Brachytherapy for Prostate Cancer

14-16 June 2018 – Avignon, France

ESTRO School

Speakers

Course Director

- Peter Hoskin PH

Faculty

- Bashar Al-Qaisieh BAQ
- Stefan Machtens SM
- Carl Salembier CS
- Frank-Andre' Siebert FAS

Local organiser

- Nicolas Pourel

ESTRO School

Programme

Day 1		Thursday 14 June	
09:00	09:10	Welcome and introduction	PH
09:10	09:30	Prostate anatomy for brachytherapy	SM
09:30	10:00	Patient Selection for LDR seed brachytherapy	CS
10:00	10:30	Patient Selection for HDR seed brachytherapy	PH
10:30	11:00	Coffee break	
11:00	11:30	Imaging for prostate brachytherapy	SM
11:30	12:00	QA for brachytherapy	BAQ
12:00	13:00	LDR seed techniques and video demonstrations	CS/SM/BAQ
12:30	13:30	Lunch	
13:30	14:30	HDR techniques and video demonstrations	PH/FAS
14:30	15:30	CTV definition and Falcon exercise review	CS
15:30	16:00	Coffee break	
16:00	16:30	Radiation protection and incidents	BAQ
16:30	17:00	Adjuvant treatment in brachytherapy	CS
17:00	17:30	Review and interactive session	All

ESTRO School

Programme

Day 2		Friday 15 June	
09:00	10:15	Clinical results of LDR	CS
10:15	11:00	Clinical results of HDR	PH
11:00	11:30	Coffee break	
11:30	12:15	Image registration	FAS/BAQ
12:15	13:00	Planning principles and solution HDR & LDR	FAS/BAQ
13:00	14:00	Lunch	
14:00	14:30	Post-treatment evaluation	FAS/CS
14:30	15:30	Complications of prostate brachytherapy	SM
15:30	16:00	Coffee break	
16:00	17:00	Management of toxicity and complications	SM
17:00	17:30	Review and interactive session	All
Day 3		**Saturday 16 June**	
09:00	10:00	Focal therapy: concepts and LDR	SM
10:00	10:30	Focal therapy: HDR	PH
10:30	11:00	Coffee break	
11:00	11:30	Brachytherapy for salvage	CS
11:30	12:00	Prostate brachytherapy: LDR, HDR, surgery or IMRT	PH
12:00	12:30	Final discussion session	All

Marien-Hospital Bergisch Gladbach

ESTRO Teaching Course on Brachytherapy for Prostate Cancer
Avignon, June 14th-16th2018

ESTRO School

The prostate surrounds the urethra and is situated below the bladder.

The prostate produces fluid that is needed by sperms to move.

Department of Radiotherapy-Oncology
Europe Hospitals – Brussels - Belgium

EUROPE EUROPA
2 Alice St-Michel St-Elisabeth
Cliniques - Ziekenhuizen

Patient selection:

- do we have recommendations ?
- if yes, what do they learn us ?

BRIEF HISTORY

- The initial ABS recommendations (1999)
- The ESTRO recommendations (2000)

- The 2012 ABS recommendations

- Int. J. Radiation Oncology Biol. Phys., Vol. 44, No. 4, pp. 789–799, 1999

- **AMERICAN BRACHYTHERAPY SOCIETY (ABS) RECOMMENDATIONS FOR TRANSPERINEAL PERMANENT BRACHYTHERAPY OF PROSTATE CANCER**

- *SUBIR NAG, M.D.,*† DAVID BEYER, M.D.,*‡ JAY FRIEDLAND, M.D.,* § PETER GRIMM, D.O.,*\ AND RAVINDER NATH, PH.D.*¶*

1999 AMERICAN BRACHYTHERAPY SOCIETY (ABS) RECOMMENDATIONS FOR TRANSPERINEAL PERMANENT BRACHYTHERAPY OF PROSTATE CANCER

- **Brachytherapy as Monotherapy:**
- Stage T1 to T2a and
- Grade Gleason sum 2–6 and
- PSA < 10 ng/ml
- *(i.e , Low-risk patients)*

1999 AMERICAN BRACHYTHERAPY SOCIETY (ABS) RECOMMENDATIONS FOR TRANSPERINEAL PERMANENT BRACHYTHERAPY OF PROSTATE CANCER

- **Clinical Exclusion Criteria:**
- Life expectancy < 5 years
- Large or poorly healed TURP defect
- Unacceptable operative risks
- Distant metastases

- **Relative Contraindications for Brachytherapy (1) :**
- *These patients are not ideal candidates for brachytherapy, but have nevertheless been successfully implanted. Beginners should not implant these patients.*
- Patients at increased risk of developing complications
- Large median lobes
- Previous pelvic irradiation
- High AUA score
- History of multiple pelvic surgeries
- Severe diabetes with healing problems

- **Relative Contraindications for Brachytherapy (2) :**
- *Technical difficulties which may result in inadequate dose coverage*
- Previous *(large ?)* transurethral resection of prostate (TURP)
- Gland size > 60 cc at time of implantation
- Prominent median lobe
- Positive seminal vesicles

- **Brachytherapy as a Boost to EBRT:**
- Stage Clinical T2b, T2c *or*
- Grade: Gleason sum 8–10 *or*
- PSA > 20 ng/ml
- **Other possible indications for Brachytherapy as a Boost to EBRT:**
- Perineural invasion
- Multiple positive biopsies
- Bilateral positive biopsies
- MRI positive for capsular penetration

The ESTRO recommendations

Received 18 September 2000; accepted 27 September 2000

Indication for prostate brachytherapy

	Recommended Do well	Optional Fair	Investigational Do poorly
PSA (ng/ml)	<10	10–20	>20
Gleason score	5–6	7	8–10
Stage	T1c–T2a	T2b–T2c	T3
IPSS	0–8	9–19	>20
Prostate volume (g)	<40	40–60	>60
Q_{max} ml/s	>15	15–10	<10
Residual volume cm^3			>200
TURP ±			+

Clinical exclusion criteria :

- **Life expectancy < 5 years**
- **Large or poorly healed TURP defect**
- **Unacceptable operative risks**
- **Bleeding disorder or anticoagulation that cannot be stopped**
- **Distant metastases**
- **Prostate volume greater than 50 cc (60 ?) at the time of implantation**

Relative contra-indications :

- **Large median lobes**
- **Previous pelvic irradiation**
- **High AUA score (IPSS > 15)**
- **History of multiple pelvic surgery**

ABS 1999

ESTRO 2000

Actually only minor differences with the ABS paper ...

[10]*Department of Radiation Oncology, Massachusetts General Hospital, Boston, MA*
[11]*Department of Radiation Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY*

Table 1
Elements of patient history for permanent prostate brachytherapy

1. Urologic history including:
   a. Prior transurethral or open resection of the prostate or other surgery on the urethra
   b. Prior procedure for benign prostatic hyperplasia such as transurethral needle ablation (30) or microwave therapy
   c. Medications for treatment of urinary obstructive symptoms
   d. Erectile function
2. Prior diagnosis of cancer, especially bladder or rectal
3. Prior pelvic radiotherapy, surgery, or fracture
4. Inflammatory bowel disease
5. Connective tissue disorders
6. Documentation of International Prostate Symptom Score
7. Documentation of erectile function, International Index of Erectile function score preferred

Table 2
Minimum required elements of workup for permanent prostate brachytherapy

1. Prostate biopsy indicating adenocarcinoma within the preceding 12 months of planned permanent prostate brachytherapy. Additional synoptic information is required and includes the Gleason grading and percent cancer in the biopsy specimen.
2. Pretherapy serum prostate-specific antigen
3. Digital rectal exam with clinical tumor classification, "T stage"
4. Prostate volume determination, transrectal ultrasound preferred
5. Determination of a patient's ability to tolerate an extended dorsal lithotomy position
6. Determination of suitability for general or spinal anesthesia

Table 3a
Absolute contraindications to TRUS-guided PPB

Limited life expectancy
Unacceptable operative risks
Distant metastases
Absence of rectum such that TRUS guidance is precluded
Large TURP defects, which preclude seed placement and acceptable radiation dosimetry
Ataxia telangiectasia

TRUS = transrectal ultrasound; PPB = permanent prostate brachytherapy; TURP = transurethral resection of the prostate.

Table 3b
Relative contraindications for TRUS-guided PPB

The items listed below are considered as essential elements of the history in determining eligibility, but the criteria by themselves do not necessarily preclude therapy. They should, however, be considered closely in electing to proceed with PPB. Published experience demonstrates that patients with such conditions may undergo PPB if appropriately evaluated by an experienced team.
High IPSS (typically defined as >20)
History of prior pelvic radiotherapy
Transurethral resection defects
Large median lobes
Gland size >60 cm^3 at time of implantation
Inflammatory bowel disease

TRUS = transrectal ultrasound; PPB = permanent prostate brachytherapy; IPSS = International Prostate Symptom Score.

Table 4
Suggested treatment schema for low-, intermediate-, and high-risk disease for PPB

Risk group per NCCN	Brachytherapy alone?	Combined with EBRT?	Combined with androgen deprivation?
Low	Yes	Not favored	Not favored
Intermediate	Optional	Optional	Optional
High	No	Yes	Favored

NCCN = National Comprehensive Cancer Network; EBRT = external beam radiation therapy; PPB = permanent prostate brachytherapy.

Indication for prostate brachytherapy

	Recommended Do well	Optional Fair	Investigational Do poorly
PSA (ng/ml)	<10	10–20	>20
Gleason score	5–6	7	8–10
Stage	T1c–T2a	T2b–T2c	T3
IPSS	0–8	9–19	>20
Prostate volume (g)	<40	40–60	>60
Q_{max} ml/s	>15	15–10	<10
Residual volume cm^3			>200
TURP ±			+

1999

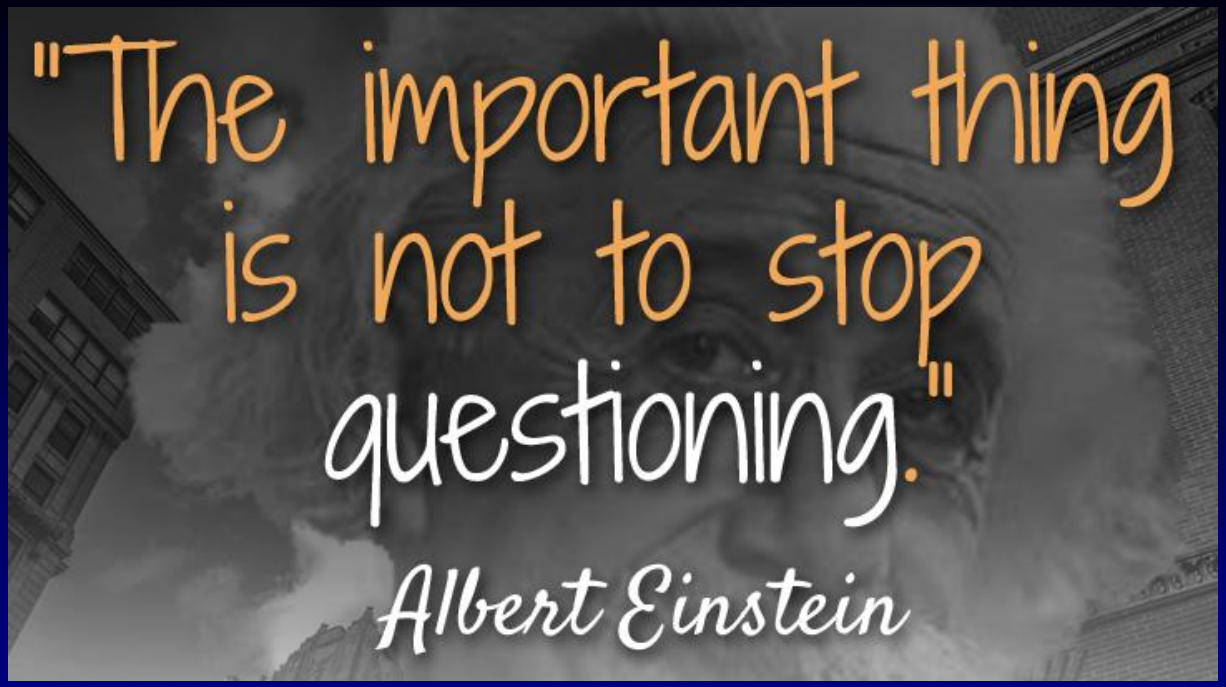
2000

2012

Suggested treatment schema for low-, intermediate-, and high-risk disease for PPB

Risk group per NCCN	Brachytherapy alone?	Combined with EBRT?	Combined with androgen deprivation?
Low	Yes	Not favored	Not favored
Intermediate	Optional	Optional	Optional
High	No	Yes	Favored

NCCN = National Comprehensive Cancer Network; EBRT = external beam radiation therapy; PPB = permanent prostate brachytherapy.



Patient selection for prostate LDR brachytherapy …. Do we have all the answers reading these recommendations ?

… no … after reading the literature some questions remain …

The main question :

- **The intermediate risk group :**
- **suitable for brachytherapy as monotherapy ?**

Oncology (Williston Park). 2016 Mar;30(3):229-36.

Favorable vs Unfavorable Intermediate-Risk Prostate Cancer: A Review of the New Classification System and Its Impact on Treatment Recommendations.

Serrano NA, Fastro MS.

Table 1. Proposed Intermediate-Risk Reclassification Schemes

Memorial Sloan Kettering Reclassification[26]		
Clinical Characteristics	**Favorable Intermediate-Risk[a]**	**Unfavorable Intermediate-Risk[b]**
	1 intermediate-risk factor[c]	> 1 intermediate-risk factor
	GS 3+4=7 or less	GS 4+3=7
	< 50% positive biopsy cores	≥ 50% positive biopsy cores

MD Anderson Reclassification[41]			
Clinical Characteristics	**Favorable[a]**	**Marginal[a]**	**Unfavorable[b]**
	GS 3+3=6	GS 3+4=7	GS 4+3=7
	≤ T2b	T2a/b	T2c

[a]*All* criteria must be met. [b]*Any* of these criteria can be met. [c]Based on the NCCN classification scheme.[5]
GS = Gleason score; NCCN = National Comprehensive Cancer Network.

*Institut Curie, Paris, France; †Cochin Hospital, Paris, France; and ‡Necker Hospital, Paris, France

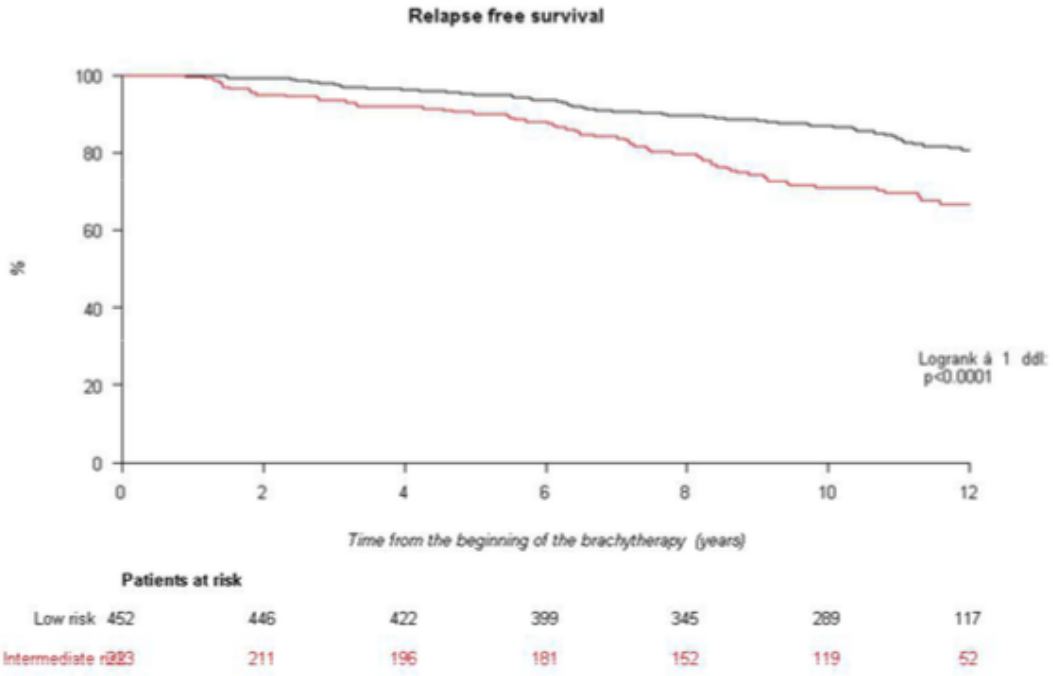
- IJRO 2008
- Purpose: The aim of this study was to analyze overall and relapse-free survivals in a cohort of 809 patients, 34% of whom corresponded to a higher risk group than ABS criteria.

- For this Institut Curie series ;
- Low-risk patients
- and
- « Favorable intermediate » patients ;
- PSA between 10, and 15 and all other low-risk criteria
- Or ;
- Gleason 7, and all other low-risk criteria

The 2016 Institut Curie experience

- **Update on 675 patients, all with a follow-up of more than 10 years**



No difference in long-term overall survival …

Conclusions

- Among men with intermediate risk (IR) prostate cancer, the addition of external beam therapy to brachytherapy did not result in superior freedom from progression compared to brachytherapy alone at 5 years in this initial report.
- Toxicity in both groups was limited, but there were fewer late effects, mostly GU, noted in the brachytherapy alone arm.
- Implications for clinical practice: Men with intermediate risk prostate cancer may be well managed with brachytherapy alone.
- Further subset analysis will be required to determine if the unfavorable IR patients do as well as those with favorable IR disease.

favourable

- **The intermediate risk group :**
- **suitable for brachytherapy as monotherapy ?**

age
is just a
number

- **What about age ?**

- In the early years, most groups were reluctant to propose brachytherapy alone to « young » (< 60 years ?) patients,
- Mostly because of the lack of long follow-up …

- Cancer J. 2006 Jul-Aug;12(4):305-8.
- **The effect of age on prostate implantation results.**
- Peschel RE, Khan A, Colberg J, Wilson LD.

- **CONCLUSIONS:**
- Patients who are 60 years of age or younger who are treated with ultrasound-guided transperineal prostate implantation can expect 5-year biochemical disease-free survival rates similar to those of older patients treated with ultrasound-guided transperineal prostate implantation therapy.

- Am J Clin Oncol. 2008 Dec;31(6):539-44.
- **Biochemical and functional outcomes following brachytherapy with or without supplemental therapies in men < or = 50 years of age with clinically organ-confined prostate cancer.**
- Merrick GS, Wallner KE, Galbreath RW, Butler WM, Brammer SG, Allen ZA, Lief JH, Adamovich E.

- **CONCLUSIONS:**
- Men < or =50 years of age have favorable biochemical and functional outcomes following brachytherapy. Depending on risk group assignment, brachytherapy with or without supplemental therapies should be considered a viable option for all healthy men regardless of age.

- Int J Radiat Oncol Biol Phys. 2010 Aug 1;77(5):1315-21.
- **Young men have equivalent biochemical outcomes compared with older men after treatment with brachytherapy for prostate cancer.**
- Burri RJ, Ho AY, Forsythe K, Cesaretti JA, Stone NN, Stock RG.
- Department of Radiation Oncology, Mount Sinai School of Medicine, New York, New York, USA.
- **CONCLUSION:**
- Young men achieve excellent 5- and 8-year biochemical control rates that are comparable to those of older men after prostate brachytherapy.

- **In CONCLUSION (Burri 2010):**
- **"Young age should not be a deterrent when considering brachytherapy as a primary treatment option for clinically localized prostate cancer".**

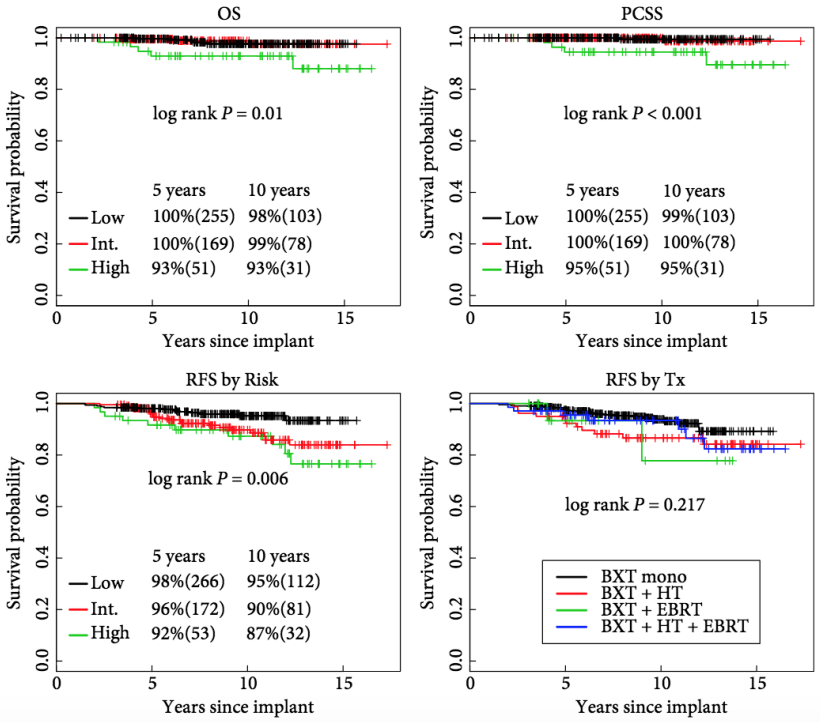
Long-term oncological outcomes and toxicity in 597 men aged ≤60 years at time of low-dose-rate brachytherapy for localised prostate cancer

Stephen E. M. Langley, Ricardo Soares, Jennifer Uribe, Santiago Uribe-Lewis, Julian Money-Kyrle, Carla Perna, Sara Khaksar and Robert Laing

St Luke's Cancer Centre, Guildford, Surrey, UK

Fig. 1 Survival analyses. Top panels: Kaplan–Meier curves for overall survival (OS) and prostate cancer-specific survival (PCSS) by disease risk. Bottom panels: Kaplan–Meier curves for RFS by disease risk and by treatment type (Tx). Percentage survival estimates (*n* at risk) at 5 and 10 years after implantation by disease risk categories are indicated. Int., intermediate; BXT, brachytherapy; Mono, brachytherapy monotherapy.



Conclusion

LDR brachytherapy is an effective treatment with long-term control of prostate cancer in men aged ≤60 years at time of treatment. It was associated with low rates of treatment-related toxicity and can be considered a first-line treatment for prostate cancer in this patient group.

- **What about median lobes and obstructive syndroms ?**

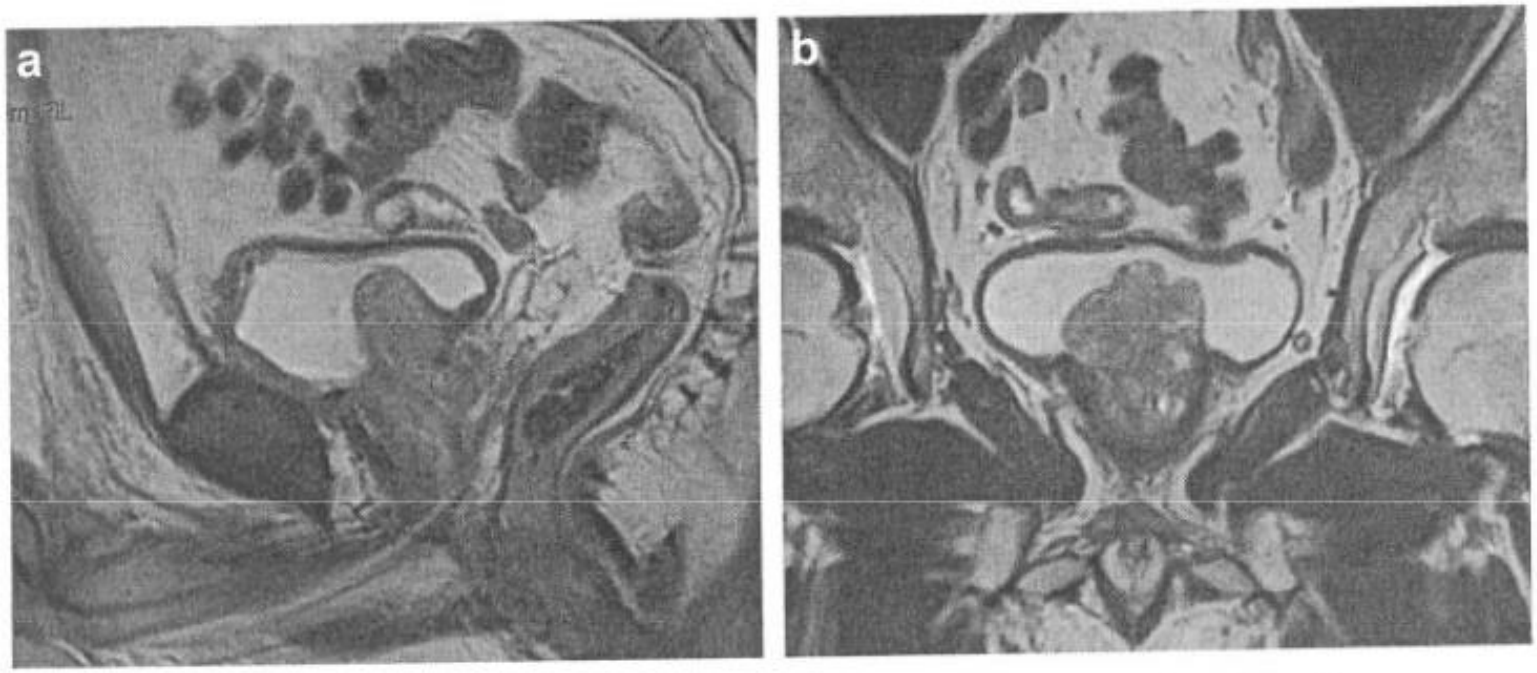


Fig. 1. (a and b) Example of a "very prominent" (+++) median lobe (Case $N = 19$).

High dose rate brachytherapy for prostate cancer: PATIENT SELECTION

HDR prostate brachytherapy

- Practical
  - Existing source, afterloading

- Physical
  - Greater implant volume
  - including seminal vesicles

- Biological
  - Low α/β tumour; greater biological dose with high dose per fraction

ESTRO School

Advantages of temporary HDR prostate brachytherapy

Radioprotection

- no free live sources
- no risk of source loss
- no radioprotection issues after discharge

Cheap: utilises existing HDR source and equipment

Day case procedure

Disadvantages of temporary HDR prostate brachytherapy

High dose rate radiation requires fractionation

- no longer!?

- logistics:
  - Quality assurance

Selection for HDR prostate brachytherapy

- Boost with external beam
- Monotherapy

Pre treatment investigations

- General medical assessment
- Prostate biopsy
- PSA
- IPSS
- IEFS
- Flow rate
- Pelvic MRI
- Staging investigations
  - PSA
  - Bone scan
  - (Whole body MRI)
  - (Choline PET)
  - (PSMA PET)

HDR monotherapy: what the guidelines say……

GEC ESTRO

Long term outcome data are not yet available from these cohorts and it is recommended that this treatment is not undertaken outside a formal study.

ABS

HDR monotherapy has been reported by several institutions (see Table 1), largely for low-risk, but also for intermediate-risk patients. The reported outcomes for disease control and toxicity are favorable. Monotherapy demands a higher degree of technical and planning expertise than boost HDR therapy. Institutions should take the requirements of HDR monotherapy into consideration before embarking on a monotherapy program. Monotherapy for high-risk patients should be considered investigational.

ESTRO School

HDR for salvage?
GEC ESTRO guidelines 2013

HDR in recurrence

There is limited experience of HDR brachytherapy for locally recurrent prostate cancer after previous irradiation and this is not recommended outside a formal prospective study. OAR constraints are critical in this setting. Published schedules (planning aim) include the following:

36 Gy in 6 fractions [44].
21 Gy in 3 fractions [45].
30 Gy in 2 fractions to peripheral zone after 30–40 Gy external beam [46].

- Rectum: D2 cc $\leqslant$ 75 Gy EQD_2
- Urethra:
  - D0.1 cc = $\leqslant$120 Gy EQD_2
  - D10 $\leqslant$ 120 Gy EQD_2
  - D30 $\leqslant$ 105 Gy EQD_2

ESTRO School

HDR for salvage?
ABS guidelines 2013

There is a promising data describing the use of HDR monotherapy as salvage for localized recurrence after prior external beam radiation or permanent seed brachytherapy. The ABS recommends that the use of HDR as salvage therapy be limited to Institutional Review Board-approved protocols or specialty centers with appropriate expertise.

- Seed afterloader
- Recalibration of dosemeters
- Multi-seed inserts

In close cooperation with seed vendors and European standard laboratories (as consultants)

Seed Calibration-Well chamber

- Calibration every two years. Med. Phys. 18, 1991.
- Consistency check.

  Cs-137, Co-60

Guidelines

"The activity of all sources should be measured, and *compared* with the calibration certificate supplied by the supplier, before being administered to a patient"…..Medical and Dental Guidance Notes, IPEM

Seed Calibration

•Sterile sources located in MICK magazine

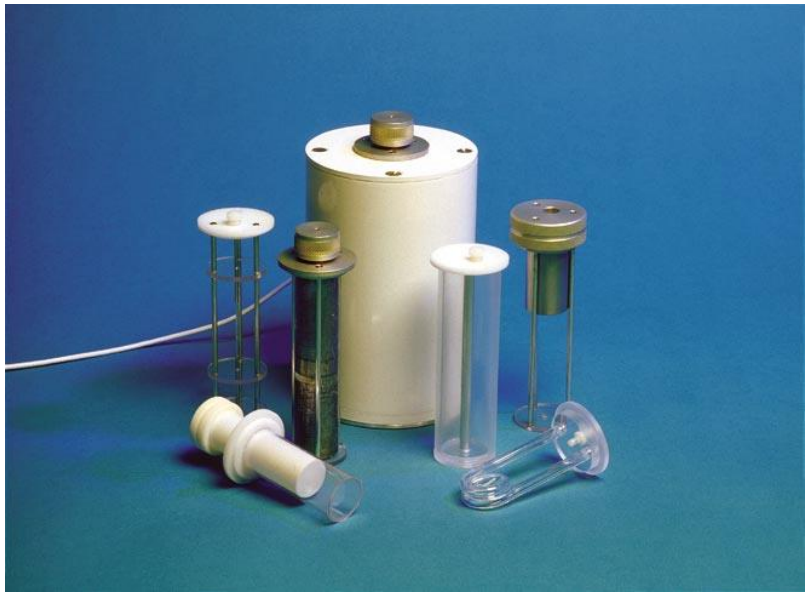
- a minimum of 10% of the total or two magazine cartridges of 15 seeds, whichever is greater.

• Sterile stranded sources.

- a minimum of 10% of the total or two strands of 10 seeds, whichever is greater.

• Loose seeds

- a minimum of 10% of the total or 20 seeds, whichever is greater.



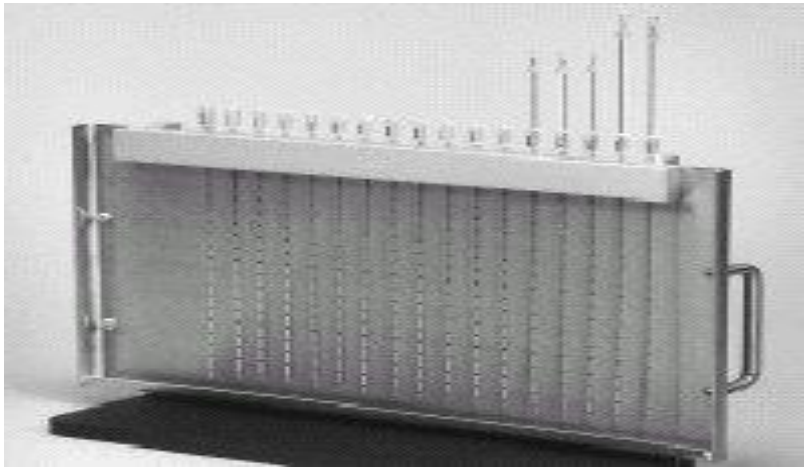
Action level if seeds are out of tolerance

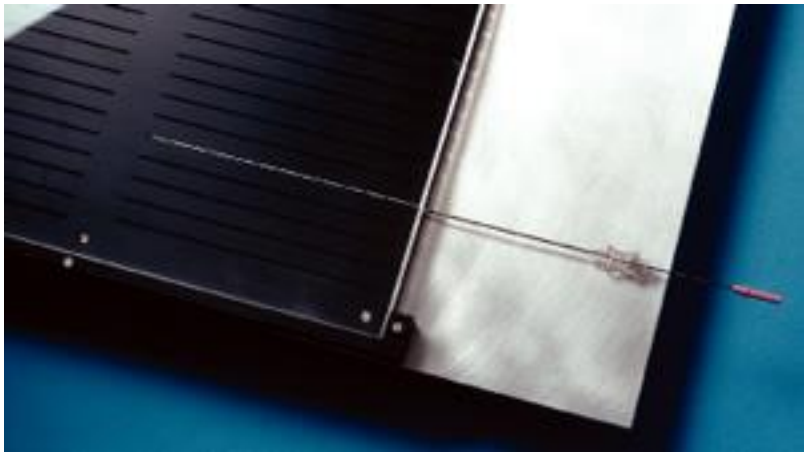
- If the mean source strength of the measured sources agrees within 3% of the manufacturer's stated source strength and the absolute difference of all the individual source/strand measurements are within the quoted calibration uncertainty on the manufacturer's certificate, the sources can be used clinically.
- If the mean difference is greater than 3%, the first step of investigation of the discrepancy should be to increase the sample size.
- After increasing the sample size, if the mean difference is still greater than 3%, further action must be taken to resolve the differences.
- If the mean difference is greater than a 5% action limit, the manufacturer should be consulted, if possible, to assist in resolving the differences. For measurements performed in the OR with the patient anaesthetised, discussions between the radiation oncologist and the MPE should take place regarding the consequences of proceeding with the implant using the measured source strength.

Clinical Oncology
The Royal College of Radiologists

Needles Check

- Verification of loaded brachytherapy needles.
- Place a film on top of the needles. The radiation from the loaded needles exposes an image in the film.
- The film will verify correct loading of seeds and spacers within each needle, or indicate any discrepancies or missing seeds.





Needles Check

Prostate Brachytherapy Course

“CTV”

C. Salembier

Prostate Brachytherapy Course

"CTV"

C. Salembier

Department of Radiotherapy-Oncology
Europe Hospitals – Brussels - Belgium

Planning : the delineation and definition of GTV, CTV and PTV

-Delineation of the prostate gland

-Delineation of the urethra prostatica

-Delineation of the anterior rectal wall

-Definition of Gross Tumour Volume - GTV

-Definition of Clinical Target Volume - CTV

-Definition of Planning Target Volume - PTV

Gross tumour volume

GTV

The gross palpable,visible or clinically demonstrable location and extent of the malignant growth.

Prostate brachytherapy:

Delineation of the GTV is possible in T2a or T2b (or higher stage)

Eventually important for location for boost dose

Clinical Target Volume

CTV

Is a tissue volume that contains the GTV and/or subclinical malignant disease at a certain probability level.

The CTV is a clinical-anatomical concept. Delineation of the CTV is based on the probability of presence of subclinical malignant cells outside the GTV and thus requires the interpretation of data and some judgment of the radiation oncologist.

Planning Target Volume

PTV

The PTV surrounds the CTV with a margin to compensate for the different types of variations and uncertainties of treatment delivery to the CTV.

The PTV is a geometrical concept, introduced for treatment planning.

A margin must be added to the CTV

- ***to compensate for expected physiological movements and variations in size, shape and position of the CTV during therapy (internal margin)***
- ***for uncertainties (inaccuracies and lack of reproducibility) in patient irradiation.***

Questionnaire (49 European brachytherapy centers – 2007):

Prostate brachytherapy

CTV =

Prostate contour: 100 %

PTV = CTV + margin

Prostate + 0 mm = 18/49

Prostate + margin = 31/49

base :	**0 mm = 13**
	3 – 5 mm = 25
	> 5mm = 5
midgland:	**0 mm= 13**
	3 – 5 mm = 28
	> 5 mm = 0
apex :	**0 mm = 13**
	3 – 5 mm = 27
	> 5 mm = 1

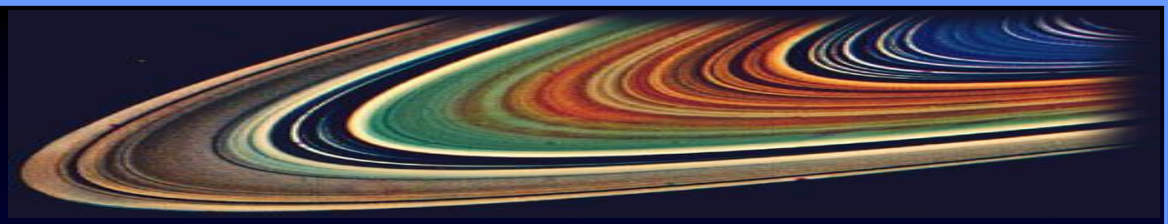
Margins ? ! ?



As shown, most centers consider a margin around the drawn prostatic contour for treatment planning.

But margins for ……

- ***microscopic spread ?***
- ***peri-prostatic extension ?***
- ***subclinical disease ?***

Δ CTV definition

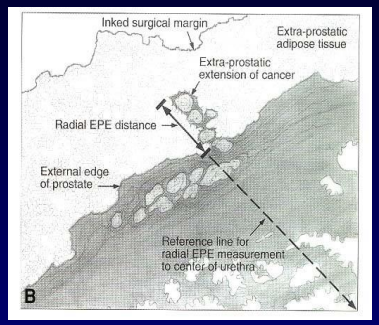
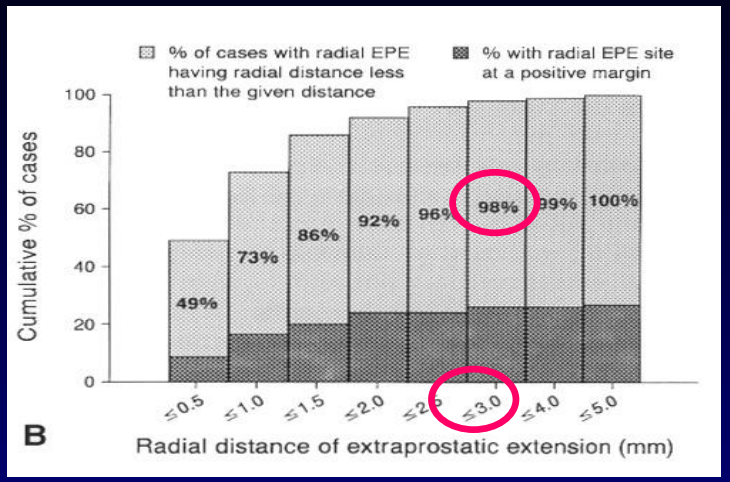
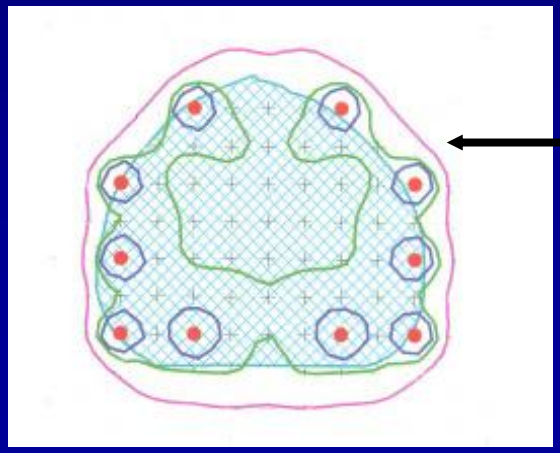
Extra-prostatic disease:



-105 prostatectomies
-Gleason 6.3 (range 3-9)
-PSA 8.6 (range 0.3-98)

Davis et al. Cancer 85(12) 1999



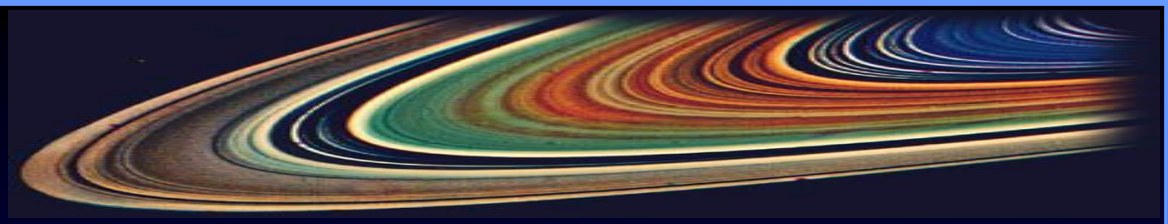


Extraprostatic disease

3 mm margins :

critical to success

Margins ? ! ?



So margins for ……

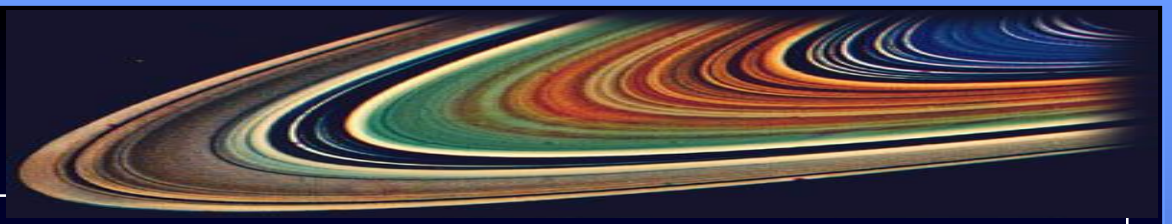
- ***microscopic spread ?***
- ***peri-prostatic extension ?***
- ***subclinical disease ?***

Δ CTV definition

ONE DEFINITION:

For prostate brachytherapy the **CTV corresponds to the visible contour of the prostate expanded with a three-dimensional volume expansion of 3 mm**.
This three-dimensional expansion can be constrained to the anterior rectal wall (posterior direction) and the bladder neck (cranial direction).
In case of >T2 disease, the macroscopic extracapsular extension in taken into account when contouring the prostate volume.

Margins ? ! ?



But margins for ……

- *uncertainties in seed placement ?*
  - *x/y direction – no problems*
  - *z direction – corrections during implantation*
- *change of volume ?*
  - *only temporary problem*
  - *edema resolves within the first ½ life of seeds*
- *change of position ?*
  - **eventual use of stabilization needles**
  - **continuous on-line verification of position**

So: *forget about margins for PTV definition ⟶ PTV = CTV*

Guidelines prostate brachytherapy

Tumour and target volumes in permanent prostate brachytherapy: A supplement to the ESTRO/EAU/EORTC recommendations on prostate brachytherapy

Carl Salembier[a], Pablo Lavagnini[b], Philippe Nickers[c], Paola Mangili[d], Alex Rijnders[a], Alfredo Polo[e], Jack Venselaar[f], Peter Hoskin[g,*], on behalf of the PROBATE group of GEC ESTRO

[a]*Department of Radiation Oncology, Europe Hospitals, Brussels, Belgium,* [b]*Department of Radiation Oncology, MultiMedica Institute, Milan, Italy,* [c]*Department of Radiation Oncology, Domaine Universitaire du Sart Tilman, Liège, Belgium,* [d]*Department of Medical Physics, IRCCS, S-Raffaele, Milan, Italy,* [e]*Department of Radiation Oncology, Catalan Institute of Oncology, Barcelona, Spain,* [f]*Department of Radiotherapy, Dr B. Verbeeten Institute, Tilburg, The Netherlands,* [g]*Mount Vernon Cancer Centre, Northwood, UK*

The aim of this paper is to supplement the GEC/ESTRO/EAU recommendations for permanent seed implantations in prostate cancer to develop consistency in target and volume definition for permanent seed prostate brachytherapy.

Recommendations on target and organ at risk (OAR) definitions and dosimetry parameters to be reported on post implant planning are given.

Tumour and target volumes in permanent prostate brachytherapy: A supplement to the ESTRO/EAU/EORTC recommendations on prostate brachytherapy

Carl Salembier[a], Pablo Lavagnini[b], Philippe Nickers[c], Paola Mangili[d], Alex Rijnders[a], Alfredo Polo[e], Jack Venselaar[f], Peter Hoskin[g,*], on behalf of the PROBATE group of GEC ESTRO

In addition:

Description of :

- Organs at risk contouring
- Recommended prescription doses
- Dosimetric parameters related to ICRU definitions for dose prescription
- Physical parameters for dose reporting
- Post-planning – definitions and parameters
-Target definition in relation to the post-plan dosimetry
- Dose parameters in the post-implant setting

The aim of this paper is to supplement the GEC/ESTRO/EAU recommendations for permanent seed implantations in prostate cancer to develop consistency in target and volume definition for permanent seed prostate brachytherapy.

Recommendations on target and organ at risk (OAR) definitions and dosimetry parameters to be reported on post implant planning are given.

AAPM recommendations on dose prescription and reporting methods for permanent interstitial brachytherapy for prostate cancer: Report of Task Group 137

sist in understanding differences in outcomes and morbidity as well as differences in postoperative dosimetry. Users are encouraged to use the following definitions and procedures for planning and postimplant evaluations, which were proposed by the PROBATE group of GEC ESTRO.[19] A brief summary of these PROBATE recommendations is presented below, and the reader is referred to the original document by Salembier *et al.* for details.[19] We acknowledge that parts of the following recommendations in this section were based on this protocol.

The aim of this paper is to supplement the GEC/ESTRO/EAU recommendations for permanent seed implantations in prostate cancer to develop consistency in target and volume definition for permanent seed prostate brachytherapy.

Recommendations on target and organ at risk (OAR) definitions and dosimetry parameters to be reported on post implant planning are given.

NEW ENERGY FOR WEAK, SAGGING MEN

Front View—Showing full, comfortable bag that entirely encloses and supports the scrotum. Note wide, adjustable, comfortable tapes that hold suspensory in position with no chance for discomfort.

Rear View—Shows radium pad, containing 20 micrograms of refined, measured radium. Size of pad, 2 in. wide, 3 in. deep. Size of suspensory, 8 in. deep, 5 in. wide. Very comfortable. Can't bind.

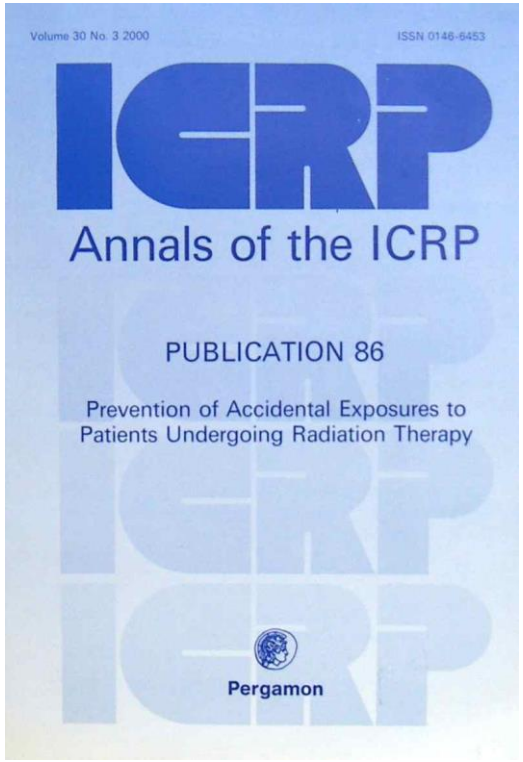
Testone Radium Energizer and Suspensory

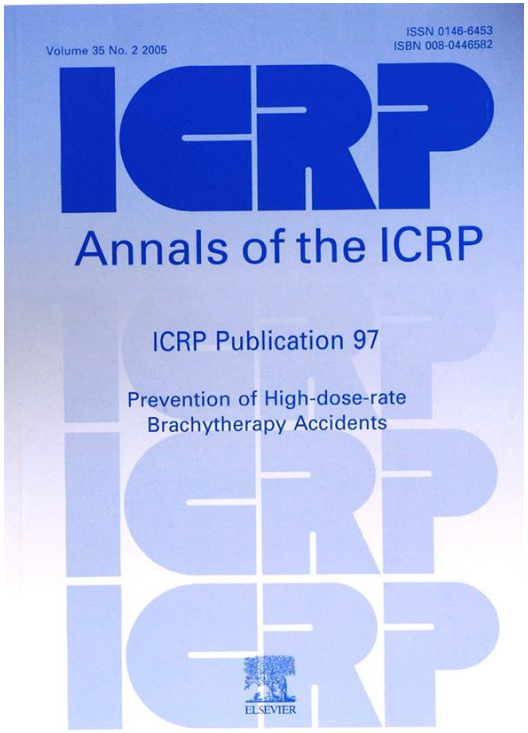
Contains 20 Micrograms Refined, Measured Radium

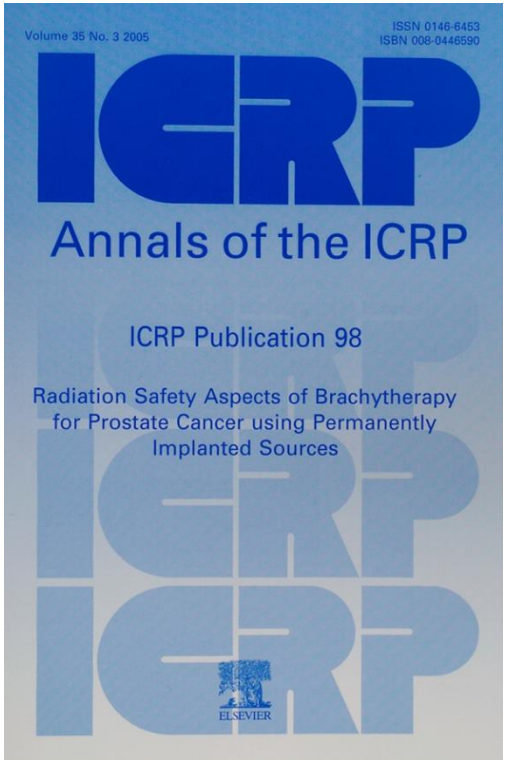
For that sagging, dragging weight that pulls you down and saps your energy—and for storing up and husbanding strength in that seat of all male activity—the testicles—this marvelous appliance has no equal!

We GUARANTEE that the Testone Radium Appliance contains only purified, highly refined radium salts, free from all injurious metallic substances. Actually contains 20 micrograms of this precious sub-

ICRP Publications







ESTRO School

ICRP 86 , released in 2000, was dealing with all types of accidents in radiotherapy, *with specific chapters for LDR and HDR brachytherapy*

- After an analysis of the accidents reported at that moment (2000),
- ICRP tried to identify the causes and the factors contributing to accidental exposures in brachytherapy

ICRP 86 : Generic lessons learned :

- In most of the accidents, a combination of contributing factors allowed an initial mistake to escalate into an accidental exposure …
- Often , the lack of concern of management was the underlying root cause…

Among the main contributing factors ;

- Lack of appropriate staff ressources
- Insufficiently qualified or untrained staff
- Lack of effective, systematic quality assurance programme/procedures
- Lack of effective communication procedures….

Not to be forgotten:

- Hospital management, source suppliers, and importers, can cause catastrophic accidents involving the public and severely affecting the environment (Examples ; the Mexico,Brazilian -Goïana- and Istanbul accidents ...)
- *(Although those accidents were linked to the loss of external radiotherapy sources).*

In 2005 ; the more specific ICRP 97 publication on « Prevention of High-dose-rate Brachytherapy accidents »

- Again, the reported accidents were analyzed …

The ICRP 97 Main points

- High-dose-rate (HDR) brachytherapy is a rapidly growing technique that has been replacing low-dose-rate (LDR) procedures over the last few years in both industrialised and developing countries. It is estimated that about 500,000 procedures (administrations of treatment) are performed by HDR units annually.

- LDR equipment has been discontinued by many manufacturers over the last few years, leaving HDR brachytherapy as the major alternative.

- HDR techniques deliver a very high dose, of the order of 1.6-5.0 Gy/min, so mistakes can lead to under- or overdosage with the potential for clinical adverse effects.

ESTRO School

The ICRP 97 main points

- More than 500 HDR accidents (including one death) have been reported along the entire chain of procedures from source packing to delivery of dose. Human error has been the prime cause of radiation events.
- Many accidents could have been prevented if staff had had functional monitoring equipment and paid attention to the results.
- Since iridium has a relatively short half-life, the HDR sources need to be replaced approximately every 4 months. Over 10,000 HDR sources are transported annually, with the resultant potential for accidents.

The ICRP 97 main points

- A team of trained personnel following quality assurance (QA) procedures is necessary to prevent accidents. QA should include peer review of cases.

- Accidents and incidents should be reported and the lessons learned should be shared with other users to prevent similar mistakes.

The most severe case …

- Occurred in 1992 ;
- The source (HDR Iridium) became detached from the drive mechanism during an anorectal cancer treatment
- Conflicting signals; the area monitor actually detected the radiation, while the equipment indicated « source shielded »
- Unfortunately, previous radiation monitor malfunctions encouraged misinterpretation and induced the staff not to trust it …

- Therefore the wrong indication of the equipment was accepted …
- And the patient, clothes and room were not checked with another radiation monitor
- The patient kept the HDR source 4 days , for a total dose of about 16,000 Gy ! (18 Gy prescribed …..)
- … and was disposed in a waste container, without identification of the source …

- The waste container was picked up by a commercial medical waste disposal company 5 days later ,
- It was then taken to an incinerator where (at last…) the source radiation was detected.
- The patient died on day 4
- During the days the source remained in the patient or in the waste container, it irradiated at various levels 94 persons …

ICRP 98 :
Radiation safety aspects of brachytherapy for prostate cancer using permanently implanted sources

published in 2005

- **At the time of publication**
- **No « real » accident reported with this technique :**
- ***« No adverse effects to medical staff and/or the patient family have been reported to date »***

However ; since that time: the reports on the Philadelphia Veteran hospital « accident »

- A succession of « malpractices » leading to ***97 medical errors out of 116 prostate cancer implantations***
- ***During 6 years,*** from 2002 to 2008 !! ....

- February 2002 : the Philadelphia Veterans Affairs Medical Center (PVAMC) initiated its prostate brachytherapy program

- February 2003 ; during a seed prostate implant**, 40 out of 74 seeds were « implanted » in the patient's bladder**; they were subsequently expelled and recovered …

- October 2005 ; 45 out of 90 seeds were again mistakenly implanted into the patient's bladder and recovered…

- May 2008 ; the National Health Physics Program (NHPP) notified the U.S. NRC (Nuclear Regulatory Commission) of a possible medical event involving a patient that received a dose less than 80 % of the prescribed dose….

- This triggered (at last …) an on site inspection
- With the first results available, the PVAMC prostate brachytherapy program was suspended in June 2008
- In October 2008, prostate cancer brachytherapy was suspended in three other VA hospitals ; Cincinatti, Jackson, and Washington …

- The first survey identified 92 medical events:
- 57 were due to a dose less than 80% of the prescribed dose (underdose),
- 35 were due to a dose to an organ or tissue out of the treatment site that exceeded the accepted limit. (Overdoses of rectum, bladder wall or prostate surrounding tissues)

- Identified causes :
- Incorrect placement of seeds
- Inadequate procedures
- Poor management oversight of contractors
- Inadequate training of licensee staff
- Poor management oversight of brachytherapy program
- No peer review
- Observed poor placement of seeds and no correction actions taken (!)
- Lack of safety culture

Rare accidents with implanted seeds

- Iodin contamination from seeds accidentally ruptured ; 4 cases reported ;
- Broga DW, Gilbert MA ; Health Physics 1983, 45(3):593-7
- Caldwell C et al. Health Physics 2007, 92 (2suppl.) :S8-S12
- Patients demonstrated significant thyroid uptake and were administered potassium iodide as a blocking agent

- Contamination from Iodin seeds ;
- May be due to the accidental rupture of a seed during the implantation (very rare)
- May be also due to a *poor design of the seeds,* with iodin leakage …

Contents

ESTRO School

Findings;

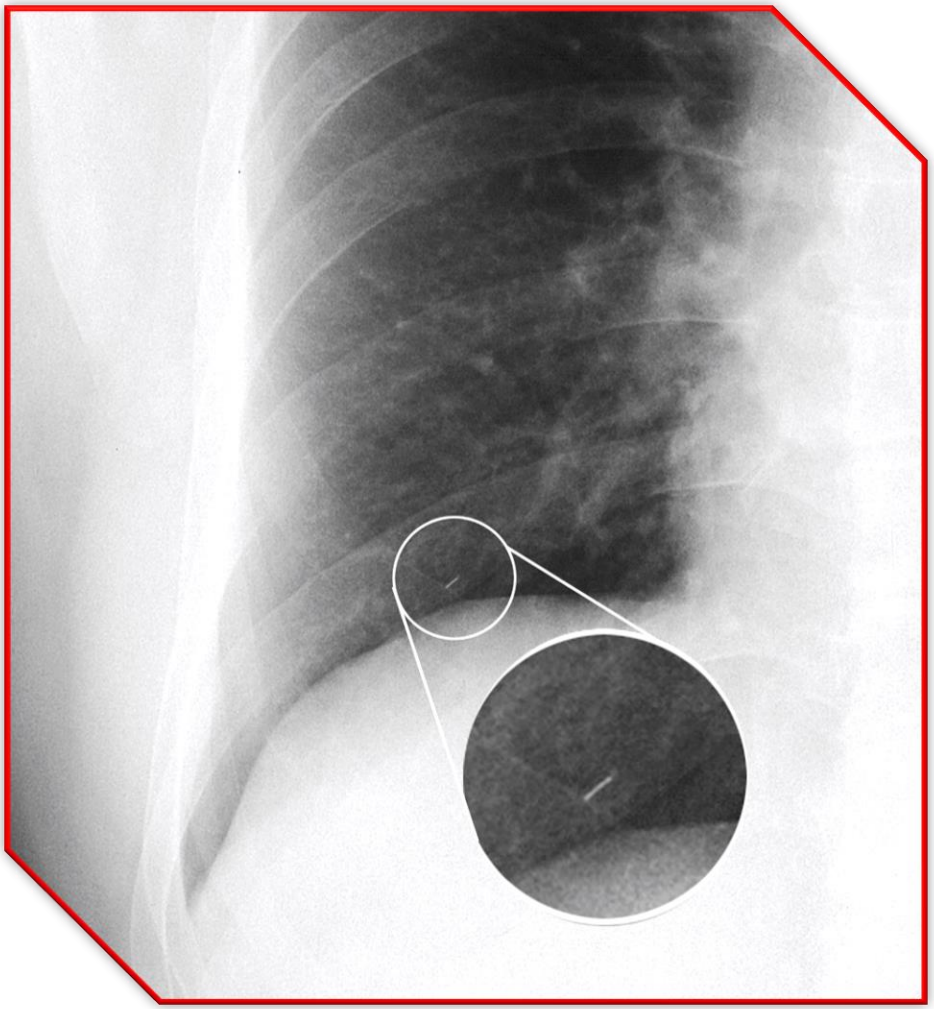
- ***Very low*** doses to family and household members
- Usually well below the 1 mSv limit for the public
- Not even reaching the « constraint level » of 5 mSv set for comforters and carers of such patients by the IAEA (1996)…

- **Recommendations**
- Doses to family or others will be below 1mSv therefore no routine precautions necessary
- Children not to sit on lap of patient for 2 months
- Avoid prolonged close contact with pregnant women

- NB: If partner is pregnant consider individual risk assessment with dose rate measurement.

ESTRO School

Seeds may migrate to the lungs (no radioprotection problem …)



- **Recommendations**

- (1) sieve the urine while in hospital and for 3 days after implant
- (2) wear condom for first five ejaculations
- (3) if seed "found" do not touch. Put in protective container with spoon or tweezers and return to department.
- (4) if seed in lavatory bowl - flush away

Cremation

- Uncommon in a number of countries
- Frequent in some others (China, India ...)
- The rule in Japan !

ESTRO School

Current national recommandations

- Delay before allowing cremation : Large variations from country to country …
- Briefly;
- From 1 year or less (Japan, US NCRP -with precautions -)
- To 2 years (Canada)
- And even 3 years (UK , France)

After considering and calculating the activity remaining in the patient's ashes and the potential airborne release,

- The ICRP considered that :
- *« Cremation can be allowed… if 12 months have elapsed since an implantation performed with ^{125}I (3 months for ^{103}Pd)… »*
- *However, it must be kept in mind that some national authorities (UK , France) selecting worse-case scenarios and using different types of calculations are recommending much longer times … (up to 3 years for ^{125}I) »*

5. SUBSEQUENT PELVIC OR ABDOMINAL SURGERY 31

- In rare cases, limited and careful transurethral resection may be necessary after brachytherapy ;
- Must be done by an ***experienced surgeon***, aware of the brachytherapy technique,
- And no sooner than 6 months after an ^{125} I implantation.
- Moreover , in case of subsequent abdominal or pelvic surgery ; warn the surgeon ! (« wallet card » ; see below)

ESTRO School

- Due to the drastic reduction in the volume of the ejaculate, patients may think they are definitively infertile ….
- Actually, the dose from the implant may not reach the threshold for castration, and a few cases of fatherhood have been reported after permanent implants !

7. TRIGGERING OF RADIATION DETECTION MONITORS..... 35

- Some radiation detection monitors are set at a very low alarm level (1.5-2 times the natural background level in given places ...)
- Entry/exit of nuclear plants and nuclear research centers, waste areas, scrap metal factories/yards, and, more and more;
- Airports and crossing borders (« nuclear terrorism »)
- Should be explained to the patient !
- Wallet card +++

ESTRO School

- **Almost no case of second cancers reported after prostate brachytherapy**

Legislation- UK

The Police, Health & Safety Executive and the Environment Agency can all prosecute us

C. Salembier

Department of Radiotherapy-Oncology
Europe Hospitals – Brussels - Belgium

Localized prostate cancer: heterogeneous group of tumours

Prognostic 'risk' groups: Low – Intermediate - High

Depending on:

- Extension of the tumour
- Initial PSA
- Gleason Score

Low Risk

Stage: T1 or T2a,b
Gleason Sum ≤ 6
PSA ≤ 10 ng/ml

Intermediate Risk

Stage T1 or T1-2 Stage T1-2
Gleason Score 7 or Gleason 6
PSA < 10 PSA 10-20

High Risk

Stage T2c or T3
Gleason score ≥ 8
PSA > 20 ng/mL

Treatment options - localized prostate cancer

External beam radiotherapy

Hormonal treatment

Interstitial: low or high dose rate

(robotic) surgery

WHAT DO YOU WANT?

QUALITY OF LIFE

1. BRACHYTHERAPY

WE ARE THE BEST DEAL WITH IT

RATIONALE for BRACHYTHERAPY

- Brachytherapy is the most conformal treatment modality
- Brachytherapy increases LC by delivering a higher radiation dose
  - Metabolic activity studies by MRI and MRI-spectroscopic imaging shows higher complete prostate metabolic atrophy and lower nadir PSA at 48 mths after PB vs EBRT
  - This higher intraprostatic tumor control is indicative of a positive therapeutic effect of the higher biological dose given with PB vs EBRT
- This observation is supported by clinical results from 3 RCTs of dose escalation using EBRT + PB vs EBRT

Morris et al, J Clin Oncol 2015;33-3
Hoskin et al, Radioth Oncol 2012; 103:217-222
Sathya et al, J Clin Oncol 2005; 23:1192-1199

- BT is considered as the ultimate dose escalation modality

- RCTs in PCA comparing EBRT with EBRT+PB in HR and high-tier IR PCA indicate further improvement of PSA recurrence free survival (20-30% at 7-10 years) with no documented CSS or OS benefit.

- However, recent publications using large databases indicate an increase in CSS and OS in PCA patients treated with any form of BT

- BT results in
  - Superior disease outcomes (mainly bPFS)
  - Higher complete prostate metabolic atrophy
  - Lower nadir PSA

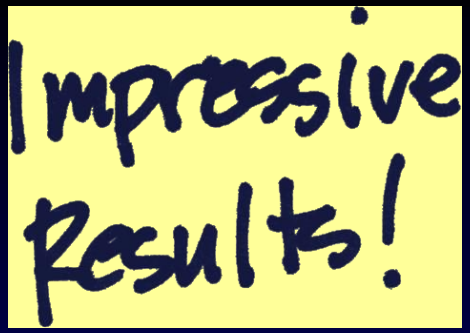
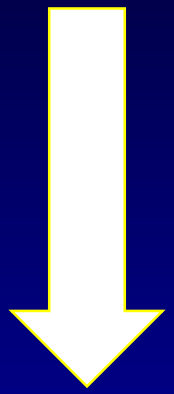
Overall, patients treated with PB have exceptionally good long-term disease outcomes and compare favorably with other treatment modalities.



- For LR and fIR: bPFS, CSS and OS are 77-95%, 93-99% and 81-99%
- For IR, bPFS, CSS and OS are 88-95%, 98-77% and 77%
- For IR and HR , bPFS, CSS and OS are 68-95%, 95-98% and 57-79%
- for HR, bPFS, CSS and OS are 80-92%, 86-98% and 68-97%

Results given in terms of biochemical control ….

However, this biochemical control depends on “local” control but also on “distant” control



What about the “local cure rates” after PB?

Patterns of Recurrence After Low-Dose-Rate Prostate Brachytherapy: A Population-Based Study of 2223 Consecutive Low- and Intermediate-Risk Patients

Andrea C. Lo, MD, W. James Morris, MD, FRCPC,
Tom Pickles, MD, FRCPC, Mira Keyes, MD, FRCPC,
Michael McKenzie, MD, FRCPC, and Scott Tyldesley, MD, FRCPC

"we estimate that the local recurrence rate of LDR-PB in our study cohort likely lies in the range of 1.8% to 2.7%."

10-YEAR EXPERIENCE WITH I-125 PROSTATE BRACHYTHERAPY AT THE PRINCESS MARGARET HOSPITAL: RESULTS FOR 1,100 PATIENTS

JUANITA CROOK, M.D.,* JETTE BORG, PH.D.,† ANDREW EVANS, M.D.,‡ ANTS TOI, M.D.,¶
E. P. SAIBISHKUMAR, M.D.,* SHARON FUNG, M.SC.,§ AND CLEMENT MA, M.SC.§

Thus, *the local relapse rate should range from 1.0% to 2.2%*, but it is likely to be closer to the biopsy-proven 1.0% of patients, because all other men with biochemical failure in this cohort had negative biopsy results

Distant and local recurrence in patients with biochemical failure after prostate brachytherapy

Richard G. Stock, Jamie A. Cesaretti, Pamela Unger, Nelson N. Stone

"Hence, at a median follow-up of 6.8 years, the local recurrence rate of the Mt. Sinai cohort treated with LDR-PB should fall between 1.3% and 4.5%"

Brachytherapy, 7 (2008), pp. 217–222

Patterns of failure after iodine-125 seed implantation for prostate cancer ☆

David S. Lamb [a,b,*], Lynne Greig [c], Grant L. Russell [d], John N. Nacey [a,d], Kim Broome [e], Rod Studd [d], Brett Delahunt [a], Douglas Iupati [b], Mohua Jain [f], Colin Rooney [c], Judy Murray [a], Peter J. Lamb [a], Peter B. Bethwaite [a]

"by combining the 0.2% who had local failure with the 2.2% whose site of failure was unknown, the local relapse rate should range from 0.2% to 2.4%"

Radiotherapy and Oncology 112 (2014) 68–71

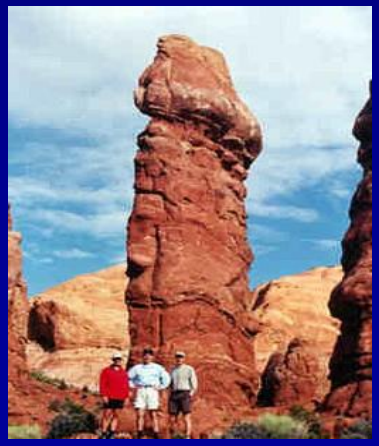
Cure

Prostate brachytherapy

Is highly effective

Local control is extremely high

Quality of Life – Side Effects



Quality of Life – Side Effects

Prostate brachytherapy

Toxicity is low and acceptable

No decrease in long term QoL

2. ADT

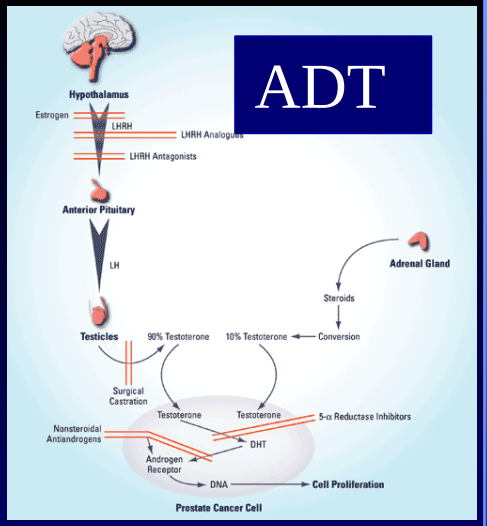
Prostate Cancer Cell

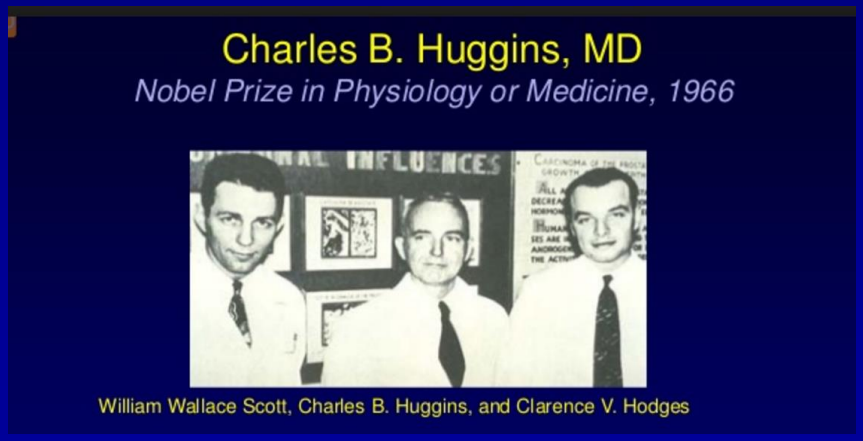
1940: Canadian born Charles Huggins recognized the androgen dependence of PCA

1966: nobel price for medecine: discoveries concerning hormonal treatment of PCA

1997: Zietman: the combination of radiation with orchiectomy for Shionogi tumors treated in vitro resulted in significant increase in control

Now, several large national and international RCT's confirmed and quantified the therapeutic benefit of ADT in combination with EBRT





Wolff FR et al: Eur J Cancer, 2015;51:2345-2367

The Seven Dwarves of ~~Menopause~~ ADT

Itchy, Bitchy, Sweaty, Sleepy, Bloated, Forgetful & Psycho

….. and they still have many other friends …

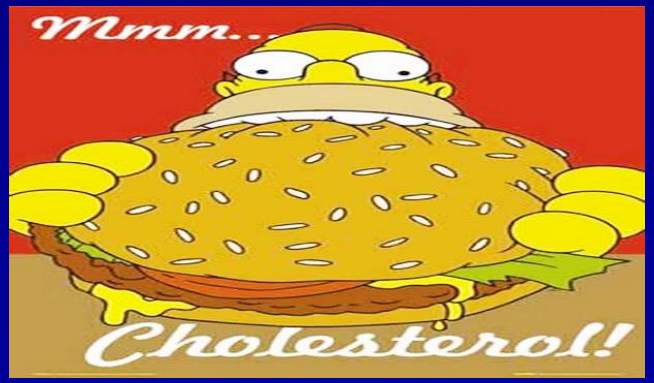
Well-documented side effets of ADT are:

- Sexual dysfunction
- Loss of libido
- Hot flashes
- Fatigue
- Decreased muscle mass
- Cognitive dysfunction
- Depression – where as up to 27% of patients on ADT may suffer psychiatric illness during their treatment

Well-documented side effets are:

- Increased risk of osteoporosis (23% increase in incidence of fractures)
- Increased incidence of metabolic syndrome (50% in ADT patients vs 20% in normal population - even with 1 year ADT)
- Central and peripheral obesity (9 – 11% increase in fat mass after 1 yr of ADT)
- Increase of total cholesterol (by 9%), Triglycerides (by 27%) and decreased HDL-cholesterol (by 11%) after only 3 mths of ADT
- Elevated blood pressure
- Elevate fasting glucose and fasting insulin
- Decrease insulin sensitivity and increase of diabetes

➔ All increasing the risk of a cardiovascular event and/or sudden cardiac death 12-60 mths after starting ADT



Even short time ADT can:

- negatively impact QOL
- increase morbidity
- increase mortality

Evidence shown in observational studies

This is however NOT confirmed in RCTs

(? inclusion of older, more frail patients – reports on non-fatal events?)

Voog et al Eur Urolo 2016;69:204-210
Sanda et al N Eng J Med 2008; 358:1250-1261
Beyer D et al Int J Radiat Oncol Biol Phys 2005; 61:1299-1305

PRIMARY CAUSES OF DEATH AFTER PERMANENT PROSTATE BRACHYTHERAPY

NATHAN BITTNER, M.D., M.S.,[†] GREGORY S. MERRICK, M.D.,[*] ROBERT W. GALBREATH, PH.D.,[*]
WAYNE M. BUTLER, PH.D.,[*] KENT E. WALLNER, M.D.,[†‡] ZACHARIAH A. ALLEN, M.S.,[*]
SARAH G. BRAMMER, B.S.,[*] AND MARK MOYAD, M.D., M.P.H.[§]

1354 patients – 5,4 years median FU – 51% ADT use

Primary causes of death in patients treated with PB (+EBRT) (+ADT)

- cardiovascular disease 42 %
- 30% other cancer 30 %
- Prostate cancer: 8,7 %

Patients with HR-disease had double the risk of dying from CVD compared with IR and LR

- HR: 19,8% vs IR 9,3% vs LR 8,7%

Excess morbidity and mortality is seen predominantly in patients with pre-existing cardiovascular co-morbidity

Bittner et al, Int J Radiat Oncol Biol Phys 2008;72:433-440

Nanda et al, JAMA 2009;302:866-873
Nguyen et al, Int J Radiat Oncol Biol Phys 2012;82:1411-1416

Even short term ADT gives an absolute increase 5,3% at 10 years ! (Kobutek et al)

Re-analysis of 6 RCTs (Albertsen et al)

- the increase in cardio-vascular mortality and morbidity might be an LHRH agonist class effect
- significantly less CVD events in men treated with LHRH antagonists vs LHRH agonists (HR: 0,44 - 95% CI 0,26-0,74 - p=0,002)

Pronounce NCT02663908: RCT comparing major CV events with LHRH agonists vs antagonists in patients with pre-existing CV morbidity

Kobutek et al, Int J Radiat Oncol Biol Phys 2014;90:S15
Albertsen et al, Eur Urol 2014;65:565-573

3. EBRT + ADT

RATIONALE for combining EBRT and ADT:

-(neo-adjuvant ADT) improves the geometry of the prostate target by decreasing the volume juxtaposed to adjacent OAR

-If given before EBRT (in experimental setting), the anti-angiogenesis effect of ADT may

- 'normalize' the vasculature and lead to better perfusion
- increase the oxygenation
- increase the radiation tumor sensistivity
- increase the LC. Reducing local failure may reduce second-wave metastatic spread and thus improve OS

-The synergistic relationship in concurrent administration might produce a biologic advantage

-Several RCTs show an improvement in bPFS and LC but also in DSS and 0S … so … ADT might have an influence on local and systemic disease

-Clinical evidence supports the hypothesis that ADT can eliminate subclinical micro-metastases.

- Addition of ADT to EBRT, RCTs have shown benefit in improving OS, CSS and bPFS in HR
  - RTOG 85-31 - RTOG 92-02 - TROG 96-01
  - RTOG 86-10 - RTOG 94-08 - EORTC 22961
  - EORTC 22863 - Harvard/DFCI - TROG 96-01
- Addition of ADT to EBRT, RCTs have shown benefit in improving OS, CSS and bPFS in IR
  - RTOG 94-08
  - Harvard/DFCI 95-096

- A Spanish RCT showed even in a dose escalation to 78 Gy, 24 vs 4 months of ADT improves bPFS, metastatic-free survival and OS in patients with IR and HR disease.

- It is clear that ADT has an additive effect on improving disease outcomes with EBRT even at high doses of 78 or 81 Gy

  Optimal duration with EBRT for each risk category has not been established

Zapatero et al, Lancet Oncol; 2015;16:320-327
Zelefsky et al, Eur Urol: 2011; 60; 60:1133-1139

REFLECTIONS:

- The benefit of ADT in combination with EBRT (even with dose-escalated EBRT) may be because of compensation for suboptimal radiation dose and less effective therapy.

- Because of the very high intraprostatic dose and excellent disease control, ADT is likely to have less biologic effect with PB, except perhaps in cases with very high-volume diesease or through spatial cooperation for suppression of micrometastic disease

- Addition of ADT to PB in IR and HR patients has been shown to decrease 2-yr post PB positive biopsy rate from 14% to 3,5%

Lo et al, Int J Radiat Biol Phys, 2015;91:745-751
Stone et al, Int J Radiat Biol Phys, 2010; 76:355-360
Stone et al: Mol Urol 2000; 4(3): 163-168

REFLECTIONS:

If we disregard normal tissue tolerance, one can speculate that any truly localized PCA can be cured with radiation alone, given suffisiently high dose and ensuring complete coverage of the tumortarget.

4. Do we need ADT in addition to PB ?

Cytoreduction

- The aim is to downsize the prostate
- Most common used is a LHRH agonist
- Alternative: dutasteride and bicalutamide
  - RCT shows a non-inferiority of this regimen in comparaison with LHRH
  - So because of the potential impairment of QoL associated with ADT, one may consider the less toxic combination fo 5-&-reductase inhibitor + oral anti-testosterone for cytoreduction.
- No improved oncologic outcome

Gaudet et al; Brachytherapy 2015;14:S33-34

American Brachytherapy Society Task Group Report: Use of androgen deprivation therapy with prostate brachytherapy—A systematic literature review

M. Keyes[1,*], G. Merrick[2], S.J. Frank[3], P. Grimm[4], M.J. Zelefsky[5]

In this review: studies grouped based on risk stratification

Low Risk and favourable Intermediate Risk

5 studies

- 4 studies describing outcome in patients treated with LDR +/- ADT
- 1 study describing outcome in patients treated with LDR +/- EBRT +/- ADT

ADT used in 27-65% of patients
ADT duration 3-6 mths

Most often: downside prostate volume before BT and in one study for IR features

- None of the studies showed any benefit from ADT to bPFS.
- Effect on CSS not reported
- Not associated with improved or detrimental OS

Ciezki *et al.* (70)	Multi-institutional, USA	1996—2001	1668
Potters *et al.* (71)	New York Institutions, USA	1992—2000	1449
Ohashi *et al.* (72)	Multi-institutional Japan	2003—2009	663
Morris *et al.* (73)	British Columbia, Canada	1998—2003	1006
Martin *et al.* (74)	Quebec City Canada	1994—2001	396

Intermediate Risk

6 studies describing outcome in patients treated with LDR +/- ADT or LDR +/- EBRT +/- ADT (5854 patients)

ADT used in 17-81% of patients
ADT duration 4 months

Results:

- bPFS:
  - 4 studies: no overall benefit with ADT
  - 2 studies: no report on bPFS
- CSS:
  - 1 study shows an absolute 2% benefit on CSS with ADT
  - 1 study shows a benefit in unfavourable IR patients
  - 1 study shows a benefit if BED < 150 Gy
- OS:
  - 4 studies did not report on the association between ADT and OS
  - 1 study showed no benefit

Rosenberg *et al.* (75)	Chicago	1997–2007	807
Tran *et al.* (76)	Multi-institutional, UK	2003–2007	615
Ho *et al.* (77)	Mount Sinai, NY	1990–2004	558

Bittner *et al.* (79)	Multi-institutional, USA	1995–2001	932
Stock *et al.* (80)	Mount Sinai, NY	1994–2006	432

Intermediate and High Risk

8 studies describing outcome in patients treated with mono(brachy-)therapy or combination therapy

- 6 LDR – 1 HDR and 1 HDR or LDR
- ADT used in 32-66% of patients
- ADT median duration 6 months (4-28 months)

LDR			
Lee (81)	Mount Sinai, NY	1990–1998	201
Strom (82)	Tampa, FL	2001–2011	120

Merrick *et al.* (86)	Multi-institutional, USA RCT—0 vs. 20 vs. 44 Gy EBRT + PB	1999–2013	630
HDR/LDR			
Kraus *et al.* (87)	William Beaumont	1991–2004	1044 Patients
HDR			
Schiffmann *et al.* (88)	Hamburg Germany	1999–2009	392

Results:

•bPFS:

- 6 (out of the 8) studies: no benefit with ADT except in patients with low D90
- 1 (HDR) study showed 12% (in IR disease) and 20% (in HR disease) benefit to adding ADT

•CSS:

- None of the studies showed overall benefit

•OS:

- None of the studies showed overall benefit

High Risk

11 studies describing outcome in patients treated with combination therapy

- 10 LDR + EBRT and 1 HDR + EBRT
- 1 included also patients treated by LDR PB alone
- ADT used in 40-91% of patients
- ADT median duration 3-12 months

LDR			
Ohashi *et al.* (89)	Japan	2003–2009	206

Liss (95)	Multi-institutional, USA	1998–2008	141
Fang *et al.* (96)	Multi-institutional, USA	1995–2005	174
HDR			
Prada *et al.* (97)	Oviedo, Spain	1998–2006	252

Results:

- bPFS: 9 studies showed an association between ADT and bPFS
  - 6 showed a benefit with ADT (2 studies showed a 13% benefit with longer ADT duration)
  - 3 showed no benefit with ADT
- CSS: 9 studies showed an association between ADT and CSS
  - 3 showed a benefit with ADT
  - 6 showed no benefit with ADT
- OS: 5 studies reported on an association between ADT and OS
  - None of the studies showed an overall benefit

LR – IR - HR

A lot of studies describe outcomes in all risk categories
In the ABS review: 22 studies – 23.180 patients
16 using LDR (20991 patients) – 5 using HDR (2189 patients)
Median FU: 3,8 – 10 years
ADT use: 18 – 83 % - median duration: 3 – 9 months

Results:

- bPFS: 16 studies showed an association between ADT and bPFS
    - 4 showed a benefit with ADT
        - 1 study reported a 15% benefit only with longer ADT duration
        - 1 study reported a 24% benefit only if BED was < 150 Gy
        - 1 study reported a 9-15% benefit only in HR disease
    - 12 showed no benefit with ADT (including all HDR studies)
    - Remark: one study showed a detriment to bPFS with the addition of ADT in IR disease

LR – IR - HR

Results:

- CSS: 7 studies showed an association between ADT and CSS
    - All 7 showed no benefit with ADT

- OS: 6 studies reported on an association between ADT and OS
    - 3 studies showed no impact on OS
    - 3 showed a statistically detriment to OS using ADT
    - One showed a trend to worse OS

- 6 ongoing RCTs evaluation the role of ADT with PB in IR and HR patients
- Only one completed RCT adressed (at least indirectly) the role of ADT in PB

Australian multicenter TROG 03.04 RADAR 2 x 2 factorial RCT in men with locally advanced PCA

–1071 men

–randomization to receive ADT for 6 to 18 months with dose-escalated EBRT (66-70-74 or 46 Gy + HDR 19,5 Gy in 3 fractions) and also randomized between 0 and 18 months of Zoledronic Acid

–Primary endpoint bPFS subsequently changed to a PCSM. Median follow-up: 7,4 years

–No significant difference in PCSM or OS

–However: 18 months of ADT had a positive effect on the PSA and LC outcome on all EBRT dose levels with greater benefit in lower doses and had almost NO effect for patients treated with HDR boost (absolute difference 3%)

–This data suggest minimal (if any) benefit to longer ADT using PB – however, it does not answer the question if ADT is needed with PB at all

Denham et al; Radiother Oncol 2015;15:1076-1089

Literature shows significant heterogeneity

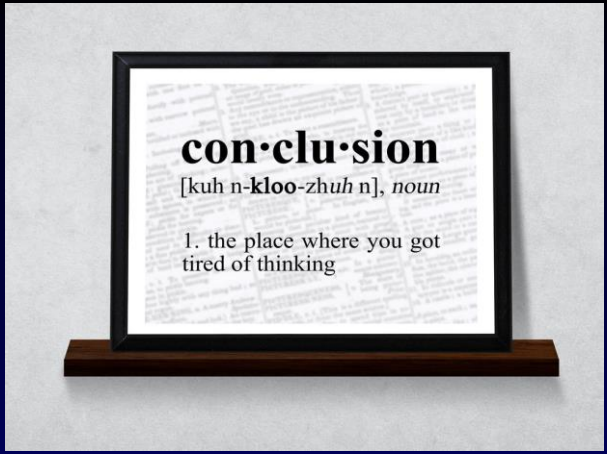
- of the patient populations
- in the risk categories
- in the definition of risk factors
- in the follow-up time
- in ADT administration
- in the duration for ADT administration

The retrospective analyses induces unavoidable patient selection and treatment selection bias !

	bPFS	CSS	OS
Total studies 52	Reported in 42 studies (80%)	Reported in 24 studies (46%)	Reported in 19 studies (36%)
Benefit to ADT	12 (28%)	4 (16%)	0
No benefit	30 (71%)	19 (79%)	16 (84%)
Detriment with ADT	1 (2%)	—	3 (15%)

- No clinical or biochemical benefits from the addition of ADT in LR en fIR

- Beneficial in bPFS
  - in most patients with HR disease using LDR
  - some patients with uIR
  - In patients with low D90 or low BED



- Not beneficial in CSS
  - A very small absolute benefit (2%) to CSS was found in only a few studies and was predominantly with 3-modality treatment vs PB monotherapie

- No OS survival benefit was found in any study

- However: three studies reported on a detriment to OS using ADT (cave: older patients, existing CV disease)

- With high-quality brachytherapy, the dose is sufficient so that any synergistic local effect of ADT with radiation is likely to be of little benefit (unless high volume disease *perhaps …*)
- uIR and HR: ADT is likely to play a role through spatial cooperation for suppression of micro-metastatic disease
- Duration in addition to BT: none or short(er) than with EBRT

THANK
YOU!

Prostate Brachytherapy Course

“Outcome of LDR prostate brachytherapy”

C. Salembier

Outcome of LDR prostate brachytherapy

C. Salembier

Department of Radiotherapy-Oncology
Europe Hospitals – Brussels - Belgium

Treatment options - localized prostate cancer

External beam radiotherapy

Hormonal treatment

Interstitial: low or high dose rate

(robotic) surgery

Localized prostate cancer: heterogeneous group of tumours

Prognostic groups: Good – Intermediate - Poor

Depending on:

- Extension of the tumour
- Initial PSA
- Gleason Score

Low Risk

Stage: T1 or T2a,b
Gleason Sum ≤ 6
PSA ≤ 10 ng/ml

Intermediate Risk

Stage T1 or T1-2 Stage T1-2
Gleason Score 7 or Gleason 6
PSA < 10 PSA 10-20

High Risk

Stage T2c or T3
Gleason score ≥ 8
PSA > 20 ng/mL

Which treatment should be given?

No randomized trials

Comparing RP, EBRT, seeds:

Outcome:

Up to high risk patients:

- No difference in outcome
- Total BED dose matters

Toxicity

- Type of toxicity differs
- No difference severe toxicity rate

Quality of life

- No difference baseline – 6 months

CLINICAL INVESTIGATION Prostate

RADICAL PROSTATECTOMY, EXTERNAL BEAM RADIOTHERAPY <72 Gy, EXTERNAL BEAM RADIOTHERAPY ≥72 Gy, PERMANENT SEED IMPLANTATION, OR COMBINED SEEDS/EXTERNAL BEAM RADIOTHERAPY FOR STAGE T1–T2 PROSTATE CANCER

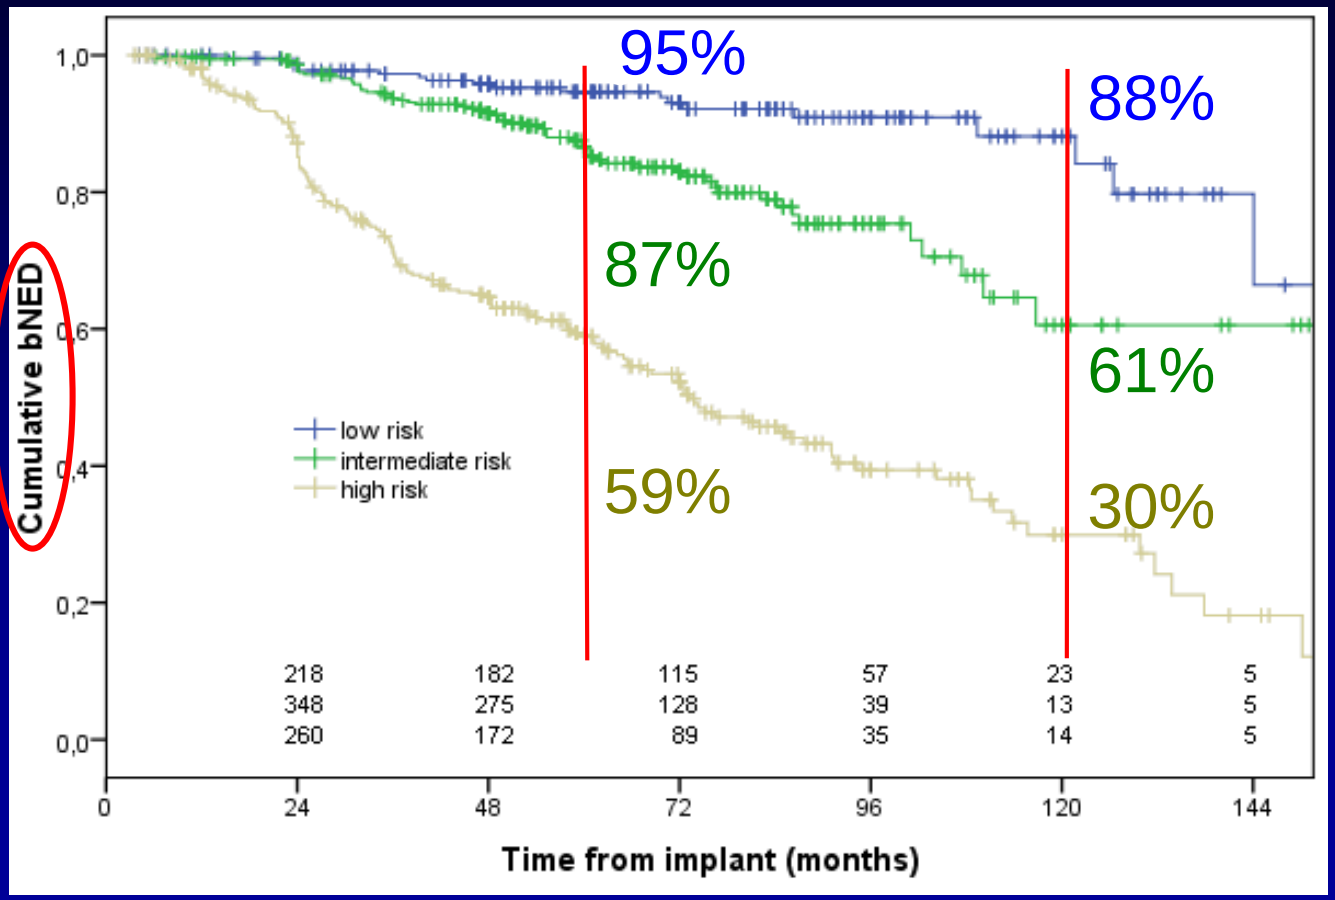
Long-term biochemical and survival outcome of 921 patients treated with I-125 permanent prostate brachytherapy

IJROBP 2010;76(5):1433-8.

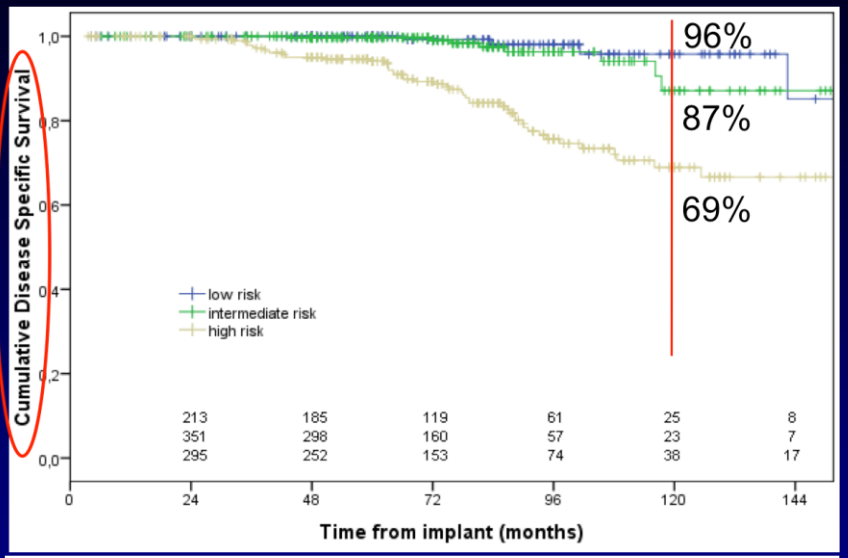
Hinnen et al.



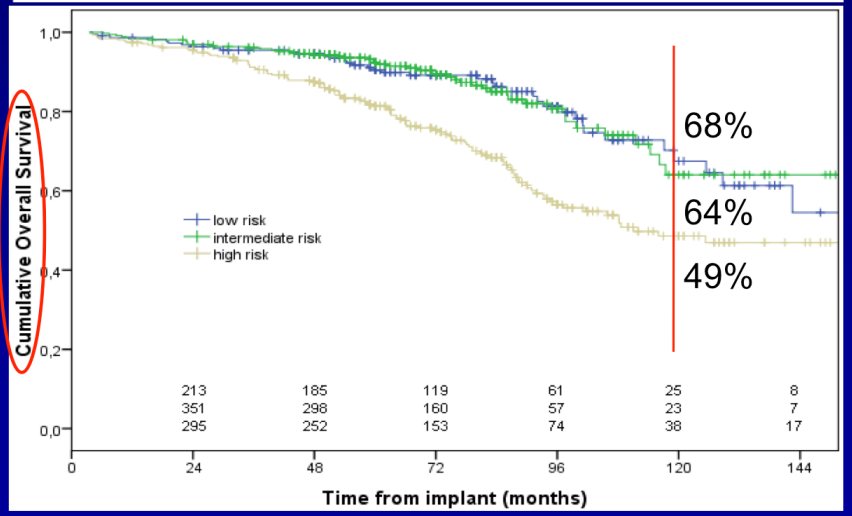
bNED

Long-term biochemical and survival outcome of 921 patients treated with I-125 permanent prostate brachytherapy

Hinnen et al.



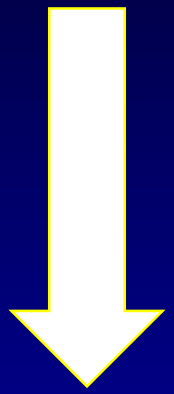
Disease specific survival



Overal survival

Results given in terms of biochemical control ….

However, this biochemical control depends on “local” control but also on “distant” control



What about the “local cure rates” after PB?

Patterns of Recurrence After Low-Dose-Rate Prostate Brachytherapy: A Population-Based Study of 2223 Consecutive Low- and Intermediate-Risk Patients

Andrea C. Lo, MD, W. James Morris, MD, FRCPC, Tom Pickles, MD, FRCPC, Mira Keyes, MD, FRCPC, Michael McKenzie, MD, FRCPC, and Scott Tyldesley, MD, FRCPC

"we estimate that the local recurrence rate of LDR-PB in our study cohort likely lies in the range of 1.8% to 2.7%."

"In the context of the limitations of our study design, this population-based analysis indicates that the local recurrence rate after LDR-PB appears to be as low or lower than that following RP in our jurisdiction."

IJROBP, Vol 91, Issue 4, 15 March 2015, Pages 745–751

Distant and local recurrence in patients with biochemical failure after prostate brachytherapy

Richard G. Stock, Jamie A. Cesaretti, Pamela Unger, Nelson N. Stone

"Hence, at a median follow-up of 6.8 years, the local recurrence rate of the Mt. Sinai cohort treated with LDR-PB should fall between 1.3% and 4.5%"

Brachytherapy, 7 (2008), pp. 217–222

Patterns of failure after iodine-125 seed implantation for prostate cancer ☆

David S. Lamb [a,b,*], Lynne Greig [c], Grant L. Russell [d], John N. Nacey [a,d], Kim Broome [e], Rod Studd [d], Brett Delahunt [a], Douglas Iupati [b], Mohua Jain [f], Colin Rooney [c], Judy Murray [a], Peter J. Lamb [a], Peter B. Bethwaite [a]

"by combining the 0.2% who had local failure with the 2.2% whose site of failure was unknown, the local relapse rate should range from 0.2% to 2.4%"

Radiotherapy and Oncology 112 (2014) 68–71

10-YEAR EXPERIENCE WITH I-125 PROSTATE BRACHYTHERAPY AT THE PRINCESS MARGARET HOSPITAL: RESULTS FOR 1,100 PATIENTS

JUANITA CROOK, M.D.,* JETTE BORG, PH.D.,† ANDREW EVANS, M.D.,‡ ANTS TOI, M.D.,¶
E. P. SAIBISHKUMAR, M.D.,* SHARON FUNG, M.SC.,§ AND CLEMENT MA, M.SC.§

In the Toronto study of 776 patients, all patients with a PSA rising beyond 30 months were investigated by prostate biopsy examination,
and, if the biopsy was negative, systemic staging was initiated as PSA approached 10 ng/ml and there were:

- 8 local failures (1.0%)
- 8 distant failures (1.0%)
- 9 failures of unknown site (1.2%)

Thus, *the local relapse rate should range from 1.0% to 2.2%*, but it is likely to be closer to the biopsy-proven 1.0% of patients, because all other men with biochemical failure in this cohort had negative biopsy results

So……..monotherapy gives:

- excellent results for low risk disease
- very good results for intermediate risk disease
- not optimal results for high risk disease

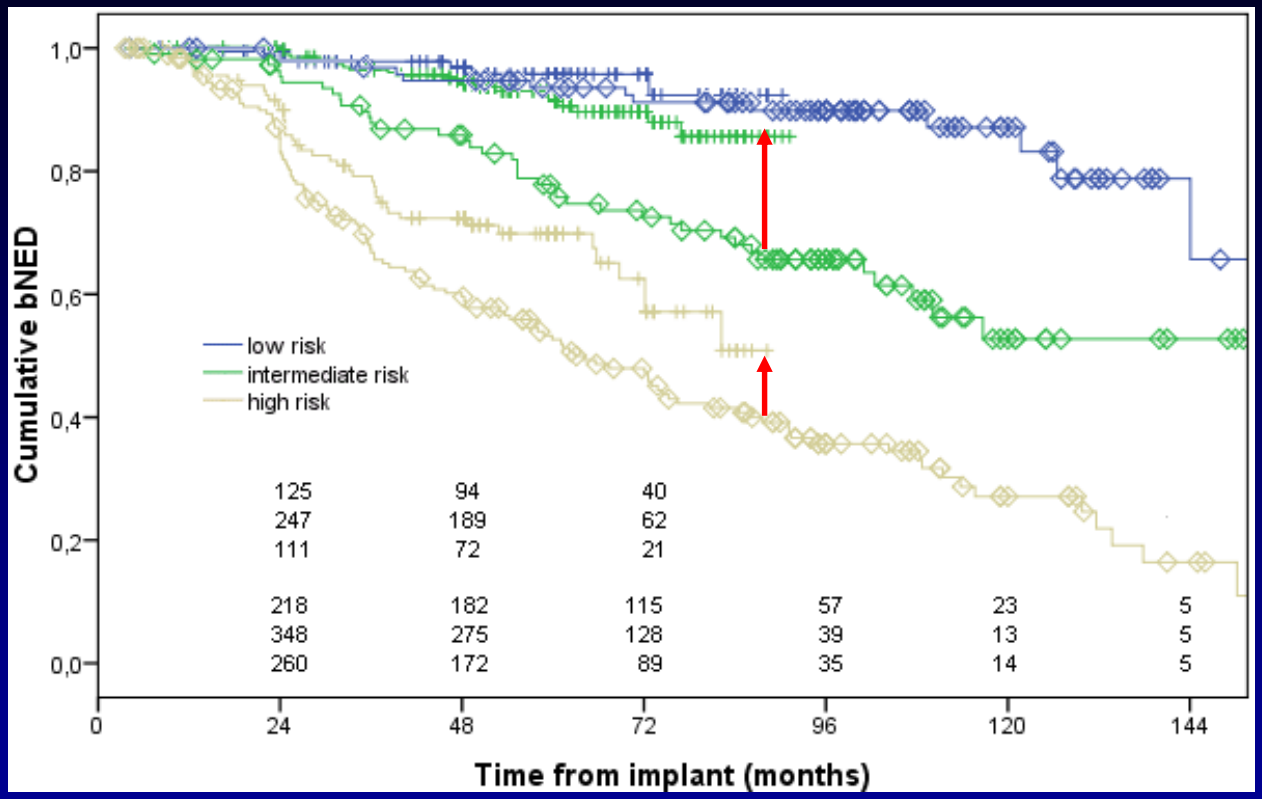
Seeds: factors that might or might not influence outcome

Factors:

1. Implant related -technique:
   - Margins
   - D90
   - Total BED
   - …
2. Risk groups - individual tumor characteristics – staging uncertainties
3. Age

1. Hormonal therapy
2. PSA bouncing
3. Obesity
4. …

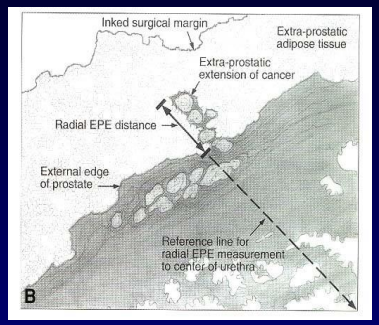
UMC database: bNED before and after 2000



n=921 - 1989-2004

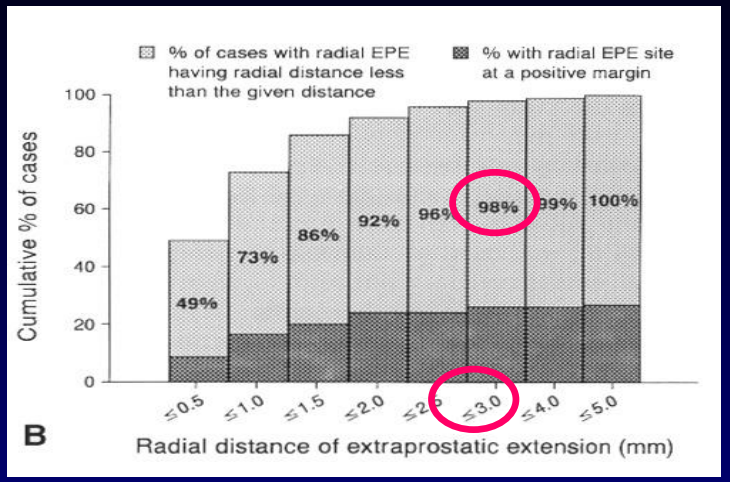
- There seems to be a trend for improved outcome in time
- Raison: technique? patient selection? learning curve? other factors?

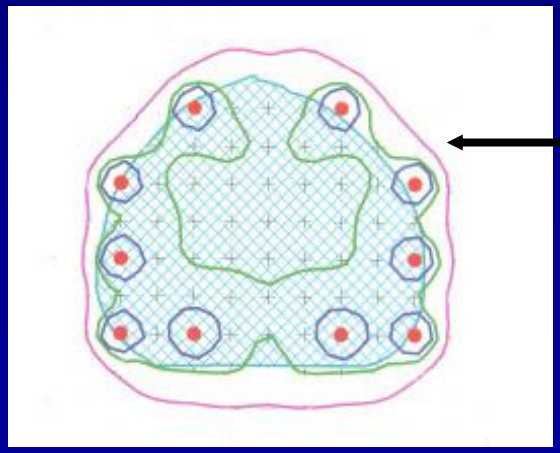
Implant related: Margins:



-105 prostatectomies
-Gleason 6.3 (range 3-9)
-PSA 8.6 (range 0.3-98)

Davis et al. Cancer 85(12) 1999



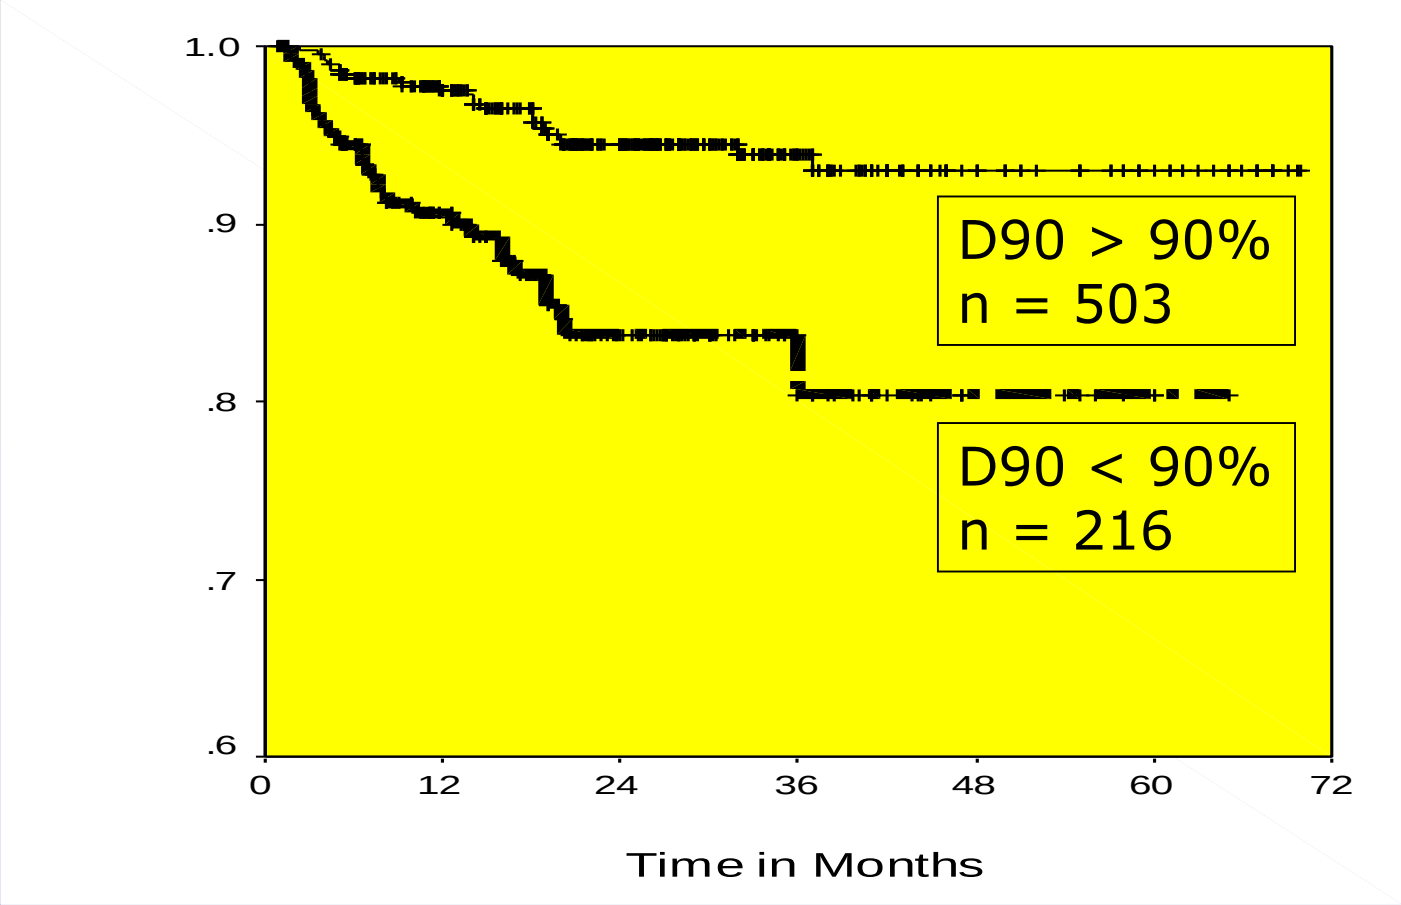


Extraprostatic disease

3 mm margins :

critical to success

Implant quality: Post-implant D90:



Potters et al Urology 62 (6) 2003

Risk groups - Staging:

- Finding capsula infiltration large consequences with regard to outcome
  - Choice of treatment (outcome, hormonal therapy)

- Differentiate between stage 2 and 3: specificity
  - Ultrasound 40 – 50%
  - MRI 80 – 90%

Still, current clinical practice Ultrasound….

Conclusion: many brachy studies in literature contain T3 patients

Risk groups – Individual tumor characteristics:

Biopsies: at random - systematic

- Chance of hitting tumor per biopsy=15-20%

Gleason score: poorly reproducible

- Biopsy agreement with prostatectomy: (n=1670)
  - Gleason 5-6 undergrading: 35%
  - Gleason 8-10 overgrading: 35%

PSA

  - Suspected linear relation with amount of tumor cells
  - Irreliable due to leakage, often false positive

Conclusion: Literature contains probably higher Gleason scores too

Age:

Treatment outcomes in men aged ≤55 yrs (1)

- 1,204 pts treated (Surgery *vs* External Beam RT *vs* Brachytherapy) between 1996-2008. (ASTRO#2283)

The Addition of Low-Dose-Rate Brachytherapy and Androgen-Deprivation Therapy Decreases Biochemical Failure and Prostate Cancer Death Compared With Dose-Escalated External-Beam Radiation Therapy for High-Risk Prostate Cancer

Mark Shilkrut, PhD, MD[1]; Gregory S. Merrick, MD[2]; P. William McLaughlin, MD[1]; Matthew H. Stenmark, MD[1]; Eyad Abu-Isa, MD[1]; Sean M. Vance, MD[1]; Howard M. Sandler, MD[3]; Felix Y. Feng, MD[1]; and Daniel A. Hamstra, MD, PhD[1]

In conclusion, the results from this multi-institutional, retrospective study suggest that, for patients with HiRPCa, the receipt of an LDR brachytherapy boost decreased the risk of BF and PCSM compared with dose-escalated EBRT. Furthermore, even with dose-escalated EBRT or combination therapy, ADT decreased BF and PCSM in a duration-dependent fashion, and the greatest benefit was observed for long-term ADT. Validation of these findings in the University of British Columbia Androgen Suppression Combined with Elective Nodal and Dose-Escalated RT trial, which is comparing dose-escalated EBRT (78 Gy) versus CMRT plus ^{125}I LDR boost (both with 12 months of ADT), may significantly change the treatment standard for patients with HiRPCa.[31]

RTE + Seeds (+ ADT) > (Dose escalated) RTE (+ ADT)

JOURNAL OF CLINICAL ONCOLOGY

ORIGINAL REPORT

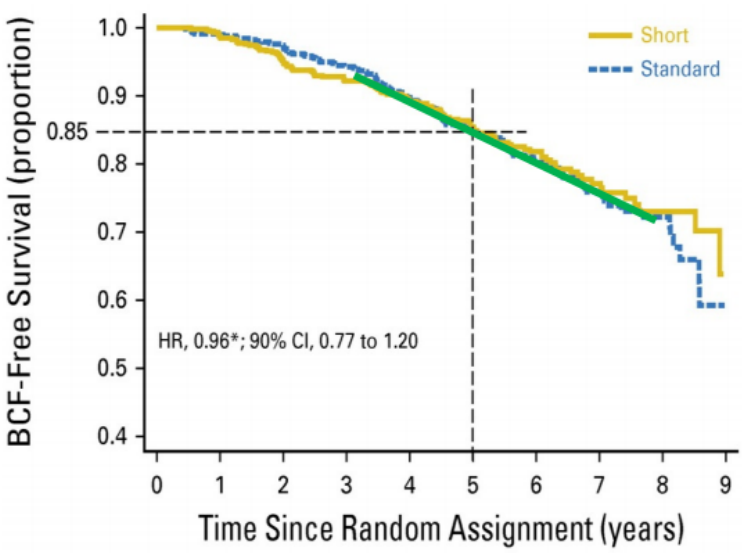
Randomized Trial of a Hypofractionated Radiation Regimen for the Treatment of Localized Prostate Cancer

Charles N. Catton, Himu Lukka, Chu-Shu Gu, Jarad M. Martin, Stéphane Supiot, Peter W.M. Chung, Glenn S. Bauman, Jean-Paul Bahary, Shahida Ahmed, Patrick Cheung, Keen Hun Tai, Jackson S. Wu, Matthew B. Parliament, Theodoros Tsakiridis, Tom B. Corbett, Colin Tang, Ian S. Dayes, Padraig Warde, Tim K. Craig, Jim A. Julian, and Mark N. Levine

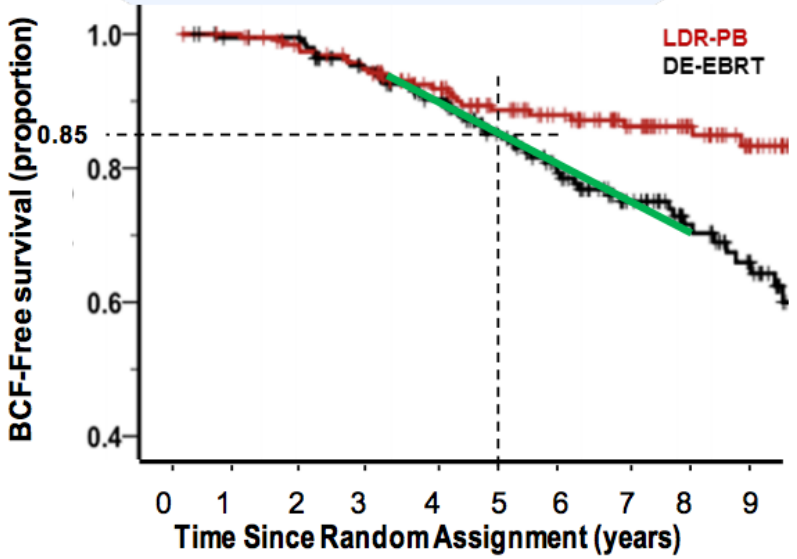
Conclusion

The hypofractionated RT regimen used in this trial was not inferior to conventional RT and was not associated with increased late toxicity. Hypofractionated RT is more convenient for patients and should be considered for intermediate-risk prostate cancer.

Catton *et al.* Hypofractionation Trial vs ASCENDE-RT



78 Gy/39#s or 60/20#s IMRT
All low and intermediate risk PCa
Only 6% had ADT
Median FU = 6 years



78 Gy/39#s (black line)
69% high risk PCa, no low risk
100% got ADT
Median FU =6.5 years

Catton *et al.* Hypofractionation Trial vs ASCENDE-RT

Hegde, MD; Sun Mi Yoo, MD, MPH; Ryan Fiano, MPH; Anthony V. D'Amico, MD, PhD; Nicholas G. Nickols, MD, PhD; William J. Aronson, MD; Ahmad Sadeghi, MD; Stephen Greco, MD; Curtiland Deville, MD; Todd McNutt, PhD; Theodore L. DeWeese, MD; Robert E. Reiter, MD; Johnathan W. Said, MD; Michael L. Steinberg, MD; Eric M. Horwitz, MD; Patrick A. Kupelian, MD; Christopher R. King, MD, PhD

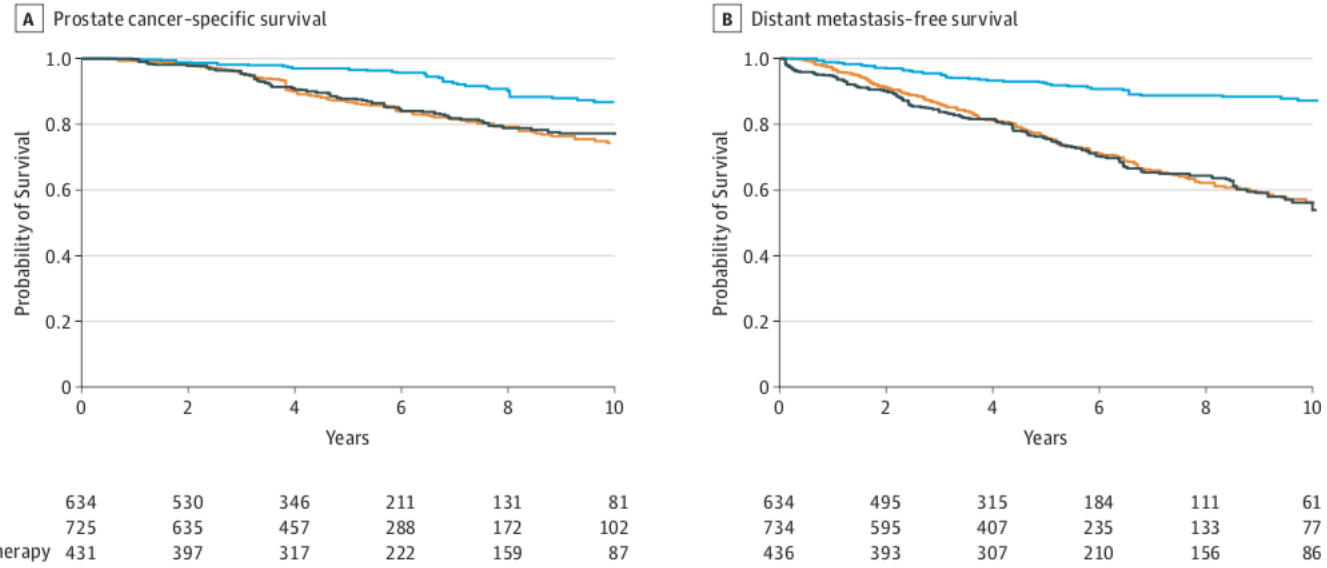
OBJECTIVE To compare clinical outcomes of patients with Gleason score 9-10 prostate cancer after definitive treatment.

DESIGN, SETTING, AND PARTICIPANTS Retrospective cohort study in 12 tertiary centers (11 in the United States, 1 in Norway), with 1809 patients treated between 2000 and 2013.

EXPOSURES Radical prostatectomy (RP), external beam radiotherapy (EBRT) with androgen deprivation therapy, or EBRT plus brachytherapy boost (EBRT+BT) with androgen deprivation therapy.

Brachytherapy type	
Low-dose rate	262 (62.0)
High-dose rate	174 (38.0)

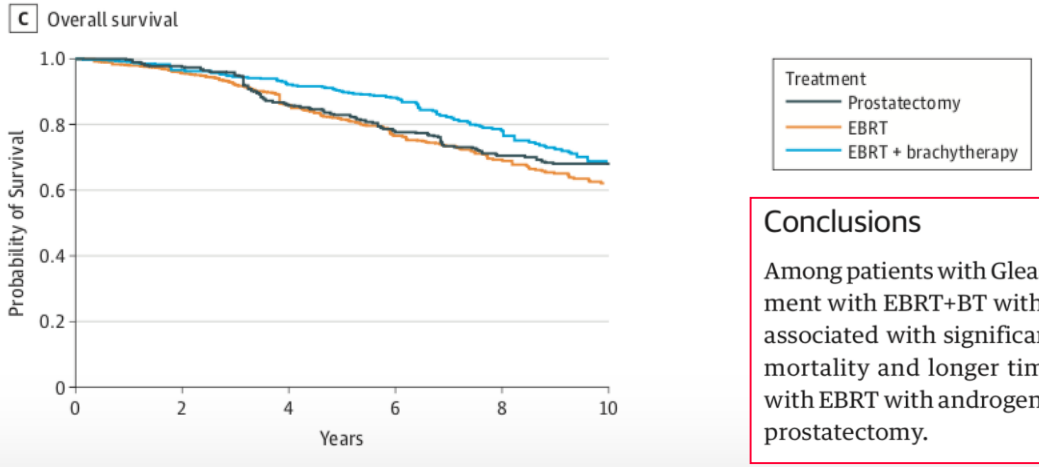
Figure. Adjusted Survival Curves for Prostate Cancer-Specific Survival, Distant Metastasis-Free Survival, and Overall Survival by Treatment Group, Weighted by the Inverse Probability of Treatment



No. at risk

Prostatectomy	634	530	346	211	131	81
EBRT	725	635	457	288	172	102
EBRT + brachytherapy	431	397	317	222	159	87

634	495	315	184	111	61
734	595	407	235	133	77
436	393	307	210	156	86



Conclusions

Among patients with Gleason score 9-10 prostate cancer, treatment with EBRT+BT with androgen deprivation therapy was associated with significantly better prostate cancer-specific mortality and longer time to distant metastasis compared with EBRT with androgen deprivation therapy or with radical prostatectomy.

Conclusions

- Low Risk: Brachy alone

- (F) Intermediate Risk: Brachy + EBRT = Brachy alone

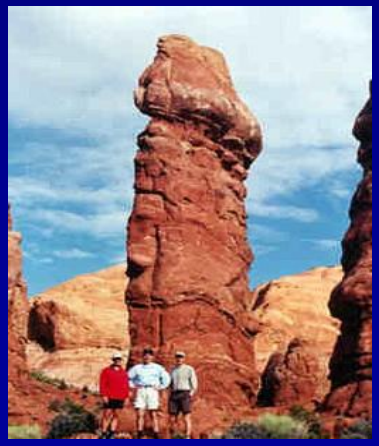
- UF Intermediate Risk: Brachy + EBRT >>> EBRT
- High Risk: Brachy + EBRT >>> EBRT

So: in all cases: Brachy (+/- EBRT)

The question becomes:

"When do we need to do 'a EBRT boost' to Brachy ?"

Quality of Life – Side Effects



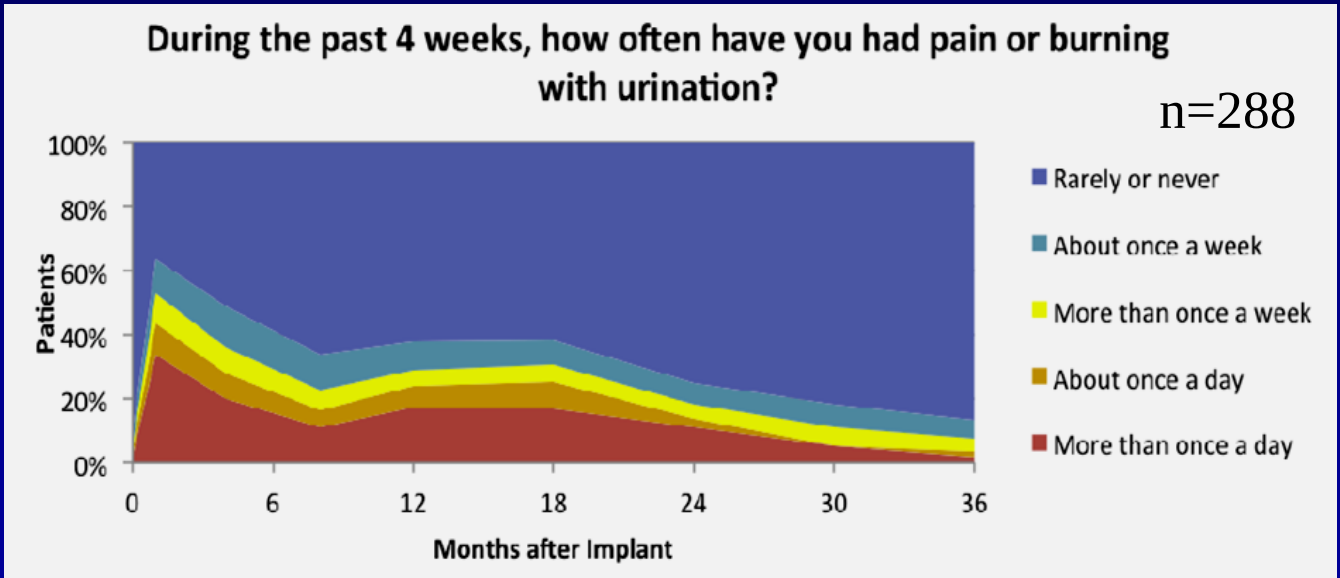
Toxicity grading:

- Severe toxicity (grade ≥ 3) most important
- Urinary Grade ≥ 3 toxicity rates:
  - Acute urinary retention: ± 10% (5-34%) = highest incidence
  - Urinary incontinence: ±1.5% (0-17%)
  - Urinary bother: ± 1-3%
  - Hemorr. cystitis <<<1%
  - Infection <<<1%
  - Fistula <<<1%
- Rectal Grade ≥ 3 toxicity rates: <1%
- Erectile dysfunction: complicated, baseline function matters

Anderson et al. Urol 2009;74:601-5
Gore et al. JNCI 2009;101:888-92
Bottomley et al. RO 2007;82-46-9
Chen et al. JCO 2009;27:3916-22

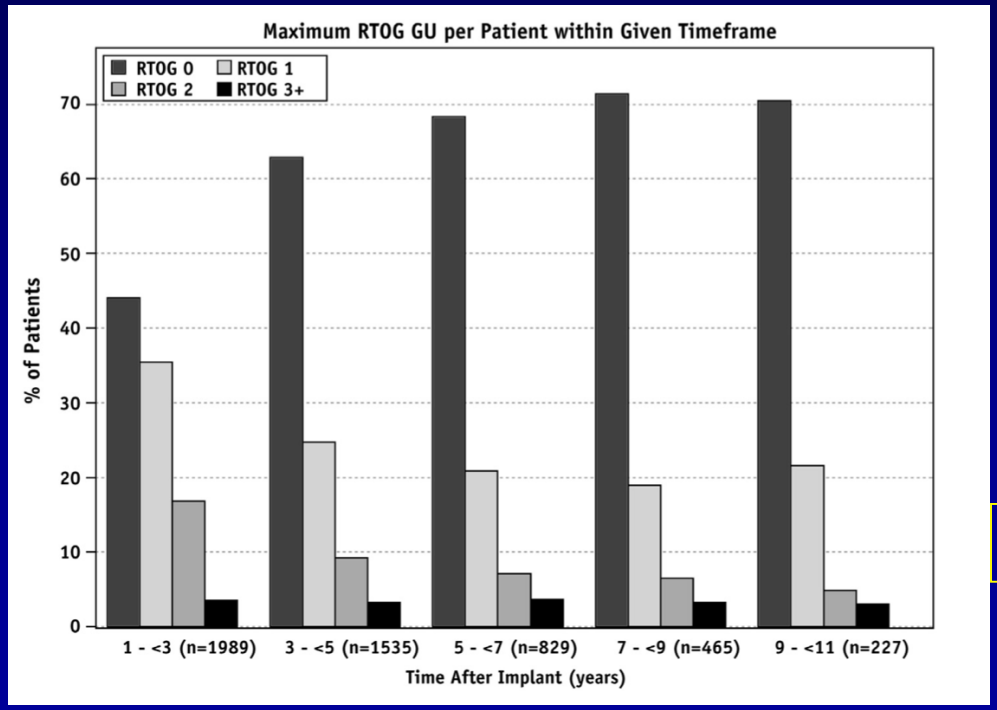
Urinary Bother

- Is pain or burning with urination
- Cause: detrusor overactivity
- Grade 3 urinary bother: 1-3%
- Even grade I and 2 urinary bother may severely disturb quality of life



Late Urinary Side Effects 10 Years After Low-Dose-Rate Prostate Brachytherapy: Population-Based Results From a Multiphysician Practice Treating With a Standardized Protocol and Uniform Dosimetric Goals

Mira Keyes, MD, Stacy Miller, MD, Tom Pickles, MD, Ross Halperin, MD, Winkle Kwan, MD, Vincent Lapointe, BSc, Michael McKenzie, MD, Ingrid Spadinger, PhD, Howard Pai, MD, Elisa K. Chan, MD, and W. James Morris, MD



"At 5-13 years' follow-up, 90% of patients have no (RTOG 0) or minimal (RTOG 1) urinairy morbidity"

"Long-term urinary toxicity is low"

Dose to the Bladder Neck Is the Most Important Predictor for Acute and Late Toxicity After Low-Dose-Rate Prostate Brachytherapy: Implications for Establishing New Dose Constraints for Treatment Planning

Lara Hathout, MD,* Michael R. Folkert, MD,* Marisa A. Kollmeier, MD,* Yoshiya Yamada, MD,* Gil'ad N. Cohen, MS,† and Michael J. Zelefsky, MD*

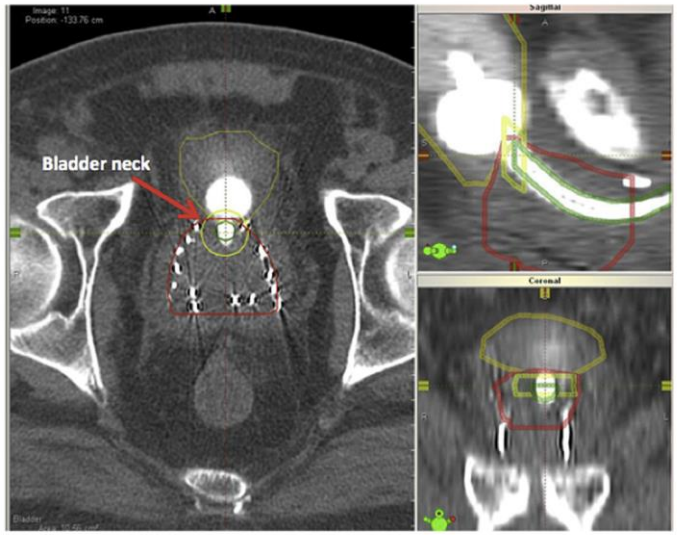


Fig. 1. Contour of bladder neck on computed tomographic scan on day 0 after implantation.

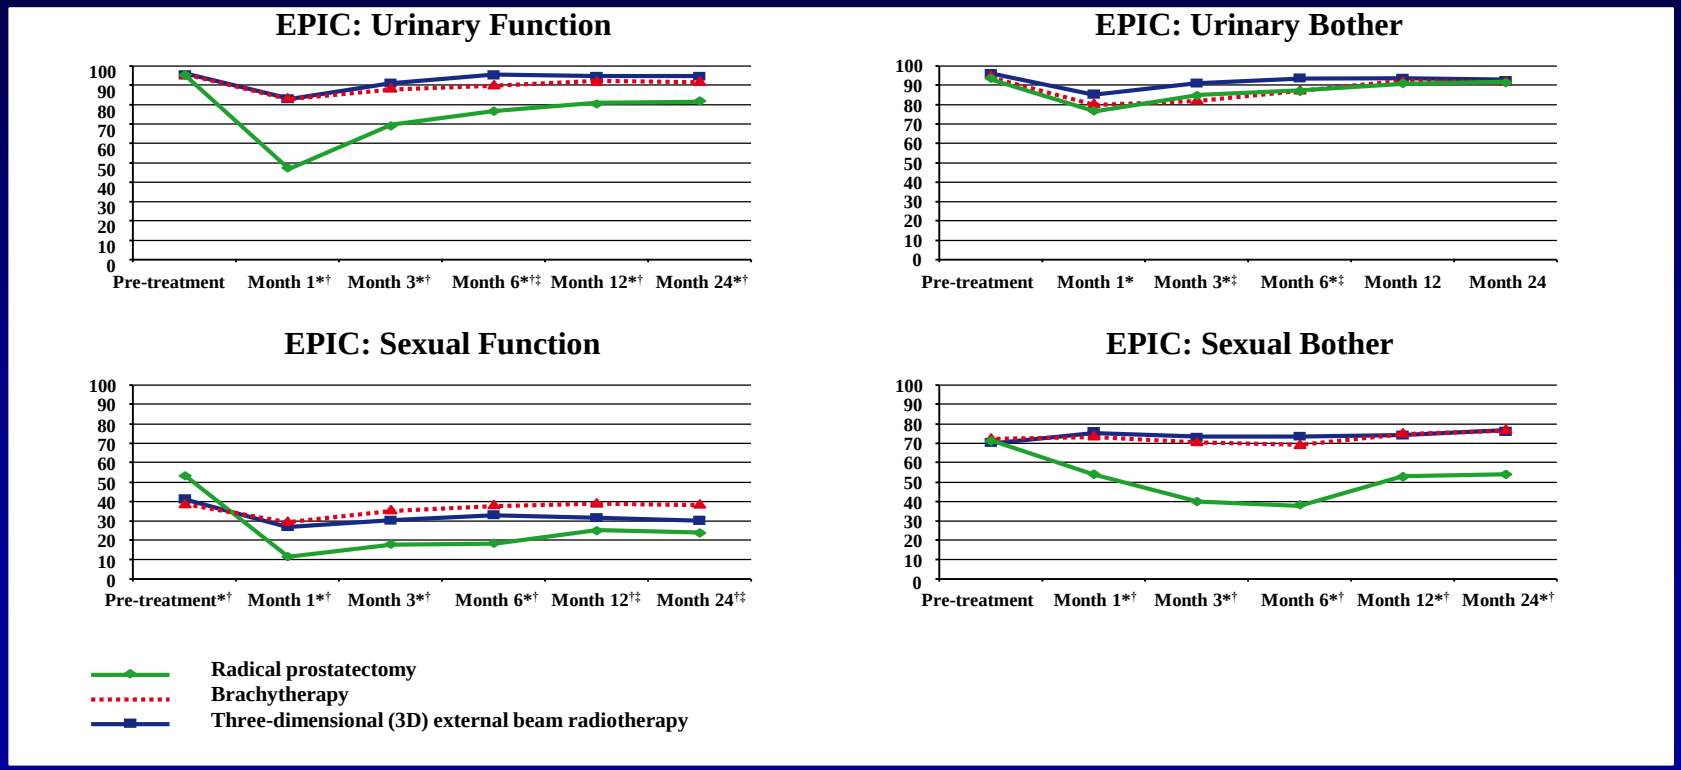
Bladder neck D2cc >50% was identified as a strong predictor of acute and late urinary toxicity in patients treated with LDR brachytherapy with and without supplemental EBRT. These data support the potential benefit for inclusion of bladder neck constraints into brachytherapy treatment planning, because constraining the dose to this region may decrease urinary-related symptoms after treatment. Our findings will require further studies to validate. A prospective study is presently under way at our institution to assess the validity of the proposed bladder neck dose constraint.

Int J Radiation Oncol Biol Phys, Vol. 90, No. 2, pp. 312-319, 2014

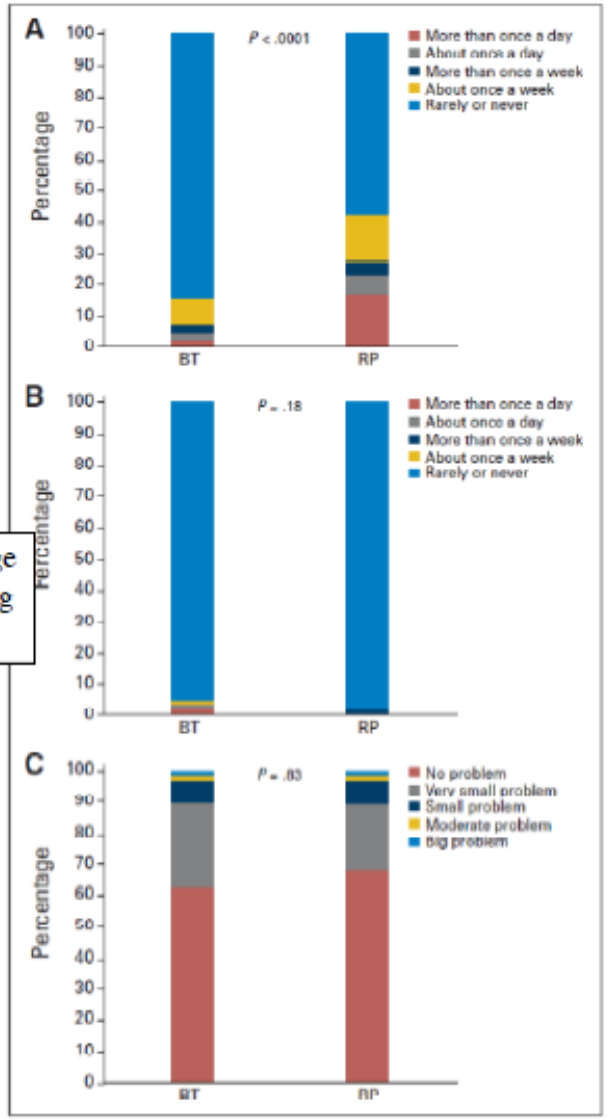
Quality of life following prostate cancer treatment

Prostate brachytherapy, prostatectomy and EBRT have different effects on patients' quality of life

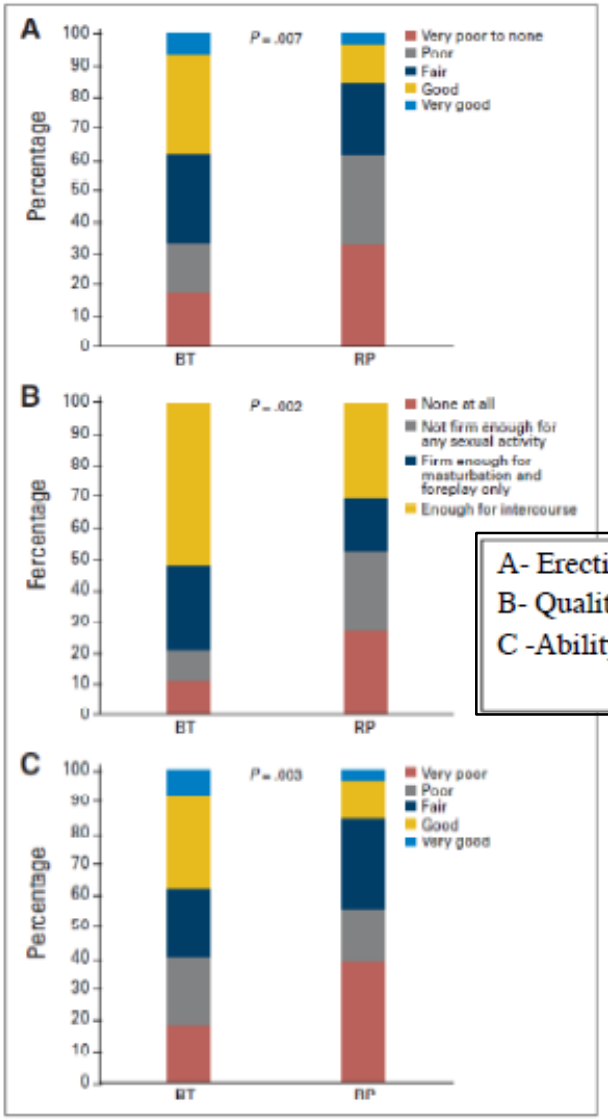


Ferrer M et al. *Int J Radiat Oncol Biol Phys* 2008; 72: 421–32.

- Crook J. et al : JCO 2010 29 362-368



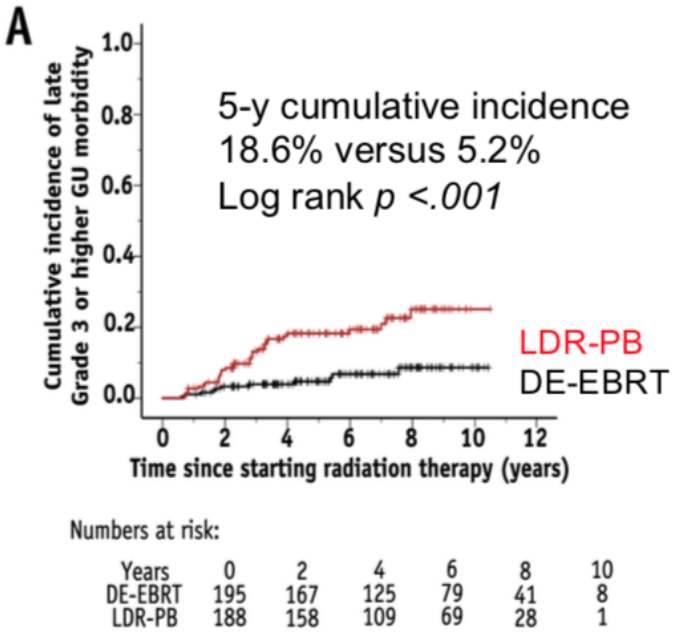
A- urinary leakage
B -pain & burning
C -weak stream

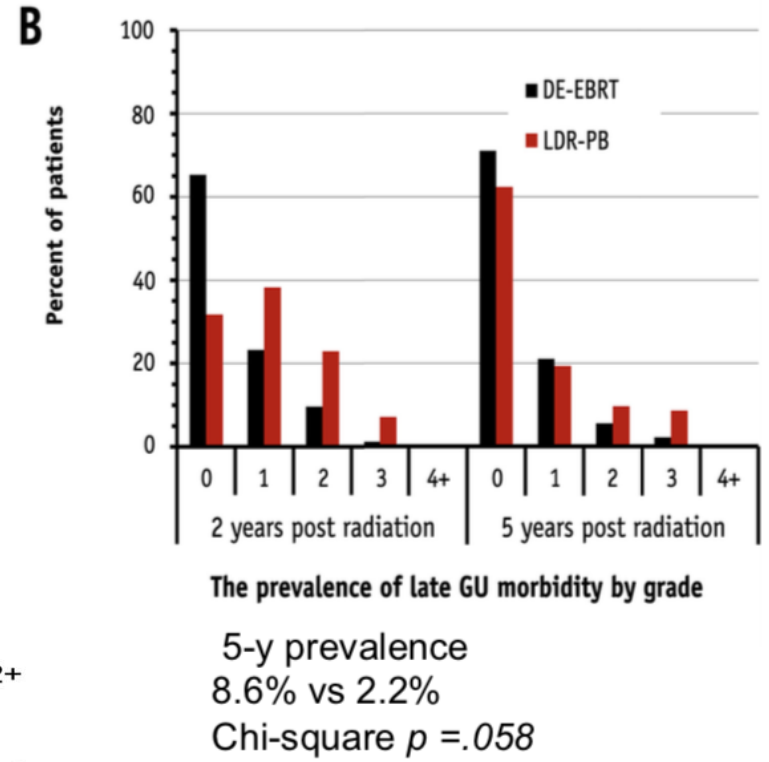


A- Erection
B- Quality of E
C -Ability to sex

The addition of Brachy to EBRT increases the toxicity
The addition of EBRT to Brachy increases the toxicity

ASCENDE-RT: Late GU Adverse Events





- LDR-PB ARM - twice as likely to have **acute** Grade 2+ GU toxicity (32.5% vs 16.3%, Chi square p <.001)
- LDR-PB ARM ~3 times higher cumulative incidence of **late** grade 3 GU adverse event (18.6% versus 5.2%, Log rank p <.001)

Brachytherapy	External Beam	Surgery
Less time of work	8 weeks of treatment + recuperation	6 -12 weeks recovery
Continence unaffected Mild LUTS in 70% Moderate LUTS in 30%	Continence unaffected Mild LUTS in majority Moderate LUTS in 50%	50% immediate continence 75% by 3 months 90-95% by 6 months
Very low gastro-intestinal toxicity	Moderate GI toxicity in majority Severe GI toxicity low, but dose related	Extremely low GI toxicity
Preservation of potency Preservation of ejaculation but may be reduced Fertility is preserved	Relative preservation of potency Preservation of ejaculation but may be reduced Potential impact on fertility	Potency never the same True ejaculation does not occur Infertile (need IVF)

Cave: - adjunction of adjuvant external beam after surgery
- adjunction of hormonal treatment

Conclusions

- Excellent long term results of permanent seed implants for low-risk and (F) IR-patients
- UF- IR and HR patients may benefit from combined EBRT and seed treatment (+ ADT)
- Toxicity is low and acceptable
- No decrease in long term QoL
- Quality assurance very important

THANK
YOU!

HDR-BT alone schedules

From 2005-2013, two hundred and ninety three patients enrolled:

- **19 Gy single dose: n = 23**
- **20 Gy single dose: n = 26**
- **26 Gy in 2 fractions: n = 138**
- **31.5 Gy in 3 fractions: n = 106**

Number of patients treated with single-doses is small,
Late morbidity and bRFI are similar……
……therefore the two groups were combined

***Group A** (19 Gy and 20 Gy), **Group B** (26 Gy) and **Group C** (31.5 Gy)*

ESTRO School

Functional MRI guided HDR prostate brachytherapy tumour boost

ELSEVIER

Brachytherapy - (2013) -

BRACHYTHERAPY

Multi-parametric MRI-guided focal tumor boost using HDR prostate brachytherapy: A feasibility study

Josh Mason[1,4,*], Bashar Al-Qaisieh[1], Peter Bownes[1], Dan Wilson[1], David L. Buckley[4], David Thwaites[4,5], Brendan Carey[2], Ann Henry[3]

- HDR prostate brachytherapy
- Trans-rectal ultrasound guided catheter insertion and treatment planning
- 15Gy to whole prostate in 1 fraction followed by 37.5 Gy/15 fraction external beam treatment

F-GTV delineation

F-GTV = union of suspicious areas in all 3 MRI datasets

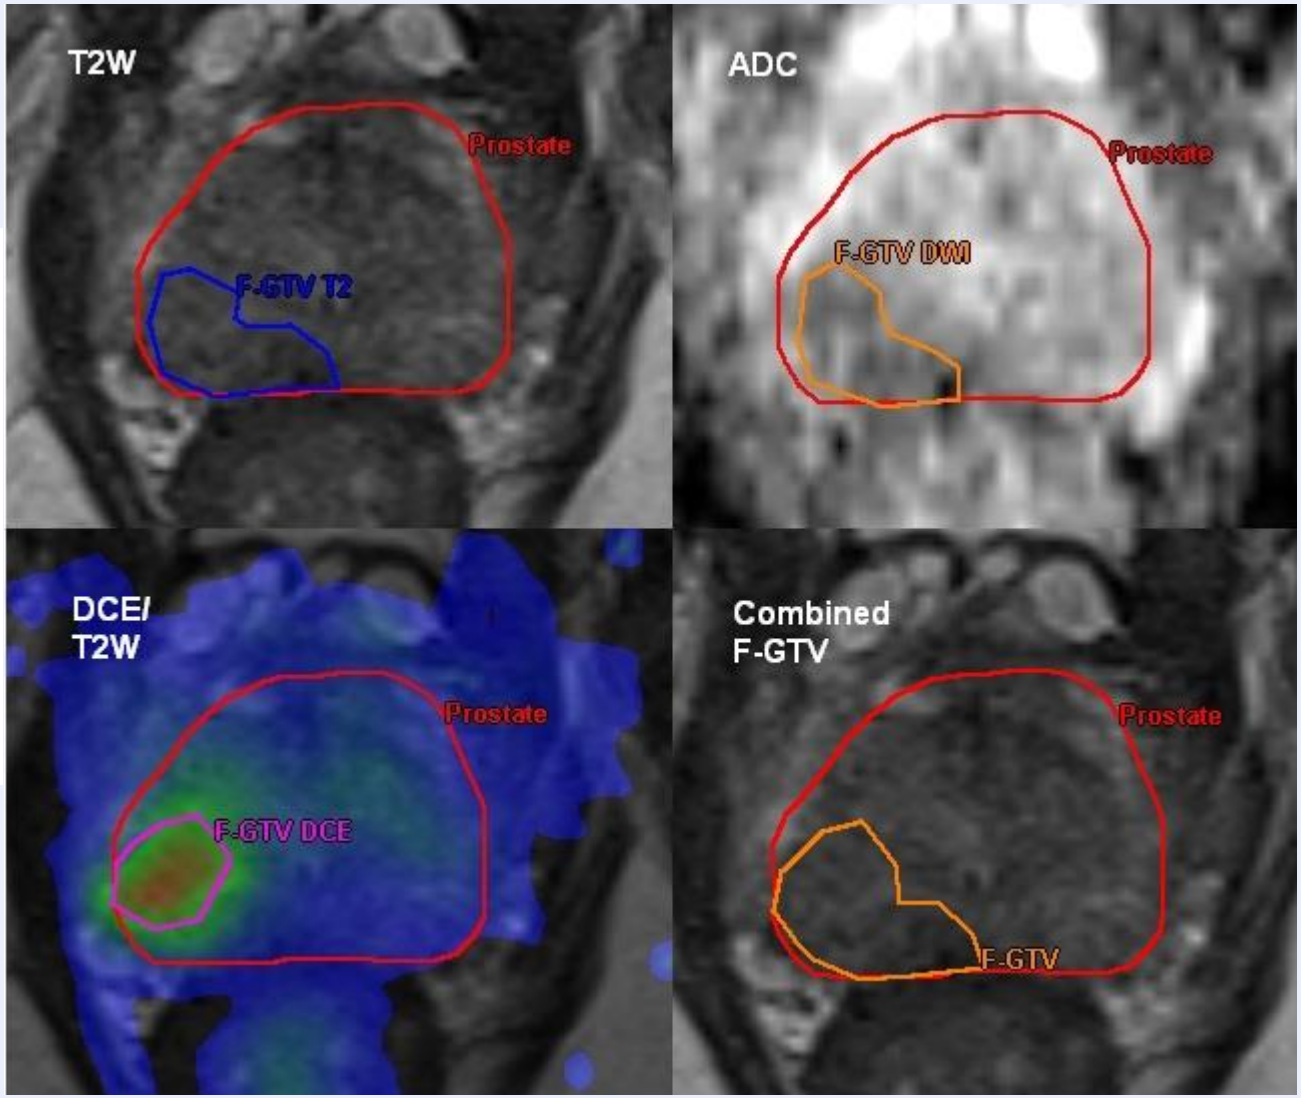

Image registration MRI-TRUS

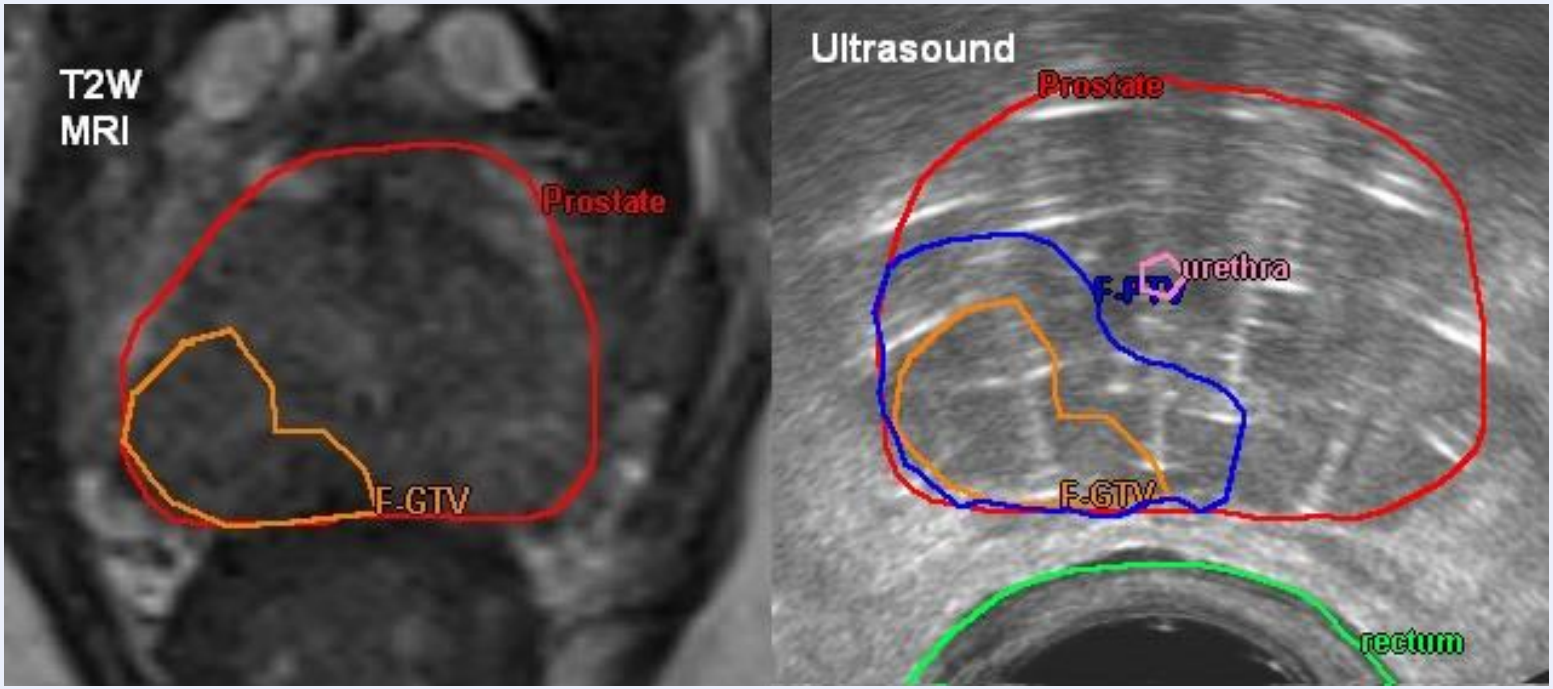
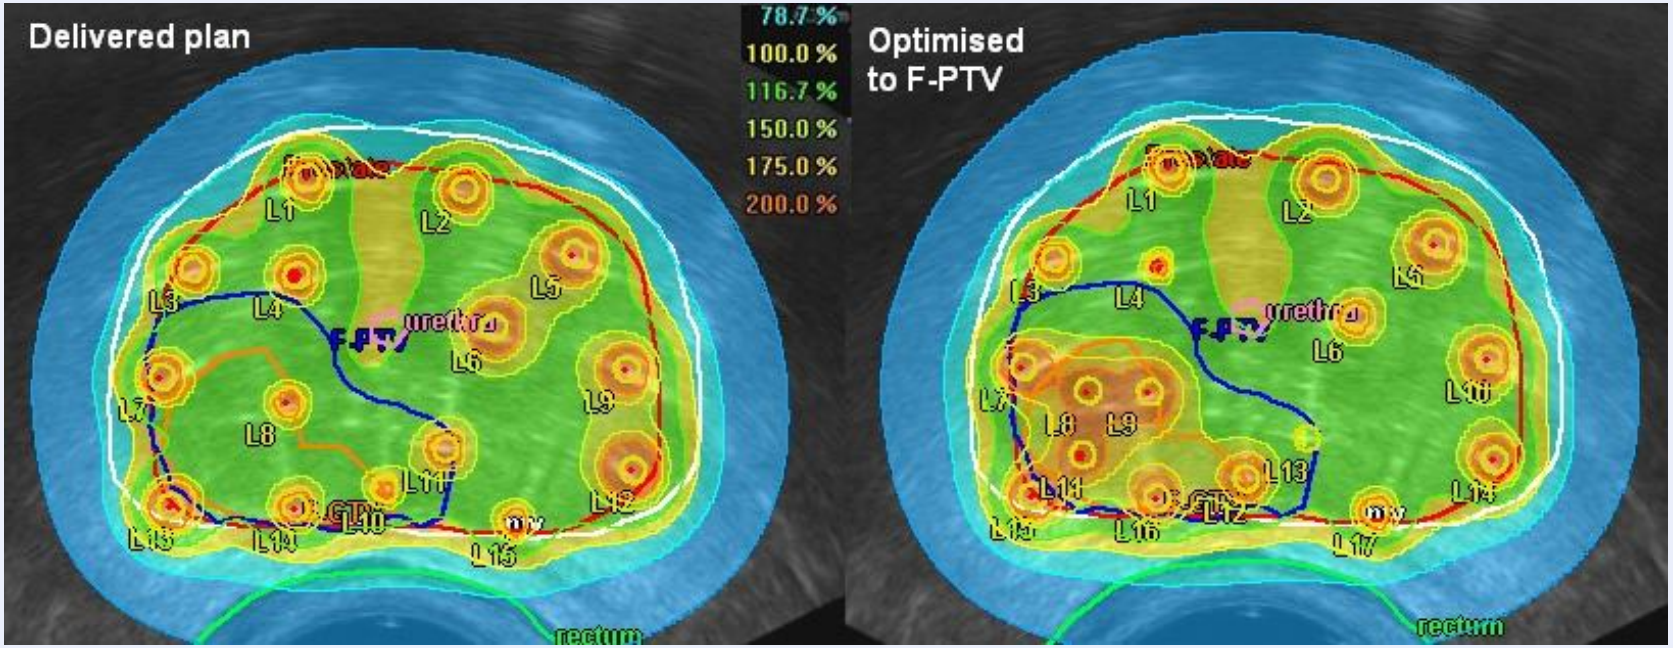
- Manual rigid registration
- Margin added to F-GTV (constrained by prostate/OAR) to create F-PTV



Dose optimisation

- Compared delivered plan to plan optimised to boost dose to F-PTV
- Added up to 2 needles to target F-PTV if necessary
- Maintain dose objectives/constraints for prostate, PTV, urethra, rectum



Results – median values for 15 patients

	Volume (cc)	DVH parameter	Objective/ constraint	Delivered plan	Optimised to F-PTV
Prostate	29.7	V100 (%)	>95%	99.5	99.4
		D90 (Gy)	-	16.8	17.0
PTV	43.3	V100 (%)	>90%	90.7	93.7
Urethra	0.3	D10 (Gy)	<17.5Gy	17.2	17.4
Rectum	13.2	D2cc (Gy)	<11.8 Gy	8.0	9.1
F-GTV	1.9	D90 (Gy)	-	18.2	23.4
		V150 (%)	-	23.2	99.2
F-PTV	6.5	D90 (Gy)	-	17.6	20.9
		V150 (%)	-	27.3	75.9

Summary

- MRI guided tumour boost is feasible
- Main uncertainties are in tumour delineation and image registration
- F-PTV boost dose is achievable in HDR brachytherapy

TREATMENT PLANNING FOR PERMANENT SEED IMPLANTATION

Bashar Al-Qaisieh

The Leeds Teaching Hospitals NHS
NHS Trust

Seed Type

I-125	Pd-103	Cs-131
• 4.6mm long and 0.8mm diameter • I-125 adsorbed on silver rod, encased in titanium • Half-life of 59.4 days • Energy 27.4 & 31.4keV x-rays (electron capture) Also 35.5keV gamma photons	• 4.6mm long and 0.8mm diameter • Pd plated graphite pellets 0.9mm x 0.6mm • Titanium end cap • Half-life 17 days • Energy 20.8 KeV	• Short half-life (9.7 days) may provide radiobiological advantage for some prostate cancers • γ-ray emitter with highest peaks from 29 to 34 keV • Clinical protocol developed in Texas Cancer Center by Prestidge et al.

Update of AAPM Task Group No. 43 Report: A revised AAPM protocol for brachytherapy dose calculations

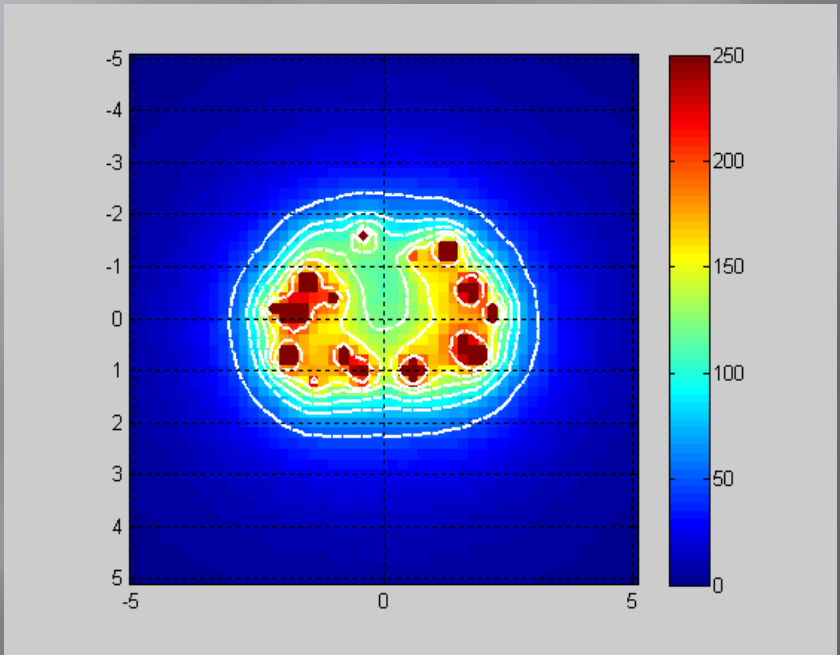
Medical Physics, 31 (3), 633-674 Mar 2004

Clinical dose calculations

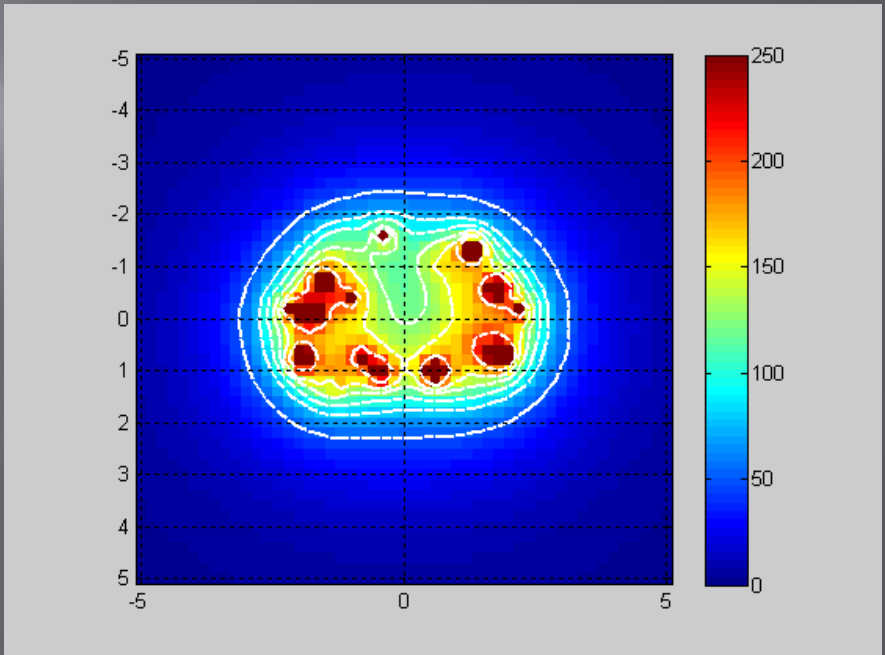
- Assumptions and possible errors in TG43
  - Dose to liquid water
    - Tissue variation/air/bone/calcification
  - Superposition of independent sources
    - Applicators/seeds attenuation
  - Fixed phantom dimensions
    - Patient boundaries

Initial results

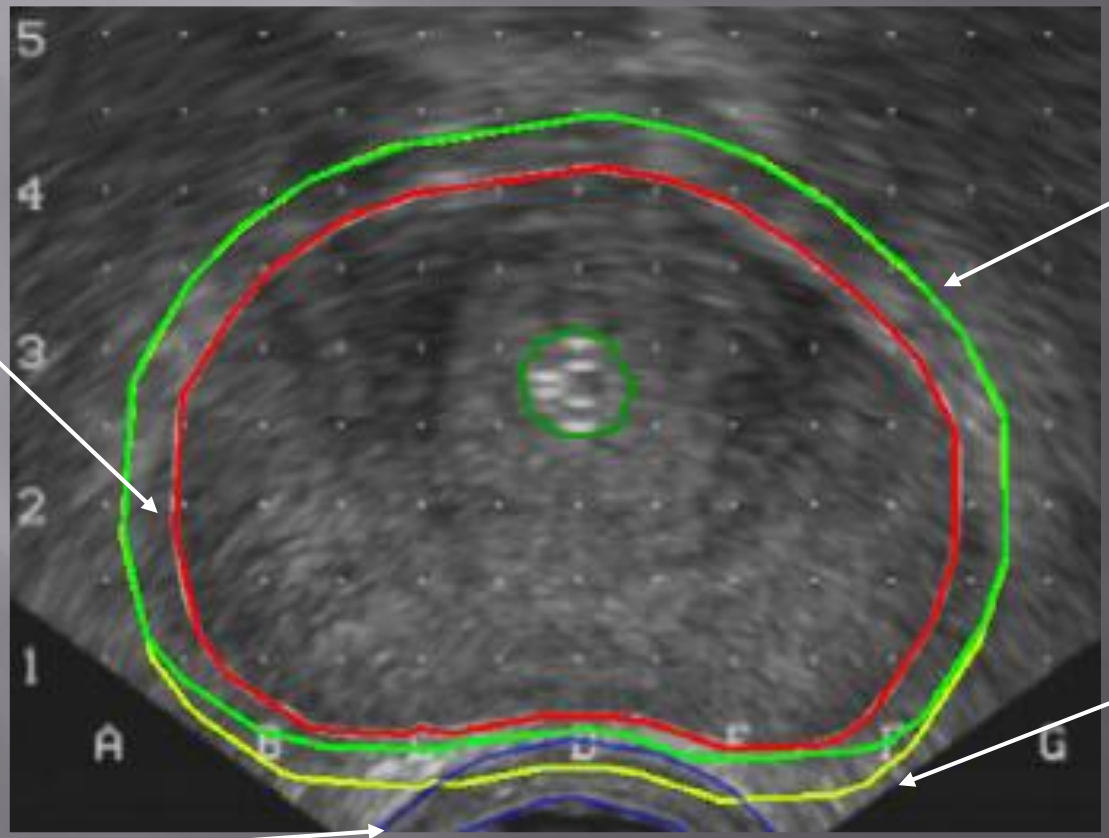
MC Simulation



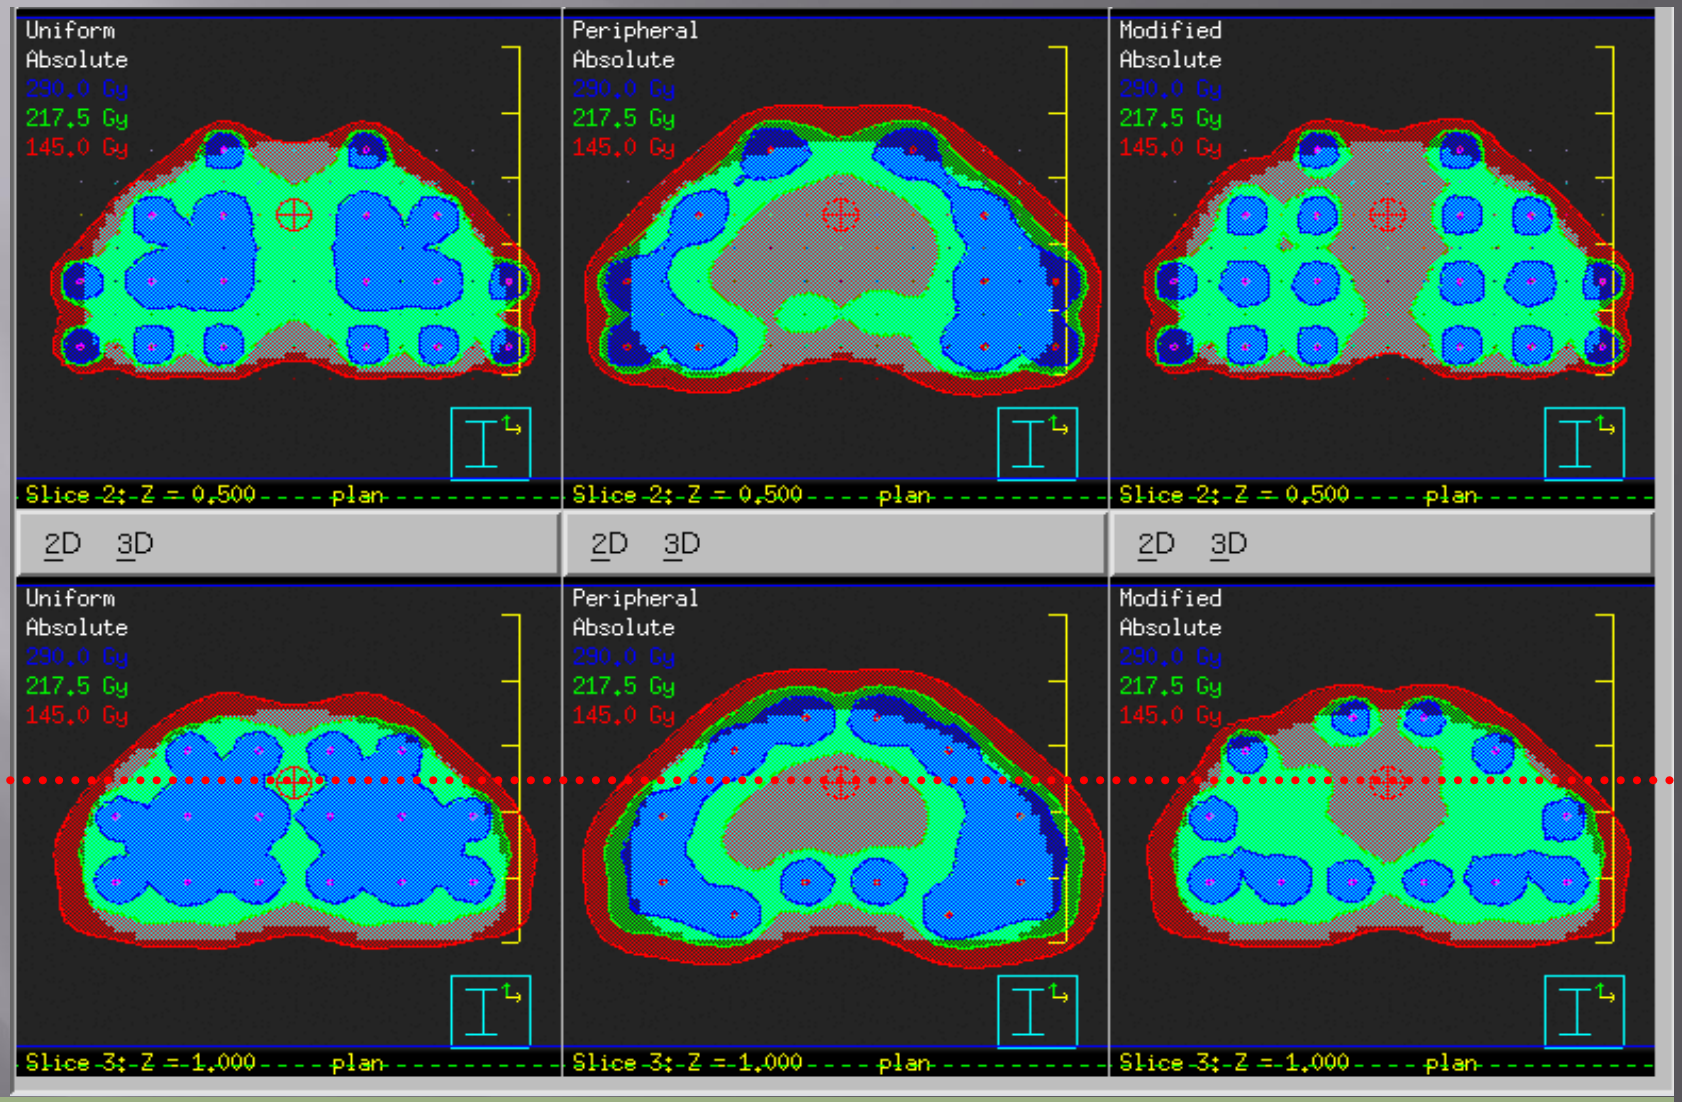
Superposition



PTV= CTV = Prostate Gland + "0-3mm" margin *(GEC/ESTRO Recommendations, Salembier et al 2007)*

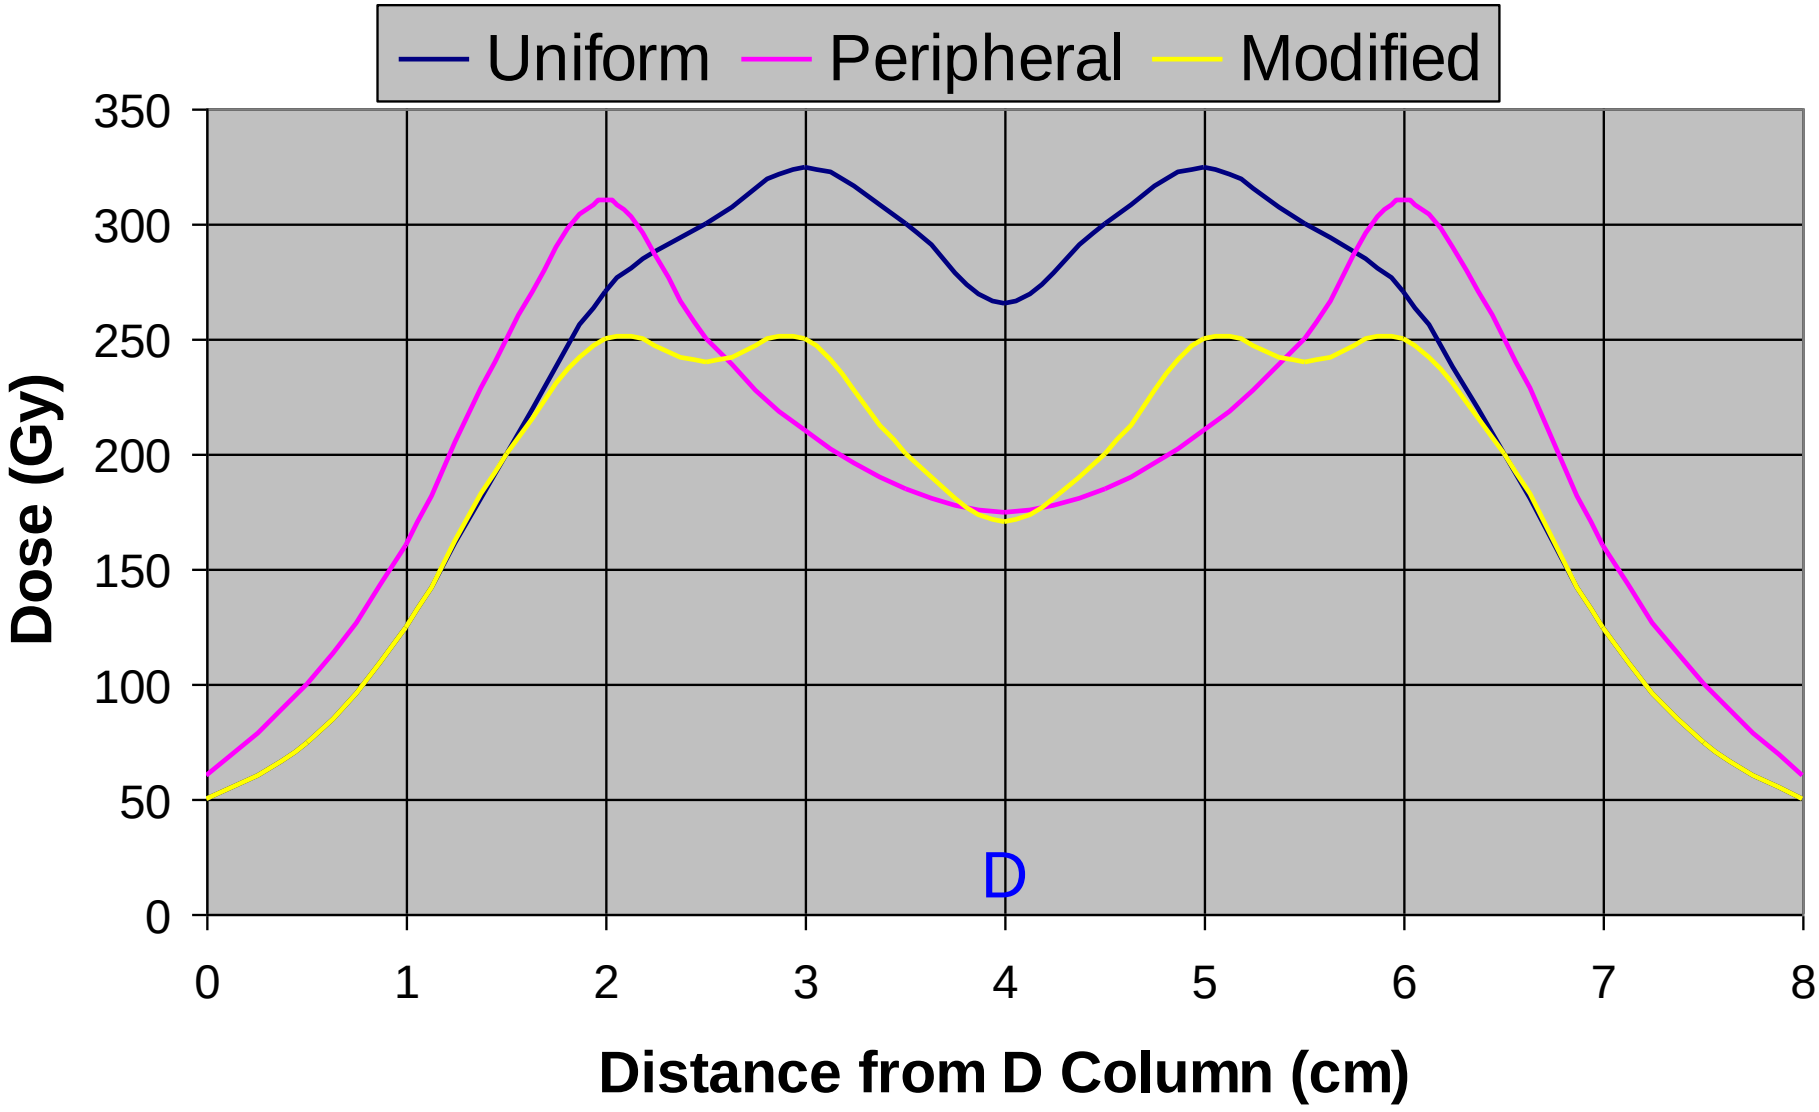


Seed Distribution



Uniform Loading	Peripheral Loading	Modified Peripheral
<0.3U	>0.8U	~0.4U

Dose Profile Through Urethra and Row 3 for Different Loading Techniques



Factors may affect accurate seeds positioning

- Patient set-up:

  - Prostate mis-match (day of volume study/day of implant).

- Implant progression:

  - Pubic-arch interference.
  - Prostate movement (linear and rotational).
  - Bleeding affect seeds and needles visualisation on U/S.
  - Seeds jamming and operator error.

- Prostate oedema:

  - Change in prostate size during and after the implant (seeds migration).

Theatre Dosimetry Planning

Department of Radiotherapy-Oncology
Europe Hospitals – Brussels - Belgium

Why evaluate after the procedure ?

- Individual implant assessment
- Programmatic improvements
- External incentives
- Standard of Care

Individual Implant Assessment: Inadequate Target Dose

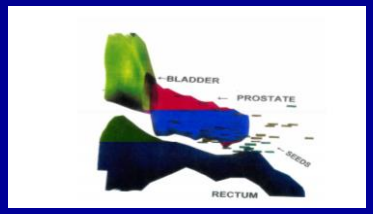
- Therapeutic intervention
  - Adjuvant therapies
    - Re-implantation
    - External beam radiation
    - Chemotherapy / hormonal manipulation
    - Surgical intervention
  - Salvage therapy: follows recurrence
- Increased vigilance
  - Follow up and diagnostics (imaging and biochemical evaluation)

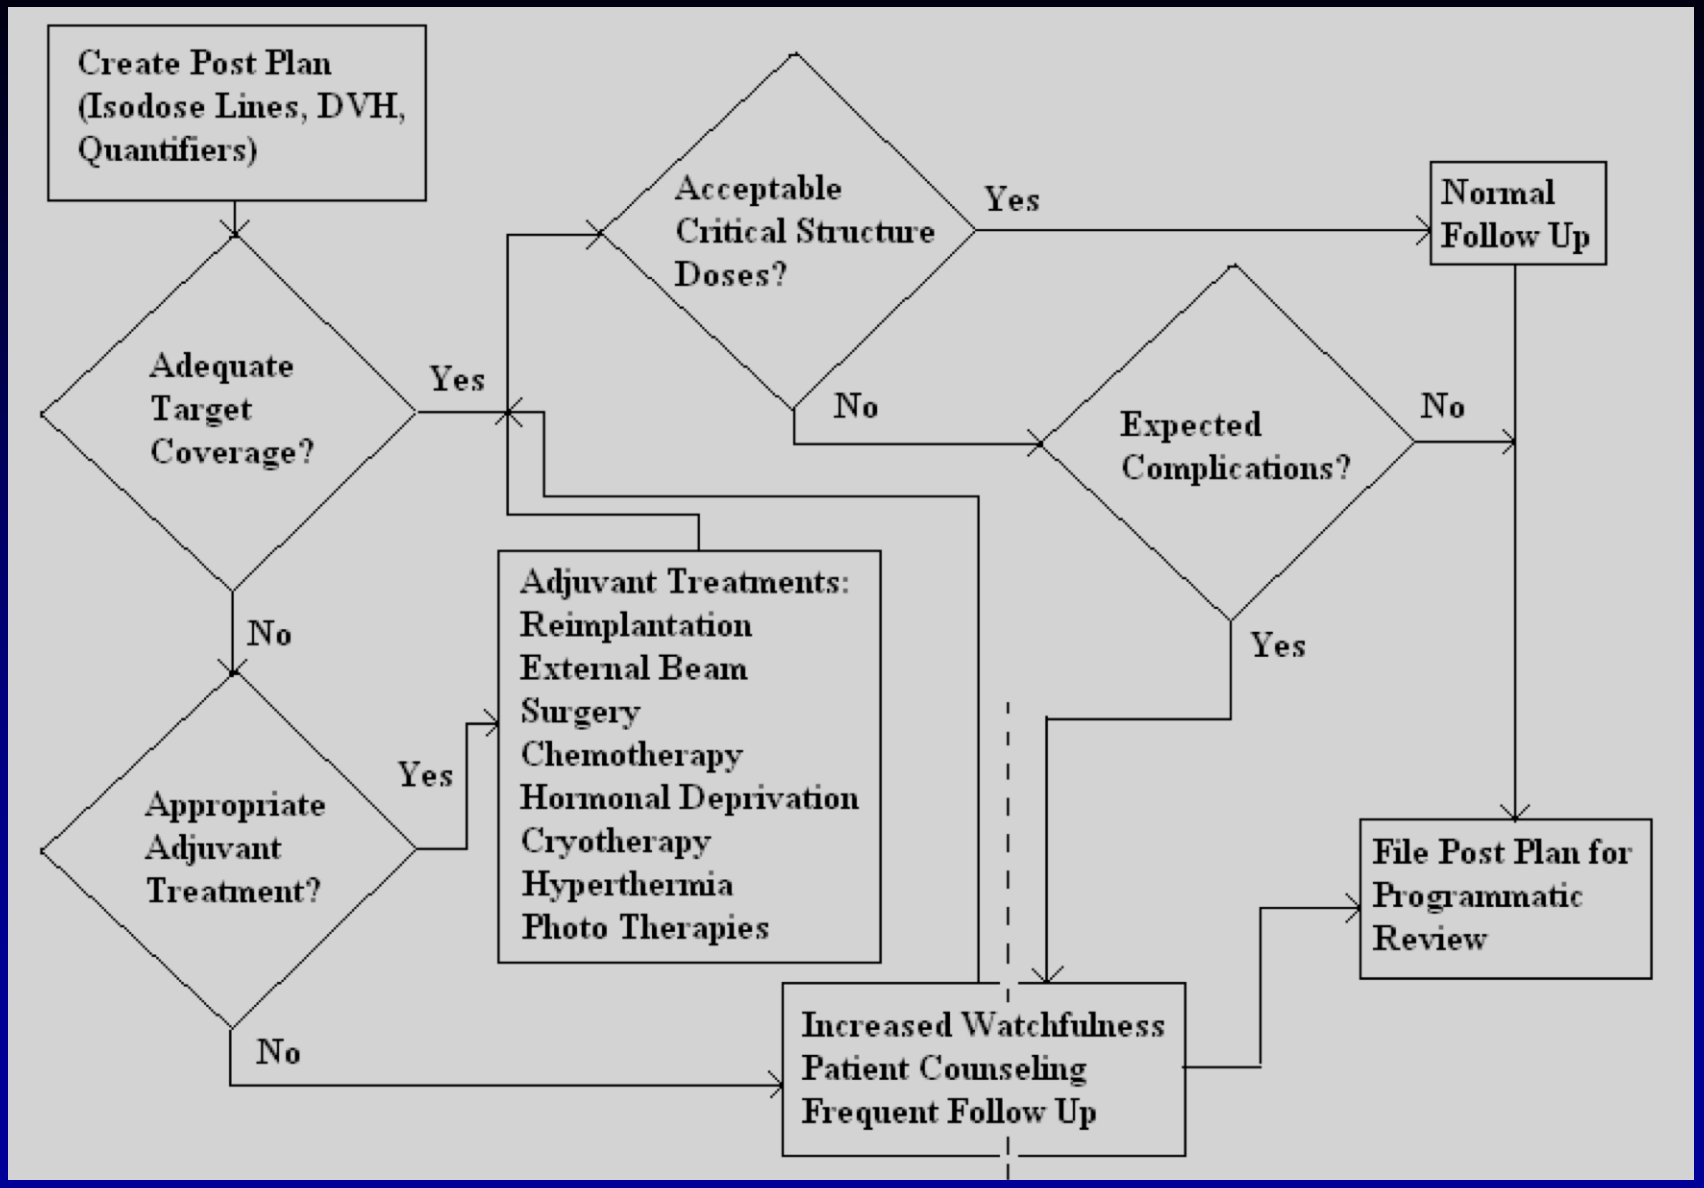
Individual Implant Assessment: Excessive dose to normal tissues

- Therapeutic intervention:
  - Almost always salvage rather than adjuvant (cross your fingers)
  - Hyperbaric oxygen to promote healing
  - Surgical intervention
- Increased vigilance
  - Patient awareness
  - Follow-up visits
  - Diagnostic procedures

Programmatic Improvement

- Technique evaluation
  - Planning
  - Delivery
    - OR methods (Example: patient alignment)
    - Brachytherapist
- Equipment evaluation
  - Delivery systems
    - Example: Loose seeds / Mick applicator
    - Example: Loose / stranded seeds
  - Broken on maladjusted equipment





Create Post Plan (Isodose Lines, DVH, Quantifiers)
Adequate Target Coverage?
Yes
No
Appropriate Adjuvant Treatment?
Yes
No
Adjuvant Treatments:
Reimplantation
External Beam
Surgery
Chemotherapy
Hormonal Deprivation
Cryotherapy

Score	0.2
Stage	0.9

R. G. Stock *et al* 1998

Customized dose prescription for permanent prostate brachytherapy: insights from a multicenter analysis of dosimetry outcomes.

Stone NN, Potters L, Davis BJ, Ciezki JP, Zelefsky MJ, Roach M, Fearn PA, Kattan MW, Stock RG

- 6 centers – 3928 PB patients with post-implant dosimetry results
- Stratification in low- (2188), intermediate (n=1188) and high (n=522) risk groups

AND

- Into 3 BED groups:
  - < 140 Gy (n = 524)
  - 140-200 Gy (n = 2284)
  - >200 Gy (n = 1115)

Int J Radiat Oncol Biol Phys. 2007 Dec 1;69(5):1472-7

- The corresponding bFFF rate for the low-risk patients by dose group was **85.2%, and 88.1% and 88.3%** for the low-, intermediate, and high-dose group, respectively (p <0.0001).
- The corresponding bFFF rate for the intermediate-risk patients by dose group was 77.7%, and 94.3% and 88.8% for the low-, intermediate-, and high-dose group, respectively (p < 0.0001).
- The corresponding bFFF rate for high-risk patients by dose group was 53.2%, 90% and 69.6% for the low-, intermediate-, and high-dose group, respectively (p < 0.0001).

These data suggest that PB-dose prescriptions can be customized to risk status. In low-risk patients, achieving a BED of >or=140 Gy might be adequate for prostate-specific antigen control.

However, high-risk disease might require a BED dose of >or=200 Gy.

ASTRO 2009 , Abstract 2974:

The Mount Sinaï experience ; 1072 patients: 10 years RFS

- D90 < 120 Gy ; 42 %
- D90 120-140 Gy ; 74 %
- D90 140-160 Gy ; 82 %
- D90 160-180 Gy ; 87 %
- D90 > 180 Gy ; 89 %

RADIATION DOSE PREDICTS FOR BIOCHEMICAL CONTROL IN INTERMEDIATE-RISK PROSTATE CANCER PATIENTS TREATED WITH LOW-DOSE-RATE BRACHYTHERAPY

CONCLUSION: A predictive model for a postimplant nomogram for prostate cancer recurrence at 9-years after PPB has been developed and validated from a large multi-institutional database.

This study also demonstrates the significance of implant dosimetry for predicting outcome.

International Journal of Radiation Oncology, Biology, Physics, 2010, Vol.76(4), pp.1061-1065

NATURAL HISTORY OF CLINICALLY STAGED LOW- AND INTERMEDIATE-RISK PROSTATE CANCER TREATED WITH MONOTHERAPEUTIC PERMANENT INTERSTITIAL BRACHYTHERAPY

AL V. TAIRA, M.D.,* GREGORY S. MERRICK, M.D.,† ROBERT W. GALBREATH, PH.D.,† KENT E. WALLNER, M.D.,‡ AND WAYNE M. BUTLER, PH.D.†

*Department of Radiation Oncology, University of Washington, Seattle, WA; †Schiffler Cancer Center and Wheeling Jesuit University, Wheeling, WV; and ‡Puget Sound Healthcare Corporation, Group Health Cooperative, University of Washington, Seattle, WA

RESULTS: ….The bPFS rate was

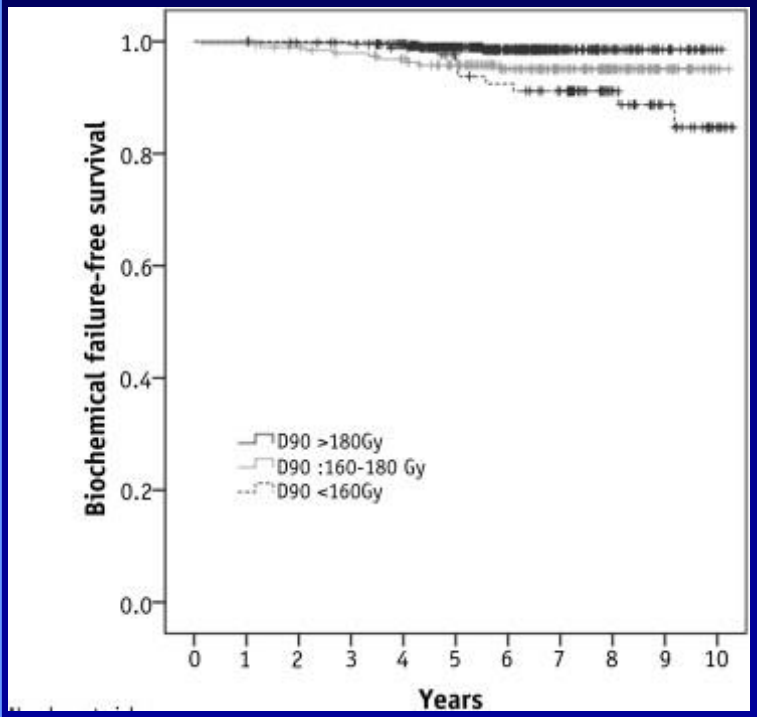
98.8% for low-risk patients with high-quality implants
versus
92.1% for those with less adequate implants ($p < 0.01$)

98.3% for intermediate-risk patients with high-quality implants
versus
86.4% for those with less adequate implants ($p < 0.01$).

International Journal of Radiation Oncology, Biology, Physics, 2010, Vol.76(2), pp.349-354

A Dose—Response Analysis of Biochemical Control Outcomes After ^{125}I Monotherapy for Patients With Favorable-Risk Prostate Cancer

Yutaka Shiraishi, MD, PhD,*,† Atsunori Yorozu, MD, PhD,† Toshio Ohashi, MD, PhD,* Kazuhito Toya, MD, PhD,† Shiro Saito, MD, PhD,‡ Toru Nishiyama, MD, PhD,‡ Yasuto Yagi, MD, PhD,‡ and Naoyuki Shigematsu, MD, PhD*



Improvements in BFFS rates were seen with increasing D90 levels. Day 30 D90 doses of 130 to 180 Gy were found to serve as cutoff levels.

For low-risk and low-tier intermediate-risk prostate cancer patients, high prostate D90s, even with doses exceeding 180 Gy, achieve better treatment results and are feasible.

International Journal of Radiation Oncology, Biology, Physics, 2014, Vol.90(5), pp.1069-1075

When I disagree with a rational man, I let reality be our final arbiter; if I am right, he will learn; if I am wrong, I will; one of us will win, but both will profit.

EVALUATION OF DOSIMETRIC PARAMETERS AND DISEASE RESPONSE AFTER ^{125}IODINE TRANSPERINEAL BRACHYTHERAPY FOR LOW- AND INTERMEDIATE-RISK PROSTATE CANCER

W. James Morris, M.D.,* Mira Keyes, M.D.,* David Palma, M.D.,* Michael McKenzie, M.D.,* Ingrid Spadinger, Ph.D.,* Alex Agranovich, M.D.,† Tom Pickles, M.D.,* Mitchell Liu, M.D.,† Winkle Kwan, M.D.,† Jonn Wu, M.D.,* Vince Lapointe, B.Sc.,* Eric Berthelet, M.D.,‡ Howard Pai, M.D.,‡ Robert Harrison, Ph.D.,* William Kwa, Ph.D.,* Joe Bucci, M.D.,§ Violet Racz, R.T.T.,* and Ryan Woods, Ph.D.‖

In contrast to some previous studies, dosimetric outcomes did not correlate with biochemical recurrence in the first 1,006 patients treated with 125I prostate brachytherapy at the British Columbia Cancer Agency.

International Journal of Radiation Oncology, Biology, Physics, 2009, Vol.73(5), pp.1432-1438

The correlation between annular treatment margins and biochemical failure in prostate brachytherapy patients with optimized intraprostatic dosimetry

Nathan Bittner, Gregory S. Merrick, Wayne M. Butler, Zachariah A. Allen, Brittany White, Ashley Adamovich, Kent E. Wallner

- …The D(90) and V(100) at the anterior, posterior, superior, inferior, right lateral, and left lateral aspects of the annulus were not statistically different between biochemically controlled and failed groups
- In this study, there was no relationship observed between annular dosimetry and biochemical control.

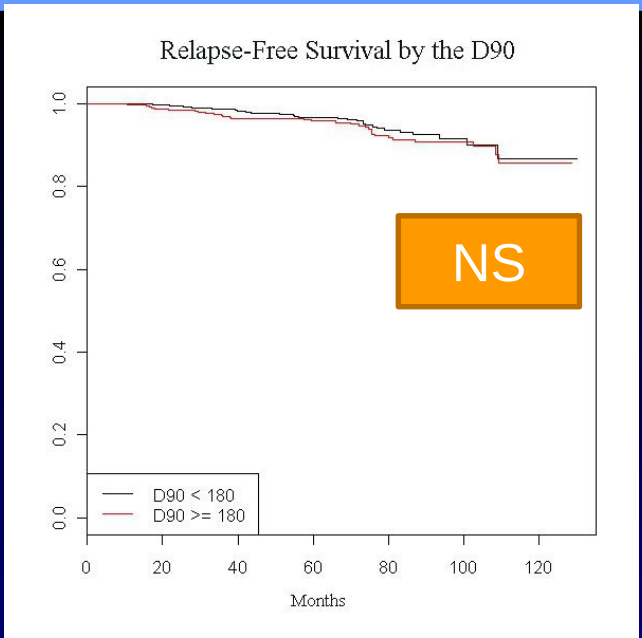
Evaluation of radiobiologic biochemical control in a large permanent prostate brachytherapy population from a single institution using AAPM TG-137 parameters.

Butler WM[1], Stewart RR, Merrick GS.

- There was no significant difference in BED between biochemical failures and nonfailures
- In a large prostate implant population, dosimetric and derived radiobiologic parameters did not predict for failure.
- Apparently, too few patients had total BEDs below the level necessary for optimum biochemical control.

Brachytherapy. 2011 Jan-Feb;10(1):16-28

ABS 2011: Wakil et al.
The Paris group experience



ABS 2011: Wilcox et al
The Dallas group experience

When tested for their association with PSA-RFS: D90,V100 and BED were not found to be statistically significant

Fig 2. Overall actuarial prostate-specific antigen (PSA) relapse-free survival (nadir+2) using a D90 threshold of 140 Gy as calculated from computed tomography post-implant dosimetry ($P < 0.01$) in cohort of 711 historic patients with post-implant dosimetry and a minimum follow-up of 5 years.

Clinical Oncology (2015)

Factors influencing the calculation of the D90

Post-implant dosimetry

Contouring

Seed reconstruction

- CT
- MRI

- CT

Fusion process

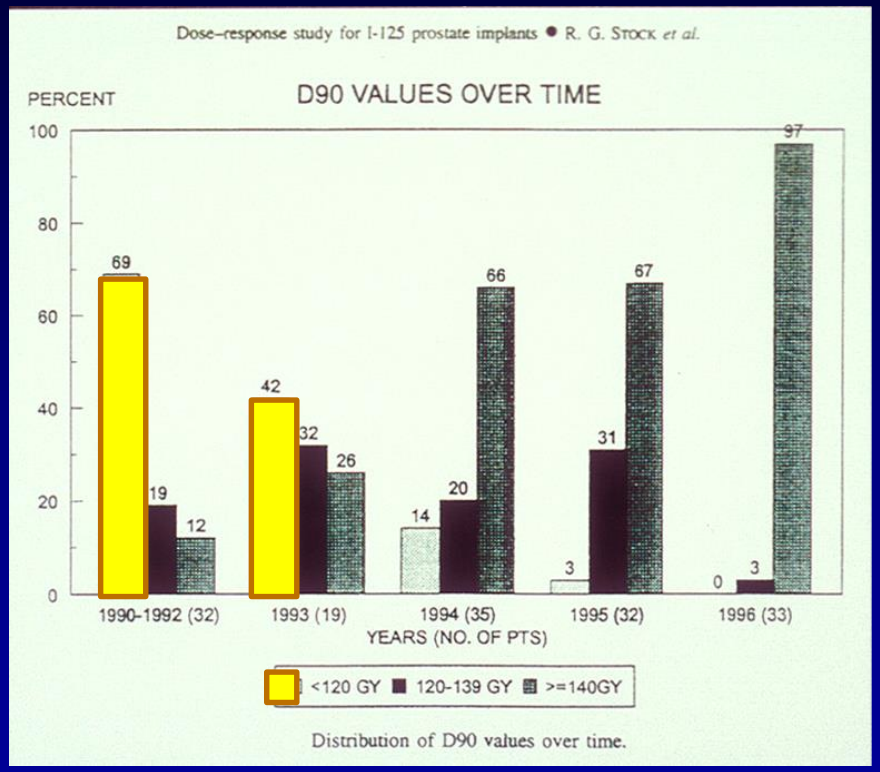
Prostate post-implant dosimetry: interobserver variability in seed localisation, contouring and fusion.
De Brabandere M, Hoskin P, Haustermans K, Van den Heuvel F, Siebert FA
Radiother Oncol. 2012 Aug;104(2):192-8.

Timing of post-implant evaluation is important

If too early: possible persistance of some oedema increasing the distance between seeds and thus leading to *decrease* the D90 !

Interpretation of the D90

To detect a role for D90 implies at least some variability of D90



Distribution of D90 values over time.

A number of D90 < 120 Gy before 1993 !!…

Series with a very homogeneous D90 can hardly detect a difference in DFS…

And actually, most « modern » published series presently show D90 with (often very) limited variations …

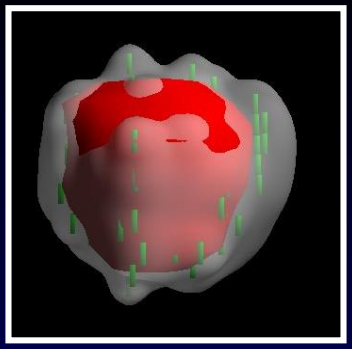
Where is the underdosage?



”Significant underdosage of the ASQ relative to other regions of the prostate <u>was not</u> predictive of relapse”

Quadrant dosimetry as a predictor of relapse in I^{125} prostate brachytherapy
Spadinger et al. ABS 2009 ; OR47

In contrast, a significant underdose at the apex (f.ex.), in a patient with an histological apex involvement on biopsies, must be taken into account …

What to do about a low D_{90} ?

Ask a few questions (and act if necessary):

1. How “low” is it ?
   - If < 120 Gy , maybe something should be done …
   - If between 120 and 145 Gy, maybe ***nothing*** should be done
2. Was it measured accurately ? (image modalities, contouring, time frame, …)
3. Where is the underdose ?
4. Where is the tumour ?

Low D 90 ….

According to the answers to the previous questions :

- Watch and wait ?
- Add external beam RT ?
- Add complementary seeds ?

Conclusions

Available data strongly suggest that ***there might be*** a dose-response relationship for permanent implant brachytherapy of prostate cancers.

- However, one cannot expect this relationship to be a very close one
- a large number of reasons may bias, or even totally hide, the relationship between dose and clinical issues
- The main reasons which may be responsible for such a blurring of the results are the following:
  - Variations in the prostate contours
  - Timing of the post-implant CT
  - The underdose location

BUT ALSO:

-Results given in terms of biochemical control (almost the rule); this biochemical control depends on local control (expected to be related to dose), but also on “distant” control (this essentially for high-risk patients), with no (or much less) relation to local dose (?)

-The percentage of patients receiving Androgen deprivation therapy (ADT). Large variations from one series to another may introduce a bias in biochemical control in some instances.

-The follow-up, which may be inadequate in some series.

-The narrow range in D90 in most of the modern series

-……..

Post-implant dosimetry :

Do it but do not overestimate it

Thank you

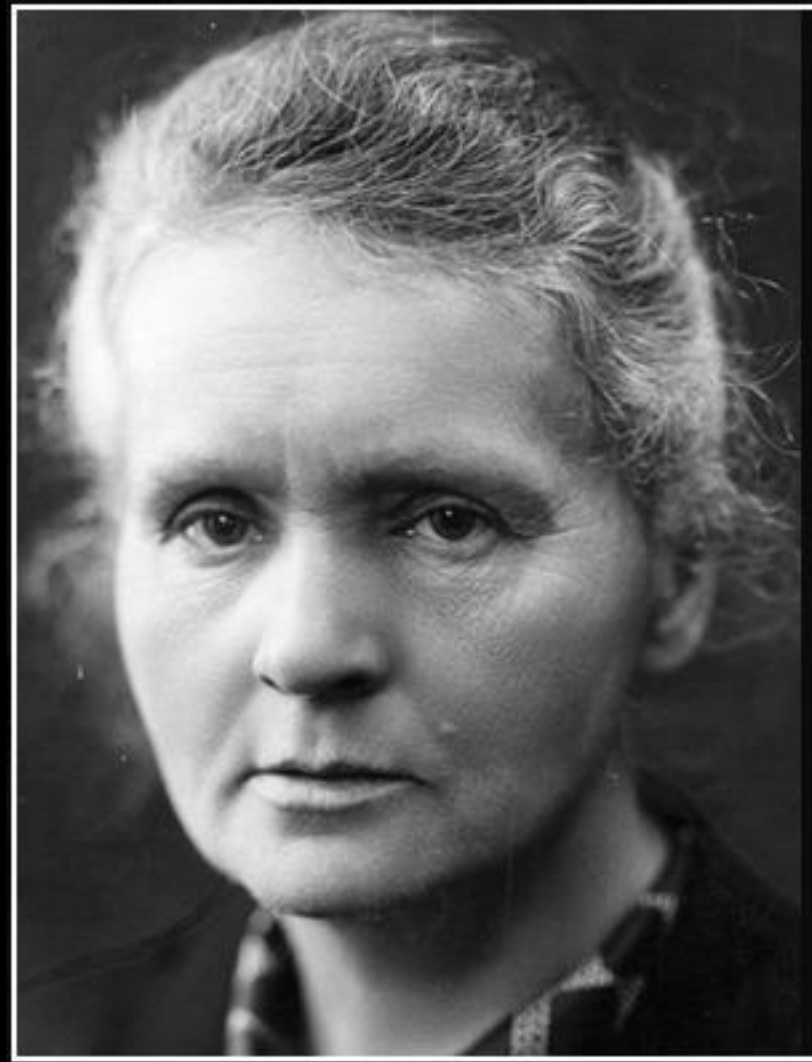
ESTRO Teaching Course
14th-16th June 2018



Nothing in life is to be feared, it is only to be understood. Now is the time to understand more, so that we may fear less.

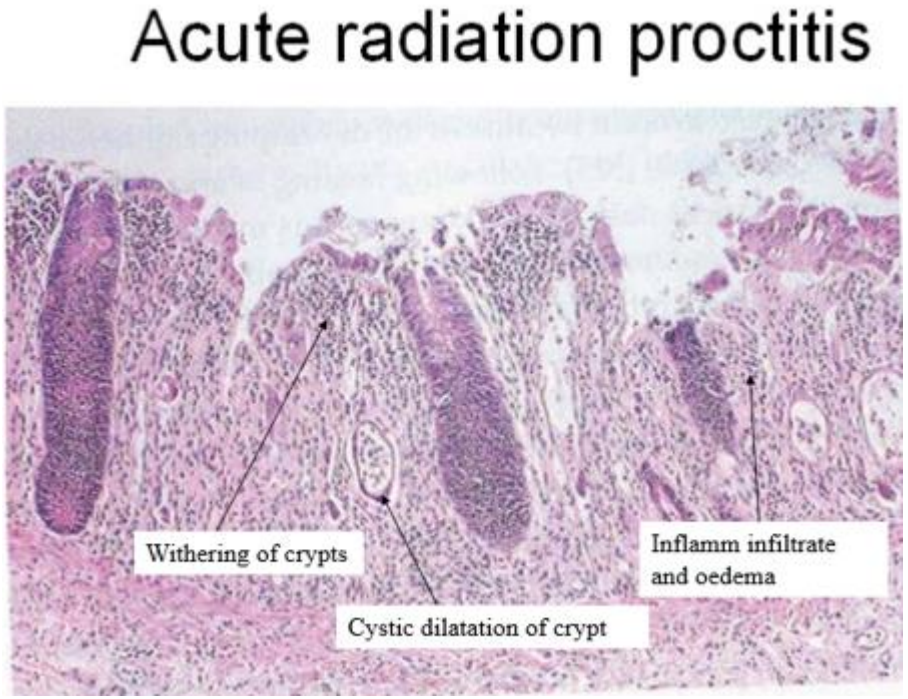
— Marie Curie —

Radiation proctitis - Acute

Pathophysiology

Histopathology findings

- Transient mucosal atrophy
- Submucosal oedema
- Inflammation and infiltration of the lamina propria with polymorphonuclear leukocytes and plasma cells
- In addition, mitotic arrest, karyorrhexis, and lysis of the crypt and deep epithelial cells



Radiation proctitis - **Acute**

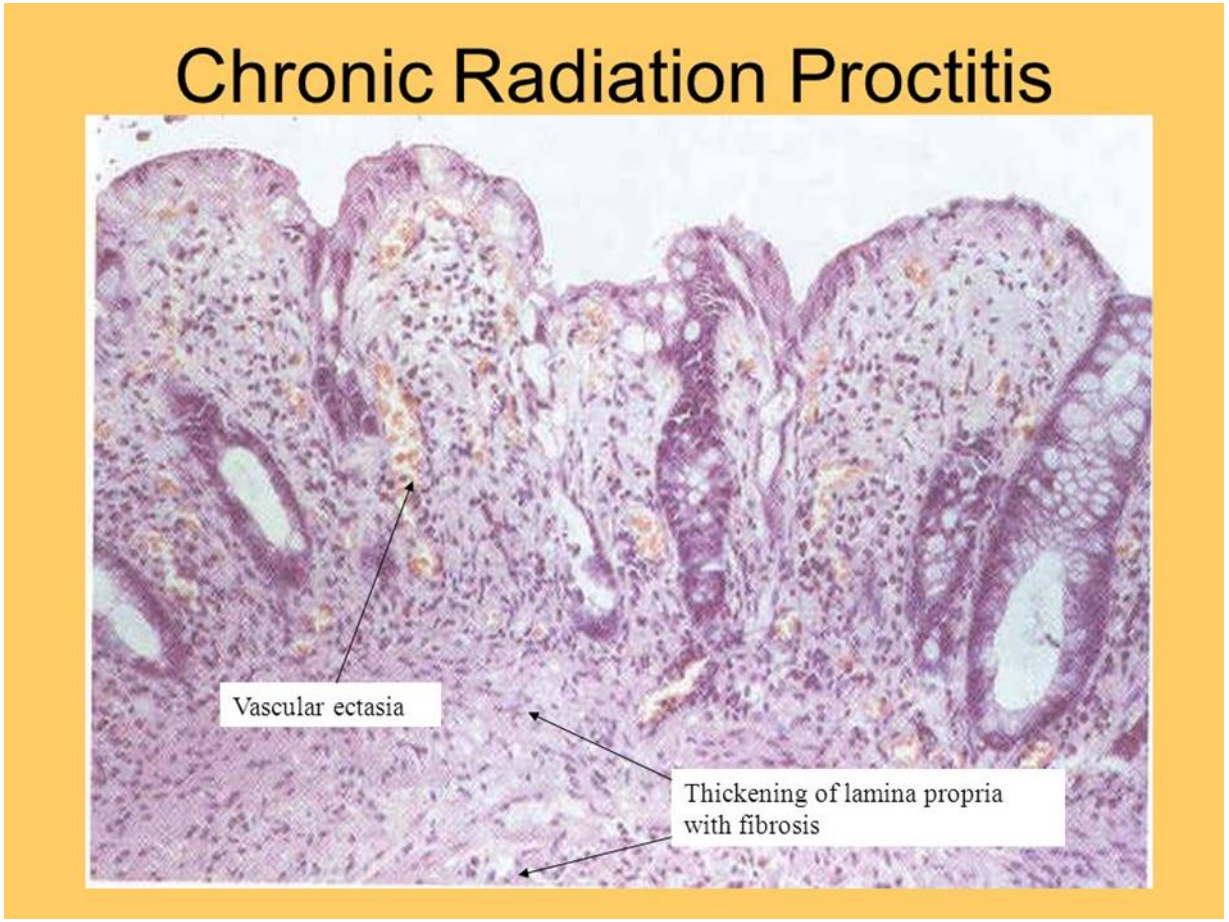
- If the submucosal damage is not prominent, the epithelial cells regenerate and the changes regress.
- Severe submucosal changes leads to progression of mucosal injury, ulcerations, and erosion of the villi.
- histologic findings in the acute phase correlate poorly with clinical symptoms.

Normal tissue effects and injury – **Acute effects** – LDR prostate brachytherapy – **rectal mucosa**

	Acute effects	symptoms	outcome	management
Rectal mucosa	Inflammation, oedema, hyperaemia, cellular loss with loss of epithelial integrity	• diarrhoea • tenesmus • mucoid discharge • haematochezia • anorectal pain • cramps	• Mostly self-limiting • Resolves spontaneously • Typically takes a few months • Does not generally convey risk of late complications	Reassurance Pharmacological • Antidiarrhoeals • Antispasmodics • laxatives • Dietary modification • Steroid enemas

Radiation proctitis - **Chronic**

- Repopulation of the mucosal cells occurs in the later stage of the acute phase
- The severity of the damage to supportive connective tissue limits the degree of reepithelialization
- Fibrosis of the underlying connective tissue causes patchy ischemia of the mucosa, which may cause ulceration
- Local trauma or infection often precipitates these ulcers



Radiation proctitis - **Chronic**

Histological findings

- obliterative endarteritis of the small vessels in the intestinal wall characterizes chronic radiation intestinal injury
- Associated lymphoid atrophy, lymphatic dilation, and fibrosis of the submucosal tissue are observed
- The progressive vascular sclerosis leads to chronic ischemia of the overlying tissue, ultimately resulting in mucosal atrophy
- Scar tissue replaces the submucosal tissue, resulting in further decrease in vascularity and contracture of the intestinal wall
- Chronic mucosal ulceration may result in fistula formation and hemorrhage

Rectal Morbidity

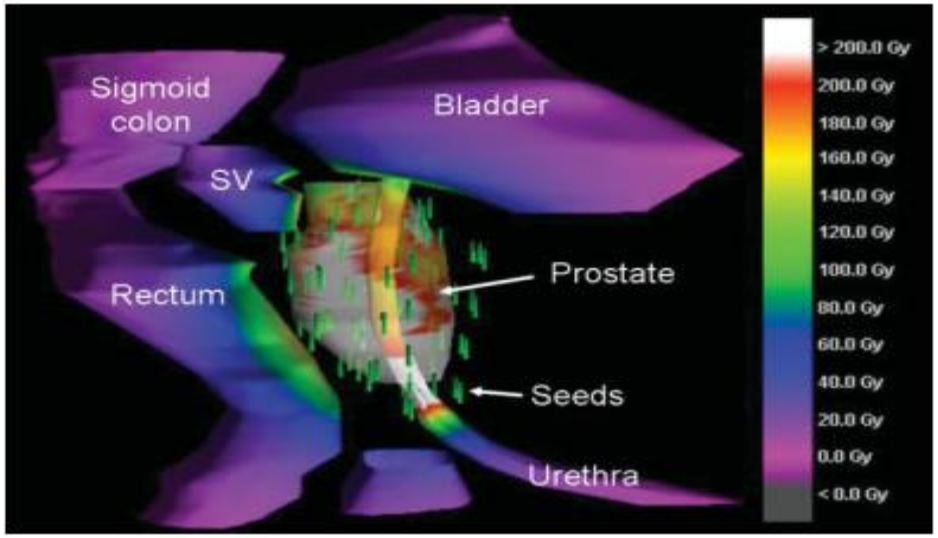


FIGURE 1. A typical 3-dimensional-rendered plan (lateral view) of a stranded seed implant. The close proximity of the anterior rectal makes it difficult to limit radiation dose to this area without compromising prostate dose coverage. Stranded seeds were used to maintain better seed spacing and alignment. SV indicates seminal vesicle; Gy, grays.

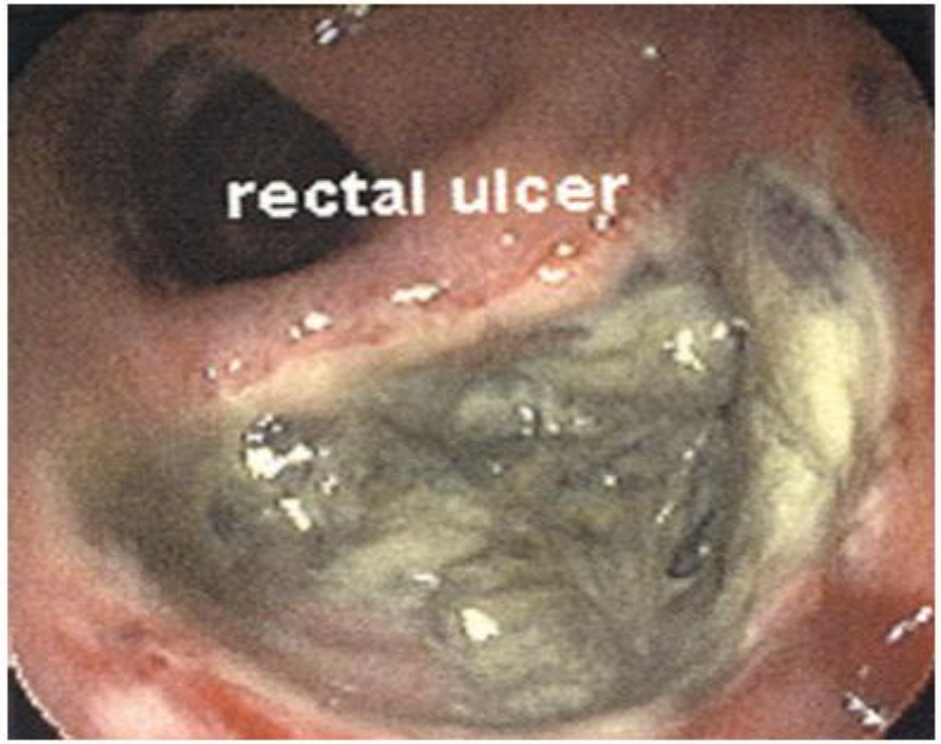

Classification of Rectal Morbidity

Table 1. Modified Radiation Therapy Oncology Group Rectal Toxicity Scale

Grade 1	Mild and self-limiting	Minimal, infrequent bleeding or clear mucous discharge, rectal discomfort not requiring analgesics, loose stools not requiring medications
Grade 2	Managed conservatively, lifestyle (performance status) not affected	Intermittent rectal bleeding not requiring regular use of pads, erythema of rectal lining on proctoscopy, diarrhea requiring medications
Grade 3	Severe, alters patient lifestyle	Rectal bleeding requiring regular use of pads and minor surgical intervention, rectal pain requiring narcotics, rectal ulceration
Grade 4	Life-threatening and disabling	Bowel obstruction, fistula formation, bleeding requiring hospitalization, surgical intervention required

RTOG indicates Radiation Therapy Oncology Group.

Cancer 2009;115:1827–39.

Rectal toxicity and rectal dosimetry in low-dose-rate iodine-125 permanent prostate implants: A long-term study in 1006 patients

Mira Keyes[1,*], Ingrid Spadinger[1], Mitchell Liu[1], Tom Pickles[1], Howard Pai[2], Amy Hayden[1], Veronika Moravan[1], Ross Halperin[3], Michael McKenzie[1], Winkle Kwan[4], Alexander Agranovic[4], Vince Lapointe[1], W. James Morris[1]

RESULTS: Rectal dosimetry in 93.5% and rectal toxicity in 96.2% have been recorded. Median VR_{100} = 1.05 cc. Late RTOG Grades 0, 1, 2, 3, and 4 were recorded in 68%, 23%, 7.3%, 0.9%, and 0.2% patients, respectively. On multivariate analysis, acute RTOG ≥2 rectal toxicity was associated with urinary retention ($p = 0.036$) and learning curve ($p = 0.015$); late RTOG ≥2 was associated with the presence of acute toxicity ($p = 0.0074$), higher VR_{100} ($p = 0.030$) and learning curve ($p = 0.027$).

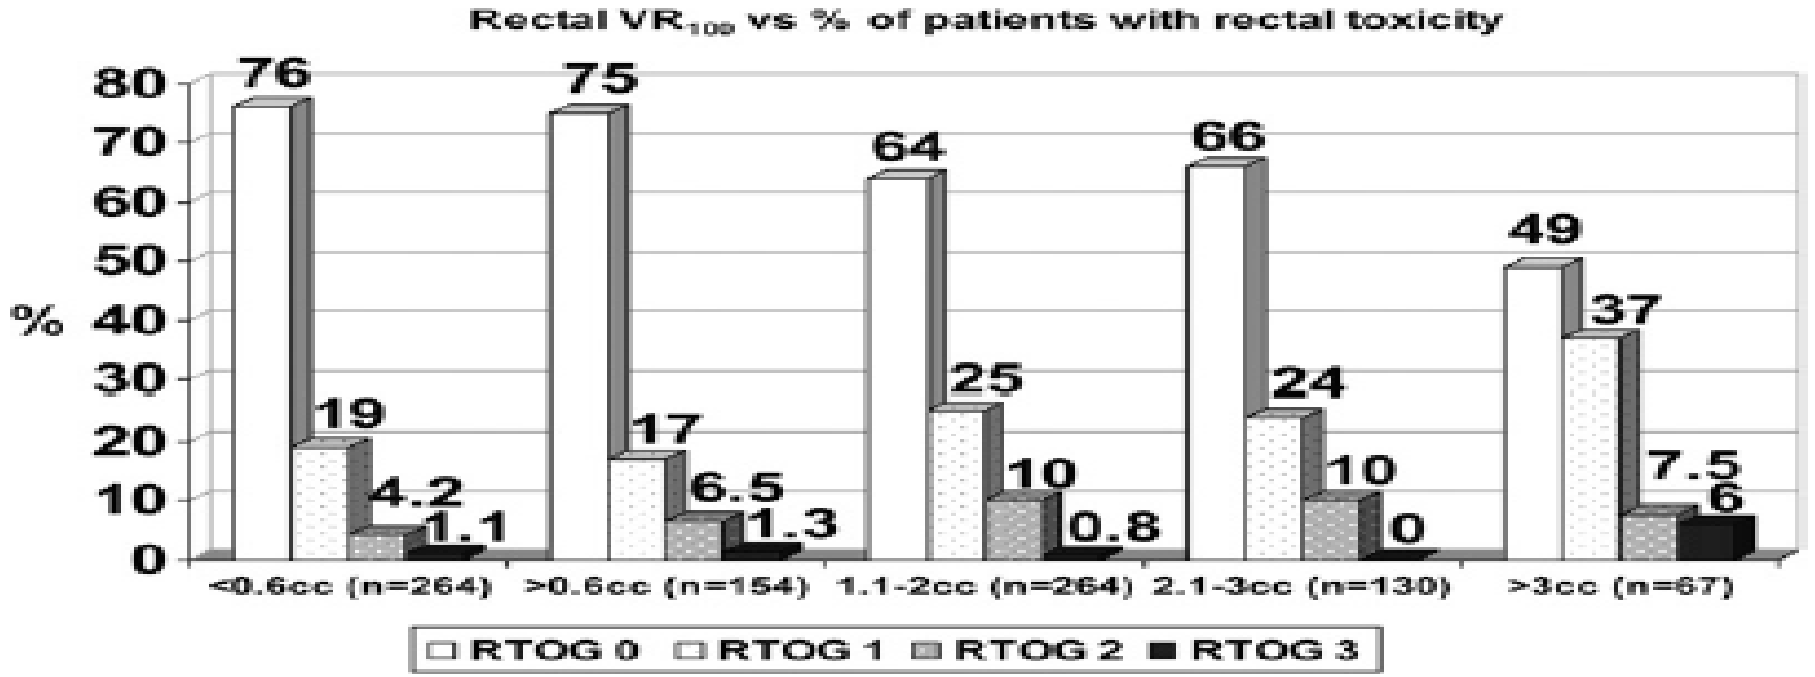

Fig. 1. Percentage of patients with late rectal toxicity by rectal V_{100cc}, patients with available toxicity data ($\geq$12 months followup) and available rectal dosimetry ($n = 879$). For each dose—volume histogram group, we gave number of patients and percentage of patients in the group with Radiation Therapy Oncology Group (RTOG) 0, 1, 2, and $\geq$3 toxicity. For patients with $VR_{100} \leq 3$ cc incidence of RTOG 3 is 0.8%. For those with $VR_{100} > 3$ cc, incidence of RTOG $\geq$3 is 6%.

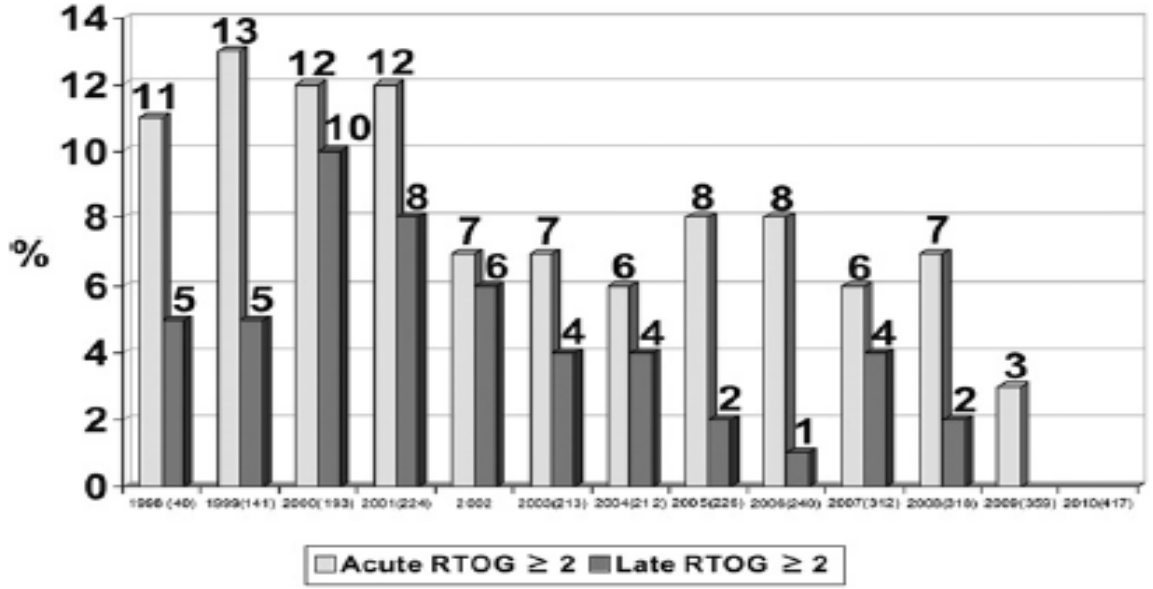

Fig. 3. Institutional crude Radiation Therapy Oncology Group ≥2 acute and late rectal toxicity, expressed as a percentage of patients wit toxicity recorded for each implant year 1998–2009.

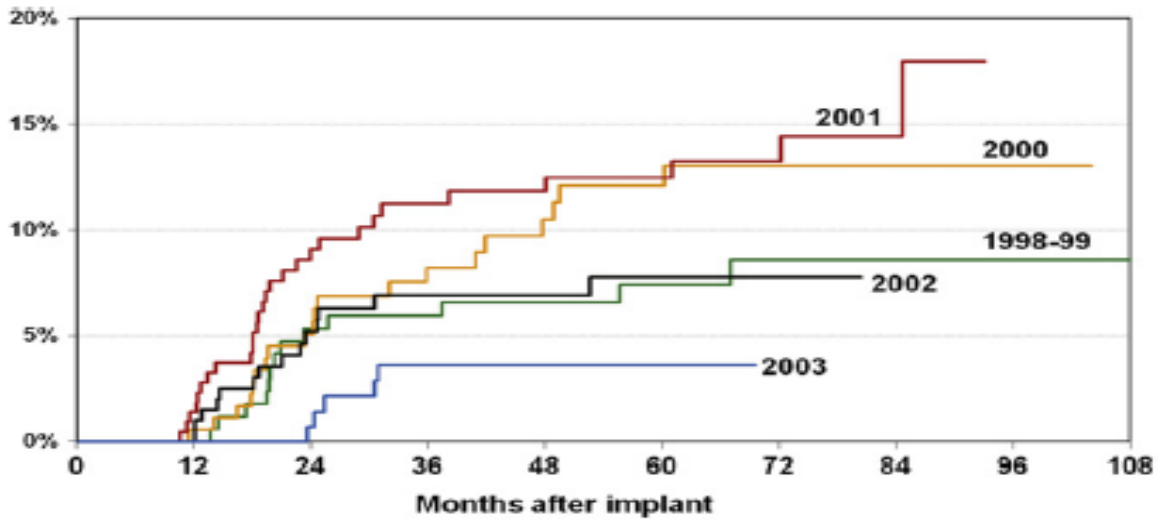

Fig. 2. Kaplan–Meier curves for late rectal Radiation Therapy Oncology Group ≥2, illustrating the institutional learning curve.

METHODS AND MATERIALS: The functional outcomes of patients treated with FBT at the base of the prostate were compared with those of patients treated with FBT at the apex. Urinary symptoms, continence, and erectile dysfunction were measured using the International Prostate Symptom Score (IPSS), International Continence Score (ICS), and International Index of Erectile Function (IIEF-5) questionnaires, respectively, at baseline and at 6, 12, and 24 months after treatment.

Brachytherapy 2017, in press

RESULTS: Twenty-eight and 13 patients were treated with FBT at the apex and the base, respectively, of the prostate. A significant difference between groups was found in the IPSS score at 6 months (mean IPSS: apex 6.4 ± 4.7, base 10.6 ± 5.7; $p = 0.02$), but not at baseline or at 12 and 24 months after treatment. On multivariate analysis, only FBT at the base of the prostate remained an independent predictor of worsening urinary symptoms (odds ratio, 5.8; $p = 0.04$).

CONCLUSIONS: At 6 months after FBT, significantly less urinary toxicity was found in patients who underwent FBT at the apex versus the base of the prostate. Continence and sexual side effects were minimal in all patients.

One-step customized transurethral resection of the prostate and permanent implant brachytherapy for selected prostate cancer patients: Technically feasible but too toxic

ABSTRACT

INTRODUCTION: Patients with prominent median lobe hyperplasia and/or high International Prostate Symptom Score (IPSS) are often contraindicated for prostate brachytherapy, mainly because of the risk of post-implant urinary retention. We evaluated an approach combining in the same operative step a limited transurethral resection (TURP) of the median lobe, immediately followed by permanent implant-free seed brachytherapy.

METHODS AND MATERIALS: From January 2007 to November 2008, 22 patients underwent a customized limited TURP of their median lobe immediately before brachytherapy. All patient fulfilled our criteria for permanent implant brachytherapy, but presented with a more or less prominent median lobe and/or a high IPSS.

RESULTS: The procedure appeared to be technically feasible, with only 0.3% of migrating seeds, a mean post-implant D90 of 173.4 Gy and a mean post-implant V100 of 96.6%. However, 5 patients (23%) experienced a urinary retention, with two patients having to undergo a complementary post-implant TURP. Moreover, urinary toxicity was more pronounced than in our current experience, with high IPSS at 2 months (mean 19.2) and 6 months (mean 15.8).

CONCLUSION: Although technically feasible, with relatively few migrating seeds and satisfactory post-implant dosimetric parameters, one-step TURP and brachytherapy was found to be poorly tolerated, with higher than usual urinary retention and urinary toxicity rates. Considering those results, our group is presently evaluating a two-step procedure, with a customized TURP followed after 4–6 months by brachytherapy.

Results: The LDR-PB boost increased the risk of needing temporary catheterization and/or requiring incontinence pads. At 5 years the cumulative incidence of grade 3 GU events was 18.4% for LDR-PB, versus 5.2% for DE-EBRT ($P<.001$). Compared with the cumulative incidence, the 5-year prevalence of grade 3 GU morbidity was substantially lower for both arms (8.6% vs 2.2%, $P=.058$). The 5-year cumulative incidence of grade 3 GI events was 8.1% for LDR-PB, versus 3.2% for DE-EBRT ($P=.124$). The 5-year prevalence of grade 3 GI toxicity was lower than the cumulative incidence for both arms (1.0% vs 2.2%, respectively). Among men reporting adequate baseline erections, 45% of LDR-PB patients reported similar erectile function at 5 years, versus 37% after DE-EBRT ($P=.30$).

Secondary malignancy after prostate radiation

Rectal cancer RR compared to RP (SEER database – *Nieder et al - 2008*)

- RP - 1.0
- EBXRT – 1.26
- BT – 1.08
- BT + EBXRT – 1.21

Bladder cancer – more common than rectal cancer - RR 1.5

Secondary malignancy after prostate radiation

Second malignancies after prostate brachytherapy: Incidence of bladder and colorectal cancers in patients with 15 years of potential follow-up

Stanley L. Liauw, M.D., John E. Sylvester, M.D., Christopher G. Morris, M.S., John C. Blasko, M.D., Peter D. Grimm, D.O.

- *Liauw et al* reported a 4.3% incidence in second cancers at 15 years after BT (n=125) or BT + EBXRT (n=223)
- **bladder 3.1%**
- **colorectal 0.8%**

Absolute excess risk 35 per 10 000 treated patients

Secondary malignancy after prostate radiation

Consistent direct causal correlation difficult to quantify

CaP conveys increased risk of developing second malignancy regardless of treatment

Guideline for the Management of Clinically Localized Prostate Cancer: 2007 Update

Eur Urol in press, 2017

Background: Evaluation of treatment options for localized prostate cancer (PCa) remains among the highest priorities for comparative effectiveness research. Surgery and radiotherapy (RT) are the two interventions most commonly used.
Objective: To provide a critical narrative review of evidence of the comparative effectiveness and harms of surgery and RT in the treatment of localized PCa.
Evidence acquisition: A collaborative critical narrative review of the literature was conducted.

Table 2 – Key studies examining functional outcomes for treatment of localized prostate cancer with radiotherapy and radical prostatectomy

	Study			
	Hamdy [17]	Lennernas [21]	Gilberti [37]	Resnick [42]
Study design	Randomized controlled trial	Randomized controlled trial	Randomized controlled trial	Observational cohort study
Exposures	RP vs EBRT + ADT	RP vs EBRT + BT boost + ADT	RP vs BT	RP vs EBRT
Sample size	1098	89	174	1655
Findings				
Global HRQoL	Equivalent	Equivalent	Equivalent	-
Incontinence	Greater in RP	Equivalent	Equivalent	Greater in RP at 2/5 yr Equivalent at 15 yr
Erectile dysfunction	Greater in RP	Equivalent	Greater in RP (short term) Equivalent (long term)	Greater in RP at 2/5 yr Equivalent at 15 yr
Bowel symptoms	Greater in RT	Equivalent	Greater in RT (short term) Equivalent (long term)	Greater in RT at 2/5 yr Equivalent at 15 yr
Obstructive urinary symptoms	Greater in RT	Equivalent	Greater in RT (short term) Equivalent (long term)	

EBRT = external beam radiotherapy; BT = brachytherapy; ADT = androgen deprivation therapy; RP = radical prostatectomy; RT = radiotherapy; HRQoL = health-related quality of life.

Table 3 – Comparison of key outcomes following radical prostatectomy and radiotherapy in the treatment of locali stratified by evidentiary study design

Outcome	Randomized controlled trials		Observational cohort studies	
	Evidence	Caveats	Evidence	
Survival	No difference	Underpowered and over-representation of low-risk patients	Significantly better overall and prostate cancer–specific survival for patients treated with surgery	Residual c design un baseline d
Global HRQoL	No difference	–	No difference	Residual c
Urinary function	Conflicting evidence: probably no long-term differences	–	Greater incontinence early after surgery and greater urinary bother after RT; no differences long term	Residual c
Erectile function	Conflicting evidence: probably no long-term differences	–	Worse erectile function early after surgery; no difference long term	Residual c
Bowel function	Worse after RT	–	Worse bowel function early after RT; no difference long term	Residual c
Other complications	No data		Higher risk of urologic and rectal-anal procedures, major surgeries, and hospitalization to manage treatment-related effects after RT	Residual c
Secondary malignancies	No data		Higher risk of bladder, rectal, and colorectal cancer after RT	Despite si small abs confoundi

Summary

- Long-term morbidity rate is low. (LoE: III)
- Technical advances improve tumor control and lower toxicity.
- Careful patient selection is important to avoid unacceptable morbidity
- Urgent need for prospective trials to investigate on medical approaches to the treatment of morbidity.

“You must never be fearful about what you are doing when it is right.”

-Marie Curie

ESTRO School

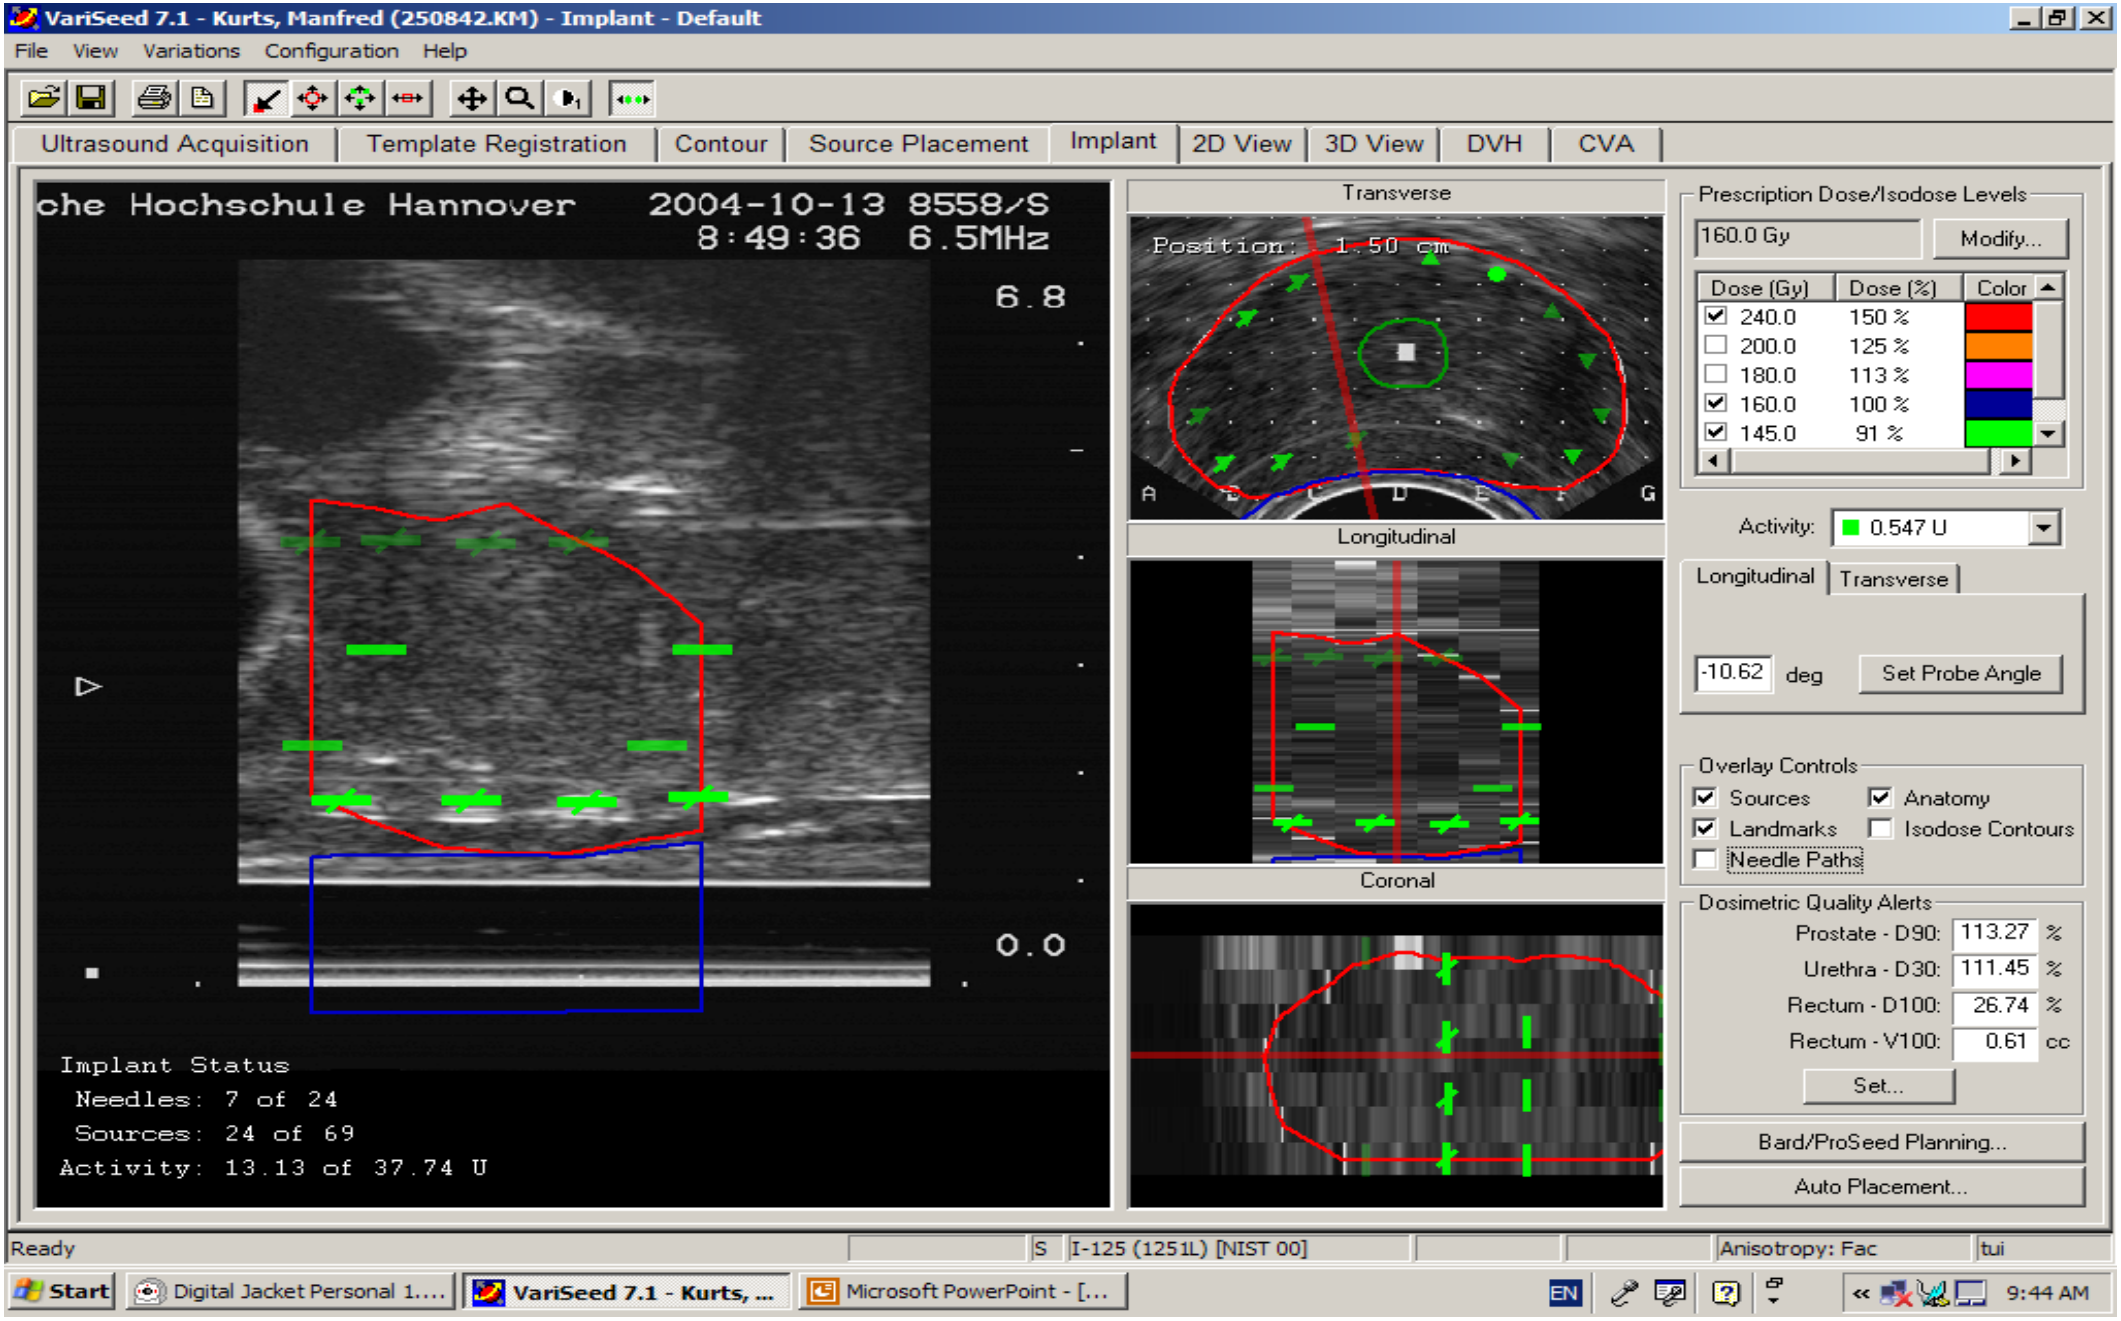
Summary of first presentation

- **Long-term morbidity rate is low. (LoE: III)**
- **Technical advances improve tumor control and lower toxicity.**
- **Careful patient selection is important to avoid unacceptable morbidity.**
- **Urgent need for prospective trials to investigate on medical approaches to the treatment of morbidity.**

Reduction of rectal morbidity

- **Limiting the anterior maximal mucosal dose to 120% mPD.**
- **Limiting the length of the rectal mucosa receiving 100-120% mPD to 10 and 5mm.**
- **Avoid constipation.**



ESTRO School

- **Moving seeds from 5mm to 3mm from the edge increases maximum rectal dose by 17%.**

- **Posterior seeds 3mm from edge:**

  - 1mm margin: 187±6Gy; ≤ 1% (max. rectal dose; % late rectal toxicity)

  - 2mm margin: 222±8Gy; ≤ 2%

  - 3mm margin: 257±11Gy; ≤ 3%

  -4 mm margin: 292±14Gy; ≤ 5%

  -5mm margin: 327 ±17Gy; ≤ 7%

[Waterman et al.; Int J Radiat Oncol Biol Phys, 2003]

Reduction of rectal morbidity

- **3/3 (1455) patients with recto-urethral fistulas had undergone endoscopy and low rectal biopsy.**

[Shakespeare et al., May 9(4):328-331, 2007

Reduction of rectal morbidity

- **Biopsies of the anterior rectal wall should be avoided !!!**
- **Injection of hyaluronic acid into the anterior rectal wall in the end of procedure.**

Treatment of rectal complications

- **Calm the patient! Expectative management as long as possible.**
- **Local application of corticosteroides.**
- **Protective AP in case of fistulas.**

Type of Therapy	Proposed Mechanism	Summary
Medical therapies		Historically used as first-line therapy with mixed results; few randomized trials available; HBOT appears to be effective
5-Aminosalicylic acid	Anti-inflammatory	
Sucralfate	Anti-inflammatory	
Steroid enemas	Anti-inflammatory	
Short-chain fatty acid enemas	Promote healing	
HBOT	Promote healing	
Endoscopic therapies		More effective than medical therapies but associated with higher rectal complication rate; APC is preferred over laser coagulation
Topical formalin	Chemical cauterization	
Heater and bipolar cautery	Thermoelectric cauterization	
Nd:YAG and KTP laser	Noncontact electrocoagulation	
Argon plasma coagulation	Noncontact electrocoagulation	
Surgical therapies		High risk of postoperative morbidity, reserved for severe rectal strictures and rectal fistulas
Proctectomy		
Diverting colostomy		

Phan et al., Cancer 115:1827-1839, 2009

ESTRO School

Table 4. Literature Review of Endoscopic Therapies

Therapy	No. of Studies	Results	No. of Sessions Needed	Complications	Study(s)
Topical formalin	5	Initial response rate, 59%-100%; PR rate at 1 y, 19%-38%	1-3	Rectal strictures, <1%; perianal ulcers fissures, 5%	Wilson & Rex 2006,[65] Mathai & Seow-Chen 1995,[67] Seow-Chen 1993,[68] Saclarides 1996,[69] Biswal 1995,[70] Counter 1999,[71] Roche 1996,[72] Yegappan 1998[73]
Heater and bipolar probe	2	Response rate, 100%	1-4	None	Fuentes 1993,[75] Davila 1996[76]
Nd:YAG and KTP laser	5	Response rate at 1-3 y, 75%-90%	2-5	Ileus, pain, 1%-5%; rectal fistula, <1%	Taylor 1993,[78] Buchi 1991,[80] Buchi & Dixon 1987,[82] Chapuis 1996,[83] Taylor 2000[84]
Argon plasma coagulation	5	Response rate at 1-2 y, 90%-100%	2-3	Rectal strictures, 2%	Tam 2000,[88] Silva 1999,[89] Fantin 1999,[90] Sebastian 2004,[91] Rotondano 2003[93]

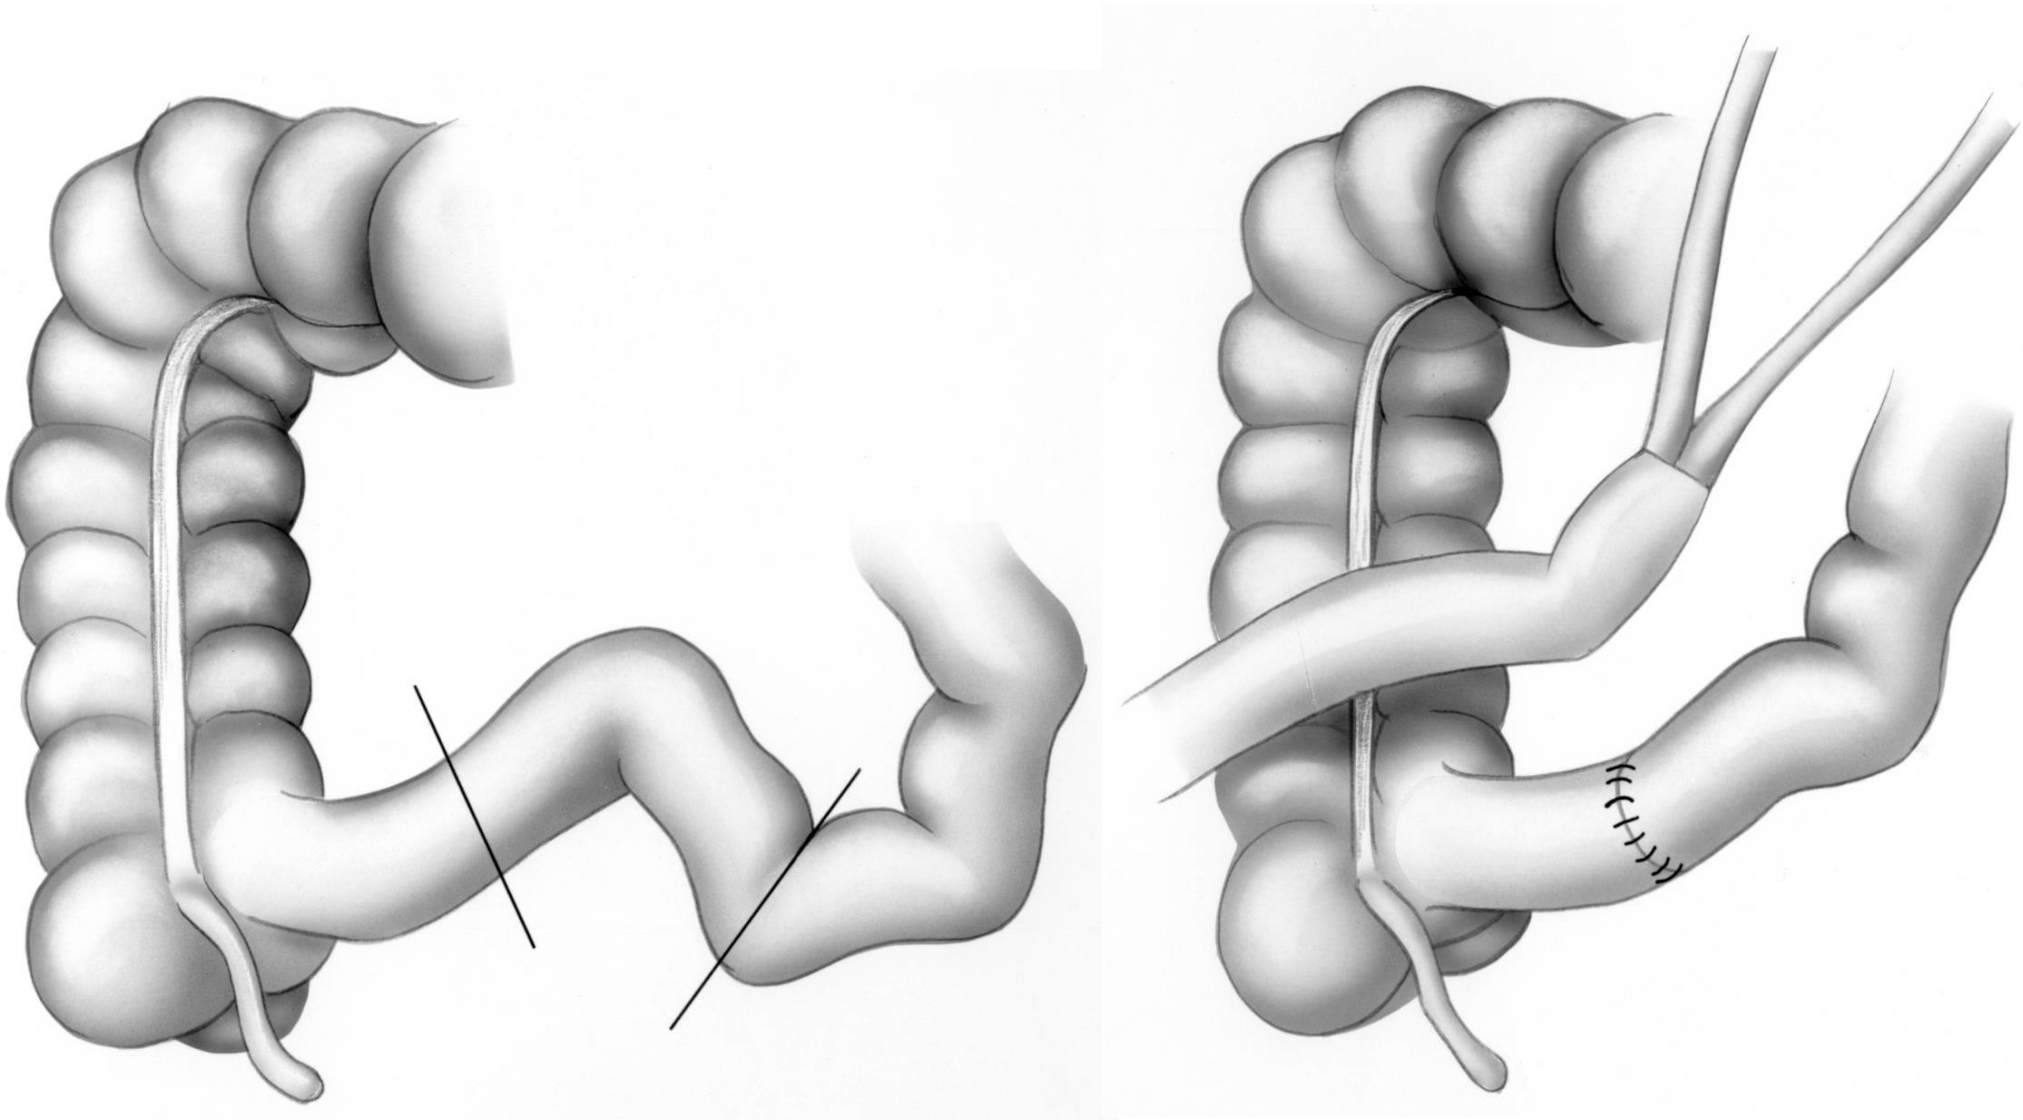
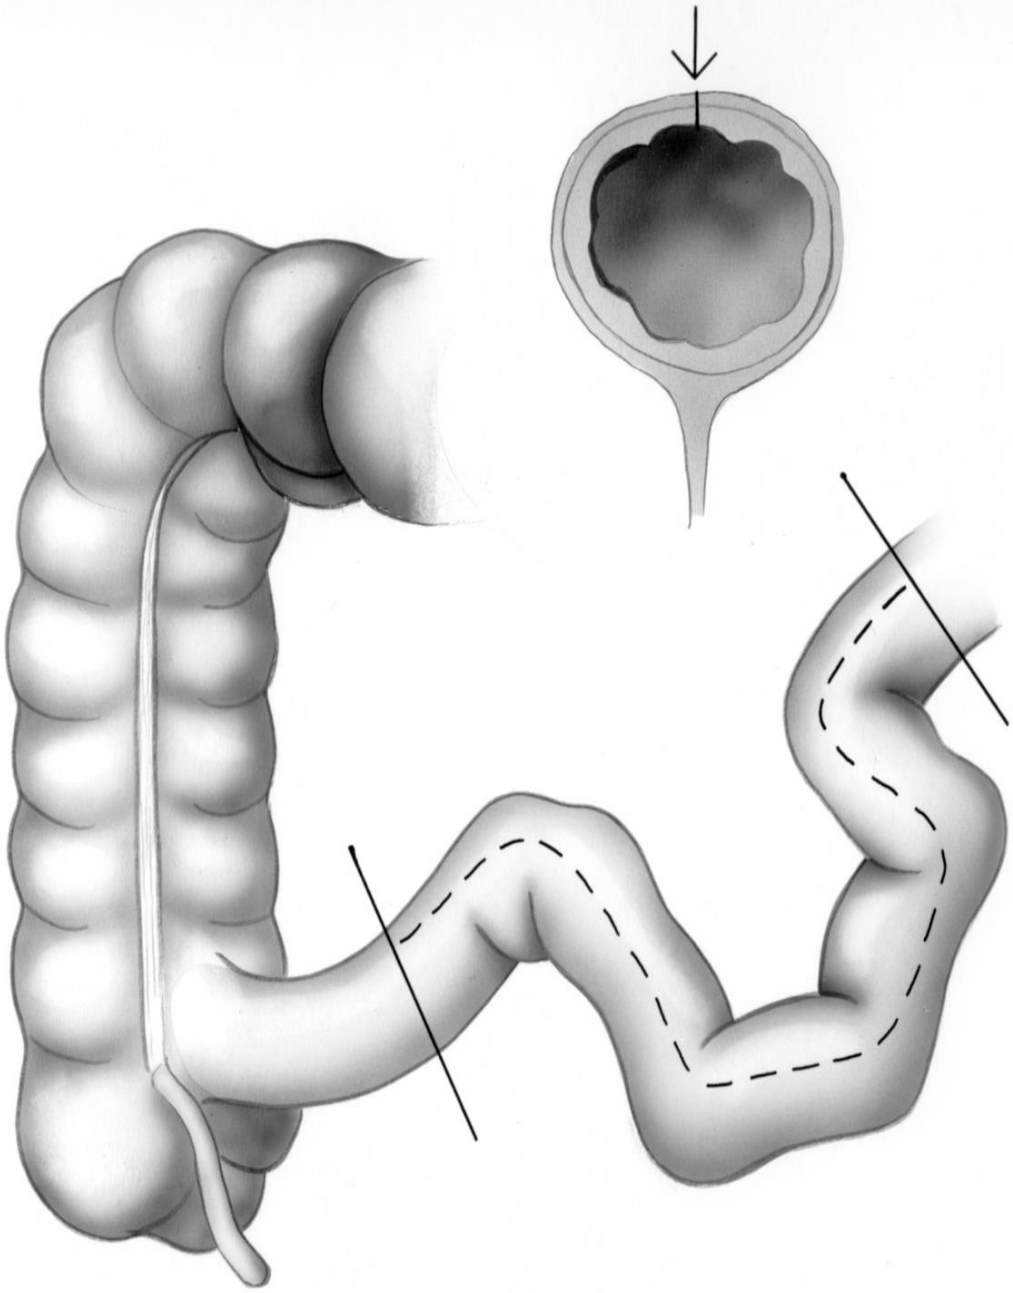
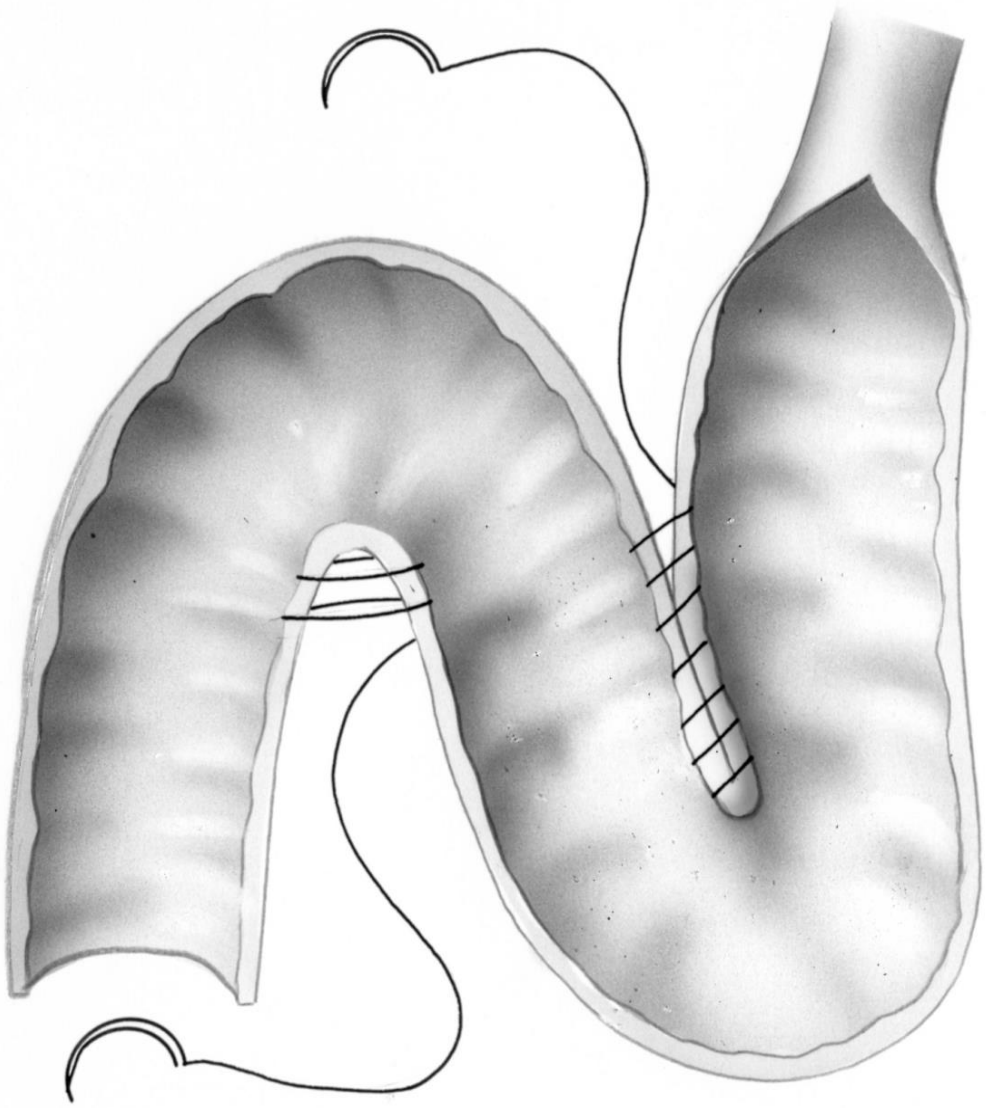
Treatment of rectal complications

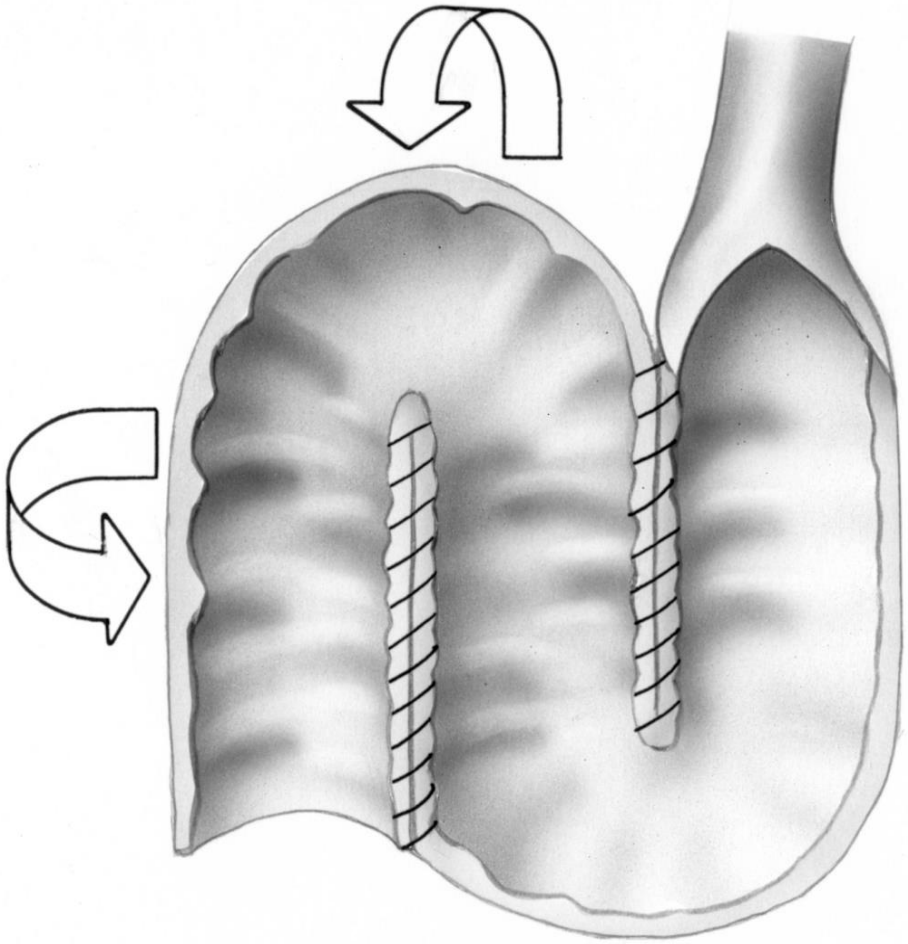
- **Plastic reconstruction of the rectal wall with gracilis muscle.**
- **Radical operation with construction of neobladder.**

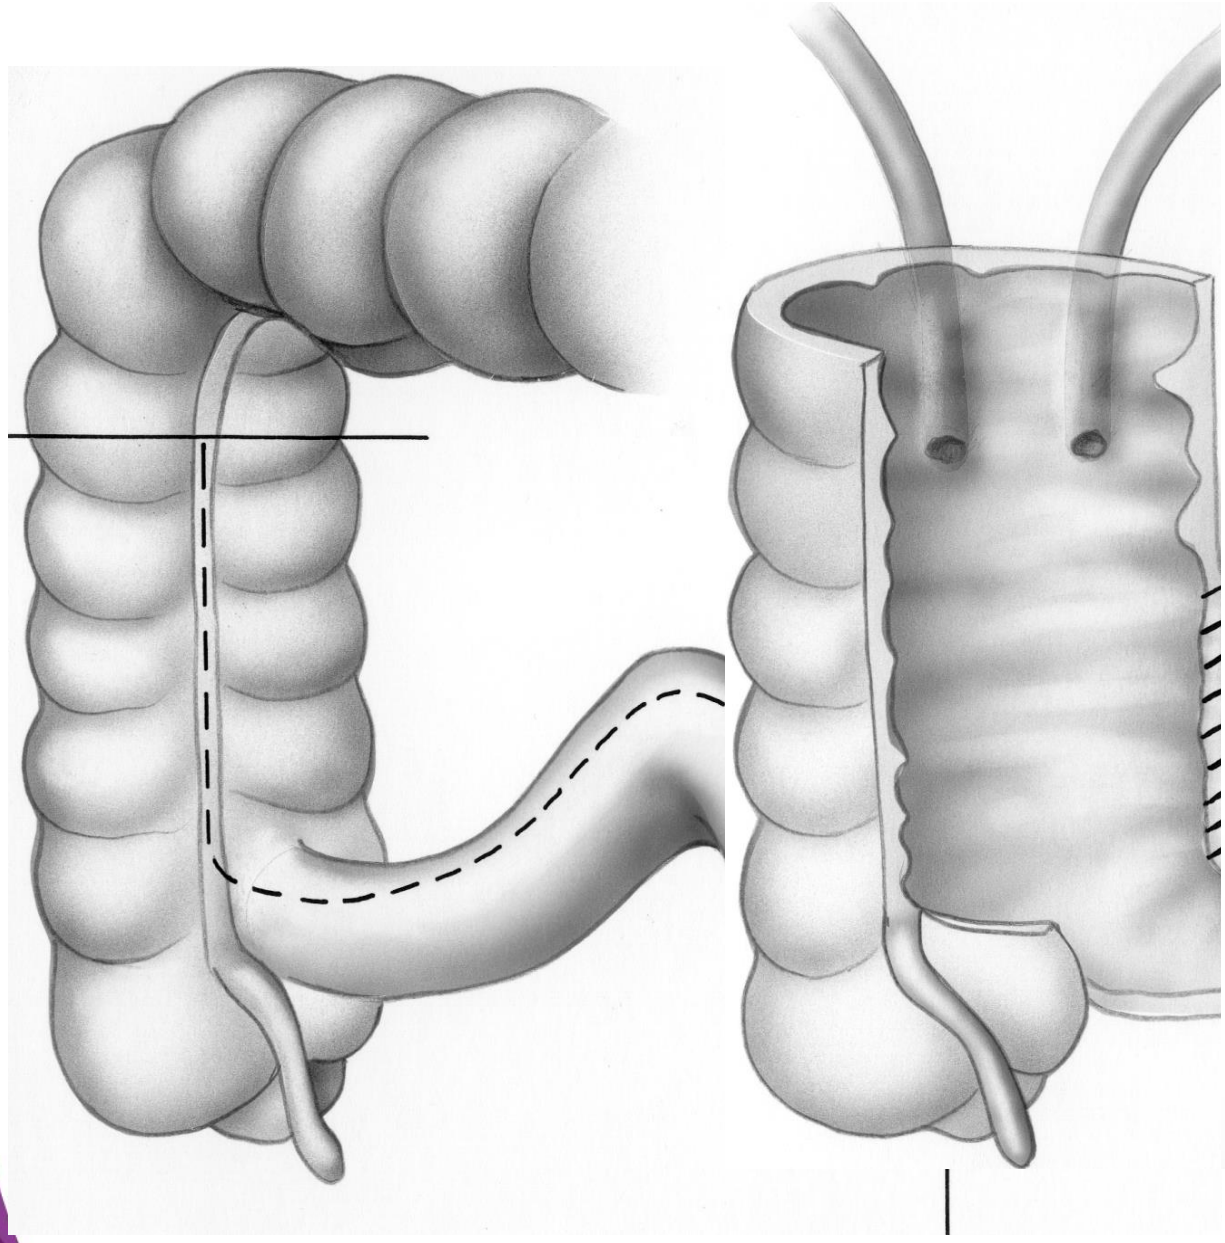


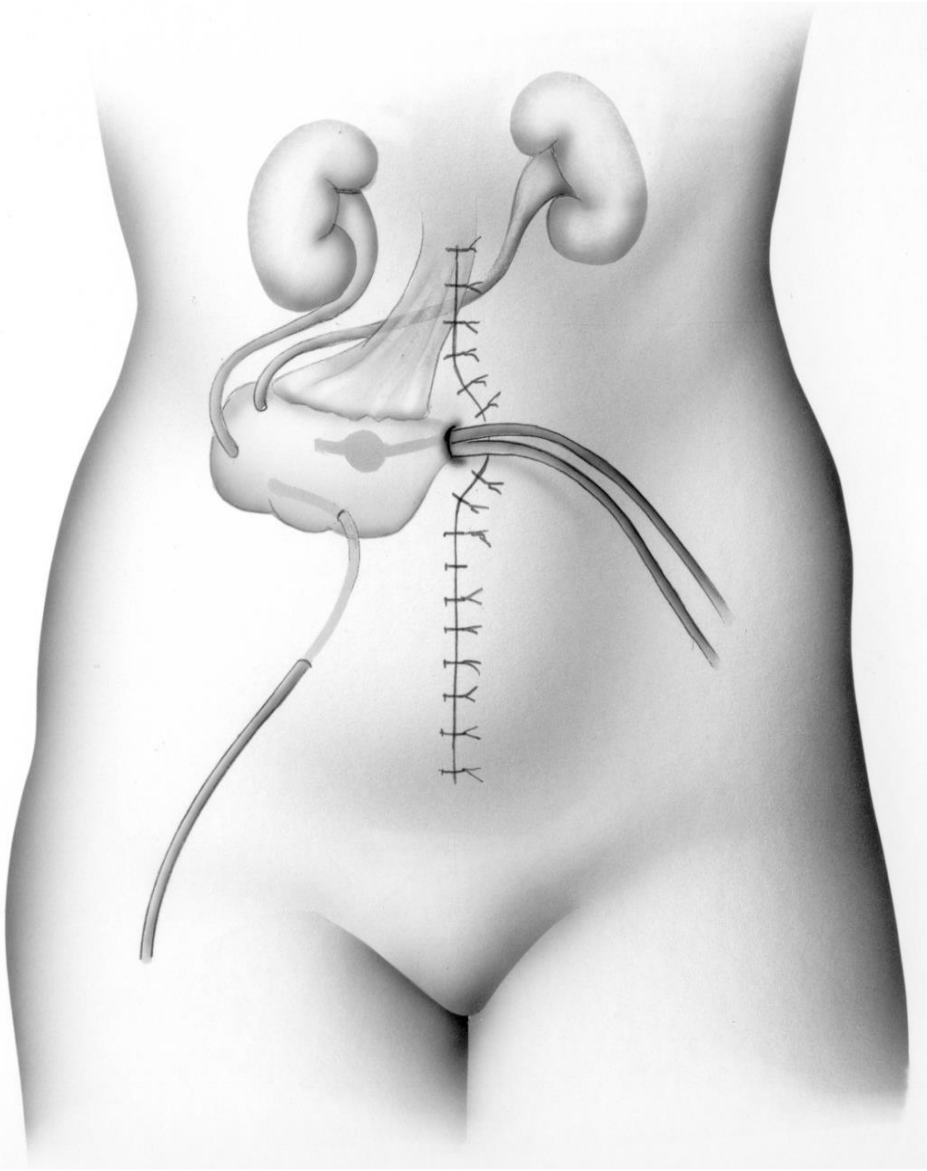




ESTRO School







Reduction of urinary morbidity

- **Careful selection of patients by IPSS.**
- **Technical considerations in planning.**
- **Careful resection of large medium lobes preinterventionally.**
- **Expectative management in the first 12 months after implant.**

Treatment of urinary morbidity

- α-Blockers in obstructive patients.
- Suprapubic catheter in case of complete urinary retention for 12 months.
- Anticholinergics in irritative patients
- Increase in urinary pH by medication. Avoidance of acidic diet.

The pathophysiology of lower urinary tract symptoms after brachytherapy for prostate cancer

Jerry G. Blaivas, Jeffrey P. Weiss and Mark Jones
The Joan and Sanford I. Weill Medical College of Cornell University, New York, NY, USA

JOURNAL COMPILATION © 2006 BJU INTERNATIONAL | 98, 1233–1237 | doi:10.1111/j.1464-410X.2006.06491.x

- **Comparison of 47 men with LUTS after brachytherapy with 541 men with LUTS without prostate cancer.**
- **Significant more detrusor overactivity (47 vs.85%) after brachytherapy.**
- **Higher incidence of urethral and prostatic strictures.**

Treatment of urinary morbidity

- **Hyaluronic acid intravesically after failure of anticholinergics.**
- **Botox injection to the bladder neck in patients with prolonged irritation.**
- **Careful TUR-P after 12 months in patients with complete urinary retention without irritation.**

TUR-P after implantation

- **As late as possible.**
- **Best timíng between 12-24months after implantation to avoid incontinence .**
- **Safe 5‘ and 7‘ o clock position at the baldder neck.**

Technical considerations in TUR-P

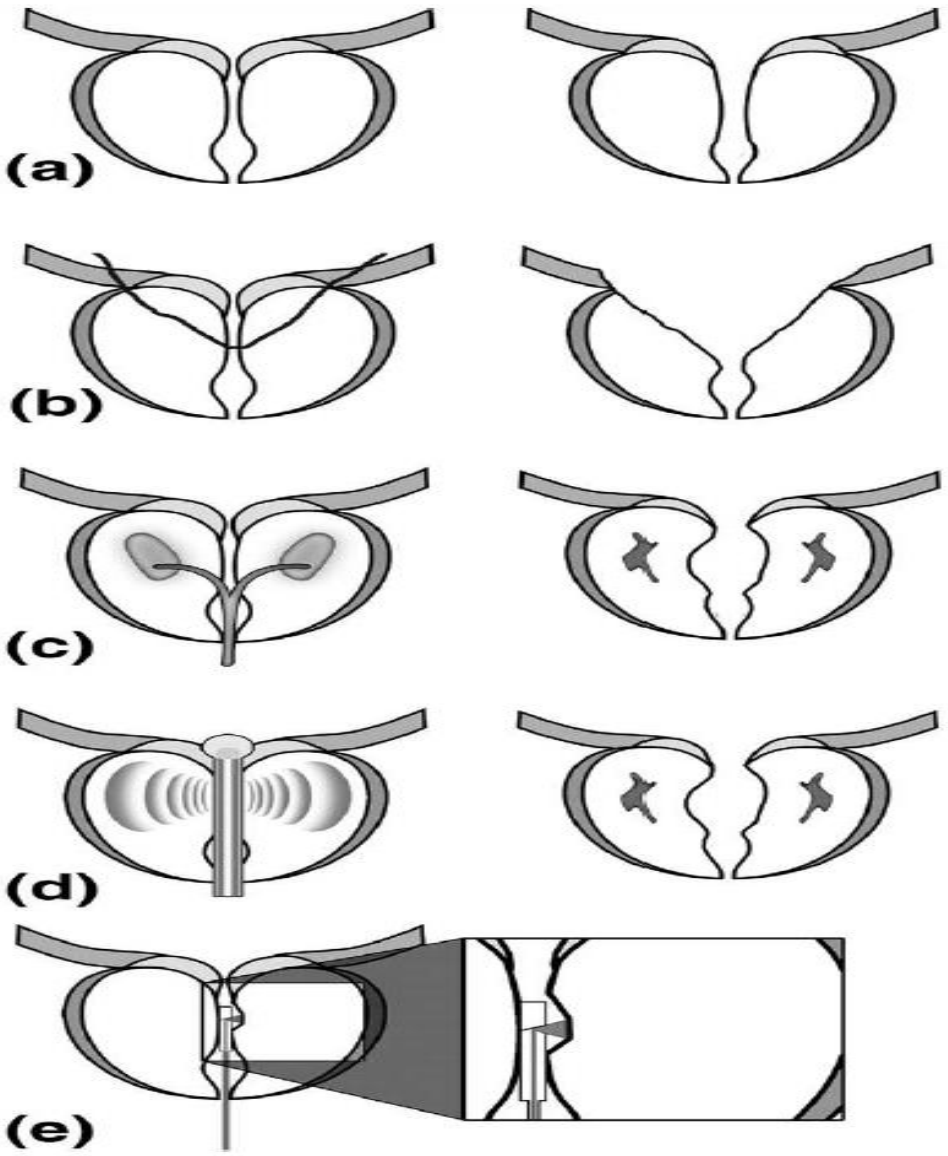


Fig. 9. Surgical procedures to relieve obstruction. (a) Transurethral incision. (b) transurethral prostatectomy. (c) Interstitial (laser or ultrasound). (d) Microwave. (e) Superficial (holmium) laser.

URINARY MORBIDITY AND INCONTINENCE FOLLOWING TRANSURETHRAL RESECTION OF THE PROSTATE AFTER BRACHYTHERAPY

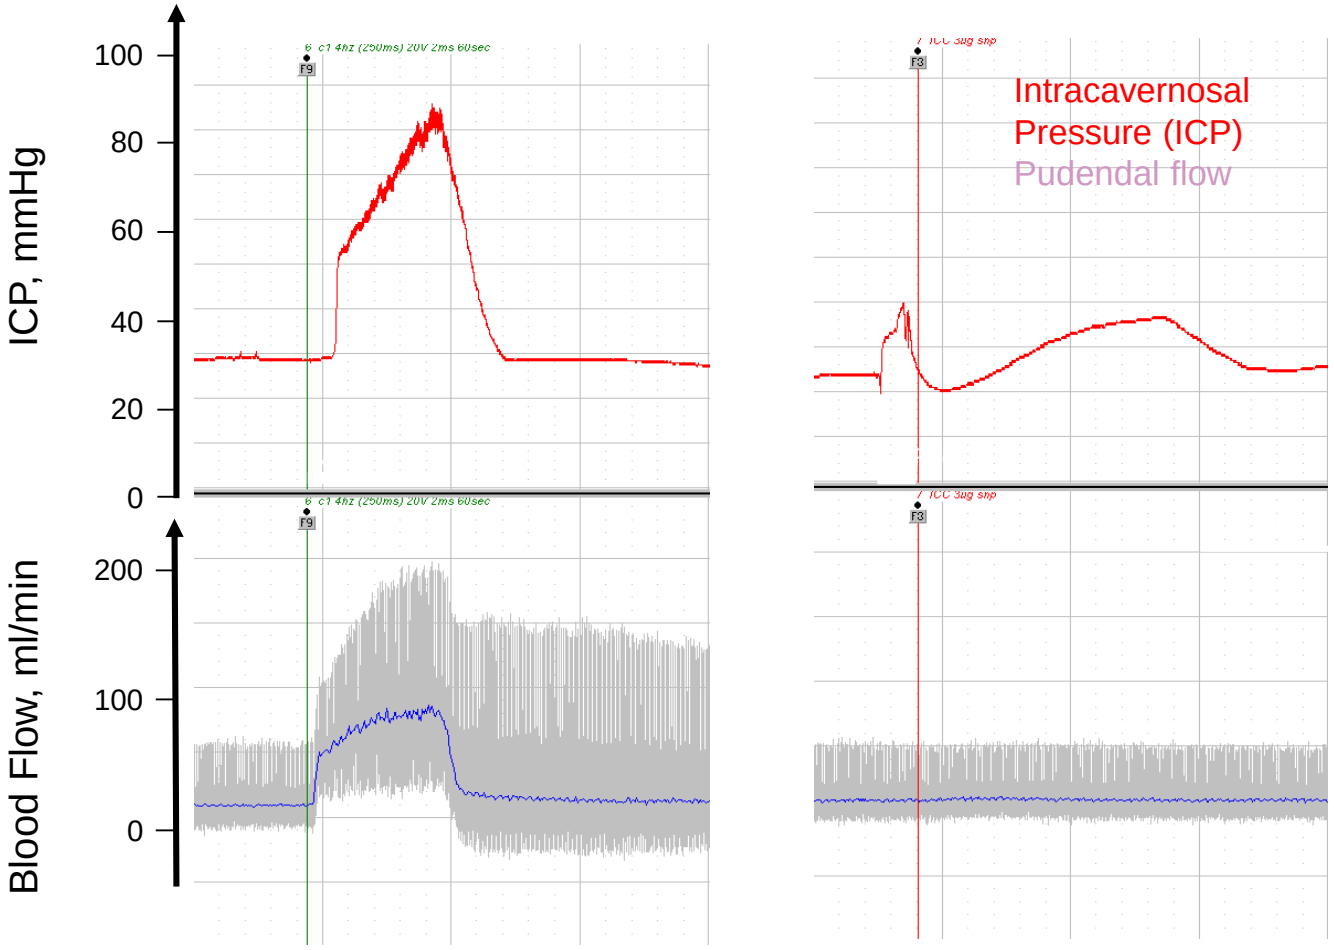
M. A. KOLLMEIER,* R. G. STOCK, J. CESARETTI AND N. N. STONE
From the Departments of Radiation Oncology and Urology (NNS), Mount Sinai School of Medicine, New York, New York

- **38/2050 (2%) patients underwent minimal TUR-P.**
- **7/38 (18%) with incontinence.**
- **2/24 (8%) against 5/14 (36%) with incontinence in case TUR-P was performed <1 or > 2years after implant.**
- **No correlation of incontinence with D90 prostate or D30 urethra or dose to 5cm² urethra.**

Reduction of erectile dysfunction

- **50% of the bulb of the penis should not receive more than 40% mPD.**
- **Judicious use of EBRT and hormonal therapy.**
- **Early use of PDE Inhibitors.**

Rate of Erection Hardness (ICP) Increases With Increased Pudendal Flow to the Penis



- Electrical cavernous nerve stimulation increases pudendal blood flow and provides rapid increases in intracavernosal pressure (ICP)
- Intracavernosal injection of a nitric oxide donor, sodium nitroprusside, produces slow increases in ICP but has no effect on pudendal flow

Illustrates importance of flow-mediated vasodilation in the initiation and maintenance of penile erection in preclinical model

Wayman C et al. ESSM. 4-7 December2005. Poster M-05-141.

Principles of the management of complications

- **Avoidance is better than treatment.**
- **Management as minimal invasive as possible.**
- **Overtreatment can cause series of serious further complications.**

Measures to improve outcome and minimize risk of complications

- Work patients up thoroughly
- Identify and alleviate obstructive prostates beforehand
- Tailor the seed activity according to the volume
  – NB volume measurement of the prostate should always be done at initial assessment prior to referral
- Optimal procedure setup, good u/s visualization
- Accurate contouring of structures of interest
- Critically observe dose constraints

Measures to improve outcome and minimize risk of complications

- Apply meticulous technique
- Don’t drag seeds back into the rectal hump
- Keep implant needles closest to the rectum at the prostato-rectal interface at least 5mm higher than the posterior prostatic boundry (c1 and d1 – use the 1.5 row rather) particularly in thin patients and prostates with longer sagittal measurements (long prostates – more than 8 slices)
- Keep the urethra and TURP defect cooler than the periphery
- Avoid implanting seeds into the urethra or TURP defect
- If the seeds are too hot for the volume, use some cooler seeds even if they are just used for the rows closest to the rectum or urethra

Measures to improve outcome and minimize risk of complications

- Understand the biology and pathophysiology of the type of radiation being delivered and timing of side effects and complications
- Patients must be well informed regarding anticipated irritative and obstructive symptoms and duration, risks of rectal procedures after BT and informed to seek guidance from their Radonc or Urologist first before undergoing any investigation or intervention
- Avoid biopsy the rectum or prostate transrectally after BT
- Manage side effects and complications with efficiency
- Many side effects and complications resolve spontaneously
  – don’t be in a rush to intervene!

ESTRO School

Salvage options

1. Salvage radical prostatectomy (RPE) after radiation therapy
2. Salvage EBRT after RPE
3. Salvage HDR or LDR brachytherapy after EBRT or after seeds
4. Salvage EBRT after EBRT
5. (Cryotherapy, HIFU)

There are these two dogmas…

- 1. RPE after radiation therapy is not possible
- 2. If performed, significant complications will occur

Salvage RPE (SRP)

- In the past major morbidity after SRP
- New datas show acceptable morbidity because of better radiotherapeutic and surgical techniques

best candidate

- histologically verified recurrent prostate cancer
- neg. CT scan and skeletal scintigraphy
- PSADT> 12 months
- PSA $\leq$ 15ng/ml
- bladder capacity $\geq$ 300ml, competent sphincter, no bladder neck invasion

4 larger studies complications and outcome

BJUI SUPPLEMENTS

Report of a consensus meeting on focal low dose rate brachytherapy for prostate cancer

Stephen Langley[1], Hashim U. Ahmed[2], Bashar Al-Qaisieh[3], David Bostwick[4], Louise Dickinson[2], Francisco Gomez Veiga[5], Peter Grimm[6], Stefan Machtens[7], Ferran Guedea[8] and Mark Emberton[2]

BJU INTERNATIONAL © 2012 BJU INTERNATIONAL | 109, SUPPLEMENT 1, 7–16

TABLE 3 Consensus findings on patient selection for focal therapy

1. Life expectancy >10 years
2. PSA ≤15 ng/mL
3. Multi-parametric (T1W/T2W, diffusion-weighting, dynamic contrast enhancement ± spectroscopy) MRI prior to biopsy
4. Bilateral template-guided prostate mapping biopsy with 5-mm sampling frame
5. Unilateral disease; lesion size ≤0.5 mL (approximately equates to maximum cancer length of 10 mm) with or without clinically insignificant disease on the contralateral side (cancer core length ≤3 mm)
6. Gleason score of index lesion 6–7 (3 + 4)
7. Tumour stage ≤T2b
8. Prostate size ≤60 mL

Focal Therapy: Patients, Interventions, and Outcomes—A Report from a Consensus Meeting

Ian A. Donaldson [a,b,], Roberto Alonzi [c], Dean Barratt [d], Eric Barret [e], Viktor Berge [f], Simon Bott [g], David Bottomley [h], Scott Eggener [i], Behfar Ehdaie [j], Mark Emberton [a,b], Richard Hindley [k], Tom Leslie [l], Alec Miners [m], Neil McCartan [a], Caroline M. Moore [a,b], Peter Pinto [n], Thomas J. Polascik [o], Lucy Simmons [a,b], Jan van der Meulen [m], Arnauld Villers [p], Sarah Willis [m], Hashim U. Ahmed [a,b]*

Design, setting, and participants: Fifteen experts in focal therapy followed a modified two-stage RAND/University of California, Los Angeles (UCLA) Appropriateness Methodology process. All participants independently scored 246 statements prior to rescoring at a face-to-face meeting. The meeting occurred in June 2013 at the Royal Society of Medicine, London, supported by the Wellcome Trust and the UK Department of Health.

There was agreement, with a high level of consensus, that based on current National Comprehensive Cancer Network classifications [7], focal therapy should be recommended for intermediate-risk patients. There was also agreement, with a lower level of consensus, for treating men with low-risk disease.

The shift in the attitude of the group over time from providing focal treatment to low-risk patients to now treating intermediate-risk patients was discussed. The shift was thought to be in part because of growing confidence in the technique and promising medium-term follow-up results [8,9]. The group recognized concerns about overdiagnosis and overtreatment [10–12] and agreed that providing focal therapy to men with well-characterized low-risk disease would represent overtreatment and that these men may be best served with active surveillance.

Focal Therapy: Patients, Interventions, and Outcomes—A Report from a Consensus Meeting

Ian A. Donaldson[a,b,], Roberto Alonzi[c], Dean Barratt[d], Eric Barret[e], Viktor Berge[f], Simon Bott[g], David Bottomley[h], Scott Eggener[i], Behfar Ehdaie[j], Mark Emberton[a,b], Richard Hindley[k], Tom Leslie[l], Alec Miners[m], Neil McCartan[a], Caroline M. Moore[a,b], Peter Pinto[n], Thomas J. Polascik[o], Lucy Simmons[a,b], Jan van der Meulen[m], Arnauld Villers[p], Sarah Willis[m], Hashim U. Ahmed[a,b]*

It was agreed that focal therapy can be performed in patients who have undergone an MRI-targeted prostate biopsy and in patients who have had a standard transrectal ultrasound (TRUS) biopsy in which the positive cores reflect, and are concordant with, a high-quality mp-MRI reported by an expert radiologist. When using an MRI-targeted strategy, the Standards of Reporting for MRI-targeted Biopsy Studies guidelines [14] should be followed.

For patients who have not had an mp-MRI because of lack of availability or physician preference, it was agreed that only a full transperineal template–mapping biopsy was sufficient to perform focal therapy [15]. The panel did not agree that the delivery of focal therapy can be based on only the information from a standard or extended TRUS biopsy without further imaging or template-mapping biopsies.

Utilization of multiparametric prostate magnetic resonance imaging in clinical practice and focal therapy: report from a Delphi consensus project

Received: 1 August 2016 / Accepted: 6 September 2016

Results mpMRI should be performed in patients with prior negative biopsies if clinical suspicion remains, but not instead of the PSA test, nor as a stand-alone diagnostic tool or mpMRI-targeted biopsies only. It is not recommended to use a 1.5 Tesla MRI scanner without an endorectal or pelvic phased-array coil. mpMRI should be performed following standard biopsy-based PCa diagnosis in both the planning and follow-up of FT. If a lesion is seen, MRI-TRUS fusion biopsies should be performed for FT planning. Systematic biopsies are still required for FT planning in biopsy-naïve patients and for patients with residual PCa after FT.

Standard repeat biopsies should be taken during the follow-up of FT. The final decision to perform FT should be based on histopathology. However, these consensus statements may differ for expert centers versus non-expert centers.

Conclusions The mpMRI is an important tool for characterizing and targeting PCa in clinical practice and FT. Standardization of acquisition and reading should be the main priority to guarantee consistent mpMRI quality throughout the urological community.

New and Established Technology in Focal Ablation of the Prostate: A Systematic Review

Massimo Valerio[a,b,c,†,*], *Yannick Cerantola*[c,†], *Scott E. Eggener*[d], *Herbert Lepor*[e], *Thomas J. Polascik*[f], *Arnauld Villers*[g], *Mark Emberton*[a,b]

Evidence synthesis: Thirty-seven articles reporting on 3230 patients undergoing focal therapy were selected. Thirteen reported on high-intensity focused ultrasound, 11 on cryotherapy, three on photodynamic therapy, four on laser interstitial thermotherapy, two on brachytherapy, three on irreversible electroporation, and one on radiofrequency. High-intensity focused ultrasound, cryotherapy, photodynamic therapy, and brachytherapy have been assessed in up to Stage 2b studies. Laser interstitial thermotherapy and irreversible electroporation have been evaluated in up to Stage 2a studies. Radiofrequency has been evaluated in one Stage 1 study. Median follow-up varied between 4 mo and 61 mo, and the median rate of serious adverse events ranged between 0% and 10.6%. Pad-free leak-free continence and potency were obtained in 83.3–100% and 81.5–100%, respectively. In series with intention to treat, the median rate of significant and insignificant disease at control biopsy varied between 0% and 13.4% and 5.1% and 45.9%, respectively. The main limitations were the length of follow-up, the absence of a comparator arm, and study heterogeneity.

Conclusions: Focal therapy has been evaluated using seven sources of energy in single-arm retrospective and prospective development studies up to Stage 2b. Focal therapy seems to have a minor impact on quality of life and genito-urinary function. Oncological effectiveness is yet to be defined against standard of care.

Summary

Background Radical whole-gland therapy can lead to significant genitourinary and sexual side-effects for men with localised prostate cancer. We report on whether selective focal ablation of unifocal and multifocal cancer lesions can reduce this treatment burden.

Methods Men aged 45–80 years were eligible for this prospective development study if they had low-risk or high-risk localised prostate cancer (prostate specific antigen [PSA] ≤15 ng/mL, Gleason score ≤4+3, stage ≤T2c) with no previous androgen deprivation or treatment for prostate cancer, and who could safely undergo multiparametric MRI and have a general anaesthetic. Patients received focal therapy using high-intensity focused ultrasound, delivered to all known cancer lesions, with a margin of normal tissue, identified on multiparametric MRI, template prostate-mapping biopsies, or both. Primary endpoints were adverse events (serious and otherwise) and urinary symptoms and erectile function assessed using patient questionnaires. Analyses were done on a per-protocol basis. This study is registered with ClinicalTrials.gov, number NCT00651314.

Findings 41 men were included between June 27, 2007, and June 30, 2008; one man died from an unrelated cause (post-enrolment) 3 months after treatment and was excluded from analyses. After treatment, one man was admitted to hospital for acute urinary retention, and another had urethral instrumentation requiring hospital admission. Nine men (22%, 95% CI 11–37) had mild-resolving, mild to moderate, intermittent dysuria (median duration 5·0 days [IQR 2·5–18·5]). Urinary sepsis occurred in six men (15%, 95% CI 6–30), with a median duration of 11·5 days (IQR 6·8–16·5). Urinary tract infection was noted in seven men (17%, 95% CI 7–32). Median overall International Index of Erectile Function-15 (IIEF-15) scores were similar at baseline and at 12 months (p=0·868), as were median IIEF-15 scores for intercourse satisfaction (p=0·414), sexual desire (p=0·444), and overall satisfaction (p=0·357). Significant deteriorations between baseline and 12 months were noted for IIEF-15 erectile (p=0·047) and orgasmic functions (p=0·005). Of 35 men with good baseline function, 31 (89%, 95% CI 75–97) had erections sufficient for penetration 12 months after focal therapy. Median UCLA Expanded Prostate Cancer Index Composite (EPIC) urinary incontinence scores were similar at baseline and 12 months (p=0·969). There was an improvement in lower urinary tract symptoms, assessed by International Prospective Symptom Score (IPSS), between baseline and 12 months (p=0·026), but the IPSS-quality of life score showed no difference between baseline and 12 months (p=0·078). All 18 men with no baseline urinary incontinence were leak-free and pad-free by 3 months. All 40 men pad-free at baseline were pad-free by 3 months and maintained pad-free continence at 12 months. No significant difference was reported in median Trial Outcomes Index scores between baseline and 12 months (p=0·115) but significant improvements were shown in median Functional Assessment of Cancer Therapy (FACT)-Prostate (p=0·042) and median FACT-General scores (p=0·048). No histological evidence of cancer was identified in 68 of 98 cases biopsied at 6 months (77%, 95% CI 63–87); 36 (88%, 75–95) were free of clinically significant cancer. After retreatment for four men, 39 of 41 (95%, 95% CI 83–99) had no evidence of disease on multiparametric MRI at 12 months.

Interpretation Focal therapy of individual prostate cancer lesions, whether unifocal or multifocal, leads to a low rate of genitourinary side-effects and an encouraging rate of early absence of clinically significant prostate cancer.

Funding Medical Research Council (UK), Wellcome Trust Cancer Foundation, and St Peter's Trust

Introduction

The management of localised prostate cancer remains controversial because the systematic over-diagnosis that accompanies the current diagnostic pathway results in over-treatment.[1] At present, radical whole-gland surgery or radiotherapy can result in substantial side effects that are a consequence of damage to surrounding structures. These include urinary incontinence (5–20%), erectile dysfunction (10–70%), and bowel toxicity (5–10%).[2,3] Technological refinements do not seem to have reduced the burden of harm.[4]

Apart from active surveillance for low risk disease, few strategies are available to address the burden of treatment-related side-effects in older risk categories. One strategy that has shown promise relates to managing prostate cancer in the same manner as most other solid organ malignancies—by focusing the therapy to the cancer lesion, sparing as the

- **41 patients** treated by focal HIFU
- 92% free from clinically significant PCa
- **100% continence preservation**
- QOL preservation
- **89% erection sufficient for penetration**

Inclusion criteria

- 1 positive core of 3-5mm CCL*
- 2-3 positive cores and ≤5mm CCL per core
- Absence of Gleason pattern 4 or 5
- PSA ≤ 10 ng/ml
- Clinical stage up to cT2a
- Prostate volume ≥ 25 cc and ≤ 70 cc

*Cancer Core length

Primary End points (24 months)

- **Cancer progression**
  - from histological low risk to a higher risk
- **Absence of cancer**

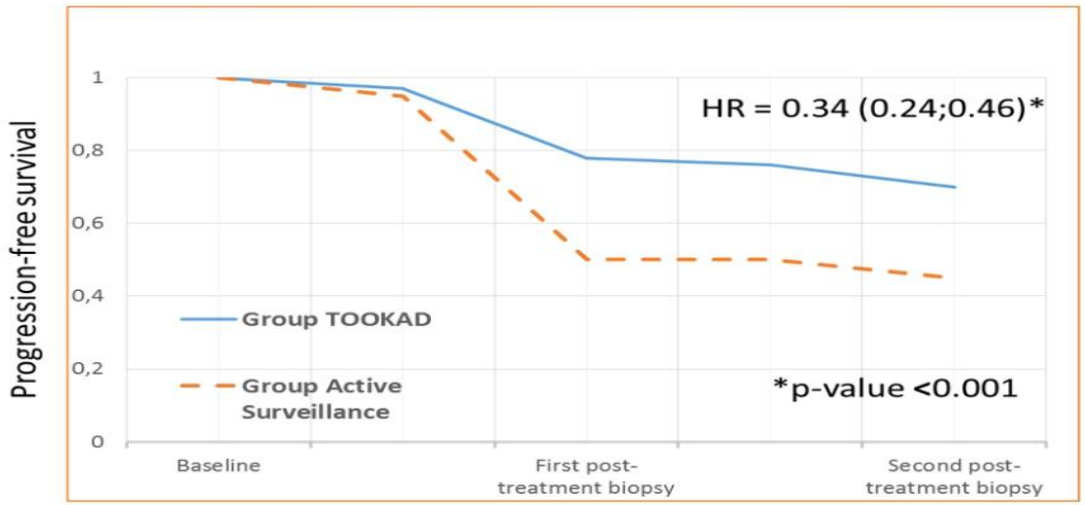
Secondary End points (24 months)

- **Cross-over to radical therapy**
- **Safety**
- **Functional status / Quality of life**

Results - Progression

	TOOKAD® [N=206]	Active surveillance [N=207]
Subjects who progressed – n (%)	58 (28%)	120 (58%)

Results - Progression



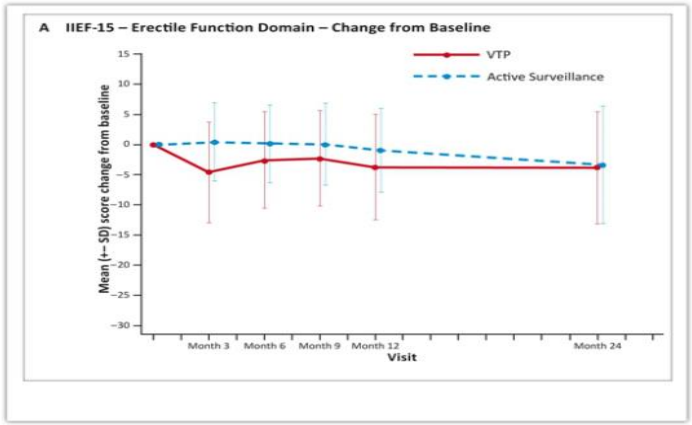
Fewer TOOKAD® treated men underwent radical therapy within 24-months: 6% vs. 29%, RR=0.20 [0.11-0.36]

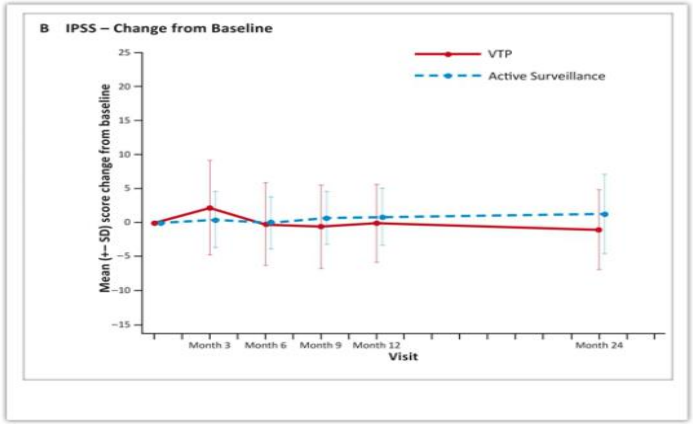
Results – Negative Biopsy

	TOOKAD® [N=206]	Active surveillance [N=207]
Number(%) of subjects with negative biopsies at 24 Months	101 (49%)	28 (14%)

TOOKAD® increased the probability (RR) of a negative prostate biopsy at 24 months after treatment by 3.62 times compared to active surveillance ($p<0.001$)

Results – Functional status





Results – Adverse events

	TOOKAD® VTP Drug, device or procedure related events [N=197]	Active Surveillance [N=207]
Grade 1 (Mild)	54 (27.4%)	42 (20.3%)
Grade 2 (Moderate)	81 (41.1%)	52 (25.1%)
Grade 3 (Severe)	19 (9.6%)	19 (9.2%)
Grade 4 (Life-threatening)	1* (0.5%)	1 (0.5%)
Grade 5 (Death)	0 (0%)	0 (0%)
Missing	0 (0%)	0 (0%)

*One Anaphylactic shock following general anesthesia before injection of TOOKAD®

One case of incontinence (previous TURP)
Two urethral strictures requiring dilatation
No recto-urethral fistulae

Summary

In a multi-centre, phase 3 pivotal randomized study, TOOKAD® VTP appears:

- ☐ **Desirable to European men**
- ☐ **Safe**
- ☐ **Well tolerated**
- ☐ **Amenable to quality control**
- ☐ **Effective at:**

  - **Reducing rates of progression**
  - **Conferring a negative biopsy status**
  - **Diminishing the need for radical therapy**

These are very low-risk patients

Inclusion criteria	Final cohort	PRIAS*
PSA <10 ng/mL	PSA 5.9-6.2ng/mL	5.6ng/mL
cT1c-cT2a	86% T1c	85.1% T1c
Gleason 3+3=6 • One core 3-5mm • Two-three cores <3mm length	Gleason 3+3=6 • No of cores =2.1 • Mean total core length = 3-8-4.3mm	Gleason 3+3=6 • One core 68.8% • Two cores 31.2%

100% disease-specific survival

Offer active surveillance to patients with the lowest risk of cancer progression: > 10 years life expectancy, cT1/2, PSA ≤ 10 ng/mL, biopsy Gleason score ≤ 6, ≤ 2 positive biopsies, minimal biopsy core involvement (≤ 50% cancer per biopsy).	2a	A

Standard repeat biopsies should be taken during the follow-up of FT. The final decision to perform FT should be based on histopathology. However, these consensus statements may differ for expert centers versus non-expert centers.

Conclusions The mpMRI is an important tool for characterizing and targeting PCa in clinical practice and FT. Standardization of acquisition and reading should be the main priority to guarantee consistent mpMRI quality throughout the urological community.

Focal radiotherapy as focal therapy of prostate cancer

Morbidity of Focal Therapy in the Treatment of Localized Prostate Cancer

Eric Barret[a,*], *Youness Ahallal*[a], *Rafael Sanchez-Salas*[a], *Marc Galiano*[a], *Jean-Marc Cosset*[a], *Pierre Validire*[b], *Petr Macek*[a], *Matthieu Durand*[a], *Dominique Prapotnich*[a], *François Rozet*[a], *Xavier Cathelineau*[a]

EUROPEAN UROLOGY 63 (2013) 618–622

Table 1 – Patient characteristics

Characteristic	Patients, *n* = 106
Age at first biopsy, yr (IQR)	66.5 (61–73)
PSA, ng/ml (IQR)	6.1 (5–8.1)
D'Amico low risk, %	100
Gleason score 3 + 3, %	100
Positive biopsies, no. (IQR)	1 (1–2)
Prostate weight g (IQR)	43 (33–55)
Energy modality for FT, no. (%)	
Cryotherapy	50 (47)
VTP	23 (22)
HIFU	21 (20)
Brachytherapy	12 (11)

IQR = interquartile range; PSA = prostate-specific antigen; FT = focal therapy; VTP = vascular-targeted photodynamic therapy; HIFU = high-intensity focused ultrasonography.

This pilot study showed that there is a reasonably low level of complications due to FT. This finding is very encouraging. There is more and more evidence accumulating that FT may represent a viable option for low-risk PCa, and because of our results, we think that this kind of treatment could potentially be extended to intermediate-risk patients. However, clinical trials and long-term follow-up data for assessing oncologic, functional, and quality-of-life outcomes are still needed before solid conclusions can be drawn.

Fazit: FT ist eine Therapiemodalität, die bei niedrig-Risiko Patienten berücksichtigt werden kann.Evtl. auch intermediäre-Risiko Patienten als Kandidaten.

Table 2 – Preliminary oncologic and functional results

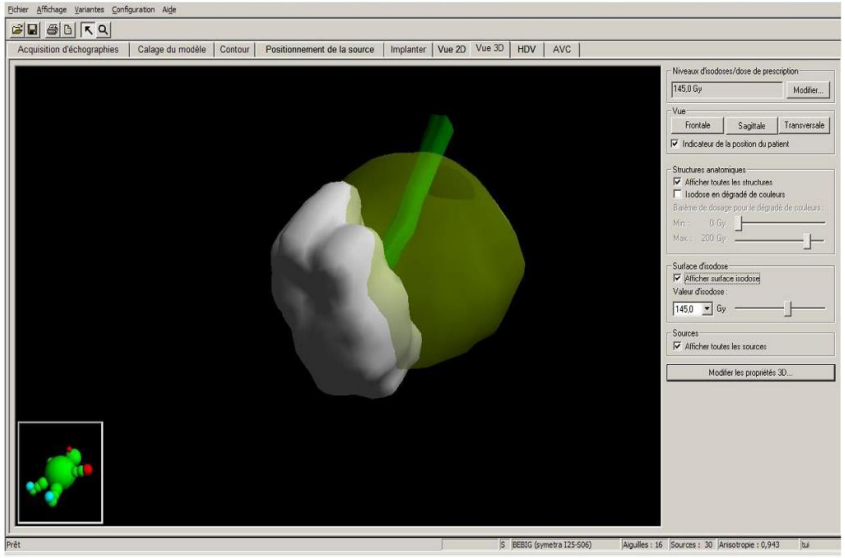
Energy modality	PSA, ng/ml, median (IQR)				IPSS, median (IQR)		IIEF-5, median (IQR)	
	Baseline	3 mo	6 mo	12 mo	Baseline	12 mo	Baseline	12 mo
Cryotherapy	6.2 (5.0–7.9)	2.9 (2.0–5.0)	2.8 (1.2–4.6)	2.5 (0.9–4.4)	9 (3–10)	5 (1–11)	19 (9–25)	14 (8–25)
Brachytherapy	6.2 (5.4–7.5)	3.3 (2.5–5.7)	3.2 (2.0–5.1)	2.8 (1.2–4.7)	3 (1–7)	7 (2–12)	21 (10–25)	14 (8–24)
VTP	5.7 (4.8–6.7)	3.0 (2.2–4.9)	2.8 (1.1–4.4)	3.2 (2.1–4.7)	6 (2–9)	6 (3–10)	23 (17–25)	13 (7–25)
HIFU	6.0 (5.1–8.1)	2.7 (1.8–4.7)	3.1 (2.1–5.3)	3.1 (2.4–4.3)	3 (1–7)	6 (2–11)	20 (15–25)	14 (8–25)

PSA = prostate-specific antigen; IQR = interquartile range; IPSS = International Prostate Symptom Score; IIEF-5 = International Index of Erectile Function; VTP = vascular-targeted photodynamic therapy; HIFU = high-intensity focused ultrasonography.

Focal brachytherapy for selected low-risk prostate cancers: A pilot study

Jean-Marc Cosset[1,2,*], Xavier Cathelineau[2], Georges Wakil[1,3], Noelle Pierrat[1], Olivier Quenzer[4], Dominique Prapotnich[2], Eric Barret[2], François Rozet[2], Marc Galiano[2], Guy Vallancien[2]

[1]*Department of Oncology/Radiotherapy, Institut Curie, Paris, France*
[2]*Department of Urology, Institut Mutualiste Montsouris, Paris, France*
[3]*Department of Radio-Oncology, Hospital Charles LeMoyne, Montréal, Canada*
[4]*Department of Statistics, Institut Curie, Paris, France*



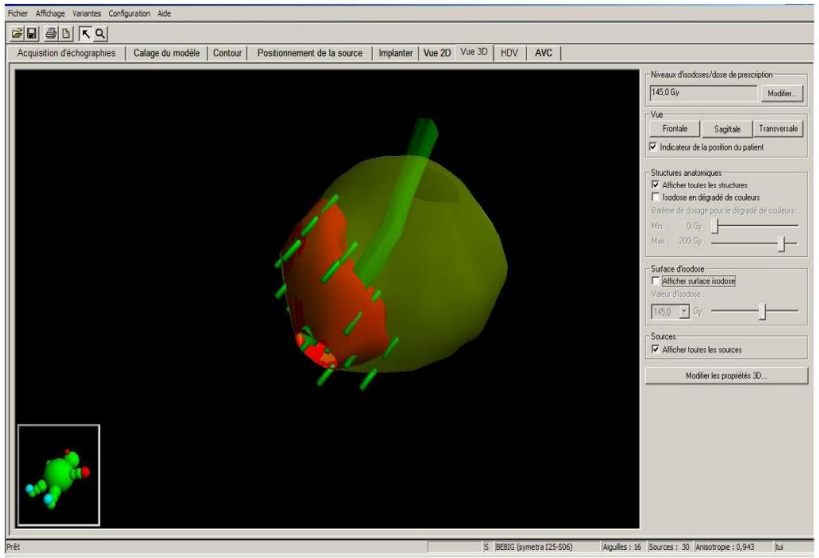


Table 1
Urinary toxicity (IPSS) and sexual toxicity (IIEF5) for focal prostate brachytherapy

	Mean (range)
Initial IPSS	5.4 (0–15)
IPSS at 2 mo	11.8 (1–28)
IPSS at 6 mo	6.6 (2–17)
IPSS at 12 mo	6.1 (2–9)
Initial IIEF5	20.1 (5–25)
IIEF5 at 2 mo	18.6 (5–25)
IIEF5 at 6 mo	19.1 (5–25)
IIEF5 at 12 mo	19.8 (5–25)

RESULTS: The treated volume corresponded to a mean value of 34% of the total prostatic volume (range, 20–48%). For the focal volume, the mean D_{90} and V_{100} was 183.2 Gy (range, 176–188 Gy) and 99.3% (range, 98.8–100%), respectively. The technique was performed in an hour and a half. When compared with a previous cohort treated by whole-prostate brachytherapy, urinary toxicity (International Prostate Symptom Score) was borderline reduced ($p = 0.04$) at 6 months only, whereas the recovery of the International Index of Erectile Function 5 was better ($p = 0.014$). The International Continence Score was nil in almost all cases as well as rectal toxicity.

- **we did compare the toxicities observed in this series of focal brachytherapy with the ones that were registered in a series of 100 patients treated by a “whole prostate” brachytherapy by our group in the same institution (Institut Mutualiste Montsouris) , and analyzed with the same questionnaires.**

» **For IPSS,** the mean scores and variations were comparable at 2 and 12 months in both groups, focal and total***, but there was a borderline difference favoring the "focal"group at 6 months****, both in terms of direct comparison of the mean scores (p=0.04) and in terms of variation compared with the initial values (p=0.05).*

» **For erectile toxicity (IIEF)**, we did not observe any significant difference between the mean scores in the “focal” and “total” groups at 2, 6 and 12 months (p=0.43 ; p=0.46 ; p=0.17 respectively), *but* ***the re-increase of the score was significantly better in the focal group*** *at 6 and 12 months (p=0.014 et p=0.012, respectively).*

Focal brachytherapy for localized prostate cancer: Urinary toxicity depends on tumor location

Victor Srougi[1,2], Eric Barret[1], Igor Nunes-Silva[1], Mohammed Baghdadi[1], Silvia Garcia-Barreras[1], Noelle Pierrat[3], Francois Rozet[1], Marc Galiano[1], Rafael Sanchez-Salas[1], Xavier Cathelineau[1], Jean-Marc Cosset[1,3,4,*]

[3]*Département d'oncologie-radiothérapie, Institut Curie, Paris, France*
[4]*Centre de radiothérapie Charlebourg-La Défense, groupe Amethyst, La Garenne-Colombes, France*

METHODS AND MATERIALS: The functional outcomes of patients treated with FBT at the base of the prostate were compared with those of patients treated with FBT at the apex. Urinary symptoms, continence, and erectile dysfunction were measured using the International Prostate Symptom Score (IPSS), International Continence Score (ICS), and International Index of Erectile Function (IIEF-5) questionnaires, respectively, at baseline and at 6, 12, and 24 months after treatment.

Focal brachytherapy for localized prostate cancer: Urinary toxicity depends on tumor location

Victor Srougi[1,2], Eric Barret[1], Igor Nunes-Silva[1], Mohammed Baghdadi[1], Silvia Garcia-Barreras[1], Noelle Pierrat[3], Francois Rozet[1], Marc Galiano[1], Rafael Sanchez-Salas[1], Xavier Cathelineau[1], Jean-Marc Cosset[1,3,4,*]

6 months	28	13	6.4 ± 4.7	10.6 ± 5.7	0.02
12 months	28	13	5.1 ± 4.3	7.6 ± 5.0	0.09
24 months	20	12	6.4 ± 5.2	6.2 ± 5.3	0.90
ICS					
Baseline	31	100	0.04 ± 0.2	0.08 ± 0.3	0.58
6 months	28	13	0.25 ± 0.7	0	0.21
12 months	27	13	0.59 ± 1.1	0.46 ± 0.9	0.71
24 months	20	12	0.55 ± 1.4	0.08 ± 0.3	0.26
IIEF5					
Baseline	18	12	19 ± 7.6	18 ± 6.9	0.71
6 months	26	13	14.7 ± 8.7	16.3 ± 5.6	0.56
12 months	28	13	16.5 ± 7.5	16.2 ± 6.3	0.92
24 months	20	13	17 ± 7.7	16.5 ± 7.4	0.84

IPSS = International Prostate Symptom Score; ICS = International Continence Score; IIEF-5 = International Index of Erectile Function.

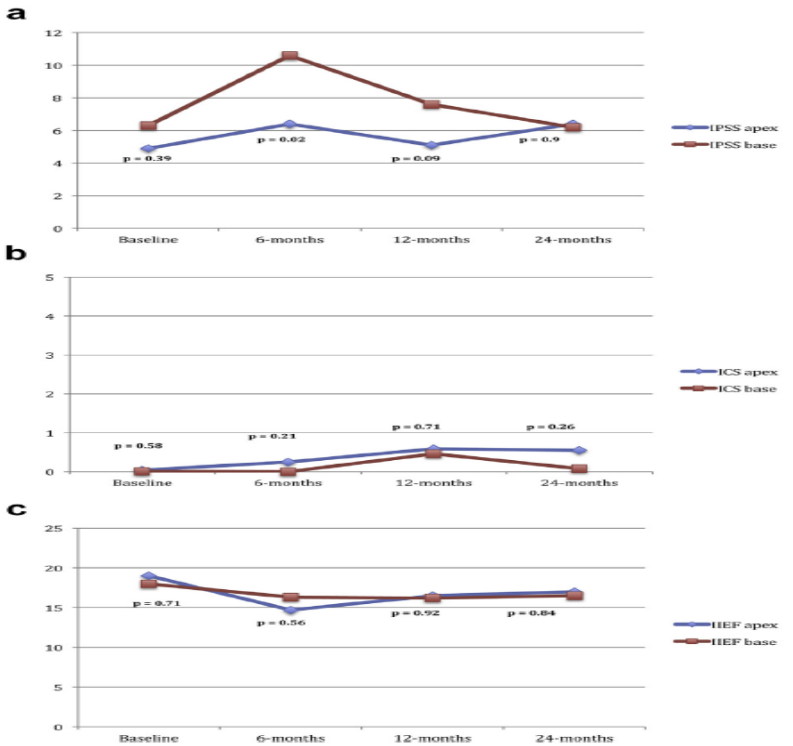

Fig. 2. (a) IPSS among treatment location in different time points: apex versus base. (b) ICS among treatment location in different time points: apex versus base. (c) IIEF among treatment location in different time points: apex versus base. IPSS = International Prostate Symptom Score; ICS = International Continence Score; IIEF = International Index of Erectile Function.

Focal brachytherapy for localized prostate cancer: Urinary toxicity depends on tumor location

Victor Srougi[1,2], Eric Barret[1], Igor Nunes-Silva[1], Mohammed Baghdadi[1], Silvia Garcia-Barreras[1], Noelle Pierrat[3], Francois Rozet[1], Marc Galiano[1], Rafael Sanchez-Salas[1], Xavier Cathelineau[1], Jean-Marc Cosset[1,3,4,*]

[1]*Department of Urology, Institut Montsouris, Université Paris-Descartes, Paris, France*
[2]*Division of Urology, University of Sao Paulo, Sao Paulo, Brazil*
[3]*Département d'oncologie-radiothérapie, Institut Curie, Paris, France*
[4]*Centre de radiothérapie Charlebourg-La Défense, groupe Amethyst, La Garenne-Colombes, France*

RESULTS: Twenty-eight and 13 patients were treated with FBT at the apex and the base, respectively, of the prostate. A significant difference between groups was found in the IPSS score at 6 months (mean IPSS: apex 6.4 ± 4.7, base 10.6 ± 5.7; $p = 0.02$), but not at baseline or at 12 and 24 months after treatment. On multivariate analysis, only FBT at the base of the prostate remained an independent predictor of worsening urinary symptoms (odds ratio, 5.8; $p = 0.04$).

CONCLUSIONS: At 6 months after FBT, significantly less urinary toxicity was found in patients who underwent FBT at the apex versus the base of the prostate. Continence and sexual side effects were minimal in all patients.

EAU Guideline 2016

Focal therapy of PCa is still in its infancy and cannot be recommended as a therapeutic alternative outside clinical trials.	A

Conclusion

- **mpMRI and transperineal biopsies remain the most reliable tools to identify candidates for a focal therapy.**
- **Focal therapy should only be performed under controled conditions..**
- **So far focal therapy is not a guideline recommended therapy.**

"You must never be fearful about what you are doing when it is right."

-Marie Curie

For patients with locally or locally advanced prostate cancer, external beam radiation therapy is a commonly used primary treatment modality

Although conventional-dose EBRT may result in good clinical disease control, post-EBRT PSA determinations might suggest that locally persistent tumour may exist in a certain proportion of patients

Salvage therapy of intraprostatic failure after radical external-beam radiotherapy for prostate cancer: A review

Filippo Alongi [a], Berardino De Bari [b,*], Franco Campostrini [c], Stefano Arcangeli [d], Deliu Victor Matei [e], Egesta Lopci [f], Giuseppe Petralia [g], Massimo Bellomi [g], Arturo Chiti [f], Stefano Maria Magrini [b], Marta Scorsetti [a], Roberto Orecchia [h], Barbara Alicja Jereczek-Fossa [h]

The rate of intraprostatic relapses after primary EBRT is still not negligible:

- 20-40% (20-25.000 failure/year)
- 60% - 72% of patients with negative metastatic workup and rising PSA after RT will have positive prostatic biopsies

Abstract

The clinical suspicion of local recurrence of prostate cancer after radical treatment is based on the onset of biochemical failure. The use of multiparametric magnetic resonance imaging (MRI) for prostate cancer has increased over recent years, mainly for detection, staging, and active surveillance. However, suspicion of recurrence in the set of biochemical failure is becoming a significant reason for clinicians to request multiparametric MRI. Radiologists should be able to recognize the normal posttreatment MRI findings. Fibrosis and atrophic remnant seminal vesicles (SV) after radical prostatectomy are often found and must be differentiated from local relapse. Moreover, brachytherapy, external beam radiotherapy, and focal therapies tend to diffusely decrease the signal intensity of the peripheral zone on T2-weighted images due to the loss of water content, consequently mimicking tumor and hemorrhage. The combination of T2-weighted images and functional studies like diffusion-weighted imaging and dynamic contrast-enhanced imaging improves the identification of local relapse. Tumor recurrence tends to restrict on diffusion images and avidly enhances after contrast administration. The authors provide a review of the normal findings and the signs of local tumor relapse after radical prostatectomy, external beam radiotherapy, brachytherapy and focal therapies.

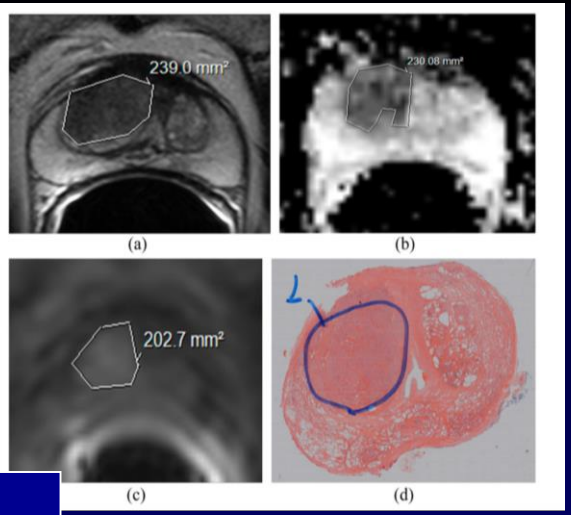
[3]Department of Histopathology, Institute of Cancer Research and Royal Marsden NHS Foundation Trust, London, UK



mpMRI-derived GTV measurements of DIPLs derived from T2W, DW-MRI and DCE sequences are reproducible

- GTV is largest on T2W images

- GTV is smallest on DCE-MRI images

- T2W GTVs best approximate to in vivo tumour volume.

Therefore, GTV should be delineated on T2W images when defining the DIPL

Harvey H, Orton MR, Morgan VA, Parker C, Dearnaley D, Fisher C, et al. Volumetry of the dominant intraprostatic tumour lesion: intersequence and interobserver differences on multiparametric MRI. *Br J Radiol* 2017; **90**: 20160416.

Prostate MR Imaging for Posttreatment Evaluation and Recurrence

Sonia Gaur, BS, Baris Turkbey, MD*

Radiol Clin N Am 56 (2018) 263–275

mpMR imaging after EBRT

- EBRT causes overall changes in signal intensity and structure of the prostate

- The irradiated prostate appears smaller as a result of gland atrophy and differentiation of the zones is made difficult by effacement of the prostatic tissue

- The entire prostate appears more hypointense on T2w imaging inducing difficulties in the:
  - differentiation between central and peripheral zone
  - distinction between benign and tumour tissues

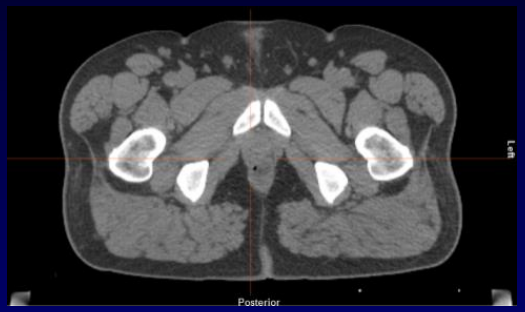
- Sensitivity for T2w alone is varies between 36% and 75% and specificity ranged fro m65% to 81% (Sala et al.)

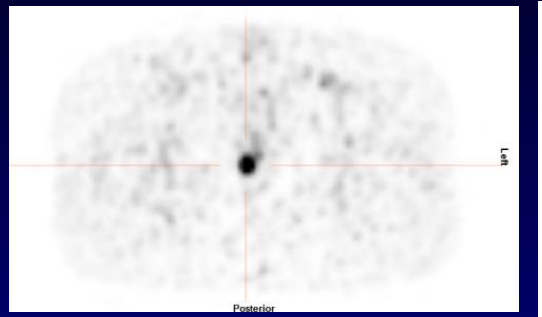
So: limited value of T2w in this setting.

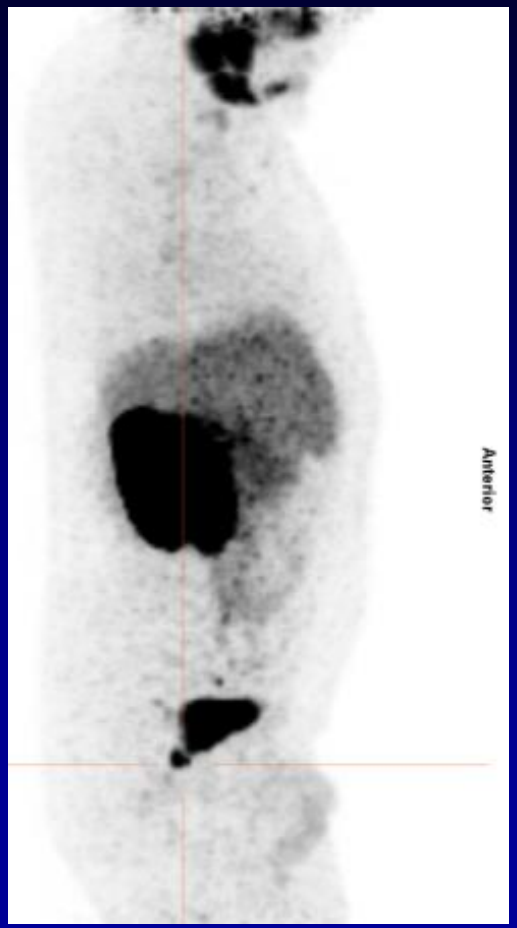
mpMR imaging after EBRT

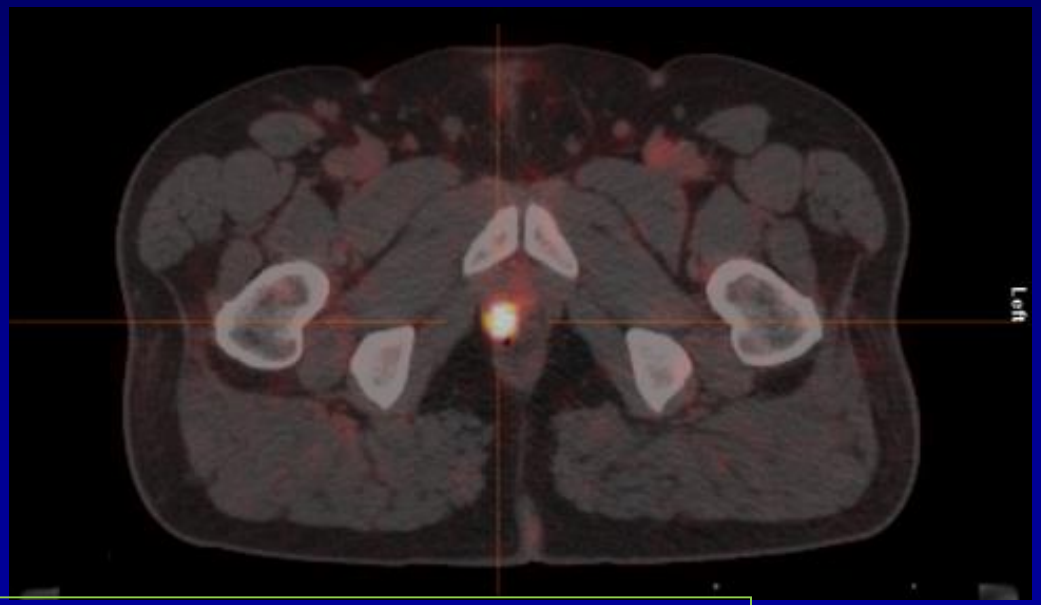
- Dominant role of the functional sequences of mpMRI
  - on DWI: signal characteristics are similar to normal setting with a focal hypointensity on the ADC map and hyperintensity on high-b value imaging
  - on DCE: although the vascularity of the overall irradiated prostate decreases with gland atrophy, the recurrences :
    - retain their highly vascular network
    - Show the early hyper-enhancement on DCE relative to the treated prostate.

CHOLINE - PSMA sensitivity









Afshar-Oromieh A. Eur J Nucl Med Mol Imaging. 2014

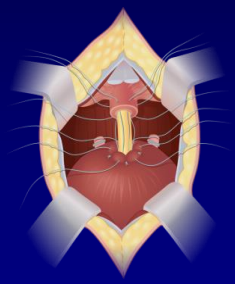
At present, many patients with locally recurrent prostate cancer after EBRT are often managed with palliative intent, such as watchful waiting or androgen suppression

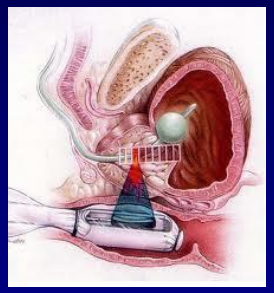
What about local treatment for isolated local relapses?

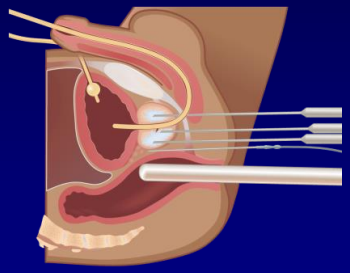
Lacking of high level evidence supporting salvage therapies after EBRT.

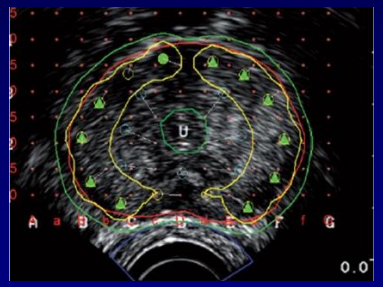
Potential treatment options after intraprostatic failure alone are:

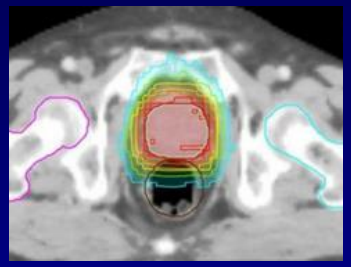
2013











Surgery HIFU Cryotherapy Brachytherapy EBRT

INTRAPROSTATIC FAILURE:

SURGERY AS AN OPTION

When curative therapy is considered, radical prostatectomy might be performed

However, EBRT induced fibrosis tends to obliterate the usual tissue planes for surgical resection. This increases the degree of technical difficulties as well as the morbidity of the procedure, resulting in a general reluctance amongst surgeons to perform salvage surgery.

Underutilization of Salvage Surgery after primary RT

Less than 800 of salvage RP in the literature

Metastasis After Radical Prostatectomy or External Beam Radiotherapy for Patients With Clinically Localized Prostate Cancer: A Comparison of Clinical Cohorts Adjusted for Case Mix

Michael J. Zelefsky, James A. Eastham, Angel M. Cronin, Zvi Fuks, Zhigang Zhang, Yoshiya Yamada, Andrew Vickers, and Peter T. Scardino

	Tx failure	Salvage therapy	Salvage RP	Salvage EBRT	Median time to secondary Tx (months)
EBRT	207	92 (44%)	4 (2%)	-	69
RP	141	107 (76%)	-	59 (42%)	13

Zelefsky, JCO, 2011

INTRAPROSTATIC FAILURE:

EBRT AS AN OPTION

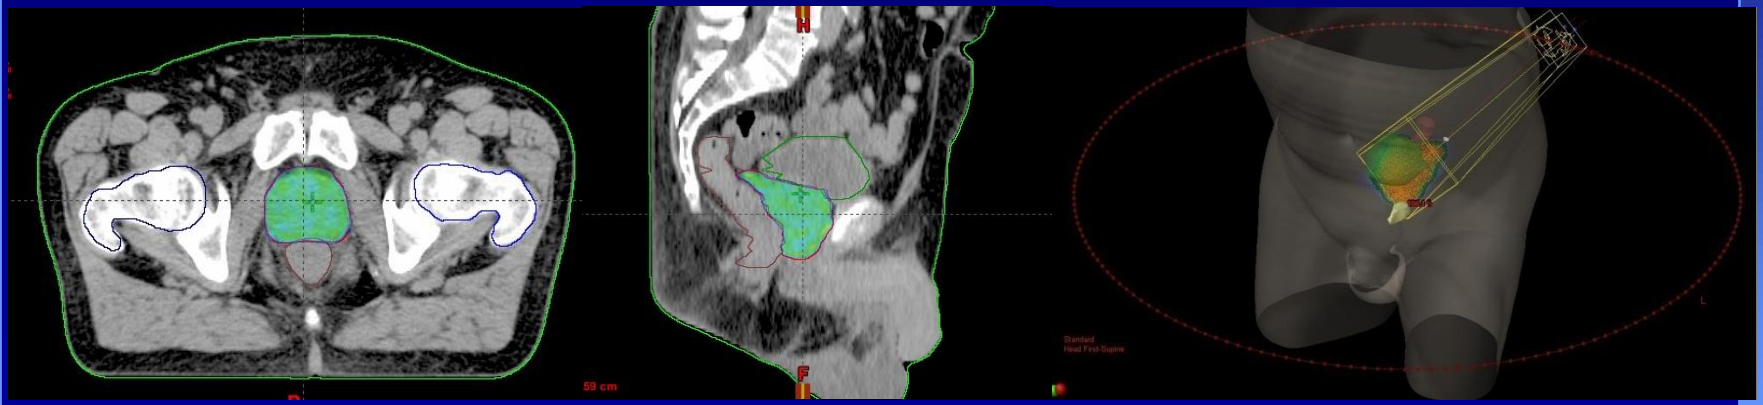
✓**EBRT** is the only NON INVASIVE approach for intra-prostatic relapse .

✓However, EBRT has been documented in a very limited group of patients.

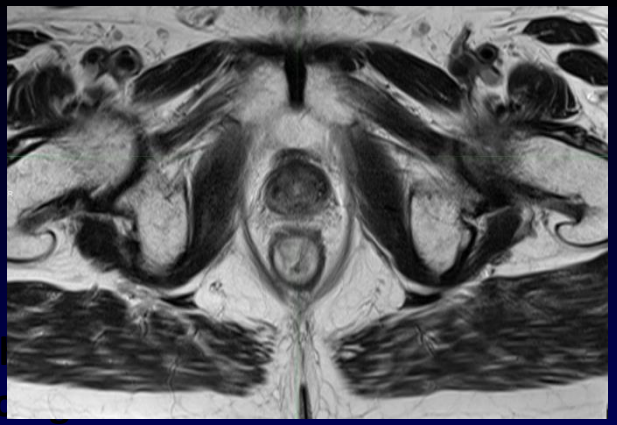
SBRT in prostate re-irradiation:

✓it allows the *reduction of the safety margins* around the target (thus minimizing the exposure of the previously irradiated surrounding normal tissues)

✓It can be delivered by *hypofractionation* that could be of particular value for PC considering its low alpha/beta ratio



Pre treatment MRI



Post treatment MRI

HIFU: high intensity focused ultrasound; NR: not reported; FU: follow up.

Arcangeli et et al, RPROR 2015

INTRAPROSTATIC FAILURE:

BRACHYTHERAPY AS AN OPTION

Prostate brachytherapy is increasingly common modality for the primary treatment in prostate cancer

Compared with EBRT, it is possible to administer a high radiation dose to a tightly confined volume

Thus, it may be possible to use this modality to provide a second opportunity for tumour control in the patient with locally recurrent prostate cancer after EBRT

INTRAPROSTATIC FAILURE:

QUESTIONS DURING THE PATIENT SELECTION FOR SALVAGE APPROACH

1. Is the cancer potentially curable?

- Initial cancer (before radiation) curable: T1-3a N0 M0
- Current cancer T1-3a, PSA < 10 - 15, no evidence of metastases, positive re-biopsy

2. Is the patient appropriate?

Good health, life expectancy >10 years

Highly motivated, willing to accept risks of salvage therapy

3. Would the treatment be safe?

No evidence of severe radiation cystitis or proctitis

Lyle H. Ungar, PhD,§ Adam Cunha, PhD,* Timothy D. Solberg, PhD,*
and I-Chow Hsu, MD*

*Radiation Oncology Department, University of California San Francisco, San Francisco, California; †Data Analytic Program, University of San Francisco, San Francisco, California; ‡Department of Statistics, The Wharton School, and §Department of Computer and Information Science, University of Pennsylvania, Philadelphia, Pennsylvania

Received Jul 20, 2017, and in revised form Jan 7, 2018. Accepted for publication Mar 6, 2018.

- The most important features analyzed are percentage of positive cores after biopsy and disease-free interval after the first definitive treatment.
- Patients with HisPercentPositive $\geq$0.35 and a disease-free interval <4.1 years benefit the least from sHDRB (p[BF = yes] = 0.75).
- Patients with HisPercentPositive <0.354 or disease-free interval $\geq$4.1 years (p[BF = yes] = 0.38) benefit the most from sHDRB.
- There is a 70% probability that these findings are not due to chance.
- The accuracy is limited by the number of patients in the study and will be improved if additional data become available.
- It will take 20 years to collect data at 1 institution to statistically prove or disprove the hypothesis generated.

Focal salvage BRT

Focal salvage brachytherapy might reduce the frequency of adverse events while achieving acceptable cancer control.

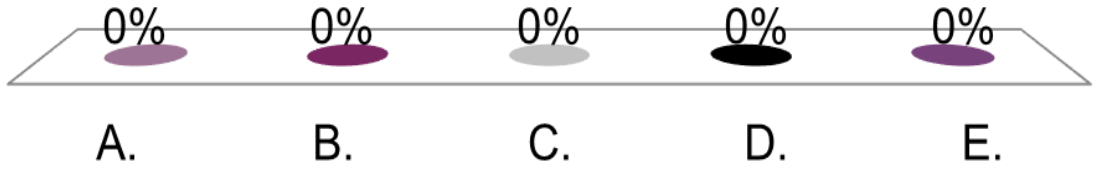
What is your preferred management for a patient aged 66 years presenting with a PSA of 13.6, Gleason score 4+3 prostate cancer which is stage T2B on MR staging? He has no significant co-morbidities

A. Radical prostatectomy
B. Active surveillance
C. External beam IMRT to 78Gy
D. LDR seed brachytherapy
E. External beam IMRT + HDR boost



Which is best?

- Surgery vs IMRT
- Surgery vs BT
- BT vs IMRT
- Surgery vs IMRT vs BT
- LDR BT vs HDR BT

Radical prostatectomy

ADVANTAGES

- Pathological diagnosis
- No bowel toxicity
- Relief of LUTS
- Established salvage with external beam RT
- No additional second malignancies

DISADVANTAGES

- Erectile dysfunction 50%+
- Urinary control
- Anaesthetic procedure

IMRT

ADVANTAGES

- Outpatient process
- No anaesthetic
- Low urinary toxicity
- Lymphatic treatment possible

DISADVANTAGES

- No pathological diagnosis
- Lengthy treatment course
- Bowel toxicity
- Erectile dysfunction
- Adjuvant ADT
- Second malignancies
- Limited salvage options

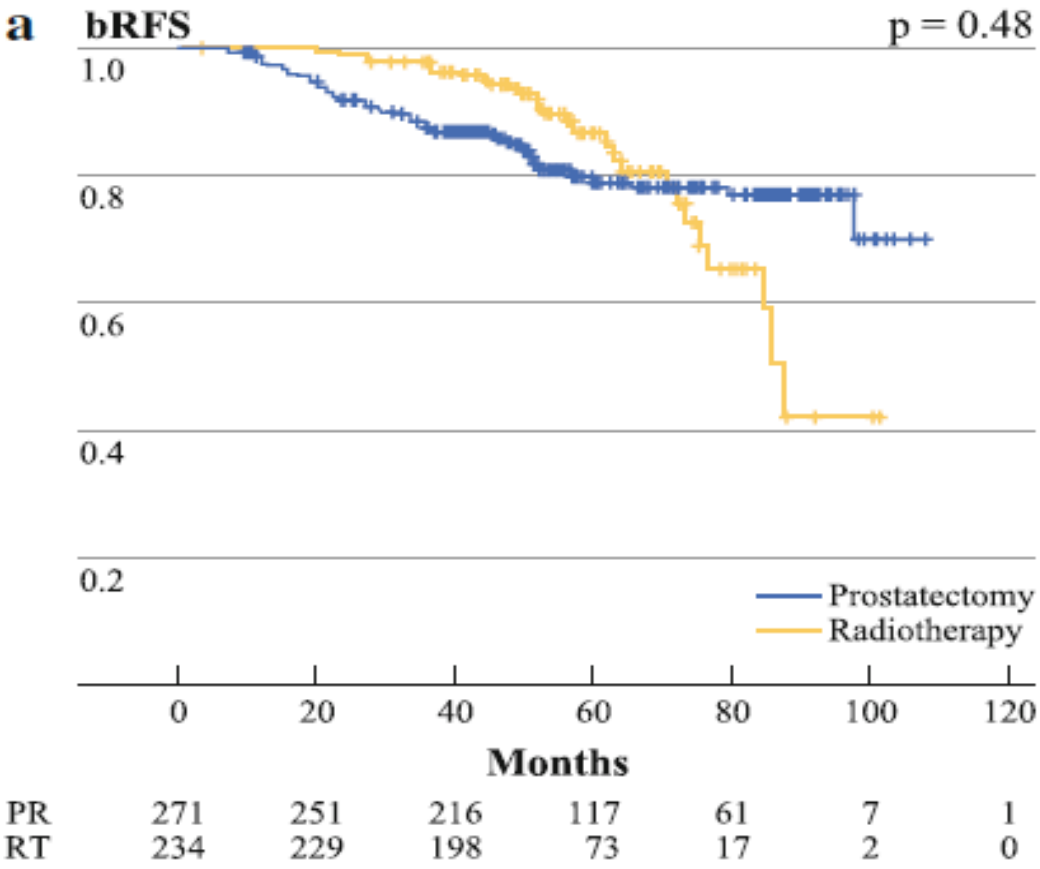
Radical Prostatectomy Versus External-Beam Radiotherapy for Localized Prostate Cancer: Long-Term Effect on Biochemical Control—In Search of the Optimal Treatment

Carmen González-San Segundo, MD, PhD[1], Felipe Herranz-Amo, MD, PhD[2], Ana Álvarez-González, MD[1], Pedro Cuesta-Álvaro, PhD[3], Marina Gómez-Espi, MD[1], Eva Paños-Fagundo, MD[2], and Juan A. Santos-Miranda, MD, PhD[1]

Ann Surg Oncol (2011) 18:2980–2987



Toxicity

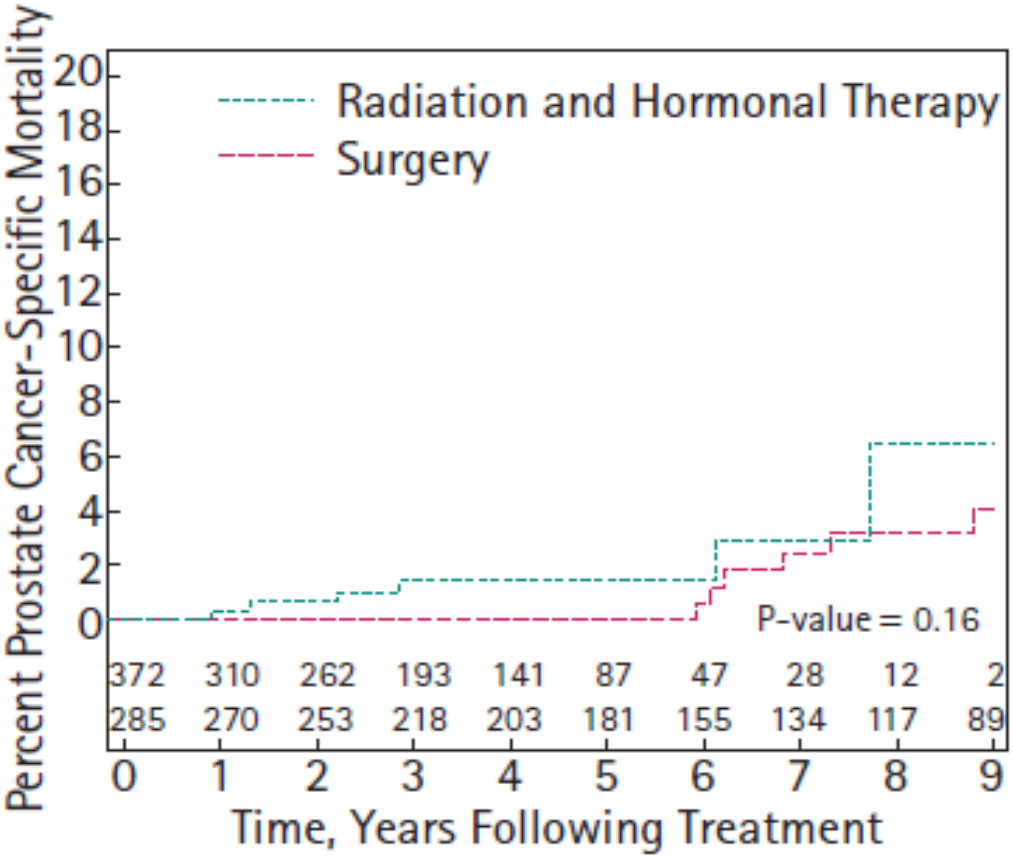
Radiation-induced toxicity greater than grade 2 in the rectum (acute 3%, late 0.5%) and bladder (acute 7.5%, late 3%) was low. The risk of incontinence in the surgical group was 25% (international prostate symptom score and/or expanded prostate cancer index composite scores). No sexual toxicity was analyzed because reliable data were only available for 211 cases.

Radical prostatectomy vs radiation therapy and androgen-suppression therapy in high-risk prostate cancer

Kenneth Westover, Ming-Hui Chen*, Judd Moul†, Cary Robertson†, Thomas Polascik†, Daniel Dosoretz‡, Michael Katin‡, Sharon Salenius‡ and Anthony V. D'Amico

2012 BJU INTERNATIONAL | 110, 1116–1121

High risk: Gleason 8-10



Adjuvant RT in only 17/285 RP patients

No toxicity data

ESTRO School

Relative advantages and disadvantages: LDR vs HDR

LDR

- Single step procedure
- Low radioprotection

- Volume limited
- Limited cover of ECE/SV
- Dose determined by implant accuracy
- QA post implant

HDR

- (Fractionation)
- Requires HDR facility

- Can implant large glands
- Can implant ECE and SV
- Accurate dose delivery
- Biologically higher dose
- QA pre delivery

Dosimetric comparison between treatment plans of patients treated with low-dose-rate vs. high-dose-rate interstitial prostate brachytherapy as monotherapy: Initial findings of a randomized clinical trial

Brachytherapy 16 (2017) 608–615

T. Major*, C. Polgár, K. Jorgo, G. Stelczer, P. Ágoston

RCT → HDR 19Gy

RCT → LDR 145Gy

n=87

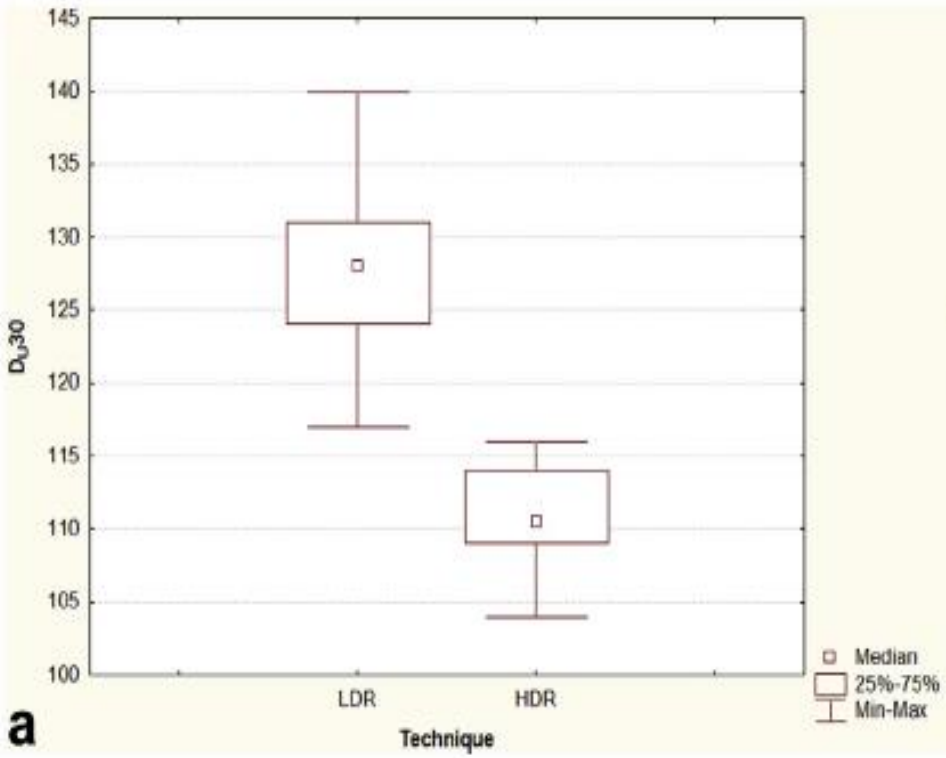
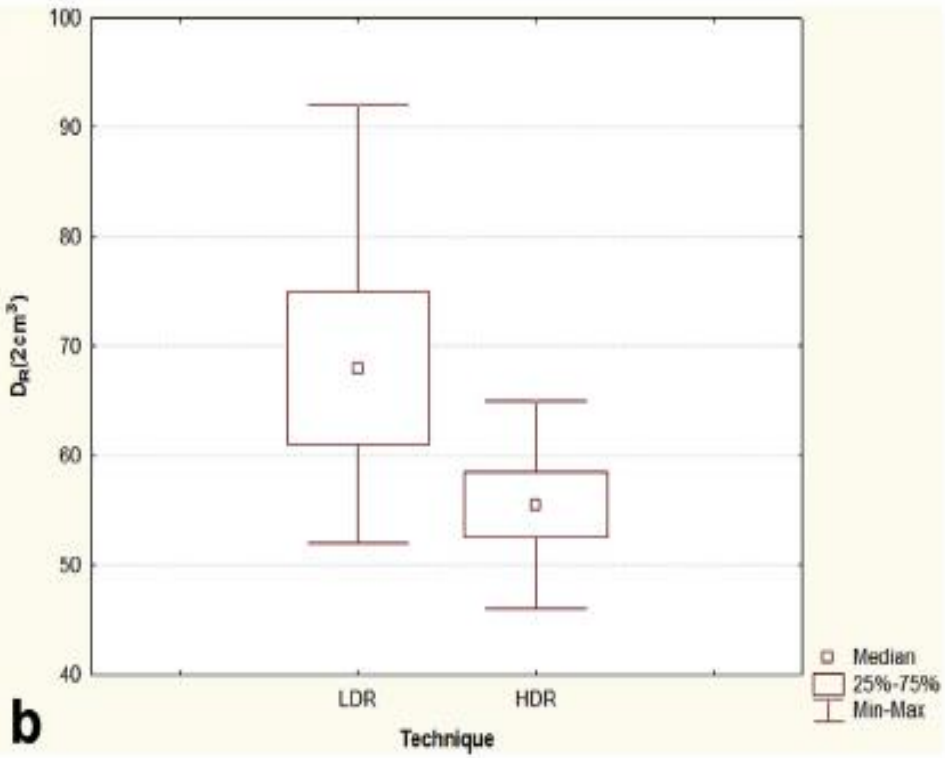
Urethra



Rectum



Treatment costs

- Implant equipment similar for PPB and HDR:
  - Fixation device with stepping unit
  - US apparatus
  - Planning system
  - Disposables: catheters, needles etc
  - OR facilities and support
  - Anaesthesia
  - Hospitalisation
  - Supportive medication

Treatment costs

HDR

Use of afterloader

Capital cost

- Assume 30% use for prostate and 50/year
- 400 Euro/patient

Source cost

- Assume as above
- 40 Euro/patient

TOTAL:

440 Euro/patient

LDR SEEDS

Cost of seeds

- Assume average 100 seeds per patient

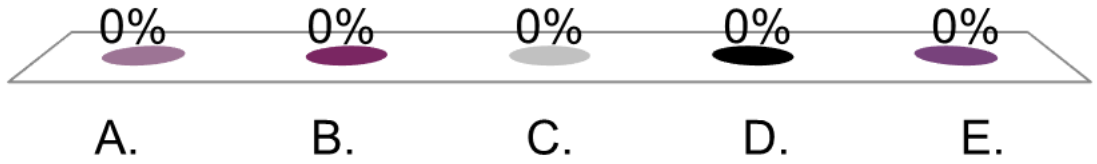
TOTAL:

3500 Euro/patient

ESTRO School

What is your preferred management for a patient aged 66 years presenting with a PSA of 13.6, Gleason score 4+3 prostate cancer which is stage T2B on MR staging? He has no significant co-morbidities

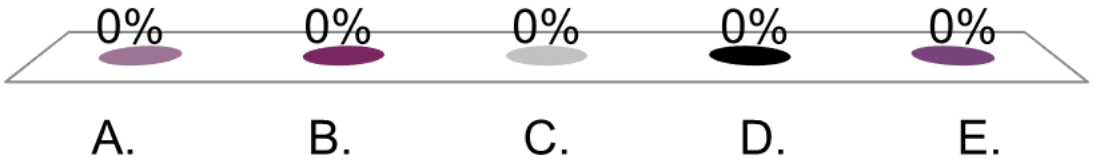
A. Radical prostatectomy
B. Active surveillance
C. External beam IMRT to 78Gy with ADT
D. LDR seed brachytherapy with ADT
E. External beam IMRT + HDR boost



ESTRO School

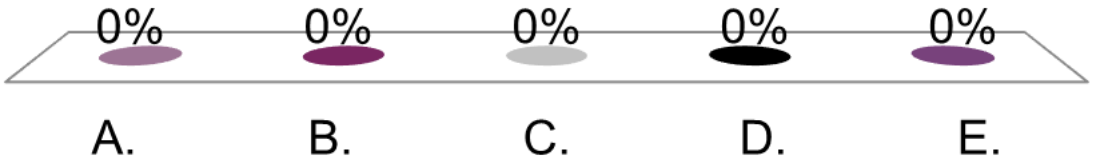
What is your preferred management for a patient aged 66 years presenting with a PSA of 13.6, Gleason score 4+3 prostate cancer which is stage T3a on MR staging? He has no significant co-morbidities

A. Radical prostatectomy
B. Active surveillance
C. External beam IMRT to 78Gy with ADT
D. LDR seed brachytherapy with ADT
E. External beam IMRT + HDR boost



What is your preferred management for a patient aged 66 years presenting with an IPSS of 19, PSA of 13.6, Gleason score 4+4 prostate cancer which is stage T3a on MR staging? He has no significant co-morbidities

A. Radical prostatectomy
B. Active surveillance
C. External beam IMRT to 78Gy with ADT
D. LDR seed brachytherapy
E. External beam IMRT + HDR boost



Does the technique matter?
