 18F-FDG PET/CT sensitivity was 87%, specificity 98%, VPP 96%, VPN 93%, and accuracy 0.94. This group showed 7 (8%) doubt scans: 3 scans (3.5%) as "score 2" that in follow-up were 1 negative and 2 positives and 4 scans (4.5%) as "score 3" that were found out to be 2 negatives and 2 positives. Group III showed "score 1" in 24 patients and "score 4" in 6 patients and therefore 18F-FDG PET/CT sensitivity was 86%, specificity 100%, VPP 100%, VPN 96%, and accuracy 0.97. This group showed only 1 doubt scan (3%) as "score 2" that was found out to be negative.

Conclusion: According to our data, PET/CT with 18F-FDG showed an excellent prognostic value of treatment response to primary concomitant RCT if performed at least 14 weeks after the end of RCT. We also observed that the numbers of "doubt scans" significantly decrease 14 weeks after the end of RCT.

EP-1050

Volume definition in radiotherapy planning for thyroid cancer: a retrospective observational study

E. Farina¹, S. Cammelli¹, A. Arcelli¹, G. Zanirato¹, R. Frakulli¹, L. Tagliaferri², A.G. Morganti¹, S. Fanti³, F. Monari¹

¹Radiation Oncology Center- Sant'Orsola-Malpighi Hospital-University of Bologna, Department of Experimental-Diagnostic and Specialty Medicine- DIMES, Bologna, Italy

²Policlinico Universitario "A. Gemelli"- Università Cattolica del Sacro Cuore, Department of Radiotherapy, Roma, Italy

³Nuclear Medicine Unit- Sant'Orsola-Malpighi Hospital-University of Bologna, Department of Experimental-Diagnostic and Specialty Medicine- DIMES, Bologna, Italy

Purpose or Objective: The role of post-operative external beam radiotherapy (EBRT) in differentiated thyroid carcinomas is still discussed considering the low clinical aggressiveness and the possibility to perform a radioiodine ablation (RAI). However, there are dedifferentiated tumors that, over time, lose their capacity to capture iodine. The aim of this study is to evaluate the utility of 18F-FDG PET/CT in volumes defining and the clinical response rate after EBRT in these patients.

Material and Methods: Patients with locally recurrent thyroid cancer, treated with radical EBRT from October 2011 to March 2015 after total thyroidectomy and RAI, were included in the study. When EBRT was planned, thyroglobulin (HTG) was detectable and there was negative post-RAI whole body scintigraphy (WBS) and no surgical indications. All patients underwent a pre-treatment 18F-FDG PET/CT that resulted positive: 3 in loggia, 3 in loggia and lymph nodes, 9 in lymph nodes, 1 in lymph nodes and in lung. EBRT was delivered with IMRT-SIB technique: a dose of 66 Gy (2.2 Gy/fr) to increased FDG-uptake areas, 60 Gy (2 Gy/fr) to ipsilateral lymph nodes and 54 Gy (1.8 Gy/fr) to contralateral ones, in 30 fractions, 1 fr/die. A reevaluation 18F-FDG PET/CT and HTG dosage during the follow-up (range: 5-43 months) was performed. Acute and late toxicity were assessed with CTCAE v. 4.03 and EORTC-RTG scales respectively, the metabolic, clinical and instrumental response with PERCIST and RECIST criteria. Local control (LC) and overall survival (OS) were analysed with Kaplan-Meier method.

Results: Sixteen patients were treated and analyzed consecutively [M / F: 8/8; median age: 71 years; range: 36-81; histology: 15 papillary carcinomas and 1 follicular carcinoma; UICC stage: III-IV]. Post-EBRT 18F-FDG PET/CT showed CR in 7 (43.8%), PR in 5 (31.2%), SD in 4 (25.0%) patients and unknown lung metastases in 2 patients (12.5%). HTG decreased in agreement with PET/CT results. 4 patients (25.0%) had G3 skin acute toxicity and no one showed G4 late toxicity. LC and OS rates were 100% at last follow-up (median F-UP: 12.3 months).

Conclusion: 18F-FDG PET/CT is useful to target volumes delineation for radiotherapy planning, allowing a clear definition of GTV, not detected with 131I WBS. Disease response and local control justify future prospective studies.

EP-1051

Long-term quality of life and second tumours in T1N0 glottic cancer treated with radical radiotherapy

R. Benlloch Rodriguez¹, J. Romero Fernandez¹, D. Rincón Cruz¹, G. Martín Hernández², J.R. García-Berrocal³, B. Vaquero Barrón¹, I. Zapata Paz¹, O. Alvarez montero³, S. Gonzalo Ruiz¹, A. De la Torre Tomas¹

¹Hospital Universitario Puerta de Hierro, Radiation Oncology, Madrid, Spain

²Complejo Asistencial de Ávila, Radiation Oncology, Ávila, Spain

³Hospital Universitario Puerta de Hierro, Otolaryngology, Madrid, Spain

Purpose or Objective: To evaluate long-term results, prognostic factors, quality of life (QoL) and voice and thyroid toxicity and risk of second tumors in T1N0M0 glottic carcinoma.

Material and Methods: A total of 100 patients with stage T1N0M0 histologically proven squamous cell glottic carcinoma treated between 2000 and 2012 were retrospectively analyzed. Mean age: 62.14 years; 90 males, 10 female; stage: T1a:80, T1b:20. Treatment: radical external radiotherapy with a mean dose of 70 Gy (2Gy/fraction). Statistical analysis: Kaplan-Meier method and Chi-square test. In 35 patients, we prospectively evaluated the Voice Handicap Index (VHI 30) and the QoL with (EORTC)-QLQ C30 questionnaire and organ-specific EORTC-Head & Neck-35 module. In the functional and QoL scales of the QLQ C30 questionnaire a higher score represent better functioning and quality of life, whereas in symptoms scales of both questionnaires a high score implies a higher level of symptoms. The last two questions in QLQ C30 represents a QoL scale ranging from 1 ("very poor") to 7 ("excellent"). Blood determination of TSH, T4, T3 levels was performed in 19 patients. Second primary tumors were defined as those originated outside the head and neck area.

Results: Median follow-up: 91.5 months. Five- and 10-year actuarial OS and disease free survival were 83% and 70%, and 70% and 57% respectively. Five- and 10-year actuarial LC and metastasis free survival were 84% and 77%, and 97% and 94% respectively. Eighteen patients had recurrent disease. Mean time to local recurrence was 80 months. Sex, stage, grade and Overall Treatment Time were not statistically significant prognostic factors. Mean score (MS) for the VHI30 was 19.16, which is considered as a minimal amount of voice handicap. Patients reported excellent QoL in the C30 questionnaire which showed functional scores above 93 and symptoms scores below 14. The global health status and QoL scale were 5.93 and 6, respectively, which should be considered as "good" or "very good". In the H&N 35 questionnaire the worse scores were dry mouth and thick saliva (MS 30.6 for both). Most patients have no problems in open mouth, swallowing, speaking and social contact (MS of 0, 6.9, 18.6 and 16.6, respectively). There were no patients with clinical or subclinical hypothyroidism. Mean TSH, T3, and T4 were 2.32, 3.16 and 1.31, respectively. Mean TSH was not statistically different from normal values (P: 0.34) Eighteen patients (18%) had second tumors: 11 lungs, 2 prostates, 5 others. Ten years probability of second lung cancer was 28%.

Conclusion: In our series radical radiotherapy for T1 glottic cancer was well tolerated and achieved excellent tumor control comparable to surgery. In our opinion radical radiotherapy should be the standard treatment of these patients given the excellent results in QoL and voice preservation. The high probability of second lung cancer could justify performing thoracic CT scan during follow-up.

EP-1052

Treatment outcome of induction bio-chemotherapy followed by IMRT in advanced NPC patients

P.J. Lin¹, W.Y. Wang², Y.C. Liu³, J.C. Lin³

¹Tung's Taichung MetroHarbor Hospital, Department of Radiation Oncology, Taichung, Taiwan

²Hung Kuang University, Department of Nursing, Taichung, Taiwan

³Taichung Veterans General Hospital, Department of Radiation Oncology, Taichung, Taiwan

Purpose or Objective: We investigated the treatment outcome of induction bio-chemotherapy followed by IMRT for advanced nasopharyngeal carcinoma (NPC) and the prognostic impact of plasma EBV DNA viral load.

Material and Methods: Forty-two NPC patients with previously untreated, stage III/IV received induction chemotherapy of weekly P-FL (cisplatin 60 mg/m² d1, [5-fluorouracil 2500 mg/m² + leucovorin 250 mg/m²] d8) ± docetaxel 50 mg/m² or gemcitabine 1000 mg/m² d15, for 10-12 weeks and concurrent Cetuximab 400 mg/m² day 1, then weekly 250 mg/m². Conventional (70 Gy/35fr) or hyperfractionated (76.4 Gy/64fr for T4 tumor) RT were delivered by IMRT technique. Plasma EBV DNA levels were measured before, during and after treatment regularly.

Results: Baseline characteristics are median age=44; male/female=28/14; performance status ECOG 0/1=13/12; stage III/IV=22/20, and pathological type (WHO) IIa/IIb=20/22. Each patient received a mean of 11 weekly cetuximab. During induction bio-chemotherapy period, cetuximab-associated toxicity included 100% skin rashes (grade 50% III/IV), 64.3% (27/42) dry skin, 52.4% (22/42) paronychia, and 28.6% (12/42) hypomagnesia. Grade III/IV conventional toxicities were rare (11.9% leucopenia, 9.5% anemia, 2.4% thrombocytopenia, and 2.4% mucositis). Response after induction bio-chemotherapy revealed 50% CR and 50% PR. After a median follow-up of 24 months, there were 1 local, 1 regional, and 5 distant failures. The 3-year local failure-free, neck failure-free, distant metastasis failure-free (DMFS), progression-free survival (PFS), and overall survivals (OS) were 96.6%, 96.0%, 87.4%, 79.9%, and 92.1% respectively. Patients with high pretreatment plasma EBV DNA predict significantly lower PFS and DMFS (P=0.0108 and P=0.004) but not OS (P=0.6291). Patients with detectable plasma EBV DNA after bio-chemotherapy had a significantly lower OS, PFS, and DMFS (P=0.0294, P=0.0078, and P=0.0082). Patients with persistently detectable plasma EBV DNA one week after IMRT predict a significantly lower PFS (P=0.0258).

Conclusion: Induction Bio-chemotherapy followed by IMRT is a highly effective protocol with very low toxicity in advanced NPC. Plasma EBV DNA monitoring are the most important prognostic factors in outcome prediction.

EP-1053

Toxicity and clinical outcome for patients treated for advanced head and neck cancer with VMAT-SIB

E. Villa¹, C. Franzese¹, A. Fogliata¹, D. Franceschini¹, G.R. D'Agostino¹, E. Clerici¹, P. Navarria¹, T. Comito¹, F. De Rose¹, C. Iftode¹, A.M. Ascolese¹, A. Tozzi¹, R.L.E. Liardo¹, P. Mancosu¹, M. Scorsetti¹

¹Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

Purpose or Objective: The choice of fractionation scheme in radiotherapy of head and neck cancer (HNC) is still debated. In fact it is well known that a shorter overall treatment time and a dose escalation, may improve loco-regional control of disease by reducing cell repopulation. Nevertheless, shortening overall treatment time can result in worse acute toxicity. Volumetric modulated arc therapy (VMAT) with Simultaneous Integrated Boost (SIB), allowing hypofractionation with a better sparing of the organs at risk, has showed promising results in terms of outcome and pattern of toxicity. In this study we retrospectively analyzed a series of patients with stage III-IV HNC treated with VMAT-SIB

radiotherapy, with the aim to verify possible correlations between the planned dose distributions to the main dose limiting structures and the observed levels of toxicity like mucositis, xerostomia and dysphagia.

Material and Methods: Data of histologically confirmed advanced HNC patients, in stage III and IV (AJCC), were reviewed in a retrospective dosimetric and clinical evaluation. Patients were treated with VMAT (RapidArc) and SIB in 33 fractions for a total dose of 69.96 Gy to the tumor and positive-nodes, and 54.45Gy to the elective volume, respectively. Toxicity was graded according to CTCAE3.0 Correlation was explored between OAR dose parameters and related acute and late toxicities.

Results: From December 2008 to August 2014, 102 patients were treated. Acute mucosal and swallowing toxicities higher than grade 3 were reported in only 11% and 6% of patients, respectively; late morbidities (G1-G2) were present in only 3% of cases. No G3 Toxicity was reported. A statistically significant correlation was found between the dosimetric parameters of oral cavity V30Gy, V40Gy, and V70Gy, and mucosal toxicity (p = 0.01, 0.03, and 0.05, respectively). Concerning salivary glands, late toxicity profile was worse compared to acute side effects, with 19% of persisting late grade equal or higher than 2. Regarding the constrictors and the swallowing toxicity, most of the dosimetric parameters of the inferior constrictor muscle (mean dose, D1/2V, D1/3V, D2/3V) were significant at the univariate analysis, while no correlations were found for middle and superior constrictors. With a median follow-up of 19 months (range 1-61 months), Overall Survival (OS) at 3 and 5 years was 83%±4% and 73%±10%. Mean OS was 51±3 months. Disease Free Survival (DFS) at 3 and 5 years was 71%±7%, and 34%±16%. Mean DFS was 43±3 months.

Conclusion: Volumetric modulated arc therapy (VMAT) with Simultaneous Integrated Boost (SIB), that allow a shorter overall treatment time, a dose escalation, associated with a better sparing of OARs, showed a good toxicity profile. From our analysis toxicity to dose-limiting structures was significantly correlated to the dosimetric parameters explored.

EP-1054

Temporal patterns of patient-reported trismus and associated mouth-opening distances in RT of HNC
M. Thor¹, C.E. Olsson², J.H. Oh³, J. Hedström⁴, N. Pauli⁴, J.O. Deasy³, C. Finizia⁴

¹Memorial Sloan Kettering Cancer Centre, Department of Medical Physics, NYC, USA

²Institute of Clinical Sciences- the Sahlgrenska Academy at the University of Gothenburg, Department of Radiation Physics, Gothenburg, Sweden

³Memorial Sloan Kettering Cancer Center, Department of Medical Physics, NYC, USA

⁴Institute of Clinical Sciences- Sahlgrenska Academy at the University of Gothenburg, Department of Otorhinolaryngology- Head and Neck Surgery, Gothenburg, Sweden

Purpose or Objective: To investigate the association between temporally robust domains of patient-reported trismus symptoms with mouth-opening ability as assessed by maximal interincisal opening distance (MIO) in head and neck cancer (HNC) patients treated with radiotherapy (RT).

Material and Methods: The study included 196 patients previously treated with primary state-of-the-art RT for HNC in 2007-2012. A five answering-category-based (no/mild/moderate/severe/very severe symptom) patient-reported trismus questionnaire (Gothenburg Trismus Questionnaire, GTQ) was completed pre-RT, and at 3, 6, and 12 months post-RT. This study focuses on the 14/21 potentially RT-induced physical trismus symptoms from GTQ. At each follow-up, symptom domains were generated by means of factor analysis and these symptoms were correlated with MIO (categorized into five intervals (mm): 1: >50; 2:

>40-≤50; 3: >35-≤40; 4: >25-≤35; 5: ≤25) for each follow-up using Pearson's correlation coefficient (Pr).

Results: The three symptom domains *Jaw aches/pains*, *Jaw-related problems*, and *Eating limitations* were identified at each follow-up, and included one, two and three temporally robust symptoms, respectively. Correlations between MIO and these symptoms were weak to modest (Pr= 0.22-0.58; *Table*) with the overall stronger correlations for 'Opening mouth difficulty' and 'Current mouth-opening ability' in the *Jaw-related problems* domain at 6 and at 12 months post-RT (Pr=0.49-0.58; *Figure*).

Table. Symptom domains with symptom importance and prevalence for a moderate-severity or worse, as well as correlations (Pr) with MIO.

Pr: Pearson's correlation coefficient. *Moderate-severity or worse. †Moderate-severity or worse. ‡Moderate-severity or worse. §Moderate-severity or worse. ¶Moderate-severity or worse. ††Moderate-severity or worse. †††Moderate-severity or worse. ††††Moderate-severity or worse. †††††Moderate-severity or worse.

Figure. The prevalence of the Jaw-related symptom 'Opening mouth difficulty' at 6m post-RT, and the distribution of MIOs.

Conclusion: Mouth-opening distances can be explained in terms of associated patient-reported symptom severities on jaw-related problems. Translating the patient's experience into objective measurements and vice versa widens possibilities to monitor and possibly prevent progression of trismus symptoms after RT.

EP-1055

Determination of EGFR in lesions of the oral cavity and evaluating the role of Gefitinib
Y. Umesh¹

¹All India Institute Of Medical Sciences-New Delhi, Radiation oncology, New Delhi, India

Purpose or Objective: Determination of expression of EGFR in premalignant and malignant lesions of the oral cavity and evaluating the role of Gefitinib in the same

Material and Methods: 130 Patients with premalignant and malignant lesions of oral cavity from JK cancer institute, Kanpur were selected. EGFR status evaluation was done in all the patients. Premalignant lesions over expressing EGFR were observed for transformation into malignant lesions and were given Tab Gefitinib 250 mg OD daily. Malignant lesions with over expression of EGFR were randomly divided into 2 groups first group consisted of patients who were given CCRT(cisplatin). The other group had the same regimen but with the addition of Tab Gefitinib 250 mg daily

Results: Out of 130 patients registered 53 were premalignant out of which EGFR(+) positive in 73%(39) patients. EGFR(++)over expression were in 8%(4)patients, EGFR negative in 18%(10) patients. 77 were malignant lesions EGFR positive in 89%(51) patients. EGFR(+in 38%(27) of patients, EGFR(++)in 40%(28) patients ,EGFR(+++) were expressed by 11%(11) patients. EGFR negative in 11%(11 patients)

Total of 40 Malignant Lesions were Randomized into the two arms 19patients(total 22) in CCRT+ gefitinib arm have shown complete response in comparison to 11patients(total 18) in CCRT arm

Conclusion: EGFR status evaluation in premalignant can be used as a screening tool for detection of transformation into malignant lesions. We can prevent this transformation by EGFR inhibitors. In malignant lesions it can be really important for the role of EGFR inhibitors .Eg Gefitinib has shown good results when combined with the conventional CCRT.

EP-1056

Treatment delays are associated with disease upstaging in oropharyngeal squamous cell carcinoma

S. Baker¹, R. Banerjee², B. Debenham¹

¹Cross Cancer Institute, Radiation Oncology, Edmonton, Canada

²Tom Baker Cancer Centre, Radiation Oncology, Calgary, Canada

Purpose or Objective: Increasingly limited health care resources coupled with a rising incidence of oropharyngeal squamous cell carcinoma (OPSCC) is resulting in longer wait times for definitive treatment. Our objectives were to determine the impact of treatment delays on disease upstaging and outcomes in OPSCC.

Material and Methods: Demographic features, number of days from diagnosis until surgery, and clinical and pathological staging information were determined for 139 patients diagnosed with OPSCC between January 2006 and November 2011. Patients were stratified on the basis of whether or not their disease was upstaged between clinical and pathological T, N or M stage. Statistics were performed using MedCalc Statistical Software.

Results: A total of 62 (45%) of patients were upstaged. Upstaged patients had a longer median time to surgery compared to non-upstaged patients (81 vs 68 days, $p=0.017$) and 21% (n=13) were upstaged to T \geq T3 or N \geq N1. There was a trend to higher incidence of margin positivity in upstaged patients (19%, n=12) compared to non-upstaged patients (9%, n=7) ($p=0.141$). Groups did not differ in the rate of nodal extracapsular extension (50% and 41%, $p=0.363$). Median overall survival (OS) for upstaged patients was 5.82 years and was not reached for non-upstaged patients. There was a trend to lower OS in upstaged patients ($p=0.0746$).

Conclusion: Longer duration between diagnosis and surgery is associated with significant pathological upstaging. Allocating resources to reduce treatment delays may result in overall health care savings due to a reduced rate of requirement for adjuvant treatment, reduced patient morbidity, and improvement in disease outcomes.

EP-1057

Impact assessment of Sankol drug on the excretion of radioiodine-131 from patients DTC

S. Saadatmand¹

¹Radiotherapy Sadra Center Qom, Department of Medical Physics and Engineering Isfahan University of Medical Sciences and Healthcare Isfahan- Iran, qom, Iran Islamic Republic of

Purpose or Objective: The aim of this study was to investigate the impact assessment of Sankol drug on the excretion of 131I from patients with differentiated thyroid cancer (DTC).

Material and Methods: Fifty-four patients with DTC who had normal renal function in two groups of control and intervention were included in this study. The herbal diuretic was given orally to the intervention group from 3 hours after the 131I administration, and then every 8 hours for 24 hours. The control patients received placebo with the same timing. The radioactivity of the urine samples from each maturation

was measured and expressed as the percentage of the administered dose. Exposure from patients were measured after the drug administration and then at the time of 3, 9, 15, 21 and 24 hours after the patient isolation.

Results: The obtained mean percentage of activity excreted during 24 hours after intake of radioactive iodine in the urine in the intervention and control group were 68.85 ± 4.3 , 59.11 ± 5.3 with $p<0.001$ respectively. The obtained percentage of residual activity in the body after 24 hours was 25.17 ± 4.6 , 19.56 ± 3.6 with $p < 0.001$, respectively. Radiation dose rate at 300cm after 24 hours for the intervention and control group were $9.52\pm 3.4 \mu\text{SV/h}$, $11.92 \pm 6.0\mu\text{SV/h}$ with $p > 0.05$, respectively.

Conclusion: : Our results demonstrated that Sankol given as an adjuvant medication in the patients with DTC was caused a significant increase in urinary excretion of radiiodine and shorten the hospital stay.

EP-1058

Organ preservation in locally advanced larynx and hypopharynx cancer: non surgical strategy

P. Cucarella Beltran¹, M.A. De la Rúa Calderon¹, J.R. Alonso Pantiga¹

¹Hospital Universitario Central de Asturias, Radiation Oncology, Oviedo, Spain

Purpose or Objective: To present protocol larynx preservation results in patients treated for carcinoma of the larynx or hypopharynx in stage III and IV.

Material and Methods: Data from a serie of 50 patients treated under the guidance of larynx preservation protocol implemented at our institution in 2007 were analyzed. Treatment protocol is divided into two phases. Patients meeting the inclusion criteria receive CDDP and 5FU cycle. At 3 weeks CT evaluation is performed. If the answer is $> 50\%$ are included in the arm radiochemotherapy : CDDP every 3 weeks and RT 70Gy 2 Gy per session 5 days a week. Those who do not respond or $<50\%$ are scheduled to total laryngectomy + neck dissection. If indicated received postoperative RT. The cases analyzed belong the period 2007-2012 (minimum three years follow-up). All patients were considered evaluable.

Results: The serie includes 50 patients with a median age of 56 years. 42 men and 8 women with tumors in the larynx (28) and hypopharynx (22); 27 stage III and 23 stage IV. 22 not reached a sufficient response ($<50\%$) and yes they got 27; in one case we missed the information. Laryngectomy was performed in 19 patients out of 22 unanswered (3 refused). Among the 27 respondents, received RT / CT, 6 LT for recurrences were performed. Larynx preservation was achieved in 50% of patients. The survival of the entire group was 51% at 5 years and 62.6% cause-specific survival. The specific survival at 5 years with RT / CT was 60% compared to 65% of total laryngectomy gupo ($p = 0.568$).

Conclusion: The larynx preservation protocol achieves the same survival rates that total laryngectomy, contributing 50% of preservation of organ function. It is necessary more cases for a final evaluation.

EP-1059

Structured assessment of radiation-induced fibrosis following treatment for head and neck cancer

G. Adigbli¹

¹University College London, Surgery and Interventional Science, London, United Kingdom

Purpose or Objective: To robustly assess features of radiotherapy-induced fibrosis in patients within the reconstructive/plastic surgery clinic and establish a baseline for comparison against following treatment.

Material and Methods: Patients awaiting fat-graft treatment for radiotherapy-induced fibrosis were assessed with regard to their symptomatology using a quality of life questionnaire. They also underwent clinical examination for functional impairment secondary to the fibrotic process and assessment of the microcirculation and mechanical properties by speckle contrast blood flow assessment and thermographic imaging, durometry and skin cutometry respectively. The results were compared against age-matched healthy controls.

Results: Health-related quality of life in these patients was impaired, with 36% of patients overall rating their quality as "fair" or "very poor". On clinical assessment, movement of the neck was impaired with approximately 50% reduction in flexion and rotation movements. 100% of patients had sensory impairment in the fibrotic region. Microcirculatory changes were seen with increased flux (mean = 411.47 vs. 348.83 contralaterally) and temperature (mean difference of 1.3°C vs. control) in the regions of fibrotic change compared with the contralateral side and with controls respectively. Significant differences in hardness of skin and subcutaneous tissues of the neck were seen between treated and untreated areas and between patients and controls (51.5 vs. 16.8 durometer units). Significant increases in the firmness and fatiguability of the skin were seen on cutometry and non-significant decreases in elasticity.

Conclusion: Our methods provide us with important baseline information about how affected our patients are by radiotherapy-induced fibrosis. This baseline can be compared post-operatively to quantify benefits afforded by fat-graft treatment and guide future research into the underlying mechanisms.

EP-1060

Can reduced CTV margin for IMRT in Head and Neck cancers improve therapeutic outcomes?

T.P. Chitradurga Abdul Razack¹, U.K. Annasagara Srinivasa¹, V. Chandraraj², A. Shenoy³, L. Jacob⁴, N. Ramar⁵, P. Anchineyan⁶, L. Vishwanath¹, N. Thimmiah¹, S. Palled¹, S. Patil⁷, C.N. Patil⁸

¹Kidwai Memorial Institute Of Oncology, Radiation Oncology, Bangalore, India

²Kidwai Memorial Institute Of Oncology, Radiation Physics, Bangalore, India

³Kidwai Memorial Institute Of Oncology, Head And Neck Oncology, Bangalore, India

⁴Kidwai Memorial Institute Of Oncology, Medical Oncology, Bangalore, India

⁵Apollo Cancer Institute, Radiation Physics, Bangalore, India

⁶Health Care Global, Radiation Physics, Bangalore, India

⁷Health Care Global, Medical Oncology, Bangalore, India

⁸Apollo Cancer Institute, Medical Oncology, Bangalore, India

Purpose or Objective: To assess efficacy & toxicity of reduced CTV margins in the IMRT of head and neck cancers

Material and Methods: Between 2010 and 2015, 83 consecutive patients with locally advanced Head & Neck squamous cell cancers, treated with a radical intent with chemoradiation by IMRT, with reduced CTV margins were

analysed for local control, toxicity, compliance & survival. Nodal delineation was as per DAHANCA guidelines. Toxicity was assessed by CTCAE version 4.0

Results: Median age of the cohort was 58 years (32-76) with 65 males & 18 female patients. Hypopharyngeal cancers were 47% followed by oropharyngeal (27%) and laryngeal (26%) cancers. TNM stage grouping in the cohort was IVA in 72% followed by IVB & III. CECT based delineation of the involved primary and nodal volumes were expanded uniformly by 5 mm to create the high risk CTV and this expanded by 5 mm to create the PTV1. Similarly the involved nodal level was considered as intermediate risk (PTV2) and remaining nodal levels as low risk (PTV3). Inverse planning was performed using Varian Eclipse planning system with dose constraints to OAR's as per guidelines. SIB-IMRT was delivered to a dose 70, 63 and 56Gy in 35 fractions to high, intermediate and low risk volumes respectively. Median overall treatment time was 49(40-70) days. 24% of the patients received 6 fractions per week. Weekly Cisplatin (40mg/sqm) was given concurrently with IMRT except in 10 patients receiving Carboplatin (2AUC), 90% received a minimum of 4 cycles. Grade 3 mucositis was seen in 40%, grade 3 dysphagia in 6%, radiation dermatitis was predominantly grade 2, Xerostomia was predominantly grade 1 in 93%, 10% required placement of nasogastric tube and treatment interruption. Myelosuppression of grade 3 was seen towards completion of treatment in 24% of the cohort, predominantly in total leukocyte count. A complete response of 90% and 86% was seen in primary and nodal disease at the end of the treatment and eventually in 100% and 94% in first three months. 3 patients needed neck dissection and showed residual disease. At a median follow up of 2 years, 62 patients are controlled with an overall survival of 74.7%. Deaths are due to distant metastasis in 4% and 8% due to other medical causes.

Conclusion: Reduction of CTV margin to 5 mm seems to be appropriate, with good loco-regional control, reduced overall treatment time, better compliance, reduced toxicity & superior outcomes. This study forms basis for a prospective controlled randomised study to generate further evidence.

EP-1061

Progressive resistive exercise training for shoulder function: a randomised controlled trial

V. Murthy¹, M. Chatterjee², S. Kannan³, T. Gupta¹, A. Budrukkar¹, S. Ghosh Laskar¹, J. Agarwal¹

¹Advanced Centre for Treatment- Research and Education in Cancer- Mumbai, Radiation Oncology, Mumbai, India

²Advanced Centre for Treatment- Research and Education in Cancer- Mumbai, Physiotherapy, Mumbai, India

³Advanced Centre for Treatment- Research and Education in Cancer- Mumbai, Biostatistics, Mumbai, India

Purpose or Objective: Significant shoulder dysfunction persists in a majority of the oral cancer patients after surgery even on performing active exercises. Progressive Resistive Exercise Training (PRET) involves gradual and incremental increase in resistance for improved muscular rehabilitation. This randomized controlled trial was done to compare active shoulder exercise and PRET with active exercises for shoulder dysfunction in patients undergoing Radiation Therapy (RT).

Material and Methods: Ninety four eligible patients with shoulder abduction Active Range of Motion (AROM)⁰ were randomized to either active shoulder exercises only (n=47) or PRET plus active shoulder exercises (n=47). Resistance was gradually progressed over 6 weeks according to the capacity of patients in PRET arm. AROM was measured at week 0, 2, 4, 6 and 6 months. Shoulder Pain and Disability Index (SPADI) was also measured in both arms at the base line and after completion of the intervention at the end of 6th week.

Results: Improvement in shoulder abduction AROM was significantly greater in the PRET Arm (mean = 73.3° ± 14.3° at baseline to 132.5° ± 28.5° at 6 weeks) than in standard arm (mean = 74.8° ± 12.5° at baseline to 97.1° ±

22.4° at 6weeks, $p < 0.001$). The SPADI pain and disability score also indicated significant improvement in PRET arm at 6 weeks when compared to standard arm ($p < 0.05$)

Conclusion: Early institution of PRET program provides maximal benefit to the post surgical oral cancer patients undergoing RT than active exercises only and should be considered the standard of care.

EP-1062

Primary (chemo)radiation therapy in organ-sparing treatment of tongue squamous cell carcinoma

A. Gevorkov¹, A. Boyko¹

¹Moscow Research Gerzen Oncology Institut, Radiation Oncology, Moscow, Russian Federation

Purpose or Objective: To evaluate the efficacy of primary (chemo)radiation therapy in a organ-sparing combined or radical nonsurgical treatment modality for tongue squamous cell carcinoma.

Material and Methods: From January 2003 to January 2015 166 consecutive patients with histologically proven the base (49 pts, 30%) and the mobile part of the tongue (MOT) cancer (117 pts, 70%) received radiotherapy +/- chemotherapy (concomitant) to the dose of 50Gy in the preoperative mode treatment and to 70Gy as radical irradiation. Most of them suffered from III (39%) and IV (35%) staged tumors, with the invasive nature of growth at 88 % and regional metastases in 70%. Patients with base of tongue (BOT) cancer had locally advanced process more often (92% vs 66%), especially stage IV (69% vs 20%). Nonresectable process was diagnosed in 38% patients with BOT cancer and in 23% cases of MOT cancer primary tumor. We also assessed tumors for potential biologic predictors of treatment effectiveness (p53, COX-2, VEGF, Ki67, E-cadherin, p21, Bcl-2 and others). Radiomodification with 5FU/cisplatin or cisplatin/cetuximab was performed in 133 (80%) cases. All patients started with photon external beam radiation to the dose of 50Gy with subsequent decision of necessity of surgery by applying our prognostic model (combined clinical and biological predictive model with multivariate analysis, $p < 0.05$). Nonsurgical treatment was performed in 56 (34%) cases. Patients with BOT primary tumor underwent conservative therapy more often (62% vs 22%). Combined treatment with surgery was performed to 110 (66%) patients, with the preservation of the organ in 76 (69%) cases. Organ-sparing surgery was possible in 89 (76%) cases of MOT cancer and only in 16 (33%) cases of BOT cancer.

Results: After irradiation we observed complete response in 21% cases of BOT cancer and 7% of MOT cancer, partial response in 79% and 82% respectively. Stabilization and progression was diagnosed in 8% and 3% of cases MOT cancer. Complete morphological response in surgically removed tissues was obtained in 48% of BOT cancers and 22% of MOT cancers. 5-year general and disease-free survival were 70% and 58% respectively and there was not reliable difference between localizations. Surgical treatment for local relapse were performed 30 of 62 (48%) patients.

Conclusion: In our single experience primary (chemo)radiation therapy has been shown to be feasible and resulted in high probability of organ-sparing treatment with reliable locoregional control, survival and better quality of life.

EP-1063

Patient reported voice outcomes after laser surgery or radiotherapy for T1 laryngeal cancer

R. Simcock¹, D. Walker², A. Addison², M. Harries²

¹Brighton and Sussex University Hospitals NHS Trust, Sussex Cancer Centre, Brighton, United Kingdom

²Brighton and Sussex University Hospitals NHS Trust, Otolaryngology, Brighton, United Kingdom

Purpose or Objective: Disease free survival and overall survival figures for early laryngeal cancer (T1) are excellent

regardless of treatment modality used; either laser surgery or external beam radiotherapy. Randomised controlled trials of laser versus radiotherapy have failed to recruit. In comparing treatment modalities we must therefore look for other comparators including cost efficacy and patient reported outcomes (PROMS). Voice outcomes are an important PROM in larynx cancer treatment.

Material and Methods: A retrospective review of all patients treated at a regional Head and Neck centre over a 7 year period with T1a and T1b laryngeal cancers and subsequently followed up in the voice clinic. Patients were routinely asked to complete the Voice Handicap Index 10 (VHI-10) as part of standard care. The VHI-10 is an abbreviated version of the VHI which gives a subjective score of the degree of handicap experienced by the patient due to voice quality (Rosen 2004). The abbreviated score is validated and consistent. High scores indicate greater disability due to voice effects. VHI-10 scores and data on disease status were collected. Patients were treated with either Type 1,2 or 3 carbon dioxide laser cordotomy (as per ELS classification) by a single surgeon or external beam radiotherapy to 55Gy in 20 fractions in 26 days with 6MV photons to a CT planned volume to the larynx only (no elective nodal irradiation)(PTV = CTV+5mm). Patients treated with radiotherapy usually had contraindications to laser surgery (tumour position or access).

Results: 44 patients were identified with follow-up VHI data, 30 of these had been treated with laser surgery (28 with T1a) and 14 with radiotherapy (8 with T1a). Mean follow up was 3.01 years (0.5-5 years). Recurrence occurred in two patients after laser. One patient underwent further laser excision and the other received radiotherapy. There was 100% disease specific survival. The results were analysed by a General Linear Regression model with multiple imputations to address response gaps, using an SBS analysis tool. Both groups showed a statistically significant increase in mean VHI-10 scores over time and from pre-treatment baselines. VHI scores were higher for the radiotherapy treated cohort in the first year of follow up. Return to a VHI score of less than 10 was 6-9 months for laser and 9-12 months for radiotherapy. Graph shows average VHI score from pre-treatment up to 62 months post treatment.

Conclusion: PROMs are an appropriate way to compare treatment modalities with similar disease outcomes. The VHI-10 is an appropriate PROM for patients treated for laryngeal cancer. In an unselected retrospective population subjective voice outcomes are no worse with laser than with radiotherapy and therefore laser may be a preferred option due to lower cost and greater convenience.

EP-1064

Reirradiation results in head and neck tumours

L. Gutierrez Bayard¹, M. Salas Buzón¹, L. De Ingunza Barón¹, S. Garduño Sánchez¹, E. González Calvo¹, I. Villanego Beltrán¹, V. Díaz Díaz¹, L. Díaz Gómez¹

¹Hospital Universitario Puerta del Mar, Radiation Oncology, Cadiz, Spain

Purpose or Objective: The treatment of choice for recurrences or second tumors of head and neck area, in areas

previously irradiated surgery is not always feasible. The poor results obtained exclusive chemotherapy. We have the objective to study treatment outcome in these tumors recurrent head and neck, previously irradiated.

Material and Methods: We evaluated 57 patients with recurrent disease, between 2005 to 2014. 27 larynx, 6 nasopharynx, 12 oropharynx, 6 hypopharynx and 6 oral cavity. The initial dose received between 50 and 70 Gy, 25/57 received radical radiotherapy, 17/57 radical chemoradiation; other adjuvant radiotherapy, of which 8/57 was combined with chemotherapy. In 24/57 nodal recurrence (N1-N2), local 18/57 (T2-T4), 6/57 local+nodal recurrence, 9/57 second tumor. Reirradiation with external 3D conforma/IMRT techniques/ and dose between 50 Gy and 70 Gy. Time between initial treatment and relapse: 11 to 72 months.

Results: 39/57 cases were complete response, 8/57 partial response, 7/57 stabilization, 3/57 progression. Late toxicity: xerostomia (G: 2/26/57, G: 3/4/57), moderate fibrosis (6/57, one case trismus), 2 osteoradionecrosis fistula required surgical treatment. Local control: 80%, median survival one year and 50% 2 years free of disease, two died of distant metastasis greater than 35 months after second treatment.

Conclusion: This type of treatment, once considered contraindicated, after analyzing various authors, the potential has not seen a high incidence of severe damage expected in healthy tissues. Aggressive treatment of this disease recurring, allowing long survival, even in extensive disease is superior to best supportive care.

EP-1065

Post-treatment FDG-PET CT in detecting residual disease in head & neck squamous cell carcinoma

J. Price¹, A. Pascoe¹, C. Weston¹, S. Kathirgamakarathigeyan¹, M. Griffin¹, R. Ganatra², J. Christian¹

¹Nottingham City Hospital, Department of Oncology, Nottingham, United Kingdom

²Queens Medical Centre, Department of Radiology and Nuclear Medicine, Nottingham, United Kingdom

Purpose or Objective: Head and neck squamous cell carcinoma (HNSCC) is the 6th most common cancer worldwide, and both the disease and its treatment are associated with high morbidity. FDG-PET CT imaging can be performed approximately 12 weeks following IMRT to exclude persistent disease at the primary tumour site and/or local neck nodes. This report considers how post-treatment PET CT scans may be utilised to inform the follow up of patients treated for HNSCC.

Material and Methods: A retrospective review of HNSCC patients treated with IMRT with radical intent between December 2010 and February 2013 and who underwent a post-treatment PET CT scan. Overall, relapse-free and loco-regional relapse-free survival calculated from date of biopsy to date of death, relapse or last follow up. PET CT reports were noted and categorised as follows:

'Low-risk' - normal scan

'Intermediate-risk' - showing post-treatment change or inflammation

'High-risk' - in keeping with or highly suspicious of residual disease

Results: 100 patients were identified. Median follow up was 2.8 years (range 58 days to 3.9 years). On review of PET CT reports, 47 patients were categorised as low-risk, 27 as intermediate-risk and 26 as high-risk. 13 of the 26 high-risk patients underwent a subsequent biopsy, with residual disease in 3. 6 of the 27 intermediate-risk patients underwent biopsy, with residual disease in 1.

3-year overall survival was 93.3% (95% C.I. 80.7 to 97.8%) for the low-risk group, 79.3% (95% C.I. 56.7 to 91.0%) for the intermediate-risk group and 38.8% (95% C.I. 18.3 to 58.9%) for the high-risk group [p < 0.0001].

3-year relapse-free survival was 78.5% (95% C.I. 60.1 to 89.1%) for the low-risk group, 74.0% (95% C.I. 50.1 to 87.7%) for the intermediate-risk group and 33.9% (95% C.I. 15.3 to 53.6%) for the high-risk group [p < 0.0001].

3-year loco-regional relapse-free survival was 91.4% (95% C.I. 78.6 to 96.7%) for the low-risk group, 81.6% (95% C.I. 56.5 to 93.0%) for the intermediate-risk group and 71.5% (95% C.I. 49.1 to 85.3%) for the high-risk group [p = 0.0310, figure]

Conclusion: This report confirms the value of the 12-week post-treatment PET CT scan in identifying the risk of loco-regional relapse and death following IMRT treatment for HNSCC. This information could be used to identify patients in a good prognostic group who may benefit from entering follow-up protocols aimed at addressing psychosocial and survivorship issues, with high-risk patients undergoing more intensive follow-up aimed at detecting relapse of disease.

EP-1066

Low FDG-PET detection rate of the primary tumor for patients with cervical lymph node metastases

E. Dale¹, J.M. Moan¹, T.V. Bogsrud²

¹Oslo University Hospital Radium, Avdeling for Krefthbehandling - Radiumhospitalet, Oslo, Norway

²Oslo University Hospital Radium, Department of Nuclear Medicine, Oslo, Norway

Purpose or Objective: FDG-PET is perceived as a valuable diagnostic tool for patients with cancer of unknown primary (CUP). In the literature, detection rates are approximately 30% for pooled patient populations. Patients with isolated neck lymph nodes of squamous cell carcinoma, are usually examined by an ENT specialist with panendoscopy, sampling blind biopsies, CT or MRI of the neck, sometimes ultrasound of the neck and a chest CT. After these examinations have been performed without finding the primary cancer, FDG-PET detection rates are reported to be approximately 25%. For our head and neck cancer patient population with CUP intended for definitive radiochemotherapy, we hypothesize that the previously reported FDG-PET detection rates are too high.

Material and Methods: In our hospital during 2007-2013, 361 head and neck cancer patients had an FDG-PET-CT examination in fixation mask as part of the radiotherapy treatment planning. In this group, 31 patients had cervical lymph node metastases of squamous cell carcinoma of unknown origin.

Results: Two (cancer of the vallecula and esophagus) of these 31 patients had their primary cancer detected by FDG-PET-CT giving a detection rate of 6.5% (95% C.I.: 2%, 21%).

Conclusion: The FDG-PET detection rate of the primary cancer for patients with cervical lymph node metastases of squamous cell carcinoma, who have been through the standard diagnostic work-up, is lower than previously reported. FDG-PET may be less useful for this purpose than what has been anticipated.

EP-1067

Assessing the outcome in 3D and IMRT head and neck (H&N) cancer patients: are we doing well?

L. Prieto¹, J. Luna¹, J. Olivera¹, J. Vara¹, A. Perez¹

¹Fundación Jimenez Díaz, Radiation Oncology, Madrid, Spain

Purpose or Objective: IMRT is the standard of care in the treatment of H&N carcinoma based on level 1 evidence. However, today there is a greater chance of missing the tumor due to uncertainties in target volume definition by the clinician that is demanded by the highly conformal planning process involved with IMRT. The aim of this work is to compare the outcome in 3D and IMRT treatments in our first two years using IMRT.

Material and Methods: From January 2011 to December 2014, 152 head and neck cancer patients were treated with adjuvant or radical radiotherapy at the Fundación Jimenez Díaz Radiation Oncology Department. Patients received standard treatments with surgery and chemotherapy following international guidelines. Most of them were locally advanced cancer patients with extensive fields of treatment and high doses of radiotherapy. We have analyzed retrospectively the outcome of these patients regarding local/regional control. Data from technique of treatment employed (3D/IMRT), failure location (infield/outfield) and time to failure (persistence/early recurrence or before 6 months/late recurrence or after 6 months) were collected and compared with spss tools. Employed technique depended on the year and the availability. Our department started IMRT techniques in March 2013.

Results: In this group of 152 patients, 30 (19%) recurrences were found: 21 (20%) in the group treated with 3D techniques (101 patients) and 9 (17%) in the group treated with IMRT (51 patients). 21 recurrences were in field, 2 of them in the elective nodal radiation field. Seven (23%) of the recurrences infield were included the IMRT group, and 21 (66%) in the 3D group. Tumor persistence was identified in 6 (20%) patients treated with 3D and 4 (13%) with IMRT. Recurrences outfield were similar in both techniques, slightly higher in the IMRT group (28% vs 33%). However, this data has no relevance keeping in mind the number of patients in each group. In the 3D group there were found 6 patients with early recurrence (before 6 months) and no patients in the IMRT group.

Conclusion: In this group, recurrences were mostly infield, regardless of the employed technique. These data confirm conclusions previously published in large series with 3D radiotherapy. The IMRT group showed lower treatment failures and no early recurrences. However, it is needed to go on checking the IMRT implementation in the departments: to review possible uncertainties in target volume, to define the target with the best image techniques and to assess retrospectively the outcome.

EP-1068

Impact of pretreatment primary tumor volume on survival of patient with T4a larynx cancer

A. Mohamed¹, J. Shiao¹, J. Messer¹, W. Morrison¹, M. Zafereo¹, A. Hessel¹, S. Lai¹, M. Kies¹, R. Ferrarotto¹, A. Garden¹, R. Weber¹, D. Rosenthal¹, C.D. Fuller¹

¹MD Anderson Cancer Center, Radiation Oncology, Houston, USA

Purpose or Objective: To determine the impact of CT-determined pretreatment primary tumor volume on the overall survival (OS) in T4a laryngeal squamous cell carcinoma (LSCC) patients.

Material and Methods: We retrospectively reviewed patients with proved diagnosis of T4a (AJCC 7th) LSCC from 1983 to 2011 at MD Anderson Cancer Center under an approved IRB protocol. Primary tumors were manually contoured on pretreatment diagnostic CT scans for all patients with available scans then total tumor volumes were recorded. Cox regression multivariate analysis was done to investigate the impact of the following variables (age, sex, ethnicity, LSCC

subsite of origin, performance status, nodal stage, surgical treatment, radiation use and dose, chemotherapy use, and tumor volume) on OS. Recursive partitioning analysis (RPA) was used to determine cut point of tumor volume associated with OS then Kaplan-Meier curves were plotted for groups above and below the RPA-derived cut point and log-rank tests was used to compare OS in both groups.

Results: A total of 124 patients were included. Median follow-up was 68 months, and median age at the time of diagnosis was 58 years. Table 1 summarizes patients, disease, and treatment characteristics.

Table 1 – Patients, Disease, and Treatment Characteristics

Sex [n(%)]	
Male	101 (83)
Female	23 (17)
Ethnicity [n(%)]	
African American	26 (21)
White	75 (60)
Hispanic	21 (17)
Other	2 (2)
Disease Site [n(%)]	
Glottic	30 (24)
Subglottic	3 (2)
Transglottic	26 (21)
Supraglottic	65 (53)
Nodal Staging [n(%)]	
N0	41 (33)
N1	5 (4)
N2A	2 (2)
N2B	26 (21)
N2C	27 (22)
N3	2 (2)
Smoking History [n(%)]	
Yes	120 (97)
No	4 (3)
Treatment Method [n(%)]	
Total Laryngectomy followed by Post-Operative Radiotherapy (TL-PORT)	41 (33)
Larynx Preservation (LP) with Radiotherapy (RT)	83 (67)
Radiotherapy Dose	60 (40-72)
Fractionation	30 (12-42)
Chemotherapy Use	
No chemotherapy	56 (45)
Concurrent	46 (37)
Induction	5 (4)
Induction and chemoradiotherapy	17 (13)

A total of 83 patients (67%) received total laryngectomy followed by postoperative radiotherapy (TL-PORT), and 41 patients (33%) received larynx preservation (LP) with radiotherapy (RT). The distribution of sex was 101 males (81%) and 23 females (19%). On multivariate analysis, the only independent predictor of OS was tumor volume (HR 2.6; 95% CI 1.5-4.5, $p=0.0006$). RPA derived the cutpoint at 21cc. Patients with tumors ≥ 21 cc had significantly worse 5-year OS compared to <21 cc (44% vs. 64%, $p=0.003$) as in Figure 1.

Conclusion: Our results suggest that pretreatment primary tumor volume was the only independent predictor of OS in T4a LSCC patients. We recommend the routine measurement

of primary tumor volume for its prognostic impact and for treatment stratification in future clinical trials.

EP-1069

Nasopharyngeal carcinoma screening by plasma EBV DNA and serum antibodies in an outpatient clinic

C.W. Twu¹, J. Jin-Ching Lin¹, W. Wen-Yi Wang²

¹Taichung Veterans General Hospital, Otolaryngology-Head and Neck Surgery, Taichung, Taiwan

²Hung Kuang University, Department of Nursing, Taichung, Taiwan

Purpose or Objective: To investigate the role of plasma EBV (pEBV) DNA and serum antibodies tests in nasopharyngeal carcinoma (NPC) screening.

Material and Methods: From Feb. 2008 to Nov. 2009, a total of 467 subjects coming to an otorhinolaryngology outpatient clinic were enrolled in a prospective screening study. Paired serum and plasma samples were collected and subjected to an immunofluorescence assay for IgA antibodies against the viral capsid antigen (VCA) and early antigen (EA) and a real-time quantitative polymerase chain reaction assay for pEBV DNA measurement. Nasopharyngoscopy was done for subjects with risk factors associated with NPC or abnormal reports of blood tests. Biopsy was performed for suspected lesions to confirm the diagnosis.

Results: We divided the studied population into three subgroups- group A (n=139, symptoms/signs mimicking NPC, presence of family history of NPC, or abnormal antibody tests at other hospital), group B (n=191, symptoms/signs not related to NPC), and group C (n=137, healthy volunteers). After a minimal follow-up of five years, 9 of 467 screened subjects were proven to have NPC. All NPC patients were found in the group A. The sensitivity, specificity, positive predictive value, and negative predictive value for the pEBV DNA test were 100%, 99.8%, 90.0%, and 100%. The sensitivity, specificity, positive predictive value, and negative predictive value for the VCA-IgA test were 77.8%, 88.9%, 12.1%, and 99.5%. The corresponding numbers for the EA-IgA test were 33.3%, 97.6%, 21.4%, and 98.7%.

Conclusion: The pEBV DNA test is a useful screening tool in the detection of NPC. Both VCA-IgA and EA-IgA antibody tests have a low sensitivity and positive predictive value in clinical practice.

EP-1070

Prognostic role of FDG-PET performed before or during radiotherapy in head and neck cancer

M. Min¹, P. Lin², M. Lee¹, I. Ho Shon², M. Lin², D. Forstner¹, M.T. Tieu³, A. Chicco², V. Bray⁴, A. Fowler¹

¹Liverpool Hospital, Radiation Oncology, Liverpool, Australia

²Liverpool Hospital, Nuclear Medicine, Liverpool, Australia

³Calvary Mater Newcastle, Radiation Oncology, Newcastle, Australia

⁴Liverpool, Medical Oncology, Liverpool, Australia

Purpose or Objective: The aim of this study is to evaluate the prognostic value of metabolic parameters derived from 18F-FDG PET-CT performed before definitive radiation therapy (RT) (prePET) in patients with mucosal-primary head and neck squamous-cell-carcinoma (MPHNSCC) and to assess the additive prognostic values of 18F-FDG PET-CT performed during RT (iPET).

Material and Methods: One hundred consecutive patients who had radical RT for MPHNSCC and underwent staging prePET and iPET performed during the third week of treatment, were retrospectively analysed. The maximum-standardised-uptake-value (SUVmax), metabolic-tumour-volume (MTV) and total-lesional-glycolysis (TLG) of primary tumour were analysed for both prePET and iPET, and results were correlated with oncological outcomes including loco-regional-recurrence-free-survival (LRF5), disease-free-survival (DFS), metastatic-failure-free survival (MFFS) and overall-survival (OS), using Kaplan-Meier analysis. Optimal-

cutoffs (OC) were derived from Receiver-Operating-Characteristic curves for the best combined sensitivity and specificity.

Results: Median age was 61 years (range 39-81), median follow-up of 20 months (range 4-70, mean 27), and AJCC 7th Edition clinical stage II, III and IV were 8, 24 and 68 patients respectively. All patients in this study received definitive RT using IMRT or TomoTherapy®: 15 patients were treated with RT only; 68 patients with chemoradiotherapy; 17 patients with RT and concurrent Cetuximab; and 17 patients received induction chemotherapy. Addition of iPET significantly improves the prognostic values of all three metabolic parameters. Metabolic values below cutoffs in both prePET and iPET (compPET) were found to be associated with significant improvements in DFS (p<0.01), LRF5 (p<0.05) and OS (p<0.05). In addition, patients with SUVmax above the OC in compPET were associated with worse MFFS (p = 0.011) and confirmed on both univariate (p=0.019) and multivariate analyses (p=0.04).

Conclusion: The predictive value of FDG-PET is significantly improved by addition of iPET. CompPET is found to be predictive of oncological outcomes including MFFS and can potentially be used in future adaptive local and systemic therapy trials.

EP-1071

Maintenance metronomic chemotherapy for recurrent/metastatic nasopharyngeal carcinoma

C. Wu¹, W.Y. Wang², C.W. Twu³, P.J. Lin⁴, Y.C. Liu⁵, J.C. Lin⁵

¹Changhua Show-Chwan Memorial Hospital, Department of Radiation Oncology, Changhua, Taiwan

²Hung Kuang University, Department of Nursing, Taichung, Taiwan

³Taichung Veterans General Hospital, Departments of Otorhinolaryngology, Taichung, Taiwan

⁴Tung's Taichung MetroHarbor Hospital, Department of Radiation Oncology, Taichung, Taiwan

⁵Taichung Veterans General Hospital, Department of Radiation Oncology, Taichung, Taiwan

Purpose or Objective: The prognosis of recurrent/metastatic nasopharyngeal carcinoma (r/m NPC) after curative radiotherapy is very poor. We aim to investigate the survival impact and toxicity of maintenance metronomic chemotherapy in patients with r/m NPC.

Material and Methods: Patients with r/m NPC were first salvaged by iv cisplatin-based or gemcitabine-based chemotherapy. Local therapy (either radiotherapy or surgery) was administered for suitable patients and feasible disease (local tumor or oligometastasis) as a local consolidation boost therapy. We started to give maintenance chemotherapy with oral tegafur-uracil (two capsules per day) with/without oral cyclophosphamide 50 mg per day for at least 12 months or until disease progression/intolerable toxicity/patient's refusal in our hospital since 2005. A total of 89 patients were collected. We analyzed the treatment outcome between patients with (n=45) and without (n=44) maintenance chemotherapy.

Results: Baseline patient characteristics at diagnosis of recurrence/metastasis (age, sex, pathological type, performance status, disease extent) and response to antecedent iv salvage chemotherapy were comparable in both arms. The median overall survival for patients with and without maintenance chemotherapy were 26 and 11 months, respectively (P<0.01). We observed 5 and 1 patients with biopsy-proven distant metastasis surviving more than 5 years and no evidence of disease in patients with and without maintenance chemotherapy. The toxicities during maintenance oral chemotherapy period were usually mild and no occurrence of grade 3/4 non-hematological toxicity.

Conclusion: Maintenance metronomic chemotherapy strategy significantly improves overall survival and has low toxicity in patients with r/m NPC after iv salvage chemotherapy.

EP-1072

Early stage hypopharyngeal cancer: treatment outcome and treatment strategy

N. Kim¹, K.H. Kim¹, J. Lee¹, C.G. Lee¹, K.C. Keum¹

¹Yonsei University, Radiation Oncology, SEOUL, Korea Republic of

Purpose or Objective: Hypopharyngeal squamous cell carcinoma (HPSCC) is rarely diagnosed in early stage due to the nonspecific nature of early symptoms. Since its rarity, few reports regarding the treatment outcome are available and the most optimal treatment for early stage HPSCC has not yet been clarified. We assessed patterns of failure and factors that influence failures.

Material and Methods: total of 36 patients with pathologically confirmed stage I (n = 10) and II (n = 26) treated between January 1992 and March 2014 were retrospectively reviewed. Ten patients (28%) received definitive RT delivered with a median fraction dose 2.1 Gy (range, 1.8–2.3 Gy) to median total dose 69.1 Gy (range, 60.8–70.2 Gy) (R group). Nineteen patients (53%) underwent surgery only (S group). Seven patients (19%) treated with surgery followed by postoperative RT with a median fraction dose of 1.8 Gy (range 1.8–2.3 Gy) to median total dose was 63.0 Gy (range, 54.0–66.6 Gy) (PORT group). Twenty-six patients received surgery included mass excision/partial pharyngectomy (n = 20), total laryngectomy with partial pharyngectomy (n = 4), and total pharyngolaryngectomy (n = 2). Additionally, 4 of S group had no elective neck node dissection, seven patients had ipsilateral and eight patients had bilateral dissection. All of 10 patients in the R group and in the PORT group received elective bilateral neck irradiation.

Results: At a median follow-up of 48 months, the 5-year locoregional control rate (LRC) was 65%. Of the 36 patients, 5 patients had local failure (LF), one had regional failure (RF), three had combined locoregional failure (LRF) and two had distant failure. No differences were observed in the 5-year LRC among three groups (R, S, and PORT = 67%, 52%, and 100%;, $P = 0.17$). In the RT group, 3 patients experienced LF without RF. In the S group, 7 patients experienced LRF; 2 LF, 1 RF, and 3 combined LRF. There was no LRF in the PORT group though resection margin status of patients in the PORT group were more risky than in the S group (Close/Positive margin 85% vs. 32%; $P = 0.03$) Patients with pyriform sinus apex extension showed a trend toward lower LRC (38% vs. 76%; $P = 0.09$). Patients with bilaterally treated neck (Treated neck group) showed lower trend of RF rate (4% vs. 27%; $P = 0.08$). Of the 10 patients who experienced LRF, 9 patients were successfully salvaged and 5-yr LRC after salvage treatment was 80%. Although late events of gastrostomy or tracheostomy were observed in 8 patients; 2 patients in the untreated or ipsilaterally treated neck group, 6 patients in the treated neck group (18% vs. 24%; $P = 0.70$)

Conclusion: Multimodal approach achieved favorable locoregional disease control despite of the risk factor. There is no difference in LRC between R group and S group. Prophylactic treatment of lymph nodes in the neck improves regional control in selected early HPSCC. Future research in the significance of tumor extension and elective neck treatment will be necessary to define the optimal treatment.

EP-1073

The usefulness of 18F-FDG PET and PET-based considerations in locally advanced nasopharyngeal cancer
H.I. Yoon¹, K.H. Kim¹, J. Lee¹, Y.H. Roh², M. Yun³, B.C. Cho⁴, C.G. Lee¹, K.C. Keum¹

¹Yonsei Cancer Center- Yonsei University, Department of Radiation Oncology, Seoul, Korea Republic of

²Yonsei University College of Medicine, Biostatistics Collaboration Unit, Seoul, Korea Republic of

³Yonsei University College of Medicine, Department of Nuclear Medicine, Seoul, Korea Republic of

⁴Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea Republic of

Purpose or Objective: We investigated 18F-fluorodeoxyglucose positron emission tomography (PET)-derived parameters as prognostic indices for disease progression and survival in locally advanced nasopharyngeal carcinoma (NPC) and the effect of high-dose radiotherapy for a subpopulation with PET-based poor prognoses.

Material and Methods: Ninety-seven stage III and IVa-b NPC patients who underwent definitive treatment and PET were reviewed. For each primary, nodal and whole tumor, maximum standardized uptake value, metabolic tumor volume, and total lesion glycolysis (TLG) were evaluated. The primary endpoint was progression-free survival (PFS). PFS was calculated from the treatment start date to the date of disease progression, relapse, death from any cause, or last contact. Overall actuarial survival (OS) was calculated from the treatment start date to the date of death or the last follow-up. PFS and OS were calculated using the Kaplan-Meier method. The Contal and O'Quigley method was performed to determine the cut-off value for the most useful PET parameter from the C-index and iAUC to allow for dichotomization in an objective manner.

Results: The median follow-up duration among surviving patients was 47 months (range, 8-127). Based on the C-index (0.666) and iAUC (0.669), the whole tumor TLG was the most useful predictor for progression-free survival (PFS); the whole tumor TLG cut-off value showing the best predictive performance was 322.7. The low-whole tumor TLG group showed significantly higher 5-year PFS (77.0% vs. 43.0%, $P < 0.001$), overall survival (OS) (85.7% vs. 54.0%, $P = 0.003$), loco-regional failure free survival (77.0% vs. 49.1%, $P = 0.001$) and distant-failure free survival (81.6% vs. 60.3%, $P = 0.012$) rates than the high-whole tumor TLG group. The whole tumor TLG was one of the significant prognostic factors for PFS (HR, 0.29; 95% CI, 0.13-0.64; $P = 0.002$) and OS (HR, 0.29; 95% CI, 0.11-0.79; $P = 0.02$) in multivariate analysis. Patients with low-whole tumor TLG showed higher 5-year PFS in the subgroup for only patients receiving intensity-modulated radiotherapy (77.4% vs. 53.0%, $P = 0.01$). In the subgroup of patients with high-whole tumor TLG, patients receiving an EQD2 ≥ 70 Gy showed significantly greater complete remission (71.4% vs. 33.3%, $P = 0.03$) and higher 5-year OS rates (74.7% vs. 19.6%, $P = 0.02$).

Conclusion: Our findings demonstrated that the whole tumor TLG could be an independent prognostic factor and high-dose radiotherapy could improve outcomes for NPC showing high whole tumor TLG.

EP-1074

Circulating cell free DNA: dynamics in patients with head and neck cancer during radiochemotherapy

K. Zwirner¹, F. Hilke², C. Schroeder², O. Rieß², D. Zips¹, S. Welz¹

¹Department of Radiation Oncology, Medical Faculty and University Hospital- Eberhard Karls University Tübingen, Tübingen, Germany

²Institute of Medical Genetics and Applied Genomics, Medical Faculty and University Hospital- Eberhard Karls University Tübingen, Tübingen, Germany

Purpose or Objective: The analysis of circulating cell free DNA (cfDNA) in plasma samples of cancer patients ('liquid biopsy') is an upcoming option in detecting cancer characteristics, dynamics, prognosis and recurrence. Combining quantitative analysis, genetic information and clinical data appears as a promising tool in personalised medicine.

Material and Methods: In a prospective pilot study a total of 9 patients with head and neck cancer (median age 64.7 years) receiving primary radiochemotherapy were analysed regarding cfDNA dynamics and genetic alterations. Blood samples were taken prior to therapy, during therapy (week 1,4,6) and 6 weeks after end of treatment.

Results: Sequencing results of the tumours in the first three analysed patients showed somatic alterations of the cell cycle (*TP53*, *CDKN2B*), PI3K; AKT; RAS signaling cascades (*ERBB3*, *HRAS*, *VHL*, *MTOR*), chromatin regulation (*TET2*, *ARID1A*, *KMT2A*, *EZH2*, *MEN1*), Notch signaling (*FBXW7*, *NOTCH1*) and DNA damage response (*BRCA1/2*, *MLH1*). The amount of cfDNA varied among patients and during treatment. Quantitatively, in 5 patients the amount of cfDNA increased during therapy (after week 1). In 4 patients no initial relevant change could be seen (stable after week 1). Currently patients are in follow up for evaluation of clinical outcome.

Conclusion: Our initial results suggest that monitoring cfDNA identifies different patient subsets. As a proof of concept, detection of cfDNA is feasible and a potentially promising tool to identify tumour specific 'finger prints'. Perspectively we hope to use cfDNA as a liquid biopsy and biomarker to identify individual tumour signatures to personalise treatments, detect mutations for targeted therapies and to monitor treatment response.

EP-1075

Squamous cell carcinoma of maxillary sinus : 25-years experience in a single institution

S.H. Jeon¹, H.G. Wu¹, J.H. Kim¹, C.I. Park¹

¹Seoul National University Hospital, Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: To evaluate the clinical outcomes to find optimal treatment and analyze prognostic factors for squamous cell carcinoma of maxillary sinus.

Material and Methods: Between January 1990 and December 2014, 97 patients with histologically proven squamous cell carcinoma of maxillary sinus without distant metastasis, treated with either radical surgery and adjuvant radiotherapy (Op+RT) or radical radiotherapy (RT). Median age at diagnosis was 61. There was no stage I patient and only 5 patients were stage II, all treated with Op+RT. Among twenty-three patients with stage III disease, fifteen patients were treated with Op+RT and eight patients were treated with RT. For stage IVA cancer, thirty-three patients received Op+RT, and twenty-eight patients were treated with RT. All eight patients with stage IVB cancer were treated with RT. Neoadjuvant chemotherapy and concurrent chemotherapy were used in forty-five and nineteen patients, respectively.

Results: Median follow-up period after diagnosis was 30 months for all patients. For stage III cancer, Op+RT showed better outcomes than RT (5-year OS : 63.8% vs. 29.2%, p=0.12; 5-year PFS : 43.2% vs. 18.8%, p=0.16), although not statistically significant. For stage IVA cancer, however, two treatment options showed comparable results (5-year OS : 52.6% vs. 51.3%, p=0.80; 5-year PFS : 37.6% vs. 28.6%, p=0.53). Local failure was the most common pattern of failure, found in forty-two of ninety-seven patients (43.3%). Proportion of regional failures in initially node-positive patients was 21.4% (three out of fourteen). For initially node-negative cancer, regional failure was not observed in fifteen patients who received either neck dissection or neck irradiation, but in 14.7% (ten out of sixty-eight) who did not receive neck treatment. In multivariate analysis, age younger than 60, positive resection margin and masticator space invasion were bad prognostic factors in Op+RT group. Masticator space invasion and subcutaneous tissue of cheek invasion were bad prognostic factors in RT group.

Conclusion: In squamous cell carcinoma of maxillary sinus, radical surgery followed by adjuvant radiotherapy should be recommended for stage III disease. For stage IVA, however, radical radiotherapy can be a good alternative option to surgery. Prophylactic neck treatment for initially node negative patients can prevent regional recurrence, with absolute risk reduction of about 15%. Masticator space invasion was found to be a bad prognostic factor for both treatment arms.

EP-1076

Phase II study of prophylactic radiotherapy in cN0 HNSCC patients based on sentinel node(s) SPECT/CT

E. Longton¹, G. Lawson², B. Bihin³, S. Deheneffe¹, I. Mathieu⁴, J. Installé⁴, T. Vander Borgh⁵, M. Laloux⁶, J.F. Daisne¹

¹Clinique et Maternité Sainte-Elisabeth, Radiation Oncology, Namur, Belgium

³Namur Research Institute for Life Sciences Narillis, Unit of Biostatistics, Namur, Belgium

⁴Clinique et Maternité Sainte-Elisabeth, Nuclear Medicine, Namur, Belgium

⁵CHU Dinant-Godinne, Nuclear Medicine, Yvoir, Belgium

⁶Clinique et Maternité Sainte-Elisabeth, Head and Neck Surgery, Namur, Belgium

Purpose or Objective: Due to a risk of 18 to 45% of occult nodal metastases in cN0 HNSCC patients, prophylactic neck irradiation is often mandatory. Anyway, it leads to a large irradiation of normal tissues because bilateral drainage is the rule in only 30 to 50 % of individuals. Moreover, 15 to 30 % of the tumors drain in unpredicted nodal basins (risk of geographical miss). SPECT/CT lymphoscintigraphy of sentinel lymph nodes (SLN) could help individualizing prophylactic irradiation levels in cN0 patients and, hence, reduce irradiated volume and improve quality of life (QoL). This ongoing prospective phase II study investigates its oncological safety.

Material and Methods: Twenty-six patients with newly diagnosed cN0 SCC of the oral cavity, oropharynx, larynx or hypopharynx were included. All patients were imaged with SPECT/CT after 99mTc nanocolloid injection around the tumor. The neck levels containing up to four hottest SLN were identified and selected for prophylactic irradiation (CTVn-LS) by volumetric modulated arc therapy. A comparative virtual planning was performed with volumes selected according to international guidelines (CTVn-IG). QoL was assessed using EORTC C30 and HN25 scales.

Results: Migration was observed in all of the 26 patients (one with gamma probe only) with an average of 2.8 sentinel nodes detected per patient. CTVn-LS was totally encompassed by CTVn-IG in all patients but two with an unpredicted drainage in homolateral retropharyngeal levels. More than half of the patients has only a unilateral drainage. CTVn-LS and related PTV were systematically smaller than IG ones, by a factor of two on average. This led to significant dose decrease in identified OAR as well as remaining volume at risk. With a median follow-up of 24 months, no regional relapse was observed while 3 patients had a local one (11%). Crude overall survival rate is 89%. QoL preliminary data will be presented.

Conclusion: SPECT/CT lymphoscintigraphy of SLN allows individualizing prophylactic node CTV in cN0 HNSCC patients eligible for definitive radiotherapy. Both CTV and PTV are significantly reduced, which results in a significant dose decrease in OAR. At a median follow-up of 24 months, no regional relapse was observed but further follow-up and recruitment are necessary to ensure the oncological safety. QoL data are being analyzed.

EP-1077

Could site, age and stage be clinical factors for development of adaptive RT in head-neck cancer?

L. Lastrucci¹, S. Bertocci¹, S. Nanni¹, V. Bini², S. Borghesi¹, A. Rampini¹, G. Buonfrate¹, R. De Majo¹, P. Pernici¹, P. Gennari¹, C. Ceccarelli¹

¹San Donato Hospital Radiotherapy Unit, Oncology Department, Arezzo, Italy

²University of Perugia, Department of Medicine Section of Internal Medicine Endocrine & Metabolic Sciences, Perugia, Italy

Purpose or Objective: The aim of this study is to identify prognostic factors of treatment related toxicity after

concomitant radiochemotherapy in patients affected by head and neck cancer.

Material and Methods: 226 patients, 38 female and 188 male, with head and neck cancer, treated with chemoradiotherapy from 1995 to 2014 at our department, were retrospectively reviewed. 59,7% of patients were younger than 60 years. The anatomical sites of cancer were: 36 nasopharynx, 63 oropharynx, 34 oral cavity, 51 larynx, 26 hypopharynx, 16 others sites. 64 patients underwent to post-operative treatment and 162 to radical treatment. They were treated with 2D-3DCRT (80%) or IMRT technique (20%). The mean dose administered was 68 Gy (range 60-74). The schedule of chemotherapy most used included cisplatin and 5-FU. Acute and late toxicity are assessed according to CTCAE v.4.0 scale. Age, gender, tumor/nodal stage, primary site, tumor grading, RT technique and dose were assessed as potential prognostic factors influencing treatment toxicity.

Results: Acute dysphagia and mucositis G2-3 were observed in 82,7% and 84,9% respectively of patients and were related with young age ($p=0,03$ and $p=0,02$), pharynx site ($p=0,004$ and $p<0,003$) and advanced stage ($p=0,02$ and $p=0,009$). Acute xerostomia G2-3 (15%) was associated with oropharyngeal and oral cavity sites ($p=0,03$) and RT technique ($p=0,004$). Late xerostomia G2-3 (25,2%) was related with oropharyngeal site ($p=0,04$) and late fibrosis (14,1%) with nodal stage ($p=0,005$). Acute and late hearing loss (4,8%) was observed more frequently in nasopharyngeal cancer ($p=0,03$ and $p=0,001$ respectively). 3,5% of patients had acute neurotoxicity and 4,8% late neurotoxicity; this adverse effect was associated with nasopharyngeal site ($p=0,03$ and $p=0,03$ respectively).

	Gender	Age	Pharynx site	Stage	Nodal stage	Grading	Dose	RT technique
dysphagia	acute	$p=0,6$	$p=0,03$	$p=0,004$	$p=0,02$	$p=0,9$	$p=0,6$	$p=0,1$
	late	$p=0,1$	$p=0,8$	$p=0,3$	$p=0,9$	$p=0,9$	$p=0,4$	$p=0,1$
mucositis	acute	$p=0,6$	$p=0,02$	$p<0,003$	$p=0,009$	$p=0,2$	$p=0,1$	$p=0,1$
	late	$p=0,6$	$p=0,9$	$p=0,03$	$p=0,08$	$p=0,04$	$p=0,08$	$p=0,7$
xerostomia	acute	$p=0,6$	$p=0,02$	$p=0,003$	$p=0,009$	$p=0,2$	$p=0,1$	$p=0,1$
	late	$p=0,1$	$p=0,2$	$p=0,04$	$p=0,9$	$p=0,6$	$p=0,7$	$p=0,6$
neurotoxicity	acute	$p=0,8$	$p=0,8$	$p=0,03$	$p=0,4$	$p=0,09$	$p=0,7$	$p=0,4$
	late	$p=0,7$	$p=1$	$p=0,03$	$p=0,7$	$p=0,5$	$p=0,01$	$p=0,1$
hearing loss	acute	$p=1$	$p=0,5$	$p=0,03$	$p=0,7$	$p=0,5$	$p=0,6$	$p=0,8$
	late	$p=1$	$p=0,2$	$p=0,001$	$p=0,1$	$p=0,5$	$p=0,6$	$p=0,5$
fibrosis	acute	$p=0,9$	$p=0,8$	$p=0,6$	$p=0,3$	$p=0,005$	$p=0,2$	$p=0,6$
	late	$p=0,9$	$p=0,8$	$p=0,6$	$p=0,3$	$p=0,005$	$p=0,2$	$p=0,6$

Conclusion: Clinical and technical data may be predictive of severe toxicity. Younger patients with pharynx cancer are more susceptible to dysphagia, mucositis and xerostomia. In this subset of patients it's critical evaluate strategies of adaptive radiotherapy with the aim to decrease the toxicity.

EP-1078

Nasopharyngeal Carcinoma: prognostic factors analysis in patients treated with IMRT and chemotherapy

N.A. Iacovelli¹, A. Cavallo², E. De Ponti³, P. Bossi⁴, S. Alfieri⁴, G. Rossi¹, S. Naimo¹, C. Bergamini⁴, S. Tana¹, L. Licitra⁴, E. Pignoli², C. Fallai¹, E. Orlandi¹

²Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics Unit, Milan, Italy

³AO San Gerardo, Medical Physics Unit, Monza, Italy

⁴Fondazione IRCCS Istituto Nazionale dei Tumori, Head And Neck Medical Oncology Unit, Milan, Italy

Purpose or Objective: To analyze clinical outcome and prognostic factors in a consecutive series of 160 non-metastatic nasopharyngeal carcinoma (NPC) patients (pts) treated curatively with intensity modulated radiotherapy (RT) techniques (IMRT, Intensity Modulated Radiation Therapy or VMAT, Volumetric Modulated Arc Therapy) and chemotherapy (CT).

Material and Methods: Pts were treated between October 2004 and April 2014 at our institution. Median age at diagnosis was 49 years (range 18-92). According to WHO, 144 patients (90%) were suffering from undifferentiated NPC, 5

patients (3.1%), 3 patients (1.9%) and 8 patients (5%) were respectively affected by squamous cell carcinoma G1, G2 or G3. One pt was in stage I (0.6%), 31 pts (19.4%) were in stage II, 47 pts (29.4%) in stage III, 31 pts (19.4%) in stage IVA and 50 pts (31.2%) in stage IVB. Seven pts (4.4%) received RT alone: 1 pt in stage I and 6 pts in stage II. Of the remaining 153 pts (95.6%) (25 pts with stage II and 128 pts with stage III and IV) 34 patients (21.2%) received CT concomitant to RT and 119 patients (74.4%) were treated with induction CT followed by RT-CT. IMRT was given with standard fractionation at a total dose of 70 Gy. In 134 patients (83.75%) circulating plasma EBV-DNA has been measured before treatment using quantitative PCR. A dedicated software (VODCA, www.vodca.ch) was used to collect and analyze dosimetric parameters in 137 pts.

Results: With a median follow up of 55.7 months (range 3.8 - 118.7) actuarial rates at 2 and 5 years were respectively: overall survival (OS) 92.36% and 82.81%, disease-free survival (DFS) 83.1% and 77.2%, local control (LC) 92.17% and 90.43%, locoregional control (LRC) 94.78% and 93.04% and distant control (DC) 89.57% and 86.96%. At univariate analysis N stage (N0+N1+N2+N3a vs N3b) was found to be a prognostic factor for DM ($p = 0.029$). At multivariate analysis conducted on the following parameters: T stage, N stage, stage, RT technique, V95%, Dmean and D99% (relative to High Risk PTV), the stage of T (T1+T2+T3 vs T4) was found to be a prognostic factor for LRC ($p = 0.035$). Both at univariate and multivariate analysis the stage of T was found to be a prognostic factor for LC ($p = 0.004$ and $.011$ respectively) and N stage (N0+N1+N2 vs N3) for DM and RC. Pts with a V95% > 90% had better LC ($p=0.004$) and DFS ($p=0.047$). Pts with a Dmean > 69 Gy had better LC ($p=0.029$). Pts with a D99% > 64 Gy had better LC ($p=0.008$) and OS ($p=0.004$). The threshold value of 45 cc of GTV T (Gross Tumor Volume of the primary tumor) was prognostic for LC ($p = 0.0095$). The threshold value of 1500 copies of EBV-DNA was prognostic for DC ($p = 0.048$).

Conclusion: The intensified treatment of CT-IMRT / VMAT achieves excellent clinical outcomes. Besides traditional prognostic factors, we demonstrated the prognostic value of dosimetric parameters. Finally, for the first time in a non-endemic area threshold values of GTV T and EBV-DNA prognostic for LC and DC respectively have been confirmed.

EP-1079

Clinical outcomes in locally advanced oropharyngeal cancer 18FDG PET-guided dose escalation IMRT-SIB

A. Chiara¹, C. Fiorino², M. Picchio³, A. Fodor¹, S. Broggi², M. Pasetti¹, E. Incerti³, P. Mapelli³, F. Zerbetto¹, C. De Antoni¹, M. Azizi¹, R. Calandrino², I. Dell'Oca¹, N. Di Muzio¹

¹IRCCS San Raffaele Scientific Institute, Radiotherapy, Milano, Italy

²IRCCS San Raffaele Scientific Institute, Medical Physics, Milano, Italy

³IRCCS San Raffaele Scientific Institute, Nuclear Medicine, Milano, Italy

Purpose or Objective: Technological advances have enabled clinicians to explore dose escalation strategies in various tumor sites. Intermediate and high risk oropharyngeal cancers have unsatisfactory 3 year outcomes. The simultaneous integrated boost (SIB) technique with dose per fraction slightly higher than 2Gy offers the advantages of shortening the treatment time and increasing the biologically equivalent dose to the tumor. This retrospective study is aimed to evaluate the clinical outcome of radiation dose escalation to 18FDG PET/CT positive tumor and nodal sub volumes using the Simultaneous Integrated Boost (SIB) IMRT technique by means of Helical Tomotherapy (HT) in locally advanced Oropharyngeal cancer patients (pts).

Material and Methods: 37 pts, median age 59 years (range: 41-81), treated between 2005 and 2014, were evaluated. Reported stage were III-IVAB (4 and 33 respectively). HT was delivered with the SIB technique at different dose levels: 69Gy (2.3 Gy/day) to the PET-positive volume (GTV-PET), 66

Gy (2.2 Gy/day) to the clinical target volume for tumor and metastatic nodal station, 54 Gy (1.8 Gy/day) to the clinical negative neck region concomitantly in 30 fractions. Concurrent chemotherapy was given to 32 pts (cisplatin 75-100 mg/m²/21 days for 25 pts, cisplatin 30-40 mg/m²/week for 5 pts and Cetuximab for 2). Possible correlation between Overall Cancer specific (OS) and GTV-PET Volumes (GTV-T+N, GTV-T, GTV-N) was also considered.

Results: The median follow-up was 39.2 months (range: 3-125); 27%, 62% and 11% pts has respectively never smoked, a smoking history of more than 10 packs/year and not assessed. 36 pts completed the treatment as scheduled. Temporary treatment interruption due to acute toxicity, mainly mucosae, was observed in 5 patients. No grade 4 acute mucosae and skin toxicity was reported. Seventeen pts (46%) experienced grade 3 toxicity, mostly dermatitis and mucositis. Late grade 3 and 2 xerostomia was seen respectively in 3% and 32% pts. No grade 4 late toxicity was observed. The 3-year OS, Local disease-free Tumor (LTC), Local disease-free Nodal (LNC) and distant metastasis-free (DMFS) survivals were 87%, 83%, 89% and 92% respectively. Multivariate Cox regression analyses revealed that GTV-T+N and GTV-T are predictors for OS with a best-cut-off value equal to 30.9 cc (p=0.005) and 22.4 cc (p=0.038).

Conclusion: The slightly accelerated dose escalation in oropharyngeal cancers to 18FDG-PET positive tumour subvolumes is likely to be safe even with concurrent chemotherapy. Very interesting 3-year OS and loco-regional disease control rate are obtained. The results of the present study suggest that GTV-PET has a predictive value for the SIB-HT outcome. These findings may constitute the basis for more personalized treatments.

EP-1080

Definitive or adjuvant IMRT for locally advanced sinonasal tumors: outcome and prognostic factors

E. Orlandi¹, A. Cavallo², E. De Ponti³, N.A. Iacovelli¹, P. Bossi⁴, P. Nicolai⁵, P. Castelnuovo⁶, M. Guzzo⁷, G. Calareso⁸, S. Naimo¹, C. Bergamini⁴, L. Locati⁴, L. Licitra⁴, E. Pignoli², C. Fallai¹

⁷Fondazione Irccs Istituto Nazionale Dei Tumori, Otorhinolaryngology Unit, Milan, Italy

⁸Fondazione Irccs Istituto Nazionale Dei Tumori, Radiology Department, Milan, Italy

Purpose or Objective: There are limited and heterogeneous data on prognostic factors of locally advanced epithelial non glandular sinonasal cancer (ESNC) treated with multimodal treatment strategy. Prognosis of ESNC remains poor, with an overall 5-year survival rate of 30-50%. We analyzed a retrospective series of consecutive patients (pts) treated with IMRT at our institution, with a specific focus on the prognostic implications of clinical and treatment-related factors.

Material and Methods: Since 2007, 49 pts with ESNC staged III and IVA-IVB were treated at our Institution. Histology was squamous cell carcinoma (SCC) in 22 pts (44.9%), undifferentiated carcinoma (SNUC) in 20 pts (40.8%) and neuroendocrine carcinoma (SNEC) in 7 pts (14.3%). Prevalent primary site was ethmoid sinus (24 pts, 49%). Thirteen pts (26.5%) had N stage $\geq 2b$ and 12 (24.5%) had positive retropharyngeal nodes (RPNs). Orbital apex invasion (OAI), nasopharyngeal involvement, gross nerves involvement (GNI) and positive surgical margins (R1) were found in 24 (49%), 12 (24.5%), 10 (20.4%) and 5 (10.2%) pts respectively. Thirty

(61.2%) and 19 (38.8%) pts received definitive and postoperative IMRT, respectively. Thirtyfive pts (71.5%) received induction chemotherapy before surgery or RT and/or concomitant CHT. Thirtyeight pts (77.5%) received concomitant CHT. IMRT was given with standard fractionation at a total dose of 65-72 Gy in definitive cases and 54-66 Gy in adjuvant cases, according to histological findings. Gross tumor volume (GTV) was defined in all radical pts, and dose-volume histograms to all targets were analyzed in all pts.

Results: Median follow up was 22.4 months (range 6-85). Three-year overall survival (OS), disease free survival (DFS) and locoregional control (LRC) were respectively 66.5%, 55.4% and 66.3% for the entire cohort. OS and DFS were statistically better in pts with SCC or SNUC compared to pts with SNEC, in pts with ethmoid primary compared to other sites, in pts with N0 compared to pts with N stage $\geq 2b$, in pts with RPNs compared to pts without RPNs (see Fig. 1), in pts with OAI compared to pts without OAI and in pts with GNI compared to pts without GNI. LRC was better even though statistically not different in pts without R1 compared to pts with R1. A multivariate analysis showed that ethmoid as primary origin site was a positive independent prognostic factor on OS, whereas RPNs positivity and OAI were negative independent prognostic factors for OS. For pts receiving definitive IMRT, pts with GTV <79.7cc had better OS, DFS and LRC compared to pts ≥ 79.7 cc, even if the difference was not statistically significant. Dosimetric factors were not found to have any prognostic role.

Conclusion: In a monoinstitutional series of locally advanced ESNC we obtained a 66.5% 3-yr OS and a 55.4% 3-yr DFS. We were able to identify RPNs involvement, ethmoid primary site and OAI as independent prognostic factors.

EP-1081

Advanced head and neck ca - chemoradiotherapy with conventional fraction and accelerated fraction

H.A. Gaffor¹, F. Ruzina¹, C.H. Sridhar²

¹Father Muller Medical College, Radiation Oncology, Mangalore, India

²Father Muller Medical College, Radiation Physics, Mangalore, India

Purpose or Objective: To compare early tumor response and compliance of locally advanced head and neck cancer patients receiving concurrent chemo-radiation, weekly Cisplatin with conventional fractionation versus weekly Cisplatin with accelerated fractionation and to assess toxicity profile

Material and Methods: Patients with histologically confirmed primary head and neck squamous cell carcinoma, stage III and IV (Oral cavity, oropharynx, hypopharynx and larynx) attending the department of Radiotherapy, Father Muller Medical College Hospital, Mangalore Between November 2013 to April 2015.

Total of 64 patients were recruited and randomized into conventional and accelerated arm each having 32 patients.

Both the arms received concurrent chemo-radiation. Chemotherapy with inj Cisplatin 35 mg/m² weekly IV infusion was given as a radiosensitizer before Radiotherapy for 6 cycles and external beam radiotherapy 69.99-70Gy in 33-35 fractions 2 - 2.121Gy/fraction using Linear accelerator of 6MV photons by Conventional arm received standard regimen 5 fractions/week with overall treatment time of 6 weeks and Accelerated arm received 6fractions/week with overall treatment time of 7weeks.

Patients were evaluated in both the arms for early tumor response and acute Toxicities

Results: The mean age of patients were 53.44 years,76.60%were male and 23.4% were female .

Concurrent chemoradiation using accelerated fractionation showed higher percentage of complete response rate , in stage III-100%, IVA-88.50%and IVB- 50%,were as in conventional fractionation it was in stage III-87.50% and IVA-80.00%.

According to site complete response rate in oral cavity 87.50%and 50.00% , oropharynx 92.90% and 72.70% in accelerated fractionation and conventional fractionations respectively.

Total number of cycles of chemotherapy received were same in both the arms. There was significant weight loss during treatment in accelerated fractionation compared to conventional fractionation arm.

Conclusion: In our study, Locally advanced head and neck cancers showed better early tumor response with acceptable acute toxicities when treated with concurrent chemoradiation using accelerated fractionation compared to conventional fraction and the quality of life was not stastically different in both the arms.

EP-1082

Interim 18F-FDG-PET/CT during chemoradiotherapy for early outcome prediction of head and neck cancer

C. Garibaldi¹, S. Ronchi², M. Cremonesi¹, M. Ferrari³, L. Gilardi⁴, L. Travaini⁴, D. Ciardo², F. Botta³, G. Baroni⁵, C. Grana⁴, B.A. Jereczek-Fossa⁶, R. Orecchia⁷

¹European Institute of Oncology, Radiation Research, Milan, Italy

²European Institute of Oncology, Radiation Oncology, Milan, Italy

³European Institute of Oncology, Medical Physics, Milan, Italy

⁴European Institute of Oncology, Nuclear Medicine, Milan, Italy

⁵Politecnico di Milano, Elettronica Informazione e Bioingegneria DEIB, Milano, Italy

⁶European Institute of Oncology- University of Milano, Radiation Research- Department of Health Sciences, Milan, Italy

⁷European Institute of Oncology- University of Milano, Radiation Oncology- Department of Health Sciences, Milan, Italy

Purpose or Objective: It is established that in the management of locally advanced head and neck cancer (HNC) patients, 18F-FDG-PET/CT (FDG) plays a significant role in the pre-treatment setting to predict outcome and prognosis and at the end of the chemo-radiotherapy (CRT) to assess the tumor response. This systematic review aims to evaluate the use of FDG acquired during CRT, ad interim FDG (FDGint), with the aim to identify tumor responsiveness in an early stage of the treatment in order to allow modification of the treatment plan and/or to setup alternative therapeutic strategies to enhance the therapeutic ratio.

Material and Methods: Data search was performed in PubMed for full original papers published from 2005 up to August 2015, written in English and based on the use of 3D hybrid PET/CT only, with eight different combination of keywords. The literature search brought 568 articles. Twenty-one original papers fulfilled the inclusion criteria: 8 studies investigated the predictive role of FDGint assessing correlations between metabolic variations and clinical outcomes, 7 studies draw conclusions about a potential role

of response assessment during RT for treatment adaptation without reporting any correlation with the clinical data, and 6 studies were focused on the use of FDGint for biology-guided adaptive RT.

Results: The results of the analysis considering only the papers focusing on the predictive role of FDGint are reported in the table. All patients underwent at least a FDG at baseline, and one at a dose in the range of 10-20 Gy (early PETint), or in the range of 40-50 Gy (late PETint). Most of the studies reported a qualitative or semi-quantitative method of delineation of the FDG uptake, using a threshold value of the SUVmax, usually 40% or 50%. All the studies have in common the SUVmax and its variation as the main parameters considered for FDG evaluation, although the largest and first study evaluating all metabolic parameters of FDGint, found that tumor lesion glycolysis was a better and statistically more significant predictor of outcome than SUVmax. Two papers comparing FDGint with FLTint revealed that reduced FLT SUV preceded reduced FDG uptake, suggesting that FLTint is expected to assess the therapeutic response much earlier than FDGint.

Table. Statistics of cohort characteristic

	Value
N° of papers included	15
N° of patients	431
N° of patients/study (median, range)	29 (8 - 72)
Chemotherapy	Different schedules and pharmaceuticals
Radiotherapy	3D-CRT or IMRT
Total dose (range)	T = 60-78 Gy N° = 60-66 Gy N° = 50-56 Gy
Studies with <i>early</i> FDG _{int}	4
Dose at which <i>early</i> FDG _{int} is acquired (median, range)	20 (10-35)
Studies with <i>late</i> FDG _{int}	5
Dose at which <i>late</i> FDG _{int} is acquired (median, range)	49 (40-66)
Studies with both <i>early</i> and <i>late</i> FDG _{int}	6
Studies PRO prognostic value of FDG _{int}	4/8
Studies CONTRA prognostic value of FDG _{int}	2/8
Studies comparing FDG _{int} with FLT _{int}	2/8

Conclusion: Most of the works confirmed the value of FDGint in predicting the response to CRT, while few highlighted the poor prognostic value of FDGint compared to FDG acquired 2-3 months after the end of CRT which revealed a strong correlation with local and regional control and with survival. Although the best timing to assess tumor response during RT remains a matter of debate, the two week time point seems most favorable, also because there is still sufficient opportunity for adaptation of the treatment strategy. Such contradictory findings deserve to be further analyzed and confirmed in a more numerous and homogeneous series according to the tumor site and radio-chemotherapy schedules.

EP-1083

Usefulness of PET/CT in definition of treatment volumes of head and neck tumors

L.P. Luigi Perrone¹, A.D. Anna Destito¹, R.M. Rosa Molè¹, E.M. Elvira Mazzei¹, M.S. Mariaquila Santoro¹, M.A.M. Maria Angela Molinaro¹, D.P. Domenicantonio Pingitore¹, C.B. Cataldo Bianco²

¹Hospital Pugliese-Ciaccio, Department of Hemato-Oncology-Operative Unity of Radiotherapy and Radiobiology, 88100 Catanzaro, Italy

²University of "Magna Graecia", Department of Clinical and Sperimental Medicine, 88100 Catanzaro, Italy

Purpose or Objective: The radiation therapy of head and neck tumors is burdened by high toxicity to organs at risk (OARs) with consequent administered dose limitations to the target and compromised clinical outcome. We investigated the contribution of functional/biological imaging obtained by Positron Emission Tomography (PET/CT) in Gross Tumor Volume (GTV) and Clinical Target Volume (CTV) definition of primary tumor and regional lymph nodes in head and neck cancer, for a more accurate target delimitation resulting in lower toxicity to OARs.

Material and Methods: From March 2103 to June 2014 we examined 51 patients with head and neck cancer and defined clinical volumes with the aid of only morphological CT images and with the aid of diagnostic PET/CT images. Then we evaluated, through tests of statistical significance, the overlap of GTV and CTV obtained with each of the two methods respectively. Moreover usefulness of PET/CT in preventing geographic errors for a more accurate target definition, resulting in peritumoral tissues preservation and less toxicity to the OARs, was evaluated as well. The influence of two different imaging techniques in TNM staging, which is important for treatment planning, was investigated.

Results: In 33 of 51 patients the TNM staging obtained by PET/CT was similar to that performed by CT images, but in 39% of the cases the primary tumor GTV defined by PET/CT was significantly smaller and restricted compared to that defined by CT only ($p < 0.016$). Due to the better GTV definition in terms of size and location, the OARs are potentially better preserved. In 12 patients the more accurate definition of tumor margins made possible by PET/CT produced a different T than that obtained with CT evaluation only; in 6 patients PET/CT identified metastases to regional lymph nodes not assessed with CT images only. It was not observed significant variation of the nodal volumes.

Conclusion: The use of PET/CT imaging allows the realization of more precise target volume and better defined clinical volumes, with a possible better preservation of the OARs and lower toxicity. Functional imaging PET/CT helps the radiation oncologist not only in the process of treatment planning, but has the advantage of identify treatable disease not highlighted on morphological CT images. It is therefore recommended to use a PET/CT scan in the radiotherapy planning process in order to achieve a more appropriate treatment planning in head and neck tumors.

EP-1084

Elderly patients concomitant radiotherapy + cetuximab in locally advanced head and neck cancer

A.T. Falk¹, C. Hébert², M. Paquet³, A. Tran⁴, F. Peyrade², E. Saada², J. Reure², O. Dassonville⁵, G. Poissonnet⁵, A. Bozec⁵, J. Thariat¹, A. Leysalle¹, M.E. Chand¹, K. Benezery¹

¹Centre Antoine Lacassagne, Radiation Therapy, Nice, France

²Centre Antoine Lacassagne, Medical Oncology, Nice, France

³Centre Antoine Lacassagne, Nuclear Medicine, Nice, France

⁴Hôpitaux Pédiatriques de Nice CHU Lénval, Medical, Nice, France

⁵Institut universitaire de la face et du cou, Service de cancérologie ORL, Nice, France

Purpose or Objective: Concomitant radiotherapy + cetuximab association has shown superiority to exclusive radiotherapy for locally advanced head and neck cancers (LAHNC). Data on this association are scarce for the elderly despite its rising incidence. Initial clinical trials that led to its approval have not included patients >70 years. The objective of this study was to assess efficacy and toxicity of concomitant radiotherapy and cetuximab for patients aged >70 years with LAHNC

Material and Methods: A retrospective monocentric data collection was performed in the Antoine Lacassagne center, France. Inclusion criterias were: age >70 years at time of diagnosis, histologically proven LAHNC, treated with radiotherapy combined with cetuximab. Non-inclusion criterias were: previous radiotherapy and metastases at time of diagnosis

Results: Thirty-five patients were included between 2008 and 2012. Median follow up was 22 months. Median age was 74 years (70-86). Median performance status was 1(0-2). Female/male sex ratio was 0.34. Tumor sites were: Oropharynx(57.1%), larynx(20%), hypopharynx(14.3%), oral cavity(2.9%), rhinopharynx(2.9%), lymph node with unknown primary(2.9%). Using TNM classification, tumors were: T1(5.9%), T2(35.3%), T3(35.3%), T4(22.9%), N0(28.6%), N1(8.6%), N2(48.6%), N3(14.3%). Median radiotherapy dose was 70 Gy(60-70). 40% of patients were treated with intensity-modulated radiotherapy, the rest were treated with conventional 3D radiotherapy. 94.3% of patients paused radiotherapy due to toxicity. 29% had a cetuximab dose-reduction and 1 patient had a definitive interruption. Median survivals were respectively: 49 months for overall survival(Standard-Error (SE)=8) and 32 months for relapse free survival(SE=10). Two-year local-regional relapse and metastatic relapse free survivals were respectively 59%(SE=10) and 74%(SE=10). Median body mass index (BMI) was 24.6(17.3-38) before treatment and 23, 24 after treatment(16.3-34.7). Median weight variation was 4 kilograms(-16 to +6). Ninety-four percent of patients had nutritional support: 37.8% had oral nutritional supplements only, 56.8% had enteral nutrition and 2.7% parenteral nutrition. Skin reaction and mucositis were the major toxicities recorded. Toxicities details are reported in table 1

Type	Total incidence (%)	G1 (%)	G2 (%)	G3 (%)	G4 (%)
Skin toxicities	80	8.6	8.6	62.9	0
Mucositis	74.3	5.7	37.1	31.4	0
Xerostomia	20	0	2.9	17.1	0
Dysgeusia	11.4	0	5.7	5.7	0
Anorexia	8.6	0	0	8.6	0
Constipation	8.6	2.9	5.7	0	0
Esophagitis	8.6	2.9	2.9	2.9	0
Pain	5.7	5.7	0	0	0
Dysphagia	5.7	0	0	5.7	0
Nausea	2.9	2.9	0	0	0

Table 1

Conclusion: Concomitant radiotherapy and cetuximab seems to be an effective therapy in the elderly population with encouraging results similar to the literature concerning its efficacy and toxicity. This treatment should be considered for patients > 70 years.

EP-1085

EGFR expression in head and neck cancer : does it have a role as prognostic factor in radiotherapy?

D. Alterio¹, A. Ferrari², F. Maffini³, G. Marvaso², L. Santoro⁴, C. Fodor², M. Cossu Rocca⁵, M. Ansin⁶, S. Dicuonzo², M. Muto², D. Zerini², S. Chiocci⁷, R. Orecchia^{1,8}, B. Jereczek-Fossa^{1,8}

¹European Institute of Oncology, Radiation Oncology, Milano, Italy

²European Institute of Oncology, Radiation Oncology, Milan, Italy

³European Institute of Oncology, Pathology, Milan, Italy

⁴European Institute of Oncology, Epidemiology and Biostatistics, Milan, Italy

⁵European Institute of Oncology, Medical Oncology, Milan, Italy

⁶European Institute of Oncology, Head and Neck Surgery, Milan, Italy

⁷European Institute of Oncology at the IFOM-IEO, Experimental Oncology, Milan, Italy

⁸University of Milan, Health Sciences, Milan, Italy

Purpose or Objective: In an era of personalized treatment there is a great interest in identifying factors which might help to predict patient response to RT. EGFR role in this

setting remains still controversial, despite the large consensus as a promising candidate to become a biomarker that could further improve application and efficacy of radiation therapy (RT) in head and neck squamous cell carcinoma (HNSCC). Moreover, most of the studies refer to series of patients who underwent RT alone or in combination with Cetuximab. We performed a retrospective analysis on the prognostic value of EGFR expression in HNSCC treated with surgery and postoperative RT.

Material and Methods: We analyzed 69 patients with an histological diagnosis of HNSCC who underwent adjuvant RT after surgery in our Institute from 1997 to 2003. A 3D conformal RT was delivered with a 6MV accelerator using a conventional fractionation (median 60 Gy, range 34.2-70 Gy) Median follow-up was 3.73 years (range 0.17-12.25 ys). None of these patients were treated with postoperative concomitant chemotherapy. Tumor samples used for the determination of EGFR were obtained from surgical specimens. Membrane features (intensity, extension, distribution) and percentage of EGFR expression were evaluated and a statistical analysis (univariate) was conducted to correlate these parameters with Overall Survival (OS) and Disease Free survival (DFS).

Results: EGFR was overexpressed in 45,5% of our patients (median value used as threshold). No significant correlation (p value= 0.90) has been found between patients with an overexpression of EGFR and OS or DFS. Among patients with laryngeal carcinoma, those with overexpressed EGFR have showed a lower OS (not statistically significant) and DFS ($p=0.05$). Considering separately the membrane features, the intensity of the EGFR staining has been found statistically correlated with both OS ($p= 0.03$) and DSF ($p=0.001$). Moreover, a stratification of patients was performed combining extension and intensity of EGFR immunolabelling in tumour cell membranes, and their distribution following a three-point score: patients with 3+ score (intense and complete labelling and patchy distribution) presented the lowest OS and DFS and the difference was highly significant for both OS and DFS ($p= < 0.0001$). The same result was observed in the subgroup of patients with a diagnosis of larynx carcinoma.

Conclusion: Based on our results it is still reasonable that the analysis of EGFR expression, especially referring to membrane features, might be a prognostic value for OS and DFS in locally advanced HNSCC treated with adjuvant RT. A clinical validation in prospective trials of the suggested three-point score system could be useful to select patients with worse prognosis that might benefit from more aggressive treatments.

EP-1086

Finding the right threshold for determining hypoxic subvolumes in F-MISO-PET/CTs for HNSCC

H. Kerti¹, L. Majerus¹, A. Bunea¹, N. Wiedenmann¹, M. Mix², C. Stoykow², P.T. Meyer², A.L. Grosu¹

¹University Hospital Freiburg, Department of Radiation Oncology, Freiburg, Germany

²University Hospital Freiburg, Department of Nuclear Medicine, Freiburg, Germany

Purpose or Objective: Tumor hypoxia is a common feature of locally advanced head and neck cancer (HNSCC) that is associated with higher malignancy and increased radioresistance. Tumor-to-blood ratios ≥ 1.2 are generally thought to indicate hypoxia. Nevertheless, previous studies use various thresholds to define tumor hypoxia. The following analysis tries to elucidate which threshold may be the most appropriate to determine hypoxic volume in respect to treatment success.

Material and Methods: A prospective study was performed to determine changes in tumor hypoxia during primary chemoradiation (pRCTX) of HNSCC at our institution. Tumor hypoxia was non-invasively assessed by [18F]-Fluoro-Misonidazole (F-MISO) PET/CT 2.5 h p.i. at baseline (week 0)

and in week 2 and 5 of treatment, respectively. Hypoxic volumes (HV) were generated using thresholding at different levels of 1.2, 1.3, 1.4, 1.5 multiplied with the background-uptake, which was defined as SUVmean within the ipsilateral trapezium muscle, as advised by a nuclear-medicine specialist. Δ -values of decrease of HV (Δ HV) during treatment were obtained in weeks 0, 2 and 5 and correlated with local failure. As four patients showed local failure (LF), two groups of four patients each were made: four showing LF, four patients showing complete remission (CR). Before t-test analysis normal sample distribution was confirmed with Shapiro-Wilk test. Significance-level was defined as $p < 0.005$.

Results: We analysed 4 patients without local failure in comparison to 4 patients with LF to show differences Δ f - values in weeks 0 to 2, 2 to 5 and 0 to 5 of the HV. All patients primarily treated for HNSCC with dRCTX were included. Each patient received a total dose of 70Gy in 35 fractions. Concomitant cisplatin chemotherapy was administered in weeks 1, 4 and 7. The mean follow-up time was 16.9 months (range: 10-22 months). Mean time to LF was 9.5 months (range: 6-15 months). For patients in CR Δ -HV (mean) show proportional decrease in weeks 0 to 5. This is true for every threshold factor from 1.2 to 1.5. In those patients showing LF, Δ -HV (mean) demonstrates not only a decrease in HV but also some increase at each of the time increments. There is a general decrease ($p=0.0073$) between week 0 and 5, while between week 0 and 2 and 2 and 5, a rise in Δ -HV(mean) can be shown ($p=0.2339$, $p=0.0649$, respectively).

Conclusion: A decrease in Δ -HV (mean) was shown at any time point, for any factor the tumor-to-background-ratio was multiplied with, in patients with CR. In patients with LF, the hypoxic volume showed inconsistency over time, at least at one time of measurement there was an increase in hypoxic volume. The choice of the threshold for determination of hypoxic volume in F-MISO-PET/CT remains a crucial question that could not be answered at this point. To elucidate this larger patient numbers are needed.

EP-1087

Screening for symptoms in HNC: Italian translation and validation of a patient-reported outcome

M. Maddalo¹, M. Buglione¹, L. Costa¹, N. Pasinetti¹, S. Tonoli¹, M. Urpis¹, L. Pegurri¹, S. Ciccarelli¹, F. Foscarini¹, F. Frassine¹, D. Tomasini¹, S.M. Magrini¹

¹University and Spedali Civili- Brescia - Italy, Radiation Oncology, Brescia, Italy

Purpose or Objective: The aim of this prospective observational study was to: (1) linguistically validate the Italian translation of the Vanderbilt Head and Neck Symptom Survey (VHNSS), a patient-reported outcome measure to screen for symptoms in the head and neck cancer (HNC) patients (pts) population; (2) perform a pilot test on the translated survey (VHNSS-IT) to assess the feasibility and utility, both for clinicians (cls) and for pts, of its administration in clinic as a symptoms' screening procedure.

Material and Methods: A multi-step linguistic process was conducted to generate and validate the VHNSS-IT: a forward translation, a backward translation and a patient testing (n = 35). For the pilot test 6 cls and 38 pts were recruited. Each pts completed the survey before the scheduled visit with the cls. Time to completion (TC), caregiver help (CH) and VHNSS-IT scores distribution reflecting symptom's intensity (SI) were recorded. The visit of the first three pts of each cls was performed per standard of care and the cls had to review the VHNSS-IT after the visit; time of revision (TR), perception regarding the acceptability of time burden, ease of use, and identification of potential problems that were previously unrecognized were reported. For the last three pts, cls were allowed to review the questionnaire during the visit, reporting the global perceived utility (GU).

Results: Two intermediate Italian versions were created during the process: the first Italian version derived from a reconciliation of three forward translations and the second Italian version derived from changes in the first version after the backward translation step. During the patient testing step only 2 pts reported problems with items comprehension and the rate of comprehension problems per single item was lower than expected: 2,9% in 16 items and 5,7% in 1 item. Pts could give suggestion in order to make items clearer and easier to understand: 43% of pts proposed a revision of the survey and most of these suggestions were retained. For the pilot test median TR was 2'15". Time burden was perceived to be acceptable for all cls; they all also found the questionnaire easy to use. The rate of GU was 100%. Reviewing the survey, 4 of 6 cls identified symptoms unaddressed during the visit (swallowing problems, xerostomia, mucus, pain, speech and hearing problems). 30% of pts requested CH: these pts were significantly older (p < 0.001). Median TC was 6'57". TC was related to age (p = 0.02), educational level (p = 0.023) and employment status (p = 0.004). Time after the start of the radiotherapy course (< 6 months vs > 6 months) and surgery (yes versus no) were considered as variables that could possibly influence average SI scores per subscale. Figure 1 shows relevant findings.

Conclusion: The VHNSS-IT represents a suitable instrument to screen for symptoms in Italian HNC pts treated with surgery and radio-chemotherapy and it can help cls to identify symptoms that require referral, education or intervention.

EP-1088

Is time from symptom to treatment a prognostic factor in stage III-IV head and neck cancer patients?

C. Furlan¹, J. Polesel², C. Gobitti¹, E. Minatel¹, E. Vaccher³, L. Barzan⁴, G. Grando⁵, G. Franchin¹

¹Centro di Riferimento Oncologico, Radiation Oncology, Aviano, Italy

²Centro di Riferimento Oncologico, Epidemiology and Biostatistics, Aviano, Italy

³Centro di Riferimento Oncologico, Medical Oncology, Aviano, Italy

⁴Centro di Riferimento Oncologico, Oncologic Surgery, Aviano, Italy

⁵Azienda Ospedaliera Santa Maria degli Angeli, Otorhinolaryngology, Pordenone, Italy

Purpose or Objective: The impact of time from symptoms to treatment on survival of head and neck squamous cell carcinoma (HNSCC) patients has been investigated with conflicting results. This might be explained by the heterogeneity of studies with respect to stage and treatment modality. To reduce bias, this study focused on patients diagnosed with stage III-IV HNSCC managed with definitive chemo-radiotherapy to assess the effect of total interval and treatment delay on survival.

Material and Methods: A single-centre retrospective cohort analysis on 185 patients with stage III-IV HNSCC of oropharynx (n = 124), larynx (n = 36), and hypopharynx (n = 25) managed with definitive chemo-radiotherapy between 2008-2014 was performed. Patients characteristics included sex, age, smoke, Adult Comorbidity Evaluation (ACE-27), stage, tumor site, and HPV status (table 1). Treatment modalities included concomitant chemoradiation (CCRT, n = 33) for stage III patients, and induction chemotherapy followed by radiotherapy (IC-CRT, n = 152) for stage IV patients. Total interval (time from first symptoms to the start of treatment) and treatment interval (interval between the date of the pathology report and the start of treatment) were defined in accord with the Aarhus Statement Guidelines. We chose

median total interval and median treatment interval as cutoff points to divide patients. Univariable and multivariable Cox proportional hazard model was used to evaluate overall survival (OS).

Table 1. Patients characteristics and treatment modalities

Patient parameter	
Sex	
Female	37 (20%)
Male	148 (80%)
Age	
= 65 y	134 (73%)
> 65 y	51 (27%)
ACE-27 comorbidity grade	
0-1	133 (72%)
2-3	52 (28%)
Tobacco	
Yes	143 (77%)
No	42 (23%)
T stage	
T1-2	62 (34%)
T3-4	123 (66%)
N stage	
N0-1	56 (30%)
N2-3	129 (70%)
TNM stage	
III	48 (26%)
IV	137 (74%)
HPV status	
Positive	39 (21%)
Negative	41 (22%)
Unknown	105 (57%)
Treatment parameter	
PET for staging	
Yes	100 (54%)
No	85 (46%)
IMRT	
Yes	210 (79%)
No	55 (21%)

Results: At a median follow up of 37 months, the 3-year OS for the entire cohort was 63%. Median total interval and treatment interval were of 98 days and 29 days, respectively. Patients with longer total interval were more likely to be patients with a low comorbidity grade (ACE-27 grade 0-1). On multivariable analysis a longer total interval was associated with a reduced risk of dying (hazard ratio 0.37, 95% CI 0.13 - 1.01; $p = 0.05$). No association of longer treatment interval with OS was noted on univariable and multivariable analysis. Longer treatment interval resulted associated with the use of PET for staging ($p = 0.13$), and with the use of CCRT for treatment ($p = 0.05$). In the subgroup analysis by treatment modality, no difference in OS according to treatment interval was noted.

Conclusion: In HNSCC patients with stage III-IV at diagnosis, a reduction of total interval and of treatment delay does not ameliorate survival. Development of fast track referral strategies should be aimed at increasing the ratio of stage I-II patients.

EP-1089

Accelerated hypofractionated IMRT-IGRT and concurrent chemotherapy in oropharyngeal cancer

B. Meduri¹, E. D'Angelo¹, P. Barbieri¹, L. Rubino¹, A. Ghidini¹, F. Bertolini¹, R. Depenni¹, P. Giacobazzi¹, F. Bertoni¹

¹University Hospital of Modena, Radiation Oncology, Modena, Italy

Purpose or Objective: In head and neck cancer absolute improvements in locoregional control rate and overall survival rate are achieved when radiotherapy is accelerated. Concurrent chemotherapy also have been used to improve outcomes at the cost of increased toxicity. The use of IMRT for head and neck cancer has been associated with reduced acute toxicity. Clinical experience with accelerated IMRT-SIB with concurrent chemotherapy for advanced oropharyngeal squamous cell carcinoma (LAOC), however, is limited. Objective of our study is to evaluate efficacy and toxicity of

an accelerated hypofractionated SIB-IMRT with Tomotherapy and concurrent chemotherapy in LAOC.

Material and Methods: Between July 2009 and February 2014, 59 consecutive patients with LAOC received accelerated hypofractionated radiotherapy with tomotherapy and concurrent chemotherapy. The disease was stage III in 8% and stage IVa in 92% of patients. Prescribed doses to primary tumor and involved nodes was 66 Gy at 2,2 Gy/fraction, high risk and low risk nodes received simultaneously 60 Gy and 54 Gy at 2,0 Gy and 1,8 Gy/fraction, over 6 weeks. Acute toxicity was scored according to RTOG and late toxicity according to CTCAE-4 criteria. The disease free survival (DFS), local disease free survival (local-DFS), metastasis free survival (MFS) and overall survival were calculated using the Kaplan-Meier method.

Results: With median follow-up of 38 months (range 14-70) the estimated 3-years local-DFS rate, MFS, DFS and OS were 88%±0.04SE, 91%±0.04SE, 82%±0.05SE, and 83%±0.04SE, respectively. The complete response rate was 88%. All the patients completed the radiotherapy; the median treatment duration was 43 days, six patients have temporarily discontinued treatment (median: 5 days) because of toxicity. No grade 4 acute toxicity was observed, maximal acute toxicities were G3: mucosa 31%, skin 15%, dysphagia 24%, leukopenia 5%. Maximal late toxicities were: xerostomia G2 36%, mucosa G2 23%, skin G2 12%, laryngeal G2 17%, dysphagia G2 14%, osteoradionecrosis 3%, trismus 9%.

Conclusion: This analysis shows that a moderately accelerated hypofractionated IMRT-SIB in tomotherapy and concurrent chemotherapy achieved high tumor local control and acceptable toxicity compared with previous chemoradiotherapy treatment with standard fractionation. Based on these results we elaborate a randomized clinical trial with a more hypofractionated regimen in order to obtain a better local control without increasing toxicity.

EP-1090

Overall treatment time is not a prognostic factor in chemoradiation for nasopharyngeal carcinoma.

E. Netto¹, M. Ferreira², I. Sargento², J. Cabeçadas³, A. Mota⁴, F. Pires⁴, T. Alexandre², P. Montalvão², M. Magalhães⁴, M. Roldão⁴

¹Nova Medical School, Medicine - Radiation Oncology, Lisboa, Portugal

²Instituto Português de Oncologia de Lisboa Francisco Gentil-EPE, Medical Oncology, Lisboa, Portugal

³Instituto Português de Oncologia de Lisboa Francisco Gentil-EPE, Pathology, Lisboa, Portugal

⁴Instituto Português de Oncologia de Lisboa Francisco Gentil-EPE, Radiation Oncology, Lisboa, Portugal

Purpose or Objective: Overall treatment time (OTT) is an important factor in head and neck radiotherapy of squamous-cell carcinoma, the authors investigate its role in a nasopharyngeal carcinoma (NPC) population.

Material and Methods: We reviewed 109 patients charts with NPC. Pathological, clinical and dosimetric data were retrieved. All patients received concomitant chemo-radiation (CCRT) with IMRT-SIB with 69.96Gy to GTVs, 59.4 and 54Gy to CTVs in 33 fractions (RTOG0615). Cisplatin-based chemotherapy (CT) was prescribed as per Intergroup 0099. OTT was recorded from the first day of radiation through the last day of CCRT regardless adjuvant CT. Per protocol treatment was defined as OTT < 7 weeks. Any interruption was recorded as well its length and cause. Kaplan-Meier curves were created by SPSS (IBM Statistics), log-rank test was applied to detect differences and Cox regression model was adjusted to compare variables.

Results: From 109 patients, median age was 53; 74% male; 71% were WHO grade III; 43% T1; 14% T2; 18% T3, 25% T4; 17% N0; 17% N1; 39% N2; 27% N3. With a median follow up of 22 months, 2-year local control was 95,9%, freedom from metastases was 88% and overall survival was 79,8%. 9

patients were excluded because didn't receive CT (T1N0). From the remaining 100, 95 received concomitant plus adjuvant CT and 5 concurrent CT. We found a median OTT of 49 days (range: 11-83 days). 39 patients completed CCRT in more than 7 weeks (50-83 days) from which 31 (79%) in 8 weeks and the remaining 8 (21%) in more than 8 weeks. Interruption causes were by medical indication in 6 (15%), and non-clinical reasons in 33 (85% - patient no show, machine breakdown, and mis-coordination between departments). Compensations were performed at the discretion of the treating physician in the 8 patients with OTT longer than 8 weeks. No difference in local control (LC, $p=0.766$), overall survival (OS, $p=0.855$) or metastases free survival ($p=0.131$). Cox regression confirmed age, N stage, local control and distant metastases status as prognostic factors however no impact was found for OTT ($p=0.890$ for <7 weeks; $p=0.959$ for <8 weeks; and $p=0.960$ for >8 weeks).

Cox Regression – Overall Treatment Time vs. Survival
Variables in the Equation

	B	SE	Wald	df	Sig.	Exp(B)
Age	,079	,024	10,454	1	,001	1,082
NStage			10,159	3	,017	
NStage(1)	-2,102	1,004	4,387	1	,036	,122
NStage(2)	-1,661	,742	5,007	1	,025	,190
NStage(3)	-1,851	,722	6,571	1	,010	,157
LCSTATUS	-2,219	,998	4,943	1	,026	,109
MetsStatus	-1,670	,653	6,543	1	,011	,188
OTTime (<7 weeks)			,232	2	,890	
OTTime (7-8 weeks)	8,344	161,761	,003	1	,959	4206,337
OTTime (>8 weeks)	8,055	161,762	,002	1	,960	3149,082

Conclusion: In our study, we found no differences in LC and OS regardless OTT. These data must be interpreted with caution due to the high number of patients receiving CT that may compensate the unplanned interruptions in such a sensitive entity. Further studies with longer follow up are necessary to recommend or not withholding compensations in this setting.

EP-1091

Stratifying patients of head and neck cancer into risk groups for local control: predictive models
B. Dua¹, K. Chufal², G. Jadhav¹, A. Thakwani², A. Bhatnagar²
¹Apollo Hospital, Radiotherapy, Delhi, India
²Batra Hospital, Radiotherapy, Delhi, India

Purpose or Objective: There have been numerous studies that have shown the importance of tumor volume as an independent prognostic factor over and above the T stage in head and neck cancer. However, data from the Indian subcontinent is sparse, even more so in patients treated by IMRT. This merits further study owing to possible differences in the biology of Indian head and neck cancer compared to its western counterpart. Ours was a prospective study that attempted to elucidate the role of tumor volume as a prognostic factor in locally advanced oropharyngeal and hypopharyngeal cancer.

Material and Methods: We enrolled 87 patients of Stage III-IV squamous cell cancer of the hypopharynx(30), and oropharynx(57), who subsequently received definitive concurrent chemo radiation with IG-IMRT. The tumor volume was the gross tumor volume (TV) delineated on the planning CT scan and was calculated by the volume algorithm in the treatment planning system. The impact of TV on Locoregional relapse free survival (LRFs), Response to chemo radiation (RR), overall survival (OS), local control(LC) and regional control was assessed over a follow up of 2 years. The Shapiro wilk test was done for assessing normality. Survival analysis was by kaplan meir method with log rank testing for assessing significance between groups. Univariate analysis was done by mann-whitney/chi square/fisher's exact test, multivariate analysis was done by logistic regression forward stepwise method and a model to predict LC was generated. An ROC curve analysis was done for estimation of cut offs.

Results: The 2 year OS, LRFs, RR, LC& RC were 64%, 56%, 65%,63% and 83% respectively. The T stage distribution was

T2, T3&T4 (5/41/41).The TV was not normally distributed and the mean TV was 48 cc (5-167cc) with mean TV in T3 /T4 patients of 39.9/60.9 cc. The mean TV in locally controlled patients was 35.4cc vs 70.8cc in uncontrolled patients. While the TV was a significant prognostic predictor for the OS, LRFs, RR, and LC on univariate analysis, on the multivariate analysis only the TV predicted for LC. ROC curve analysis found cut off of 38 cc with 2 year LC of 84% / 40% for TV<38cc / >38cc respectively with log rank $p=0.001$ with AUC of 0.759(0.653-0.865) and sensitivity/specificity of 82%/64%. ROC curve analysis of our oropharyngeal subgroup revealed similar results with a cut off of 38cc with AUC of 0.770 (0.644-0.896) and sensitivity / specificity of 80%/66%.with 2 year LC of 79%/30% for TV<38cc / >38cc ($p=0.001$). The likelihood of local failure increased by 3% for 1cc increase in TV for the entire cohort & 3% for our oropharyngeal subgroup.

Figure: Kaplan Meir curve for patients with TV < 38 cc and >38cc

MULTIVARIATE LOGISTIC REGRESSION MODEL FOR LC

ODDS OF LOCAL FAILURE (P): $\text{LOG}(P) = 2.036 + 0.030 \times \text{TV}$ (ALL PATIENTS)

ODDS OF LOCAL FAILURE (P): $\text{LOG}(P) = 1.857 + 0.032 \times \text{TV}$ (OROPHARYNX PATIENTS)

Conclusion: TV is an independent prognostic factor in patients with head and neck cancer in predicting local control. Implications for existing management paradigms include, stratification according to TV in future randomized trials, consideration of altered fractionation and/or dose escalation to the primary disease for patients with TV>38cc.

EP-1092

Intensive radiotherapy in locally advanced head and neck squamous cell cancer- is it worth the pain?

A. Pascoe¹, C. Weston², J. Christian¹, M. Griffin¹, J. Price³
¹Nottingham University Hospitals NHS Trust, Department of Oncology, Nottingham, United Kingdom
²University of Nottingham, School of Medicine, Nottingham, United Kingdom
³Derby Teaching Hospitals NHS Foundation Trust, Department of Oncology, Derby, United Kingdom

Purpose or Objective: With increasing evidence for combined modality treatment in locally advanced squamous cell cancer of the head and neck (HNSCC), there remains debate about the best treatment approach for patients with T4 disease. Local control in HNSCC is extremely important due to the morbidity and mortality associated with local recurrence. However treatment itself can be associated with significant morbidity. The purpose of this review is to determine both overall survival (OS) and local control rates for patients with T4 tumours treated with Intensity Modulated Radiotherapy (IMRT) with or without prior surgery.

Material and Methods: Retrospective review of all patients with T4 HNSCC treated with IMRT at our centre, between December 2010 and February 2013. Overall, relapse free and local relapse-free survival were calculated from date of biopsy to date of death, relapse or last follow up.

Results: Of the 69 patients with T4 tumours, 73.9% were male and median age was 69 (41-84). 50.7% were oropharyngeal tumours and 73.9% were node positive. Primary resection was performed in 18 patients. Eighteen patients underwent radiotherapy alone and 51 received concurrent chemotherapy (45 cisplatin, 6 cetuximab). Median follow up was 3.0 years (range = 3 months to 3.9 years). 28 patients died; 22 related to HNSCC, 6 from other causes. Overall survival at 3 years was 58.0% (95% CI: 44.6 to 69.1). 28 patients (40.6%), relapsed with median time to relapse of 8 months. 20 patients (29.0%) relapsed locoregionally and 11 patients (15.9%) developed distant metastatic disease. For 8 patients, distant metastases were the only site of relapse. Surgical salvage was performed in 6 patients with locoregional relapse only, 2 of whom have since died from causes related to HNSCC. Relapse free survival at 3 years was 54.0% (95% CI: 40.5 to 65.8) and loco-regional relapse free survival at 3 years was 65.5% (95% CI: 51.2 to 76.5). Nineteen patients (27.5%) had residual disease on PET scan 12 weeks post treatment. These patients were at greater risk of relapse and death with 3 year overall survival of 37.0% (95% CI 15.4 to 59.0) and 3 year relapse free survival of 40.5% compared to 3 year overall survival of 85.7% (53.9 to 96.2) and 3 year relapse free survival of 79.0% (47.9 to 92.7) in patients with normal PET scans.

Conclusion: There is a significant risk of relapse and death in T4 HNSCC tumours, particularly in those with residual disease following radiotherapy. However, IMRT, either alone or in combination with chemotherapy or surgery, achieved 3 year locoregional control of 65.5% (95% CI 51.2%-76.5%). This is a meaningful local control rate for locally advanced disease in which local relapse confers significant morbidity.

EP-1093

Impact of comorbidity, polypharmacy and HPV status in elderly patient with oropharyngeal cancer

F. Caparrotti¹, S. Huang¹, J. Ringash¹, Y. Song², A. Bayley¹, S. Bratman¹, J. Cho¹, M. Giuliani¹, A. Hope¹, J. Kim¹, J. Waldron¹, A. Hansen³, D. Goldstein⁴, B. Perez-Ordenez², I. Weinreb⁵, L. Tong¹, W. Xu², B. O'Sullivan¹

¹Princess Margaret Cancer Centre/University of Toronto, Radiation Oncology, Toronto, Canada

²Princess Margaret Cancer Centre/University of Toronto, Biostatistics, Toronto, Canada

³Princess Margaret Cancer Centre/University of Toronto, Medical Oncology, Toronto, Canada

⁴Princess Margaret Cancer Centre/University of Toronto, Otolaryngology - Head and Neck Surgery, Toronto, Canada

⁵Princess Margaret Cancer Centre/University of Toronto, Pathology, Toronto, Canada

Purpose or Objective: To investigate the role of HPV status, comorbidity and polypharmacy on outcomes of elderly patient with oropharyngeal carcinoma (OPC).

Material and Methods: We retrospectively reviewed a prospectively compiled cohort of elderly patients (>70 years) with newly diagnosed OPC treated with curative radiotherapy (RT)+/- systemic therapy in 2000-2013. Tumor HPV status was assessed by p16 staining. Comorbidities were quantified by Charlson Comorbidity Index (CCI). The Comorbidity-Polypharmacy Score (CPS), a validated predictor of outcome for older trauma patients, was used to take into account the number of medications as a surrogate of the severity of comorbidities. Overall survival (OS), and relapse-free survival (RFS) were calculated and compared between HPV-positive [HPV(+)] and HPV-negative [HPV(-)] cohort. Two multivariate analysis (MVA) models [one included CCI (MVA-CCI), one included CPS (MVA-CPS)] were used to confirm the prognostic value of HPV, CCI or CPS, pack-year (PY) smoking, ECOG

performance status (PS), and age for OS adjusted for disease extent (T, N).

Results: Tumor HPV status was ascertained in 229 of 287 (80%) patients revealing 115 HPV(+) and 114 HPV(-). Median age was 74.8 years (range 70-93). Systemic agents were given in 48 (21%) patients [chemo 17; EGFR inhibitor 31]. RT incompleteness [5 (4%) vs 8 (7%), p=0.41] and unplanned RT break rates [22 (19%) vs 28 (25%), p=0.34] were similar between HPV(+) vs HPV(-) cohorts. No significant difference in distribution of CCI (p=0.30) or CPS score (p=0.22) between HPV(+) vs HPV(-) cases. CCI and CPS have a moderate correlation (Kappa: 0.51). Median follow-up was 4.6 years. HPV(+) patients had better 5-year OS (59% vs 32%, p<0.001) and RFS (75% vs 54%, p<0.001) compared to HPV(-). MVA adjusted for T and N-category confirmed HPV(+) status was the strongest prognostic factor (PF) for OS [MVA-CCI: HR 0.52 (95% CI 0.34-0.79), p=0.002; MVA-CPS: HR 0.56 (0.36-0.85), p=0.007]. CPS was also a PF for OS [HR 1.05 (1.00-1.11), p=0.044]. CCI was not significant (p=0.17). ECOG PS was also a PF [MVA-CCI: HR 2.31; MVA-CPS: HR 2.32, both p<0.001]. Smoking (>20 PY) was prognostic in MVA-CCI (HR 1.62, p=0.035) and marginally prognostic in MVA-CPS (HR 1.56, p=0.056). Age was not significant in MVA-CCI (p=0.16) or MVA-CPS (p=0.65) models.

Conclusion: In elderly patients with OPC, HPV status is a strong PF for OS. Neither chronologic age nor CCI is prognostic. Higher CPS is correlated with poorer OS, which implies that inclusion of polypharmacy in addition to comorbidity might be a better reflection of competing mortality risk in this population, and attention to competing mortality causes may influence outcome for this complex patient group. Further validation of prognostication of CPS in elderly OPC population is warranted.

EP-1094

Total tumour volume predicts response in head and neck cancer: regression tree analysis and models

B. Dua¹, K. Chufal², G. Jadhav¹, A. Thakwani², A. Bhatnagar²

¹Apollo Hospital, Radiotherapy, Delhi, India

²Batra Hospital, Radiotherapy, Delhi, India

Purpose or Objective: While the total tumor volume(TTV) has been extensively analyzed in literature as a prognostic factor in head and neck cancer, there exist no studies to date that have analysed the impact of TTV on response to chemo radiation(CCRT), particularly from the Indian subcontinent and in patients treated with IMRT. We did a prospective study that attempted to elucidate the role of total tumor volume as a prognostic factor in locally advanced oropharyngeal and hypopharyngeal cancer.

Material and Methods: We enrolled 87 patients of Stage III-IV cancer of the oropharynx(57),and hypopharynx(30) , who received definitive CCRT with IMRT. The TTV was the sum of the gross tumour volume and the nodal volume delineated on the planning CT scan. The impact of TTV on Locoregional relapse free survival (LRF5), response to chemoradiation (RR) and overall survival (OS) was assessed over a follow up of 2 years. Survival analysis was by kaplan meir method with log rank testing for assessing significance between groups Univariate analysis was by mann-whitney/chi square test ,multivariate analysis was by logistic regression forward stepwise method and a model to predict response was generated .ROC curve analysis was done for calculating cut offs. A classification tree for Response was generated using CART analysis (CHAID method).

Results: The 2 year OS, LRF5, and RR were 64%, 56% & 65%. The T stage distribution was T2(5) , T3(42) ,T4(2) & N stage was N0 (11),N1(28),N2A(10),N2B (17),N2C(17) & N3(4).The mean TTV was 67.4 cc (8-191) cc. The mean TTV in Responders/ non responders was 51.9 cc / 95.5cc.On multivariate analysis, the TTV was a significant prognostic factor for RR & LRF5 but not for OS. ROC curve analysis found cut off of 48 cc for RR with AUC of 0.778(0.672-0.884) ans sensitivity/specificity of 87% /60%.The RR for the <48cc and

>48cc group was 90% vs 46% (chi square $p = .001$). ROC curve analysis of our oropharyngeal subgroup revealed similar results with a cut off of 48cc with AUC of 0.802 (0.677-0.927) and sensitivity / specificity of 86%/70%. The RR for the <48cc and >48cc group was 88% vs 40% (chi square $p = .001$). The likelihood of not responding increased by 1.8% for 1cc increase in TTV for the entire cohort and by 2.4% for our oropharyngeal subgroup.

Figure. Classification tree for response according to prognostic factors. AVGHGB = average hemoglobin during treatment, TTV = total tumor volume

MULTIVARIATE LOGISTIC REGRESSION MODEL FOR RESPONSE

ODDS OF NON RESPONDING (P): $\text{LOG}(P) = 4.075 + 0.018 \times \text{TTV} - 0.478 \times \text{AVGHGB} - 1.375(\text{IF STAGE 3})$

Conclusion: Our study shows that the TTV is a significant and independent prognostic factor in patients with locally advanced head and neck cancer in terms of predicting local control. Implications for existing management paradigms include, stratification according to TTV in future randomized trials and consideration of altered fractionation and/or dose escalation to the primary disease for patients with $\text{TTV} > 48\text{cc}$.

EP-1095

Prognostic role of FDG PET-CT performed before and during radiotherapy for nasopharyngeal cancer
P. Lin¹, M. Min², M. Lee², L. Holloway³, D. Forstner², V. Bray², A. Fowler²

¹Liverpool Hospital, Nuclear Medicine and PET, Liverpool, Australia

²Liverpool Hospital, Cancer Therapy Centre, Liverpool, Australia

³Liverpool Hospital, Ingham Institute of Applied Medical Research, Liverpool, Australia

Purpose or Objective: To evaluate the prognostic value of 18F-FDG PET-CT performed prior to (prePET) and during the third week (iPET) of radiation therapy (RT) in patients with newly diagnosed nasopharyngeal carcinoma (NPC).

Material and Methods: Thirty patients with newly diagnosed NPC treated with radical RT and Cisplatin-based chemotherapy underwent prePET and iPET. The median follow up was 26 months (range 8-66.9). AJCC staging included 12 patients in stage II, 8 in stage III and 10 in stage IV. The maximum standardised-uptake-value (SUVmax), metabolic-tumour-volume (MTV) and total-lesional-glycolysis (TLG) of primary tumour (PT), the index-node (IN) (defined as lymph node with highest TLG), total lymph nodes (TN) and combined primary tumour and nodal (PTN), and their % reductions in iPET were analysed, and results were correlated with 2-year loco-recurrence-free-survival (LRFS), regional-failure-free-survival (RFFS), distant-metastatic-failure-free-survival (DMFFS), disease-free-survival (DFS), and overall-survival (OS), using Kaplan-Meier (KM) analysis. Optimal-

cutoffs (OC) were derived from Receiver-Operating-Characteristic curves for the best combined sensitivity and specificity.

Results: For LRFS, the only statistically significant predictor was reduction in primary tumour MTV by >50% in iPET (95.2% vs 75.0%, $p=0.024$). For other treatment outcomes, only nodal or combined PTN predicted treatment outcomes. The IN SUVmax (pre-PET OC=10.45g/mL and iPET OC=8.15g/mL) and TLG (pre-PET OC=90g and iPET OC=33.4g) provide the overall best predictor of outcome, with significant associations with RFFS (iPET only), DMFFS (prePET), DFS (prePET and iPET) and OS (prePET): For RFFS, iPET IN SUVmax and TLG were best predictors: the 2-year KM survivals were 100% vs. 50%, $p<0.001$ and 100% vs. 44%, $p=0.032$ respectively. For DMFFS, prePET IN SUVmax and TLG were best predictors: 100% vs. 51.9%, $p=0.004$ and 100% vs. 47.6%, $p=0.002$. For DFS, prePET IN TLG and iPET IN SUVmax were best predictors: 87.5% vs. 33%, $p=0.045$ and 78.7% vs. 20%, $p=0.01$. For OS, prePET IN TLG and iPET IN TLG were best predictors: 100% vs 72.7%, $p=0.048$ and 91.7% vs 68.6%, $p=0.05$. The IN metabolic parameters demonstrated stronger correlation with outcome than PT or PTN, and equivalent correlation to the TN except IN was better in predicting OS.

Conclusion: The metabolic parameters of prePET and iPET can provide complementary prognostic biomarkers of patient outcomes, These parameters may have a role in adaptive therapy for NPC, and identifying the best treatment strategy for precision individualised chemo-radiotherapy combinations. We have demonstrated IN to be a useful novel imaging biomarker for predicting all treatment outcomes, and offers additional potential advantage of ease of generation and reproducibility compared to TN or PTN.

EP-1096

Prognostic value of pretreatment FDG-PET features in laryngeal cancer patients treated with RT

R. Kabarriti¹, P.N. Brodin¹, A. Ginsburg Berkowitz¹, A. Ingber¹, N. Ohri¹, K.P. McGovern¹, C. Modi¹, T.J. Ow², A. Tassler², S. Packer³, B.A. Schiff², R.V. Smith², M. Haigentz³, C. Guha¹, S. Kalnicki¹, W.A. Tome¹, M.K. Garg¹

¹Montefiore Medical Center- Albert Einstein College, Radiation Oncology, New York, USA

²Montefiore Medical Center- Albert Einstein College, Otolaryngology- Head & Neck Surgery, New York, USA

³Montefiore Medical Center- Albert Einstein College, Medical Oncology, New York, USA

Purpose or Objective: Statistical image features from computed tomography (CT) and positron emission tomography (PET) scans are being investigated for the potential prognostic value in predicting outcome for various clinical indications. Here, we analyze primary tumor image features from pretreatment FDG-PET and the relation to clinical outcomes in patients treated with definitive radiation therapy (RT) for laryngeal cancer.

Material and Methods: We identified 83 consecutive patients with laryngeal squamous cell carcinoma treated with definitive RT with available pretreatment PET/CT scans at our institution. Clinical variables related to disease and patient characteristics, treatment information, and clinical outcomes data were collected for each patient. Pretreatment PET/CT scans were used for image feature analysis of the primary tumor volume for each patient. Multiple statistical image features were computed, along with several measures related to the standardized uptake value (SUV). Redundant image features were excluded based on a strong correlation with parameters commonly reported as important such as metabolic tumor volume (MTV) and maximum SUV value (SUVmax). A LASSO procedure was applied to select appropriate variables to include in Cox proportional hazard models for local control (LC) progression-free survival (PFS) and overall survival (OS). The concordance index or "C-index" was computed to evaluate the discriminative ability of each model, both on the training data set (apparent C-index) and using bootstrap cross-validation (bcv). Correction for

multiple testing in statistical analysis was done using the Benjamini-Hochberg method.

Results: With a median follow up of 34 months, the 3-year LC, PFS and OS (with 95% confidence intervals) were 64% (53% - 75%), 51% (39% - 62%) and 77% (67% - 87%), respectively. No image features were significantly correlated with LC or PFS and adding image features to the clinical variables did not improve the performance of the Cox model in the bCV setting, as seen in Table 1 where the C-index is highlighted in bold if adding image features improved performance.

Patient #	Minimum distance (Cord to Thecal sac) [mm]	% of Cord closer than 1mm from Thecal sac [%]	Potential max point dose to Cord (SBRT) [Gy]	Potential max point dose to Cord (EQD2) [Gy _{EQ2}]	Estimated potential myelopathy risk [%]
1	1.71	0.0	18.2	36.6	4.6
2	0.02	13.3	21.9	50.7	10.0
3	2.07	0.0	17.4	33.8	4.1
4	1.01	0.4	19.7	42.1	6.0
5	0.64	5.5	20.5	45.3	7.2
6	1.65	0.0	18.3	37.0	4.7
7	0.92	1.9	19.9	42.9	6.2
8	0.49	4.2	20.8	46.5	7.7
9	0.96	0.6	19.8	42.6	6.2
10	0.59	3.8	20.6	45.7	7.3
11	0.60	5.3	20.6	45.6	7.3
12	1.53	0.0	18.5	37.9	4.9
13	0.02	16.0	21.9	50.8	10.0
14	0.67	5.6	20.4	45.0	7.1
15	0.02	8.7	21.9	50.7	10.0

MTV was the image feature most closely related to OS and for OS the addition of image features did improve the predictive performance of the Cox model. Figure 1 shows the effect of dividing the patient population based on the statistically most important variables, where it is clear that Karnofsky performance score and MTV affect the OS.

Conclusion

Adding image features to complement clinical parameters was seen to improve the prognostic value for OS. Although no significant image features were found related to LC and PFS, we found that a smaller MTV was predictive of improved OS.

EP-1097

Comparison of outcomes and toxicities between IMRT and SIB-IMRT in cancers of hypopharynx

M.S. Raghunathan¹, R. Subramaniam¹, A. Vaz¹, N. Senthil Kumar¹

¹Kovai Medical Center And Hospitals, Department Of Radiation Oncology, Coimbatore, India

Purpose or Objective: Among cancers of head and neck, hypopharyngeal cancers tend to have an aggressive clinical course. Chemoradiation has become the standard of care for patients who are candidates for an organ preservation strategy. IMRT planning has incorporated a simultaneous integrated boost (SIB-IMRT) in order to efficiently develop comprehensive radiation therapy plans and also potentially lessen treatment time and toxicity. Outcomes and toxicities of patients with hypopharyngeal cancers treated in a single

institute with standard IMRT and SIB-IMRT schedules were analyzed retrospectively.

Material and Methods: A total of 86 patients with hypopharyngeal squamous cell carcinomas were treated between September 2010 and December 2014. Among 44 patients who were treated using SIB-IMRT, 8 received neoadjuvant chemotherapy (NACT) and 42 received concurrent chemotherapy. Among 42 patients who were treated using IMRT with conventional fractionation (IMRT), 16 received NACT and 40 received concurrent chemotherapy. The dose for SIB-IMRT group was 65 Gy in 30 fractions to gross and high risk disease and 54 Gy in 30 fractions to low-risk nodes. The dose in IMRT group was 66-70 Gy to gross disease, 60 Gy to high risk nodes and 50 Gy to low risk nodes in 1.8-2 Gy per fraction.

Results: At a median follow-up of 16.5 months (6-56 months) the median OS of entire cohort was 38.9 months. The mean OS was 37.5 months and 38.3 months (p=0.91) for SIB-IMRT and IMRT respectively. The mean treatment duration for SIB-IMRT and IMRT groups was 42 days (range: 38-51 days) and 48.4 days (range: 45-73 days) respectively. 98 % in SIB-IMRT and 93 % patients in IMRT group completed the intended treatment. Complete response was noted in 89 % and 93 % in SIB-IMRT and IMRT groups respectively. The estimated 1 year, 2 year LR control and 2-year DFS were 81%, 66.6%, 67.4% in SIB-IMRT and 84%, 74%, 62% (p<0.81) in IMRT groups respectively. Grade 3 mucositis occurred in 10 (23%) and 12 (28%), grade 3 dermatitis in 9 (20.5%) and 12 (28%) of SIB-IMRT and IMRT patients respectively. Grade 2 xerostomia occurred in 11 patients (27%) and 15 patients (34%) in IMRT and SIB-IMRT groups. Grade 3 soft-tissue fibrosis and esophageal stricture rates were 2 (4.7 %) and 5 (11.4%) in SIB-IMRT and IMRT groups.

Conclusion: Clinical outcomes, acute and late toxicities of chemo-radiation with SIB-IMRT were comparable with IMRT. Overall treatment duration was reduced and more patients completed intended treatment in SIB-IMRT group with relatively lesser acute toxicities.

EP-1098

Radiation induced brachial plexopathy in head and neck carcinoma (acute and chronic)

S. Yahya¹, M. Hickman¹, A. Hartley¹, P. Sanghera¹
¹Hall-Edwards Radiotherapy Research Group- Queen Elizabeth Hospital, Cancer Center, Birmingham, United Kingdom

Purpose or Objective: Radiation Therapy Oncology Group (RTOG) guidelines recommend brachial plexus dose constraints ranging from 60-66Gy in 2Gy per fraction (BED = 120-132Gy₂). However there remains limited data on brachial plexus (BR.P) toxicity and furthermore the dose limits are

often below those required to control gross disease. This study was done to explore the incidence of brachial plexus injury following radical (chemo) radiotherapy in the IMRT era.

Material and Methods: Patients with head and neck cancer that had completed IMRT to unilateral or bilateral neck with a minimum of 2 years of follow up were identified from a prospective database. All patients underwent clinical review as per local protocol which was commonly 6 weekly. The brachial plexus was contoured based on RTOG Atlas. Maximum dose (Dmax) to brachial plexus was recorded from DVH. All doses were converted to BED using an α/β ratio of 2. A review of electronic records was performed to determine brachial plexus toxicity using CTCAE v 3.0.

Results: Seventy five patients met the inclusion criteria. Ten patients were excluded due to insufficient dose metric data. Of sixty five patients analysed, 37 patients were treated for oropharyngeal, 2 for nasopharyngeal, 6 for Hypopharyngeal, 9 for Larynx, 8 for oral cavity cancers and 3 for unknown primary site. Forty five patients had concurrent chemotherapy (31 cisplatin, 8 carboplatin and 6 cetuximab). Brachial plexus dosimetry is given in table 1. Maximum point BED to brachial plexus reached 149.5Gy2 (41.3-149.5). There were no reported symptoms of brachial plexopathy during this period.

Dose and Fractionation	Dmax Left BR.P (*BED)	Dmax Right BR.P (*BED)
55 Gy in 20# (n=11/65)	57.5 (*140Gy2) (*63- 130.2)	59.8(*149Gy2) (*41.3-132.1)
64Gy in 25# (n=3//65)	62.4 (*140 Gy2) (*107.6-149.5)	58.4(*127Gy2) (*103.6-121.9)
67.2 Gy in 28# (n=1/65)	62.6 (*132Gy2)	61.1 (*128Gy2)
60 Gy in 30# (n=20/65)	58.5 (*115Gy2) (*43.6 – 133.8)	60.3(*121Gy2) (*56.5- 136)
65Gy in 30# (n=30/65)	59.3 (*118Gy2) (*86.9 – 141.1)	60.0 (*120Gy2) (*129.7- 144.1)

Table 1: Showing the dose and number of fractions delivered and Dmax to brachial plexus

Conclusion: It is often necessary to accept higher than conventional maximum point doses to the brachial plexus to ensure adequate PTV coverage for head and neck cancers. Although longer term follow-up is required ideally with nerve conduction studies, such an approach of exceeding conventional limits appears to be acceptable. Further data will be presented for patients exceeding conventional constraints.

EP-1099

Re-irradiation for head and neck tumors: efficacy versus late toxicity in 137 patients

W. Bots¹, S. Van den Bosch¹, L.C. Verhoef¹, E.M. Zwijnenburg¹, T. Dijkema¹, G. Van den Broek¹, W. Weijs¹, G.O. Janssens², J.H.A.M. Kaanders¹

¹Radboud university medical center, Department of Radiation Oncology, Nijmegen, The Netherlands

²UMC Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands

Purpose or Objective: To present long-term results on disease control and late toxicity in both primary and post-operative re-irradiation in the head and neck region.

Material and Methods: Retrospective single center analysis of 137 patients re-irradiated between 1986 and 2013 for a recurrent or second primary malignancy. Inclusion criteria were a prescribed dose of at least 45 Gy in first treatment and re-treatment and histological proof of disease. Exclusion criteria were age under 18 years, the presence of metastatic disease and the use of brachytherapy. Endpoints were locoregional control (LRC), disease-free survival (DFS), event-free survival (EFS), overall survival (OS) and grade 3 late complications according to EORTC/RTOG criteria. EFS includes both disease recurrence and late treatment complication as an event.

As 3D-dose distribution data was not available for all patients, a descriptive approach was used to determine the

highest cumulative dose in radiation overlap and organs at risk (spinal cord, larynx, mandible and optical nerve).

Results: Patient and tumor characteristics are presented in table 1.

Patient characteristics (n=137)		%
Age (range)	65 (31-87)	
Median follow-up in months (range)	16 (2-128)	
Median time between radiation treatments (years)	1.8	
Median re-irradiation dose in Gy (range)	60 (45-70)	
Median cumulative dose in Gy (range)	126 (70-138)	
Concurrent chemotherapy at re-irradiation	7	5.1%
IMRT use at re-irradiation	60	44%

Tumor characteristics		
Tumor location		
Larynx	73	53%
Oral cavity	19	14%
Oropharynx	17	12%
Other	28	21%
Histology		
Squamous cell	118	86%
Other	19	14%
T-stage		
0	1	1%
1	33	24%
2	60	44%
3	23	17%
4	20	15%
N-stage		
N0	88	64%
N+	49	36%

The median re-irradiation and cumulative radiation dose were 60 Gy (range 45-70) and 126 Gy (range 68-138) respectively. Two- and five-year LRC were 52% and 40%, two- and five-year DFS were 38% and 28% respectively (figure 1). There were 17 observations of serious late toxicity in 11 patients (actuarial 26% at 5 years): chondronecrosis (n=1), osteoradionecrosis (n=8), soft tissue necrosis (n=3), arterial blowout (n=3), and stricture/fistula (n=2). Three cases of treatment-related death were reported. Multivariate analysis revealed IMRT as re-irradiation technique to be protective of late complications (HR, 0.10; 95% CI, 0.01-0.96). The five-year actuarial EFS was 18%.

Figure 1

One-hundred-and-seven patients (78%) were re-irradiated post-operatively and had a better LRC in comparison to re-irradiation alone (actuarial 5-yr 46% vs 16%, p<0.05). Of patients re-irradiated alone without surgery, patients re-irradiated for a second primary tumor had significant better LRC-rates in comparison with patients re-irradiated for

recurring tumors (actuarial 5-yr 44% vs 0% $p < 0.05$). Four cases of mandibular osteoradionecrosis were seen (cumulative dose range 106-128 Gy). Fifty-three patients received a cumulative dose of 100 Gy or higher. The actuarial 5-year mandibular necrosis rate in this group was 26%.

Conclusion: Re-irradiation in the head and neck region for a recurrent or second primary malignancy is associated with LRC-rates of 40%. Results in patients re-irradiated post-operatively are more favorable. Approximately one in six patients survived at 5 years without a recurrence or a serious late toxicity. The most important limitation for re-irradiation is late toxicity, which can be limited with current IMRT techniques.

EP-1100

External validation of a mixture NTCP model of radiation-induced hypothyroidism (HT)

M.F. Roenjom¹, C. Brink², S. Bentzen³, L. Hegedüs⁴, J. Overgaard⁵, J. Petersen⁶, H. Prindahl⁷, J. Johansen¹

¹Odense University Hospital, Department of Oncology, Odense, Denmark

²Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

³Division of Biostatistics and Bioinformatics- University of Maryland Greenebaum Cancer Center and, Department of Epidemiology and Public Health- University of Maryland School of Medicine, Baltimore, USA

⁴Odense University Hospital, Department of Endocrinology and Metabolism, Odense, Denmark

⁵Aarhus University Hospital, Department of Experimental Clinical Oncology, Aarhus, Denmark

⁶Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark

⁷Aarhus University Hospital, Department of Oncology, Aarhus, Denmark

Purpose or Objective: We have previously developed a mixture NTCP model for radiation-induced HT in a cohort of patients with head and neck cancer treated at the Department of Oncology, Odense University Hospital (OUH), Denmark. The model was validated in an independent cohort of patients treated at the Department of Oncology, Aarhus University Hospital (AUH). One plasma TSH assessment after RT was used in the external validation cohort and the latency time function of the model could therefore not be validated. The aim of this study was to validate the latency function by including repeated thyrotropin (TSH) measurements and a longer follow-up in the validation cohort.

Material and Methods: Initially, 198 patients were included in the validation cohort. From July 2012- October 2014 further TSH measurements were collected in 171/198 patients, increasing the median follow-up from 22 to 38 months after RT. The endpoint, HT, was defined as TSH > 4.0 mU/l. Data were analyzed using a mixture model taking both thyroid volume (V_{thyroid}) and dose (D_{mean}) into account. From the repeated blood samples, latency was estimated and both the latency time function and NTCP models in AUH were compared to OUH. Validation was performed using a calibration plot of binned groups of patients showing the clinically observed outcome in the validation cohort compared with the predicted outcome from the original NTCP model.

Results: With the additional follow-up, 40 patients (20%) developed HT (19 after one TSH assessment). D_{mean} and V_{thyroid} were still significant risk factors for HT, OR=1.11 (1.06-1.19) and OR=0.85 (0.74-0.93), respectively. The cumulative events showed that 94% (59-100%) of the events would develop within the first five years after RT in the validation cohort, in line with the original cohort's 97% (85-100%). Mean thyroid volumes were 17.4 (OUH) and 17.3 (AUH) cm³, and tolerance estimates around this level showed TD25 = 38 Gy and 34 Gy, respectively, at 15 cm³ and 48 Gy and 42Gy, respectively, at 20 cm³. The calibration plot (Fig. 1) showed good agreement between the observed incidences of HT in the validation group versus the expected probability of

HT from the original model. Thus, the NTCP model has external validity in the cohort with multiple blood tests.

Conclusion: Increasing thyroid dose and a decreasing thyroid volume were confirmed as significant risk factors for radiation-induced HT, which likely develops within the first five years after RT. The calibration plot shows that the original NTCP model has external validity, supporting that risk estimates from the NTCP model may be used to support clinical treatment planning decisions relating to development of hypothyroidism after RT to the neck area.

EP-1101

Knowledge of HNC risk factors and symptoms - a survey among 1903 young Polish respondents

E. Sierko¹, A. Krentowska¹, A. Skoneczny¹, A. Strzałka², W. Pietruszewska³, M.Z. Wojtukiewicz⁴, E. Sierko⁴

¹Medical University of Bialystok, Students' Scientific Association in the Department of Oncology, Bialystok, Poland

²Medical University of Lodz, Student's Scientific Association in the Department of Otolaryngology and Laryngological Oncology, Lodz, Poland

³Medical University of Lodz, Department of Otolaryngology and Laryngological Oncology, Lodz, Poland

⁴Medical University of Bialystok, Department of Oncology, Bialystok, Poland

Purpose or Objective: Head and neck cancer (HNC) is the sixth most common type of cancer in Europe. Its early symptoms are usually non-specific and easy to miss, which in many patients lead to late presentation and diagnosis. Main risk factors of HNC include alcohol consumption and smoking. Both of them are usually present in young people, thus health education in this group is of great importance. The aim of the study was to assess the level of HNC awareness among young population in Poland.

Material and Methods: An anonymous online survey about HNC was conducted among 1903 people in the age of 18-35 years, mainly students of high schools and universities. The closed-ended questions concerned HNC risk factors, symptoms and prognosis. Participation in the study was voluntary.

Results: 85% of respondents had heard about HNC. The main source of information was the Internet (57%). Seventy-eight percent of participants associated smoking with HNC development, but alcohol consumption was mentioned by less than a half, and human papillomavirus (HPV) infection by approximately 1/3 of them. The main risk factors mentioned by students of non-medical schools included smoking (66%), stress (33%), and excessive sunbathing (32%). One fourth of the respondents (38% when excluding medical students) were unaware of any HNC early symptoms. The symptoms mentioned most often included chronic hoarseness (55%), lump in the neck (52%), and chronic sore throat (51%). Over 3/4 of medical students and half of other respondents were aware that early diagnosis is associated with a great chance

of cure. In contrast to that, if they noticed the symptoms in themselves, as much as 5% of medical students and 9% of students of other schools would seek medical advice only when they made everyday functioning impossible.

Conclusion: The level of HNC cancer knowledge among young population is alarmingly low. A large number of students of non-medical schools and universities are unaware of its risk factors and early symptoms. This group would benefit from increasing the number of educational campaigns, which would lead to earlier presentation, diagnosis and treatment of HNC.

EP-1102

Parotid toxicity in head and neck cancer patients treated with IMRT

G. Mantello¹, G. Capezzali¹, F. Cucciarelli¹, L. Vicenzi¹, M. Giacometti², M. Valenti², S. Maggi², M. Cardinali¹

¹Azienda Ospedaliero Universitaria Ospedali Riuniti, Radiotherapy Department, Ancona, Italy

²Azienda Ospedaliero Universitaria Ospedali Riuniti, Physics Department, Ancona, Italy

Purpose or Objective: The aim of this study was to evaluate the parotid glands toxicity and its relationship with the dose in a cohort of head and neck cancer patients treated with IMRT.

Material and Methods: 78 patients out of 110 treated in our department between January 2011 and October 2015 were included in the analysis. Criteria to select patients were: at least 6 months follow up, the omo-lateral parotid (OP) close to the high (HR) and / or intermediate (IR) risk CTV. Characteristics of the studied patients population are shown in Table1. The GTV, whenever present, CTV HR (regions at high risk of microscopic disease), CTV IR (regions at intermediate risk) and CTV LR (regions at low risk) were contoured on each slice. The targets were expanded 3 mm to obtain the PTVs. The prescribed dose was 66-70 Gy (2 - 2.13 Gy /fr) to PTV HR, 59.4 - 66 Gy (1.8 - 2 Gy/fr) to PTV IR; 56.1Gy (1.7 Gy/fr) to PTV LR. IMRT with Simultaneous Integrated Boost (SIB) technique was used (41patients were treated with Tomotherapy and 36 with VARIAN 21EX). The OP and the CP were contoured; PTV SV1 OP and SV2 CP were defined as overlapping volumes of PTVs and glands. Priority was given to PTV when OP was partially included. The dose limit (Dmean) was \leq 25 Gy to the whole contralateral gland (if not close to GTV N) and $<$ 24 Gy to the volume of CP not included in the PTV (external CP). Salivary gland toxicity was assessed weekly, during RT, and at 3,6,9,12,18,24 months after RT and was graduated using the RTOG toxicity scale.

Age (y), mean (range)	62 (39–82)	
Gender	Female	15 (19.2%)
	Male	63 (79.8%)
Tumor site	Nasopharynx	8 (10.2%)
	Oral cavity	26 (33.3%)
	Oropharynx	28 (36.0%)
	Larynx	16 (20.5%)
Adjuvant Chemotherapy	Yes	6 (7.7%)
	No	72 (92.3%)
Concurrent Chemotherapy	Yes	37 (47.4%)
	No	41 (52.6%)
PreRadiotherapy surgery	Yes	50 (64.1%)
	No	28 (35.9%)
Stage (TNM staging system)	I–II	20 (25.6%)
	III–IV	58 (74.4%)

Table 1. Patient and tumor characteristics (n = 78). Values are number (percentage)

Results: The dose delivered to the PTVs was 67.9 Gy (range 66-70) 2.02 Gy/fr (1.9 -2.2) to PTV HR, 62.3 Gy (range 58-66) 1.86 Gy/fr (1.7-2) to PTV IR, 55.9 Gy (range 51-60) 1.68 Gy/fr (1.65-2) to PTV LR. The mean dose was 41.56 Gy (range 17.8 - 66.8) to OP and 24.9 Gy (range 4.7-39.7) to CP; the external CP received 21.7 Gy mean dose. 36 (46.1%) patients experienced mouth dryness, thickened saliva and altered taste (31 G1 and 5 G2) during RT. At a median follow up of 24 months (range 6-56.2) 19 cases with xerostomia were recorded, 15 (19%) G1 and 4 (5,1%) G2. No G3 was observed. The symptom was recorded on an average of 8 months (range

6-15) after RT. Only 13/36 patients with acute salivary problems experienced late xerostomia.

Conclusion: In our experience 25 Gy mean dose to the whole contra-lateral parotid, with $<$ 24 Gy mean dose to the external CP, even with sacrifice of the OP, allowed our patients to maintain an adequate salivation. 24% of cases experienced G1 and G2 xerostomia. No G3 toxicity was observed.

EP-1103

Review of thyroid ablation rates with RAI based on I131 uptake in differentiated thyroid carcinoma

M. Keys¹, C. Faul¹, O. Boychek¹

¹St. Lukes Radiation Oncology Network, Radiation Oncology, Dublin 6, Ireland Republic of

Purpose or Objective: Recent studies show that low activity (1.1GBq) of RAI is as effective as high activity (3.7GBq) in treating those with low-intermediate-risk differentiated thyroid cancer (DTC). The purpose of our study was to retrospectively review post-operative I131 uptake and ablation rates in those with DTC.

Material and Methods: Data was obtained from St. Luke's Radiation Oncology Network (SLRON) patient registry. Selection criteria included histologically proven DTC; post-thyroidectomy; pre and post RAI ablation scan and RAI ablation in SLRON. There were 68 cases of DTC treated with RAI identified between 2005-2007 that were suitable for analysis and met criteria and follow up of \geq 5 years

Results: Of the cases analysed 73% were female and 27% male with a mean age of 44 years. The predominant histological subtype was papillary (73%), followed by follicular (22%). Most had early stage disease; Stage I (65%), Stage II (22%), Stage III (13%), 39 cases were pN0 and 29 had pN1 disease. Regarding surgery performed 39 patients had a complete excision CE, 22 had residual disease and there was no information for 7 cases. Thirty seven (37) cases had microscopically positive margins, 26 were negative and it was unknown in 5. Pre RAI ablation, Post op. RAI (I131) uptake in these patients was an average of 3.6 % in pN1 disease and 5.1% in those with pN0 disease. The max uptake was 28%. The extent of the surgery tended to influence the trend of uptake. There was a trend to a higher mean uptake in those who didn't have a CE with an uptake of 0.1-17%, and mean of 6.3%. Patients that had a CE had an uptake of 0-28%, and mean of 3.9%. In the SLRON there was no standard protocol for RAI dosage at the time the patients were treated The mean and range of doses of RAI administered was looked at based on pre-ablation uptake scans. Group 1 had a pre-ablation uptake of $<$ 4% and group 2 $>$ 4%. For group 1 the mean dose was 3.9GBq with a range 2.2-7.4GBq, and group 2 had a mean of 3.7GBq with a range of 2.8-7.4GBq. Post-ablative RAI131 scans showed an average of 0.07% uptake with the majority of patients (33) having $<$ 0.1% uptake. At the time of analysis 23 patients remained disease free, 10 had metastases (M1) and 2 had died from metastatic disease.

Conclusion: In those that received RAI ablation, high ablation rates \geq 90% were shown despite variability in post-op. I131 uptake and dose of RAI administered. There didn't appear to be an association between those with recurrent or metastatic disease and their pre-ablation uptake rates, it was more associated with original stage.

EP-1104

Role of perfusion CT in evaluation of tumour response after radiochemotherapy in H&N cancer

P. Ferrazza¹, P. Cocuzza¹, F. Pancrazi², D. Delishaj¹, L. Fatigante¹, A. Cristaudo¹, L. Faggioni², F. Orlandi¹, F. Matteucci¹, S. Ursino¹

¹Azienda Ospedaliero Universitaria Pisana, Department of Radiation Oncology, Pisa, Italy

²Azienda Ospedaliero Universitaria Pisana, Department of Diagnostic and Interventional Radiology, Pisa, Italy

Purpose or Objective: The aim of this prospective study is the comparison of perfusion parameters changes (CTPp) before and after radio-chemotherapy (RCT) and their correlation with maximum standard uptake values variations (Δ SUV max) among patients (pts) with head and neck tumor (HNT), in order to evaluate the prognostic value of perfusion CT parameters (CTPp) in predicting response to RCT.

Material and Methods: We enrolled pts with intermediate and advanced stage of HNT (stage III-IV), candidated to RCT with curative intent. All pts underwent to a pretreatment diagnostic and staging workup including perfusion CT (CTP) and FDG-PET/CT total body. Pts also perform a CTP 3 weeks after the end of RCT (CTP3w) and both CTP and PET/CT 3 months after the end of RCT (CTP3m and PET/CT respectively). We analysed variations of following CTPp: Blood Flow (BF), Blood Volume (BV), Mean Transit Time (MTT) and Permeability-surface product (PS). All RCT treatments were performed using intensity modulated radiotherapy technique with simultaneous integrated boost. Prescribed doses were 66 Gy at 2.2 Gy per fraction to high risk volume PTV and 60-54 Gy at 2.0- 1.8 Gy per fraction respectively to intermediate (optional) and low risk PTVs, delivered in 30 daily fractions. Concurrent weekly Cisplatin 40 mg/ m² or Cisplatin 100 mg/m² day 1, 22 an 43 was offered to all pts.

Results: From July 2012 to July 2015 25 pts affected by stage III/IV HNT candidate to RCT were enrolled in our study. FDG-PET/CT 3 months after the end of RCT showed a complete metabolic response in 16 pts (64%), a partial metabolic response in 7 pts (28%), a stable metabolic disease in 1 pts and progression metabolic disease in 1 pts (according PERCIS criteria). A significant reduction of all CTPp was observed from baseline CTP to CTP3w, except for MTT that did not show a significant variation ($p=0,722$). The analysis of differences between baseline CTP and CTP3m showed a significant reduction of all CTPp ($p<0,001$), including MTT ($p=0,001$). PET/CT response resulted statistically correlated to reduction of all CTPp both at 3 weeks and at 3 months after the end of RCT, except for MTT ($p=0,998$ and $0,692$). At the multivariate analysis the PS was the only parameter that maintain a statistical significance at CTP3m ($p=0,037$) with a significant trend also at CTP3w ($p=0,099$).

Conclusion: The induced damage on the intratumor microvascularization and low resistance flow of neoplastic vessels, explain the decrease of BV and BF whereas the reduction of neoangiogenesis phenomenon could explain the observed decrease of PS. Despite poor sample size, our preliminary results seem to be promising for a potential role of CTP to predict tumor response. PS seems the most valuable to predict the FDG-PET/CT tumor response. Due to the small sample size and short follow up, our results need to be confirmed in other series. Both functional and morphological datas of the CTP can be usefull in order to reduce as much as possible the rate of false positive.

EP-1105

Impact of waiting time for treatment initiation on glottic T1N0M0 cancer radiotherapy results

A. Mucha-Matecka¹, K. Urbanek¹, A. Chrostowska¹, J. Jakubowicz², P. Hebzda¹, K. Matecki³

¹Centre of Oncology - Institute MSC Kraków, Head and Neck Cancer, Krakow, Poland

²Centre of Oncology - Institute MSC Kraków, Clinic of Oncology, Krakow, Poland

³University Children's Hospital of Cracow, Radiotherapy of Children and Adults, Krakow, Poland

Purpose or Objective: The goal of this study is was to evaluate the results of treatment of T1N0M0 glottic cancer with irradiation, with emphasis on the influence of time from diagnosis to the beginning of radiation therapy.

Material and Methods: We performed the retrospective analysis of the group of 539 patients with T1N0M0 glottic cancer, treated with radiation therapy in one institute between 1977 and 2004. In 481 cases (89%) the tumor was

limited to single vocal cord and in the remaining 58 involved both of them. Anterior commissure involvement was observed in 173 (32%) of the patients. According to the radiotherapy technique and fractionation schedule, we have divided patients into three separate groups: I - two oblique fields, TD 60 Gy/24 - 277 patients (51%); II - two opposite fields, TD 60 Gy/30 - 160 (31%); III - one lateral photon-electron beam, TD 60 Gy/30 - 102 (19%). The average time from laryngeal biopsy to the beginning of radiotherapy was 56 days (range: 3 -145 days).

Results: The 5-year OS and 10-year OS were 84% and 69%, 5- and 10-year DFS were 90% and 88%, and the 5- and 10-year LC rates were 89% and 87%, respectively. One- dimensional analysis revealed following prognostic factors for LC and DFS: tobacco smoking, radiotherapy technique, and the anterior commissure involvement. The 5- and 10-year LC rates in the group of patients smoking less than 20 cigarettes a day were 90% and 87%, compared to 76% and 70%, respectively, in the group smoking more than 20 cigarettes a day ($p=0,01$). Considering the RT technique, the lowest 5- and 10-year LC rates were observed in the group treated with opposite beams (80% and 78%, respectively), and the highest when the oblique fields were used - 91% and 88%, respectively ($p=0,002$). The tumor involvement of the anterior commissure decreased 5-year LC by 15% (92 to 77%), and 10- year LC rate by 19% (89 to 70%, respectively, $p=0,000$). The waiting time for the beginning of RT longer than 30 days from the biopsy was statistically significant poor prognostic factor for DFS and LC. 5- and 10- year LC rates in the group of patients who started RT during the period of 30 days from the biopsy were 92% and 90%, respectively, and in the group which started treatment after that time, these LC rates were 84% and 82%, respectively ($p=0,01$).

Conclusion: Radiation therapy is efficient method of treatment the T1N0M0 glottic cancer. Prolonged time of waiting for the beginning of RT decreases the LC and DFS rates

EP-1106

A prospective novative docetaxel-based neoadjuvant chemotherapy for advanced head and neck cancer

Y. Ting Shih³, Y.C. Liu¹, M.D. Po-Ju Lin², M.D.-P.D. Jin-Ching Lin¹

¹Taichung Veterans General Hospital, RadioOncology Department, Taichung, Taiwan

²Tung's Taichung MetroHarbor Hospital, Radiation Oncology Department, Taichung, Taiwan

³St. Martin De Porres Hospital, Radiation Oncology Department, Chiyai, Taiwan

Purpose or Objective: To evaluate the overall response rate and access the toxicity for patients with locally advanced squamous cell carcinoma of head and neck (HNSCC) receiving a novative docetaxel-based outpatient neoadjuvant chemotherapy regimen.

Material and Methods: The inclusion criteria for this prospective study are (1) Age \geq 20 years old (2) Histologically proven squamous cell carcinoma of the oral cavity, oropharynx, hypopharynx, or larynx (3) Stage III or stage IVA or IVB without distant metastasis, (4) No prior chemotherapy given for HNSCC (5) Physician's intention to treat with docetaxel- baed induction therapy (6) Patients' informed consent will be obtained. Tumor response for induction chemotherapy will be evaluated in patient with measurable disease according to institutional guidance. The induction chemotherapy regimen is a novative outpatient regimen. This regimen consists of cisplatin 60mg/m² on day 1, docetaxel 50 mg/m² on day 8, 5-Fu 2500 mg/m² and leucovorin 250 mg/m² on day 15, and methotrexate 30 mg/m² and epirubicin 30 mg/m² on day 21, cycles will be repeated for a total 3 to 4 cycles followed by surgery or radiotherapy. Responses rate will be reported using *Response Evaluation Criteria In Solid Tumors* (RECIST) criteria in patients with at least one measurable lesion. Toxicity will be recoreded using the NCI-CTC v.4.03.

Results: From September 2011 to December 2013, 80 patients were enrolled and two patients withdrew consent, finally 78 patients included for analysis. There were 73 male and 5 female. There were 96.2% of them had 0-1 WHO ECOG. For the primary site, 23(29.5%) patients were oral cavity, 26 (33.3%) patients were oropharynx, 24(30.8%) patients were hypopharynx, and 5 (6.4%) patients were larynx. Treatment compliance was well. There were 92.3% patients completed planned schedule. After the induction chemotherapy, the overall response rate were 92.3%, which included 37.2% complete response and 55.1% partial response, respectively. Only 2(2.6%) patients had stable disease and 1(1.3%) patient had progression disease. The response rate of oral cavity, oropharynx, hypopharynx, and larynx were 82.6%, 92.3%, 100%, 100%, respectively. There were 47.4% grade 3 or 4 neutropenia and 20.5% grade 3 anemia. Only 6 severe adverse event were report, including 4 febrile neutropenia with sepsis, one osteomyelitis, and one massive bleeding.

Conclusion: This outpatient docetaxel-based neoadjuvant chemotherapy regimen is a effective regimen in locally advanced squamous cell carcinoma of head and neck.

EP-1107

Impact of waiting time for treatment initiation on glottic T1N0M0 squamous cell carcinoma RT results

A. Mucha-Malecka¹, K. Urbanek¹, A. Chrostowska¹, K. Malecki², P. Hebzda¹, J. Jakubowicz¹

¹Center of Oncology, Head and Neck Department, Kraków, Poland

²University Children's Hospital of Krakow, Department of Radiotherapy of Children and Adults, Krakow, Poland

Purpose or Objective: The goal of this study is was to evaluate the results of treatment of T1N0M0 glottic cancer with irradiation, with emphasis on the influence of time from diagnosis to the beginning of radiation therapy.

Material and Methods: We performed the retrospective analysis of the group of 539 patients with T1N0M0 glottic cancer, treated with radiation therapy in the Center of Oncology in Cracow between years 1977 and 2004. In 481 cases (89%) the tumor was limited to single vocal cord and in the remaining 58 involved both of them. Anterior commissure involvement was observed in 173 (32%) of the patients. According to the radiotherapy technique and fractionation schedule, we have divided patients into three separate groups: I - two oblique fields, TD 60 Gy/24 - 277 patients (51%); II - two opposite fields, TD 60 Gy/30 - 160 (31%); III - one lateral photon-electron beam, TD 60 Gy/30 - 102 (19%). The average time from laryngeal biopsy to the beginning of radiotherapy was 56 days (range: 3 -145 days). The overall survival (OS) and disease- free survival (DFS) were calculated using the Kaplan - Meier method. Log - rank test was used to calculate differences between each groups, and the independent prognostic factors were selected by the Cox multiparameter analysis.

Results: The 5-year OS and 10-year OS were 84% and 69%, 5- and 10-year DFS were 90% and 88%, and the 5- and 10-year LC rates were 89% and 87%, respectively. One- dimensional analysis revealed following prognostic factors for LC and DFS: tobacco smoking, radiotherapy technique, and the anterior commissure involvement. The 5- and 10-year LC rates in the group of patients smoking less than 20 cigarettes a day were 90% and 87%, compared to 76% and 70%, respectively, in the group smoking more than 20 cigarettes a day (p=0,01). Considering the RT technique, the lowest 5- and 10-year LC rates were observed in the group treated with opposite beams (80% and 78%, respectively), and the highest when the oblique fields were used - 91% and 88%, respectively (p=0,002). The tumor involvement of the anterior commissure decreased 5-year LC by 15% (92 to 77%), and 10- year LC rate by 19% (89 to 70%, respectively, p=0,000). The waiting time for the beginning of RT longer than 30 days from the biopsy was statistically significant poor prognostic factor for DFS and LC. 5- and 10- year LC rates in the group of patients who

started RT during the period of 30 days from the biopsy were 92% and 90%, respectively, and in the group which started treatment after that time, these LC rates were 84% and 82%, respectively (p=0,01). Tumor interior commissure involvement was proven to be an independent prognostic factor affecting DFS and LC.

Conclusion:

1. Radiation therapy is efficient method of treatment the T1N0M0 glottic cancer
2. Prolonged time of waiting for the beginning of RT decreases the LC and DFS rates
3. The tumor involvement of anterior laryngeal commissure proved to be an independent adverse prognostic factor for LC and DFS

EP-1108

Chemoimmunotherapy with hyperfractionated radiotherapy in head and neck carcinoma.

R. Carmona Vigo¹, J.M. Blanco¹, M. Lloret¹, R. Cabrera¹, P.C. Lara¹

¹Hospital Dr. Negrín, Radiation Oncology, Las Palmas de Gran Canaria, Spain

Purpose or Objective: The aim of the present study is to analyze clinical outcomes and toxicity in patients with locoregionally advanced head and neck carcinoma treated with concurrent hyperfractionated radiotherapy with Cetuximab and Carboplatin.

Material and Methods: Forty-one patients (8 cases ST.III and 33 cases ST.IV) were prospectively included in this study from September 2009 to November 2014. Radiotherapy consisted in hyperfractionated radiotherapy: 1.15-1.20 Gy/fraction, BID, 5 days/week during 7 weeks. The average dose administered was 80.2 Gy (79.2-80.5). Carboplatin was administered 5 mg/m² before each fraction of radiotherapy. Cetuximab was administered 400 mg/m² one week before hyperfractionated radiotherapy and then 250 mg/m² weekly while radiotherapy. Seven patients were not evaluable for response (in 3 patients, Capecitabine was added to the treatment; in 1 patient nodal metastases came from a papillary thyroid carcinoma; 3 patients were not evaluable for response because 2 patients died within 30 days after treatment and 1 patient has not enough follow-up to be evaluated for response).

Results: All but 2 of the 34 evaluable patients showed objective response (19 complete responses). The local relapse-free survival, cause specific survival, and overall survival was 58.7%, 57%, 49% at 5 years, respectively. Severe (Grade III) acneiform rash resulted predictive of Clinical Response (p=0,005), Local relapse (p=0,008), distant metastases (p=0,012) and tumour related dead free survival (p<0,0001). Severe (Grade III) acute cutaneous and mucosal toxicity was present in almost 60% of the cases.

Conclusion: This protocol induces a high rate of clinical responses and excellent survival figures in patients developing an strong immune response after combined radio-chemoimmunotherapy.

EP-1109

Role of adjuvant EBRT for papillary thyroid carcinoma invading the trachea: a single-instn study

Y.S. Kim¹, J.H. Choi², K.S. Kim², G.C. Lim³, J.H. Kim³, H.S. Song⁴, S.A. Lee⁵, G. Koh⁵, C.L. Hyun⁶, G.E. Kim¹

¹Jeju National University Hospital, Department of Radiation Oncology, Jeju, Korea Republic of

²Jeju National University Hospital, Department of Surgery, Jeju, Korea Republic of

³Jeju National University Hospital, Department of Otorhinolaryngology, Jeju, Korea Republic of

⁴Jeju National University Hospital, Department of Nuclear Medicine and Molecular Imaging, Jeju, Korea Republic of

⁵Jeju National University Hospital, Department of Internal Medicine, Jeju, Korea Republic of

⁶Jeju National University Hospital, Department of Pathology, Jeju, Korea Republic of

Purpose or Objective: The current standard of care for newly diagnosed papillary thyroid carcinoma invading the trachea is surgical resection followed by radioactive iodine therapy (RAI) and thyroid stimulating hormone suppression. However, the local recurrence rate is high. Several studies reported adjuvant external beam radiotherapy (EBRT) reduced the local recurrence. The benefit of adjuvant EBRT remains controversial. We evaluated the effect of adjuvant EBRT on local control in a single institution database.

Material and Methods: Between May 2003 and October 2013, 36 patients with locally advanced papillary thyroid carcinoma invading the trachea (pathologic stage T4) were treated with surgical resection. After surgery, 16 patients received adjuvant EBRT using intensity modulated radiation therapy followed by RAI, and 20 patients were treated with RAI alone. The age range was 36-87 years (median 64 years). EBRT doses ranged from 30-66 Gy (median 60 Gy). There was no statistically significant difference in terms of clinical characteristics between the EBRT and no EBRT groups.

Results: Median follow up was 26.6 months (range, 16.5-40.1) in EBRT group, and 43.9 months (range, 13.9-117.6) in no EBRT group. There was no local or distant failure in EBRT group during the follow up. There were five local failures and one distant failure in no EBRT group. The two-year & five-year local failure free survival rates were 95.0% and 49.8% in no EBRT group. There were acute grade 2 esophagitis (n=1) and grade 2 skin reaction (n=3). There were no grade 2 late complications in EBRT group.

Conclusion: Adjuvant EBRT was found to be an effective treatment for local control in papillary thyroid carcinoma invading the trachea with tolerable complications, in a study at a single institution. Longer follow up will be required to demonstrate outcomes for tumor control and complications

EP-1110

Combination of RT and cetuximab for aggressive, high-risk CSCC of h&n: a propensity score analysis

A. Raben¹, J.D. Palmer², J. Strasser¹, A. Hanlon³, M. Dzeda¹, N. Hockstein⁴, C.J. Schneider⁵

¹Helen F. Graham Cancer Center, Radiation Oncology, Newark- DE, USA

²Sidney Kimmel Medical College at Thomas Jefferson University, Radiation Oncology, Philadelphia, USA

³University of Pennsylvania, Department of Nursing, Philadelphia, USA

⁴Helen F. Graham Cancer Center, Medical Oncology, Newark- DE, USA

⁵Helen F. Graham Cancer Center, Surgery, Newark- DE, USA

Purpose or Objective: Locally advanced, high-risk cutaneous squamous cell carcinoma (CSCC) of the head and neck are typically aggressive and treated with combined modality therapy. These patients tend to be older, frail with multiple comorbidities which makes chemotherapy difficult to tolerate. Cetuximab is a monoclonal antibody against the EGFR receptor and has demonstrated activity in CSCC. We investigate the safety and efficacy of combined therapy in advanced, high risk CSCC with the addition of cetuximab.

Material and Methods: Patients were identified with locally advanced CSCC with high risk or very high risk features who were treated with cetuximab and radiotherapy between 2006 and 2013. A matched cohort over the same time period was identified who were treated with radiation. Propensity score analysis was performed with weighted factors including: Charlson Comorbidity Index score (age-adjusted), age, KPS, primary location, T and N stage, recurrent status, margin status, LVSI, PNI and grade. Overall survival, progression free survival and freedom from local or distant recurrence were evaluated with the Kaplan-Meier method for both the unadjusted and propensity score adjusted groups. Multivariate analysis was performed using cox proportional hazard models.

Results: 29 patients were in the cetuximab and 39 in the control group. Median follow-up for alive patients was 30 months. Patients in the cetuximab group were more likely to have advanced N stage, positive margins and recurrent disease. After propensity score matching the groups were well balanced. OS was not statistically significant between the two groups but depicted in Table 1 below there were approximately 20% more long term survivors in the cetuximab group after matching. Local control was 76% and 79% in the cetuximab and control groups, respectively. The rate of distant metastases was lower in the cetuximab group 6.8% versus 10%. The incidence of grade 2-3 toxicity was 41% in the cetuximab group. There was one grade 3 cetuximab acneiform rash, one grade 4 dysphagia and no grade 5 toxicity.

Table 1 Overall Survival Probabilities by year in both unadjusted and Propensity Score Adjusted Cohorts

Years:		1	2	3	4	5
Unadjusted	Cetuximab	96%	74%	74%	74%	74%
	No Cetuximab	93%	85%	75%	69%	69%
Propensity Score Adjusted	Cetuximab	98%	80%	80%	80%	80%
	No Cetuximab	81%	73%	66%	61%	61%

Conclusion: Although limited by small numbers, we found that there were more long-term survivors and less distant metastasis in the cetuximab group. This is the largest report of CSCC patients treated with cetuximab. In the absence of prospective data, we believe this data reveals that the addition of cetuximab is well tolerated and reveals signs of efficacy in this typically poor performing group of patients and should be pursued in clinical trials.

Electronic Poster: Clinical track: CNS

EP-1111

A cut point for Ki-67 proliferation that predicts for poorer survival in high-grade glioma

E. Wong¹, P. Sundaresan², W. Varikatt³, V. GebSKI², N. Nahar², T. Ng³, J. Jayamohan²

¹The University of Sydney, Sydney Medical School, Sydney, Australia

²Crown Princess Mary Cancer Center- Westmead, Radiation Oncology, Sydney- NSW, Australia

³Westmead Hospital, Department of Tissue Pathology & Diagnostic Oncology, Sydney, Australia

Purpose or Objective: Ki-67 index is used to assess cell proliferation during histopathological assessment of various tumours including high grade gliomas (HGG): Anaplastic astrocytoma, Anaplastic Oligodendroglioma and Glioblastoma Multiforme (GBM). We aimed to determine if there is a correlation between percentage staining of Ki-67 and overall survival in patients with HGG and determine a cut-point for percentage staining of Ki-67 that predicts for poorer survival.

Material and Methods: Records of adult patients diagnosed with HGG on histopathological specimens examined at the Institute of Clinical Pathology and Medical Research at Westmead Hospital, NSW, between 1st of January 2002 and 30th of July 2012 were identified. The specimens of these patients were examined for quantification of Ki-67 staining by two independent pathologists. Patient, disease, treatment and survival data were collected from hospital and cancer care service records. Descriptive statistical analyses were performed on the patient, disease and treatment data. Survival curves were constructed using Kaplan Meir methods. Using the minimum p value approach we obtained a cut-point for Ki-67 percentage staining that predicts for poorer survival.

Results: Of the eligible 78 patients (median age = 57, range 18 - 87) 46 (59 %) were males and 32 (41%) were females. 59 (76%) patients were of ECOG performance status 0 -1. Seven patients had anaplastic astrocytoma or anaplastic

oligodendroglioma and the rest had GBM. There was a clear inverse correlation between Ki-67 percentage staining and overall survival. In patients with Ki-67 \leq 30% (n=18), 5 year survival was approximately 50% compared to those with Ki-67 >30% (n=60) with survival of 10% (logrank P-value 0.02, HR 0.39, 95% CI 0.17 - 0.88).

Conclusion: There appears to be a correlation between percentage staining of Ki-67 and overall survival in patients with HGG. Percentage staining of Ki-67 > 30% appears to predict for poorer survival in HGG.

EP-1112

Optic toxicity in radiation treatment of meningioma: a retrospective study in 213 patients

M. Farzin¹, M. Molls¹, S. Kampfer¹, S. Astner¹, R. Schneider², K. Roth¹, M. Dobrei³, S. Combs¹, C. Straube¹

¹Klinikum rechts der Isar- TU München, Radiation- Oncology, München, Germany

²Paul Scherrer Institute, proton therapy, zurich, Switzerland

³Kliniken Kreis Mühldorf am Inn, Innere Abteilung, Mühldorf, Germany

Purpose or Objective: Background and purpose: In this retrospective evaluation, we correlated radiation dose parameters with occurrence of optical radiation-induced toxicities.

Material and Methods: Patients and methods: 213 meningioma patients received radiation between 2000 and 2013. Radiation dose and clinical data were extracted from planning systems and patients' files. The range of follow-up period was 2-159 months (median: 75 months).

Results: Median age of patients was 60 years (range: 23-86). There were 163 female and 50 male patients. In 140 cases, at least one of the neuro-optic structures (optic nerves and chiasm) was inside the irradiated target volumes. We found 15 dry eye (7%) and 24 cataract (11.2%) cases. Median dose to affected lacrimal glands was 1.47 Gy and median dose to affected lenses was 1.05 Gy. Age and blood cholesterol level in patients with cataract were significantly higher. Patients with dry eye were significantly older. Only 2 patients with visual problems attributable to radiation treatment (RION) were seen. They did not have any risk factors. Maximum and median delivered doses to neuro-optic structures were not higher than 57.30 Gy and 54.60 Gy respectively.

Conclusion: Low percentages of cases with radiation induced high grade optic toxicities show that modern treatment techniques and doses are safe. In very few patients with optic side effects, doses to organs at risk were higher than the defined constraint doses. This observation leads to the problem of additional risk factors coming into play. The role of risk factors and safety of higher radiation doses in high grade meningiomas should be investigated in more comprehensive studies.

EP-1113

Light seeing in radiotherapy of patients with brain tumours and head and neck malignancies

M. Farzin¹, M. Molls¹, S. Astner¹, S. Reitz¹, K. Kreiser², S. Kampfer¹

¹Klinikum rechts der Isar- TU München, Radiation- Oncology, München, Germany

²Klinikum rechts der Isar- TU München, Department of Neuroradiology, München, Germany

Purpose or Objective: Evaluating the radiation doses delivered to different parts of the visual pathway for better understanding of light vision in radiotherapy patients.

Material and Methods: 20 patients with brain tumors and head and neck malignancies who received radiotherapy and experienced any kind of light or color vision during radiation treatment. All the components of visual pathway including

lenses, eyeballs, retinas, optic nerves, chiasm, optic tracts, optic radiations and visual occipital cortexes were contoured.

Results: 11 patients were male (55%) and 9 were female (45%). Age median was 56 years. The range of dose/fraction and total prescribed dose were 1.8-3 Gy and 36-70.4 Gy respectively. Twelve patients reported white, 11, blue, 2, yellow and 2, gray color visions. Seven patients experienced more than one color, while 2 patients did not attribute any special color to their light seeing experiences. Four patients had a kind of smell experience and 1 patient had a taste experience.

Conclusion: Cherenkov radiation in eye balls may be the origin of light seeing experiences in patients receiving radiation treatment for head and neck malignancies, since treatments are performed with ionizing radiations with energy capable to produce this effect. Also this effect may be due to phosphores produced by radiation treatment in different parts of the visual pathway (from retina to visual cortex). In order to investigate the mechanism of this phenomenon in patients and to define a radiation dose threshold - if the origin of this phenomenon is phosphores produced in visual pathway - larger studies are needed.

EP-1114

Clinical outcomes in modern management of infratentorial ependymoma

R. Allison¹, D. Remonde², S. Salenius³, A. Hnatov¹, C. Ballenger¹, C. Mantz¹, E. Fernandez², D. Dosoretz⁴, S. Finkelstein⁵

¹21st Century Oncology, Radiation Oncology, Greenville, USA

²East Carolina University, The Brody School of Medicine, Greenville, USA

³21st Century Oncology, Research, Fort Myers, USA

⁴21st Century Oncology, Radiation Oncology, Fort Myers, USA

⁵21st Century Oncology, Radiation Oncology, Scottsdale, USA

Purpose or Objective: Ependymomas are central nervous system (CNS) tumors that due to their rare prevalence have considerable controversy regarding their prognostic factors and clinical management. As such, many of the reported series involve accumulation of patient data that spans many decades, making current management decisions difficult. In this study, we report the outcomes and possible prognostic factors of patients with histologically confirmed infratentorial ependymomas treated in the modern era.

Material and Methods: A retrospective chart review of our patient registry was conducted to identify 15 patients diagnosed with infratentorial ependymoma between 2007–2013. Mean age at diagnosis was 29 years (range 1.0–79.0 years). There were 8 males and 7 females, with headache being the most common presenting symptom among the entire cohort. Eleven were newly diagnosed with ependymoma and the remaining 4 were recurrent patients who had failed primary therapy. Of the newly diagnosed patients, all received surgery and post-operative radiation therapy (RT) with a mean dose of 54.3 Gy (range 45.0–59.4 Gy). Two also received chemotherapy. Patients in the recurrent group experienced only local recurrences after initial treatment and underwent salvage RT with a mean dose of 45.6 Gy (range 15.0–59.4 Gy).

Results: With a mean follow-up time of 15 months (range 1.4–61.7 months) for the cohort, a significant difference in overall survival (OS) was found between primary and recurrent patients (p=0.0082). Overall, 9 patients (60%) had no acute complications with the remainder Grade I or II following initial treatment. All were free of late complications throughout follow-up. Moreover, there were no statistically significant differences in OS or local control when tumor size or RT dose were analyzed.

Conclusion: Our findings indicate that recurrence is a prognostic factor for decreased OS in patients with infratentorial ependymomas. Involved field radiation therapy following surgical resection of these tumors offers high local

control rates and may ultimately improve OS. The combination of surgery followed by RT appears to be the current standard of care.

EP-1115

Stereotactic radiosurgery for brain metastases: neuropathological report of three autopsy cases

M. Sakuramachi¹, H. Igaki², A. Nomoto¹, N. Sekiya¹, W. Takahashi¹, K. Ookuma¹, M. Ikemura³, H. Yamashita¹, K. Nakagawa¹

¹Tokyo University, Radiology, Tokyo, Japan

²National Cancer Center, Radiation Oncology, Tokyo, Japan

³Tokyo University, Pathology, Tokyo, Japan

Purpose or Objective: To elucidate the radiobiological effects of stereotactic radiosurgery (SRS) on brain metastases using autopsy cases.

Material and Methods: From 1995 to 2013, 9 brain specimens from 3 patients were available. They underwent autopsy after SRS in our hospital. These specimens were all brain metastases. The timing of autopsy was from 7 days to 20 months (median 10 months) after SRS. The 9 tumors received a margin dose of 16-20 Gy (median 20 Gy) at the 40-75% isodose line (median 40%), with a maximal dose of 16-50 Gy (median 45 Gy). Histopathological investigations were performed. The specimens were fixed in 20% neutral buffered formaldehyde and embedded in paraffin. Hematoxylin-eosin, Azan-Mallory, and Bodian stains were used. Immunohistochemical reactions included glial fibrillary acidic protein, alpha-smooth muscle actin, CD34, and CD68 antigens. Ki67 and p53 reactions were also used.

Results: The first case was a 59-year-old man diagnosed with 2 brain metastases from renal cell carcinoma. Both lesions were irradiated with SRS. He received SRS 4 times after the first SRS. At 1 week after the last SRS, he died from carcinomatous lymphangiosis. The second case was a 63-year-old man diagnosed with 2 brain metastases from lung cancer. Both lesions were irradiated with SRS plus whole brain radiotherapy (WBRT). Seven months later, he died from carcinomatous peritonitis. The third case was a 35-year-old woman diagnosed with 2 brain metastases from breast cancer. Both lesions were irradiated with WBRT plus SRS. When one of the lesions enlarged 1 year later, repeated SRS was performed. At 7 months after reirradiation, she died from carcinomatous lymphangiosis. In the first case, necrosis and viable tumor cells were observed mainly in the center of the lesion at 1 week after SRS, while apoptosis and fibrosis were observed in a small part of the lesion. Glial cells and neutrophilic leukocytes had accumulated around the lesion. In the lesions at 2 months after SRS, tumor cells and fibrosis were not observed; only macrophages and glial cells were observed in the SRS irradiated field. In the second case, fibrosis was observed at the periphery of the center necrotic region at 7 months after SRS. In the third case, almost all parts of the lesions were replaced with fibrosis at 19 months after SRS, while small foci of viable tumor cells, a large number of glial cells, and macrophages were observed around the fibrotic area.

Conclusion: In the tumors, apoptosis was only observed at 1 week after SRS. The time of fibrosis initiation varied in each case. Around the tumors, neutrophilic leukocytes and glial cells accumulated within 1 week after SRS. Macrophages accumulated at least 2 months after SRS. Stromal changes remained for a considerable period of time. It was remarkable that fibrosis occurred very soon after SRS, and other observations were generally compatible with previous reports.

EP-1116

Staged radiosurgery for petroclival meningiomas: preliminary results

V. Pinzi¹, M. Marchetti¹, I. Milanese¹, E. De Martin², L. Fariselli¹

¹IRCCS Istituto C. Besta, Neurosurgery Radiotherapy Unit, Milan, Italy

²IRCCS Istituto C. Besta, Health Department-, Milan, Italy

Purpose or Objective: The goal of surgical treatment of meningiomas is the total resection of the tumour. The complete removal of petroclival meningiomas can be difficult because of their proximity to cranial nerves. Stereotactic radiosurgery (SRS) is a well established treatment for many patients with intracranial meningiomas, either in the exclusive or adjuvant setting. However, SRS of large meningiomas might be associated with significant morbidity. Under these circumstances s-SRS has the potential to deliver sharply focused high doses per fraction without increasing the risk of toxicity. The aim of this study is to prospectively evaluate the feasibility of s-SRS for petroclival meningiomas, including large volume lesions.

Material and Methods: Between September 2011 and October 2013 at our Institute, s-SRS using the CyberKnife was prospectively performed on 30 patients (24 women and 6 men, mean age 57 years) with petroclival meningiomas. Patients with atypical or malignant meningiomas and those who had received prior radiotherapy were excluded. The average tumor volume was 11,86 cm³ (range 2,2-126,3 cm³); the average tumor prescription dose was 24,4 Gy, the number of fraction was 4 or 5.

Results: After a median follow-up of 30 months (range 13-36 months) the overall tumour control rate was 100% (25 patients with stable disease, 3 patients with partial response and 2 patients with complete response). Tumor control rates at 2 and 3 years was 100%. Among 28 patients who were symptomatic before staged radiosurgery, neurological follow-up showed an improvement in 43%, stable clinical course in 43% and a persistent deterioration of clinical symptoms in 14% of the patients. A transient neurological deterioration was observed in 11% of patients within the first year after treatment.

Conclusion: Our findings show that s-SRS using the CyberKnife is a safe and effective option in the treatment of large-volume petroclival meningiomas. A good tumour control and a low morbidity rate was achieved in our series, either as a primary or adjuvant approach. Long-term follow-up is warranted to confirm these results.

EP-1117

Frameless radiosurgery for acoustic schwannoma: a five-year experience

S. Pavano Hernandez¹, O. Hernando Requejo¹, M. Lopez Gonzalez¹, E. Sanchez Saugar¹, M. Garcia-Anda Pez¹, J. Valero Albarrán¹, A. Montero Luis¹, R. Ciervide Jurio¹, A. Rodriguez¹, R. Alonso¹, X. Chen¹, C. Rubio Rodriguez¹, R. Guimaraes Domingos da Silva¹

¹Hospital Universitario Madrid Sanchinarro - Grupo Hospital de Madrid, Oncologia Radioterápica, Madrid, Spain

Purpose or Objective: Frameless radiosurgery (SRS) plays an important role in the management of acoustic neuromas. This retrospective study aims to evaluate tumor control using this technique.

Material and Methods: Thirty four patients with unilateral acoustic neuromas (vestibular schwannomas) who underwent linear accelerator-based frameless SRS at low dose (12 Gy) to the tumor from July 2008 to February 2015 were evaluated. Twenty-one patients were male and 13 patients were female. The median age was 62 years (range 23-84) with a median follow-up period of 12.4 months (range 1-60). Treatment volume was 0.1 to 3.8 cm³ (median 0.93 cm³).

Results: Preliminary results from follow-up magnetic resonance imaging (MRI) showed: the tumor of 15 patients decreased in diameter, no changes was found in 14 and the tumor increased slightly in only one patient. All patients are alive, except for 1p who died from intercurrent disease 2 years after radiosurgery. Among 23p with acufeno, full improvement was demonstrated in four. There were no reported complications related to treatment.

Conclusion: We experienced excellent short term local control and low incidence of complication for acoustic schwannomas undergoing frameless SRS treatment. Our data compare favorably with the literature. Additional follow-up will be necessary to evaluate long term results of treatment.

EP-1118

Impact of susceptibility-weighted imaging MRI on radiosurgery for melanoma and RCC brain metastases

A. Klimov^{1,2}, S. Rogers², L. Boxheimer³, S. Bodis²

¹Saint Petersburg State University, Faculty of Surgery, Saint Petersburg, Russian Federation

²Canton Hospital Aarau, Institute of Radiation Oncology, Aarau, Switzerland

³Canton Hospital Aarau, Department of Neuro-radiology, Aarau, Switzerland

Purpose or Objective: A patient with malignant melanoma and 4 visible lesions on a gadolinium (Gd)-enhanced T1 MRI scan of the brain was reported at the tumor board as having at least 7 probable metastases on the basis of the matching susceptibility-weighted imaging (SWI). SWI detects cerebral microbleeds and may therefore be more sensitive than Gd-T1 MRI in the detection of small haemorrhagic metastases and prediction of future sites of intra-cranial relapse. Our aim was to explore the potential usefulness of SWI in 1) the selection for radiosurgery and 2) the follow-up of patients with brain metastases from malignant melanoma and renal cell carcinoma (RCC).

Material and Methods: At the time of referral for radiosurgery, a 3-D Gd-T1 MRI was evaluated at the neuro-oncology multidisciplinary tumor board to determine the number of brain metastases. We retrospectively analysed the synchronous SWI sequence to explore any difference in the number of detectable lesions and hence putative metastases. Subsequent enhanced T1-weighted MRIs were evaluated for new metastases at the site of SWI abnormalities.

Results: T1 MRI scans detected 16 metastases in a sample of 11 patients with melanoma and RCC who were treated with primary or postoperative linear accelerator-based radiosurgery in our center. 25 regions of signal change were detectable on the matching SWI sequences. The scans were reviewed by a board-certified neuro-radiologist who confirmed that the 9 additional SWI lesions were non-metastatic. To date, none of the additional lesions have developed into enhancing brain metastases. Indeed, additional SWI changes on postoperative imaging resolved completely on subsequent imaging. Thus the 16 SWI changes with metastatic features correlated perfectly with the 16 metastases on Gd-T1 MRI. (Figure 1)

Fig 1. Top: Melanoma metastasis on T1 MRI (left) and SWI (right). The frontal SWI change is falcine calcification. Bottom: The SWI signal change (right) has no T1 correlate (left) and represents postoperative blood.

Conclusion: SWI sensitively detects blood products in primary and secondary brain tumours, but also in veins, vascular malformations and postop-operative bleeding and calcification. An expert neuro-radiology opinion in the context of the tumour board is essential for the accurate

interpretation of SWI to avoid “overdiagnosis” of metastases, particularly in the post-operative setting. Occasionally however, additional lesions that are highly suspicious for metastases may be detected on SWI. The sensitivity and specificity of SWI for metastases should be determined in a larger cohort as it may assist patient selection for radiosurgery in borderline cases.

EP-1119

Treatment of Subependymal giant cell astrocytoma (SEGA): Is there a place for radiotherapy?

R. Atef Kamel¹

¹Universitair Ziekenhuis Brussel, Department Radiotherapy, Brussels, Belgium

Purpose or Objective: SEGA is a WHO grade I glioma that is almost exclusively seen in young patients with tuberous sclerosis complex (TSC). Despite the benign histology, SEGA can be severely symptomatic as it typically arises intraventricularly and can cause obstructive hydrocephalus. The current standard treatment of SEGA includes surgical resection and chemotherapy, the m-TOR inhibitor everolimus. Based on expert opinion, there is an international consensus that radiotherapy should not be used in the treatment of SEGA.

Here, we present a case of a patient with TSC, with inoperable bilateral ventricular SEGA. Years long before the availability of everolimus or its approval for treating SEGA, we treated this patient exclusively with radiotherapy.

Material and Methods: With stereotactic fractionated radiotherapy, a dose of 60 Gy in 30 fractions of 2 Gy, was delivered on the GTV. The patient was afterwards followed up with MR imaging. We did volumetric assessment of tumour size on each follow up MRI and tracked the changes in tumour size after radiotherapy.

We performed an extensive literature study to verify the sources of the consensus against radiotherapy in treatment of SEGA.

Results: The patient tolerated the treatment very well. No acute or chronic side effects were seen. A follow up over a period of 8 years, using MR imaging, showed about 70% decrease in tumour volume.

We found that the advice against radiotherapy appears to be based on very little, if any, evidence.

Conclusion: Radiotherapy can be a potential useful tool in the treatment of SEGA. The slow but progressive response of SEGA to radiotherapy resembles what is seen in other benign brain tumors e.g. meningioma. Radiotherapy has been discarded prematurely as a therapeutic option for SEGA and could be very well used to consolidate effect of everolimus. Prospective registration of patients and treatment outcome is needed to enhance knowledge.

EP-1120

Experience with robotic SBRT in treatment of intraspinal tumours

R. Garcia¹, A. Velazquez-Pacheco¹, I. Marrone¹, I. Santa-Olalla¹

¹Instituto Madrileño de Oncología, Centro de Radioterapia y Radiocirugía Robotizada Cyberknife, Madrid, Spain

Purpose or Objective: The role of radiotherapy in the treatment of intraspinal tumors constitutes a paradigm, justified by tolerance of spinal cord. Advances in SBRT (Stereotactic Body Radiation Therapy) as robotic and image-guided treatments have revolutionized in this group. The aim of this study is to analyze our preliminary experience treating intraspinal tumors using robotic SBRT.

Material and Methods: Clinical and dosimetric data on 19 patients between 2011 and 2015 were reviewed, patients with lesions in spinal canal including intramedullary and intradural extramedullary were selected solely. All patients were treated with robotic SBRT image-guided in real time (Cyberknife).

Results: A total of 26 lesions were included in the analysis. Median follow-up was 14 months (3-41 months). Thirteen were metastatic lesions with histology as breast cancer, medulloblastoma, adenoid cystic among others. Response rates were: 31% complete response and partial response / stable at 69%. 13 benign lesions highlighting arteriovenous malformations, neurofibroma and melanocytoma. Response rates for this group: complete response in 8%, partial response / stable at 92%. During the follow-up time only 5 patients had relapsed 100% to distance. Median overall average dose was 21 Gy (14-35 Gy), the median was three fractions (1-5 Fractions), median prescription isodose was 83% (77-88%) with an average coverage of 97.27% (93.13-100%). There were no data as myeloparagrade II associated to treatment in the whole cohort, the most common symptom after treatment was fatigue.

Conclusion: The treatment of intraspinal tumors with image-guided robotic SBRT, has proven to be a feasible, safe and effective option for treatment, where treatment options are scarce. In our experience, the data are encouraging and comparable with those reported by other authors.

EP-1121

Treatment outcome of adult brain stem Glioma: a single institution experience

S. Chaudry¹, A. Rashid¹, S. Butt¹, A. Rashid¹, S. Hameed¹, A. Jamshed¹

¹Shaukat Khanum Memorial Cancer Hospital, Radiation Oncology, Lahore, Pakistan

Purpose or Objective: Adult brain stem gliomas are rare accounting for 1-2% of adult gliomas. They are heterogeneous with varying clinical and radiological presentation. Prognosis remains poor because of limited surgical options and radiotherapy still remains the main treatment option. We report our clinical experience of treating brain stem glioma.

Material and Methods: A Retrospective review was made to analyze the clinical presentation, diagnosis, treatment outcome and survival in adult brain stem glioma patients treated at Shaukat Khanum Memorial Cancer Hospital Lahore. Between July 2007 and August 2014.

Results: 46 patients were identified from Hospital record system. Diagnosis was mostly based on radiological findings with MRI brain and biopsy was done only in 11 patients. 98% of the patients were treated with radiotherapy as a first line treatment on presentation and 1 patient was kept under close surveillance which was treated on progression. Median radiotherapy dose used ranged between (20-60Gy) with a median dose of 51Gy. Age of the patients ranged from 18 to 72 years (median 33 years) with a Male to female ratio of 3:1. Median follow up duration was 9 months (range 1-72). Radiological response was seen in 65% (13% partial & 52% stable) of the patients. The median overall survival (OS) for entire cohort was 10 months. One and two year OS rates were 46% and 25% respectively. Radiological Low grade Glioma showed a median survival of 11.5 months and was found to be 9.5 months for High grade Glioma. (p=0.864). ECOG Performance status 0,1,2 and 3 showed median survival of 13.6, 11.5, 6 and 3 months respectively (p=.02)

Conclusion: Survival still remains dismal despite high radiotherapy dose. The role of cytogenetics and chemotherapy should be explored to improve outcome.

EP-1122

Efficacy and safety of stereotactic reirradiation for recurrent brain metastases.

F. Meniai-Merzouki¹, S. Maillard¹, B. Coche-Dequéant¹, T. Boulanger², E. Tresch³, F. Crop⁴, T. Lacomerie⁴, E.F. Lartigau¹

¹Centre Oscar Lambret, Radiation oncology, Lille, France

²Centre Oscar Lambret, Medical Imaging Department, Lille, France

³Centre Oscar Lambret, Methodology and Statistics Department, Lille, France

⁴Centre Oscar Lambret, Medical physicist, Lille, France

Purpose or Objective:

Background: Brain metastases (BM) are the most common CNS malignancies. They represent an important cause of morbidity and mortality in cancer patients. In the literature, few studies have evaluated the efficacy of stereotactic reirradiation (SRT) for recurrent brain metastases as a salvage treatment option after a prior radiotherapy.

Objectives: This study reports the clinical outcome and tolerance of repeat irradiation with CyberKnife robotic stereotactic delivery in patients with recurrent brain metastases and a history of prior cerebral radiotherapy. Overall survival (OS), intracranial progression-free survival (PFS), local control (LC) and prognostic factors associated with overall survival (OS) were evaluated.

Material and Methods: Patients treated from April 2010 to January 2015 for recurrent brain metastases were retrospectively included. Univariate and multivariable analyses included age, performance status, recursive partitioning analysis (RPA), extracranial disease control, and time from initial RT to SRT. The prior radiotherapy was WBRT for 27 patients (dose from 30 Gy to 45 Gy), radiosurgery with Gamma knife for 8 patient (dose from 18 Gy to 25 Gy) and hypo fractionated stereotactic radiotherapy in 2 patients. The tumor size ranged from 1 to 4 cm (median 2 cm).

Results: In total, 37 Patients with 53 recurrent brain metastases and a median age of 58 years (Range 33-82 years) were included. The median number of metastases per patient was 2 (range 1-4), treated with a median dose of 21 Gy (range 10-36) per treatment, with a median of 3 fractions (range 1-9) per patient. The median follow-up was 10,1 months (range 1-19 months). The OS rate from the SRT was 57,2% (IC 95%: 34.6-74.6). Two (5%) of 12 deaths were from neurologic causes. The median PFS was 5.8 months (IC 95%: 3.6-9.3). On multivariate analysis, controlled extracranial disease is correlated with better overall survival 31% (IC 95%: 15-50; p=0,005). Adverse radiation events developed was acceptable.

Conclusion: Stereotactic reirradiation with CyberKnife for recurrent brain metastases, seems to be a safe and effective approach in selected patients. However, in the absence of prospective trials, no recommendation can be strongly established.

EP-1123

New aspects regarding the radiation of thalamic gliomas

E. Boelke¹, W. Budach¹, C. Matuschek¹, A. Hayman²

¹University Hospital Düsseldorf Heinrich Heine University Düsseldorf, Radiation Oncology, Düsseldorf, Germany

²University of Texas- MD Anderson Cancer Center, Radiology, Houston, USA

Purpose or Objective: Thalamic tumours represent 5.2% of all intracranial tumours and are typically diagnosed in the paediatric population. These tumors arise from glial cells with an aggressive behavior and a high grade histology. They have a poor prognosis. The aim of this study was to find new approaches for defining the clinical target volume for these tumors.

Material and Methods: Clinical data were collected from archived files of 30 patients diagnosed with thalamic gliomas based on pathologic and radiologic criteria.

Results: Three patterns of tumor spread were found. The first pattern followed the thalamic tributaries of the posterior part of the internal cerebral veins. These were the anterior and superior thalamic veins. For the second pattern the close proximity of the internal cerebral vein branches of the superior thalamic veins was a potential route of spread between the medial surfaces of the thalami. In addition to spread across the midline tumours could also spread along the adjacent tectal, pineal and/or vermian veins. The third pattern of thalamic tumor spread was found in gliomas which use the anterior tributaries of the internal cerebral venous architecture of the posterior and inferior branches from the basal vein of Rosenthal.

Conclusion: Thalamic gliomas spread upon the peritumoral architecture of the perivenous/subglial Scherer structures and this knowledge should be used for redefining the clinical target volume for radiation therapy in thalamic gliomas

EP-1124

Outcomes of patients with 4 or more cerebral metastases treated with stereotactic radiosurgery

H. Benghiat¹, A. Hartley¹, A. Kapadia¹, G. Heyes¹, P. Sanghera¹

¹Queen Elizabeth Hospital, Hall-Edwards Radiotherapy Research Group- The Cancer Centre, Birmingham, United Kingdom

Purpose or Objective: Evidence for the use of stereotactic radiosurgery (SRS) to 1-3 brain metastases (BM) can be derived from historic prospective trials. With improvements in the ability to control systemic disease, better access to SRS and concerns with WBRT associated neurocognitive toxicity many institutions now offer SRS to patients with greater than 3 metastases. The purpose of this study was to review local control and survival outcomes of patients with 4 or more BM treated with SRS.

Material and Methods: Patients with BM treated with SRS for 4 or more lesions between June 2011 and April 2015 were identified from a prospective database. Patients were deemed suitable for SRS if they had preserved Karnofsky performance status (> 70), controllable systemic disease and an estimated prognosis of > 6 months with a total intracranial metastatic volume of < 20 cm³. Local control and overall survival rates were estimated using Kaplan Meier curves.

Results: A total of 16 patients (median age 54 years) with 85 lesions were treated with primary pathology as follows: breast 3 (18.6%); lung 5 (31.3%); melanoma 6 (31.3%) and others 2 (12.5%). Median number of lesions treated was 5, with median total volume of BM per patient of 1.63cm³. Minimum follow up post SRS in all patients was 6 months. Six (37.5%) patients had received previous WBRT. Eight patients (50%) experienced distant intracranial relapse, 6 (75%) of whom had not received prior WBRT. Of these 6 patients; 3 (50%) received salvage WBRT, 2 (33.3%) were suitable for further SRS and 1 (16.7%) refused further intervention. Of the 10 patients who had not received WBRT prior to SRS, 6 had confirmed distant relapse. The median whole brain radiotherapy free survival (i.e. time from initial SRS to either salvage WBRT or death) was 6.1 months. Eleven lesions (12.9%) recurred locally after a median of 226 days (range 85 - 235) post SRS. Median overall survival was 8.3 months (range 21 - 548).

Conclusion: The median survival in this series suggests there may be a group of patients with greater than 3 metastases that could benefit from SRS. Although patient numbers are small, this data may suggest that durable whole brain free survival (an important quality of life outcome) may be achievable in patients initially treated with SRS only.

EP-1125

Survival, clinical response and prognostic factors in the reirradiation of recurrent brain tumors

M.S. Mariaquila Santoro¹, M.A.M. Maria Angela Molinaro¹, A.P. Armando Pingitore¹, L.R.F. Lucia Rachele Fabiano¹, A.C. Angelo Chirillo¹, A.S. Angela Saccomanno¹, L.P. Luigi Perrone¹, M.L. Marianna Lacaria¹, E.M. Elvira Mazzei¹, R.M. Rosa Molè¹, A.D. Anna Destito¹, D.P. Domenicantonio Pingitore¹

¹Hospital Pugliese-Ciaccio- Via Pio X- 88100 Catanzaro, Department of Hemato-Oncology- Operative Unity of Radiotherapy and Radiobiology-, Catanzaro, Italy

Purpose or Objective: The primary objective of the study is to assess the survival and quality of life after re-irradiation of relapsing malignant brain tumors. The second objective was to evaluate the influence of some prognostic factors on survival.

Material and Methods: Fifteen patients received radiation re-treatment for relapse in primary brain tumor between October 2011 and May 2015. The interval between two consecutive treatments was at least 1 year. Treatment was carried out with Conformal Radiotherapy (3D-CRT). The total dose radiation of the first treatment was 60 Gy, while the second treatment was 40-50 Gy. During follow-up, patients were evaluated at regular intervals both in taking drugs and corticosteroids for the performance status. Radiological response was evaluated by examining all available imaging

modalities, namely CT and MRI. Potential prognostic factors in survival were evaluated in the univariate analysis that multivariate analysis.

Results: An objective clinical response (ie clinical improvement) was observed in 24% of patients. Of the evaluable patients, almost one third showed a complete radiological response (8%) or partial (22%). The median overall survival (OS) and progression-free survival (PFS) after retreatment were 10.9 and 8.6 months, respectively. By multivariate analysis, we have identified four independent prognostic factors for survival: (1), the first performance status of reprocessing (P = 0.002), (2), the duration of the interval between treatments (P 0.008) (three), histology of the tumor and (4), the response to initial treatment (P values, 0.04). The median survival for patients with performance status = 0-1 and <2 was of 14.0 and 7.4 months, respectively. Patients with oligodendrogliomas showed a median OS of 27.5 months while patients with astrocytoma had a median OS of 6.9 months after retreatment. There were no long-term complications of reprocessing. Quality of life after reprocessing and to clinical progression, however, was good: all patients remained able to ambulate independently and were able to take care of itself.

Conclusion: Re-irradiation in selected patients with relapsed brain tumors seems feasible option.

EP-1126

Postoperative hypofractionated stereotactic radiotherapy to the resection cavity in brain metastases

M. Lopez Gonzalez¹, X. Chen¹, O. Hernando-Requejo¹, A. Muniz², S. Paredes³, R. Ciervide Jurio¹, A. Montero Luis¹, E. Sanchez Saugar¹, M. Garcia-Aranda¹, A. Ortiz de Mendivil⁴, J. Valero¹, C. Rubio Rodriguez¹

¹Hospital Universitario Madrid Sanchinarro - Grupo Hospital de Madrid, Radiation Oncology, Madrid, Spain

²Hospital Universitario Marques de Valdecilla, Radiation Oncology, Santander, Spain

³Hospital Clinico Universitario Lozano Blesa, Radiation Oncology, Zaragoza, Spain

⁴Hospital Universitario Madrid Sanchinarro - Grupo Hospital de Madrid, Radiology, Madrid, Spain

Purpose or Objective: Whole brain radiotherapy is the standard treatment after resection of brain metastases however due to its neurotoxicity some other treatments such as stereotactic radiotherapy are under investigation. Our purpose is to evaluate the acute toxicity and efficacy of postoperative hypofractionated stereotactic radiotherapy to the resection cavity in brain metastases.

Material and Methods: From october 2011 to september 2015, we treated and analyzed 20 patients diagnosed with intracranial metastasis who were treated by resection followed by postoperative hypofractionated stereotactic radiotherapy. All treatment decisions were based on a multidisciplinary approach, all patients signed consent form before treatment. In all cases countouring was based on MRI and CT fused images, and three different fractionation schemes were used : 7 x5 Gy (n=10), 5x6Gy(n=7) and 10x4Gy (n=3). Treatment has been performed using the Novalis ExacTrac image guided system which consists of a non invasive frame-based mask system that allows us to perform stereotactic treatments. Treatment plan was performed on lplan-net (v. 4.1) with either multiple non coplanar conformal beams or dynamic conformal arcs, using 3Dconformal radiation therapy or IMRT if it was needed. On treatment room the Novalis IGRT is based on two X-ray orthogonal images that fuse bone structures with DRR reconstructed from CT simulation scan. A Robotic 6D coach corrects with submillimeter accuracy translational both and rotational errors before treatment.

Results: The median age was 57 years. Seven patients were male and 13 female. The most frequent primary tumor was lung in 65%, followed by breast in 25%, and ovary and hepatocarcinoma in 5%. All the patients received treatment

with dexametasona during the treatment and maintained it for at least two weeks after the treatment completion. 85% of patients remained asymptomatic during treatment. 15% had grade I toxicity. Local control was achieved in 85% of patients with a median follow up of 13 months. Intracranial median free survival was 11,9 months. Median survival time was 12 months (range 1- 34months). 30% had new brain metastases who were treated with whole-brain radiation therapy or radiosurgery.

Conclusion: Stereotactic hypofractionated radiotherapy after resection brain metastasis seems feasible and well tolerated. No significant toxicity was observed. Whole brain radiotherapy can be reserved in cases of progression.

EP-1127

Combined chemotherapy and craniospinal irradiation of adults medulloblastoma and PNET tumors.

E. Nowicka¹, W. Bal¹, M. Jarzab¹, M. Gawkowska-Suwińska¹, H. Grzbiela¹, B. Bobek-Billewicz², R. Tarnawski¹

¹Center of Oncology MSC Memorial Institute, 3rd Radiotherapy and Chemotherapy Department, Gliwice, Poland

²Center of Oncology MSC Memorial Institute, Department of Radiology, Gliwice, Poland

Purpose or Objective: Medulloblastoma and central nervous system PNET are rare primary brain tumors in adults. The role of chemotherapy as a part of standard treatment in adult patients is not defined. We aimed to evaluate the toxicity and early results of combined treatment: surgery, multiagent chemotherapy followed by craniospinal irradiation in adult patient.

Material and Methods: From January 2011 to December 2014, 13 adult patients:6 women and 7 men, with medulloblastoma or PNET were treated. Median age was 30,4 years (20,8-46,7). All patients underwent surgery. There were five PNET and eight medulloblastomas, including desmoplastic variant in 2 pts, anaplastic in 1 pt, nodularis in 2 pts and the no specific type in remaining. Neuraxis MRI performed after surgery showed active tumor and spinal metastases in three pts, tumor in operated site in 5 and no signs of disease in 5 pts. There were 6 standard and 7 high risk patients. All patients were treated with multiagent chemotherapy including cisplatin, cyclophosphamide, etoposide and vincristine and received G-CSF as a primary prevention of febrile neutropenia. After chemotherapy the craniospinal irradiation was performed using conformal radiotherapy (8 pts) or tomotherapy (5 pts) with the mean dose 32,7 Gy (14,4-36 Gy) to the craniospinal axis and mean boost dose of 18,8Gy (18-23,4 Gy) to the primary tumor location. MRIs were performed after treatment to monitor response. All patients completed the whole protocol.

Results: Ten patients received 2 courses, 2 patients 3 courses and one patient received only one course of chemotherapy. Chemotherapy was given on time. The hematological toxicity of chemotherapy was: neutropenia WHO IV in 2 and WHO III in 4 pts after the first course and WHO IV in 4 and WHO III in 3 pts after the second course of chemotherapy. There was no febrile neutropenia. Radiological complete and partial response were recorded in 2 and 4 pts respectively in those with previous active disease. Two patients progressed while waiting for radiotherapy. Mean time of radiotherapy was 1,6 mo. During radiotherapy hematological toxicity was observed: leucopenia - WHO II in 5 pts that started in second week of irradiation and WHO III in 2 pts in the third and fourth week, thrombocytopenia - WHO I in 5 pts, WHO II in 3 pts and WHO III in one. Five patients required treatment interruptions with median duration of 12 days. Median overall treatment time was 6,4 mo. Median follow up was 17,9 mo. Six patients relapsed after median time of 13,1 mo, four of them locally and two disseminated via cerebral fluid. Five patients died in spite of salvage treatment. Median time of DFS and OS were 13,3 mo and 17,9 mo respectively. One and 2 year OS and DFS are 92% and 45% and 68% and 42% respectively.

Conclusion: Sequential chemotherapy and radiotherapy in adult medulloblastoma/PNET tumors is feasible with acceptable toxicity. High relapse rate in our patients indicate the need of treatment intensification with better coordination of combined therapy.

EP-1128

Outcome of high grade glioma patients: To prioritise dose to primary tumour or organs at risk?

F.C.J. YIM¹, L. Howell², S.Y.Y. Pan³, V.S. Kumar³, S.R. Kennedy³

¹University of Manchester, School of Medicine, Manchester, United Kingdom

²University of Central Lancashire, School of Health, Preston, United Kingdom

³Lancashire Teaching Hospitals NHS Trust, Rosemere Cancer Centre, Preston, United Kingdom

Purpose or Objective: Glioma is a primary brain tumour arising from the glial cells. High grade glioma, defined as grade III and IV, have poor survival rates. Glioblastoma multiforme is the commonest, but is also, the most aggressive type of glioma and is associated with a poor prognosis. Median survival of patients after treatment with debulking surgery followed by concurrent chemoradiotherapy and adjuvant chemotherapy is 14.6 months. Currently, post-operative fractionated radiotherapy is prescribed to a range of 54 to 60 Gy in fractions of 2 Gy.

Organs at risk (OARs) including optic chiasm, optic nerves and the brain stem, may lie within, or in close proximity to the PTV. Neuropathy and/or necrosis has been shown to occur when the maximum dose exceeds 55Gy in the optic chiasm and 54Gy to the whole brainstem. The standard practice at Rosemere Cancer Centre is to prioritise the OARs at the expense of the total dose, therefore prescribing to a dose of 54Gy whenever the OARs is included in the PTV, which may have repercussions on tumour control and ultimately, overall survival.

This retrospective analysis aims to compare patient outcomes between the 54Gy/57Gy and 59.4Gy/60Gy regimes, to determine if compromising the dose to spare OARs is detrimental to tumour control and survival.

Material and Methods: The data of all glioma patients treated with radiotherapy between December 2012 and December 2014 at Rosemere Cancer Centre, were collected from our electronic databases. A total of 167 patients were identified. Patients with low grade glioma and those treated with a palliative intent were excluded. Fifty eight patients were included in the analysis.

Results: Twenty one patients were on a lower dose radiotherapy regime of 54Gy or 57Gy. The remaining 37 were on a higher dose regime of 59.4Gy or 60Gy. There was a statistically significant difference ($p=0.05$) in patients treated with the higher dose regime comparatively, of an additional 7.2 months median overall survival (mOS) benefit. The mortality hazard for the higher dose regime is 37% lower than the lower dose regime.

Conclusion: The outcome of patients treated with the 59.4/60Gy dose regime has shown to be statistically significant with a mOS benefit and lower mortality hazard. It is therefore clear that maintenance of the higher dose (59.4/60Gy) should be a priority, either at the expense of the OARs or to as much of the tumour volume as possible, whilst still observing the OARs constraints.

EP-1129

Pre and post-irradiation hypothalamic-pituitary axis dysfunction in adults treated for brain tumours

N. Taku¹, A. Powlson², M. Romanchikova³, A. Hoole³, A. Bates¹, J. Hale², R. Jena¹, M. Gurnell², N. Burnet¹

¹Addenbrooke's Hospital - University of Cambridge, Department of Oncology, Cambridge, United Kingdom

²Addenbrooke's Hospital - University of Cambridge, Institute of Metabolic Science, Cambridge, United Kingdom

³Addenbrooke's Hospital - University of Cambridge, Department of Medical Physics, Cambridge, United Kingdom

Purpose or Objective: Collateral irradiation of normal structures during whole brain radiotherapy increases the risk of secondary toxicities, including dysfunction of the hypothalamic-pituitary axis (HPA). In studies of children treated for intracranial neoplasms, Merchant et al. showed that upwards of 66% of patients had pre-irradiation endocrinopathies and that HPA dosimetry data can be used to predict the dose-volume effects of radiation on growth hormone (GH) secretion. However, no comparable endocrine studies have been performed in adult populations. Evidence exists to suggest that hypopituitarism is an independent risk factor for mortality in adults treated with whole brain radiotherapy. Increased collaboration between radiation oncologists and endocrinologists is needed to amalgamate dosimetry data with the results of endocrine testing and better characterize HPA dysfunction. The purpose of this study is to determine the presence of baseline HPA dysfunction as well as the time to onset and dose-dependence of post-irradiation HPA dysfunction in adults treated for non-pituitary brain tumours.

Material and Methods: Twelve patients, 3 males and 9 females, have been enrolled in our prospective clinical study that will continue to recruit until 2017. Primary diagnoses included meningioma (7), pineal tumor (3), and glioma (2). Median patient age is 52 (range 23-71). Enrolled patients have undergone comprehensive baseline endocrine testing of the thyroid, gonadotropins, cortisol, prolactin, and GH prior to initiation of radiotherapy. Patients have received daily image guidance imaging with positional correction and 50-60 Gy of radiation to the tumour bed. Parametrisation of available dosimetry data was performed to determine the maximum, minimum, and mean radiation doses. Endocrine testing is being repeated at 6 month intervals following radiotherapy. Patient reported outcome measures are also collected during follow-up encounters. Reviewing endocrinologists have been blinded to dosimetry data.

Results: Three patients (25%) demonstrated pre-irradiation endocrinopathies, including 2 cases of primary hypothyroidism and 1 case of primary hypogonadism. Furthermore, one patient exhibited temporary HPA suppression secondary to exogenous steroid use. Median length to endocrinology follow-up is still short at only 3 months (range 0-18). We present analyzed dose data for 10 of the 12 patients. Mean radiation doses to the hypothalamus and pituitary were 35 Gy (range 20-55) and 31 Gy (range 13-50), respectively. No cases of new, radiation-related HPA dysfunction have been identified to date.

Conclusion: The incidence of pre-irradiation HPA dysfunction underlines the need for baseline endocrinology studies. The range of radiation doses to the HPA should allow for identification of dose-volume responses.

EP-1130

Hair-sparing whole brain radiotherapy with simultaneous integrated boost using high density bolus

S. Velázquez Miranda¹, E. Montero-Perea², R. Dorado-Dorado¹, M. Rubio²

¹Hospital Universitario Virgen Rocío, Radiofísica, Sevilla, Spain

²Hospital Universitario Virgen Rocío, Radioterapia, Sevilla, Spain

Purpose or Objective: Present and retrospectively evaluate our protocol of WBRT + SIB regarding radiation-induced alopecia

Material and Methods: We use masks type 35764 / ZMA / M Orfit a subnet mask with eXaskin and compatible base resonance (eXaFrame). A similar number of slices is used in the images of CT and MRI, both acquisitions with identical position and immobilization and slice thickness of 1 mm. This is possible thanks to eXaFrame, resulting in excellent quality

fusion. The treatment was designed with SmartArc with multiple arches made with Synergy. The dosage regimen used is Lagerwaard one: [RCT (20 Gy) + SIBmts (40 Gy)] / 5 frac. Positioning of the patient was checked daily with conebeam. Before starting the optimization we must be contoured 3mm ring around the calote we call follicles, and a contraction of the outer contour of 12mm we call volume CPE. We define two arcs (VMAT CCW 178 ° -60 ° and 300 ° -182 °), with the following objectives: follicles (DSEmax = 16 Gy, weight = 20; DSEmax = 5 Gy, weight = 1), brain-CPE (Dmax = 21Gy, weight = 100 and Dmin = 20 Gy, weight = 50), eyes (Dmax = 10 Gy, weight = 1). Later, we focus on separate metastases: optimization blocked prophylaxis (Optimization Type None) and create three structures: VI1 = PTV (MTS1) 5 mm VI2 = PTV (m2) 5 mm Epx = brain-VI1-VI2 . The objectives were PTVI (Dmax = 44Gy, despite Dmin = 100 and = 40 Gy weight = 50), Epx (Dmax = 30 Gy) and brainstem (Dmax = 23Gy), follicles (DSEmax = 16 Gy, weight = 20 ; DSEmax = 5 Gy, weight = 1)

Verifying treatment was performed with the Compass software, and the Matrixx detector with gamma (4%, 1 mm) conditioning.

Results: So far we have treated 15 patients, the differences in the images of fusion of less than 1 mm and the average correction IGRT of 1.24mm. No acute toxicity. Nor alopecia, or temporary removal,

Conclusion: If we consider our VMAT optimization alopecia in WBRT + SIB with eXaFrame and eXaSkin, produce optimal aesthetic results.

EP-1131

Hypofractionated Radiotherapy with temozolomide in poor prognosis glioma: a retrospective study

E. Pelle¹, E. Trino¹, M. Levis¹, M. Magistrello², C. Mantovani¹, U. Ricardi¹

¹University Of Turin, Radiotherapy, Turin, Italy

²University Of Turin, Neuro-Oncology, Turin, Italy

Purpose or Objective: To describe clinical outcomes of hypofractionated radiotherapy, either in combination or not with temozolomide (TMZ) in poor performance status glioblastoma (GBM) patients

Material and Methods: We retrieved the charts of 96 patients treated with hypofractionated radiotherapy plus/minus TMZ for GBM at our Institution

Results: Patients characteristics were summarized in Table 1.

Variables	N (%)
Total	96
Gender	
Female	41 (42,7%)
Male	55 (57,3%)
Age at diagnosis (years)	
Median	66
Range	25-81
≥ 65	53 (55.2%)
KPS at presentation	
< 70	26 (27.1%)
≥ 70	70 (72.9%)
Extent of surgical resection	
Gross total resection	4 (4.2%)
Partial resection	66 (68.8%)
Biopsy	26 (27.1%)
Type of adjuvant treatment	
Short-course radiotherapy alone	57 (59.4%)
Short-course RT plus concomitant TMZ	7 (7.3%)
Short-course RT plus concurrent and adjuvant TMZ	12 (12.5%)
Short-course RT followed by adjuvant TMZ	20 (20.8%)
Patients on corticosteroids	
Yes	16 (16.7%)
No	80 (83.3%)

Among elderly patients, 38 (71.6%) were treated with RT alone, 9 patients (16.9%) with adjuvant TMZ, while 6 patients (11.3%) with a KPS ≥70 received hypoRT plus concurrent TMZ, followed by adjuvant chemotherapy in 3 (5.6%) of these cases. The median follow up time of the entire cohort was 13.6 months (range 1-47 months). A significant improvement in KPS from baseline to the end of radiation therapy was observed in 73 patients (76%). The median overall survival time was 6.7 months, reducing to only 2.5 months and 4 months respectively in elderly and younger patients with low performance status (KPS<70). The 6 months and 1 year survival rates were respectively 56.4% and 29.1%. In multivariate analysis, concomitant Temozolomide (HR:0.38, 95% CI 0.16-0.85, $p=0.020$) and adjuvant TMZ (HR:0.28, 95% CI 0.14-0.56, $p=0.000$) emerged as significant indices of longer OS rates, while weaning from steroids ($p=0.18$), extent of surgical resection ($p=0.17$) and tumor site ($p=0.10$) were not significant predictors of overall survival but showed a positive trend. Patients who received concomitant TMZ had a median survival time of 12.5 months compared with 6.3 months for those treated with RT alone ($p=0.017$). Also the use of adjuvant chemotherapy resulted in improved survival compared to no sequential Temozolomide (10.8 vs 5.2 months, $p=0.001$). In the elderly cohort, patients treated with adjuvant TMZ had median OS of 8.15 months as opposed to 6.4 months of those not receiving adjuvant chemotherapy ($p=0.001$). A stronger impact of adjuvant TMZ has been reported in younger patients, with a median OS of 13.5 months in adjuvant TMZ group compared to 3.7 months ($p=0.001$) in the other group. Moreover, younger patients receiving concurrent Temozolomide showed a significantly longer OS of 20 months compared to 5.1 months in patients not having TMZ ($p=0.006$). Acute tolerance to radiotherapy was generally good. No grade 3-4 acute toxicity was observed.

Conclusion: Our findings seem to suggest that frail elderly patients with KPS at baseline < 70 do not benefit of an active treatment and could be carefully offered best supportive care. In the presence of a good functional status and a wide surgical resection, patients older than 65 years may take advantage of hypo-fractionated radiotherapy, followed by adjuvant TMZ. In younger patients with poor performance status, the significant survival gains obtained with combined modality treatment suggest that a maximum resection followed by combined radiation and chemotherapy should be recommended.

EP-1132

Application of IMRT technique in treatment of malignant gliomas: assessment of treatment tolerance

K. Urbanek¹, A. Mucha-Malecka¹, P. Hebzda¹, K. Kisielewicz², K. Matecki³, E. Góra², J. Jakubowicz⁴

¹Centre of Oncology - Institute MSC Kraków, Head and Neck Cancer, Krakow, Poland

²Centre of Oncology - Institute MSC Kraków, Medical Physics, Krakow, Poland

³University Children's Hospital of Cracow, Radiotherapy of Children and Adults, Krakow, Poland

⁴Centre of Oncology - Institute MSC Kraków, Clinic of Oncology, Krakow, Poland

Purpose or Objective: Assessment of tolerance of combined modality therapy of patients with malignant gliomas irradiated using IMRT technique. We compared dose distribution in IMRT and conformal 3D treatment plans.

Material and Methods: Between 2009 and 2013 in the Oncology Center in Krakow 60 patients with malignant gliomas received combined modality treatment. Mean age was 53 years (range 24-72 years). All patients were in good performance status (WHO 0-1). There were 48 patients with glioblastoma multiforme and 12 with anaplastic astrocytoma. 48 patients underwent complete resection and 12 partial resection. Patient were irradiated using IMRT technique with a total dose of 60Gy in 30 fractions. All patients concurrently received temozolamide in the dose of 75mg/m2. In all patients we performed additional plans using 3D conformal

radiotherapy (3D-CRT) techniques and compared with IMRT plans. The 3D-CRT plans were prepared using 3-4 fields and IMRT plans consisted of 7-8 fields. The primary objective was to treat the planning target volume and to minimize the dose to organs at risk (OAR). Volumetric analysis, target coverage and conformity of prescribed doses were used in plan comparison.

Results: Treatment tolerance was very good in all patients. Only 12 patients needed steroids during treatment. Adjustment of the dose distribution to the target volume was improved and the critical structures were better spared in the IMRT plans than in 3D-CRT plans. For all patients the mean dose and the maximum dose to OAR were significantly reduced in IMRT plans. With respect to target volume, IMRT technique reduced the maximum dose while increasing the minimum dose, resulting in improved conformity. In same patients with tumors located very close to OAR it was impossible to give 60Gy for target volume with 3D-CRT technique because of not acceptable doses in OAR.

Conclusion: The IMRT technique combined with concurrent temozolamide is well tolerated and offers significant advantages comparing to 3D-CRT. Application of IMRT allows dose reduction at OAR without compromising target coverage.

EP-1133

Long-term follow-up and prognostic factors in low-grade glioma (WHO II) postoperatively irradiated.

K. Urbanek¹, A. Mucha-Matecka¹, K. Matecki², A. Chrostowska¹, J. Jakubowicz³

¹Centre of Oncology - Institute MSC Kraków, Head and Neck Cancer, Krakow, Poland

²University Children's Hospital of Cracow, Radiotherapy of Children and Adults, Krakow, Poland

³Centre of Oncology - Institute MSC Kraków, Clinic of Oncology, Krakow, Poland

Purpose or Objective: There is little consensus about the optimal treatment for low-grade glioma (LGG), and the clinical management of LGG is one of the most controversial areas in neurooncology. Radiation therapy is one option for treatment of patients with LGG whereas other options include postoperative observation. The aim of the study is to report the long-term follow-up of a cohort of adult patients with LGG post-operatively irradiated in one institution, and to identify prognostic factors for progression free survival.

Material and Methods: Between 1975 and 2005, 180 patients with LGG (WHO II) received postoperative irradiation after non radical (subtotal or partial) excision. Patients had to be 18 years of age or older, and have histologic proof of supratentorial fibrillary (FA), protoplasmic (PA) or gemistocytic astrocytoma (GA). Radiotherapy was given within 3 to 10 weeks after surgery. The treatment fields were localized and included the preoperative tumor volume, with a 1-2 cm margin, treated to a total dose of 50 to 60 Gy in 25 to 30 fractions over 5 to 6 weeks.

Results: Actuarial ten- year progression free survival (APFS) in the whole group was 19% . The worse prognosis was reserved for patients with GA. Ten-year APFS rates for GA, PA and FA were 10%, 18% and 22% respectively.

Conclusion: The findings from our long-term cohort of 180 patients with LGG confirmed by uni- and multivariate analysis demonstrated that only astrocytoma histology significantly determined the prognosis. The best survival is reserved for patients with the fibrillary variant, and the worst for the gemistocytic one.

EP-1134

Proton therapy re-irradiation for large-volume recurrent high-grade gliomas

D. Amelio¹, L. Widesott¹, F. Maines², F. Fellin¹, R. Righetto¹, S. Vennarini¹, B. Rombi¹, M. Cianchetti¹, F. Dionisi¹, D.

Donner³, U. Rozzanigo⁴, M. Schwarz¹, F. Chierichetti³, E. Galligioni², M. Amichetti¹

¹Centro di Protonterapia, U.O. Protonterapia- Azienda Provinciale per i Servizi Sanitari - Trento, Trento, Italy

²Ospedale S. Chiara, U.O. Oncologia Medica- Azienda Provinciale per i Servizi Sanitari - Trento, Trento, Italy

³Ospedale S. Chiara, U.O. Medicina Nucleare - Azienda Provinciale per i Servizi Sanitari - Trento, Trento, Italy

⁴Ospedale S. Chiara, U.O. Radiologia - Azienda Provinciale per i Servizi Sanitari - Trento, Trento, Italy

Purpose or Objective: To report preliminary results of re-irradiation with proton therapy (PT) for large-volume recurrent high-grade gliomas (rHGG).

Material and Methods: Between January and September 2015 eight patients (pts) with rHGG (7 glioblastoma - GBM, 1 anaplastic oligodendroglioma - AOD) were re-irradiated with PT. Age at re-irradiation was between 40 and 64 years while Karnofsky performance status was 60-100%. Minimum time between prior radiotherapy and PT was 8 months. Target definition was based on CT, MR, and 18F-DOPA PET imaging. GTV included any area of contrast enhancement at MR imaging after contrast medium administration plus any uptake regions at PET imaging. CTV was generated by adding to GTV a 3-mm uniform margin manually corrected in proximity of anatomical barriers. CTV was expanded by 4 mm to create PTV. PTV volume varied between 55 and 260 cc. The patient with AOD received 50.4 GyRBE in 28 fractions (fx) while GBM pts 36 GyRBE in 18 fx. Four GBM pts also received concomitant temozolomide (75 mg/m²/day, 7 days/week). All pts were treated with active beam scanning PT using 2-3 fields with single field optimization technique.

Results: All pts completed the treatment without breaks. Registered acute side effects (according to Common Terminology Criteria for Adverse Events versione 4.0) include skin erythema with pruritus, alopecia, fatigue, conjunctivitis, and headache. All the side effects were grade 1 or 2. There were no grade 3 or higher toxicities. One patient developed grade 1 neutropenia. Three pts started PT under steroids (2-8 mg/day); two of them reduced the dose during PT, one kept the same steroids dose. None of remaining pts needed steroids therapy. During follow-up two pts developed radionecrosis (diagnosed at imaging) with mild symptoms controlled with steroids. All pts are alive. Four pts have stable disease one months after PT, three pts have stable disease three months after PT, and one pts progressed five months after PT.

Conclusion: PT re-irradiation of large volume rHGG is feasible and safe even with concomitant chemotherapy administration. Longer follow-up is necessary to assess definitive efficacy.

EP-1135

Hypofractionated Stereotactic Radiation Therapy for cavernous sinus meningiomas

F. Meniai-Merzouki¹, B. Coche-Dequèant¹, T. Boulanger², F. Crop³, T. Lacornerie³, E. F.Lartigau¹

¹Centre Oscar Lambret, Radiation Oncology, Lille, France

²Centre Oscar Lambret, Radiology Imaging Department, Lille, France

³Centre Oscar Lambret, Medical Physics, Lille, France

Purpose or Objective: We evaluate the tolerance and efficiency of robotic hypo fractionated stereotactic radiotherapy (hSRT) for patients with Cavernous sinus meningiomas in our Institution.

Material and Methods: We retrospectively reviewed patients who were treated with robotic hSRT for Cavernous sinus meningioma. Multidisciplinary staff approved treatment. A dose of 36 Gy was prescribed in 9 fractions. Treatment was delivered every other day.

Results: Between 2010 and 2013, 18 evaluable patients with a total 18 lesions were treated in our institution with hSRT

with median follow up of 18 months (6-40 months). Six patients had prior surgical resection of tumor, 12 received treatment as first line. The majority (60 %) of lesions were close to the optic pathway with median values for GTV volume was 9,4 cm³ (0,38-55,66 cm³). The control rates at low years were favorable with stable disease in 100 % patients, vision was preserved and improved symptoms in 65% patients. We observed no grade 3 or 4 toxicity. The most frequent being grade 1 retro-orbital pain (20%). No late toxicity was reported and no death during the follow - up period.

Conclusion: Robotic Hypo-fractionated stereotactic radiotherapy for Cavernous sinus meningioma is feasible and provides a satisfactory local control with acceptable tolerance, either as a first line treatment or as adjuvant to incomplete surgery or relapse. Although this type of tumor has a slow evolution, extended follow-up is mandatory.

EP-1136

Treatment with radiosurgery (stereotactic radiotherapy) in single session in brain metastases

P. Vargas Arrabal¹, J. Expósito¹, I. Tovar¹, M. Zurita¹, R. Del Moral¹, R. Guerrero¹, I. Linares¹, C. Prieto¹, S. Rodríguez¹, A. Ruiz¹

¹Hospital Universitario Virgen de las Nieves, Radiation Oncology, Granada, Spain

Purpose or Objective: Until the advent of stereotactic radiotherapy, the main treatment option consisted of cranial radiation for palliation. With a more radical intent, and only in selected patients, surgical resection and adjuvant radiotherapy was indicated later. The purpose of this study is to evaluate the results obtained after treatment with single-session radiosurgery.

Material and Methods: Between 2002 and 2014, has collected a representative sample of 592 patients with histological diagnosis of brain metastases, of which 340 were men and 252 women. The average age in this group was 55.67 years (14-82 years) and with a KPS of 90 in 58.3% of patients. The most common location of these was lung 51%, followed by 17.1% mom. The most frequent pathological study adenocarcinoma was 23.5%, followed by squamous 10.6%. In most 63.2% no surgery was performed. The most common site was the frontal 24.4%. All patients were treated with radiosurgery (stereotactic radiotherapy) single session with a median dose of treatment of 18 Gy.

Results: With a median follow-up of 7 months, median survival was 14.23 months in a range of 0-117 months. In terms of toxicity, only 3.5% of the presented radiation necrosis (21 patients), while the cerebral edema was reported in 10.8% (64 patients).

Conclusion: The single session radiosurgery is a conservative but with a radical purpose, offering technical and few side effects is very convenient for the patient.

EP-1137

Volumetric Modulated Arc Therapy (VMAT) and simultaneous boost for brain metastases patients

A. Papaleo¹, D. Russo¹, E. Donno¹, E. Cavallera¹, F.P. Ricci¹, G. Di Paola¹, M. Santantonio¹

¹Vito Fazzi Hospital ASL LE, Radiation Oncology, Lecce, Italy

Purpose or Objective: To access treatment toxicity and patients' survival after Volumetric Modulated Arc Therapy, a novel rotational Intensity Modulated RadioTherapy (IMRT) technique, with Simultaneous in-field Boost (SIB) for patients with brain metastases.

Material and Methods: Between November 2010 and March 2015, 26 patients with 1-3 brain metastases were treated with SIB-IMRT in the Department of Radiation Oncology at V. Fazzi Hospital (maximum diameter of largest metastasis: 3 cm, KPS ≥ 70, RPA < III). Mean age was 61 ± 7.5 years. Patients were neurologically stable. Extracranial disease

well-controlled (6-month estimated median life expectancy). Patients will undergo contrast-enhanced TC scan of the brain for radiotherapy planning purposes. The macroscopic (gross) tumor volume (GTV) was drawn on the MRI images. The prescription isodose line was generally 3 mm larger than the GTV. Patients will be treated with WBRT/SIB using VMAT, delivering a total of 30 Gy in 10 fractions to the whole brain and SIB doses to brain metastases were 40 Gy to lesions >or= 2.0 cm and 50 Gy to lesions <2.0 cm in diameter, delivered once daily on working days. Following therapy completion, patients will be seen every 3 months for the 1st year, then every 6 months thereafter. Patients will have MRI brain at 3 months and 1 year, and every 6 months after the first year. Any toxicity was recorded according to the RTOG.

Results: The median follow-up interval was 9 months (range, 2 months- 16 months). The median overall survival time was 11 months, and 3 of patients died of disease progression. The 6-month overall survival was 91%. After SIB-IMRT treatment of 42 brain lesions, 35 lesions demonstrated complete responses, 5 lesions demonstrated partial responses, 2 lesion demonstrated stable disease. Actuarial local tumor control rates at 6 months, 1 year and 2 years were 93.9, 82% and 54%, respectively. Thirty-eight patients did not have any adverse events >grade1. The majority of common adverse events were grade 2 headaches (4 patients), grade 2 motor neuropathy (2 patients), and grade 2 lethargy (2 patient). One patient developed a grade 3 headache 5 months after receiving SIB-IMRT.

Conclusion: The delivery of 40/50 Gy in 10 fractions to 1 - 3 BM using VMAT provides a high level of tumor control with minimal toxicity. Therefore, we believe there is a need for a larger prospective study to establish dosing guidelines for SIB-IMRT and to pave the way for a randomized trial to compare SRS/STS plus WBRT with this approach.

Electronic Poster: Clinical track: Haematology

EP-1138

Evolution of radiation techniques in the treatment of mediastinal lymphomas: single center experience

N. Besson¹, S. Zefkili¹, V. Pernin¹, S. Horn¹, D. Peurien¹, N. Fournier Bidoz¹, Y. Kirova¹

¹Institut Curie, Radiothérapie, Paris, France

Purpose or Objective: To evaluate radiation techniques in the treatment of Hodgkin's Lymphoma (HL) and Non-Hodgkin's Lymphoma (NHL) with mediastinal disease over 10-year period, and the toxicity.

Material and Methods: Between 2003-2015, 173 patients (pts) with stage I-III nodal lymphoma were treated in our institution: some of these patients were irradiated for HL or NHL with mediastinal disease. Some of the patients were treated by 3DCRT, others by IMRT

Results: We studied 26 men and 43 women with a median age of 26 years. The median follow-up was 43 months. Forty nine pts were treated by 3DCRT and 20 pts-by IMRT. The median dose received by patients treated for NHL was 40 Gy (range: 36-44 Gy) and the median dose received by pts with HL was 30 Gy (range: 30-36 Gy). Between 2003-2006, 16 pts were treated by 3DCRT vs. 0 by IMRT. Between 2007-2009, 16 pts received 3DCRT and 1-IMRT. Between 2010-2015, 19 pts received IMRT, and no patients 3DCRT. Eleven of the 20 patients (55%) treated by IMRT and 35/49 pts (71.4%) treated by 3DCRT experienced acute toxicity. Among the patients treated by 3DCRT, 1 patient experienced grade 1 radiation pneumonitis and 2 patients experienced grade 1 acute mucositis. No late toxicity was observed in the patients treated by IMRT.

Conclusion: Improvement of radiation techniques for HL and NHL appears to have improved acute and late clinical safety. Longer follow-up is necessary to evaluate very late toxicity.

EP-1139

Clinical results of radiation therapy for localised gastric lymphoma

H. Ihara¹, K. Katsui¹, K. Hisazumi¹, N. Katayama¹, M. Takemoto², M. Iwamuro³, Y. Kawahara³, H. Okada³, S. Kanazawa¹

¹Okayama University Hospital, Radiology, Okayama, Japan

²Japanese Red Cross Society Himeji Hospital, Radiology, Okayama, Japan

³Okayama University Graduate School of Medicine- Dentistry- and Pharmaceutical Sciences, Gastroenterology and Hepatology, Okayama, Japan

Purpose or Objective: To report the outcome of localized gastric lymphoma treated with radiation therapy.

Material and Methods: This study included 27 patients (14 men, 13 women; median age 67 years, range 37 - 83 years) with localized gastric lymphoma and who received radiation therapy between January 2005 and December 2014 at our institution. Patients with a follow-up period < 6 months were excluded. Twenty-three patients were mucosa-associated lymphoid tissue (MALT) lymphoma, and 4 patients were diffuse large B-cell lymphoma (DLBCL). The stage was classified by Lugano international conference classification. All patients with MALT lymphoma were Stage I. In DLBCL, 2 patients were Stage I, and 2 patients were Stage II. The median radiation dose in MALT lymphoma was 30Gy (range, 7.5-30), and in DLBCL was 40.5Gy (range, 30-40.5). All MALT lymphoma patients with *Helicobacter pylori*-positive were received eradication therapy before radiation therapy. All patients with DLBCL were treated with chemotherapy followed by radiation therapy. Acute and late adverse events were evaluated in accordance with Common terminology criteria for adverse events, version 4.0. The local recurrence rate was calculated using Kaplan-Meier analysis.

Results: The median follow-up period was 58 months (range, 6.0-120.0). Local recurrence occurred in only 2 patients with MALT lymphoma. No distant recurrence was observed. Local recurrence rate in MALT lymphoma was 91% at 1 year, 91% at 3 years. In acute adverse events, 5 patients had grade 3 white blood cell decreased, 1 patient had grade 4 white blood cell decreased and platelet count decreased, and 1 patient had grade 3 anorexia. One patient with MALT lymphoma could not achieve the planned radiation therapy because of grade 4 white blood cell decreased and platelet count decreased. There was no grade 3 or greater late adverse events. One patient with MALT lymphoma suffered from gastric cancer, and underwent endoscopic excision. No patients died of gastric lymphoma. One patient died of lung cancer.

Conclusion: Radiation therapy for localized gastric lymphoma was safe and effective. Our result was similar to previous reports.

EP-1140

Role of radiotherapy in treatment of Hodgkin and non Hodgkin lymphomas - our experience

D. Scepánovic¹, A. Masarykova¹, M. Pobijakova¹, M. Fekete¹, A. Hanicova¹, M. Masar¹, Z. Dolinska¹

¹National Cancer Institute, Radiation Oncology, Bratislava, Slovakia

Purpose or Objective: Radiation therapy (RT) is an important component of therapy for patients with Hodgkin (HL) and non Hodgkin lymphomas (NHL).

In our retrospective analyze we showed the role of radiotherapy in treatment of lymphomas and its influence on disease free (DFS) and overall survival (OS) of patients.

Material and Methods: From 2000 to 2010, we treated 347 patients (pts) with lymphomas (Hodgkin - 286 and non Hodgkin - 61). There were 24 pts with stage I, 186 with stage II, 40 with stage III and 36 pts with stage IV of Hodgkin lymphoma. Among group of pts with non Hodgkin lymphoma

there were 20 pts with stage I, 17 with stage II, 7 with stage III and 17 pts with stage IV. Sixty-nine percent of pts had favorable HL and 81% of pts nodular sclerosis as histological type. Sixty-four percent of pts with NHL had aggressive disease. Three dimensional conformal radiotherapy has been planned by computed tomography (CT) alone or by 18-FDG positron emission tomography/CT (18-FDG PET/CT). Mostly, patients received chemotherapy (95%) before RT. However, 67% of pts with NHL did not receive rituximab. Whole group of our pts have been irradiated by involved field radiotherapy (IFRT). Most of patients received 36Gy (1.8-2Gy daily) (71%) and 29% more than 36Gy, in both groups.

Results: Median follow-up time was 8 years. Among patients with HL, 33 pts (12%) had relapse and 11 pts (18%) with NHL. Relapses occur most often outside of irradiated volume in both groups of pts. Twenty five percent with HL patients had toxicity, most commonly pulmonary and 7% pts with NHL. During the median time of 13.5 years the incidence of a secondary malignancies (SM) was 3% in pts with HL and 2% with NHL. In group who had HL 91% of these pts lived and 74% in group with NHL. Ten-years DFS was 89% (HL) and 74% (NHL) and 10-years OS was 91% (HL) and 82% (NHL).

Conclusion: Radiotherapy had an important place in the treatment of our patients with HL, as well as in a group of NHL with acceptable toxicity and incidence of secondary malignancies.

EP-1141

Second cancer in Primary Mediastinal Lymphoma treated with MACOP-B ± R and mediastinal radiotherapy

V. De Sanctis¹, M. Alfò², A. Di Rocco³, A. Ansuinelli³, E. Russo³, M. Osti¹, M. Valeriani¹, G. Minniti¹, L. Grapulin⁴, D. Musio⁴, S. Bracci¹, A. Spagnoli¹, M. Moleti³, V. Tombolini⁴, M. Martelli³

¹Sapienza Università di Roma, Department of Medicine and Surgery and Translational Medicine, Rome, Italy

²Sapienza Università di Roma, Department of Statistical Sciences, Rome, Italy

³Sapienza Università di Roma, Department of Cellular Biotechnologies and Hematology, Rome, Italy

⁴Sapienza Università di Roma, Department of Radiological-Oncological and Anatomic-pathological Sciences, Rome, Italy

Purpose or Objective: To assess the incidence of second cancer in a mono-institutional cohort of long-time surviving Primary Mediastinal B Cell Lymphoma (PMBCL) patients treated with combined radio-chemo-immunotherapy.

Material and Methods: Between 1991 and December 2006, 107 consecutive untreated patients (pts) with PMBCL were treated at our Departments. Ninety-two/107 pts were evaluable for the second cancer incidence. All patients were treated with standard Methotrexate, Adriamycin, Cyclophosphamide, Vincristine, Prednisone and Bleomycin (MACOP-B) ± Rituximab; all patients underwent mediastinal radiation therapy (RT) at a dose of 30-36 Gy.

Results: At the end of combined treatment, the overall response rate (ORR) including CR+Cru/PR was 91.3% while 7 (7.6 %) patients showed progressive disease. Nine/84 (9.7%) patients relapsed within 10 months (range 3-10 months) from the end of therapy. After a median follow-up of 142 months (1-212 months), the actuarial 15-year OS and PFS were 87% and 84%, respectively. We recorded secondary malignancies in 3/80 long-surviving patients (3.75%) with cumulative incidence of thyroid and A acute myeloid leukemia of 3.47 at 15 years and with a 20-year second cancer-free survival of 82%. We observed 2 papillary thyroid cancers with a Standardized Incidence Ratio of 7.97 and with an Absolute Excess Risk of 17.84. Moreover, we observed 1 Acute Myeloid Leukemia (AML) versus 0.015 expected cases with a SIR of 66.53 and with an AER of 10.05. No breast cancer occurred

Conclusion: Combined modality treatment of chemotherapy± with/without Rituximab and mediastinal RT was related to a

statistically significant SIR and AER for thyroid cancer and acute myeloid leukemia.

EP-1142

Role of radiotherapy(RT) in patients undergoing haemopoietic stem cell transplant(HSCT) for lymphoma

M. Singhera¹, M. Kazmi², N. Mikhaeel¹

¹Guy's and St Thomas' NHS Foundation Trust and King's Heath Partner's Academic Health Sciences Centre, Radiotherapy, London, United Kingdom

²Guy's and St Thomas' NHS Foundation Trust and King's Heath Partner's Academic Health Sciences Centre, Haematology, London, United Kingdom

Purpose or Objective: Despite the use of RT before or after salvage haemopoietic stem cell transplant for relapsed and refractory lymphoma, the indications, timing and benefit of radiotherapy are not well established and it is unlikely that these questions will be tested in a randomised study. We present the outcomes of a retrospective analysis of the benefit of radiotherapy given before or after HSCT for lymphoma.

Material and Methods: We reviewed our transplant and radiotherapy databases to identify patients. Inclusion criteria were patients who underwent HSCT from 2004-2010 for refractory or relapsed lymphoma. Primary end point was progression-free survival (PFS) and secondary end point was overall survival (OS). Risk of relapse and death was compared for those who received radiotherapy and those who did not using Cox' proportional hazards ratio using age at diagnosis as an independent predictor. Rates of death were analysed using Fisher's exact test.

Results: We identified 330 patients who underwent HSCT from 2004-2010 for relapsed lymphoma. 72 patients had Hodgkin's and 258 patients had non-Hodgkin's lymphoma. The median age at diagnosis was 46.5 years (14.6-72 years). The median age at transplant was 50.6 years (17.4-73.2 years). 121 patients (36%) underwent an allogeneic and 209 patients (64%) underwent an autologous transplant. Median follow-up was 1.8 years (0.0-10.0 years).

94 patients (28%) underwent radical RT before or after transplant (excluding TBI). 58 patients underwent radiotherapy before HSCT and 36 subsequent to HSCT. Of those who underwent RT before HSCT 64% were in remission going to HSCT compared with 75% of those who received RT after HSCT. There was a trend towards a shorter PFS for those who did not receive RT (HR1.72, 95% CI 0.96-3.67). There was no difference in mortality at 3 years between the two groups (p=0.78). There was no difference in OS between the two groups (HR=0.98, 95% 0.67-1.56). We are currently analysing the pattern of relapse and the impact of different variables on relapse and overall survival.

Conclusion: Peri-transplant RT seems to offer a progression free survival benefit in patients with relapsed/refractory lymphoma undergoing HSCT although confirmation is required.

EP-1143

Splenic irradiation as treatment modality in neoplastic hematological disorders

L. Diaz Gómez¹, A. Seguro Fernandez², J. Jaen Olasolo¹, I. Villanego Beltran¹, V. Diaz Diaz¹, E. Gonzalez Calvo¹, L. Ingunza Baron¹, L. Gutierrez Bayard¹, M.C. Salas Buzon¹, S. Garduño¹

¹Hospital Universitario Puerta del Mar, Department of Radiation Oncology, Cadiz, Spain

²H.U. Rey Juan Carlos, Medical Physics, Mostoles Madrid, Spain

Purpose or Objective: Splenic irradiation has been used as first treatment for several hematological neoplasm, including chronic leukemia or myeloid malignancies, but with the availability of new drugs its application was restricted. In selected cases, not only with palliative intentions, irradiation can be useful treatment modality

Material and Methods: Our study included 11 patients: 5 with chronic lymphocytic leukemia, 5 with high-grade B-cell lymphoma and 1 with diagnose of polycythaemia Vera. In 5 patients the treatment was with radical intention (all of them with high grade lymphoma) and the rest were palliatives as treatment of pain or normalization of red blood cell that allows more time between transfusions. The doses were generally low with range between 5 and 10 Gy in 0.5Gy daily fractions because doses higher than 10Gy did not provide benefits according to literature.

Results: We got 5 complete responses confirmed by PET but after 2 years 2 of them relapsed and were treated with radiotherapy again with the same scheme and obtain the same response to the present day. In terms of palliative intention, splenic irradiation provided a relief of pain from 6 to 12 months, and in 4 patients the disease progressed without new splenic symptoms. One patient received 3 courses of radiotherapy for painful splenomegaly with a gap of 12, 9 and 6 months without acute toxicity and died due to non-splenic leukemia progression.

Conclusion: In selected patients who are not responsive, not suitable for systemic treatment or palliatives, splenic irradiation can be an efficient therapy with little toxicity and sustained response over time. f of pain from 6 to 12 months, and in 4 patients the disease progressed without new splenic symptoms. One patient received 3 courses of radiotherapy for painful splenomegaly with a gap of 12, 9 and 6 months without acute toxicity and died due to non-splenic leukemia progression.

EP-1144

Clinical outcomes according to molecular subtypes in locally advanced breast cancer patients

H. Kim¹, W. Park¹, S.J. Huh¹, D.H. Choi¹, J.M. Noh¹

¹Samsung Medical Center, Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: We evaluated the tumor response and clinical outcomes according to molecular subtypes in locally advanced breast cancer patient who received neo-adjuvant chemotherapy (NAC) followed by surgery and radiotherapy.

Material and Methods: We retrospectively reviewed 400 patients with clinical stage II-III breast cancer who received NAC followed by surgery and radiotherapy in Samsung Medical Center, between 2007 and 2011. Among these, 329 patients who completed recommended therapy were analyzed on clinical outcomes and prognostic factors, with focusing on the molecular subtypes. Luminal A and B, HER2-enriched, and triple-negative subgroups were identified according to the hormone receptor (ER and PR), HER2, and Ki-67 receptor status.

Results: Overall pathologic complete response (pCR) rate after NAC were 20.1% and HER2- enriched subgroup was associated with the highest rates of pCR (43.6%), whereas luminal A showed the lowest rates of pCR (4.6%). A significant correlation was found between pathologic response (pCR vs. non-pCR) and molecular subtypes (p value <0.001). The median follow-up duration was 55 months (range, 5 to 98 months). The 5-year overall survival (OS) and disease-free survival (DFS) rates were 88.9% and 72.9%, respectively. In subgroup analysis, according to the pathologic response (pCR vs. non-pCR), triple-negative subtype proved significant difference in 5-year OS rate (100.0% vs. 71.6%, p value =0.005) and 5-year DFS rate (93.1% vs. 55.1%, p value <0.001). HER2-enriched subtype also showed significant difference in 5-year OS rate (100.0% vs. 79.1%, p value =0.05). A distinct survival difference according to molecular subtypes was found especially in non-pCR group (5-year OS and DFS, p value <0.001, respectively), in contrast, pCR group did not show a statistical difference of survival according to molecular subtypes. When compared

with luminal A, only triple-negative breast cancer was significantly related with decreased 5-year OS and DFS rate (p value <0.001, respectively).

Conclusion: Non-pCR group showed significantly decreased 5-year OS and DFS rates than pCR group, especially in triple negative and HER2-enriched breast cancer patients. In the case of pCR, there was no difference in survival rates regardless of molecular subtypes. While a significant difference between survival rates and molecular subtypes was found in the patients who failed to attain pCR. Compared to luminal A, only triple-negative subtype was associated with distinctly decreased 5-year OS and DFS rates.

EP-1145

EBRT vs IORT for breast conserving therapy A large mature single institution matched-pair evaluation

V. Vanoni¹, S. Bou Selman¹, S. Mussari¹, L. Menegotti², A. Ferro³, A. Caldara³, M. Nagliati¹, G. Berlanda⁴, C. Prezzi⁴, L. Tomio¹

¹Ospedale Santa Chiara di Trento, Radiation Oncology, Trento, Italy

²Ospedale Santa Chiara di Trento, Medical Physics, Trento, Italy

³Ospedale Santa Chiara di Trento, Oncology, Trento, Italy

⁴Ospedale Santa Chiara di Trento, Surgery, Trento, Italy

Purpose or Objective: Comparative outcome data after intraoperative radiotherapy (IORT) and external beam radiotherapy (EBRT) for breast cancer at >5ys median follow-up are rare. We present a large, mature single-institution matched-pair-comparison reporting survival and relapse-rates in patients treated with either modality.

Material and Methods: Complete datasets for 258 IORT-pts treated between 2000 and 2010 were matched with 258pts postoperatively treated with EBRT by age/histology/tumor size, grading/lymph-node-status/hormone-receptors/type of adjuvant therapy/surgical margins/treatment-date. EBRT was performed with 2 tangential fields to whole breast (50Gy/25fractions) and with 9-12MeV direct-electron-field-boosts to tumor bed (10-16Gy/5-8 fractions). A non-dedicated Linac (green-line-setup) with direct 8-12MeV electron fields (21Gy prescribed to 90%-isodose) delivered IORT. Relapse at surgical intervention site was classified as true local recurrence(LR). All recurrences in the treated breast (any quadrant) were classified as Ipsilateral Recurrence(IR).

Results: Median follow-up was 79 months (12-156) for both groups. IR were 11 after IORT and 6 after EBRT. LR for IORT and EBRT groups were 8 and 3, respectively. Cumulative incidence of IR at 5ys were 2.3%(IORT) and 1.4%(EBRT), (p=n.s., HR 1.8 CI 95% 0.69-5). Cumulative incidence of LR at 5ys was 1.5%(IORT) and 0.8%(EBRT), (p=n.s., HR 3.1 CI 95% 0.8-11.3) Overall survival(OS) at 3/5ys was 98.8%/96.1%(IORT) and 98.8%/95.3%(EBRT), (n.s.). Disease-free survival(DFS) at 3/5 ys was 97.2%/93.2%(IORT) and 98%/93.5%(EBRT) (n.s.). Between IORT and EBRT, no differences in non-breast-cancer-related-deaths or second-cancer-incidence were recorded. When analyzed according to ASTRO-criteria for accelerated-partial-breast-irradiation(APBI), outcome was better in the APBI-suitable group than in the entire cohort and the APBI-unsuitable group. The IR at 5ys for APBI-suitable/cautionary/unsuitable were 0%/2,7%/8% respectively

Conclusion: In line with published randomized-trial-data, IR-rate was higher after IORT than after EBRT if no stringent patient selection was performed. Non-breast-cancer-mortality and second-cancer-incidence did not differ between IORT and EBRT. In patients suitable for APBI according to ASTRO-criteria, similar IR-, LR- and OS-data indicate that IORT is a viable alternative to EBRT.

EP-1146

Non-surgical therapy of early breast cancer with novel enzyme-targeting radiosensitisation

K. Kobayashi¹, A. Nishioka², Y. Ogawa³, T. Yamagami¹

¹Kochi Medical School, Department of Radiology, Nankoku, Japan

²Kochi Health Sciences center, Radiation Oncology, Kochi-city, Japan

³Hyogo Prefectural Kakogawa Medical center, Radiology, Kakogawa-city, Japan

Purpose or Objective: The current standard treatment for early breast cancer is a combination of conserving surgery and endocrine therapy or that of endocrine therapy and chemotherapy or chemotherapy alone. Even after remarkable technical advances in breast cancer surgery, physical and mental invasion for patients after surgery is a problem to be solved. Also patients of dying from breast cancer for surgery denial exist. In this study, we evaluated the usefulness and safety of novel non-operative enzyme-targeting radiosensitization: Kochi Oxydol-Radiation Therapy for Unresectable Carcinoma, type II (KORTUC II) with endocrine therapy for stage I and II breast cancer.

Material and Methods: From October 2006 to September 2013, radiation therapy was performed for 44 women (median age 63years ranging from 37 to 88 years) of breast cancer (Stage 0; n=2, Stage I; n=19, and stage II; n=23). All patients refused both surgery and systemic chemotherapy. Radiation therapy performed was 44Gy/ 16fr/ 3.5W for total breast with field-in-field technique, then electron beam boost 9Gy / 3fr / 3days was added to the tumor bed. We injected the sensitizer (0.5% hydrogen peroxide solution + 0.83% sodium hyaluronate) under ultrasound guidance, before radiation therapy twice a week. Median follow-up period was 51 months (21-104 months). After the treatment, both PET-CT and breast MR were performed every year.

Results: About adverse event no skin symptoms more than grade3 was observed Beauty effect was excellent or good in all cases. Local recurrence was seen in only 2 case (4.5%). Distant metastasis was not observed. Only one patient died from other disease.

Conclusion: From the results of this study it was suggested that KORTUC II followed by endocrine therapy is effective and safe as the therapy for stage I and II breast cancer.

EP-1147

Hypofractionated vs conventional radiotherapy: is there a difference in local recurrence?

R. Yadav¹, P. Lal¹, S. Agrawal¹, M. Verma¹, S. Misra¹, K. Maria¹, S. Senthil Kumar¹, S. Kumar¹

¹Sanjay Gandhi Post Graduate Institute Of Medical Sciences, Radiotherapy, Lucknow, India

Purpose or Objective: Randomized trials have established the role of hypofractionated radiation therapy (HFRT) in early breast cancer. HFRT allows for less costly and more accessible treatment. However, there is paucity of data for HFRT in locally advanced breast cancer (LABC). We report the impact of HFRT in unselected breast cancer patients (all stages except metastatic, both BCS /MRM) and compared with CFRT for any differences in outcomes.

Material and Methods: 463 patients of BCS/MRM treated between Jan'08 and July'13 with CFRT (50Gy/ 25fr) or HFRT(42.4Gy/16 fr or 40Gy/15) to the breast/chest wall (CW) ± SCF ± Ax, treated in 2 time periods were retrospectively reviewed. RT was given by direct electron field/ bitangential photons to the CW and by latter to the breast. SCF ± Ax RT was given by enface photons (when indicated). All patients of BCS received a tumor bed boost. Statistical analysis to compare the 2 groups for survival outcomes, was done in Sept'15. The primary endpoint was to compare the differences in loco regional recurrences (LRR) between the 2 groups.

Results: Of the 463 patients, 209 received CFRT and 254 received HFRT. Median age was 48yrs (IQR:40-56),premenopausal(CFRT:23%vs HFRT 39%,p=0.005), and LABC presentation(CFRT36% vs HFRT 52%, p=0.01) was seen in higher proportion of patients receiving HFRT. The commonest pathology was IDC (81%) with grade III tumors (45%),ER (+) was seen in 44%,TNBC in 34% and Her2Neu (3+) were seen in 27%. 254 patients(54.5%)had undergone BCS and 209 patients (45%) MRM. 54% had left sided cancer and neoadjuvant chemotherapy(NACT) was given in 38%.The grade, HR status, laterality, NACT administration, BCS/MRM were similar in the 2 arms. For MRM patients, enface electrons were used in 88% patients treated with CFRT and 76% patients with HFRT. LN RT was delivered in 76% vs 64% in patients receiving CFRT vs HFRT respectively (p=0.005). With a median follow-up of 40mo in CFRT (IQR:14-55) and 29 mo in HFRT (IQR 17-38), 9/209 (4.3%) patients in CFRT and 7/254 (2.7%) in HFRT had LR .On univariate analyses, the 2yr actuarial LRFs in CFRT vs HFRT was 95% vs 97% (p=0.37). The 2yr OS in CFRT vs HFRT was 81% vs 85%(p=0.035) and 2year DDFS was 80% vs 83 % (p=0.15)respectively.

Conclusion: The risk of local recurrence among patients of breast cancer treated with HFRT after BCS or MRM was not worse when compared to conventional radiation therapy despite a younger population with locally advanced clinical presentation in HFRT.

EP-1148

A comparison study of whole breast irradiation of hypo- and conventional fractionation

K.H. Shin¹, S.W. Lee¹, Y.J. Kim², K. Kim¹, E.K. Chie¹, H.G. Wu¹, S.W. Park³, H.J. Yoo⁴

¹Seoul National University Hospital, Radiation Oncology, Seoul, Korea Republic of

²National Cancer Center, Center for breast cancer, Goyang, Korea Republic of

³Chung-Ang University Hospital, Radiation Oncology, Seoul, Korea Republic of

⁴Korea Institute of Radiological and Medical Sciences, Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: This investigation retrospectively compared early-stage breast cancer patients treated with accelerated hypofractionation (AHF) to the age- and stage-matched patients treated with conventional fractionation (CF).

Material and Methods: Three hundred seventy-nine early-stage (pT1-2 and pN0-1a) breast cancer patients who received radiation therapy (RT) with AHF after breast-conserving surgery (BCS) were included. These patients were matched by the years in which BCS was performed, age (± 3 years), and stage to the 379 corresponding patients in a different center, who received BCS and RT with CF. The AHF regimen was delivered as 39Gy in 13 fractions to the whole breast and consecutive 9-12Gy in 3-4 fractions to the tumor bed. The CF was composed of whole breast irradiation up to 50.4Gy in 28 fractions and then boost to the lumpectomy cavity with 9-14Gy in 5-7 fractions.

Results: The median follow-up time was 75 months (range: 3.8-110.8 months). There was no statistically significant difference in the age, T and N stage, resection margin, and histologic grade. There were five ipsilateral breast tumor relapse (IBTR) in the AHF group compared with seven in the CF group. Seven and eight loco-regional relapse (LRR) was observed in the AHF and the CF group, respectively. The 7-year rates of IBTR-free survival (IBTRFS), LRR-free survival (LRRFS), and disease-free survival (DFS) were 98.9%, 98.4%, and 97.1% in the AHF arm and 98.1%, 97.9% and 96.0% in the CF arm, respectively (p > 0.05). Among AHF patients, no risk factors including histologic grade or molecular subtype were associated with IBTR. The incidences of mild, grade 1 edema, hyperpigmentation, and wet desquamation at the end of RT were observed higher in the CF group.

Conclusion: While reducing fraction number, AHF radiotherapy of 39Gy whole breast plus 9Gy boost in 16 fractions is comparable to CF radiotherapy with excellent tumor control and tolerable skin toxicity in patients with early-stage breast cancer.

EP-1149

Changing practice patterns for breast cancer radiotherapy: hypofractionation in KFSYSCC at Taiwan

Y.C. Tsai¹, J.J. Jian¹, S.H.C. Cheng¹, B.L. Yu², C.M. Chen², C.F. Horng³

¹Koo Foundation Sun Yat-Sen Cancer Center, Radiation Oncology, Taipei, Taiwan

²Koo Foundation Sun Yat-Sen Cancer Center, Surgery, Taipei, Taiwan

³Koo Foundation Sun Yat-Sen Cancer Center, Clinical Research Office, Taipei, Taiwan

Purpose or Objective: Hypofractionated whole breast irradiation (HF-WBI) following breast conserving surgery has produced excellent outcomes, but utilization remains limited. We evaluated the impact of the landmark study (START) in the adoption of HF-WBI in Sun Yat-Sen Cancer Center (KFSYSCC) at Taiwan.

Material and Methods: Information was obtained from the institutional breast cancer data base with stage I to III breast cancer receiving adjuvant whole-breast radiotherapy between 2012 and Aug 2015. Patients treated with palliative intent, accelerated partial breast radiation were excluded. HF-WBI was defined as ≤ 21 fractions with a dose/fraction ≥ 2.5 Gy.

Table 1 Baseline characteristics of patients treated in the study

		HF-WBI	CF-WBI	Total patients	HF-WBI/CF-WBI (%)
Year	2012	6	180	186	3.2
	2013 Jan-June	7	145	152	4.6
	2013 July-Dec	46	94	140	32.8
	2014	208	147	355	58.6
	2015 Jan-Aug	144	65	209	68.9
Age	< 40 y/o	48	80	128	37.5
	40-49 y/o	120	181	301	39.9
	50-59 y/o	140	196	336	41.7
	>60 y/o	103	174	277	37.2
T stage	Tis	100	108	208	48.1
	T1	204	255	459	44.4
	T2	67	74	141	47.5
	T3	40	194	234	17.1

CF-WBI: Conventional whole breast irradiation

Results: We identified 1042 patients meeting inclusion criteria. HF-WBI utilization increased significantly from 4% before July 2013 to 57% afterwards. The adoption of HF-WBI reach 77% since July 2015. The reimbursement structure here is based on "course" rather than "number" of treatment, the increased adoption of HF-WBI saved an estimated \$700,000 annually in our Cancer Center.

Fig1: The rate of breast hypofractionation utilization is graphed over time between 2012 and Aug 2015. A substantial increase in adoption of hypofractionated whole breast irradiation (HF-WBI) in July 2013

CF-WBI: Conventional whole breast irradiation

Conclusion: We found that the publication of START A and B trials in 2013 substantially increased adoption of HF-WBI for breast cancer at KFSYSCC, which increased the use of HF-WBI by 19-fold. The reimbursement structure allow us to quick adopt state of art and standard care for early stage breast cancer.

EP-1150

Patient quality of life treated with IORT during BCS followed by whole breast radiotherapy (WBI)

B. Urbanski¹, A. Roszak¹, K. Bratos¹, P. Milecki², A. Karczewska-Dzionk², M. Litoborski³, S. Adamczyk⁴

¹Greater Poland Cancer Centre, Radiotherapy and Gynecological Oncology, Poznan, Poland

²Greater Poland Cancer Centre, Radiotherapy Ward I, Poznan, Poland

³Candela, Candela, Warsaw, Poland

⁴Intra Op, Intra Op, Sunnyvale, USA

Purpose or Objective: The aim of the study was to report quality of life and others aspects based on EORTC questionnaire intraoperative radiotherapy (IORT) given as a boost during breast conserving surgery (BCS) followed by adjuvant whole breast radiotherapy (WBRT).

Material and Methods: Between 2008 and 2011 in 150 breast cancers patients treated in Greater Poland Cancer Centre. Intraoperative radiotherapy as a tumor bed boost was applied using mobile electron accelerator Mobetron 1000 (IntraOp Medical, Inc.). IORT boost (10 Gy) was followed by 50 Gy whole-breast external beam radiotherapy (EBRT). Chemotherapy, if indicated, was given before EBRT. The observation period was 1,5-5,5 years. The data was assessed by EORTC questionnaires (QLQ-C30 and QLQ-BR23) 1 month after RT, 6 months, 1 year, 2 years, 3 years and 4 years.

Results :

Tab 1. QLQ-C30 questionnaire data

SCALE	1 month	6 months	1 year	2 years	3 years	4 years	Reference EORT score	P value
Global health status	64,2	66	62	57,5	66,2	69	61,8	0,2143

Upset by hair loss	21,6	13,1	17,6	20,3	26,3	22,1	5,0	0,854

There was statistical significance change in body image between 1 and 6 months after radiation therapy (p=0,008), but it was lower than EORTC reference score. Sexual enjoyment was lower than EORTC reference score in any follow up period time. Systemic therapy side effects was higher than EORTC control group in any follow up period time.

Conclusion: Intraoperative radiotherapy is proved to be tolerable and perspective treatment procedure with no statistical significance influence on quality of life.

EP-1151

Lymph flow guided irradiation of internal mammary lymph nodes

S. Novikov¹, S.V. Kanaev¹

¹Prof. N.N. Petrov Research Institute of Oncology, Radiotherapy and Nuclear Medicine, St. Petersburg, Russian Federation

Purpose or Objective: to analyze possible clinical value of lymph flow visualization as the guide for irradiation of IMLN.

Material and Methods: On the first stage of the study we combined data of 8 published studies that analyzed lymph flow from primary BC (4541 patients) after intra- peritumoral injection of nanosized ^{99m}Tc-colloids. Using this data we determined probability of lymph flow from BC of internal/central or lateral localization to IMLN. In 7 studies (4359 women) axillary staging was accompanied by biopsy of sentinel lymph nodes localized in internal mammary region. This data made it possible to estimate probability of IMLN metastatic invasion in relation with the status of axillary LN. At the final stage of the study we calculated probability of IMLN invasion by BC in 4 randomized and 2 observation studies that analyzed effect of IMLN irradiation on overall survival. Additionally, we tried to calculate possible additional gain in survival if patients from this 6 (4+2) trials would be treated according to lymph flow guided irradiation of IMLN.

Results: According to results of 8 published studies lymph-flow from lateral BC to IMLN was detected in 16% (727/4541), from internal/central lesions - in 35% (1589/4541). Evaluation of 7 studies (4359 women) showed that in patients with noninvolved axillary LN metastases in IMLN were revealed in 7.8%, in patients with positive axillary nodes - in 38.1% cases. In all 6 studies that evaluated clinical value of IMLN irradiation, calculated probabilities of IMLN metastatic invasion in "high risk patients" didn't exceed 10%. If IMLN irradiation would be performed only in patients with lymph flow to IMLN about 72.1%-76.8% of "high risk patients" would escape RT to IM region. In remained 23.2%-28.9% patients with visualized internal mammary sentinel lymph nodes their irradiation would improve overall survival from 1.6%-3.3% to 6.9%-14.2%.

Conclusion: visualization of lymph flow from breast cancer after intratumoral injection of ^{99m}Tc-nanocolloids make decision about irradiation of IMLN more precise and efficient. Irradiation of visualized IMLN can significantly (6.9%-14.2%) improved overall survival in this group of patients with BC.

⁷Bellaria Hospital, Radiotherapy Department, Bologna, Italy

⁸Policlinico Universitario "A. Gemelli" - Catholic University of Sacred Heart, Department of Radiotherapy, Roma, Italy

Purpose or Objective: To assess the feasibility of Simultaneous Integrated Boost in Intensity Modulated Radiotherapy (SIB-IMRT) for breast cancer (BC) in the attempt to reduce the radiation treatment time. Results in terms of late toxicity and local control were compared with a control group (CG) of patients treated with 3-dimensional (3-D) conformal radiotherapy plus sequential boost.

Material and Methods: MARA-2 was conceived as a single arm phase I-II trial. Patients with moderate-high risk BC were enrolled and treated with forward-planned IMRT technique. Whole breast and tumor bed received a total dose of 50 Gy and 60 Gy (10 Gy concomitant boost) in 25 daily fractions, respectively. In CG group, prescribed dose to the breast was 50.4 Gy in 28 fractions with a sequential 10 Gy boost to the tumor bed in 4 fractions. Late skin and subcutaneous toxicity were evaluated using EORTC/RTOG scoring scale.

Results: Four hundred and fifty one patients were included in our study (MARA-2: 321; CG: 130). Median follow up was 52 months (range: 3-115). G1 and G2 late skin toxicities were acceptable without significant differences between the two groups. No G_{≥3} late skin toxicity was observed in MARA-2. At univariate analysis, late G1 and G2 subcutaneous toxicities were significantly higher in MARA-2 (p<0.001). 5-year G1 subcutaneous late toxicity free-survival (LTF5) were 73.4% and 38.5% in CG and MARA-2, respectively; moreover, 5-year G2 subcutaneous LTF5 were 96.5% and 80.0% in CG and MARA-2, respectively. 5-year G3 subcutaneous LTF5 was 0.9% in MARA-2 and 0% in CG, respectively. No differences were found in term of loco-regional control (LC) with a 5-LC of 96.7% and 97.6% in CG and MARA-2, respectively (p=0.676).

Conclusion: The use of SIB-IMRT technique in postoperative radiotherapy of BC allowed to reduce overall treatment time without significantly increasing the incidence of G>2 late effects.

EP-1153

Hypofractionated radiotherapy and simultaneous boost in breast cancer: preliminary result in elderly

N. Gaj-Levra¹, A. Fiorentino¹, R. Mazzola¹, S. Fersino¹, F. Ricchetti¹, G. Sicignano¹, S. Naccarato¹, R. Ruggieri¹, F. Alongi¹

¹Ospedale Sacro Cuore - Don Calabria, Radiation Oncology, Negrar - Verona, Italy

Purpose or Objective: To evaluate the feasibility and toxicity profile in elderly women, with a diagnosis of early stage breast cancer, underwent to adjuvant hypofractionated Volumetric Modulated Arc Therapy (VMAT) and simultaneous integrated boost (SIB) after conserving surgery (CS).

Material and Methods: Between September 2013 to March 2015, 50 consecutive women with a diagnosis of early stage of breast cancer were treated with SIB-VMAT after CS in our Institution. Inclusion criteria were: age ≥ 65 years, pT1 -2 disease, pN 0-1, no neoadjuvant chemotherapy, no-metastatic disease. A dose prescription of 40.5 Gy in 15 fractions was prescribed to the whole breast (PTVbreast) and an additional radiation dose of 48.5 Gy in 15 fractions to the tumour bed was prescribed (PTVboost). Hypofractionated treatment was purposed in patients with negative margins after surgery (> 1 mm). All patients were followed with periodic clinical evaluation. Acute toxicity were scored using EORTC/RTOG radiation morbidity score system. Both patient and physician recorded cosmetic outcome evaluation with a subjective judgment scale at the time of scheduled follow-up.

Results: Median follow-up was 20 months. At the time of the analysis, overall survival and local control rates were 100%. All patients completed the SIB-VMAT without interruptions. Acute skin toxicity was recorded as follow: grade 0 in 22 patients (44%), grade 1 in 24 cases (48%), grade 2 in 4 patients (8%). Regarding late adverse events, skin toxicity was registered as follow: grade 0 in 40 patients (80%), grade 1 in 10 cases (20%). No toxicity ≥ grade 2 was registered. In

terms of cosmetic results, 99% and 1% of patients considered the result as good/excellent and as fair after RT, respectively. No patients had a poor cosmetic outcome.

Conclusion: These results support the feasibility and good tolerability of SIB-VMAT in elderly patients with a diagnosis of breast cancer following CS with acceptable acute and late treatment-related toxicity. These preliminary results justified continuing the clinical study with the goal to establish the impact of hypofractionated SIB-VMAT in elderly patients with diagnosis of early stage breast cancer.

⁹University of Bologna, Department of Medical and Surgical Science, Bologna, Italy

¹⁰Policlinico Universitario "A. Gemelli"- Catholic University of Sacred Heart, Department of Radiotherapy, Rome, Italy

Purpose or Objective: To investigate the pathogenesis of peri-prosthetic capsule contraction (CCPP) related to post mastectomy radiotherapy in breast cancer patients undergoing breast reconstruction with heterologous material.

Material and Methods: Patients developing (early or late) CCPP after breast reconstruction were enrolled in this study. CCPP was clinically evaluated by Baker score in order to define pain, rigidity, firmness and dislocation of implant. CCPP was analysed considering pathological aspect after sub-total capsulectomy with anterior removal of peri-prosthetic capsule. Patients were split into two groups according to radiotherapy administration. Group 1 accounted for irradiated patients (50 Gy, 2 Gy per fraction on chest wall, using tangential field-in-field technique). Group 2 included not irradiated patients. Baker Score and microscopic observation (simil-synovial reaction, hyalinosis, vascular reaction, giant cells) of the two groups were compared by univariate and multivariate analysis.

Results: Analysis was performed on 26 patients who developed CCPP (29 capsulectomy, because 3 bilateral) in the period between April 2012 and February 2015 (34 months). All patients developed CCPP within 1 year from first reconstructive surgery. Characteristics of both groups are reported in Table 1.

	GROUP 1	GROUP 2
N° (%)	12	14
Median age (range)	47-5 (37-65)	48 (40-60)
Median BMI (range)	22.7 (16.5-33.0)	26.3 (22.10-46.3)
Histology		
Ductal Infiltrating Carcinoma (G1, G2, G3)	5	6
Lobular Infiltrating Carcinoma (G1, G2, G3)	4	5
Invasive Mix Carcinoma	3	3
Reconstructive procedure		
Immediate monolateral	1	3
Immediate bilateral	0	2
In two operating sessions Monolateral	11	8
In two operating sessions Bilateral	0	1
Adjuvant treatment		
Chemotherapy	3	3
Hormone therapy	0	6
Chemotherapy + Hormone therapy	8	1
No adjuvant therapy	1	4

Univariate analysis showed a positive association between Baker Score and radiotherapy (OR: 1.65), and hyalinosis and radiotherapy (OR: 1.2). Multivariate analysis confirmed association between CCPP and radiotherapy (OR: 17.9); chemotherapy (OR: 4.3) and hormone therapy (OR: 48.44) in terms of contraction grade and simil-synovial reactions respectively.

Conclusion: Radiotherapy after breast reconstruction significantly influenced onset and severity of CCPP, although other variables contributed to CCPP multifactorial aetiology. In particular, hormone therapy and chemotherapy played a role in modifying capsular architecture.

EP-1155

Radiation-induced morbidity evaluated by high-frequency ultrasound: a pilot study

L.M. Schack¹, J. Overgaard¹, B.V. Offersen², J. Alsner¹

¹Aarhus University Hospital, Experimental Clinical Oncology, Aarhus C, Denmark

²Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

Purpose or Objective: Evaluation of radiation-induced morbidity is routinely done as an integrated part of treatment response follow-up, and can be scored according to clinical assessment tools such as the CTCAE or LENT-SOMA. Objective measures in this evaluation would be valuable given their quantitative nature, facilitating comparison across cohorts and treatment institutions. High-frequency ultrasound (US) is a high-precision, objective tool to measure dermis thickness of the skin. We aimed to analyze dermis thickness in a cohort of women following radiotherapy (RT) for breast cancer with various grades of induration and edema.

Material and Methods: The cohort was recruited from the DBCG HYPO/PBI RT protocols and comprised 15 women treated for early breast cancer during 2009-2013 with lumpectomy and RT 50 or 40 Gy +/- systemic therapy. Clinical morbidity follow-up of induration and edema was done at baseline and annually according to the LENT-SOMA scale. Dermis thickness was measured in mm using high-frequency US. Points of measurement were 3 cm from the areola in four quadrants in both irradiated and contralateral non-irradiated breasts. Differences in mean dermis thicknesses were tested by two-tailed paired t-test. The US scanner utilized was a high-resolution 20 MHz DermaScan® C from Cortex Technology ApS. This device is optimized for recognizing structures at 60 µm, corresponding to tissue microstructures sized like collagenous fibres.

Results: Median follow-up time was 3.0 years (range 1.0 - 4.6). Overall, mean dermis thicknesses were 2.22 mm (1.78 - 2.66) in the irradiated (I) breast and 1.26 mm (95% CI: 1.08 - 1.44) in the contralateral (C) breast. Mean difference between breasts was 0.96 mm (0.49 - 1.43, p<0.001). Dermis thickness was distributed in quadrants as follows: Lower lateral I: 2.62 (1.92 - 3.31) C: 1.11 (0.96 - 1.26), lower medial I: 2.64 (2.06 - 3.21) C: 1.45 (1.18 - 1.72), upper lateral I: 1.55 (1.33 - 1.78) C: 1.17 (1.01 - 1.34), upper medial I: 2.08 (1.49 - 2.67) C: 1.31 (1.09 - 1.53). In patients without clinical edema, the mean difference in dermis thickness for grade 1 induration was 0.35 mm (-0.46 - 1.16, p=0.21) and for grade 2 induration 0.71 mm (-0.01 - 1.43, p>0.05). In patients with clinical edema, only one patient had grade 1 induration (dermis thickness difference 1.34 mm). In

patients with clinical edema and grade 2 induration, mean difference in dermis thickness was 1.61 mm (0.27 - 2.95, $p=0.03$). Edema was associated with a more diffuse signal and an indistinct demarcation against the subcutaneous tissue. This was more pronounced in the lower quadrants (Figure).

Conclusion: High-frequency US has potential to measure increased dermis thickness associated with radiation-induced induration in breast cancer patients. Edema may increase dermis thickness and lead to a more diffuse US signal.

High-resolution ultrasound images of two patients without- and with edema. Both have grade 2 fibrosis.

EP-1156

Radiotherapy for ductal carcinoma in situ: patterns of recurrence and risk factors stratification

I. Meattini¹, L. Livi¹, P. Bastiani², V. Scotti¹, L. Paoletti², C. De Luca Cardillo¹, R. Barca², D. Greto¹, F. Martella³, G. Simontacchi¹, G. Tinacci³, J. Nori⁴, H. Smith³, L. Sanchez², L. Galli¹, L. Orzalesi⁵, S. Fondelli², S. Bianchi⁶, F. Rossi²

²S. Maria Annunziata Hospital, Radiation Oncology Unit, Florence, Italy

³S. Maria Annunziata Hospital, Breast Unit, Florence, Italy

⁴Azienda Ospedaliero-Universitaria Careggi, Radiology Senology Unit, Florence, Italy

⁵Azienda Ospedaliero-Universitaria Careggi, Breast Surgery Unit, Florence, Italy

⁶Azienda Ospedaliero-Universitaria Careggi, Pathology Unit - University of Florence, Florence, Italy

Purpose or Objective: Ductal carcinoma in situ (DCIS) represents around 20% of breast cancers (BC). Standard treatment after breast conserving surgery is still adjuvant radiotherapy (RT). Several randomized trials and meta-analysis showed a 50% risk reduction in LR after adjuvant RT. The aim of our analysis was to evaluate the LR rate and possibly to identify a risk groups stratification for DCIS treatment optimization.

Material and Methods: We analyzed 457 patients that underwent BCS and adjuvant RT between 1990 and 2012. Median dose to the whole breast was 50 Gy in 25 fractions; patients with positive/close final surgical margins received a tumor bed boost. We stratified patients in low risk group using well known risk factor for LR (n=203; age ≥ 50 years, surgical margins ≥ 10 mm, nuclear grade 1-2, $pT \leq 25$ mm), and intermediate-high risk group (n=254; age < 50 years, surgical margins < 10 mm, nuclear grade 3 or $pT > 25$ mm). We performed also a patient stratification according to Van Nuys Prognostic Index. Estrogen and progesterone receptors status, nuclear grade, and Ki-67 proliferative index were available for most patients.

Results: The mean age was 57 years (range 33-80). Hormonal status was positive in 92% of patients, 83 cases (18.2%) received adjuvant endocrine therapy. All patients received postoperative RT, 198 cases (43%) received also a RT boost on tumor bed.

At a median follow up time of 12 years (range 3-23), we observed 26 LR (5.6%). Following risk groups stratification, we observed seven LR (3.4%) in low risk group and nineteen LR (7.4%) in intermediate-high risk group ($p < 0.001$).

Conclusion: Our experience evidenced a significant difference in LR incidence after adjuvant RT based on our risk factors stratification.

This confirms the wide heterogeneity of DCIS. Identification of clear subgroups of patients following risk factors is still lacking. Waiting for results from ongoing clinical phase 3 trials and genomic studies, postoperative RT still remains a mainstay in adjuvant treatment for DCIS.

EP-1157

Abstract withdrawn

EP-1158

Should breathing adapted radiation therapy also be applied for right-sided breast irradiation?

M. Essers¹, P.M. Poortmans², K. Verschuere³, S. Hol³, D.C. Cobben³

¹Dr. Bernard Verbeeten Instituut, Department of Medical Physics, Tilburg, The Netherlands

²Radboud University Medical Centre, Radiation Oncology, Nijmegen, The Netherlands

³Dr. Bernard Verbeeten Instituut, Radiation Oncology, Tilburg, The Netherlands

Purpose or Objective: Voluntary moderate deep inspiration breath-hold (vmDIBH) is widely used for patients with left sided breast cancer. The purpose of this study was to investigate the utility of vmDIBH in local and locoregional radiation therapy (RT) for patients with right-sided breast cancer.

Material and Methods: For fourteen patients with right-sided breast cancer, forward IMRT plans were calculated on free-breathing (FB) and vmDIBH CT-scans, for local- as well as locoregional breast treatment, with and without internal mammary lymph nodes (IMN). We compared dose volume parameters to estimate the reduction in the risk of radiation pneumonitis, the influence on pulmonary lung function tests and the risk of secondary lung cancer with the use of vmDIBH.

Results: For local breast treatment, no relevant reduction in mean lung dose (MLD) was found. For locoregional breast treatment without IMN, the average MLD reduced from 6.5 to 5.4 Gy ($p < 0.005$) for the total lung and from 11.2 to 9.7 Gy ($p < 0.005$) for the ipsilateral lung. For locoregional breast treatment with IMN, the average MLD reduced from 10.8 to 9.1 Gy ($p < 0.005$) for the total lung and from 18.7 to 16.2 Gy ($p < 0.005$) for the ipsilateral lung. We also found a reduction in mean heart dose between 0.6 and 2.6 Gy in four patients; with a mean of 0.4 Gy for all 14 patients together ($p = 0.07$). We estimate that 1 out of 100 patients will not develop radiation pneumonitis when breath-hold is applied during locoregional right-sided breast cancer treatment. For ever-smoking women, the risk of secondary lung cancer might also be reduced by vmDIBH.

Conclusion: Breathing adapted radiation therapy in patients with left-sided breast cancer is becoming widely introduced. As a result of the slight reduction in lung dose found for

locoregional right-sided breast cancer treatment in this study, a slightly lower risk of pneumonitis and secondary lung cancer (in ever-smoking patients) can be expected. In addition, we estimate that for 10-25% of the patients the heart dose will also be reduced. We therefore suggest to also apply breath-hold for locoregional irradiation (with and without IMN) of patients with right-sided breast cancer.

EP-1159

Does a SPECT-CT improve the delineation of internal mammary nodes for breast cancer patients?

M. Essers¹, K. Van der Klugt², R.H. Tijssen³, R. Pijpers⁴, B. Oei², P.M. Poortmans⁵

¹Institute Verbeeten, Department of Medical Physics, Tilburg, The Netherlands

²Institute Verbeeten, Radiation Oncology, Tilburg, The Netherlands

³University Medical Centre Utrecht, Medical Physics, Utrecht, The Netherlands

⁴Institute Verbeeten, Nuclear Medicine, Tilburg, The Netherlands

⁵Radboud University Medical Centre, Radiation Oncology, Nijmegen, The Netherlands

Purpose or Objective: A large recent study(1) has shown that in patients with early-stage breast cancer, irradiation of the regional (internal mammary and medial supraclavicular) nodes improves disease-free and distant disease-free survival, while breast-cancer mortality is reduced. However, internal mammary nodes (IMN) are usually delineated using anatomical landmarks, e.g. using the ESTRO delineation atlas (2), since the nodes are not visible on CT. We studied the impact of SPECT-CT lymphoscintigraphy on the localisation of IMN and on the subsequent treatment planning and dose distribution.

Material and Methods: For 10 breast cancer patients (5 right, 5 left), SPECT-CT lymphoscintigraphy of the IMN was performed. Using the Eclipse TPS (Varian), the SPECT-CT and planning CT images were co-registered. The 70% of the maximum uptake value was used to contour the IMN on SPECT-CT images. Using the ESTRO atlas, the IMN were also contoured on the planning CT images. The localisation of IMN based on the SPECT-CT images and based on the ESTRO atlas were compared, as well as treatment plans based on the two contouring methods.

Results: For 2 patients, no drainage to the IMN was visible. For 6 out of the remaining 8 patients, the caudal border of the IMN based on SPECT-CT was situated at the second intercostal (IC) space, whereas the ESTRO atlas prescribes to include the third or fourth IC space depending of the position of the tumour in the breast. In the lateral direction, the lymph nodes mostly follow the veins, but for one patient, the position on SPECT-CT was more medial (and missed by the ESTRO atlas) and for one more lateral. On treatment planning, for one patient only 50% of the IMN seen on SPECT-CT would have been covered following contouring using the ESTRO atlas. The mean heart dose (MHD) increased by 0.8 Gy for one patient and decreased by 1.0 Gy for one patient and the mean lung dose (MLD) decreased by 2 Gy for one of the patients following SPECT-CT based delineation. For the other patients, the differences in MHD and MLD were less than 0.5 Gy.

Conclusion: Delineation of the IMN using SPECT-CT lymphoscintigraphy is easier and less user dependent than using the delineation atlas. In general, the agreement between atlas and SPECT-CT based delineation is good. However, the caudal border of the IMN was overestimated in 6 out of 8 patients. Differences in the medial border were also observed, resulting in underdosage of the IMN in 1 and overdose to lung and heart in 1 other patient. SPECT-CT lymphoscintigraphy might be applied for patients with a high heart dose, to investigate whether the caudal and medial border of the IMN may be reduced.

EP-1160

What drives post-mastectomy radiation therapy receipt in T2N0 patients?

C. Fisher¹, R. Rabinovitch¹, J. Jagar¹, A. Amini¹, P. Kabos¹

¹University of Colorado Denver, Radiation Oncology, Aurora-CO, USA

Purpose or Objective: Increased biological information on individual tumors can be obtained with 21-gene recurrence score (RS) testing, which has revolutionized receipt of chemotherapy. Similar biological drivers of outcomes may be useful in determining who might benefit from post-mastectomy radiation, as is being investigated in the SUPREMO and other trials. This study aimed to determine who was getting post-mastectomy radiation in a T2N0 cohort, as well as whether the recurrence test score affected radiation radiation therapy receipt.

Material and Methods: The National Cancer Data Base captures about 75% of all US cancer patients and was queried for breast cancer patients from 2004-2012. 5302 T2N0 post-mastectomy patients were identified. Multivariate logistic regression analysis was used to estimate the covariates associated with test utilization and impact on radiation therapy decisions (see table). Z-test was used to measure the difference between radiation receipt for those who had the test and those who did not.

Results: Post-mastectomy radiation was delivered for 431 patients (8.1%) of the 5302 included patients. Multivariate statistics were used to investigate potential radiation drivers including age, race, insurance status, grade, recurrence score, and presence of cells in the nodes on immunohistochemical staining (N0i+ versus N0i-). The strongest association with receipt of radiation therapy was N0i+ status (p<.002) versus N0. Age, race, insurance status, grade, and actual recurrence score did not predict for receipt of post-mastectomy radiation therapy.

Conclusion: As expected, radiation was used in a minority of this cohort. Presence of cells in a lymph node was the largest driver, even though the disease burden in the nodes was very low to be T2N0i+. In patients where the recurrence score was ordered, it also predicted for non-receipt of radiation therapy as a rationale de-escalation of care. The biggest driver of radiation was Noi+ status, where at least a small number of cells reached the lymph nodes and radiation might be expected to have an impact. Interestingly, increasing recurrence score reflecting aggressive biology and poorer outcomes did not drive PMRT receipt in this population. In the future, use of the recurrence score may help select patients in whom personalized use of local therapy is possible.

EP-1161

Does sentinel-node biopsy affect the use of supine MRI for regional breast radiotherapy?

T. Van Heijst¹, D. Eschbach-Zandbergen¹, B. Van Asselen¹, J.J.W. Lagendijk¹, M. Van Vulpen¹, H.M. Verkooijen², R.M. Pijnappel³, A.J. Witkamp⁴, T. Van Dalen⁵, H.J.G.D. Van den Bongard¹, M.E.P. Philippens¹

¹UMC Utrecht, Radiotherapy, Utrecht, The Netherlands

²UMC Utrecht, Epidemiology, Utrecht, The Netherlands

³UMC Utrecht, Radiology, Utrecht, The Netherlands

⁴UMC Utrecht, Surgery, Utrecht, The Netherlands

⁵Diakonessenhuis, Surgery, Utrecht, The Netherlands

Purpose or Objective: Regional radiotherapy (RT) is replacing axillary lymph node (LN) dissection in breast-cancer patients with tumor-positive sentinel node(s) (SNs). In regional RT, only part of the LNs can be visualized using

computed tomography (CT); consequently, LN levels are delineated according to vessels and muscular boundaries. Magnetic resonance imaging (MRI) allows high resolution and high contrast images for explicit LN visualization in supine RT position. The purpose of the study was to assess effects of sentinel-node-biopsy (SNB) on MRI detection rate and on patient endurance, and relate MRI detection rate to CT.

Material and Methods: Currently, 8 of in total 25 female early-stage breast-cancer patients (cT1-3, N0) have been enrolled, scheduled for SNB and breast-conserving surgery (BCS). Additional to standard postoperative CT for RT planning, all patients were scanned on 1.5 T MRI, before and after BCS. CT and MRI were performed in supine RT position, with both arms abducted and supported. MRI comprised two T1-weighted (T1w) spoiled gradient echo techniques, two T2w fast spin echo methods, and diffusion-weighted MRI, all covering the axillary and periclavicular areas using posterior and anterior 16-array coils. MRI acquisition was limited to 20 minutes per session. Patient endurance to undergo MRI was monitored qualitatively. A radiation oncologist delineated LN levels on both MRI and CT (levels I-IV, interpectoral) according to ESTRO contouring guidelines. By inspection of all MRI scans acquired in one session, individual LNs were delineated. The detection rate, i.e. number of LNs identified, was determined for CT and for each MRI session. The pre- and postoperative MRI detection rates were compared to assess influence of SNB, and also compared to CT. For each LN, the corresponding LN level was denoted.

Results: The number of LNs on postoperative MRI exactly matched the preoperative number for all 8 patients (range: 19 - 42), when adding the excised SNs. All SNs were retrospectively identified in level I on preoperative MRI. In 7 out of 8 patients, spatial correspondence of all other LNs between MRI sessions was established. In one patient, a post-SNB seroma was visible, but detection number was unaffected. The majority of LNs were located in the LN levels, while up to 7 were found outside (up to 6 mm). LN detection on CT (7 - 21 LNs) was much lower than MRI. Endurance was excellent and unaffected by BCS/SNB.

Patient number	Numbers of LNs			Pre- vs. postop MRI	SNs excised	Location of LNs					Ext.
	Preop MRI	Postop MRI	Postop CT			Level I (SNs)	Level II	Level III	Level IV	Level IP	
1	28	27	21	1	1	15 (1)	7	1	2	0	3
2	42	40	21	2	2	28 (2)	6	3	3	0	2
3	35	33	16	2	2	22 (2)	3	1	2	2	5
4	26	25	10	1	1	13 (1)	4	3	0	2	4
5	34	33	7	1	1	18 (1)	8	1	0	0	7
6	30	29	8	1	1	20 (1)	2	2	0	3	3
7	19	18	7	1	1	13 (1)	2	0	1	3	1
8	23	22	10	1	1	10 (1)	2	2	0	3	6

Table 1: Numbers of LNs found in each patient, on pre- and postoperative MRI, and postoperative CT. The difference between MRI sessions is denoted, as well as the number of SNs excised during SNB. Numbers of LNs per axillary contour, or outside, are listed. IP = inter-pectoral. Ext. = exterior LNs, i.e. those located outside of the standard levels.

Figure 1: (a) Coronal CT scan with axillary levels contoured (axillary levels I-IV are yellow, green, sky blue, dark blue; inter-pectoral level is brown), according to ESTRO delineation guidelines. (b) Coronal T1-FFE MRI scan with in red individually delineated axillary LNs. (c) Preoperative coronal 3D T2 TSE scan where individual LNs are clearly visible (showing hyper-intense signal). The yellow arrows point to the two SNs which are excised during SNB. (d) The corresponding postoperative 3D T2 TSE; the SNs are now absent, while seroma due to the SNB is visible, as indicated by the green arrow.

Conclusion: MRI after SNB is able to identify the exact numbers of LNs as found on pre-SNB MRI. CT detection rate is much lower than MRI. SNB does not affect patient endurance. All excised SNs were identified on preoperative MRI. Some LNs were located just outside the LN levels. MRI in RT planning may lead to better target definition compared to CT. In future studies, we will study personalized RT using MRI guidance, possibly leading to reduced target volume. Based on current patient inclusion rate, updated results on all 25 patients are expected soon.

EP-1162
 Cyberknife stereotactic partial breast irradiation for early stage breast cancer
 O. Obayomi-Davies¹, S. Rudra¹, L. Campbell¹, S.P. Collins¹, B.T. Collins¹
¹Georgetown University Hospital, Radiation Oncology, Washington DC, USA

Purpose or Objective:
 Background: Partial breast irradiation (PBI) is an attractive treatment option for well selected women undergoing breast conserving therapy for early stage breast cancer. In properly selected women, outcomes following PBI are comparable to conventional whole breast radiation. The CyberKnife linear accelerator may offer meaningful technical improvements to existing PBI techniques. We report our experience with CyberKnife stereotactic accelerated partial breast irradiation (CK-SAPBI).

Material and Methods: Between 11/2008 and 09/2015, CK-SAPBI was attempted on 21 patients with early stage breast cancer. Four to six gold fiducials were implanted around the lumpectomy cavity prior to treatment. Fiducials were tracked in real-time using the CK Synchrony tracking system. Prior to 2014, the clinical target volume (CTV) was defined on contrast enhanced CT scans using surgical clips and the obvious post-operative cavity. A 5 mm uniform expansion was added to generate the planning treatment volume (PTV). Starting in 2014, the CTV was defined on contrast enhanced CT scans as the lumpectomy cavity plus a 10 mm uniform expansion confined to the breast tissue. A 3-5 mm uniform expansion was added to generate the PTV. All patients received 30 Gy in five fractions delivered to the PTV. Dosimetry was assessed per institutional protocol, the National Surgical Adjuvant Breast and Bowel Project B-39

guidelines, and TG-101. Cosmesis was assessed using the Harvard Breast Cosmesis Scale.

Results: Twenty patients were treated successfully. At a median follow-up of 18 months (1-78), all patients remain locally controlled (100%) and no significant adverse events have occurred. All patients continue to experience good-excellent cosmetic outcomes. At least 3 fiducials were tracked in 85% of cases. Fiducial tracking was not successful in one patient. The mean number of beams delivered was 145 (77-196). The mean treated PTV30Gy was 74 cm³ (15-142 cm³) with a mean prescription isodose line of 82% (75-86%). 99% of the PTV30Gy received the prescription dose (95-100%) with a mean maximum dose of 36 Gy (34.5-40Gy). The mean ipsilateral breast V30Gy and V15Gy were 12% (3-26%) and 30% respectively (8-58%) sparing significant amounts of normal breast tissue. Patient tolerance was excellent and acute toxicity was rarely observed. 2 patients experienced grade 1 localized dermatitis at the initial 4 week follow-up visit.

Conclusions: CyberKnife stereotactic accelerated partial breast irradiation is a suitable radiotherapy technique for the delivery of partial breast irradiation. The CK platform produces highly conformal treatments with excellent normal tissue sparing and offers improvements over existing PBI techniques. Our experience indicates that CK-SAPBI delivered in five fractions is well tolerated with excellent short term local control and breast cosmesis. Longer follow-up is needed for assessment of late toxicity and oncologic outcomes.

EP-1163

Selection of patients with left breast cancer for Deep-Inspiration Breath-Hold Radiotherapy Technique

B. Czeremyszynska¹, S. Drozda², M. Górczyński¹, L. Kępką¹
¹*Independent Public Health Care Facility of the Ministry of the Interior, Radiotherapy Department, Olsztyn, Poland*
²*University of Warmia and Mazury, Faculty of Mathematics and Computer Science, Olsztyn, Poland*

Purpose or Objective: The voluntary deep-inspiration breath-hold radiotherapy technique (DIBHRT) in the treatment of left breast cancer has the ability to reduce doses to heart left anterior descending coronary artery (LAD) and lung. Before introduction of DIBHRT into routine clinical practice, we conducted a prospective study to assess the extent of dosimetric benefit of this technique in order to select a group of patients for whom this technique should be routinely applied

Material and Methods: Thirty one consecutive patients qualified for whole breast irradiation (WBI) with tangential fields following breast conserving surgery for left-sided early breast cancer were included. All patients underwent breath-hold training, free-breathing (FB) and DIBH planning-CT. Separate radiotherapy treatment plans for WBI in total dose of 39.9Gy in 15 fraction were prepared based on both planning-CT. Doses like mean heart, heart V20Gy, maximum LAD, left lung V20Gy were calculated for each plan and the difference of respective values (delta) for FB and DIBH were calculated. If relative improvement of at least 20% for any evaluated dosimetric parameter were found for DIBH plan without significant worsening of other measures, this plan was selected for treatment. Daily three-dimensional surface imaging (VisionRT) and weekly electronic portal imaging were performed. The data distribution were assessed using chi² test, correlations were analyzed using the Pearson test. Furthermore, receiver operating characteristic (ROC) analysis was performed.

Results: In 30 of 31 patients a reduction at least 20% in one or more evaluated parameters (i.e. mean heart, heart V20Gy, maximum LAD and left lung V20Gy in 29, 29, 26, and 7 patients respectively) was achieved. The relative worsening of left lung V20Gy was found for in 10 and cases and of maximum LAD in 2 cases. Eventually 25 patients were qualified to DIBHRT. Mean delta(Gy) were: mean heart 1.51 (range:0.06-6.45), heart V20Gy:3.0 (range:0.0-6.59), maximum LAD:18.5(range:-3.29-36.68), left lung V20Gy:1.7(range:-

2.71-8.7). Correlations between delta values of mean heart, maximum LAD, heart V20Gy with length of cardiac contact distance (CCD) ($p < 0.05$, $AUC > 0.6$) and maximum LAD, heart V20Gy with Body Mass Index (BMI) ($p < 0.05$; $AUC > 0.6$) were found. ROC analysis showed that a 2.5 cm of CCD is a threshold for reduction at least 20% in one or more parameters. For BMI no specific threshold for predefined improvement of any dosimetric parameter was identified, which means that despite correlation of dosimetric cardiac benefit with higher BMI, some patients with low BMI may also have cardiac doses reduced with DIBHRT.

Conclusion: In our center we have prospectively confirmed an ability of DIBHRT for heart and LAD but not for lung-sparing. We are going to use this technique routinely for left-sided breast cancer patients with CCD above 2.5 cm

EP-1164

Outcomes of postmastectomy radiotherapy in patients with 1 to 3 positive nodes in single institute

Y. Kumai¹, M. Oguchi¹, Y. Miyagi², Y. Ito², T. Iwase², F. Akiyama³, K. Yoshida⁴, A. Harada¹, H. Okubo¹, T. Asari¹, K. Murofushi¹, T. Toshiyasu¹, T. Kozuka¹, M. Sumi¹

¹*Cancer Institute Hospital, Radiation Oncology, Tokyo, Japan*

²*Cancer Institute Hospital, Breast Oncology Center, Tokyo, Japan*

³*Cancer Institute Hospital, Division of Pathology, Tokyo, Japan*

⁴*Showa General Hospital, Radiology, Tokyo, Japan*

Purpose or Objective: Post-mastectomy radiation therapy (PMRT) is standard care for breast cancer patients with high risk for locoregional recurrence after mastectomy. The indication for PMRT in patients with 1 to 3 positive nodes has been in discussion. We reported that patients concomitantly with 1 to 3 positive nodes and extensive lymphatic invasion, who had not been treated with PMRT from 1990 to 2000, had 13.1% (12/92) of locoregional recurrence rate. Since then we have performed PMRT for patients with 1 to 3 positive nodes and extensive lymphatic invasion.

To investigate the effectiveness of PMRT for patients with 1 to 3 positive nodes and extensive lymphatic invasion.

Material and Methods: Between 2005 and 2013, 639 patients were treated with PMRT and 277 patients of those have not been without neoadjuvant chemotherapy until the lymph node dissection. Among these patients, 81 were diagnosed with 1 to 3 positive nodes pathologically, 65 were with 1 to 3 positive nodes and extensive lymphatic invasion. The 3-D conformal RT, using the partial wide tangent technique to the chest wall, internal mammary lymph nodes and supra-clavicular nodes, was applied for all patients, delivering 50 Gy in 25 fractionation over 5 weeks. In the patients with positive surgical margin, 10 Gy of electron boost to the tumor bed was added. We retrospectively reviewed and compared locoregional recurrence rates of 65 patients with 1 to 3 positive nodes and extensive lymphatic invasion treated with PMRT and that of 92 patients without PMRT.

Results: Baseline patient characteristics; the median age of these patients was 47 years old (range; 34-76). Survivals; the median duration of overall survival was 114 months (30 to 121 months), the five-year survival rate is 97%, and the median progression-free survival time after PMRT was 93 months (7.0 to 110 months). Of the 65 patients in the current analysis, 58 patients (89%) were alive and free of cancer. Initial failure patterns; the locoregional recurrence was observed in 3 patients (4.6%), classifying into 1 chest wall, 1 regional lymph node, and 1 both. All patients with locoregional recurrence were developed the distant metastases then after. As toxicity; radiation induced pneumonitis graded 1 was observed in 9 patients, nor been graded 2 or more observed. Acute radiation induced dermatitis was observed almost all patients at least grade 1, grade 3 was observed in 9 patients. One patient denied continuing PMRT at dose of 46Gy, 7 months later her chest wall recurrence was observed.

Conclusion: The 4.6% of local recurrence rate of PMRT cohort registered from 2005 to 2013 was lower than 13.1% (12/92) of non-PMRT cohort registered from 1990 to 2000.

EP-1165

Impact of nodal status on clinical outcome of breast cancer patients: a monoinstitutional experience

C. Cefalogli¹, M. Trignani¹, L.A. Ursini¹, A. D'Aviero¹, M. Di Tommaso¹, S. Di Santo¹, A. Pamio², M. Di Nicola², D. Genovesi¹

¹*Ospedale Clinizzato S.S. Annunziata, Radiotherapy, Chieti, Italy*

²*Laboratory of Biostatistics, Biomedical Science, Chieti, Italy*

Purpose or Objective: The aim of our study was to determine the impact of nodal status and other prognostic factors on clinical outcome of patients with breast cancer treated with surgery and adjuvant radiotherapy.

Material and Methods: A total of 774 breast cancer patients treated between 2001 and 2013 were retrospectively analyzed. Qualitative and quantitative characteristics were summarized as frequencies and percentages, average and standard deviations. The rates of Overall Survival (OS), disease free survival (DFS), and loco-regional recurrence (LR) were calculated at 36 and 60 months with the Kaplan-Meier method. Multivariate analysis was also performed and a p value of 0.05 was considered statistically significant.

Results: We identified 774 patients treated with adjuvant RT of which 595 patients (75.4%) without nodal involvement (pN0), 118 (14.9%) pN1-3 and 61 (7.75%) with more than 3 positive lymph nodes (pN>3). In our sample, supra-clavicular region was irradiated in 62 patients (13 pN>3, 17 pN1-3, 32 pN0). Median follow-up was 36 months (range 1-144 months). There were 14 cases of LR, of which 13 in pN0 and 1 in pN1-3 patients. A total of 31 patients developed distant metastases (48.4% in pN0, 19.4% in pN1-3, 32.2% in pN>3 group). The mortality rate was of 2.8% (68.1% pN0, 18.2% pN1-3 and 13.6% pN>3). There were no statistically significant differences in terms of OS, DFS and MFS among the three treatment groups. Multivariate analysis showed that clinical outcomes were significantly correlated with margin status (p-value: 0.00), T-stage (p-value: 0.053), Her2-neu gene amplification (p-value: 0.00), Ki-67 (p-value: 0.00) and SCRT (p-value: 0.00). Variables such as age, surgery, ER and PgR expression and grading, were not significant.

Conclusion: In our study we observed higher rates of events in pN0 and pN1-3 patients, but none statistically significance was demonstrated between pN0, pN1-3 and pN>3 in terms of OS, DFS and MFS. Furthermore pN0 was in this experience the bigger group and this certainly influenced statistical analysis. In breast cancer, nodal status plays a key role both in the prognostic evaluation and in the therapeutic choice, and the clinical outcome of patients pN1-3 is comparable to pN>3 patients; so in this group (pN1-3) it is also necessary the evaluation of other prognostic factors such as receptor status, Ki 67 and surgical margins. Nodal status alone seems incapable to really guide treatment choice, with particular regard to the SCRT appropriateness.

EP-1166

Management of chest wall irradiation in patients with breast reconstruction

S. Falivene¹, F.M. Giugliano¹, R. Di Franco¹, A. Argenone¹, D. Borrelli², V. Borzillo¹, E. Esposito³, M. D'Aiuto³, P. Muto¹

¹*Istituto Nazionale Tumori Fondazione Pascale, Radioterapia, Napoli, Italy*

²*Emicenter, Radiotherapy, Napoli, Italy*

³*Istituto Nazionale Tumori Fondazione Pascale, Chirurgia Senologica, Napoli, Italy*

Purpose or Objective: The aim of this study was to evaluate treatment related complications and patient satisfaction in women with locally advanced breast cancer who received post-mastectomy radiation therapy after breast reconstruction.

Material and Methods: Between 2009 and 2014, 65 patients, median age 48 years, with locally advanced breast cancer who underwent mastectomy with breast reconstruction in the same time, received post-mastectomy radiation therapy. Two patients received excision of local recurrence, 46 patients nipple sparing mastectomy, 10 skin sparing mastectomy and 7 modified radical mastectomy. Post-mastectomy radiation therapy was delivered to the chest wall with a dose of 50 Gy in 25 fractions over 5 weeks (57 with 3Dconformal RT and 8 with tomotherapy).

Results: A patient interrupted radiation therapy to 20 Gy for severe acute toxicity with rejection of implants (delayed removal of the prosthesis). Acute dermal toxicity G2 for erythema, telangiectasia (1 patient) and edema was relieved in 26 patients, G1 toxicity in 36 patients, G0 in 2 patients and G3 in 1 patient. Two patients in systemic progression were not considered for local evaluation. At median follow-up of 35 months: 43 patients presented late toxicity G1 due to hyperpigmentation, edema, periprosthetic fibrosis. 7 patients referred sense of tension or pain and not satisfaction about the final aesthetic result. Two patients presented arm lymphedema. Two patients received replacing of the implants after 36 months due to contraction, encapsulation, dislocation, swelling.

Conclusion: Radiotherapy can be safely delivered after breast reconstruction, with a low complication rate and good patient satisfaction. Further randomized studies are needed to better define the optimal management of breast reconstruction and post-mastectomy radiation therapy.

EP-1167

Radiation therapy and breast reconstruction: outcomes and complications in our experience

M. Gatti¹, G. Belli¹, A. Salatino¹, A. Maggio², G. Cattari¹, S. Squintu¹, A. Rivolin³, R. Ponzone⁴, P. Gabriele¹

¹*FPO-IRCCS Candiolo, Radiotherapy, Candiolo, Italy*

²*FPO-IRCCS Candiolo, Medical Physics, Candiolo, Italy*

³*FPO-IRCCS Candiolo, Plastic Surgery, Candiolo, Italy*

⁴*FPO-IRCCS Candiolo, Oncological Gynecology, Candiolo, Italy*

Purpose or Objective: The impact of adjuvant therapy on the surgical outcomes following breast reconstruction is poorly understood. The purpose of this work is to evaluate surgical outcomes following autologous and prosthetic reconstruction in the setting of post-mastectomy radiation therapy (PMRT) and adjuvant chemotherapy. We assessed the outcome and complications of irradiated patients in our department.

Material and Methods: From May 2015 to July 2015 we analyzed acute, late toxicity and cosmetic results of 76 patients with a median age of 50 ± 10 years undergoing mastectomy with immediate reconstruction with prosthesis (79.7%), autologous technique (7.2%) or expander-implant (13%) following adjuvant radiotherapy. 24 patients underwent to Nac- Sparing Mastectomy, 10 of which with periareolar pexy. 31 patients underwent to Skin reducing Mastectomy and 5 patients to Skin Sparing Mastectomy. The radiotherapy dose was 50 Gy to chest wall and supraclavicular lymph nodes when indicated with 6 MV X-ray delivered with Linac (60pt), or with tomotherapy (16pt).

Results: With a median follow-up of 25±24 months utilizing RTOG toxicity scale we observed a grade I acute toxicity in 74.6% of patients, grade II in 6% of patients while in 19.4% of patients was not observed any sign of toxicity. Late toxicity was not observed in 68.7% of patients while in 28.4% of patients a grade I late toxicity was noted. No post-operative complications was observed in 62.3% of patients while in 15.9% a capsular contracture was responsible in 20.3% of patients of explantation of prosthesis. None of patients developed post-operative skin ulcers. Cosmetic results was analyzed with Harvard Scale and was excellent in 4.5% of patients, good in 32.8%, fair in 16.4% and poor in 46.3%. The chi-test showed no correlation between early or late toxicity or cosmetics results with type of surgery (p>0.1). Univariate

analysis showed no relationship between cosmetic result and age ($p>0.13$).

Conclusion: Our experiences is limited to a low number of cases but confirm that adjuvant radiotherapy is not contraindicated when reconstructive surgery is expected. The patient must be informed about the possible radiation sequelae.

EP-1168

Phase II trial of hypofractionated VMAT treatment for early stage breast cancer: 2-years outcomes

F. De Rose¹, D. Franceschini¹, A. Fogliata¹, C.S. Iftode¹, E. Villa¹, A.M. Ascolese¹, P. Navarra¹, C. Franzese¹, T. Comito¹, A. Tozzi¹, E. Clerici¹, R.L.E. Liardo¹, F. Lobefalo¹, G.R. D'Agostino¹, M. Scorsetti¹

¹Istituto Clinico Humanitas, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

Purpose or Objective: To report 2-years toxicity and clinical results of hypofractionated simultaneous integrated boost (SIB) technique with Volumetric Modulated Arc Therapy (VMAT) as adjuvant treatment after breast-conserving surgery.

Material and Methods: Patients presenting early-stage breast cancer were enrolled in a phase II trial. Eligibility criteria: age >18 years, invasive cancer or DCIS, Stage I-II (T <3 cm and N ≤3), breast-conserving surgery without oncoplastic reconstruction, any systemic therapy was allowed in neoadjuvant or adjuvant setting. All patients underwent VMAT-SIB technique to irradiate the whole breast and the tumor bed. Doses to whole breast and surgical bed were 40.5Gy and 48Gy, respectively, delivered in 15 fractions over 3 weeks. Acute and late skin toxicities were recorded based on RTOG scoring criteria and CTCAE v. 4.0, respectively. Cosmetic outcome was assessed as excellent/good or fair/poor, according to the Harvard scale.

Results: The present study focused on long-term results of a cohort of 144 patients with a minimum follow-up of 24 months (median 37, range 24-55 months). Median age was 62 y.o. (range 30-88). At one year, the highest reported skin toxicity was G1, in 14% of the patients; this data dropped to 4% at the last follow-up, after more than 2 years. Breast pain was recorded in 21.6% of the patients 6 months after treatment, while it was present in 3.5% of the patients at the last follow-up, showing a significant improvement with time. No correlation with liponecrosis as recorded from ultrasound exam, nor with dosimetric data. Skin toxicity was correlated with breast volume. No pulmonary or cardiological toxicities were recorded. After an early evaluation of clinical outcomes, only one case presented disease relapse, as liver metastases.

Conclusion: The hypofractionated VMAT-SIB course as adjuvant treatment after breast-conserving surgery showed to be safe and effective with optimal local control. This approach requires validation with long-term follow-up data.

EP-1169

The effect of escalating boost dose in breast cancer patients with involved resection margin

S. Park¹, S.D. Ahn¹

¹Asan Medical Center, Radiation oncology, Seoul, Korea

Purpose or Objective: To investigate the impact of the boost dose escalation on ipsilateral breast tumor recurrence (IBTR), for breast cancer patients with involved surgical margins after breast conserving surgery.

Material and Methods: Between January 1998 and December 2010 at Asan Medical center, among 4275 breast cancer patients who were treated with breast conserving therapy (BCT), a total 192 patients were treated with boost dose over 10 Gy for involved resection margin. We retrospectively analyzed the outcomes in 192 patients who had whole breast irradiation of 50.4 Gy followed by median boost dose 15.0 Gy

(range, 12 - 16 Gy) for breast cancer with involved resection margin. Surgery preceded referral for radiotherapy with a 1-2 mm margin of macroscopically normal tissue. The resection margins were evaluated by pathologist for the presence of invasive carcinoma or ductal carcinoma in situ at the inked margin. Neoadjuvant chemotherapy was done in 3 patients (1.6 %). Adjuvant chemotherapy was given in 93 patients (48.4%). 157 patients (81.8%) received systemic hormone therapy. The median age was 46 years (range, 25-73 years). 182 patients (94.8%) were stage 0 to II and 10 patients (5.2%) with stage III breast cancer were also included. The boost dose delivered with electrons or tangential fields given in daily fractions of 1.5 to 2.5 Gy. The boost volume was described as the site of the primary tumor with a margin of 1.5 cm to the field borders after breast conserving surgery.

Results: The median follow-up duration for all patients was 6.7 years. IBTR were considered as any local failures on ipsilateral breast regardless of the location. The 5-year cumulative risk of ipsilateral breast tumor recurrence as a first event was 5.4%. The 5-year local relapse free survival (LRF5) was 94.4%. IBTR occurred as a first failure in 13 of 192 patients. In boost field recurrences were found in 11 patients (85%). 5 patients (39 %) were out-of boost field failures and 3 of them were both failures. On univariate analysis, age, cell type, pT stage, pN stage, extensive intraductal component (EIC), multiplicity and location of resection margin were prognostic factor for IBTR ($p < 0.05$). In multivariate analysis only young age (<40 years old) and positive radial resection margin were unfavorable prognostic factor for LRF5 ($p = 0.037$, $p = 0.021$ respectively). pT stage was marginally significant prognostic factor for IBTR. ($p = 0.088$)

Conclusion: Median boost dose of 15 Gy is comparable to historical boost research results for local control in breast cancer patients with involved resection margin after BCT. Young age (<40 years old) and positive radial resection margin rather than superficial or deep margin were important risk factors for ipsilateral breast tumor recurrence. More than 80% of local recurrences were in boost field, more boost dose escalation needs to be considered.

EP-1170

Onset of fatigue during and after radiotherapy in breast cancer patient

M.S. Mariaquila Santoro¹, M.A.M. Maria Angela Molinaro¹, A.P. Armando Pingitore¹, R.M. Rosa. Molè¹, A.C. Angelo Chirillo¹, M.L. Marianna Lacaria¹, L.R.F. Lucia Rachele Fabiano¹, V.M. Vita Margheriti¹, D.P. Domenicantonio Pingitore¹

¹Hospital Pugliese-Ciaccio- Catanzaro Via Pio X- 88100 Catanzaro, Department of Hemato-Oncology- Operative Unity of Radiotherapy and Radiobiology, Catanzaro, Italy

Purpose or Objective: Cancer-related fatigue is one of most prevalent symptom among women submitted to radiotherapy (RT) for breast cancer (BC). Despite its prevalence the mechanism of onset is unknown still: one possible mechanism is activation of the immune system, through the mediation by proinflammatory cytokines interleukin (IL), IL1-b,, IL-6, and tumor necrosis factor- α (TNF- α) as host response to tissue damage determined by the radiant treatment. To purpose of this study was to determine the level of fatigue in a group of BC patients its relation to anxiety, depression, serum cytokines, cortisol and blood count levels

Material and Methods: Between October 2013 and May 2015 twenty-eight patients who received adjuvant RT after breast conserving surgery were studied. The patients' subjective feeling of fatigue intensity was measured according to with two standardized self-assessment instruments the Fatigue Assessment Questionnaire (FAQ) and a visual analog scale (VAS) on fatigue intensity before the start and weekly during RT, as well as 14 days and 3-6 and 12 months after RT. In addition, a differential blood cell count and the serum levels of the cytokines- IL1-b,, IL-6, and TNF- α , were determined in parallel to the fatigue assessments.

Results: 60% of patients reported non presence of fatigue before the start of RT. Fatigue intensity as assessed with the VAS increased gradually during radiotherapy, 14 days after the end of radiotherapy, the fatigue intensity was still higher than before treatment, but 3 months later, fatigue was lower than at the pre-treatment level. Fatigue measured with the FAQ did not increase significantly during treatment, but the subscores on physical and cognitive fatigue were elevated during treatment weeks 4 and 5. IL-1b, IL-6, and TNF- α , and hemoglobin levels did not change during therapy. Peripheral blood cell levels declined significantly during therapy and were still low 3 months after treatment. Until treatment week 5, lymphocytes were reduced to almost 50% of their initial values. Patients that introduce fatigue had significantly lower serum levels of cortisol than the nonfatigued patients as well as differences in two lymphocyte populations, at 3-6 and 12 months after the end of radiotherapy.

Conclusion: This study has shown that significant fatigue is common in patients receiving breast irradiation and is precipitated during radiotherapy in some patients but not other. In the patients that show an increase of the fatigue during adjuvant RT, fatigue returned to pre-treatment levels 3 months after treatment. In our study, no evidence was found that anxiety, depression, serum levels of IL1-b, IL6, TNF- α and hemoglobin levels were correlate with treatment induced fatigue. The results of our observation suggest the existence of a mechanism among activation of the immune system and alteration in cortisol and lymphocyte subsets.

EP-1171

The impact of body mass index on organs at risk in breast axillary nodal radiotherapy

L. Pettit¹, A. Welsh¹, C. Puzey-Kibble¹, M. Williams¹, J. Santos¹, G. Wardle¹, S. Khanduri¹

¹Shrewsbury and Telford Hospital NHS Trust, Lingen Davies Cancer Center- Royal Shrewsbury Hospital, Shrewsbury, United Kingdom

Purpose or Objective: There has been recent move within the U.K. to contour the nodal CTV for patients receiving adjuvant radiotherapy for breast cancer. Axillary radiotherapy (ART) following a positive sentinel lymph node biopsy is becoming more common for certain groups of patients. Organs at risk (OAR) should be delineated and considered during the planning process. Body mass index (BMI) has been shown to impact upon spinal cord and brachial plexus doses in irradiation of the supraclavicular fossa. The impact upon the OAR in the axilla has not yet been well documented.

Material and Methods: Patients undergoing ART between 01/04/15-01/10/15 were identified. Non - contrast radiotherapy planning CT scans were taken. External beam radiotherapy was planned with extended tangents using a field in field approach with an additional low weighted anterior oblique field if deemed appropriate for adequate dose coverage. Dose delivered was 40.05 Gy in 15 fractions. BMI was calculated by: weight(kg)/height (m)². CTV's were contoured in accordance with the RTOG contouring atlas. OAR including ipsilateral lung, humeral head and brachial plexus were delineated.

Results: Fifteen patients were identified. Six patients had a BMI between 20-25, 3 between 25-30, 5 between 30-40 and 1 BMI>40. Mean ipsilateral lung V12 was 10.44% (range 2.3%-14.33%). Mean V12 did not vary with BMI (BMI 20-25; mean V12=9.33%, BMI 25-30; mean V12=8.52%, BMI 30-40; mean V12=9.51%, BMI>40 mean V12=6.38%, p=0.55 Chi-Squared). The mean humeral head maximum dose was 35.2 Gy (range 1.2-41.5 Gy). Mean humeral head maximum dose did not vary with BMI (BMI 20-25; mean=34.2Gy, BMI 25-30; mean=27.8Gy, BMI 30-40; mean=40.3Gy, BMI>40; mean=38.2Gy, p=0.49 t-test). The ipsilateral brachial plexus D2 mean was 15.6Gy (range 1.2-37.4 Gy). Mean ipsilateral brachial plexus D2 dose did not vary with BMI (p=0.21 t-test).

Conclusion: BMI did not significantly impact upon OAR dosage although this series is limited by a small sample size. Ipsilateral lung and brachial plexus were comfortably within departmental tolerance. A planning risk volume of 10 mm around the humeral head has now been adopted within the department. It is recognised that intravenous contrast provides better quality images for delineating OAR in particular for the brachial plexus. However, this impacts upon resources in terms of radiographer scanning time. Adequate time needs to be allocated in consultant and physics teams job plans to enable high quality delineation and subsequent radiotherapy plans to be produced.

EP-1172

Thyroid tolerance in adjuvant supraclavicular fossa nodal radiotherapy in breast cancer

L. Pettit¹, A. Welsh¹, S. Khanduri¹

¹Shrewsbury and Telford Hospital NHS Trust, Lingen Davies Cancer Center- Royal Shrewsbury Hospital, Shrewsbury, United Kingdom

Purpose or Objective: Hypothyroidism is the most commonly reported long-term toxicity following radiotherapy to structures near to the thyroid gland. Emami suggested the thyroid gland tolerance as 45Gy (TD 5/5) although a much wider range of 10-80 Gy has been reported in the literature. When irradiating the supraclavicular fossa (SCF) in adjuvant radiotherapy for breast cancer, it is inevitable that the thyroid gland will receive a high dose of radiation due to its proximity to the target volume. Recently there has been a move to CT based delineation of the CTV and organs at risk (OAR) in patients requiring nodal radiotherapy for breast cancer compared with the previous bony land mark/field based techniques. Dose received by the thyroid gland and subsequent late toxicity has not yet been well studied in breast cancer.

Material and Methods: Patients undergoing external beam radiotherapy to the breast or chest wall plus SCF between 01/04/15-01/10/15 were identified. Radiotherapy planning contrast enhanced CT scans were taken. External beam radiotherapy was planned with tangents using a field in field approach with a matched direct anterior field. A low weighted posterior field was added if deemed appropriate for adequate dose coverage. Angle corrections were used as appropriate. A dose of 40.05 Gy in 15 fractions prescribed at depth was employed. CTV's were contoured in accordance with the RTOG contouring atlas. The thyroid gland was prospectively delineated and D5% was recorded.

Results: Seventeen patients undergoing adjuvant SCF radiotherapy were identified. T stage was as follows: T1:2 patients, T2:9 patients, T3:4 patients, T4a:1 patient, T4d:1 patient. N stage; N1:1 patient, N2:14 patients, N3:2 patients. Fourteen were hormone receptor positive, 3 hormone negative. Twelve were HER2 negative, 5 HER2 positive. Mean D5% thyroid was 37.9Gy (range 7-42.7 Gy). Excluding one patient with a previous hemi-thyroidectomy, the mean D5% thyroid was 39.8 Gy (range 16-42.7 Gy). An abnormality requiring referral to a surgeon for was discovered in one patient.

Conclusion: Our departmental tolerance for the thyroid gland was set as 40Gy (for 2.67Gy per fraction). It is hard to achieve this without compromise of the CTV. The effect modern chemotherapy/targeted agents may have on this prior to receiving radiotherapy is unknown. Baseline TSH recording is desirable. Long-term follow up to detect clinical or biochemical thyroid dysfunction is needed to inform practice but would present challenges with capacity in busy oncology departments.

EP-1173

10-years results of accelerated hypofractionated RT for breast cancer

I. Gladilina¹, O. Kozlov¹, L. Klepper², M. Chernykh¹, E. Makarov¹, A. Petrovskiy¹, M. Nechushkin¹

¹NN Blokhin Cancer Research Center, RadioSurgery Brachytherapy, Moscow, Russian Federation

²Central Economic Mathematical Institute Russian Academy of Sciences, Computer Engineering, Moscow, Russian Federation

Purpose or Objective: The aim of the survey - to compare the results of different regimen of whole-breast irradiation (accelerated hypofractionated and standard radiation treatment) following breast-conserving surgery for breast cancer I-IIA stages.

Material and Methods: From 2000 till 2005 203 patients aged R54 years received whole-breast irradiation following breast-conserving surgery (lumpectomy + axillary and internal lymphatic dissection). The most commonly seen invasive ductal carcinoma (55%), the rare - invasive lobular carcinoma (27%), invasive ductal cancer with extensive in situ component (3%) and special forms (15%). Metastasis in ipsilateral axillary lymph nodes fixed in 17,4% cases. All patients received whole-breast irradiation over a five-day period with different regimens RT: first group - accelerated hypofractionated (AHRT: 3 Gy per fraction over 2,5 weeks, total dose of 39 Gy, N=112) and second group - standard radiotherapy (SRT: 2Gy per fraction over 5 weeks, total dose of 50 Gy, N=91). We used three dimensional CT-based treatment planning, two traditional tangential fields 6-18 MV, changing the gantry angle, collimator angle, blocks to result in coverage of the breast while excluding the heart from the treatment fields and minimized dose to the lung. A LQM to predict rate of tumor control, late normal tissue effects and cosmetic outcome was used in our research. For tumor control the value α/β was 4 Gy, acute toxicity - 10 Gy, side effects - 3,1 Gy, cosmetic outcome - 3,6 Gy (for AHRT EQD2 53,0/44,4/46.7/46,0). We calculate (LQM) following formula for AHRT:

$$BED = (1 + d/\alpha/\beta) - k(T - T_k)$$

Tumor: $k=0,7$, $T_k=21$.

Results: Local recurrence at 5y/10y: 1/3 (1 group) vs 0/1 (2 group) ($p>0.05$). Overall survival 5y/10y: 99,1%/95,0% (1 group) vs. 97,8%/85,0% (2 group), ($p<0.05$). Only 8% of the patients of the 1 group developed grade 2 erythema and 14,3% of the patients of the 2 group ($p<0,048$). No complications at heart, complications at the lungs (only 1 degree) 5y/10y: 7(7,7%)/7(7,7%) vs. 6 (5,4%)/6(5,4). The other results are presented in Table 1.

Table 1 (5 and 10 year outcome).

Regimen RT	SRT 5 years	SRT 10 years	AHRT 5 years	AHRT 10 years
tumor control	1 (1,1 %)	3 (3,3 %)	0 (0 %)	1 (0,9 %)
side effects (skin)	6 (6,6 %)	8 (8,8 %)	5 (5,5 %)	8 (7,1 %)
side effects (fibrosis)	11 (12%)	16 (17,6 %)	12 (10,7 %)	15 (13,4 %)
cosmetic outcome (good or excellent)	74,6 %	74,6 %	79,5 %	79,5 %

Conclusion: AHRT decrease adverse effects, increase five and ten-year event free survival and cosmetic results vs. SRT. We had confirmed our calculations with clinical results. AHRT had been proved to be a successful parameters combination of a dose for fraction, durations of an irradiation and the common dose. Prominent feature of this regimen is increase of the tumor control in comparison with SRT, thus early and late reactions are essentially decreased

EP-1174

Interobserver variation in CT vs. MRI based delineation of the lumpectomy cavity

N. Al-Hammadi¹, S. Divakar¹, M. Riyas¹, P. Caparrotti¹, S. Chandramouli¹, M. McGarry¹, S. Sheim¹, R. Hammoud¹, P. Petric¹

¹National Center for Cancer Care & Research A member of Hamad Medical Corporation, Radiation Oncology, Doha, Qatar

Purpose or Objective: To assess the magnitude of inter-observer contouring uncertainties on CT- and MRI-based boost volume contouring in breast cancer patients without clips in lumpectomy cavity.

Material and Methods: CT and MRI data-sets of 12 consecutive patients, treated with surgery (no clips in lumpectomy cavity) and postoperative irradiation were included. Five experienced radiation oncologists independently contoured the boost clinical target volume (CTVb) on CT. Three weeks later contouring was repeated on MRI. Finally, expert consensus (EC) contours were created on both modalities by combining the opinions of all 5 experts. Contour Analysis software Tool 1 (CAT 1) was used for global volumetric computations and assessment of local contouring variation for each case and contouring approach. Inter-observer volumetric conformity index (VCI) was calculated for all pairs of observer's delineations and the EC contour. In topographic analysis, absolute inter-delineation distances (IDDs) between observers' and EC delineations were measured in contouring plane (Figure). Paired sample t-test was used to for statistical analysis of differences between contouring approaches.

Results: None of the observed differences in results were statistically significant ($p>0.05$). Mean CTVb size was 154 +/- 26 cm³, and 152 +/- 16 cm³, for CT and MRI, respectively. Mean relative standard deviation (rSD) revealed higher spread of volumes for CT (18 %) when compared with MRI (11 %). Mean ratio between the smallest and largest volume was comparable (CT: 0.7 +/- 0.1; MRI: 0.8 +/- 0.1). Mean VCI was non-significantly higher for MRI (0.81 +/- 0.04) than CT (0.76 +/- 0.07). MRI-based mean VCI was superior to CT-based approach in 10 (83 %) cases. In one case, mean VCI was identical (0.88 +/- 0.1), and in one case CT-based VCI (0.81 +/- 0.04) was slightly superior to MRI (0.8 +/- 0.05). Analysis of mean IDD values revealed non-significantly superior results for MRI when compared to CT (3 +/- 0.5 mm vs. 4 +/- 1.5 mm) (Figure). Mean rSD for IDDs was lower on MRI than CT contouring (49 % vs. 61 %). In contouring plane, predilection regions of variation were in the direction of breast parenchyma, while agreement was highest at the breast-chest wall and breast-air interface (Figure).

Figure. Example of coordinate system (left) and distance maps (right) or topographic assessment of variation.

Conclusion: Although statistically insignificant, superiority of MRI over CT for accurate boost delineation in patients without clips in lumpectomy cavity may be clinically important. We recommend using information from both modalities, pre-treatment imaging and clinical information to arrive at best results.

EP-1175

Accelerated Partial Breast Irradiation using Carbon-iron Radiotherapy for stage I breast cancer

K. Karasawa¹, T. Omastu², M. Wakatsuki², S. Shiba², S. Fukuda², T. Kamada², N. Yamamoto³, T. Ishikawa⁴, M. Saito⁵

¹Tokyo Women's Medical University, Radiation Oncology, Tokyo, Japan

²National Institute of Radiological Sciences, Research Center Hospital for Charged Particle Therapy, Chiba, Japan

³Chiba Cancer Center, Breast Surgery, Chiba, Japan

⁴Tokyo Medical University, Breast Surgery, Tokyo, Japan

⁵Juntendo University, Breast Surgery, Tokyo, Japan

Purpose or Objective: Our institute started a clinical study on radical C-ion RT for patients with low risk T1N0M0 invasive

ductal carcinoma in 2013. The idea is to develop a short course C-ion RT to be finished in one week, which, we believe, could replace surgery and more than 5 weeks of radiotherapy. The purpose of this report is to evaluate preliminary treatment results.

Material and Methods: There are 2 treatment studies. One is phase I/II clinical trial and the other is "general treatment protocol" (GP). In clinical trial, candidates are patients with low-risk stage I breast cancer who are suitable for APBI in ASTRO consensus statement. A dose escalation study was designed as a phase I clinical trial. Total dose is 48.0 GyE, 52.8 GyE and 60.0 GyE in 4 fractions within 1 week. In phase I, patients planned to undergo surgery for pathological evaluation 90 days after C-ion RT and then received endocrine therapy. In phase II, patients had C-ion RT at recommended dose and then received endocrine therapy. Three-field C-ion beams with 290 MeV/n energy are used by means of passive broad beam methods using individual collimators and a compensation bolus absorber. Irradiation is performed using respiratory gating. The other study, GP is for the patients desiring to receive C-ion RT but ineligible to enroll in the clinical trial due to minor variance or refusal to enroll in the clinical trial. The first 2 patients of this GP were treated by 52.8 GyE and the others by 60 GyE. All patients were suitable for endocrine therapy after RT.

Results: From April 2013 to October 2015, 18 patients were treated. There were 3 cases of 48 GyE and 52.8 GyE and 1 case of 60 GyE of phase I, and 2 cases of 52.8 GyE and 9 cases of 60 GyE of GP. Median age was 66 (44 - 81). Median tumor size was 12 mm (4 - 20 mm). Median f/u period was 12 mos. No normal tissue adverse events were observed except for grade 1 skin reaction of CTC-AE v4 in 9 cases. At the time of analysis, 7 patients underwent surgery and 2 of them reached pCR. Of the GP patients, 6 reached CR, 4 reached PR and 1 developed PD on MRI. It took 3 months to 2 years with a median of 6 months to reach CR on MRI. So the pathological evaluation in phase I trial after 3 months must be too early for evaluation. The PD patient with basal subtype tumor was successfully salvaged by mastectomy.

Conclusion: C-ion RT for primary tumor of breast needed long time to reach CR on MRI. Low grade stage I breast cancer has a potential to cure by accelerated partial breast irradiation with C-ion RT.

EP-1176

Abstract withdrawn

EP-1177

Hypofractionated radiotherapy with concomitant boost for breast cancer: a dose escalation study
C. Rinaldi¹, E. Ippolito¹, M. Fiore¹, P. Matteucci¹, A. Di Donato¹, P. Trecca¹, S. Ramella¹, R. D'Angelillo¹, L. Trodella¹
¹Campus Biomedico University, Radiotherapy, Roma, Italy

Purpose or Objective: to test the maximum tolerated dose (MTD) of a concomitant boost to the tumor bed for patients at high risk of recurrence treated with whole breast radiotherapy (RT). The secondary endpoints are to evaluate the acute and late toxicity and the cosmetic result recorded by appropriate scales.

Material and Methods: between June and August 2014 we selected 9 patients with histologically proven breast cancer with pathological stage pT1-2 and at least one of the following risk factors for local recurrence: N1 disease, lymphovascular invasion, extensive intraductal component, close margins, non hormone sensitive disease, grading G3. All patients were treated with hypofractionated RT to whole breast to a dose of 40.05 Gy in 15 fractions. The dose escalation to the tumor bed was delivered through a daily concomitant boost technique at 3 levels of dose: 48 Gy (3.2 Gy/die), 50.25 Gy(3.35 Gy/die) and 52.5 Gy (3.5 Gy/die) for the first, second and third level, respectively. We included 3 patients for each step (3 additional patients if a dose limiting

toxicity (DLT) Grade ≥ 2 occurred); dose escalation to a higher step was allowed if all patients of the lower one had completed the treatment without DLT. MTD was defined as the dose level below the dose induced DLT in at least 3 patients treated at a given dose level. A clinical evaluation of the patients was carried out before treatment, 2 times a week during RT, at the end of the same, at 3, 6 and 12 months after the end of RT. In addition to skin toxicity a cosmetic evaluation was performed by radiation oncologist, an in-training physician and by the patient herself. The latter also filled the EORTC QLQ - C30 / BR23 on quality of life at each evaluation.

Results: we enrolled a total of 9 patients (3 for each dose level) with a median age of 62 years (range 44-83). Patients' characteristics are reported in Table 1. No dose limiting toxicity Grade ≥ 2 occurred. The maximum toxicity collected during RT was G2 skin toxicity in 7 (77%) patients (2 patients with brisk erythema and 5 with moist desquamation). This toxicity resolved at the first follow up. At a median follow up of 11 months we recorded G2 induration/fibrosis in 3 (33,3%) patients, one for each level of dose. There was a worsening in the self perception of cosmetic outcome at the end of treatment in 6 cases (66%) even if with no statistical significance. Moreover, patients at the end of treatment, reported a worse (not statistically significant) cosmetic outcome compared to that expressed by the in-training physician and the radiation oncologist. The evaluation of QoL found an improvement of the score at the end of treatment compared to initial in 7 of 9 patients (77%), above all in elderly patients (≥ 62 years).

CHARACTERISTICS	NUMBER OF PTS	PERCENTAGE
Adjuvant chemotherapy	4	44%
ER -	9	100%
PgR-	8	88%
HER2 -	2	22%
Ki 67 >20%	4	44%
Lymphovascular invasion	1	11%
N1	5	55%
G1	1	11%
G2	4	44%
G3	4	44%
extensive intraductal component	3	33%
Lobular Carcinoma	1	11%
Ductal carcinoma	8	88%

Conclusion

The 3-week course of postoperative RT with dose escalation to the tumor bed to 52,5 Gy has been achieved without dose limiting toxicities. Long-term follow-up data are needed to assess late toxicity and clinical outcomes.

EP-1178

Predictive factors of patient compliance for breath-holding during radiotherapy for breast cancer

R. Walshaw¹, C. Robinson¹, S. Yousif¹, E. Young¹, M. Hogg¹, S. Susnerwala¹, A. Hindley¹, C. Lim¹, F. Danwata¹, D. Williamson¹

¹Royal Preston Hospital, Rosemere Cancer Centre, Preston, United Kingdom

Purpose or Objective: Radiation to the heart during radiotherapy (RT) for breast cancer may lead to increased risk of ischaemic heart disease years afterwards. A proposed method of reducing cardiac dose is with breath-holding techniques. Patients undergoing adjuvant breast RT form a heterogeneous group in terms of demographics and comorbidities. We aimed to determine what proportion of patients from an unselected group eligible for adjuvant RT would be able to comply with a simple breath-holding technique pre-treatment, and whether any individual characteristics may help predict success or failure.

Material and Methods: We prospectively identified all patients due to receive adjuvant RT to left breast after surgery for early breast cancer, and offered participation. After RT planning scan patients were kept in treatment position and asked to hold their breath for 20 seconds twice, with one minute between attempts. Demographics and patient factors were recorded. Treatment was subsequently delivered as normal with no breath-holding used.

Results: Fifty-eight patients were included, median age 60.0 years (range 35.1-85.2), median body mass index 26.8 (18.1-39.3). WHO Performance status was 0-1 in 56, and 2 in 2 patients; 3 patients had mobility issues, 2 were unable to climb on the scanner couch unaided. Seven patients had a diagnosis of chronic respiratory disease, 7 using inhalers regularly. Twenty patients were ex-smokers, 7 current smokers, 31 never smoked. At diagnosis, 6 patients (10%) had ductal carcinoma in-situ, 36 (62%) T1, 15 (26%) T2, and 1 (2%) T3 disease; 9 (16%) had nodal disease; 7 (12%) had full axillary node clearance and 16 (28%) had chemotherapy prior to RT. Fifty three (91%) were successful in breath-holding for both 20 second periods, 2 (3%) were unsuccessful on both attempts. Two (3%) were unsuccessful first, but successful a minute later; 1 (2%) was successful for the first period but not the second.

Conclusion: The vast majority of patients from an unselected cohort of patients due to undergo adjuvant RT to the breast or chest wall were able to maintain breath-hold successfully for two 20-second periods one minute apart in a simulated treatment position. No consistent patient factors were identified that would reliably predict success or failure to breath-hold. We anticipate most patients will tolerate breath-holding techniques during breast RT should they be employed more in the future. In the era of stereotactic ablative RT, breath-holding may also become important in other patient cohorts.

Preoperative parallel PET/MR predicts the disease free survival in patients with breast cancer

I. LIM¹, J. Park¹, W.C. Noh², H.A. Kim², K.W. Park³, H. Seol⁴, J.K. Myung⁴, I.O. Ko¹, K.M. Kim¹, B.H. Byun¹, B.I. Kim¹, C.W. Choi¹, S.M. Lim¹

²Korea Institute of Radiological And Medical Sciences, Surgery, Seoul, Korea Republic of

³Korea Institute of Radiological And Medical Sciences, Radiology, Seoul, Korea Republic of

⁴Korea Institute of Radiological And Medical Sciences, Pathology, Seoul, Korea Republic of

Purpose or Objective: The aim of this study was to determine whether PET/MR could predict disease-free survival (DFS) in patients with operable breast cancer.

Material and Methods: Seventy-eight patients with breast cancer were enrolled. All patients underwent preoperative parallel PET/MR: whole body PET/CT at 1 h after 18F-FDG injection, breast dynamic contrast enhanced MR, and breast PET/CT at 2h after 18F-FDG injection sequentially in prone position. All patients were analyzed by diverse parameters (maximum SUV at 1 h [SUV1], maximum SUV at 2 h [SUV2], retention index of SUVmax [RI], metabolic tumor volume [MTV], total lesion glycolysis [TLG], initial slope of the enhancement curve [IS], transfer constant [Ktrans], reflux constant [Kep], extravascular extracellular space volume fraction [Ve], and initial area under the curve [iAUC]). A relationship between covariates and DFS after operation was analyzed using Kaplan-Meier method and multivariate Cox proportional-hazard regression method.

Results: The median follow-up of 78 patients was 55 months (31-67 months), and 9 (11.5 %) patients developed recurrence or metastasis. Among parameters, higher RI ($p = 0.0010$), lower Ktrans ($p = 0.0046$), and lower Ve ($p = 0.0035$) were significantly associated with poorer DFS. In contrast, SUV1,

SUV2, MTV, TLG, IS, Kep, and iAUC were not. On multivariate analysis, RI ($p = 0.016$; HR = 5.20; CI 1.4-19.7), and Ktrans ($p = 0.035$; HR = 0.22; CI 0.054-0.89) were found as independent predictors of DFS. Patients with higher RI and lower Ktrans revealed a significantly higher recurrence rate (66.7 %) than the rest of patients (6.9 %, $P < 0.0001$).

Conclusion: RI and Ktrans measured by preoperative parallel PET/MR can predict DFS in patients with operable breast cancer. The combination of these parameters could make improvement of patients care because tailored surveillance would be applied for high risk group.

Postoperative IMRT with helical tomotherapy for breast cancer: outcome and toxicity analysis

J. Fourquet¹, F. Crop¹, T. Lacomberie¹, E. Tresch², F. Le Tinier¹, S. Horn¹, F. Vasseur¹, E. Lartigau³, D. Pasquier³

¹Centre Oscar Lambret, Academic department of Radiation Oncology, Lille, France

²Centre Oscar Lambret, Unité de Méthodologie et de Biostatistique, Lille, France

³Centre Oscar Lambret, Academic department of Radiation Oncology- Université de Lille- CRISTAL UMR CNRS 9189, Lille, France

Purpose or Objective: Radiation therapy (RT) plays a key role in the management of breast cancer. Intensity-modulated radiotherapy (IMRT) has been shown to provide a more homogeneous dose distribution and to decrease skin toxicity. It covers a wide spectrum of techniques, ranging from static IMRT to helical tomotherapy (HT). HT could be relevant for complex volumes and/or difficult anatomies, but it needs to be evaluated since clinical data are still limited. The objective of this retrospective study is to investigate the short-term outcome and toxicity in a series of patients treated with adjuvant breast HT.

Material and Methods: Patients with an indicated breast adjuvant radiotherapy using an IMRT technique were included after a staff discussion. The treatment was performed with HT with concomitant boost if needed: 50 Gy (2 Gy/fraction) over the breast or the chest wall and lymph nodes, 60 Gy (2.4 Gy/fraction) on the tumor bed, 58 Gy (2.33 Gy/fraction) on the mastectomy scar if indicated. Toxicities were evaluated according to the NCI-CTCAE v4.0. A search for factors related to toxicity was conducted using univariate and multivariate analysis.

Results: 98 patients were treated between January 2013 and September 2014. The following target volumes were irradiated: breast (53.4%) or chest wall (46.6%), locoregional lymph nodes i.e. internal mammary chain, infra and supraclavicular levels (79.6%). 54.4% of them were treated for left side breast cancer. The acute toxicities were mainly skin toxicity (grade (gr) 1: 63.1%; gr 2: 28.2%; gr 3: 3.9%) and esophagitis (gr 1: 42.9%; gr 2: 15.3%). Other acute toxicities were gr 1 laryngitis (2.0%); gr 2 pneumonitis (1.0%); gr 1 (3.1%) and gr 2 (1.0%) cough. With a median follow-up of 8.4 months (1.1-20.7), there were skin toxicity (gr 1: 41.2%, gr 2: 2.1%) and dysphagia (gr 1: 1.0%). No local recurrence occurred, two metastatic relapse occurred and one patient died (death related to cancer). Factors significantly ($p < 0.05$) correlated with toxicity in multivariate analysis were: breast size and average skin dose for acute skin toxicity; chemotherapy, esophageal D2%, average esophageal dose, esophageal V30Gy and V45Gy for esophagitis. For the short-term skin toxicity, PTV volume, PTV D2% and average PTV dose were associated with toxicity.

Conclusion: In this retrospective study with a short follow-up, postoperative breast HT is a well-tolerated treatment for patients in need of a complex irradiation. Several clinical and dosimetrical parameters related to toxicity have been identified.

EP-1181

Prostheses irradiation in breast cancer: clinical and aesthetic outcomes in retrospective series

D. Smaniotto¹, V. Masiello¹, F. Beghella Bartoli¹, L. Boldrini¹, G. Mattiucci¹, F. Marazzi¹, S. Manfrida¹, A. Di Leone², G. Franceschini², R. Masetti², V. Valentini¹

¹Policlinico Universitario Agostino Gemelli- Catholic University, Radiation Oncology Department - Gemelli ART, Roma, Italy

²Policlinico Universitario Agostino Gemelli- Catholic University, UOC Breast Surgery, Roma, Italy

Purpose or Objective: Post-mastectomy radiation therapy (RT) is a prophylactic adjuvant treatment for high risk patients with breast cancer. Mammary prostheses or expanders often do not tolerate RT causing a reduction of aesthetic profile and, even more, an exposure to clinical risks or new surgery. In this retrospective study clinical and aesthetic results were quantified in patients who did or did not undergo adjuvant RT after reconstruction for breast cancer

Material and Methods: Patients who underwent mastectomy with immediate mammary reconstruction for breast cancer and who had a follow-up (FUP) period of at least six months were selected for this retrospective study. Two subgroups were defined between irradiated or not patients. All the patients were submitted to the scheduled surgical and oncologic FUP and the irradiated ones underwent also a RT FUP program. For both groups local infection rate (IR), lipofilling rate (LR), reconstruction with DIEP flap rate (DIEPR), local control (LC) and distant failure rate (DFR) were analyzed. All chi square tests were performed on MedCalc. For the irradiated patients acute and late toxicities were also registered according to CTCAE v4.0 scale

Results: From January 2012 to April 2015, 152 patients underwent mastectomy with prostheses or expanders. Out of them, 76 pts were candidates to standard adjuvant RT for high risk factors, according to NCCN guidelines. Mean age was 48 years (range 32-74). Median FUP was 28 months (range 6-44). IR, LR, DIEPR are reported in Table 1. 21% of not irradiated pts underwent second surgery to replace the expander with the prostheses. LC was equal in both group. High risk pts had higher DFR than low-medium risk ones (5.26% vs 0 with p<0.05). Regarding irradiated patients acute skin toxicities G0, G1, G2 and G3 were 38%, 40%, 12% and 9.8% respectively. We reported late skin toxicities rates of: G0 20%, G1 28%, G2 42% and G3 10% (Figure 1).

	Adjuvant RT	No adjuvant RT	Chi square test
Lipofilling rate	10 (13,1%)	16 (21%)	1.2 (p<0,01)
DIEP flap rate	15 (19,7%)	7 (9,2%)	2.5 (p<0,01)
Infection rate	1 (1.3%)	1 (1.3%)	0

Conclusion: In this preliminary analysis RT after mastectomy with breast reconstruction resulted well tolerated and can ensure to high risk patients local control rates comparable to low-medium risk patients in the early FUP. A longer period of observation and specific Quality of Life questionnaires are needed to better describe the results

EP-1182

Prone whole breast irradiation: multimodal imaging for target delineation

A. Huscher¹, M. Centurioni¹, L. Donadoni¹, D. Santus², A. Soregaroli², C. Bassetti³, A. Zaniboni⁴, M. Bignardi¹

¹Poliambulanza Foundation, Radiation Oncology Unit, Brescia, Italy

²Poliambulanza Foundation, Radiology Department, Brescia, Italy

³Poliambulanza Foundation, Medical Physics, Brescia, Italy

⁴Poliambulanza Foundation, Oncology Department, Brescia, Italy

Purpose or Objective: Whole breast clinical target volume (CTV) contouring rules have been defined for supine set-up. The same indications do not seem to fit properly for prone set-up and no clear definition could be found nowadays in

literature. This study was planned first to evaluate definition of prone CTV (pCTV) based on breast glandular tissue (BGT) distribution on diagnostic MRI, and then to analyse MRI/CT image fusion for treatment planning.

Material and Methods: We first analyzed BGT distribution in 30 diagnostic MRI in respect to the following structures: major and minor pectoralis muscles, caudal edge of clavicular head, sternum, skin, medial and lateral thoracic arteries and infra-mammary fold. Reference structures were derived from the latest ESTRO contouring guidelines for supine irradiation. The anatomical region including BGT in all cases was defined as pCTV. After that MRI and CT were acquired for treatment planning in 10 patients, planned for prone irradiation. Eight channel contrast-enhanced MRI was acquired. Axial T2 IDEAL sequences were used for pCTV definition. CT for treatment plan was acquired with 3 mm thickness and step, with dedicated prone breast board (New Horizon Breastboard - CIVCO Medical Solutions). pCTV was defined on MRI according to the above described references and transferred to CT with a dedicated deformable fusion workflow (MIM 6.4.9 - MIM Software Inc.).

Results: Mean age of patients was 46 year. The well-known distinction in BGT distribution pattern (intermingled and centralized) was confirmed. pCTV could be defined superiorly by the caudal edge of clavicular head, inferiorly 3 mm above infra-mammary fold, medially by the medial thoracic artery (or if not visible 3 mm laterally to the sternal margin) laterally by a plane passing through the lateral surface of the pectoralis muscles and perpendicular to the skin, posteriorly by the anterior surface of pectoralis muscles and anteriorly 3 mm from skin. Image fusion performed easily and transferred pCTV was consistent with anatomy on CT slices. Visualization of BGT on MRI images allowed more precise definition of volumes and the limits chosen for pCTV definition on MRI fit adequately on CT.

Conclusion: Although derived from a small sample, the above reported contouring suggestions could be of aid in defining pCTV; we confirm the superiority for BGT visualization on MRI. The good consistency between MRI and CT anatomy seems to suggest that MRI criteria could be transferred on CT in everyday workflow for pCTV definition

EP-1183

Investigation on the absorbed dose to organs at risks using an IOERT planning software

H. Ozcan^{1,2}, M. Ghorbanpour Besheli^{1,2}, C. Matuschek¹, S. Mohrmann³, C. Illana⁴, R. Rodriguez⁴, E. Boelke¹, W. Budach¹, I. Simiantonakis^{1,2}

¹University Hospital, Department of Radiotherapy and Radiation Oncology, Duesseldorf, Germany

²Heinrich-Heine University, Faculty of Physics/Medical Physics, Duesseldorf, Germany

³Medical Faculty- University Hospital, Department of Gynecology, Duesseldorf, Germany

⁴GMV, R&D, Madrid, Spain

Purpose or Objective: In the intraoperative electron radiotherapy (IOERT), as a part of breast-conserving therapy, a single high dose is applied on the tumor bed in order to eradicate the residual tumor cells. Currently, dose profiles obtained by radiochromic films are used to estimate the applied energy. The energy is selected by measuring the distance to the rib as dose limiting organ at risk by intraoperative ultrasound. This method is fast and practical for clinical applications but it is not possible to estimate the absorbed dose on critical organs like heart and lung. Therefore, an IOERT planning system was tested in order to evaluate the adsorbed dosage for organs at risk.

Material and Methods: The dedicated mobile IOERT accelerator, NOVAC7 (SIT, Vicenza/Italy) was used for electron beam generation. The dose calculation was performed in Radiance (GMV, Madrid/ Spain) IOERT treatment planning software. Before dose calculation, the Radiance system was configured based on the measured data

obtained from the electron beams. Dose calculation was performed based on the CT images registered a few days after IOERT irradiation (post-operative CT image). The absorbed dose in lung, heart and ribs were shown by DVHs and documented quantitatively. From a database of irradiated 53 patients n=6 patients were selected who developed fibrosis grade 2, edema grade 2, pneumonitis and suspicious heart effect (not confirmed). All of the patients received whole breast irradiation with 50,4 Gy/1,8 Gy SD. Dose constrains of the dose plans showed no exceeding the threshold doses.

Results: Calculated dose resulted for ribs, heart and lung are presented in table 1. As it is shown, the absorbed dose at the ribs varied from 3.8 Gy to 9.2 Gy. This is partially higher than our tolerance dose of 7 Gy. The calculated dose values of different organs depend on the applied energy, the location of the tumor bed, the number of ribs located in the treatment field and the distance of the organ from the tumor bed. The overdoses resulted for ribs imply that the evaluation method of absorbed dose to rib in clinical practice should be optimized. On the other hand, these overdoses could be due to the uncertainty arising from the planning procedure. Because in this investigation a so-called off-line planning through a post-operative image was performed. This makes the actual applicator position and tumor bed localization in relation to the patient's anatomy during the planning procedure difficult.

Table 1: Investigated patients and calculated doses on ribs, lung and heart

Patient	Side effect	Energy [MeV]	Applicator	Estimated dose on ribs [Gy]	Dose on ribs [Gy]	Dose on lung [Gy]	Dose on heart [Gy]
1	fibrosis grade 2	7	40mm, 0°	4,4	5,9	4,3 (right)	0
2	fibrosis grade 2	7	40mm, 0°	5	6,4	5,8 (right)	0
3	fibrosis grade 2	5	40mm, 22.5°	5,5	8,3	6,6 (left)	0
4	edema grade 2	5	40mm, 0°	5,5	8,2	3,0 (left)	0
5	heart effect	7	40mm, 22.5°	5	5,2	6,1 (left)	1,1
6	lung effect	7	50mm, 22.5°	6 – 7	9,7	7,2 (right)	0

Conclusion: No direct relation was observed between the side effects and the absorbed dose on heart and lung. Intraoperative imaging is highly recommended in order to increase the accuracy of the planning procedure and consequently the estimation of the calculated absorbed dose in patient.

EP-1184

Radiotherapy on nodal areas after breast conserving surgery according to histopathological features

G. Lazzari¹, G. Silvano¹, G. Della Vittoria Scarpati¹, R. Marchese¹, M. Soloperto¹, A. Nikolaou¹, A. Terlizzi², F. Perri³

¹Azienda Ospedaliera SS. Annunziata Presidio Osped, Radiology, Taranto, Italy

²Azienda Ospedaliera SS. Annunziata Presidio Osped, Physician Department, Taranto, Italy

³Azienda Ospedaliera SS. Annunziata Presidio Osped, Oncology, Taranto, Italy

Purpose or Objective: To examine locoregional and distant recurrence rate (LLR and DR) in breast cancer patients treated with breast conserving surgery and adjuvant radiotherapy on whole breast and nodal areas according to histological subtype and prognostic characteristics.

Material and Methods: Between 2004 and 2013, 500 breast cancer patients (pts) were reviewed for this analysis. All pts received breast conserving surgery and adjuvant radiotherapy extended to nodal area because of pN+: 210 pts with pT1-2

pN1 stage, 190 pts with pT1-2 N2 while 100 pts with pT1/2 pN3 stage. Hystological subtype was luminal A (LA=Er+/Pr+, Her neg G1-G2) in 164 pts; luminal B (LB=Er+/Pr+, Her2 neg G3) in 170 pts; triple negative (TN=Er-Pr-Her2 neg) in 166 pts. Mean age was 65 yrs (range: 40-72 yrs). Patients were treated with chemotherapy according to prognostic features. All patients received whole breast radiotherapy with a total dose of 50 Gy + 10 Gy boost and 48-50 Gy on supraclavicular fossa. In case of medial tumors, the internal mammary chain was included. Kaplan-Meier and paired t-test were used for statistical analysis.

Results: The 5-year LRR and DR were obtained with a median of 6.3 yrs. The 5-year LRR was 1.9% in LA, 2.8% in LB, 2.1% in TN ($p = .72$). The 5-year DR was in LA 2%, LB 4.5%, 8% in TN ($p < .001$). According to nodal status LRR was 1.7% in N1, 2.3% in N2 and 3.8% in N3 status ($p = .005$). The 5-year DR in N1 LA was 2.4%, for LB was 3%, for TN was 3.5% ($p = .82$) while in N2 LA it was 3%, for LB was 5% and for TN it was 7.3% ($p = .06$); for N3 LA was 3.5%, for LB was 4.8%, for TN was 8.5%; overall DR of pN1 versus pN2/N3 was statistically significant ($p = .02$). On multivariate analyses high risk of LRR was related to T size ($T > 2$ cm), presence of lymphovascular invasion, lobular histology; high risk of DR was observed for $N > 4$ nodes, presence of ECE, Ki 67 $> 30\%$ and age < 50 years.

Conclusion: In this analysis triple negative breast cancer patients with pN1 seem to benefit by nodal radiation, but further studies are necessary

EP-1185

Male breast cancer - outcome with adjuvant treatment

B. Yadav¹, S. Sharma¹, R. Singh¹, S. Ghoshal¹

¹PGIMER, Radiation Oncology, Chandigarh, India

Purpose or Objective: To analyze outcome with adjuvant treatment in male breast cancer (MBC) patients.

Material and Methods: From 1991 to 2013, 68 men with breast cancer were retrospectively analyzed for demographic, clinico-pathological and treatment outcomes. Disease-free survival (DFS) was defined as time duration from diagnosis to first recurrence. Overall survival (OS) was defined as time duration from pathologic diagnosis to death or last follow-up with any death defined as an event. DFS and OS were estimated using Kaplan-Meier method and compared between patients receiving and not receiving adjuvant treatment using log-rank test.

Results: Mean age was 55 years (range 30-76). Right, left and bilateral BC was seen in 37(54%), 30(44%) and 1(1%) men respectively. Mean duration of symptoms was 25 months (range 1-240). Comorbidity was present in 22(36%) patients. Family history was present in 3(4%) patients. Mean tumor size was 5x5cm (range 1x1-10x10cm). Nipple was involved in 24(35%) men. Early, locally advanced and metastatic disease was seen in 27(39%), 29(43%) and 13(19%) patients respectively. Majority 51(84%) had IDC histology. In radically treated 56 men, NACT with FAC regimen was given to 10(18%) patients; with CR in 4(40%) and PR in 6(60%) patients. Mastectomy was done in 48(86%) and WLE in 8(14%) men. Margins and nodes were positive in 13(23%) and 30(54%) men respectively. ER, PR and Her2neu positive were 22(39%), 12(22%) and 2(3.5%) patients respectively. Adjuvant radiotherapy, chemotherapy and tamoxifen was received by 45(80%), 25(45%) and 37(66%) men respectively. Median follow up was 52 months (range 1-278). Local recurrence occurred in 8(14.5%) and distant metastasis in 18(33%) men respectively. DFS and OS at 10 year was 41% and 49% respectively. DFS and OS was significantly better in men with adjuvant radiation (53% vs 12%, $p = 0.002$ and 57% vs 22%, $p = 0.005$ respectively) and hormonal therapy (58% vs 14%, $p = 0.004$ and 58% vs 39%, $p = 0.036$). Chemotherapy had no impact on DFS and OS.

Conclusion: Adjuvant radiotherapy and hormonal therapy significantly improve DFS and OS in male patients with breast cancer. Chemotherapy had no impact on DFS and OS.

EP-1186

Late side effects and cosmetic outcome after intraoperative electron radiotherapy in breast cancer

C. Matuschek¹, E. Boelke¹, K. Halfmann¹, M. Ghorbanpour¹, J. Hoffmann², T. Fehm², W. Budach¹, S. Mohrmann²

¹University Hospital Düsseldorf Heinrich Heine University Düsseldorf, Radiotherapy and Radiooncology, Düsseldorf, Germany

²University Hospital Düsseldorf Heinrich Heine University Düsseldorf, Gynecology, Düsseldorf, Germany

Purpose or Objective: The intraoperative boost radiotherapy is a validated method to irradiate the tumor bed immediately after surgery with an effective dose. The most homogeneously dose can be achieved with electrons (intraoperative radiotherapy with electrons = IOERT). Because of the high individual dose are chronic side effects of particular interest. Therefore we investigated the late side effects with a median of 31 months (5-54 months).

Material and Methods: From 10/2010 until 12/2013 $n = 138$ patients received IOERT (NOVAC 7, New Radiant Technology, Aprilia, Italy) with 1×10 Gy covering the 90% isodose followed by whole-breast radiotherapy with 50.4 Gy/1.8 Gy SD. 58 patients were re-evaluated regarding late side effects and cosmetic outcome until 10/2015. The energy was determined by measuring the distance from the surface to the rib by intraoperative ultrasound. We investigated the radiogenic side effects according to the LENT-SOMA criteria. Furthermore, we evaluated the cosmetic results (subjective / objective).

Results: Pain in the irradiated breast was denied by 81% of all patients. Pain grade 1 was reported by 15.5% and grade 2 by 3.4% of the patients. There was no breast edema detectable in 91.4%. We found an edema grade 1 in 5.2% and grade 2 in 3.4% of the patients. There was no significant correlation between edema and pain ($p = 0.326$). A lymph edema grade 1 in the arm occurred in 5.2%. A retraction of the scar was not recorded for 91.4%, a retraction grade 1 in 6.9% and a retraction grade 2 in 1.7%. None of the patients developed a radiogenic ulcer. Fibrosis was not recorded in 75.9%, a fibrosis grade 1 in 20.7%, a fibrosis grade 2 in 3.4%. Telangiectasia's have not occurred in 96.6%. No visible hyperpigmentation was found for 70.7%, and 29.3% had a grade 1 hyperpigmentation. One patient showed inhomogenities in the heart MRT, which was performed to rule out heart disease. One patient developed pneumonitis. The cosmetic results (patient's view) was very good in 41.4%, good in 41.4%, moderate in 10.3% and bad in 3.4%. The assessment of the physician (physician's view) was in 48.3% very good, good in 34.5%, moderate 6.9% and bad in 1.7%. Moderate or bad results mostly occurred in patients with small breasts and large tumor size.

Conclusion: IOERT followed by whole-breast radiotherapy by 50.4Gy/1.8 Gy SD is associated with a low incidence of late side effects. The cosmetic outcome is after objective and subjective assessment in the majority (82.8%) of patients very good or good.

EP-1187

T-lysyl based cream (Repalysal) in the prevention of acute skin toxicity in breast cancer patients

A. Rese¹, E. D'ippolito¹, F. Piccolo¹, P. Romanelli¹, A. Romano¹, L. Faraci¹, E. Tosca¹, F. Pastore¹, V. De Chiara¹, L. Coppa¹, G. Salzano¹, A. Farella¹, R. Solla¹, M. Conson¹, L. Cella², R. Pacelli¹

¹University of Naples "Federico II", Advanced Biomedical Sciences, Naples, Italy

²National Research Center, Institute of Biostructures and Biomaging, Naples, Italy

Purpose or Objective: Acute skin toxicity is a frequent side effect of breast irradiation affecting quality of life of breast cancer patients. Ameliorating these unwished events may have a positive impact on the therapeutic course of the patients. In this study we tested a thymine-lysine-hyaluronic

acid based cream in the prevention of radiation induced skin toxicity (RIST).

Material and Methods: Patients undergoing breast irradiation after conservative surgery for breast cancer were considered for the study. The patients were randomly assigned to use T-lysal (repalysal, a thymine-lysine-hyaluronic acid based cream) vs. patients using a moisturizing cream. The patients were stratified for age, breast size, and phototype. Radiation therapy was delivered with 3D conformal radiation therapy, with 20 fraction of 2.25 Gy (concomitant boost dose 2.5 Gy) on the residual breast for a total dose of 45 Gy in 4 weeks (50 Gy boost dose to the tumoral bed). The appearance of any grade of skin toxicity was the endpoint of our study. RIST was assessed weekly from the beginning of treatment and graded according to the RTOG acute skin toxicity scale.

Results: Fifty two consecutive patients undergoing radiation therapy after breast conserving surgery for breast cancer were randomized to have the skin treated with 2 daily application of Repalysal or a simple moisturizing cream. Median age of the patients was 54. At the end of treatment (4 weeks) 15/26 patients in the Repalysal group vs. 26/26 patients in the control group had any grade of skin toxicity ($p=0.0001$). Moreover, among patients that developed skin toxicity, 3/15 vs. 18/26 developed G2 toxicity in Repalysal and control group, respectively (0.0036).

Conclusion: Repalysal ameliorates the acute skin toxicity profile of patients undergoing radiation therapy after conservative surgery for breast cancer.

EP-1188

The protective role of lipofilling in women subjected to radiotherapy.

N. Costantino¹, V.M. Margheriti¹, M. Santoro², E. Mazzei², M.A. Molinaro², R. Mole², A. Destito², D. Pingitore², C. Bianco¹

¹University Of Catanzaro "Magna Graecia", Oncology Radiotherapy, Catanzaro, Italy

²Hospital Of Catanzaro "Pugliese-Ciaccio", Oncology Radiotherapy, Catanzaro, Italy

Purpose or Objective: Many authors suggest, when the patients is suitable, the complete reconstruction of the breast which has undergone radiation by autologous tissue, discouraging prosthetic placing because of the high level of post-radiotherapeutic complications observed. The aim of this study is the assessment of radiation-induced outcomes in women with breast cancer who have been subjected to radiotherapy after reconstruction.

Material and Methods: Between January 2011 and March 2013 we chose 17 patients, median age of 45 years; 15 of these had undergone a radical mastectomy and 2 a quadrantectomy. During the mastectomy 7 patients were given an immediate prosthesis, 9 underwent reconstruction by lipofilling by way of classical breast expander and following prosthesis, 1 quadrantectomy and breast remodelling by lipofilling. All the patients received adjuvant chemotherapy and/or hormone therapy, conformational radiotherapy on the thoracic wall or residue breast (total dose of 50 Gy) and local prophylactic therapy so as to minimize the radiation-induced adverse effects. All patients have gone through a clinical-instrumental follow-up over an median time of 12 months and an assessment of cutaneous toxicity according to the SOMA-LENT scale.

Results: It was observed in 2 of the cases capsular contracture of the prosthesis of high grade which needed further replacing and appearance of cutaneous ulcers (grade 2) in 1 patient; in the remaining cases of prosthetic reconstruction erythema and edema were found (grade 2). A tolerable erythema was observed in the patients with expander and simultaneous lipofilling without late fibrosis. No complications were found in the patients with rimodelling by lipofilling post quadrantectomy, with conservation of the shape and symmetry of the breast.

Conclusion: The grafting of the autologous fat, high in stamina cells, represents an alternative technique in breast reconstruction with complete functional recovery of the tissue, so improving the surrounding tissue and therefore the capacity to heal in the irradiated tissues. The use of lipofilling is becoming an ever increasing importance as a coadjuvant in the breast reconstruction and avoids radiotherapy-induced complications. This gives notable psychophysical benefits and improves the quality of life in the patients.

EP-1189

Hypofractionated RT with or without boost in breast cancer: an institutional analysis of toxicity

C. Mariucci¹, A.M. Podlesko¹, E. Perrucci¹, L. Falcinelli¹, V. Bini², M. Di Benedetto¹, E. Arena¹, S. Nucciarelli¹, V. Lancellotta¹, I. Palumbo¹, C. Aristei¹

¹Ospedale Santa Maria della Misericordia, Radiotherapy, Perugia, Italy

²Ospedale Santa Maria della Misericordia, Internal Medicine Endocrin and Metabolic Sciences, Perugia, Italy

Purpose or Objective: Whole breast irradiation (WBI) is the gold standard after breast conserving surgery (BCS), followed by an additional boost when negative prognostic factors are present. WBI can be administered with hypofractionated schedules, on the basis of the relatively low α/β ratio for breast cancer (BC). The aim of our study was to investigate the effects of an additional hypofractionated boost (HB) in terms of acute and short-term late skin and subcutaneous tissue toxicity.

Material and Methods: Between March 2014 and April 2015 156 women, median age 62 years (range 34-88) with early BC (pT1-pT2, N0-N1) underwent hypofractionated RT (single dose of 2.65 Gy to 42.4 Gy in 16 fractions over 3 weeks) \pm HB (single dose 2.65 Gy to 10.6 Gy in 4 fractions). The study enrolled 71 patients (pts) without HB (45.5%) and 85 with HB (54.5%). The additional HB was delivered if risk factors such as young age, positive nodes, negative hormonal receptors, high Ki67 or HER2/neu overexpression were present. According to the risk of relapse chemotherapy (CT) and/or Hormonal Therapy (HT) and/or Trastuzumab were administered. For the analysis of the acute and late toxicity CTCAE 4.03 scale was used. Pts had physical examination at 5th, 10th, 16th and 20th day of RT and then 1 and 6 months after the end of treatment. Statistical analysis was carried out by the Chi-square test and the Mann-Whitney's U-test was used to compare continuous variables.

Results: HB group characteristics were: younger age (median 56 vs 67), longer time gap between surgery and RT (median time 20 weeks vs 16), more advance stage (43.6 % stage II vs 14.1%), CT (37 pts vs 2), HT (71 pts vs 48). Hypofractionated RT was well tolerated with or without HB and no G3 overall toxicity was documented. HB did not contribute to major skin toxicity; at the end of the treatment only 14 cases had G2 dermatitis vs 5 which did not receive HB ($p = 0.073$). One month after RT HB and CT significantly impacted upon edema occurrence: 15.5% HB group vs 1.5% no HB ($p = 0.008$) and 18.4 % CT group vs 6.2% no CT ($p = 0.016$). Furthermore, CT emerged as a risk factor for hyperpigmentation 6 months after RT: 37.0% vs 10.4% ($p = 0.003$). Attached Table summarizes the toxicity time-related events.

TOXICITY EVENTS

	WITHOUT BOOST (71 pts)					WITH BOOST (85 pts)					
	5 days	10 days	16 days	1 month	6 months	5 days	10 days	16 days	20 days	1 month	6 months
G1											
Dry Skin	0	0	0	3	0	0	1	0	1	2	1
Hyperpigmentation	0	0	1	39	8	0	3	5	5	47	12
Induration/fibrosis	0	0	1	3	6	0	0	0	0	3	14
Pruritus/itching	0	0	3	2	0	1	2	3	3	2	0
Desquamation	0	1	6	5	0	0	0	3	10	4	0
Rash: dermatitis	6	21	42	13	0	8	30	49	51	11	3
Teleangiectasia	0	0	0	0	0	0	0	0	0	0	0
Skin ulceration	0	0	0	0	0	0	0	0	1	0	0
Burn	0	0	0	0	0	0	0	0	0	0	0
Edema	3	1	3	1	6	11	15	12	12	13	8
G2											
Dry Skin	0	0	0	0	0	0	0	0	0	0	0
Hyperpigmentation	0	0	0	1	0	0	0	0	1	2	0
Induration/fibrosis	0	0	0	0	0	0	0	0	0	0	0
Pruritus/itching	0	0	0	0	0	0	0	0	0	0	0
Desquamation	0	0	0	0	0	0	0	0	1	0	0
Rash: dermatitis	0	1	5	0	0	0	0	5	14	0	0
Teleangiectasia	0	0	0	0	0	0	0	0	0	0	0
Skin ulceration	0	0	0	0	0	0	0	0	0	0	0
Burn	0	0	0	0	0	0	0	0	0	0	0
Edema	0	0	0	0	2	0	0	0	0	1	0

Conclusion: Administration of an additional HB is feasible, safe and well tolerated in terms of acute and short-term late skin and subcutaneous toxicity even though it seems to have a role in the edema occurrence. Although G2 dermatitis occurred in 16.47% of pts receiving HB vs 7.04% not receiving it, the difference was not significant, probably due to few observed events. Long term follow up data and a larger sample size are needed to confirm these data, assess late toxicity and clinical outcomes.

EP-1190

Boost volume assessment in breast cancer: preop tumor volume vs clips used in oncoplastic surgery

A. Altinok¹, M. Doyuran¹, M. Caglar¹, D. Canoglu, (1), E. Kucukmorkoc¹, H. Acar¹, N. Kucuk, (1), H. Caglar¹
¹Medipol University, Radiation Oncology, Istanbul, Turkey

Purpose or Objective: The aim of this study was to compare the volumes obtained with surgical clips during breast conserving surgery of breast cancer patients with volume determined using FDG positive tumor volumes outlined in pre-operative PET-CT imaging and find out the deviations that arise.

Material and Methods: For initial diagnostic PET-CT requested by the surgeon, the patients were positioned on the breast board with the arm on the ipsilateral side up. Those without metastatic tumors and applicable for breast conserving surgery went under operation in compliance with oncoplastic surgery principles. 4 clips were placed at the tumor lodge. For 15 of the patients, before continuing with further therapy, the tumor volume outlined with the surgical clips and that contoured using the area with FDG affinity viewed on the PET-CT were determined. Results were statistically analyzed with SPSS software.

Results: This study determined that methods used in oncoplastic surgery (such as flap shifting) resulted in displacements of the tumors from their original locations. For statistics we apply paired t test to the results that we have from these different techniques and found the values respectively for x,y,z as 0.929, 0.119, 0.991. Even the p value that we found is higher than 0.05 and not seems to be significant when we evaluate the center of mass deviation that we measure with these two techniques makes us to have an impact in overall results.

Conclusion: Determination of boost volume using pre-op tumor volume is not trustable in cases where tumor volume is not marked using clips during oncoplastic surgery of breast cancer and may result in geographical misses.

EP-1191

Pattern of metastasis in different molecular sub-types of locally advanced carcinoma breast

A.D. Sharma¹, J. Poddar¹, S. Patel Shah¹, U. Suryanarayan¹, M. Mehta¹, P. Nandwani Patel¹, J.P. Neema¹, A. Parikh¹, R.K. Vyas¹

¹GCRI, Radiation Oncology, Ahmedabad, India

Purpose or Objective: To investigate the association between the molecular sub-types and the pattern of distant metastasis in carcinoma breast.

Material and Methods: 400 patients of locally advanced breast carcinoma, without any distant metastasis, both clinically or by imaging were studied retrospectively. (Jan 2010- Dec 2011) The ER/ PR and HER-2neu status of the patients was noted and the patients were classified into luminal A/B, Triple negative, Her2/neu enriched and Luminal/Her.

All patients had received the treatment for carcinoma breast as per the standard protocols i.e. Curative treatment with surgery, Chemotherapy, and radiotherapy followed by hormonal therapy as per the indications.

All the patients were followed up for local as well as distant failure and pattern of failure was co-related with the molecular subtypes.

The major sites of distant metastasis were lungs, liver, bones and brain.

molecular subtypes bone Liver Lungs brain local recurrence

Luminal A/B 16/30 10/30 2/30 6/30 4/30

Luminal Her 16/28 11/28 2/28 8/28 6/28

Triple Negative 7/19 6/19 7/19 4/19 0/19

Results: Brain was the most common site of metastasis in Her 2 /neu enriched subtype.

Bone is the most common site of metastasis in all subtypes

Conclusion: A strong association of different metastatic sites with the molecular status suggests vigilance about the symptoms (metastatic) beforehand. Organ specific metastasis may depend on the molecular subtype of the cancer. High rate of bone metastasis might be due to the role of bone marrow as a homing organ for the cancer cells. Early treatment of Her-2/ neu patients with Trastuzumab might reduce the rate of metastasis. Tailored strategies against distant metastasis concerning the molecular subtypes in breast cancer may be considered.

EP-1192

Management of the axilla after neoadjuvant systemic therapy in breast cancer: A systematic revision

A. Manterola¹, G. Asin¹, F. Arias¹, M. Errasti¹, M. Barrado¹, M. Campo¹, I. Visus¹, M. Dominguez¹

¹Complejo Hospitalario de Navarra, Oncol Radioterápica, Pamplona, Spain

Purpose or Objective: Worldwide, breast cancer is the most common invasive cancer in women. The management of breast cancer depends on multiple factors. The purpose of this work is review the currently management of the axilla after neoadjuvant systemic therapy in breast cancer especially from the point of view of an oncology radiotherapist

Material and Methods: In May 2015, we searched clinical trial registers, the Cochrane Central Register of Controlled Trials, Web of Science, EMBASE and MEDLINE and reviewed reference lists. Further hand searches were conducted of relevant journal proceedings. At the end, we principally reviewed both meta-analyses regarding the results of the SNB following NAC in patients with a diagnosis of clinically negative axillae, the results of NSABPB-18 and NSABP B-27

Trials, The ASCO recommendations about SNB, The Canadian SN FNAC and German SENTINA, The MD Anderson trials, and the ACOSOG Z 1071 and AO11202 ALLIANCE (NCT0 1901094)

Results: For patients treated with NAC, patients with advanced stages (T3-4 /N2-3) should receive RT after independent NAC response. In early stages, it would be reasonable to receive treatment if there were residual disease; if doubts exist in cases of pRC, such cases should be assessed individually. It seems clear that patients with clinical regional involvement who present affectations of the lymph nodes following NAC will benefit from locoregional RT, but it is less clear in those who are pN0 following the NAC, as their risk of LRR is low.

Conclusion: The benefit of locoregional RT is not clear in patients with pN0 following the NAC. The ongoing NSABPB-51 /RTOG1304 (NRG 9353) study has been designed to answer this question. We must wait for the results of this important trial. Until these results, we must follow the recommendations previously prescribed.

EP-1193

ABPI with 3D-CRT, and image-guided IMRT, after BCS - 4 year results of a phase II trial

N. Mészáros¹, G. Stelczer¹, T. Major¹, Z. Zaka¹, C. Polgár¹

¹National Institute of Oncology, Radiotherapy, Budapest, Hungary

Purpose or Objective: To present the clinical results of ABPI using 3D-CRT and IG-IMRT following breast-conserving surgery (BCS) for early-stage breast cancer.

Material and Methods: Between 2006 and 2014, 104 low risk breast cancer patients were treated with postoperative APBI given by means of 3D-CRT (n=44) using 3-5 non-coplanar, isocentric wedged fields, or IG-IMRT (n=60) technique using KVBCCT guidance for each fraction. The total dose of APBI was 36.9 Gy (9 x 4.1 Gy) using twice-a-day fractionation for 5 consecutive days. Survival results, side effects, and cosmetic results were assessed.

Results: At a median follow-up of 48 months (range: 25-112) one (0.9%) local recurrence was observed. Two patients (1.9%) died of internal disease. One (0.9%) contralateral recurrence and three (2.8%) secondary tumours were observed. Neither regional nor distant failure was detected. Acute side effects included grade 1 (G1) and G2 erythema in 54 (51.9%) and 2 (1.9%), G1 parenchymal induration in 43 (41.3%), G1 and G2 pain in 26 (25%) and 2 (1.9%) patients. No ≥G3 or higher acute side effect occurred. Late side effects included G1 telangiectasia in 10 (9.6%) G1, G2, and G3 fibrosis in 26 (25%), 3 (2.8%) and 1 (0.9%) patients respectively. Asymptomatic (G1) fat necrosis occurred in 8 (7.7%) patients. The rate of excellent/good and fair/poor cosmetic results was 96 (92.3%), 8 (7.7%) respectively.

Conclusion: Both 3D-CRT and IG-IMRT for delivery the ABPI is feasible and the 4 years clinical results and toxicity profile is comparable to other results using multicatheter APBI brachytherapy.

EP-1194

Cardiac toxicity after breast cancer patients treatment

D. Gabrys¹, A. Piela², A. Walaszczyk³, R. Kulik⁴, A. Namysł-Kaletka¹, I. Wziętek¹, K. Trela-Janus¹, S. Blamek¹

¹Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Radiotherapy Department, Gliwice, Poland

²Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Oncological and Reconstructive Surgery Department, Gliwice, Poland

³Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Center for Translational Research and Molecular Biology, Gliwice, Poland

⁴Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Radiotherapy and Brachytherapy Department, Gliwice, Poland

Purpose or Objective: Radiation and anthracyclines are known to induce cardiac damage. Despite the use of 3D planning the heart is still irradiated with non-negligible doses, therefore this problem needs further investigation. We perform an analysis of cardiac function in the left sided breast cancer survivors. Patients were treated with surgery alone (S), additional radiation (RT), additional anthracycline based chemotherapy (A) or both (RA).

Material and Methods: A total of 140 patients were subjected to cardiological evaluation more than 8 years after primary treatment. We performed ECG and ECHO (in a part of patients we also had an ECG and ECHO performed before surgery), blood tests, chest X-ray. We also collected additional relevant information on patients (history, comorbidities, current treatment, etc.). Distribution of patients was as follows 50% RA arm, 18% S, 8% RT, 24% A. The mean time from the beginning of the treatment to examination was 12.2 years (8-15.9) in S, 11.7 (8-16.9) in A, 10.7 (8-15.3) in RT, 10.1 (8.1-14.5) in RA. The majority of patients were treated with amputation (74%), the remaining with BCT. In chemotherapy arms 47% were treated with FAC, 31% with CAF, 19% with AC, and 3% with TE. Hormonal treatment was given to 64% of patients, in the majority of them it was Tamoxifen-based. Radiotherapy dose varied between 50 and 70 Gy.

Results: There was no significant difference in ejection fraction (EF) between the groups: median 56 (47-65) in S, 50 (25-65) in A, 55 (47-62) in RT and 54 (35-67) in RA. Other evaluated parameters like size of the right and left ventricle, left atrium, thickness of septum and posterior wall also did not differ between groups. In the whole group in 21% of patients we observed chronic cardiac insufficiency. In 58% of patients there were other cardiovascular disorders as hypertension, hypercholesterolemia, atherosclerosis, arrhythmias, and valvular disorders. Only in one patient treated with radiation and chemotherapy we found impaired heart function without other additional causes.

Conclusion: In the current series no unequivocal association between treatment regimen and long-term cardiac dysfunction could be found. Further studies in a well-balanced patient population are needed to elucidate the impact of contemporary anthracycline-based systemic treatment and modern irradiation techniques on cardiac outcome.

The research received funding from National Science Center Poland under grant no. N N 402 685640

EP-1195

Active breathing coordinator in left-sided breast cancer radiotherapy: dosimetric comparison study

N. Pascinetti¹, L. Pegurri¹, R. Cavagnini¹, L. Costa¹, P. Vitali¹, L. Bardoscia¹, B. Bonetti¹, L. Spiazzi², B. Ghedi², S.M. Magrini¹

¹University and Spedali Civili Brescia, Radiation Oncology, Brescia, Italy

²Medical Physics Spedali Civili Brescia, Radiation Oncology, Brescia, Italy

Purpose or Objective: Incidental radiation dose to the heart and lung during left breast radiation therapy (RT) has been associated with an increased risk of cardiopulmonary morbidity especially in patients treated with anthracycline as neoadjuvant/adjuvant chemotherapy schedules after surgery. We conducted two different dosimetric analyses (by NTCP and Bio-DVH) to determine if left breast RT with the Active Breathing Coordinator (ABC) can reduce heart/left anterior descending artery (LAD) and lung dose without target coverage impairment.

Material and Methods: Patients with stages 0-III left breast cancer (LBC) were enrolled and underwent simulation with both free breathing (FB) and ABC for comparison of dosimetry. ABC was used during the patient's RT course if the heart exposition was $V(30) \geq 12\%$. The prescription dose was 50 Gy plus a boost in 88% and 2,75 Gy up to 44 Gy plus a boost in 22%. The primary endpoint was the magnitude of

heart reduction dose when comparing ABC to FB. Analysis was performed with BIOPLAN (Biological evaluation of PLANs) PC based user-friendly software (evaluation of Dmax, Dmin, Dmean) and home-made Planning Reporting Orienteering (PRO)-DVH software. PRODVH produced Bio-DVH (Equivalent Dose Volume histograms for 25 fractions) that allowed the comparison regardless of the treatment schedule and that were used to calculate the average DVH for each set up. Secondary endpoints included dose reduction to the lung and procedural success rate.

Results: Between May 2012 to February 2015, 50 patients with LBC are selected for receiving RT using ABC after both FB and ABC simulation. Procedural success was good, all patients have sufficient compliance and are been selected for this procedure. The primary endpoint was achieved: use of ABC reduced LAD/heart exposition ($p < 0.01$ T-student test). There was no significant difference between the free-breathing and moderate deep inspiration breath-holding in the target volume coverage. The volume of the ipsilateral lung in the free-breathing technique was smaller than the moderate deep inspiration breath-holding techniques. All these data were confirmed with both software.

Conclusion: ABC was well tolerated and significantly reduced heart/LAD dose without impairment in target volume coverage. No difference was found in lung dose reduction. Use of the ABC device during RT should be considered to reduce the risk of ischemic heart disease in populations at risk.

EP-1196

Atlas-based segmentation for delineating the locoregional node levels during breast radiotherapy

C. Pirson¹, P.V. Nguyen¹, M. Baiwir¹, P.A. Coucke¹, F. Lakosi¹, A. Gulyban¹

¹C.H.U. - Sart Tilman, Radiotherapy Department, Liège, Belgium

Purpose or Objective: Proper multi-atlas automated delineation can streamline clinical routine only when the proposed volume determination reasonably approximates the manual delineation. In this investigation we aimed to evaluate the automatic atlas-based segmentation of supraclavicular and level 3 lymph nodes for loco-regional irradiation of breast cancer. Further analysis were performed on the final plan's dose coverage to the automated clinical target volume.

Material and Methods: Between June and September 2015 five consecutive breast cancer patients with clinical indication for loco-regional irradiation were selected. Pre-defined breast delineation atlas of Mirada RTx (version 1.6.2, Mirada Medical, Oxford, United Kingdom) software were used to generate automated clinical target volumes (CTVauto) including the supraclavicular and the axillary level 3 lymph nodes. Responsible radiation oncologist delineated the reference CTV (CTVref) for each individual patients as well. Comparison metrics of Dice similarity (DI) and commonly contoured volume (CCV) were used. Furthermore the CTVauto was expanded with 1,2,3,4 and 5 mm uniform margin consecutively followed by an evaluation of the volumetric coverage of CTVref. Finally clinical plans were created expanding CTVref with 5 mm uniform margin using either direct antero-posterior beam or multi-beam IMRT. Dose coverage of the 95% of prescribed dose (V95) were compared for both CTVs.

Results: The average CTVref was 35.1 cc (Standard deviation = 10.2), while for the CTVauto 42.1 cc (SD = 12.1). Mean DI and CCV were 0.73 (SD: 0.26) and 0.72 (SD: 0.28) respectively. Expanding the CTVauto up to 5 mm in 1 mm increments covered the CTVref with 53.9%, 77.9%, 88.1%, 90.9%, 92.7% and 95.7% respectively. (Figure 1). For two patients single direct ante-posterior (AP) beam were used for the loco-regional treatment, while for the other three cases 6 beam IMRT were used. Average V95% dose coverage of CTVref was 98.5% (SD: 3.0) which lowered to 92.0% (SD: 9.1%) for CTVauto. For the two patient with single AP field the

CTVref were 93.0% and 99.5%, which dropped to 79.8% and 99.4% for CTVauto. The multi-beam IMRT cases showed 100%, 99.9% and 99.8% CTVref_V95 and 100%, 88.5% and 94.0% CTVauto_V95.

Conclusion: CTV delineation using an atlas-based auto-segmentation shows promising results even in a small complicated volume delineation such as the loco-regional lymph nodes of breast. Further improvement of the delineation accuracy is expected by adding more cases to the initial multi-atlas (with 3 provided cases).

EP-1197

Hypofractionated radiotherapy in locally advanced breast cancer

A.C. Carvalho¹, P. Fernandes¹, J. Casalta-Lopes¹, A. Cleto¹, M. Borrego¹

¹Hospitais da Universidade de Coimbra, Radiation Oncology, Coimbra, Portugal

Purpose or Objective: Locally advanced breast cancer (LABC), clinically classified as cT4, is mostly identified in elderly patients, typically featuring unfavorable prognosis. It is usually associated with ulceration, bleeding and local pain, with prolonged course. Radiation therapy (RT) shows an important role in local control and symptomatic control. Hypofractionation radiotherapy scheme, with a dose of 13 Gy in two fractions with an interval of 48 hours (also known as RT-FLASH), allows acceptable results. With this study we aim to evaluate the response of the patients treated with RT-FLASH.

Material and Methods: LABC patients treated from 2001 to 2015 with RT-FLASH were retrospectively included. Local response was clinically assessed. Kaplan-Meier method was used for locoregional progression-free survival (LPFS) and overall survival (OS) analysis. Type I error of 0.05.

Results: 63 patients were included, with a median age of 78 years (39-92 years), 61.9% with Karnofsky 80 and median progression time of 13.5 months (2-180 months). Carcinoma not otherwise specified (NOS) was the most common histological type (84.1%), with estrogen receptor-positive in 71.4%. Most of the tumors were cT4b (50.8%) and cT4c (36.5%) with cN+ in 60.3% and cM1 in 44.4%. At the initial evaluation 46.0% had bleeding injuries. Two RT-FLASH were performed in 65.1% of the patients. During treatment there was no record of toxicity. There was reduction of bleeding (81.5%), size (69.8%) and ulceration (39.6%). Surgical conditions were acquired in 23.8% of the patients. Patients cM1 received chemotherapy more often than cM0 (57.7% vs. 17.6%; $p=0.001$). Of the 63.9% patients that received hormone therapy (HT), 77.5% had 2 RT-FLASH ($p=0.002$ non-HT), with a greater dimensional reduction in patients undergoing HT (81.1% vs 43, 8%, $p = 0.010$). LPFS at 2 and 5 years was 76.6% and 66.1%, respectively. The 2-year OS was 39.7% and 5-year OS was 19.5%, higher in cM0 patients ($p<0.001$), patients subjected to 2 RT- FLASH ($p=0.003$), or under HT ($p=0.001$). Multivariate analysis showed significant

impact of HT and cM1 ($p=0.018$ with $HR=0.593$ and $p=0.006$ with $HR=2.574$, respectively). In the multivariate analysis of LPFS, HT and 2 RT-FLASH had prognostic impact ($p=0.039$ with $HR=0.297$ and $p=0.036$ with $HR=0.257$, respectively).

Conclusion: In the context of LABC, with poor prognosis, RT-FLASH improves the quality of life, without registration of acute toxicity, and with reasonable OS. HT and the absence of metastasis at diagnosis had a positive impact on prognosis, significantly. LPFS was significantly higher in patients who underwent two RT-FLASH or HT.

EP-1198

Evaluation of pulmonary acute/ subacute toxicity after different techniques of breast radiotherapy

B. Serarslan¹, Y. Sanli², M. Fayda¹, C. Türkmen¹, M. Erelel³, N. Dönmez Kesen⁴, N.S. Küçüçük¹

¹Istanbul University- Faculty of Medicine, Department of Radiation Oncology, Istanbul, Turkey

²Istanbul University- Faculty of Medicine, Department of Nuclear Medicine, Istanbul, Turkey

³Istanbul University- Faculty of Medicine, Department of Pulmonary Medicine, Istanbul, Turkey

⁴Istanbul University, Department of Medical Physics, Istanbul, Turkey

Purpose or Objective: The increase in the local control and survival of breast cancer patients with postoperative radiotherapy (RT) has been demonstrated by many of randomized trials and metaanalysis. Because of this longer life expectancy; quality of life and minimizing of treatment toxicity have gained importance. More homogenous dose distribution in the treatment field and reduction of side effects is possible with new RT techniques. The aims of our study are to evaluate acute/subacute pulmonary effects and their differences with different RT modalities of postoperative breast RT via pulmonary function tests (PFT) and single photon emission computer tomography (SPECT) based lung perfusion scintigraphy (SLPS), and to exhibit optimum lung dose constraints data for breast cancer RT. Additionally this study enables to detect early pulmonary toxicity in the asymptomatic period and to treat it, if necessary.

Material and Methods: In our study, voluntary breast cancer patients eligible for postoperative RT, who completed adjuvant systemic chemotherapy were separated equally into two groups of different RT techniques [3D conformal RT (3D-CRT) and intensity-modulated radiotherapy (IMRT)]. To assess the acute/subacute pulmonary toxicity, we performed PFT and SLPS just before RT (baseline) and after 3 months of RT (control). After 1 month of RT patients were rechecked with only PFT. We assessed the relation between dosimetric data and the study changes (Figure1).

Figure 1: Fusion of single photon emission computer tomography (SPECT) based lung perfusion scintigraphy (SLPS) images and radiotherapy plans via VelocityAI® programme

Results: Mean lung doses and lung volumes receiving 20Gy (V1, V5, V10, V20) were significantly higher in IMRT group ($p<0.001$) (Figure 2). There was no significant difference in PFT changes after RT between the two RT techniques ($p>0.05$). Higher lung doses ($p<0.001$) and more significant mean reduction of scintigraphic uptake were observed in low dose volumes with IMRT ($p<0.05$). In 3D-CRT group, the mean reduction of scintigraphic uptake was higher in the lobe, that

receives the highest mean dose (ipsilateral lobe) ($p<0.05$). Furthermore, even though right supraclavicular area, which effects the upper lung zone was irradiated, frequently the right middle lobe received more radiation, not right upper lobe. Eventually, none of the patients had grade 2 LENT - SOMA lung toxicity. We didn't find any relationship between patient characteristics (smoking history, age, chemotherapy type, surgery type, tumor location, RT field and technique) and radiation induced pulmonary toxicity.

Figure 2: Bilateral lung, ipsilateral lung ve ipsilateral lung lobe mean V1, V5, V10, V20, V30, V40, V50 values

Conclusion: We found that V20 volume of lung is a similar parameter for evaluation of different breast RT techniques and evaluation of low and high dose volumes can be more feasible. Larger group of patients and longer follow-up can lead to more significant results.

EP-1199

Cardiac dose delivered by left sided tumour bed electron boost; a potential source of toxicity

V. Gajapathy¹, L. Hill¹, S. Cleator¹

¹Charing Cross Hospital, Radiotherapy, London, United Kingdom

Purpose or Objective: Cardiac dose delivered during tangential radiotherapy is increasingly scrutinized, but the cardiac dose delivered during electron boost is not routinely calculated. We retrospectively reviewed cases in which an electron boost was employed to deliver a phase 2 to a tumour bed (TB) overlying the heart to establish the proportion of cases and type of cases in which this treatment delivered a significant cardiac dose.

Material and Methods: A cohort of left sided breast cancer cases receiving radiotherapy in a single treatment centre over a 4 month period were reviewed. Those patients receiving a phase 2 electron boost to a TB in the mid/ lower part of the left breast were identified. For those in which an electron beam was incident on the heart, fully commissioned Monte Carlo dose calculation was used to derive the dose delivered to whole heart and left anterior descending artery assuming a boost dose of 16Gy in 8 fractions to the 100%.

Results: A total of 24 patients received a boost to a TB in the mid/ lower part of the left breast. Of these, 15 were treated with an electron beam incident on the heart. In 6/15 (40%) the mean heart dose delivered by the boost component was 0.5Gy. The maximum mean heart dose was 1.02Gy. In all 6 cases, the energy employed was >9MeV.

Conclusion: The heart dose delivered by an electron boost with beam incident on the heart can be significant, especially if an energy >9MeV is employed. In such cases, mini-tangential treatment in deep inspiratory breath hold is recommended.

EP-1200

Evaluation of response to stereotactic body radiation therapy for non-small cell lung cancer

K. Jingbo¹, D. Rui¹, F. Henghu¹, Z. Xinhong¹, W. JuYi¹, L. YingKui¹¹Department of Radiation Oncology and Integrative Oncology-Navy General Hospital, Department of Radiation Oncology and Integrative Oncology-Navy General Hospital, Beijing, China

Purpose or Objective

Recommendations for surveillance after stereotactic body radiation therapy (SBRT) for early stage non-small cell lung cancer (NSCLC) are not well defined. Recently, PET response criteria in solid tumors (PERCIST) have been proposed as a new standardized method to assess radiotherapeutic response metabolically and quantitatively. The aim of this study was to evaluate therapeutic response to Stereotactic Body Radiotherapy for Early Stage Non-small Cell Lung Cancer, comparing PERCIST with the currently widely used response evaluation criteria in solid tumors (RECIST).

Material and Methods

Forty-nine patients with locally early Stage Non-small Cell Lung Cancer who received Stereotactic Body Radiotherapy were studied. Radiotherapeutic lesion responses were evaluated using CT and 18F-FDG PET according to the RECIST and PERCIST methods. The PET/CT scans were obtained before SBRT and about 3 to 6 month after SBRT. Associations were statistically analyzed between overall survival and clinicopathologic results (histology, tumor location, tumor size, lymphatic invasion, clinical stage, radiotherapeutic responses in RECIST and PERCIST).

Results

Median follow-up was 30 months. Thirteen patients had stage IA, 9 stage IB, 10 stage IIA, and 17 stage IIB biopsy-proven NSCLC. Three-year overall survival was 79.6%. CT scans indicated 3 regional recurrences. PET/d-chest indicated 3 regional recurrences and distant metastasis. There was a significant difference in response classification between RECIST and PERCIST (Wilcoxon signed-rank test, P=0.0041). Univariate analysis showed that clinical stage, RECIST and PERCIST were significant factors associated with overall survival in this study, while by multivariate analysis PERCIST was the only predictor of overall survival in early NSCLC patients. In fact, SMD, PMD/PMR, CMR in PERCIST criteria was indicative of a 9.900-fold increase in the risk of overall survival in early NSCLC patients [RR 9.900 (95% CI 1.040, 21.591), P=0.001].

Conclusion

RECIST based on the anatomic size reduction rate did not demonstrate the correlation between therapeutic responses and prognosis in patients with Early Stage NSCLC receiving SBRT. However, PERCIST was found to be the strongest independent predictor of outcomes. PERCIST might be considered more suitable for evaluation of radiotherapeutic response to NSCLC than RECIST.

EP-1201

Impact of low skeletal muscle mass on survival after SBRT for non-small cell lung cancer

Y. Matsuo¹, T. Mitsuyoshi¹, A. Nakamura¹, Y. Iizuka¹, T. Kishi¹, W. Mampuya¹, H. Hanazawa¹, M. Hiraoka¹¹Kyoto University, Department of Radiation Oncology and Image-applied Therapy, Kyoto, Japan

Purpose or Objective: Sarcopenia is a syndrome characterized by low muscle mass and low muscle function. Several authors reported that low skeletal muscle mass (SMM) was associated with decreased survival in cancer patients. The purpose of the present study was to retrospectively evaluate impact of SMM on survival and cause of death after

stereotactic body radiotherapy (SBRT) for primary non-small cell lung cancer (NSCLC).

Material and Methods: Of consecutive 253 patients who received SBRT for primary NSCLC between 2004 and 2013, 186 patients whose abdominal CT before the treatment was available were enrolled into this study. SMM was evaluated through total psoas area (TPA) at a level of the third lumbar vertebra according to a method proposed by Jones *et al.* (*Colorectal Dis* 2015;17:O20). TPA was estimated by multiplying the greatest anterior/posterior and transverse muscle diameters and then normalizing for patient height. The patients were divided into two groups of SMM according to gender-specific thresholds for TPA. Regression analysis was done for the cumulative incidence function for competing risks of death from lung cancer and from other causes. Evaluated variates were SMM, age, gender, performance status, body mass index (BMI), Charlson comorbidity index (CCI), operability, modified Glasgow prognostic score (mGPS), recursive partitioning analysis (RPA) class, and histology. In multivariate analysis, step-wise selection was applied to identify potential factors.

Results: edian TPAs were 293 and 240 mm²/m² in male and female, respectively, and these values were used as the gender-specific thresholds. Patients with lower SMM tended to be elderly and lean in BMI compared with the higher SMM. A potential median follow-up period was 55.6 months. Overall survival at 5 years was 41.1% and 55.9% in the lower and higher SMM groups, respectively (P = 0.115). Cumulative incidence of non-lung cancer death was significantly worse in the lower SMM (31.3% at 5 years compared with 9.7% in the higher SMM, P = 0.006). Multivariate regression analysis identified SMM and operability as significant factors for non-lung cancer death (Table). Impact of SMM on lung cancer death was not significant with cumulative incidence of 27.6% and 34.4% at 5 years in the lower and higher SMM groups, respectively (P = 0.332).

		Univariate		Multivariate	
		HR	P-value	HR	P-value
SMM	Lower vs higher	2.60	0.006*	2.66	0.004*
Age	>75y vs ≤75y	2.01	0.078	1.96	0.094
Gender	Male vs female	1.88	0.140		
PS	1 vs 0	0.78	0.042*		
	2-3 vs 0	2.68			
BMI	Lean vs normal	2.43	0.046*		
	Obese vs normal	1.09			
CCI	1-2 vs 0	5.75	0.059	3.71	0.096
	≥3 vs 0	9.10		6.24	
Operability	inop vs operable	2.60	0.015*	2.22	0.040*
mGPS	1-2 vs 0	1.45	0.260		
T-stage	1b vs 1a	1.00	0.702		
	2a vs 1a	0.72			
RPA class	II vs I	1.27	0.460		
Histology	Sq vs Ad	1.13	0.987		
	Others vs Ad	1.03			
	Unproven vs Ad	1.14			

Table. Univariate and multivariate regression analysis for non-lung-cancer death

Abbreviations: SMM = skeletal muscle mass, PS = performance status, BMI = body mass index, CCI = Charlson comorbidity index, mGPS = modified Glasgow prognostic score, RPA = recursive partitioning analysis

BMI was classified into lean (<18.5), normal and obese (≥25.0). RPA class I is female or patients with T1a. mGPS of 0 was defined as CRP<0.3 mg/dL and albumin>3.5g/dL.

Conclusion: Low SMM is a significant risk factor for non-lung cancer death after SBRT for NSCLC.

EP-1202

CBCT in Lung FFF-SABR: predictive parameters of early response

F. Alongi¹, R. Mazzola¹, F. Ricchetti¹, N. Giaj Levra¹, S. Fersino¹, G. Sicignano¹, A. Fiorentino¹, R. Ruggieri¹

¹Ospedale Sacro Cuore Don Calabria, Radiation Oncology, Negrar - Verona, Italy

Purpose or Objective: aim of the study was to analyze tumor volume variations, by contouring on cone-beam computed tomography (CBCT) images, to evaluate early predictive parameters of Flattening Filter Free Stereotactic Ablative Radiation Therapy (SABR) treatment response.

Material and Methods: the prescribed dose of SABR varied according to the tumor site (central or peripheral) and maximum diameter of the lesions using a strategy of risk-adapted dose prescription with a range of dose between 48 and 70 Gy (3-10 consecutive fractions). For the purpose of the analysis, gross tumor volume (GTV) was re-contoured for each patient at first and last CBCT using two lung levels/window: 1) -600/1000 Hounsfield Units (HU) and 2) -1000/250 HU. Statistical analysis was performed to evaluate correlations between target variations on CBCT, using the two window-levels, and treatment response three months after the end of SABR. The analysis was conducted considering the following variables: number of fractions ≥ 5 , BED 95-110, BED > 110 and GTV volume pre-SABR > 6 cc.

Results: 41 lung lesions were evaluated. The median follow-up was 14 months (range, 5 - 43 months). For both the CBCT level/windows, GTV shrinkage of at least 20% was associated to the probability of achieving a disease complete response (CR) at 3 months. The probability of CR ranged between 6 and 8 times higher, in respect to the CBCT lung level adopted, comparing to patients without a GTV decrease of 20%. This cut-off value was confirmed for all the variables analyzed.

Conclusion: according to current findings, a tumor shrinkage cut-off of at least 20% at last session of SABR is predictable for CR

EP-1203

Stereotactic radiotherapy for oligometastases or oligorecurrence within a mediastinal lymph node

H.H. Wang¹, M.B. Meng¹, X.L. Zeng¹, F.T. Li¹, L.J. Zhao¹, Z.Y. Yuan¹, P. Wang¹, Y.C. Song¹

¹Tianjin Cancer Hospital, Department of Radiation Oncology, Tianjin, China

Purpose or Objective: This study was to evaluate the safety and efficacy of stereotactic radiation therapy (SRT) in the treatment of patients with oligometastases or oligorecurrence within a mediastinal lymph node (MLN).

Material and Methods: Between October 2006 and May 2015, patients with oligometastases or oligorecurrence within MLNs originating from different primary tumor were enrolled and treated with SRT at our hospital. The primary end-point was MLN local control (LC). Secondary end-points were: time to symptom alleviation; overall survival after SRT (OS); and toxicity using the Common Terminology Criteria for Adverse Events (CTCAE v4.0).

Results: Eighty-five patients with 98 MLN oligometastases or oligorecurrence were treated with SRT. For the entire cohort, the 1-year and 5-year actuarial LC rates were 97.3% and 77.2%, respectively. Symptom alleviation was observed in 28 patients (28/32, 87.5%), with symptomatic lesions after a median of 5 days (range, 3-30 days). The median OS were 27.17 months for all patients and 32.20 months for those with NSCLC. Univariate and multivariate analyses revealed that an interval between diagnosis of primary tumors and SRT and MLN PTV volume were independent prognostic factors for OS in patients with NSCLC. CTCAE v4.0 Grade 3 toxicities occurred in six patients (7.06%), with Grade 5 in three patients (all with radiotherapy history to MLN station 7).

Conclusion: SRT is a safe and efficacious treatment modality for patients with oligometastases or oligorecurrence to MLN, except for patients who received radiotherapy history to MLN station 7. Further investigation is warranted to identify the patients who benefit most from this treatment modality.

Predicting toxicity after lung stereotactic radiation therapy

J.E. Bibault¹, X. Mirabel¹, T. Lacomberie¹, E. Tresch², E. Lartigau¹

¹Oscar Lambret Cancer Center, Academic Radiation Therapy Department, Lille, France

²Oscar Lambret Cancer Center, Biostatistics Department, Lille, France

Purpose or Objective: Lung SBRT has shown excellent local control rates for inoperable patients with early-stage lung cancer without lymph node involvement. The reported toxicity is low, but factors associated with toxicity such as pneumonitis or lung fibrosis have not been well documented.

Material and Methods: All inoperable patients treated in our institution between August 2007 and April 2013 with SBRT for peripheral early-stage lung cancer were included. Endpoints of the study were rib fracture, acute pneumonitis, lung fibrosis, hemoptysis. Univariate binary logistic regressions were used to look for statistical associations between binary (eg, gender), ordinal (eg, age, dose per fraction, total dose, number of treatment session, V20, mean lung dose, volumes) or nominal (eg tracking method, previous treatment) variables and the study endpoints. Multivariate logistic regression was to be performed if more than 1 factor was associated with 1 of the outcomes of interest with a P value of less than .2. Treatment fractionation regimens were adapted according to tumor localization.

Results: 205 patients with 214 lesions were included in the study (67 central and 147 peripheral). 73 patients (36%) had toxicities: 14 patients (6.8%) had acute pneumonitis and 56 lung fibrosis (27.3%) without clinical effects. Two patients had a rib fracture (1%) and 1 patient had rib cage pains. No other toxicities were observed. In univariate analysis, a lower number of treatment sessions ($p=0.018$) and higher dose per fraction ($p=0.011$) were associated with more toxicity. Longer treatment sessions were associated with more acute pneumonitis ($p=0.001$). Lung fibrosis was associated with a higher dose per fraction ($p=0.027$). Tracking was also associated with a higher rate of lung fibrosis, but patients treated with tracking had bigger tumors (mean diameter : 21.9 mm vs 28 mm). Tumor localization (central vs peripheral) was not a predictive factor of toxicity.

Conclusion: A higher dose per fraction and fewer treatment sessions were associated with more toxicity. Tumor localization was not associated with toxicity, suggesting that treatment regimens adapted for central tumors are efficient in minimizing toxicity.

EP-1205

Resected pN1 non-small cell lung cancer: recurrence patterns and nodal risk factors

P. Borghetti¹, F. Barbera¹, M. Bonù², P. Vitali¹, F. Trevisan², S. Ciccarelli², M. Maddalo², L. Triggiani², N. Pasinetti², S. Pedretti¹, B. Bonetti¹, G. Parisenti³, A. Tironi⁴, A. Caprioli⁵, M. Buglione², S. Magrini²

¹Spedali Civili di Brescia, Radiation Oncology, Brescia, Italy

²Brescia University, Radiation Oncology, Brescia, Italy

³Spedali Civili di Brescia, Thoracic Surgery, Brescia, Italy

⁴Spedali Civili di Brescia, Pathology, Brescia, Italy

⁵Spedali Civili di Brescia, Pneumology, Brescia, Italy

Purpose or Objective: To describe the pattern of recurrence in resected pN1 non-small cell lung cancer (NSCLC), aiming to identify clinical, pathological, treatment and nodal factors predicting an increased risk of locoregional recurrence (LR) or distant metastasis (DM), in order to define a selected population who may benefit of postoperative radiotherapy (PORT).

Material and Methods: All patients who underwent surgery for NSCLC with pathologically confirmed N1 disease at the Spedali Civili Hospital of Brescia between 2001-2011 were identified. Patients with positive surgical margins, undergoing neoadjuvant treatment or PORT were excluded. LR was defined as first event of recurrence at the surgical bed, ipsilateral hilum or mediastinum, other sites were considered as DM. Kaplan-Meier actuarial estimates of overall survival (OS), progression free survival (PFS), freedom-from LR (FFLR) and freedom-from DM (FFDM) in different subgroups were compared with the log-rank test. The Cox proportional hazard regression model was used for multivariate analysis.

Results: Among 285 patients who underwent surgery during the interval, 202 met the inclusion criteria. Clinical pathological, treatment and nodal factors are reported in table 1. Twenty four percent received adjuvant chemotherapy. The median follow-up was 39 months. The total number of recurrences was 118 (64.4%): 44 (24%) and 74 (40.4%) for LR and DM, respectively. 5-year OS and PFS rates were 39,2% and 33,3%, respectively. Patients with recurrences experienced a statistically worse OS than patients without recurrences (p<0.001) and patients with DM had in turn OS rates significantly worse than those with LR (Figure 1). At multivariate analysis, extra capsular extension (ECE) (RR 2.10 p 0.01) and lymph nodal ratio (LNR)> 0:15 (RR 1.68, p = 0.015) were associated with a worse PFS. ECE and LNR> 0,15 were significantly related to a worst FFLR (RR 3.04 and 4.42, respectively), adenocarcinoma to an unfavorable FFDM (RR 1.97, p = 0.013).

Number of lymph nodes	90-91	101 (50.0%)
Number of lymph nodes	92-93	101 (50.0%)
Number of lymph nodes	94-95	101 (50.0%)
Number of lymph nodes	96-97	101 (50.0%)
Number of lymph nodes	98-99	101 (50.0%)
Number of lymph nodes	100-101	101 (50.0%)

Conclusion: LR are common in pN1 NSCLC patients. Nodal factors as high LNR and ECE can predict an increased risk of worse FFLR and PFS. Prospective data on selected patients, treated with modern radiotherapy techniques, need to be collected to re-evaluate the role of radiotherapy.

⁷S. Orsola-Malpighi Hospital, Department of Medical Oncology, Bologna, Italy

⁸Bellaria Hospital, Radiotherapy Department, Bologna, Italy

Purpose or Objective: To verify adequacy of dose volume constraints reported in literature about stereotactic radiotherapy (SBRT) and radiosurgery of thoracic area. This study is based on the toxicity recorded in organs at risk (OARs) of patients enrolled in dose-escalation trials.

Material and Methods: This is a retrospective study evaluating treatment plans of neoplasms in thoracic area. All 55 patients were treated between November 2009 and December 2013 using SBRT (37 pt) or SBRS (18 pt). Prescribed doses were 30-35 Gy in 5 fractions in SBRS treatments and 16-28 Gy in single fraction in SBRS treatments. All patients underwent radiotherapy with V-MAT technique. Main OARs were heart, oesophagus, and ribs with suggested Dmax of 35 Gy, 32.5 Gy and 32.5 Gy in SBRT treatment, respectively, and 22 Gy, 15 Gy and 30 Gy in SBRS treatment, respectively. Plans were evaluated by DVH analysis. Dosimetric data were compared with clinical data on early and late toxicity.

Table 1: Patients' characteristics

	SBRT (N, %)	SBRS (N, %)
N*	37 (67.3)	18 (32.7)
M/F	28/9	6/12
Age (range; media)	45-86; 65	37-75; 56
Primary tumor		
Lung	19 (51.4)	3 (16.7)
Rectum	4 (10.8)	0 (0)
Colon	3 (8.1)	2 (11.1)
Breast	2 (5.4)	8 (44.4)
Endometrial	1 (2.7)	2 (11.1)
Prostate	1 (2.7)	2 (11.1)
Other	6 (16.2)	2 (11.1)
Treated lesion		
Primary tumor	12 (32.4)	0 (0)
Nodal metastases	9 (24.3)	6 (33.3)
Distant metastases	16 (43.3)	12 (66.7)

Results: SBRT treatment: considering heart, oesophagus and ribs, Dmax constraints were exceeded in 7/37 patients (18.9%), 4/37 (10.8%) and 16/37 (43.2%) respectively. In these patients results about OARs were as follow: heart Dmax 36.6-50 Gy, V35 0.5-4.7 cc; oesophagus Dmax 35.7-41.3 Gy, V32.5 0.1-0.9cc; ribs Dmax 35.7-52.5 Gy, V32.5 0.1-7.9cc. SBRS treatment: dose on heart and ribs exceeded Dmax constraints in 1/18 patients (5.6%) with a Dmax of 23.3Gy (V22=0.6cc) and 33.6Gy (V30=0.3cc) respectively. With a median follow up of 18 months considering SBRT treatment and 16 months considering SBRT, no Grade >2 (CTCAE 4.3), early or late toxicity of heart or ribs was reported. In SBRT group, 1 grade 2-oesophagus toxicity in a patient exceeding DMax constraint was registered.

Conclusion: Patients irradiated did not develop severe toxicity on heart, oesophagus, and ribs although the administered doses were above constraints proposed in literature. A prolonged follow up and a larger population are needed to confirm the safety of dose-volume constraints

other than those reported in literature about SBRT and SBRS on abdominal area.

EP-1207

Can DIBH technique be used for SABR of large and mobile tumors of lung and liver? A clinical study

C. Srinivas¹, S. Subramaniam¹, N. Mohammed¹, A. Gandhi¹, M. Kathirvel¹, T. Swamy¹, K. Kiran Kumar¹, A. Jotwani¹, N. Yadala¹

¹Yashoda Cancer Institute, Department of Radiation Oncology, Hyderabad, India

Purpose or Objective: To assess clinical feasibility, local control and toxicity of deep inspiratory breath hold (DIBH) technique for delivery of SABR for large and mobile tumors of lung and liver.

Material and Methods: All patients suitable to undergo SABR, underwent respiratory training consisting of DIBH on demand for 15-25 seconds at a time. Patients underwent 2 sets of immobilization and imaging, one in DIBH phase and other in free breathing (FB) phase. Respiratory monitoring was performed using Varian RPM system and a 4mm gating threshold window was allowed. Set-up verification was performed using KV imaging and gated cone beam CT both taken in DIBH. All patients were planned with 2-4 arc VMAT using 6MV flattening filter free (FFF) photon beams to a dose of 60Gy in 5 fractions.

Results: 12 patients of lung tumors and 9 patients of liver tumors were treated with DIBH based SABR. In patients with lung tumors, DIBH resulted in 1.53 times higher mean lung volumes (3937 cc vs. 2576 cc, $p=0.003$). Compared to ITV based contours, PTV volumes were 1.48 times smaller for lung and 1.38 times smaller for liver tumors in DIBH CT compared to FB CT (36.15 cc vs. 53.83 cc, $p=0.002$, 57.76cc vs. 79.78, $p=0.03$). All the plans accepted for delivery met the standard criteria (ROSEL for lung and RTOG 1112 for liver) for both target and OAR constraints. On an average, V20 was reduced by 30%(18-38) in DIBH plans compared to FB plans. Time taken to deliver each session in DIBH phase with FFF beams was longer by an average of 2 minutes due to interruptions (maximum 4 interruptions/arc each lasting <10 seconds). Mean setup errors in cm quantified on CBCT were 0.1, 0.2 and 0.1 in vertical, longitudinal and lateral dimensions respectively and a uniform margin (based on Van Herk's formula) of 4mm appears to be safe. Except for 1 patient with symptomatic grade 2 pneumonitis and 1 patient with grade 2 chest wall pain, none had any major toxicities. With a median follow-up of 16 months, 18 month local control was 95%.

Conclusion: DIBH based SABR is clinically feasible and effective and should be considered standard for treating mobile and especially large tumors of lung and liver provided patient is suitable for treatment with DIBH technique. DIBH-CBCT based verification appears to be reproducible and effective to reduce setup errors. A margin of 4 mm appears to be safe in DIBH setting with 4 mm gating threshold window. Despite minimal increase in treatment time, DIBH is an effective way to deliver high throughput high quality SABR.

EP-1208

Radiation-induced pulmonary function change after postoperative radiotherapy in NSCLC

H. Kim¹, N. O Kyu¹, O. Young-Taek¹, C. Mison¹, K. Sang-Won¹, C. Oyeon¹, H. Jaesung¹, K. Mi-Hwa¹, P. Hae-Jin¹

¹Ajou University Hospital, Radiation Oncologist, Suwon City, Korea

Purpose or Objective: We aimed to establish the model predicting radiation-induced pulmonary function change after postoperative radiotherapy (PORT) in non-small cell lung cancer (NSCLC).

Material and Methods: From March 2003 to December 2011, 37 patients with NSCLC who underwent PORT were analyzed.

All patients took the forced expiratory volume in 1 second (FEV1) at the beginning of PORT and follow-up FEV1 within 6-36 months after the completion of PORT. We calculated mean lung dose (MLD) as a dosimetric parameter of the lung. Simple linear correlation and regression model were implemented to establish the prediction model between MLD and radiation-induced pulmonary function change.

Results: The median absolute value of FEV1 at the beginning of PORT, and follow-up FEV1 were 1.76 L (range, 0.90-3.05), and 1.66 L (range, 0.93-3.08), respectively. Radiation-induced pulmonary function change (follow-up FEV1 minus FEV1 at beginning of PORT) ranged from -0.71 to 0.40 L (median, 0.06). The median MLD of PORT was 12.3 Gy (range, 0.5-20.4). Radiation-induced FEV1 change and MLD showed statistically significant correlation (correlation coefficient = -0.357, $p = 0.030$). PORT-induced FEV1 change could be predicted by simple linear regression model [FEV1 change (L) = 0.295 - 0.026 MLD (Gy)].

Conclusion: Radiation-induced FEV1 change was significantly correlated with MLD in patients with NSCLC who underwent surgery followed by PORT. Follow-up FEV1 after the completion of PORT can be predicted by simple linear regression model using this correlation.

EP-1209

WBRT plus SRT versus WBRT alone or SRT alone for brain metastases from non-small cell lung cancer

R. Suwinski¹, B. Jochymek²

¹Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology- Gliwice Branch, Radiotherapy and Chemotherapy Clinic and Teaching Hospital, Gliwice, Poland

²Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology- Gliwice Branch, Radiation Oncology, Gliwice, Poland

Purpose or Objective: The benefits of addition of whole brain radiotherapy (WBRT) to stereotactic radiotherapy (SRT) with respect to overall survival of patients with brain metastases from non-small cell lung cancer (NSCLC) are unclear. Most of the published studies addressing this issue recruited the patients with diverse histology and primary sites, with only few focusing on NSCLC. We addressed this issue by evaluating institutional experience in efficacy of SRT plus WBRT vs. SRT alone or WBRT alone in patients with NSCLC.

Material and Methods: The analysis encompassed 143 patients with brain metastases from NSCLC, including 65 with squamous-cell cancer (45.5%), 53 adenocarcinoma (37.1%), 25 NOS (17.4%). SRT alone was used in 52 patients (36.4%), WBRT alone in 33 patients (23.1%) and WBRT plus SRT in 58 patients (40.5%). Two chief subgroups were considered: those with 1-3 brain metastases (121 patients, 84.6%) and those with >3 metastases (22 patients, 15.4%). WBRT doses ranged from 20-30 Gy in 3.0-4.0 Gy per fraction, SBRT was given in 1-6 fractions (median 1 fraction) of 6-22 Gy (median 15 Gy).

Results: 1-year actuarial overall survival was 8%, 6% and 27% for SRT, WBRT and SRT+WBRT respectively. The difference in overall survival among 143 patients treated with SRS+WBRT vs. SRS or WBRT was highly significant ($p<0.0001$). The difference in overall survival between SRS+WBRT vs. SRS or WBRT was also apparent in a subgroup of patients with 1-3 metastases (1-year OS of 9%, 0% and 26%, respectively). By contrast, the differences in OS according to treatment were not significant among the patients with >3 metastases. A multivariate analysis showed that out of several variables considered only WBRT alone or SRT alone (HR=1.85, $p=0.001$) and age over 70 years (HR=2.08, $p=0.005$) were associated with unfavorable survival.

Conclusion: Although conclusions from this study are limited by nonrandomized selection of the treatment schedule and some heterogeneity in prescription practice the data presented suggest that combination of WBRT and SRT vs. WBRT alone or SRT alone result in considerably improved

survival among the patients with 1-3 brain metastases from non-small cell lung cancer.

EP-1210

Definitive Radiotherapy with or without chemotherapy for T4N0-1 Non-small Cell Lung Cancer

Y.J. Kim¹, S.Y. Song¹, S.Y. Jeong², S.W. Kim³, J.S. Lee³, S.S. Kim¹, W. Choi⁴, E.K. Choi¹

¹Asan Medical Center- Univ of Ulsan, Radiation Oncology, Seoul, Korea

²Asan Medical Center- Univ of Ulsan, Institute of Innovative Science, Seoul, Korea

³Asan Medical Center- Univ of Ulsan, Medical Oncology, Seoul, Korea

⁴Gangneung Asan Hospital, Radiation Oncology, Gangneung, Korea

Purpose or Objective: To know the failure patterns and survival of T4N0-1 non-small cell lung cancer (NSCLC) treated with definitive radiotherapy.

Material and Methods: Ninety five patients with T4N0-1 NSCLC who received definitive radiotherapy with or without chemotherapy from May 2003 to Oct 2014 were retrospectively reviewed. Standard radiotherapy scheme was 66 Gy in 30 fractions. Main concurrent chemotherapy regimen was weekly Paclitaxel 50 mg/m² combined with Cisplatin 20 mg/m² or Carboplatin AUC 2. Primary outcome was overall survival (OS). Secondary outcomes were failure patterns and toxicities.

Results: The median age was 64 (range, 34-90). Eighty eight percent (n=84) of patients had ECOG performance status 0-1 and 42% (n=40) experienced pretreatment weight loss. Sixty percent (n=57) of patients had no metastatic regional lymph nodes. The median radiation dose was EQD2 67.1 Gy (range, 56.9-83.3). Seventy one patients (75%) were treated with concurrent chemotherapy. Among them, 13 patients were also administered neoadjuvant chemotherapy. At the median follow-up of 21 months (range, 1-102), 3-year OS was 44%. Three-year cumulative incidence of local recurrence and distant recurrence were 48.8% and 36.3%. Pretreatment weight loss and combination of chemotherapy were significant factors in OS. Acute esophagitis over grade 3 was occurred in 3 patients and only one grade 3 chronic esophagitis was reported. There was no grade 3-4 radiation pneumonitis.

Conclusion: Definitive radiotherapy for T4N0-1 NSCLC resulted in favorable survival with acceptable toxicity rates and local recurrence was a major pattern of recurrence. For improving local tumor control, the application of intensity modulated radiotherapy and radio-sensitizing agents would be needed.

EP-1211

Prognostic factors in patients with Stage I NSCLC treated with 3-D noncoplanar conformal RT

K. Karasawa¹, K. Ito¹, Y. Shibata¹, S. Hayakawa¹, H. Tanaka¹, T. Shimizuguchi¹, Y. Machitori¹, M. Fujii¹, K. Nihei¹, K. Fuse¹, T. Kawamoto¹, H. Kuramoto¹

¹Tokyo Metropolitan Komagome Hosp., Department of Radiology, Tokyo, Japan

Purpose or Objective: Stereotactic Body Radiation Therapy has become one of the standard treatments in Stage I NSCLC. However, there exists the problem of reoxygenation for large tumors and BED for serial organs locating near the central lung. Therefore, we have been treating especially these cases by decreasing the fraction dose while increasing overall treatment time and total dose (so-called hypofractionated 3-dimensional noncoplanar conformal radiation therapy). To clarify the prognostic factors of this treatment method, we carried out this investigation.

Material and Methods: Eligibility criteria were as follows: maximum tumor diameter not greater than 5cm, PS between 0 and 2, and no limitation regarding age and pulmonary

function. Radiotherapy was given with 6MV photon beam by fixed 10 non-coplanar conformal beams to a total dose of 75Gy in 25 fractions in 5 weeks. Irradiation was aiming at the ITV with proper margins. No ENI was given. Between Jan. 2002 and Jan. 2011, 109 eligible cases were treated. Age ranged from 53 to 93 (median 78). The male/female ratio was 79/30. There were 100 PS 1 and 9 PS 2 cases. There were 22 low risk operable cases, 31 high risk operable cases (surgeons recommended RT), and 56 inoperable cases. There were 63 T1 tumors and 46 T2. Forty-six cases were central tumors and the other 63 were peripheral tumors. Seventy tumors were adenocarcinoma, 23 tumors were squamous cell carcinoma, and 16 others. Regarding tumor markers, pretreatment CEA was elevated (>5ng/ml) in 36 cases. Using these 8 parameters, multivariate analysis (MVA) for overall survival (OS) and local control (LC) was performed by Cox's Proportional Hazard Model. Median follow-up period was 67 months.

Results: Five-year LC and OS rates were 84% and 50%, respectively. As for LC, MVA revealed that histology (p=0.0279) was prognostic and PS (p=0.0541) and pretreatment CEA (p=0.0560) had a tendency. As for OS, MVA revealed that gender (p=0.0081) and pretreatment CEA (p=0.0189) were prognostic and operability (p=0.0520) and histology (p=0.0913) had a tendency. On the other hand, age, T-stage or tumor location was not prognostic regarding neither LC nor OS.

Conclusion: Our overall results of this method were promising considering the status of the patients. Regarding LC, adenocarcinomas were better controlled compared with other histologies, and patients with good PS and tumors with normal pretreatment CEA tended to be better controlled. Regarding OS, female patients, patients with normal pretreatment CEA survived better than their counterpart, and operable cases and adenocarcinoma cases tended to survive better than their counterpart, respectively. Unlike other reported series, T2 stage and central tumors did not carry worse prognoses with this treatment method.

EP-1212

Are the encouraging SABR results for NSCLC reproducible outside of pioneering academic institutions?

C. Peedell¹, E. Aynsley¹, D. Shakespeare¹, J. Green¹, P. Summers¹, J. Reynolds¹, K. Burke¹, H. Bayles¹, C. Huntley¹, N. Richmond¹

¹The James Cook University Hospital, Radiotherapy and Oncology, Middlesbrough, United Kingdom

Purpose or Objective: Stereotactic ablative radiotherapy (SABR) is an internationally accepted standard of care in the management of early stage medically inoperable NSCLC [1]. However, the issue of whether the excellent results of SABR for lung cancer can also be achieved when patients are treated outside pioneering academic institutions remains a pertinent one [2]

South Tees NHS Trust is a large general hospital with a non-academic cancer centre, serving a population of 1.1 million in the North-East of England. In 2009, we became the first non-academic cancer centre in the UK to establish a SABR programme. To date, over 200 patients have been treated with SABR.

We present outcome data of 167 patients with Stage IA-IIB lung cancer, all of whom have at least 6 months of follow up and CT assessment of response.

Material and Methods: Data was collected prospectively between Sept 2009 - Sept 2015. Only patients with stage IA-IIB histologically proven NSCLC or PET +ve growing lesions, and at least 6 months of follow up, were included in the analysis. All patients were treated according to local protocols based on the national guidelines of the UK SABR Consortium. The following risk adapted treatment schedules were used depending on size and location of the tumour: 54Gy in 3 fractions (40patients), 55Gy in 5 fractions (105pts), 60Gy in 8 fractions (15pts), or 50Gy in 10 fractions (7pts)

Follow up was with CXR at 6months followed by CT at 6 months and clinical follow up, 3 monthly.

Results: 167 patients with stage IA-IIB disease treated. 55% histologically proven. There were 4 (2.4%) radiologically confirmed local recurrences giving a local control rate of 97.6%. Median survival was 43.2months. 3 year Overall Survival was 56.4% (see Fig 1). Treatment was well tolerated with minimal G3 toxicity (5 patients).

Conclusion: Our results suggest that SABR for medically inoperable NSCLC can be safely and effectively implemented in a non-academic institution with appropriate equipment and training. Clinical outcomes are comparable with internationally published series [3], with encouraging 3yr OS rate of 56%. Toxicity is minimal. Longer term follow-up is required to confirm findings and provide data regarding long-term toxicity.

EP-1213

Changes in pulmonary function after single-fraction carbon-ion radiotherapy for stage I NSCLC

W. Takahashi¹, N. Yamamoto², M. Nakajima², M. Karube¹, H. Yamashita¹, K. Nakagawa¹, H. Tsuji², T. Kamada²

¹University of Tokyo, Department of Radiology, Tokyo, Japan
²National Institute of Radiological Sciences, Research Center Hospital for Charged Particle Therapy, Chiba, Japan

Purpose or Objective: In patients with inoperable stage I non-small cell lung cancer (NSCLC) or for those refusing surgery, stereotactic body radiotherapy and particle radiotherapy have become therapeutic options. We conducted a Phase I/II study on single-fraction carbon ion radiotherapy (SF-CIRT) for stage I NSCLC that yielded a 3-year survival rate of 75.5% for 218 patients. Until now, the effect of hypofractionated CIRT on pulmonary function (PF) has not been well documented. The purpose of this study was to assess the long-term impact of SF-CIRT on PF in stage I NSCLC patients.

Material and Methods: A review of prospectively collected data from SF-CIRT-treated patients was performed. Patients underwent PF tests (PFT) (or: underwent a PF test) immediately before, and at 6, 12, and 24 months after irradiation. Patients who relapsed or needed adjuvant treatment were excluded as these events might affect PF.

Results:

■ Patient characteristics (n = 40)

Median age		75 (51-89)
Male/Female		26 / 14
Stage	T1 (IA)/T2 (IB)	25 / 15
Histology	Adeno./Squamous/NSCLC	30 / 9 / 1
Location	Left upper/Lower	12 / 11
	Right upper/Middle/Lower	9 / 2 / 6
Medical inoperability		19 (47.5%)
COPD*		13 (32.5%)
Dose prescription	44/46/48/50 GyE in single fraction	13 / 12 / 6 / 9

* FEV1/FVC ratio <70%

Forty patients treated between 2007 and 2012 fulfilled the inclusion criteria. According to the dose escalation study protocol, a median prescribed single-fraction dose of 46 GyE (range, 44-50 GyE) was delivered. All treatment-related complications were self-limited, without any grade 3-5

toxicities. Two years post-CIRT, the mean values of forced expiratory volume in 1 sec (FEV1) [-8.4% ± 11.9% (p < 0.001)] and the FEV1 per unit of forced vital capacity (FEV1/FVC) [-8.9% ± 11.7% (p < 0.001)] were less than the pre-CIRT values. There were no significant overall changes in total lung capacity, vital capacity, FVC, and residual volume before SF-CIRT and 2 years after SF-CIRT. At 6 months post-treatment, the diffusion capacity of the lung for carbon monoxide (DLCO) was significantly less than the pretreatment value (86.7 ± 32.7% vs. 78.1 ± 31.1%; p = 0.002); however, at 24 months post-treatment, the mean DLCO recovered to pretreatment levels (86.9 ± 30.5%). This might have been due to recovery from non-symptomatic radiation pneumonitis and/or smoking cessation.

Conclusion: We found stage I NSCLC patients had good long-term preservation of PF after SF-CIRT. Follow-up PFT revealed the following: Declines in FEV1 and FEV1/FVC were statistically significant but clinically trivial, DLCO decreased temporary, thereafter it tended to recover to pretreatment levels within 2 years.

EP-1214

Radiotherapy as adjuvant or definitive treatment method in thymic tumours

A. Napieralska¹, L. Miszczyk¹

¹Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Radiotherapy Department, Gliwice, Poland

Purpose or Objective: An evaluation of thymic tumors patient radiotherapy results.

Material and Methods: 93 patients (54F [58%], 39M [42%]) aged from 3 (6 children) to 77 (median 48) treated for thymic tumors since 1981. 84 patients (90%) were diagnosed with thymoma, 9 (10%) with thymic carcinoma. Masaoka stage was assessed in 93% (56% stage II, 31%-III, 6%-IV). All patients were irradiated. In 76 cases radiotherapy (RT) followed surgery - in 41 patients after radical and in 35 after incomplete resection. In 17 cases RT was definitive treatment, combined in 14 patients with chemotherapy. Patients were irradiated with fraction dose of 1.1-4.0Gy (median 2.0) to the total dose of 20-68Gy (median 49.5). Patient- and treatment-related factors potentially affecting survival and local control (LC) were evaluated with log-rank test. Survival analysis was performed with Kaplan-Meier method.

Results: Tumors relapsed in 17 patients. Metastases occurred after 6-129months (median 10.1) in 12 patients (in 8 in lungs). During the follow-up 17 patients died due to progression(13) or recurrence(4) of the disease. Median overall survival (OS) in the whole group (since diagnosis) was 140.2months. OS was significantly longer in patients with WHO B1 type(p=0.02), in good performance status (PS)(p=0.0005), without radiation-induced pulmonary fibrosis(p=0.02) or second cancer(p=0.03). Difference in OS between patients treated with radical surgery+RT, non-radical surgery+RT and definitive RT was of borderline significance(p=0.065). Factors significantly decreasing LC were: male sex(p=0.04), WHO B2 type(p=0.01), bad PS(p=0.0007), presence of metastases(p=0.003) and second cancer(p=0.03).

Conclusion: Obtained results do not permit to form robust conclusion concerning role of RT in the management of thymic tumors patient. Besides clear, unquestionable bad prognostic factors as bad PS, low differentiation, presence of local relapse, lung fibrosis, second malignancy or distant metastases, we found only one more - male sex, decreasing LC.

EP-1215

Do higher doses of palliative radiotherapy still prolong survival in stage III/IV NSCLC?

A. Price¹, K. MacLennan¹, S. Campbell¹, S. Erridge¹, F. Little¹, T. Evans¹

¹Western General Hospital- Edinburgh Cancer Centre, Edinburgh Cancer Centre, Edinburgh, United Kingdom

Purpose or Objective: In a UK Medical Research Council trial carried out before the widespread use of chemotherapy or CT-PET, palliative thoracic radiotherapy delivering 39 Gy in 13 daily fractions conferred an overall survival (OS) benefit when compared to 17 Gy in 2 weekly fractions in good performance status patients with radically treatable NSCLC. To determine whether this benefit persisted with contemporary standards of staging and systemic therapy, we studied the outcomes of patients with locally advanced/metastatic NSCLC receiving palliative radiotherapy in our centre over a 2 year period.

Material and Methods: The case records of 176 patients who received palliative thoracic radiotherapy in 2011 or 2012 were reviewed retrospectively. Data collected included age, stage, performance status, dose/fractionation, additional treatments and survival.

Results: 36 patients received high dose thoracic radiotherapy (HDTRT, 36-40 Gy in 12-15 fractions) and 140 received a lower dose (LDTRT), 20 Gy in 5 fractions. Median OS in the HDTRT group was 8.5 months and 5.5 months in the LDTRT group (hazard ratio 0.6, p <0.01). 12 patients received chemotherapy and HDTRT with median OS 12m vs 7m in the 25 patients receiving chemotherapy and LDTRT. In those who received HDTRT alone, median OS was 6.5m vs 4m for LDTRT alone. In patients with stage II-III disease median OS was 9.6m vs 6m for LDTRT. In those with stage IV disease, median OS was 8m for HDTRT vs 5m for LDTRT. In patients with performance status 0-2 median OS was 9m for HDTRT vs 6m for LDTRT, while in the two patients with performance status 3 who were irradiated it was 1m with HDTRT vs 3m with LDTRT.

Conclusion: This audit of contemporary practice suggests that the survival benefit of high dose palliative radiotherapy reported by Macbeth (Clin Oncol (R Coll Radiol). 1996;8:167-75) persists with modern staging and systemic therapy practices, and may also extend to patients with small volume stage IV disease excluded from that trial, but not those with poor performance status.

EP-1216

Differential diagnosis between toxicity and recurrence after SBRT in early stage inoperable NSCLC

R. Frakulli¹, F. Salvi², D. Balestrini², M. Palombarini³, S. Cammelli¹, G. Macchia⁴, M. Zompatori⁵, A.G. Morganti¹, G. Frezza²

¹Radiation Oncology Center- Sant'Orsola-Malpighi Hospital- University of Bologna, Department of Experimental-Diagnostic and Specialty Medicine - DIMES, Bologna, Italy

²Ospedale Bellaria, Radiotherapy Department, Bologna, Italy

³Ospedale Bellaria, Medical Physics Unit, Bologna, Italy

⁴Fondazione di Ricerca e Cura "Giovanni Paolo II"- Catholic University of Sacred Heart, Radiotherapy Unit, Campobasso, Italy

⁵Sant'Orsola-Malpighi Hospital- University of Bologna, Radiology Department, Bologna, Italy

Purpose or Objective: SBRT is the standard treatment of early stage inoperable NSCLC. Parenchymal changes (PC) after SBRT make it difficult the differential diagnosis

between treatment effects and disease recurrence. The purpose of our study was to identify the radiographic features (High Risk Features: HRFs) with high specificity (SP) and sensitivity (SE) for early detection of recurrence.

Material and Methods: We retrospectively evaluated patients treated with SBRT for inoperable early stage NSCLC. Median dose was 50 Gy in 5 fractions (range, 45-60 Gy /3-12 fractions) prescribed to 80% isodose. All patients underwent chest computed tomography (CT) before SBRT and after 3, 6, 12 months (thereafter annually). Using a chest CT scan radiological aspects according to Huang et al. classification (Huang et al., Radiother Oncol 2013;109:51-57) were evaluated. 18F FDG-PET was used in case of suspected tumor recurrence.

Results: Forty-five patients were included, 34 males and 11 females; mean age was 75.7 years (range, 60-86 years); 77.8% of patients had stage IA disease and 22.2% stage IB with a mean follow-up of 21 months, local control was 69%. Benign acute CT changes (up to 6 months after SBRT) were observed in 34 patients (patchy consolidation was the most frequent) and late changes (after 6 months) in 44 patients (mass-like fibrosis was the most frequent). HRFs were identified in 20 patients, enlarging opacity at primary site in 9 patients, enlargement after 12 months in 20 patients, bulging margin in 7 patients, disappearance of linear margin in 2 patients, loss of air bronchogram in 18 patients and cranial-caudal growth in 15 patients. These HRFs were individually significantly associated with local recurrence of the disease. The better predictor of relapse was enlargement opacity at 12 months (p <0.001) with SE: 84.6% and SP: 71.8%. The presence of > 1 HRFs demonstrated a higher SE (93.3%) (p <0.02) with SP: 59.4%.

Conclusion: Detection of HRFs is predictive of relapse with a SE increasing with the number of observed HRFs. This observation allows to better define the diagnostic algorithm in follow-up, suggesting to perform further exams only in patients with > 1 HRFs.

EP-1217

Effect of overall treatment time in dose escalation for radiotherapy of NSCLC. BED-time analysis

J. Cabrera¹, A. Torres¹, A. Ruiz¹, A. Corbacho¹, M.A. Gonzalez¹, J. Quiros¹, F. Ropero¹, J. Muñoz¹

¹Hospital Infanta Cristina, Radiation Oncology, Badajoz, Spain

Purpose or Objective: Because there is a positive correlation between radiation dose and local control (LC) in non-small cell lung cancer (NSCLC) although with no impact on overall survival (OS) our institutional protocol allowed moderate radiotherapy dose escalation up to 70 - 74 Gy (BED: 84 - 88.8 Gy) on the standard 60-66 Gy (BED: 72 - 79.2 Gy) providing that organs-at-risk are keep in tolerance. This retrospective study aims to assess the impact of dose escalation in clinical outcome when the duration of radiotherapy is taken in to account through the use of BED model corrected by time (tBED)

Material and Methods: 78 consecutively patients with unresectable NSCLC were retrospectively analyzed. All were PET-CT staged and were treated with platinum-based chemotherapy (either concomitant or sequential) and 3DCRT. Two groups were compared according to prescribed dose level: Standard Dose Group (SD) n = 38 those receiving nominal prescribed BED ≤ 79.2 Gy and Escalated Dose Group (ED) n = 40 those receiving > nominal prescribed BED >79.2 Gy. For both groups actual administered dose corrected for the duration of treatment (tBED) was calculated using the formula $[tBED (Gy) = n d (1+d/\alpha/B) - KT]$ (Sinclair, IJROBP 1999. 44:381) Multivariate Cox regression analysis was performed to identify significant predictors of OS, Disease Free Survival (DFS) and Thoracic Progression Free Survival (TPFS). For purposes of comparison a nominal prescribed dose of 60 Gy @2Gy in 39 days have a tBED = 44, 7 Gy.

Results: For the entire group median follow-up and overall survival (OS) were: 17.7 months (mo) (IQR: 10.3-27.9) and 19.1 mo (95% CI 13.9-24.3). Median tBED for entire group was 45.8 Gy (IQR 40.5-49) tBED in SD and ED group were 42.2 (IQR 37.4-45.2) and 48.9 Gy (IQR 45.7-49.7) Univariate analysis by groups: Actuarial median OS: SD vs. ED was: 17 mo (95% CI 13.6-20.3) vs. 22.3 mo (95% CI 9.6-35) $p = 0.18$. Actuarial median DFS SD vs. ED was: 8.3 (95% IC 7.2 - 9.3) vs. 12.8 mo (95% IC 3 - 22.7) $p = 0.009$. Actuarial median TPFs (mo) SD vs. ED was: 8.4 (95% CI 7.2-9.5) vs. 21.8 (95% CI 13.2-30.5) $p = 0.003$.

On multivariate analysis significant predictors for OS, DFS and TPFs are depicted on table: radiotherapy dose was found not to be a significant factor.

Variable	OS. HR (95% CI)	DFS. HR (95% CI)	TPFS. HR (95% CI)
PS [0 1 vs. 2]	19,03 (2,48 – 145,6)	17,13 (2,9 – 98,66)	2,49 (1,31 – 4,75)
Mediastinoscopy [-/+]	0,64 (0,005 – 0,93)	0,12 (0,25 – 0,66)	
Weight loss (no /yes)		3,85 (1,73 – 8,6)	

Conclusion: On univariate analysis, but not on multivariate, ED associated statistically significant better DFS and TPFs and non-statistically significant better OS, even when adjusted to overall treatment time. Due to treatment time delays SD group received a suboptimal dose of radiotherapy and ED group received a tBED which virtually match nominal 60 Gy. Our data in agreement with those resulting from randomized trials strongly support that 60 Gy @2 Gy with stringent control of time delays is the gold standard in the radiotherapy for NSCLC.

EP-1218

Salvage radiotherapy for locoregionally recurrent non-small cell lung cancer after resection

E. Kim¹, J.S. Kim¹

¹Seoul National University Bundang Hospital, Radiation Oncology, Seongnam, Korea Republic of

Purpose or Objective: Radiotherapy with or without chemotherapy is commonly used for isolated loco-regional recurrence of non-small cell lung cancer (NSCLC) after initial surgery. This study was undertaken to evaluate the outcomes and complications of curative radiotherapy for locoregionally recurrent NSCLC.

Material and Methods: Medical records of 57 patients who received curative radiotherapy for locoregionally recurrent NSCLC without distant metastasis after surgery from 2004 to 2014 were retrospectively reviewed. At the time of recurrence, the median age was 67 years (range 34-81 years), and most patients (84.2%) have good ECOG performance status. All patients initially received a curative intent operation, and the median disease-free interval was 14 months. For locoregionally recurrent lung cancer, forty-two patients were treated with concurrent chemoradiotherapy (CCRT), and 15 patients with radiotherapy alone. Radiation dose ranged from 45 Gy to 70 Gy (median 66 Gy) by a three-dimensional conformal technique. Lung function change after radiotherapy was evaluated by comparing pulmonary function tests before and after radiotherapy.

Results: Median follow-up after recurrence was 20 months. Six patients showed a complete response, and 39 patients showed a partial response. The median survival was 30 months. Two-year locoregional recurrence-free survival (LRFS), distant metastasis-free survival (DMFS), disease-free survival (DFS) and overall survival (OS) rate were 46.1%, 37.2%, 31.9%, and 65.1%, respectively. Eleven patients showed disease progression within the radiation field after radiotherapy. Pulmonary function decreased meaningfully after radiotherapy, and radiation pneumonitis of any grade was seen in 19 patients. In the multivariate analysis, age

under 70 years was associated with good OS ($p=0.047$); concurrent chemoradiotherapy with good OS ($p=0.014$), and DFS ($p=0.003$); and single-station recurrence with good OS ($p=0.01$), DFS ($p=0.022$), and LRFS ($p=0.01$).

Conclusion: Patients who have locoregionally recurrent NSCLC showed favorable survival outcomes with salvage radiotherapy. However, lung function should be carefully evaluated before and after radiotherapy. Young age, single site recurrence, and the use of CCRT were good prognostic factors of overall survival. In patients with good prognostic factors and suitable for curative radiotherapy, CCRT could be considered to improve treatment outcomes.

EP-1219

Utilisation of new functional imaging in NSCLC radiotherapy: Can we use DW-MRI?

M. Al Daly¹, R. Hani¹, M. Fayec², S. Talima¹, H. Khafagy¹, M. Kmal³, M. Hassan¹

¹Cairo University- Fac. of Medicine, Clinical Oncology, Cairo, Egypt

²Cairo University- Fac. of Medicine, Radiodiagnosis, Cairo, Egypt

³Cairo University- Fac. of Medicine, Medical physics, Cairo, Egypt

Purpose or Objective: Precise delineation of primary lung cancer mass and involved mediastinal LN is very important requirement in order to improve radiotherapy outcome and minimize treatment toxicity. Diffusion weighted MRI (DW-MRI) is a recently introduced functional imaging modality, having higher sensitivity and specificity than CT to differentiate lung cancer from post-obstructive lobar collapse. And also able to pinpoint lymph nodes with and without metastasis. The apparent diffusion coefficient (ADC) is the quantitative parameter of DW-MRI with cut off value $1.4 \times 10^3 \text{ mm}^2/\text{s}$ which can be used as a good tool to contour Target volumes in lung cancer.

the aim is to study the feasibility of using the images of DW-MRI and data of ADC map for radiotherapy contouring purposes

Material and Methods: Twenty cases of newly diagnosed lung cancer patients underwent CT chest with contrast and respiratory gated DW-MRI with b value of 0, 500, 1000s/mms. Both studies were obtained in the same position, respiratory phase and slice thickness (5mm) in order to allow proper image fusion. For each patient, we've delineated GTV for primary lung mass and GTV- LN for involved mediastinal LN on both CT scan (guided by size) and DW-MRI (guided by T2W and the ADC map) together with delineation of the nearby risk structures. Auto margins were taken for the CTV and the PTV. The impact of using MRI on stage and different treated volumes was assessed and compared.

the ADC values in differentiating the lung lesion and the nearby consolidation/collapse.

Case #4: shows level 6 LN station positive in both the CT scan but on the ADC image, the mean value 2.01 indicating non malignant involvement (?? Inflammatory)

Results: The main result was the reduction in primary and nodal volumes due to better definition of lung mass and nearby lung Collapse, the latter could be easily defined in 14 cases on the DW-MRI vs. 7 cases only by CT scans ($P=0.016$). Median GTV total (sum of 1ry and nodal GTV), on MRI Diffusion compared to that on the CT scan was 354 and 386 cm³ respectively ($P=0.009$). In 15 cases, a mean decrease in the GTV total of 34% \pm 56% (median, 9%; range, 0.2- 32.5%) by using DW-MRI. only in three other cases a mean increase in the GTV total of 12.7% \pm 14.9% (median, 9.7%; range, 0.4-221%) was found. The median PTVs on the CT scans vs. the MRI Diffusion were 1623 (range, 493-2965 cm³) & 1419 (range, 542-3158 cm³) respectively which was statistically non significant ($P=0.391$).

Conclusion: This pilot prospective study concluded that DW-MRI as a functional image can aid in proper definition and delineation of the target volumes after fusion of DWI and the CT images. GTV Total decreased in most cases due to exclusion of collapse, consolidation, reactionary and inflammatory LN, however GTV total was increased in 3/20 patients due to better nodal detection and better visualization of borders adjacent to the mediastinum and chest wall. DW MRI could be a future good tool for proper staging and guidance of radiotherapy in NSCLC cases indicated for chemo/radiation.

EP-1220

Postoperative hypofractionated radiotherapy of non-small cell lung cancer: pattern of the relapses

V.M. Sotnikov¹, V.A. Solodkiy¹, V.M. Kcharchenko¹, G.A. Panshin¹, V.D. Chhikvadze², S.D. Trocenko¹, A.A. Morgunov³

¹Russian Scientific Center of Roentgenoradiology, Radiation Therapy, Moscow, Russian Federation

²Russian Scientific Center of Roentgenoradiology, Surgery, Moscow, Russian Federation

³Russian Scientific Center of Roentgenoradiology, Scientific, Moscow, Russian Federation

Purpose or Objective: Purpose: The aim of this work was to compare the patterns of NSCLC relapses after combined modality therapy with postoperative hypofractionated and conventionally fractionated radiotherapy and after surgery

Material and Methods: Material/methods. We treated 528 patients between January 1990 and January 2014 (men - 445, women - 83) aged 27-78 years (median age 59) with morphologically proven NSCLC (adenocarcinoma - 161, squamous cell cancer - 289, other types - 70 patients); stage I-126, stage II - 117, III - 111. All patients were operated: pneumonectomy -180, lobe/belobectomy - 304, segmentectomy - 30, wedge resection -11. 227 patients received neoadjuvant or adjuvant platinum-based chemotherapy. Three groups were retrospectively analyzed: group I - 174 patients without postoperative radiotherapy (PORT), group II - 180 patients with postoperative hypofractionated radiotherapy with daily dose 3Gy up to the total dose 36Gy-39Gy (EQD2=43-47Gy, $\alpha/\beta=3$) and group III - 174 patients with postoperative radiotherapy with daily dose 2Gy up to the total dose 44Gy. Bronchial stump, involved regional lymphatic nodes and uninvolved groups (2R, 2L, 3a, 3p, 4R, 4L, 5, 6, 7 according to IASLC classification) were included in the CTV. The groups were comparable in the following parameters: age, ECOG status, stage, T- and N -

classification and the proportion of the patients treated with chemotherapy. The duration of the follow-up was 0,33-16,0 years, median - 2,25 years. The relapses were classified as local (in bronchial stump), regional, or distant. In the cases of mixt relapses (local \pm regional \pm distant) they were included in each category.

Results: Results. 263(49,8%) patients relapsed: 231 (43,8%) had distant metastases, local relapse - 51 (9,7%), regional relapse - 54 (10,2%). The pattern of the relapses in each group is presented in the table.

Category of the relapse	Group I	Group II	Group III	P (two-sided test)
Local	33 (19,0%)*	10 (5,6%)*	8 (4,6%)	*0,0001
Regional	38 (21,8%)*	8 (4,4%)*	8 (4,6%)	*0,0000
All locoregional	55 (31,6%)*	13 (7,6%)*	12 (6,9%)	*0,0000
Distant only	49 (28,2%)*	66(36,7%)*	68(39,0%)	*0,0924
All distant	81 (46,6%)*	74 (41,1%)*	76 (43,7%)	*0,2978
Relapsed patients	104(59,8%)*	79(43,9%)*	80(46,0%)	*0,0042

Conclusion: Conclusion. Hypofractionated postoperative radiotherapy (daily dose 3Gy, total dose 36-39Gy) significantly decrease the probability of local and regional relapse in NSCLC patients as well as the total number of the relapses without any effect with regard to distant metastases. Hypofractionated PORT is equally effective as conventional PORT (daily dose 2Gy, total dose 44Gy) with regard to locoregional control but has the clear logistical advantage.

EP-1221

Accelerated hypofractionated three-dimensional conformal radiation therapy (AHRT) for NSCLC

N. Rodriguez de Dios^{1,2,3}, X. Sanz^{1,2,3}, P. Foro^{1,2,3}, A. Reig^{1,2}, I. Membreve^{1,2}, A. Ortiz¹, J. Quera^{1,2,3}, E. Fernández-Velilla^{1,2}, O. Pera^{1,2}, M. Algara^{1,2,3}

¹Hospital de la Esperança, Department of Radiation Oncology, Barcelona, Spain

²Hospital del Mar Medical Research Institute IMIM, Oncology, Barcelona, Spain

³Pompeu Fabra University UPF, Department of Experimental and Health Sciences, Barcelona, Spain

Purpose or Objective: Increasing the radiotherapy dose can result in improved local control for non-small-cell lung cancer (NSCLC) and can thereby improve survival. This can be compromised by accelerated repopulation of tumour cells during radiotherapy. Accelerated hypofractionated radiotherapy (AHRT) can expose tumors to a high dose of radiation in a short period of time. We have employed this approach in two groups of NSCLC: 1) early stage NSCLC patients who cannot tolerate the SABR treatment process (for example, extended periods in the treatment position) or who cannot travel to a centre with SABR; and 2) stage III NSCLC unfit for concurrent chemotherapy.

This study was performed to evaluate the feasibility of utilizing AHRT for these patients.

Material and Methods: 76 patients (46 stage I-II and 30 local advanced NSCLC) were included. All patients had FDG-PET scan. Only the primary tumour and the positive mediastinal areas on the pre-treatment FDG-PET scan were irradiated. Mean age was 77.9 \pm 7.9 years. The performance status (PS) was > 2 in 50% of cases. The radiotherapy was delivered in 2.75 Gy fractions, once daily to a total dose of 66 Gy (BED10: 84 Gy). Sequential chemotherapy (mainly platinum and vinorelbine) was administered in 95% of stage III patients. Acute/late toxicity was evaluated using the RTOG criteria.

Results: After a mean follow-up of 2 years, the median overall survival (OS) and cause specific survival (CSS) were 23 and 54 months, respectively. On multivariate Cox regression analysis, PS >2 was an independent risk factor for OS ($p<0.0001$) and CSS ($p<0.0001$). The major acute adverse reactions were grade 2 dermatitis (18%), grade 2 esophagitis (10%) and grade 1 pneumonitis (26%). There were 34 patients with grade 1 late pneumonitis.

Conclusion: AHRT is a reasonable alternative to conventional fractionated radiotherapy in stage I-II NSCLC without access to SABR and in stage III patients unfit for concurrent chemotherapy. In both groups, treatment was well tolerated without grade 3 or higher treatment-related toxicity. PS >2 was an independent risk factor for OS and CSS.

EP-1222

Lung SBRT with Dynamic Tracking (DT) on the VERO (Brainlab-Mitsubishi) system

G. Jimenez¹, O. Gallocher¹, C. Chevelle¹, P. Dudouet¹, D. Franck¹, I. Latorzeff¹, M. Ducassou¹, D. Marre¹, N. Mathy¹, J. Mazurier¹, P. Navarro¹, D. Zarate¹

¹Clinique Pasteur Bât. Atrium, Department of Radiotherapy, Toulouse Cedex 3, France

Purpose or Objective: Since 2014, the VERO system equipped with dynamic tracking DT has been used in our center for lung SBRT. The purpose of this work is to compare 2 compensation techniques for lung SBRT, DT and a method based on the definition of an ITV, in terms of PTV volume reduction and treatment time.

Material and Methods: The VERO is an O ring system equipped with a gimbaled linac allowing pan and tilt rotations and with a stereoscopic dual-source kV X-ray imaging allowing the guidance of the tracking. A 4DCT is done to measure the range of the target movements with the breath: if the amplitude is < 7mm, an ITV is determined on the MIP images and if it is > 7mm, the DT method is preferred. A gold marker (Visicoil, IBA) is then implanted in the lesion and a new 4DCT is realized 1 week later. The GTVDT is drawn on the exhale phase and the PTVDT is defined with a 5mm margin. The dose is prescribed on the isodose covering 95 % of the PTV (Monte Carlo): the peripheral tumors receive 3x17 Gy, near the thoracic wall 4x12 Gy and near the mediastin 8x7,5 Gy. The metastatic diseases received 5x10 Gy. For DT, treatments are delivered with 6-8 no coplanar beams.

Results: 77 patients were treated with lung SBRT, including 22 patients treated with DT. Among these 22 patients, the PTVITV was however estimated: the average size of the PTVDT was 28.8cc(6.5 - 14.3 cc) and that of the PTVITV was 46.4cc(10.4 in 139 cc), so a 40 % reduction of the PTV volume. The average session length in DT was 35 min, the same as with the ITV method. The breathing rate of the patients was often irregular during the session and especially compared with the reference 4DCT. It did not affect the treatment delivery neither the guidance of the tracking. The clinical tolerance during and after the SBRT with tracking was excellent: 1 patient that was already treated for interstitial pulmonary fibrosis developed symptomatic radiation pneumonitis (RP). 5 other patients had radiological RP on the CT done during their first 6 months follow up period ; all of them received corticosteroid therapy and did not show any symptoms. There was no chest wall toxicity. Over a 16 months follow-up, 1 patient did not benefit from treatment with DT SBRT and had a progressive disease.

Conclusion: With a 40% reduction of the PTV, this DT technique makes it easy to monitor all the patients breathing motion, including very irregular rates, in a treatment time equivalent to more classical techniques based on the ITV.

EP-1223

Local failure after radical radiotherapy of NSCLC in relation to the pre-therapeutic PET/CT

M. Kandi¹, L. Hoffmann², J. Fledelius³, K.P. Farr¹, D.S. Moeller², M.M. Knap¹, A.A. Khalil¹

¹Aarhus University Hospital, Oncology, Aarhus C, Denmark

²Aarhus University Hospital, Department of Medical Physics, Aarhus C, Denmark

³Herning Central Hospital, Department of Nuclear Medicine, Herning, Denmark

Purpose or Objective: Local failure in lung cancer is associated with extremely poor survival. This study tested

whether the pattern of failure is associated with the most PET avid volume in the pre-therapeutic PET/CT scan.

Material and Methods: Patients with inoperable NSCLC treated in our department between 2008 and 2010 were reviewed. Forty patients, who received radiotherapy (RT) for NSCLC and had an accessible pre-therapeutic FDG PET/CT scanning, were included. Fifteen of the patients developed local failure as the first event. Patient and tumour characteristics for patients with recurrences are presented in Table 1. The peak SUV area in the pre-therapeutic PET/CT scan in both tumor and lymph nodes were identified by an experienced nuclear physician who delineated the volume encompassing 50% of the maximum SUV (SUVmax50) in all fifteen patients. All patients were followed by CT scans every third month. The CT scans which showed recurrences (rCT) were imported to the Eclipse treatment planning system (Varian MS) and the recurrence gross tumor volume(s) (rGTV) was delineated. A rigid registration between pre-therapeutic PET/CT and treatment planning CT (pCT) was performed using a soft tissue match on the tumor or the lymph nodes in SmartAdapt (Varian MS). The SUVmax50 volumes were copied to pCT using the rigid registration. The rCT with the defined rGTV were also fused with the pCT using a rigid registration based on normal tissue nearby the rGTV but excluding the rGTV. The vertebral column or the aortic arch was found to be preferable. Two radiation oncologists assessed the rigid registration between pCT and rCT.

Results: The patients received conventionally fractionated RT with a total dose of 60-66 Gy. Planning target volumes (PTV) ranged from 169 cm³ to 1065 cm³ (mean = 678 cm³). Median time to local progression was seven months (95% CI 5-9 months). In twelve patients, the recurrences of the primary tumor appeared inside the PTV. In three cases, the recurrences were both inside and outside the PTV. These three recurrences outside the PTV appeared in mediastinal lymph node region. The rGTV overlapped with the pre-therapeutic PET sub-volumes in twelve patients (Figure 1). In one case, rGTV was near the PET sub-volume area without overlapping. In one patient, part of the target was missed because an atelectasis obscured the PET/CT signal and made the delineation of GTV less optimal.

An Australian radiotherapy decision support system with contextual justification

M. Barakat¹, M. Field¹, D. Stirling², L. Holloway³, A. Ghose⁴, M. Bailey⁵, M. Carolan⁵, A. Dekker⁶, G. Delaney³, G. Goozee³, J. Lehmann¹, T. Lustberg⁶, J. Van Soest⁶, J. Sykes⁷, S. Walsh⁶, S. Vinod³, D. Thwaites¹

¹University of Sydney, Medical Physics, Sydney- NSW, Australia

²University Of Wollongong, SECTE, Wollongong, Australia

³Liverpool Hospital, Cancer Therapy Centre, Liverpool, Australia

⁴University Of Wollongong, SCSSSE, Wollongong, Australia

⁵Illawarra Cancer Care Centre, Wollongong Hospital, Wollongong, Australia

⁶MAASTRO Clinic, Knowledge Engineering, Maastricht, The Netherlands

⁷Westmead Hospital, Westmead Cancer Therapy Centre, Sydney, Australia

Purpose or Objective:

Background: There is great potential to utilise a large range of retrospective clinical data as an evidence base in decision support systems (DSS) for cancer prognosis and subsequent personalised treatment decisions. Recently, there were several DSSs built for this purpose using machine learning tools, mainly regression models, Bayesian Networks (BN) and Support Vector Machines (SVM). These machine learning tools provide only a prediction of a class (decision), based on input attributes that were used to build the model, without providing additional information to clinicians about how and why this prediction was made.

Objective: To investigate the performance of an alternative machine learning tool in building a lung cancer radiotherapy DSS that provides clinicians with an estimated prediction together with the influencing attributes and their values (evidence) in supporting the decision reached. This will provide contextual justification to clinicians regarding the decisions, which will further help them in deciding whether to adopt the machine prediction or not.

Material and Methods: A Non-Small Cell Lung Cancer 2 year survival prediction model was built, using data at Liverpool Cancer Therapy Centre in NSW, Australia. The attributes used to predict the survival were age, gender, ECOG, GTV and FEV1. The machine learning tool used is a Decision Tree which automatically extracts rules from the training data and formulates these as if-then-else patterns. A report of the used rules during the prediction process indicates the effective attributes used to reach the decision. SVM, Regression models and BN were built and tested using the

same data set; however, BN possess less, and SVM/Regression models possess none, of this reporting capability as they are learned by analysing probabilities and numerical distances among data points associated with prediction class.

Results: The DSS was learnt within the Liverpool Clinic with an unfiltered cohort of 4650 4686 patients. After filtering out patient records with missing values for the used attributes the cohort was reduced to 97 patients treated radically. The area under curve of the Decision Tree, SVM, Regression Model and BN when tested using a rigorous 10 fold cross-validation method respectively was 0.62, 0.62, 0.63 and 0.6. There is no significant difference in the performance between the four tools examined, however, the decision tree also generates an understandable context with every prediction made as a list of supporting attributes like the example in Figure 1.

Subject patient's attributes:

GTV = big
FEV1 = Normal
ECOG = 1
Age = old
Gender = Female

Output to clinician:

Will NOT Survive because GTV= Big,
FEV1 = Normal and ECOG = 1.

Scenario 1: Clinician convinced and will adopt this decision and discuss palliative treatment with the patient.

Scenario 2: As ECOG is subjective and there is potential classifier error, clinician may see that the examined patient Can have ECOG=0 and decide to ignore the decision and discuss radical treatment with the patient.

Figure 1: Part from the decision tree and the trace of example input patient and expected scenarios

Conclusion: It is possible to build a DSS for NSCLC data that provides a prediction with additional information justifying the decision with similar performance as the commonly utilised SVM, BN and regression tools. To improve the performance and avoid over fitting, more diverse and complete training data is needed by incorporating data from other centres to the learning process using distributed learning.

EP-1225

MRI-defined GTV change during SBRT for unresectable or oligometastatic disease of the central thorax

L. Henke¹, D. Przybysz¹, R. Kashani¹, O. Green¹, C. Robinson¹, J. Bradley¹

¹Washington University School of Medicine, Radiation Oncology, Saint Louis, USA

Purpose or Objective: Stereotactic body radiotherapy (SBRT) is an attractive modality for the definitive treatment of oligometastatic or unresectable primary lung malignancies. Proximity of the tumor to adjacent organs-at-risk (OAR) may limit delivery of a sufficiently ablative dose. The ability to adapt to tumor response during treatment may improve OAR sparing and/or allow dose escalation. This study aimed to evaluate the degree of daily interfractional variation in gross tumor volume (GTV) during SBRT for patients with oligometastatic or unresectable primary malignancy of the central thorax using a magnetic resonance image guided radiotherapy (MR-IGRT) treatment system.

Material and Methods: Eleven patients with unresectable primary or oligometastatic malignancy of the central thorax were treated at our institution with extended fractionation SBRT on a clinical MR-IGRT system. Treatment regimens consisted of 60 Gy in 12 fractions (n=8) or 62.5 Gy in 10 fractions (n=3). For each treatment fraction, low-field (0.35 Tesla) MR setup imaging was acquired as part of routine clinical practice. Daily GTV was retrospectively defined on MR image sets for all patients at each of 10 or 12 fractions, using initial GTVs from CT simulation as a template. Daily tumor volumes were then recorded and compared for each patient to evaluate for interfractional change in tumor volume.

Results: All patients demonstrated on-treatment reduction in MRI-defined GTV (Figure 1). Average reduction in tumor size from treatment initiation to completion of therapy was 51.0% (median 52.1%) and ranged from 30.5-70.8%. At a time point of fraction six, average reduction in GTV size was 38.2% (median 34.8%). Linear correlation across median values at each time point suggested a consistent decline over time of approximately 4% per day, with the most pronounced changes occurring between the 5th and 6th fractions.

Figure 1. On-treatment change in gross tumor volume (GTV) as defined on daily magnetic resonance (MR) set up imaging at each of 10 fractions for patients treated with SBRT to the central thorax.

Conclusion: Tumor volume decreased considerably during treatment for most patients undergoing lung SBRT. The dosimetric impact of this degree of MRI-defined tumor volume change during the course of therapy has yet to be assessed. However, adaptive planning during the course of SBRT may be dosimetrically advantageous for sparing of surrounding critical structures, particularly for disease involving the central thorax.

EP-1226

Quality of life in locally-advanced non-small cell lung cancer patients: a systematic review

L. Van der Weijst^{1,2}, W. Schrauwen³, V. Surmont^{4,5}, Y. Lievens^{1,2}

¹Ghent University Hospital, Radiation Oncology, Ghent, Belgium

²Ghent University, Radiation Oncology, Ghent, Belgium

³Ghent University Hospital, Medical Oncology, Ghent, Belgium

⁴Ghent University Hospital, Respiratory Medicine, Ghent, Belgium

⁵Ghent university, Respiratory Medicine, Ghent, Belgium

Purpose or Objective: Non-small cell lung cancer has a substantial impact on health-related quality of life (HRQoL) of affected patients. Measuring HRQoL in lung cancer patients is an important approach to forecast and assess the relative risks and benefits of a treatment as experienced by patients. A systematic literature review was performed to provide an overview of prospective studies measuring HRQoL in patients with locally-advanced non-small lung cancer (LA-NSCLC) receiving treatment with curative intent, published over the last 10 years.

Material and Methods: The literature search was performed in four electronic databases: PubMed, ScienceDirect, MEDLINE and Embase. The inclusion criteria for the studies were: English language, clinical trial, study population with LA-NSCLC, treatment with curative intent, HRQoL assessment, full text availability and published over the last 10 years.

Results: Only 5 studies out of the 225 potentially eligible studies matched our inclusion criteria. Four of these were randomized controlled trials; one was a prospective cohort study. All studies included radiotherapy at least in one of the evaluated treatment arms. Details of the studies and the analyzed parameters are shown in the table. HRQoL was a secondary endpoint in four studies and a co-primary endpoint

in one. No significant treatment-related improvement or deterioration in HRQoL has been reported in the included studies. Variability has been observed in terms of use of HRQoL instruments and statistical analysis.

Conclusion: Evaluation of HRQoL in patients with LA-NSCLC receiving curative intent treatment remains scarce. Reporting and statistical analysis of HRQoL data lacks standardization. More research is needed to address these issues in both clinical trials and daily care of patients receiving radiotherapy as part of their primary treatment for LA-NSCLC. Based on these considerations, a prospective cohort study has been launched in our institute, which aims to evaluate HRQoL, treatment-induced toxicity and neurocognitive functioning in patients with unresectable LA-NSCLC receiving radiotherapy, all or not in combination with concurrent or sequential chemotherapy.

EP-1227

Salvage radiotherapy for regional lymph node recurrence after surgery of non-small cell lung cancer

K.H. Seol¹, J.E. Lee¹, M.K. Kang², J.C. Kim¹, I.K. Park²

¹Kyungpook National University Hospital, Radiation Oncology, Daegu, Korea Republic of

²Kyungpook National University Medical Center, Radiation Oncology, Daegu, Korea Republic of

Purpose or Objective: To evaluate clinical outcomes of salvage radiotherapy for regional lymph node (LN) recurrence developing after radical surgery of non-small cell lung cancer (NSCLC).

Material and Methods: Between 2008 and 2013, out of patients with NSCLC who achieved complete response (CR) after definitive treatment (surgery with or without chemotherapy), 31 patients developed regional LN (mediastinum, hilum, and supraclavicular area) recurrence (median age, 66 years; stage I, n = 17; stage II, n = 7; stage IIIA, n = 7). The median time from definitive surgery to recurrence was 12 months (range, 3-80). Fifteen patients (48.4%) had single LN recurrence and others had multiple LN recurrence. All patients were irradiated to the recurred LN area with daily fractions of 2.0 Gy (n = 27), 2.5 Gy (n = 2), or 3.0 Gy (n = 2) by 3D-conformal radiotherapy. The median total dose for recurred LN was 66 Gy (BED 79.2 Gy10; range, 65.1-79.2 Gy10). Sixteen patients received chemotherapy either.

Results: The median follow-up was 14 months (range, 3-76). After salvage radiotherapy, 16 patients (51.6%) achieved CR, 9 patients (29.0%) partial response, and 6 patients (19.4%) stable disease. After salvage radiotherapy, one- and two-year in-field local control rate was 88.4% and 75.8%, respectively. Only two patients experienced an out-of-field mediastinal recurrence. One- and two-year progression-free survival rate from initial salvage radiotherapy was 73.1% and 50.9%, respectively. Progression site was predominantly distant. Overall, ten of 31 patients (32.3%) were successfully salvaged as CR state. Recurred LN size (<3 vs. ≥3 cm) was a significant prognostic factor for progression-free survival (p = 0.03). Pneumonitis requiring conservative treatment (grade 2 or more) occurred in 5 patients (16.1%). There was no radiation-related mortality.

Conclusion: Salvage radiotherapy for regional LN recurrence after radical surgery was suggested to be an effective treatment option with an acceptable level of toxicity. The recurred node size (3 cm cutoff value) was a strong predictor of progression-free survival. Aggressive salvage radiotherapy should be considered as a front-line treatment in regional LN recurrence of NSCLC.

EP-1228

Pulmonary toxicity after 3D-CRT or VMAT-based stereotactic radiotherapy for early stage lung cancer

A.R. Filippi¹, S. Badellino¹, R. Ragona¹, C. De Colle¹, A. Guarneri¹, U. Ricardi¹

¹Universita di Torino, Radiation Oncology Department, Torino, Italy

Purpose or Objective: To compare patterns of acute and late clinical/radiological lung toxicity following either 3D or image-guided VMAT stereotactic radiotherapy for stage I non-small cell lung cancer (NSCLC).

Material and Methods: In this observational study, we included 148 patients from a prospective mono-institutional SBRT series (time interval 2004-2014). All subjects had peripheral tumors and a prescription BED10Gy (at 80%) in the range 100-120 Gy. The first 95 patients (2004-2010) were planned with 3D-CRT, using multiple non-coplanar fields; a stereotactic body frame was used with CTV-PTV margins of 5 mm (antero-posterior and latero-lateral) and 10 mm (cranio-caudal). The second cohort (2010-2014) included 53 patients, planned with volumetric IMRT, using a single/multi arcs VMAT technique, on a PTV generated with 3 mm margins from a patient's specific ITV (obtained from 4D-CT), with a frameless approach through cone-beam CT guidance. Clinical acute and late toxicities were scored according to RTOG scales; radiological acute (<6 months from SBRT) and late (>6 months post SBRT) toxicity on the basis of modified Kimura and Koenig's classifications, respectively. Student's T test was used to compare clinical characteristics, and Pearson's chi square test to compare the incidence of any grade lung toxicity.

Results: Patients and tumors' characteristics were similar and well matched between the groups. PTV volumes were also comparable (35.1 cc for 3D-CRT vs. 40.3 cc for VMAT, p=0.16). Moreover, no significant difference was detected in Mean Lung Dose, converted in 2 Gy equivalent (11.7 vs. 10.4 Gy for 3D-CRT and VMAT, respectively, p=0.13). Frequencies of acute and late clinical toxicity (all grades) were superimposable between 3D-CRT and VMAT (acute: 10.5% vs. 22.6%, p=0.28; late: 4.2% vs. 13%, p=0.09, respectively). The crude rate of RTOG acute grade 3 radiation pneumonitis was 2.1% after 3D-CRT and 3.8% after VMAT. Acute and late radiological toxicity patterns were also similar between the two cohorts. Figures 1 and 2 depict the incidence and grade of both, according to different treatments. As expected, late radiological toxicity occurred in approximately 60% of patients, with modified conventional (25% after 3D-CRT vs. 32.6% after VMAT) and mass-like (19.6% after 3D-CRT vs. 17.4% after VMAT) patterns as the most commonly observed findings.

Conclusion: Results of the present study indicate that the pattern of clinical and radiological toxicities following SBRT in peripheral early stage NSCLC treated with comparable BED10Gy is not influenced by the different techniques used for planning and delivery.

EP-1229

Non-small cell lung cancer: marked difference in first failure site depending on histology

L. Nygaard¹, I. Vogelius¹, K. Håkansson¹, S. Langer², G. Persson², S. Bentzen³

¹The Finsen Center - Rigshospitalet, Department of Oncology - Section of Radiotherapy, Copenhagen, Denmark

²The Finsen Center - Rigshospitalet, Department of Oncology, Copenhagen, Denmark

³University of Maryland Greenebaum Cancer Center, Division of Biostatistics and Bioinformatics, Baltimore, USA

Purpose or Objective: Inoperable non-small cell lung cancer (NSCLC) comprises several histological subtypes, with squamous cell carcinoma (SCC) and adenocarcinoma (AC) being most frequent. The prognosis is poor with current chemo-radiation strategies and treatment intensification is limited by patient tolerance. It is therefore relevant to target experimental therapeutic approaches to a patient's risk of local versus distant failure. The purpose of the current study was to compare the pattern of first relapse after chemo-radiation for locally advanced pulmonary SCC and AC.

Material and Methods: We retrospectively included 193 patients with locally advanced NSCLC treated with chemo-radiotherapy from 2009 to 2012. Patients with initial stage IV (n=17) disease and/or patients with histology other than AC or SCC (n=22) were excluded leaving 155 patient for the analysis. Patients were identified and grouped according to first event as either: loco-regional (LR) failure; intra-cranial distant metastases (ICDM), extra-cranial distant metastases (ECDM); dead without evidence of disease (Dead, NED), with the remaining patients being Alive, NED at latest follow-up in August 2015. The cumulative incidence of events was compared across the histology subtypes, using the competing risk method of Fine and Gray.

Table 1 Pattern of distant failure in AC and SCC

	ICDM	ECDM	Total
AC	18 (37.5%)	30 (62.5%)	48
SCC	2 (10.5%)	17 (89.5%)	19
Total of DM	20	47	67

Results: Patients received sequential (n=49, 32%) or concomitant (n=93, 60%) chemo-radiotherapy. Eleven patients received radiotherapy alone. Competing risks analysis found a significantly higher rate of ICDM in the AC group compared to SCC (p= 0.0004) but no significant difference in incidence of ECDM (p=0.08). LR failure was higher in SCC than in AC (p=0.01). There was no significant difference between the two histology groups in the proportion dying without evidence of disease (p=0.3), see Figure. Restricting the analysis to patients with distant metastases as first site of failure, there was a significantly higher rate of cerebral metastases in AC than in SCC (p=0.04), cf. Table 1.

Conclusion: The pattern of first failure in inoperable NSCLC differs among patients with AC and SCC with intra-cranial distant metastases being more common in AC than in SCC and LR relapse being much more frequent in SCC than in AC. Experimental treatment strategies should be targeting different relapse patterns in various histological subtypes. Intensification of local therapy for example may yield a worse risk/benefit ratio in AC compared to SCC.

EP-1230

Clinical outcomes of stereotactic ablative radiotherapy in pulmonary oligometastases

B.S. Jang¹, H.J. Kim¹, B.H. Kim¹, D.W. Kim², Y.T. Kim³, Y.W. Kim⁴, H.G. Wu¹

¹Seoul National University Hospital, Department of Radiation Oncology, Seoul, Korea Republic of

²Seoul National University Hospital, Department of Internal Medicine, Seoul, Korea Republic of

³Seoul National University Hospital, Department of Thoracic and Cardiovascular Surgery, Seoul, Korea Republic of

⁴Seoul National University Hospital, Department of Internal Medicine and Lung Institute of Medical Research Center, Seoul, Korea Republic of

Purpose or Objective: In addition to its curative use in early stage lung cancer, stereotactic ablative radiotherapy (SABR) can also potentially be indicated for pulmonary oligometastatic disease. This study aims to retrospectively analyze treatment outcomes and develop nomograms to predict survival.

Material and Methods: From September 2012 to April 2015, treatment outcomes and toxicities for 85 cases of SABR in 72 patients retrospectively reviewed. Prognostic factors were analyzed via multivariate analyses using Cox proportional hazards regression. Using factors that demonstrated to be significant in the Cox regression model, nomograms were constructed and validated internally.

Results: After a median follow-up of 15 months, only 1 patient showed local failure within the radiation field. The local failure-free survival (LFFS) rate at 2 years was 98%. The 1-year and 2-year progression-free survival (PFS) and overall survival (OS) rates were 62% and 48%, and 90% and 72%, respectively. Multivariate analyses demonstrated that controlled primary cancer (p = 0.01), absence of extrapulmonary metastatic disease (p = 0.03), and disease-free interval (DFI) longer than 1 year (p < 0.01) favorably affects PFS. Furthermore, the absence of extrapulmonary metastatic disease (p < 0.01) and lower performance status (p = 0.03) increased OS as well. In terms of internal validation, nomograms for PFS and OS revealed C-index of 0.75 and 0.81, and showed a well-fitted calibration curves, respectively. Grade 1 or 2 radiation pneumonitis was found in

37 cases, and grade 1 chest wall pain was found in 1 case. Any grade 3 or higher toxicities were not identified.

Nomogram for PFS

Nomogram for OS

Conclusion: SABR demonstrated good local control with tolerable adverse effects for pulmonary oligometastases. Several factors were predictive for survival. Based on these factors, nomograms presented in this study can potentially be a useful tool for the prediction of progression-free and overall survival rates.

EP-1231

Proton and Carbon ion for stage I non-small cell lung cancer: a meta analysis

J. Tian¹, Q. Zhang¹, X. Wang¹

¹Gansu Cancer Hospital, Department of Radiotherapy, Lanzhou, China

Purpose or Objective: To synthesize and compare available evidence to compare the Long-Term clinical outcomes of proton therapy (PT) with those of carbon ion therapy (CIT) for stage I non-small cell lung cancer (NSCLC).

Material and Methods: Clinical trials were searched for in Cochrane Library, PubMed, EMBASE, Web of Science and Chinese Biomedical Literature Database through Dec 2014. Additional articles were identified from searching bibliographies of retrieved articles. Two reviewers independently selected studies and extract data. Outcomes were analyzed by random-effects model meta-analysis and reported as odds ratio (OR) with 95% confidence intervals (CI). The meta-analysis was conducted with STATA 12.0 software.

Results: Three retrospective studies were included, the meta analysis showed that there were no difference between proton therapy and carbon ion radiotherapy for stage I non-small cell lung cancer in the one year progression-free survival (PFS) was OR=1.13(95%CI:0.71,1.79), two years PFS was OR=1.25(95%CI:0.76,2.06), three years PFS was OR=1.02(95%CI:0.58,1.79), four years PFS was OR=0.73(95%CI:0.36,1.46), five years PFS was OR=0.50(95%CI:0.19,1.30), the one year overall survival (OS) was OR=1.01(95%CI:0.65,1.55), two years OS was OR=0.93(95%CI:0.59,1.46), three years OS was OR=0.94(95%CI:0.62,1.41) and four years OS was OR=0.65(95%CI:0.36,1.19), but there was difference in five years OS was OR=0.37(95%CI:0.16,0.90).

Conclusion: Our data suggest that the clinical outcomes of stage I NSCLC patients treated with PT and CIT may be similar. PT may improve 5-year OS compared with CIT. However, no firm conclusion concerning the difference in clinical outcomes between these two partial therapies can be made because of the limitations of retrospective studies; more homogeneous prospective data, large multicentric and randomized trials are needed to compare the efficacy of PT with CIT for stage I NSCLC.

⁶European Institute of Oncology- University of Milan and Centro Nazionale di Adroterapia Oncologica CNAO, Radiation Oncology- Department of Health Sciences, Milano, Italy

Purpose or Objective: Lung and esophageal cancer are characterized by aggressiveness and comprehend the majority of thorax malignancies. In both pathologies, the possibility to stratify patients (pts), early during radiotherapy (RT) or chemoradiotherapy (CRT) with interim 18F-FDG-PET/CT (FDGint) is extremely appealing to optimize treatments. CRT-responding pts could benefit from further preoperative treatment, while non responding pts should discontinue CRT, to avoid toxicity, and not to delay surgery. Although controversial findings have been reported on the early value of FDGint in thorax cancer, some notable results support therapeutic decision based on its analysis. Reviews specifically addressing FDGint in thorax cancer are lacking. The purpose of this study is to evaluate where and whether FDGint may offer predictive and prognostic potentials.

Material and Methods: A comprehensive review of the last decade literature was made, assembling studies on FDGint in pts affected by lung or esophageal malignancies. Six different searches were completed on PubMed using keywords combined by Boolean operators (and, or). Studies inherent to FDGint for adaptive RT (aRT) were also included. Restrictions were: papers in English; 3D hybrid PET/CT studies; original papers only. Cross-references of the studies selected were also manually checked to complete the literature pursuit.

Results: 1121 items in lung cancer and 193 in esophageal cancer were found. After the steps of process selection, 17 studies were extracted for lung cancer (5 related to change of FDG uptake, 9 correlation with response and prognosis, 3 aRT) reporting on 488 pts, and 8 studies for esophageal cancer (7 correlation with response and prognosis, 1 aRT) reporting on 318 pts. The main metabolic parameters correlated with outcomes, progression free survival, locoregional control, overall survival were the standardized uptake value, metabolic tumor volume, total lesion glycolysis and their variations. Lung studies did not give special emphasis to statistical analysis, while 6/8 esophageal studies reported the results of statistical ROC analysis (Figure). Among the 17 lung studies, 14 advocated the predictivity of FDGint, 3 showed the improvements by aRT. Among the 8 esophageal studies, 4 sustained predictivity, 3 did not find any correlation, 1 showed the feasibility of aRT.

Figure: Sensitivity (dark green), specificity (light green), AUC (area under the curve, gray), PPV (positive predicted value, red), and NPV (negative predicted value, pink) as percent for the various studies related to the predictivity of FDG_{int} in esophageal cancer. SUV = maximum standardized uptake value from FDG_{max}. References 1, 2, and 3 sustained correlation; References 4, 5, and 6 concluded a lack of correlation.

Conclusion: Despite heterogeneity, the studies comprised in this review denoted FDGint as promising and challenging tracer for early assessment of outcomes during CRT. In lung cancer papers, all the authors sustain the predictivity of response and prognosis of FDGint. In esophageal cancer instead, its predictive and prognostic value cannot be

definitively established due to some controversial findings, the possible reasons of which demand further research with prospective and uniform protocols and analysis, great number of pts and adequate follow-up period.

EP-1233

Carbon ion radiotherapy for stage I non-small cell lung cancer: A Meta-analysis of 369 patients

Q. Zhang¹, J. Tian¹, X. Wang¹

¹Gansu Cancer Hospital, Department of Radiotherapy, Lanzhou, China

Purpose or Objective: To synthesize and compare available evidence considering the effectiveness of carbon-ion radiotherapy for stage I non-small cell lung cancer.

Material and Methods: To synthesize and compare available evidence considering the effectiveness of carbon-ion radiotherapy for stage I non-small cell lung cancer. **Methods:** A comprehensive search was conducted in the Cochrane Library, PubMed, EMBASE, Web of Science and Chinese Biomedical Literature Database (from inception to Feb 2015). Selection of studies, and extracting data were performed by two reviewers independently. Outcomes were analyzed by random-effects model meta-analysis and reported as odds ratio (OR) with 95% confidence intervals (CI). The meta-analysis was conducted with STATA 12.0 software.

Results: Eight trials (369 patients) were included, the meta analysis showed that the one year local control rate (LCR) was OR=0.89 (95%CI:0.81,0.90), two years LCR was OR=0.81 (95%CI:0.72,0.89), three years LCR was OR=0.64 (95%CI:0.55,0.73), four years LCR was OR=0.23 (95%CI:0.13,0.33) and five years LCR was OR=0.70 (95%CI:0.67,0.73). the one year overall survival (OS) was OR=0.94 (95%CI:0.88,0.99), two years OS was OR=0.85 (95%CI:0.70,1.00), three years OS was OR=0.64 (95%CI:0.50,0.78), four years OS was OR=0.29 (95%CI:0.18,0.40) and five years OS was OR=0.34 (95%CI:0.19,0.49). the one year progression-free survival (PFS) was OR=0.79 (95%CI:0.69,0.89), two years PFS was OR=0.63 (95%CI:0.52,0.75), three years PFS was OR=0.39 (95%CI:0.28,0.51), four years PFS was OR=0.20 (95%CI:0.10,0.29) and five years PFS was OR=0.08 (95%CI:0.02,0.15). the recurrence was OR=0.46 (95%CI:0.39,0.53) and distant metastasis was OR=0.20 (95%CI:0.14,0.26).

Conclusion: Carbon beam radiotherapy, which is an excellent new modality in terms of a high local control and survival, may be a valid alternative to surgery for Stage I cancer, especially for elderly and inoperable patients.

EP-1234

VMAT based lung ablative radiotherapy: primary lesions and metastases

D. Farga¹, J.A. Burgos¹, F.J. Celada¹, F.J. Martínez¹, M.D. Badal¹, J. Bonaque², J. Gimeno², R. Chicas¹, M.J. Pérez¹, E. Cuervo¹, J. Pérez², A. Tormo¹

¹Hospital La Fe, Radiotherapy Oncology, Valencia, Spain

²Hospital La Fe, Radiophysics, Valencia, Spain

Purpose or Objective: Stereotactic ablative radiotherapy is an emerging non-invasive technique for the treatment of lung lesions. Both primary lesions and metastases may benefit from this approach, even in patients with low respiratory reserve. This work describes and evaluates institutional experience of SABR in lung location.

Material and Methods: From May '12 to November '14, 82 lesions in 67 patients were irradiated. 57 lesions were primary lung tumors and 25 metastases. Immobilization systems used in each patient was abdominal compressor and vacuum cushion or head-and-shoulders mask. An ITV was defined using three CT scans in three different phases of the respiratory cycle or with 4D RPM-Varian® system. The PTV was obtained by uniformly 5 mm ITV expanding. BED prescription was always over 100 Gy10 in 3-8 fractions following a risk-adapted

protocol. 8 patient treatments were performed on a Clinac iXTM and 74 treatments on a TruebeamTM with high definition MLC. Volumetric modulated arc therapy (RapidArcTM) was mostly used, and image-guided RT was performed with cone-beam CT (CBCT). Intra-fraction movement was controlled by post-treatment CBCT and infra-red ExacTrac.

Results: Median age was 75y.o. (44-89). The median GTV/PTV size was 3.2/27.15cm³ (0.2-129.9/5.90-263.90). Intra-fraction movement in all cases was less than 5mm according to post-treatment CBCT. At a median follow-up of 7(1-30) months, overall local control was 92.7%, 89.5% for primary lesions and 100% for metastases. Mean overall survival was 18 months for primary lesion (14.7-21.33 [95%]). No toxicities over G3 have been collected.

Conclusion: VMAT based ablative radiotherapy achieves excellent control rates in both primary lesions and metastases. Overall survival also depends on specific characteristics of the patient.

EP-1235

Necrosis / Fistulae occurring in temporal association with chest irradiation

S. Adebahr^{1,2}, S. Braasch¹, T. Schimek-Jasch¹, A.L. Grosu¹, U. Nestle^{1,2}

¹University Medical Center Freiburg, Radiation Oncology, Freiburg, Germany

²German Cancer Consortium DKTK, Partner Site Freiburg, Freiburg, Germany

Purpose or Objective: Receiving Radio(chemo)therapy [R(C)T] for pulmonary tumors some patients have or develop necrosis or fistulae (N/F) within the area of the treated tumor. Partially such N/F result in fatal complications like mediastinitis or pneumonia whereas other affected patients achieve good local control rates with long term survival after R(C)T. By retrospectively analyzing such cases we are aiming at identifying factors that might have an impact on the course of disease and should pre-therapeutically be considered in future.

Material and Methods: Retrospective analysis of patients coming up with N/F in temporal association with chest RT applied at the University Medical Center Freiburg from 2006 to 2013. Clinical and radiation parameters have been evaluated, acute and late toxicity, complications, clinical and imaging follow up have been assessed and will be analyzed with respect to local control and overall survival.

Results: We identified 40 patients irradiated for pulmonary malignancies (mainly centrally located NSCLC, UICC IIIB/IV; 16 female, 24 male; median age 64 years; 15 squamous cell-, 15 adenocarcinoma, 10 other) who developed N/F in temporal association with chest RT. Intention of treatment was curative in 31 and palliative in 9 patients. 25 patients received R(C)T, 15 received RT alone with a median total dose of 54 Gy (14-72Gy). 26 patients revealed a necrotic primary tumor, 6 additionally necrotic lymph node metastases (LNM), 8 necrotic LNM, exclusively. In 34 lesions necrosis was found previous to RT, in 3 cases it occurred during, in 3 cases after RT. 14 patients showed fistulae, all fistulae with esophageal or mediastinal involvement emerged after RT. For 16 patients G3, for 6 G4 toxicities have been reported, one patient died in consequence of an esophago-tracheal fistula. All patients with N/F-connection to the esophagus revealed toxicities ≥G3, whereas some patients with centrally necrotic tumor and fistula without esophageal involvement revealed excellent long term follow ups. Median survival was 12,6 months (median FU 6,9 months). All patients with esophago-tracheal fistula died before reaching the median. Histology and location of the necrotic lesions didn't show any significant impact on survival.

Conclusion: R(C)T of pulmonary malignancies for patients with N/ F can be associated with high toxicity. One essential factor with impact on the clinical course seems to be the

involvement of the esophagus. Without, courses with low complications and good local control are possible.

EP-1236

Does a localized NSCLC treated with SBRT affect the survival in COPD patients?

S. Jeppesen^{1,2}, N.C.G. Hansen³, T. Schytte¹, M. Nielsen⁴, O. Hansen^{1,2}

¹Odense University Hospital, Department of Oncology, Odense, Denmark

²University of Southern Denmark, Institute of Clinical Research, Odense, Denmark

³Odense University Hospital, Department of Respiratory Medicine, Odense, Denmark

⁴Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

Purpose or Objective: The most common reason for patients (pts) with localized NSCLC to be deemed medical inoperable is Chronic Obstructive Pulmonary Disease (COPD). COPD is associated with severe morbidity and mortality. It is not known if the prognosis of COPD pts is so poor that diagnosed localized lung cancer may only have little impact on survival. The aim of this study was to compare survival in SBRT treated COPD pts unfit for surgery and COPD pts without a malignant diagnosis.

Material and Methods: Data for the group of SBRT treated NSCLC pts from our institution were prospectively recorded from 2007 until 2013. The non-malignant control group was retrospectively selected among pts referred to the Department of Respiratory Medicine from 2005 until 2011 due to suspected lung cancer, which was subsequently ruled out. From both groups pts were selected for the present analysis if spirometry fulfilled the criteria for COPD defined as the ratio between forced expiratory volume in 1 second (FEV1) and forced vital capacity (FVC) less than 70%. The COPD was classified according to international GOLD criteria as mild, moderate, severe, or very severe based on FEV1 in percent of predicted (FEV1%pred). Propensity score matching (PSM) was performed to reduce confounding between the two groups based on age, gender, and FEV1%pred. The treatment survival outcome variable was calculated using the Kaplan-Meier method. Log rank test was used for testing differences in survival rates.

Results: 102 SBRT treated pts (NSCLC group) and 573 pts without malignant disease (non-malignant group) were enrolled after a spirometry revealed COPD. No SBRT-related deaths were observed. Pts in the NSCLC group were older ($p < 0.05$) and had worse FEV1%pred ($p < 0.05$). PSM identified 102 pts from each group with similar characteristics: mean age of 72.7 years, FEV1%pred of 52, and 54 women. In the matched comparison a significant difference in the median overall survival was observed, 57 months vs. 87 months in the NSCLC and non-malignant groups, respectively $p < 0.05$ (figure 1). Subgroup analyses of pts with mild/moderate COPD and pts with severe/very severe COPD showed that the difference in mOS in the unmatched and matched comparison was more pronounced in pts with mild/moderate COPD.

Conclusion: In a matched comparison, SBRT treated COPD pts with localized NSCLC had worse survival compared with COPD pts without a malignant diagnosis. Despite the serious prognosis of COPD, a diagnosis of localized NSCLC affected the survival in COPD pts.

EP-1237

Cyberknife Radiosurgery for spinal metastasis from lung cancer

I. Jung¹, S.Y. Song¹, S.D. Ahn¹, J.H. Kim¹, S.W. Lee¹, S.M. Yoon¹, Y.S. Kim¹, J.H. Park¹, S.S. Kim¹, E.K. Choi¹

¹Asan Medical Center- Univ of Ulsan, Radiation Oncology, Seoul, Korea Republic of

Purpose or Objective: To evaluate efficacy and safety of Cyberknife radiosurgery (CKRS) in patients with spinal metastasis from lung cancer.

Material and Methods: From July 2011 to October 2014, 64 patients received CKRS for spinal metastasis from pathologically confirmed lung cancer. Medical record of 75 lesions in 64 patients retrospectively reviewed. Pain control, radiological tumor control, especially epidural mass, and treatment related complications such as vertebral compression fracture and pain flare were assessed. Radiologic response was assessed following RECIST criteria. Pain response was defined according to International Bone Metastases Consensus Working Party palliative RT endpoints.

Results: Median age of patients with bone metastasis was 61 years (36-81 years). 42 patients (63.6%) had bone metastasis at initial diagnosis. Mean tumor diameter was 2.59 cm (1.2 cm-8.3cm), and 16 patients had epidural extension. was found in 16 patients (21.3%). Radiation dose were 14 - 32 Gy per 1-4 fx (BED($\alpha/\beta=10$): 28.8-57.6 Gy, median 41.6 Gy). Radiologic evaluation with CT or MR after CKRS was done at 54 lesions (72.0%). Pain response was assessed in 59 lesions (78.7%). With median follow-up of 10.5 months (1 - 40 months), local tumor progression was found in 9 lesions (12.0%), and median time to progression was 10.1 months. 1 year and 2 year local progression free survival rate was 84.6% and 79.7%. Among 16 lesions with epidural extension, 11 lesions had evaluated by CT or MR, and the tumor regression achieved in 8 lesions (72.7%). Pain response rate after CKRS was 83.1% (CR : 28.6% , PR : 71.4% , SD : 20.4%). All patients tolerated the CKRS course well. Compression fracture was found in 31 lesions (41.3%) but only 13 lesions(17.3%) collapsed among 54 lesions(72.0%) with osteolysis.

Conclusion: Cyberknife radiosurgery is an effective for local control and safe treatment modality to osteolytic spinal metastasis from lung cancer.

EP-1238

Thoracic re-irradiation following curative intent radiotherapy for non-small cell lung cancer

S. Scobie¹, G.G. Hanna², K. Franks³, J. McAleese⁴, S. Harrow⁵

¹Edinburgh Cancer Centre, Clinical Oncology, Edinburgh, United Kingdom

²Centre for Cancer Research and Cell Biology + Northern Ireland Cancer Centre, Queen's University of Belfast + Belfast City Hospital, Belfast, United Kingdom

³St James's Institute of Oncology, Leeds Cancer Centre, Leeds, United Kingdom

⁴Northern Ireland Cancer Centre, Belfast City Hospital, Belfast, United Kingdom

⁵Beatson West of Scotland Cancer Centre, Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom

Purpose or Objective: Following curative intent radiotherapy, up to 50% of patients with non-small cell lung cancer (NSCLC) experience local recurrence. This may be associated with significant symptomatology such as airways obstruction, haemoptysis and pain. Re-irradiation may be useful to palliate symptoms and to attempt cure, but little is known about effectiveness, usage rates, techniques used and clinical outcome. We report the incidence of thoracic re-irradiation following curative intent thoracic radiotherapy.

Material and Methods: Using the institutional databases of 3 large UK Cancer Centres (Belfast, Glasgow and Leeds), patients who had curative intent thoracic radiation for NSCLC during 2010 were identified. Baseline demographics were collated, along with details of initial irradiation, relapse and subsequent management. Summary statistics were generated detailing the incidence of re-irradiation, treatment intent of re-irradiation and dose fractionation used.

Results: In total, 351 patients were identified who had curative intent radiation. Of these, 188 (54%) relapsed, 60 with local relapse only. Eleven patients (18% of those with local relapse) received palliative re-irradiation to thorax for specific symptoms, with fractionation schemes including 8Gy/1 fraction, 16Gy/2 fractions, 20Gy/5 fractions and 30Gy/10 fractions. Four patients (6%) received radical re-irradiation with curative intent using 55Gy/20 fractions (3 patients) or 55Gy/5 fractions (1 patient). Thirty-five patients (58%) had no treatment at relapse and most were categorised unfit. Four patients had salvage radical surgery. The remainder had systemic therapy or palliative supportive care. Median time between initial radiotherapy and local relapse was 13.5 months (3-49 months). Median time from initial radiation and re-irradiation was 24 months (6-41 months). No excessive radiation related toxicity was reported.

Conclusion: In this selected cohort, re-irradiation is used routinely for patients with NSCLC, both with palliative and curative intent for local failure following radical thoracic radiotherapy. Further investigation of re-irradiation is warranted to assess toxicity, optimise techniques used and improve patient accessibility.

EP-1239

Clinical outcome of SBRT of central, apical or paracostal tumors in the lung, a retrospective study

C. Kristiansen¹, S.S. Jeppesen^{1,2}, M. Nielsen³, T.B. Nielsen³, T. Schytte¹, O. Hansen^{1,2}

¹Department of Clinical Oncology, Odense University Hospital, Odense, Denmark

²Institute of Clinical Research, University of Southern Denmark, Odense, Denmark

³Laboratory of Clinical Research, Odense University Hospital, Odense, Denmark

Purpose or Objective: Stereotactic body radiotherapy (SBRT) of lung tumors gives excellent local control but with higher rates of toxicity for organs at risk located close to the tumor. Treating centrally located tumors with SBRT with 3 fractions increases the risk of severe side effects especially when located near the proximal bronchial tree (PBT) known from earlier studies. We aimed to evaluate our current practice using 56 Gy in 8 fractions for tumors located centrally in the lung or close to other organs at risk (OAR) located more peripherally in the lung.

Material and Methods: Medically inoperable patients treated with 56 Gy in 8 fractions from the 1th of June 2012 until the 1th of September 2014 were reviewed and analyzed. The patients were deemed unfit for SBRT in 3 fractions or normally fractionated radiotherapy. For three patients this treatment was part of the Nordic Hilus Study

Results: Fifty patients were treated with a median follow up of 23.7 months (12.5-38.4). For baseline characteristics, see table 1. Not all tumors were centrally located; some tumors were close to column, the apex of the lung or invaded the thoracic wall. Six patients had a locally recurrence (12%) and 15 distant recurrence (30%). Twenty-seven patients had died by the end of data analysis. Thirteen patients died of recurrent lung cancer. One patient died of another cancer. Two patients died suddenly without obvious cause. Eight patients died of other reasons, primary due to infections and/or known heart disease. Three patients died of hemoptysis probably due to bleeding from the main bronchus. Only one of these patients had an autopsy. This patient was re-irradiated with 30 Gy in 10 fractions because of recurrence overlapping the initial site. The 1 year survival

was 76%, 2 year survival 41% and the 3 year survival was 38%. The median overall survival was 21.1 months (3.1 - 37.0).

Table 1: Patients characteristics

	Patients
Women	21 (42%)
Men	29 (58%)
Age, median (range) in months	74.0 (50.0 - 90.5)
Location^a	
Centrally < 2 cm of the PBT	22 (44%)
Heart/pericardium	14 (28%)
Aorta or great vessels	34 (68%)
Vertebral body	13 (26%)
Apex of the lung	5 (10%)
Costae	19 (38%)
Histology	
Adenocarcinoma	21 (42%)
Squamous cell carcinoma	19 (38%)
Other	7 (14%)
Not known	3 (6%)
Performance status	
0	6 (12%)
1	24 (48%)
2	18 (36%)
3	2 (4%)
Median GTV (cm³)	12.1 (0.9 - 145.3)
Toxicity any	
Pulmonary	
Dyspnea	3 (6%)
Atelectasis in minor degree	4 (8%)
Fatal hemoptysis	3 (6%)
Pain	5 (10%)
Fracture	1 (2%)
Pneum palsy	1 (2%)

a: tumors can be located close to more than one site

Conclusion: SBRT with 56 Gy in 8 fractions for lung cancer in relation to OAR are tolerable with an acceptable local recurrence of 12%. The three patients who died of hemoptysis had their tumor located close to the main bronchus. Treatment of SBRT close to the PBT is known to cause damage to the bronchus. Due to the retrospective format of the trial some side-effects may be underreported. It is challenging to treat tumors close to organs at risk and in particularly the bronchial tree with a dose to achieve local control and without harming the PBT or close to OAR.

EP-1240

Normal tissue exposure in SBRT: Retrospective QA on a prospective cohort - what have we learned?

S. Adebahr^{1,2}, J. Hinck¹, R. Wiehle¹, T. Schimek-Jasch¹, E. Gkika¹, A.L. Grosu¹, U. Nestle^{1,2}

¹University Medical Center Freiburg, Department of Radiation Oncology, Freiburg, Germany

²German Cancer Consortium DKTK, Partner Site Freiburg, Freiburg, Germany

Purpose or Objective: Technique and indication of stereotactic fractionated radiotherapy (SBRT) has emerged rapidly during the last decade. Delineation, dose specification and constraints have been adjusted to updated evidence. Retrospective Quality Assurance (QA) of available prospective data was performed in order to reconsider recommendations and might reveal important insights for future treatment strategies.

Material and Methods: Within a prospective monocenter phase II study (STIPRE) 100 patients, elderly or unfit for surgery, have been treated with SBRT for 120 pulmonary lesions ≤ 5 cm between 02/2011 and 12/2014. Applied doses were 3X12.5 Gy (85 lesions), 5X7Gy (30), 7X5Gy (1) 4X6.5 Gy (1), 5X6.5 Gy (1), 8X7.5 Gy (1), 12X4.5 Gy (1), prescribed to 60% isodose in all but 2 patients. Delineation of organs at risk (OARs) was requested, however not specified in a detailed way in the trial protocol. Applying a moderate dose no constraints were provided in the protocol but derived from the evidence available at that time. SBRT plans had been evaluated by at least two experienced radiation oncologists before treatment. Within the retrospective QA process of the trial we now evaluated the maximal dose applied to OARs and analyzed those data with respect to the dose constraints of the recently launched EORTC 22113-08113 Lungtech trial. If

constraints were violated we re-checked correspondence of the structures to the delineation standards of the Lungtech protocol. Association of violations and the prospectively recorded toxicity was evaluated.
