ESTRO course on IMRT and other conformal techniques
3-7 April 2016, London – United Kingdom

Sunday 03 April

8.30 – 8.45 Introduction to the course - *Marco Schwarz*

8.45 - Group B: Going to UCLH London

9.30 – 10.00 Demo 1: Plan verification using 2D and 3D methods - V*asilis Rompokos/ Narinder Lalli*

10.00 – 10.30 Demo 2: Imaging and Positional Verification with 6DOF corrections - *Chris Stacey/Maria Kilkenny*

10.30 – 11.00 Coffee break

11.00-11.30 Demo 3: Multimodality Image Registration for Volume Delineation - *Turmi Patel/Peter Lac*

11.30 – 12.00 Demo 4: Immobilisation Strategies for Sarcoma and Paediatric - *David Marsh/Kristina Quingua*

Group A : Lectures at the Hotel
Chair: *Frank Lohr*

9.15 – 9.30 Opening and welcome - *Dr Yen Chang*

9.30 – 10.00 Cancer and the current status of IMRT and UCLH - *Dr Yen Chang*

10.00 – 10.30 Coffee break

10.30 – 10.55 Treatment Image review+ adaptive strategies for H&N and Lung
RTT perspective - *Syed Moinuddin*

10.55 - 11.20 Treatment Image review+ adaptive strategies for H&N and Lung
Physics perspective - *Dr Rachel Bodey*

11.20 – 11.50 IMRT for Paediatrics - *Dr Jenny Gains*

11:50 – 12:20 IMRT for Sarcoma - *Dr Franel LeGrange*

12.30 - 13.30 Lunch

13.30 - Group A Going to UCLH London

14.00 – 14.30 Demo 1: Plan verification using 2D and 3D methods - V*asilis Rompokos, Narinder Lalli*

14.30 – 15.00 Demo 2: Imaging and Positional Verification with 6DOF corrections - *Chris Stacey/Maria Kilkenny*

15.00 – 15.30 Coffee break

15.30-16.00 Demo 3: Multimodality Image Registration for Volume Delineation - *Turmi Patel/Peter Lac*

16.00 – 16.30 Demo 4: Immobilisation Strategies for Sarcoma and Paediatric - *David Marsh/Kristina Quingua*

Group B - Lectures at the hotel:

Chair: *Matthias Soehn*

14.00 – 14.30 Opening and welcome - *Dr Yen Chang*

14.30 – 15.00 Cancer and the current status of IMRT and UCLH - *Dr Yen Chang*

15.00 – 15.30 Coffee break

15.30 – 15.55 Treatment Image review+ adaptive strategies for H&N and Lung
RTT perspective - *Syed Moinuddin*

15.55 - 16.20 Treatment Image review+ adaptive strategies for H&N and Lung
Physics perspective - *Dr Rachel Bodey*

16.20 – 16.50 IMRT for Paediatrics - *Dr Jenny Gains*

16:50 – 17:20 IMRT for Sarcoma - *Dr Beatrice Seddon*

Monday 04 April

Chair: *Giovanna Gagliardi*

9.00 - 9.30 Rational of IMRT. A clinician's point of view - *Frank Lohr*

9.30 - 10.15 IMRT delivery techniques – *Marco Schwarz*

10.15 - 10.45 Coffee Break

10.45 - 11.30 Dosimetry issues in IMRT – *Koen Tournel*

11.30 - 12.00 TPS commissioning – *M. Schwarz*

12.00 – 12.45 Potential and limitations of rotational IMRT – *Koen Tournel*

12.45 - 14.00 Lunch

Chair: *Koen Tournel*

14.00 - 14.45 Highly conformal techniques in early stage lung cancer: indications, techniques, normal tissue constraints, results – *Andrea Filippi*

14.45 - 15.30 IMRT in breast and risk of secondary cancer after IMRT – *Frank Lohr*

15.30 - 16.00 Coffee break

16.00 - 16.45 Highly conformal techniques in advanced stage lung cancer: indications, techniques, normal tissue constraints, results – *Andrea Filippi*

16.45 – 17.30 IMRT in GI and gynecology - Dr Gemma Eminowicz

Tuesday 05 April

Chair: *Marco Schwarz*

9.00 - 9.45 IMRT optimization: algorithms and cost functions – *Matthias Soehn*

9.45 – 10.30 Modeling adverse effects after 3DCRT and IMRT– *Eva Onjukka*

10.30 - 11.00 Coffee break

11.00 -11.45 Review of Dose-volume relationships I: H&N - *Giovanna Gagliardi*

11.45 - 12.30 IMRT in Head and neck – *Frank Lohr*

12.30 - 14.00 Lunch

14.00 - 15.30

Group A:
Clinical case discussion 1 (14.00-14.45)

Clinical session 1: Andrea Filippi, Koen Tournel (Room Trinity) - Lymphoma
Clinical session 2: Heather Payne, Matthias Soehn (Room Somerville) - Prostate
Clinical session 3: Frank Lohr, Giovanna Gagliardi (Room Merton) – H&N

Clinical case discussion 2 (14.50-15.30)

Clinical session 1: Heather Payne, Matthias Soehn (Room Trinity) - Prostate
Clinical session 2: Frank Lohr, Giovanna Gagliardi (Room Somerville) – H&N
Clinical session 3: Andrea Filippi, Koen Tournel (Room Merton) – Lymphoma

Group B: Vendor session (**Room Oxford**)

Chair of the session: *Marco Schwarz*

15.30 - 16.00 Coffee break

16.00 – 16.45

Group A:
Clinical case discussion 3

Clinical session 1: *Frank Lohr, Giovanna Gagliardi (**Room Trinity**) - Lymphoma*
Clinical session 2: *Andrea Filippi, Koen Tournel (**Room Somerville**) - Prostate*
Clinical session 3: *Heather Payne, Matthias Soehn (**Room Merton**) – H&N*

Group B: free

Wednesday 06 April

Chair: *Frank Lohr*

9.00 - 09.45 'Patient specific' QA – *Eva Onjukka*

9.45 - 10.30 Impact of geometrical uncertainties on IMRT dose distributions – *Koen Tournel*

10.30 - 11.00 Coffee break

11.00 - 11.45 Review of Dose-volume relationships II: Pelvis – *Giovanna Gagliardi*

11.45 – 12.30 IMRT of prostate cancer – *Heather Payne*

12.30-14.00 Lunch

14.00-15.30

Group B:
Clinical case discussion 1 (14.00-14.45)

Clinical session 1: Andrea Filippi, Koen Tournel (Room Trinity) - Lymphoma
Clinical session 2: Heather Payne, Matthias Soehn (Room Somerville) - Prostate
Clinical session 3: Frank Lohr, Giovanna Gagliardi (Room Merton) – H&N

Clinical case discussion 2 (14.50-15.30)

Clinical session 1: Heather Payne, Matthias Soehn (Room Trinity) - Prostate
Clinical session 2: Frank Lohr, Giovanna Gagliardi (Room Somerville) – H&N
Clinical session 3: Andrea Filippi, Koen Tournel (Room Merton) – Lymphoma

Group A: Vendor session (**Room Oxford**)
Chair of the session: *Marco Schwarz*

15.30-16.00 Coffee break

16.00 – 16.45
Group B:

Clinical case discussion 3

Clinical session 1: Frank Lohr, Giovanna Gagliardi (Room Trinity) – H&N
Clinical session 2: Andrea Filippi, Koen Tournel (Room Somerville) - Lymphoma
Clinical session 3: Heather Payne, Matthias Soehn (Room Merton) – Prostate

Group A: free

Thursday 07 April

Chair: *Andrea Filippi*

9.00 - 9.45 Practical IMRT planning and ‘biological optimization’ – *Marco Schwarz*

9.45 – 10.30 Dose calculations in static and rotational IMRT - *Matthias Soehn*

10.30-11.00 Coffee break

11.00 - 11.45 Image-guidance & Adaptive: concept and approaches – *Matthias Soehn*

11.45 - 12.30 Image-guidance & Adaptive: Clinical applications – *Frank Lohr*

12.30 -13.00 Final discussion and closing of the course

Radiotherapy at UCLH

- **Radiotherapy:** UCLH -a national leader in complex and highly-technical RT 55% IMRT/VMAT
- **Brain/whole CNS cancers:** NHNN is the largest neurosurgical centre in Europe
- **Paediatric cancers:** The UCLH/GOS centre = 3rd largest paediatric centre in the world
- **Sarcomas:** UCLH/RNOH provide one of Europe's largest sarcoma services
- **Head & Neck cancers:** UCLH leads in use of IMRT for head & neck - third largest caseload of any UK centre
- **Proton Beam Therapy:** UCLH has been designated by DH to be one of the first two PBT centres for UK National Service. UCLPartners already sees 1 in 6 of all patients in England eligible for PBT, and 1 in 4 of all eligible children

Treatment Image Review + Adaptive Strategies for H&N and Lung- an RTT perspective

ESTRO IMRT School 03/04/16

Syed Ali Moinuddin
Lead Research and Development Radiographer, UCLH

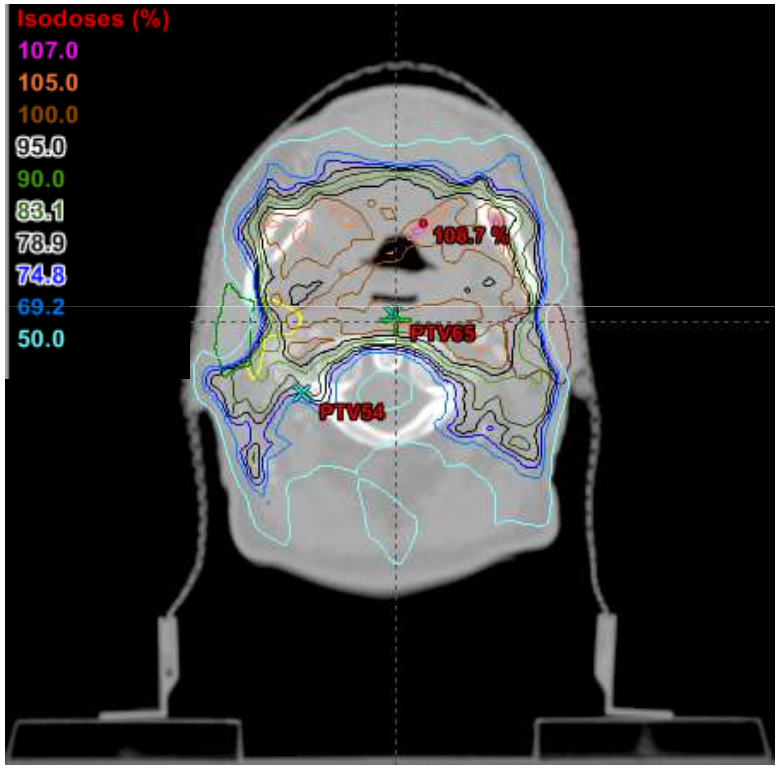
Overview

- Introduction
- Head and Neck
    - Immobilisation, CT scanning and Linac verification protocol
    - Clinical examples
- Lung
    - Immobilisation, CT scanning and Linac verification protocol
    - Clinical Examples

Introduction

The key aim of radiotherapy is to deliver a lethal dose to the tumour whilst limiting the dose (toxicity) to surrounding normal tissues.

Intensity Modulated Radiotherapy (IMRT) offers a method of delivering a much more conformal treatment with substantially lower normal tissue toxicity allowing the possibility of dose escalation to improve local control.



Introduction

However:

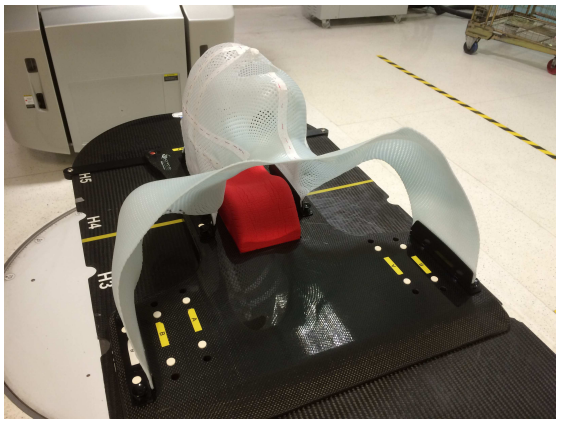
This steep dose gradient is greatly influenced/affected by:

- Variations in patient set-up
- Changes in overall patient separation/weight loss
- Changes in tumour volume size and position
- Changes in size and position of Organ at Risk (OAR) volumes.

Management of this patient cohort requires:

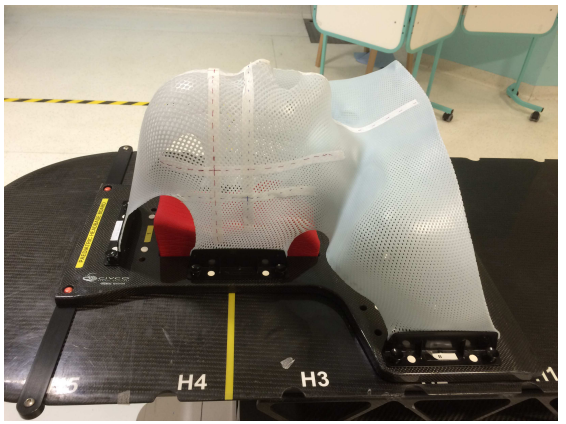
- Effective immobilisation
- Image guidance
- Comprehensive nutritional management

Head and Neck



- First UCH IMRT patient APRIL 2006

- All H/N patients
- Supine with head on foam headrest
- Arms by side
- Head and shoulders immobilised by 5 point thermoplastic shell



- 2.5mm CT scan with iv contrast

Head and Neck (current)

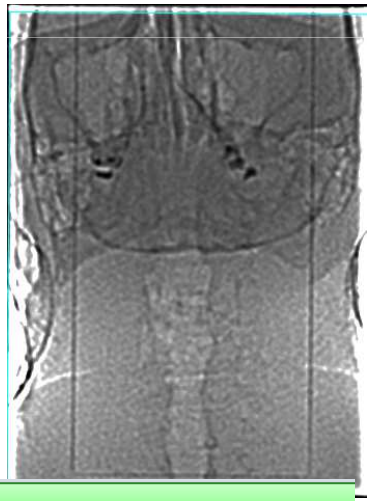
- Imaging protocol

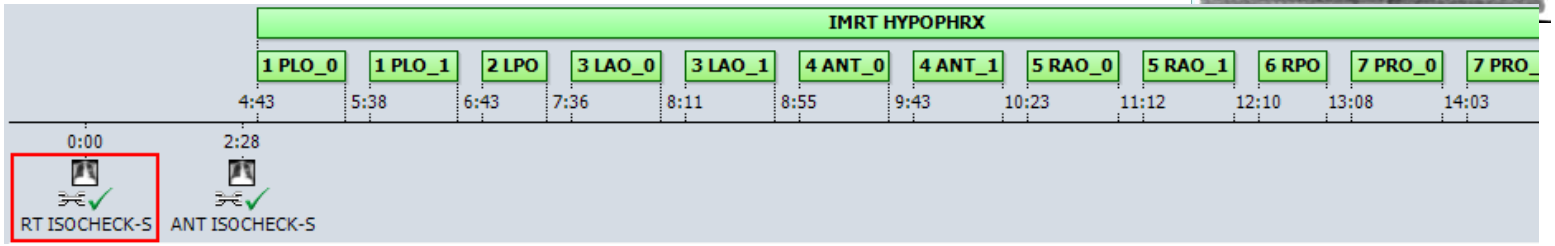
- Online daily orthogonal kV imaging with ‘shift to zero’ protocol (3mm)
- Matching to bone (systematic adjustment after #1-3)

- Additional weekly offline CBCT for PTV coverage and OAR avoidance.

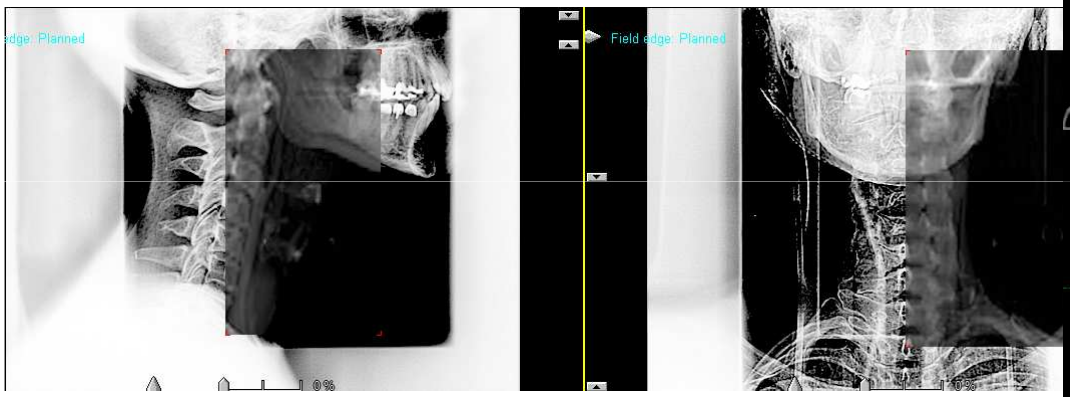
Head and Neck (historical!)

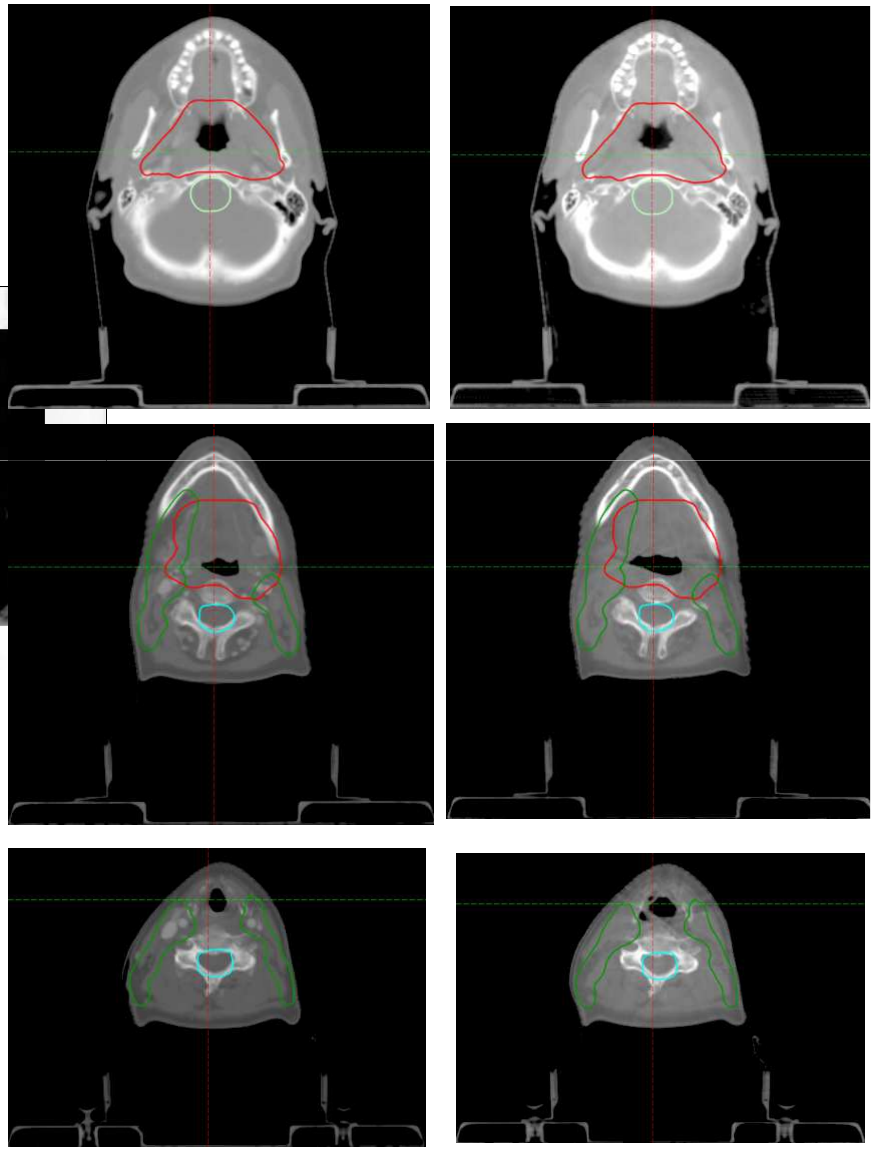
- Imaging protocol
- Orthogonal MV imaging #1-3 and weekly
- No CBCT

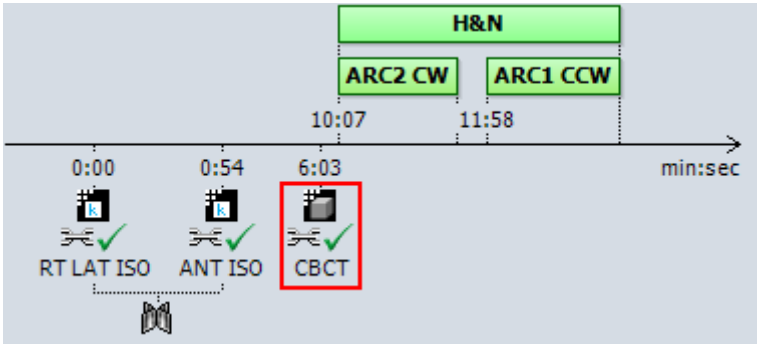




Head and Neck







uclh

Head and Neck

Issues:

Weight loss

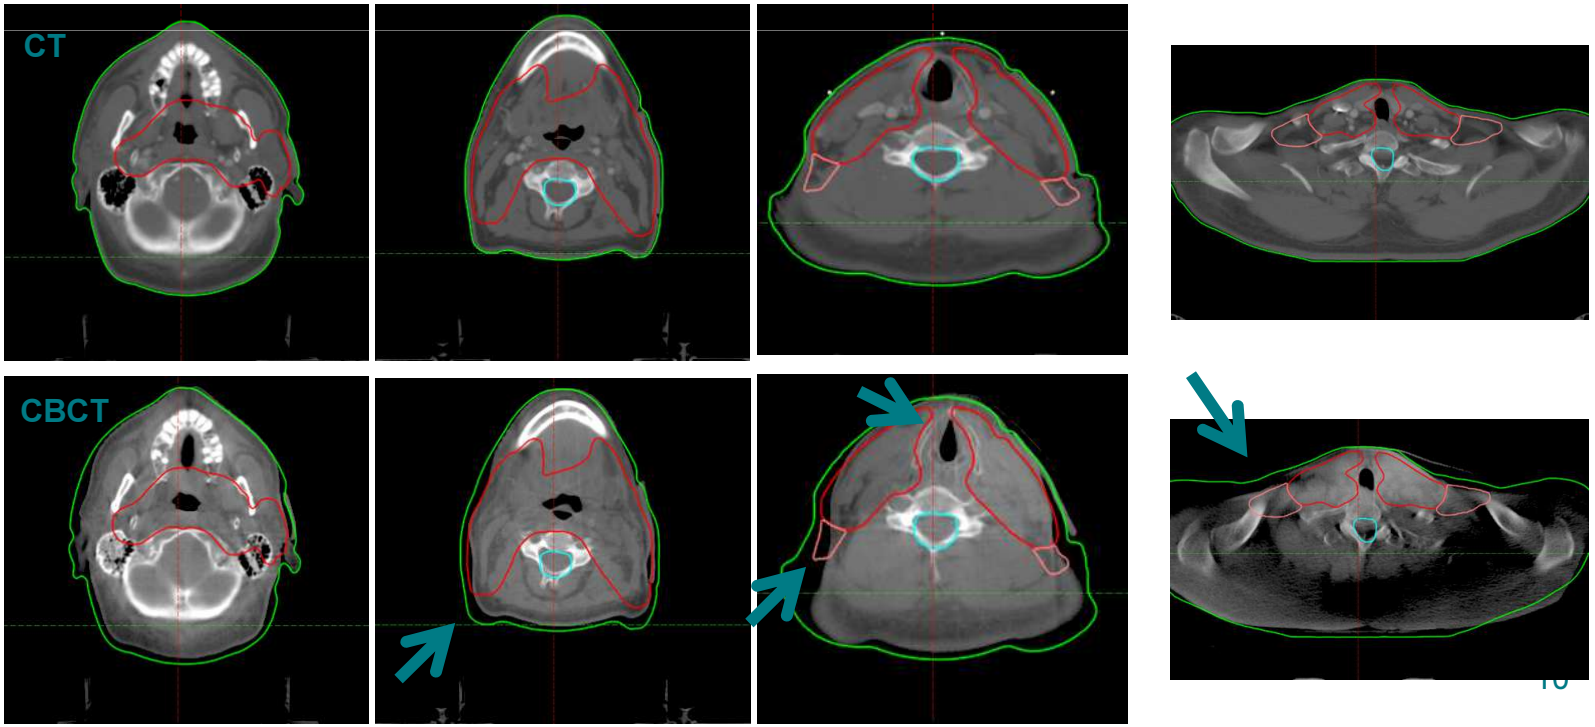
Bone positional changes

Soft tissue changes

Head and Neck

Issues:

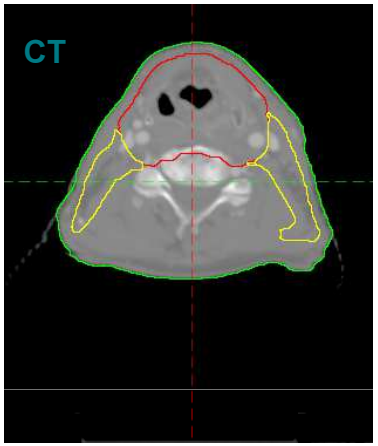
Weight loss (Non compliance)

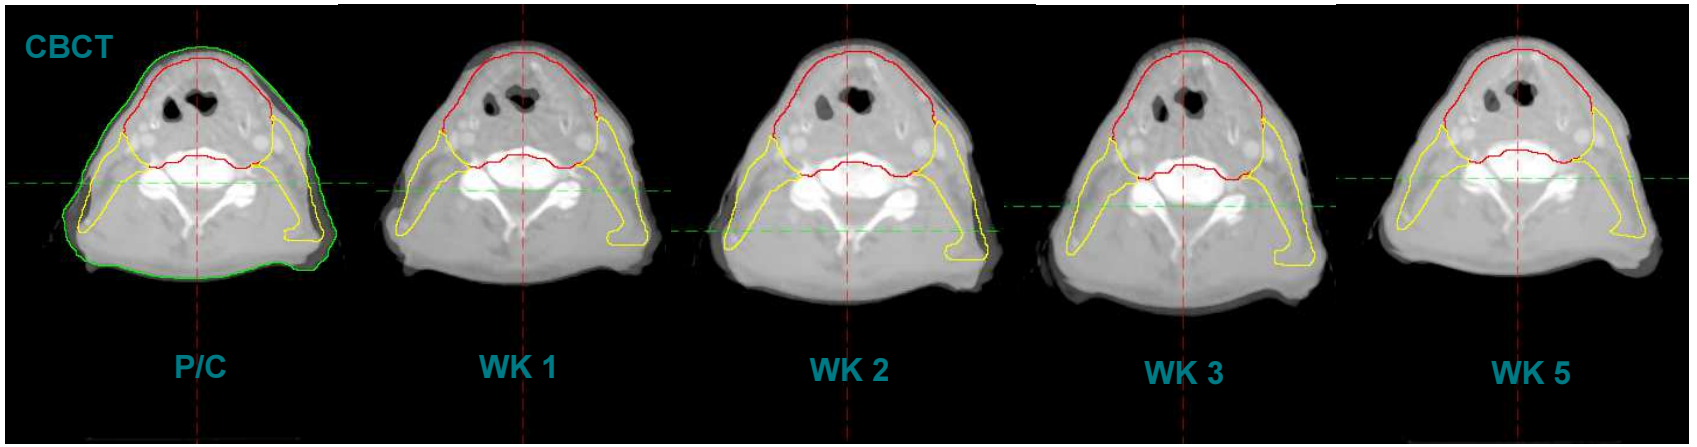


Head and Neck

Issues:

Weight loss (Compliance)





uclh

Head and Neck

Issues:

Weight loss

- Prophylactic use of PEG
- Introduction of H/N radiographer role to improve patient experience
- Introduction of twice weekly dietetic clinic

Head and Neck

Issues:

Bone positional changes

Corrected by:

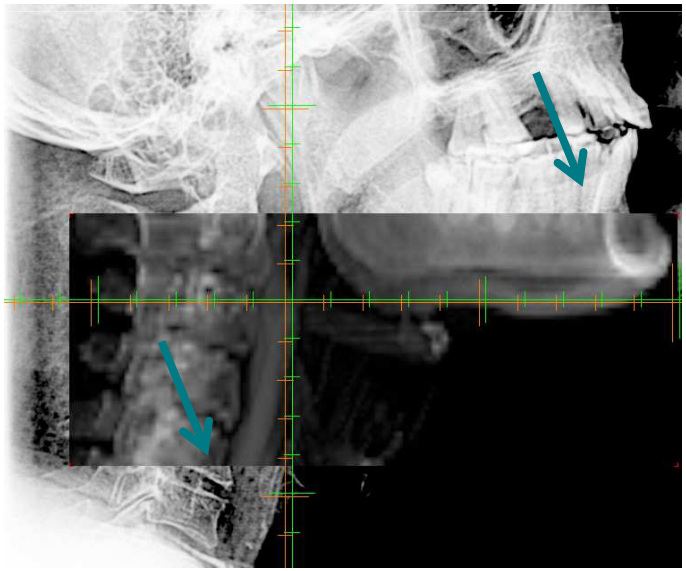
Intervention and repeat imaging
Addition of Dalzafoam
Reduction of height of the foam headrest

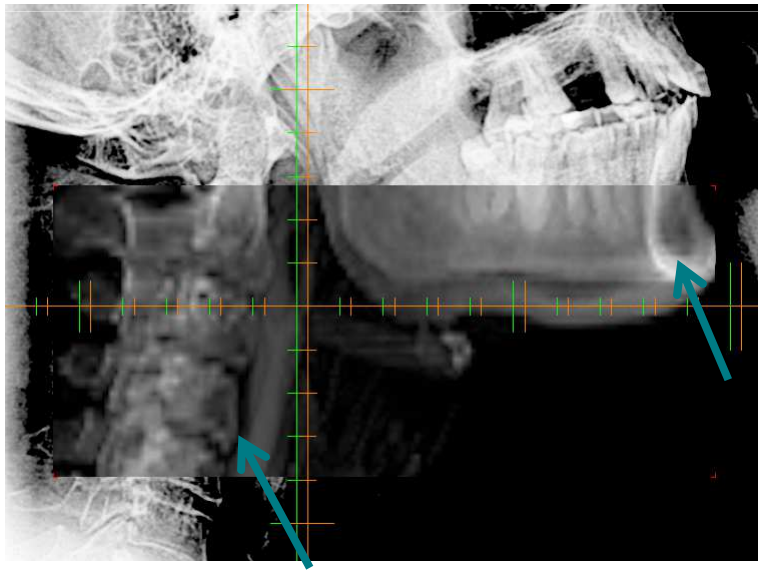
Preferential bone match to part of the cord closest to the high dose volume

Head and Neck

Issues:

Bone positional changes



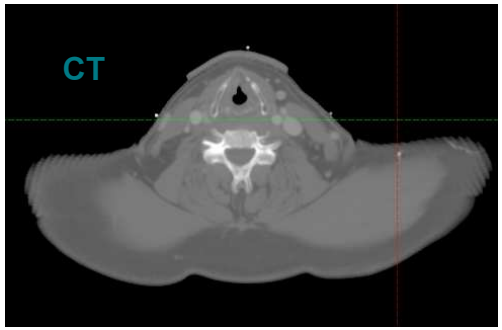


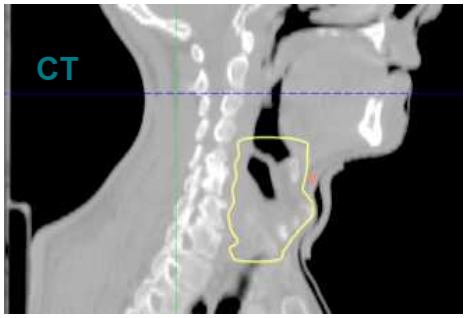
Head and Neck

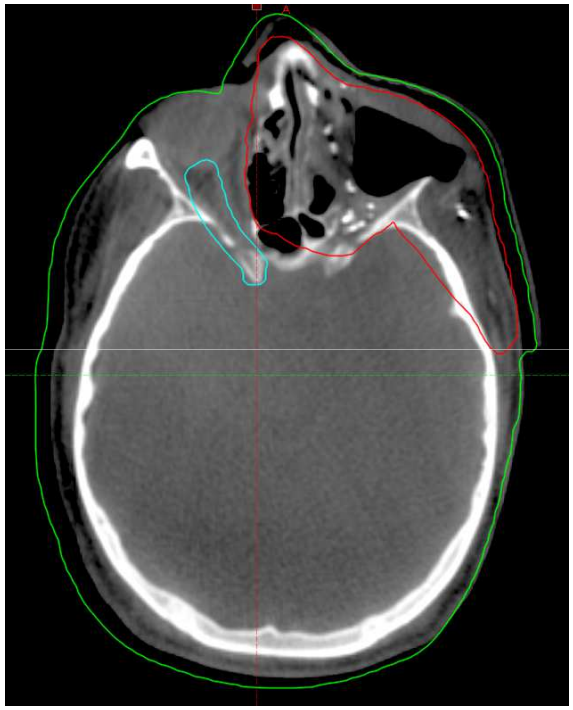
Issues:

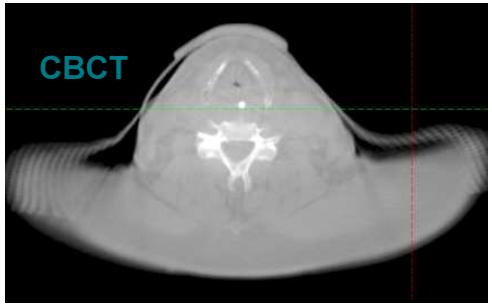
Soft tissue changes

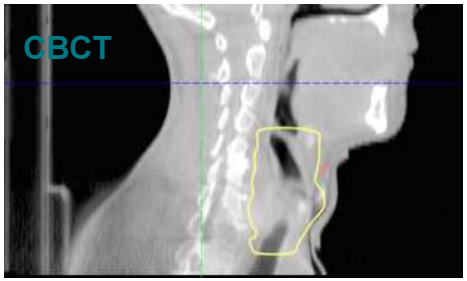
Head and Neck











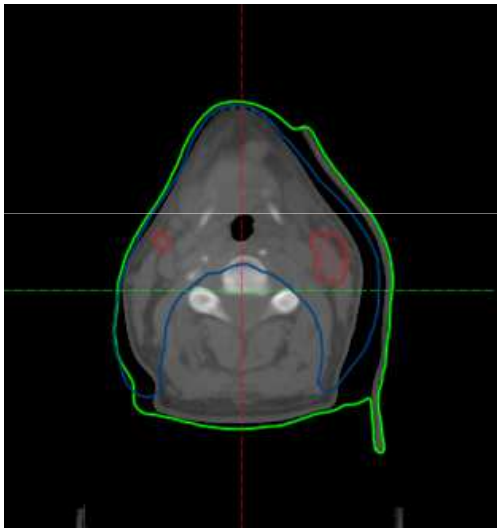
Occluded airway. May require steroids, surgical intervention or surveillance

CBCT Larynx CTV systematically in a different position.

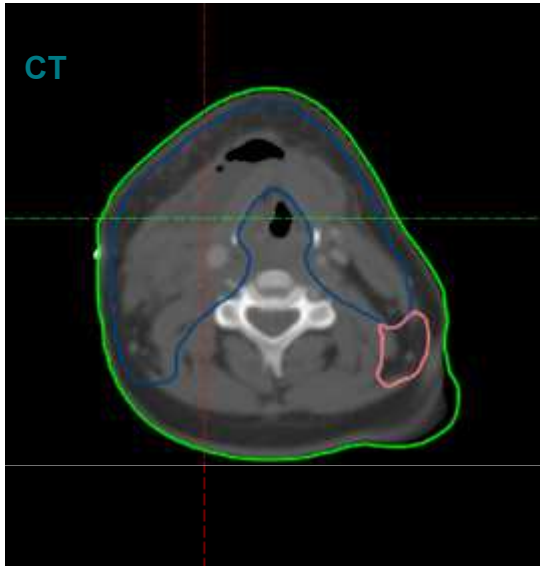
Weight loss resulting in inadequate immobilisation and roll. NB R ON outside PRV

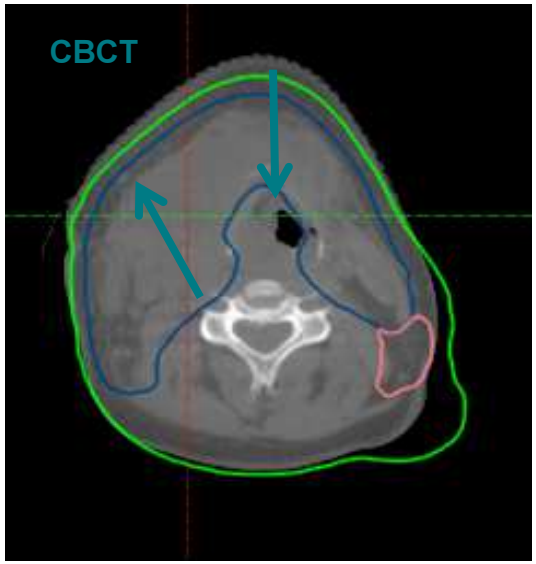
uclh

Head and Neck



Weight loss resulting separation change, increase in air gap between patient and bolus and movement of nodal volume





Tumour volume increasing resulting in airway displacement

Head and Neck

Dependent on….. MDT discussion

- Patient compliance
- Random or systematic difference
- Original plan assessment
- How many fractions left!
- Resource availability

Lung

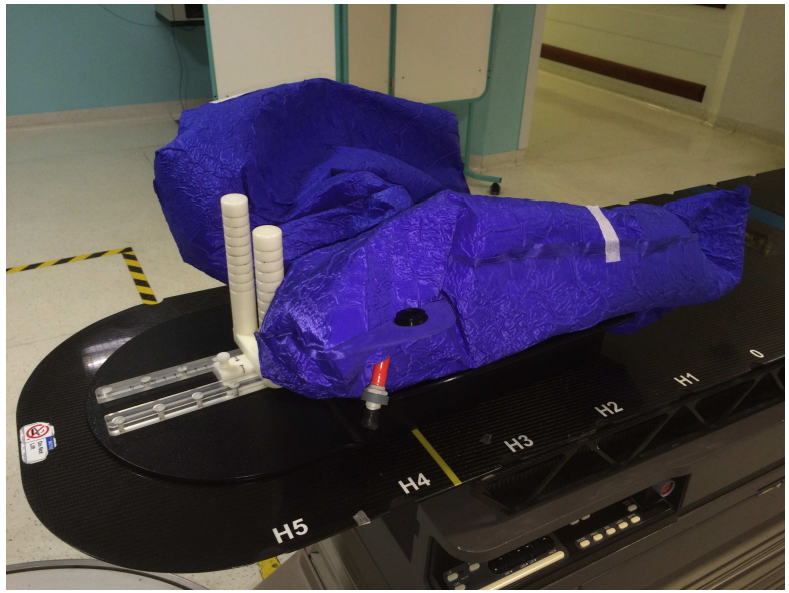
- First UCH lung IMRT patient 2012
- Lung SABR from 2013

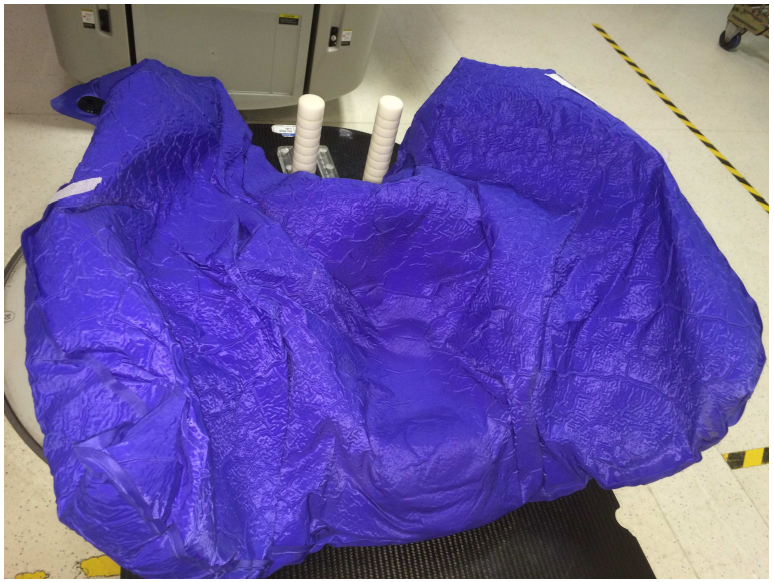
- Selected non SABR cases close to cord or brachial plexus
- Supine with arms up on a Wing Board. Arms supported by Vac Bag

- All patients have a 4d CT with contrast and coached breathing.

- Target delineation on the MIP and dosimetry on AVE-IP

Lung





Lung

- Imaging protocol (non-SABR)

- Online daily orthogonal kV imaging with ‘shift to zero’ protocol (5mm)
- Matching to bone (systematic adjustment after #1-3)

- Additional weekly offline CBCT for PTV coverage and OAR avoidance. Initial radiographer review with weekly clinical update.

Lung

- Imaging protocol (SABR)
- Online daily CBCT imaging with ‘shift to zero’ protocol (5mm)
- Matching to ITV
- Additional post treatment CBCT for PTV coverage and OAR avoidance.
- (Initial cohort also had post ‘shift to zero’ CBCT to assess effect of couch travel on coverage-not necessary!)

uclh

Lung

Issues:

Weight loss

Bone positional changes

Tumour volume changes: position and size

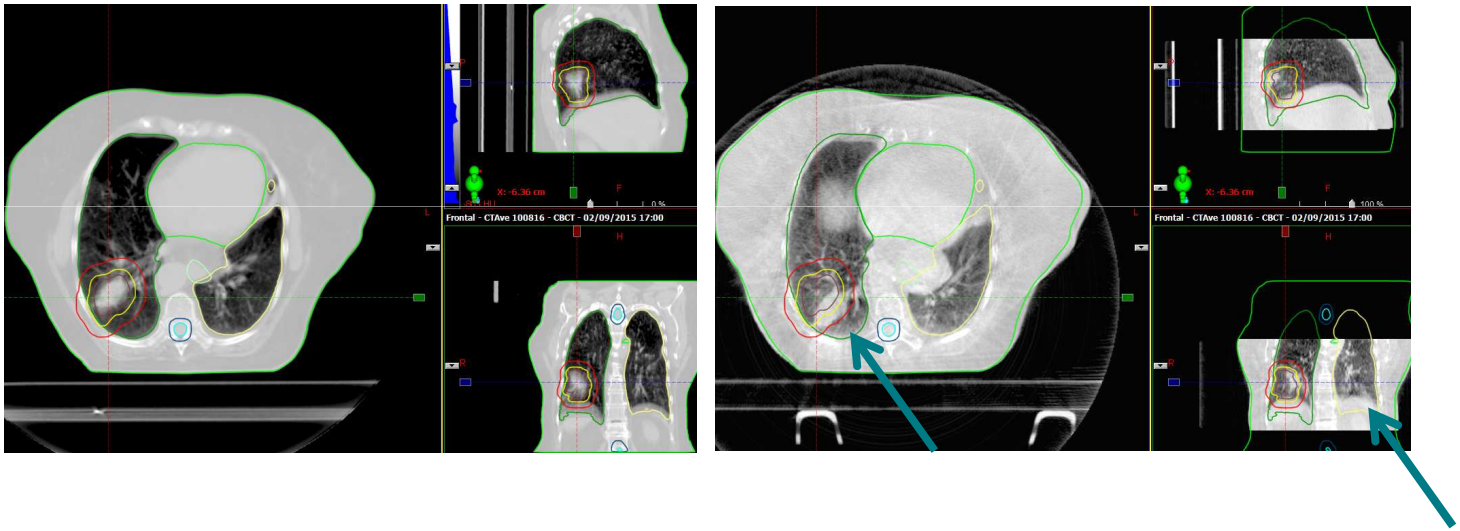
Lung deflation/Re-inflation

Infection (+/-)

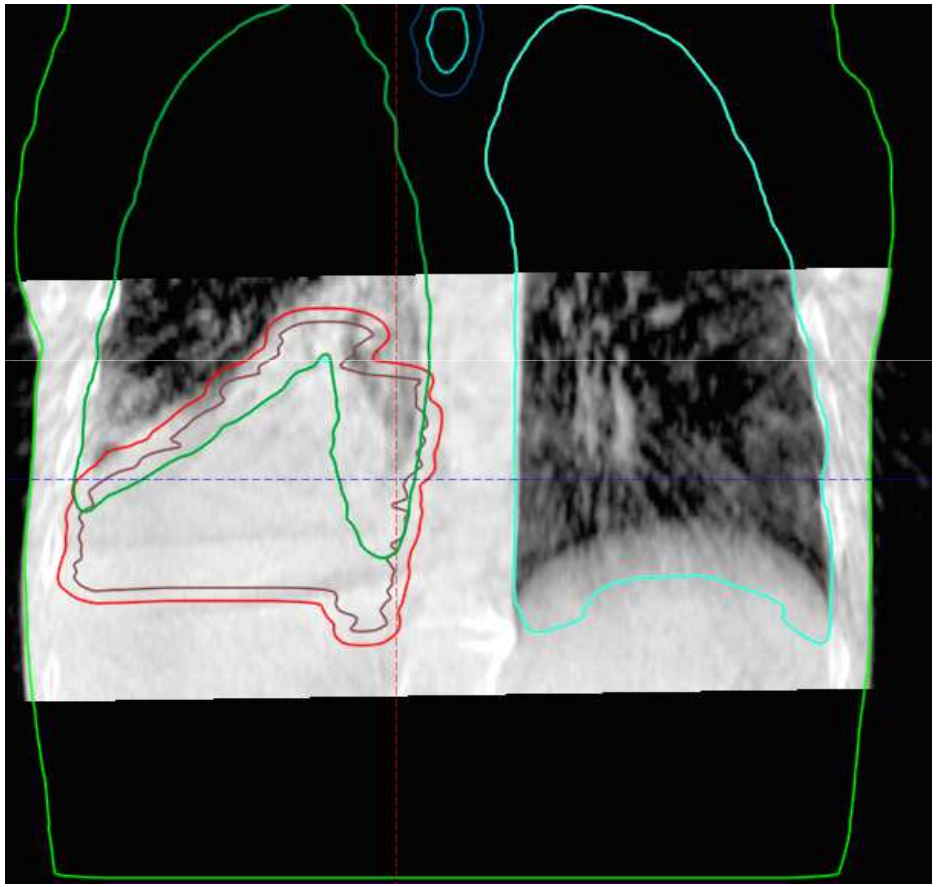
Imaging Limitations (Varian)

- kV-low dose, bone anatomy
- Maximum length is 20cm
- CBCT-not low dose, soft tissue
- Maximum length is 16cm
- Image quality
- Data acquired in 1 minute so motion artefact-4d CBCT coming soon!

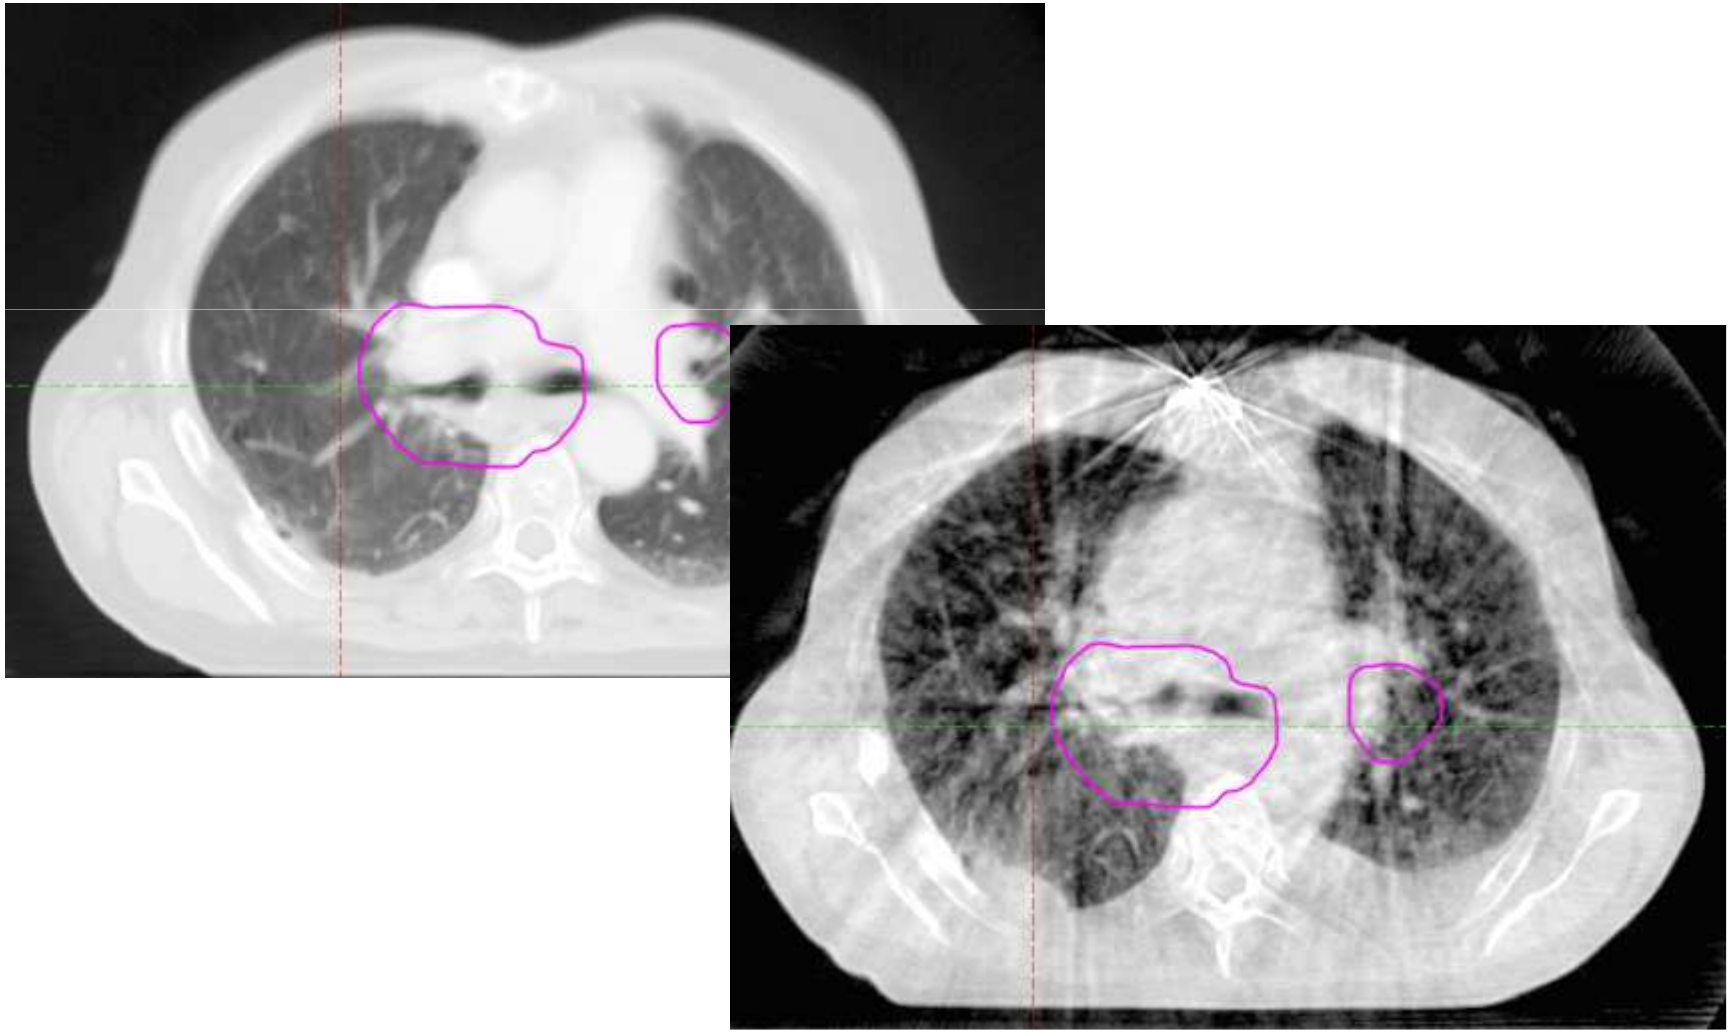
Clinical Cases- non SABR Lung



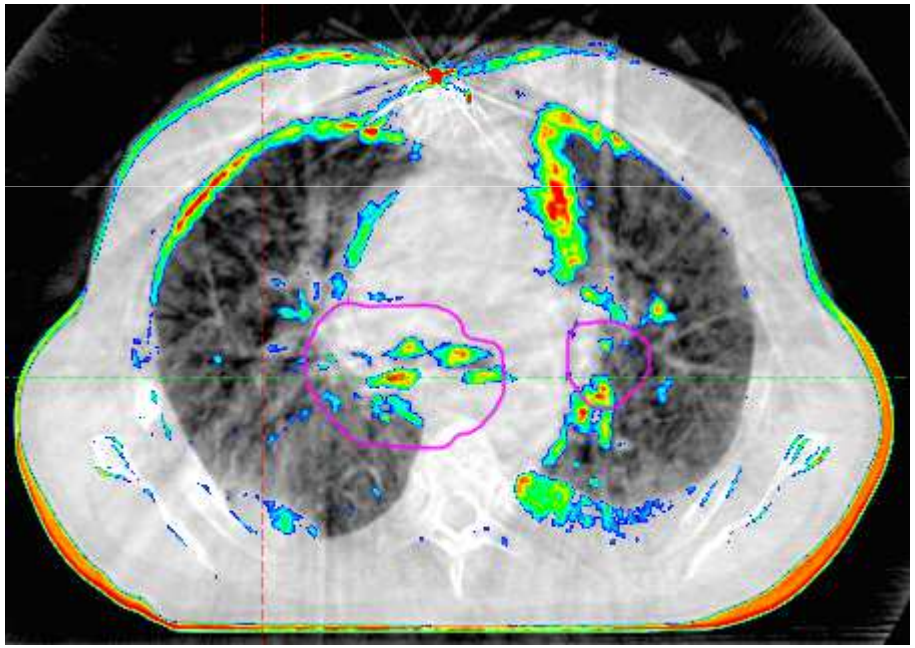
Clinical case: non-SABR

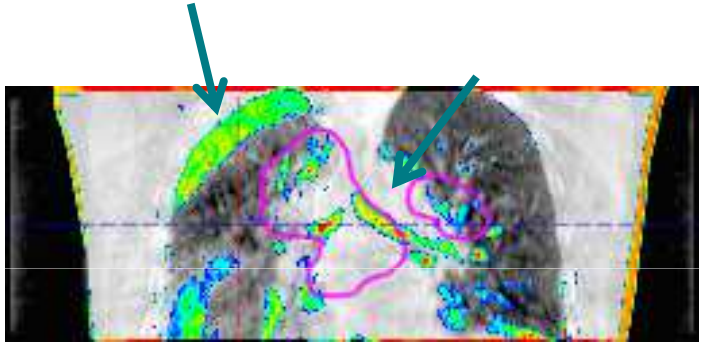


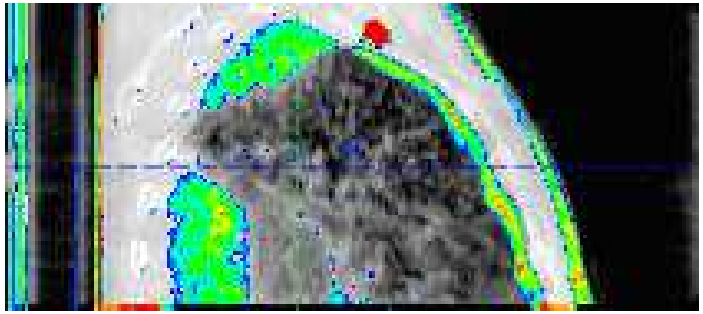
Clinical Cases- non SABR



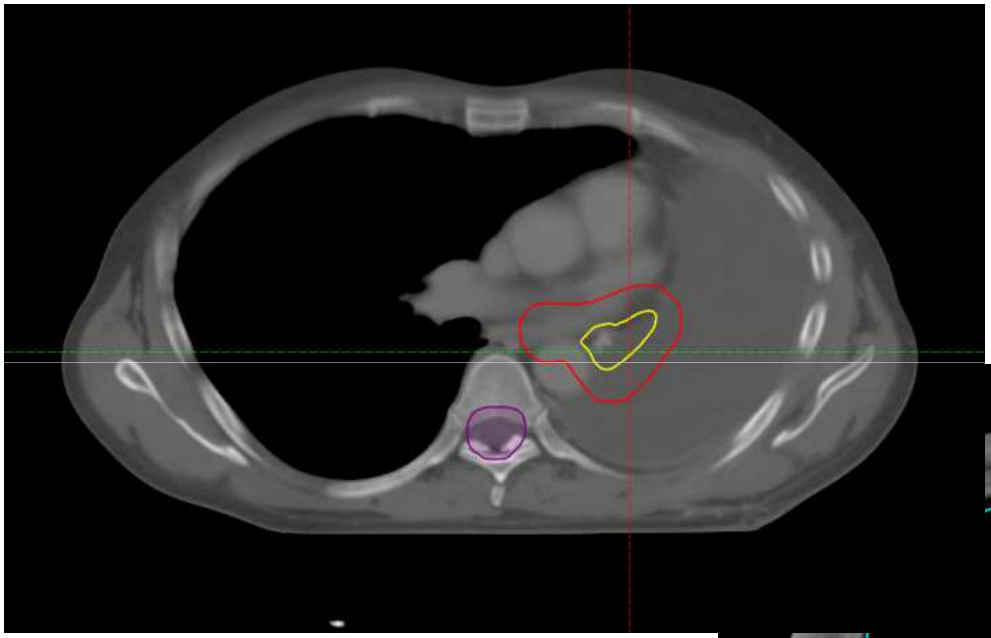
Clinical case: non-SABR

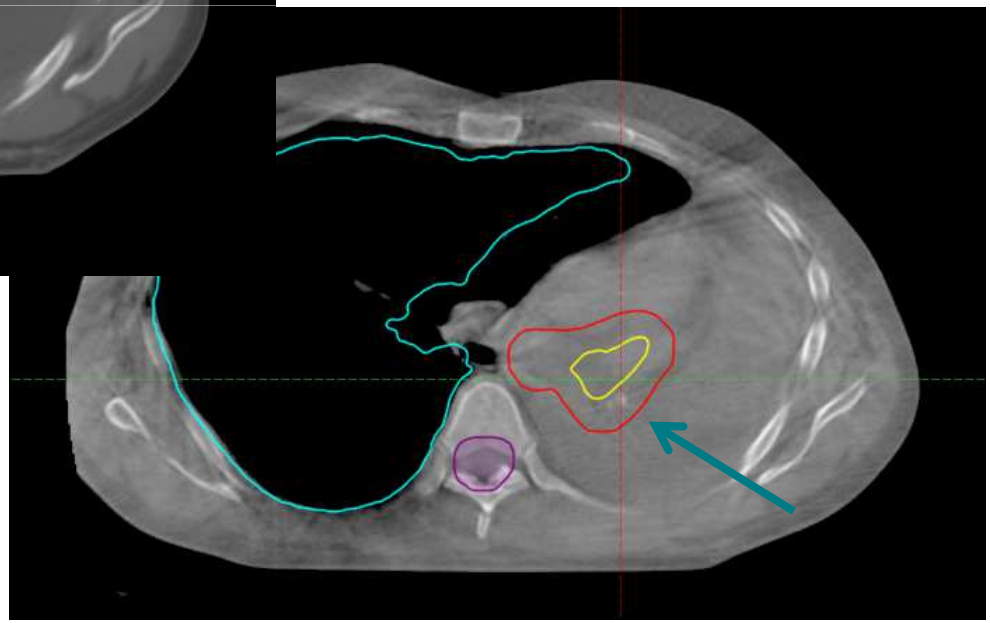






Clinical case: non-SABR

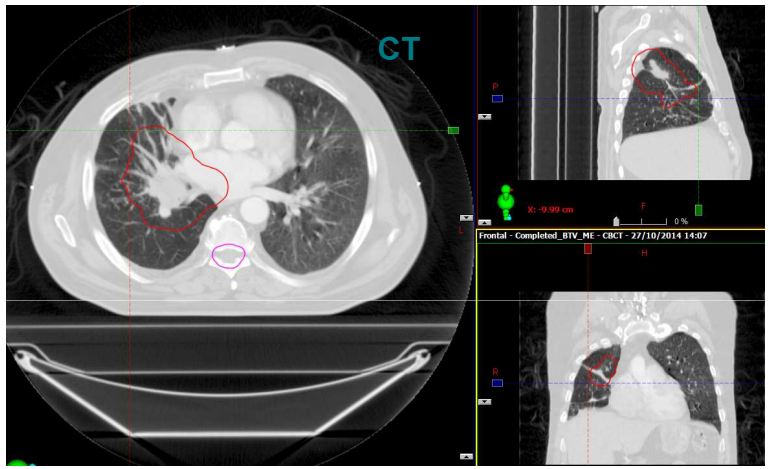


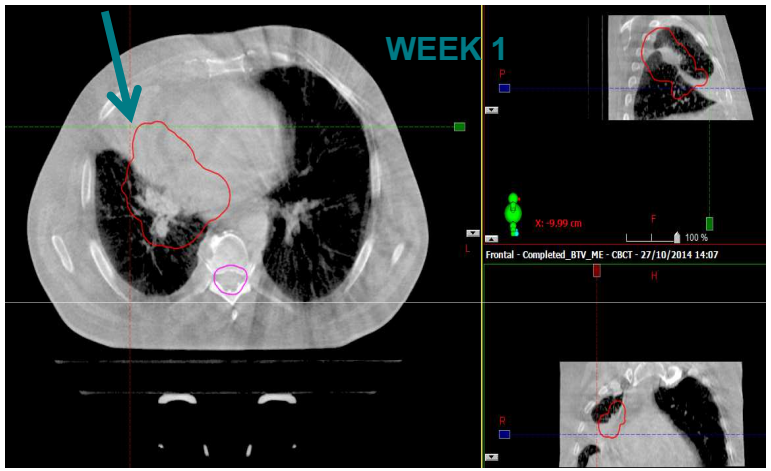


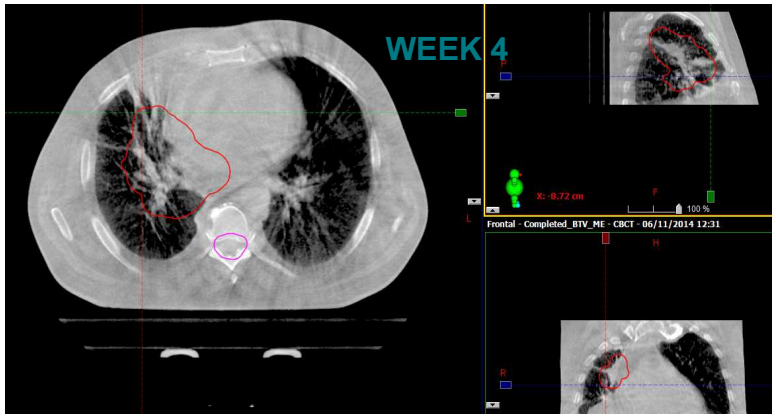
Pt has one functioning lung

kV shows good bone set up
CBCT show RT lung re-inflation
CBCT shows movement of heart etc. to left
NB calcification
Action: Re-plan!

Clinical case: non-SABR





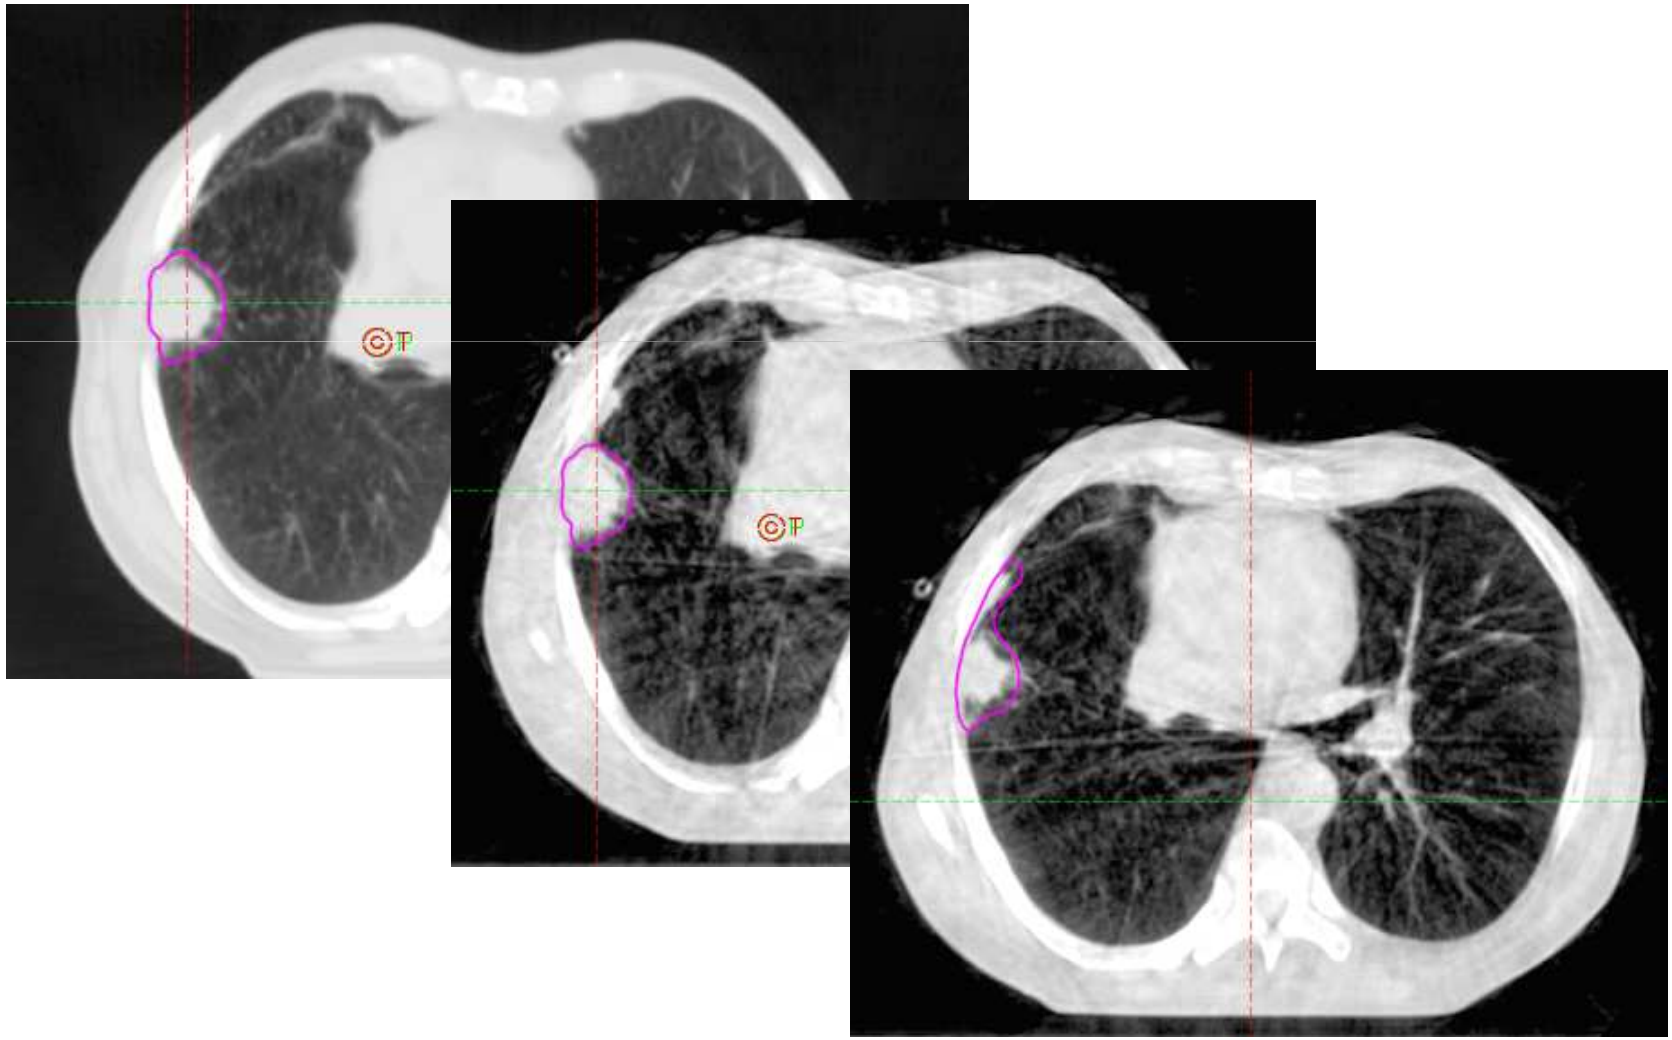


CBCT WK1 shows reduced lung volume and increased anterior density-coverage tight posteriorly

CBCT frequency changed to x2 weekly

CBCT week 4 shows resolution of change-no re-plan required

Clinical Cases-SABR lung



Summary

- CBCT is a useful imaging tool
- Highlights anatomical changes
- Does not tell you about dosimetric impact
- Density changes can have a greater impact in lung than other anatomical sites.
- Useful paper Kwint et al, (2014)

Thank you

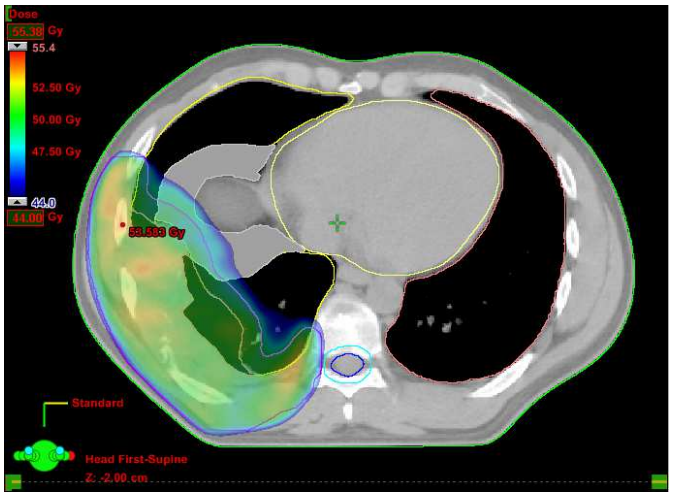
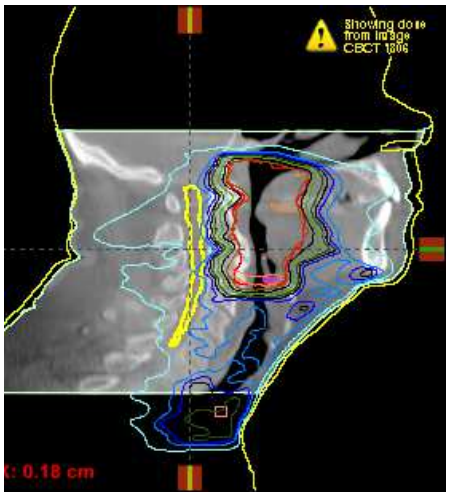
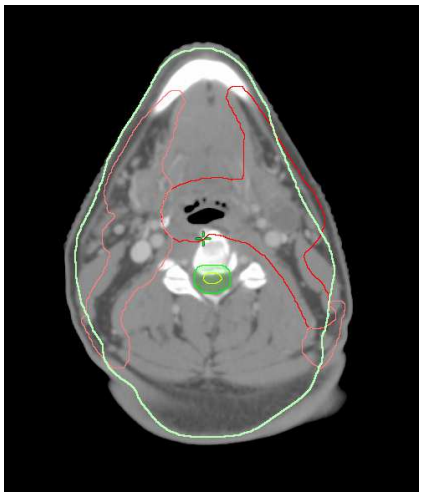
Adaptive strategies for head & neck and lung: Physics perspective

ESTRO IMRT course, London April 2016

Rachel Bodey
Principal Physicist for Treatment Planning, UCLH





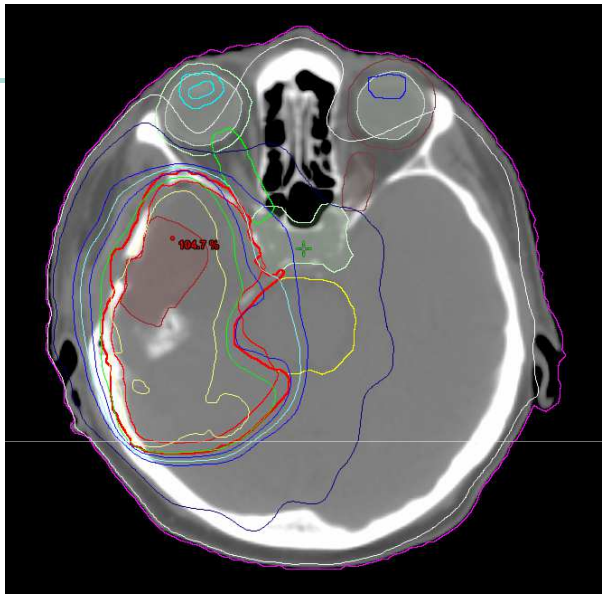


Impact of anatomical/positional changes

- Increased used of image guidance → increased information about current anatomy & position vs. plan.
- Image comparison allows us to make subjective judgements about e.g:
  - consistency of setup
  - effectiveness of immobilisation
  - external shape changes
  - internal anatomical changes

- What we REALLY want to know is impact on dose delivered.
- At what point are changes clinically significant? When is action required?

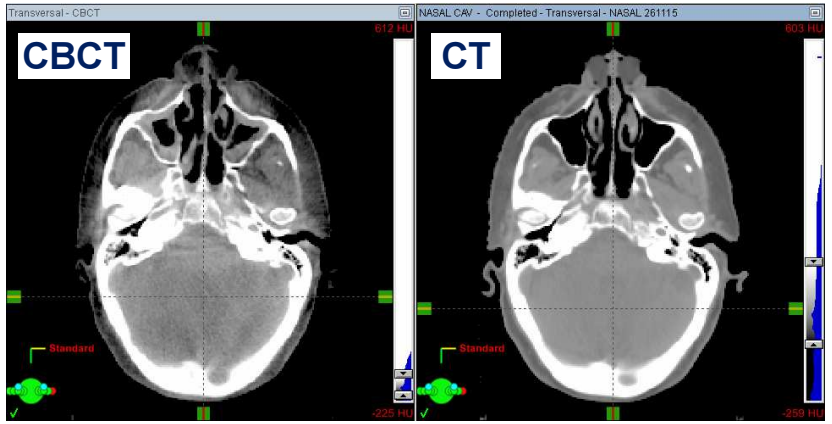
Considerations for IMRT



- Typically characterised by:
  - highly conformal dose distributions;
  - steep dose gradients at edge of PTV and OAR;
  - dose concavities to spare OAR;
  - multiple dose levels;
  - dose escalation.
- Potential advantages, but associated risks.
- A small positional change can translate to a large dosimetric difference – risk of underdosing PTV, or overdosing OAR.
- Assessing impact of changes may be less intuitive compared with conformal techniques.

Adaptive radiotherapy

- Ongoing monitoring of position and anatomy during treatment, comparison with initial conditions.
- Strategy for design or modification of treatment to accommodate changes.
- Patient-specific, image driven.
- Desirable to base decisions on dosimetric impact of changes.
- Can we use CBCT to calculate dose actually delivered, compared with that planned?
- Assess current suitability of treatment plan.



uclh

CBCT for dose calculation

- Direct use of CBCT for dose calculation can be challenging.

Review articles:

- Cone beam computed tomography: The challenges and strategies in its application for dose accumulation.

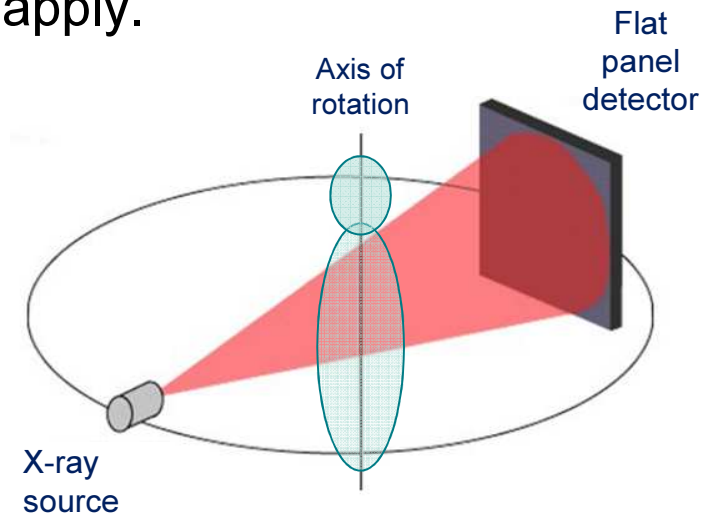
  V Kong, A Marshall, H Chan, J Med Imag Radiat Sci; March 2016; 47(1): 92–97.

- Applications of linac-mounted kilovoltage cone-beam computed tomography in modern radiation therapy: a review.

  K Srinivasan, M Mohammadi, J Shepherd; Pol J Radiol. 2014; 79: 181–193.

CBCT for dose calculation

- Volumetric imaging, scatter from whole object contributes.
- Fewer projections; less raw data.
- Poor SNR cf. fan beam CT.
- HU numbers less reliable – dependent on imaging parameters, size of object, presence of inhomogeneities, artefacts. Calibration curve may not apply.
- Large uncertainties can result from using CBCT HU for dose calculation.
- Motion artefact (gantry rotation time).
- Limited image length.

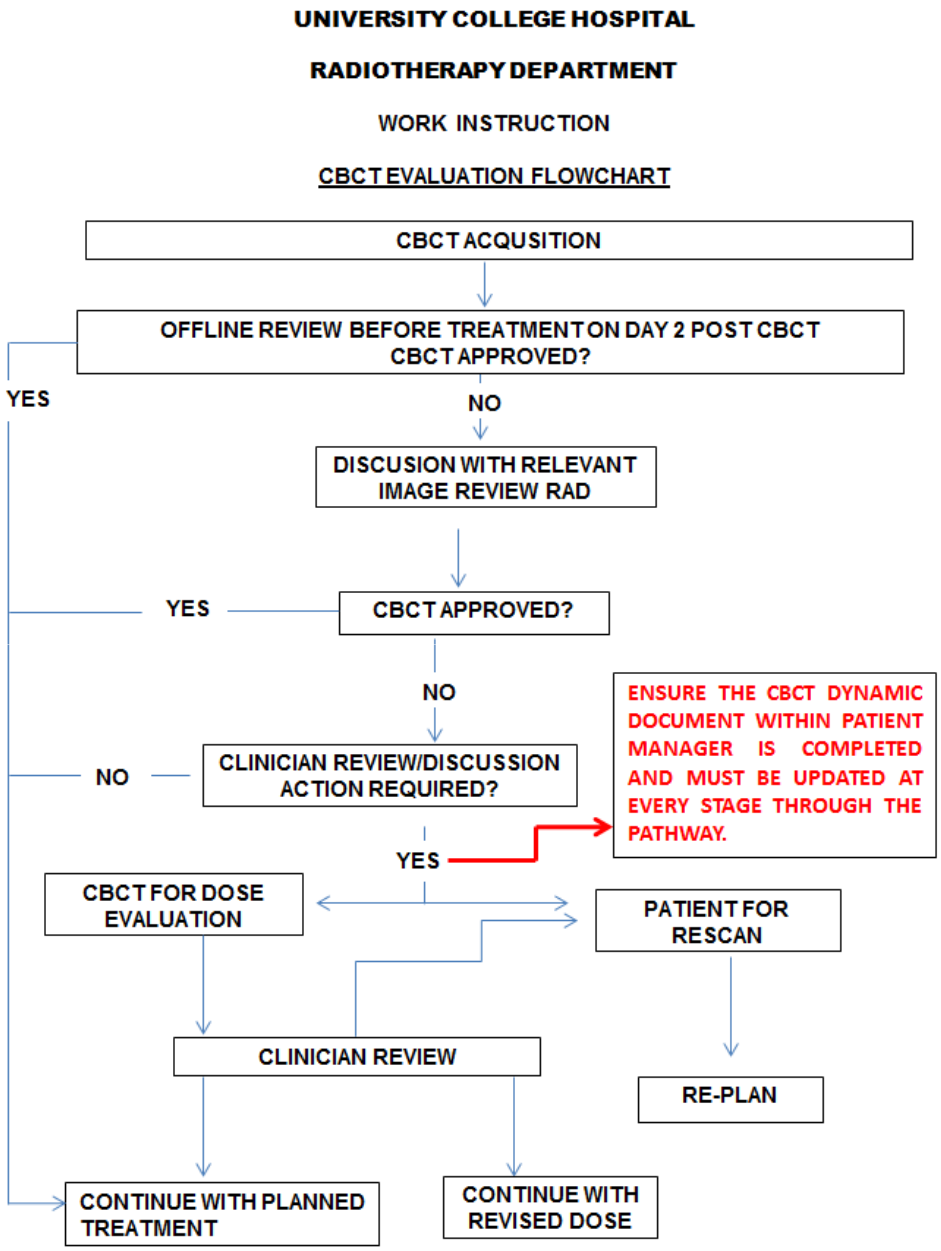


UCLH strategy

- Developed a process for CBCT based dosimetric review.
- Use CBCT to modify CT – override HU numbers in CT.
  - Head and Neck IMRT – assess impact of weight loss (or gain) though modifications to external contour.
  - Lung - override internal density changes if external shape and positioning is good.
  - Limited ability to quantify impact of positional changes or shifting internal anatomy.
- Primary aim – assess need for rescan, replan, or revised dose, if:
  - OAR tolerances likely to be exceeded.
  - PTV coverage not achieved.
  - Uncertainty is excessive.

UCLH strategy

- Flow chart – defines timescales for review and action.
- Responsibilities and requirement for staff group input – radiographers, clinicians, dosimetrists/physicists.
- Multi-disciplinary approach.



Example – head & neck weight loss

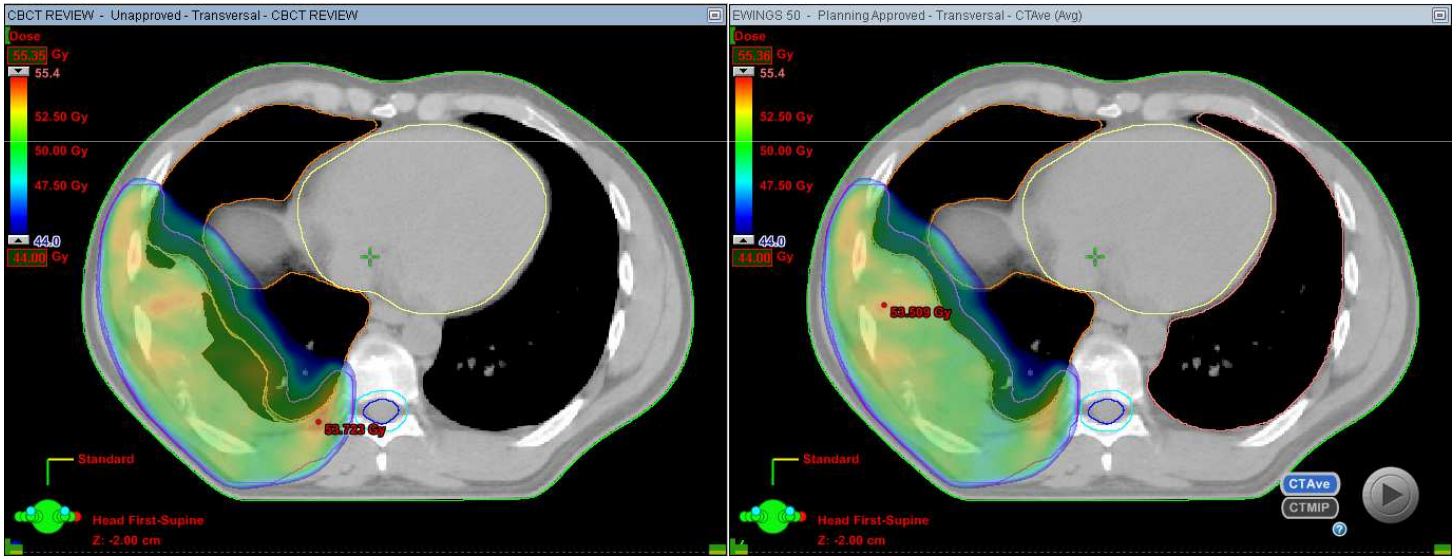
Colourwash:
95% dose

Modified CT – lung density changes

Colourwash: 44Gy



Recalculate with density override

Original plan

Adaptive RT - practical considerations

- Imaging dose - may limit imaging frequency.
- Limited quality/information of CBCT image.
- One image is only a snapshot – how representative is the assessment?
- Time is required to respond to changes:
  - Time for image review and assessment;
  - Availability of clinician;
  - Time for rescan, recontour, replan, review, plan QA.
- Take into account time through treatment course when assessing dosimetric impact.
- Dose accumulation?

Advances

- Improved imaging technology.
- Improved reconstruction algorithms.
  - Improved image quality, reduced imaging dose?
- Ability to stitch multiple images – increase imaged length.
- 4D-CBCT – reduce motion artefacts, capture respiratory motion.
- Deformable registration.
- Automatic contouring.

Conclusions

- UCLH – process established for on-treatment image review and simple dosimetric assessment of anatomical changes.
- Scope for adaptation governed by quality/quantity of imaging information and planning pathway constraints.
- Ongoing areas of research and development may lead to improved image information, streamlined processes - increased ability to adapt.

Intensity Modulated Radiotherapy for Paediatrics

Dr Jenny Gains

ESTRO teaching course on IMRT, London

3rd April 2016

Background

- Cancer in children is rare

- Between 1,500 and 1,700 children under the age of 16 years develop cancer or leukaemia in the UK *(Cancer Research UK Cancerstats: Childhood Cancer – Great Britain and UK)*

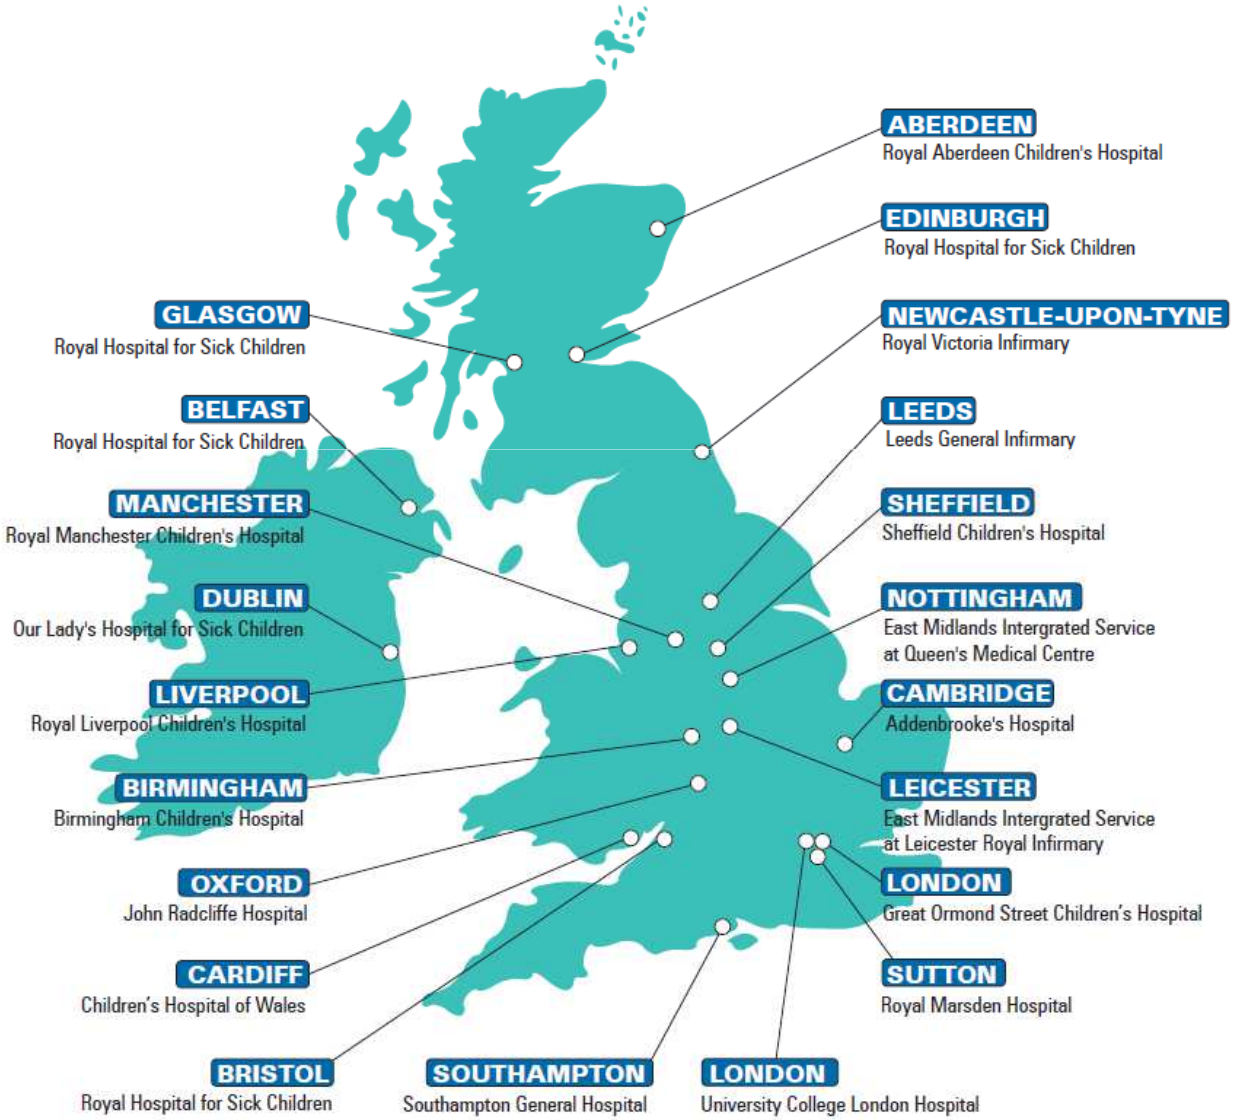
- Wide range of tumour types and anatomical sites

- Patient care is complex

Background

- Radiotherapy is a component of treatment for many children and teenagers
- Radiotherapy should only be given in specialist centres
- Specialist multidisciplinary team
- Management of acute and late effects

CHILDREN'S CANCER CENTRES



Paediatric Radiotherapy at 18 Centres: UK and Ireland

UCLH serves GOS and UCLH and more specialist services for the whole UK

IMRT

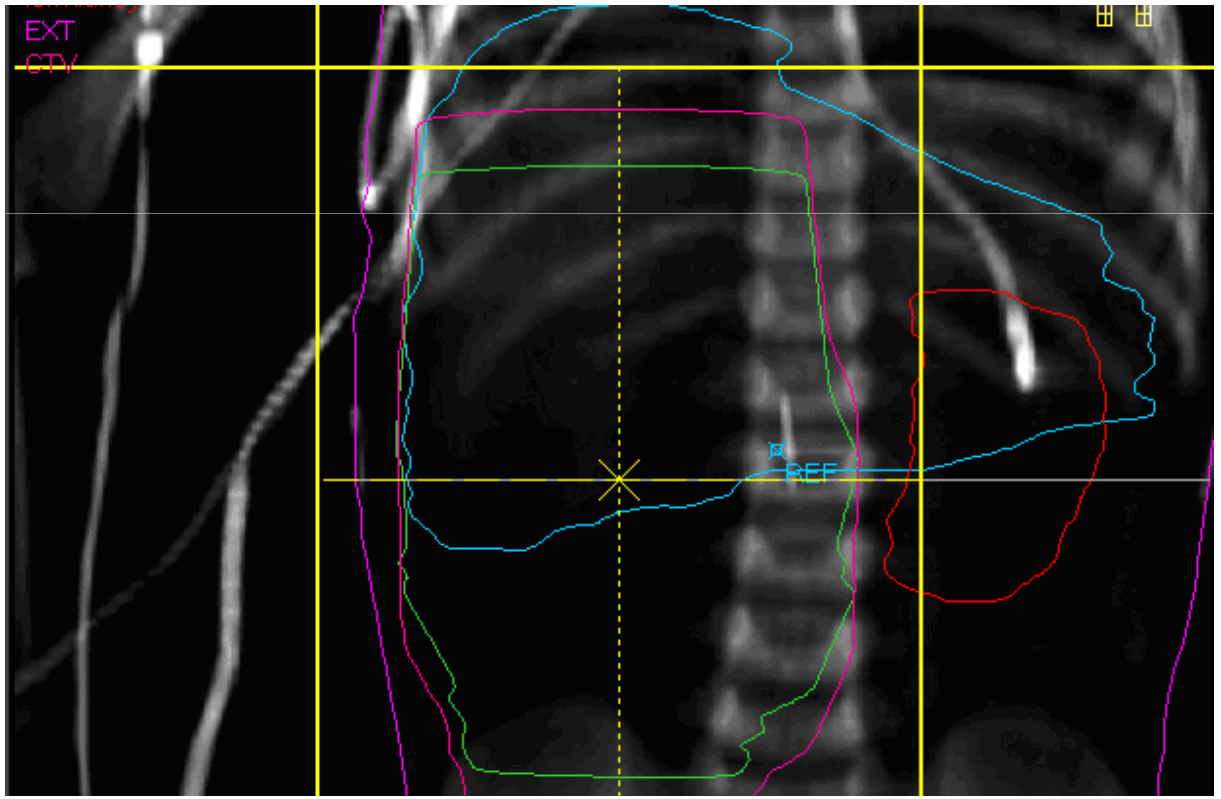
- Treatment planning studies 3D conformal radiotherapy v's IMRT clearly demonstrate the improved conformality of high dose area with IMRT
- Better PTV homogeneity
- Potential dose escalation and reduction in toxicity
- Widely adopted in the adult setting
- More reservation in paediatric population
- Lack of prospective evaluation in terms of clinical studies , determining better outcomes and long term toxicity

Paediatric IMRT

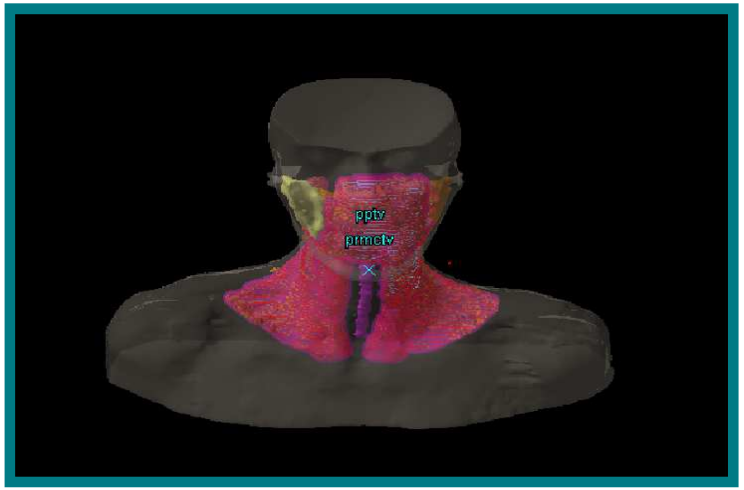
uclh

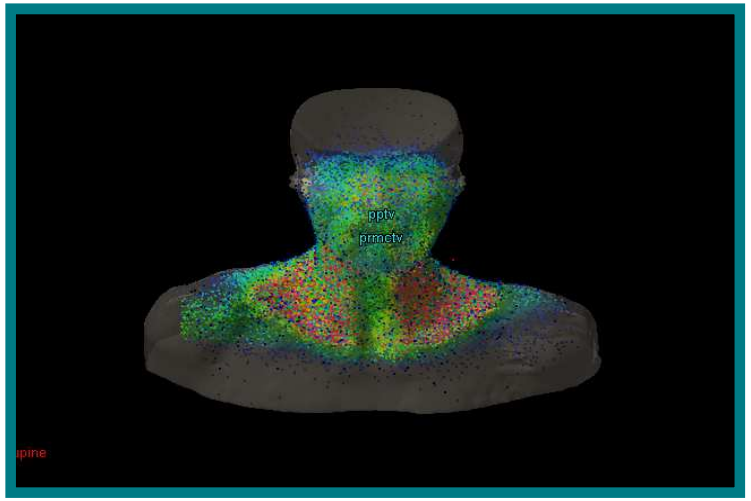
- Improved Target Volume Coverage
- OAR sparing
- Second malignancy
- Effects on growth

Effects on growth



Second Malignancies



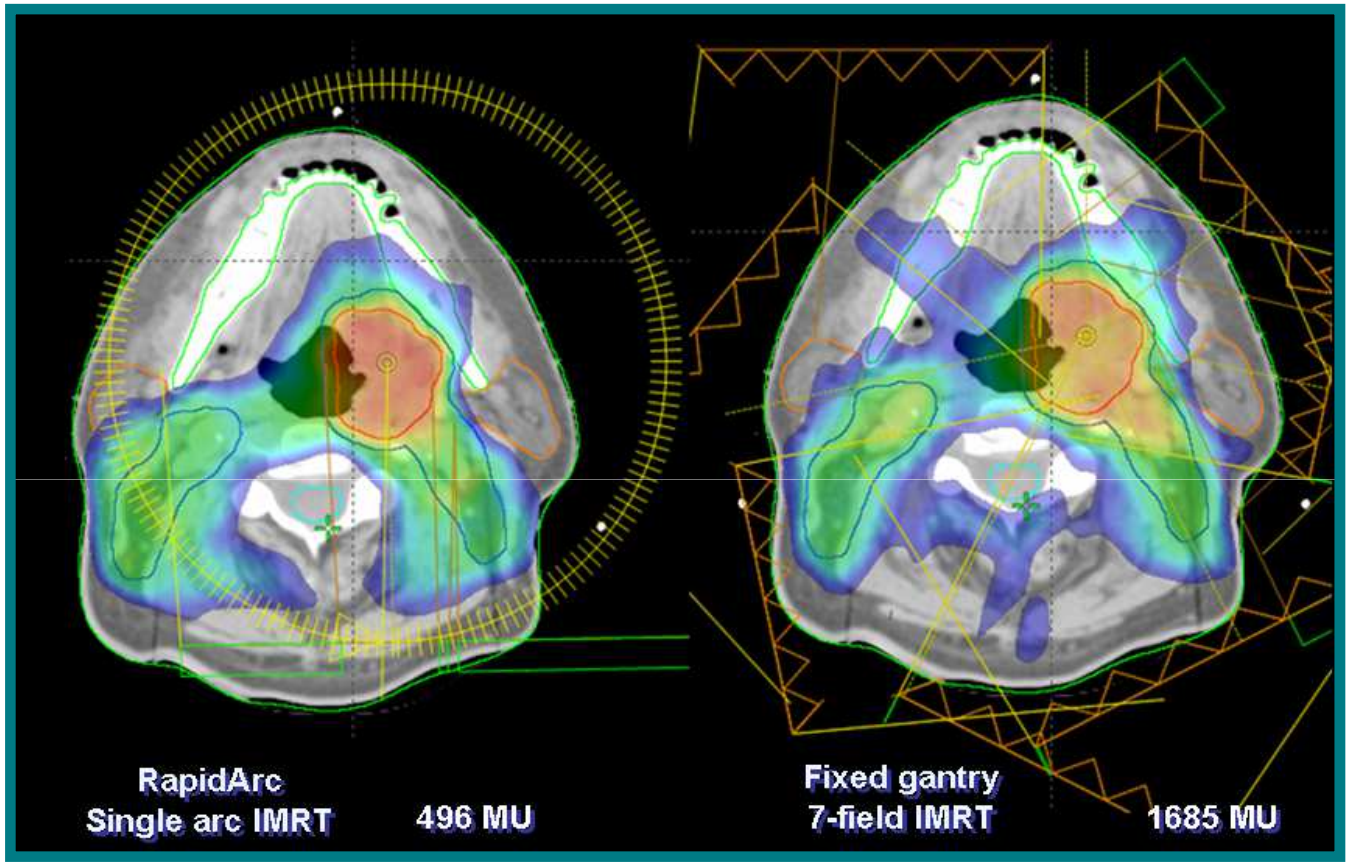


- *Hall et al.* (*IJROBP 2003*) IMRT may increase second malignancy rate from 1% to 1.75%
- Higher MU's, increased leakage resulting in increase body dose, larger volume of normal tissue receiving a lower dose
- But, most second malignancies seen in the moderate or high dose volume

Paediatrics

- More sensitive to RT induced cancers
- Scattered radiation in small body
- Genetic susceptibility

IMRT technique



- Shorter Treatment Times
- Less MU
- ? Less second malignancy
- ? Better conformality

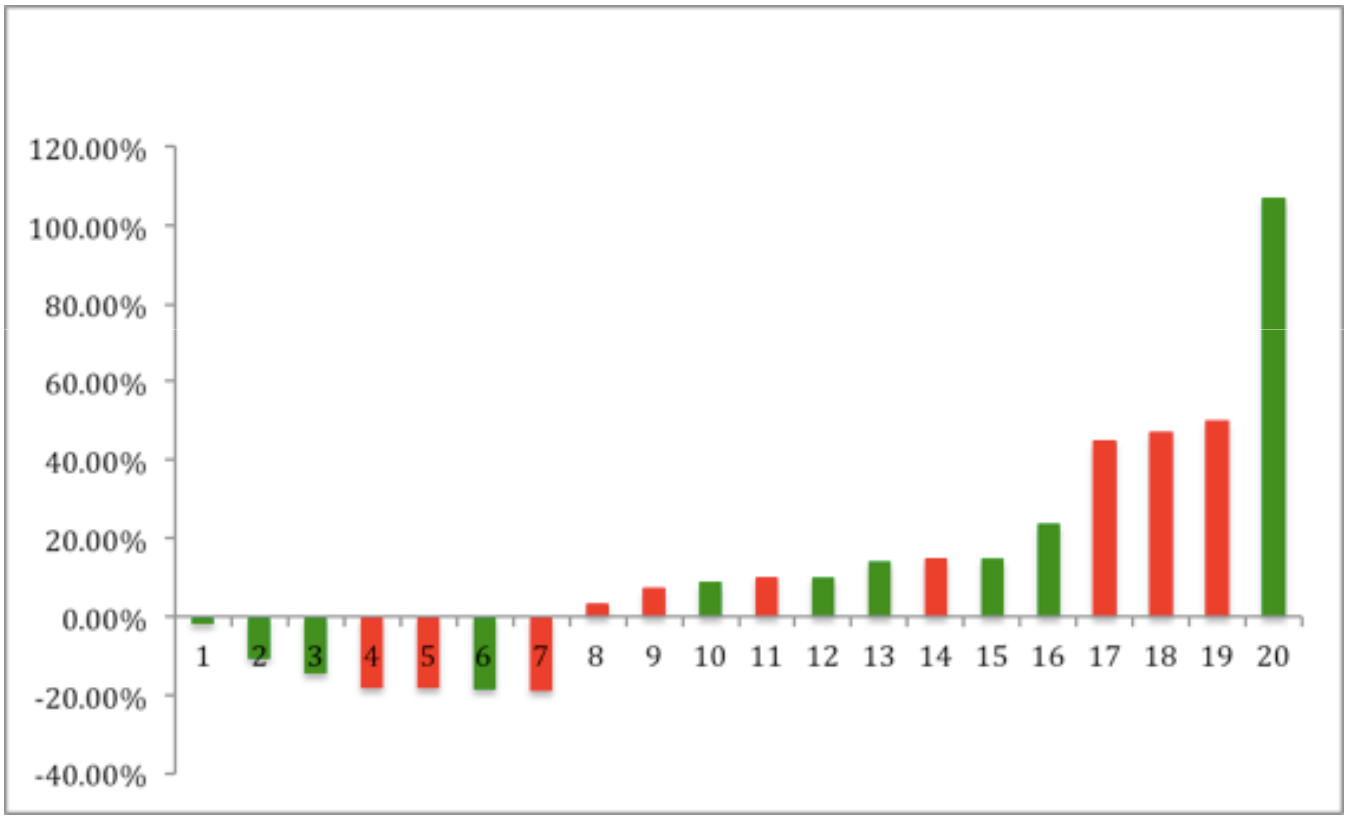
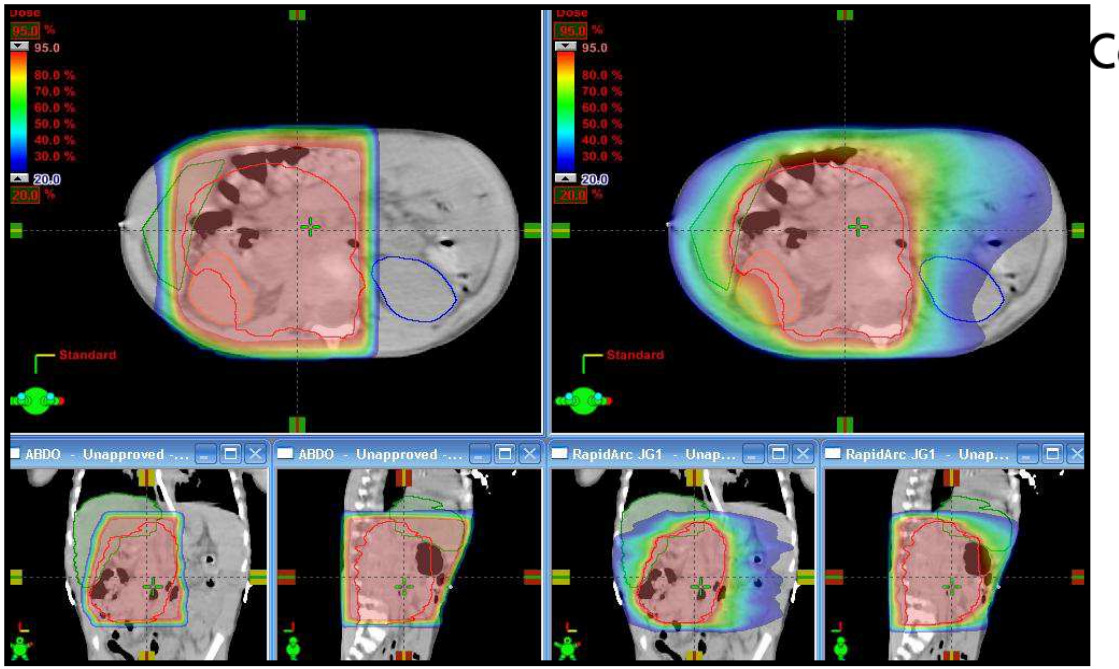
Non-PTV Integral Dose

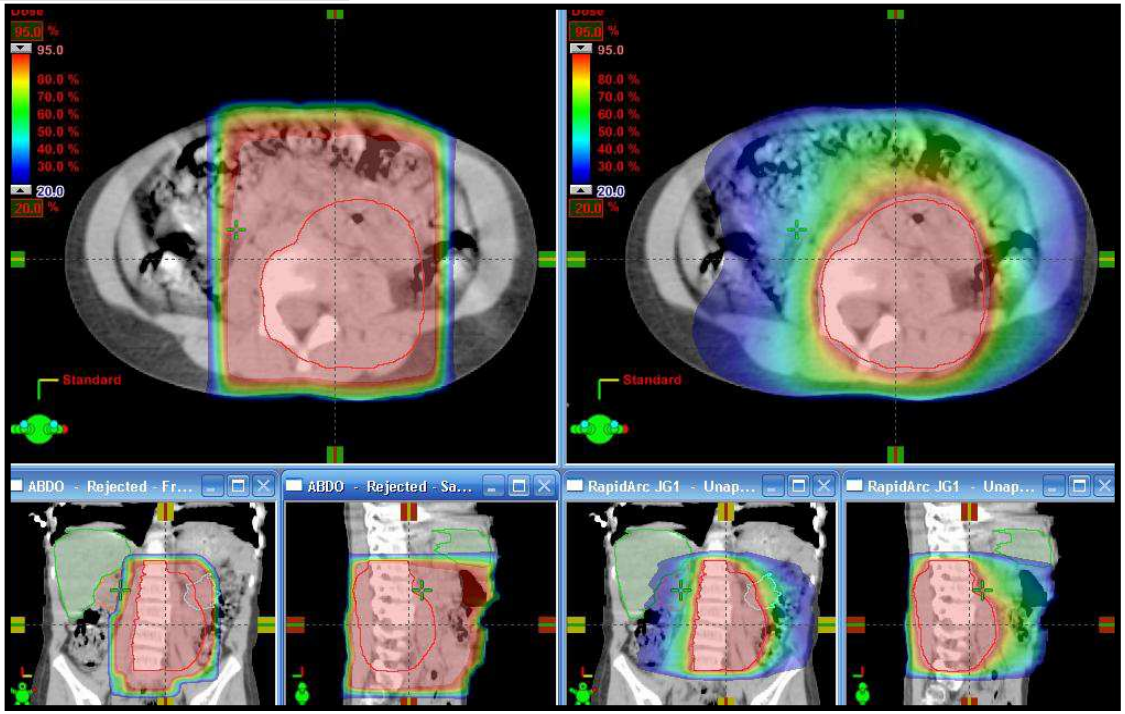


College London Hospitals NHS
NHS Foundation Trust



Increased NPID

Reduced NPID



uclh

Conclusions

- RapidArc™ gave improved dose distributions and conformity to the PTV

Main Advantages

- Midline tumours where conventional radiotherapy cannot deliver the dose within normal tissue tolerance
- Right sided tumours

Conclusions

- Long term risks of IMRT in paediatric setting are not quantified
- An inability to deliver dose to the PTV in high-risk neuroblastoma could impact on local control and possibly survival
- Dose escalation to gross residual disease unlikely to be possible with conventional techniques
- Essential that we prospectively evaluate new radiotherapy techniques in the paediatric group

Summary

- IMRT has an important role in improving dose distributions and reducing doses to OAR in paediatric patients
- Need to consider effects on growing tissues and balance the risks and benefits
- Studies with short follow up have not confirmed a rise in second malignancies
- Needs prospective evaluation and long term follow up

Thank you for listening

Intensity modulated radiotherapy in sarcoma

Dr Beatrice Seddon
Dr Franel le Grange
Sarcoma Unit, University College Hospital

3rd April 2016 ESTRO teaching course on IMRT, London

Radiotherapy in sarcoma

Soft tissue sarcoma

- Most commonly in limbs
- Standard management is surgery ± (neo)adjuvant RT
- Local control of primary tumour >80%
- Acute effects: wound healing
- Long term side effects: impact on limb function

Radiotherapy in sarcoma

Ewing Sarcoma

- Standard management with chemotherapy
- Local management: surgery/surgery + RT/ RT alone
- Young patients, need to minimise late effects of RT

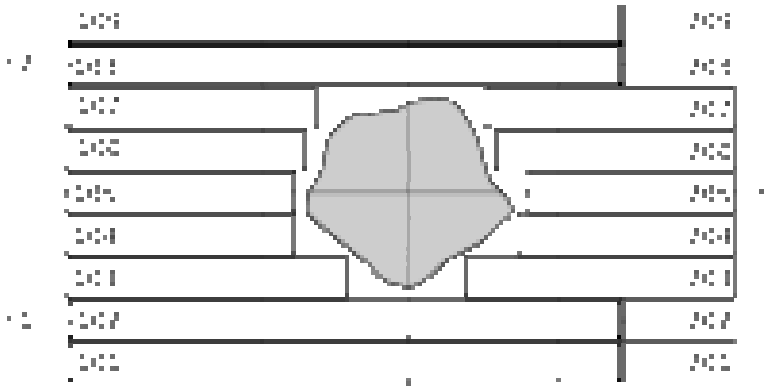
Other primary bone sarcomas/ chordoma

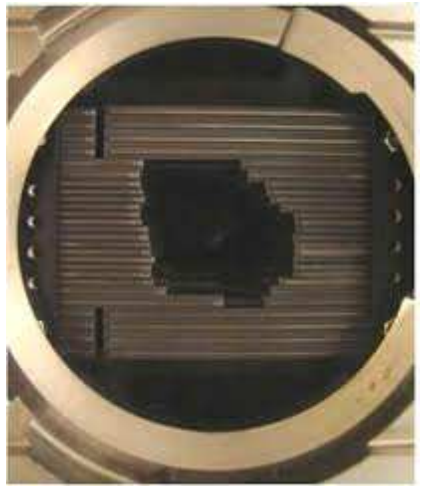
- Curative management is surgery ± chemotherapy
- Not radiosensitive, requires high doses to achieve local control

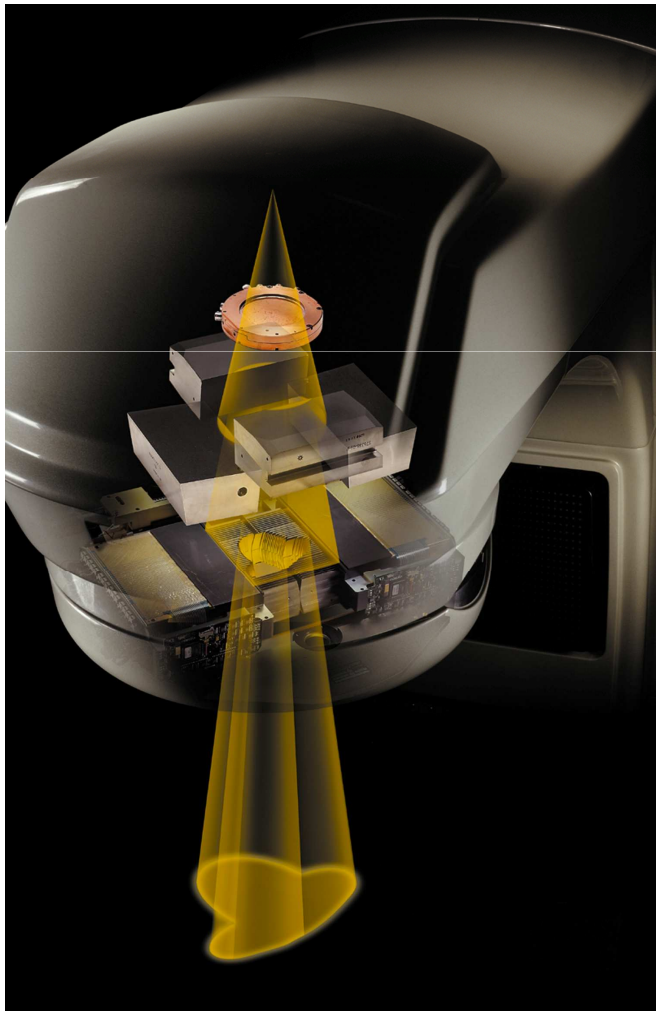
Radiotherapy in sarcoma

- Until recently standard technique was with 3D conformal radiotherapy
- Uses static beams which are shaped to conform to the tumour volume
- Results in:
  - Un-necessary treatment of large volumes of normal tissue
  - Dose inhomogeneity and hot spots in normal tissues
  - With potential consequences on toxicity and function

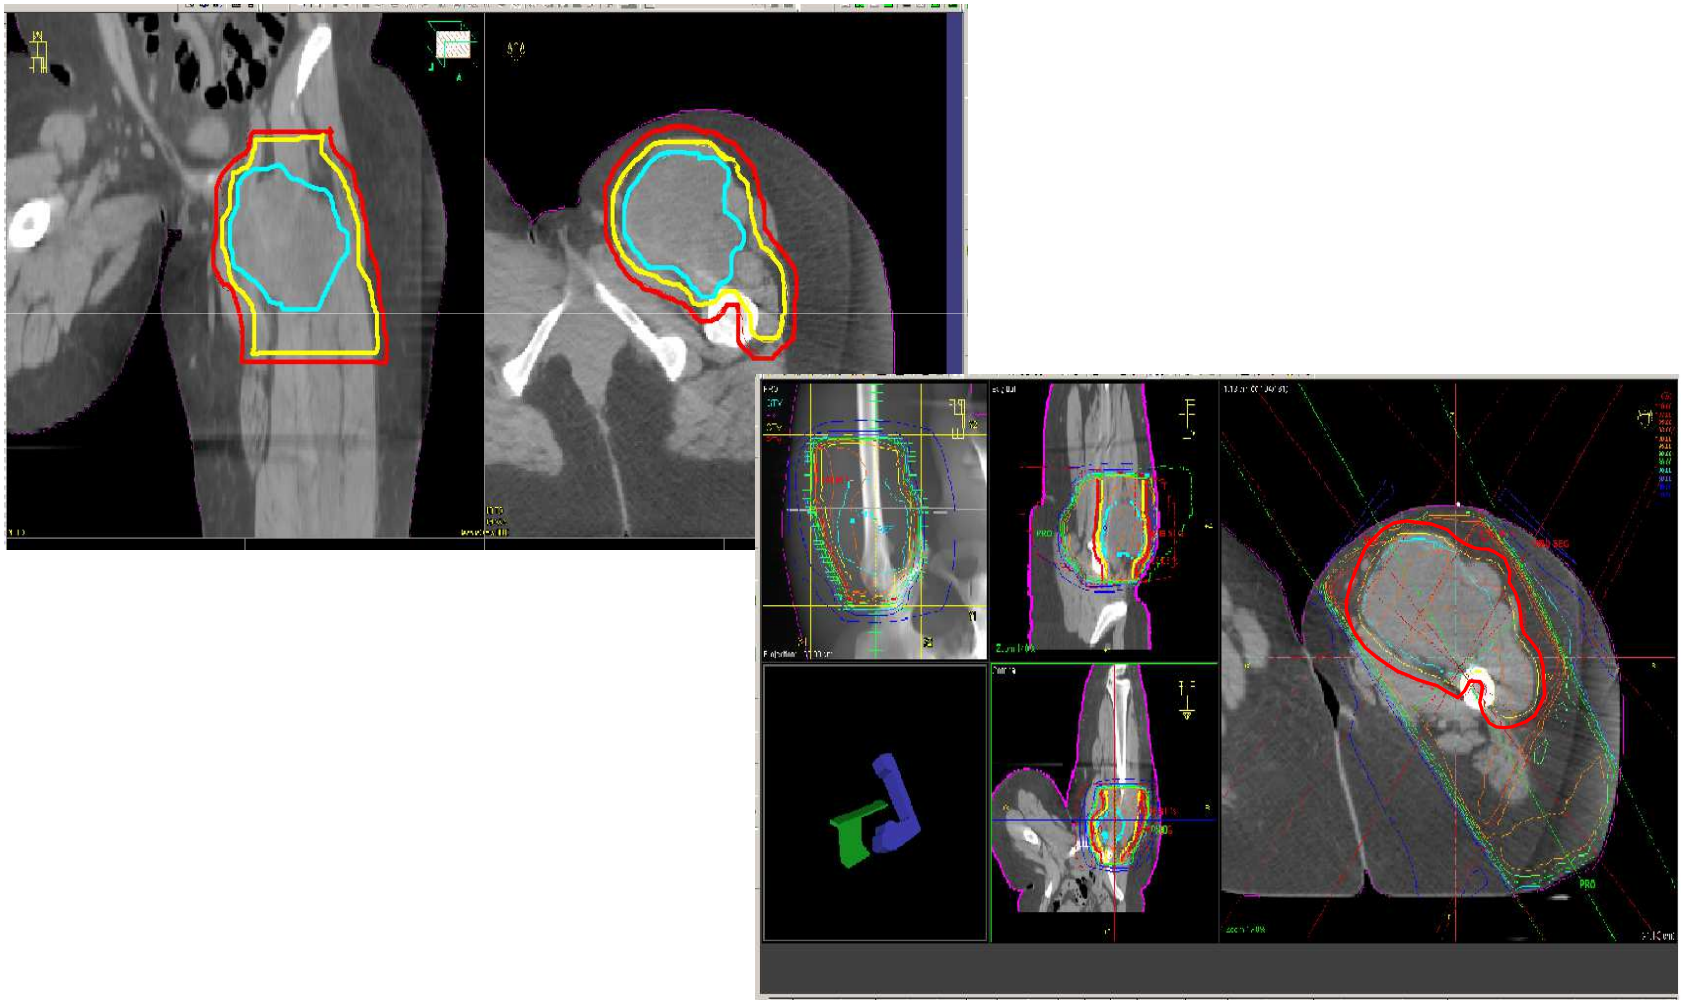
3D conformal radiotherapy



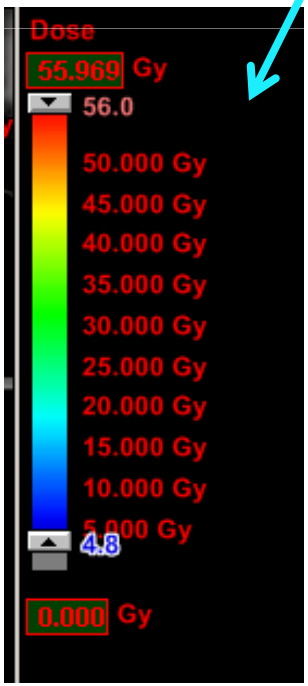




Current standard: 3D conformal radiotherapy



3D conformal radiotherapy



Late toxicity after 3D conformal radiotherapy

- Late toxicity and limb function are related to treatment volumes and RT dose
  - Soft tissue fibrosis
  - Lymphoedema
  - Bone fractures, joint stiffness
- Rates of ≥grade 2 fibrosis in 48.2% with post-operative RT

Davis et al. Late radiation morbidity following randomization to preoperative versus postoperative radiotherapy in extremity soft tissue sarcoma. Radiotherapy and Oncology 2005, 75:48–53.

- Negative impact on function

50 Gy/25# pre-op

66 Gy/33# post-op

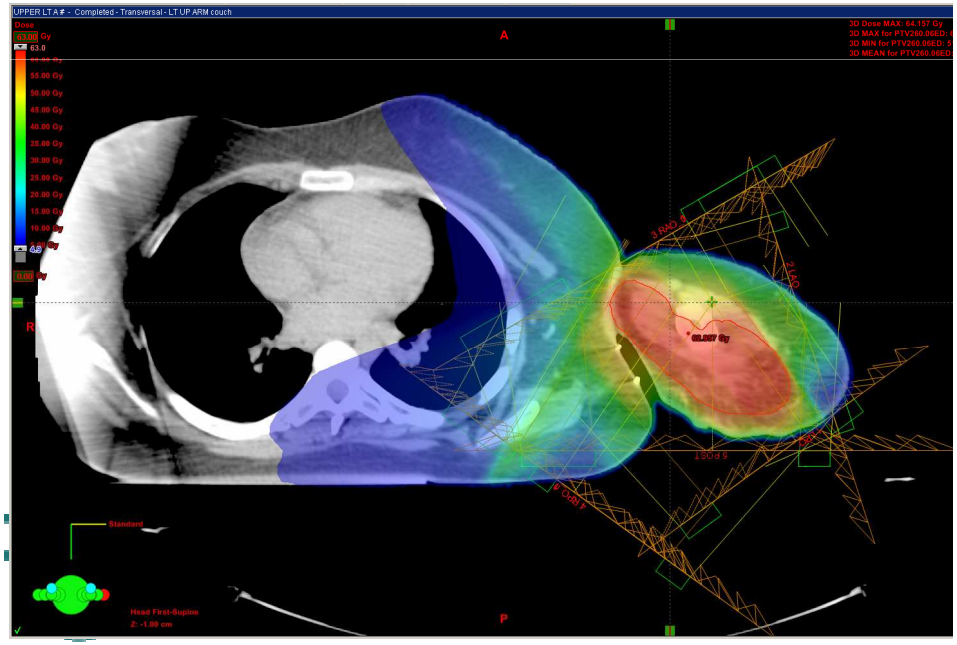
Intensity modulated radiotherapy

- Offers the opportunity to:
  - Conform better to the planning target volume (PTV)
  - Treat with greater homogeneity within PTV
  - Vary dose within PTV (‘dose painting’ concept)

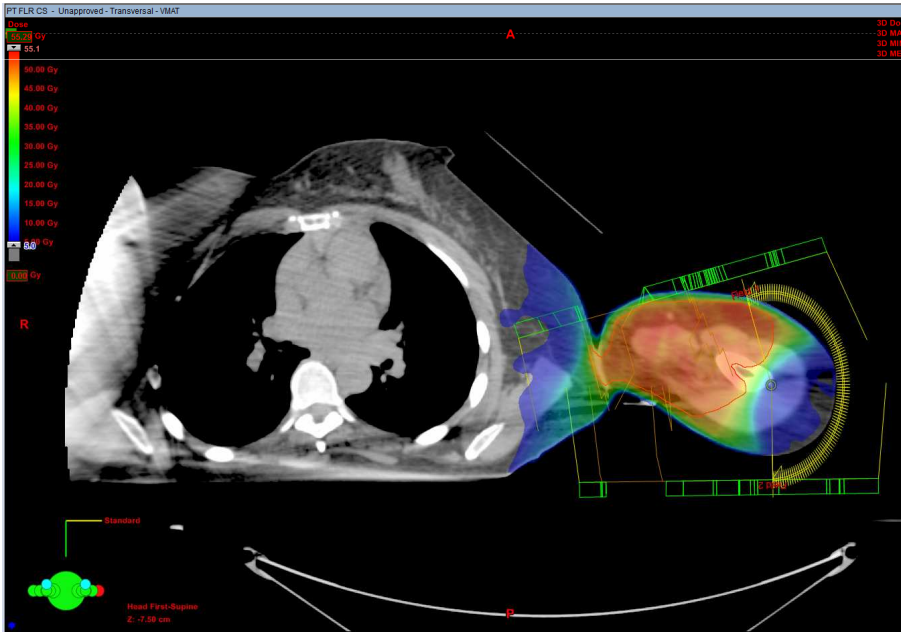
  - Spare normal tissues – soft tissues and bone
  - Allow dose escalation, improved local control, survival
  - Reduce hot spots in normal tissues
  - Reduce normal tissue acute and late toxicity
  - Improve long term function

Intensity modulated radiotherapy delivery

Multiple fixed static beam angles 'step and shoot'



Volumetric modulated arc therapy (RapidArc®), TomoTherapy®



IMRT opportunities in sarcoma

- To spare normal tissues and improve functional outcomes in limb sarcomas
- To achieve better tumour coverage in difficult locations:
  - Paraspinal tumours
  - Pelvic tumours
  - Ribs tumours
  - Head and neck tumours
  - Retroperitoneal tumours
- To deliver higher doses than normally achievable for inoperable tumours:
  - Osteosarcoma, spindle cell sarcoma of bone
  - Chondrosarcoma
  - Chordoma

IMRT in soft tissue sarcoma

IMRT planning study: Limb soft tissue sarcoma
Example cases

Dosimetric advantage for IMRT vs 3D-CRT:

- Reduction of volume of normal tissues receiving moderate or high doses of radiotherapy
- Sparing of normal tissues, e.g. femur

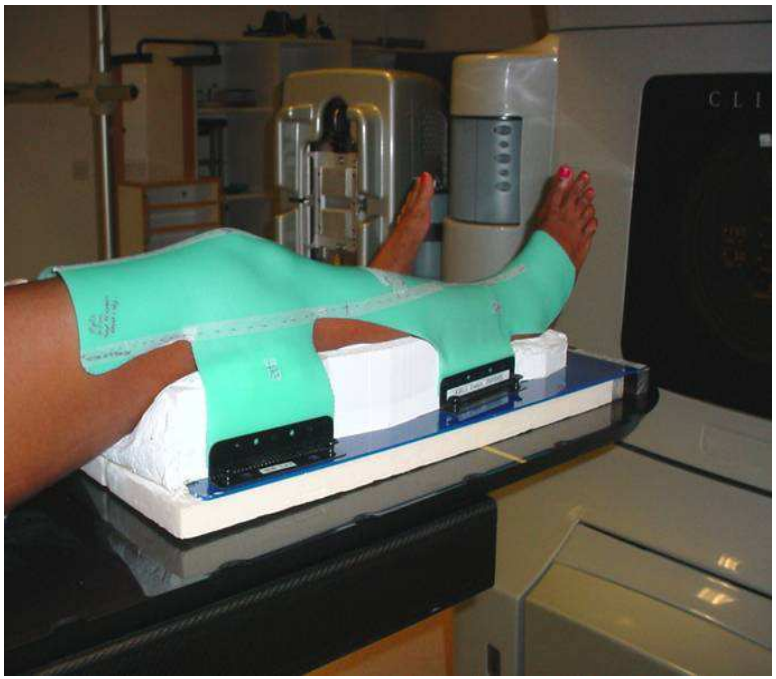
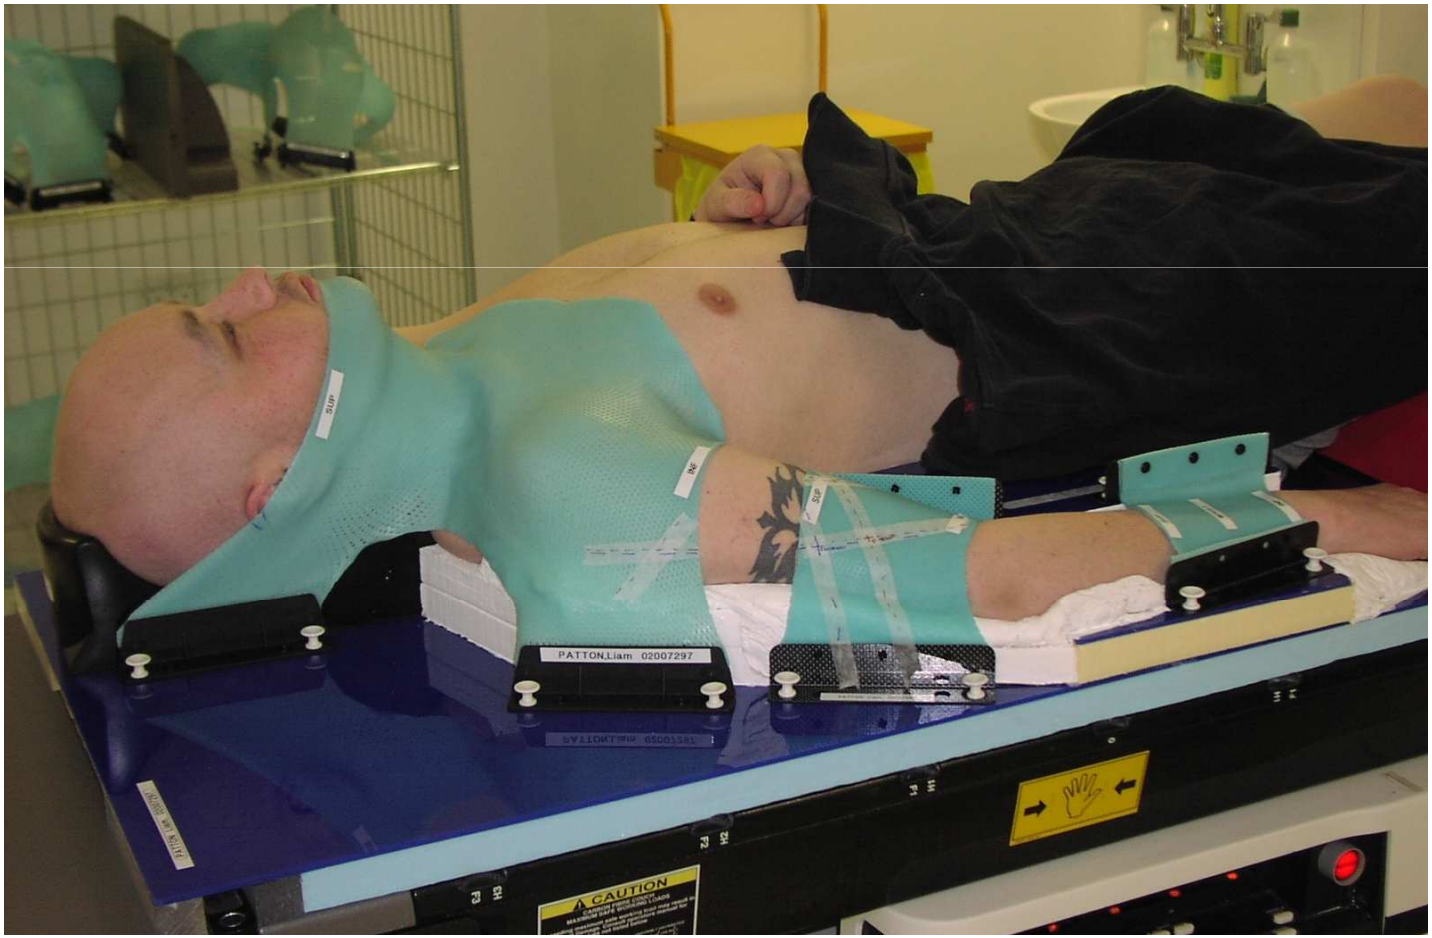
Immobilisation for limb sarcomas

- Reduce day to day variation in patient position (potential source of error)
- Impression of limb with patient in the optimum treatment position:
  - Customised foam mould fixed to baseboard
  - sheet of thermoplastic (Orfit) moulded around limb, clipped to baseboard
  - Baseboard is indexed and fixed onto the treatment couch

Immobilisation of lower limb



Immobilisation of upper limb



Evidence for using IMRT in soft tissue sarcomas

- Increasing use in soft tissue sarcomas
- Adoption by stealth
- Perceived superiority of IMRT
- Limited resource in some countries
- Little published, mostly retrospective data, in limb sarcomas

IMRT Retrospective evidence: 1

Local Control Comparison of Adjuvant Brachytherapy to Intensity-Modulated Radiotherapy in Primary High-Grade Sarcoma of the Extremity

Kaled M. Alektiar, MD[1]; Murray F. Brennan, MD[2]; and Samuel Singer, MD[2]

BACKGROUND: Based on results of a prospective randomized trial, brachytherapy (BRT) had been the preferred form of adjuvant radiotherapy for patients with high-grade extremity soft tissue sarcoma (STS) at our institution. In recent years, intensity-modulated radiotherapy IMRT had been increasingly used. This study compared local control by IMRT versus by BRT in primary-extremity STS. **METHODS:** Between January 1995 and December 2006, 134 adult patients with high-grade primary nonmetastatic STS of the extremity were treated at this institution with limb-sparing surgery and adjuvant radiotherapy (RT). Low-dose-rate BRT was given to 71 patients between January 1995 and November 2003 to a median dose of 45 Gray (Gy). IMRT was given between February 2002 and December 2006: preoperatively to 10 (50 Gy) and postoperatively to 53 (median, 63 Gy). Median follow-up was 46 months. **RESULTS:** Treatment groups were comparable in terms of gender, age, site, depth, histology (malignant fibrous histiocytoma vs other), and use of adjuvant chemotherapy. More IMRT patients had positive/close margins (<1 mm), large tumors (>10 cm), and bone or nerve stripping/resection ($P = 0.006$, 0.005, 0.02, and 0.002, respectively). Median follow-up was 46 months for IMRT and 47 months for BRT. Five-year local control was 92% (95% confidence interval [CI], 85-100) for IMRT versus 81% (95% CI, 71-90) for BRT, $P = 0.04$. On multivariate analysis, IMRT was the only predictor of improved local control, $P = 0.04$. **CONCLUSIONS:** Local control with IMRT was significantly better than BRT despite higher rates of adverse features for IMRT in this nonrandomized comparison. IMRT should be further examined as the treatment of choice for primary high-grade extremity sarcoma. *Cancer* 2011;117:3229–34. © *2011 American Cancer Society.*

KEYWORDS: IMRT, brachytherapy, sarcoma, extremity.

uclh

IMRT Retrospective evidence: 1

- Retrospective comparison of 134 IMRT patients with 71 brachytherapy (BRT) patients
- 5 year local control 92% for IMRT vs 81% with BRT
- 'IMRT should be further examined as the treatment of choice for extremity sarcoma'
- But no toxicity data published

IMRT Retrospective evidence: 2

Comparison of Local Recurrence With Conventional and Intensity-Modulated Radiation Therapy for Primary Soft-Tissue Sarcomas of the Extremity

Michael R. Folkert, Samuel Singer, Murray F. Brennan, Deborah Kuk, Li-Xuan Qin, Wendy K. Kobayashi, Aimee M. Crago, and Kaled M. Alektiar

A B S T R A C T

Purpose
The use of intensity-modulated radiation therapy (IMRT) in the treatment of soft tissue sarcoı (STS) of the extremity is increasing, but no large-scale direct comparison has been report between conventional external-beam radiation therapy (EBRT) and IMRT.

Methods
Between January 1996 and December 2010, 319 consecutive adult patients with prim nonmetastatic extremity STS were treated with limb-sparing surgery and adjuvant radiothera (RT) at a single institution. Conventional EBRT was used in 154 patients and IMRT in 165 w similar dosing schedules. Median follow-up time for the cohort was 58 months.

Results
Treatment groups were comparable in terms of tumor location, histology, tumor size, depth, a use of chemotherapy. Patients treated with IMRT were older ($P = .08$), had more high-gra lesions ($P = .05$), close (< 1 mm) or positive margins ($P = .04$), preoperative radiation ($P < .00$ and nerve manipulation ($P = .04$). Median follow-up was 90 months for patients treated w conventional EBRT and 42 months for patients treated with IMRT. On multivariable analy adjusting for patient age and tumor size, IMRT retained significance as an independent predic of reduced LR (hazard ratio = 0.46; 95% CI, 0.24 to 0.89; $P = .02$).

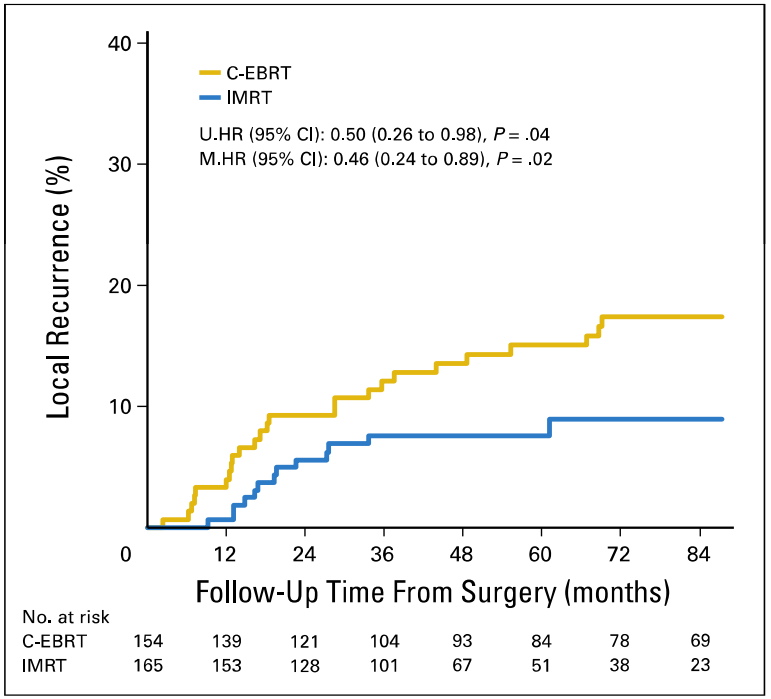
Conclusion
Despite a preponderance of higher-risk features (especially close/positive margin) in the IM group, IMRT was associated with significantly reduced local recurrence compared with conv tional EBRT for primary STS of the extremity.

uclh

IMRT Retrospective evidence: 2

- 165 IMRT vs 154 3D-CRT patients
- Median time to local recurrence 18 months
- 5 year local recurrence rates:
  - IMRT 7.6%
  - 3D-CRT 15.1% p=0.05
- Acute grade 2 skin reaction less with IMRT (48.7% vs 31.5%)
- Chronic ≥ grade 2 toxicity

(fractures, joint stiffness, oedema) no difference



Folkert MR et al. Comparison of Local Recurrence With Conventional and Intensity-Modulated Radiation Therapy for Primary Soft-Tissue Sarcomas of the Extremity. J Clin Oncol 2014, 32:3236-3241

IMRT prospective clinical trials: 1

Phase 2 Study of Preoperative Image-Guided Intensity-Modulated Radiation Therapy to Reduce Wound and Combined Modality Morbidities in Lower Extremity Soft Tissue Sarcoma

Brian O'Sullivan, MD[1,2]; Anthony M. Griffin, MSc[3]; Colleen I. Dickie, MSc[1]; Michael B. Sharpe, PhD[1,2]; Peter W. M. Chung, MD[1,2]; Charles N. Catton, MD[1,2]; Peter C. Ferguson, MD[2,3]; Jay S. Wunder, MD[2,3]; Benjamin M. Deheshi, MD[2,3]; Lawrence M. White, MD[2,4]; Rita A. Kandel, MD[2,5]; David A. Jaffray, PhD[1,2]; and Robert S. Bell, MD[2,3]

BACKGROUND: This study sought to determine if preoperative image-guided intensity-modulated radiotherapy (IG-IMRT) can reduce morbidity, including wound complications, by minimizing dose to uninvolved tissues in adults with lower extremity soft tissue sarcoma. **METHODS:** The primary endpoint was the development of an acute wound complication (WC). IG-IMRT was used to conform volumes to avoid normal tissues (skin flaps for wound closure, bone, or other uninvolved soft tissues). From July 2005 to June 2009, 70 adults were enrolled; 59 were evaluable for the primary endpoint. Median tumor size was 9.5 cm; 55 tumors (93%) were high-grade and 58 (98%) were deep to fascia. **RESULTS:** Eighteen (30.5%) patients developed WCs. This was not statistically significantly different from the result of the National Cancer Institute of Canada SR2 trial ($P = .2$); however, primary closure technique was possible more often (55 of 59 patients [93.2%] versus 50 of 70 patients [71.4%]; $P = .002$), and secondary operations for WCs were somewhat reduced (6 of 18 patients [33%] versus 13 of 30 patients [43%]; $P = .55$). Moderate edema, skin, subcutaneous, and joint toxicity was present in 6 (11.1%), 1 (1.9%), 5 (9.3%), and 3 (5.6%) patients, respectively, but there were no bone fractures. Four local recurrences (6.8%, none near the flaps) occurred with median follow-up of 49 months. **CONCLUSIONS:** The 30.5% incidence of WCs was numerically lower than the 43% risk derived from the National Cancer Institute of Canada SR2 trial, but did not reach statistical significance. Preoperative IG-IMRT significantly diminished the need for tissue transfer. RT chronic morbidities and the need for subsequent secondary operations for WCs were lowered, although not significantly, whereas good limb function was maintained. ***Cancer* 2013;119:1878–84.** © *2013 American Cancer Society.*

KEYWORDS: sarcoma, image-guided radiotherapy, intensity-modulated radiotherapy, preoperative radiotherapy, phase 2 study.

IMRT prospective clinical trials: 1

- Phase II study to determine if preoperative IMRT is effective in minimizing the dose to skin and subcutaneous tissues used to close the resection site and reduce the risk of wound complications (PMH, Toronto)(1)
- Dose was reduced to the anticipated surgical flaps by using IMRT planning
- Primary endpoint: acute wound healing within 120 days
- Secondary endpoints: limb oedema and fibrosis, bone fracture, limb function, overall patient function
- 70 patients 2005 – 9
- Median 9.5cm, 93% G3, 98% deep to fascia

(1) O'Sullivan B, Griffin AM, Dickie CI, et al. Phase 2 study of preoperative image-guided intensity-modulated radiation therapy to reduce wound and combined modality morbidities in lower extremity soft tissue sarcoma. *Cancer* 2013; **119**(10): 1878-84.

IMRT prospective clinical trials: 1

- Wound complications in 30.5% (vs 43% in SR2 study) (p=0.2, NS)(1)
- Commonest sites: buttock, adductor and posterior compartments of thigh
- Reduced need for tissue transfer for closure
- Reduced second surgery for wound complications 33% vs 43% (SR2)
- Trend for increased dose to flap and increased volume of flap receiving 50Gy in patients with wound complications
- Negative result thought to be due to compromising of flap sparing in order to ensure adequate PTV coverage
- Grade 2+ fibrosis at 2 years 9.3% vs 31.5% (SR2)
- Moderate joint stiffness 5.4% vs 17.8% (SR2)

(1) O'Sullivan B, Griffin AM, Dickie CI, et al. Phase 2 study of preoperative image-guided intensity-modulated radiation therapy to reduce wound and combined modality morbidities in lower extremity soft tissue sarcoma. *Cancer* 2013; **119**(10): 1878-84.

IMRT prospective clinical trials: 2

Wang et al Journal of Clinical Oncology 2015 Jul 10;33(20):2231-8. doi: 10.1200/JCO.2014.58.5828. Epub 2015 Feb 9.

IMRT prospective clinical trials 2

- Preoperative IGRT 50Gy in 25 fractions prior to surgery
- IGRT used in order to reduce target volumes
- Primary endpoint: 15% absolute improvement in rate of grade ≥2 radiation morbidity (subcutaneous tissue fibrosis, joint stiffness, oedema) at 2 years, from 37% to 22%
- 79 patients (2008 – 2010)
- Could receive IMRT (74.7%) or 3DCRT (25.3%)
- Results:
  - 5/74 (7%) local recurrences (all in field)
  - 57 patients assessed for late toxicity – 10.5% experienced at least one grade ≥2 toxicity (vs 37% in SR2 trial) $p<0.001$
- Conclusion: The significant reduction in late toxicities, and absence of marginal recurrences suggest that the reduced volumes used were appropriate

Wang et al Journal of Clinical Oncology 2015 Jul 10;33(20):2231-8. doi: 10.1200/JCO.2014.58.5828. Epub 2015 Feb 9.

IMRT prospective clinical trials: 3

IMRiS: Intensity Modulated Radiotherapy in Sarcoma

- UK wide multi-centre trial opened in March 2016
- Prospective phase II cohort study
- Questions:
  - How should IMRT be incorporated into current practice?
  - What is the incidence of toxicity related to IMRT?
  - Does IMRT improve function and quality of life?
- Three cohorts:
  - Cohort 1: limb soft tissue sarcoma
  - Cohort 2: Ewing's sarcoma pelvis and spine
  - Cohort 3: Primary non-Ewing's sarcomas of pelvis and spine (osteosarcoma, chondrosarcoma, chordoma, spindle cell sarcoma of bone)

IMRiS: Intensity Modulated Radiotherapy in Sarcoma

- Cohort 1: Limb soft tissue sarcoma (110 patients)
  - Does use of IMRT reduce late toxicity?
  - Primary endpoint: rate of grade 2+ late soft tissue fibrosis at 2 years following radiotherapy (aim to reduce from 30% to 20%)
  - Secondary endpoints: acute and late toxicity, patient reported limb function and quality of life, wound complications, time to local recurrence

IMRiS: Intensity Modulated Radiotherapy in Sarcoma

- Cohorts 2 and 3: Pelvic/spinal bone sarcomas (33 patients)
  - Does the use of IMRT enable achievement of a radiotherapy treatment plan that delivers the optimal dose while keeping within normal tissue tolerances?
  - Primary endpoint: The proportion of patients where the recommended optimal radiotherapy dose can be achieved with IMRT
    - Cohort 2 (Ewing's): Increase proportion of patients receiving 95% of optimal dose from 70% to 90%
    - Cohort 3 (non-Ewing's): Increase proportion of patients receiving 95% of optimal dose from 0% to 50%
  - Secondary endpoints: Toxicity, response, quality of life, time to local recurrence/disease progression, survival

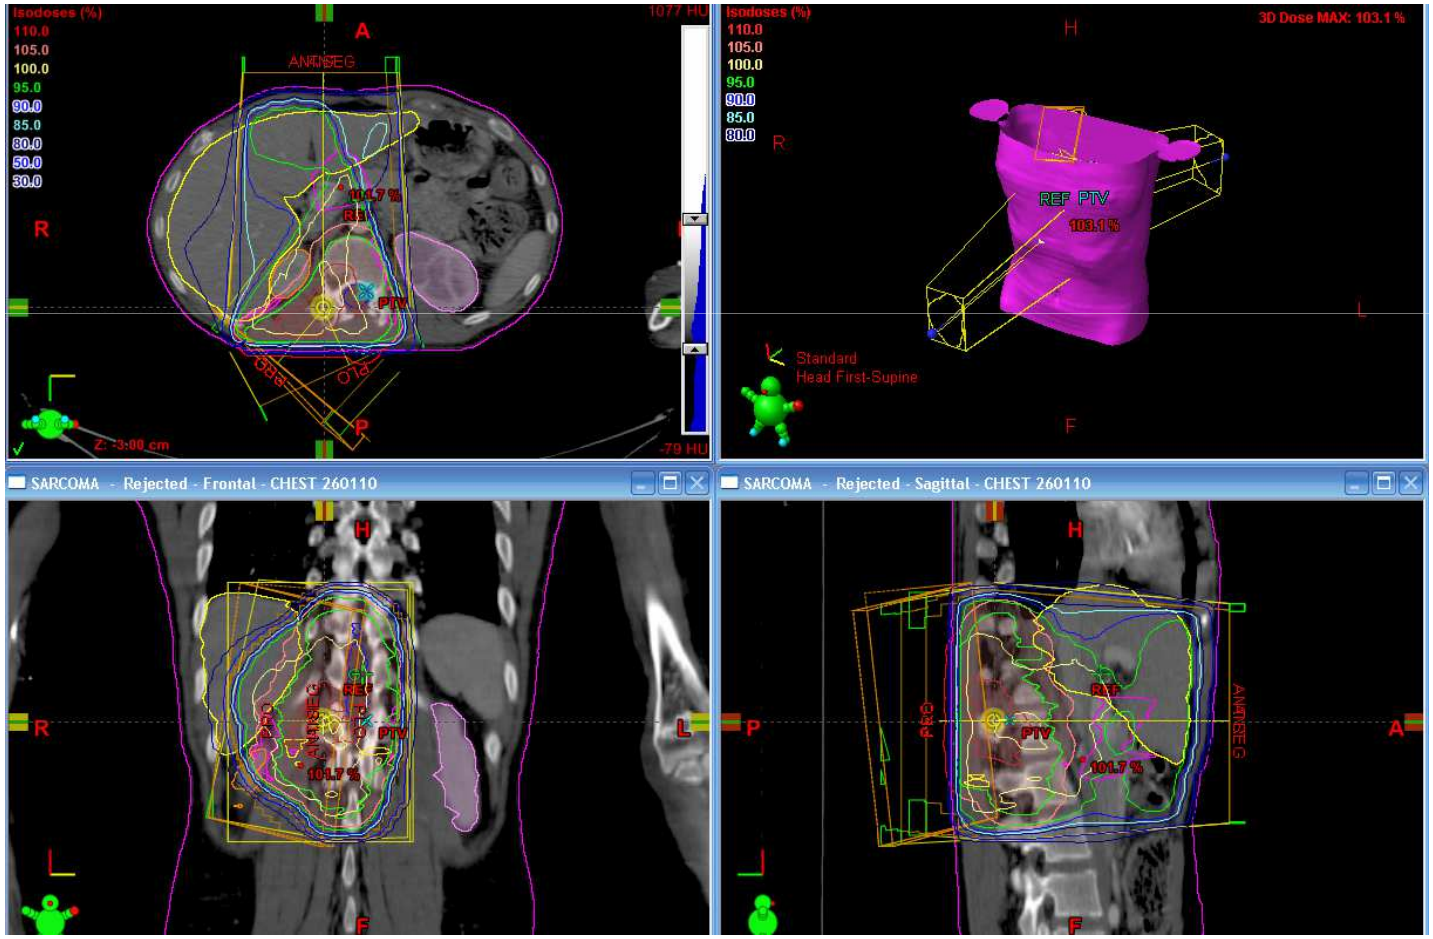
IMRT in bone sarcomas

IMRT in Ewing's Sarcoma

- IMRT shown to be superior to 3D-CRT in two small planning studies (5 patients)
- IMRT used in 43% of cases of a series of 33 spinal and pelvic tumours [1]
- Retrospective review at UCH of 24 cases of Ewing's sarcoma of pelvis/spine treated with 3D-CRT showed that the optimal radiotherapy dose could only be safely achieved in 70% (unpublished data)
- Increasing use of PBRT means that further data on IMRT unlikely

[1]La TH et al. Radiation therapy for Ewing's sarcoma: Results from Memorial Sloan Kettering in the modern era. Int J Rad Oncol Biol Phys, 2006:64:544-550.

Ewing's sarcoma T12 spine: 49.5Gy in 33#



Comparative planning study: IMRT vs PBT in pelvic Ewing Sarcoma

- Question: can PBT spare normal tissues (in particular uterus and ovaries) better than IMRT?
- Patients
  - 10 female patients (median age 20)
  - Ewing sarcoma of pelvic bones
- Dose: 54Gy in 30#
- Technique
  - VMAT
  - Intensity modulated PBT (pencil beam scattering)

Comparative planning study: IMRT vs PBT in pelvic Ewing Sarcoma

- **VMAT**
  - Good bowel, rectum and bladder sparing
  - Femoral head within tolerance
  - Spare one ovary to mean dose 4.3Gy
  - Uterus mean dose <10Gy in 80% of cases
  - Low dose bath

- **IMPT**
  - Superior sparing of:
    - Femoral head
    - Ovaries
    - Uterus
    - No low dose bath but high entry dose

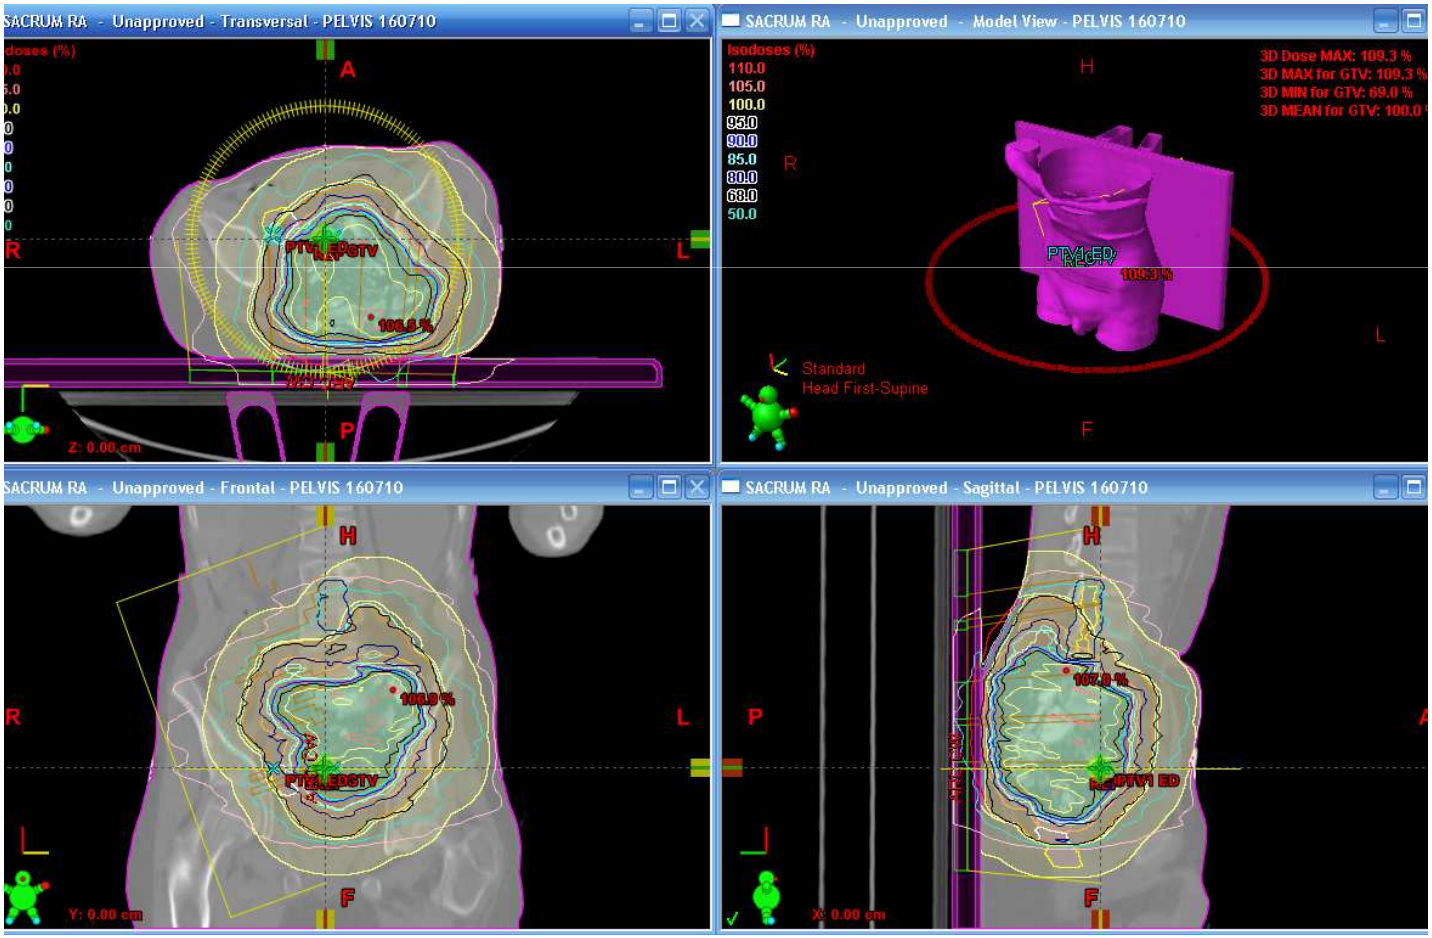
IMRT in other bone sarcomas and chordoma

- More radio-resistant tumours
- High doses of radiotherapy required ≥ 66 – 70+Gy
- Local control rates for RT alone around 40% at 5 years (protons +/- photons) [1]
- Increasingly, move towards using protons +/- photons, or carbon ions
- Inoperable tumours not approved for PBT in UK

[1] Delaney T et al. Radiotherapy for local control of osteosarcoma. Int J Rad Oncol Biol Phys. 61:492 – 498, 2005

Osteosarcoma pelvis: PTV1 50Gy in 28#, PTV2 70Gy in 28#



Conclusions

- IMRT offers opportunities across different sarcomas:
  - Soft tissue sarcomas – improved conformality to PTV, reduced dose to normal tissues, sparing of normal structures (e.g. bone), improved late toxicity?
  - Bone sarcomas:
    - Delivery of optimal dose to PTV with normal tissue sparing (Ewing's sarcoma)
    - Dose escalation for more radioresistant tumours (primary bone sarcomas, chondrosarcoma, chordoma)
    - PBT/carbon ions will offer advantage for some patients, but not easily accessible to all, so IMRT remains important

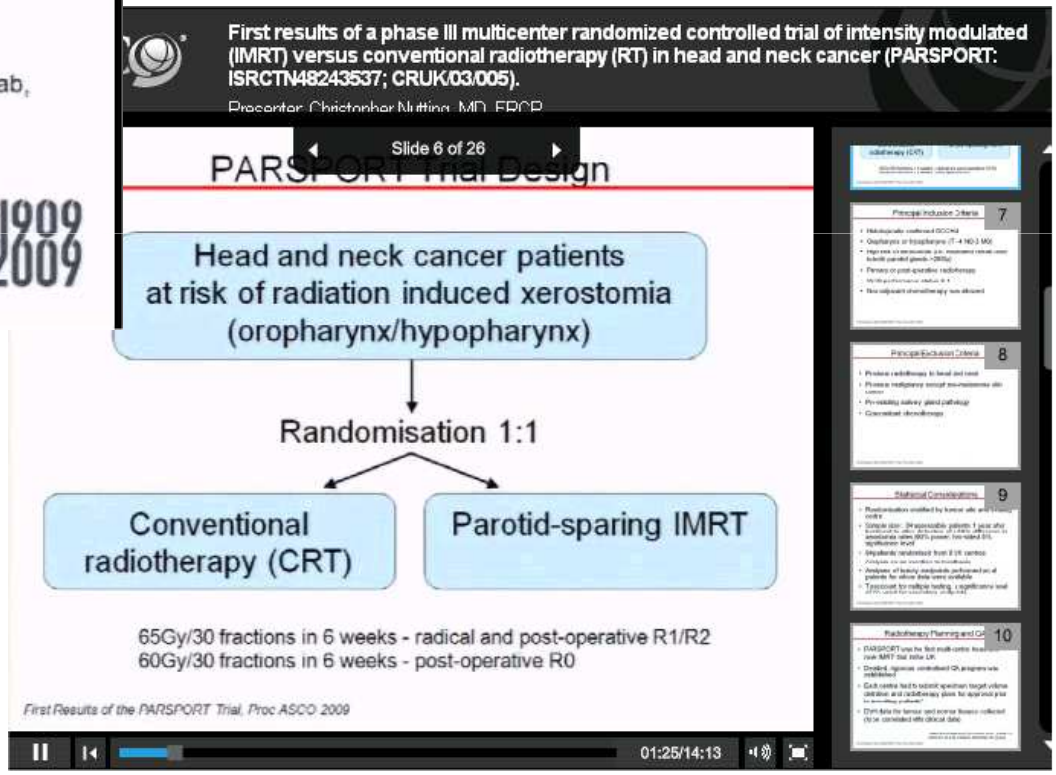
2009



First results of a phase III multicenter randomized controlled trial of intensity modulated (IMRT) versus conventional radiotherapy (RT) in head and neck cancer (PARSPORT: ISRCTN48243537; CRUK/03/005).
Slide 6 of 26
PARSPORT Trial Design
Head and neck cancer patients at risk of radiation induced xerostomia (oropharynx/hypopharynx)
Randomisation 1:1
Conventional radiotherapy (CRT)
Parotid-sparing IMRT
65Gy/30 fractions in 6 weeks - radical and post-operative R1/R2
60Gy/30 fractions in 6 weeks - post-operative R0
First Results of the PARSPORT Trial, Proc ASCO 2009
01:25/14:13

IMRT is evil….is it? The SEER-Database suggests…

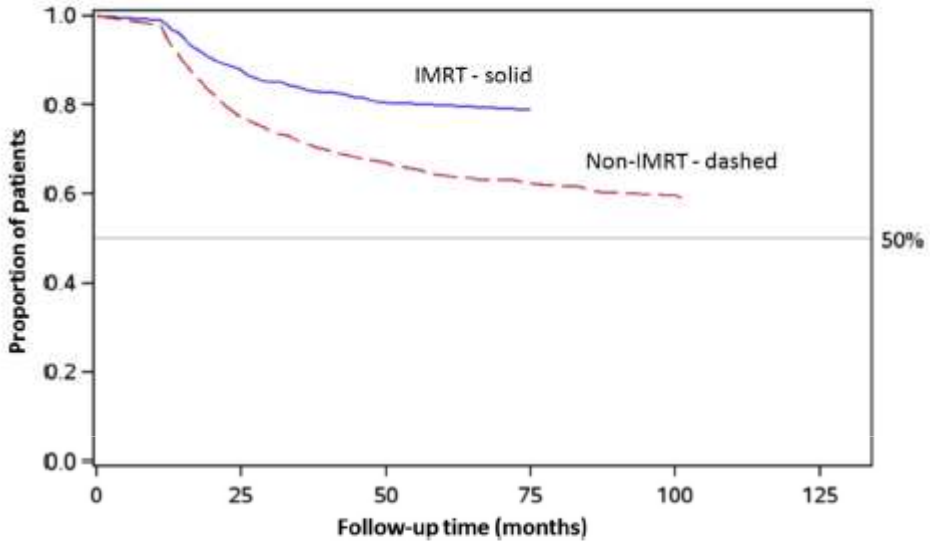


Figure 1. Impact of intensity-modulated radiation therapy (IMRT) on cause-specific survival. Kaplan-Meier curve depicting the cause-specific survival with time for patients treated with IMRT (dashed) compared to those treated with non-IMRT (solid).

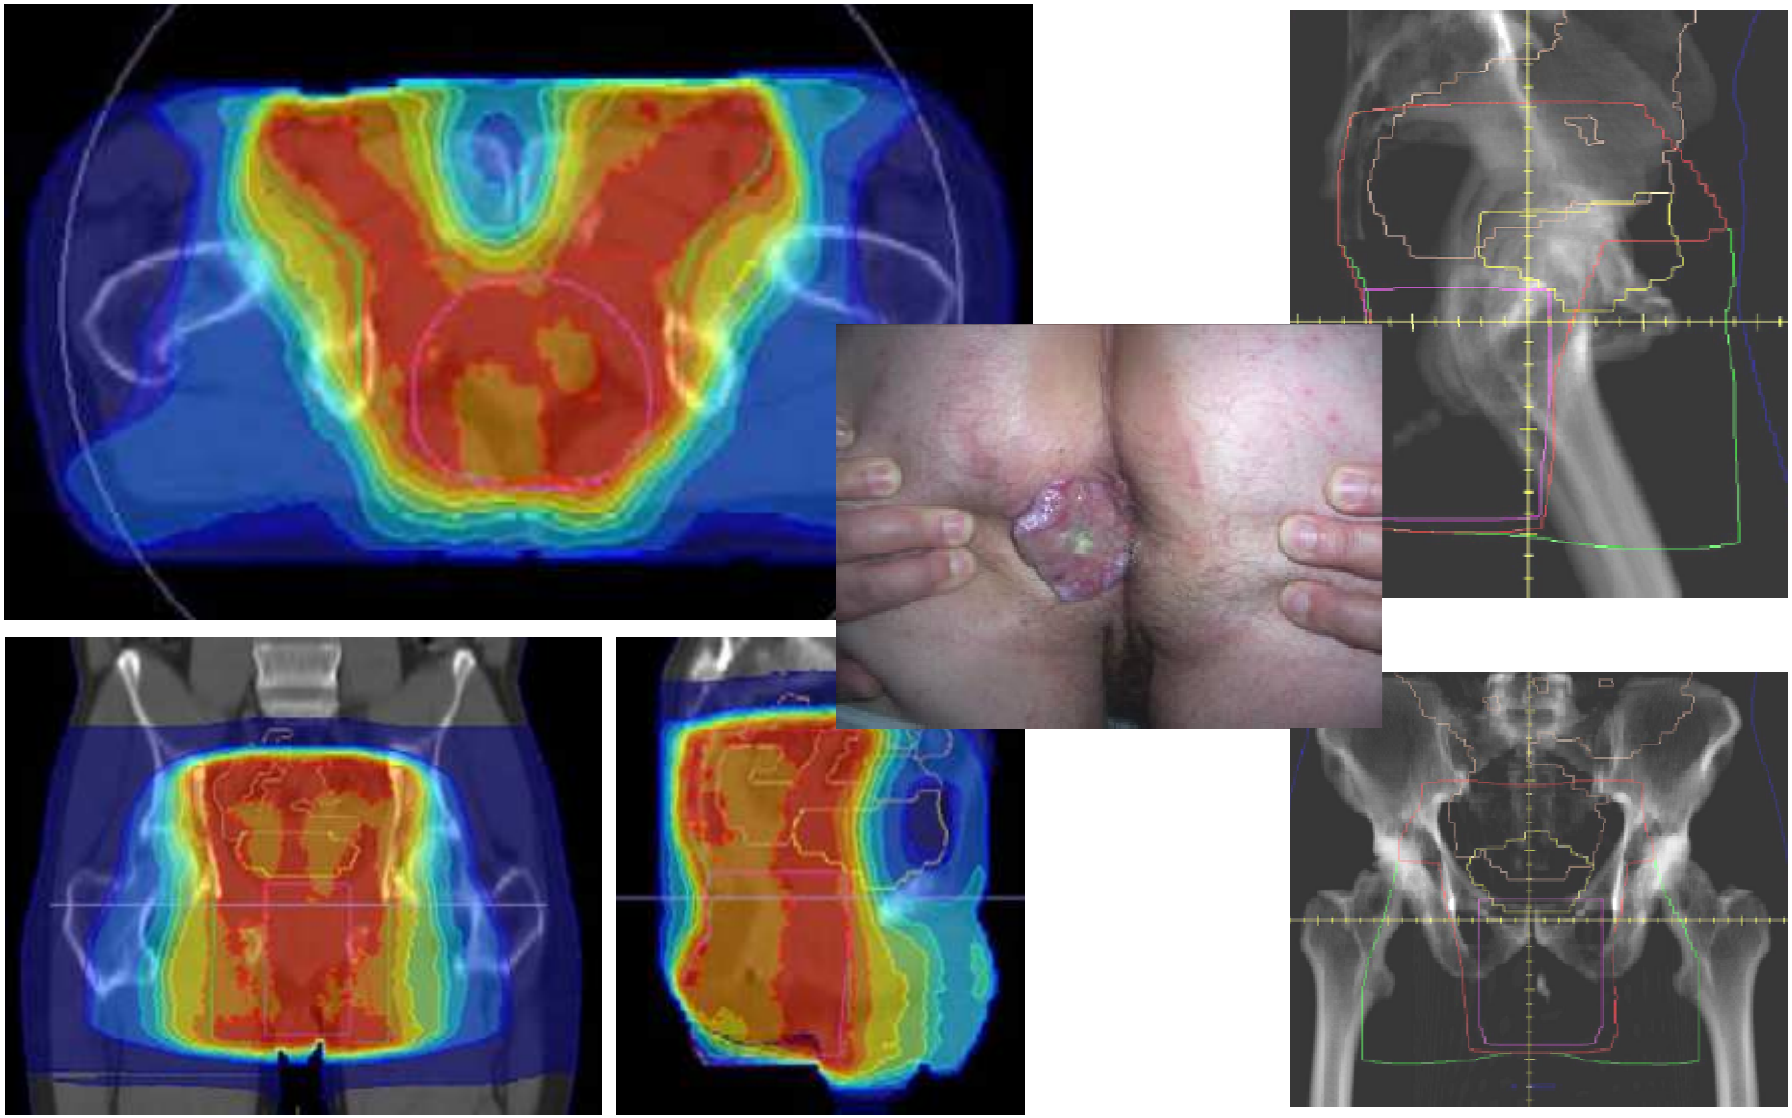
Beadle et al., Cancer, 2014

Lohr, Mai, in:
Wannenmacher, Strahlentherapie, 2013



Caveat: Marginal misses and high doses to large volumes

Tata Memorial Randomized Trial

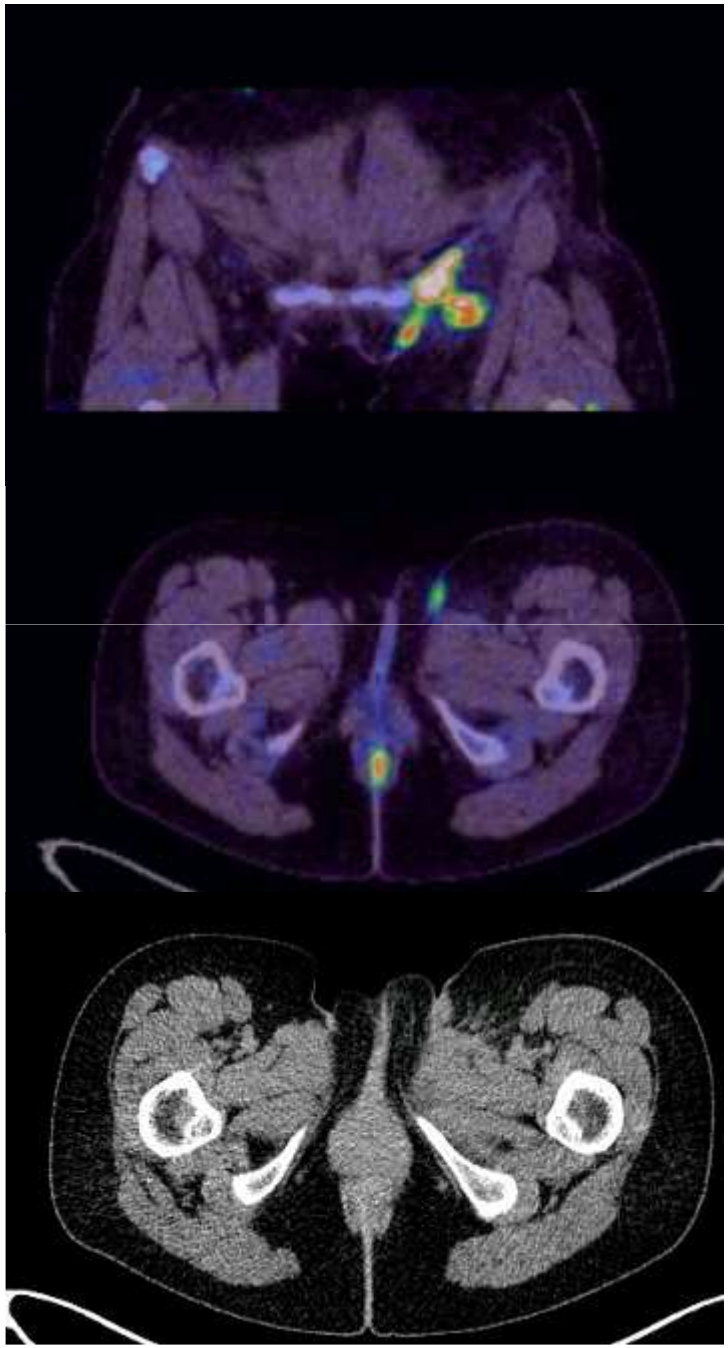
Rathod et al.,
Oral Oncol, 2013

Caveat:

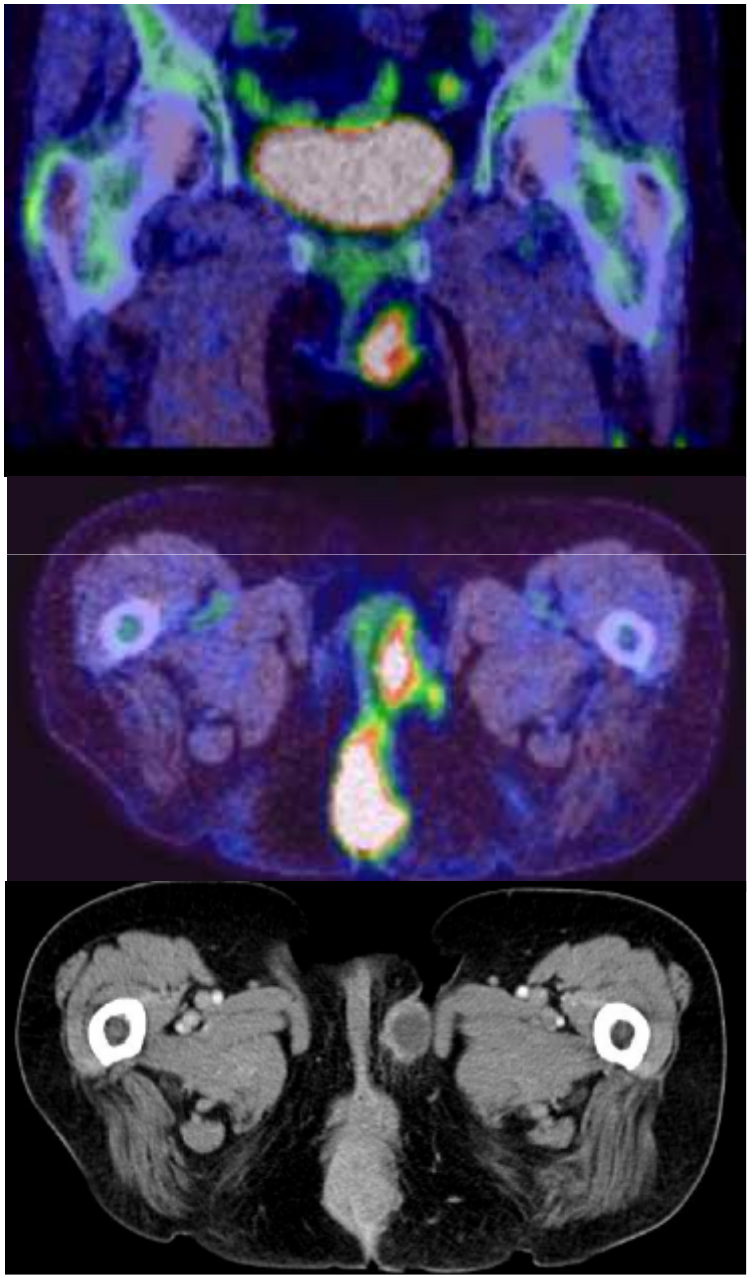
At a median followup of 40 months (inter-quartile range 26-50 months):

The 3-year estimates of loco-regional control with 95% confidence intervals (95%CI) were
88.2%** (75.4–100%) for **3D-CRT
80.5%** (66.1–94.9%) for **IMRT
(p = 0.45).

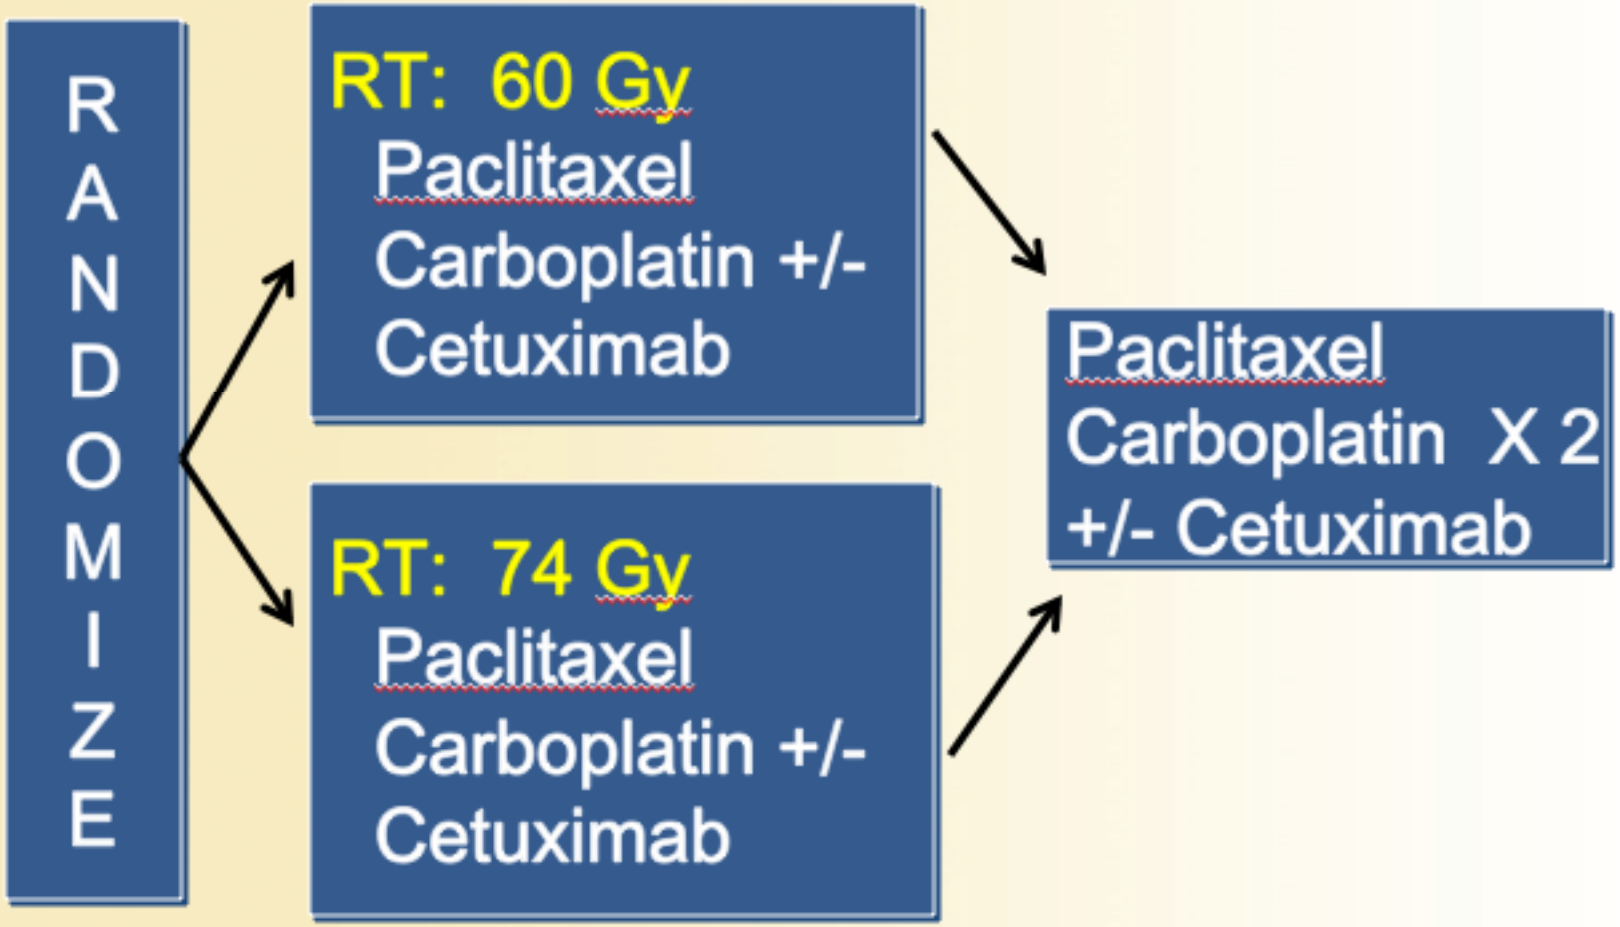
Pitfalls



Koeck et al., Radiation Oncology, 2016



RTOG 0617, NCCTG N0628,CALGB 30609
Conventional vs. High Dose RT



Now comes the strange part…..

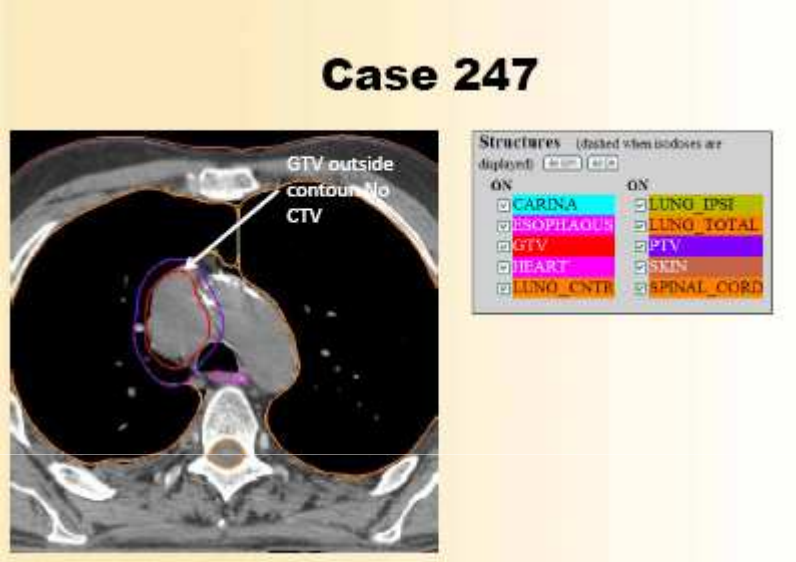
„**Local failure rates** at 18 months were

25.1% vs 34.3% for SD and HD patients,

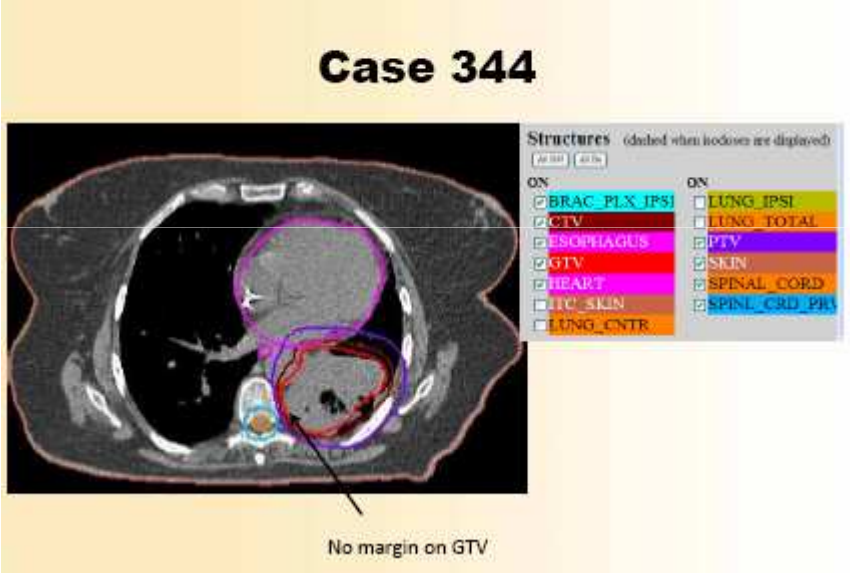
respectively(p=0.03). Local-regional and distant failures at 18 months were 35.3% vs 44%(p=0.04) and 42.4% vs 47.8%(p=0.16) for SD and HD arms, respectively. Factors predictive of less favorable OS on multivariate analysis were higher radiation dose, higher esophagitis/dysphagia grade, greater gross tumor volume, and heart volume >5 Gy“

Bradley et al., ASCO, 2013

Target Delineation



Bradley, 2014



http://thoracicsymposium.org/MeetingProgram/documents/GSIXBradley.pdf

The good news, however……

In this trial, IMRT was apparently clearly better than 3D and Lung V5 did not correlate with toxicity (V20 did, which is logical, since it marks a threshold dose…..as does V45 for heart)

This was a sneak preview to ASTRO 2015.
It is free. Donations are nevertheless accepted.

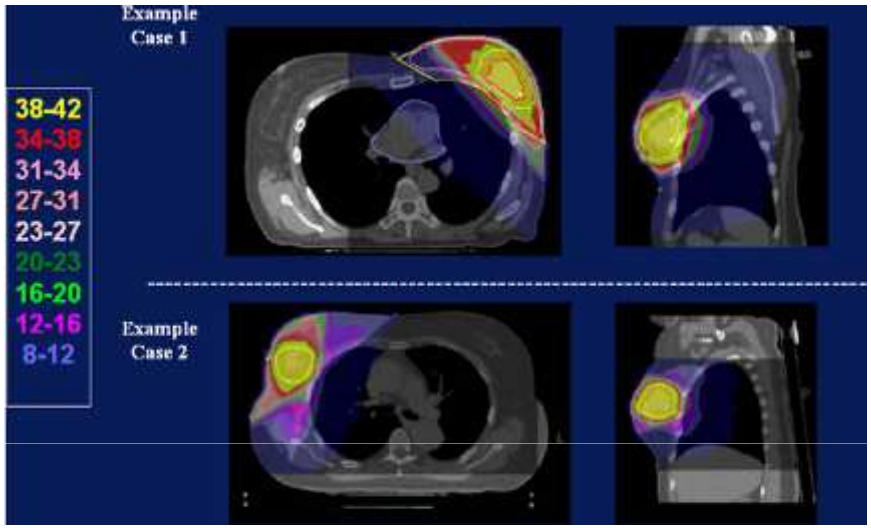
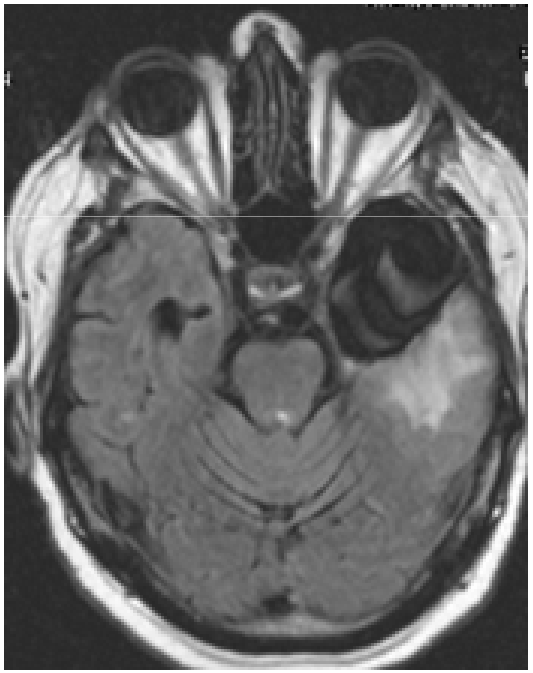
Hypofractionation/SIB-> Watch the Volume

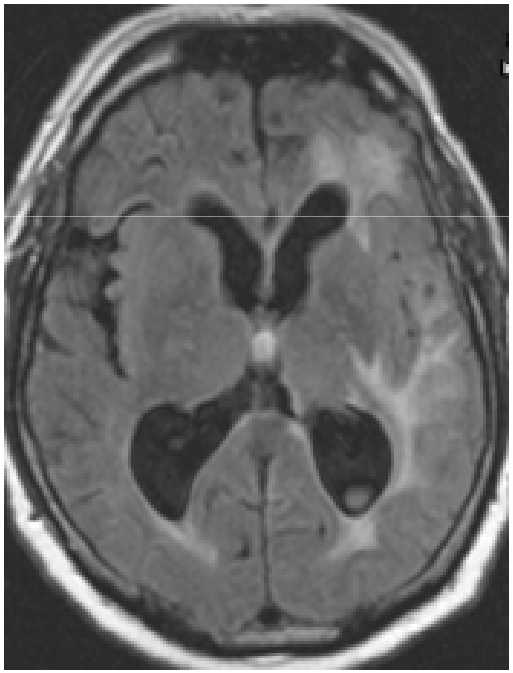


Jagsi et al., IJROBP, 2009

Fig. 3. Visible impairment in cosmesis observed in 3 patients deemed to have unacceptable cosmesis after treatment.

Brain tumor cells are interdispersed with normal cells
The Brain is the central human organ. Severe damage here alters the personality….and thus effectively kills the patient alive





There is good news on the secondary tumor front:

Randomized Data: PORTEC etc.

Wiltink et al., JCO, 2015

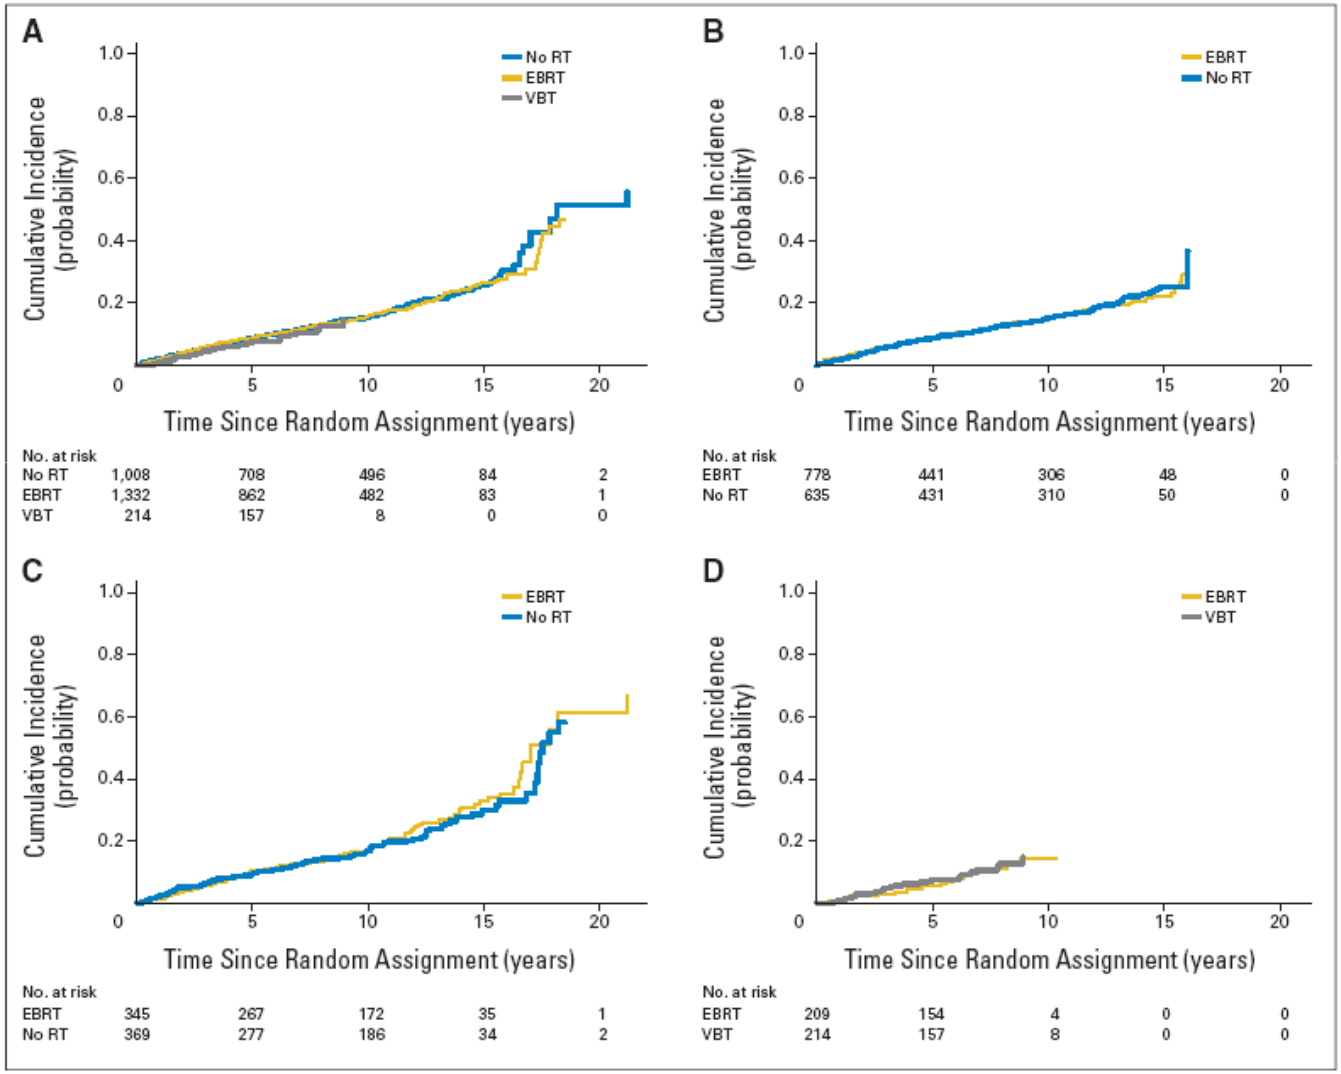


Fig 2. Cumulative probability of developing second cancer in (A) all, (B) TME (Total Mesorectal Excision), (C) PORTEC-1 (Post Operative Radiation Therapy in Endometrial Carcinoma 1), and (D) PORTEC-2 trials. NOTE. Because only four patients were included in no-RT group in the PORTEC-2 trial, these patients are not represented in panel D. EBRT, external-beam radiotherapy; RT, radiotherapy; VBT, vaginal brachytherapy.

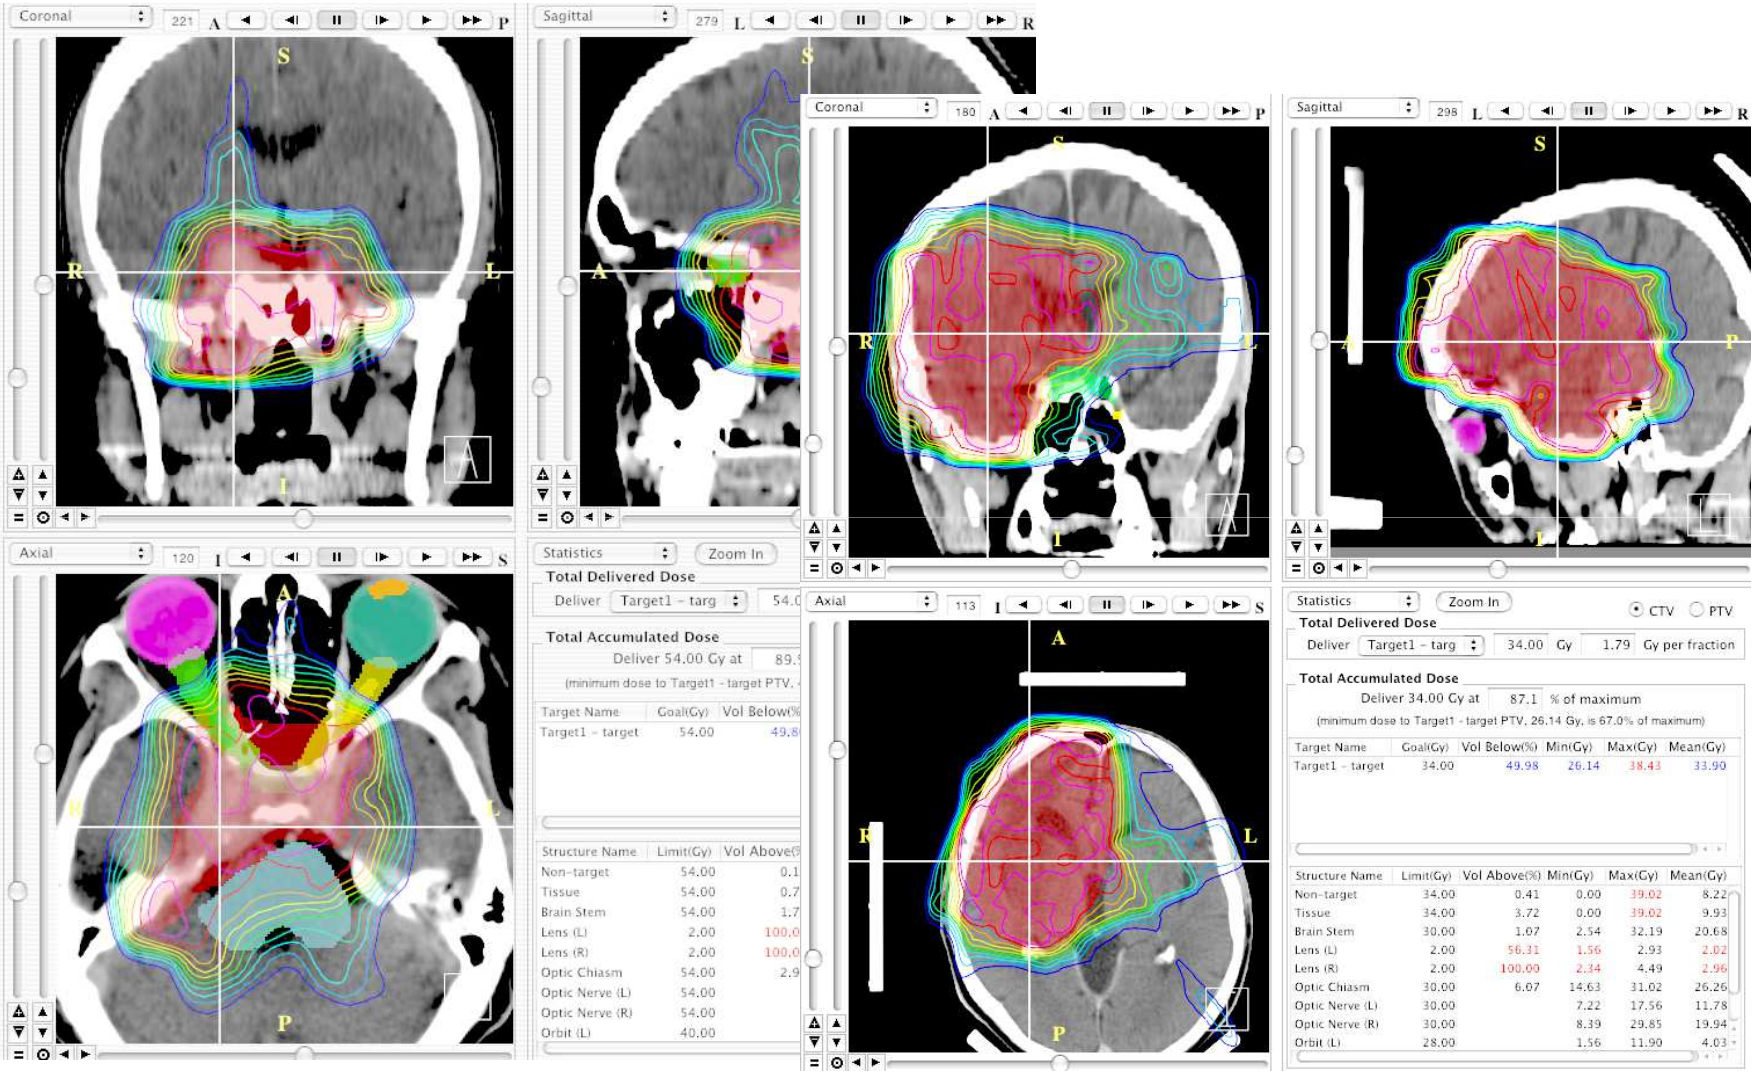
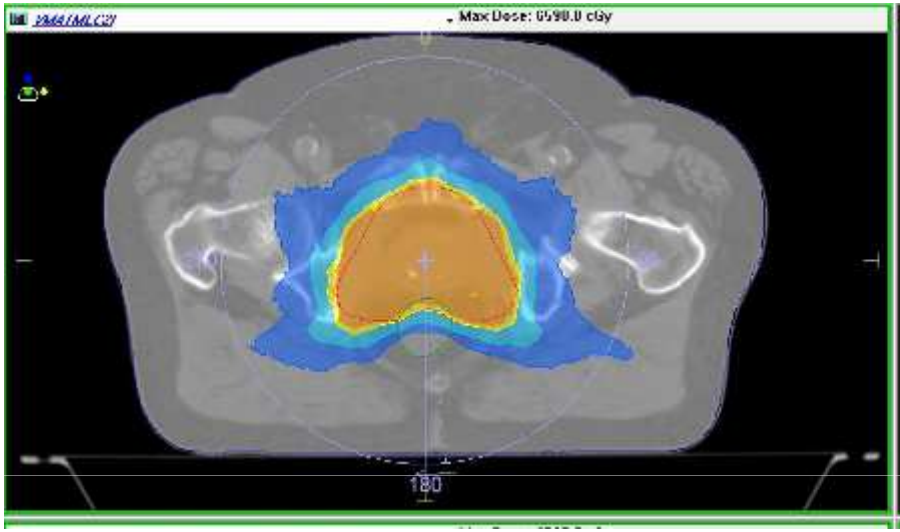
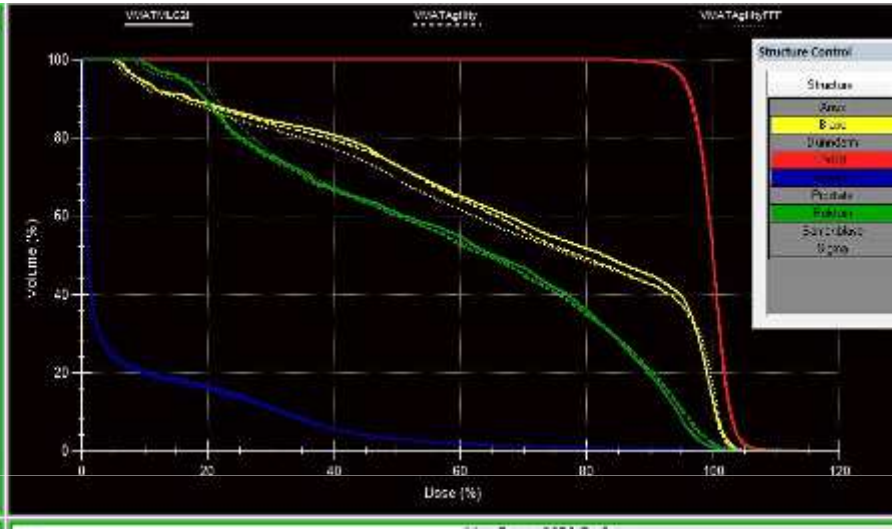
Convenience and Optimization of existing Paradigms

Head and Neck



Prostate – low degree of modulation, D= (30 × 2) Gy, 2 VMAT arcs





PROSTATE	MLCi2 Monaco 3.3	Agility Monaco 3.3	Versa HD Monaco 3.3
Homogenity index	1.09	1.09	1.09

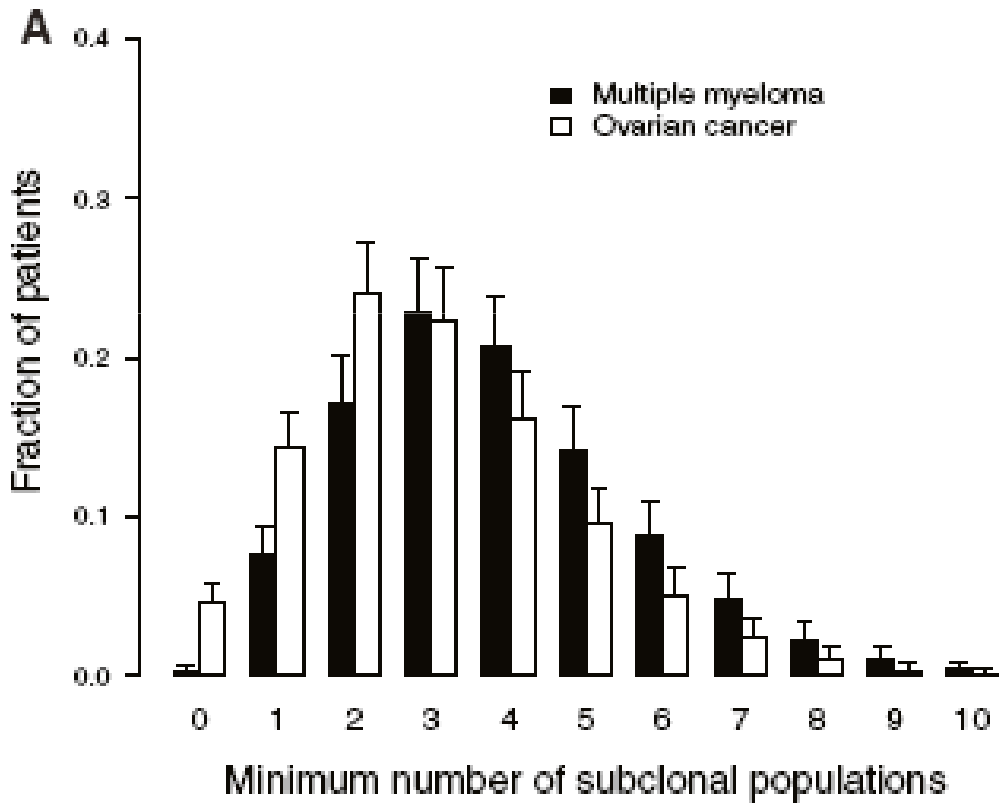
New methods for detection of subclinical metastases
a) in general ->Liquid Biopsy

Polyclonality is always a problem with any (vaccination) strategy:



Lohr, Cancer Cell, 2014

New methods for detection of subclinical metastases
b) providing topical information at high resolution->MRI

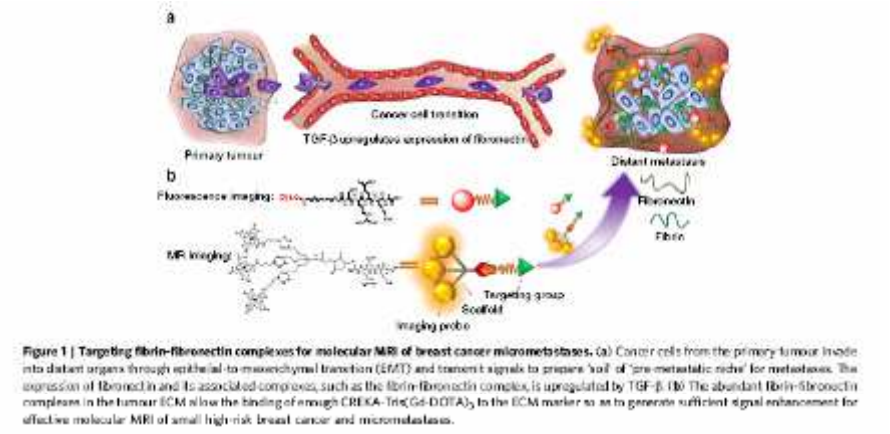


Figure 1 | Targeting fibrin-fibronectin complexes for molecular MRI of breast cancer micrometastases. (a) Cancer cells from the primary tumour invade into distant organs through epithelial-to-mesenchymal transition (EMT) and transmit signals to prepare 'soil' of 'pre-metastatic niche' for metastases. The expression of fibronectin and its associated complexes, such as the fibrin-fibronectin complex, is upregulated by TGF-β. (b) The abundant fibrin-fibronectin complexes in the tumour ECM allow the binding of enough CREKA-Tris(Gd-DOTA)$_3$ to the ECM marker so as to generate sufficient signal enhancement for effective molecular MRI of small high-risk breast cancer and micrometastases.

9/2008

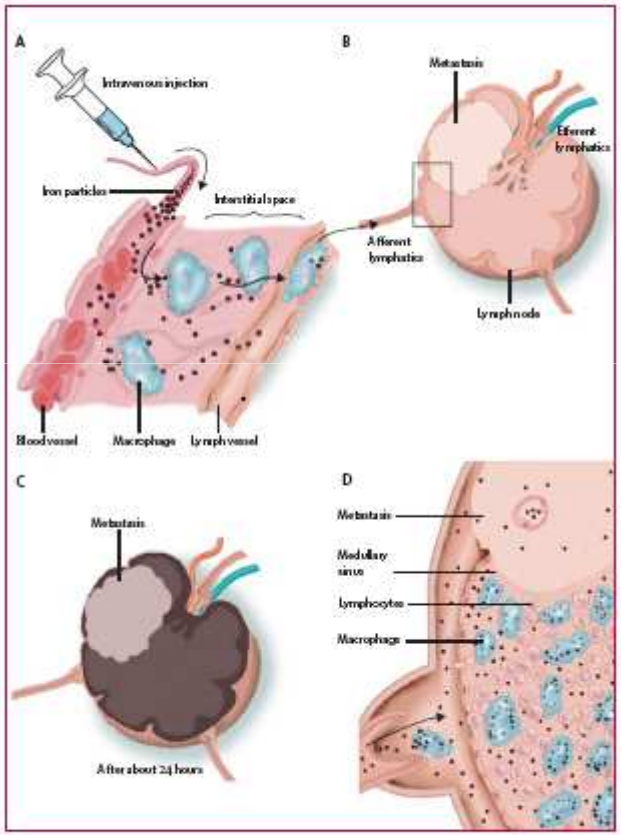

Figure 1: Mechanism of ferumoxtran-10
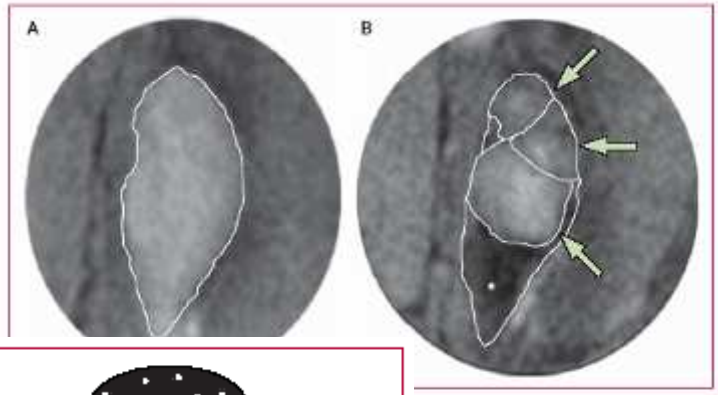
(A) Infused iron-particles slowly extravasate from the vascular to the interstitial space and are internalised by macrophages. (B) and (C) Iron-loaded macrophages are transported to lymph nodes via lymphatic vessels and accumulate in normal-sized lymph node tissue. These iron-loaded macrophages cause low signal intensity on T2*-weighted MR image. Box in B shows area depicted in D. (D) Disturbances of lymph flow or nodal architecture by metastases leads to less macrophages, depicted at MR imaging by higher signal intensity.



mage with partial metastatic lymph node before annot be discriminated. (B) MRL image, shows (arrows). Histopathology showed low signal

RT Fraction Size

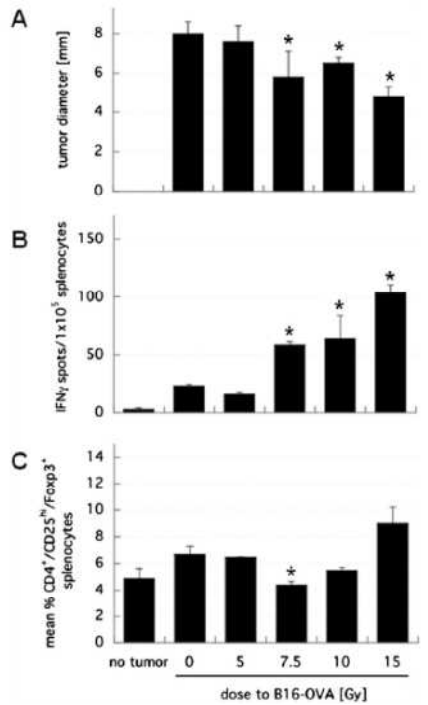

Fig. 1. Radiation dose-dependently increases tumor control and tumor-specific IFNγ$^+$ splenocytes and alters splenic regulatory T cells (Tregs). Mice were implanted with 0.8×10^6 B16-OVA cells subcutaneously in the leg and treated 10 days later with various doses of radiation. Tumor size and splenic responses were measured 7 days after treatment. (A) Tumor size as mean diameter in millimeters (2 dimension) of $n = 4-16 \pm$ standard error of the mean s.e.m. (B) Splenocytes were mixed *ex vivo* with EG7.OVA cells, and the number of IFNγ-producing cells was determined by enzyme-linked immunospot assay. Data are mean number of spots per 10^5 splenocytes of $n = 3-16 \pm$ s.e.m. (C) Splenocytes were stained for CD4, CD25, and Foxp3 and enumerated by flow cytometry. Data are mean CD4+, CD25+, and Foxp3+ Tregs as fraction of CD4+ splenocytes of $n = 1-11 \pm$ s.e.m. $*p < 0.05$ compared with 0 Gy.

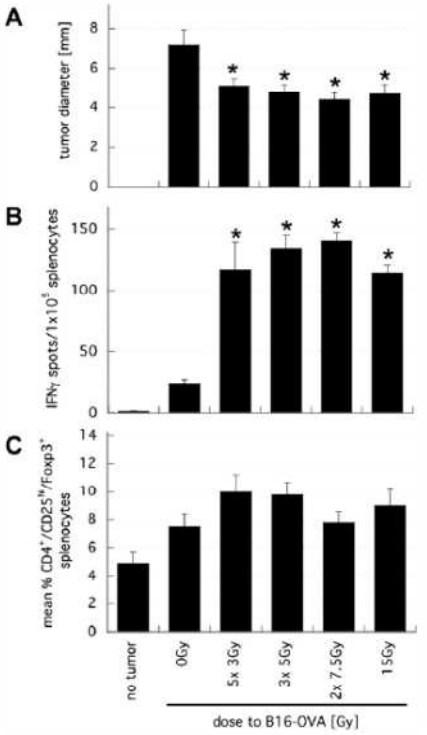

Fig. 2. Fractionated radiation affects tumor control and tumor-specific IFNγ$^+$ splenocytes and alters splenic regulatory T cells (Tregs). Mice bearing B16-OVA tumors 4 mm in size were given fractionated radiation in 6 hour intervals of a total dose of 15 Gy and left for 7 days to recover. (A) Tumor size as mean diameter of $n = 12 \pm$ standard error of the mean s.e.m. (B) Mean number of IFNγ-enzyme-linked immunospots per 10^5 splenocytes of $n = 3-6 \pm$ s.e.m. in response to EG7.OVA *ex vivo* restimulation. (C) Mean percent of splenic CD4$^+$CD25$^+$Foxp3$^+$ Tregs as analyzed by Fluorescent Activated Cell Sorting FACS of $n = 8-12 \pm$ s.e.m. $*p < 0.05$ compared with 0 Gy.

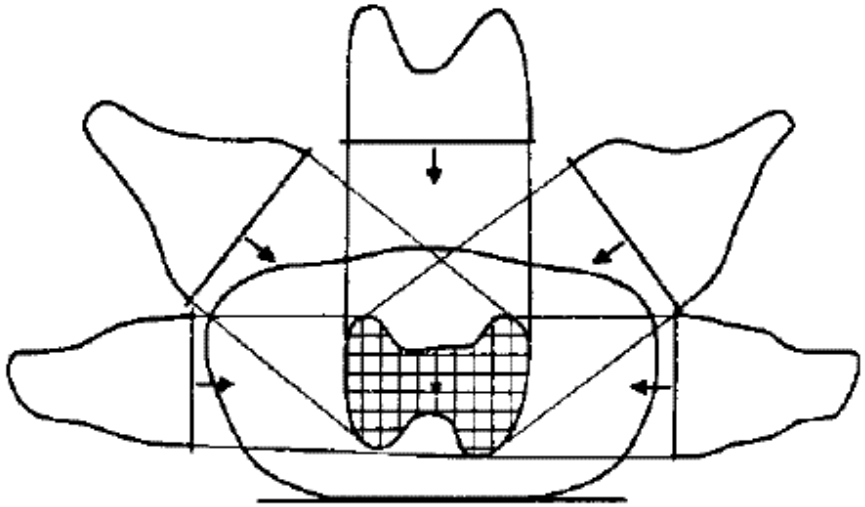
IMRT dose delivery methods



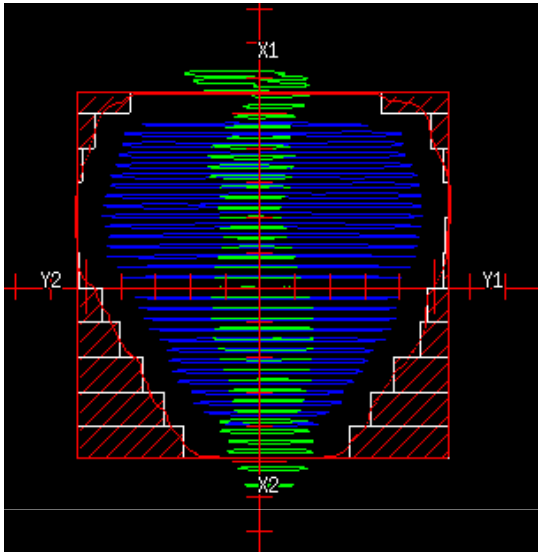
Marco Schwarz

marco.schwarz@apss.tn.it

Disclosure

My department has a contract with Philips Medical Systems concerning alpha and beta testing of treatment planning software for proton therapy with pencil beam scanning.

Why did we end up with IMRT?

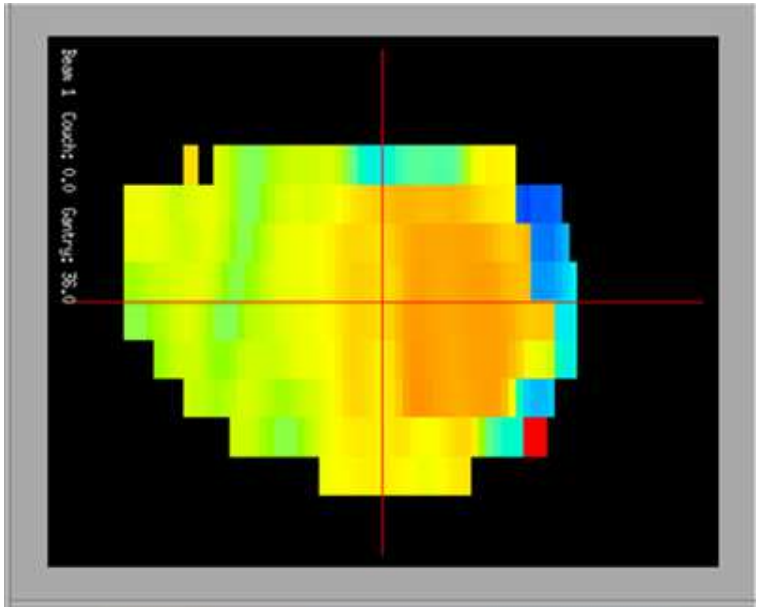


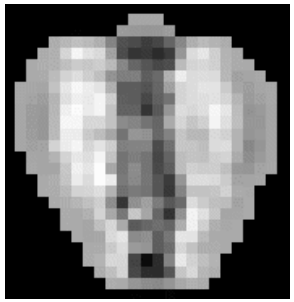
What we were calling ‘3D conformal RT’ was often not that conformal.

With photons, achieving dose modulation with the falloff along the beam direction is hopeless

No technology, however fancy, will change that.

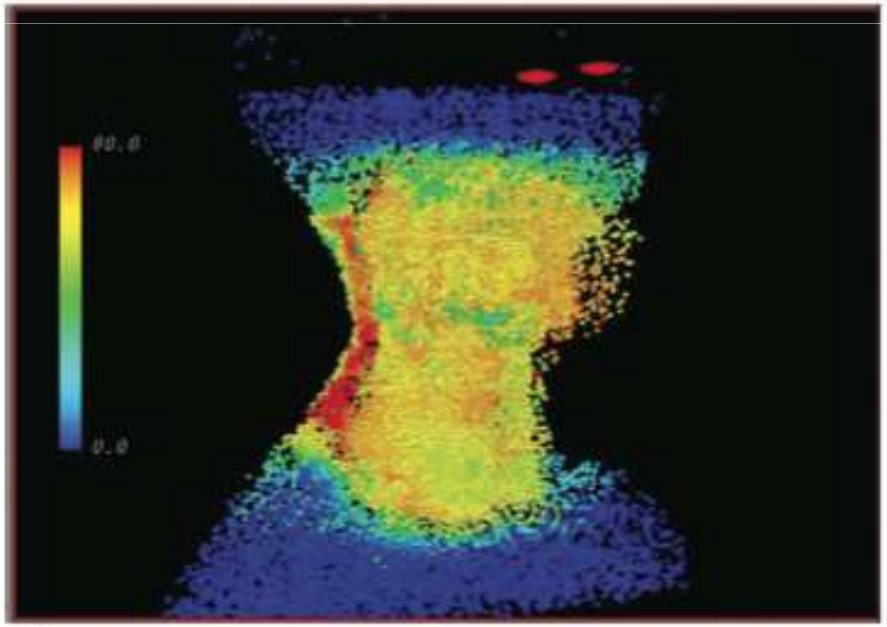
We are therefore left with modulating particles fluence in the cross plane, hence IMRT.

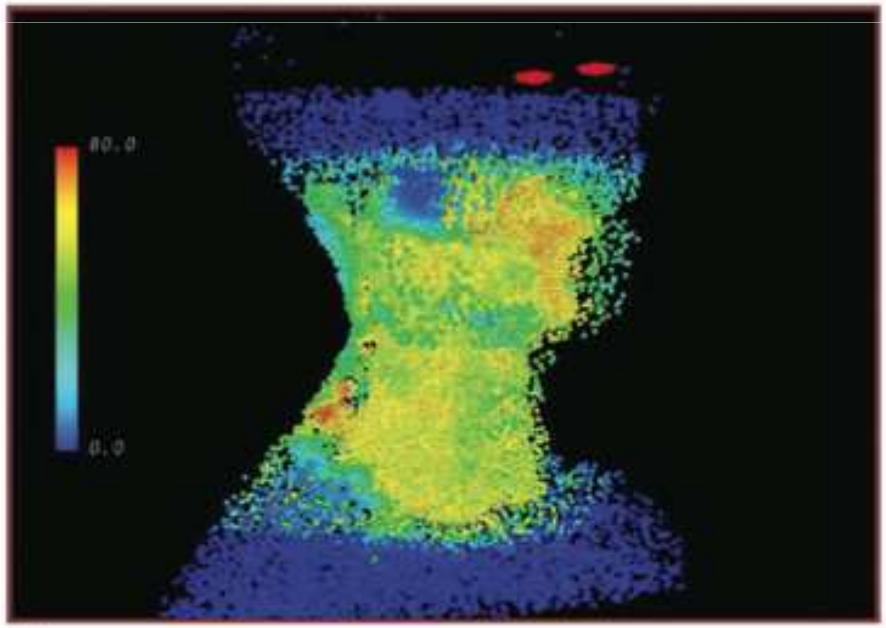




How can we modulated particle fluence?

In principle, by controlling the beam intensity at the level of the single beam elements (‘bixel’/’beamlet’)

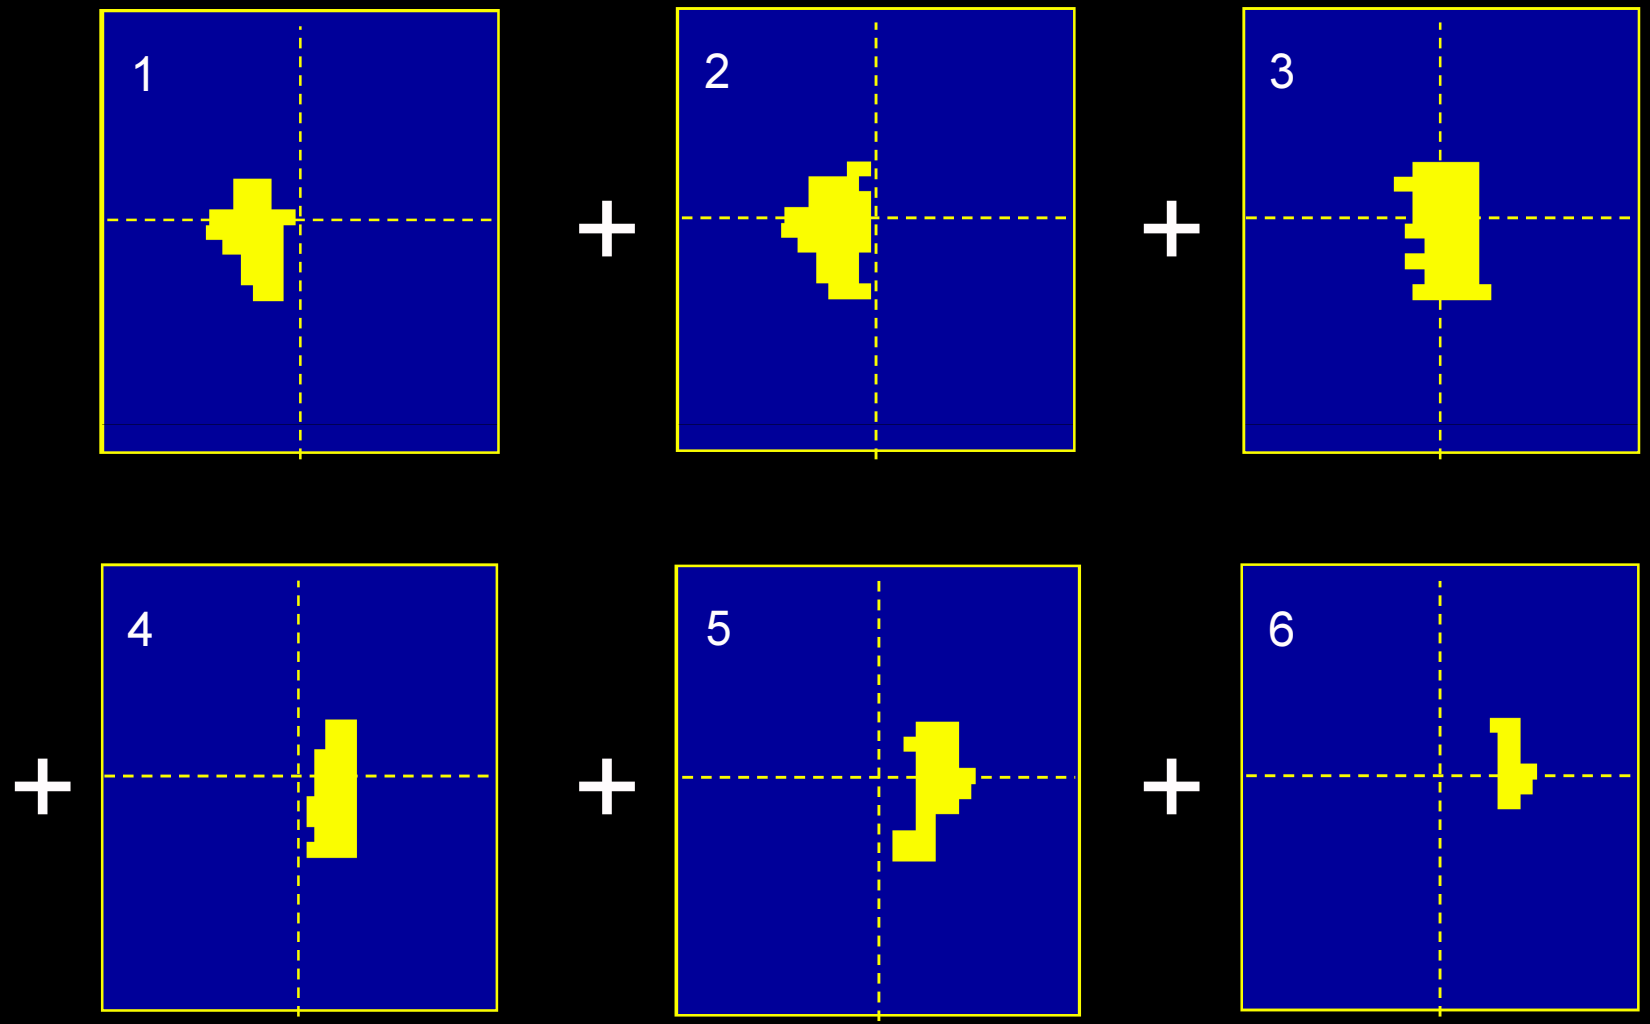




Principle and terminology

Calculated fluence map, bixels, intensity levels

Subfields (or segments)



Intensity modulation with MLC

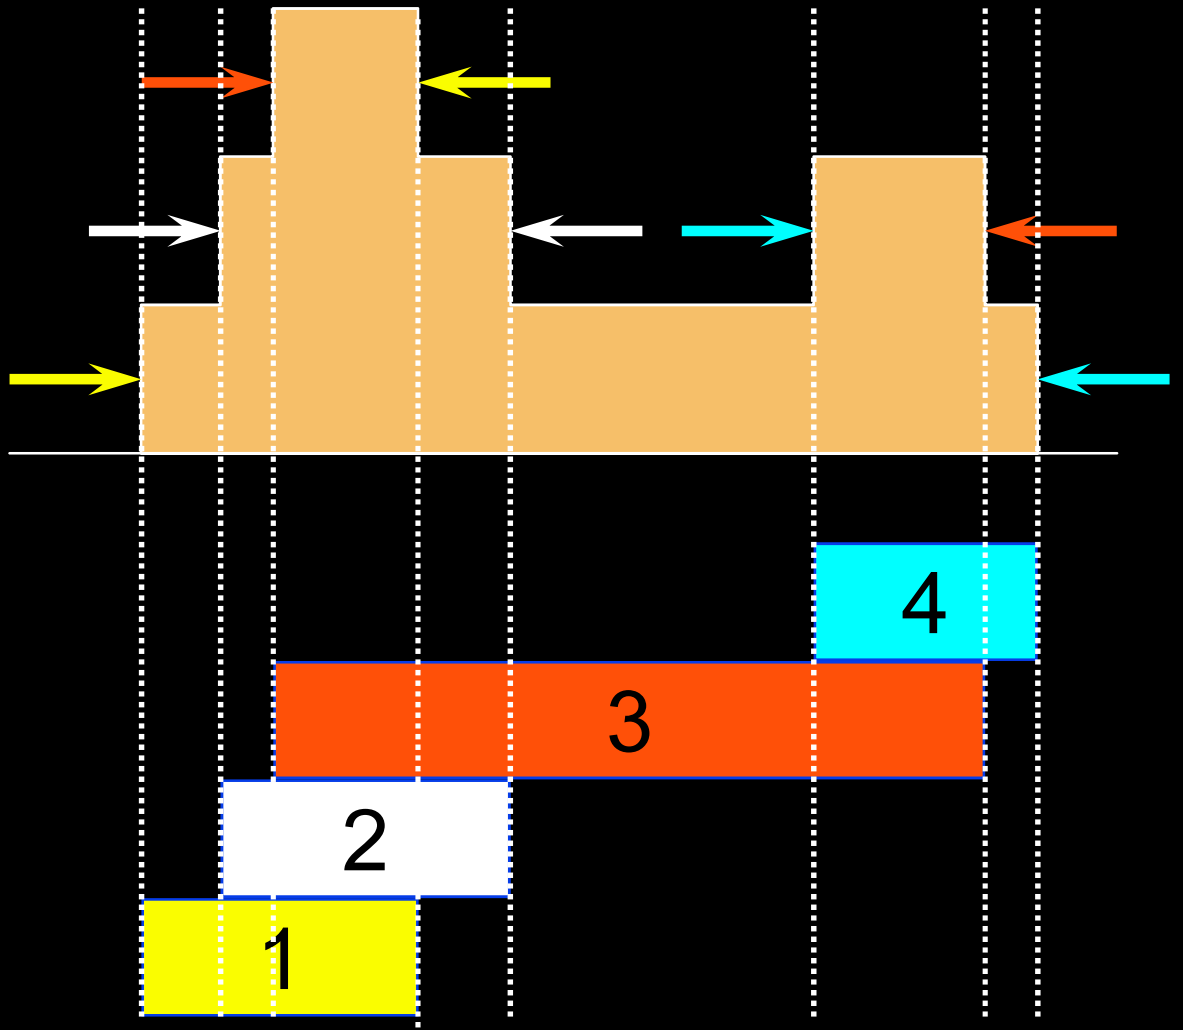
Trajectory:

“Sweep” technique

IM-Profile:

Trajectory:



Pro's and Con's

Pro static delivery

- Simpler extension of 3D-CRT techniques
- Somewhat more intuitive
- Somewhat easier to control the level of complexity

Pro dynamic delivery

- Generally faster
- Better suited for highly complex profiles
- Enables rotational therapy, dynamic tracking

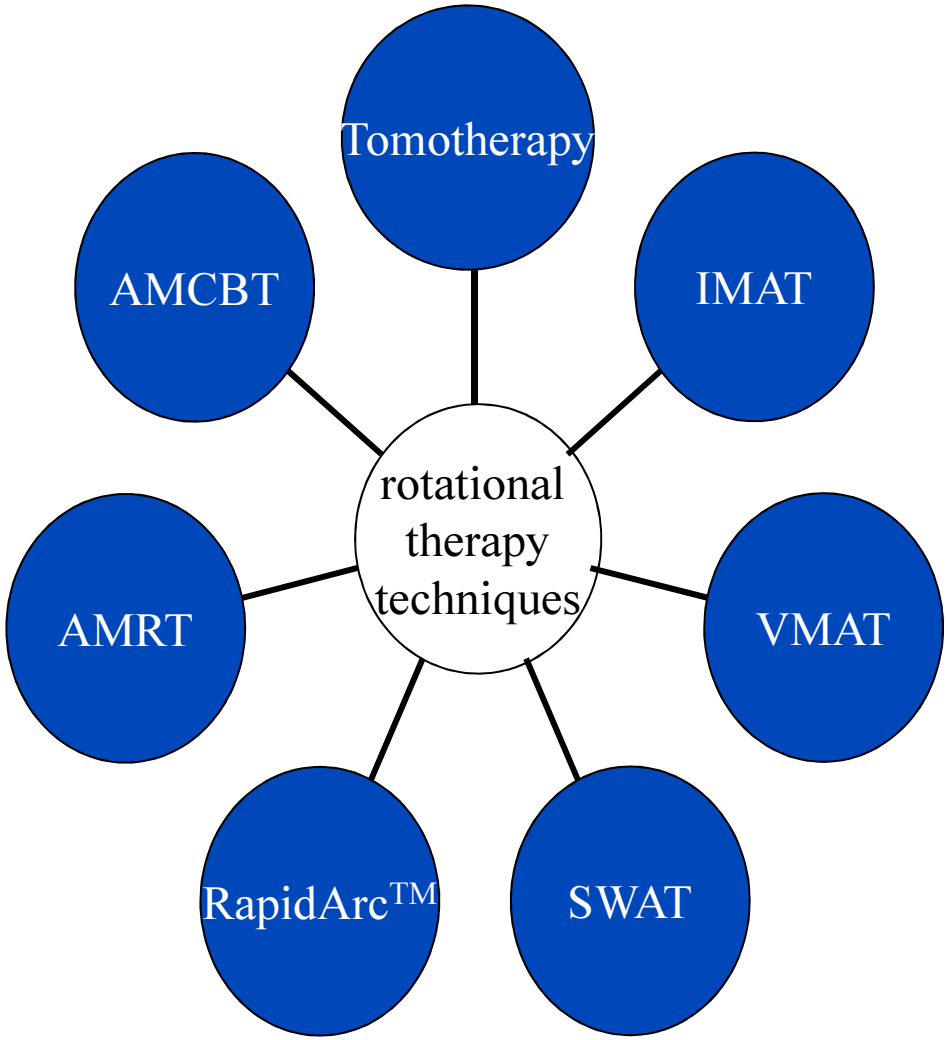
Dynamic rotational treatment techniques



Dynamic rotation therapy

In dynamic rotation therapy the following parameters can be varied during dose delivery:

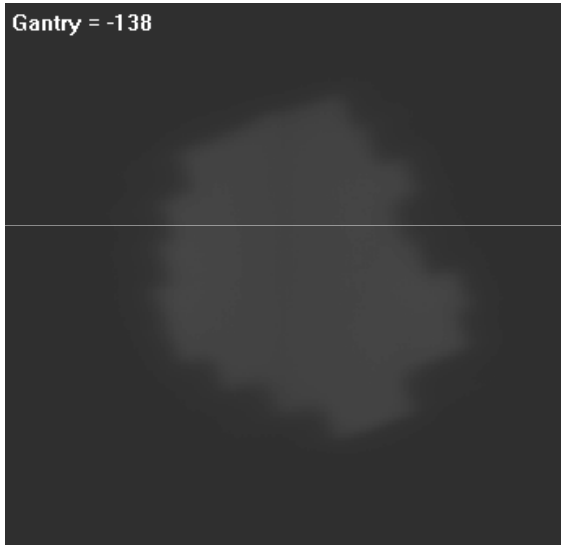
MLC leaf position

Dose rate

Gantry velocity

Collimator angle

Table angle

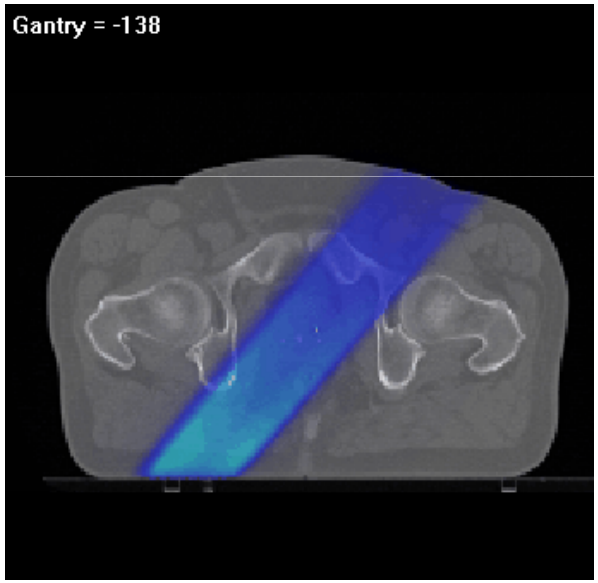


B. Mijnheer (NKI)

VMAT in action

Shape and MU for a single gantry angle

Field dose



Cumulative dose

Courtesy B. Mijnheer

Differences among techniques

Treatment machine (tomotherapy $\Rightarrow$ fan beams
conventional linac $\Rightarrow$ cone beam)

Delivery parameters (variable dose rate, variable gantry speed, …)

Number of arcs (single arc – multiple arcs)

Optimization concept (algorithm, DAO, …)

...

See lecture on comparing rotational techniques

See review in Yu PMB 2011 for treatment delivery

See review in Unkelbach Med Phys 2015 for plan optimization

Single Arc techniques

(Very) fast delivery in single rotation of the gantry

During gantry rotation the dose is delivered while varying

- MLC leave positions and
- **dose rate** and/or
- gantry rotation speed

LETTER TO THE EDITOR

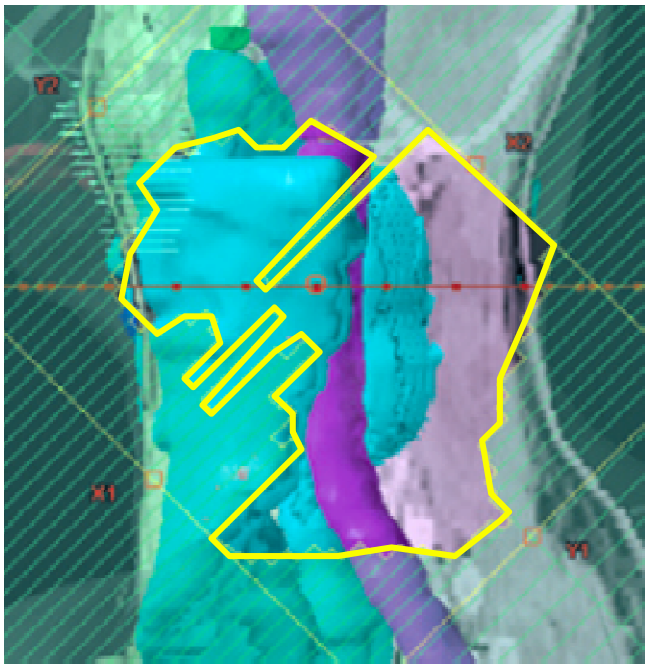
Reply to 'Letter to the Editor on 'Single-Arc IMRT?''

Thomas Bortfeld[1] and Steve Webb[2]

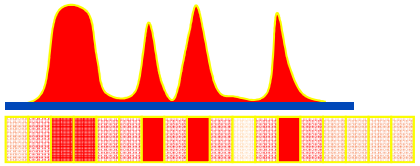
Not all rotational techniques are created equal

Single arc

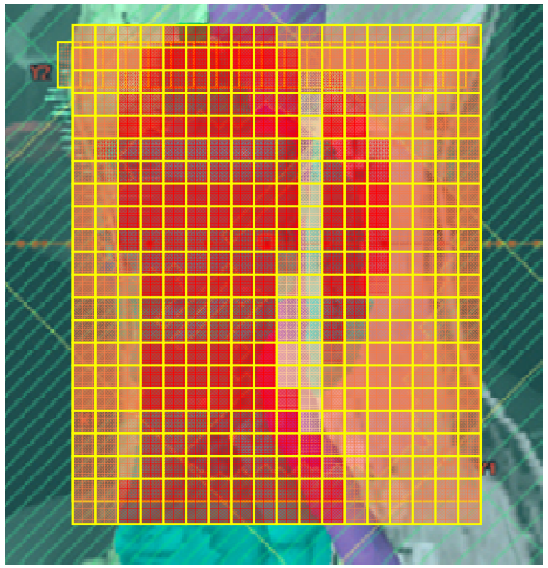


Little or no modulation for the individual gantry angle

Tomo



Modulated beam projection



One projection each rotation for this angle

Multiple modulated beam projections

Static field IMRT vs arc techniques

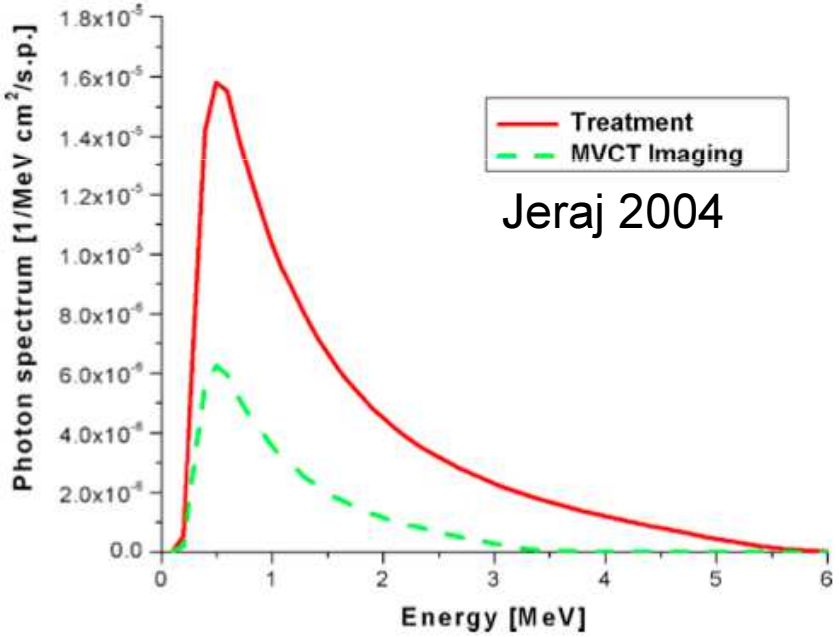
After the initial quite strong claims on (and heated discussions about) (linac-based) arc techniques, we are getting close to an objective assessment of the (dis)advantages of each techniques.

Is the focus on improved delivery efficiency (as opposed to quality of the dose distributions) an indication that we reached the limits of dose modulation with photons?

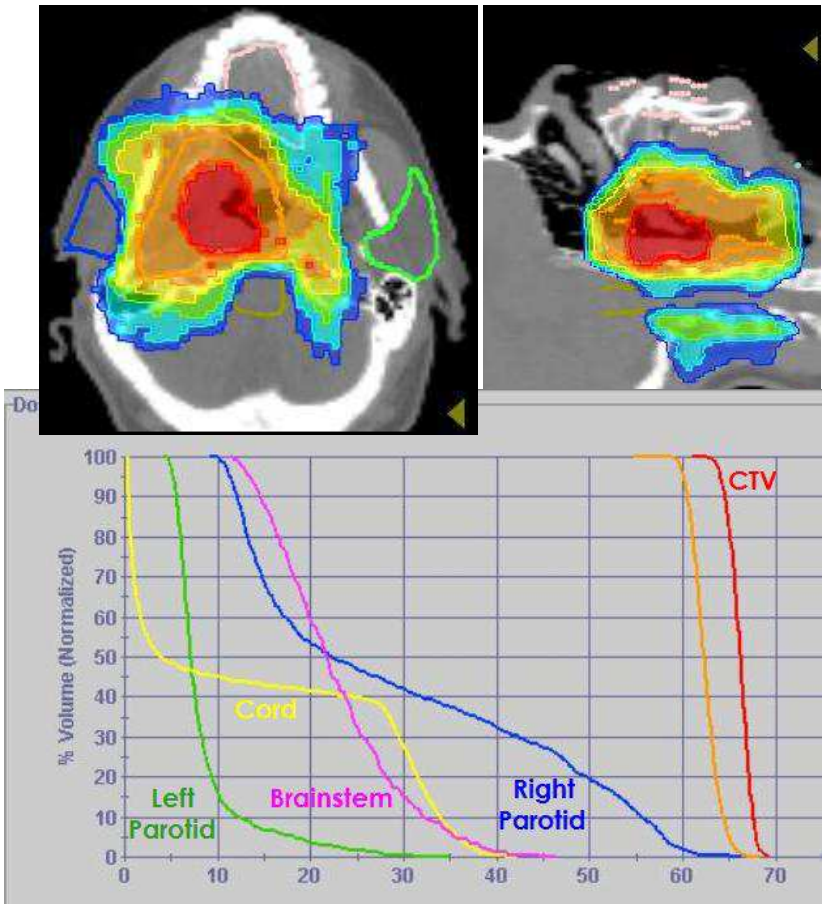
Dedicated IMRT/IGRT devices

TomoTherapy HI -ART System

85 cm Aperture
40 cm Image FOV



HT dose delivery system



6mm binary MLC over a large field (40cm)

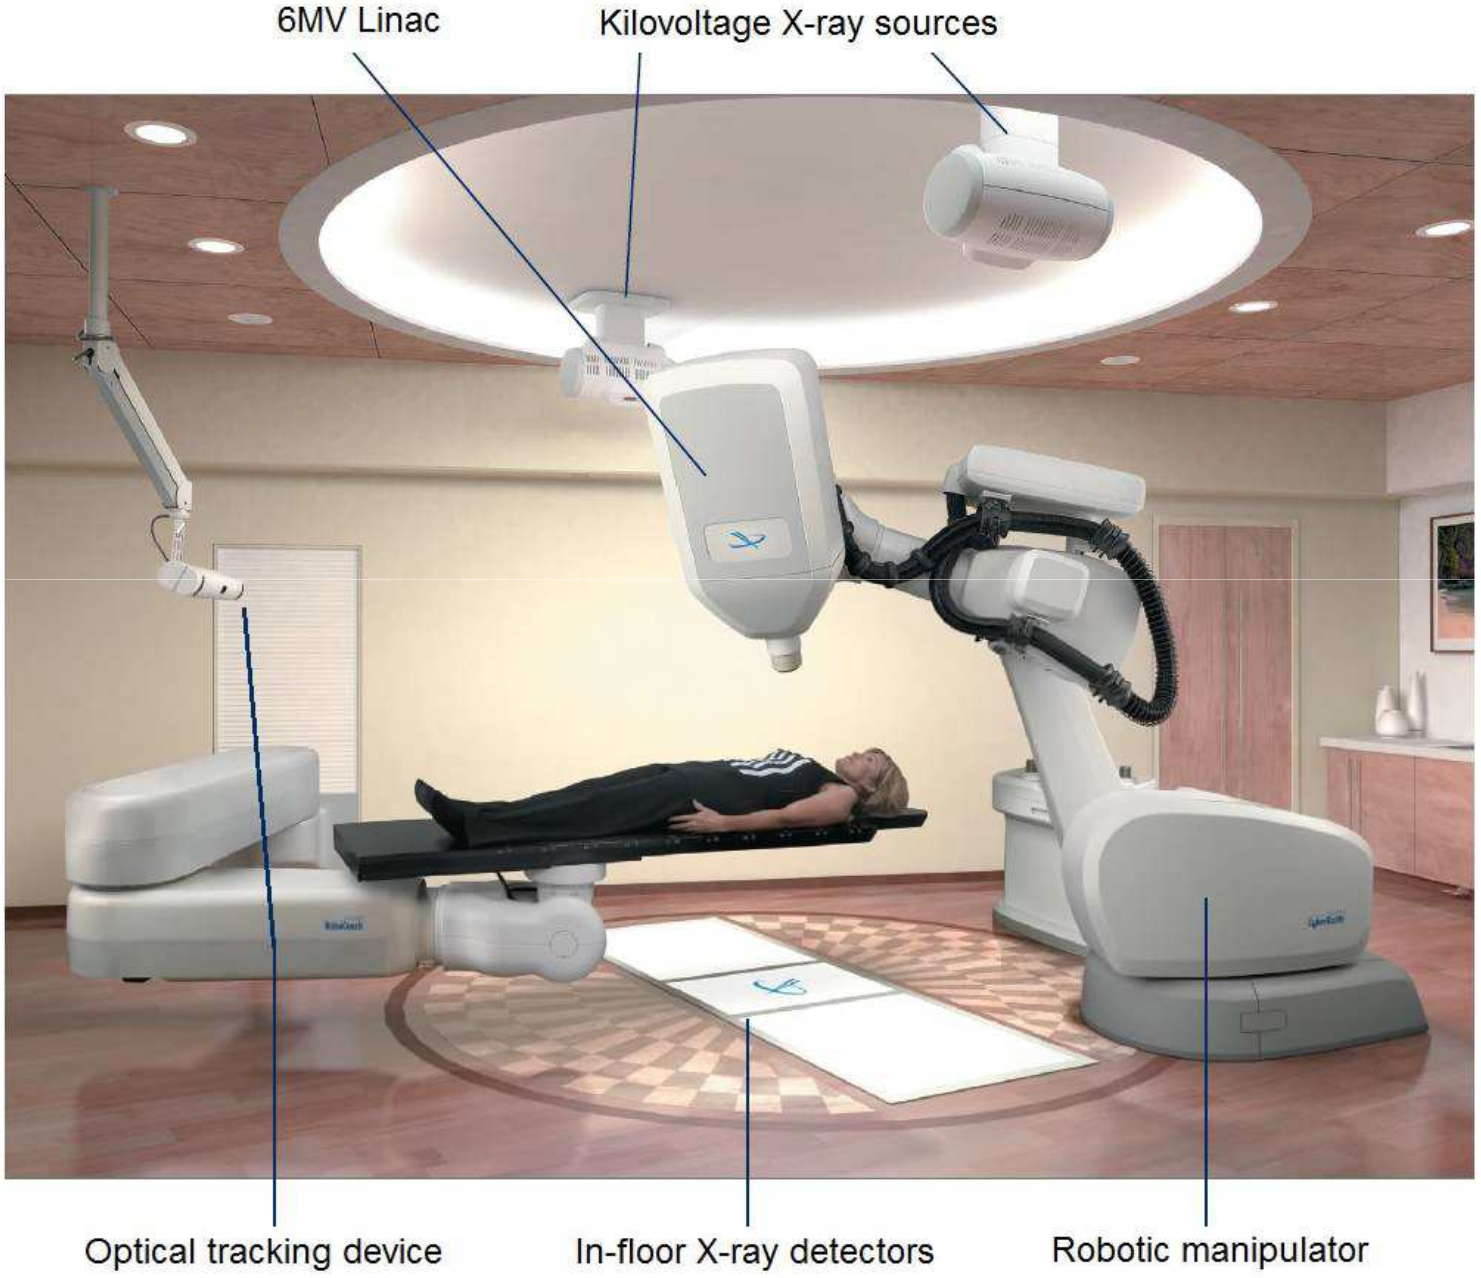
No flattening filter

10 cm leaf thickness
Designed for delivery of IMRT (i.e. low transmission)

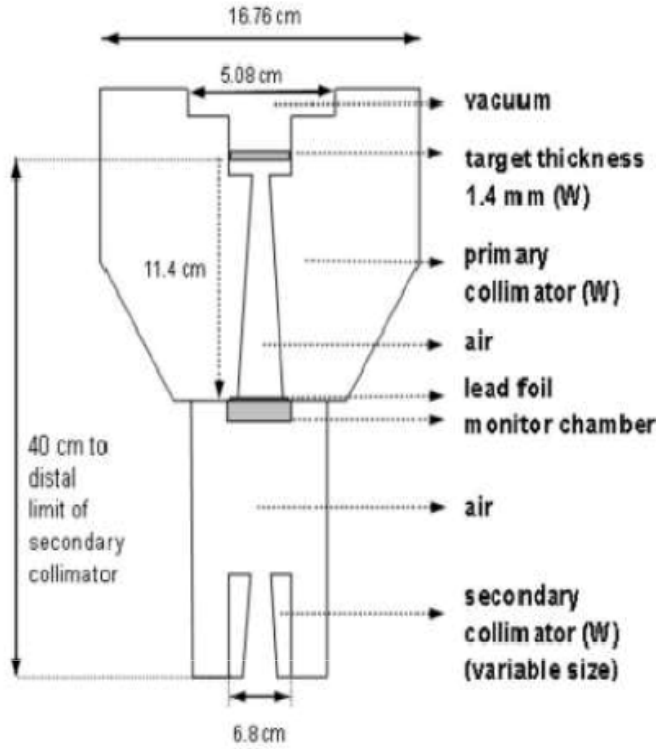
Degrees of freedom in planning and delivery:

Field width
Pitch
Modulation factor

Cyberknife



6MV Linac
Kilovoltage X-ray sources
Optical tracking device
In-floor X-ray detectors
Robotic manipulator



Robotic arm

6 degrees of freedom

About 120 positions around the patient

12 beam directions per position → 1440 possible beam entrances

Declared position accuracy < 0.12 mm

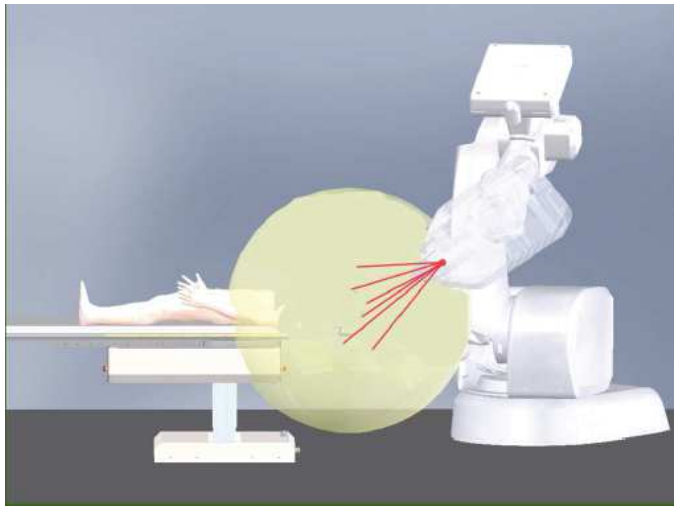
LINAC

About 160 kg

6 MV X-rays

Dose rate up to 800 MU/min

No flattening filter



Collimating systems

12 fixed circular collimators (5 to 60 mm)

IRIS – Variable aperture collimator

Its use is currently restricted to a set of 12 sizes corresponding to the sizes of the set of 12 fixed collimators, (5 to 60 mm)

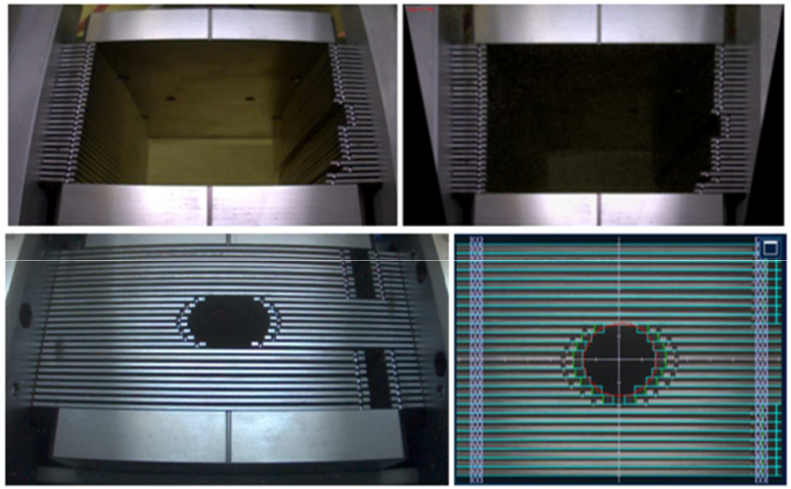
INCISE – MLC

INCISE™ MULTILEAF COLLIMATOR SPECIFICATION *As defined by IEC 60976*

Beam Targeting	Non-Isocentric, Non-Coplanar Beam Targeting
Maximum Field Size	Nominal: 120 mm (leaf motion direction) x 100 mm at 800 mm SAD
Number of Leaves	41 leaf pairs
Leaf Thickness	2.5 mm at 800 mm SAD
Leaf Tilt	Leaves tilted 0.5°
Leaf Tip Design	3-Sided
Leaf Height	90 mm
Leaf Material	Tungsten
Distal Plane of Leaves to Linac Source Distance	400 mm
Leaf Positioning Accuracy	0.5 mm at 800 mm SAD
Mechanical Accuracy	0.25 mm
Leaf Positioning Reproducibility	0.4 mm at 800 mm SAD
Mechanical Reproducibility	0.2 mm
Leaf Over-Travel	100%
Leaf Inter-Digitation	Full Leaf Inter-Digitation
Transmission Includes intra-leaf, inter-leaf and leaf tip transmission	<0.3% Average (<0.5% Maximum)
Weight	48 kg (~105 lbs)

INCISE□ 2 – MLC

Number of leaves	52
Leaf width (at 800 mm SAD)	3.85 mm
Maximum treatment field size (at 800 mm SAD)	115 mm × 100 mm
Leaf height	90 mm
Leaf tip design	Three flat, focussed edges
Leaf side design	Flat, focussed
Interdigitation	Yes, no restrictions
MLC assembly weight	54 kg
Source to collimator distance (lower side of leaves)	400 mm
MLC assembly physical envelope	375 mm tall × 572 mm wide × 295 mm deep
Maximum leaf speed (at 800 mm SAD)	25 mm s^{-1}
Maximum leaf over-travel (at 800 mm SAD)	60 mm



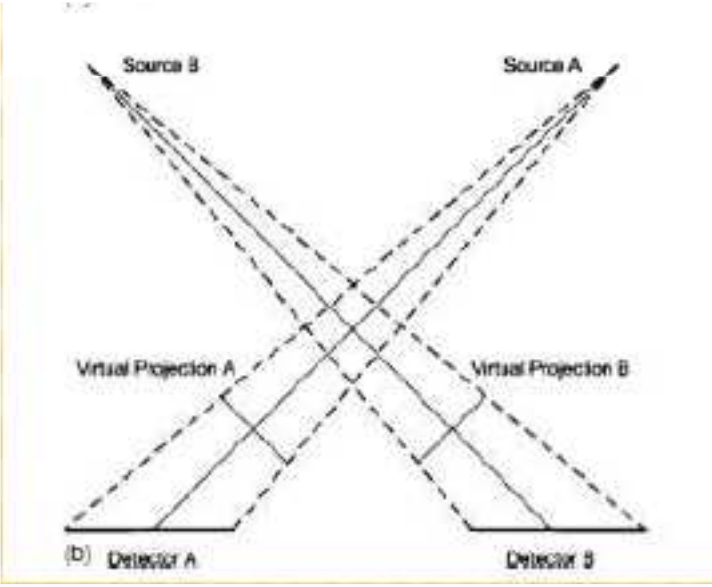
The design and physical characterization of a multileaf collimator for robotic radiosurgery, G. Asmerom et al., Biomed. Phys. Eng. Express 2 (2016) 017003

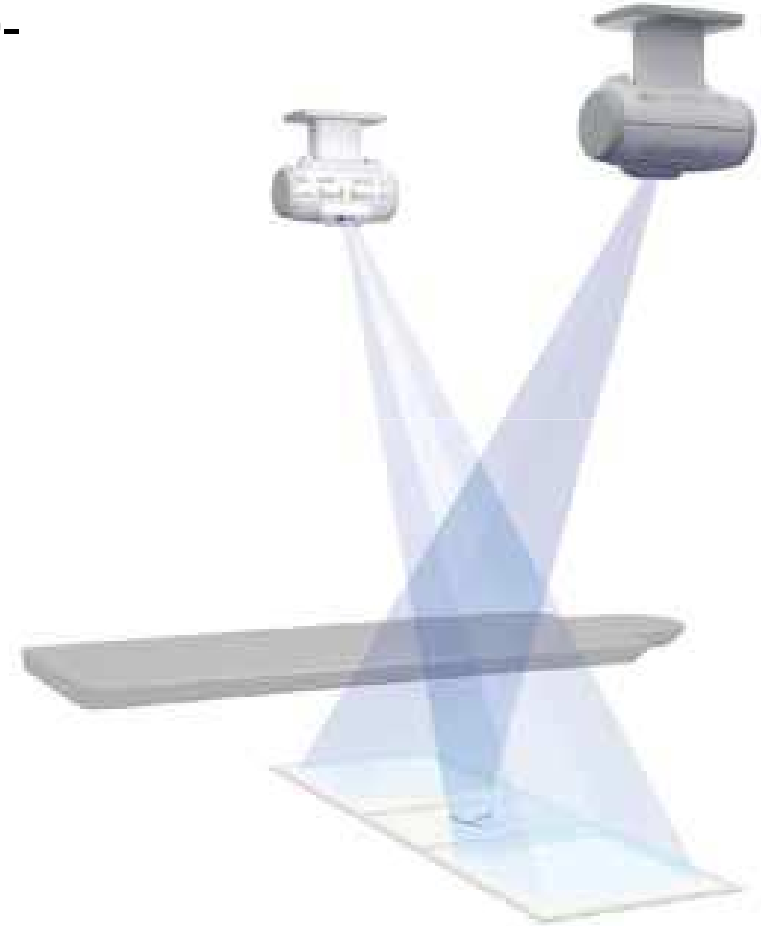
doi:10.1088/2057-1976/2/1/017003

Imaging System

kV X-rays sources on the ceiling (100-150 kV)

Two amorphous silicon flat panels (1024x1024) on the floor





General purpose vs dedicated devices

Advantages of dedicated devices should be weighted vs

Impossibility of decoupling TPS, imaging & delivery system (and Oncology Information Systems?)

- Highly ‘integrated’ devices designed to work on their own, simple needs (e.g. summing plans) may not have a simple solution

Operational issues

- multiple planning, delivery and imaging systems in the department
- Availability may not be as good as for linac. (What are you going to do in case of treatment failures?)

Conclusions

IMRT delivery systems did significantly develop in the past 10+ years.

Users have multiple (reasonable and reliable) solutions available.

Abundance of options may be a problem if it's not combined with a clear understanding of why a given machine/performace is useful (or needed).

Be careful not to get lost in the supermarket of RT hardware.

[b]COR, 'Corrected' value (see text).

- Phew, this seems to be OK...
- IMRT 2.0, however, compares to this as driving a F1 car to talking a walk

Hoornaert et al., Radiother Oncol, 1993

What's the baseline?

There has been a marked improvement in radiation dosimetry over the past three decades, and the RPC has been monitoring it through its auditing tools. Between 1970 and 1980, the compliance rate (±3%) for beam calibration increased from approximately 70% to 90%. Improvement since then has been gradual, with compliance now near 98%, for both photons and electron beam calibrations.

So we're doing well...on the basic dosimetry front that is...

Radiological Physics Center, Houston

Ibbott et al. : Challenges in credentialing institutions and participants in advanced technology multi-institutional clinical trials (Int. J. Radiation Oncology Biol. Phys. ,Vol. 71, No. 1

IMRT

- Increasing complexity
- Sold as "plug and play" by vendors
- Clinical implementation under pressure of medical -and especially- management staff
- Clinical implementation not that straightforward : In the US 30% failed to deliver IMRT

With the **complexity of therapy increasing**, discrepancies in other components of the treatment are more prevalent. Over the past four years, at approximately **45%** of the institutions reviewed by an on-site review, the RPC found at least one clinical situation where patients could be at risk to receive a dose more than **5% different** from that intended.

Ibbott et al. : Challenges in credentialing institutions and participants in advanced technology multi-institutional clinical trials (Int. J. Radiation Oncology Biol. Phys. , Vol. 71, No. 1

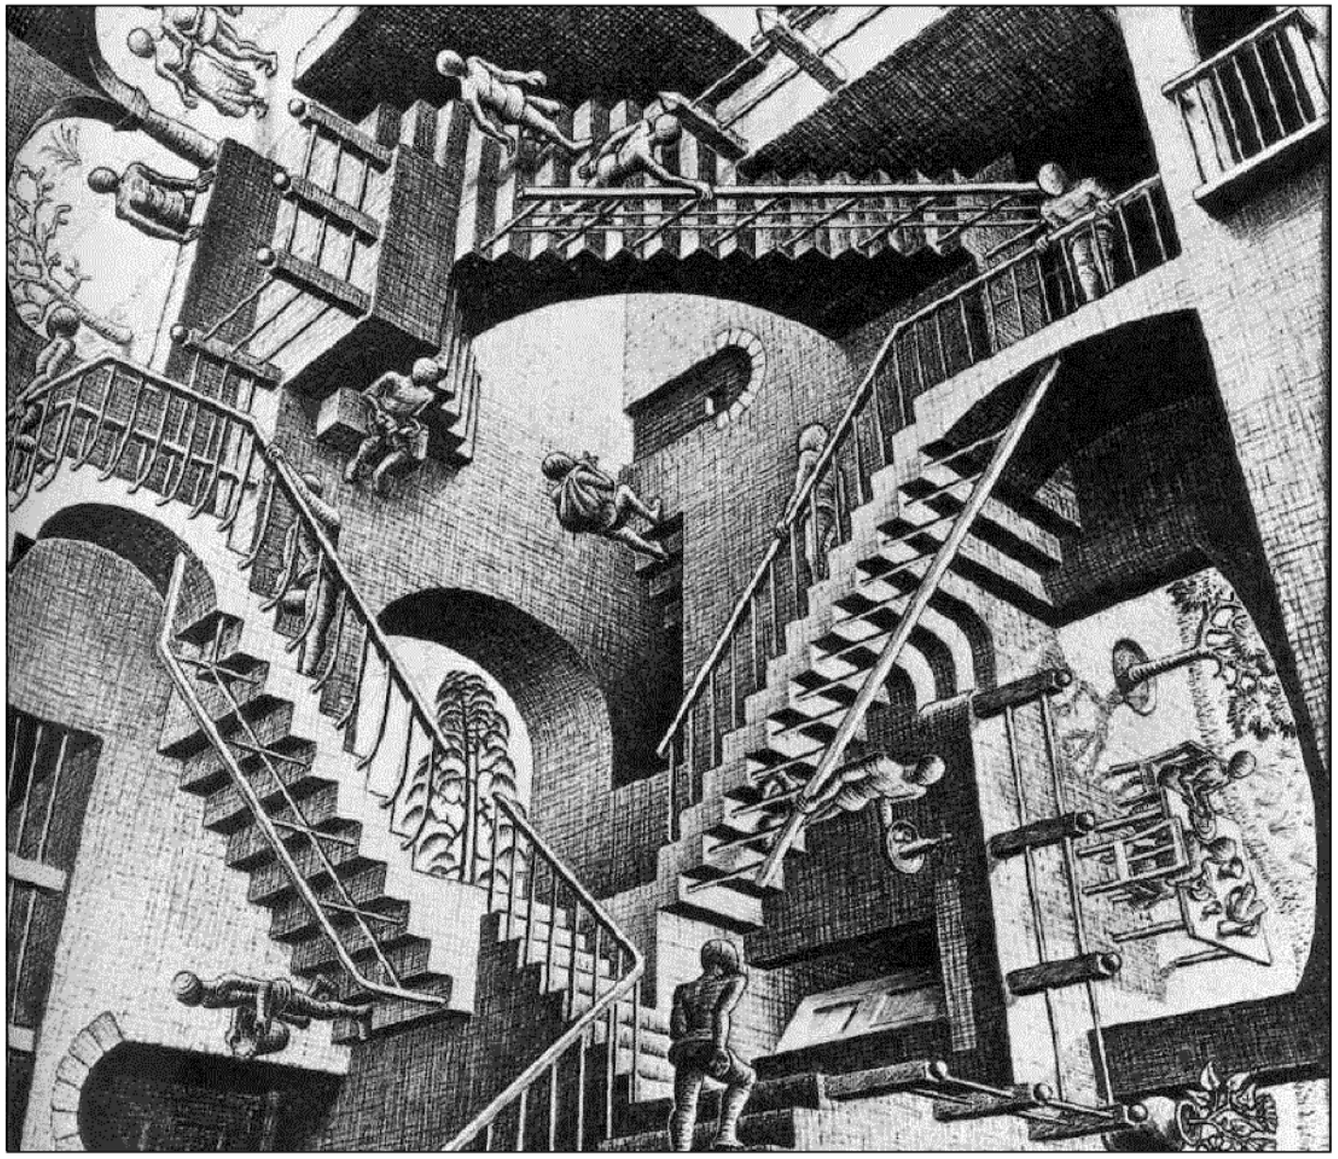
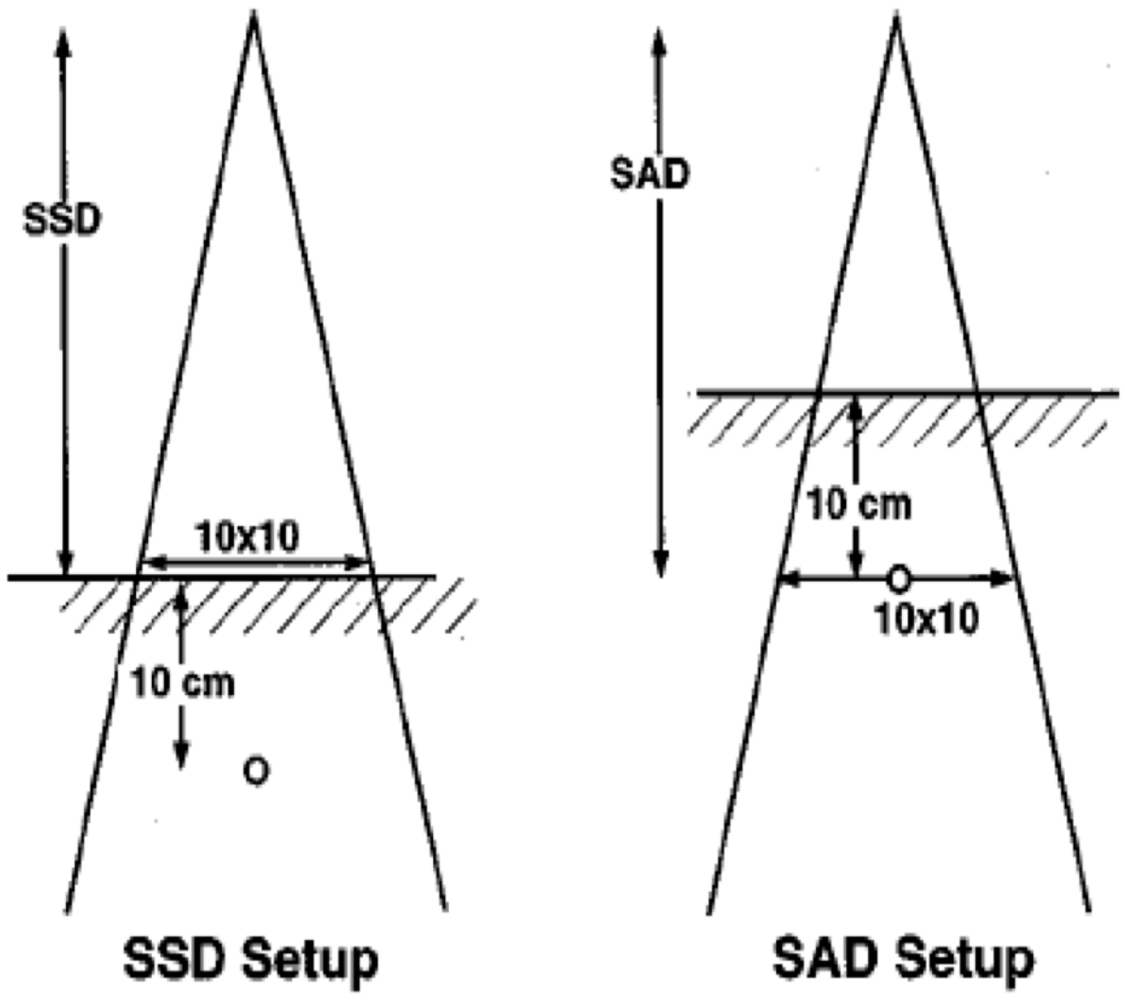
Dose Measurement

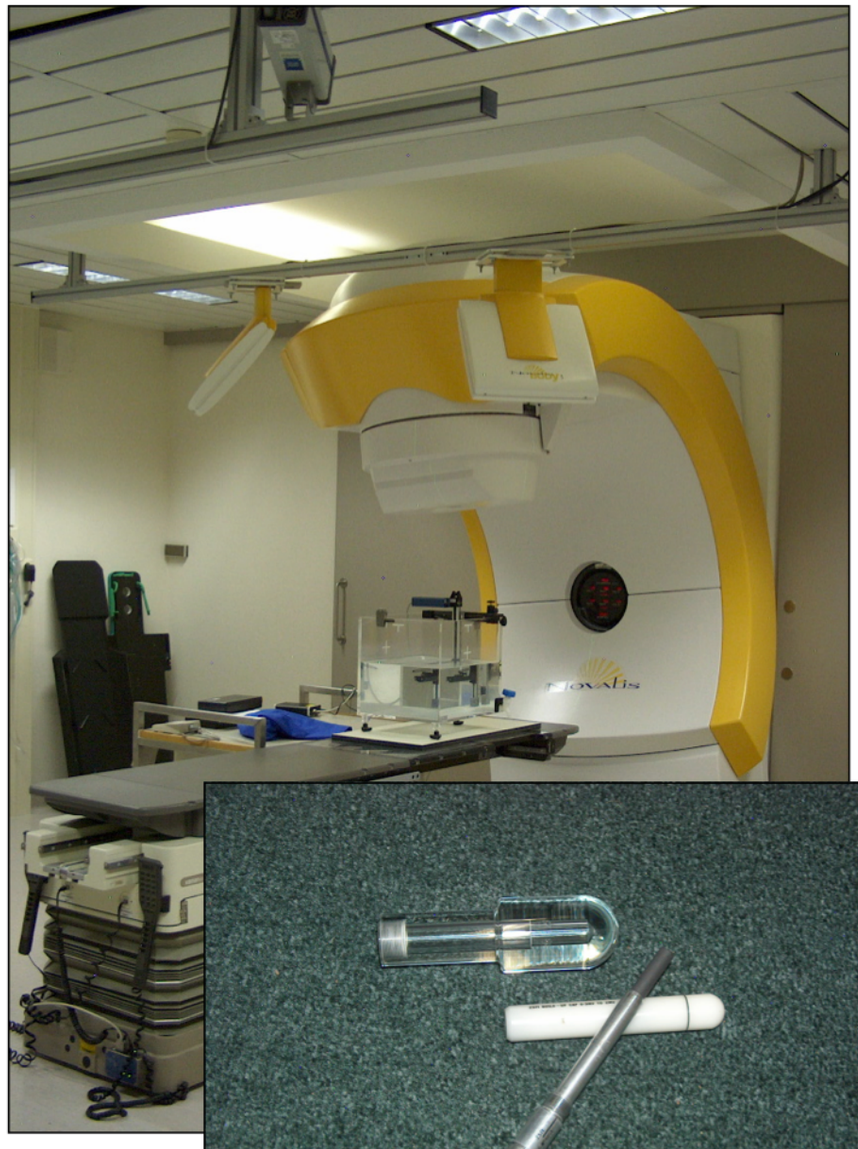
- Let's start with the concept of "Absolute Dose" in IMRT



“Reference conditions”

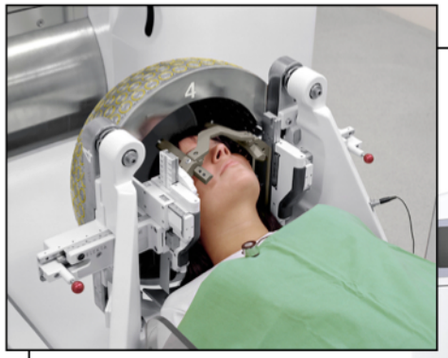


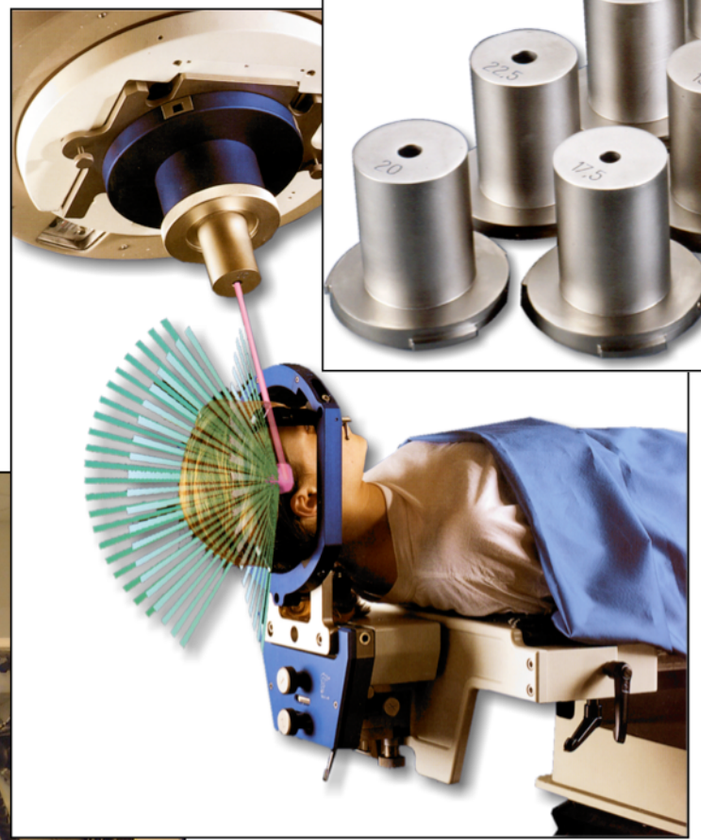
SSD Setup SAD Setup

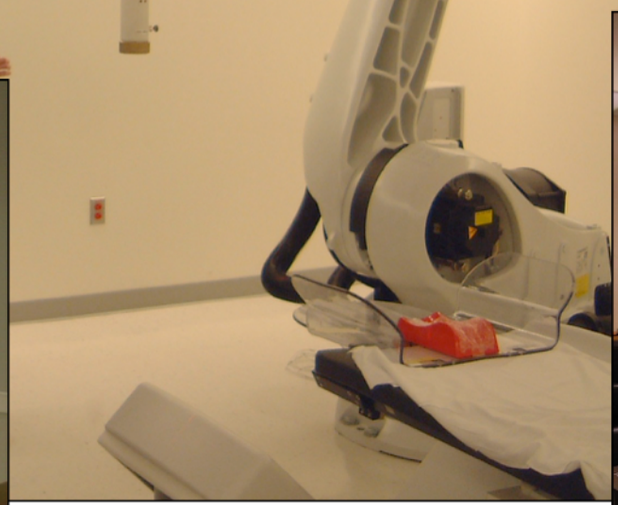


$$D_w^Q = Mk_Q N_{D,w}^{^{60}Co} \left(Gy\right)$$

Non-reference Conditions







Non-reference conditions

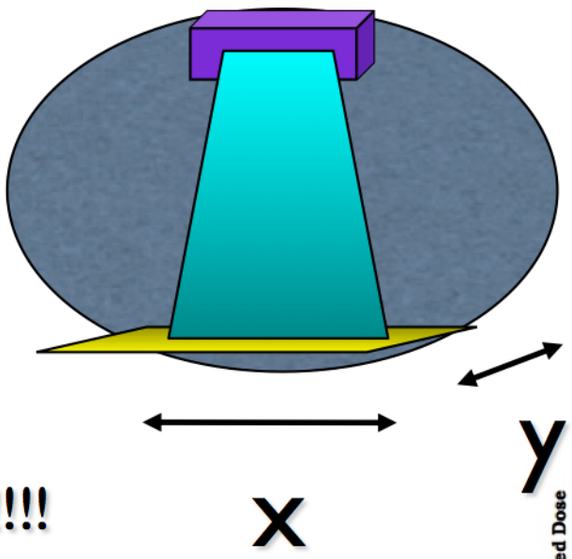
- Sudden fashion of using "flattening free" beams (tomotherapy, Varian, CK)

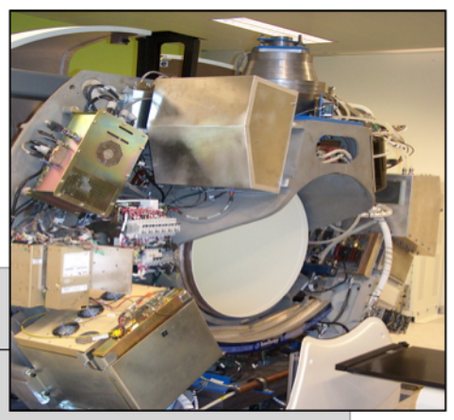
  - High dose rate to speed up dose delivery (compensating for motion, delivering hypofractionation in conventional time slots)
  - Why bother with flattening filters as we are going to use IMRT anyway (e.g. tomotherapy), moreover it makes beam modeling easier as the scatter component is reduced

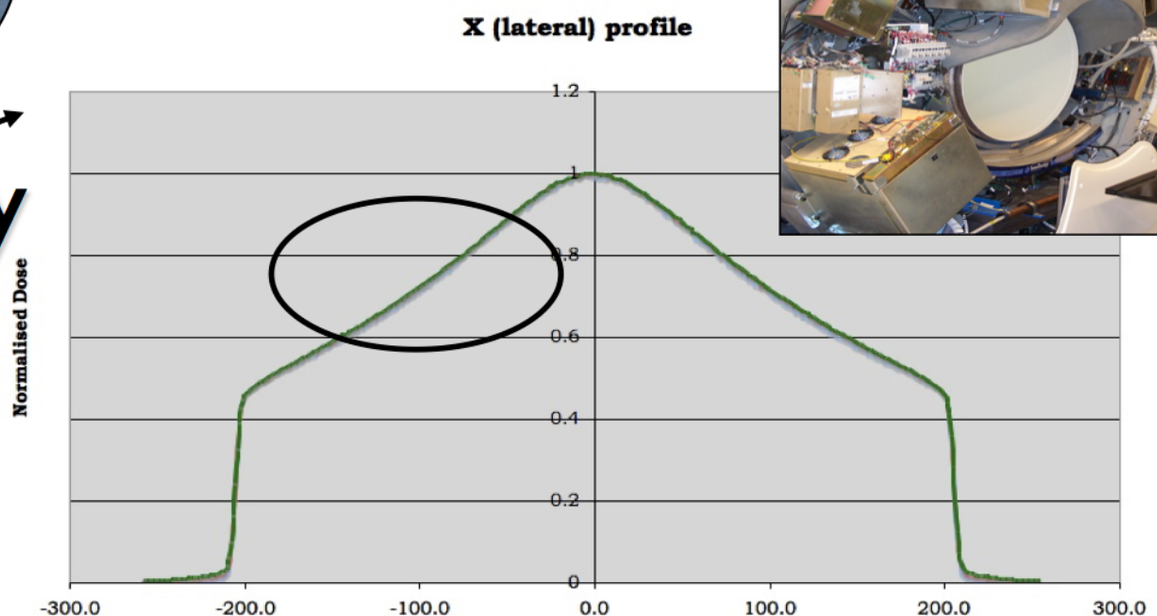
"40cm" x (1.0,2.5,5.0)cm

SSD 85cm

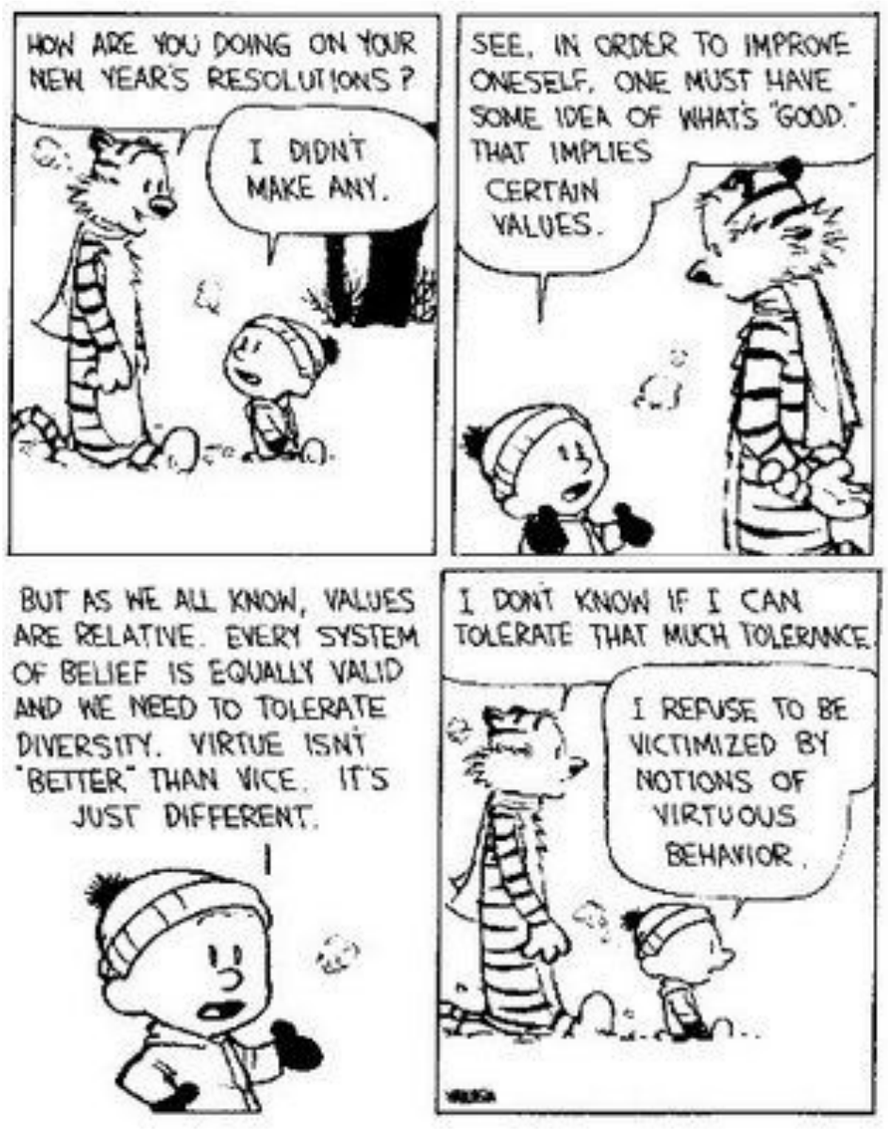
NO FLATTENING FILTER!!!!







So, what is exactly the problem?



"A relativity problem"

Conversion from ionisation to absorbed dose to water based on cavity theory and using the currently available perturbation factors used in dosimetry protocols is not accurate

“Traceability”

So, what is exactly the problem?

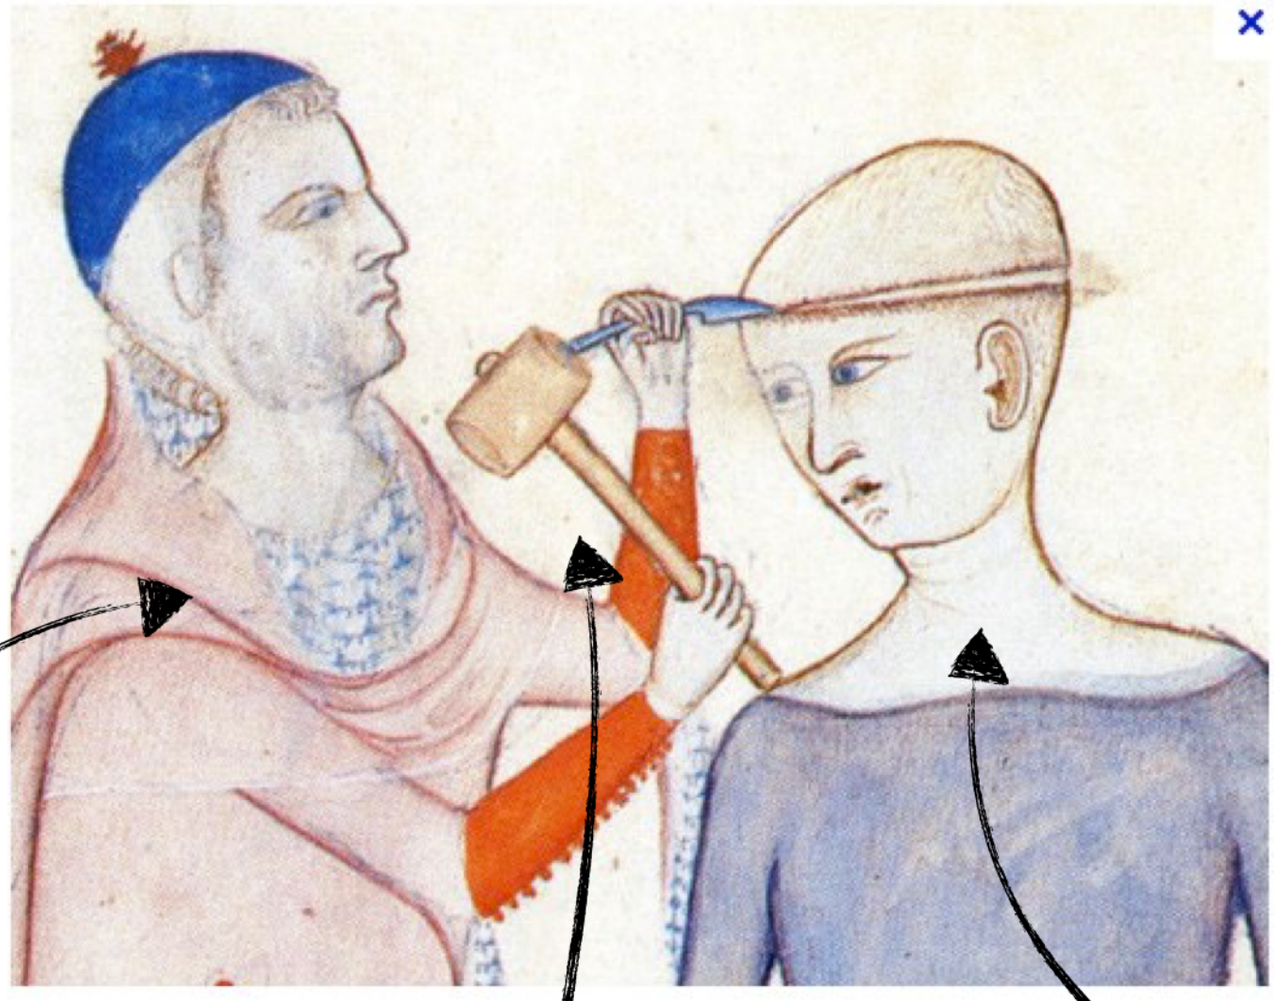
- Codes of Practice (CoP) in clinical dosimetry are undermined by the new developments in treatment delivery
  - Users have to decide by themselves how to perform clinical dosimetry. (***a highly uncomfortable situation***)
- Ionisation Chambers (IC) have traditionally been the "backbone" of radiotherapy dosimetry
  - However, they are not suitable/designed for many situations
    - High dose gradients
    - Time-dose variance
    - Non-uniform beams

So what exactly is the problem?

It is not possible to establish reference conditions on some machines

IMRT treatments for “normal” size targets are “composites” of fields in which “normal” CoPs do not apply.

So what exactly is the problem?



Physicist

CoP

Poor
IMRT-Treatment

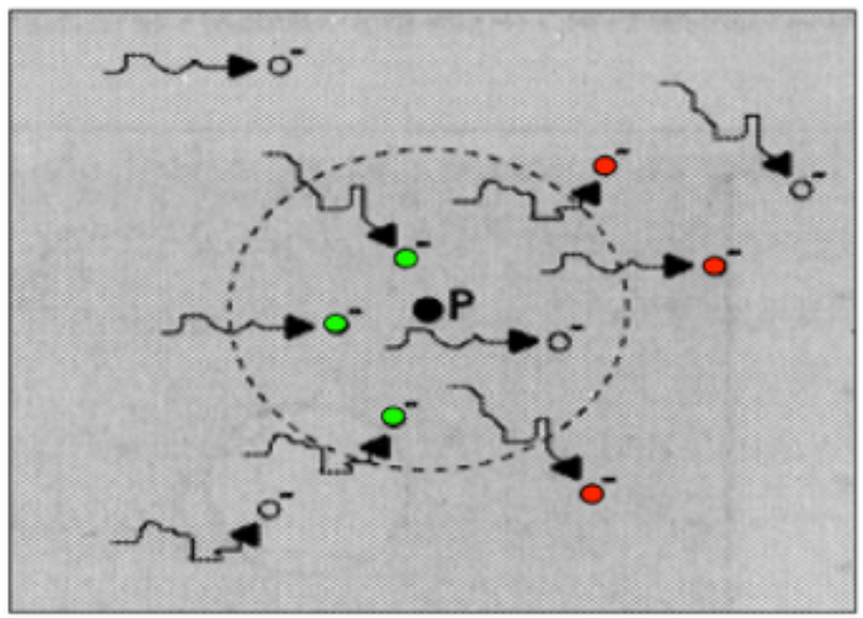
Let’s dig a bit deeper….

- IMRT Treatments are composite treatments of several small field segments*
- We need careful characterisations of these segments
- And that’s where small field dosimetry comes into the picture

*Let’ s assume that neither gantry or collimator is rotating, it’s hard enough as it is…

What is a small field?

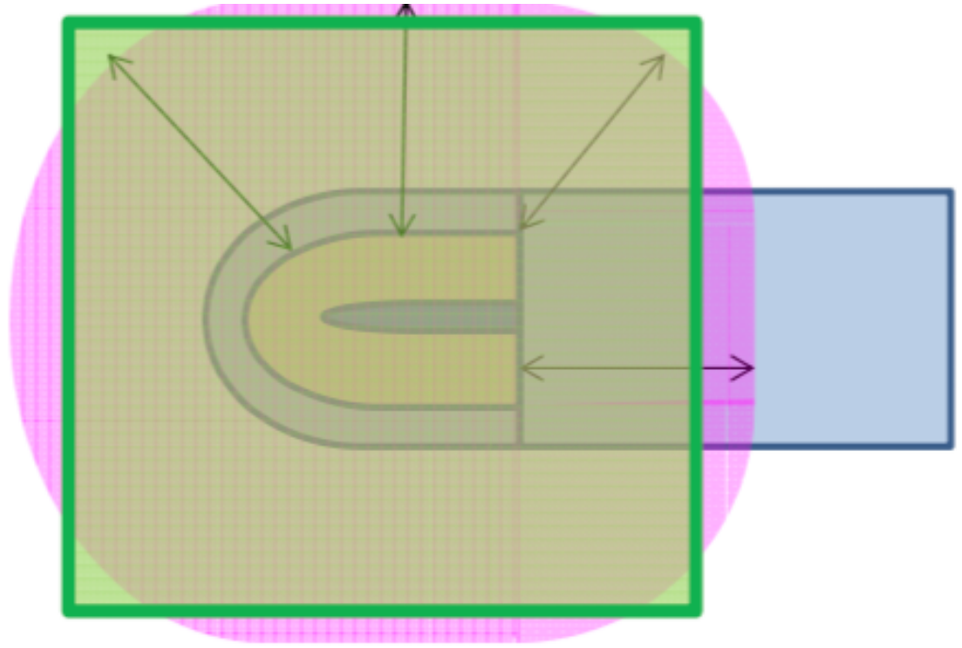
1. Loss of lateral equilibrium
2. Source Occlusion
3. Detector Size



What is a small field? (1)

“Small field conditions” exist when one of the edges of the sensitive volume of the detector is less than the lateral charged particle equilibrium range away from the edge of the field

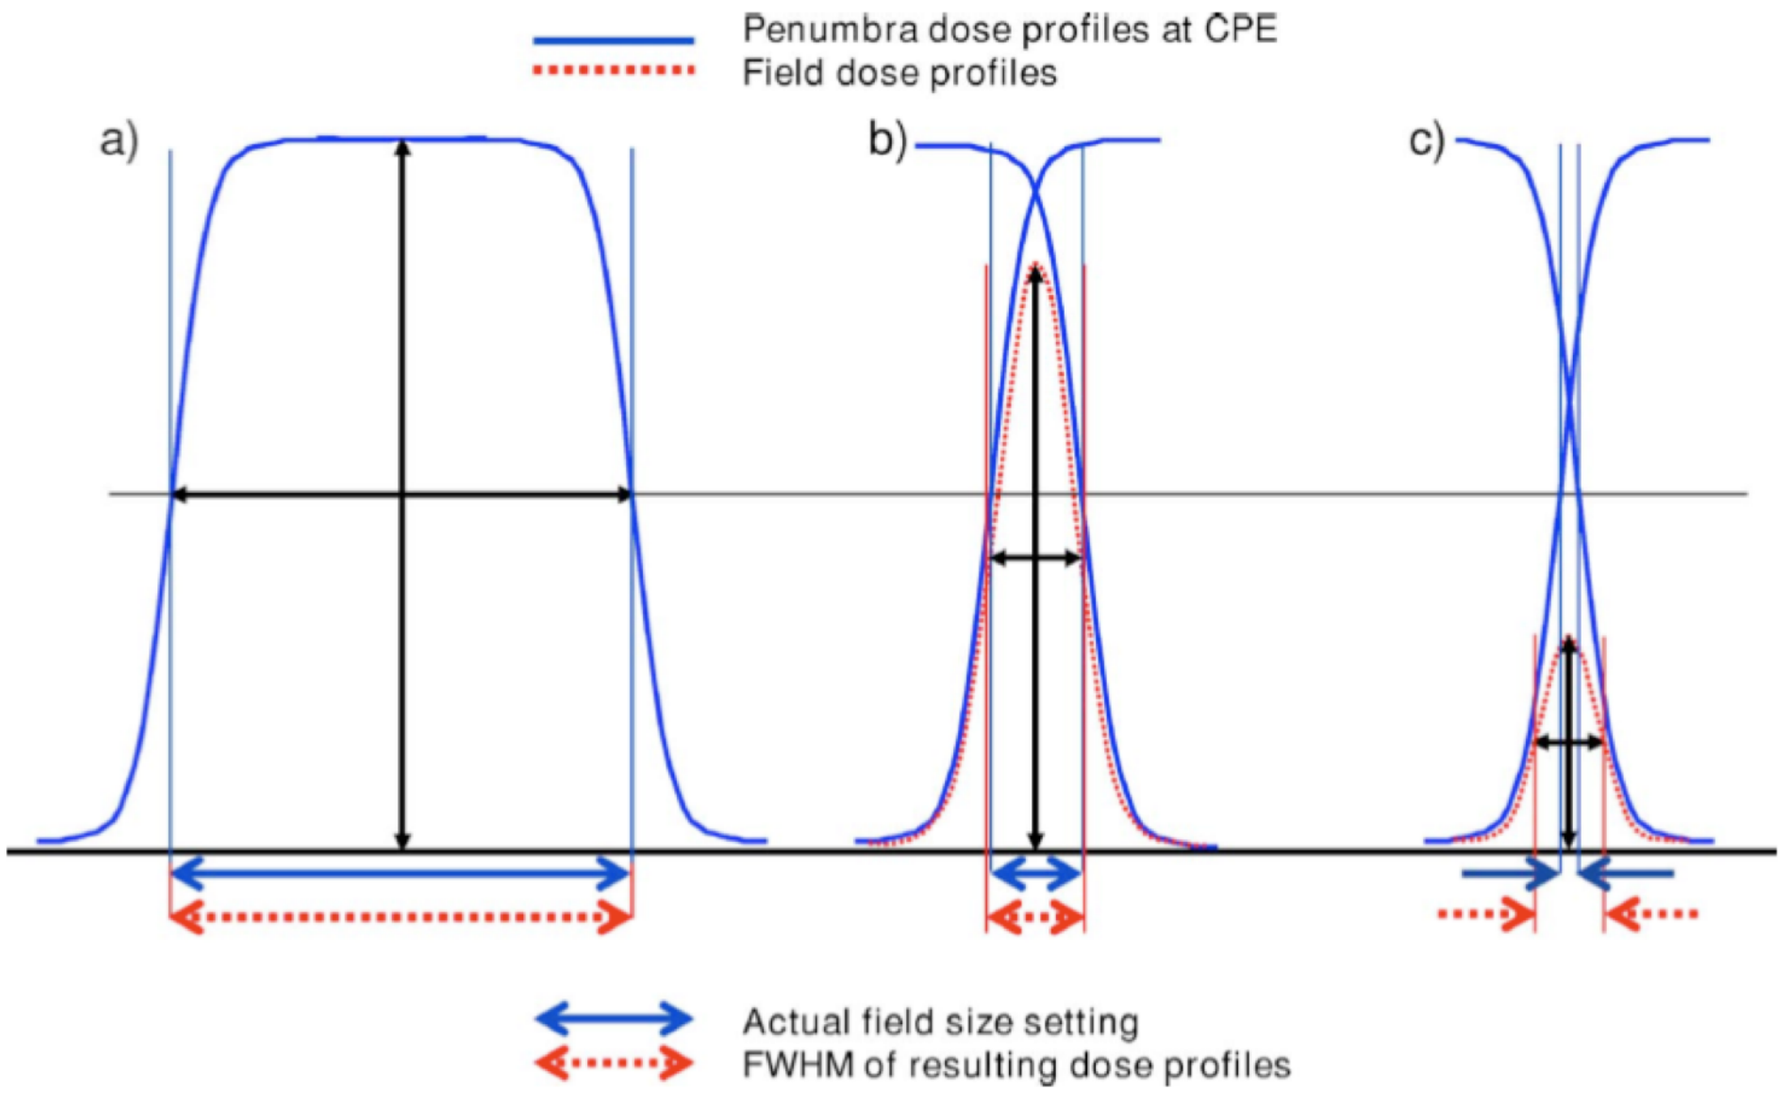
$$r_{LCPE}\ (\text{in cm}) = 5.973 \bullet TPR_{20,10} - 2.688$$



Li et al. (1995) med. Pays court. H.Palmans

“Small field”

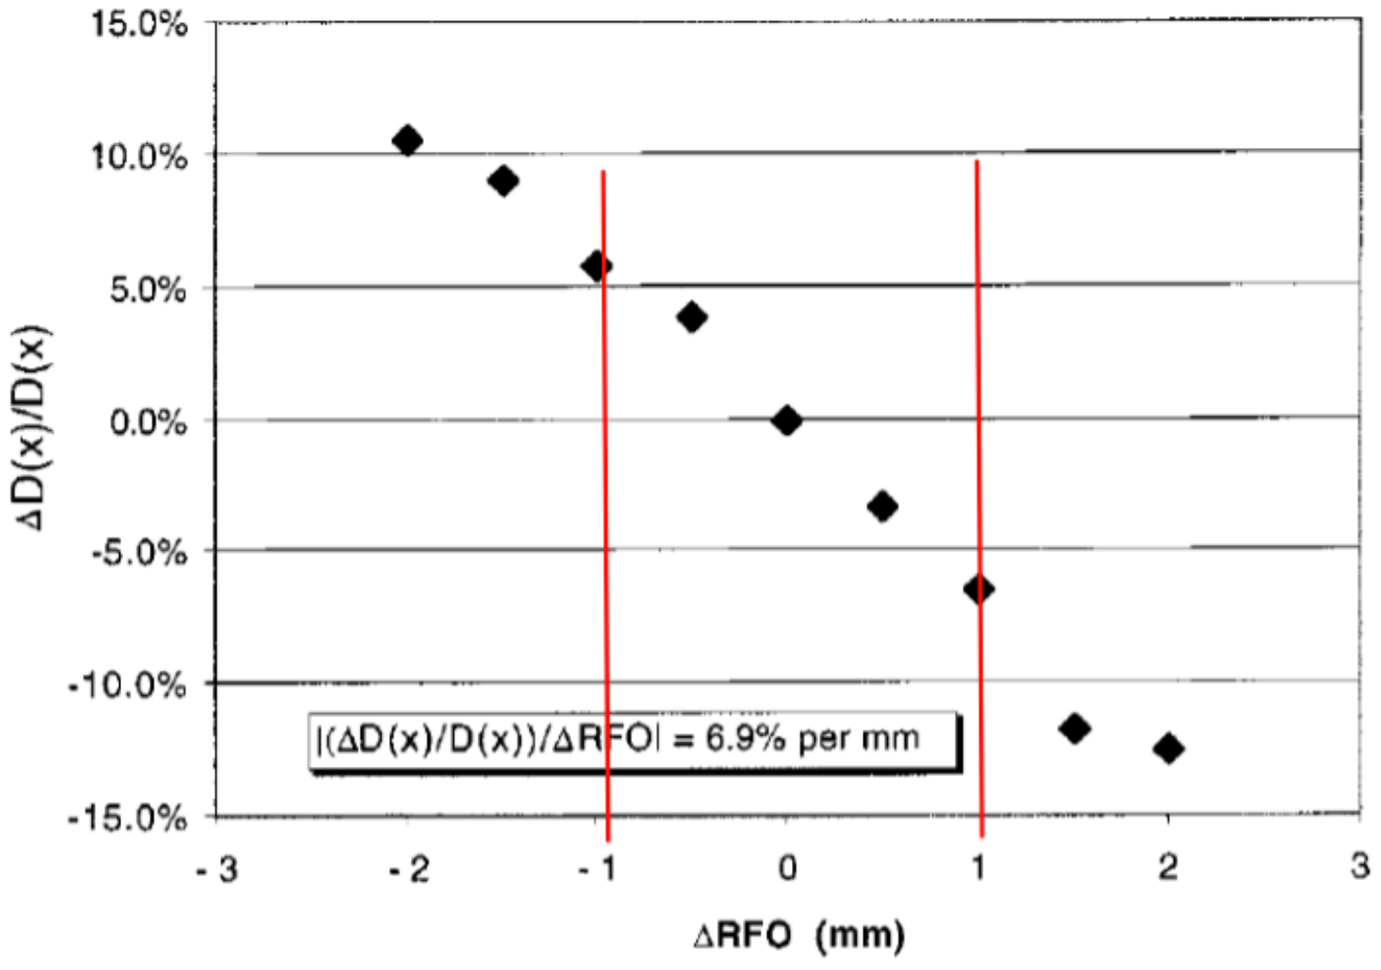
“ Beam Broadening Effect”
field size definition?



FS of same order or smaller as charged particle diffusion distance: (b) and (c).

Das et al, Medical Physics, Vol. 35, No. 1, January 2008

Field size def. vs. machine precision



RFO: Radiation and light field offset at SAD for an MLC [mm]

Kung and Chen (2000), Med Phys 27(7): 1617-22

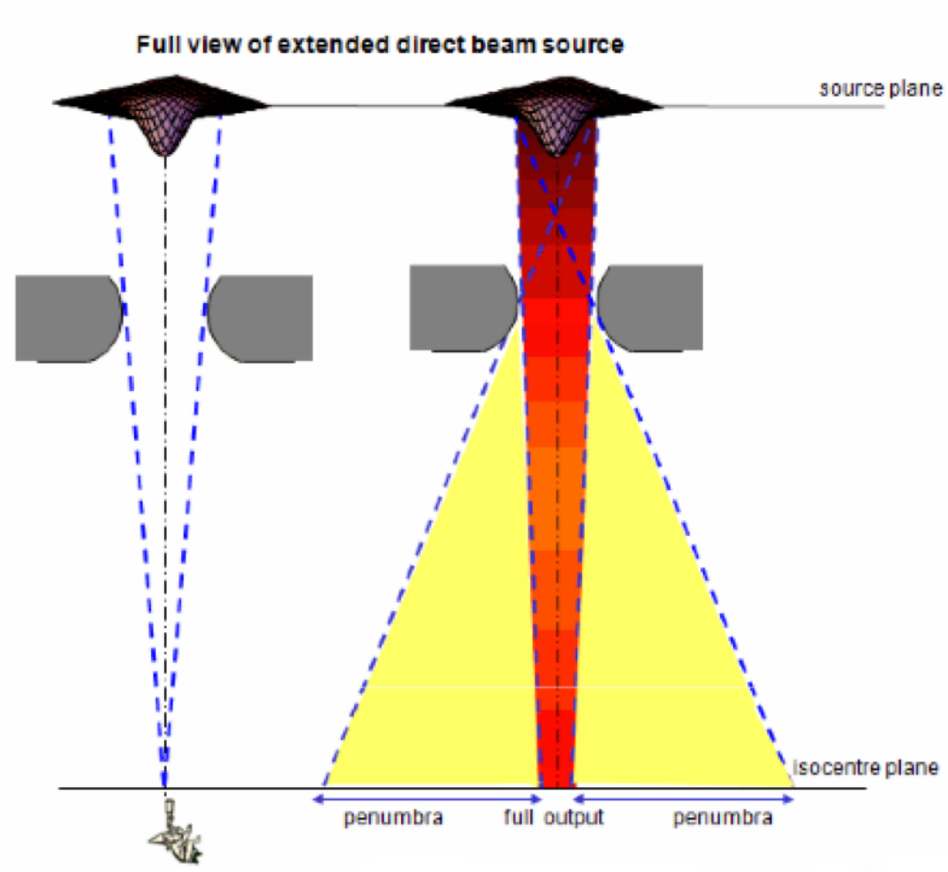
Electron range for CPE

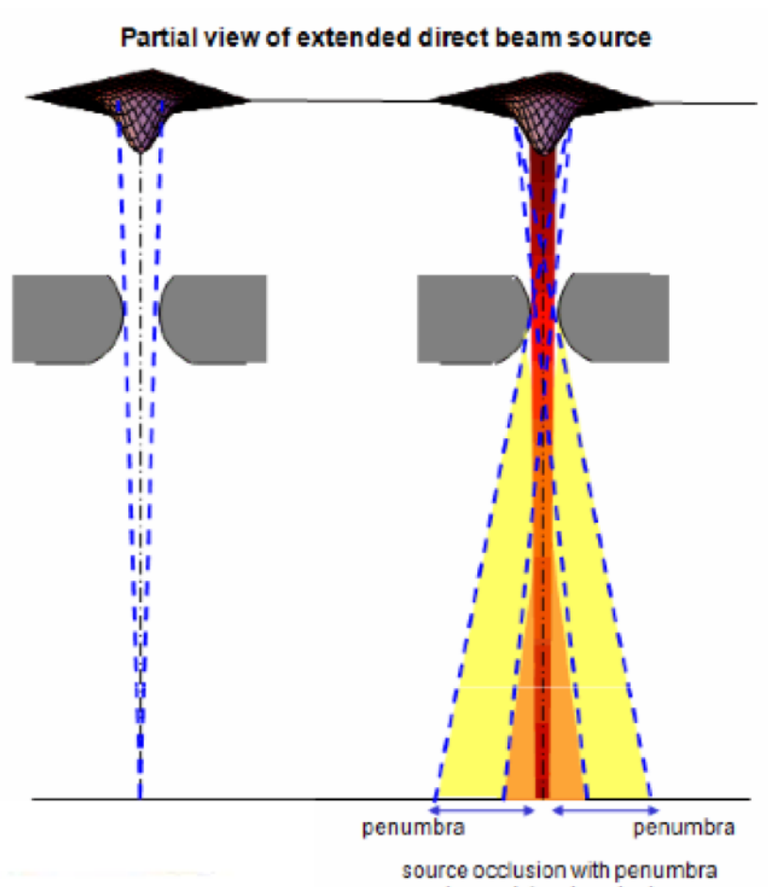
- Forward range : dmax
- lateral range (ideal spot sizes)
  - equal to penumbra, depends on energy

  - For decreasing field sizes the lateral scatter influences the dose in the center of the field
- Field size needed for CPE depends on lateral range

Small Field (2)

“Source Occlusion”

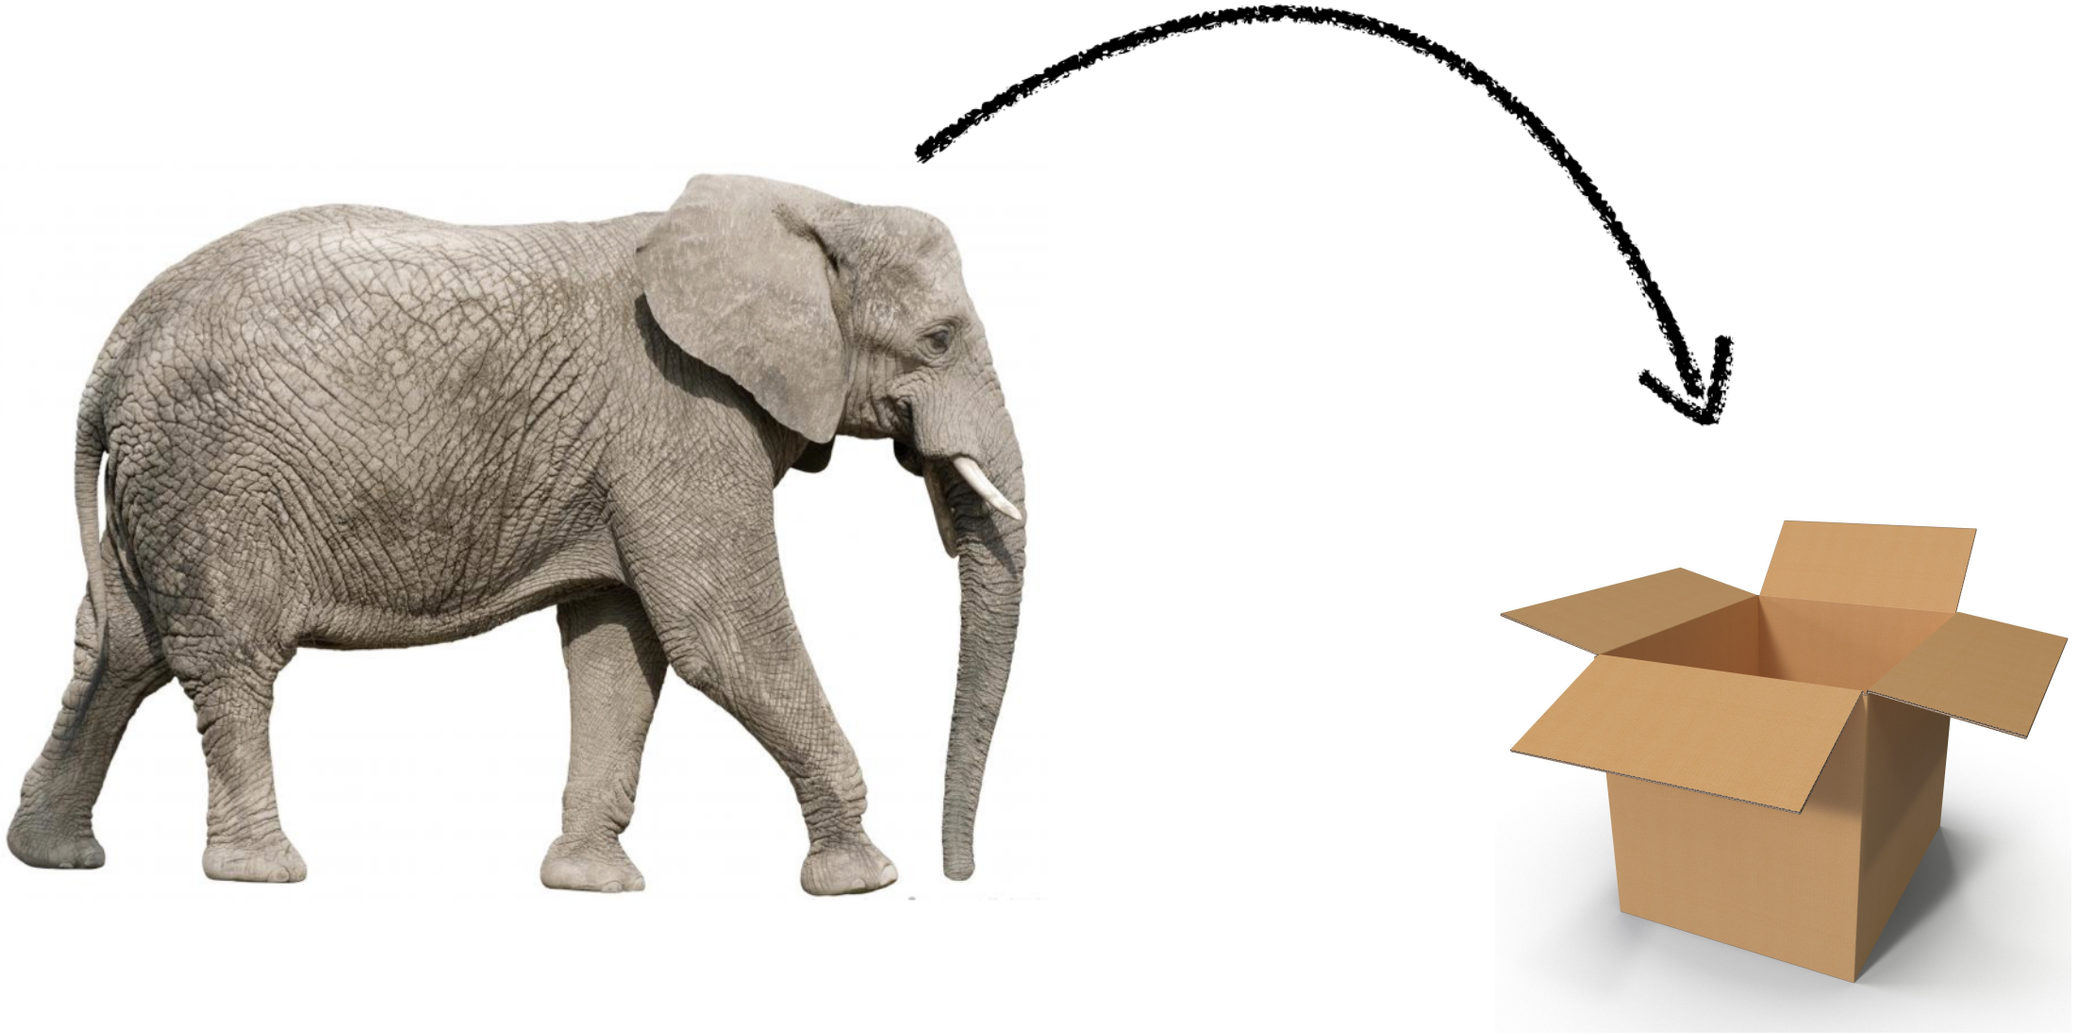




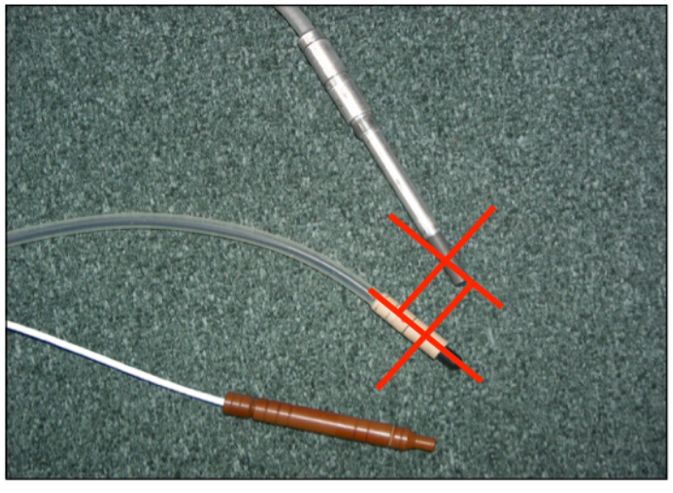
Entire Beam source not visible

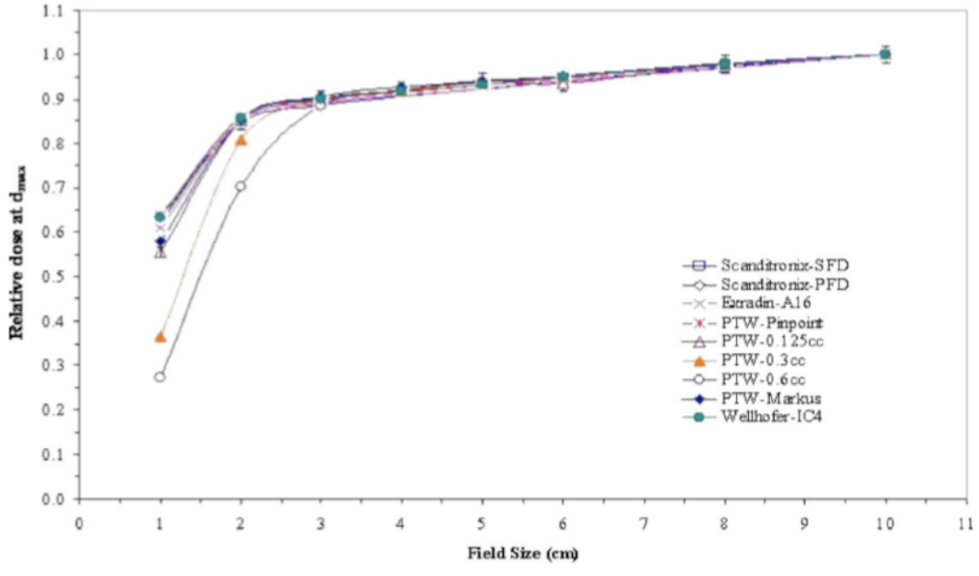
Aspradakis et al

How to measure dose in small fields?



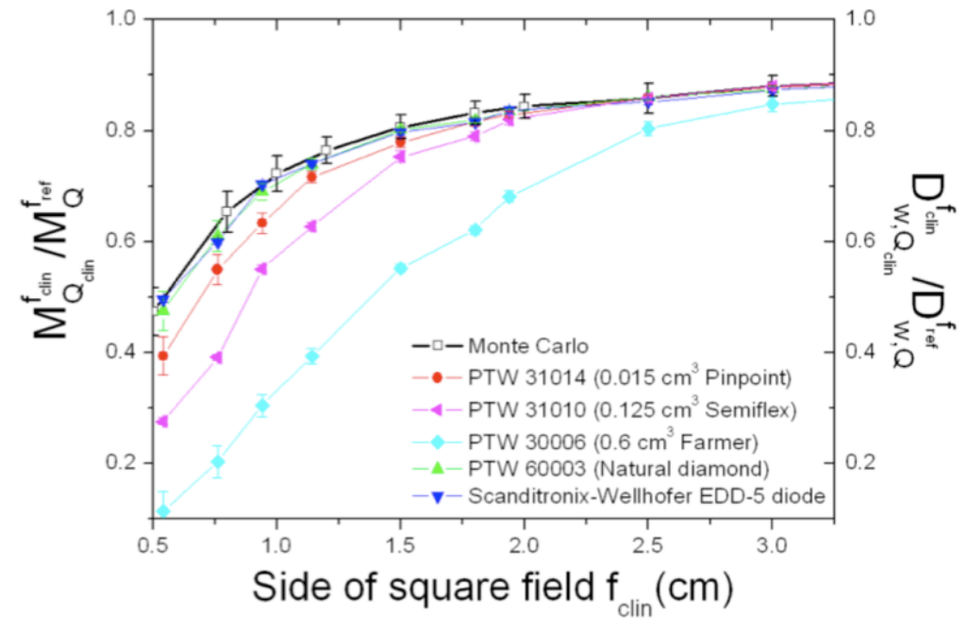
Use the correct chamber?





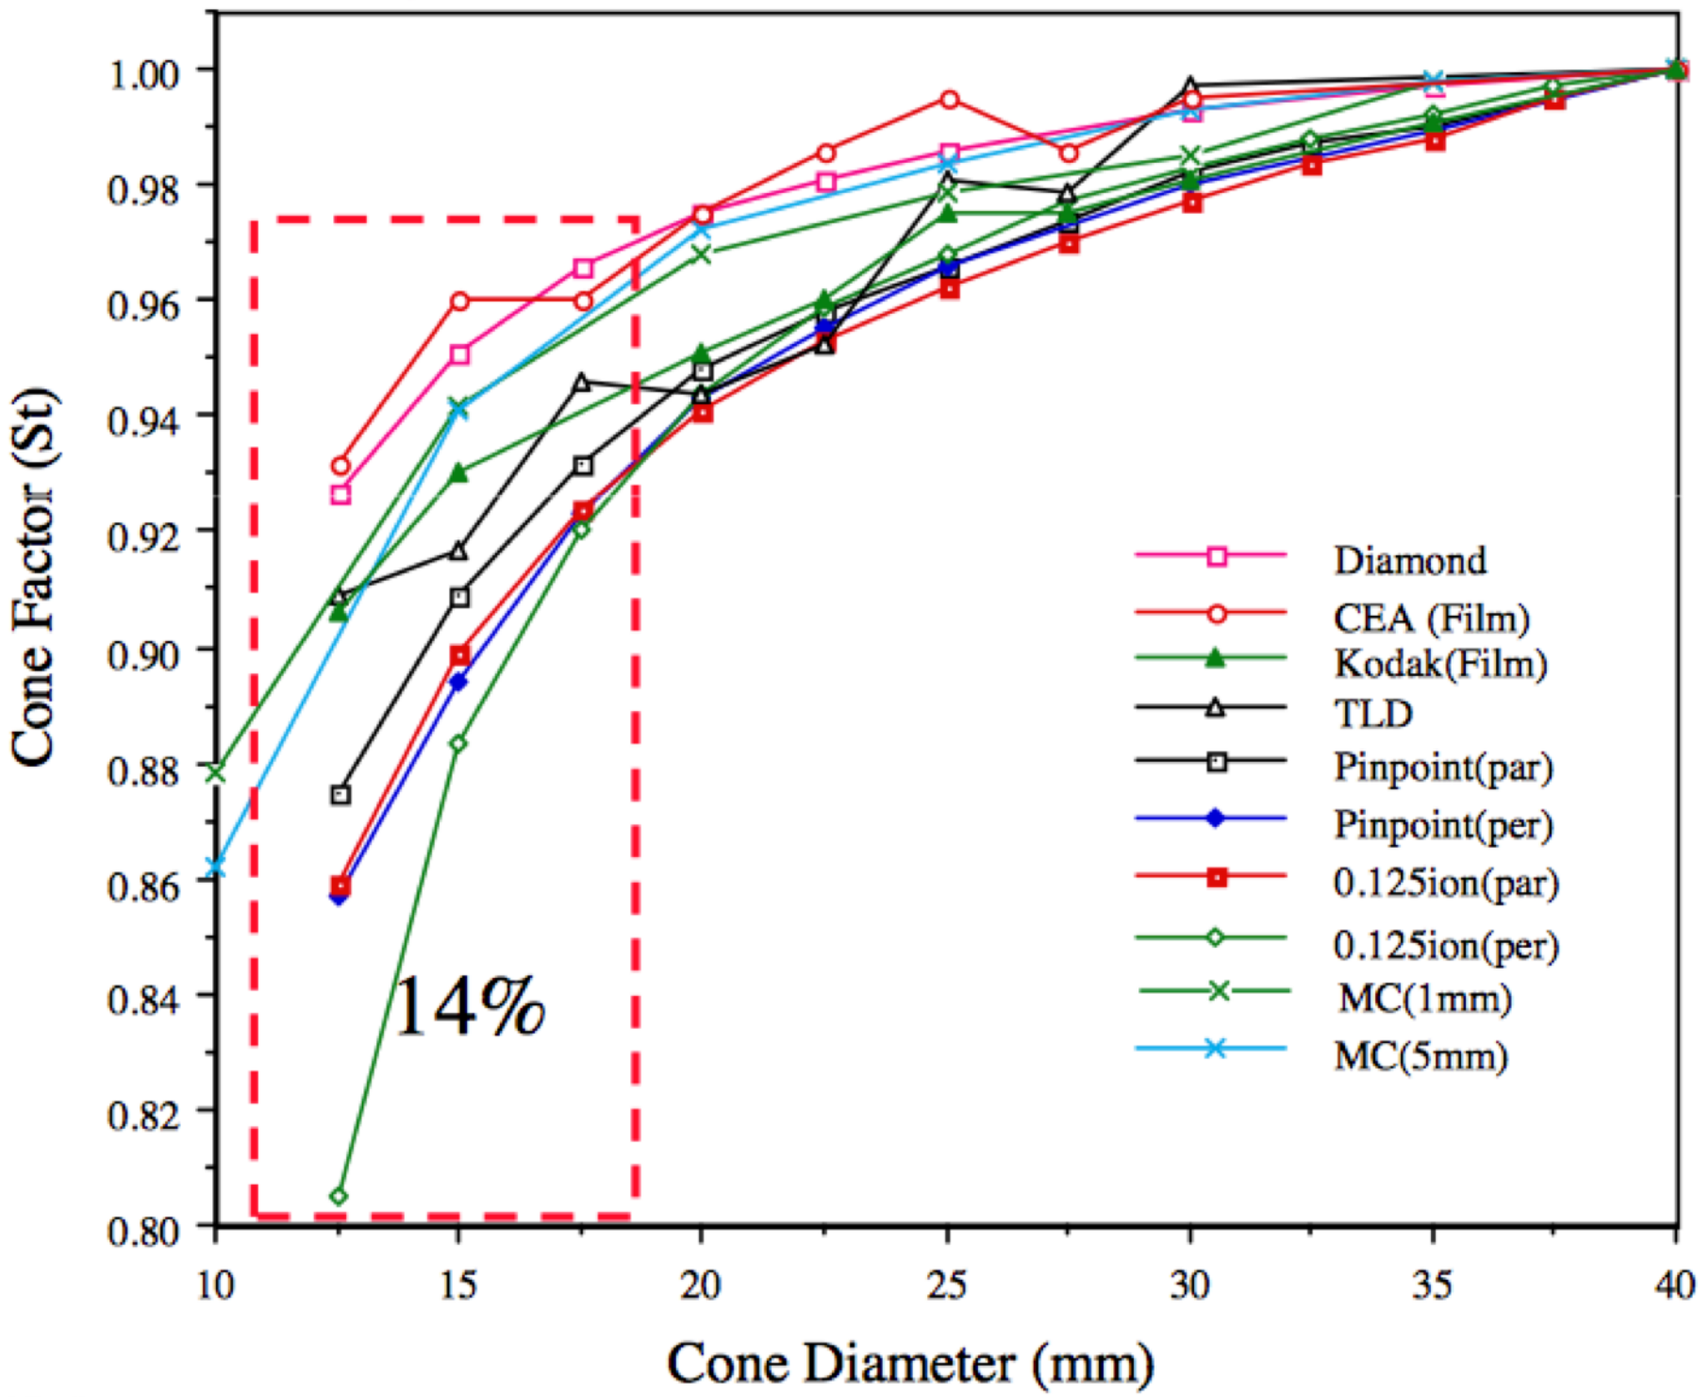
- Availability of detectors:
  - Standard chamber ($\approx 10^{-1}$ cm^3): the active volume of a standard Farmer-type IC is on average 0.6 cm^3.
  - Mini chamber ($\approx 10^{-2}$ cm^3): on average 0.05 cm^3.
  - Micro chamber ($\approx 10^{-3}$ cm^3): on average 0.007 cm^3 ideally suited for high gradient dose regions and for small field dosimetry.
- Each detector has limitations that need to be addressed!!!!!

Das IJ, *et al.*, Med Phys, 2008



Sanchez-Doblado F. *et al.*, 2007

SRS dosimetry



Das et al, J Radiosurgery, 3, 177-186, 2000

Chamber size : volume effect in FFF beams

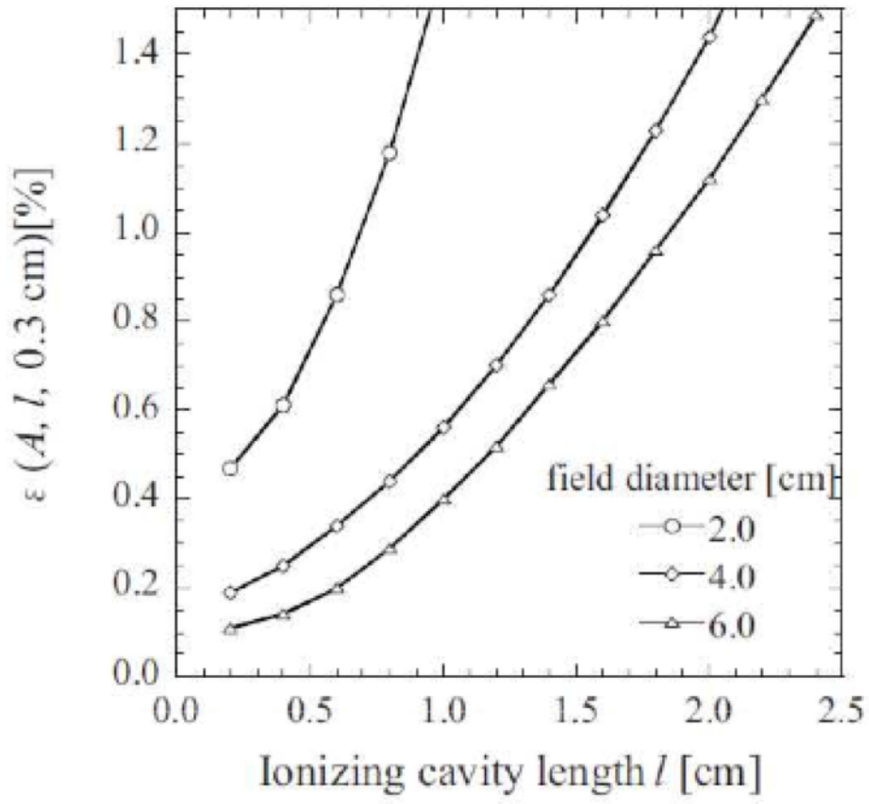


FIG. 2. The error of dosimeter reading $\varepsilon(A,l,0.3\text{ cm})$ (%) as a function of cavity length l of ionization chamber and field A. The cavity radius r is calculated in 0.3 cm, and these values are for a SCD of 80 cm at a depth of 10 cm in water.

Kawachi *el al* (2008), Med Phys 35 (10)

$$\varepsilon(A,l,r)=\frac{100\int_{-l/2}^{l/2}\int_{-r}^{r}|\mathrm{OAR}(A,x,y)-1|\,\mathrm{d}x\mathrm{d}y}{\int_{-l/2}^{l/2}\int_{-r}^{r}\mathrm{d}r\mathrm{d}y}$$

OAR(x,y) is the off axis distribution of field A in orthogonal directions x and y

Using a 24mm cavity results in 1.5% dose underestimation for a 6cm field on CK

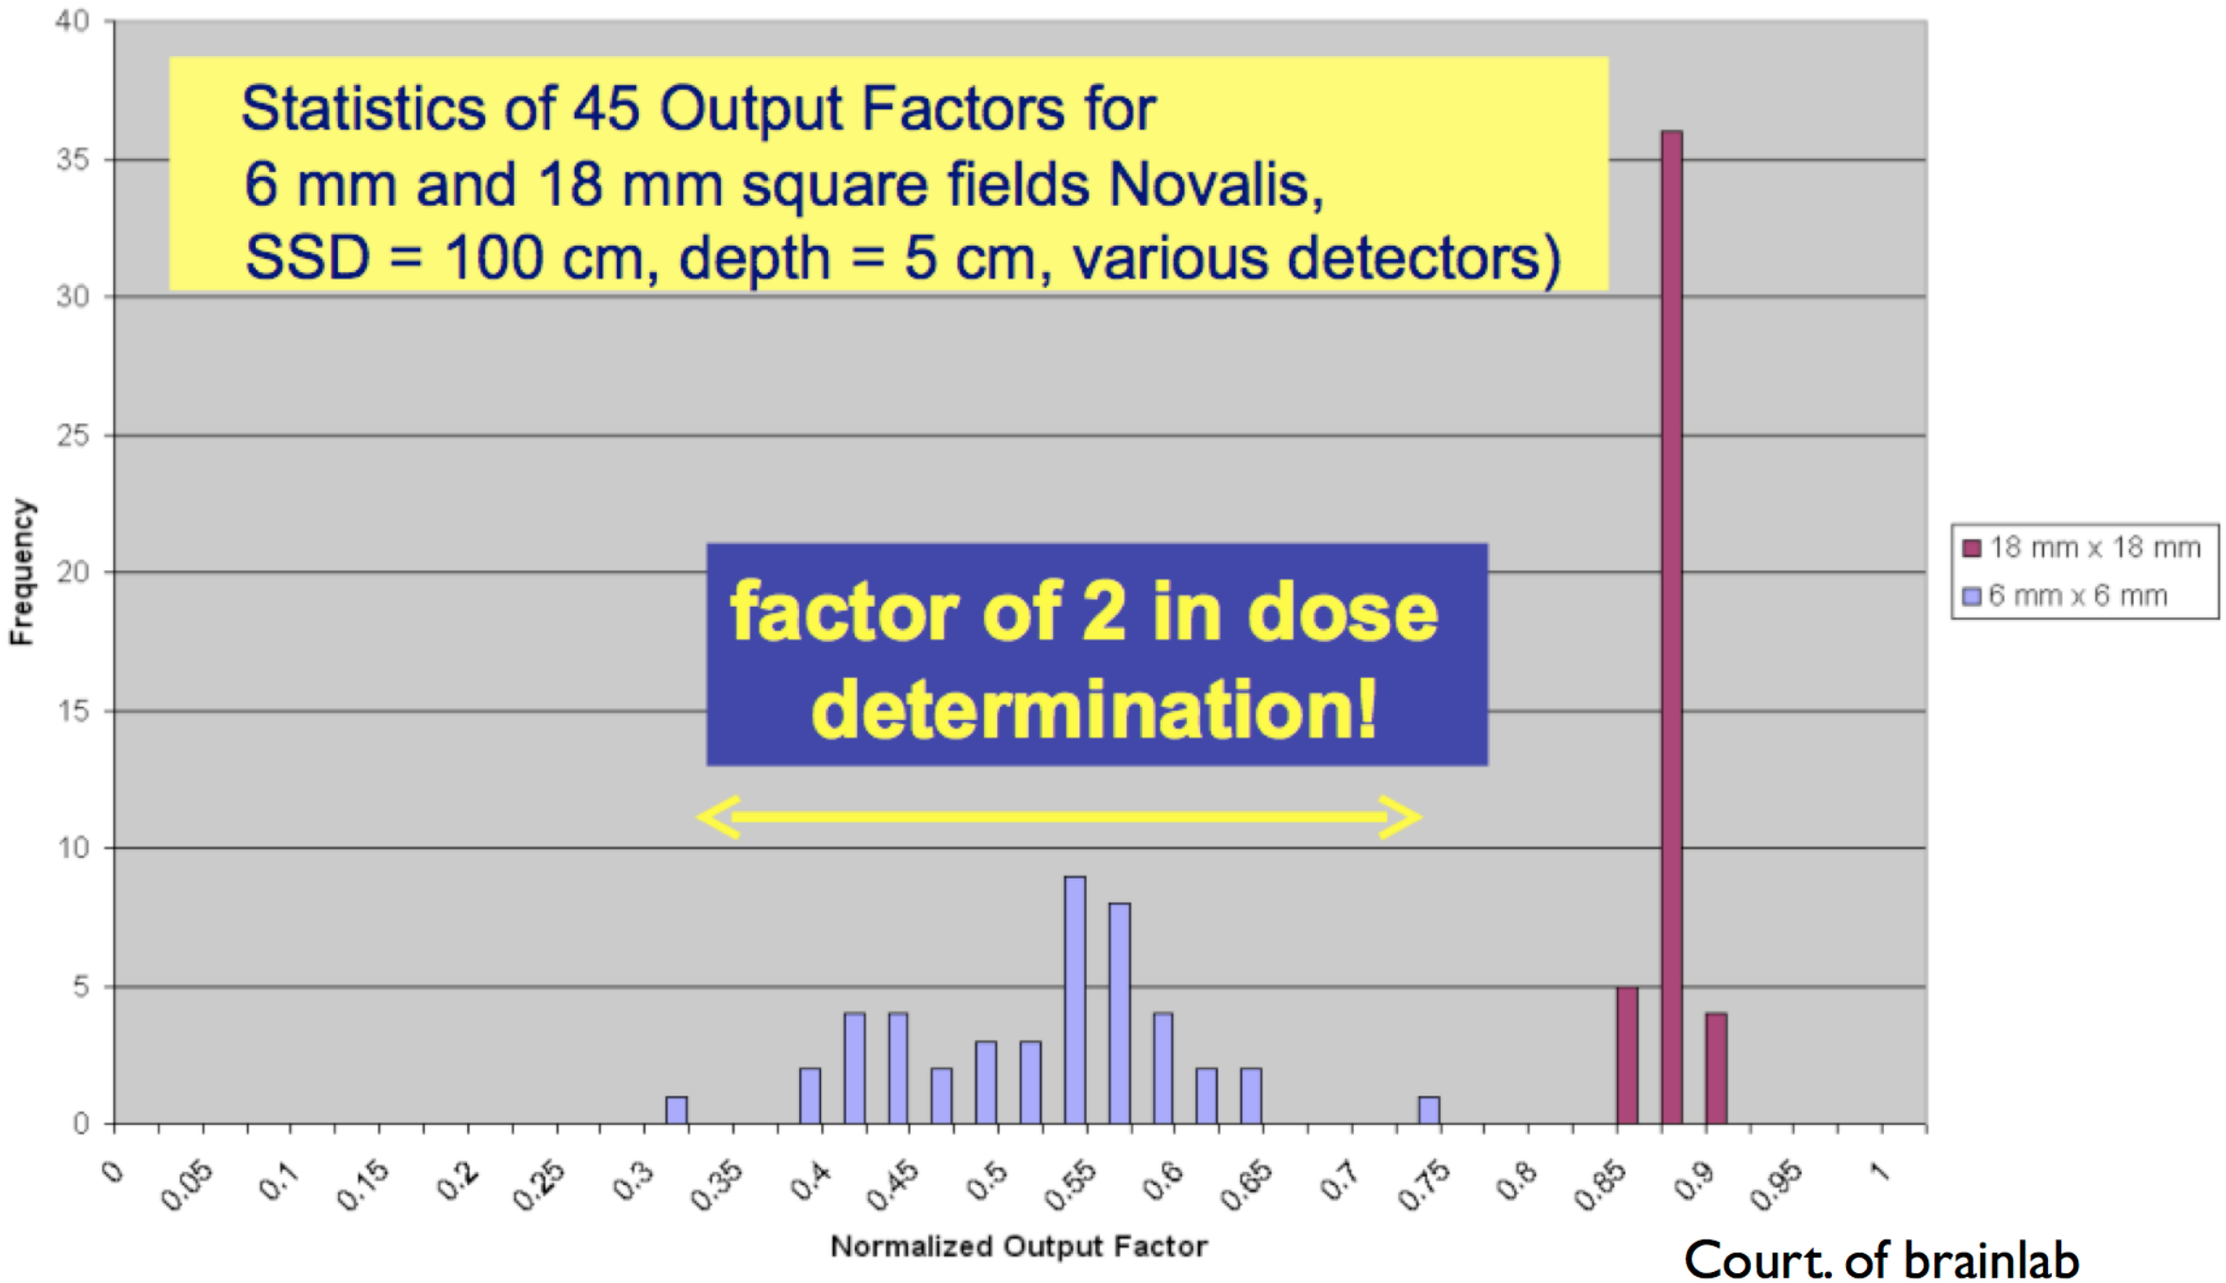
REPORT

concerning the radiotherapy incident at the university hospital centre (CHU) in Toulouse – Rangueil Hospital

Although the origin of the event is clearly identified (use of a measuring device which was inappropriate for calibrating microbeams), the underlying causes remain to be determined; this, however, was not the main goal of the inspection. The letter following the inspection therefore asks the CHU to analyse the organisational and human factors, especially human resources, work load, skills and training.

and even using the “correct” chamber...



Court. of brainlab

Let's get even more basic : standard dosimetry protocols

Reference dosimetry

$$D_{water} = M\left[\left(\frac{\overline{W}}{e}\right)\frac{1}{m_{gass}}\right]\left[\left(\frac{\overline{S}}{\rho}\right)_{air}^{water} p_{corr}\right]$$

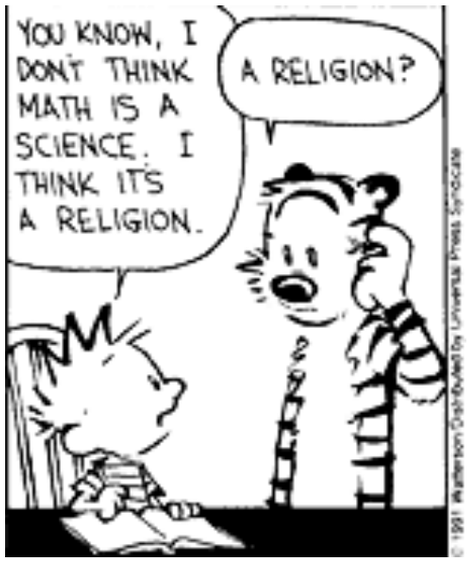
Correcting from water to air

Correcting for the fact the chamber is not perfect and does not disturb the medium

$$p_{corr} = p_{wall}\, p_{cell}\, p_{repl}$$

$$D_{\text{water},Q} = M_{\text{water},Q}\, N_{D_w,Q_o}\, k_{Q,Q_o}$$

Kq= quality index



$$k_{Q,Q_0} = \frac{\left(\frac{W_{air}}{e}\right)_Q \left[\left(\frac{\overline{S}}{\rho}\right)_{air}^{water}\right]_Q p_Q}{\left(\frac{W_{air}}{e}\right)_{Q_0} \left[\left(\frac{\overline{S}}{\rho}\right)_{air}^{water}\right]_{Q_0} p_{Q_0}}$$

Kq= quality index

$$k_{Q,Q_0} = \frac{\left(\frac{W_{air}}{e}\right)_Q \left[\left(\frac{\overline{S}}{\rho}\right)^{water}_{air}\right]_Q p_Q}{\left(\frac{W_{air}}{e}\right)_{Q_0} \left[\left(\frac{\overline{S}}{\rho}\right)^{water}_{air}\right]_{Q_0} p_{Q_0}}$$

Kq= quality index

$$k_{Q,Q_0} = \frac{\left(\frac{W_{air}}{e}\right)_Q \left[\left(\frac{\bar{S}}{\rho}\right)^{water}_{air}\right]_Q p_Q}{\left(\frac{W_{air}}{e}\right)_{Q_0} \left[\left(\frac{\bar{S}}{\rho}\right)^{water}_{air}\right]_{Q_0} p_{Q_0}}$$

In small fields; the spectrum changes, how is this affecting this term?

So…

- We've got a lot of small effects, which of course all add up to a larger uncertainty
- All these effects will be present in OF measurements, profiles, PDD-curves,…
  - …and will be higher for low density materials (TPS)
  - dose2medium vs. dose2water?
- Certainty on factors is growing thanks to MC calculations.
- Measurements on larger SSD

Effect of variation in output factors in TPS

Non-standard fields

- For IMRT:

- Even if the dose in the measurement area is large and homogeneous, generated by many beamlets, DON'T use large chambers to measure dose.

Reference dosimetry in small fields

- Use of mini or micro (air filled) IC
  - ….that fits in the field
- Perturbation factors not known in many cases (effect worse for low densities)
- Leakage, cable and polarity effects?
- Use of diamond-detectors, diodes

What do we do when reference conditions cannot be achieved?

Small & non-standard field

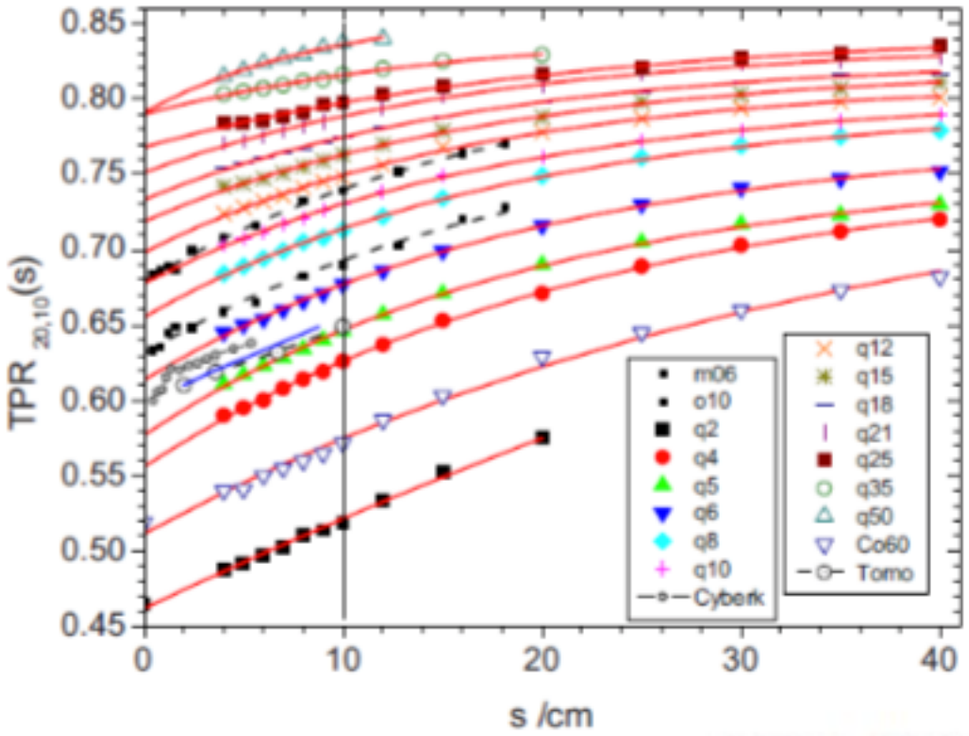
➔A proposal for a new formalism by the IAEA

- 2 routes
- Both routes require the extension of the concept of reference field to incorporate small and non-standard fields, as well as modified reference conditions such as phantom shape and material

Small and non-standard field dosimetry

- Alternative procedures to determine beam quality
- The new IAEA/AAPM formalism (aka “alfonso formalism”)

Alternative procedures to determine beam quality



Data from BJR Suppl 25

$$Q = \frac{\mathrm{TPR}_{20,10}(s) - b_1 - A_1(1 - e^{-s/t})}{b_2 + A_2(1 - e^{-s/t})}.$$

TABLE I. Parameters for Eq. (3) valid for $0.62 < Q < 0.8$.

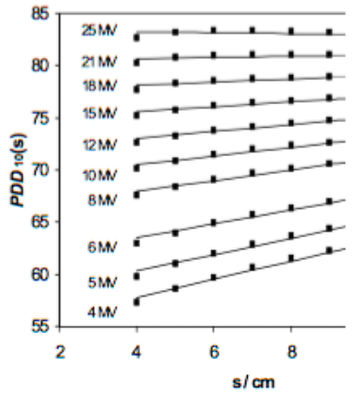
b_1	-0.208 ± 0.022	A_1	$+0.625 \pm 0.036$	t	$+19.5 \pm 2$ cm
b_2	$+1.213 \pm 0.030$	A_2	-0.679 ± 0.050		

Sauer et al, med phys (2009)

Alternative procedures to determine beam quality

e.g. for $PDD_{10X}(10) = \%dd(10)_X$

$$PDD_{10}(10) = \frac{PDD_{10}(s) + c_1 \cdot \left(e^{\frac{10-s}{t}} - 1 \right)}{1 + c_2 \cdot \left(e^{\frac{10-s}{t}} - 1 \right)}$$



$$PDD_{10x}(10) = \begin{cases} PDD_{10}(10), & PDD_{10}(10) < 75.0 \\ 1.267 \cdot PDD_{10}(10) - 20.0, & PDD_{10}(10) \geq 75.0 \end{cases} \quad \text{(TG-51)}$$

Palmans et al, med phys (2012)

IAEA/AAPM formalism

- Route 1
  - Small static field dosimetry for machines that cannot establish a conventional reference field
  - Introducing the intermediate machine-specific-reference field (msr)
- Route 2
  - Composite field dosimetry
  - Introducing msr and plan-class-specific reference field (pcsr)
  - The pcsr is a field that should be as close to a class of clinical plans as possible, while generating a homogeneous dose region “much” larger than the sensitive volume of the detector

Machine-specific-reference

- Reference calibration, reference field, f_{ref}

$$D_{w,Q_{msr}}^{f_{msr}} = M_{Q_{msr}}^{f_{msr}} \cdot N_{D,w,Q_0} \cdot k_{Q,Q_0} \cdot k_{Q_{msr},Q}^{f_{msr},f_{ref}}$$

$$k_{Q_{msr},Q}^{f_{msr},f_{ref}} = \frac{D_{w,Q_{msr}}^{f_{msr}} \Big/ M_{Q_{msr}}^{f_{msr}}}{D_{w,Q}^{f_{ref}} \Big/ M_{Q}^{f_{ref}}}$$

- Is a factor which corrects for the differences between the conditions of field size, geometry, phantom material, and beam quality of the conventional reference field, f_{ref}, and the machine-specific-reference field f_{msr}.

- This factor accounts for the difference between the responses of an ionisation chamber in the fields f_{ref} and f_{msr}.

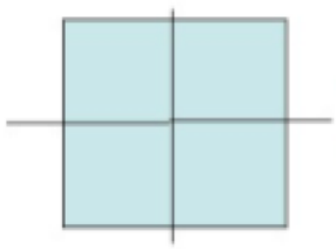
Machine-specific-reference field

1

REFERENCE DOSIMETRY

$$D_{w,Q_{msr}}^{f_{msr}} = M_{Q_{msr}}^{f_{msr}} \; N_{D,w,Q_0} \; k_{Q,Q_0} \; k_{Q_{msr},Q}^{f_{msr},f_{ref}}$$

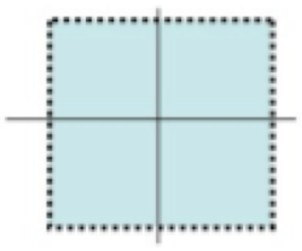
Broad beam reference field f_{ref}



$k_{Q_{msr},Q}^{f_{msr},f_{ref}}$

$N_{D,w,Q_0} \; k_{Q,Q_0}$

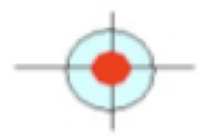
Hypothetical reference field f_{ref}



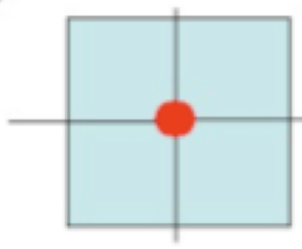
$k_{Q_{msr},Q}^{f_{msr},f_{ref}}$

● ≡ Ionization chamber

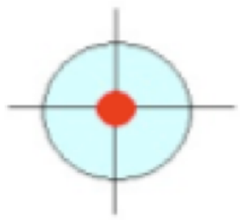
Machine specific reference field f_{msr}



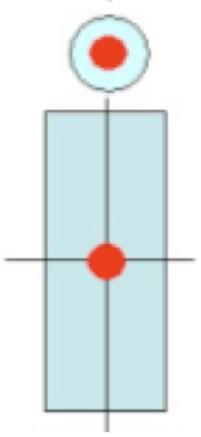
Radiosurgical collimators
∅ as low as 1.8cm



BrainLAB
micro MLC
10cm x 10cm



CyberKnife
∅ 6.0 cm



GammaKnife
∅ 1.6/1.8 cm

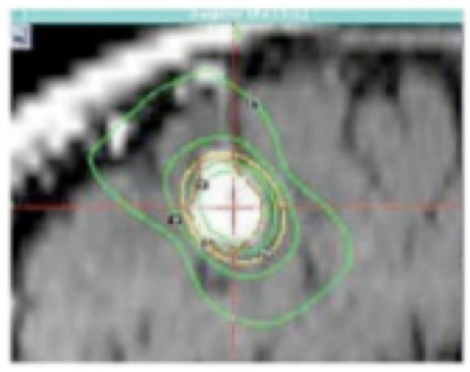
TomoTherapy
5cm x 20cm

RELATIVE DOSIMETRY

$$D_{w,Q_{clin}}^{f_{clin}} = D_{w,Q_{msr}}^{f_{msr}} \; \Omega_{Q_{clin},Q_{msr}}^{f_{clin},f_{msr}}$$

$\Omega_{Q_{clin},Q_{msr}}^{f_{clin},f_{msr}}$

Clinical f_{clin}



e.g. a GammaKnife clinical plan

Plan-class-specific-reference field

- Reference calibration, reference field, f_{pcsr}

$$D_{w,Q_{pcsr}}^{f_{pcsr}} = M_{Q_{pcsr}}^{f_{pcsr}} \cdot N_{D,w,Q_0} \cdot k_{Q,Q_0} \cdot k_{Q_{pcsr},Q}^{f_{pcsr},f_{ref}}$$

or

$$D_{w,Q_{pcsr}}^{f_{pcsr}} = M_{Q_{pcsr}}^{f_{pcsr}} \cdot N_{D,w,Q_0} \cdot k_{Q,Q_0} \cdot k_{Q_{msr},Q}^{f_{msr},f_{ref}} \cdot k_{Q_{pcsr},Q_{msr}}^{f_{pcsr},f_{msr}}$$

$k_{Q_{msr},Q}^{f_{msr},f_{ref}}$

- This factor will generally be close to unity under the condition that the addition and geometrical matching of the composite fields in the homogeneous phantom compensates for the loss of CPE in the penumbra of individual fields.
- Ideally it would be obtained by direct calibration of the IC against a primary standard or another dosimeter such as alanine, or alternatively, Monte Carlo.

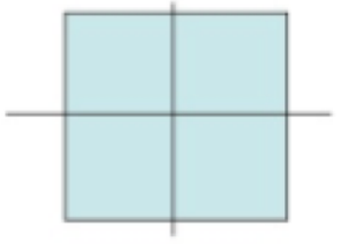
Plan-class-specific-reference field

2

REFERENCE DOSIMETRY

$$D_{w,Q_{pcsr}}^{f_{pcsr}} = M_{Q_{pcsr}}^{f_{pcsr}} \; N_{D,w,Q_0} \; k_{Q,Q_0} \; k_{Q_{pcsr},Q}^{f_{pcsr},f_{ref}}$$

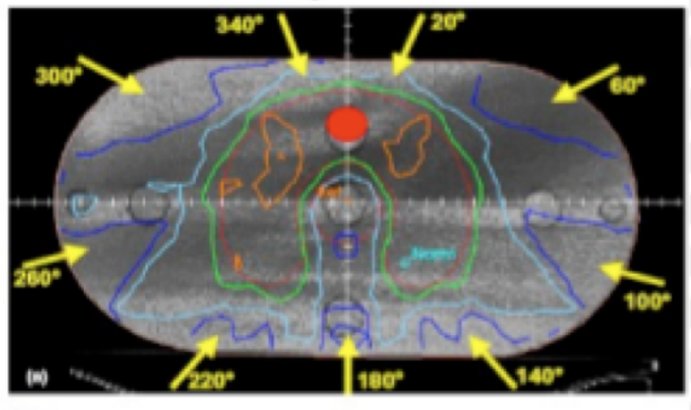
Broad beam reference field f_{ref}



N_{D,w,Q_0} k_{Q,Q_0}

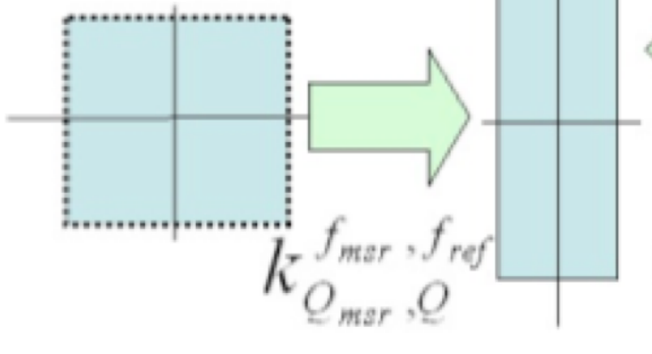
$k_{Q_{pcsr},Q}^{f_{pcsr},f_{ref}}$ (e.g. IMRT Linac)

Plan-class specific reference field f_{pcsr}



e.g. 9-field prostate *pcsr*

Hypothetical reference field



$k_{Q_{msr},Q}^{f_{msr},f_{ref}}$

f_{msr}

$k_{Q_{pcsr},Q_{msr}}^{f_{pcsr},f_{msr}}$

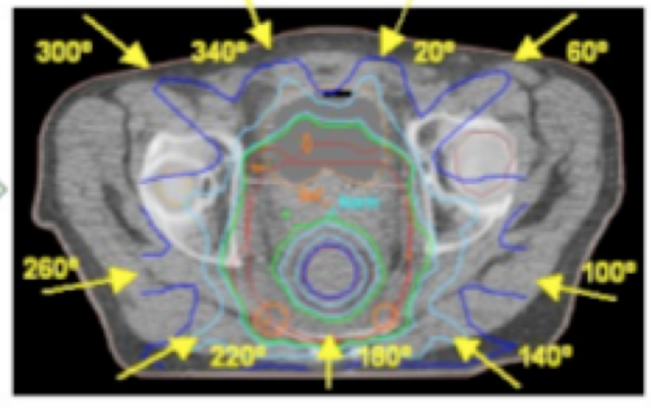
(e.g. **TomoTherapy** 5cm x 20cm)

RELATIVE DOSIMETRY

$$D_{w,Q_{clin}}^{f_{clin}} = D_{w,Q_{pcsr}}^{f_{pcsr}} \; \Omega_{Q_{clin},Q_{pcsr}}^{f_{clin},f_{pcsr}}$$

$\Omega_{Q_{clin},Q_{pcsr}}^{f_{clin},f_{pcsr}}$

Clinical f_{clin}



e.g. 9-field prostate clinical plan

● ≡ Ionization chamber

Small and composite fields

- In both cases, small and composite fields, it can be seen that the formalism stays close to the one of conventional COPs in the sense that a calibration of a reference field is performed followed by the application of output factors or an equivalent type of factors for clinical fields.

- The main difference being the extension of the concept of reference field.

- In line with this approach, it might be possible that a standards laboratory is able to provide a direct calibration coefficient , $N_{D,w,Q_{msr}}^{f_{msr}}$, for an IC in the machine-specific-reference field.

- NCS report on Tomotherapy : 1 Kq, incorporating pcsr, msr and regular kq

Don’t worry...let’s get practical

Practical Example

Helical Tomotherapy

6MV
Non-Flat "coned" field
max field size = 5x40cm^2

Practical Example

Use the msr-method on a 10x5 field

$$D_{w,Q_{msr}}^{f_{msr}} = M_{Q_{msr}}^{f_{msr}} \cdot N_{D,w,Q_0} \cdot k_{Q,Q_0} \cdot k_{Q_{msr},Q}^{f_{msr},f_{ref}}$$

Static output is correctly characterized

Clinical treatment is not static

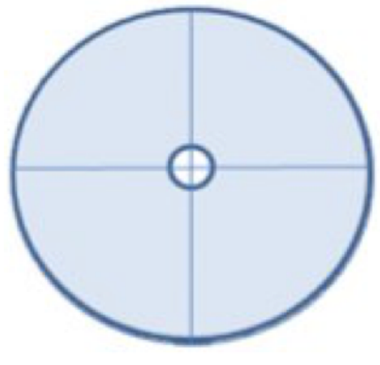
Practical Example

Use the msr-method on a nonmodulated rotational field

$$D_{w,Q_{msr}}^{f_{msr}} = M_{Q_{msr}}^{f_{msr}} \cdot N_{D,w,Q_0} \cdot k_{Q,Q_0} \cdot k_{Q_{msr},Q}^{f_{msr},f_{ref}}$$

Rotational output is correctly characterized

Clinical treatment is modulated



Practical Example

Use the pcsr-method on a modulated rotational field

$$D^{f_{pcsr}}_{w,Q_{pcsr}} = M^{f_{pcsr}}_{Q_{pcsr}} . N_{D,w,Q_0} . k_{Q,Q_0} . k^{f_{msr},f_{ref}}_{Q_{msr},Q} . k^{f_{pcsr},f_{msr}}_{Q_{pcsr},Q_{msr}}$$

Rotational output is correctly characterized

TomoDirect ?

court. Palmans

Conclusion

- The concept of 2 intermediate calibration fields is introduced:
  - A static *machine-specific-reference field* for those modalities that cannot establish conventional reference conditions
  - A *plan-class-specific-reference field* closer to the patient-specific clinical fields.
- The main challenge will be the definition of a suitable *pcsr* field.
- Technology is evolving very fast...here today, gone tomorrow.
- Dosimetry has to catch up all the time
- When new techniques/new formalisms are not there yet....an independent check should always be found

Take home message

(physicists)

- Because of increasing complexity, depending on experience and "gut-feeling" is not enough.
- A good understanding of all small parameters affecting IMRT-dosimetry is a must

- CoPs are not straightforward applicable, traceability is a necessity.
- External audits can be a very good idea.

Take home message for physicians

- IMRT is not, has not been and will not be plug-and-play, whatever the monkey in the suit told you

- It is not a case of "quickly doing some measurements".
- After commissioning the fun is just starting : loads and loads of non-plug-and-play-patient QA which will keep your physics team busy and frustrated

TPS commissioning

Marco Schwarz
Marco.schwarz@apss.tn.it

Overview

Generalities

Commissioning of the TPS

- General approach
- MLC/small fields/dose profiles
- Dose calculation during optimisation
- Accuracy criteria

Four steps to define, baseline and monitor the performances of radiotherapy equipment.

1. *Technical specifications*
2. *Acceptance tests*
3. *Commissioning*
4. *(Equipment) QA*

1/4

Define/agree upon the specifications, i.e. the performance requirements that the equipment must/should fulfill

- ✓ *'The MLC must have a positional accuracy of less than x mm'*
- ✓ *'The beam output should be stable within y%'*
- ✓ *'Calculated output factors should be within x% for fields not smaller than y'*
- ✓ *…*

Perform Acceptance (with the vendor), i.e. a series of test to demonstrate that the system complies with the specs.

(*E.g. Comparison between calculation and measurement of OF for 5 field sizes)*

IF the tests are successful

you pay for the equipment, which becomes yours.

ELSE

you ask for the problems to be fixed

N.B. No specs means no meaningful acceptance tests !!

How did you TPS acceptance tests look like?

3/4

Perform Commissioning(on your own), i.e. a series of tests that fully characterize the system before clinical use.

(*E.g. Comparison between calculation and measurement of OF for 25 field sizes)*

In general commissioning tests are a superset of the acceptance tests.

Thorough commissioning provides baseline data for **equipment** QA.

Perform equipment QA, i.e. a series of periodic tests to assess system performances over time.

(*E.g. Every day, MLC positioning accuracy is tested on five out of the 25 field shapes used in commissioning are tested.*

Check integrity of beam data in the TPS)

Commissioning data are the (initial) baseline to judge the system performances

Question: what does it mean to perform QA on a software?

Where does 'patient specific QA' fits into this scheme?

It is an additional QA element, if it is **really** patient specific.

Hardware and software are just a part of the treatment chain. The bottom line is the dose in the patient.

It may be a useful redundant check, in particular in the early phases of clinical implementation.

It is a way to compensate for incomplete/unsatisfactory commissioning.

Commissioning of TPS

Penumbra modeling

OF for small fields

Commissioning of the TPS

Heterogeneity corrections

MLC modeling

Modeling of off-axis fields

How to consider all variables in the acceptability criteria ?

Analytic approach

Find and achieve for each variable the value that will ensure the acceptability of all treatment plans.

This was the approach in CRT

ESTRO Booklets on QA for NON-IMRT beams

	Region	Homogenous, simple geometry	Complex geometry	More complex geometries
δ_1	*Central beam axis data* – high dose, low dose gradient	2%	3%	4%
δ_2*	*Build-up region of central axis beam, penumbra region of the profiles* - high dose, high dose gradient	2 mm or 10%	3 mm or 15%	3 mm or 15%
δ_3	*Outside central beam axis region* - high dose, low dose gradient	3%	3%	4%
δ_4**	*Outside beam edges* – low dose, low dose gradient	3%-3mm	4%-4mm	5%-5mm
RW_{50} ***	*Radiological width* – high dose, high dose gradient.	2 mm or 1%	2 mm or 1%	2 mm or 1%
δ_{50-90}	*Beam fringe* – high dose, high dose gradient	2 mm	3 mm	3 mm

"*… the emphasis on QA of IMRT is shifted from acceptance testing and commissioning of a TPS to patient-specific QA. However, also for patient-specific QA no guidelines are available.*"

ESTRO Booklet 9
"Guidelines on the verification of IMRT"

First, what you can NOT commission/QA

1. **The optimisation algorithm**

   How good/bad is in minimizing the cost function?

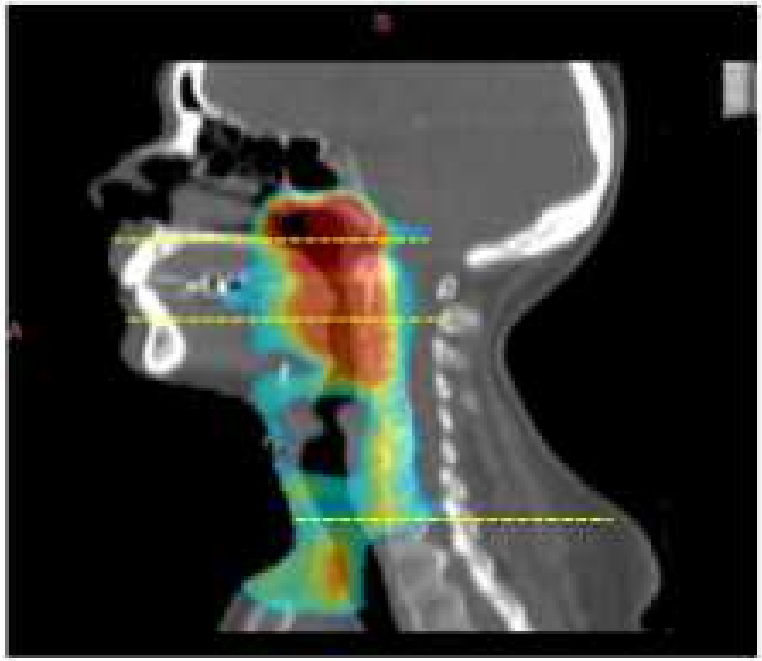
   (Unlikely to affect plan quality)

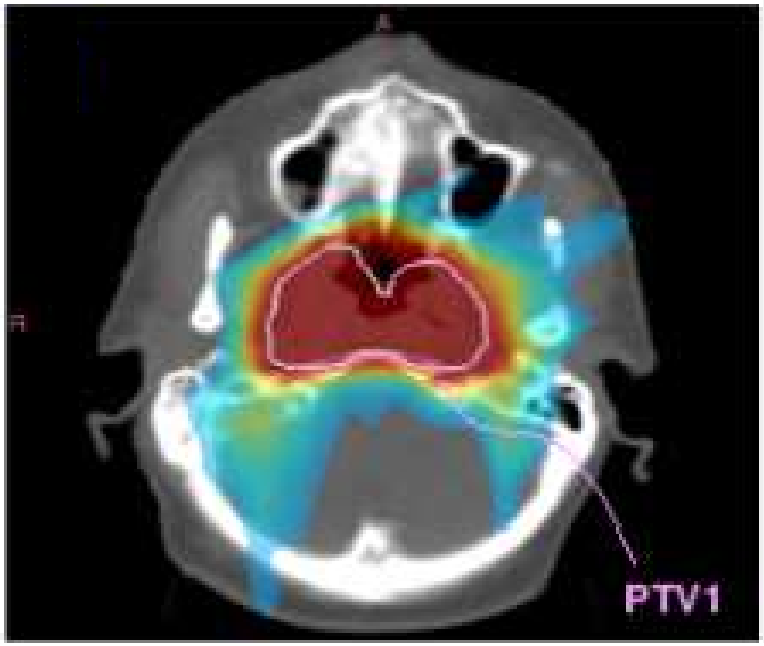
2. **The dose calculation algorithm used in fluence optimization**

   How can I check that the solution space is properly described by the TPS ?

   (Potentially affecting plan quality if there is no optimization after segmentation)

IMRT planning &
Dose calculation



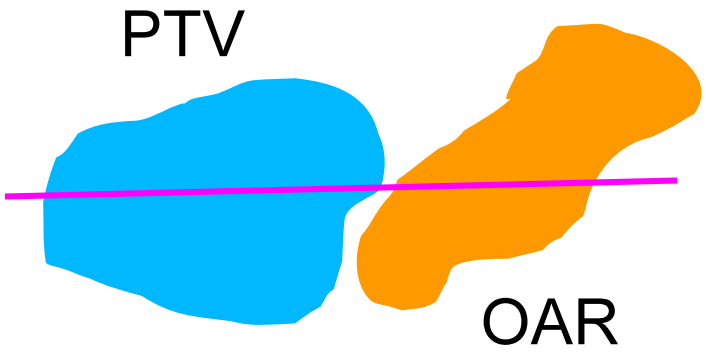


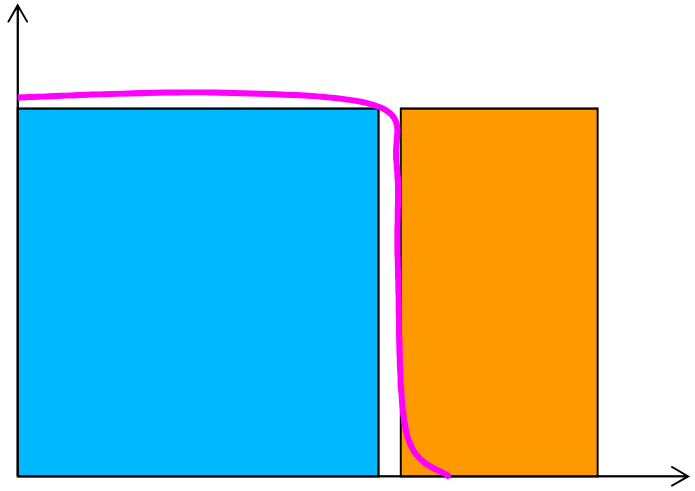
IMRT → Highly automated planning procedure

The solution is found within the solution space, which is shaped by

- ✓ Patient anatomy (geometry)
- ✓ The optimisation problem (cost function)
- ✓ The dose calculation

By defining the cost function in a dose range where calculation errors exist a bias is introduced in the optimisation problem





Ideal penumbra

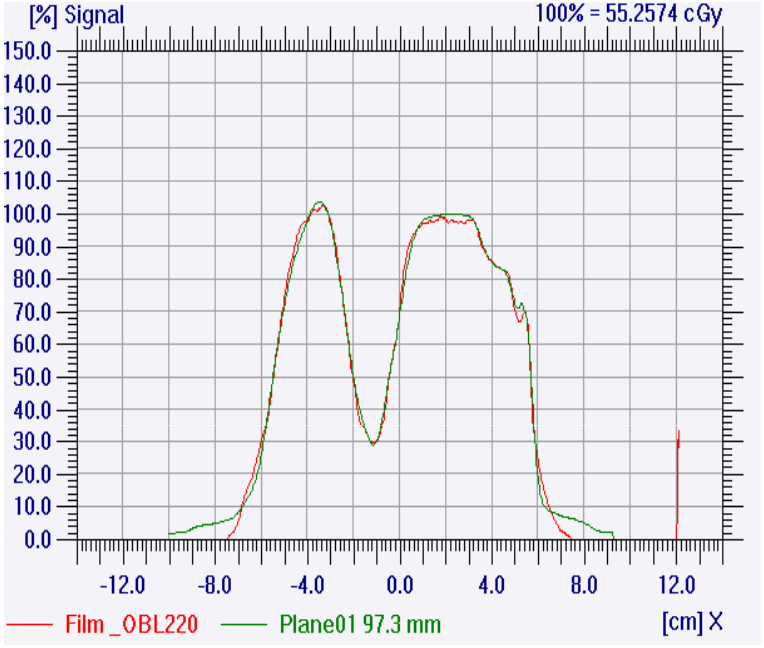
TPS characterized with IC measurements



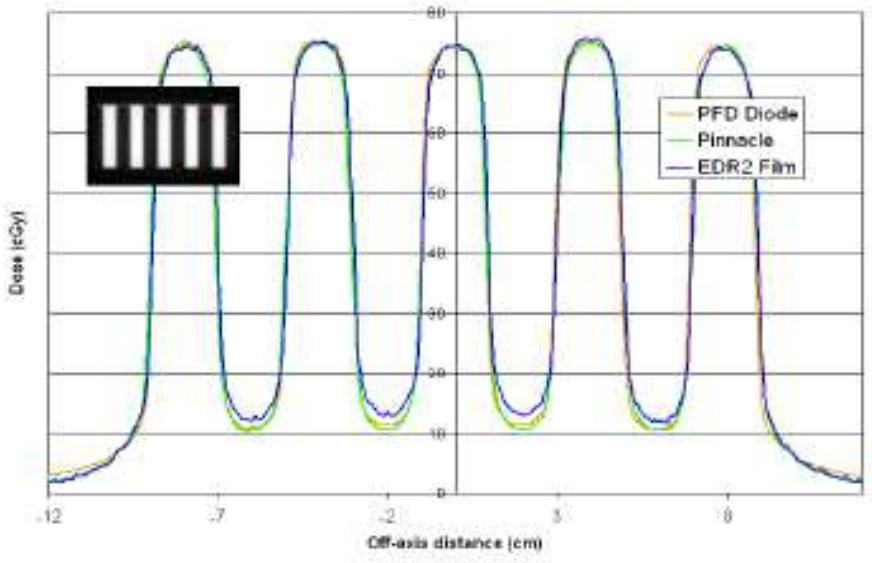
TPS characterized with diode measurements

Measurements vs. calculations
1D dose profiles

Mostly used in the commissioning phase, to

- Model/verify the profiles of small/off axis fields
- Test the capability of the MLC/TPS to generate/calculate highly modulated dose profiles

The agreement can be evaluated with the classical dose-difference and DTA parameters



Measurements vs. calculations
2-D dose distributions

Typically used for TPS commissioning and patient pre-treatment verification

- Applied per-field or on the total dose distribution
- Combined with absolute dose point measurements
- Film dosimetry or 2-D matrix of detectors are the standard tools to obtain them

The issue is how to summarize the results available comparing (stacks of) 2-D dose distributions

Gamma function

Combination of dose difference and distance to agreement (DTA), in order to apply it to both high and low dose gradient regions

$$\Gamma(\mathbf{r}_m, \mathbf{r}_c) = \sqrt{\frac{r^2(\mathbf{r}_m, \mathbf{r}_c)}{\Delta d_M^2} + \frac{\delta^2(\mathbf{r}_m, \mathbf{r}_c)}{\Delta D_M^2}},$$

RPC experience - US

Acceptance criteria: 7% and 4mm

Ibbott IJROBP 2008

Table 1. Institution passing rates with the Radiological Physics Center phantoms

Phantom	Head and neck	Prostate	Thorax	Liver
Irradiations	250	64	24	4
Pass	179	55	17	3
Fail	71	9	7	1
Year introduced	2001	2004	2004	2005

Conclusions

IMRT is about 15 years old. You can learn from other people successes and mistakes.

Specs, Acceptance, Commissioning and QA should be approached as elements of an *unicum*.

IMRT on a large scale implies effective and fast QA, which implies satisfactory TPS commissioning.

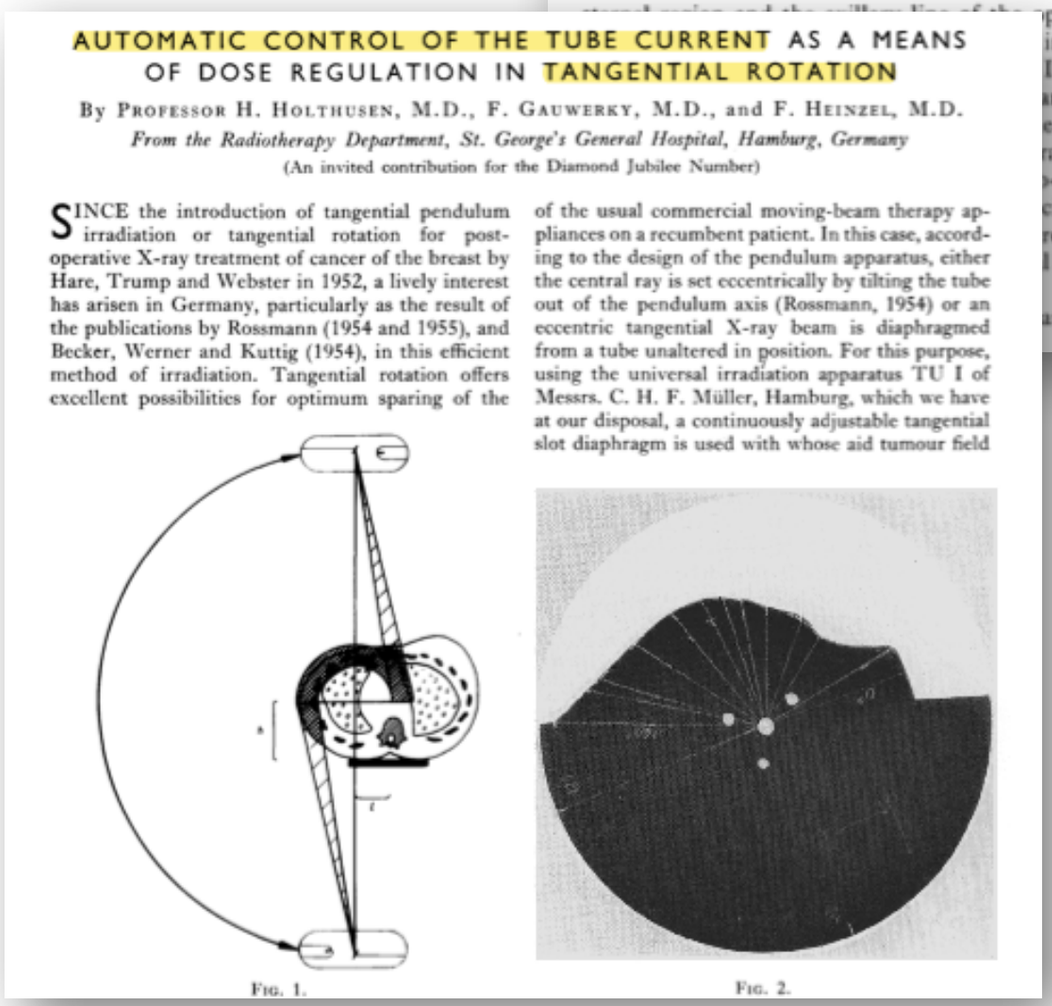
Nothing new (1956)…



AUTOMATIC CONTROL OF THE TUBE CURRENT AS A MEANS OF DOSE REGULATION IN TANGENTIAL ROTATION

By Professor H. Holthusen, M.D., F. Gauwerky, M.D., and F. Heinzel, M.D.

From the Radiotherapy Department, St. George's General Hospital, Hamburg, Germany

(An invited contribution for the Diamond Jubilee Number)

SINCE the introduction of tangential pendulum irradiation or tangential rotation for post-operative X-ray treatment of cancer of the breast by Hare, Trump and Webster in 1952, a lively interest has arisen in Germany, particularly as the result of the publications by Rossmann (1954 and 1955), and Becker, Werner and Kuttig (1954), in this efficient method of irradiation. Tangential rotation offers excellent possibilities for optimum sparing of the

of the usual commercial moving-beam therapy appliances on a recumbent patient. In this case, according to the design of the pendulum apparatus, either the central ray is set eccentrically by tilting the tube out of the pendulum axis (Rossmann, 1954) or an eccentric tangential X-ray beam is diaphragmed from a tube unaltered in position. For this purpose, using the universal irradiation apparatus TU I of Messrs. C. H. F. Müller, Hamburg, which we have at our disposal, a continuously adjustable tangential slot diaphragm is used with whose aid tumour field

Automatic Control of the Tube Current as a Means of Dose Regulation in Tangential Rotation

…perated …irradia- …It must …angle of …e direct …adiated …-lateral …circum- …rotation …l phan- …in the …art near

Of the two possibilities available in principle to carry out the desired compensation, namely variable speed of the X-ray tube movement during irradiation on the one hand and variation of dose output on the other, the latter was chosen since a regulation of the tube current in accordance with a predetermined scheme could be achieved with less constructional difficulties. Thus the tube current will have to be reduced in the higher dosed skin areas, and increased in the positions of the tube in which the surface areas are lower dosed. For this purpose, distribution schemes for the tube current

British Journal of Radiology, **1956**

"Rotational RT has been around for some time, even longer than IMRT …"

Nothing new…

- "A logical extension of multiple beam therapy is to use 1 beam, have it directed towards the tumour, and cause the machine to rotate about an axis through the tumour, or keep the machine fixed and rotate the patient about this axis …"
- When the radiotherapist was limited to the use of 250 kV X-rays, it was very difficult to get enough radiation into an internal tumour … As a result many workers developed rotation techniques …"

[57] **ABSTRACT**

A method and apparatus for delivering optimized treatment plans to deliver relatively high doses of ionizing radiation to target tissues while minimizing dose to the surrounding healthy tissues. The present invention utilizes continuous gantry motion in which field shape, which is conformed with a multi-leaf collimator, changes during gantry rotation. Using multiple superimposing arcs, arbitrary two-dimensional beam intensity distribution at different beam angles can be delivered, giving arbitrary dose distribution in the patient to maximize the therapeutic ratio.

De meerleer et al

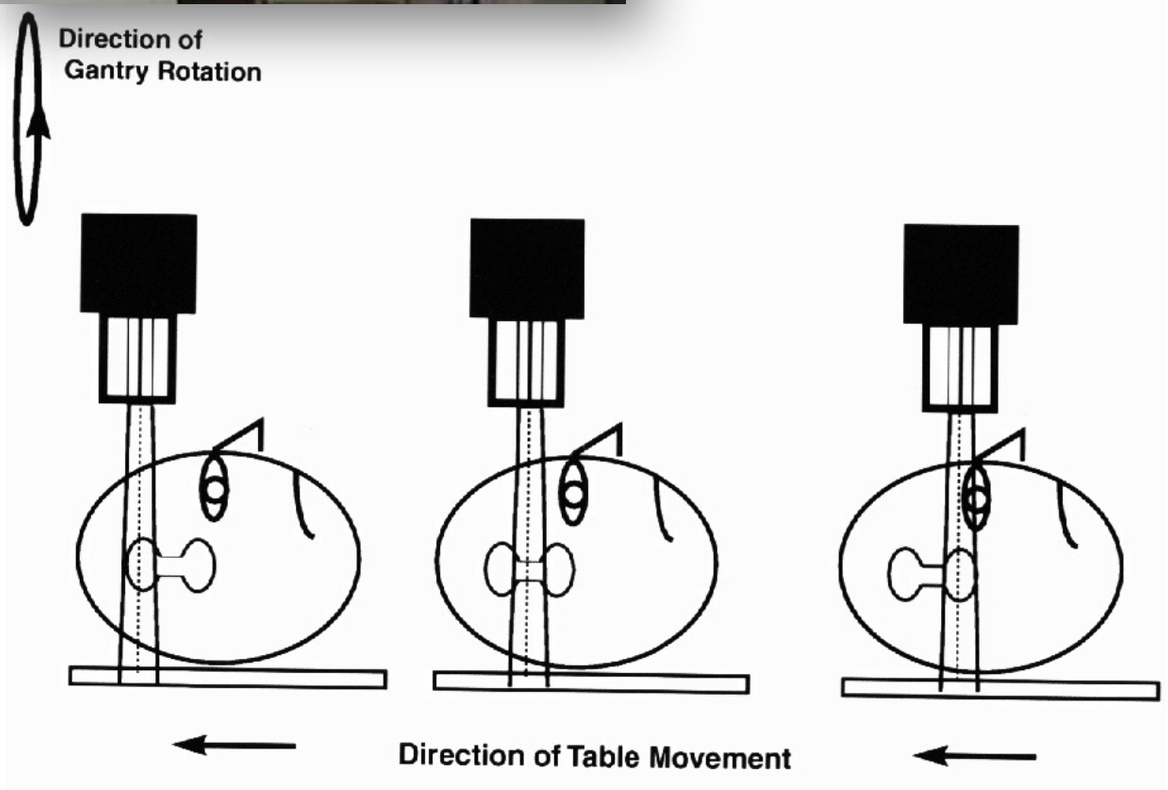
Nothing new…1998

"First commercial solutions but not a hit yet …"

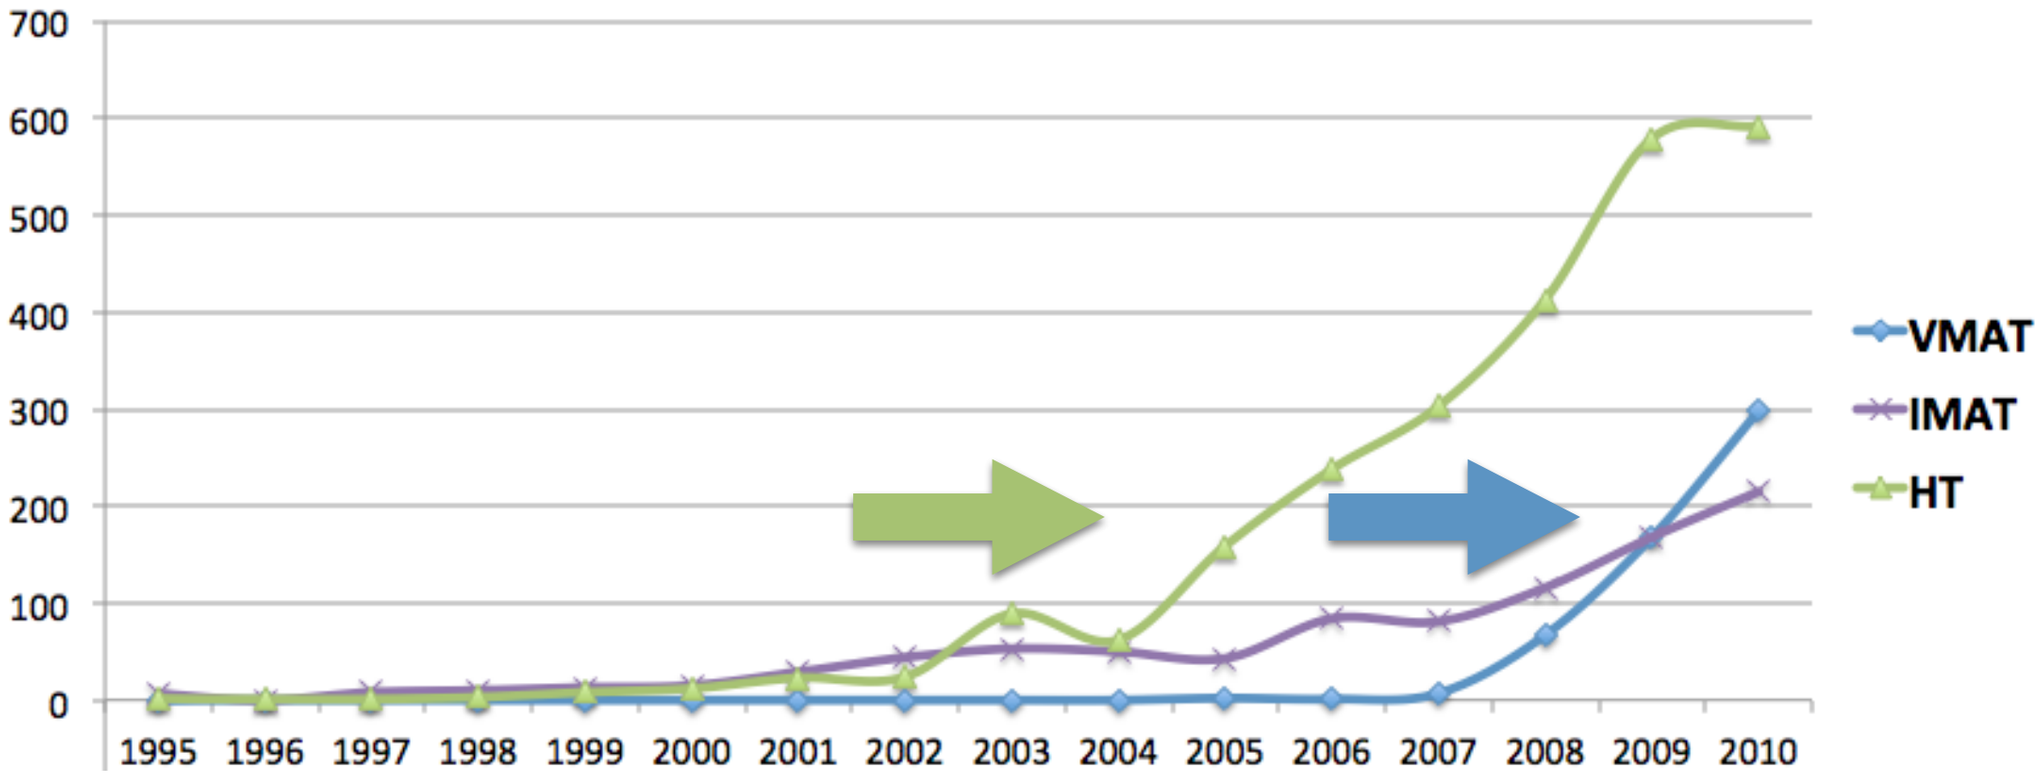
Low et al. 1998

*"A **commercial** **serial tomotherapy** intensity-modulated radiation therapy (IMRT) treatment planning (**Peacock, NOMOS** Corp., Sewickley, PA) and delivery system is in clinical use. The dose distributions are highly conformal, with large dose gradients often surrounding critical structures, and require accurate localization and dose delivery. Accelerator and patient-specific quality assurance (QA) procedures have been developed that address the localization, normalization, and delivery of the IMRT dose distributions."*

Nomos Peacock Add-on system



It took some time to get popular



Hits raise last year:

7.9% for IMRT (1982)
(last 3 years 7.1%)

2.2% for HT (1995)
(last 3 years 17.8%)

28% for IMAT (1995)
(last 3 years 26.9%)

77% for VMAT (2005)
(last 3 years 58.0%)

Issues with early solutions

- Computer treatment planning systems (TPS), inverse planning approaches and optimizer algorithms were in their early days

- Dependence on another new technology at that time, the multi-leaf collimator (MLC), which was initially designed to replace cerobend blocks

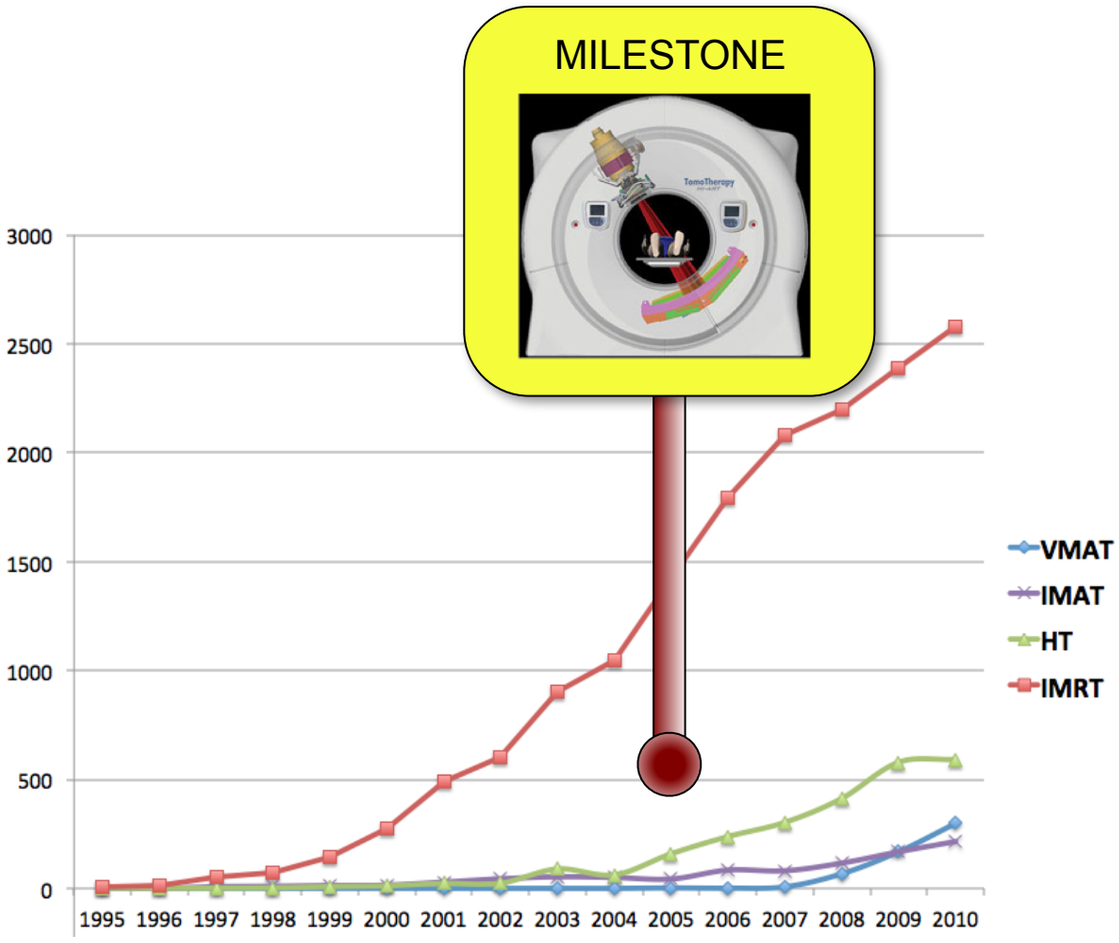
"A handful of research oriented centers developed their own **custom build solution of rotational therapy solutions** (IMAT, …)."

-William Beaumont Hospital group, USA, C. Yu et al.

-UZ Gent, Belgium, De Neve et al.

-…

An industry incentive…



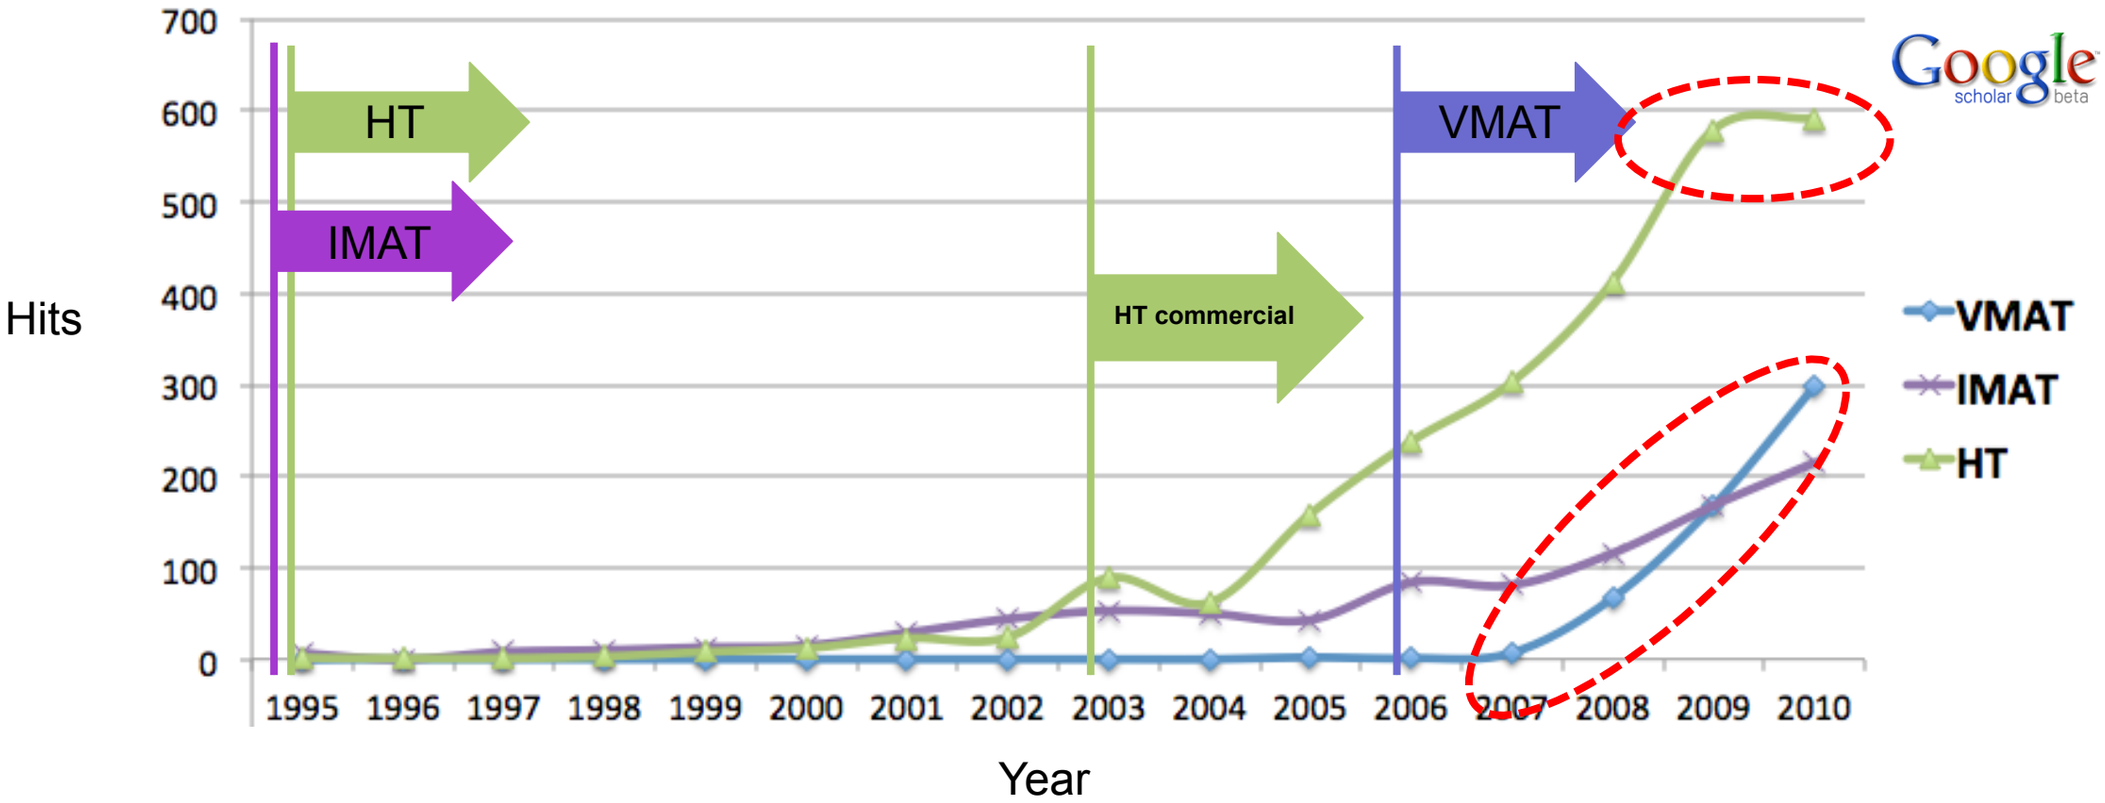
Introduction of the Tomotherapy Hi-Art system for helical tomotherapy:

"Not an add-on solution any more like serial tomo, but a new concept on a dedicated device"

"Brought rotational IMRT to a next level …"

"A new competitor in a very competitive market with only a few players"

An industry incentive



Marketing machine is not afraid to use words like
-”true REVOLUTION …”
-”MAJOR advance …”
-”DRAMATIC improvement … “

But behind the screens the R&D got a lot of resources as well to at least approximate the promises made by marketing …

The field today….

Volumetric Modulated Arc Therapy

ELEKTA with VMAT™

="cone beam delivery"

VARIAN medical systems with RapidArc

Helical Tomotherapy

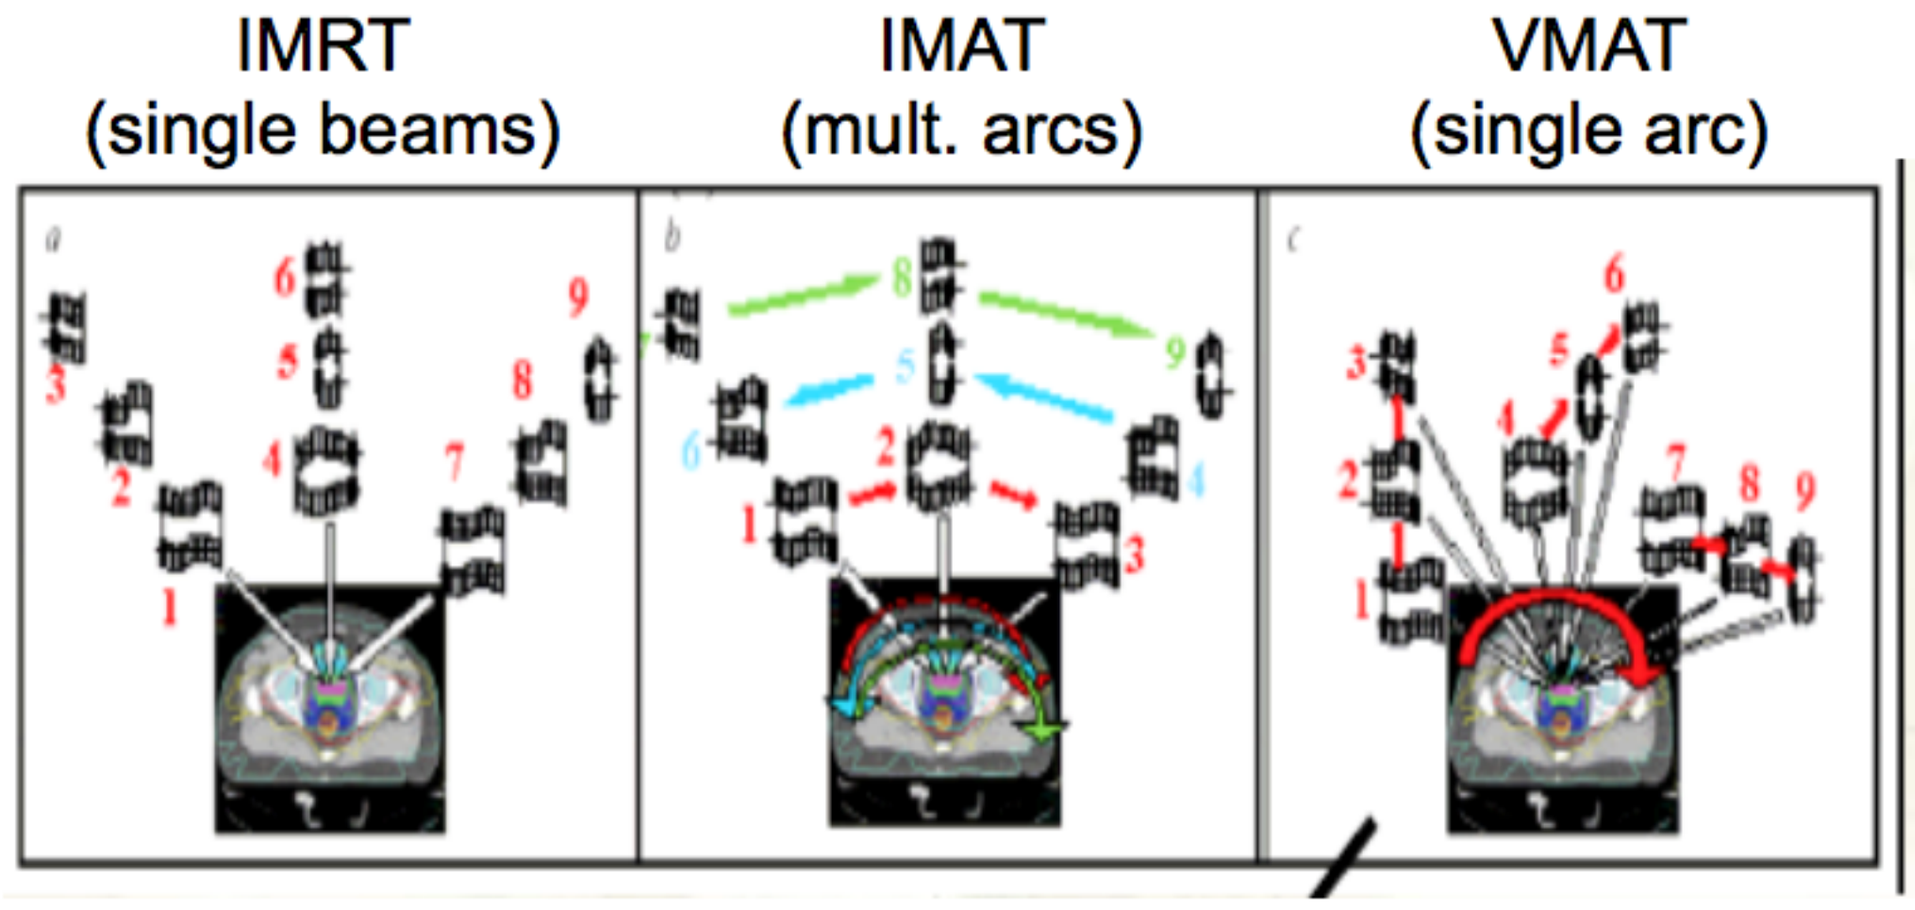
TomoTherapy INCORPORATED

ACCURAY

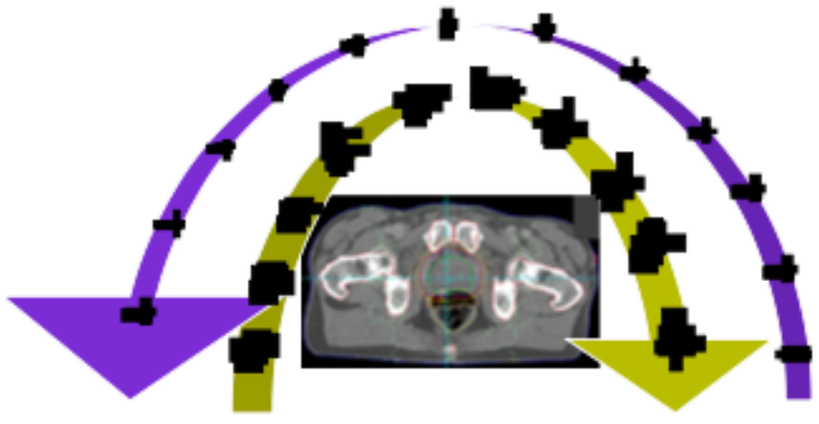
="fan beam delivery"

Static IMRT

Different names/interpretations

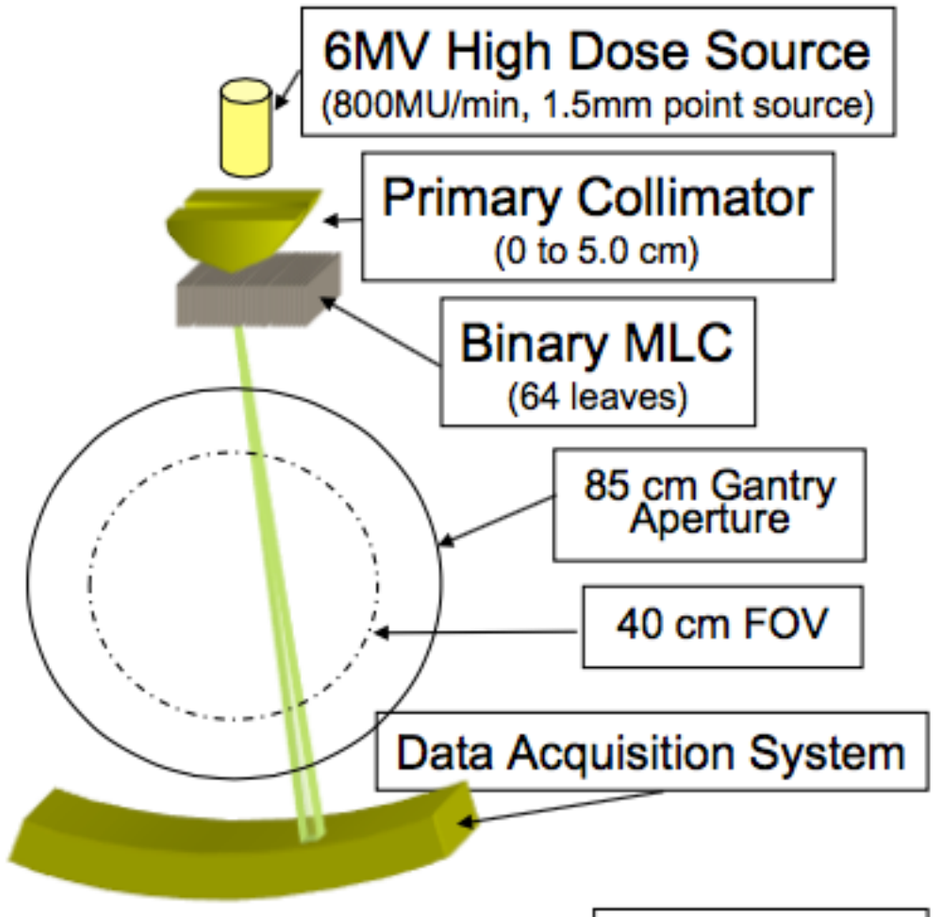


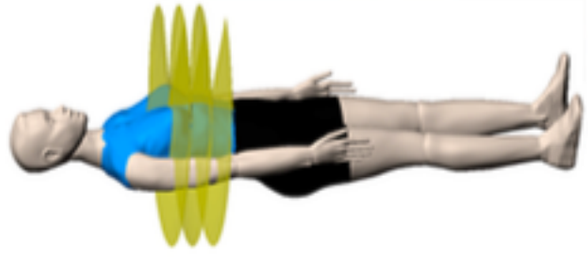
VMAT / RapidArc /



- 1 or more rotations
- Modulation by gantryspeed/doserate/ MLC

Helical Tomotherapy (Linac meets CT)





Helical Tomotherapy

- Helical Treatment
- Field of 40cmx(5, 2.5 of 1)cm
- Modulation by
  - 64 leaf-binary MLC
  - Pitch (around 0.3)
  - Modulation factor (average/max leaf open time)

“hot” a couple of years ago

- Is cone beam delivery better than helical fan-beam delivery
- Is arc therapy “better” than static beam IMRT
- Should all IMRT be rotational?

Still relevant

The battle was taking place on two fronts….

Practical : “Planning comparison studies between VMAT and HT and other IMRT solutions

Theoretical : Trying to prove differences between the various dose delivery techniques based on intrinsic/theoretical capabilities of the technique

Planning studies

- Can be described as a pragmatic approach to show what we can do with actual clinical cases
- Only valid for specific implementations of different techniques
- prone to bias
  - you are comparing optimisers, not techniques
  - you are comparing planners, not plans (pareto-optimal?)
  - The link to biology was almost never made…
- General conclusion : I’m not a big fan

VMAT (single arc) vs. IMRT (9 Fields)

- Palma et al 2008 (prostate)
- Cozzi et al 2008 (gynec)
- Fogliata et al (brain)

Simple cases (not a lot of modulation) :VMAT at least as good as IMRT
VMAT : treatment time and MU reduction

Comments

- Planningstudies are plenty, all say the same, but most don't say a lot...
- Yes, HT can achieve better target coverage and nicer sparing
  - with an inferior CC gradient
  - and a longer treatment time
- The question is : is it clinically relevant for this patient, and all my patients?
- Most studies have been catched up by upgrades
  - HT : reduction of CC gradient by "dynamic jaws"
  - reduction of treatment time by use of 5cm field and increased rotation speed.

Comparison approaches IMRT/VMAT/HT

Theoretical discussion:

"Trying to prove differences between the various dose delivery techniques based on intrinsic/theoretical capabilities of the technique."

-Independent of the maturity of currently available solutions in the clinic.
-Possibility of a general conclusion ?!

However …

-A universal theoretical framework to make this comparison for VMAT is lacking
-Not considering some practical/implementation specific issues which do count in practice

Abstract

The idea of delivering intensity-modulated radiation therapy (IMRT) with a multileaf collimator in a continuous dynamic mode during a single rotation of the gantry has recently gained momentum both in research and industry. In this note we investigate the potential of this Single-Arc IMRT technique at a conceptual level. We consider the original theoretical example case from Brahme *et al* that got the field of IMRT started. Using analytical methods, we derive deliverable intensity 'landscapes' for Single-Arc as well as standard IMRT and Tomotherapy. We find that Tomotherapy provides the greatest flexibility in shaping intensity landscapes and that it allows one to deliver IMRT in a way that comes close to the ideal case in the transverse plane. Single-Arc and standard IMRT make compromises in different areas. Only in relatively simple cases that do not require substantial intensity modulation will Single-Arc be dosimetrically comparable to Tomotherapy. Compared with standard IMRT, Single-Arc could be dosimetrically superior in certain cases if one is willing to accept the spreading of low dose values over large volumes of normal tissue. In terms of treatment planning, Single-Arc poses a more challenging optimization problem than Tomotherapy or standard IMRT. We conclude that Single-Arc holds potential as an efficient IMRT technique especially for relatively simple cases. In very complex cases, Single-Arc may unduly compromise the quality of the dose distribution, if one tries to keep the treatment time below 2 min or so. As with all IMRT techniques, it is important to explore the tradeoff between plan quality and the efficiency of its delivery carefully for each individual case.

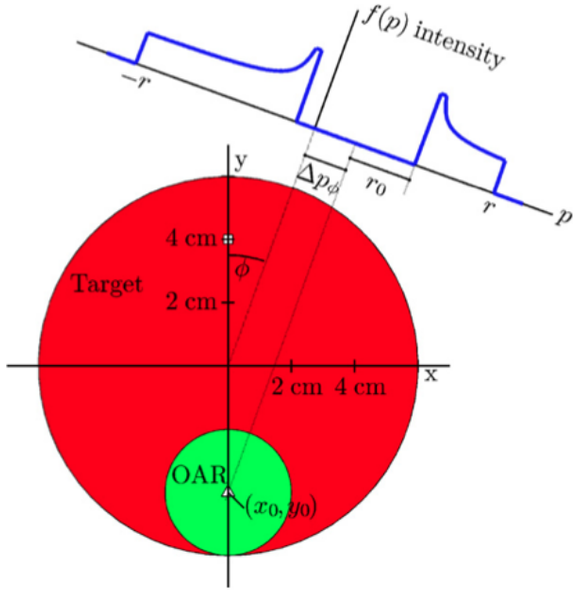

Figure 1. The archetypical IMRT example case where the target volume (red) wraps around an organ at risk (OAR) (Brahme *et al* 1982). This case requires substantial intensity modulation. Simply 'blocking' dose from reaching the OAR does not yield the desired uniform dose coverage of the target volume. One intensity profile from a gantry angle of $\phi = 20°$ is shown.

"Required ideal intensity modulation can be derived theoretically for this artificial situation"

Some considerations concerning volume-modulated arc therapy: a stepping stone towards a general theory

S Webb and D McQuaid

Joint Department of Physics, Institute of Cancer Research and Royal Marsden NHS Foundation Trust, Downs Road, Sutton, Surrey SM2 5PT, UK

Received 25 February 2009, in final form 19 May 2009

Webb&McQuaid:

"No universal theory of VMAT is known in the sense that there is no theory that can predict precisely the performance of a VMAT delivery in terms of the free parameters available (variable gantry speed, variable fluence-delivery rate, set of MLC shapes, MLC orientation, number of arcs, coplanarity versus non-coplanarity, etc). This is in stark contrast to the situation with several other IMRT delivery techniques where such theoretical analyses are known. In this paper we do not provide such a theory; the material presented is a stepping stone on the path towards this."

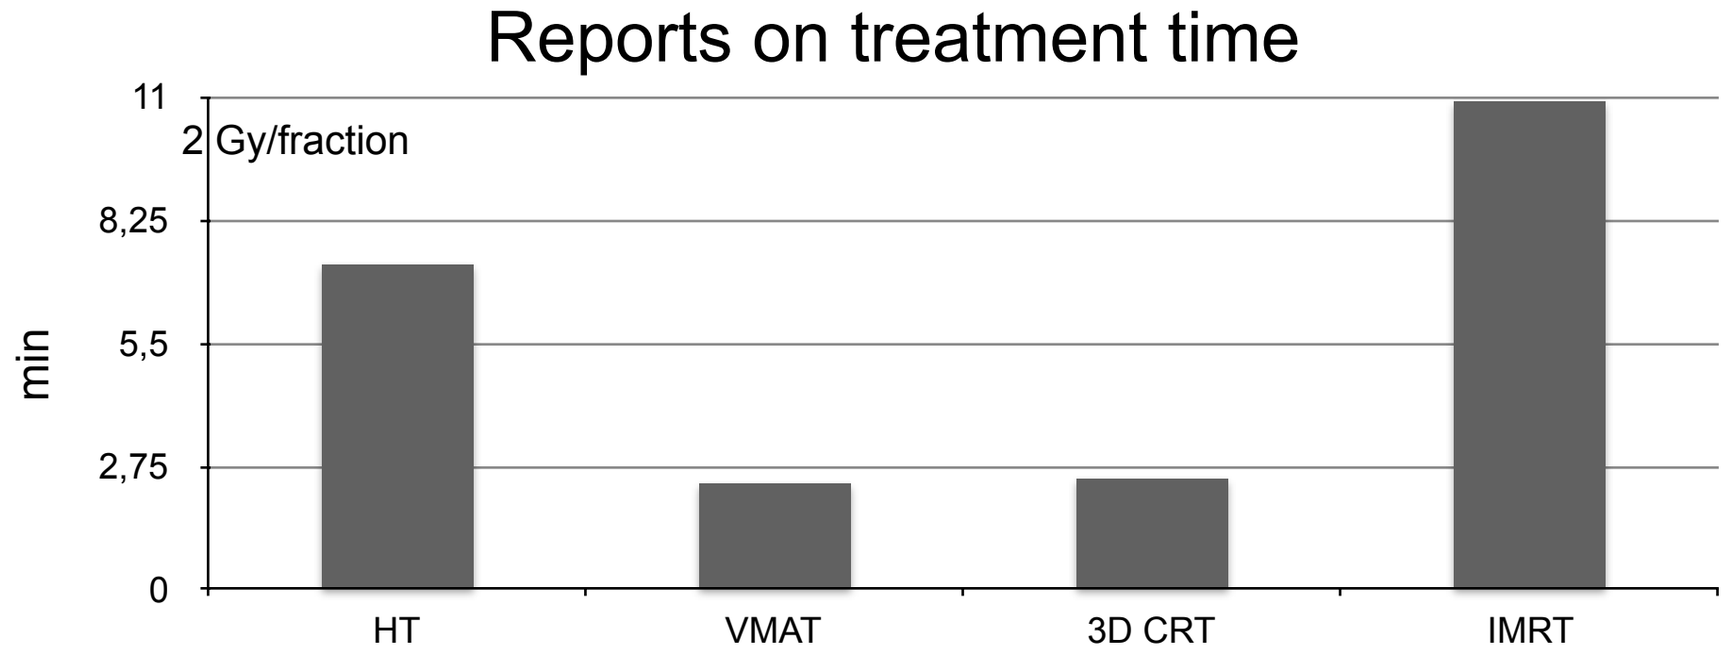
So…

In certain cases HT can be used as some kind of modulation “benchmark” for rotational therapy.

This does not mean it is clinically relevant to use it!

If not modulation, what could be another mode for comparison?

Treatment delivery times



Palma et al

The vocabulary of “Treatment Times”

Different “Times”:

- Treatment slots: reserved time on the machine, time from the patient entering the bunker, until leaving the bunker

- Total treatment time: time from the first MV photon hitting the patient until the last photon, includes gantry rotation without beam

- Beam-on time: time the therapeutic MV beam is actually on

- Dose accumulation pattern: the way a tissue volume is accumulating dose from primary beam during treatment

Reports on treatment times

Verbakel et al. :

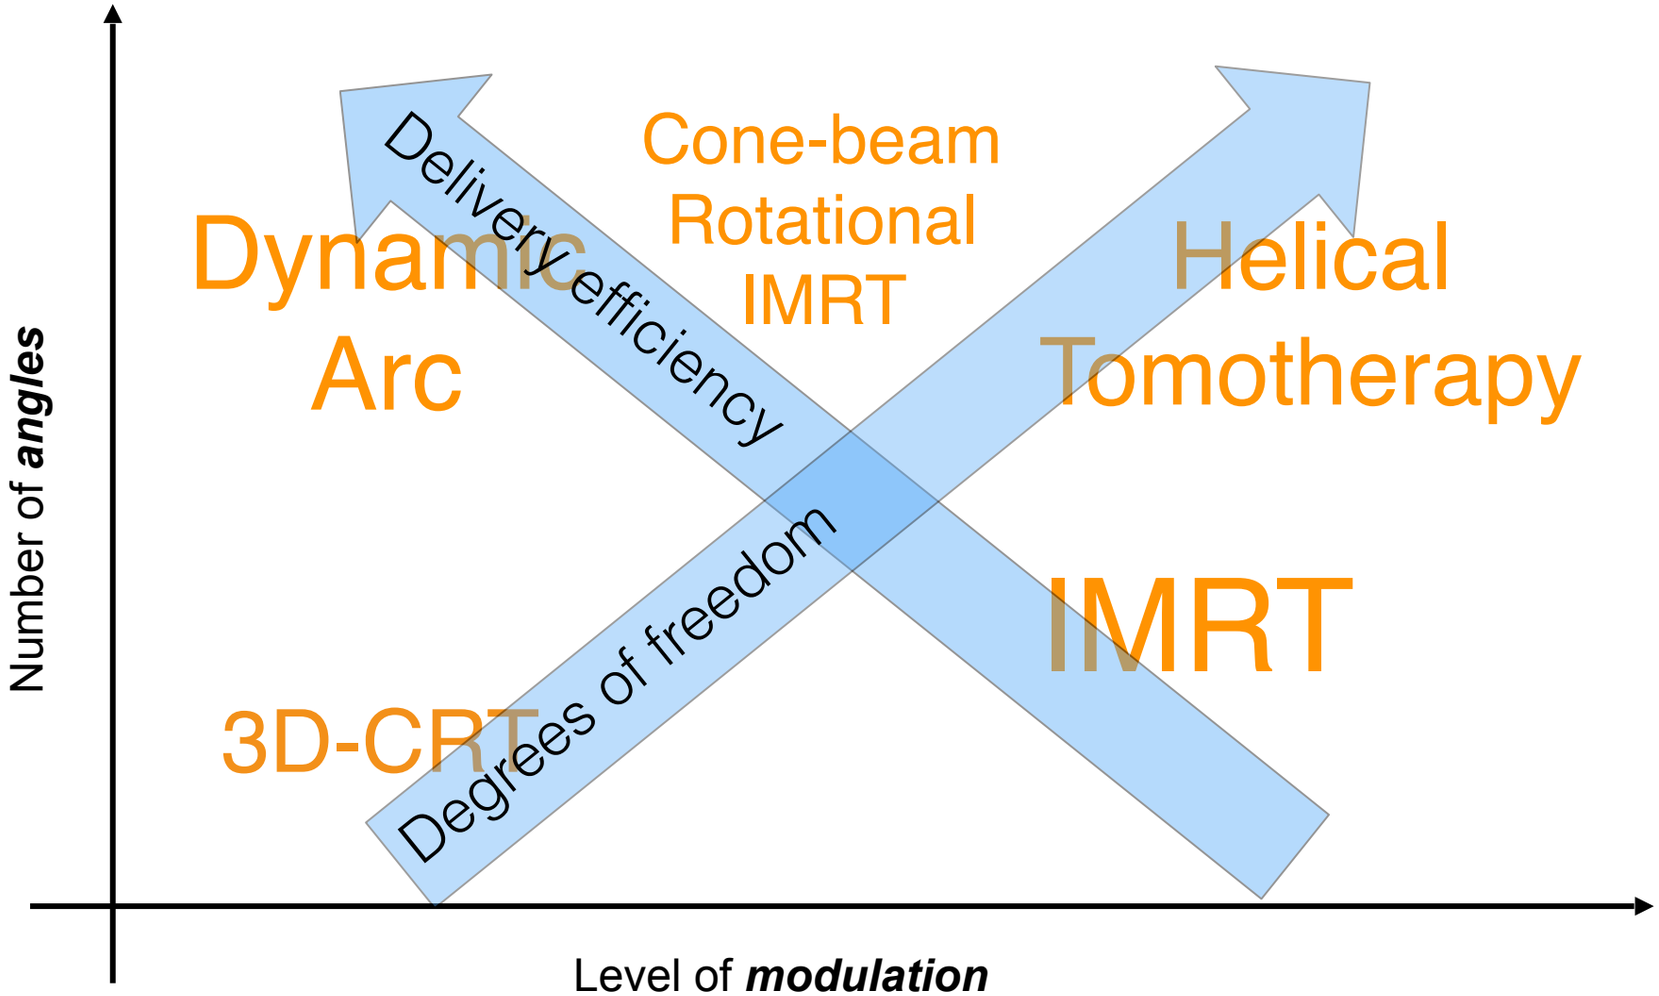
"Delivery times for standard IMRT using sliding window are much longer than for RapidArc for reasons which include the fact that

(1) no radiation is delivered during gantry rotation between fields,

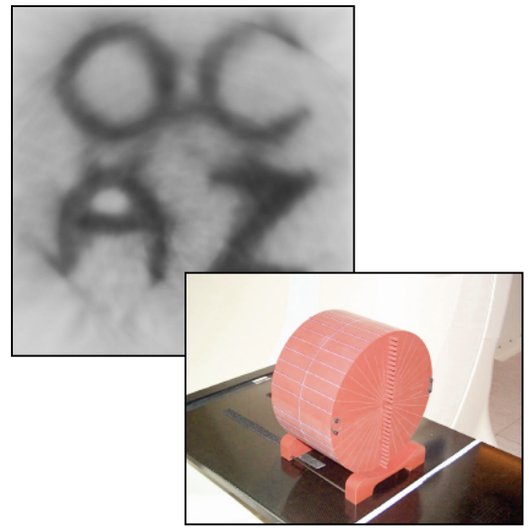
(2) multiple carriage groups are needed for large PTVs and

(3) time required for each field as complex fluence distributions require small leaf openings."

Treatment times : the trade-off



Axial slice



Tomotherapy

Verellen et al.

"High number of beam angles with moderate modulation seems to be more efficient in terms of delivery time on the current generation of treatment units"

Treatment times

➔ Conventional 3D CRT treatments usually take no more than a few minutes

- Low number of treatment beams

➔ IMRT delivery times range usually from 3 to 15 minutes BUT depending on:

- Machine type
- Delivery method (SMLC, DMLC, IMAT, VMAT, …)
- Amount of IMRT beams/segments
- Tumor complexity (Volume, surrounding OAR, …)
- Fraction size (hypofractionation schemes)

treatment times can increase to as long as 20 to 40 minutes

➔ Why are short treatment times preferable?

➔ Can Rotational IMRT techniques bring down the treatment times?

Treatment delivery time

Impact of treatment duration on:

➔ Hospital logistics, Economical aspect

➔ IGRT and intra-fraction motion

➔ Radiobiological efficiency loss

➔ ~~Secondary Cancers~~

cfr. Frank/Andrea

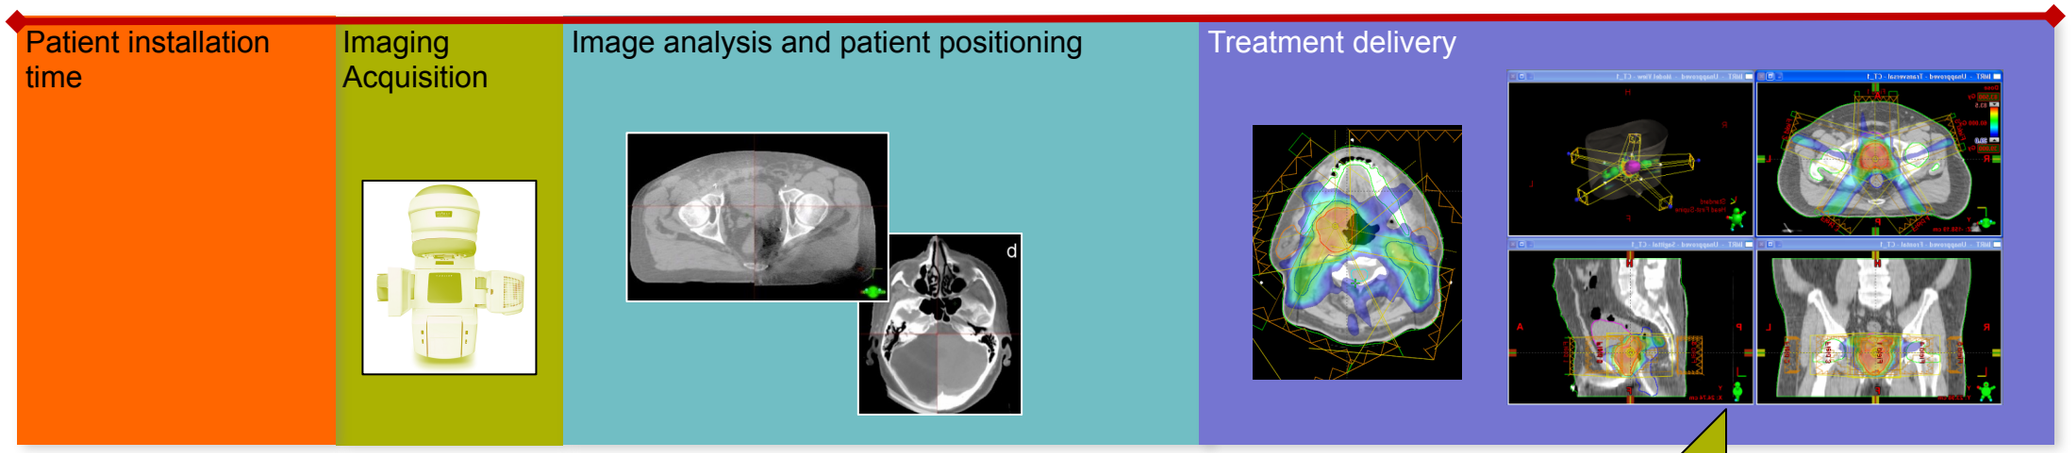
Treatment times : Delivery efficiency

Cozzi et al. :

"Faster treatments could have a clinical impact on single patients in terms of comfort on couch, immobility and minimisation of internal organ's displacement (e.g. bladder or rectum filling changes over time). This could increase the daily treatment quality and allows also more time for imaging procedures within standard time slots. In addition, faster treatments have an impact on the system throughput allowing the possibility to treat more patients per day, and to eventually reduce waiting list for selected groups of patients."

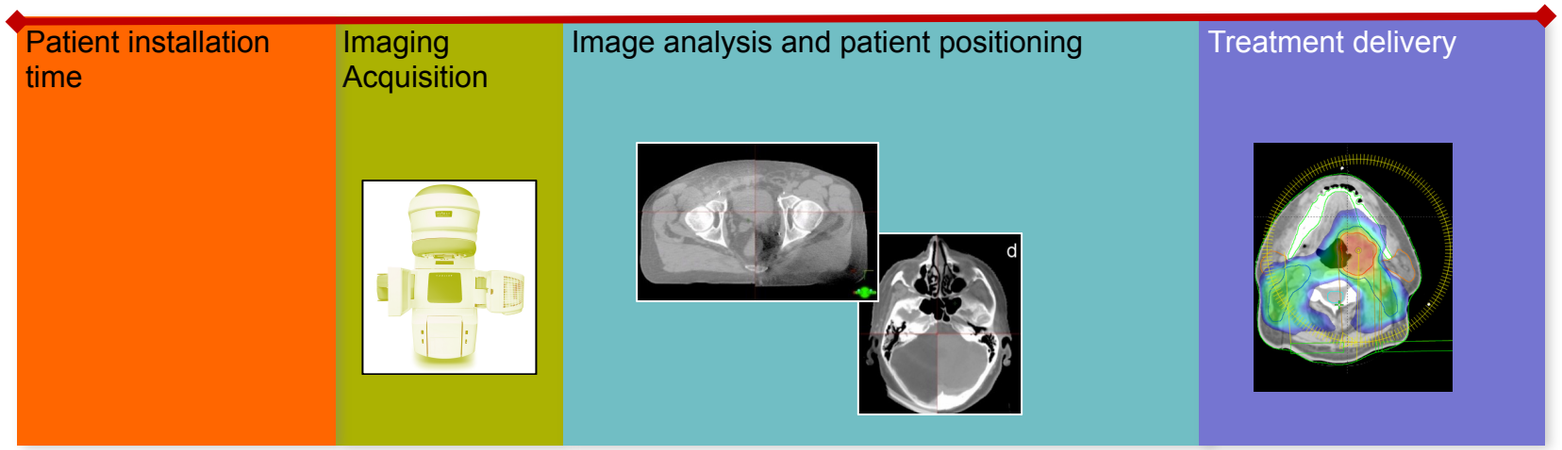
Delivery efficiency : treatment times and hospital logistics

Static Gantry IMRT workflow



20% reduction

VMAT/RA workflow



IMPORTANT:
"More efficient dose delivery **is NOT** more time for imaging and adaptation!"

Treatment delivery time

Impact of treatment duration on:

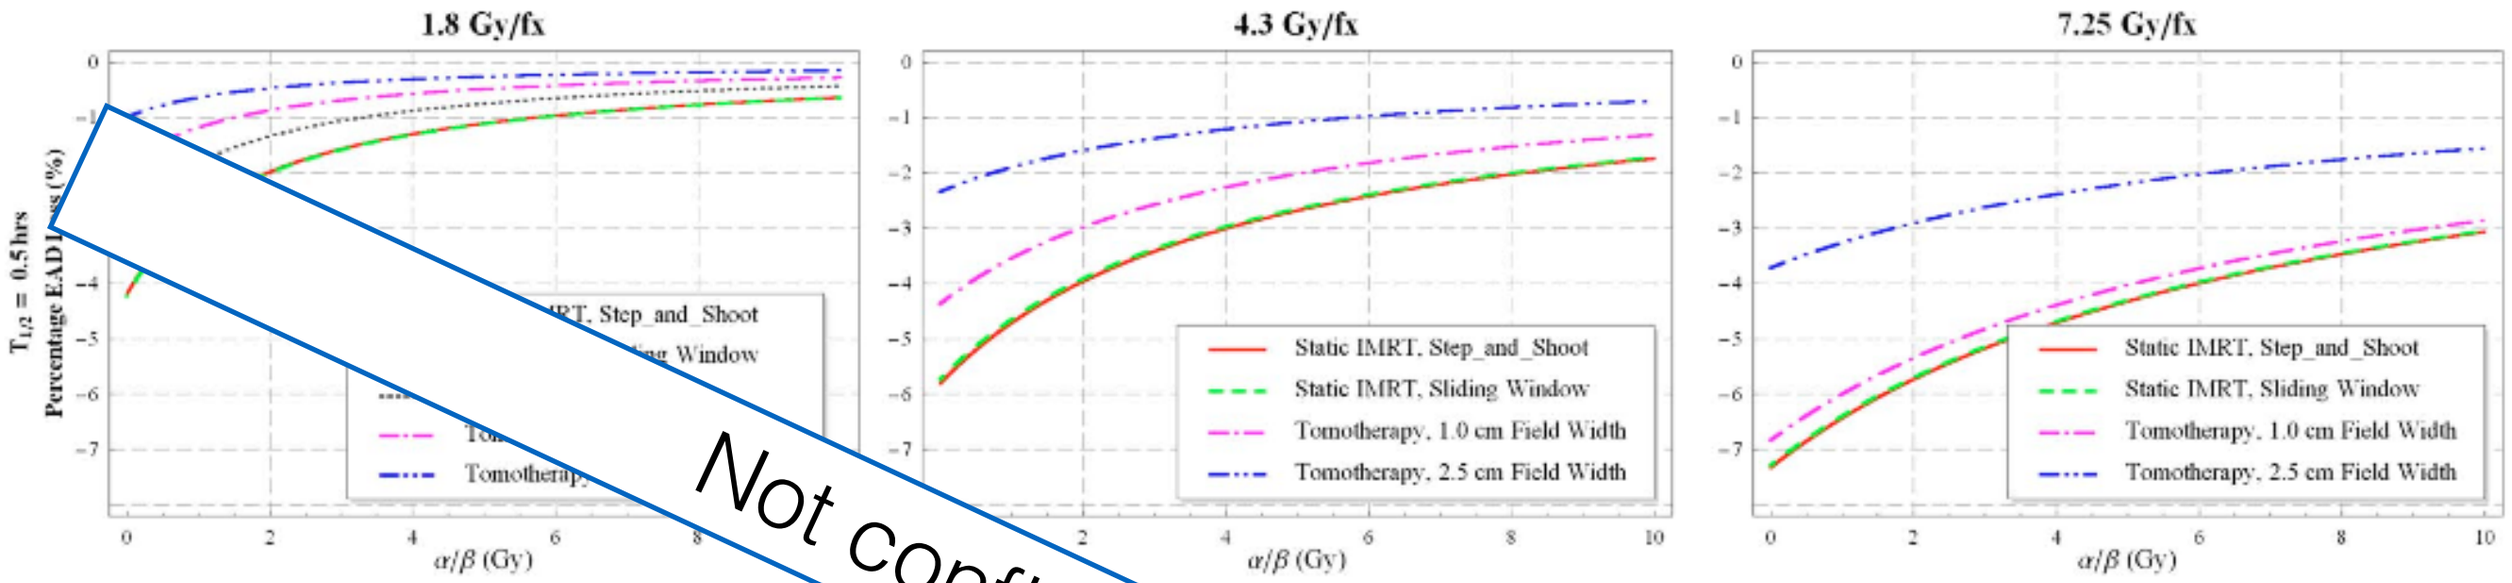
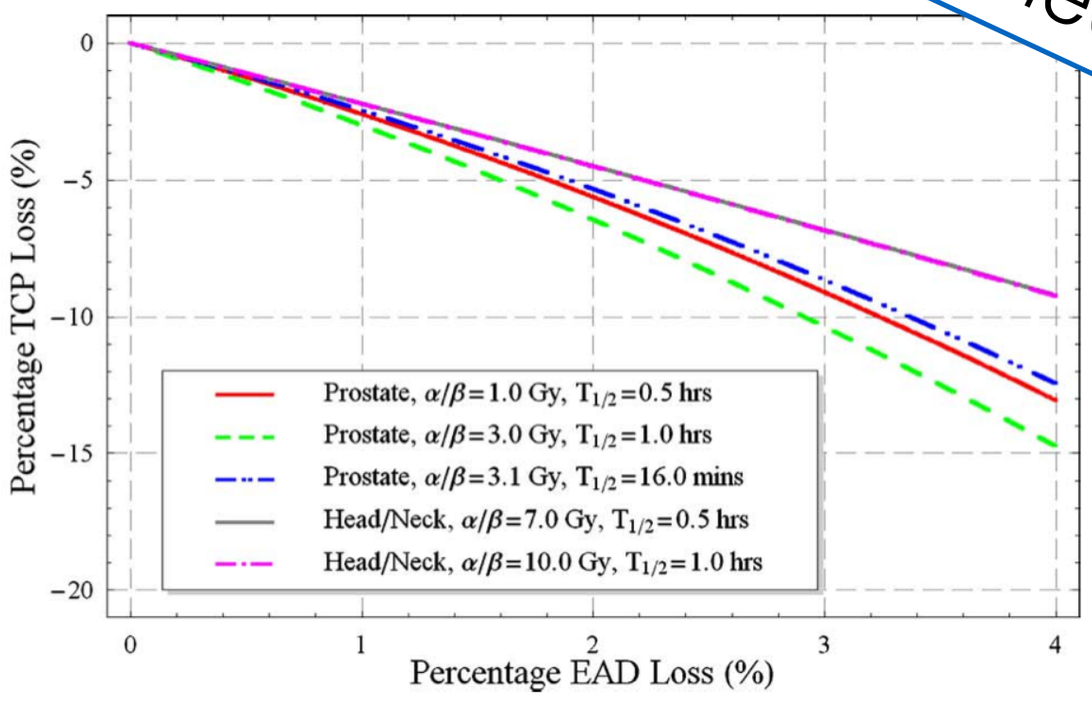
Biological model results





Not confirmed by clinical data

SMLC and DMLC IMRT delivery, for both
prost neck, the expected additional loss in
BED is abo ed to 3D CRT, which
corresponds to a –3% reduction in TCP.
For tomotherapy, the p ss is smaller in
comparison to 3D CRT; hen expect a TCP
increase of the order of 2%–3%. T ned
differences are due to the dose accumu

Shaikh et al. 2010

Shaikh et al. :

“Our analysis finds that helical tomotherapy treatments are generally superior to SMLC and DMLC treatment plans in this aspect due to the relatively rapid dose accumulation seen by a given target volume element.”

“… Newer rotational delivery techniques such as VMAT, which are capable of total treatment delivery times shorter than any of the techniques studied here, should be expected to result in similar biological effects to those from helical tomotherapy as presented here.”

“If the relationships between treatment time and biological effectiveness were accurately known for clinical situations, one could modify the prescription dose to compensate. Unfortunately, these relationships are not completely understood and depend on factors that are not accurately known (i.e., α / β ratios and repair half-times, etc.)

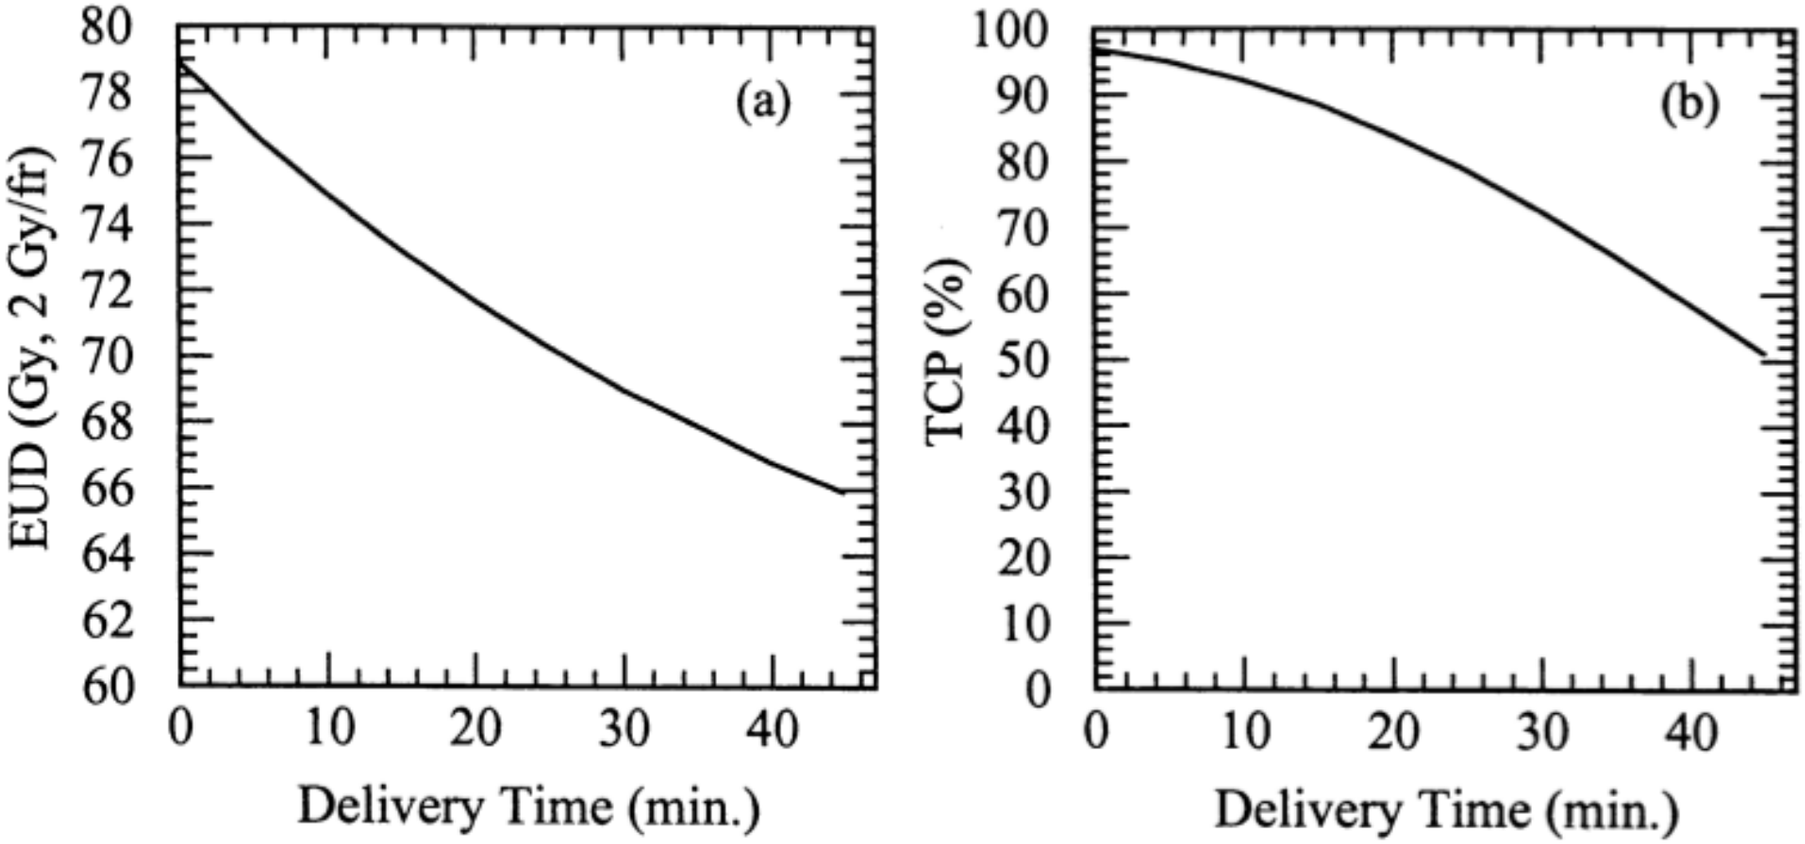


Fig. 5. (a) Equivalent uniform dose (EUD) and (b) tumor control probability (TCP) for an intermediate-risk patient group as a function of IMRT fraction delivery time for prostate cancer. The prescription dose is 81 Gy in 1.8 Gy fractions. Except where explicitly noted otherwise, the following LQ parameters were used in this study: $\alpha = 0.15\ \mathrm{Gy}^{-1}$, $\alpha/\beta = 3.1$ Gy, $T_r = 16$ min, and clonogen number $K = 3.0 \times 10^6$ (18).

Wang et al

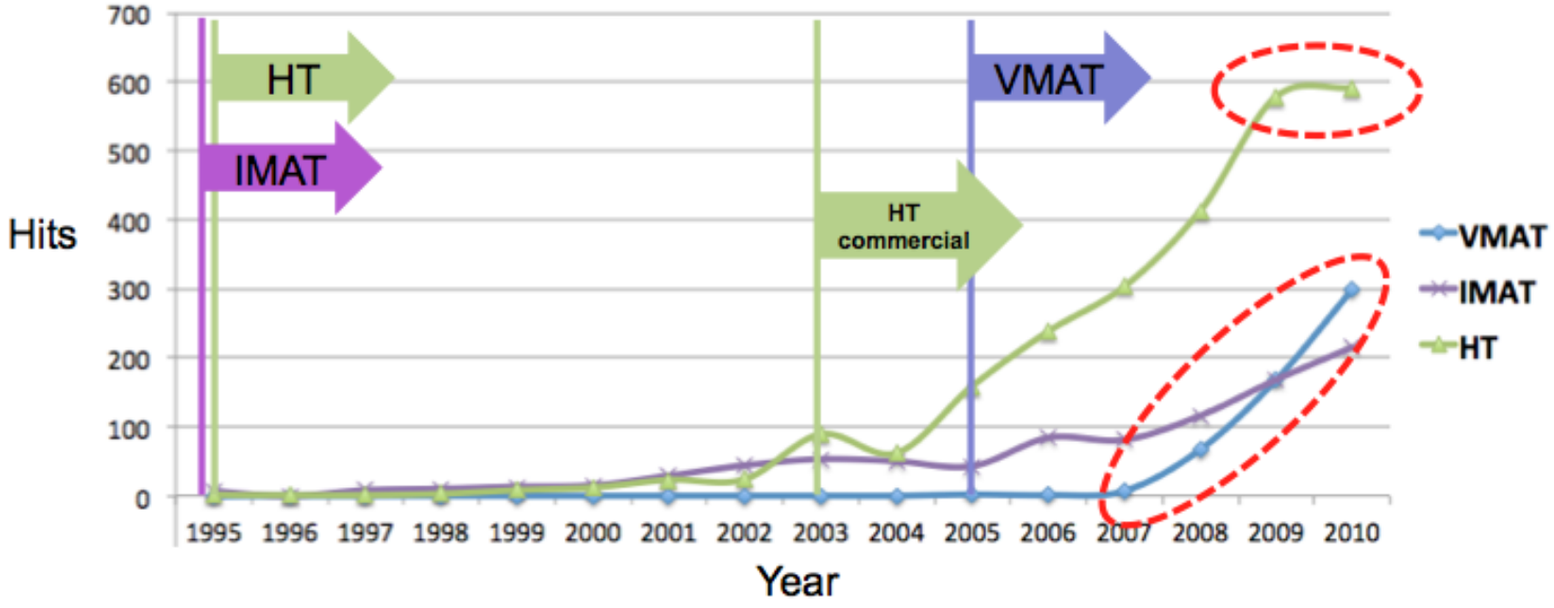
Biological efficiency loss and dose accumulation pattern

Shaikh et al. :

"Our analysis finds that helical **tomotherapy treatments are generally superior to SMLC and DMLC** treatment plans in this aspect due to the relatively **rapid dose accumulation** seen by a given target volume element."

"… Newer rotational delivery techniques such as **VMAT**, which are capable of total treatment delivery times **shorter than any of the techniques studied here**, should be expected to result in **similar biological effects to those from helical tomotherapy** as presented here."

"If the **relationships between treatment time and biological effectiveness** were accurately known for clinical situations, one could modify the prescription dose to compensate. Unfortunately, these relationships **are not completely understood and depend on factors that are not accurately known** (i.e., α / β ratios and repair half-times, etc.)



"Yes, commercial interest of some companies have boosted rotational therapy especially the HT, VMAT, RapidArc competition."

-For technical innovation on equipment level companies are an enabling partner having the required resources for engineering and manufacturing.

-Important is that we, radiation therapy professionals and users of this technology, remain cautious and critical toward newly introduced equipment and techniques. This way the commercial drive is controlled/restrained with a feedback loop and can be used to our and our patients advantage.

Should all IMRT be VMAT? or HT? or static IMRT?

- VMAT produces highly conformal dose distributions … like the other IMRT and HT. However, general superiority over other solutions has not been proven.
- After a period of extreme discussion on all fronts the dust has settled down and every department should make a choice according to needs, resources and indications.
- Reduction of treatment time may be "strongest" argument in making a difference between VMAT and the other solutions: more economical, intra-fraction motion, patient comfort, hypofractionation, … and if it would come with reduced biological efficiency loss that's even better.
- Both HT and VMAT have been upgraded and optimized since the era of the big discussion...

Examples

- HT
    - Dynamic jaws, limiting CC gradient
    - Speed and reliability updates
    - No biological optimization
    - ask you to learn to speak “tomo”
- VMAT
    - faster MLCs (6cm/s), probably no more need for ultra-small leaves
    - Higher doserates
    - In-treatment verification possible
    - TPS are getting better/faster/have biological optimization

Final conclusions

- Rotational therapy has gone mainstream.
- This has not made it the answer to life the universe and everything
- This has not made it any easier to implement, plan or QA
- In hospital economics, this time and effort should also be incorporated
- In planning:
  - Know your machine's limitations
  - Know and understand your optimizer and dose calculation
  - Don't treat it like a coffee machine
- Don't be afraid, be vigilant

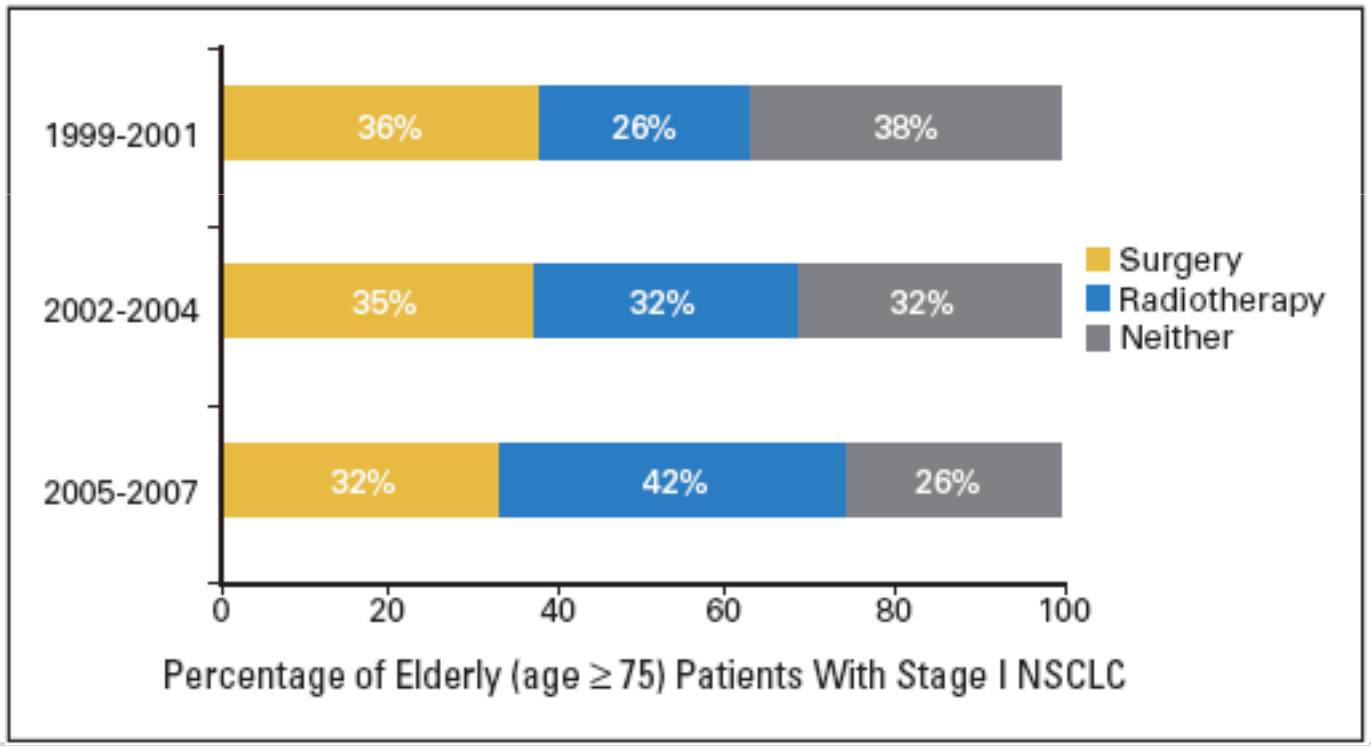
Impact of Introducing Stereotactic Lung Radiotherapy for Elderly Patients With Stage I Non–Small-Cell Lung Cancer: A Population-Based Time-Trend Analysis

David Palma, Otto Visser, Frank J. Lagerwaard, Jose Belderbos, Ben J. Slotman, and Suresh Senan



Palma DA et al, 2010

ESTRO School

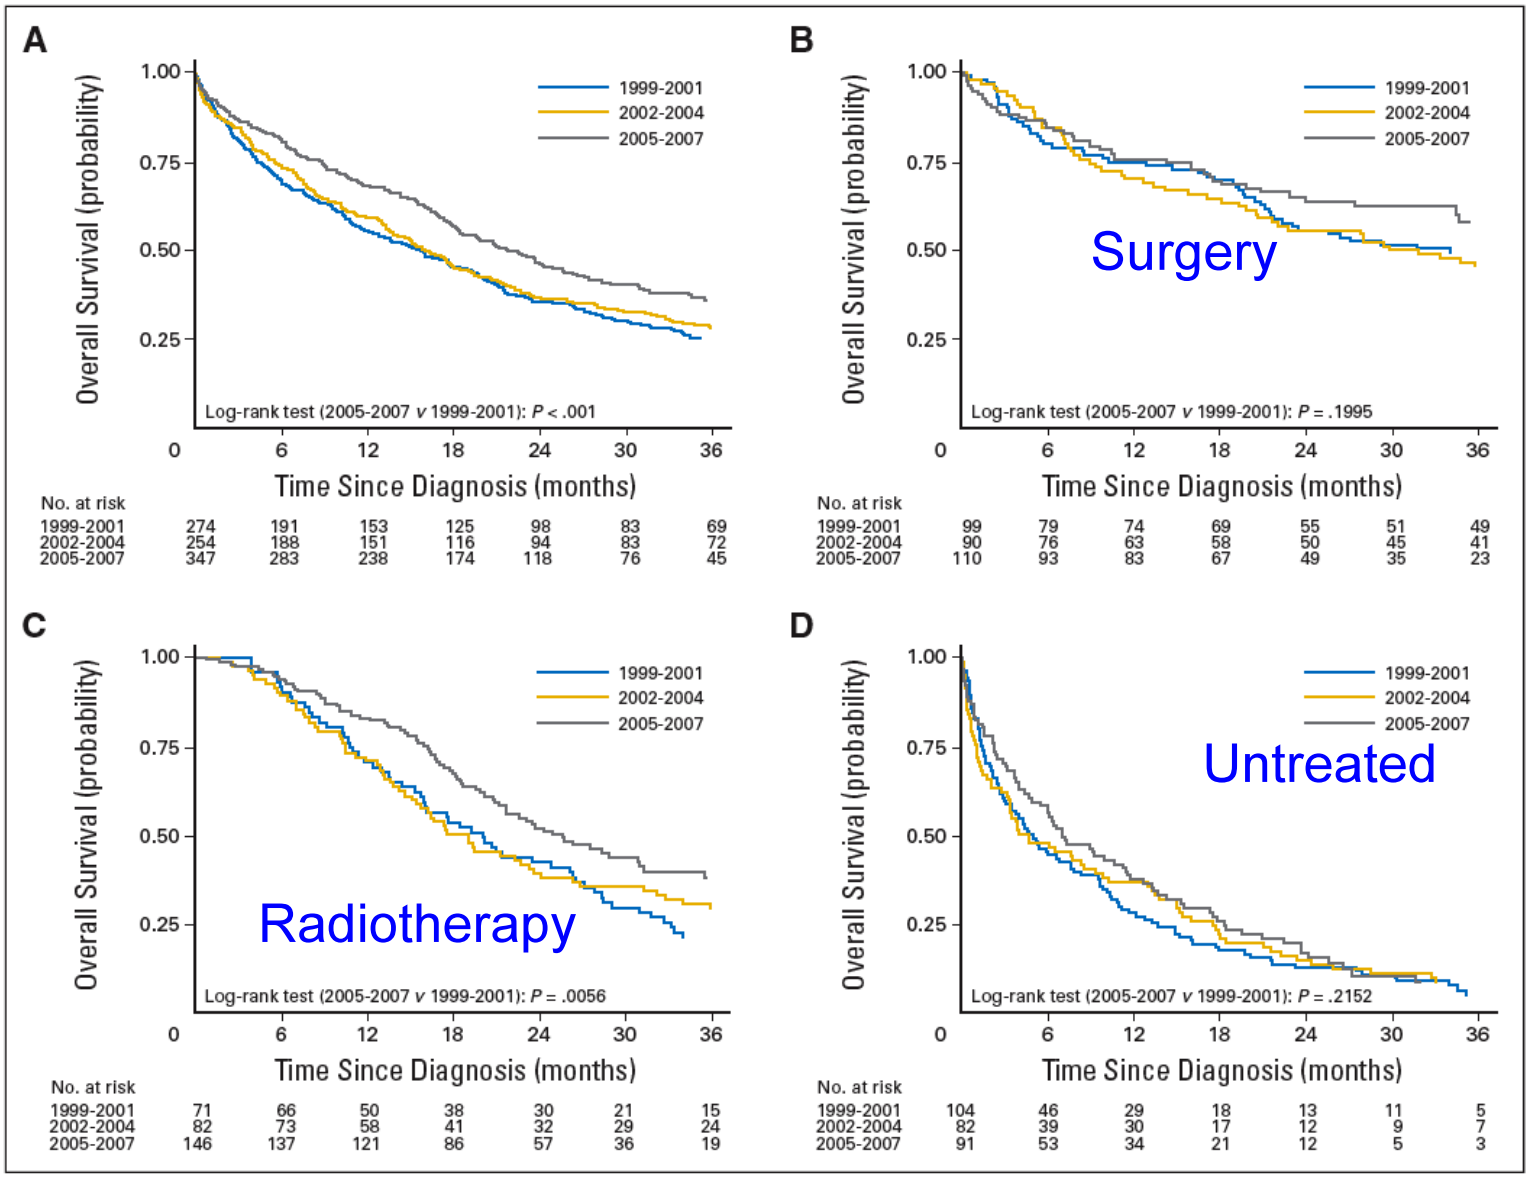


Fig 3. Overall survival for elderly (age ≥ 75 years) patients with stage I non–small-cell lung cancer by time period. (A) All patients; (B) patients treated with surgery; (C) patients treated with radiotherapy; (D) untreated patients.

Palma DA et al, 2010

ESTRO School

Pattern of failure following SBRT

	Local	Regional	Distant
Actuarial 2-year rates	4.9%	7.8%	14.7%
Actuarial 5-year rates	10.5%	12.7%	19.9%

	Median time to event
Local recurrence	14.9 months (95% CI 11.4-18.4)
Regional recurrence	13.1 months (95% CI 7.9-18.3)
Distant recurrence	9.6 months (95% CI 6.8-12.4)
2nd primary tumors	18 months (95% CI 12.5-23.5)

- Stage I-II NSCLC (2003-2011); median follow-up 32.9 months (IQR 14.9 - 50.9);
- 66% of recurrences were distant (DR); isolated DR made up 46% of recurrences

ESTRO School

SABR is well tolerated: toxicity is uncommon

Summary of common toxicity after SBRT for stage I Lung Cancer.

Toxicity	Incidence
Radiation pneumonities	≥G3: 4–8% (12–15% in pulmonary fibrosis)
Chest wall pain	11–15% (2–3% rib fractures)
Skin toxicity	4–6% (<1% skin ulceration)
Brachial plexophaty	Rare
Fatal bleeding	Rare (but 2–3% in centrally located tumours)
Late radiological changes	50–80%

Ricardi, Badellino, Filippi, Lung Cancer 2015

SBRT and severe COPD?

Systematic Review: Eligible patients had to have GOLD III-IV or a predicted postoperative FEV_1 of ≤40%

Table 3. Thirty-day mortality and complications associated with treatment of stage I NSCLC in patients with poor ventilatory function

First author	30-day mortality	Complications
Surgery		
Magdeleinat (26)	8%*	>90% admitted to ICU >45% with complications (pneumonia, air leak, and arrhythmia most common)
Lau (19)	25% after open lobectomy* 7% for open segmentectomy or VATS procedure*	Median hospital stay 8–12 days <10% admitted to ICU
SBRT		
Henderson (27)	0%*	>69% with Grade 1 or 2 toxicity of some kind†
Stephans (28)	0%*	No Grade 3 or higher pneumonitis
Palma (current study)	0%	6 patients (3%) with Grade 3 toxicity

Abbreviations: ICU = intensive care unit; VATS = video-assisted thoracoscopic surgery.
* Denotes values measured from Kaplan-Meier curves.
† 8% Grade 3–4 toxicity with some late deaths related to treatment of central tumors in larger Phase II study, but these rates not specified for subgroup with poor pulmonary function.

ESTRO School

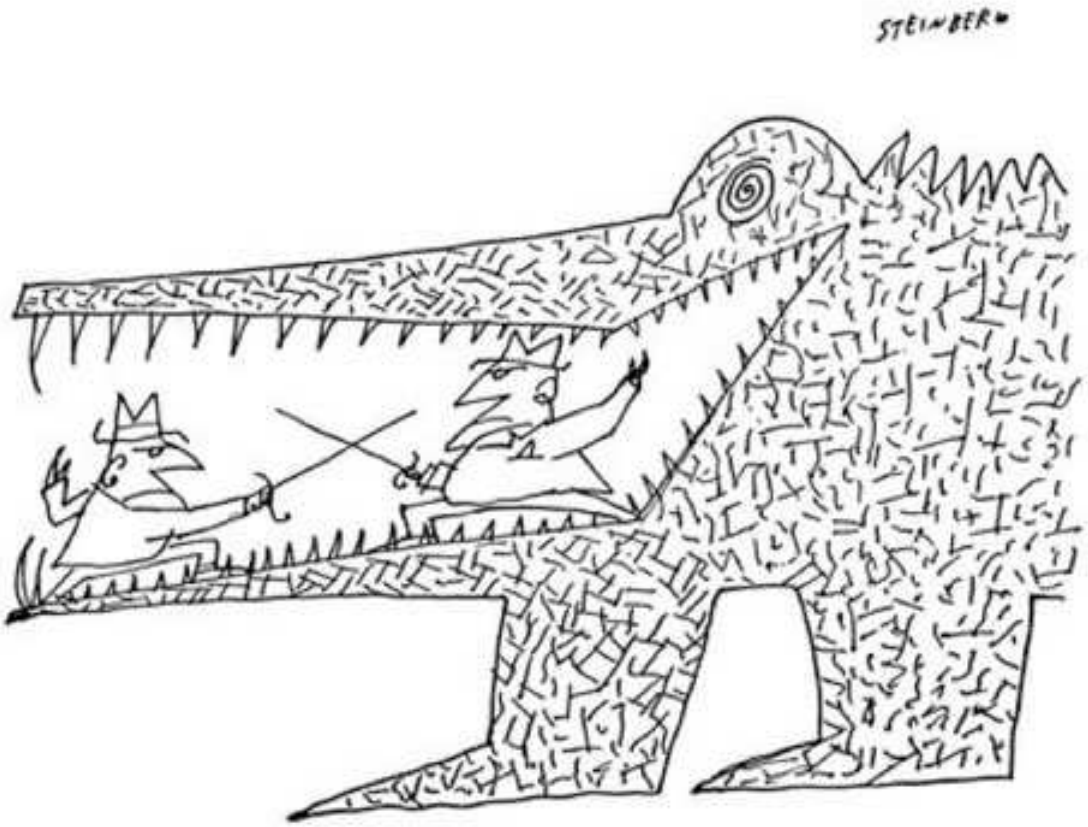
Better outcome for surgery after 3 years:

- optimal lymph node staging: adjuvant therapy
- still some differences between the two groups:
  - matching was done with only a limited number of variables
  - (i.e., staging procedure not included as covariate)
- respiratory failure over time (RILI)
- unable to provide CSS rates

SABR vs SURGERY: randomized trials?



ESTRO School

Trials of surgery versus SABR

Table 1 – Approved Phase III Randomized Trials of Operable Stage I NSCLC Patients (all prematurely terminated due to poor accrual)

Dutch ROSEL trial, NCT00687986, "Randomized Clinical Trial of Stereotactic Radiotherapy or Surgery in Patients with Stage IA Non-Small Cell Lung Cancer who are fit to undergo Primary Resection".

- Sponsored by the The Netherlands Organisation for Health Research and Development.
- Opened at 9 centers
- Opened 2008, Closed 2010
- Enrolled 22 of 960

STARS Trial, NCT00840749, "Randomized Study to Compare CyberKnife to Surgical Resection in Stage I Non-small Cell Lung Cancer"

- Sponsored by Accuray©
- Opened at 15 centers
- Opened 2009, Closed 2013
- Enrolled 36 of 1,030 patients

ACOSOG-Z4099/RTOG-1021, NCT01336894, "A Randomized Phase III Study of Sublobar Resection (+/- Brachytherapy) versus Stereotactic Body Radiation Therapy in High Risk Patients with Stage I Non-Small Cell Lung Cancer (NSCLC)"

- Sponsored by American College of Surgeons
- Opened at 53 centers
- Opened 2011, Closed 2013
- Enrolled 10 of 420 patients

Data are n (%) unless otherwise stated. SABR=stereotactic ablative radiotherapy. *Histology of six of the 14 tumours of unknown histology was confirmed after surgery in the ROSEL study (three adenocarcinoma, one bronchiolalveolar carcinoma, one squamous-cell carcinoma, and one benign disease); eight tumours in the SABR group had unknown histology in the ROSEL study.

***Table*: Patient characteristics**

- ✓ **Any difference** in age, sex, PS, histology, T stage or tumour location
- ✓ **Median follow up** was 40,2 months in SABR group and 35.4 months in surgery group
- ✓ All stage I NSCLC and were operable for lobectomy with PS 0-2
- ✓ **TC-PET** for staging
- ✓ **20 patients lobectomies,** 5 video-assisted thoracotomy lobectomies, 1 video-assisted thoracotomy biopsy, 1 aborted resection during surgery due to disease progression
- ✓ **STARS:** 16 patients peripherally lesions 54 Gy/3 fr; 4 patients central lesions 50 Gy/4 fr
- ✓ **ROSEL:** 6 patients 54 Gy/3 fr in 5-8 days, 5 patients 60 Gy/5 fr in 10-14 days

ESTRO School

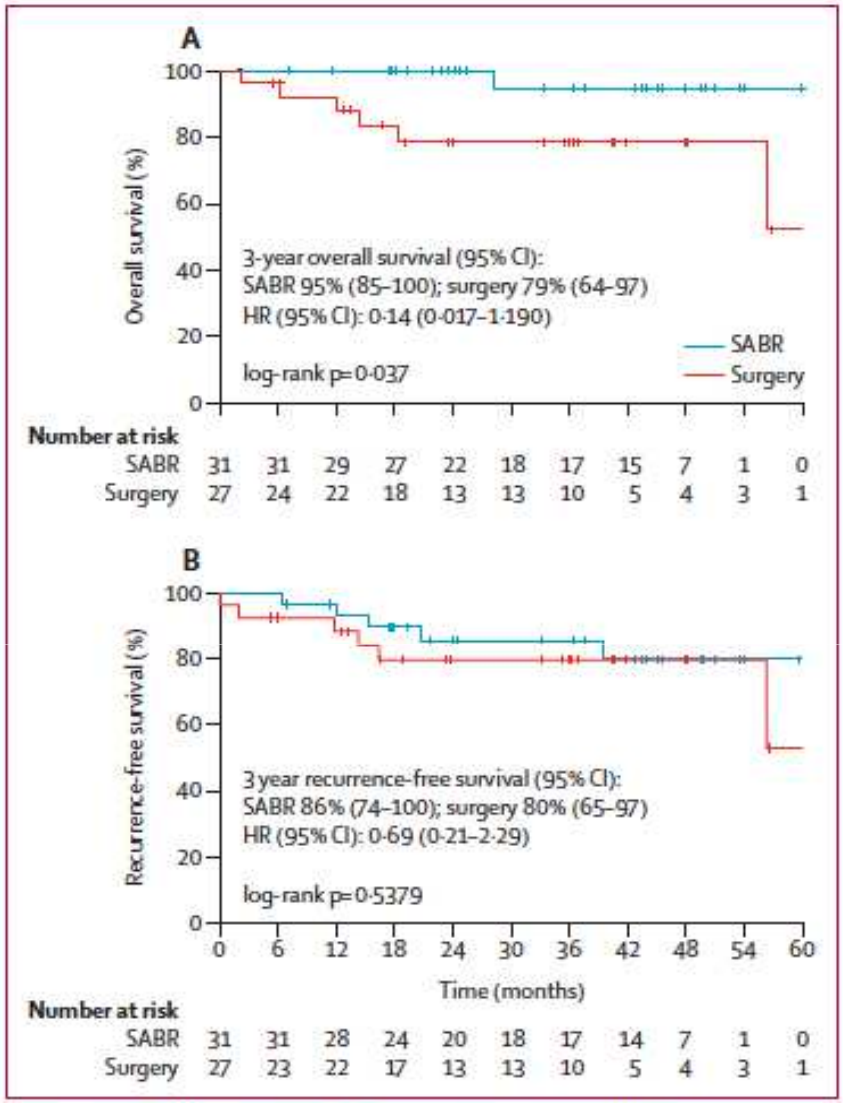

Figure 2: **Overall survival (A) and recurrence-free survival (B)**
One patient died and five had recurrence in the SABR group compared with six and six patients, respectively, in the surgery group. SABR=stereotactic ablative radiotherapy. HR=hazard ratio.

- ✓ **Pooled estimated OS at 1 and 3 years** was **100% and 95% in SABR group; 88% and 79% in surgical group**
- ✓ **Difference in OS** between the two groups was statistically significant
- ✓ This difference in OS is significant in STARS alone but not in ROSEL alone
- ✓ **7 patients died:** 6 in surgery group (2 PD, 1 secondary primary lung cancer, 1 surgical adverse event, 2 comorbidities) and 1 in SABR group (PD)

Table 1. Dosimetric limits for thoracic organs at risk

Dose limits for OARs	3D-CRT (RTOG 0617)	3D-CRT (RTOG 0972/CALGB 36050)	SBRT (RTOG 0618, 3 fx)	SBRT (ROSEL European trial, 3 or 5 fx)
Spinal cord (point dose)	Point dose ≤50.5 Gy	Any portion ≤50 Gy	≤18 Gy (6 Gy/fx)	18 Gy (3 fx) 25 Gy (5fx)
Lung	Mean lung dose ≤20 Gy, V_{20} ≤37%	V_{20} ≤35%	V_{20} ≤10%*	V_{20} <5–10%†
Esophagus	Mean dose ≤34 Gy	Not limited	≤27 Gy (9 Gy/fx)	24 Gy (3 fx) 27 Gy (5 fx)
Brachial plexus (point dose)	≤66 Gy	Not limited	≤24 Gy (8 Gy/fx)	24 Gy (3 fx) 27 Gy (5 fx)
Heart‡	≤60, ≤45, ≤40 Gy for 1/3, 2/3, 3/3 of heart	≤60, ≤45, ≤40 Gy for 1/3, 2/3, 3/3 of heart	≤30 Gy (10 Gy/fx)	24 Gy (3 fx) 27 Gy (5 fx)
Trachea, bronchus	Not limited	Not limited	≤30 Gy (10 Gy/fx)	30 Gy (3 fx) 32 Gy (5 fx)
Ribs	Not limited	Not limited	Not limited§	Not limited
Skin	Not limited	Not limited	≤24 Gy (8 Gy/fx)	Not limited

Abbreviations: OARs = organs at risk; 3D-CRT = three-dimensional conformal radiotherapy; RTOG = Radiation Therapy Oncology Group; CALGB = Cancer and Leukemia Group B; SBRT = stereotactic body radiotherapy; ROSEL = *Radiosurgery Or Surgery for Early Lung Cancer*; fx = fraction; V_{20} = percentage of both lungs (without inclusion of gross tumor volume) receiving ≥20 Gy.

* Other constraints limited dose within 2 cm of target.

† V_{20} ≤5% for tumor ≤2 cm, V_{20} ≤5% for tumor 2–5 cm.

ESTRO School

Final Remarks

- SBRT is currently widely accepted as the best alternative to surgery for inoperable early stage lung cancer
- SBRT might be offered also to operable patients
- IGRT-motion management are essential for prescribing high BED: IMRT is an option
- Mature data with long-term follow up are needed to better understand the pattern of relapse across time
- Predictive and prognostic factors are needed to possibly offer to higher risk patients adjuvant therapies

Literature overview plus some VERY SUBJECTIVE COMMENTARIES!!

Clinical Application of IMRT

Most important indications and treatment philosophy

1. **Head and Neck Cancer**
   CNS

   Paranasal Sinus Tumors / Integrated Boost
   (Better Tumor coverage and shortening of overall treatment time)

   NPC and other ENT Tumors
   (Parotid sparing when possible, better tumor coverage for NPC)

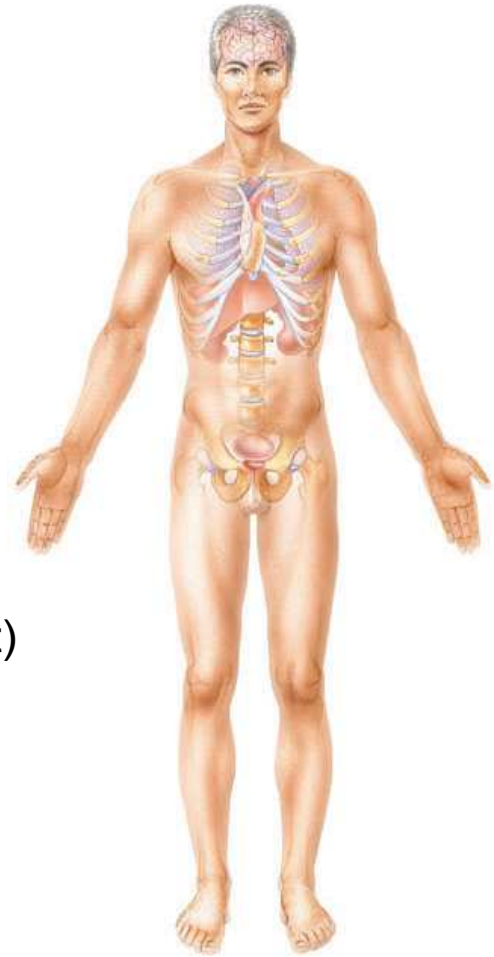
2. **Prostate / Integrated boost**
   (Potentially hypofractionation)

3. **Gastric cancer**
   (Better kidney sparing while treating the whole of the target)

4. **Breast Cancer**

5. **Lung Cancer**

6. **Metastases**



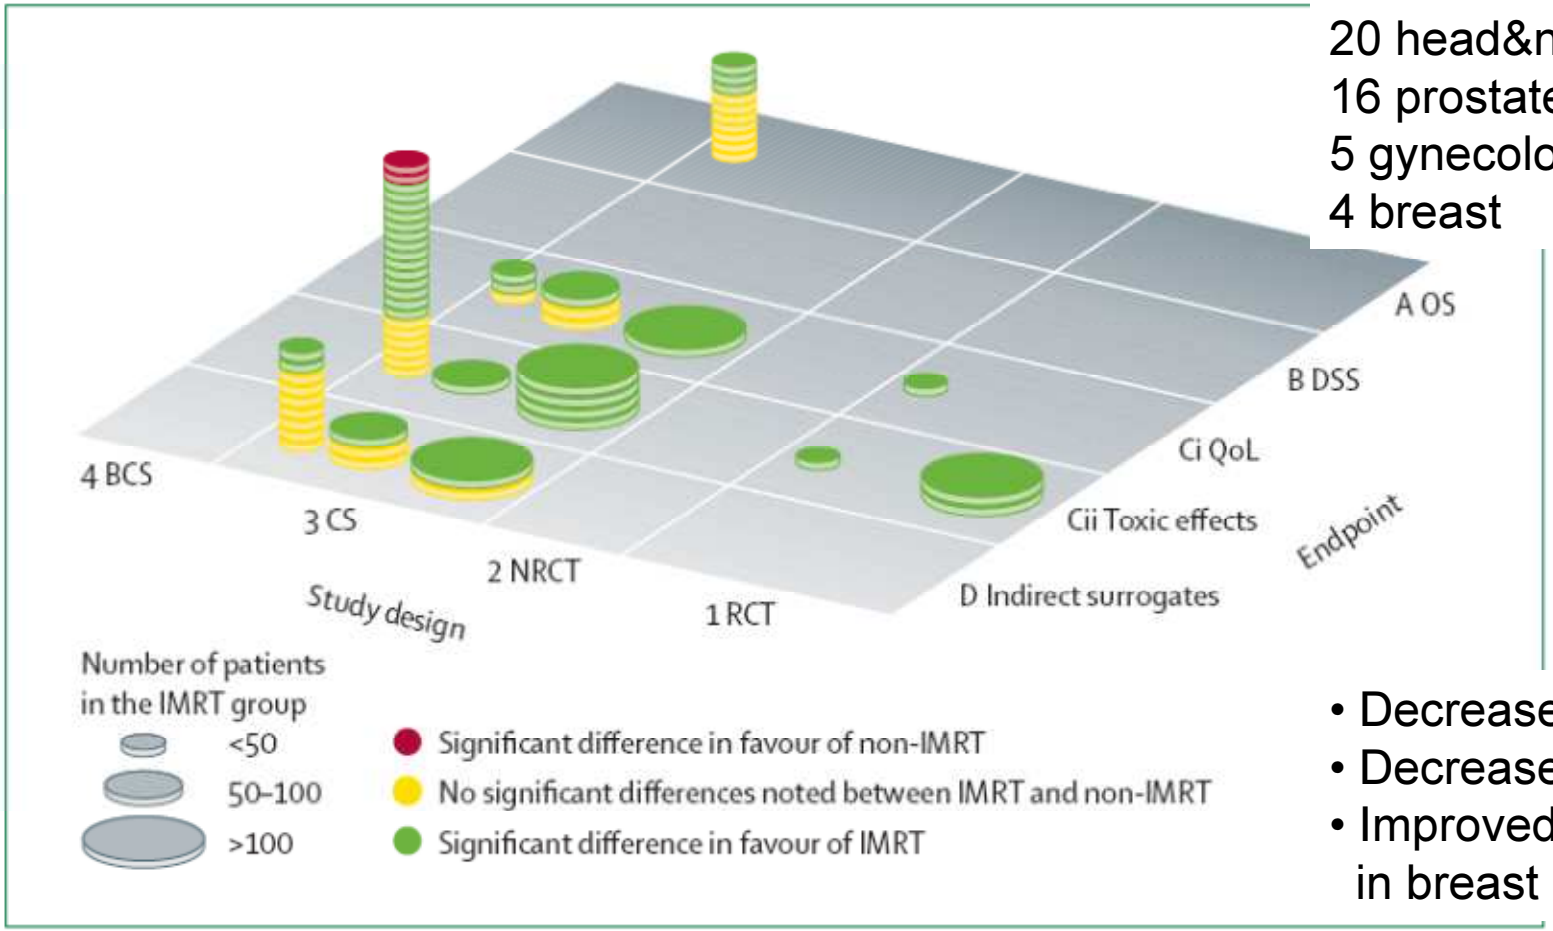
Evidence behind use of intensity-modulated radiotherapy: a systematic review of comparative clinical studies

Liv Veldeman, Indira Madani, Frank Hulstaert, Gert De Meerleer, Marc Mareel, Wilfried De Neve

Lancet Oncol 2008; 9: 367–375

56 studies/reports

20 head&neck	3 lung
16 prostate	5 GI
5 gynecological	3 CNS
4 breast	



- Decreased xerostomia
- Decreased rectal toxicity
- Improved cosmesis in breast cancer

Figure 3: **Evaluation tool for relevance of clinical statements reported in 56 studies of IMRT**
BCS=best case series. CS=case series. NRCT=non-randomised controlled trial. RCT=randomised controlled trial. OS=overall survival. DSS=disease-specific survival. QoL=quality of life.

IMRT clinical outcome

Factors influencing the rational use of IMRT for head-and-neck cancer

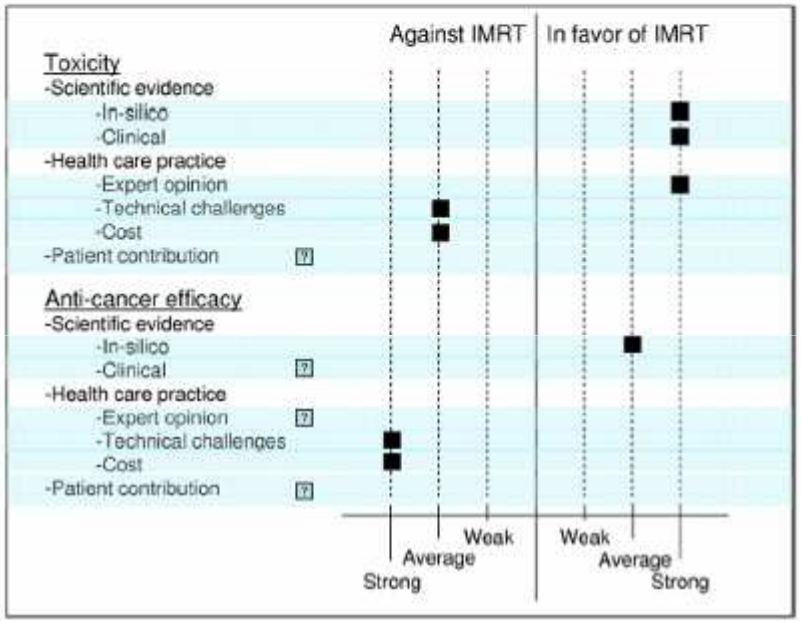


Figure 1 Factors in favor or against IMRT are represented by a rectangle on the right or on the left of the vertical solid line, respectively. A question mark inside a rectangle indicates too much uncertainty for using the factor in the graph.

Factors influencing the rational use of IMRT for whole breast irradiation

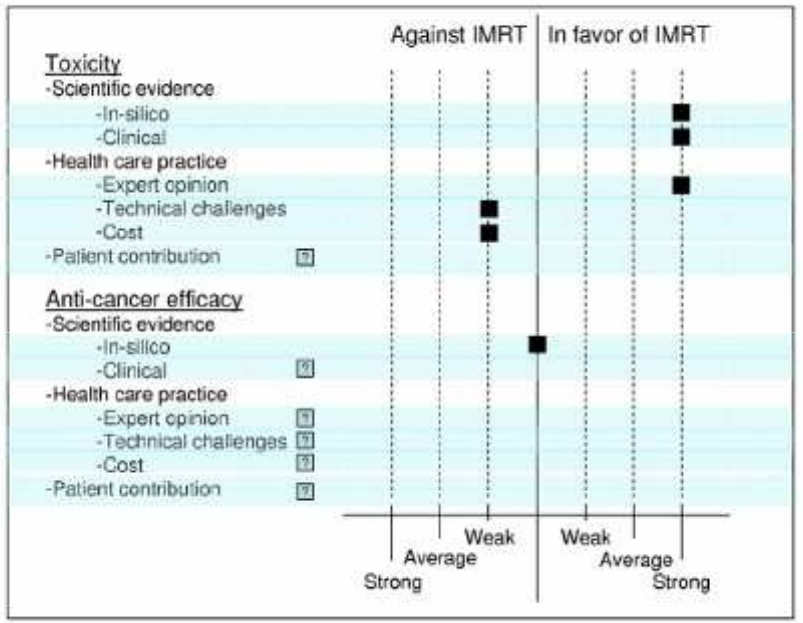

Figure 2 Factors in favor or against IMRT are represented by a rectangle on the right or on the left of the vertical solid line, respectively. A question mark inside a rectangle indicates too much uncertainty for using the factor in the graph.

Virtual Bolus

Strahlentherapie
und Onkologie

Originalarbeit

Virtueller Bolus zur inversen Bestrahlungsplanung bei intensitätsmodulierter Radiotherapie des Mammakarzinoms im Rahmen der adjuvanten Therapie

Christoph Thilmann[1], Karl Heinz Grosser[1], Bernhard Rhein[1], Angelika Zabel[1], Michael Wannenmacher[2], Jürgen Debus[1,2]

Abbildung 1. Festlegung von Bolus und CTV zur inversen Optimierung: Der Bolus wird nur zur inversen Bestrahlungsplanung verwendet. Die abschließende Dosisberechnung und auch die Bestrahlung erfolgen ohne Bolus: a) Bolus der Dicke von 10 mm (Dichte = –60 HE); b) CTV gemäß EORTC.

Fragestellung: Die intensitätsmodulierte Strahlenbehandlung (IMRT) verspricht eine verbesserte Schonung von Risikostrukturen. Wir untersuchten, in welcher Form eine inverse Bestrahlungsplanung zur IMRT der Restbrust beim Mammakarzinom durchführbar ist.

Methodik: Neben einer Bestrahlungsplanung in konventioneller Technik mit tangentialen 6-MV-Keilfilter-Feldern wurde eine IMRT-Bestrahlungsplanung mit inverser Planoptimierung (KonRad®) durchgeführt. Im Planungs-CT wurde ein Bolus von 10 mm Dicke und einer Dichte von –60 HE definiert. Der Einfluss des Bolus auf die Planoptimierung wurde bestimmt, indem die Optimierung ohne Bolus, die nachfolgende Dosisberechnung ohne und mit Bolus durchgeführt wurden. Um den Einfluss des Bolus auf die Dosisberechnung zu bestimmen, erfolgte nach Optimierung mit Bolus eine Dosisberechnung ohne Bolus und mit verschiedenen Bolusdicken. Die Planungsergebnisse wurden jeweils mit der Dosisverteilung einer konventionellen Bestrahlung verglichen.

Ergebnisse: Die inverse Planungsoptimierung mit einem Dosisalgorithmus, der Gewebeinhomogenitäten berücksichtigt, führt zu einer erhöhten Hautbelastung. Diese lässt sich reduzieren, indem man ausschließlich zur inversen Optimierung einen Hilfsbolus verwendet. Es lässt sich damit eine Hautschonung entsprechend der konventionellen Therapie erreichen. Die Relativdosisverteilung bleibt von der Verwendung des Bolus bei einer Dicke von 10 mm weitgehend unbeeinflusst. Die Absolutdosis unterscheidet sich bei Dosisberechnung mit und ohne Bolus um 3,4%. Daher muss der Bolus im Sinne eines virtuellen Bolus vor der abschließenden Dosisberechnung wieder entfernt werden.

Schlussfolgerungen: Zur inversen Optimierung einer IMRT der Restbrust ist ein virtueller Bolus erforderlich. Damit ist eine IMRT-Bestrahlung gemäß Konsensus von EORTC, BCCG und EUSOMA (1991) möglich. Insbesondere kann die gleiche Zielvolumendefinition wie bei der konventionellen Therapie verwendet werden. Es sind hiermit IMRT-Techniken in konventioneller Feldgeometrie und in Vielfeldertechnik realisierbar.

Schlüsselwörter: Mammakarzinom · IMRT · Inverse Bestrahlungsplanung

IMRT vs. VMAT

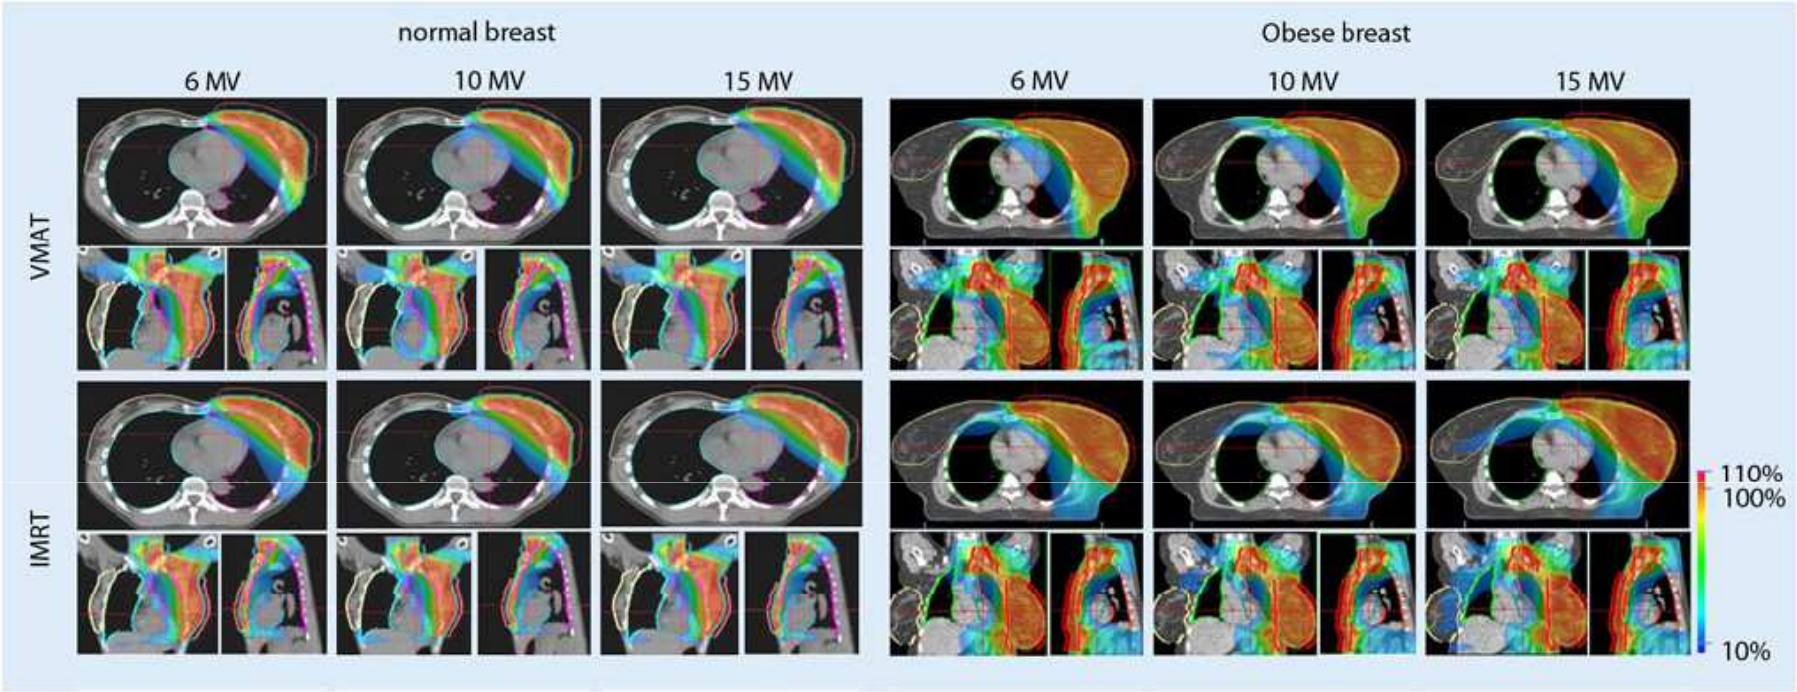

Fig. 2 ▲ Sample isodose distributions in transverse, coronal and sagittal planes (ArtiView™) for VMAT and IMRT plans of a normal (*left*) and an obese (*right*) patient at 6, 10 and 15 MV

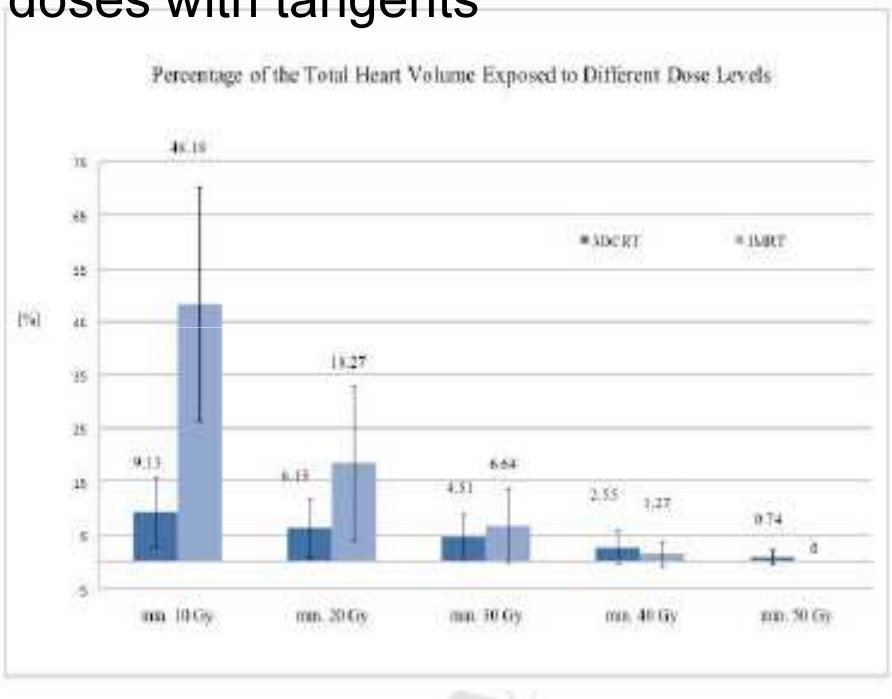
Pasler et al., SUON, 2013

First clinical data

Heggemann et al., IJROBP, 2015

- 3D-CRT in Patients with small heart volumes irradiated with tangents
- IMRT in Patients that would have had large volumes irradiated to high doses with tangents



-Noisy data
-In both groups temporary depression of heart function parameters
-In both groups recovery at 2 years
-No relevatn difference between groups

Mean Heart dose is potentially not the best parameter
(ASTRO 2015: in RTOG 0617 V45 was the best predictor…….)

A Population-Based Case–Control Study

Effect of low doses of ionising radiation in infancy on cognitive function in adulthood: Swedish population based cohort study

Per Hall, Hans-Olov Adami, Dimitrios Trichopoulos, Nancy L Pedersen, Pagona Lagiou, Anders Ekbom, Martin Ingvar, Marie Lundell, Fredrik Granath

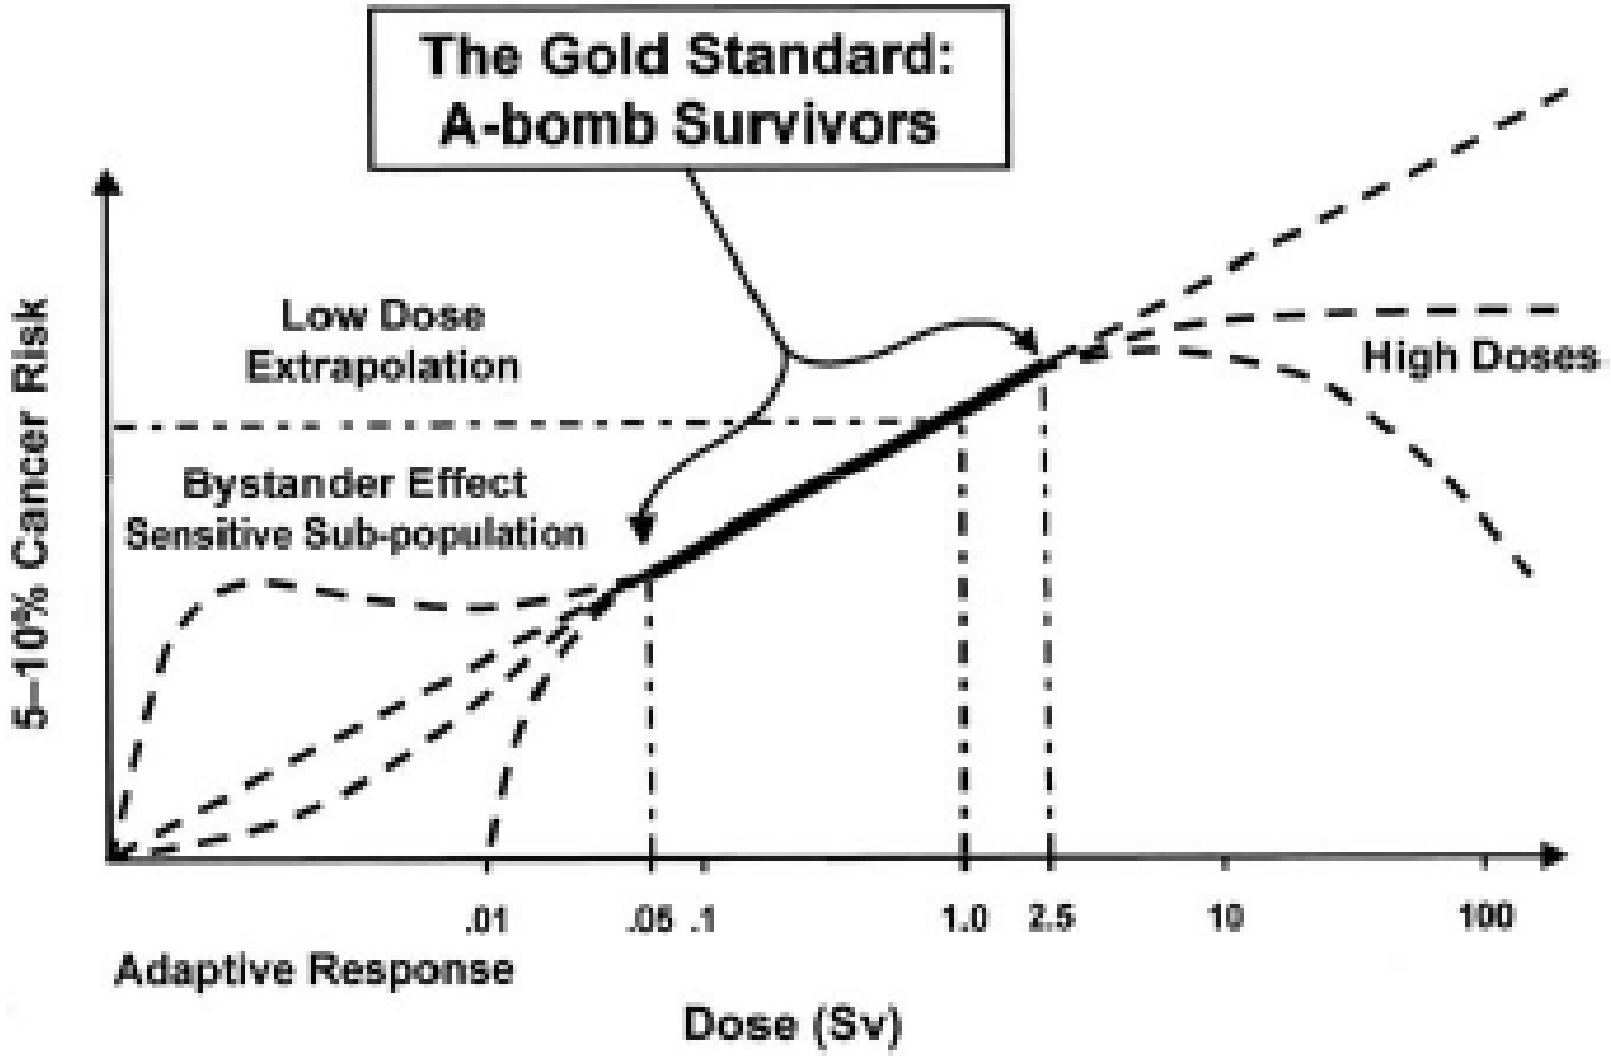
BMJ VOLUME 328 3 JANUARY 2004 bmj.com

Risk estimates for secondary cancer after exposure to ionizing radiation

1. Low dose estimates (0-2 Gy single dose exposure, based on the Atomic Bomb Survivor Study (Life Span Study, LSS), that forms the basis for the Biological Effects of Ionizing Radiation (BEIR VII model)

2. High dose estimates (>2 or >5 Gy, based on clinical follow up data after radiotherapy for benign or malignant disease

Different Aspects of Carcinogenesis - Synopsis



Problems identifying true incidence numbers of secondary cancer after exposure to ionizing radiation

1. Low dose Estimates (LSS):

- Low number of events
- Uncertain Dosimetry
- Unclear effects of other toxins
- Difficulties to maintain long follow up
- Very limited dose range (limited by acute lethalty of exposure and explosion force to 0-2 Gy with emphasis on <1 Gy)

2. High dose Estimates (clinical)

- Low number of events
- Combination Therapies
- Information on precise localization and doses at the site of second malignancies hard to obtain (10 year documentation…..)
- Long follow up necessary, hard to obtain without institutional data collection

Low Dose Models

Cause of death	ERR/Gy [a] (95%CI [b])	Cases
All causes	0.22 (0.18, 0.26)	50,620
All solid cancer	0.47 (0.38, 0.56)	10,929

Tabelle 5. Strahlendosis am Entstehungsort des Zweitmalignoms.

Hochrisikopatienten. Die Patienten mit zusätzlicher Polychemotherapie wiesen insgesamt ein signifikant höheres kumulatives Zweitmalignomrisiko auf als die Patienten mit Radiotherapie allein. Abbildungen 3a und 3b zeigen für das Kollektiv ab 1972 das kumulative Zweitmalignomrisiko selektiert für die typischen Kombinationstherapien (Radiotherapie in Kombination mit MOPP oder ABVD oder MOPP + ABVD) im Vergleich zur Radiotherapie allein, und zwar in Beziehung zur Primärtherapie (Abbildung 3a) und zur gesamten Therapie einschließlich Rezidivtherapie (Abbildung 3b). Die Kombination mit MOPP hatte, für sich betrachtet, bis zu 15 Jahren nach Therapie das geringste Zweitmalignomrisiko, so daß die Anhebung des Zweitmalignomrisikos im Gesamtkollektiv der Patienten mit Polychemotherapie signifikant zu Lasten der Kombinationen mit ABVD bzw. ABVD + MOPP ging (Abbildungen 3a und 3b).

Hodgkin III: Pediatric HD

Moskowitz, JCO, 2014

Suggestive of Dose and Volume linearity at >10 Gy

	Estimated Cumulative Risk, % (95% CI)		
	By age 40	By age 45	By age 50
Childhood cancer survivors			
Entire cohort	12 (10 to 14)	18 (16 to 21)	30 (25 to 34)
Primary cancer diagnosis			
Hodgkin lymphoma	15 (12 to 18)	22 (17 to 25)	35 (29 to 40)
Other childhood cancer*	8 (5 to 12)	15 (10 to 21)	– –
Carriers of genetic mutations			
BRCA1 carriers	14 (5 to 23)	22 (11 to 33)	31 (15 to 48)
BRCA2 carriers	5 (0 to 15)	10 (1 to 23)	10 (1 to 23)

Fig 2. Cumulative risk of breast cancer. Breast cancer risk among women treated for childhood cancer with chest irradiation contrasted with breast cancer risk in female carriers of *BRCA1* or *BRCA2* deleterious mutations and women in general US population, with a birth-year distribution reflective of CCSS (Childhood Cancer Survivor Study) participants. (*) Insufficient follow-up in this group to provide reliable estimates of cumulative risk of breast cancer by age 50 years.

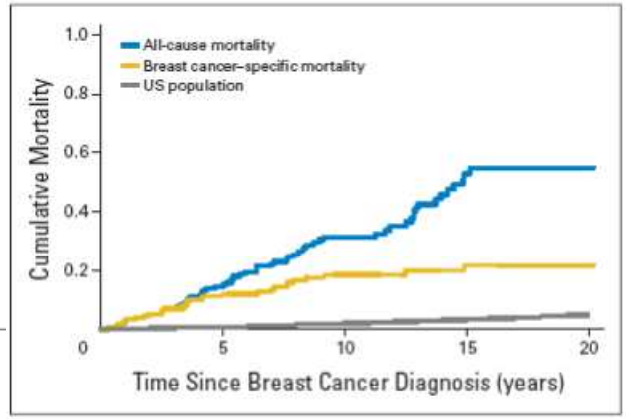

Fig 3. Death after breast cancer among childhood cancer survivors treated with chest irradiation. All-cause and breast cancer–specific mortality after breast cancer after chest radiotherapy for childhood cancer compared with expected mortality, age and year standardized to US population.

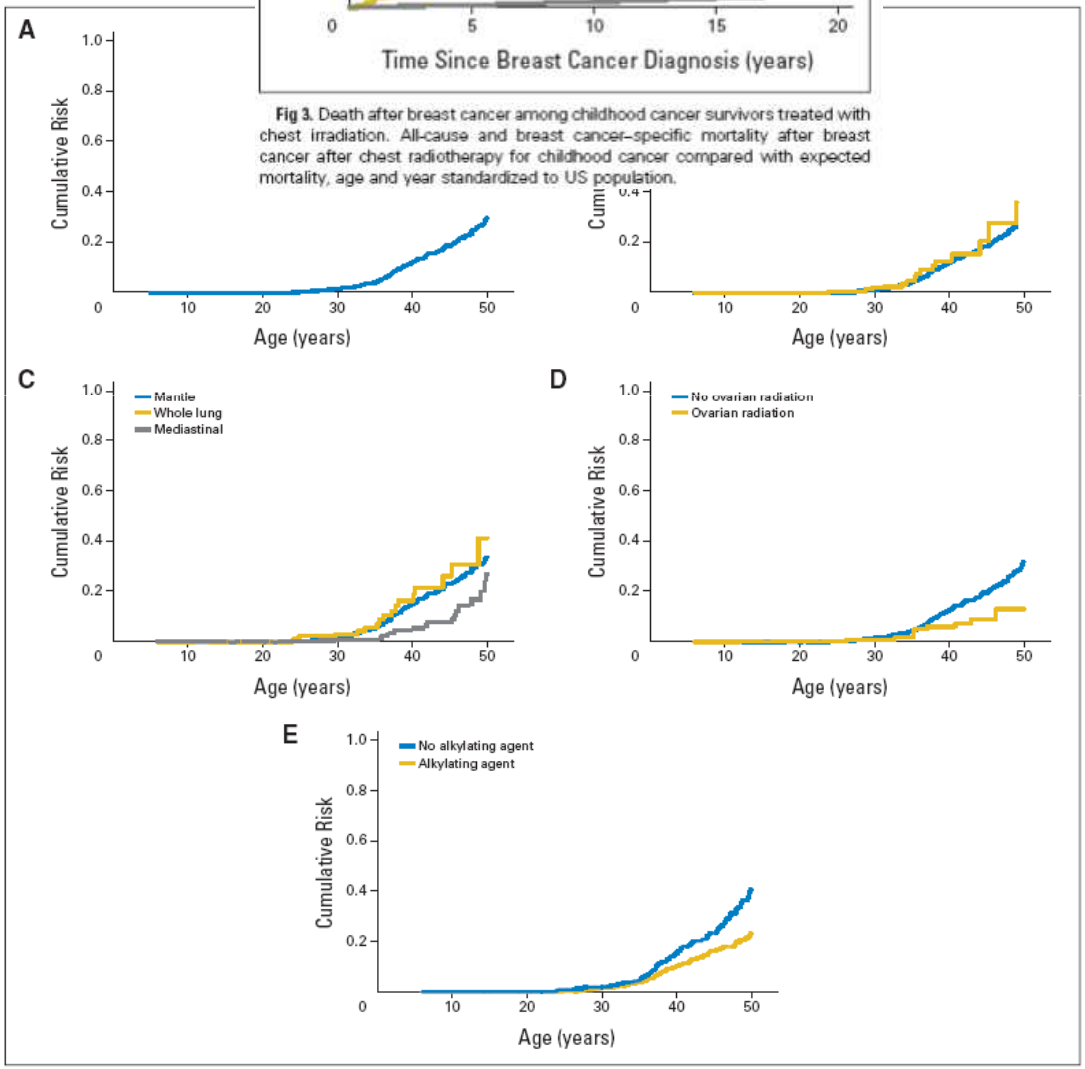

Fig 1. Cumulative risk of breast cancer among women treated for childhood cancer with chest irradiation (A) overall and by childhood cancer therapy: (B) chest radiation dose; (C) chest irradiation field; (D) ovaries in concurrent irradiation field; (E) alkylating agents.

Breast I

Localization???

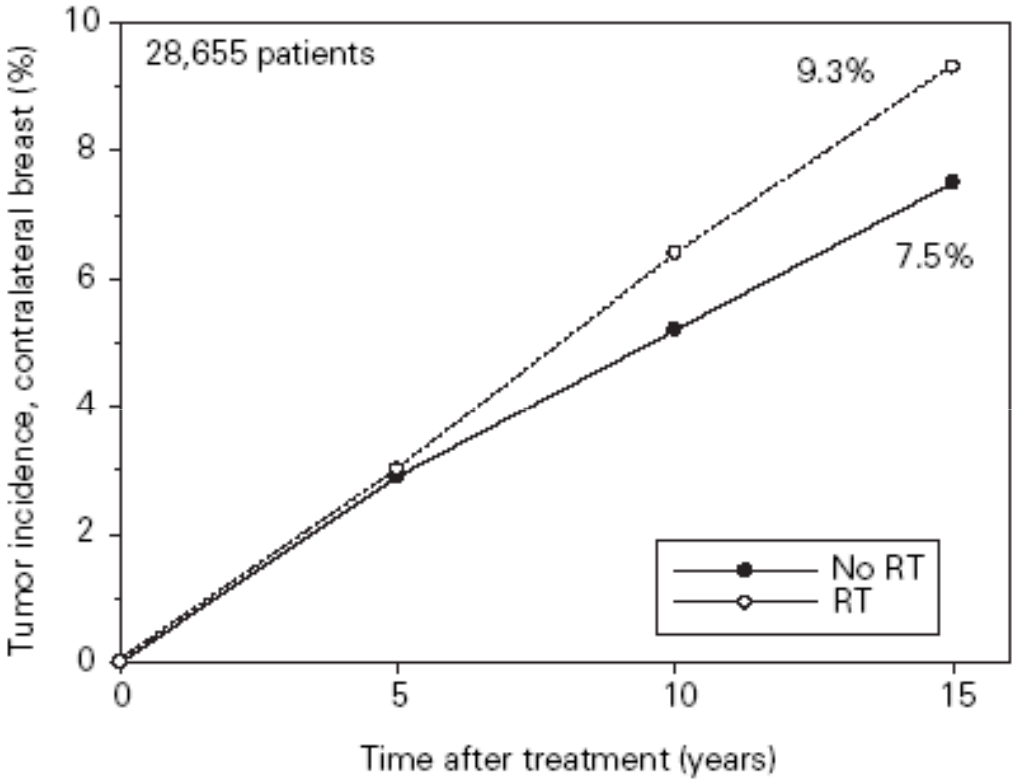

Figure 1. Incidence of contralateral breast cancer. The figure displays the time-to-event for the incidence of tumors in the contralateral breast in patients with breast cancer treated either with surgery alone or with additional irradiation (data from [5], webfigure 7; http://www.ctsu.ox.ac.uk/projects/ebctcg, August 22, 2007).

Doerr, Hermann, SUON, 2008

Breast II – Italian Data (Allegro Project)

„Our initial patient number is very high, but the incidence of a second cancer is relatively low (0.02% of all patients and 0.019% of the patients treated with adjuvant irradiation)“

Minimum F/U: 5 years

Median F/U: not given, but probably around 10 Years

Breast Cancers in High Dose Areas (in-field) excluded

Orecchia et al., Tumori, 2012

Breast III

Breast Cancer Survivors

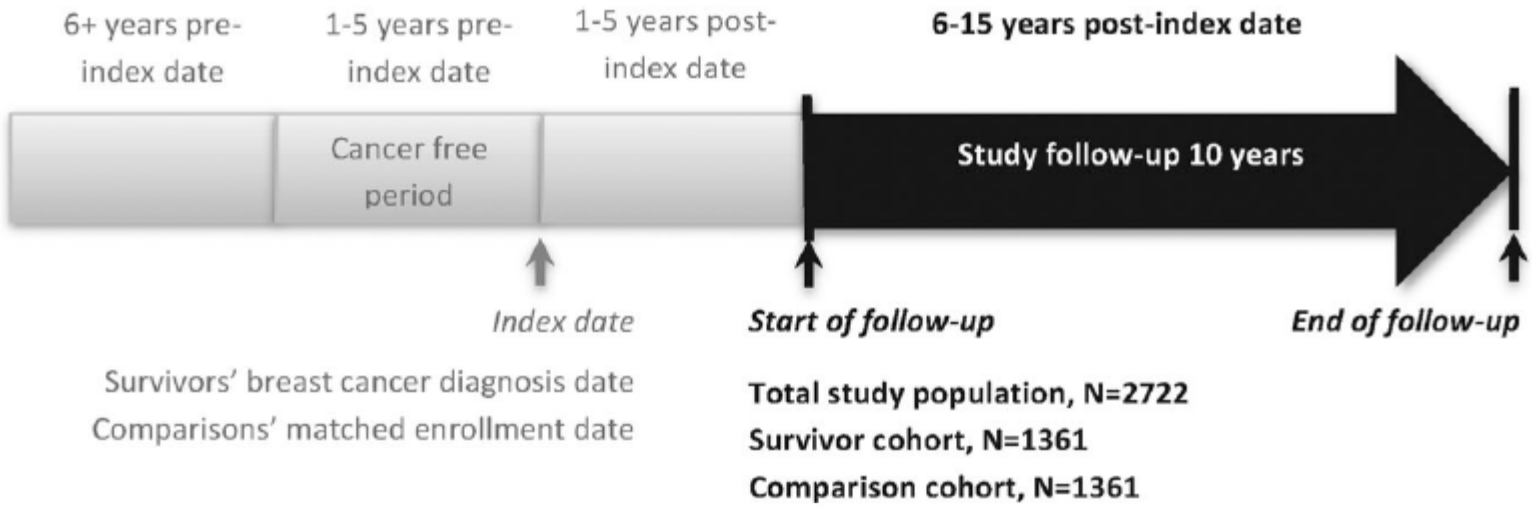

Figure 1. The study timeline is illustrated.

TABLE 3. The Risk of Incident Malignant Cancer in the Survivor Cohort Compared With the Comparison Cohort Adjusted for the Competing Risk of Death Over 10 Years of Follow-Up (6 to 15 Years After the Index Date), N = 2722[a]

	HR_{crude} (95% CI)	$HR_{adjusted}$ (95% CI)[b]
First incident all-cause malignancy	1.16 (0.93-1.46)	1.17 (0.94-1.47)
Type of first incident malignancy		
Breast	1.26 (0.81-1.95)	1.28 (0.83-1.99)
Colorectal	0.66 (0.37-1.19)	0.66 (0.37-1.20)
Gynecologic	2.53 (0.89-7.18)	2.72 (0.96-7.74)
Lymphoma/leukemia	1.33 (0.62-2.84)	1.28 (0.59-2.75)
Lung	1.21 (0.68-2.18)	1.25 (0.69-2.25)
Melanoma	1.01 (0.36-3.32)	0.93 (0.29-2.94)
Other	1.20 (0.77-1.87)	1.19 (0.77-1.86)

Abbreviations: CI, confidence interval; HR, hazard ratio.
[a] The index date was either the date of the survivor's diagnosis or the date of the matched comparison woman's enrollment.
[b] Adjusted models included site, age, race, comorbidity, and history of cancer.

The adjusted hazard of developing a first incident malignancy was slightly elevated in survivors in relation to women in the comparison group, but it was not statistically significant (hazard ratio, 1.17; 95% confidence interval, 0.94-1.47)

McClough-Gorr et al., Cancer, 2013

Breast III – DBCG Data (Allegro-Project)

Radiotherapy-associated sites:
HR 1.34 (95% CI 1.11–1.61)
10–14 years after RT: HR 1.55 (95% CI 1.08–2.24)
>15 years after: HR 1.79 (95% CI 1.14–2.81).

Non-radiotherapy-associated sites:
HR 1.04 (95% CI 0.94–1.1).

The estimated attributable risk related to radiotherapy for the radiotherapy-associated sites translates into one radiation-induced second cancer in every 200 women treated with radiotherapy.

The observed temporal-pattern for the RT-associated sites is consistent with the suggestion that radiation induced solid tumors have a minimum latency of 5–9 years

Granzau et al., R&O, 2013

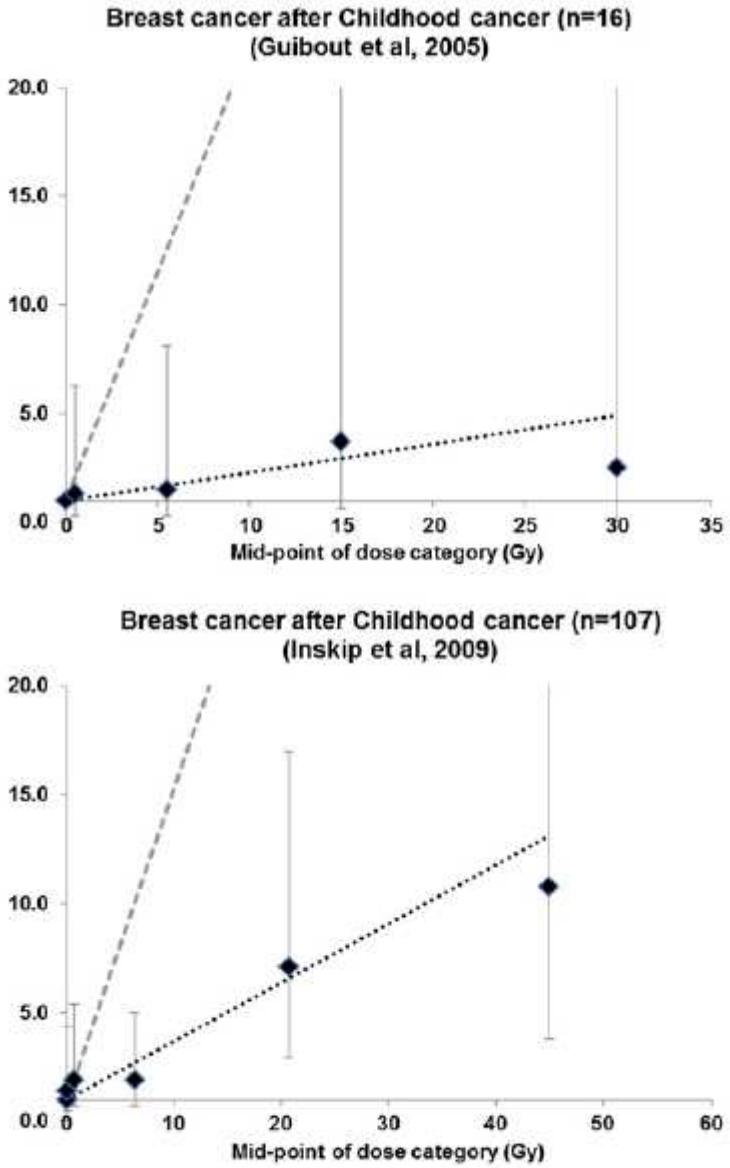

Fig. 1. Relative risk and 95% confidence interval for subsequent breast cancer according to the estimated absorbed radiation dose (Gy). Dotted black line indicates fitted linear dose-response

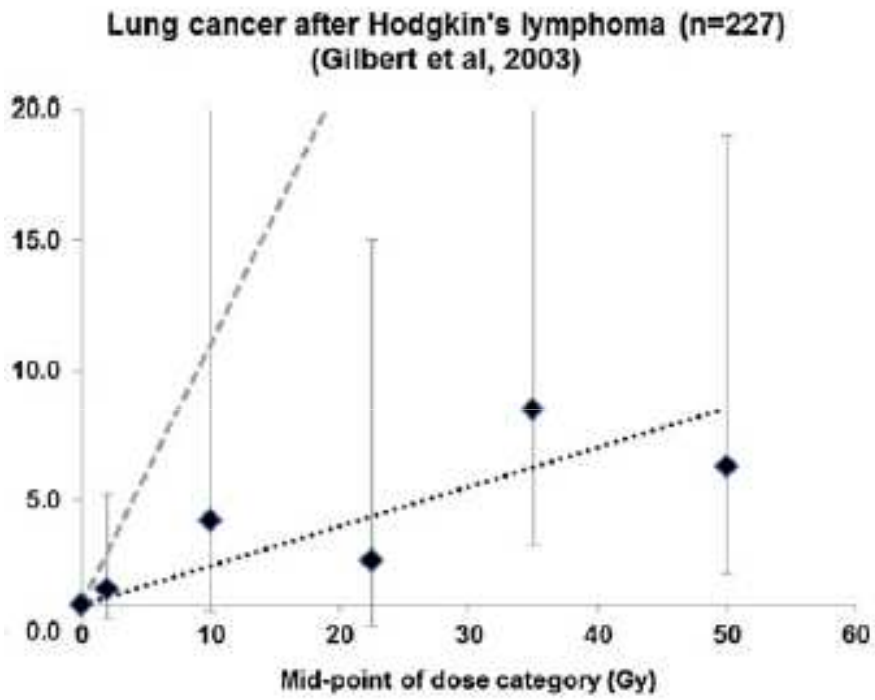
This just in…….

Overall, there was little evidence that the dose-response curve was nonlinear in the direction of a downturn in risk, even at organ doses of >60 Gy. Thyroid cancer was the only exception, with evidence of a downturn after 20 Gy. **Generally the excess relative risk per Gray, taking account of age and sex, was 5 to 10 times lower than the risk from acute exposures of <2 Gy among the Japanese atomic bomb survivors**.



Berrington et al., IJROBP, 2013

And linear again…and again….

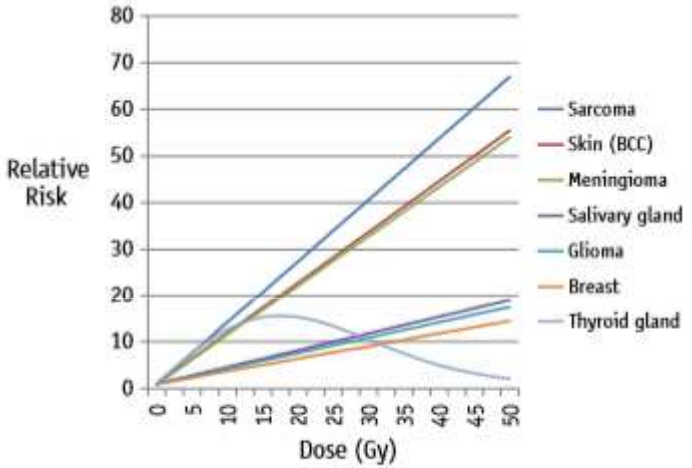


Fig. 1. Fitted radiation dose-response by type of second cancer, based on previously published studies of second sarcoma (16), skin (18), meningioma (10) salivary gland (17), glioma (10), breast (11) and thyroid gland (14). The order of second cancers from top to bottom in the graph is the same as in the key to the right of the panel.

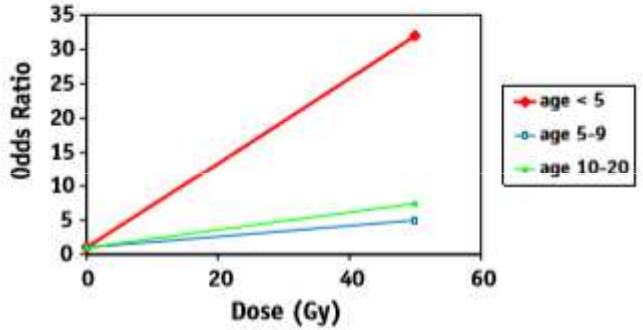

Fig. 2. Risk of glioma after radiation therapy for first cancer, by age at first cancer. Data from Neglia et al. New primary neoplasms of the central nervous system in survivors of childhood cancer: A report from the Childhood Cancer Survivor Study. *J Natl Cancer Inst* 2006;98:1528-1537.

Inskip et al., IJROBP, 2016

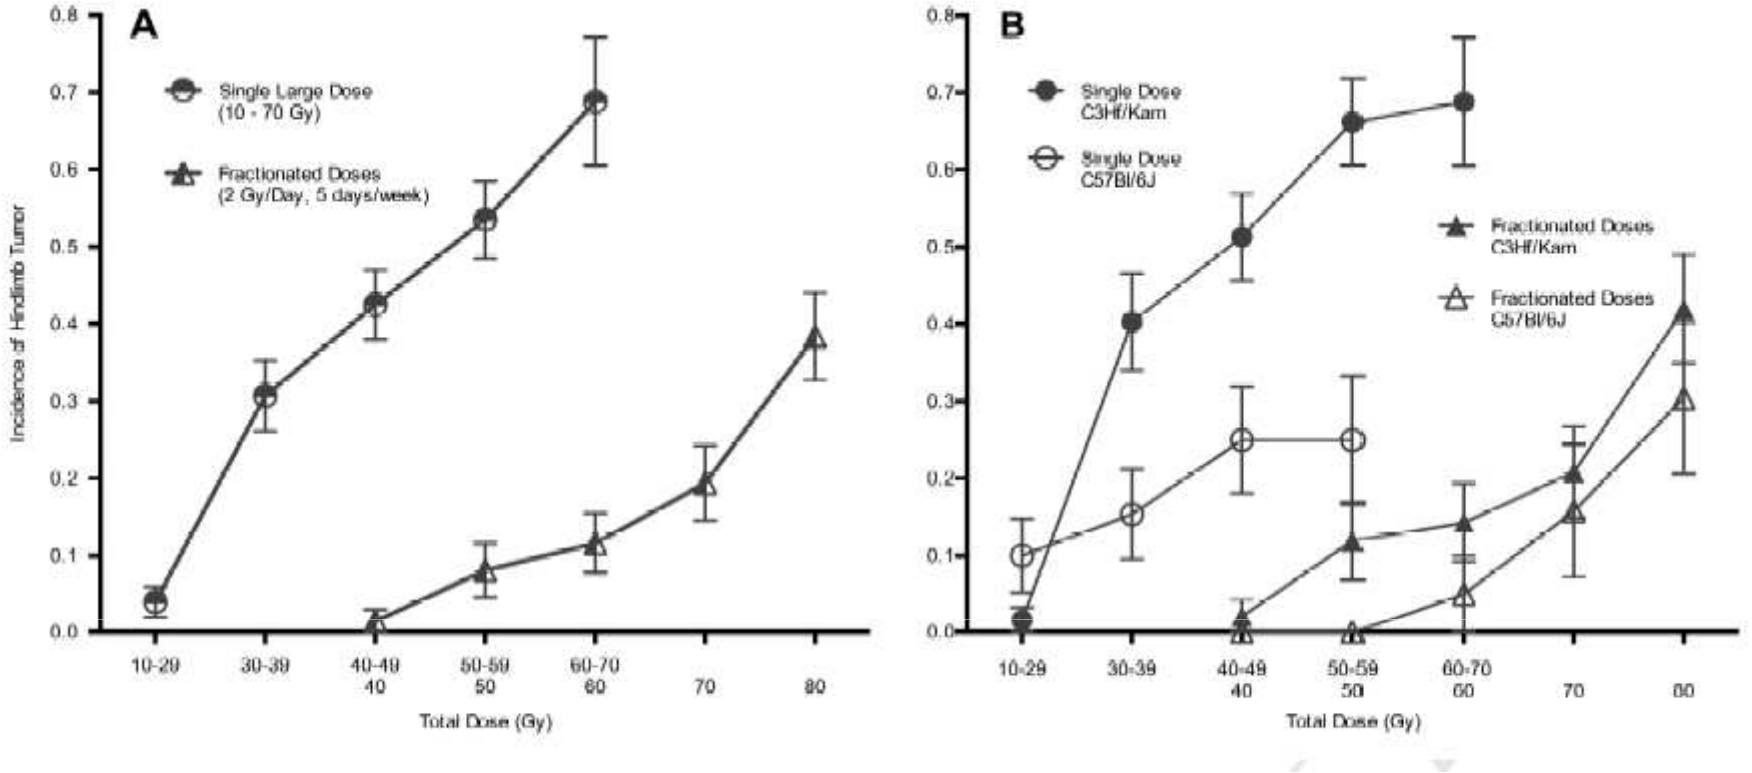

Figure 2. Incidence of hindlimb tumors by radiation dose. (A) Incidences of hindlimb tumors are significantly increased in mice exposed to a single large dose of radiation in comparison to mice exposed to fractionated radiation ($p < 0.001$). (B) Incidences of hindlimb tumors by radiation dose and mouse strain. C3Hf/Kam mice have a significantly higher incidence of hindlimb tumors following single dose exposures than C57BL/6J mice ($p < 0.001$). No significant difference in tumor incidence is observed between C3Hf/Kam and C57BL/6J mice following fractionated exposures. Single doses are grouped as 10-29, 30-39, 40-49, and 50-59 Gy. Fractionated doses were given as 2 Gy/day, 5 days/week for 4 to 8 weeks and are listed as total doses of 40, 50, 60 , 70, and 80 Gy

Edmondson et al., IJROBP, 2015

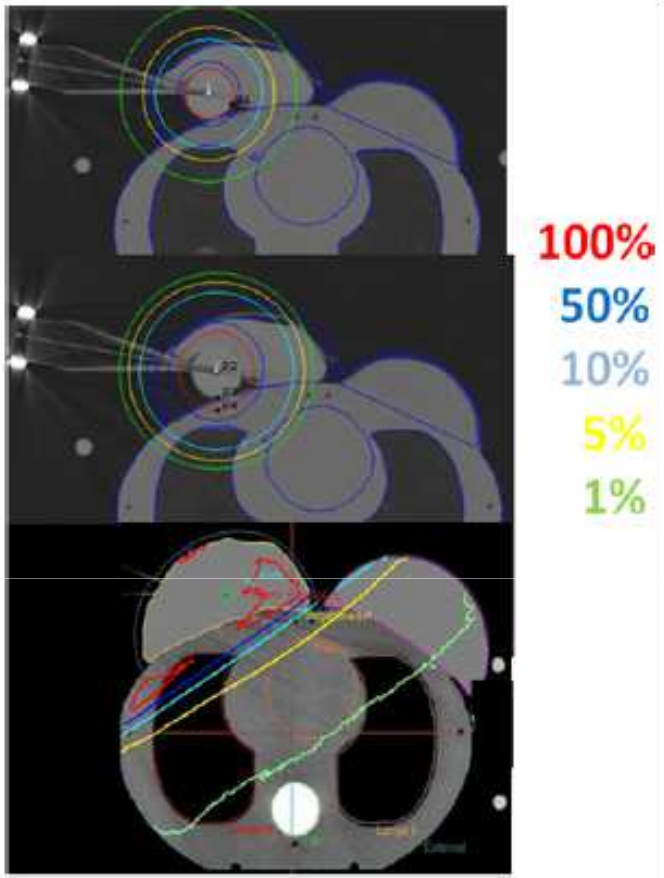

Figure 1 Planning CT of an anthropomorphic phantom with an Intrabeam applicator in the upper outer quadrant of the right breast showing calculated isodoses (1%-100%). (a) IORT (20 Gy at 0 mm, 50 kV). (b) APBI (34 Gy at 10 mm, 50 kV). (c) EBRT (50 Gy, 6 MV).

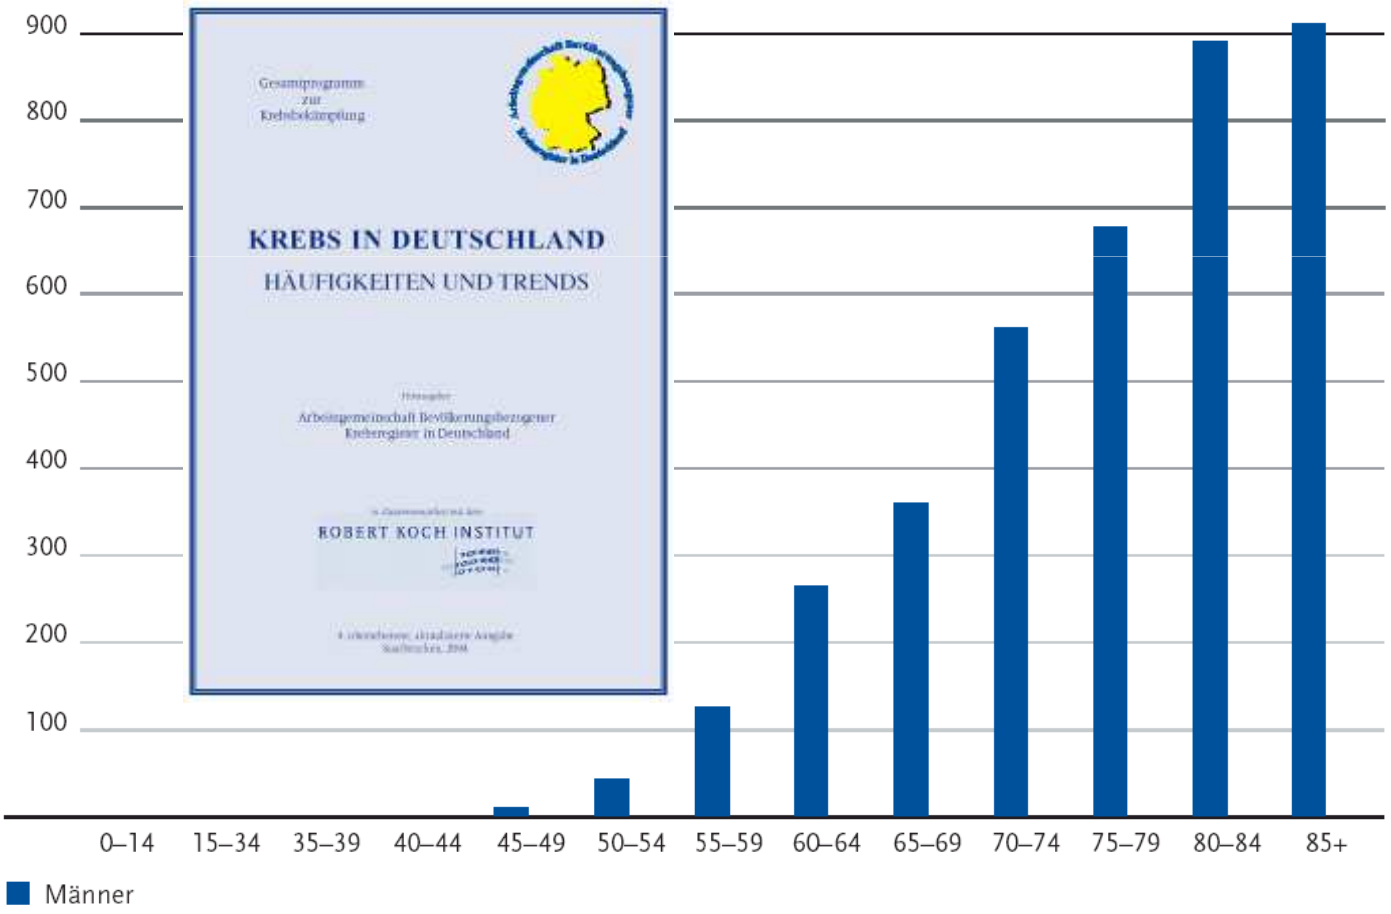
Erkrankungen pro 100.000 in Altersgruppen



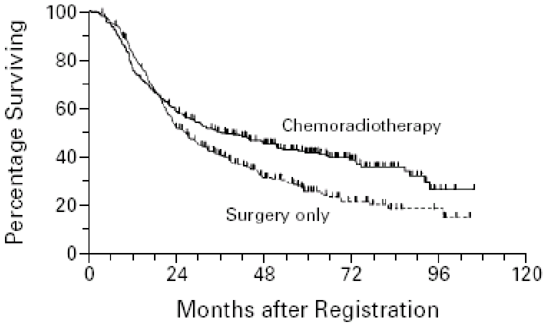


Figure 1. Overall Survival among All Eligible Patients, According to Treatment-Group Assignment.

The median duration of survival was 27 months in the surgery-only group and 36 months in the chemoradiotherapy group. The difference in overall survival was significant (P=0.005 by a two-sided log-rank test). A total of 169 of the 281 patients in the chemoradiotherapy group and 197 of the 275 patients in the surgery-only group died during the follow-up period.

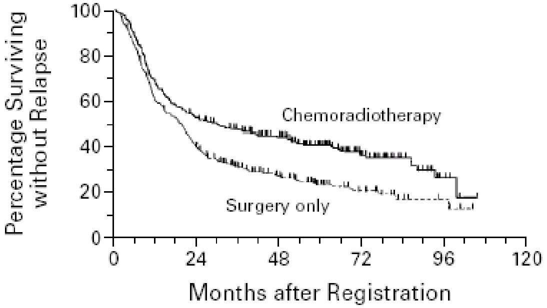

Figure 2. Relapse-free Survival among All Eligible Patients, According to Treatment-Group Assignments.

The median duration of relapse-free survival was 19 months in the surgery-only group and 30 months in the chemoradiotherapy group. This difference in relapse-free survival was significant (P<0.001 by a two-sided log-rank test). A total of 174 of the 281 patients in the chemoradiotherapy group and 206 of the 275 patients in the surgery-only group died or had a relapse during the follow-up period.

Paranasal Sinus Cancer: Caveats and Controversies

John Waldron, M.D., M.Sc.,[1] Ian Witterick, M.D.[2]

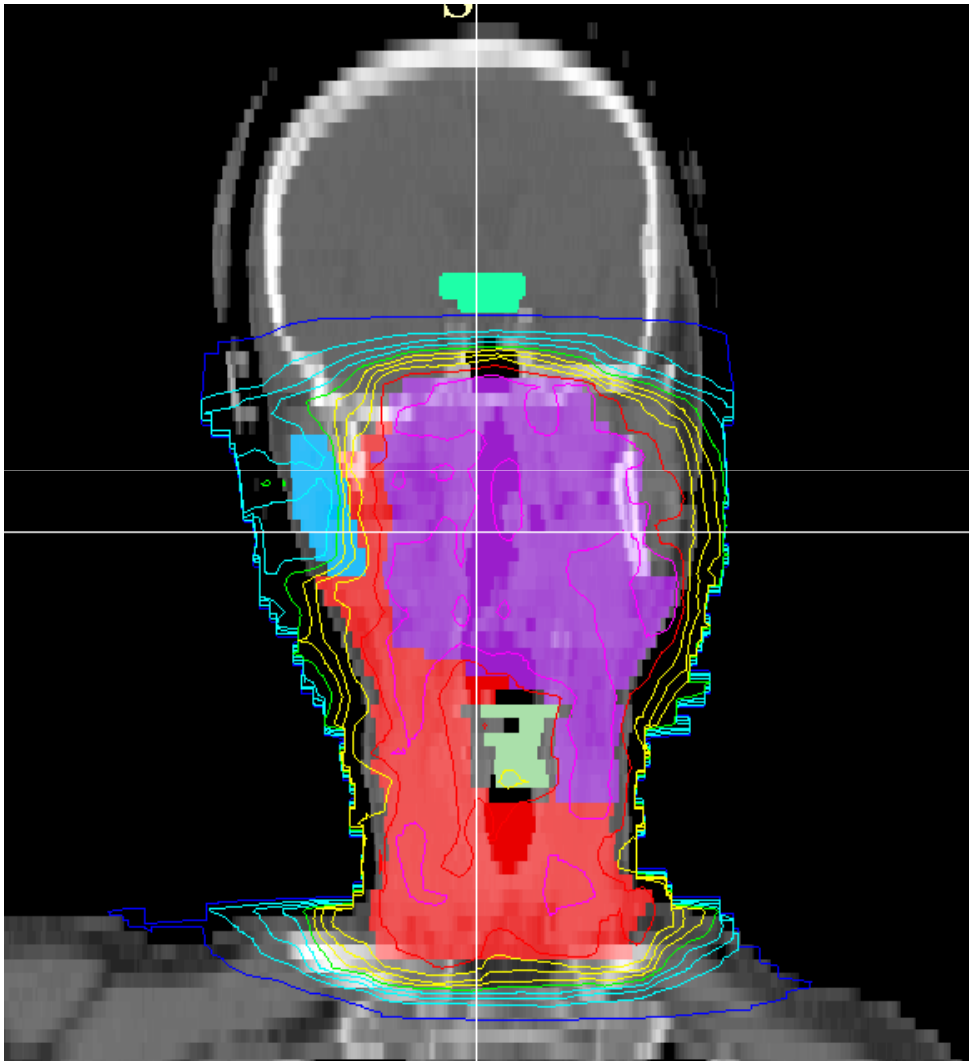
Published Online: May 14, 2003

Secondary Carcinoma

is not a relevant problem when patients with a bad prognosis (such as it is the case with advanced gastric cancer) are treated. Achieving cure is the problem for these patients.

Secondary Tumors: H&N

Risk is not different from 3D if the whole diameter is irradiated



Head and Neck:
Irradiation of (more or less) the whole neck circumference with therapeutic doses (volume very similar to conventional 3D [paradigms changing slowly])
->similar risk for secondary tumors for IMRT and 3D in the Neck area, probably slightly elevated risk outside neck due to elevated MU, increased scatter. High risk for secondary, non RT-induced cancer, though (Lung!!)

Specific Problems with IMRT

Secondary Tumors

Risk assessment of radiation-induced malignancies based on whole-body equivalent dose estimates for IMRT treatment in the head and neck region

Dirk Verellen[a,*], Filip Vanhavere[b]

Radiotherapy and Oncology 53 (1999) 199–203

RADIATION-INDUCED SECOND CANCERS: THE IMPACT OF 3D-CRT AND IMRT

ERIC J. HALL, D.SC.* AND CHENG-SHIE WUU, PH.D.†

Int. J. Radiation Oncology Biol. Phys., Vol. 56, No. 1, pp. 83–88, 2003

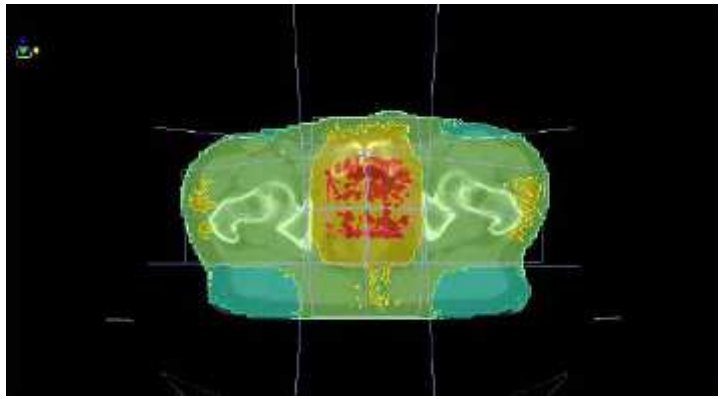
Reasons for a potentially increased incidence of secondary tumors by IMRT

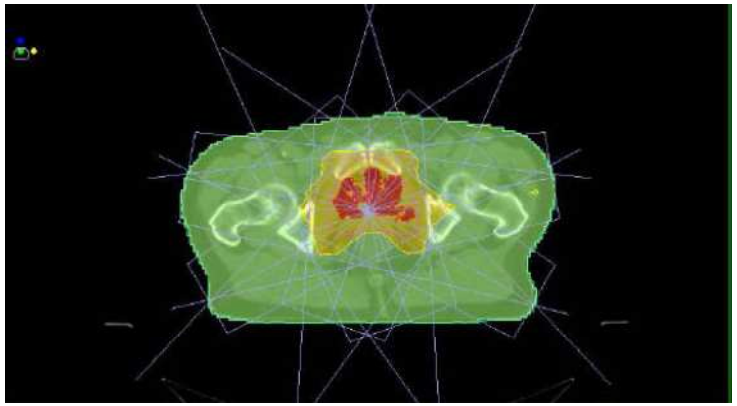
1. Increased biological effectiveness of an elevated total body neutron dose

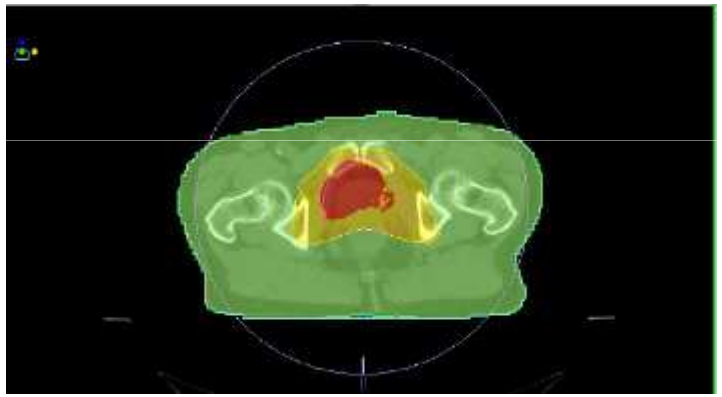
2. When compared to 3D-Conformal RT, IMRT irradiates a more tissue at lower doses

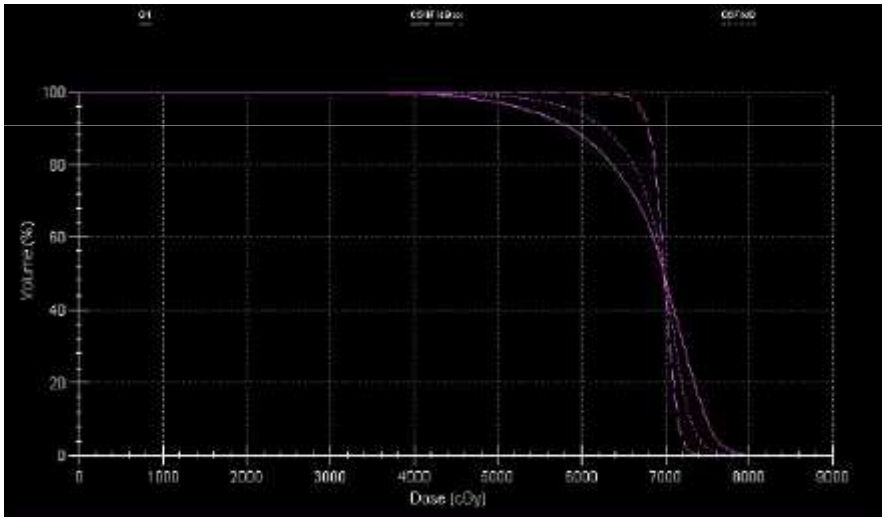
3. Increased scatter dose when dose-escalation is performed

4. Increased leakage radiation because of low MU-efficiency of IMRT









1 Gy (blue), 5 Gy (green), 45 Gy (yellow) and 70 Gy (red)

Prostate IMRT

"The risk of RISPC appears small, in the range of 1 in 220 to 1 in 290 over all durations of follow-up, based on older radiation techniques. Importantly, the risk appears to increase with time, and beyond 5 years, SPCs in the region of the original field may be considered RISPCs. To date there are insufficient clinical data to draw firm conclusions about the impact of more modern RT techniques, although limited evidence is encouraging"

Murray et al. Radiother Oncol, 2014

Secondary Tumors

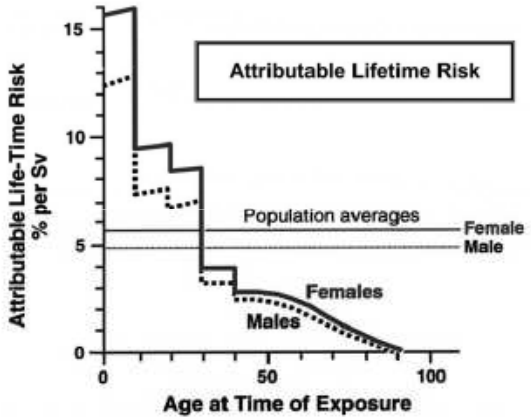


Fig. 6. The attributable lifetime risk from a single small dose of radiation at various ages at the time of exposure. Note the dramatic decrease in radiosensitivity with age. The higher risk for the younger age groups is not expressed until late in life. These estimates are based on a multiplicative model and on a dose and dose-rate effectiveness factor (DDREF) of 2. The figure was adapted from International Commission on Radiological Protection (ICRP) Publication 60 (14).

Same Leakage for Adult RT vs. Pediatric RT — But in Pediatric RT Scatter from the Treatment Volume Is More Significant

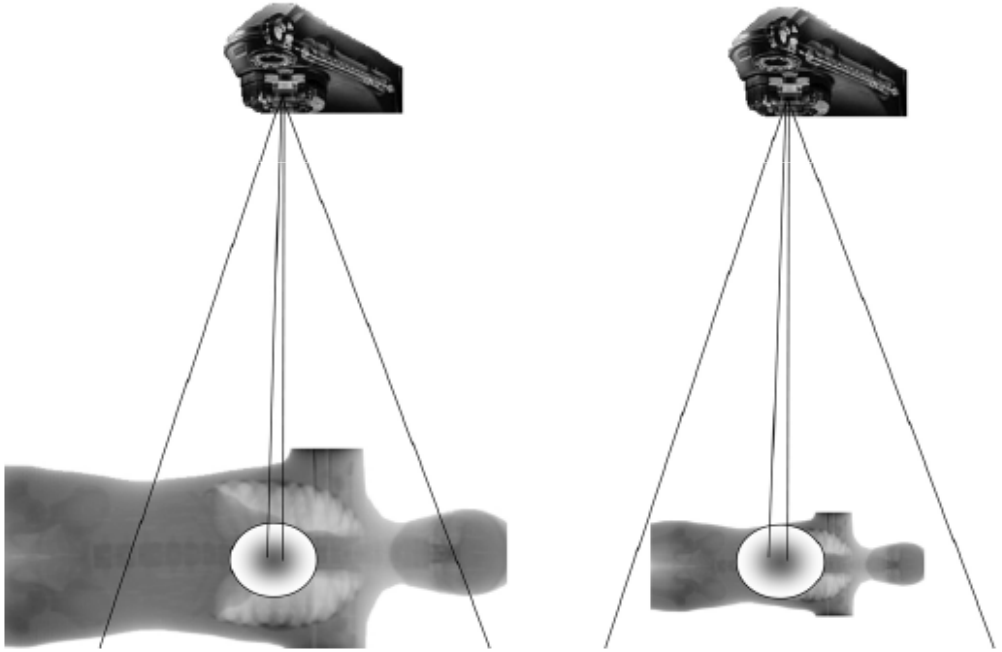

Fig. 7. When a primary tumor is treated with radiotherapy (RT) in a small child, nearby potentially radiogenic organs inevitably receive larger doses of radiation than when a comparable treatment is delivered to an adult, simply because of the closer proximity of organs in a child.

Pediatric Oncology is a problem…but not a disastrous one

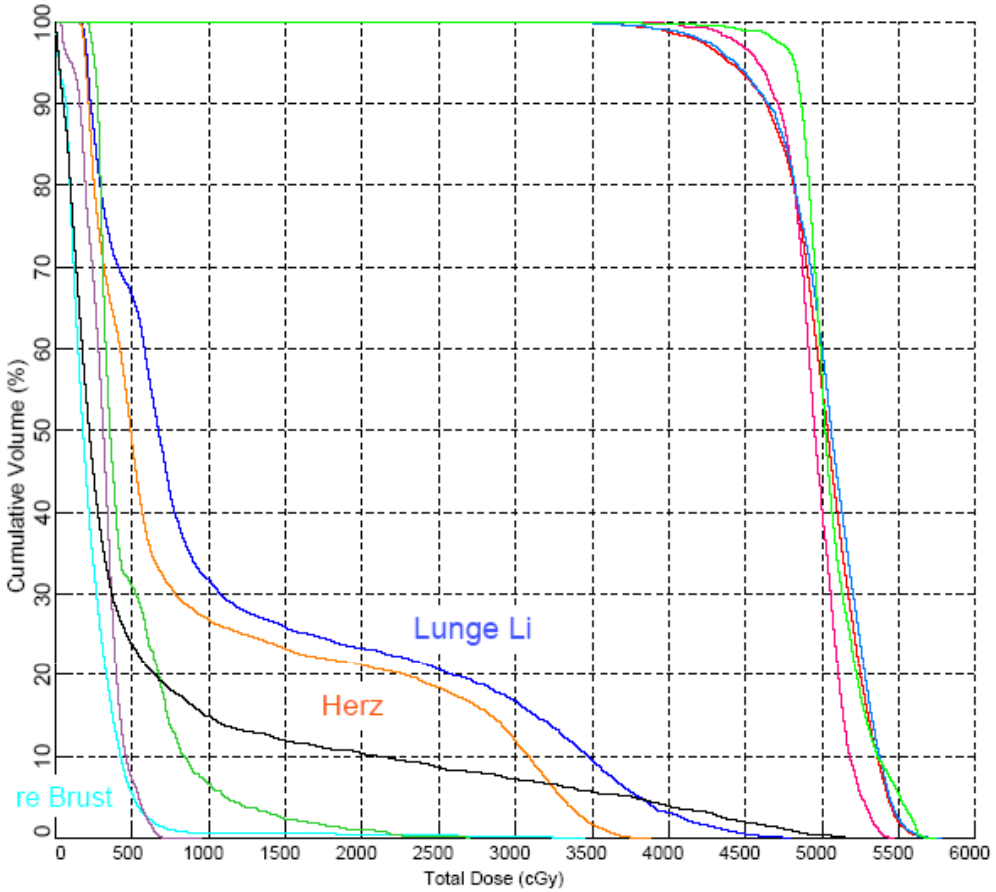
Problems with Modelling

“The mean estimated ERR for breast, lung and thyroid were significantly ($p < 0.01$) lower with INRT than with IFRT planning, regardless of the radiation technique delivery used, assuming a linear dose-risk relationship. An ERR increase was however observed with the non-linear model. With the latter, mean ERR were significantly ($p < 0.01$) increased with IMRT or RA when compared to 3DCRT planning for the breast, lung and thyroid using an IFRT paradigm. After INRT planning, IMRT or RA increased the risk of RIC for lung and thyroid only. “

Weber et al., IJROBP, 2011



Breast:

Increase of mean and median contralateral breast dose very moderate (from 1.5 to 2.5 Gy) while improved heart protection can be achieved

Conclusions

SERVIZIO SANITARIO REGIONALE
EMILIA-ROMAGNA
Azienda Ospedaliero - Universitaria di Modena
Policlinico

1. Conventional RT probably goes with a secondary tumor risk of approximately 1% (High- and Low-dose Areas together). The dose/volume effects for secondary tumor risk are currently completely unclear.

2. ***Conservative*** estimates suggest an increase by IMRT to 2%, e.g. the secondary tumor risk doubles when compared to conventional RT.

   But:
   - It is still an overall low number.
   - For most diseases, this is negligible in comparison to the risk of local recurrence.
   - Given the predominantly old age of patients, this is mostly irrelevant anyway
   - New planning systems create efficient plans, so that the number of monitor units decreases dramatically

3. ***Realistic*** estimates suggest a factor of <1.5 between the secondary tumor risk of conventional RT and IMRT.

4. It is not completely improbable, that IMRT *reduces* the risk of secondary tumors

5. Precise knowledge of the dose at SMN origin is necessary to further refine our knowledge (prospective evaluation necessary!!!!)

6. IMRT for children and breast cancer has to be used with caution, weighing benefits against potential risk, but the same holds true for IORT

Where the real danger lurks……

Concurrent Chemoradiotherapy in Stage III Non–Small-Cell Lung Cancer: What Is the Best Regimen?

Wilfried Ernst Erich Eberhardt, *West German Cancer Centre; and University Hospital of University Duisburg-Essen, Essen, Germany*

- Most common options in U.S. are carboplatin/paclitaxel and cisplatin/etoposide
- No phase III data to compare these
  - Pneumonitis rates appear higher with carbo/paclitaxel
  - Phase II survival data favors cisplatin/etoposide
- Cis-Vinca alkaloid also reasonable

from DA Palma, ASTRO 2014

A Systematic Review of Carboplatin-Paclitaxel versus Cisplatin-Etoposide Concurrent with Thoracic Radiation for Stage III NSCLC Patients

Conor E. Steuer, Madhusmita Behera, Kristin A. Higgins, Nabil F. Saba, Dong M. Shin, Suchita Pakkala, Rathi N. Pillai, Taofeek K. Owonikoko, Walter J. Curran, Chandra P. Belani, Fadlo R. Khuri, Suresh S. Ramalingam

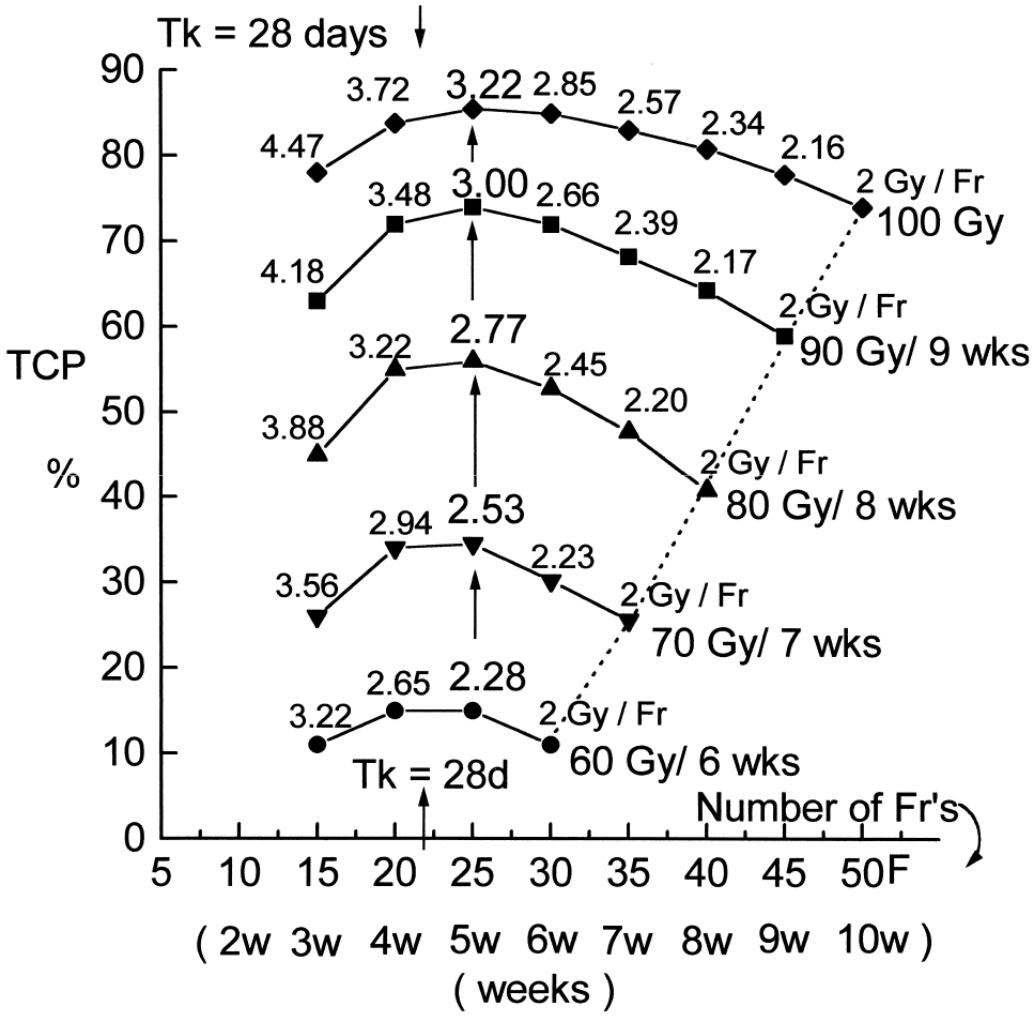
Can “adapted” hypofractionation be applied to lung cancer patients with LA disease through the use of high-tech radiotherapy?

Gain in TCP from shortening overall treatment time to 5 weeks



Fewer and larger fractions calculated to deliver equal late complications also deliver higher biologic dose to tumors

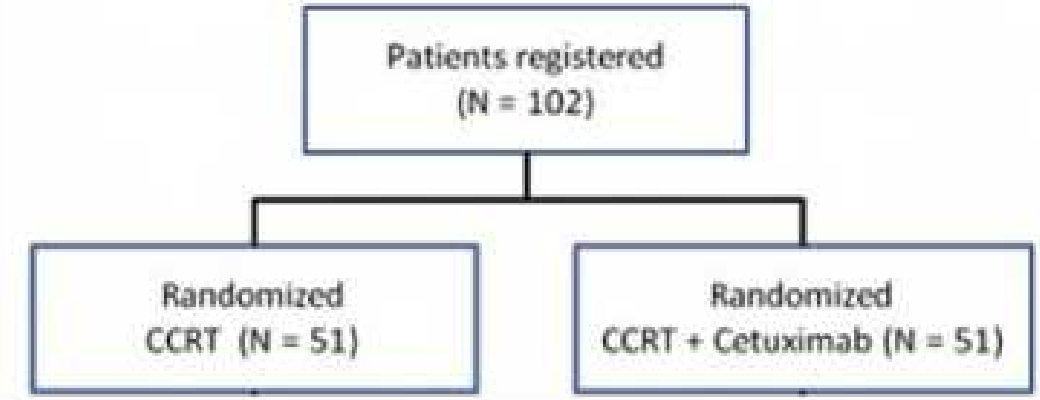
Aim

To investigate 60-month OS in LA-NSCLC patients treated with concurrent chemoradiotherapy +/- cetuximab, using a hypofractionation scheme of 24 x 2.75 Gy



NETHERLANDS CANCER INSTITUTE
ANTONI VAN LEEUWENHOEK

Raditux trial

- **Randomized multicenter phase II trial**
  - To assess the beneficial effect of cetuximab on concurrent chemoradiotherapy
- **Inclusion criteria**
  - Inclusion between February 2009 and May 2011
  - 102 inoperable stage II & stage III A/B NSCLC patients
  - WHO performance status 0–1
- **Treatment**
  - 24 x 2.75 Gy
  - Daily low-dose cisplatin (6mg/m^2)
  - +/- weekly cetuximab (loading dose 400mg/m^2 followed by a weekly dose of 250 mg/m^2 iv)

NETHERLANDS CANCER INSTITUTE
ANTONI VAN LEEUWENHOEK

Overall survival rates.

Median OS (months)	32 months	29 months	20 months

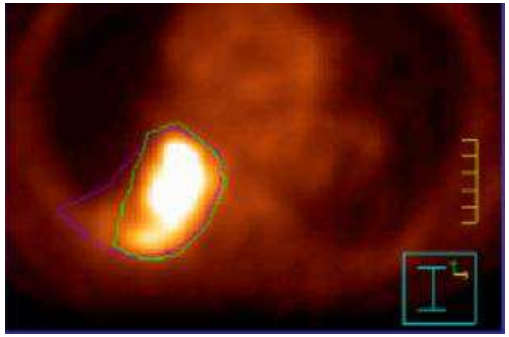
*based on 5-years of follow-up
[a]based on 2-years of follow-up

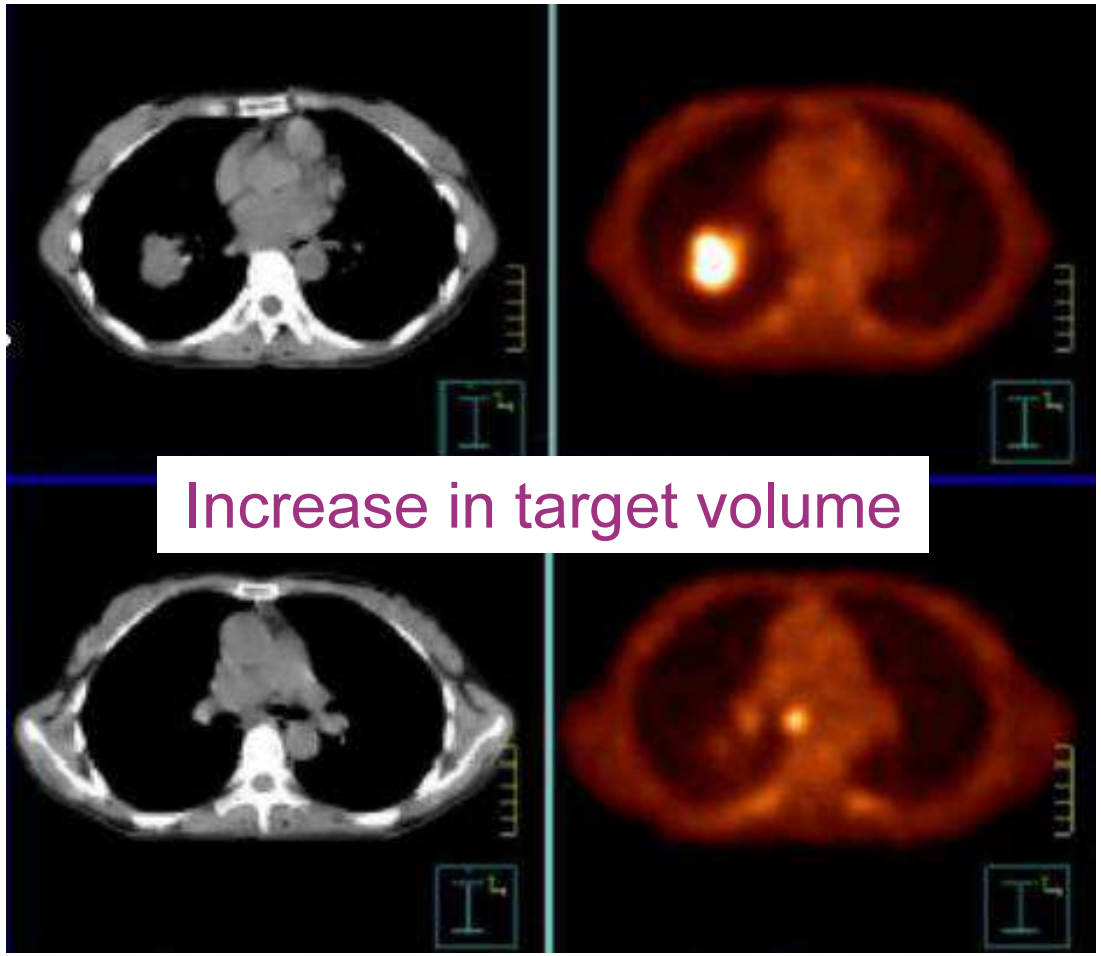
What is the preferred dose-fractionation schedule?

- 60 Gy in 30 fractions is still the standard dose
- A slight hypofractionated regimen (66 Gy/24 fractions, EORTC) may be considered as a valid alternative

GTV delineation: use of CT-PET

Decrease in target volume





Increase in target volume

PET-guided nodal contouring definitely supports the use of Involved Fields RT

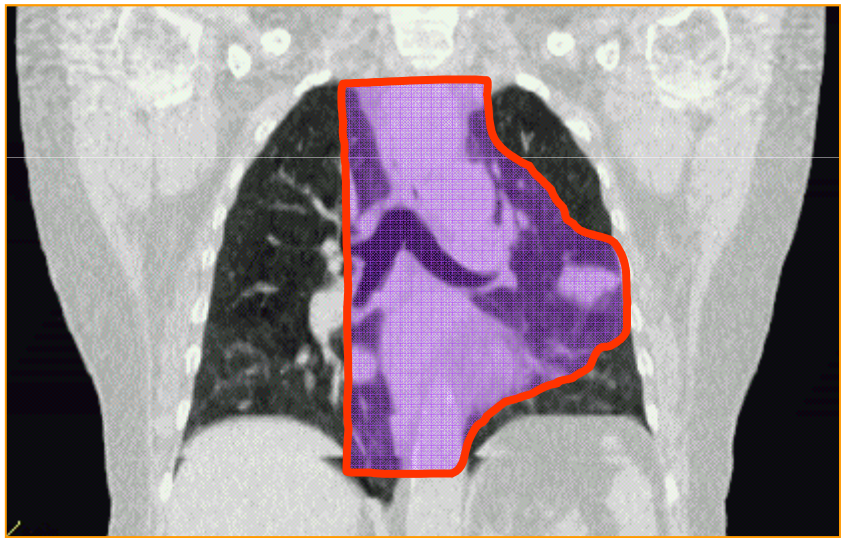
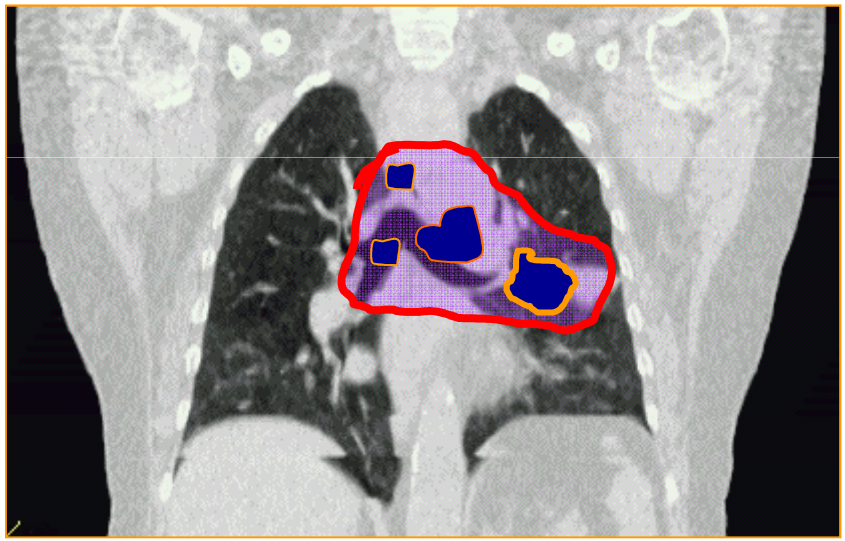
Elective nodal RT



Involved-field RT



RT volumes: EORTC reccomendations

Table 2. EORTC Recommendations for Planning and Delivery of High-Dose, High-Precision Radiotherapy for Lung Cancer (continued)

Variable	Recommendation Grade
CTV	
A fixed, 5-mm CTV margin may be used, although adjustment according to the histology of the primary tumor and the size of the lymph nodes may be done	2B
Adjustment of the CTV according to normal tissues (eg, the bones) may be appropriate	2B
PTV	
Although many viable options to generate the PTV have been described, tumor delineation in the middle or average ventilation position with calculated adequate margin appears to be a feasible and appropriate strategy	1C
Adjustment of the PTV is not permitted, as the PTV takes into account set up errors and breathing motion	1C
PRV	
The use of a PRV margin around critical serial organs should be encouraged	2B

IMRT for NSCLC: clinical outcomes

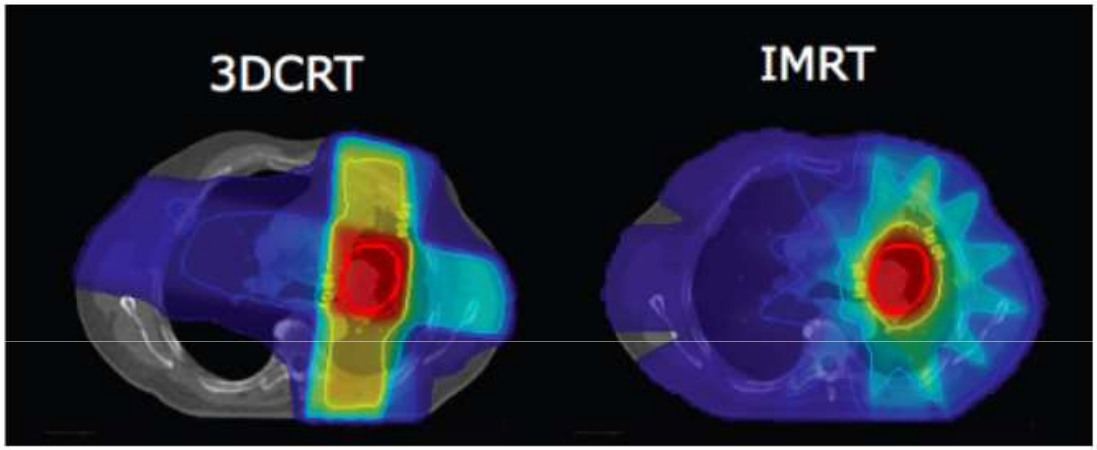
STUDY RATIONALE/HYPOTHESIS

High
60+ Gy
Intermediate
20 - 50 Gy
Low
5 Gy



- Rationale
  - IMRT improves target conformity and reduces both high and intermediate dose volumes
  - Exchange for large low-dose bath
- Hypothesis: IMRT may improve outcomes in Stage III NSCLC

NRG ONCOLOGY
Advancing Research. Improving Lives.™

IASLC 40 YEARS

938: Outcomes of intensity modulated and 3D-conformal radiotherapy for Stage III NSCLC in NRG/RTOG 0617 – Stephen G. Chun, M.D.

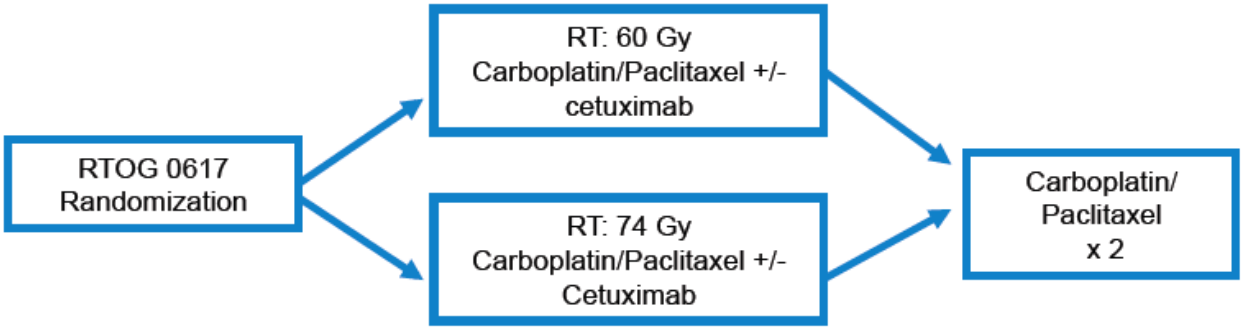
ESTRO School

IMRT for NSCLC: clinical outcomes

STUDY METHODS

Secondary Analysis of NRG/RTOG 0617



Compared RT technique in Univariate and Multivariate Analyses

- Stratified: 3D-CRT 53%, IMRT 47% in both RT dose arms
- Endpoints of secondary analysis
  - Survival – overall, progression free, local control
  - Grade 3+ toxicity
  - Amount of chemotherapy administered

NRG ONCOLOGY
Advancing Research. Improving Lives.™

Hu C et al, IALSC 2015

ESTRO School

IMRT for NSCLC: clinical outcomes

RESULTS

Effect of radiation technique on 2-year outcomes

Multivariate analysis 3D-CRT (reference) vs. IMRT

Outcome	OR (95% CI)	P-value
Overall survival	1.01 (0.8, 1.28)	0.95
Progression free survival	1.12 (0.91, 1.39)	0.28
Local control	0.91 (0.67, 1.23)	0.54
Distant metastasis free	0.92 (0.71, 1.19)	0.52

NRG ONCOLOGY
Advancing Research. Improving Lives.™

Overall and progression free survival similar
in spite of more unfavorable tumors in IMRT group

IASLC 40 YEARS

938: Outcomes of intensity modulated and 3D-conformal radiotherapy for Stage III NSCLC in NRG/RTOG 0617 – Stephen G. Chun, M.D.

Hu C et al, IALSC 2015

ESTRO School

RESULTS

Benefits of IMRT

Outcome	3D-CRT	IMRT	P-value
Grade 3+ pneumonitis	8%	3.5%	0.0462
Heart V40	11.4%	6.8%	0.0026
Full consolidative chemotherapy	29%	37%	0.05

Esophagitis, weight loss, cardiovascular, neurologic adverse effects similar in IMRT and 3D-CRT

NRG ONCOLOGY
Advancing Research. Improving Lives.™

IASLC 40 YEARS

Hu C et al, IALSC 2015

ESTRO School

IMRT for NSCLC: clinical outcomes

RESULTS

Multivariate Predictors of Grade 3+ pneumonitis

Co-variate	Comparison	OR (95% CI)	P-value
Technique	3D-CRT vs IMRT	0.44 (0.18, 1.04)	0.0621
Stage	IIIA vs. IIIB	2.35 (1.05, 5.29)	0.0385
Lung V20	Continuous	1.081 (1.02, 1.146)	0.009

Low dose bath bigger with IMRT

Lung V5 – IMRT 62% vs. 3D-CRT 55% ($P < 0.0001$)

Lung V5 did not predict pneumonitis, P = 0.14, OR 1.02, 95% CI (0.994, 1.04)

MLD did not predict pneumonitis

IMRT for NSCLC: clinical outcomes

CONCLUSIONS

- **IMRT Patient Outcomes**
  - Similar OS and PFS in spite of worse tumors
  - Improved Toxicity
  - Better tolerance of chemotherapy

- **Radiation Treatment planning**
  - Lung doses – V20 was significant
    (Lung V5/MLD was not)
  - Heart doses can be reduced with IMRT

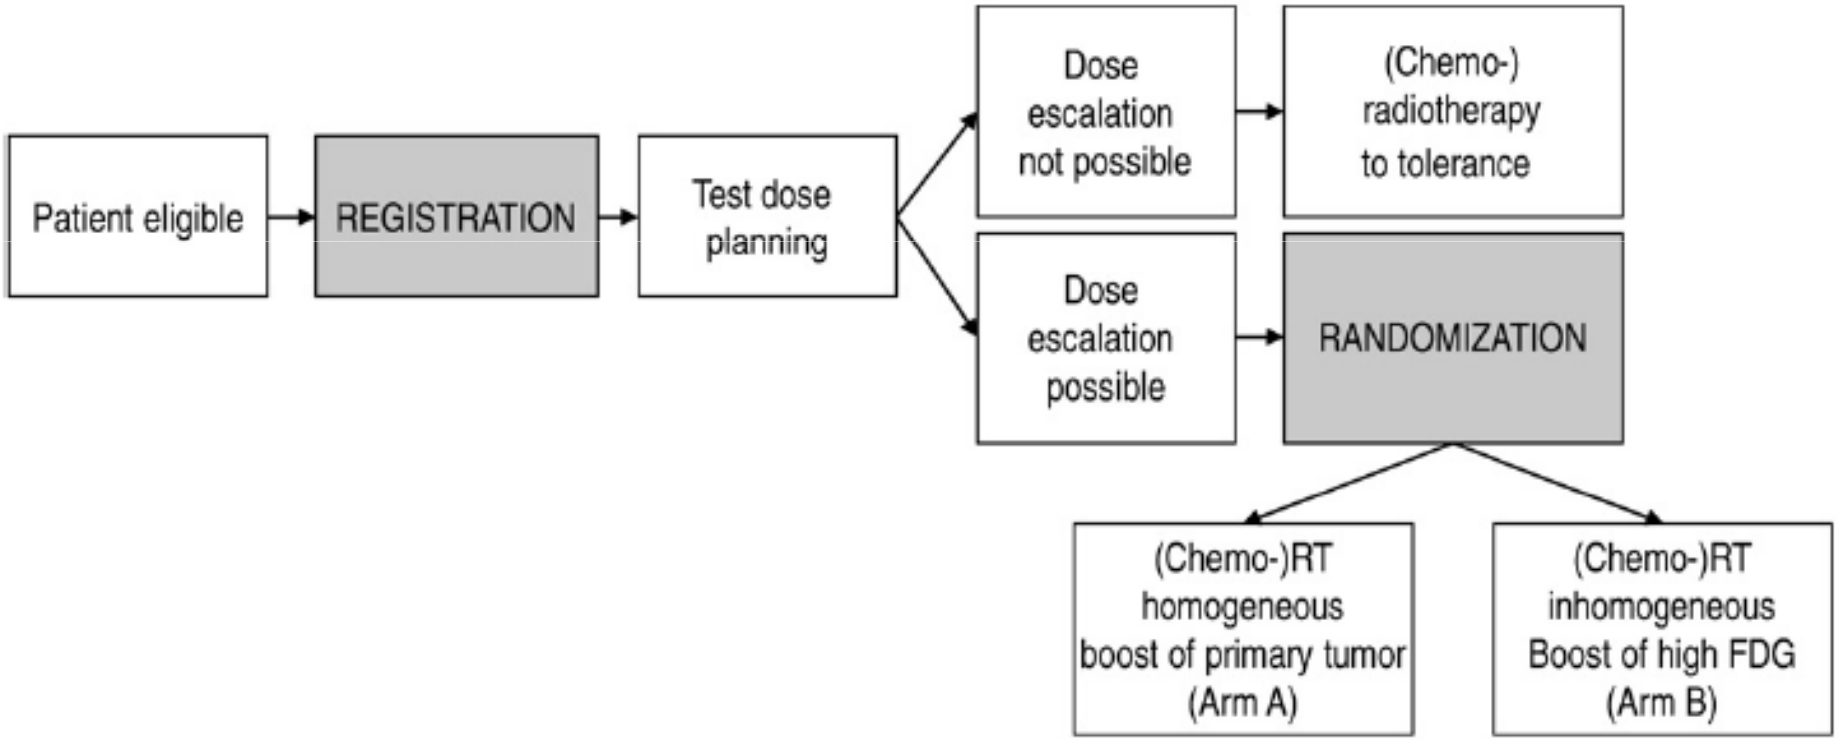
The PET-boost randomised phase II dose-escalation trial in non-small cell lung cancer

Wouter van Elmpt [a,*], Dirk De Ruysscher [a], Anke van der Salm [a], Annemarie Lakeman [b], Judith van der Stoep [a], Daisy Emans [a], Eugène Damen [b], Michel Öllers [a], Jan-Jakob Sonke [b], José Belderbos [b]

[a] *Department of Radiation Oncology, Maastricht University Medical Centre, Maastricht;* [b] *Department of Radiation Oncology, The Netherlands Cancer Institute, Amsterdam, The Netherlands*



Van Elmpt et al, Radiother Oncol 2012

Table 2
Dose parameters for the target structures.

Parameter	No escalation possible [$N = 5$]	Uniform boost (arm A) (arm A) [$N = 15$]	PET boost (arm B) (arm B) [$N = 15$]	p-value*
Prescribed dose/24 fractions	2.75 [1 patient 23#] in primary tumour	3.27 ± 0.31 [3.01–4.28] in primary tumour	3.63 ± 0.54 [3.20–5.40] in boost volume	0.001
Mean PTV dose: primary tumour [Gy]	65.5 ± 1.5 [63.3–67.3]	77.3 ± 7.9 [70.2–103.4]	77.5 ± 10.1 [71.4–112.0]	0.950
Mean PTV dose: boost area [Gy]	N.A.	79.2 ± 8.0 [72.0 – 104.9]	86.9 ± 14.9 [74.9–134.9]	0.001
Min. PTV dose ($D_{99\%}$): primary tumour [Gy]	61.3 ± 2.9 [57.8–64.6]	66.7 ± 8.1 [55.0–92.4]	62.0 ± 3.3 [56.0–69.9]	0.001

* The p-values were calculated using a Wilcoxon-Signed Rank test.

Table 3
Dose parameters for the organs at risk.

Organ-at-risk	Dose constraint	Uniform boost (arm A)	PET boost (arm B)	p-value*	Dose-limiting arm A	Dose-limiting arm B
Mean lung dose [mean dose Gy]	20 Gy (corrected to EQD2)	15.8 ± 3.9 [7.3–19.7] (corrected to EQD2)	15.7 ± 4.0 [7.3–19.9] (corrected to EQD2)	0.038	3/15	2/15
	N.A. (physical dose)	16.7 ± 4.3 [7.8–21.5]	16.8 ± 4.4 [7.8–21.9]	0.340	3/15	2/15
PRV mediast. [$D_{0.1\%}$ Gy]	<76 Gy (=EQD2 of 94 Gy)	71.1 ± 11.4 [30.3–75.7]	72.1 ± 10.4 [34.9–76.8]	0.073	13/15	14/15
Spinal cord [$D_{0.1\%}$ Gy]	<51 Gy (=EQD2 of 53 Gy)	41.7 ± 8.4 [25.1–49.7]	42.0 ± 9.2 [22.1–50.1]	0.394	1/15	1/15
Oesophagus [V_{35Gy}]	<80%	38.8 ± 15.5 [10.7–62.8]	39.1 ± 15.8 [12.0–57.0]	0.727	0/15	0/15
Heart [mean dose Gy]	<47 Gy (=EQD2 of 46 Gy)	13.2 ± 12.8 [0.3–30.9]	12.4 ± 11.9 [0.3–29.7]	0.271	0/15	0/15
Brachial plexus [$D_{0.1\%}$ Gy] (if proximity of PTV)	<66 Gy (=EQD2 of 79 Gy)	54.2 ± 14.2 [23.7–65.6]	53.7 ± 16.2 [17.3–65.7]	0.778	3/15	3/15

* The p-values were calculated using a Wilcoxon-Signed Rank test.

Remarks on IMRT for LA NSCLC

- IMRT is now an accepted standard for LA NSCLC radiotherapy
- IMRT could reduce V20 and heart dose
- IMRT could increase patients' compliance to chemotherapy
- Ongoing trials will clarify us the role of PET-guided hypo-fractionated boost and the best chemotherapy combination (these trials are made possible by the use of IMRT!)
- New drugs will hopefully amplify the benefit of the combined modality approach

F

Tumour regression

- Large radiosensitive tumours decrease in volume during RT

- Cervical tumours reduce 31-70%
- Time to 50% reduction 21/7
- Less fixation → increased mobility?
  - No dosimetric detriment

- Replanning beneficial to spare bowel

Herrera et al 2013; Van de bunt 2006

Unknown late effects

- Increased peripheral dose:
  - 0.12% prescribed dose
  - Less with 6MV vs 15MV
  - Clinical consequence unclear
- Second cancer risk
  - Absolute risk 1.75% at 10 years compared with 1% for 3D-CRT
  - Due to increased low dose volume (0.5%) and MU (0.25%)
  - Higher energy worse; <1% absolute increase risk

Salz et al 2012, Hall et al 2003, Zwahlen et al 2009

Cost effectiveness

- More expensive initial cost

- Gynaecological patients:
- Increasingly cost effective with time
    - Lower toxicity
    - Post operative pts

- Too expensive unless treating PA nodes

Chen et al Gynecol Oncol 2015;136:521. Lesnock et al Gynecol Oncol 2013;129: 574

uclh

Summary

- IMRT improves OAR protection
- Dosimetric benefit
- Clinical benefit likely
- Strict QA necessary
  - Image guidance
  - Delineation accuracy
  - Margins
  - Reproducibility

- Prospective randomised clinical trials needed

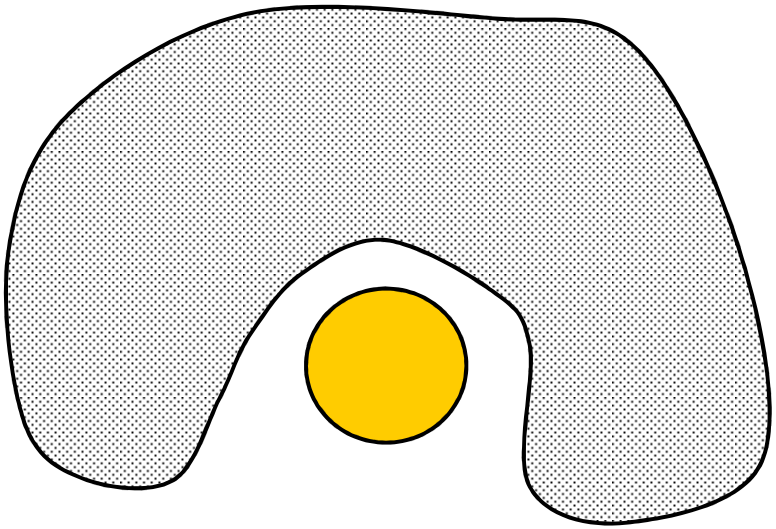
Many of the following slides are based on his presentations about "IMRT optimization" and "Costfunctions" at the ESTRO IMRT course 2012

FAQ:

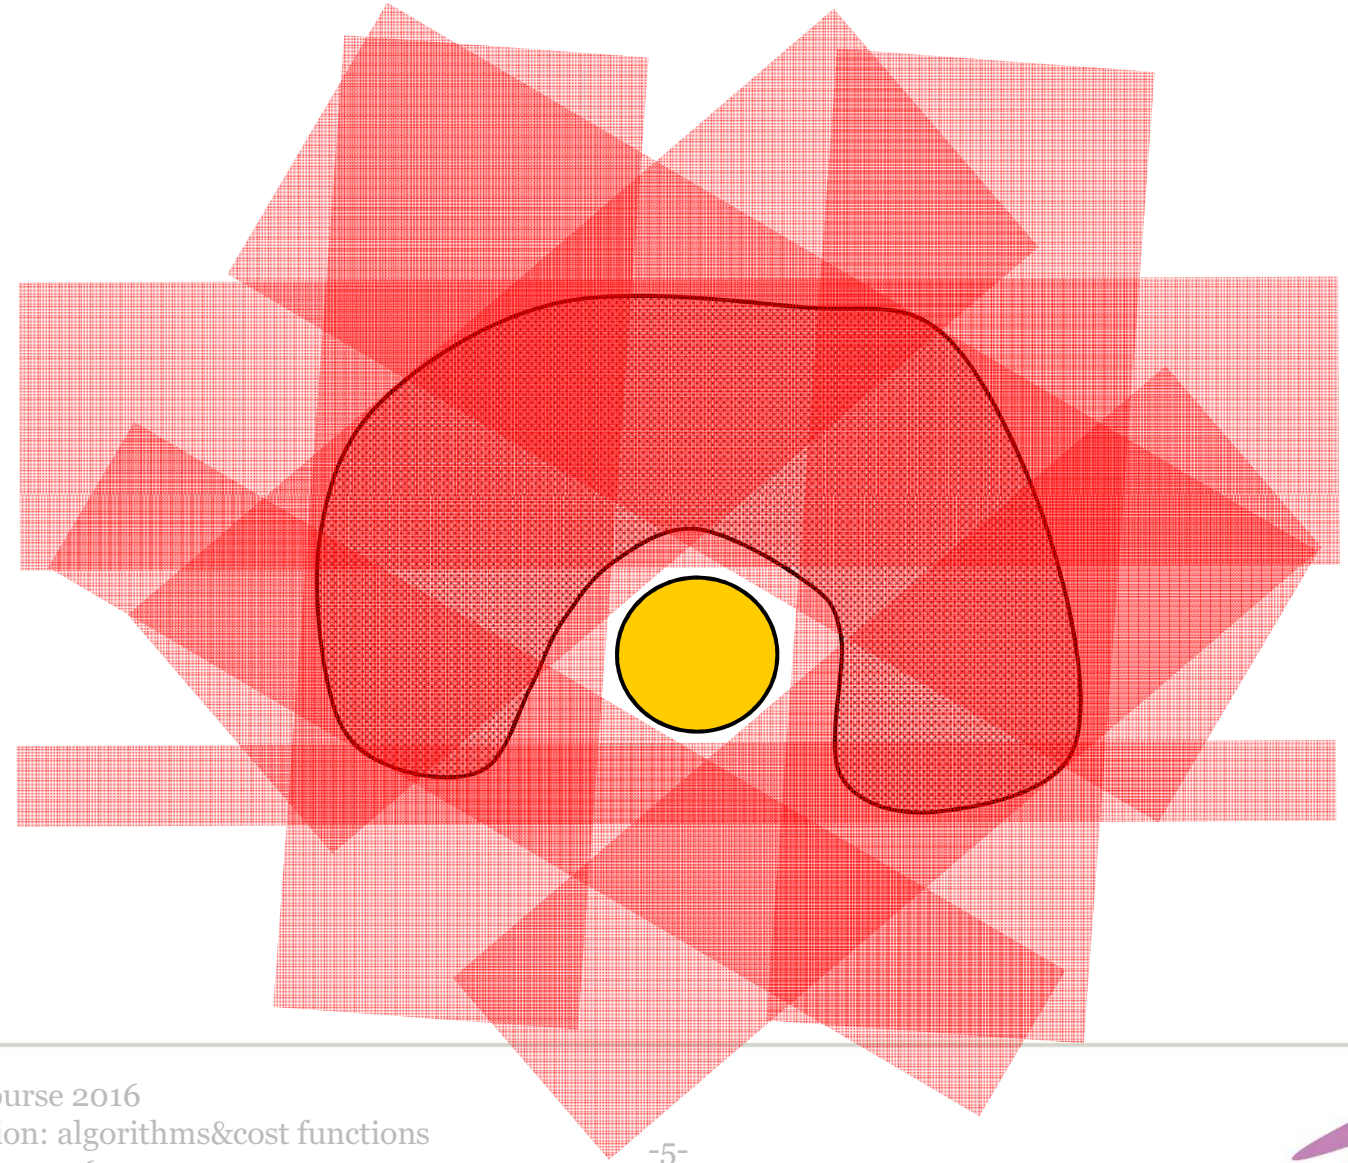
- Why do we need dose optimization if all we want to do is dose planning?

How close are our objectives to a physically feasible dose?

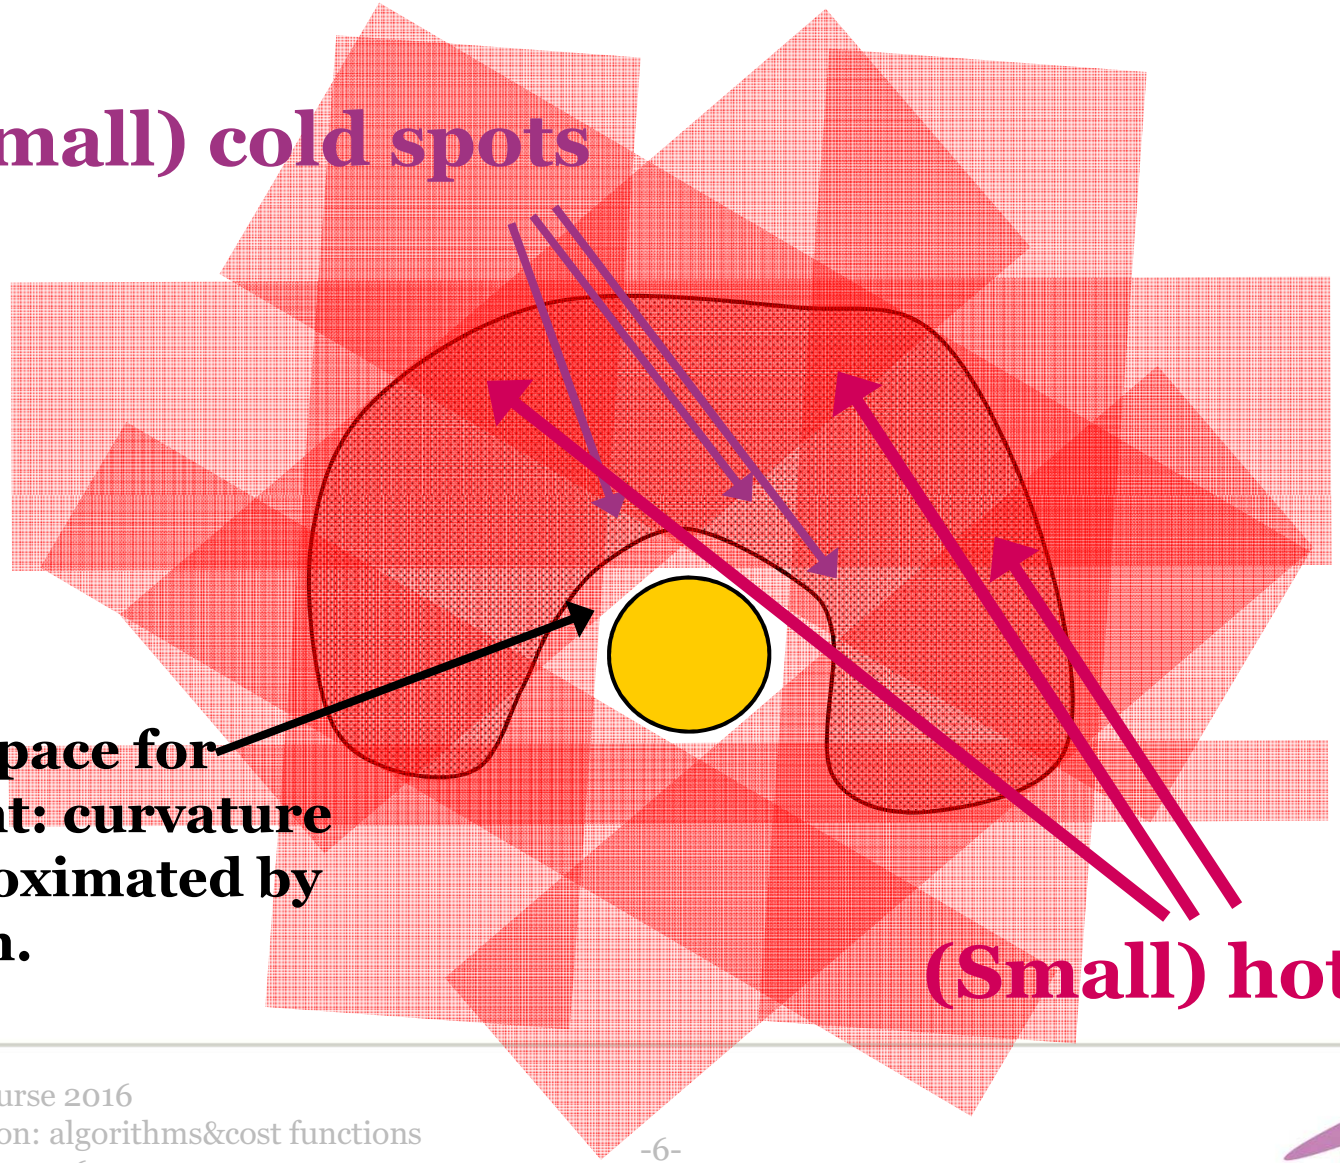
Paint a concave dose gradient!



With 4 beams…

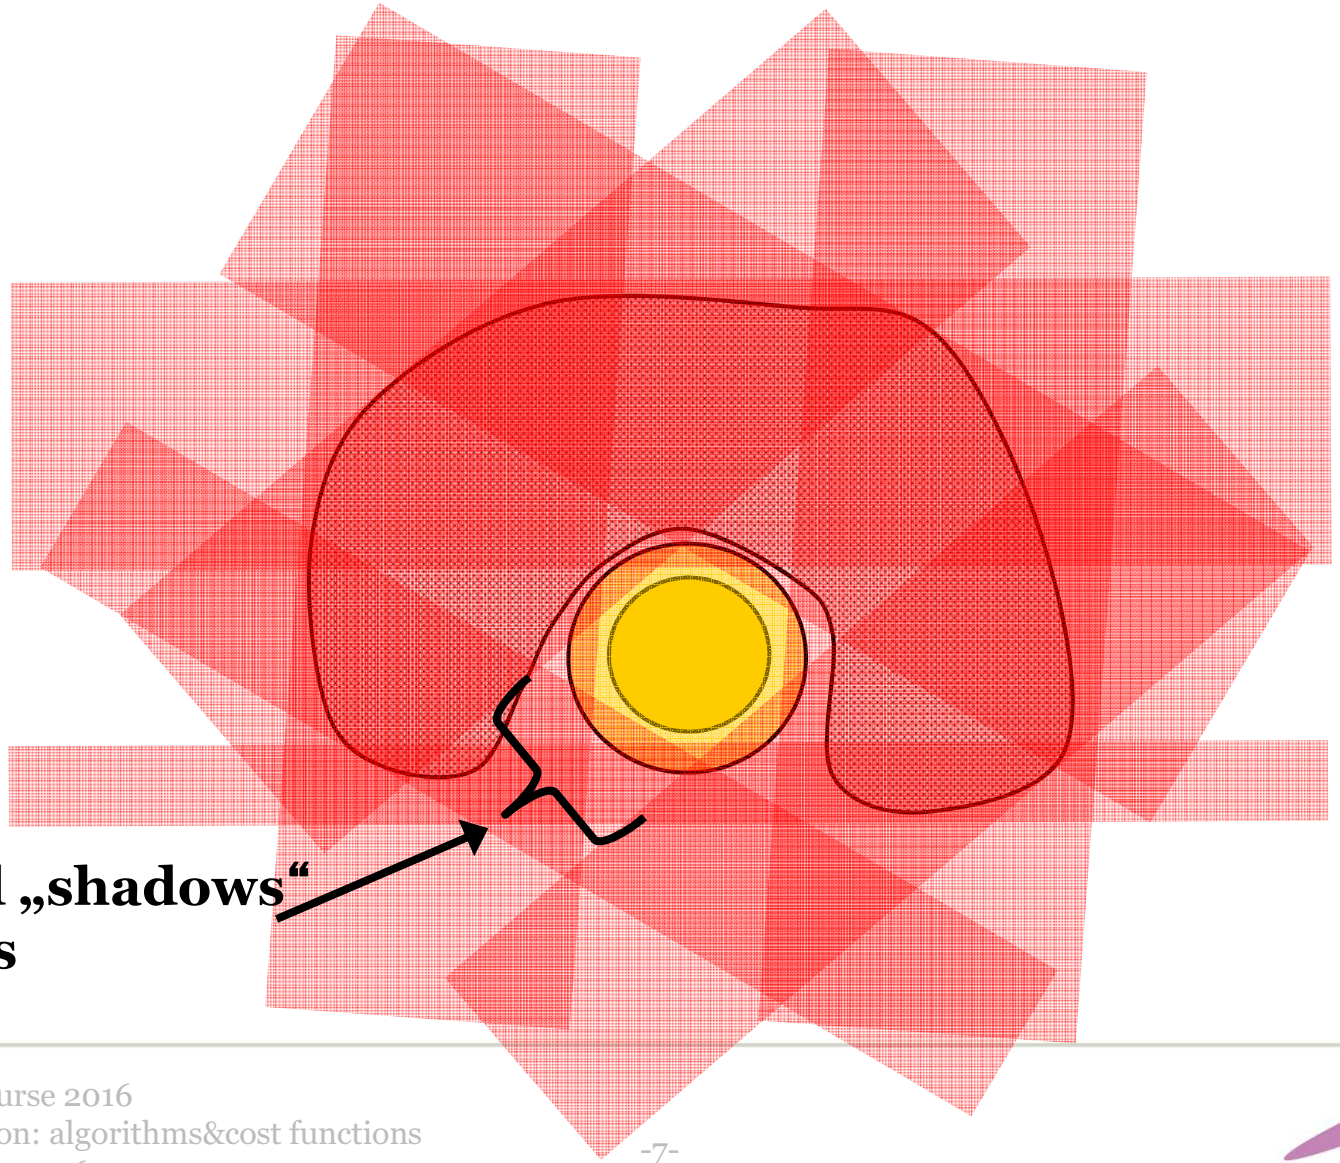


With 4 beams…

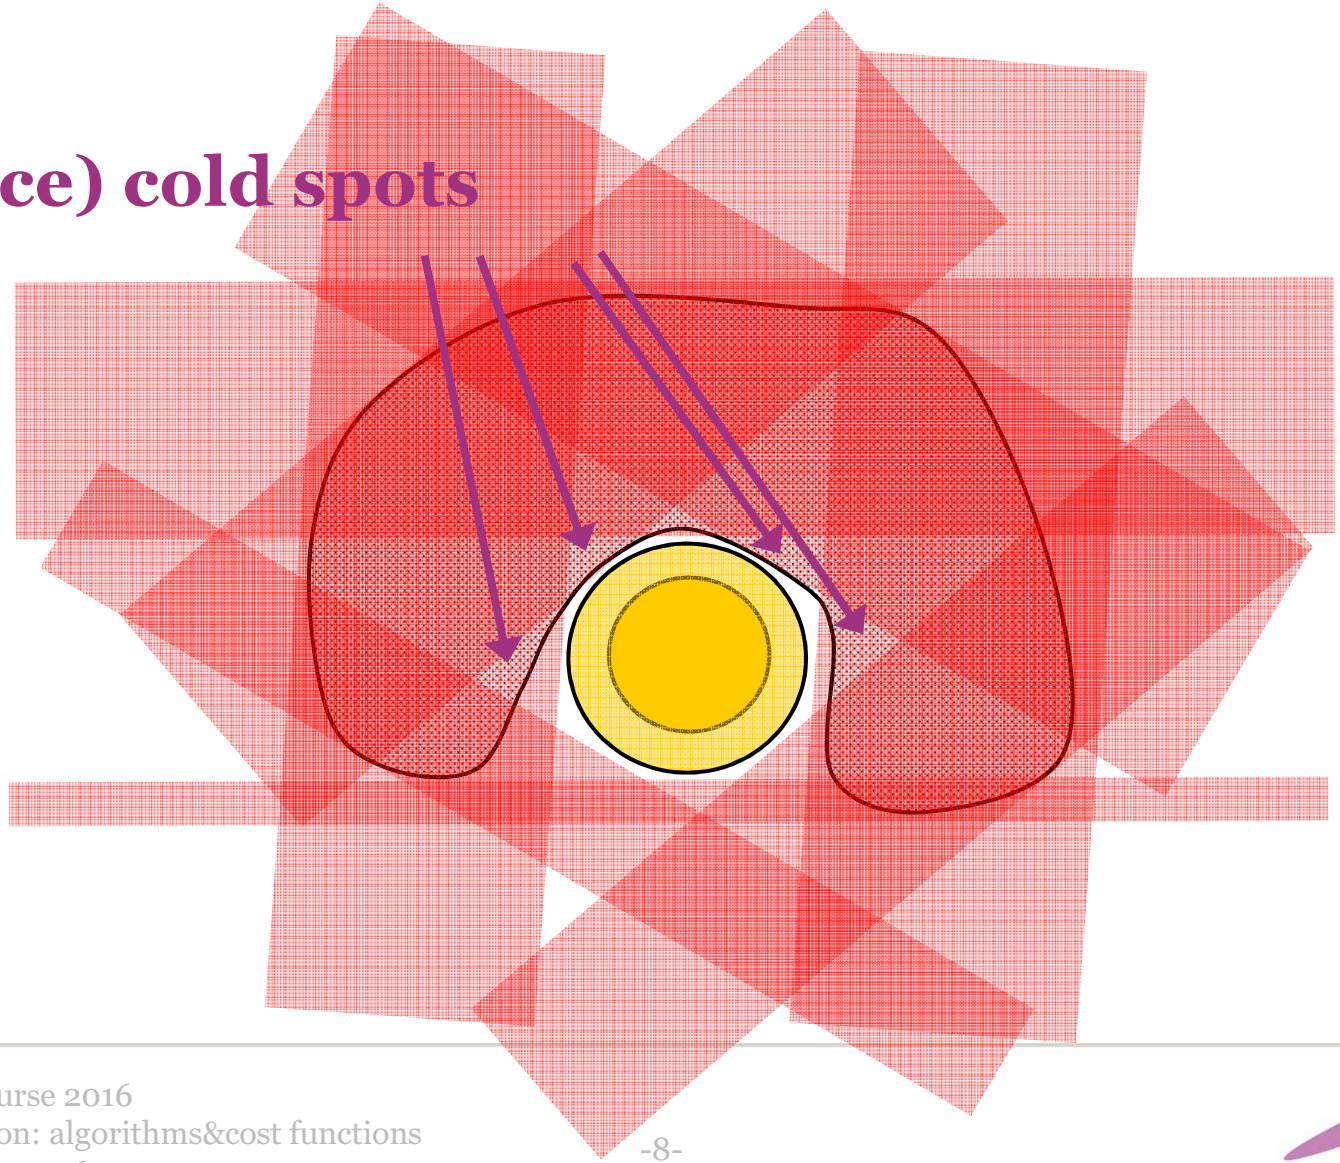


(Small) cold spots
Large space for gradient: curvature is approximated by polygon.
(Small) hot spots

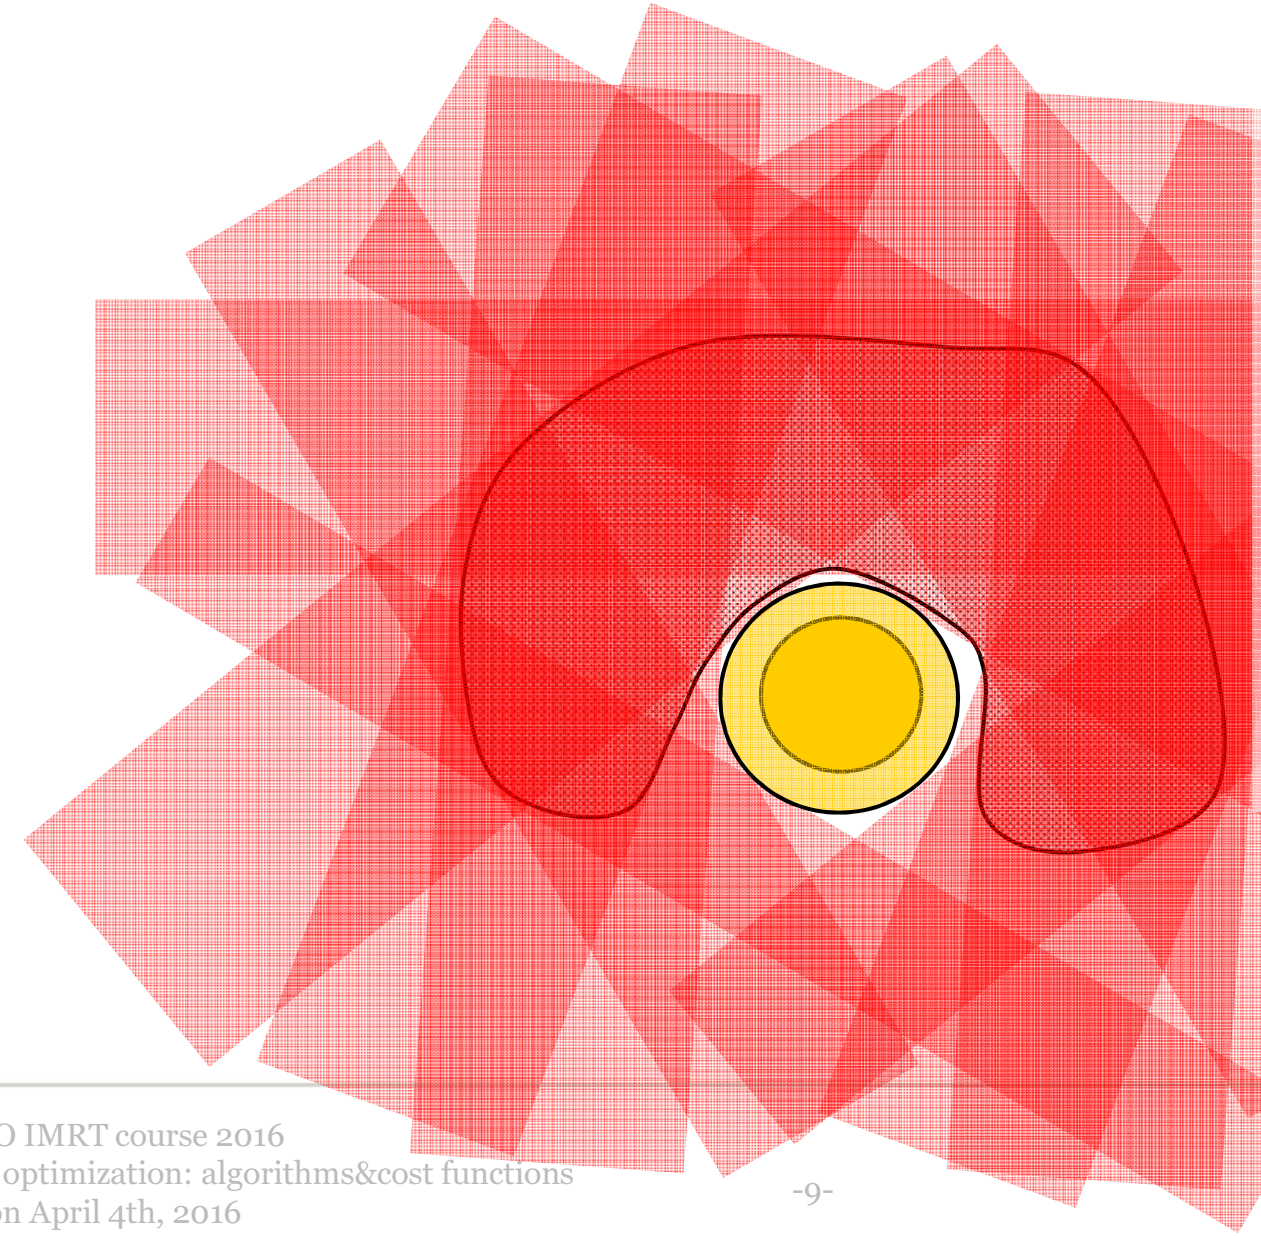
What if the gradient has to be tighter?



What if the gradient has to be tighter?



Solution *for this special case:* Use more beam angles!



What works for this special case might not be a sufficient solution for another case!

Depends on patient geometry, PTV/OAR overlaps, required amount of OAR sparing…

So, why optimization?

The best physical dose distribution depends strongly on the patient geometry, the plan setup and the treatment machine´s capabilities.

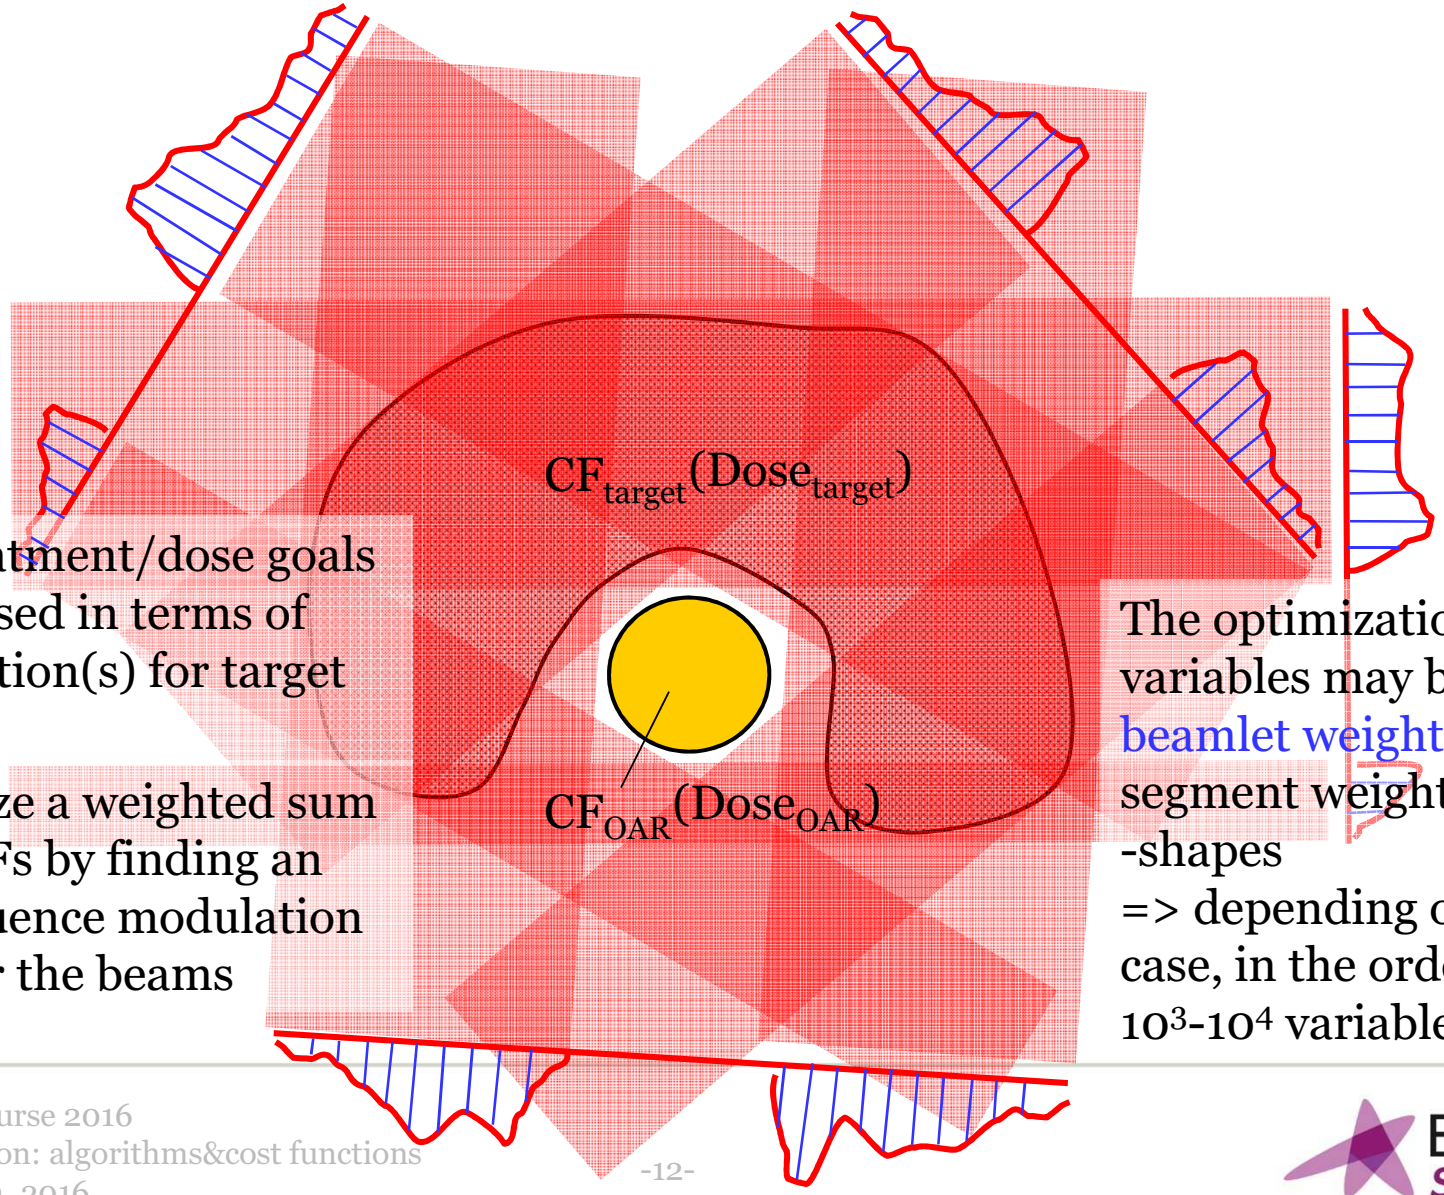
What may be easy for one patient may be infeasible for another.

Therefore, IMRT treatment planning *means exploring the limits of physics* for each patient. The big decisions still have to be made by the experts.

FAQ:

- Why do we need dose optimization if all we want to do is dose planning? √
- What do we actually optimize? Dose? Cost functions? Beamlets?

The IMRT optimization problem: What is optimized, and what are the variables?



(1) the treatment/dose goals are expressed in terms of **C**ost **F**unction(s) for target and OARs.

(2) optimize a weighted sum of these CFs by finding an optimal fluence modulation pattern for the beams

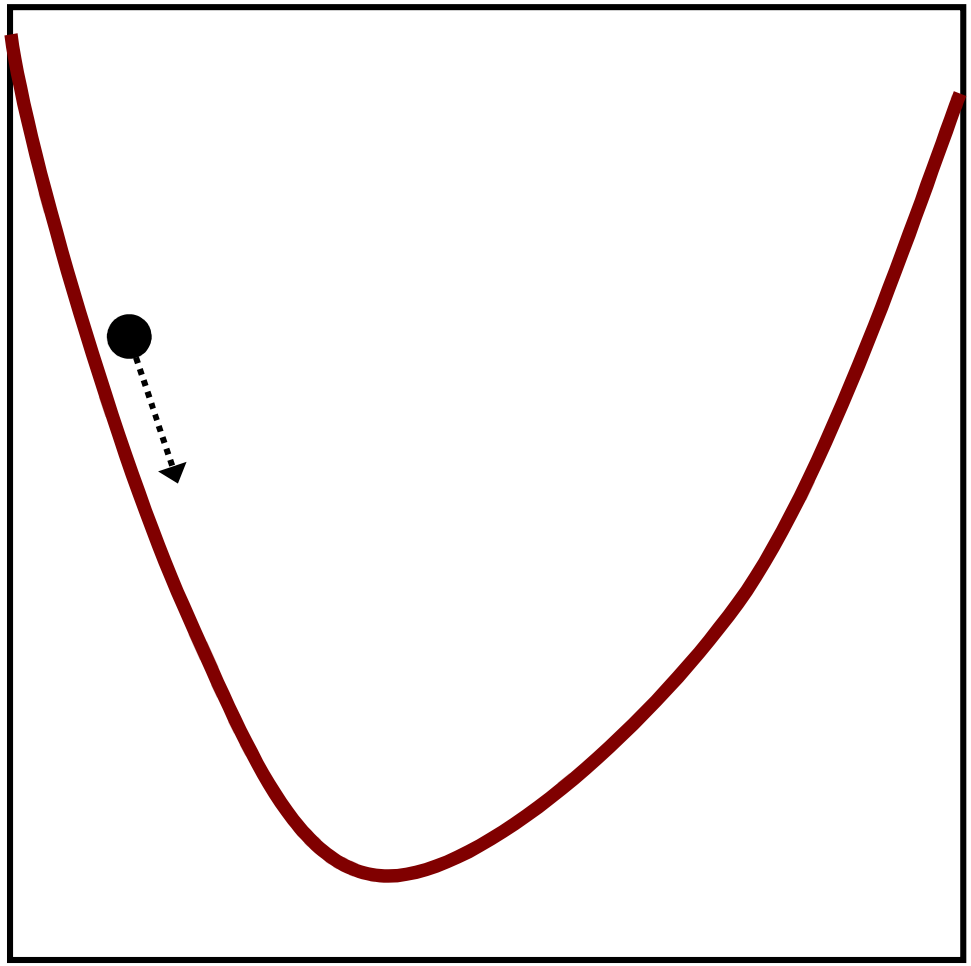
The optimization variables may be beamlet weights or segment weights and -shapes
=> depending on the case, in the order of 10^3-10^4 variables!

FAQ:

- Why do we need dose optimization if all we want to do is dose planning? √
- What do we actually optimize? Dose? Cost functions? Beamlets? √
- What optimization algorithm to use, and why?

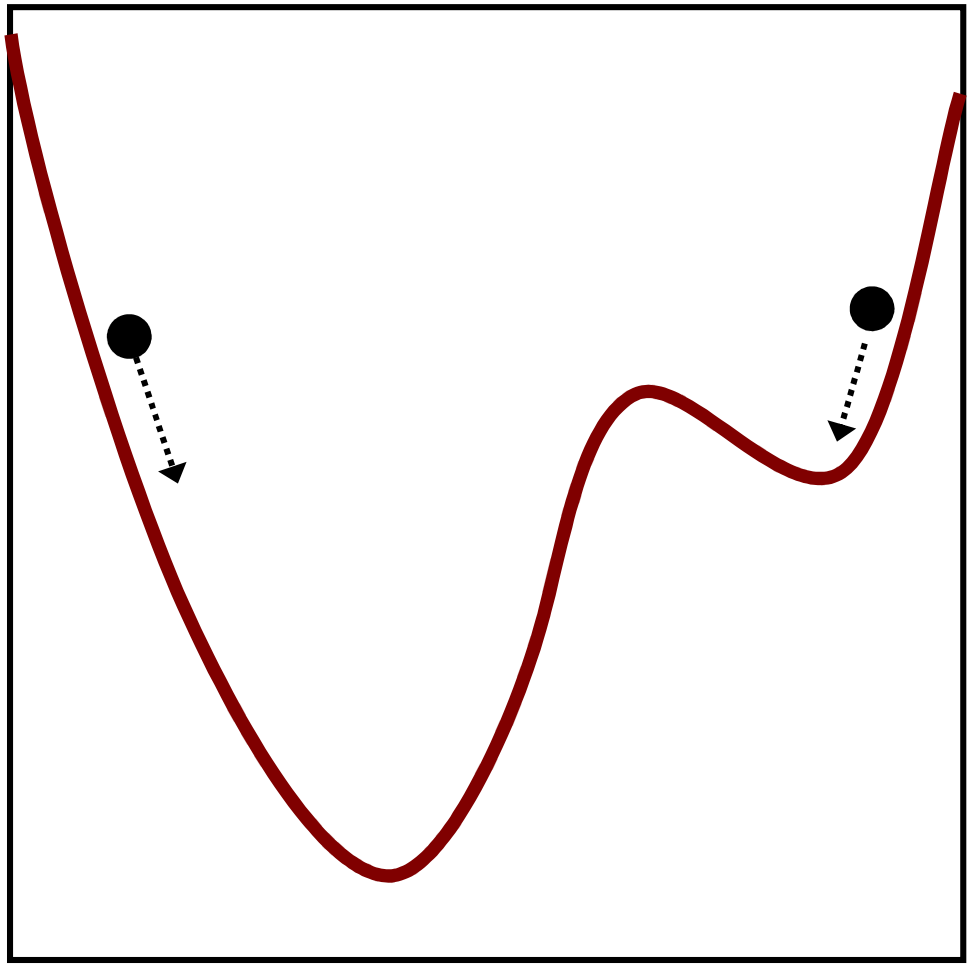
The popular understanding

Reach minimum of cost function
by going downhill in
a well-defined direction
to a well-defined minimum



The popular fear

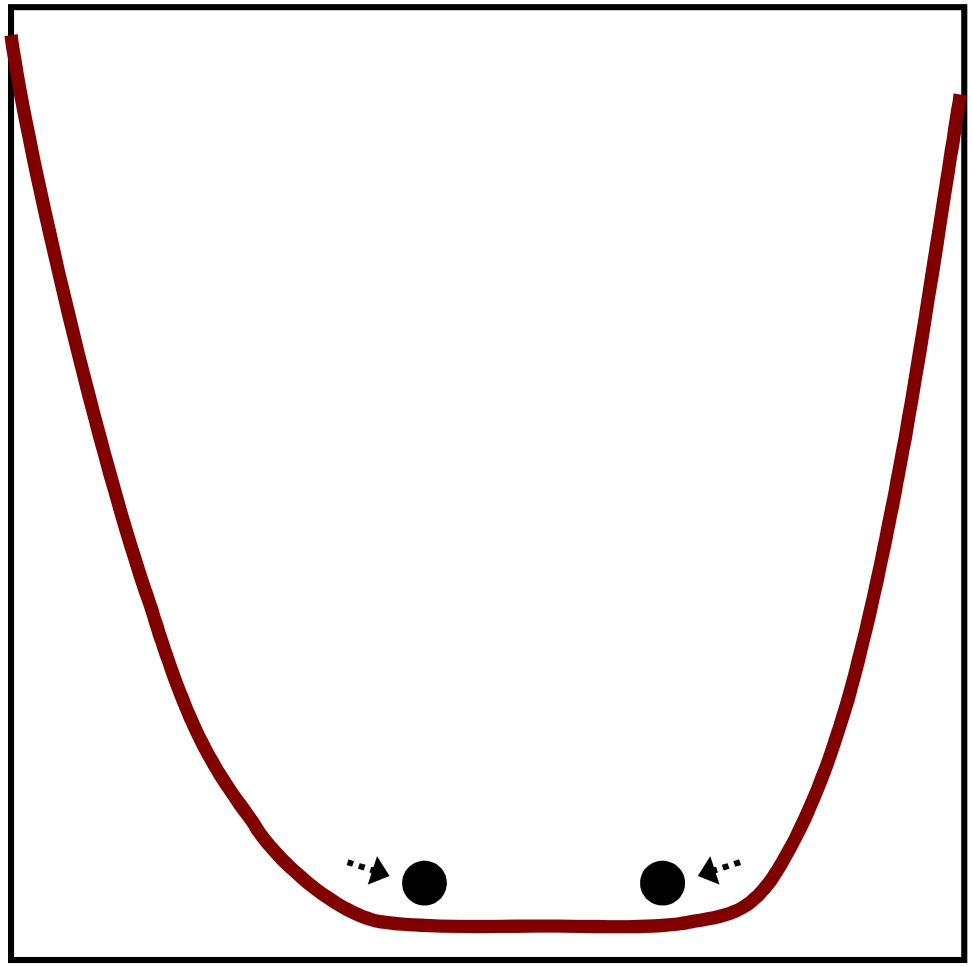
There are multiple minima, some not as good as the global minimum



The truth: degeneracy of the optimization problem, non-uniqueness of the solution

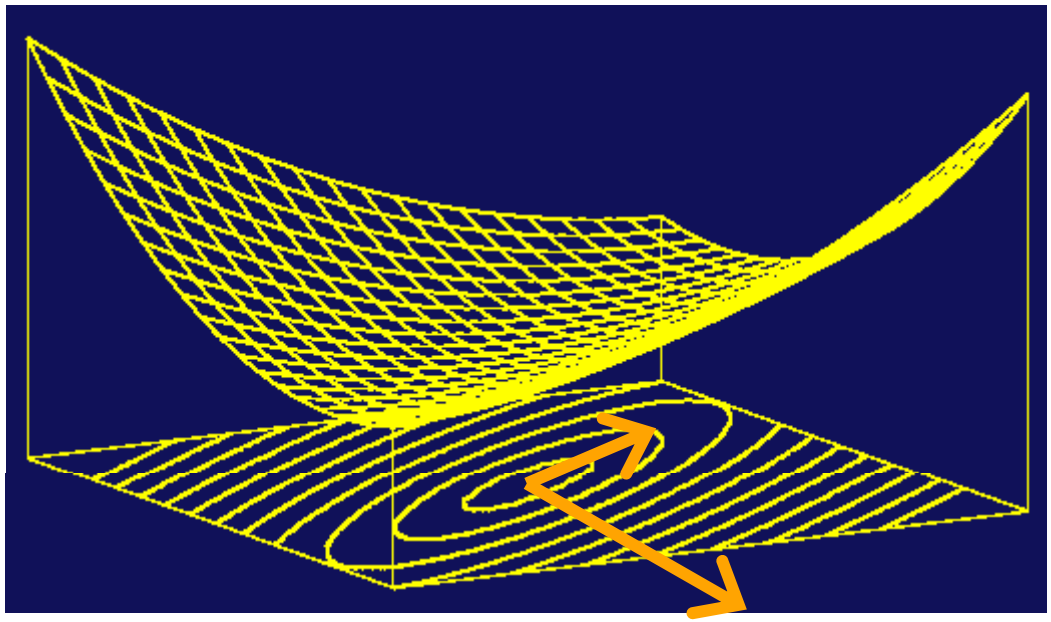
In some directions, the minimum is not sharp at all.

In others, it is.



Fluence profile optimization (No MLC)

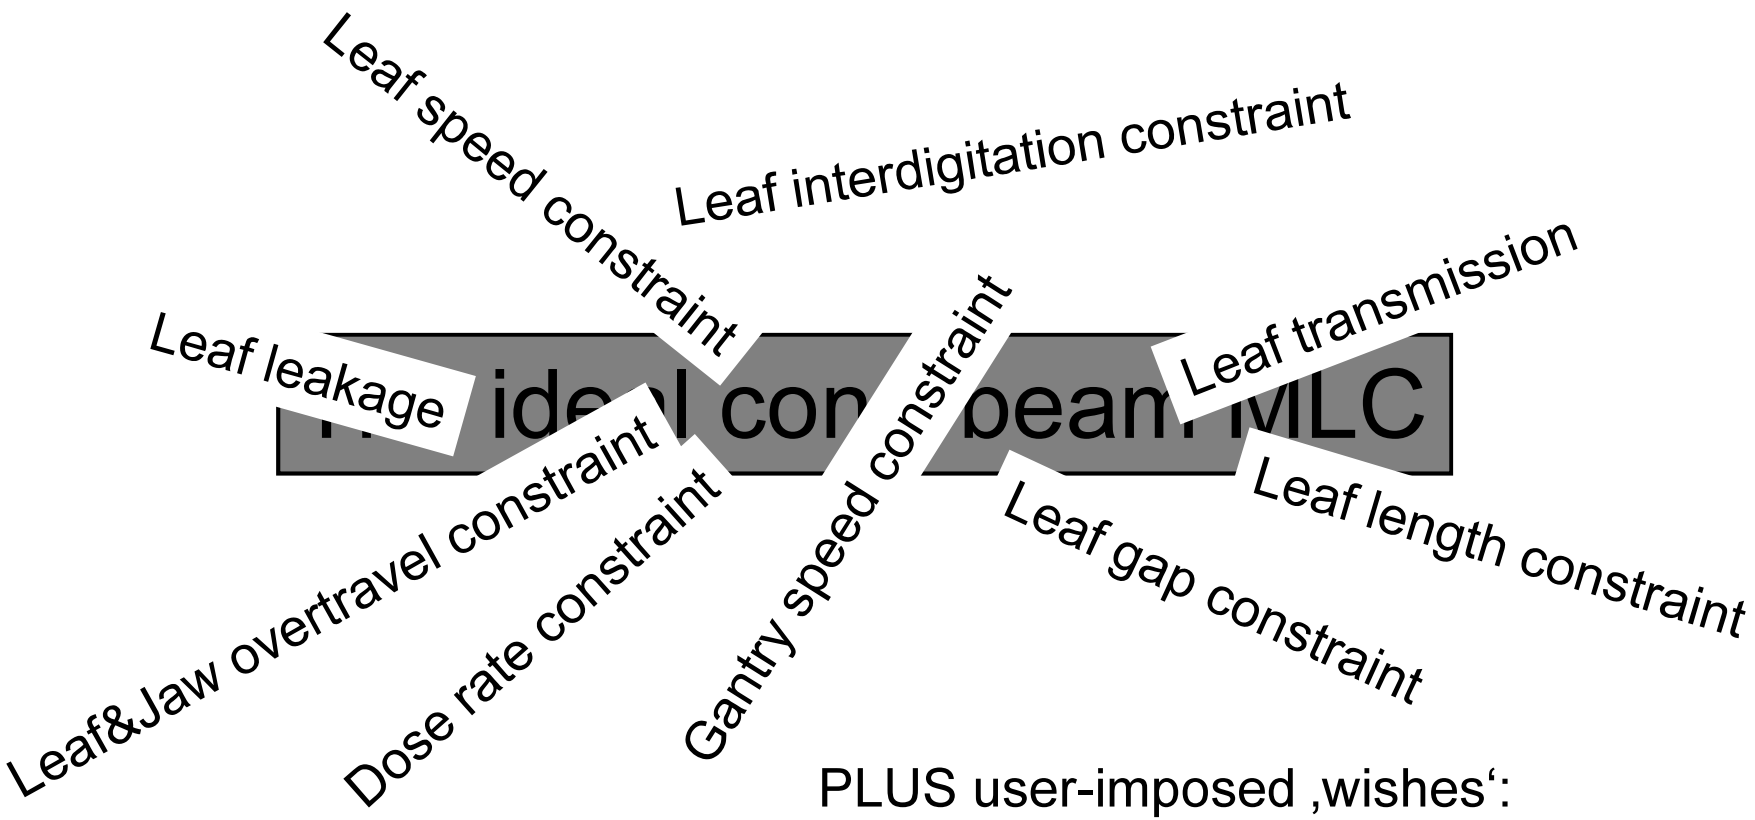
The minimum sits in a flat-pan valley, the search direction is well defined in few (ca. 100), but vague in most dimensions (ca. 10000),
a multiplicity of optimum solutions exists.



Problems for the optimization algorithm:

- **convergence** in end game is very **slow – terminate long before convergence**
- same **solution** may **not be reached** twice, although the cost functions have identical values
- no local minima, but still difficulties to find the optimum!

Next: Sequencing
Add (a lot of!) delivery constraints…



PLUS user-imposed ‚wishes‘:

- max. #segments
- max. #arcs
- minimize #MUs, treatment time...

Principles: The optimization problem for the different IMRT techniques

Static gantry, dMLC: (e.g. sliding window)	no distant local minima for 'easy' MLCs, proven algorithm for solution
Static gantry, step&shoot: ('step&shoot' IMRT)	local minima possible, but good heuristics for avoiding them (MLC sequencer)

(Notice: *algorithm* converges, *heuristic* produces a result)

Rotational-IMRT: (VMAT, Rapid Arc ©...)	So many local solutions that it becomes impossible to *identify* the global one, bold heuristics for avoiding the inevitable: getting trapped in a local minimum.

Optimization Algorithms

- Optimization algorithms find a solution by minimizing a function.
- Virtually all algorithms use gradient information for the downhill search.
- The size of the optimization problem limits the number of available algorithms to *quasi-Newton methods* and *Conjugate Gradient search*. If implemented well, none should be superior to the others.
- These algorithms are deterministic, so that given infinite time, they find a minimum, which is unique in the absence of delivery constraints.
- Some delivery constraints make the problem virtually unsolvable.
- If nothing else helps: stochastic algorithms (like Simulated Annealing) which perform a sparse, random search of the entire solution space (which is very, very big). Stochastic algorithms are the last resort when the problem is otherwise intractable.

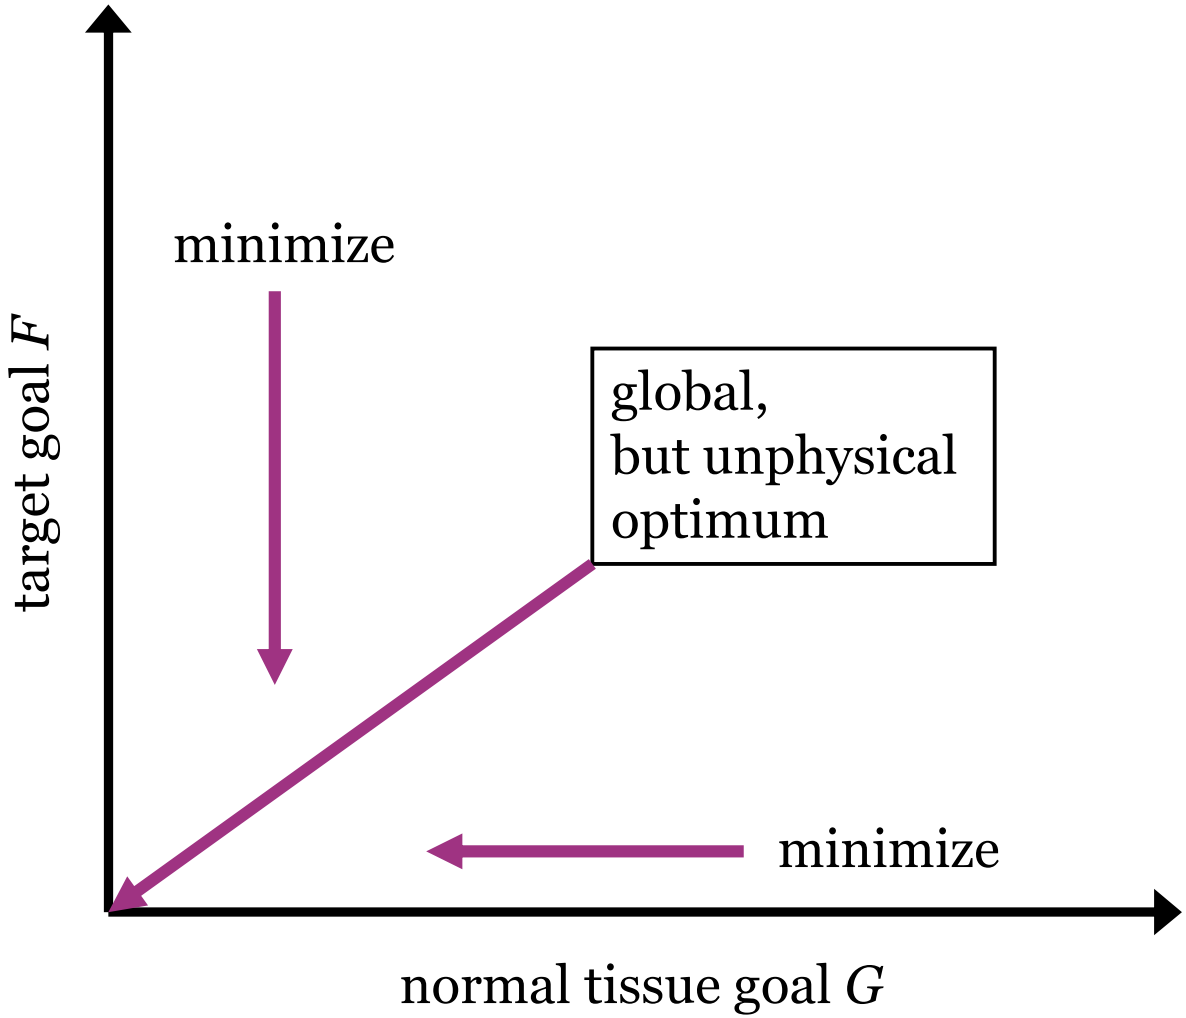
FAQ:

- Why do we need dose optimization if all we want to do is dose planning? √
- What do we actually optimize? Dose? Cost functions? Beamlets? √
- What optimization algorithm to use, and why? √
- Weight Factors, Constraints, Objectives – why is it so complex?

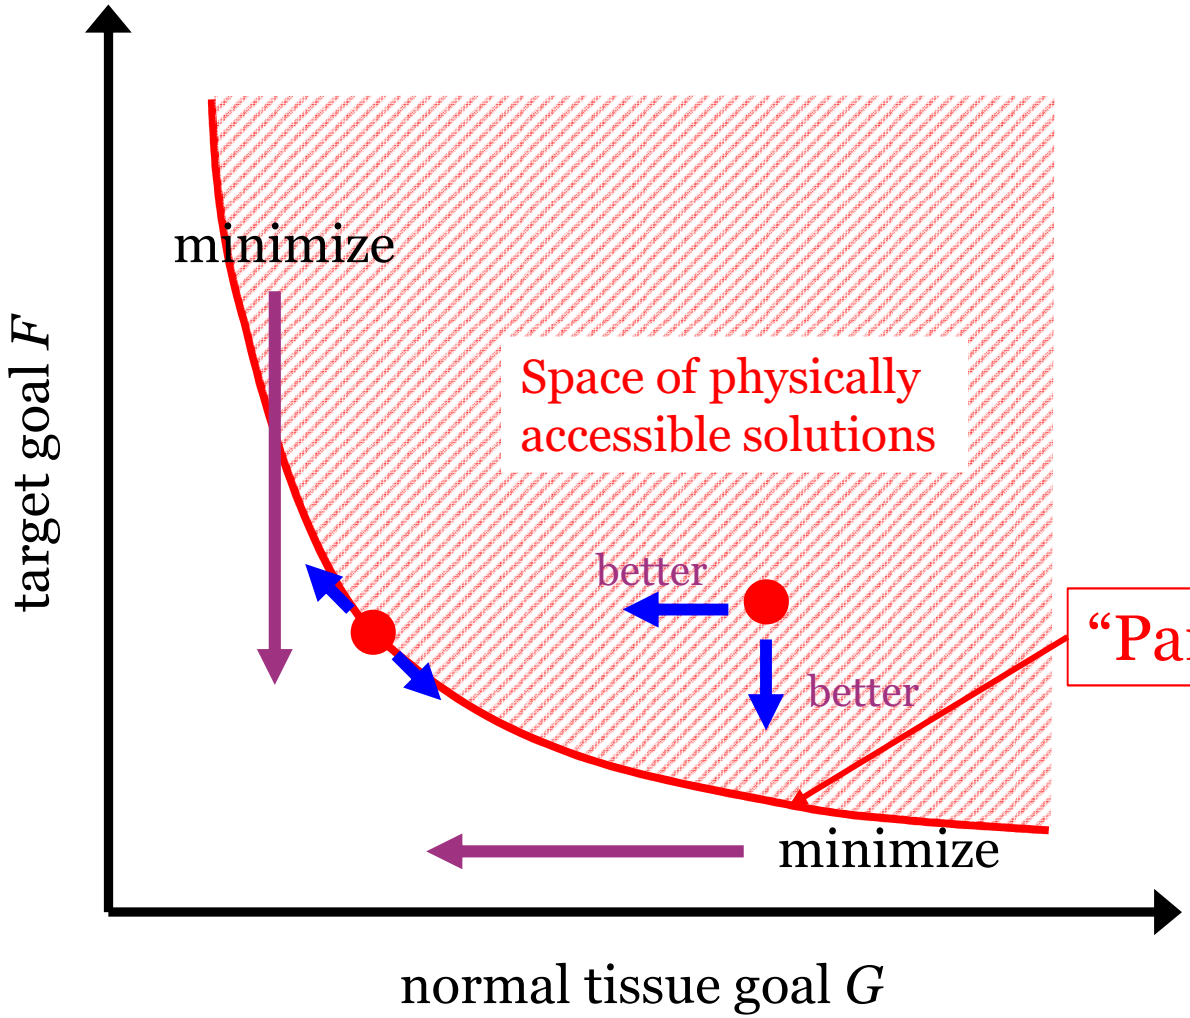
What are typical treatment goals?

Target goal:	achieve a ***sufficient target dose***
Normal tissue goals:	do not ***exceed acceptable doses*** in N ***organs***
Conformality goal:	target dose should be ***conformal***, ***spare generic normal tissue***
Homogeneity goal:	***no large*** or ***excessive hot spots*** in the ***target***

Without the laws of physics, all goals could be fulfilled simultaneously



There exists a boundary that separates physical from unphysical solutions



Any optimum solution lies on this boundary:

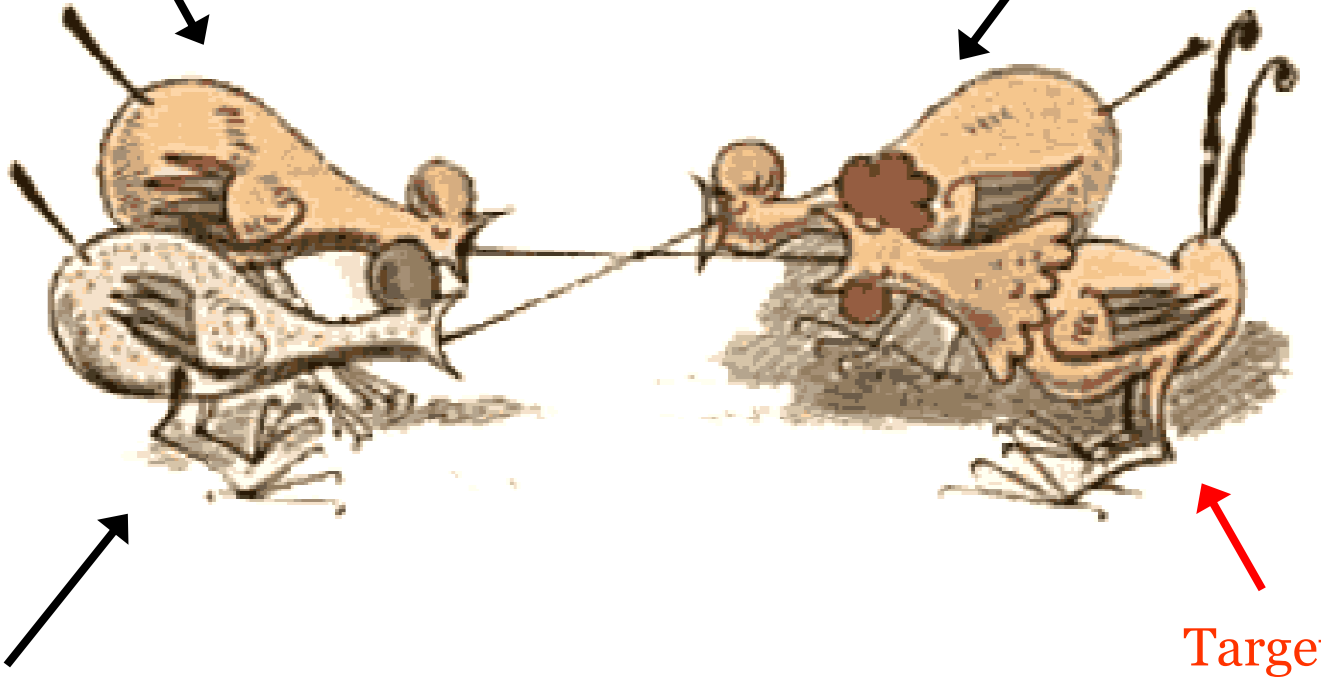
G cannot be reduced without increasing *F* and vice versa.

"Pareto-front"

In other words: Treatment goals contradict each other! How can these be balanced?

Normal Tissue Goals

Target Dose Homogeneity Goal



Dose Conformality Goal

Target Goals: only goal aiming to *increase* dose

Cost Functions can be Balanced by Weight Factors: the Lagrange Function

Combine all goals to one weighted sum:

$$L = \sum_{j=1}^{M} \lambda_j F_j$$

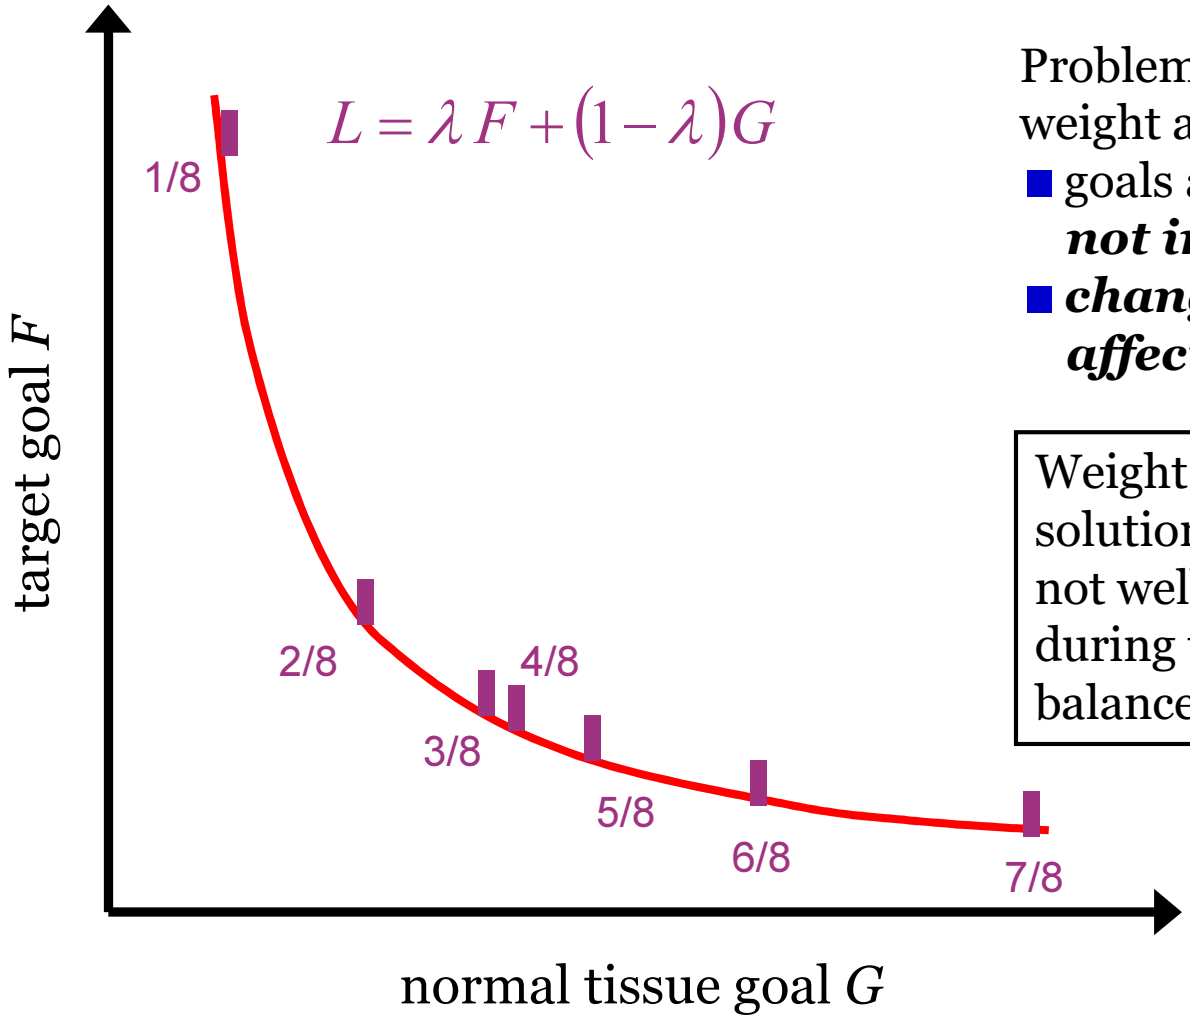
$$\sum_{j=1}^{M} \lambda_j = 1, \quad \lambda_j \geq 0$$

...and minimize the Lagrange Function L.
Tuning the weight factors λ_j makes all solutions in Solution Space accessible.

Problem: find the right set of weights that produces a dose distribution as minimizer of L which is `***closest to the intended***` treatment.

This is a decision to be made by the user, not the software

Parametrisation of the Solution Space by Weight Factors

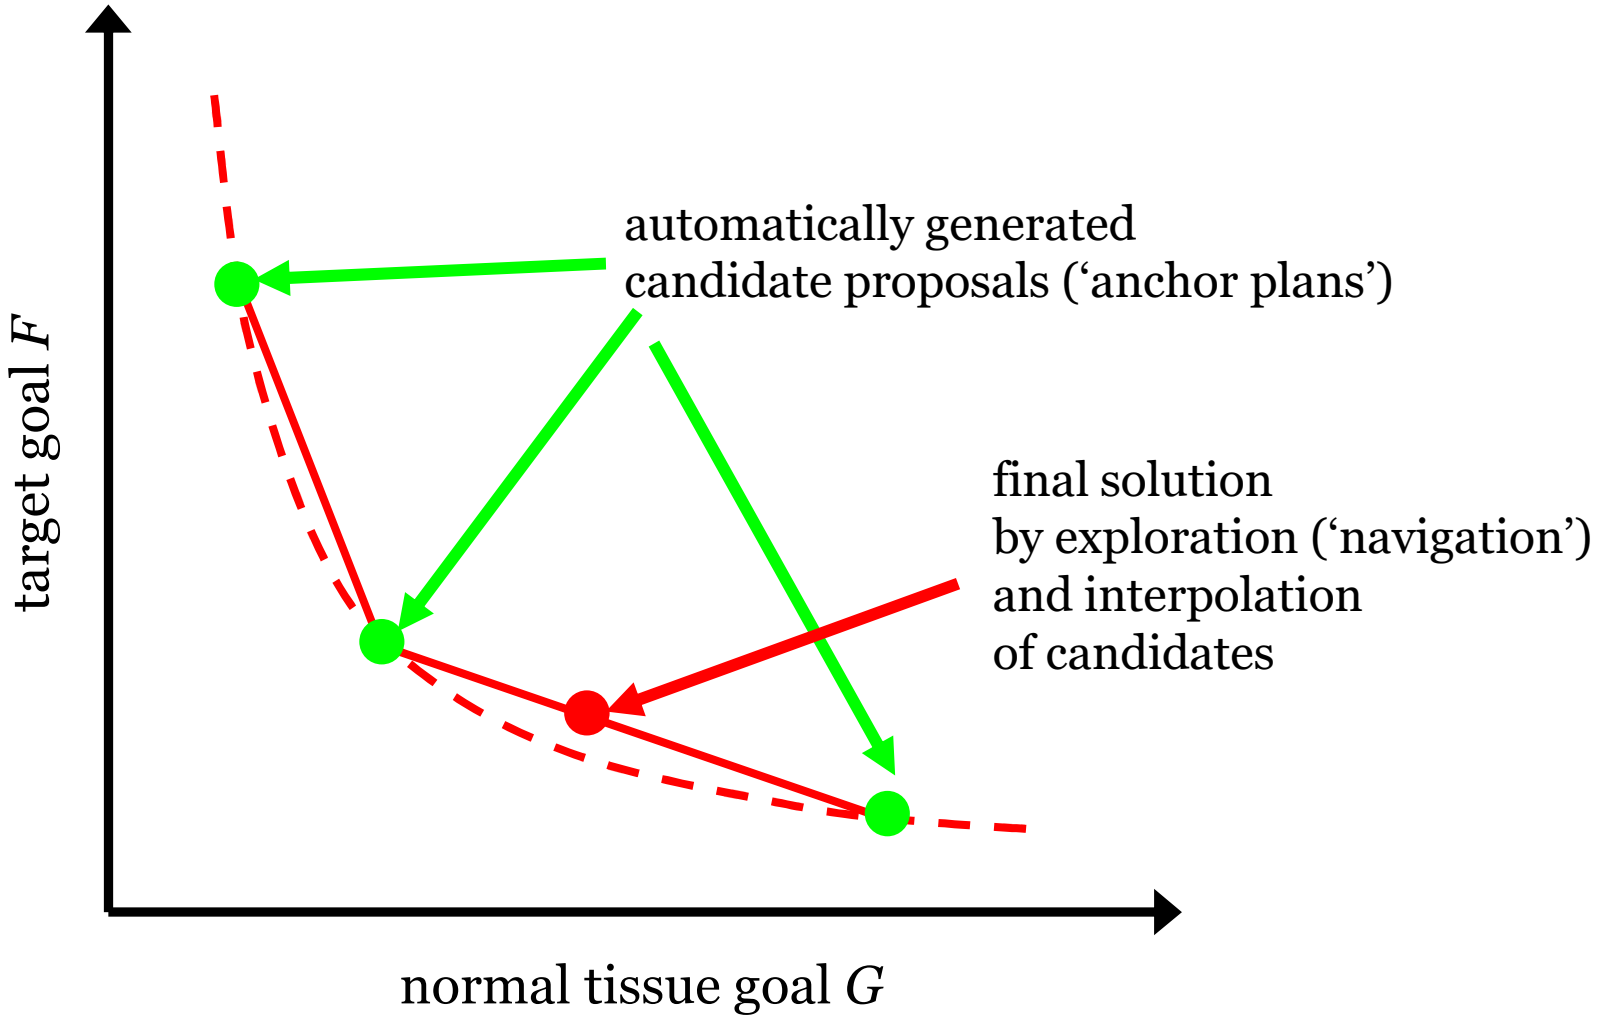


Problems with manual weight adjustments:

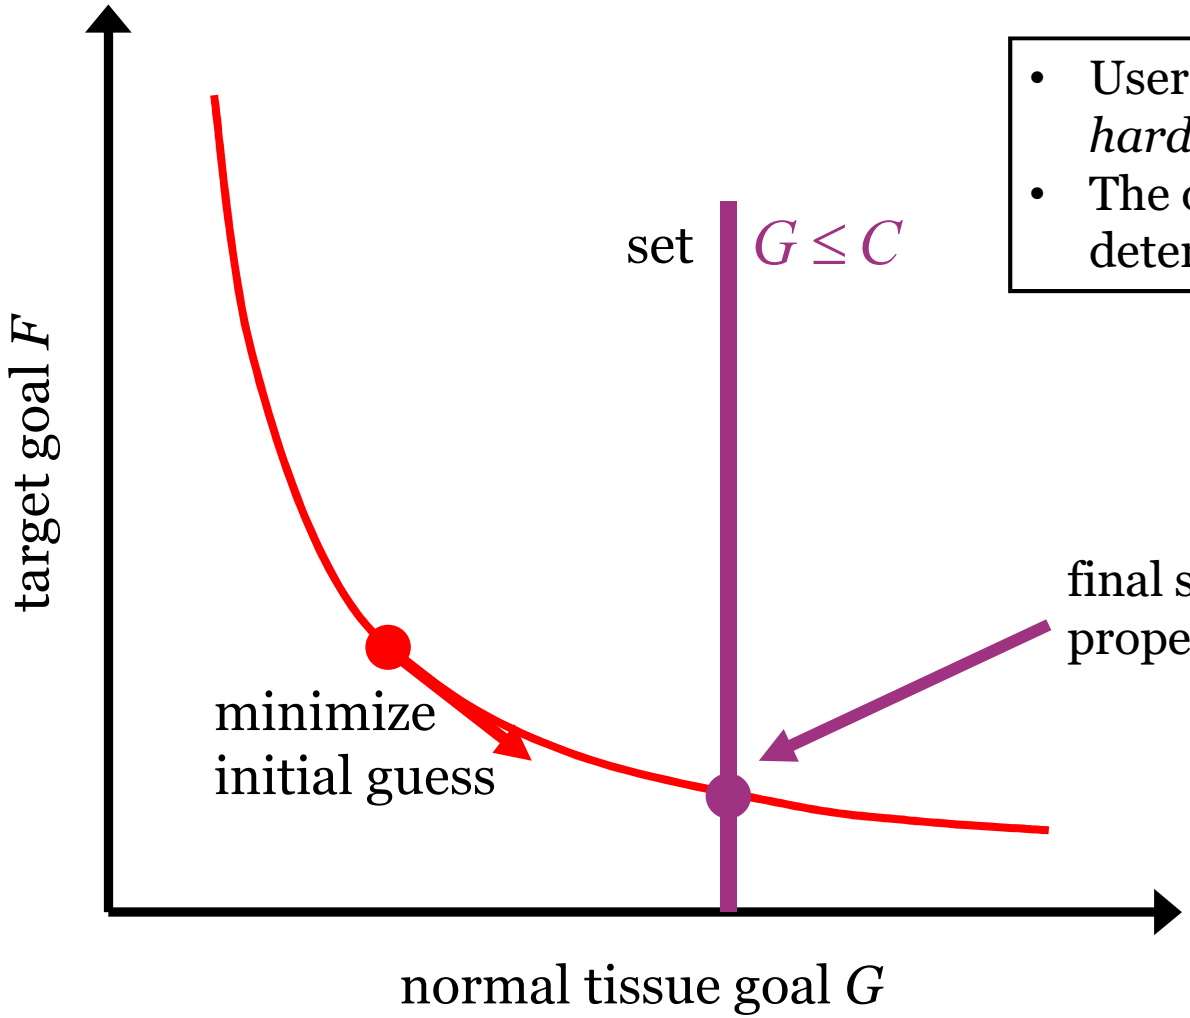
- goals and weight factors are ***not inversely proportional***
- ***changing one*** weight factor ***affects all*** other goals

Weight factors make the solution space accessible, but are not well suited for exploring it during the search for the best balance between goals.

Navigating the Solution Space: Libraries of Proposals ('multicriterial/Pareto-optimization')

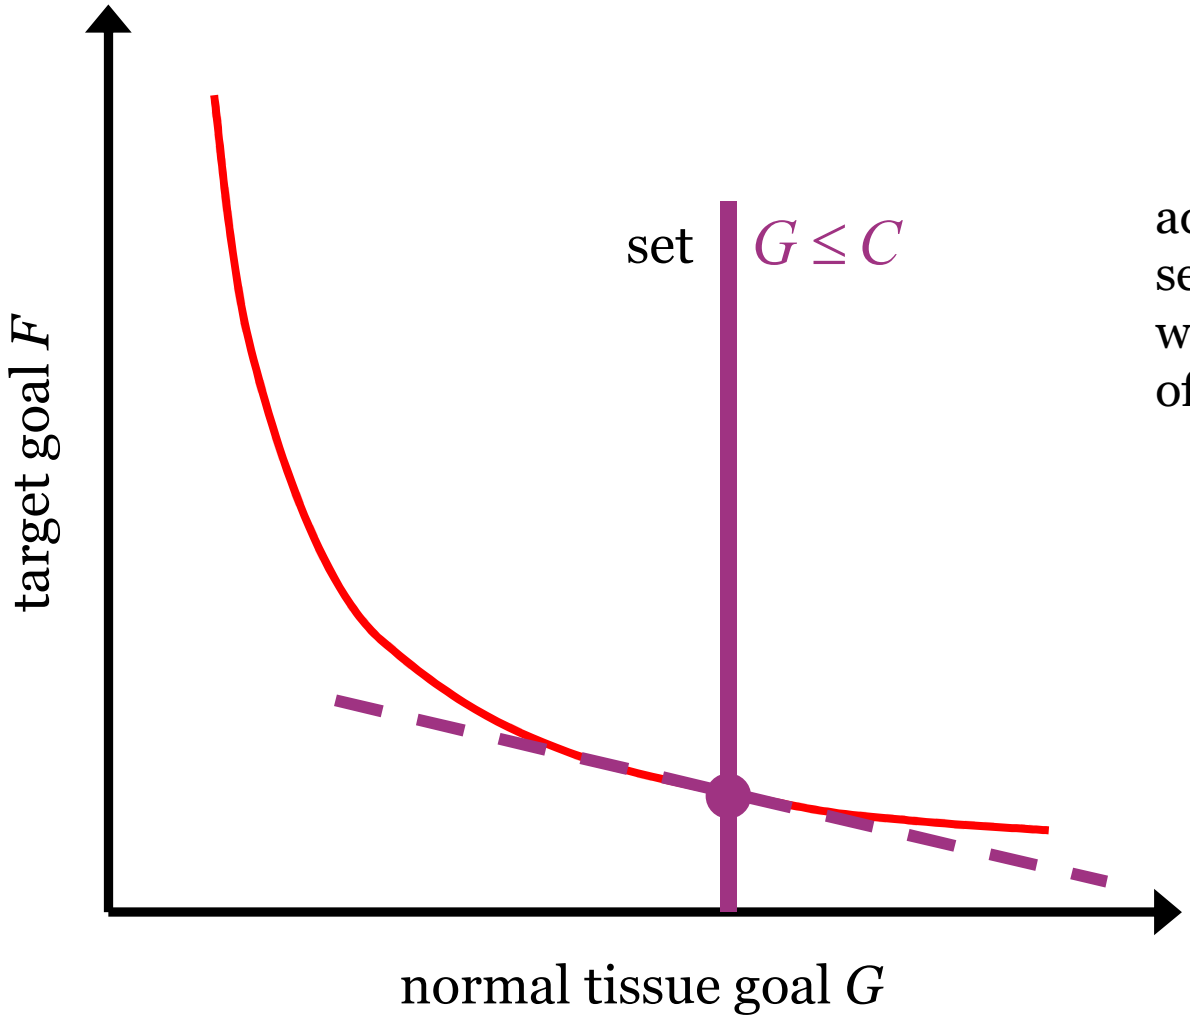


Navigating the Solution Space: Constrained Optimization



- User sets the goals in terms of *hard constraint(s)*
- The optimizer automatically determines the weight factor(s)

Navigating the Solution Space: Constrained Optimization and Sensitivity



additional information:
sensitivity of goal F
with respect to changes
of the constraint G

„Automated planning“

Automatic choice of the „optimal“ pareto-optimal plan!

Basic idea/aim:
Automatically find a patient-specific set of CF-prescriptions/constraints as starting point of an IMRT optimization that will result in the *clinically most acceptable plan* from the solution space of this patient.

How does it work?

- Finding: In a population of patients, a similar compromise of PTV coverage vs. dose constraints will be *realizable* for patients with ‚similar geometry‘
- Use of prior knowledge to predict realizable DVHs/dose presciptions for a new patient
- Algorithm based on database of patients/correlation model/machine-learning/…

To some extent institution-specific; the larger the ‚input‘ patient-database, the better it works…

FAQ:

- Why do we need dose optimization if all we want to do is dose planning? √
- What do we actually optimize? Dose? Cost functions? Beamlets? √
- What optimization algorithm to use, and why? √
- Weight Factors, Constraints, Objectives – why is it so complex? √
- What is the point in optimizing undeliverable fluence profiles first?

Because:

• The ‘free fluence’ optimization problem is well behaved. Fast algorithms can be used.

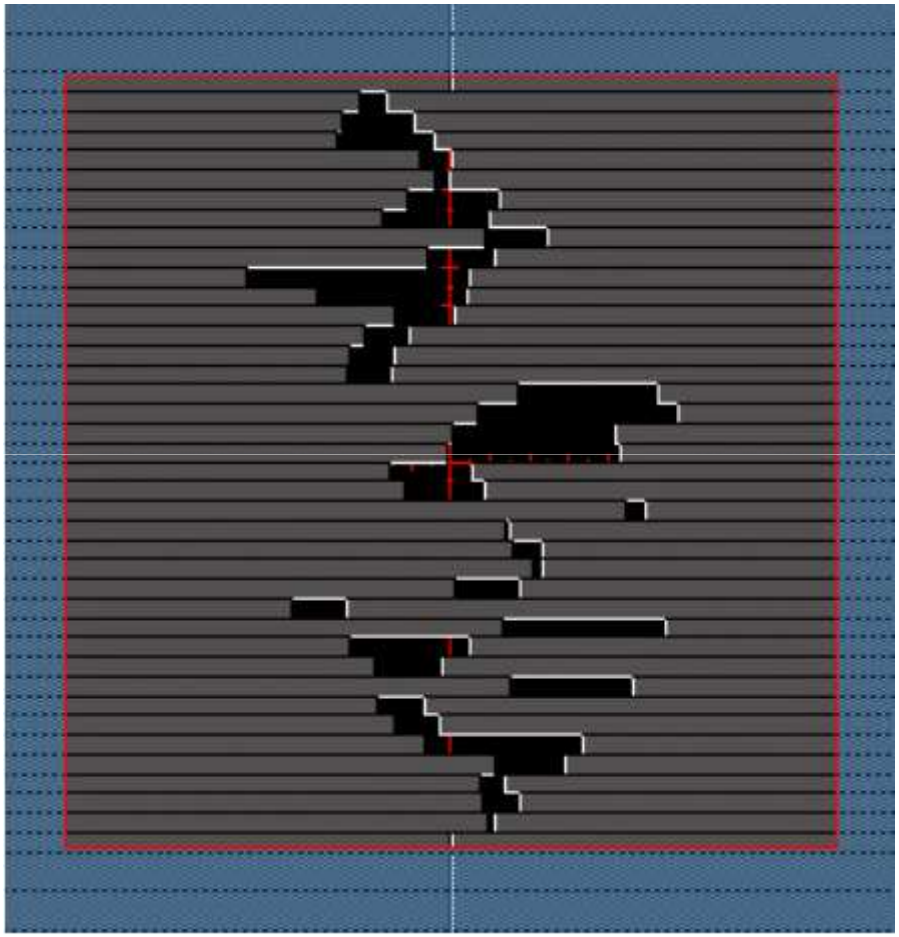
• The solution space needs to be explored in an interactive manner. MLC sequencers and precise dose calculation are too slow yet.

• e.g. ‘Pareto-optimization/navigation’ currently only works for fluence distributions

…vs. Direct Aperture Optimization (DAO), Simulated Annealing (Rapid Arc ©)…:

• It is a long way to go from coarse field shapes to the patient-specific optimum fluence distribution. *It is very easy to get trapped in local minima when directly optimizing field shapes.*

Direct aperture optimization needs a control of segment shapes and good initial segment shapes



This is what a local minimum looks like

FAQ:

- Why do we need dose optimization if all we want to do is dose planning? √
- What do we actually optimize? Dose? Cost functions? Beamlets? √
- What optimization algorithm to use, and why? √
- Weight Factors, Constraints, Objectives – why is it so complex? √
- What is the point in optimizing undeliverable fluence profiles first? √
- Why does the dose get worse after MLC sequencing?

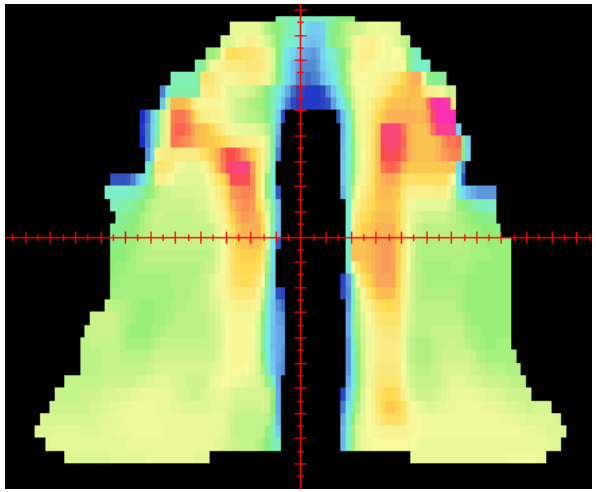
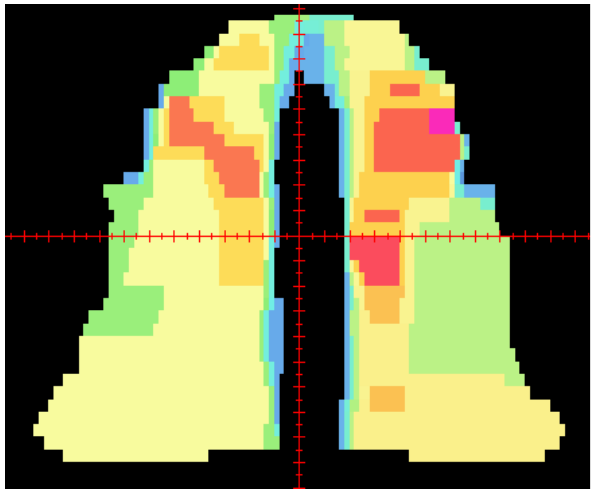
MLC delivery deviates from the ideal profiles



optimal fluence profile

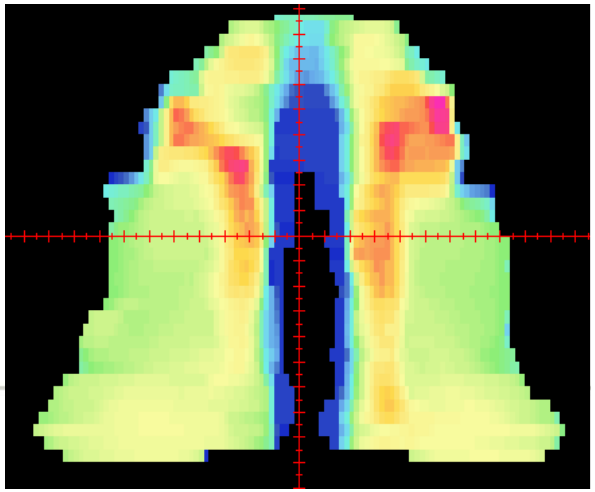
sequencing: translation into (coarser, but deliverable) segments



step and shoot

sliding-window dynamic

improvement

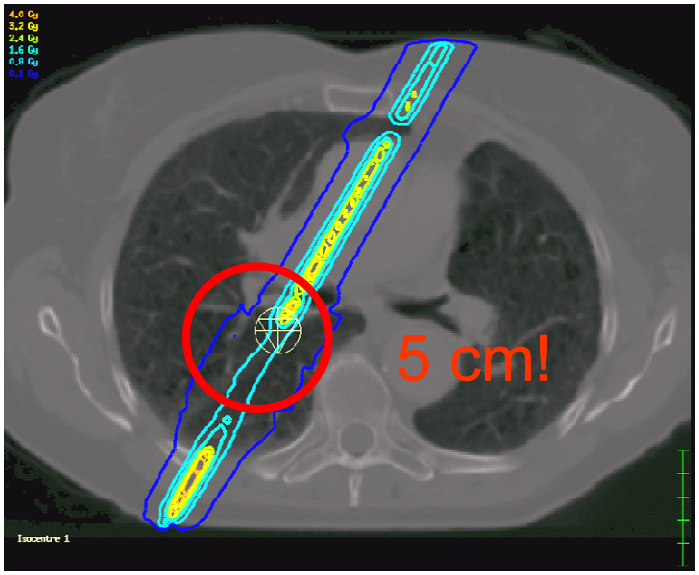


⇒ **(1) Quality loss due to *discretization***

⇒ **(2) Hi-quality dose calculation of segment doses changes dose distribution!**
(usually: to the worse)

Precise dose computation DURING fluence profile optimization is immensely expensive!

- computation time issue
- computer memory issue (10.000 beamlets can be ~Gigabyte memory)



4 mm x 2 mm beamlet, 15 MV, 3D-PB

This is why some planning system calculate simplified beamlet doses:

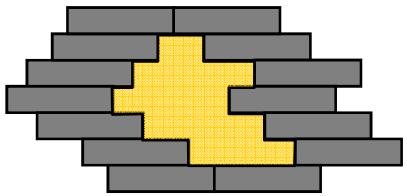
- ➢ too steep and/or truncated penumbra, esp. in presence of inhomogenieties
- ➢ thus, OARs may wrongly appear sufficiently spared
- ➢ the final, more precise dose calculation reveals such initial simplifications!

→ **plan degradation of segmented plan!**

How to tackle these problems…

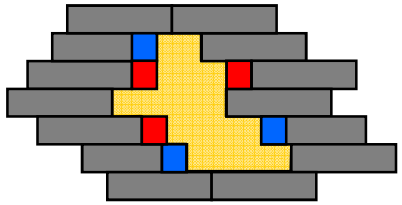
...perform a subsequent **Segment-Shape-Optimization!**

Iterative segment shape (aperture) optimization



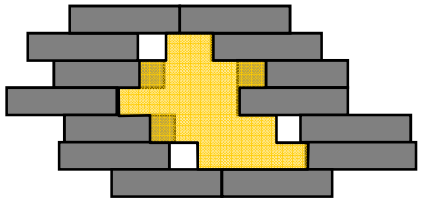
initial field

• *trial-and-error*
(e.g. simulated annealing)
• *derivatives*
• *brute force*



candidates for opening or closing leaves

dose calculation



altered field

chose next field, repeat

This is why…

…most IMRT planning methods follow a two stage process.

Idea:

stage 1 produces a guess of a good solution

stage 2 refines the result of stage 1 (Aperture optimization)

Problem: the longer the way from the initial guess to the end result, the easier it is to get lost.

Rotational IMRT techniques: Alternatives for the creation of initial guesses

+ dynamic conformal arc

+ using the projection of target volumes / organs at risk to the beam apertures (e.g. Elekta ERGO++)

+ translating a fluence profile into sliding-window segments and arranging them on an arc (Philips Pinnacle SmartArc, Elekta Monaco)

+ an iterative angular resolution refinement, starting from beam shapes at large angular intervals and interpolating them (Varian RapidArc)

FAQ:

- Why do we need dose optimization if all we want to do is dose planning? √

Again: What are Typical Treatment Goals?

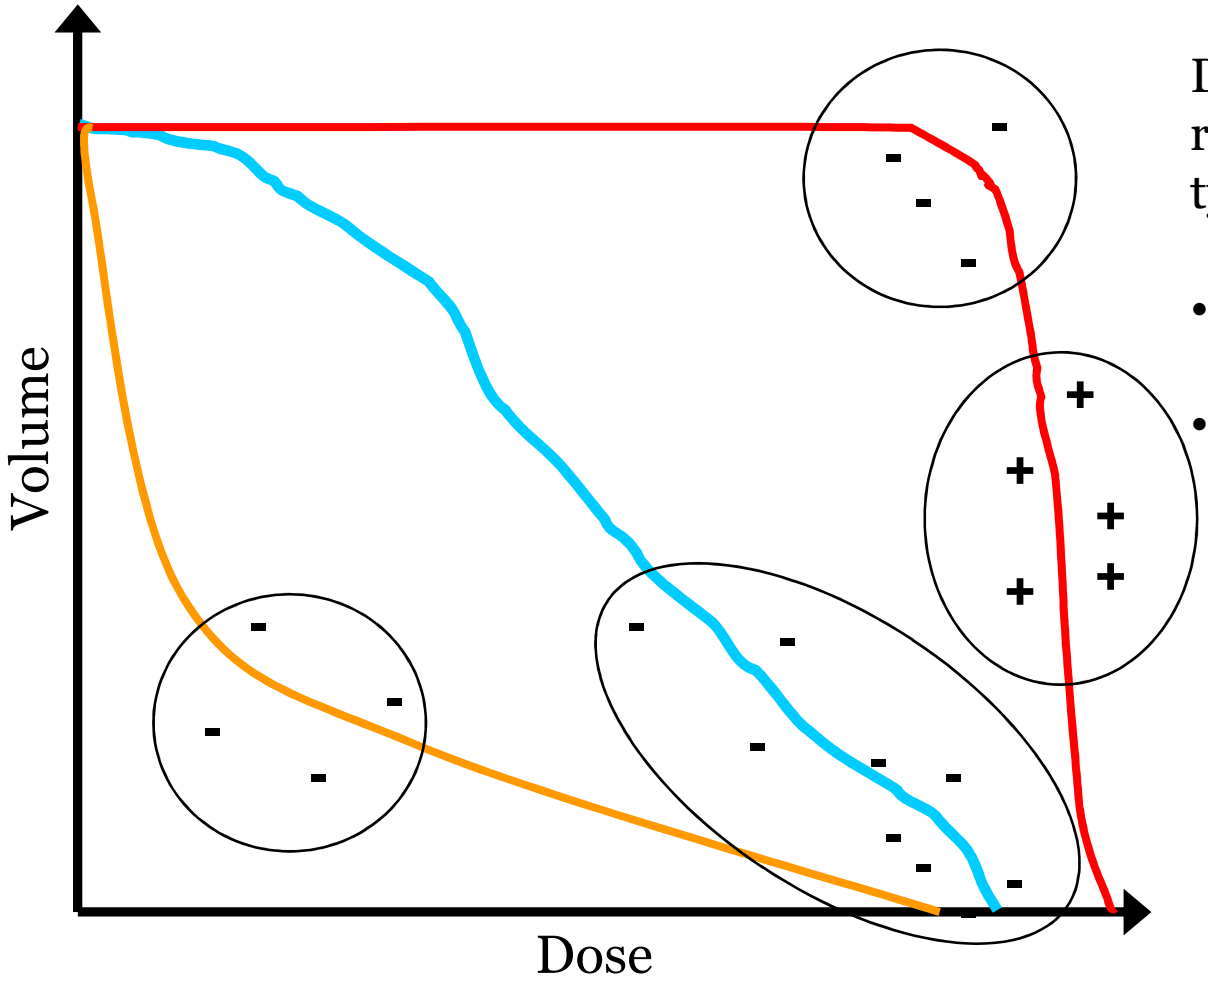
Target goal:	achieve a ***sufficient target dose***
Normal tissue goals:	do not ***exceed acceptable doses*** in N ***organs***
Conformality goal:	target dose should be ***conformal***, ***spare generic normal tissue***
Homogeneity goal:	***no large*** or ***excessive hot spots*** in the ***target***

*These goals need to be communicated to the planning algorithm in a **concise**, **comprehensive**, **transparent** and **numerically expedient** manner.*

↓

Cost Functions!

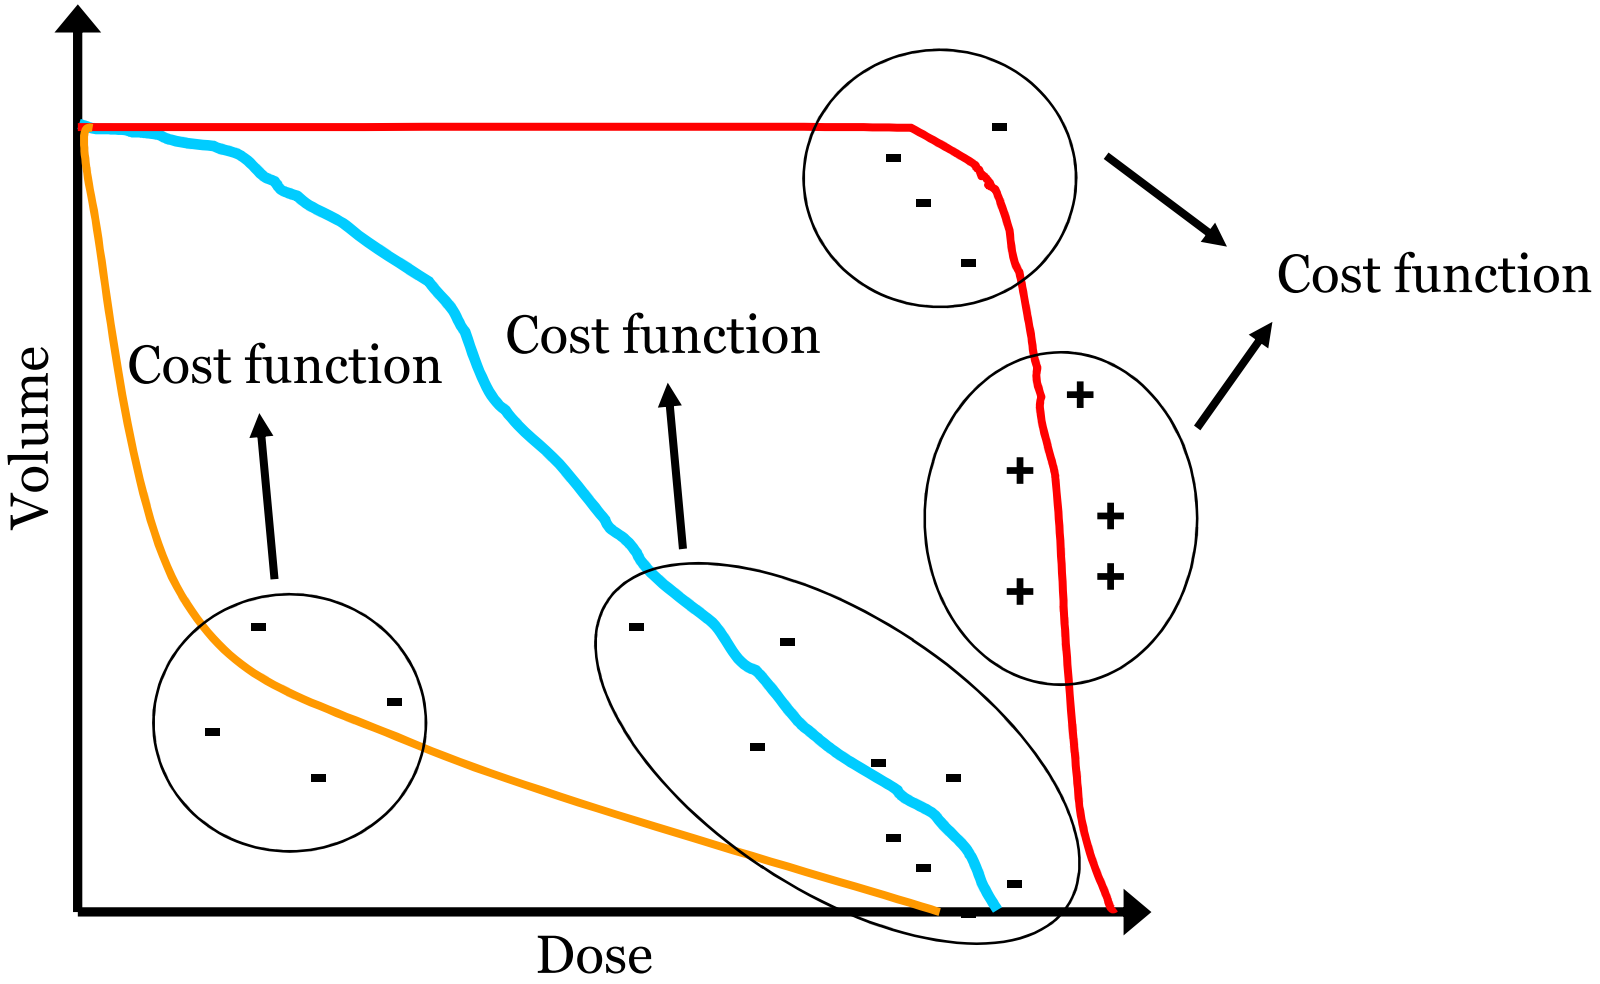
A cost function rewards the positive aspects of a DVH and penalizes the negative ones in a single number



Different goals require different types of cost functions:

- *physical:* dose-, dose/volume-based
- *biological*

A cost function rewards the positive aspects of a DVH and penalizes the negative ones in a single number



Properties of Cost Functions

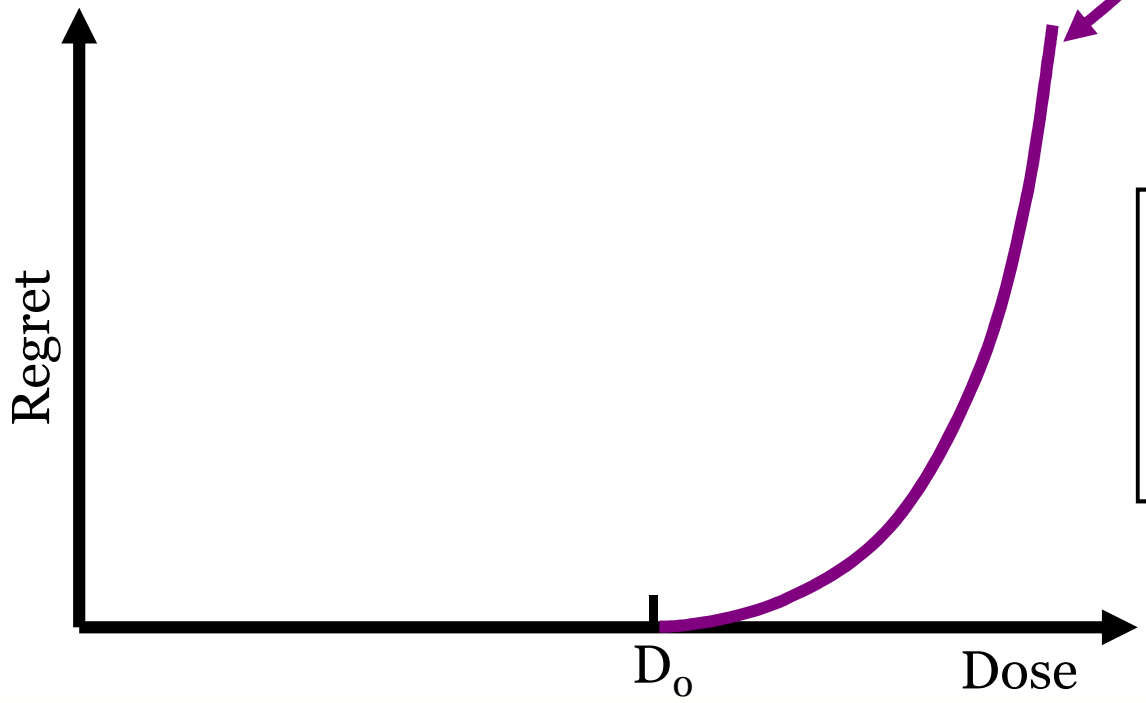
- Purpose: to ***quantify*** our concept of ***quality*** of a dose distribution
- By convention: if D_1 is ***better*** than D_2, then $F(D_1) < F(D_2)$:
  search the ***minimum*** of F.
- Commonly, the cost function has the form:

$$F = \frac{1}{N}\sum_{i=1}^{N} f(D_i)$$

D_i	Dose in volume element i of an organ/tumour
N	Number of volume elements
$f(D)$	number of **regret** assigned to the dose D in this volume element

The most Common Physical Cost Function: One-Sided Quadratic Penalties

$$F_{overdose} = \frac{1}{N}\sum_{i=1}^{N}(D_i - D_0)^2$$

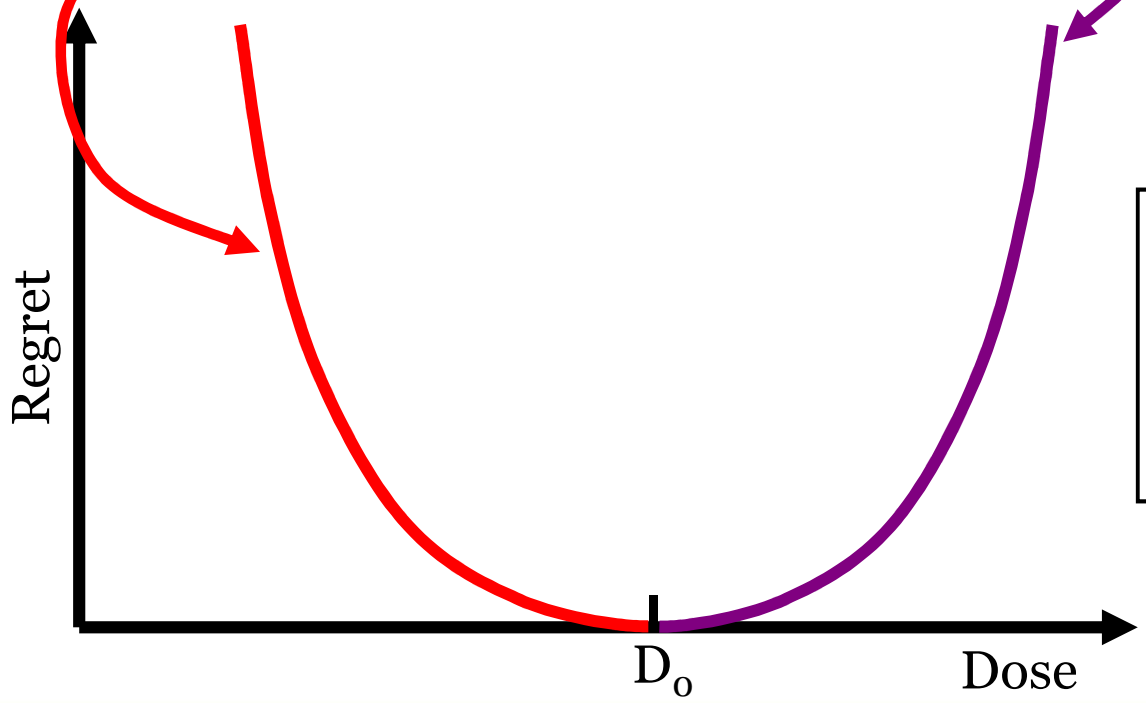


The ***regret grows quadratically*** with the violation of the required/ tolerated dose

The most Common Physical Cost Function: One-Sided Quadratic Penalties

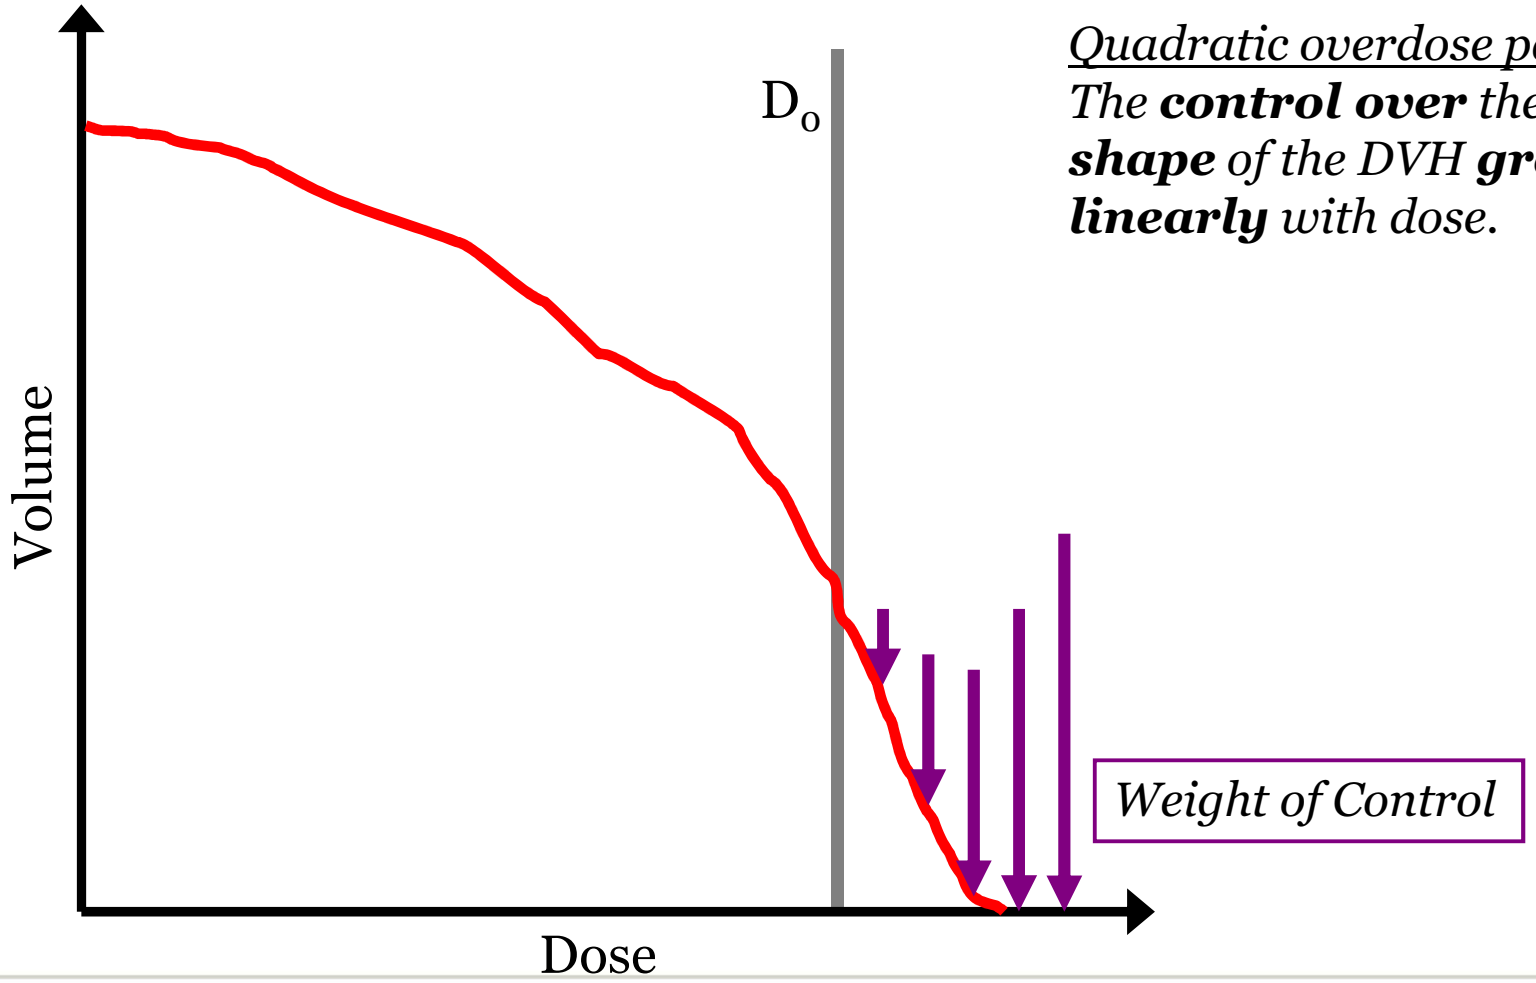
$$F_{overdose} = \frac{1}{N}\sum_{i=1}^{N}(D_i - D_0)^2\,\theta(D_i - D_0)$$

$$F_{underdose} = \frac{1}{N}\sum_{i=1}^{N}(D_i - D_0)^2\,\theta(D_0 - D_i)$$



The ***regret grows quadratically*** with the violation of the required/ tolerated dose

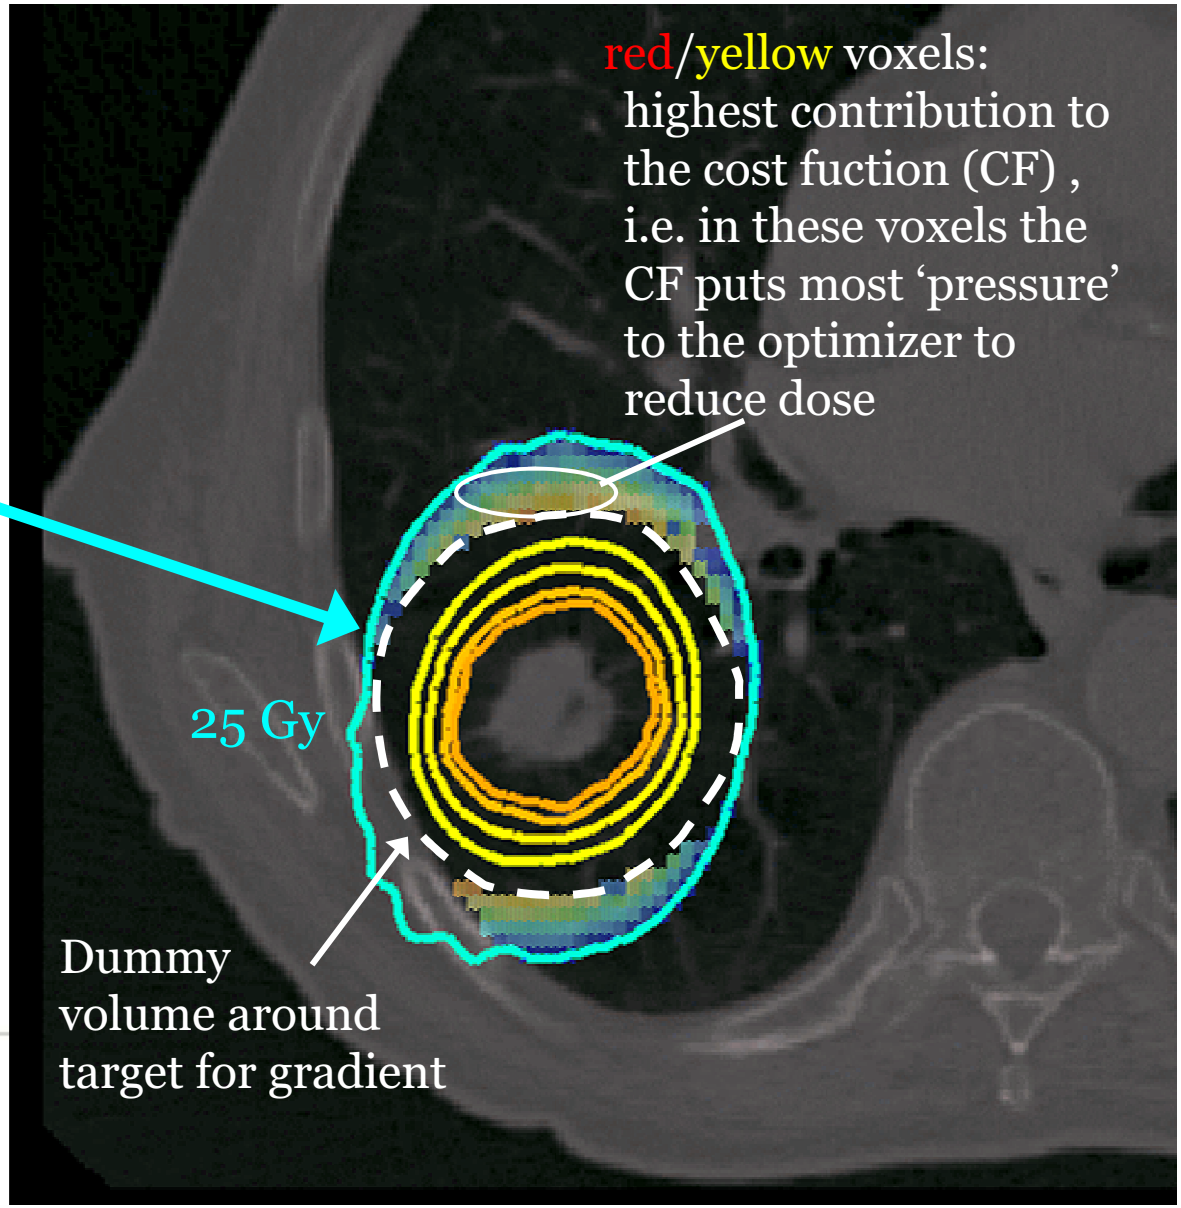
The Purpose of a Cost Function is to control the Shape of the DVH: Control Weights



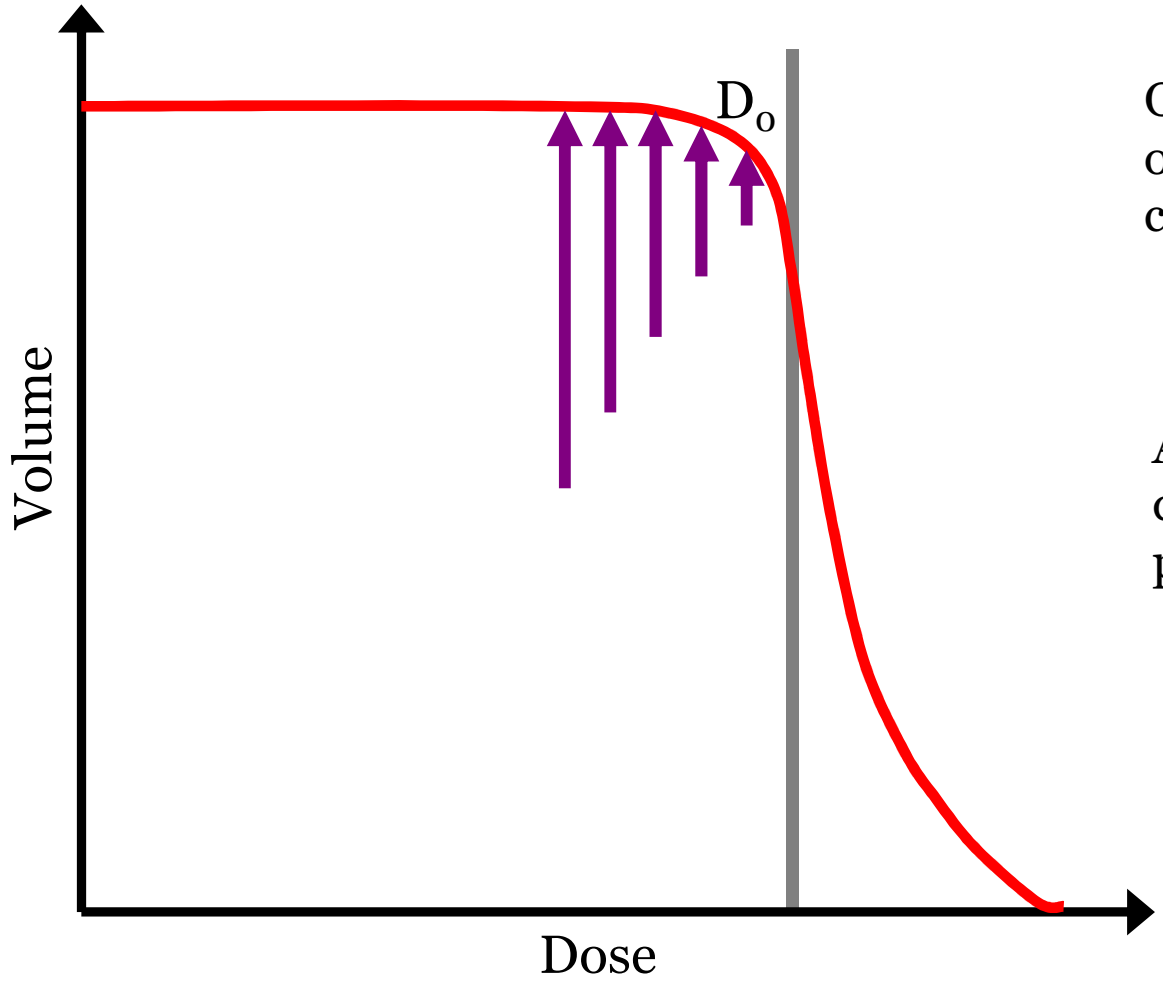
Quadratic overdose penalty:
*The **control over** the **shape** of the DVH **grows linearly** with dose.*

Local Control of a Quadratic Overdose Penalty

example:
quadratic overdose penalty for D_0=25Gy, i.e. area of control only at doses > 25 Gy



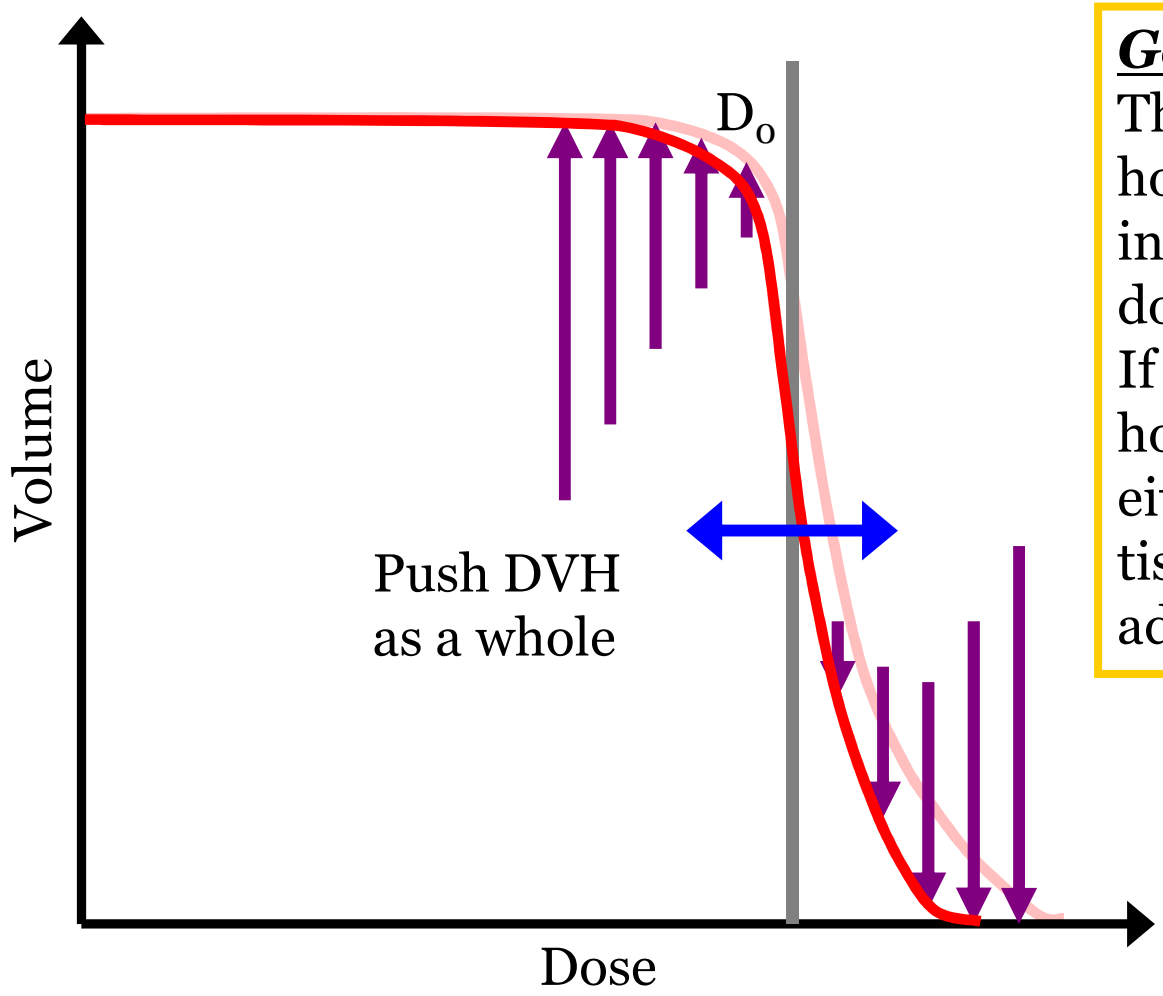
Control of a Target DVH by a One-Sided Quadratic Underdosage Penalty



Only one aspect of the target DVH is controlled.

Add a one-sided quadratic overdosage penalty!

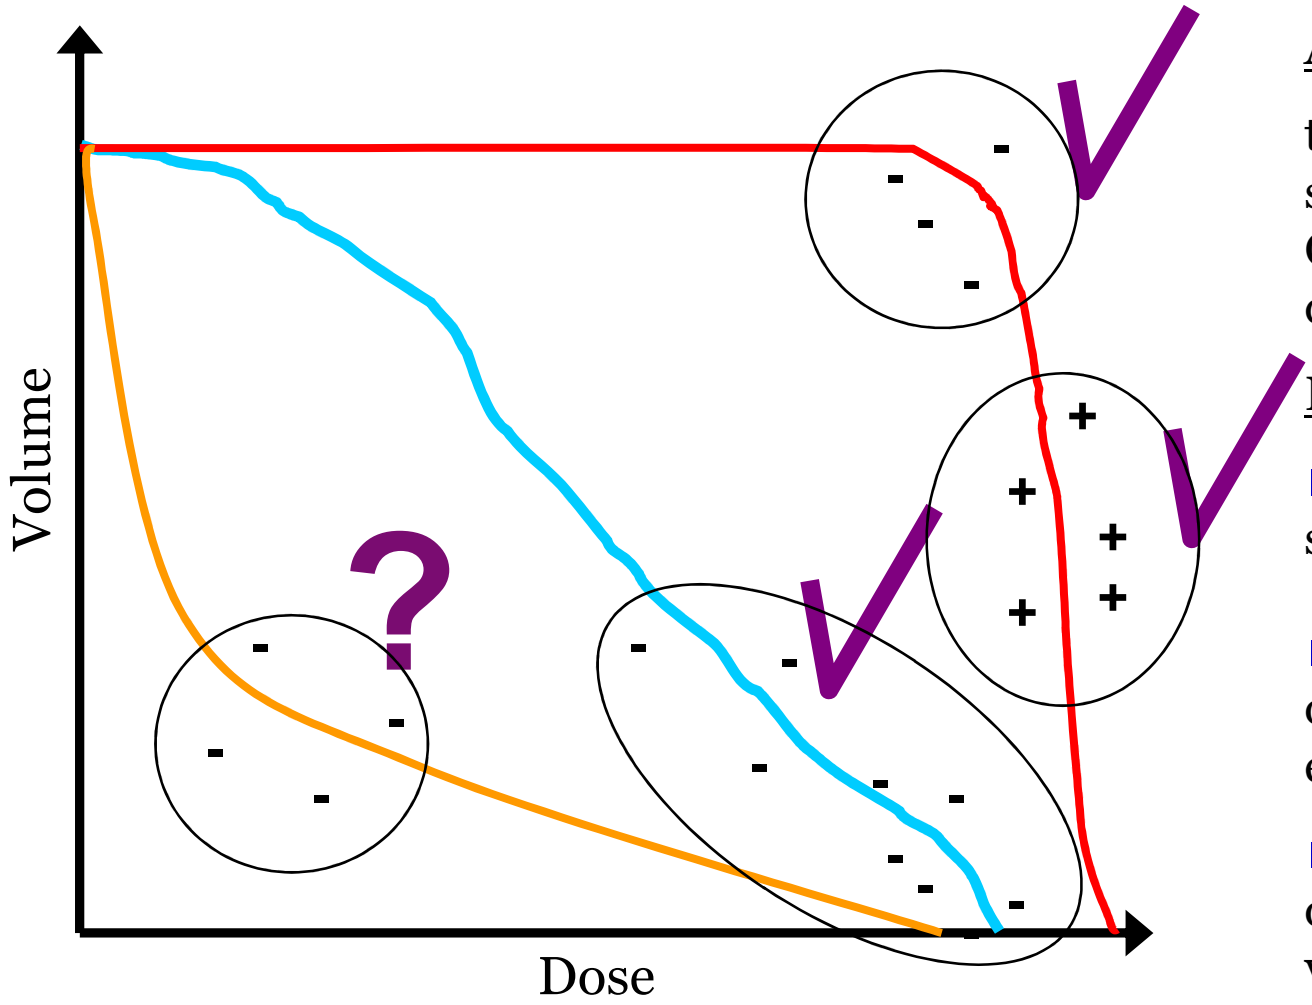
Control of a Target DVH by Two One-Sided Quadratic Penalties



Golden Rule:

The overall target dose homogeneity cannot be influenced by target dose penalties alone.
If the target dose is not homogenous enough, either reduce normal tissue sparing, or add more beams.

Can quadratic penalties control all aspects of dose?



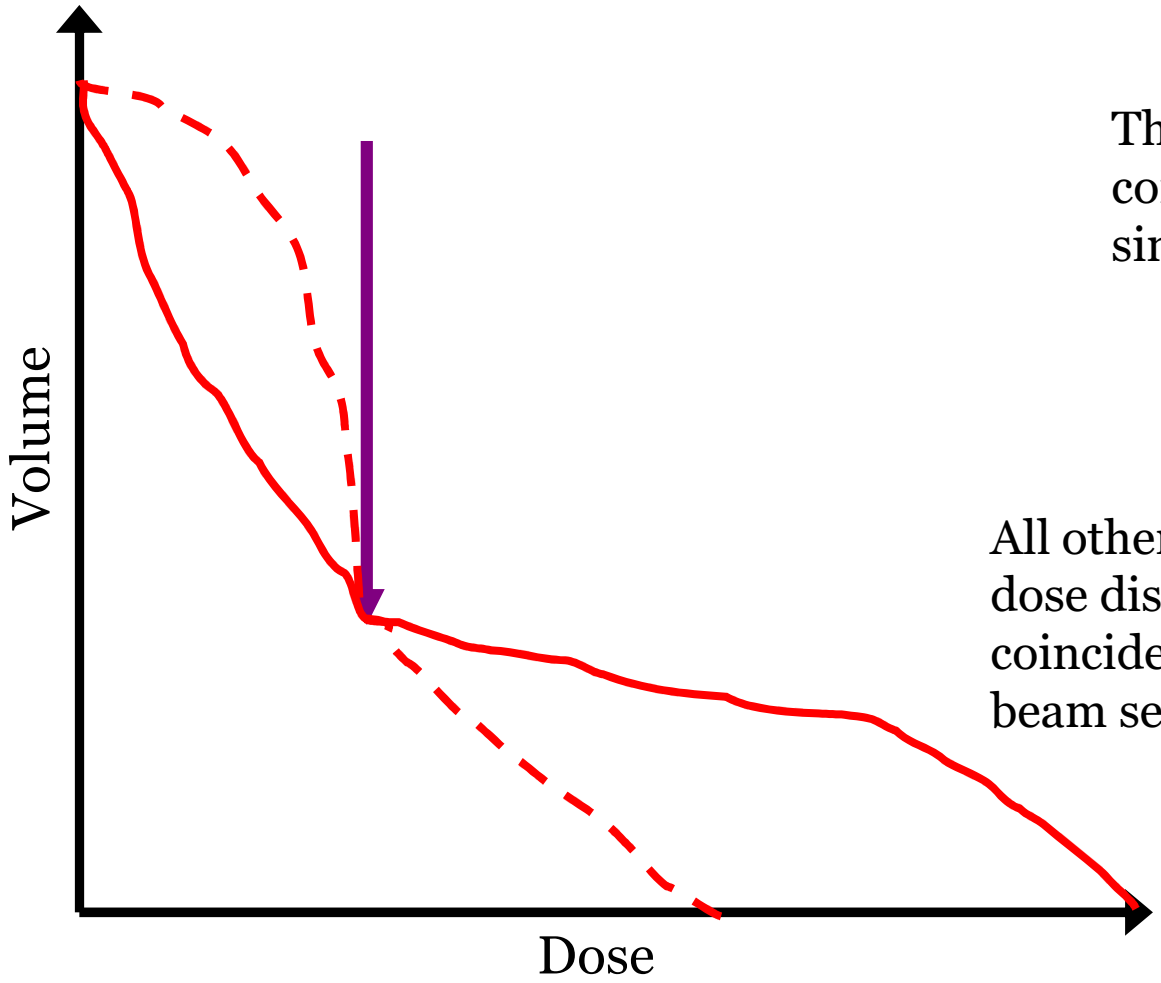
Application:

target hot and cold spots,
OARs with maximum dose restrictions.

Limitations:

- Cannot enforce a strict dose limit.
- Does not express organ specific volume effects.
- Cannot be applied to organs with a large volume effect.

DVH Control for Organs with a Large Volume Effect: DVH Constraints



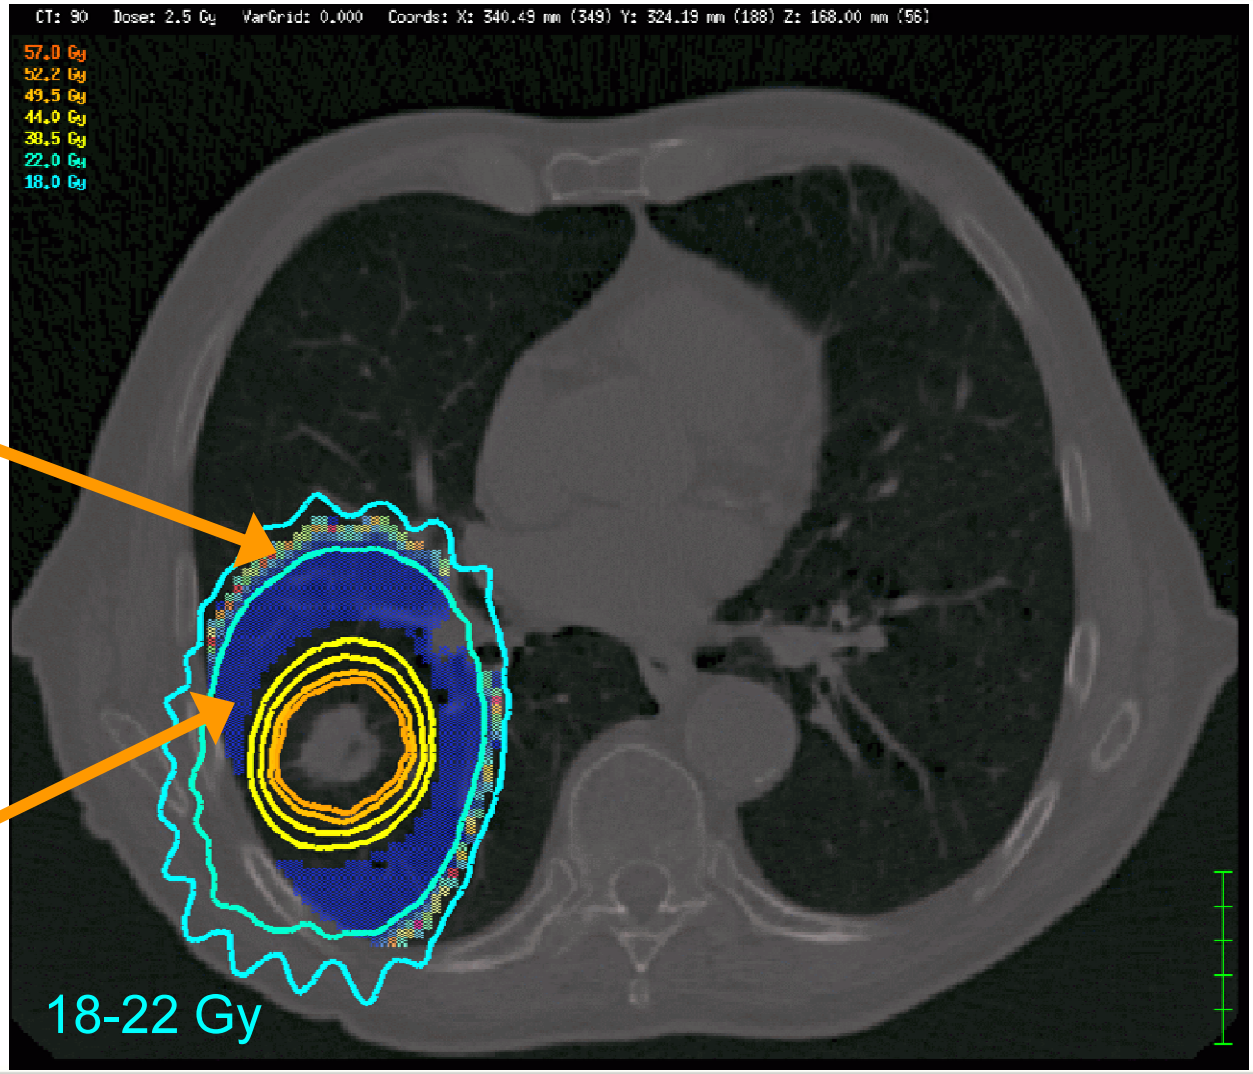
The constraint controls only a single point.

All other aspects of the dose distribution are merely coincidence (patient geometry, beam setup)

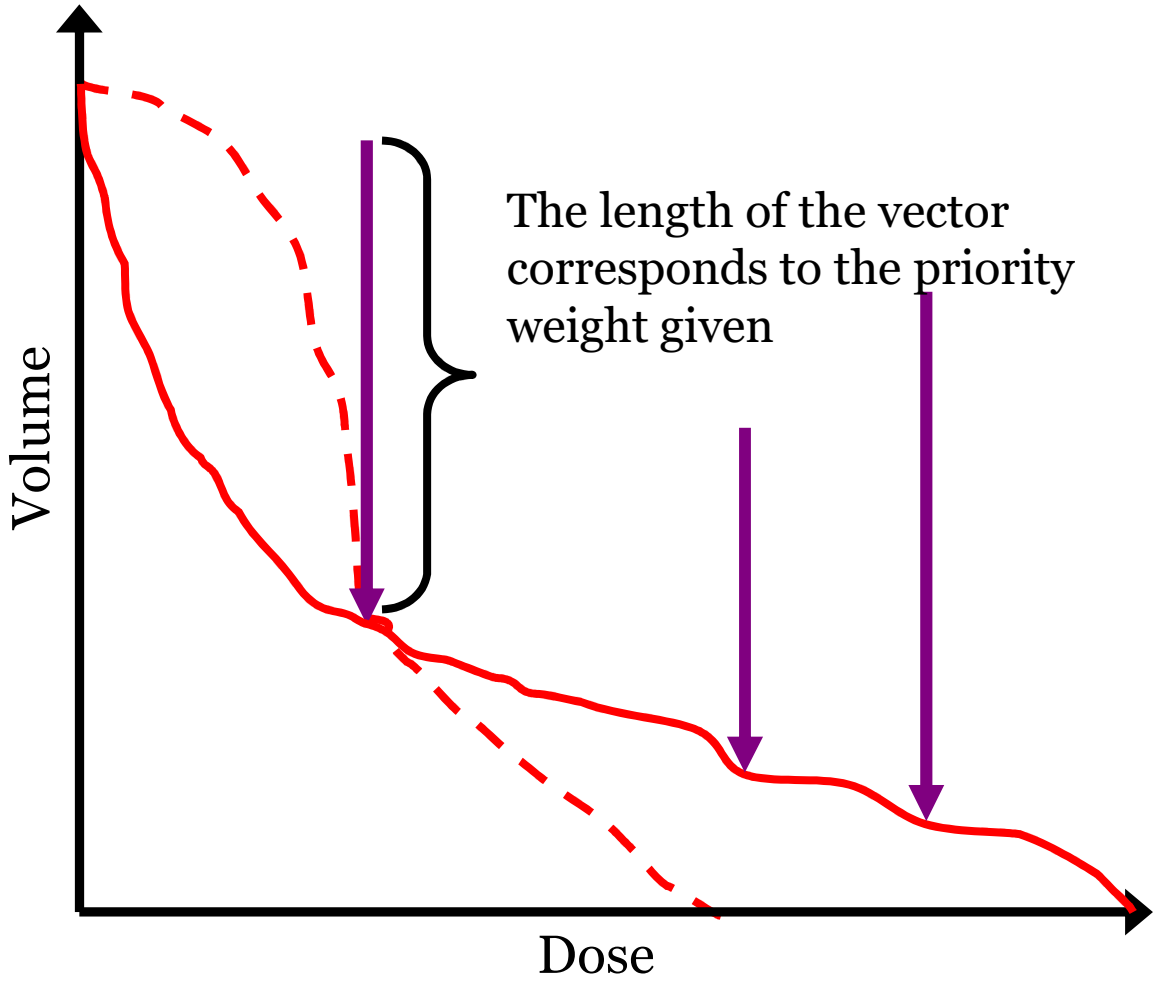
Local Control of a DVH constraint:

example:
constraint to V_{20},
i.e. area of control
only at dose = 20 Gy

Volume given up
by cost function

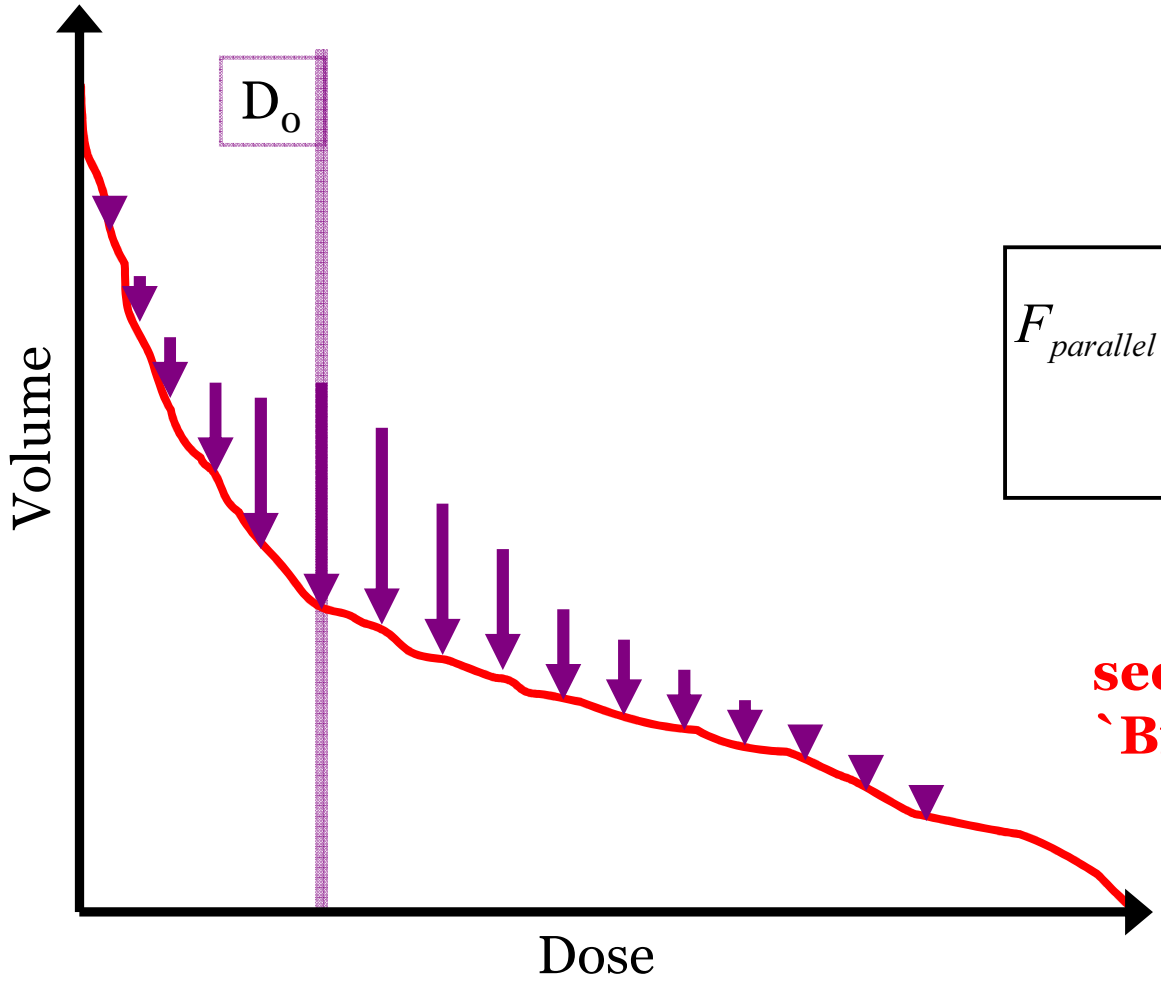


DVH Control for Organs with a Large Volume Effect: Multiple DVH Constraints



Multiple constraints may be combined to enhance control over the dose distribution.

How does a Parallel Complication Model control the DVH?



$$F_{parallel} = \frac{1}{N}\sum_{i=1}^{N}\frac{1}{1+\left(\frac{D_0}{D}\right)^k}, \quad k \geq 1$$

(or similar functions)

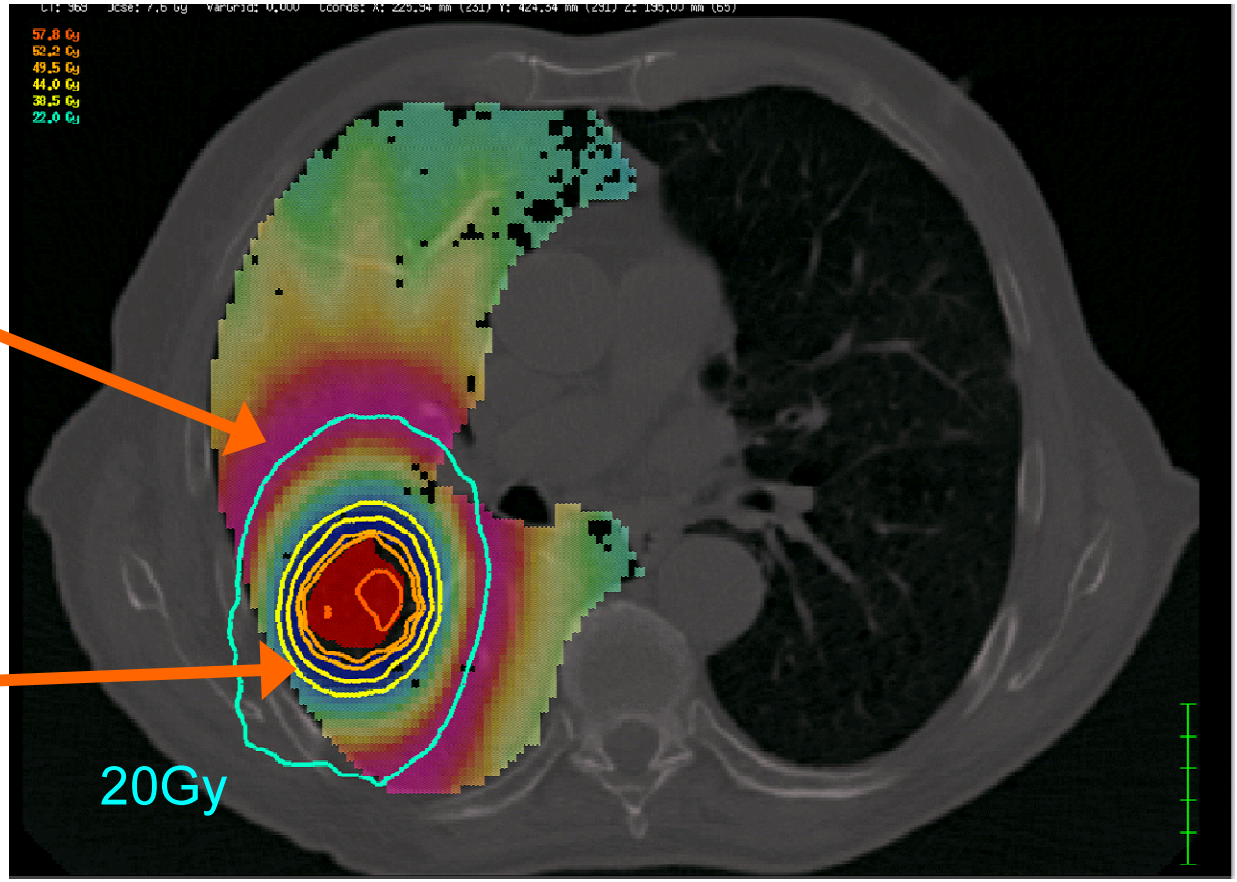
see presentation `Biological Optimization`

Local Control of a Parallel Cost Function

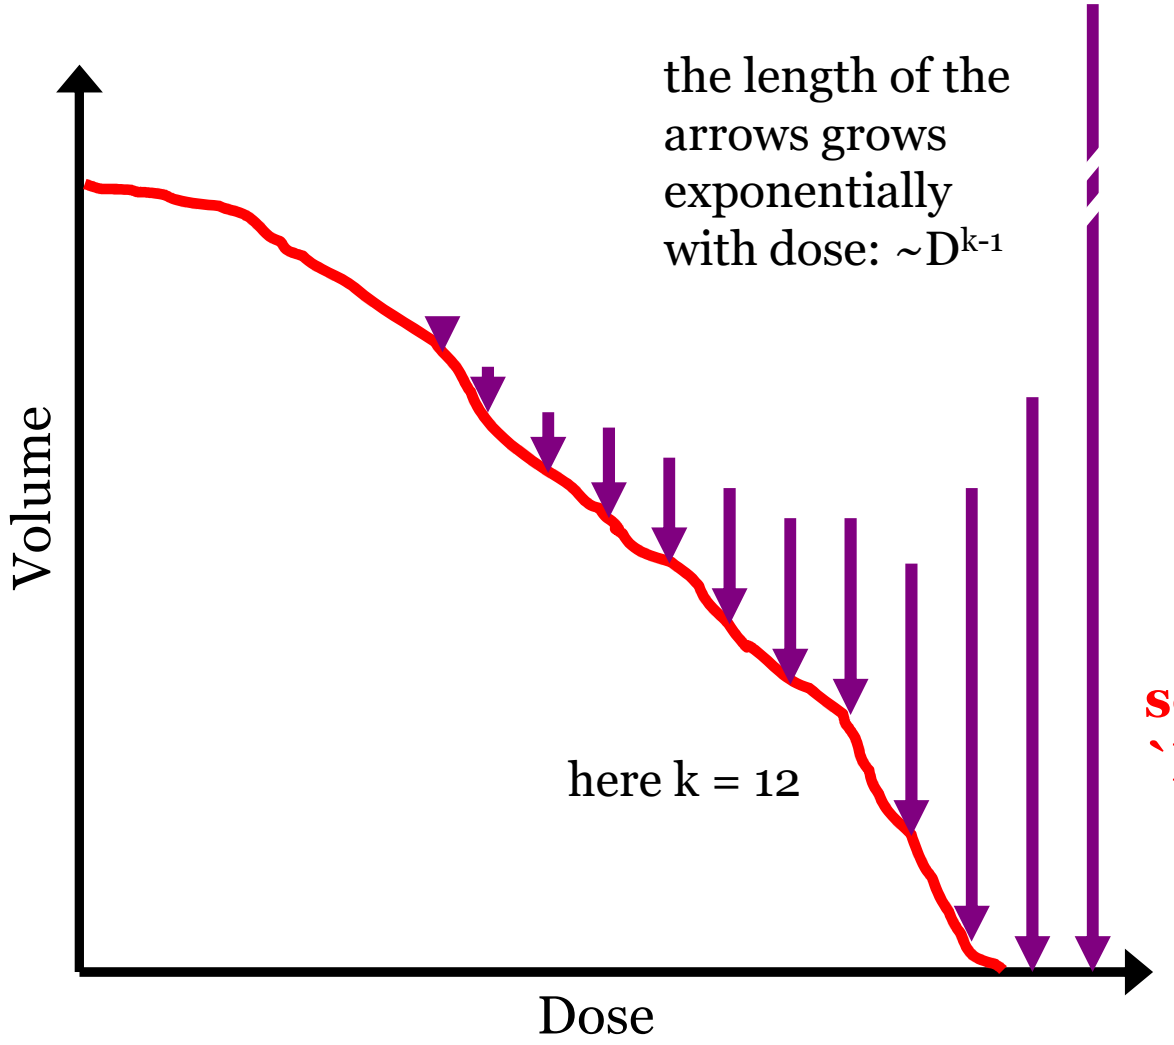
example:
parallel constraint with
D_0=20Gy

Volume of greatest weight in optimization

Volume given up by cost function



How does a Serial Complication Model control the DVH ?

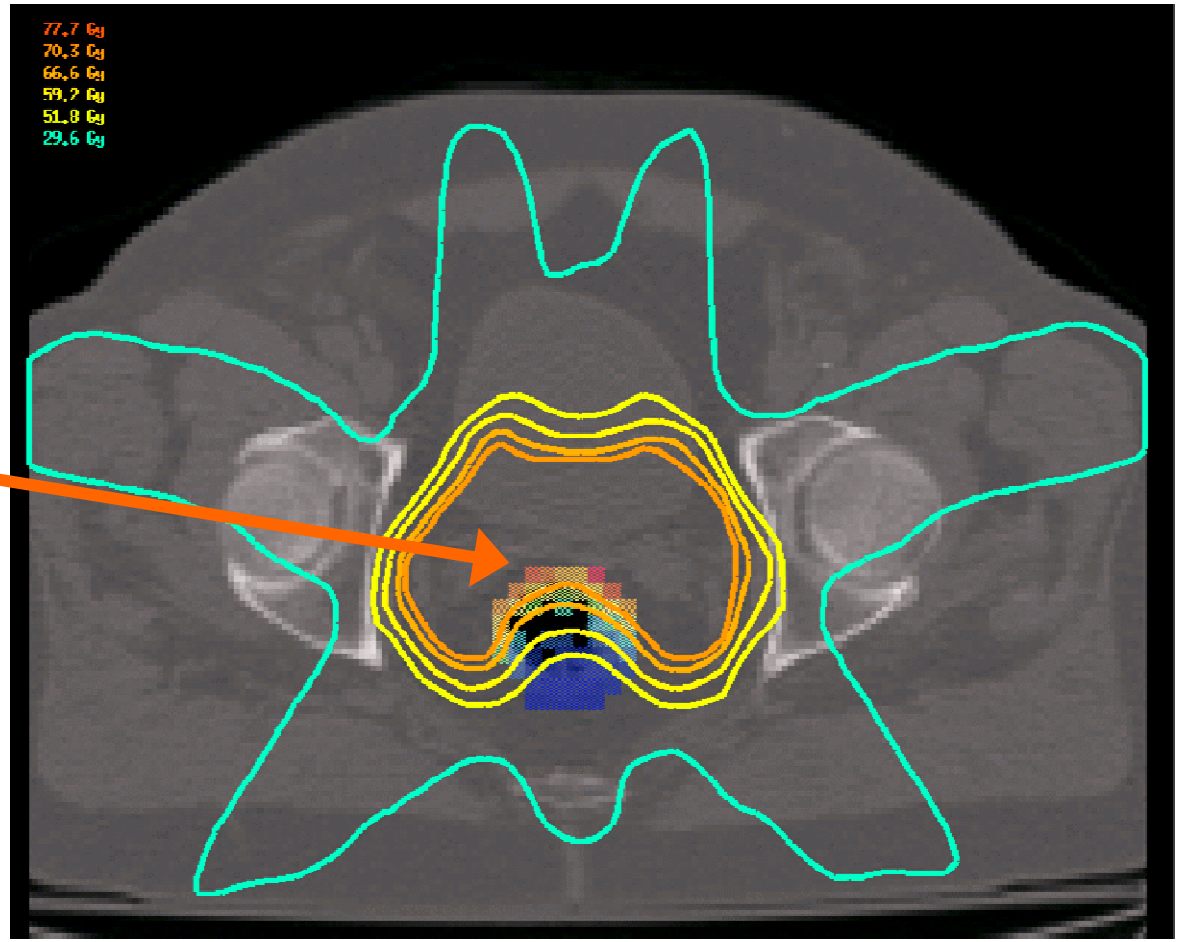


$$F_{serial} = \frac{1}{N}\sum_{i=1}^{N} D_i^{\,k}, \quad k \geq 1$$

see presentation `Biological Optimization`

Local Control of a Serial Cost Function

Volume of greatest weight in optimization



FAQ:

- Why do we need dose optimization if all we want to do is dose planning? √
- What do we actually optimize? Dose? Cost functions? Beamlets? √
- What optimization algorithm to use, and why? √
- Weight Factors, Constraints, Objectives – why is it so complex? √
- What is the point in optimizing undeliverable fluence profiles first? √
- Why does the dose get worse after MLC sequencing? √
- How much optimization is actually in an IMRT optimizer? √
- Cost functions: Which one to use when? √
- Do we really need 'complicated' cost functions like the serial complication model CF?

Clinical relevance of the serial cost function

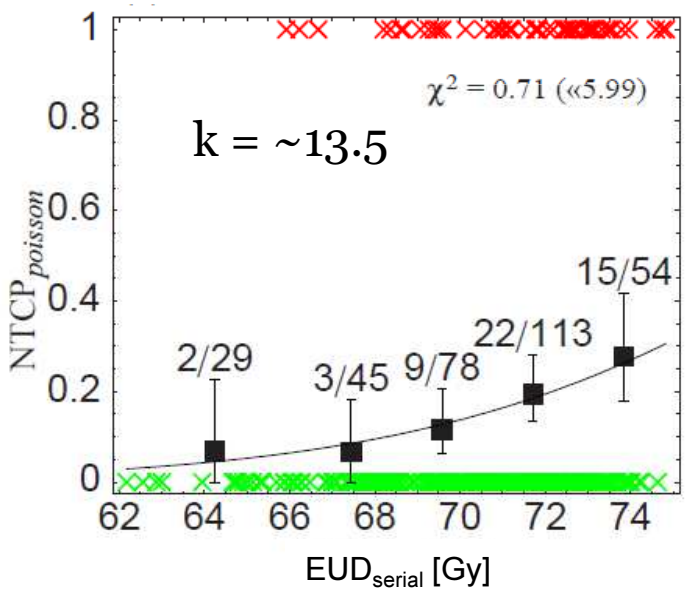
$$F_{serial} = \frac{1}{N}\sum_{i=1}^{N} D_i^{\,k}, \quad k \geq 1$$

directly related to...

$$EUD_{serial} = \sqrt[k]{\frac{1}{N}\sum_{i=1}^{N} D_i^{\,k}}$$

For rectal complications (grade>=2 bleeding) strong clinical evidence, that NTCP is clearly related to rectal EUD!

M. Söhn et al. 2007 (IJROBP 67(4))
Quantec-Report: J. M. Michalski et al. 2010 (IJROBP 76(3))



Summary & Conclusions

- **IMRT treatment planning means *exploring the limits of physics* for each patient**:
  - the 'physics in the patient': Is the desired dose distribution possible? (steepness and placement of gradients,...)
  - Applicability by MLC hardware

- numerous different and partly conflicting target and normal tissue goals need to be balanced — **IMRT *optimization algorithms* are tools to 'navigate' through the solution space**

- *'navigation'*: using weight factors, constraints, or a library of precalculated plans

- different approaches to arrive at applicable, segmented plans: typically a *two-stage optimization-process*

Summary & Conclusions [2]

- Cost functions define numerical rules for the IMRT optimizer, which features of a dose distribution should be rewarded and which ones penalized.
  CFs are essential, because the *ideal* dose distribution does usually not exist

- The dose distribution in a volume results from a complex interplay of the cost functions defined in this volume, and all other cost functions.
  It is therefore extremely important to understand which features of the dose distribution are controlled by a cost function and which are uncontrolled and thus random.

- The ideal dose distribution cannot be arrived at by the perfect set of cost functions, but only in an interactive process of exploring physically possible trade-offs between different treatment goals.

⇒ IMRT optimization is about as much art as it is science
⇒ BUT: experience helps!
⇒ …as does a good TPS: should make the effects of all actions on the dose distribution transparent to the user in order to reduce trial-and-error

Modelling adverse effects after radiotherapy

Eva Onjukka (PhD), Medical Physicist

eva.onjukka@karolinska.se

ESTRO School

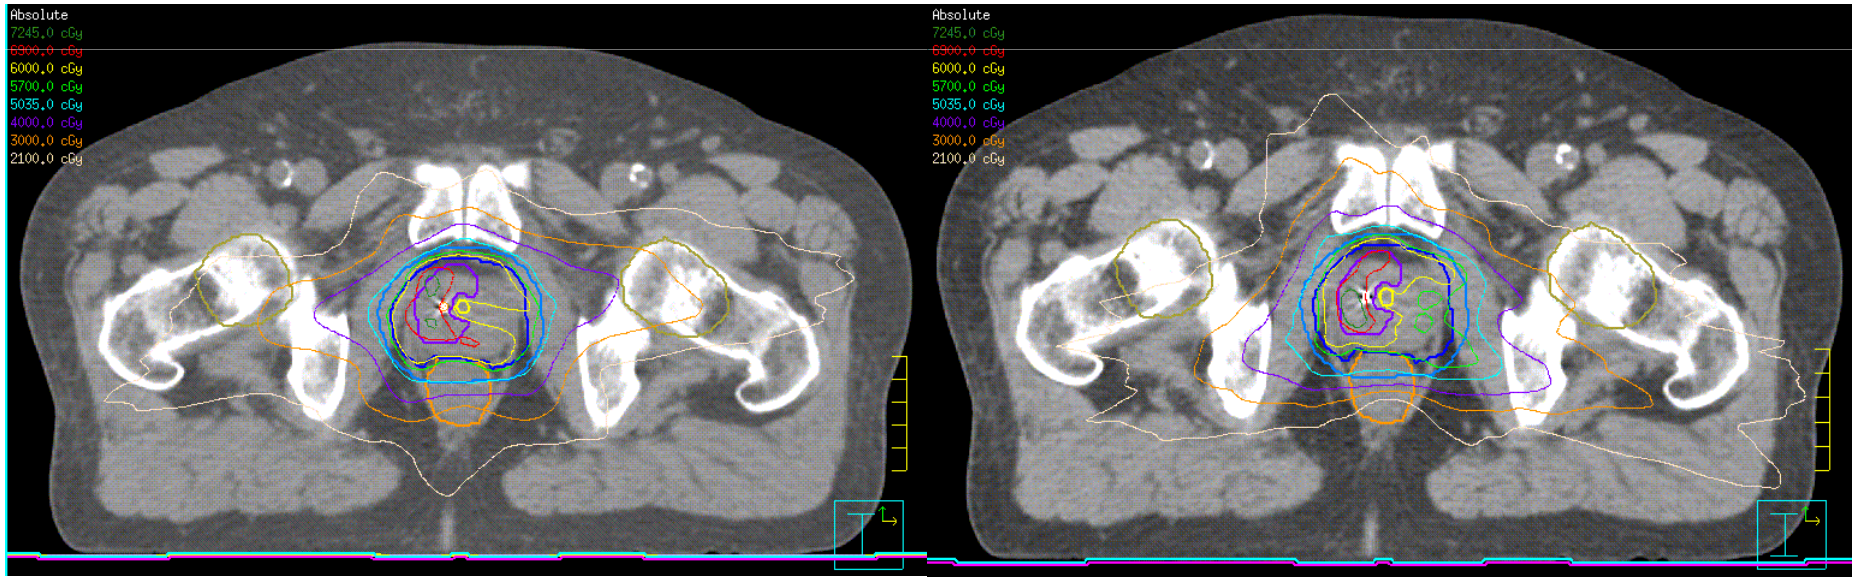
Contents

- Introduction (what, why, when?)
- Organ architecture and the volume effect
- From DVH to normal-tissue complication probability
- Models: LKB, critical volume, relative seriality
- Equivalent uniform dose
- Fractionation correction
- Model accuracy
- Applications

Objective

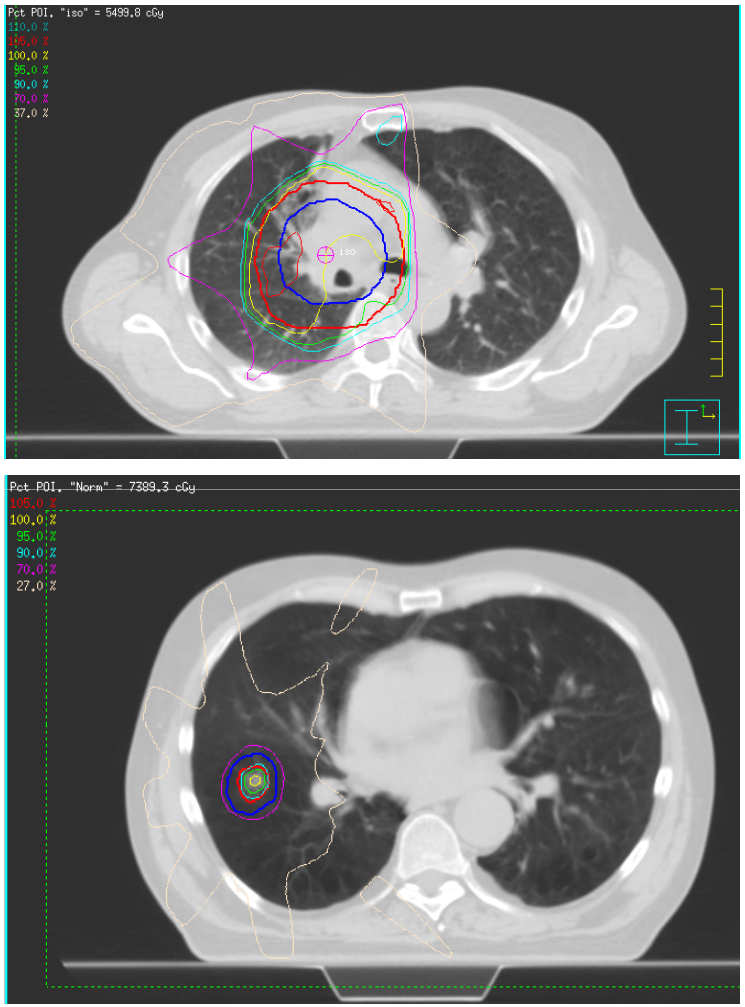
- IMRT/VMAT offers huge flexibility in distributing the dose around the target (many degrees of freedom)
- Optimisation/evaluation requires quantification/representation of the risk from very different dose distributions.

2 plans with equal estimated effect:



Which ‘dose’ is relevant for normal tissues?

- All tumours of a certain type and stage prescribed the same dose
  - based on perceived risk of toxicity in the population
- Wide variation in dose throughout the tissue
- Different anatomy = different dose distribution
- Prescription dose not a good measure of normal-tissue complication probability (NTCP) for an individual
- Good NTCP models could help us limit the risk for each individual



ESTRO School

What is an NTCP model?

Complex models have been developed to describe what happens when you irradiate a patient. These are called *mechanistic* NTCP models.

- Limited understanding of mechanisms limits the scope of the models
- Requires too many parameters to allow fitting to clinical data
- Useful for generating hypotheses and testing methodology

Outcome modelling instead looks for a statistical relationship between treatment plan parameters and the incidence of a particular complication. This is called *empirical* or *phenomenological* NTCP modelling.

- Regression-type models
- A few parameters fitted to treatment and outcome data
- Can fill the same purpose as dose-volume constraints

This lecture will focus on empirical NTCP modelling.

Organ architecture

- Consider normal tissues as consisting of multiple functional subunits (FSU)*, for tissue repair purposes
- Each organ different in terms of FSU interaction
- Parallel type response like a rope: it can perform its function even if some strands break.
  - Large volume effect
- Serial type response like a chain: function is lost if any one link breaks.
  - Small volume effect
- Kidney: nephron

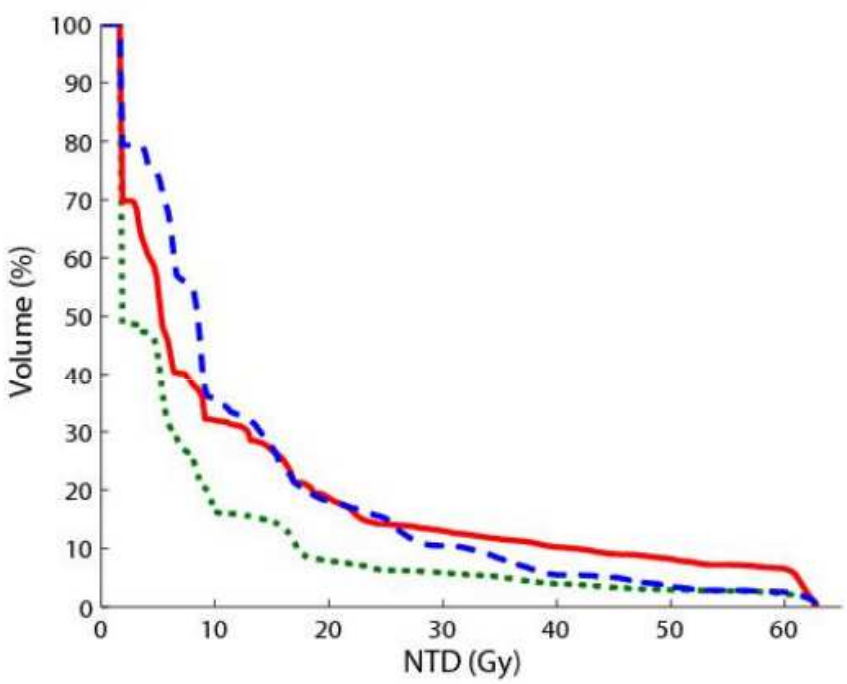
Dose-volume histogram



Dose-volume histograms (DVHs) are used when evaluating a treatment plan.

- Useful for comparing alternative plans
- If two DVHs overlap it is not clear which one is better.
- Dose-volume constraints are surrogates for a normal-tissue complication probability (NTCP)
- What if we could associate a risk value to each DVH?

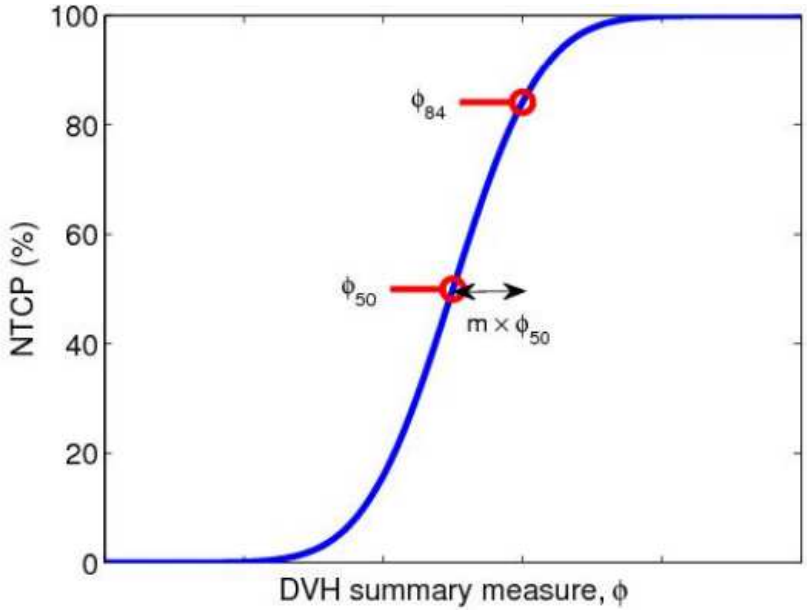
NTCP model structure

Regression models cannot handle 3D dose distributions or DVHs; requires a summary measure φ, e.g. mean dose, which takes the volume effect into account.

The most widely used (Lyman) model uses a cumulative normal function with 2 parameters: φ_{50} and m. Additional parameters might be needed for the DVH summary.

$$\mathrm{NTCP} = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{t} e^{-x^2/2} dx$$

$$t = \frac{\varphi - \varphi_{50}}{m \cdot \varphi_{50}}$$



ESTRO School

LKB model

The Lyman-Kutcher-Burman (LKB) model uses an Equivalent Uniform Dose (EUD)*:

$$EUD = \sum_i \left(D_i^{\frac{1}{n}} \frac{V_i}{V_{tot}} \right)^n$$

- D_i = total dose to bin i
- V_i = absolute volume in bin i
- V_{tot} = total organ volume
- n = volume effect parameter

Parameter 'n' is organ (endpoint) specific

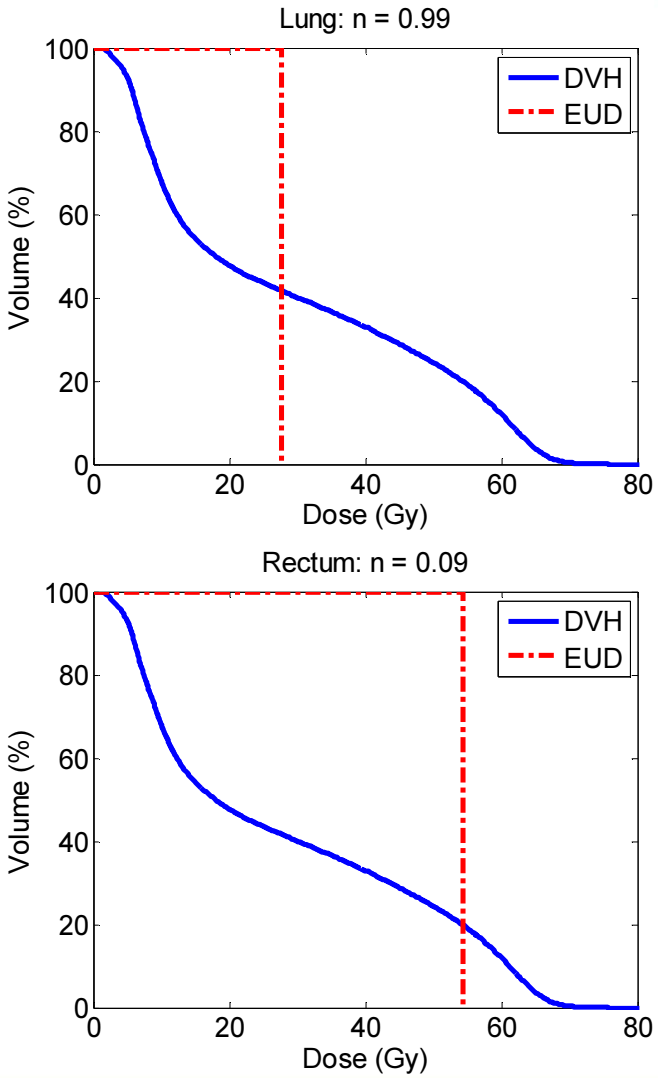
- Low (≈ 0): small volume effect, EUD ≈ max dose
- High (= 1): large volume effect, EUD = mean dose

*Original representation with *effective volume* rather than EUD

Equivalent uniform dose

Note that to apply the LKB model as described, a whole-organ inhomogeneous dose distribution must be converted to a uniform dose, EUD, which has the same likelihood of causing a complication.

The parameter *n* is introduced to represent volume dependence of the organ.



ESTRO School

Generalised equivalent uniform dose

Different expressions for EUD have been proposed, but Niemierko's GEUD has been the most widely implemented.

The parameter 'a' is equivalent to 1/n (the LKB parameter for volume effect).

NTCP scales (non-linearly) with EUD; sufficient to minimise EUD

WE-C2-09

A generalized concept of Equivalent Uniform Dose (EUD)

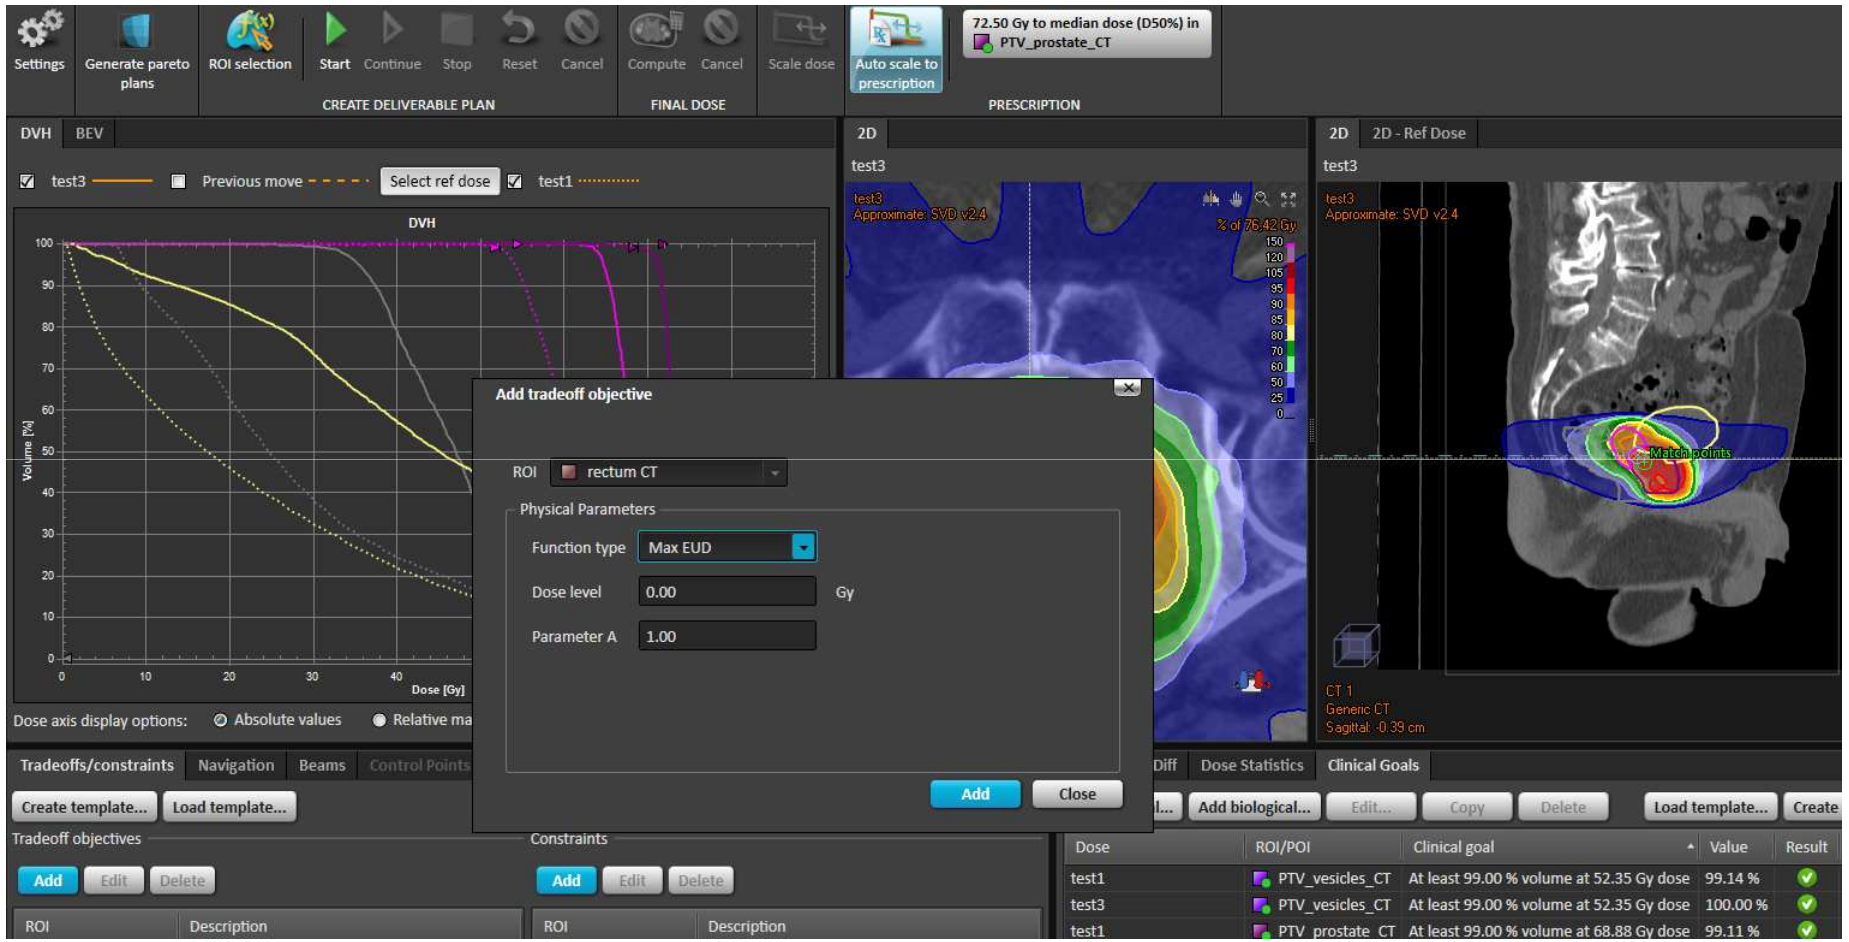
A Niemierko*, Massachusetts General Hospital, Boston, MA

Dose distributions are inherently non-uniform, especially for normal structures. Although IMRT is capable of delivering superior dose distributions tailored to the geometry of irradiated structures; it often produces inhomogeneous target dose distributions. To quantitatively evaluate a treatment plan one needs to know the consequences of dose inhomogeneity for all structures of interest. A concept of Equivalent Uniform Dose (EUD) for tumors, based on models of clonogen survival, has recently been developed and investigated in several clinical settings. Here we report on generalization of the EUD concept that applies to both tumors and normal tissues. Based on the analysis of outcomes for several clinical studies providing volumetric information for tumors and normal organs we propose that EUD for a structure of interest be estimated as:

$$EUD = \left(\frac{1}{N} \sum_{i=1}^{N} D_i^a \right)^{\frac{1}{a}}$$ or, using a differential dosevolume histo[gram] $$EUD = \left(\sum_{i=1}^{N} v_i D_i^a \right)^{\frac{1}{a}}$$

where $\{v_i, D_i\}$ are bins of the histogram and "a" is a tissue-specific parameter. *It is easy to see that EUD is bounded by the minimum and by the* maximum dose, and is equal to the mean dose for "a" equal to one. The parameter "a" is negative for all tumors and it is positive for all normal *structures. We estimated the maximum likelihood values of the parameter* "a" for several tumors and normal structures and they range from –13.1 for control of chordoma tumors to 17.7 for perforation of esophagus. We discuss the rationale for this generalized EUD concept and we will discuss the estimates of the parameter "a" for several important structures and end-points.

EUD plan optimisation



ESTRO School

Critical volume model

In the Critical Volume model the summary measure is a damaged volume, calculated using a local dose-effect function $E(D_i)$.

$$\text{Damaged volume} = \sum_i E(D_i)\frac{V_i}{V_{tot}}$$

- D_i = total dose to bin i
- V_i = absolute volume in bin i
- V_{tot} = total organ volume

Different functions can be used, but the effect increases with dose; FSU inactivation?

Local dose effect functions

$$E(D_i) = \frac{1}{1 + (D_{50}/D_i)^k}$$

2+2 parameters

$\begin{cases} D_{50} = \text{dose causing 50\% local effect} \\ k = \text{parameter for slope of curve} \end{cases}$

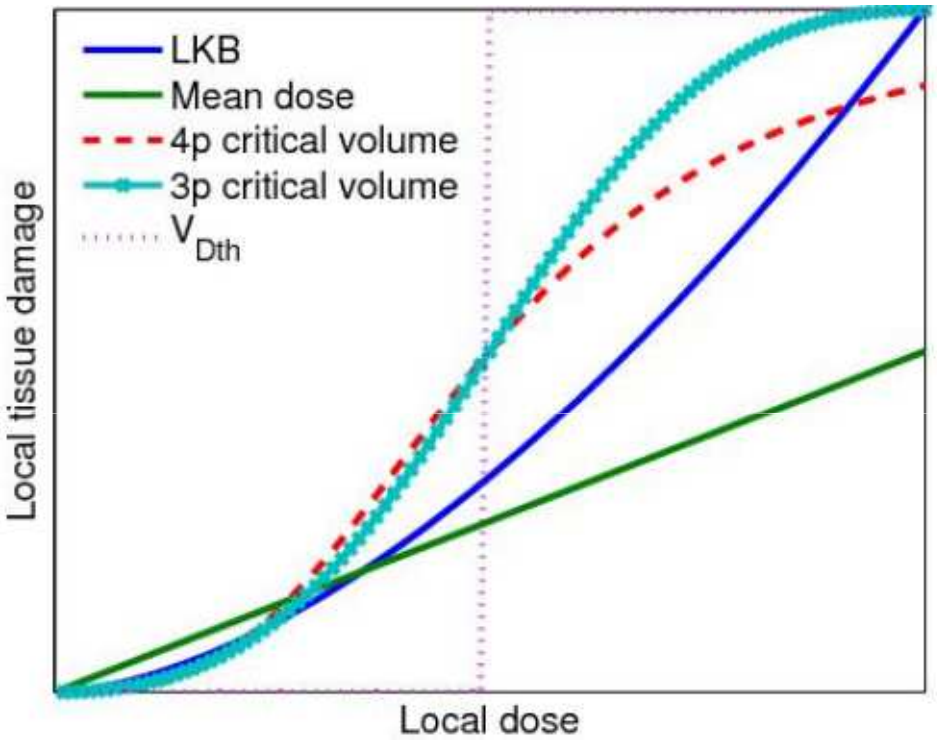
$$E(D_i) = \begin{cases} \dfrac{D_i/D_{50} - 1}{1 + (D_i/D_{50} - 1)^2} + {}^1/_2 & \text{when } D_i < 2D_{50} \\ 1 \text{ when } D_i \geq 2D_{50} \end{cases}$$

2+1 parameters

$$E(D_i) = \begin{cases} 0 \text{ when } D_i < D_{50} \\ 1 \text{ when } D_i \geq D_{50} \end{cases}$$

2+1 parameters

DVH reduction



Models use different DVH summary measures.

A function for DVH reduction can be used based on assumptions about the effect of the local dose on the local tissue (functional subunit inactivation).

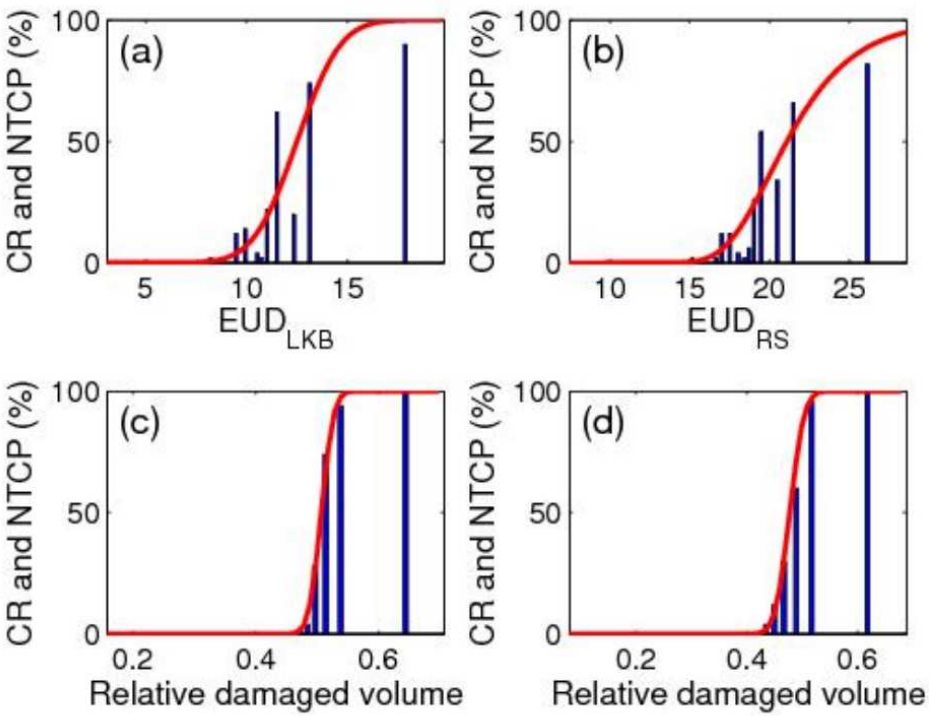
The main difference between models is whether a saturation of the response with dose is assumed.

Choosing a summary measure

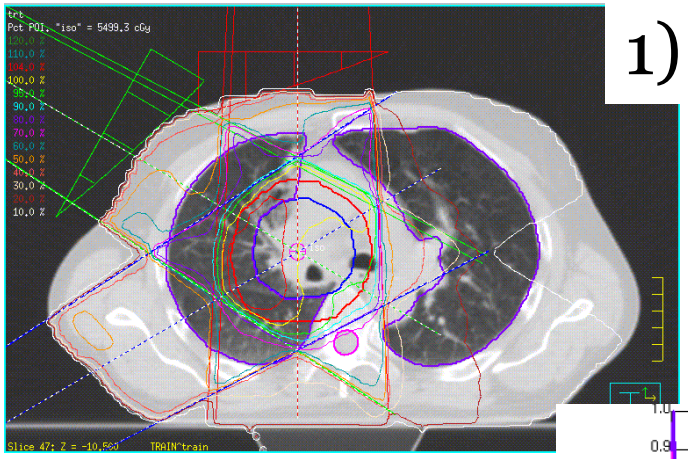
A model with a non-representative summary measure estimates the same NTCP for plans with different risk.

- Results in a shallow dose/volume-response function
- Less useful predictive tool
- Makes inefficient use of the data

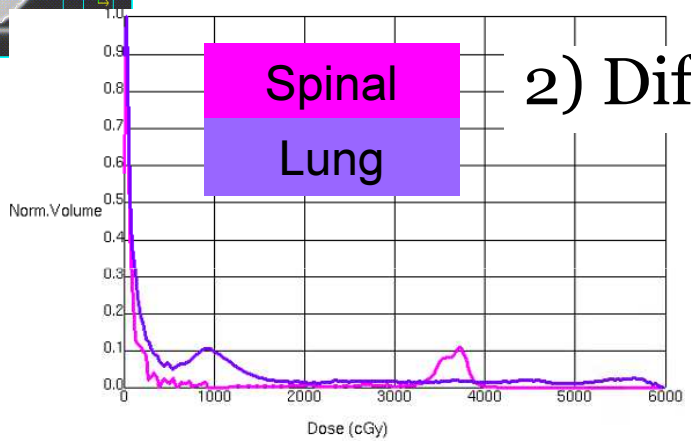
Example with simulated data



ESTRO School



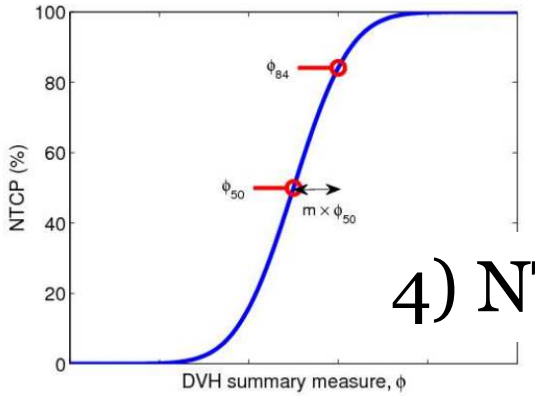
1) 3D organ dose distribution



2) Differential DVH

3) EUD or ‘damaged volume’

Parameters used in the models have been derived from data on previous treatments:
DVHs and outcome.



4) NTCP

The relative seriality model

The Relative Seriality model first calculates a probability of local damage for each dose bin in the DVH:

$$P(D_i) = 2^{-\exp\left(e\gamma\left(1-\frac{D_i}{D_{50}}\right)\right)}$$

- D_i = total dose to bin i
- D_{50} = Dose causing 50% probability
- γ = slope of the curve

Then NTCP is estimated using the relative seriality parameter 's'.

- Serial organs: $s = 1$, high doses to small volume important
- Parallel organs: $s \approx 0$, large irradiated volume important

$$\mathrm{NTCP} = \left(1 - \prod_i (1 - P(D_i)^s)^{\frac{V_i}{V_{tot}}}\right)^{1/s}$$

- V_i = absolute volume in bin i
- V_{tot} = total organ volume
- s = relative seriatlity parameter

How do I calculate NTCP?

- Available in biological packages in some treatment planning systems
- BIOSUITE: standalone executable developed by Dr Uzan and Prof Nahum at Clatterbridge Cancer Centre, UK. Available on request (dr.j.a.uzan@gmail.com).
- Good MATLAB based packages: CERR, DREES www.cerr.info
- VODCA: database software for radiotherapy data analysis www.vodca.ch
- Straightforward to calculate from exported DVHs

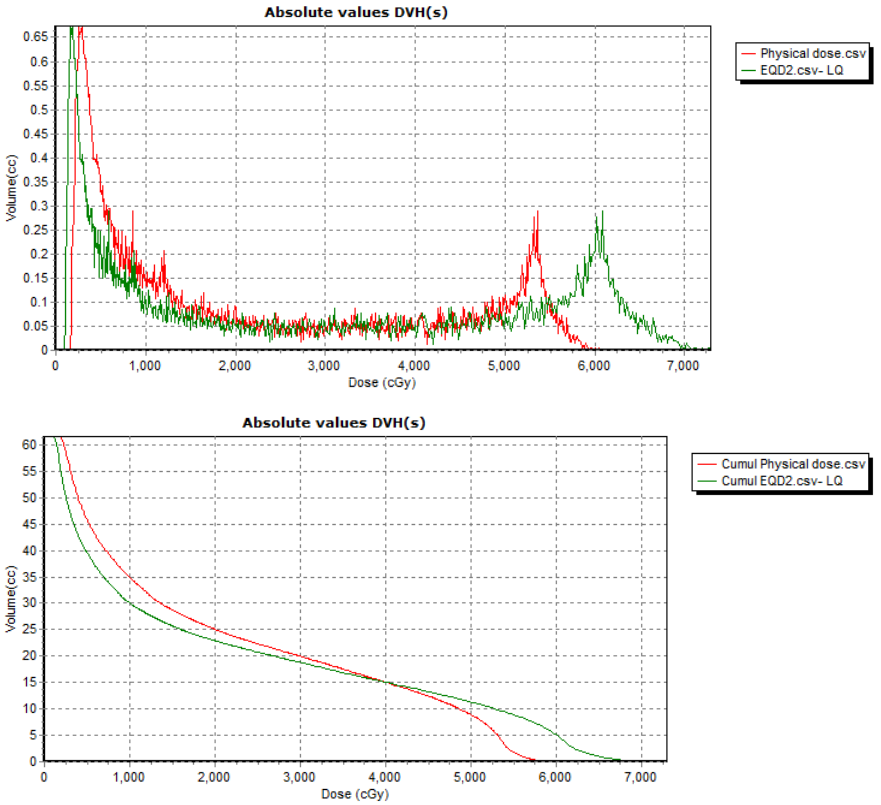
Fractionation correction!

Each bin in the DVH receives a different dose per fraction.

- Convert each dose-bin to 2Gy fraction equivalence (reference conditions).

$$BED = D\left[1 + \frac{d}{(\alpha/\beta)}\right]$$

$$EQD_{2Gy} = D\left[\frac{d + (\alpha/\beta)}{2 + (\alpha/\beta)}\right]$$



ESTRO School

Example

- DVHs for 2 lung cancer patients
- Total lung – GTV
- Fractionation correction (α/β = 3 Gy)
- NTCP estimated using 3 different models
- Parameter values from Seppenwoolde et al. 2003

	Patient 1	Patient 2
LKB	9.2%	5.4%
Critical Volume	9.9%	6.9%
Relative Seriality	8.5%	4.4%

Which model should I use?

- Preferably several
- The LKB model is the most commonly used model and has parameter values published for many organs/endpoints (e.g. QUANTEC)
- All the above models are empirical
  - Statistical fits to clinical data
  - Biological interpretation of DVH reduction method should not be relied on blindly
- The more parameters, the more clinical data needed for parameter fitting; up to 3 parameters often appropriate
- Datasets often in the order of 100-300 patients. The more 'events', the more information to model on

Parameter derivation

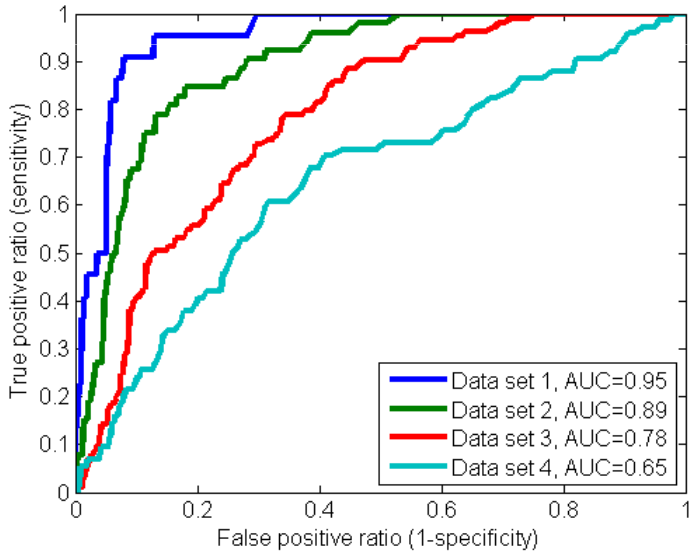
- Parameters are fitted to outcome data and DVHs (fractionation corrected) using the *maximum likelihood* method: finds parameters which makes current observation as likely as possible
- Outcome data generally binary (tox, no tox)
- Model is associated with the characteristics of the registered outcome data:
  - Endpoint, including grade
  - Co-morbidity, concomitant treatments etc.
- The confidence interval of the parameters depend on the quality of the data they're fitted to, and the sample size

Important considerations

- The model is only as good as the data used for parameter fitting.
  - Well-designed study (unbiased, representative)?
  - Sample size, number of events
  - Uncertainties in dose distributions (incl. organ motion, organ definition)
- The model is only reliable for plans reasonably similar to the plans included in the study (also applies to patient specific factors).
- When a model is used without knowledge of these factors, or for a different technique/patient group, the same limitations apply as to empirical 'tolerance doses'.
- NTCP is continuous but the patient outcome is binary
  - NTCP needs to be estimated because of limited information

Model accuracy

- The figure shows how the performance of an NTCP model deteriorates as confounding factors are increased in the patient population to which the model is fitted
- The area under the curve (AUC) is a measure of accuracy, giving the probability that the model will correctly rank sampled 'complicator' & 'non-complicator' pairs from the data set
  - 0.5-0.7: poor
  - 0.7-0.9: moderate
  - 0.9-1: excellent



ESTRO School

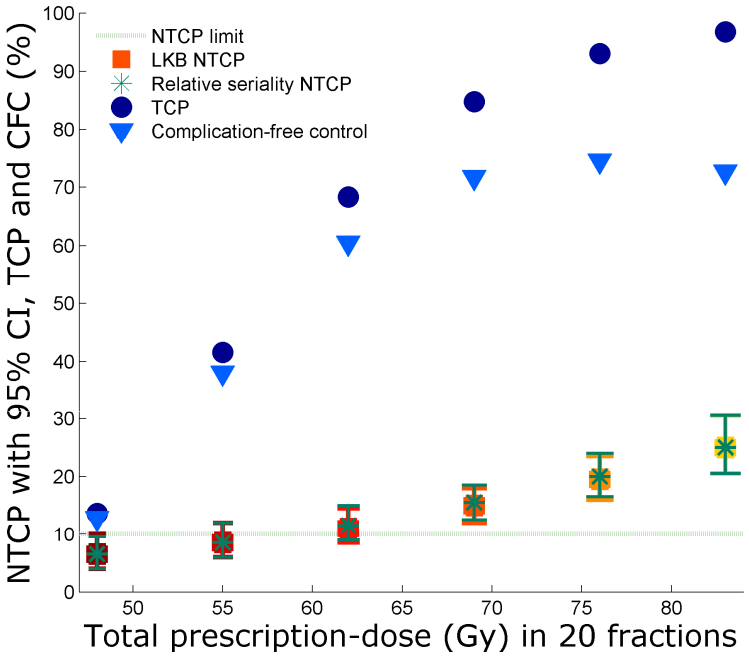
When to use NTCP models

- ICRU report 83: level 3 dose reporting
- Dose-volume constraints
- IMRT/VMAT optimisation
- Ranking treatment plans
- Evaluation of treatment data from clinical studies; derive parameter values locally
  - Better to used locally derived parameter values than published values
- Develop new potential techniques
- Dose prescription

Individualised dose prescription

Where individual dose prescription is adopted NTCP and TCP estimates for individual patients can be used by the clinician.

Due to anatomy differences between patients the TCP and NTCP estimates for a prescription dose will vary.



Complication-free control
= TCP(1-NTCP)

Taking empirical models further

Accounting for confounding factors

- Confounding factors include any non-dosimetric factors (X) influencing the outcome, as these are not modelled.
- Health status, chemo/surgery, radiosensitivity etc.
- Sharper slope, greater certainty

$$\mathrm{NTCP} = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{t} e^{-x/2} \mathrm{d}x$$

$$t = \frac{\varphi - \varphi_{50}}{m \cdot \varphi_{50}} + \beta_2 X_2 + \cdots + \beta_n X_n$$

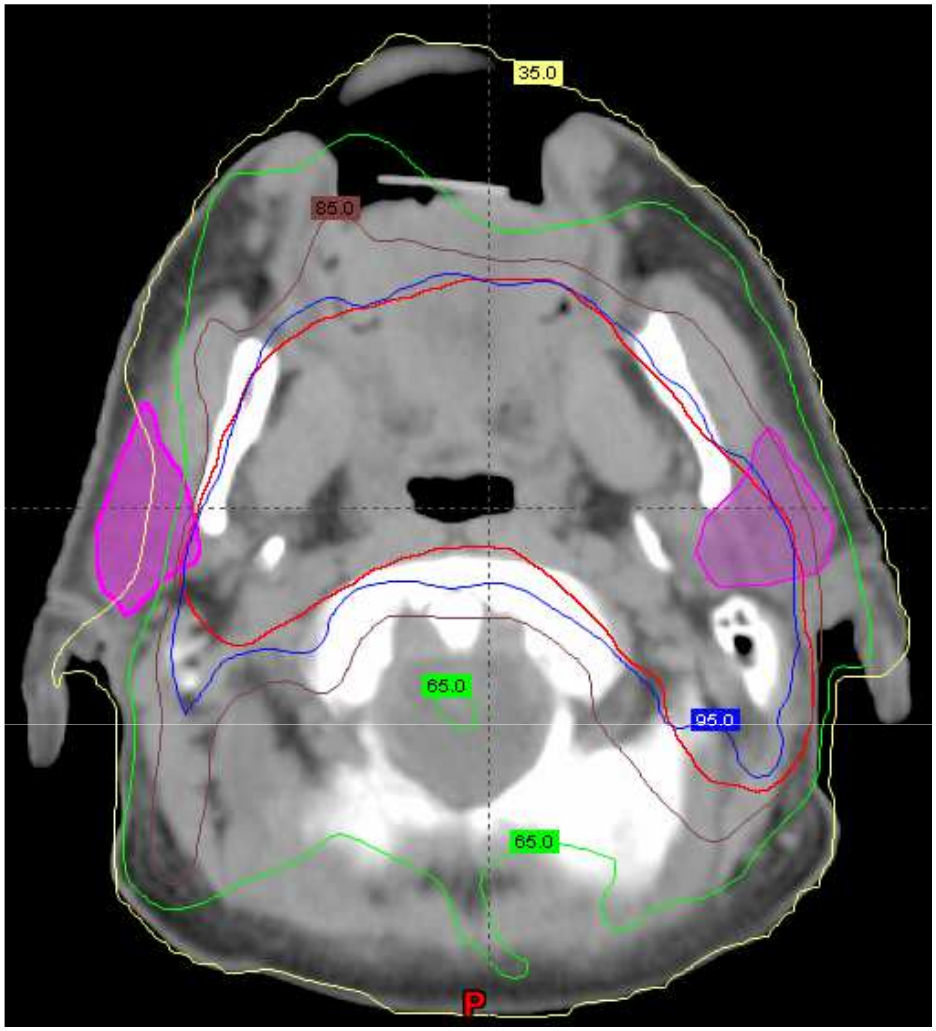
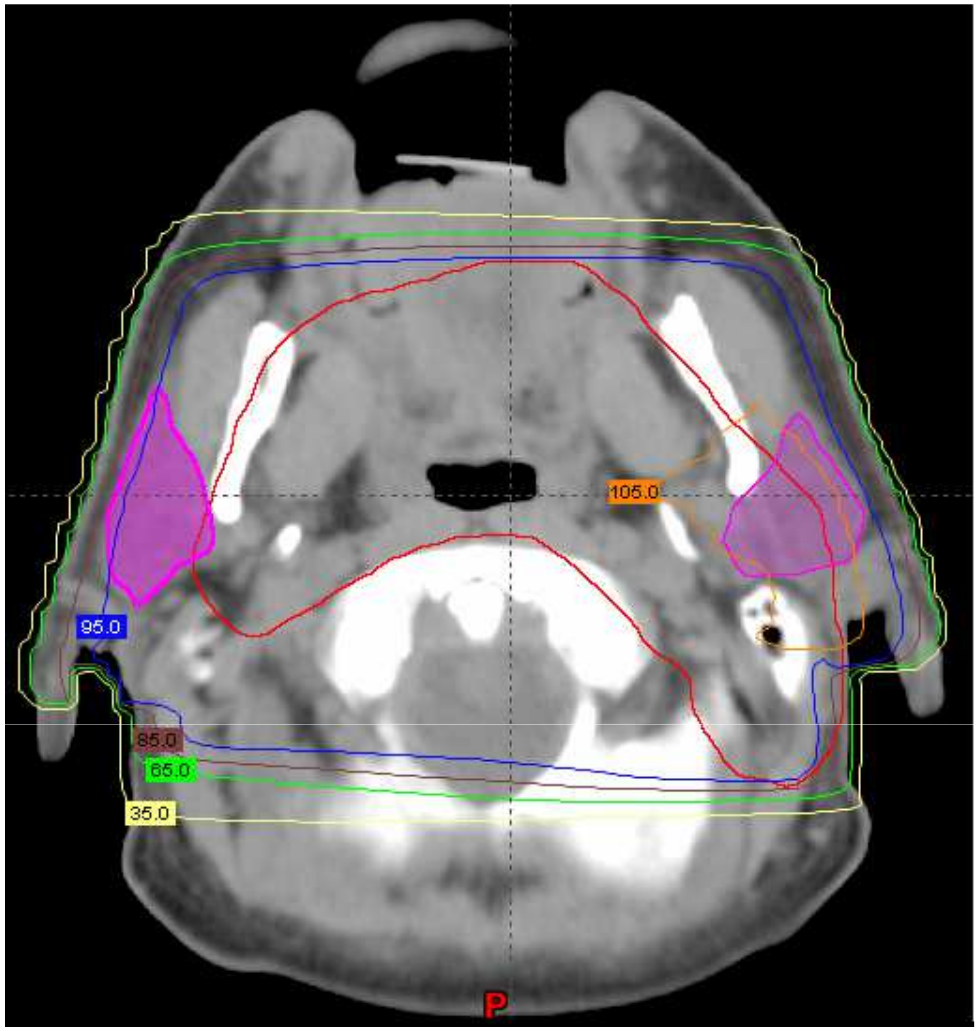
QUANTEC Supplement 2010





IMRT: Dmean (parotid dx)=18Gy

Parotid (pink) dose limit: D_{mean} 26Gy

3DCRT Dmean(parotid dx)=42Gy

BASELINE
for parotis

Xerostomia - PAROTID GLANDS

- Outcomes:
  reduced salivary output, xerostomia
  alterations in speech and taste, nutritional problems, dental hygien

- Measure of the salivary flow: quantitative information about the secretory capacity of the glands

- Salivary gland: stimulated salivary production (60-70%)
- Submandibulary and sublingual glands: unstimulated salivary production

- Subjective scoring and objective scoring missmatch
  (assessment by questionnaires interviews, patient diaries different from those performed with salivary gland flow rates, scintigraphic activity)

Eisbruch et al, IJROBP 45, 3:577, 1999

Prospective study

- 51 patients, parotid sparing bilateral neck RT
  (advanced head & neck)
  37 patients, unilateral neck RT (small lateral tumors)
- Saliva flow rates measured before and 1 year after RT
- Threshold mean dose to the glands for suppression of the salivary flow: 24 - 26 Gy

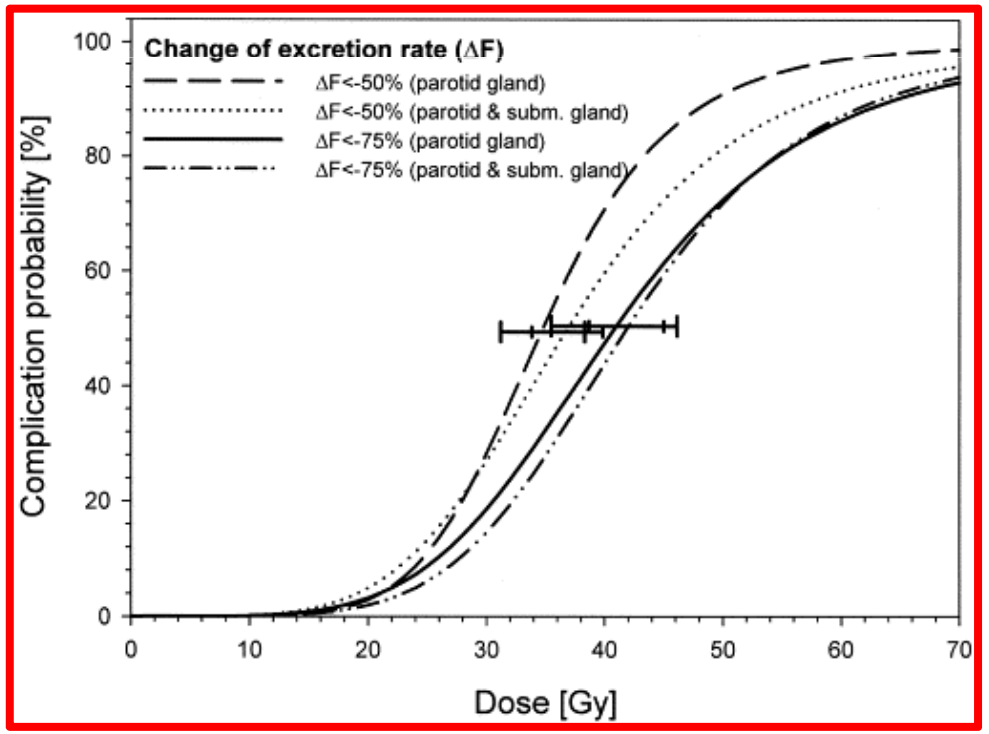
Roesink et al, IJROBP 51, 4:938, 2001

Prospective study

- 180 patients, 174 parotid glands
- Saliva flow rates measured before and after RT
  (6 weeks, 6 months, 1 year)
- Postradiotherapy saliva flow decreased with increasing irradiated volume to a mean dose between 35 and 45
- No threshold mean dose

PAROTID GLANDS

- Large volume effects confirmed in several studies (Munter 2004, 2007, Dijkema 2008,2010)
- Reducing D_{mean} < 25-30 Gy is not sufficient to reduce xerostomia



Parotid glands – xerostomia
NTCP description

LKB model	***TD50***	***m***	n
Emami (1991) No 3D - retrosp.	46 Gy	0.18	0.7
Eisbruch (1999) 88 pts – prosp.	28.4 Gy (25 – 34.7)	0.18 (0.10 – 0.33)	1 (fixed)
Roesink (2001) 180 pts – prosp. 95% CI	39 Gy (34 - 44)	0.45 (0.33 - 0.65)	1 (fixed)

”early” modelling, large volume effect

PAROTID GLANDS – dose-volume recommendations for xerostomia < 20%

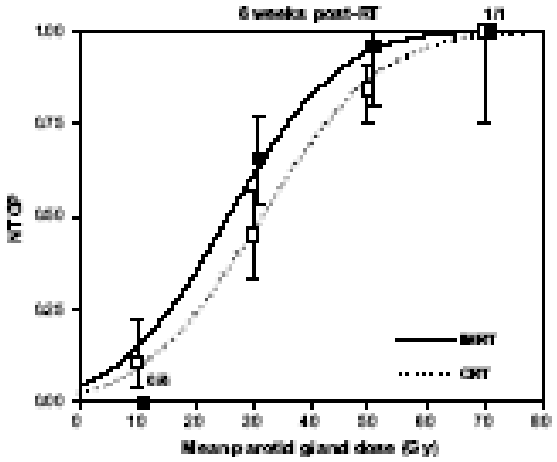
Mean dose to one parotid gland < 20 Gy

Mean dose to both parotid glands < 25 Gy

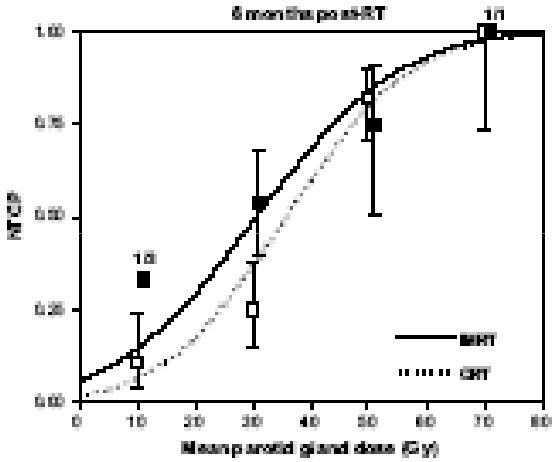
- ? Mean dose to submandibular gland < 35 Gy
- ? Threshold value, < 10 Gy

Large volume effect dependence, related to the parallel architecture of the glands

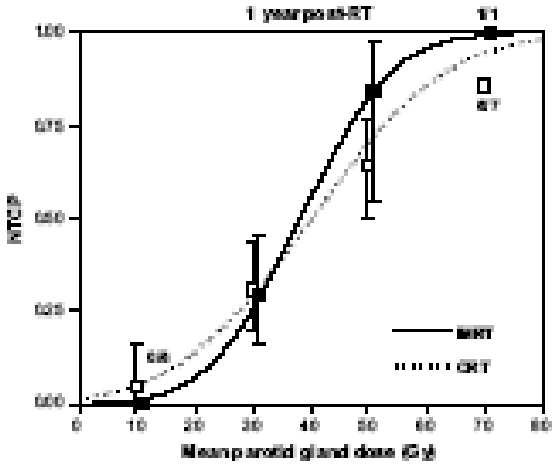
QUANTEC recommendations



6w



6m



1y

Parotids: other updates…

- Utrecht data (221 pts), stimulated flow rates 6w, 6m, 1y.
- 3DCRT (n=157) vs IMRT (n=64)
- NTCP end point: reduction < 25% baseline
- Different behaviour between IMRT and 3D
- Spatial effects (different dose distribution @ same Dmean)…more important for early reactions

Dijkema et al 2008

PAROTID GLANDS –

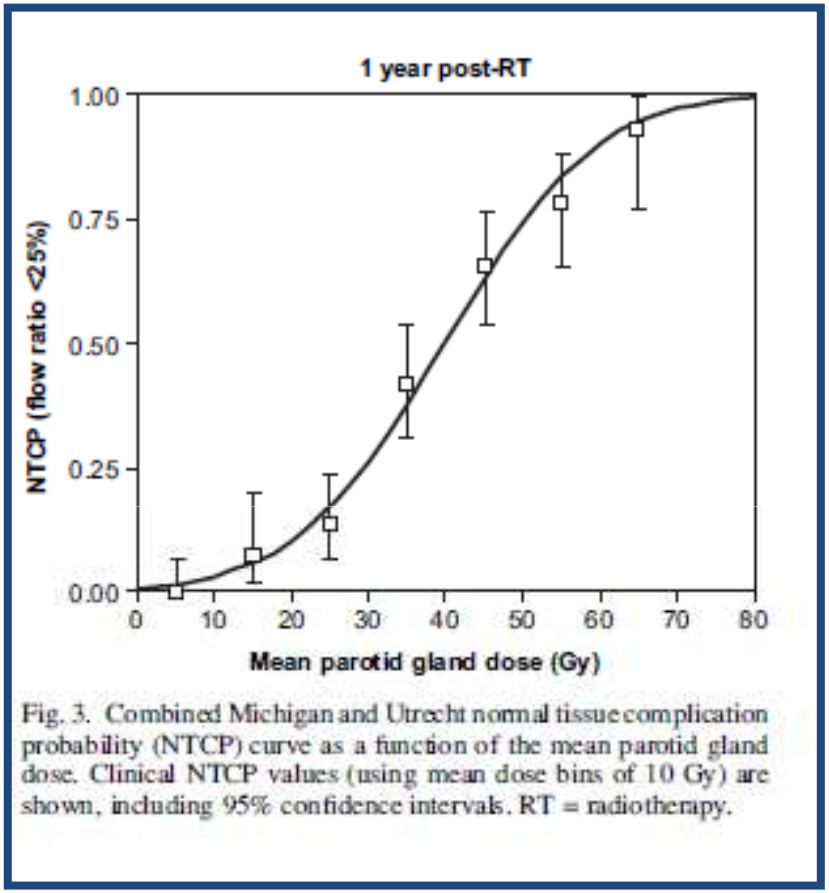


Fig. 3. Combined Michigan and Utrecht normal tissue complication probability (NTCP) curve as a function of the mean parotid gland dose. Clinical NTCP values (using mean dose bins of 10 Gy) are shown, including 95% confidence intervals. RT = radiotherapy.

Table 4. Combined analysis: Parameters TD_{50}, m, and n (95% CI) in terms of mean dose ($n = 1$) and with the full LKB-model (n) for flow data 1 year after radiotherapy

Parameter	Mean dose ($n = 1$)	Full LKB (n unrestricted)
TD_{50} (Gy)	39.9 (37.3–42.8)	39.4 (33.8–41.8)
m	0.40 (0.34–0.51)	0.42 (0.36–0.58)
n	1	1.13 (0.75–14.3)
Δ	339.2	340.6

Abbreviations: CI = confidence interval; LKB = Lyman-Kutcher-Burman model; TD_{50} = the uniform dose to the whole organ resulting in 50% complication probability; m = slope of the complication probability curve; n = volume dependency parameter.
Goodness-of-fit is expressed as the deviance (Δ).

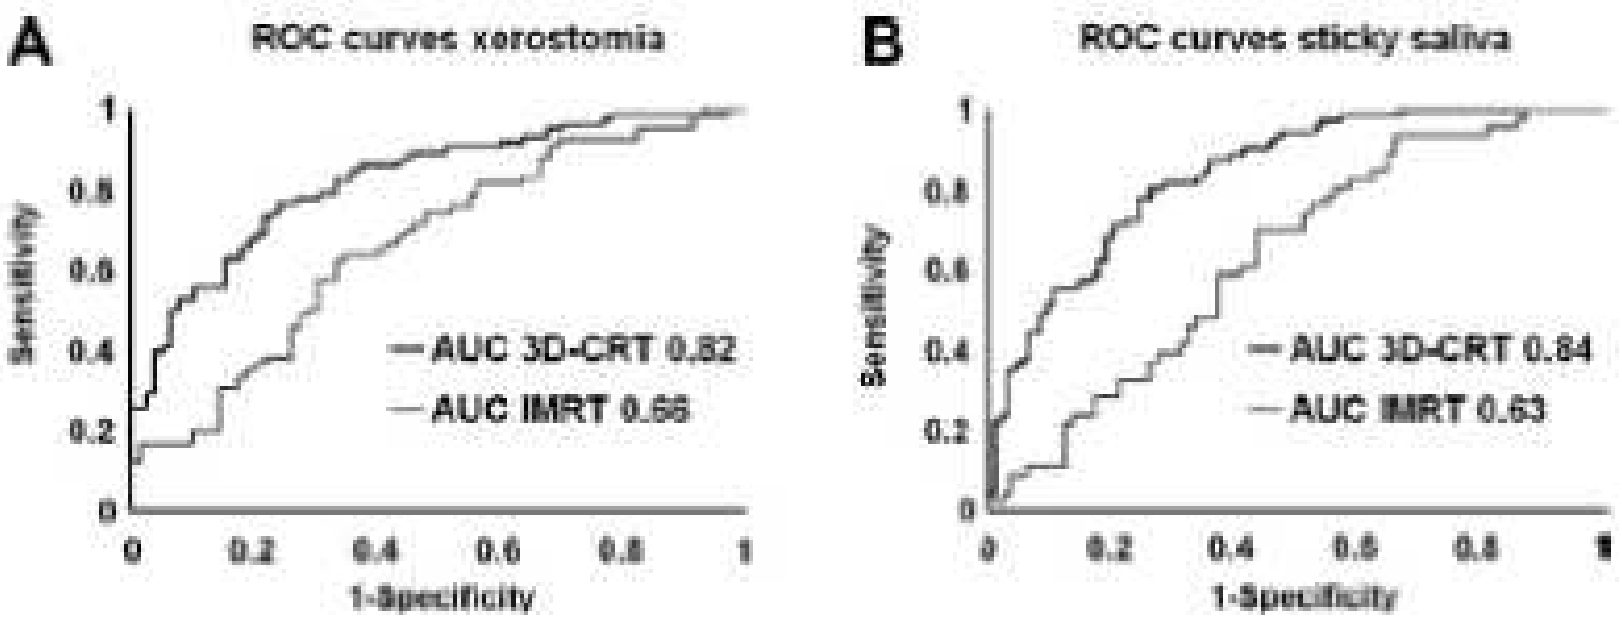
Utrecht & Ann Arbor data, 384 parotids,
Stimulated flow rates 1 year after RT

Endpoint: reduction < 25% baseline

n=1, D mean model ok

Dijkema et al, 2010

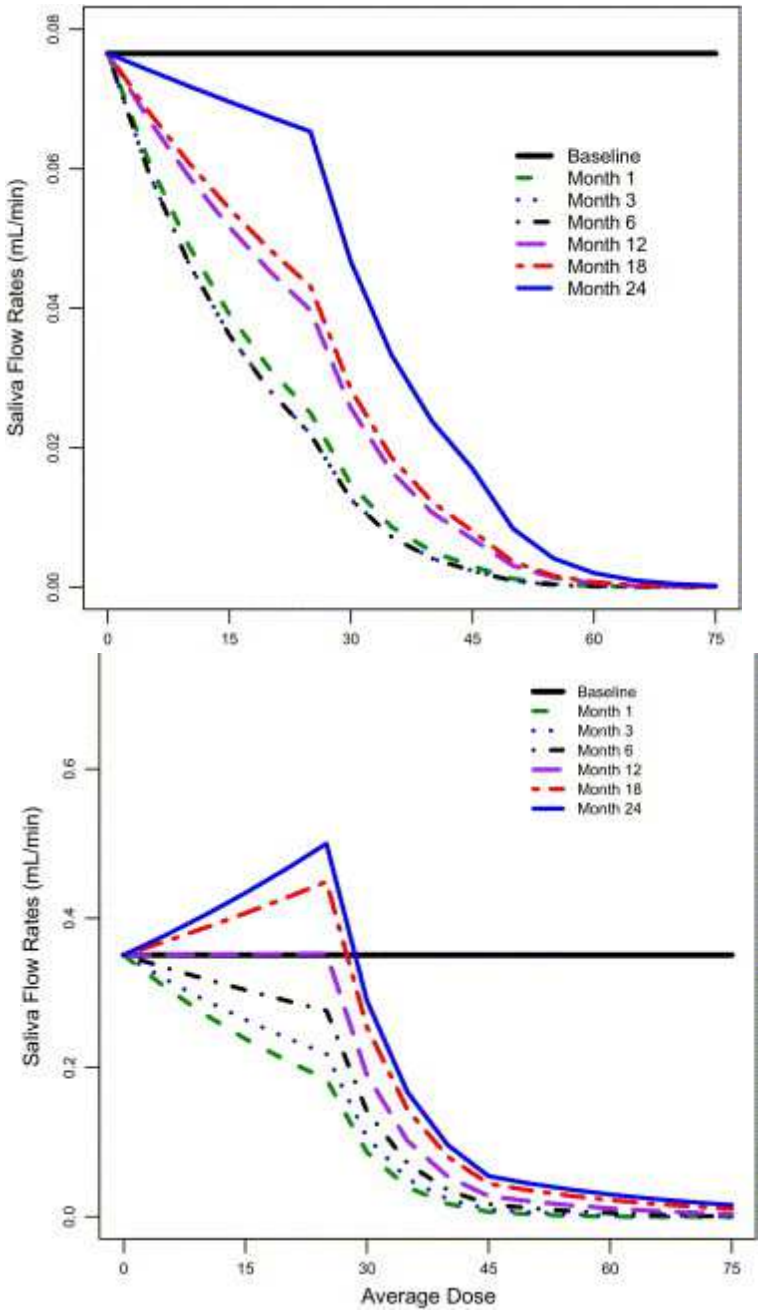
Xerostomia: **spatial effects**? 3D vs IMRT



- are there more sensitive sub regions?
- stem cells only seen in the excretory ducts (Feng 2009)
- selective sparing or stem cell transplanation to reduce xerostomia?

Beetz et al, 2011

Entity and speed of the recovery vs Dmean: a model



Unstimulated saliva
flow rate

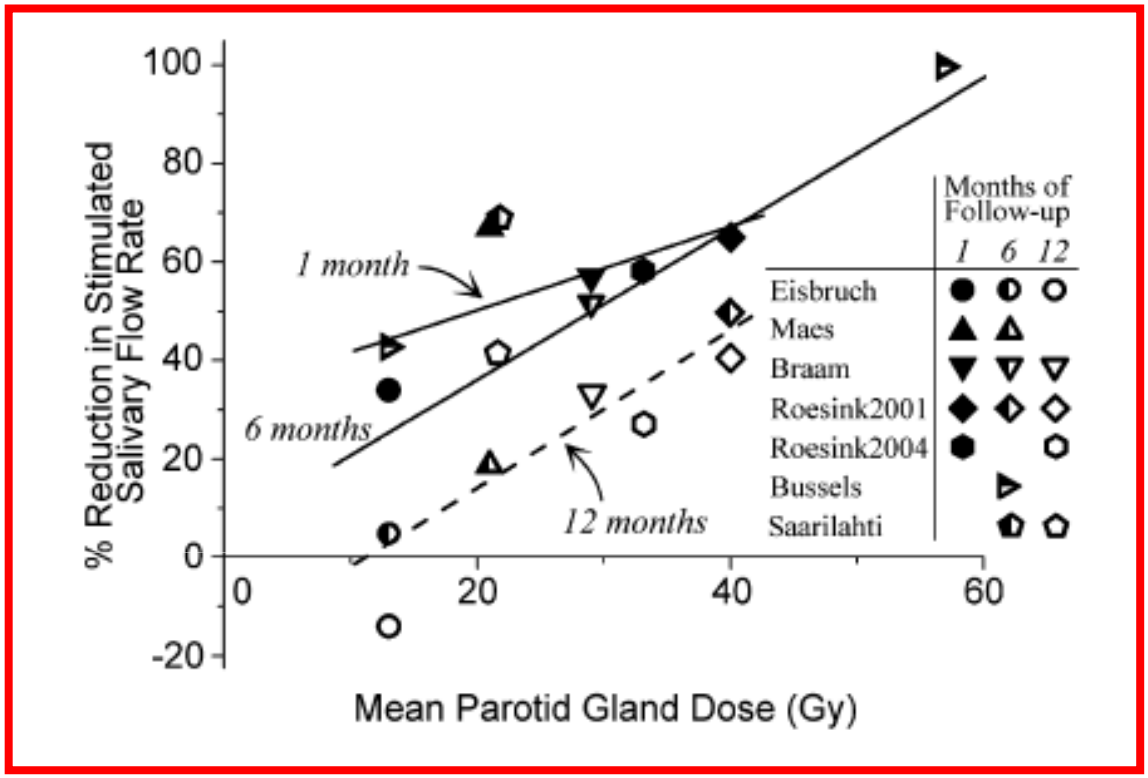
Almost complete recovery at 12-24 months for Dmean < 25-30 Gy

(Li 2007; 266 parotids; 142 pts)

Stimulated saliva
flow rate

Courtesy C. Fiorino

Xerostomia– **time aspects**



Relevance of the time of evaluation of the endpoint

Outcome data (reduction in salivary flow) and sampling time
- @ 1month: almost independent of mean dose
- shift to right: higher mean dose with longer follow-up

Deasy *et al*. IJROBP, vol 76, n3, 2010, S58-S63

PAROTID GLANDS –**shrinkage and CT density**

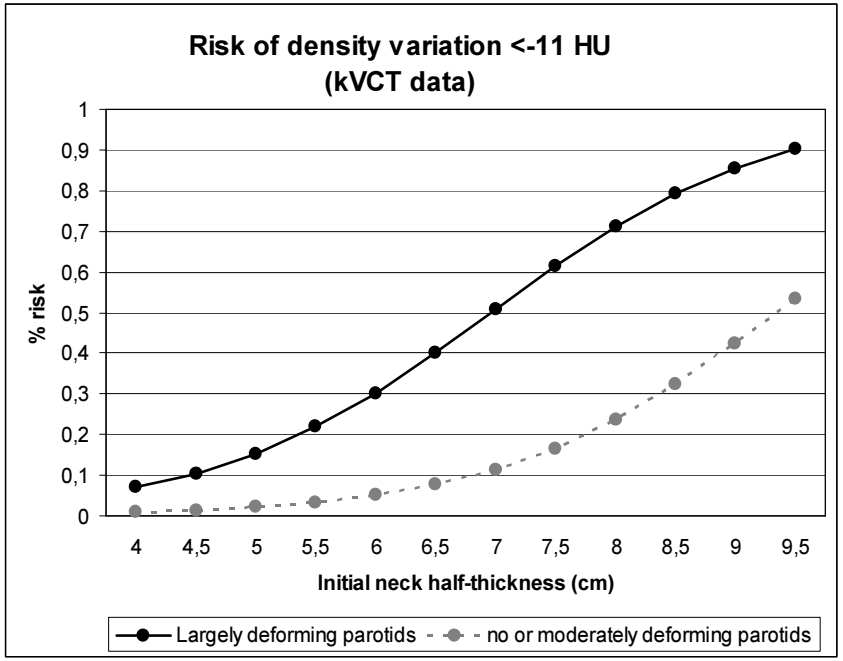
84 pts, (Fiorino *et al*, RO,2012), parotid reduced during IMRT

parotid deformation and average Hounsfield number changes evaluated through MVCT or kVCT diagnostic at treatment start

individual ΔHU highly correlated with degree of local deformation in terms of volume change and with neck thickness variation

individual assessment of density changes reliable with kVCT

density changes to score toxicity?



See also Broggi *et al* 2010

What is the best measure of xerostomia?

- Does the tolerance dose of parotid glands differ between subjective measures, objective measures and patient reported outcomes of xerostomia?

  (data from the first multicenter randomized study of IMRT and conventional RT)

- Patient reported outcomes results are associated with a higher tolerance dose (D50= 33 Gy)

- LENT-SOMA subjective xerostomia is the most useful clinical measure of salivary function (easily measured and strongly associated with the dose-response of the parotid glands)

Miah *et al*, 2013

Less xerostomy (RTOG scale) with tomotherapy than with sliding window IMRT

- 119 pts, oropharingeal ca, concurrent chemo radio: 59 pts sw-IMRT, 60 pts HT

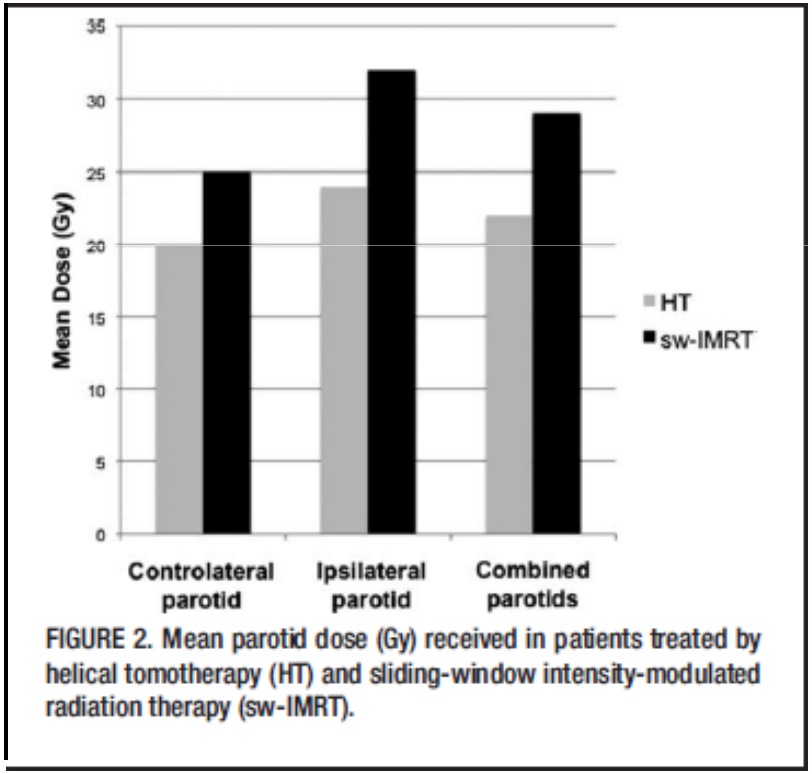


FIGURE 2. Mean parotid dose (Gy) received in patients treated by helical tomotherapy (HT) and sliding-window intensity-modulated radiation therapy (sw-IMRT).

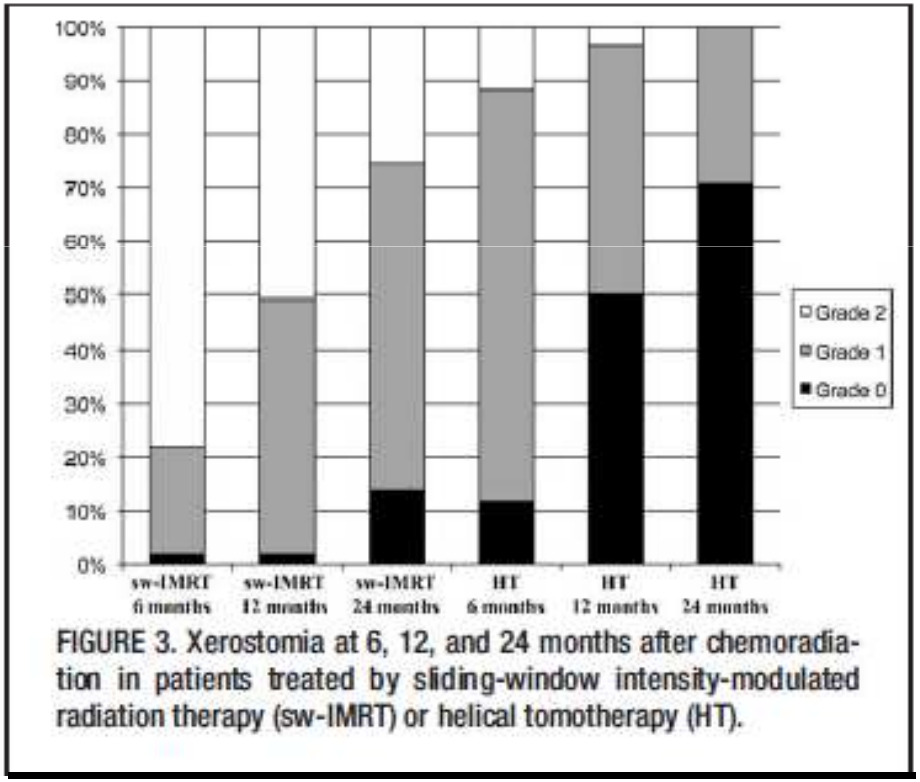

FIGURE 3. Xerostomia at 6, 12, and 24 months after chemoradiation in patients treated by sliding-window intensity-modulated radiation therapy (sw-IMRT) or helical tomotherapy (HT).

Ipsilateral parotid mean dose – HT 24 Gy; IMRT 32 Gy
Controlateral parotid mean dose – HT 20 GY, IMRT 25 Gy

Fortin *et al*, 2013

Validation of QUANTEC guidelines for xerostomia

- Lee F *et al*, R&O, 2013
- 238 pts, EORTG QoL questionnaires
- Validation of LKB parameters,

- Beetz I *et al,* Acta Oncologica, 2014
- 307 pts, chemoradio, 3D CRT (56%), IMRT (44%)
- Significanly **lower rates of xerostomia** in pts treated according to **guidelines**, but the criteria do not completely protect aganist xerostomia

- Moiseenko *et al*, IJROBP 2012
- 66 pts,, flow measurements, gr 4 xerostomia; @3 mths, flow decreases to <25% than pretreatment
- Clinical use of the ”20 Gy spared-gland rule” is justified

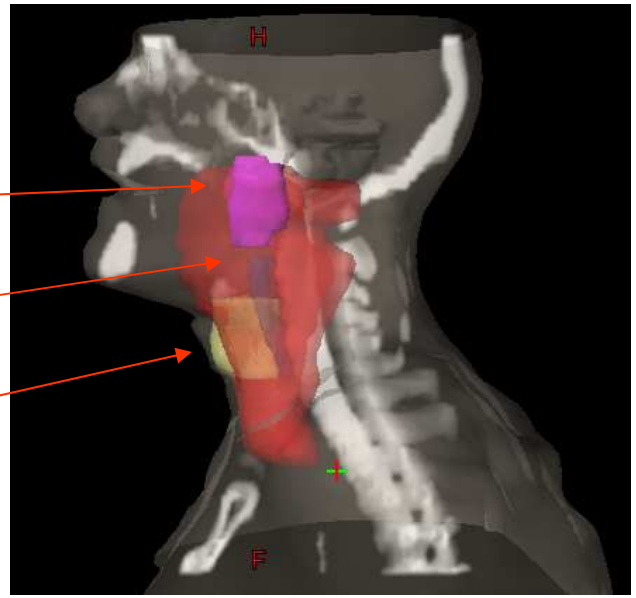
LARYNX AND PHARYNX irradiation (1/4)

- RT advantage: larynx preservation, implying speech and swallowing retention
- RT damage: laryngeal edema/fibrosis, leading in long term to problems in speech and swallowing retention
- Larynx (and pharynx): often partially included in the target

Parotid glands

Pharynx

Larynx



LARYNX, edema

- **Larynx/edema gr 2**:

  66 pts, videofluoroscopy assessed, fu=17.4m
  mean dose or V%> 50 Gy
  & neck stage (multivariate - Sanguineti *et al*, IJROBP 2007)

  V50<27%; mean dose < 43.5 Gy (EQD2)

- **Larynx/vocal disfunction**:

  complex physiology
  ≥66 Gy (prescription): decrease in function but not 3D data (Dornfeld *et al,* IJROBP 2007)

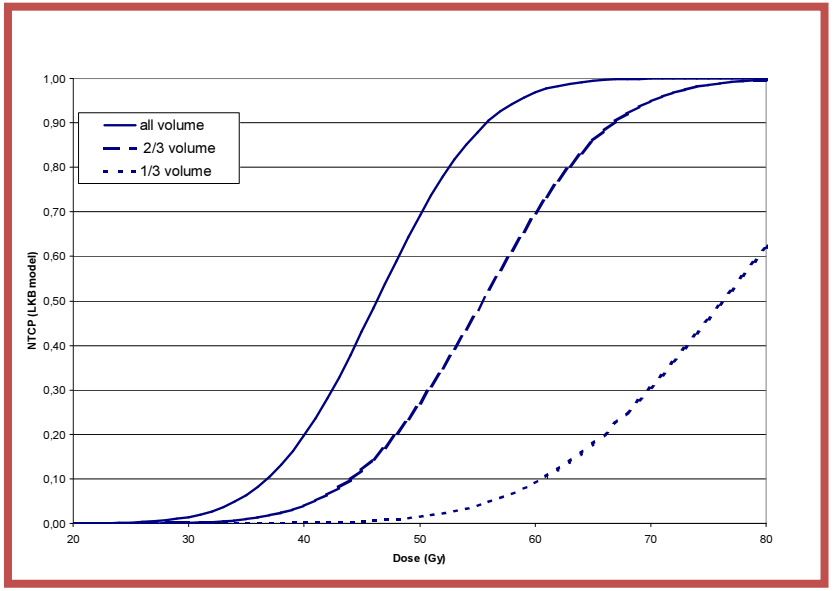
- **Risk factors**:

  concurrent chemo to high dose RT
  ≥double risk of laryngeal edema and vocal dysfunction

Rancati *et al*, IJROBP, vol, 76, n3, S64-S69

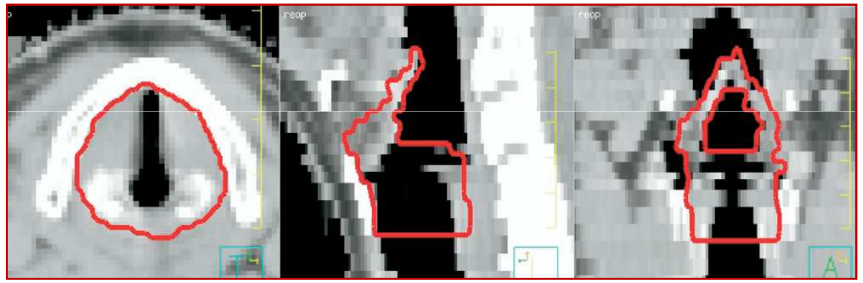
LOGEUD	*TD50*	*k*	
Rancati (2009)	46.0 ± 1.8	9.95 ± 3.46	

LKB	*TD50*	***m***	*n*
Rancati (2009)	46.3 ± 1.8	0.16 ± 0.05	0.45 ± 0.028



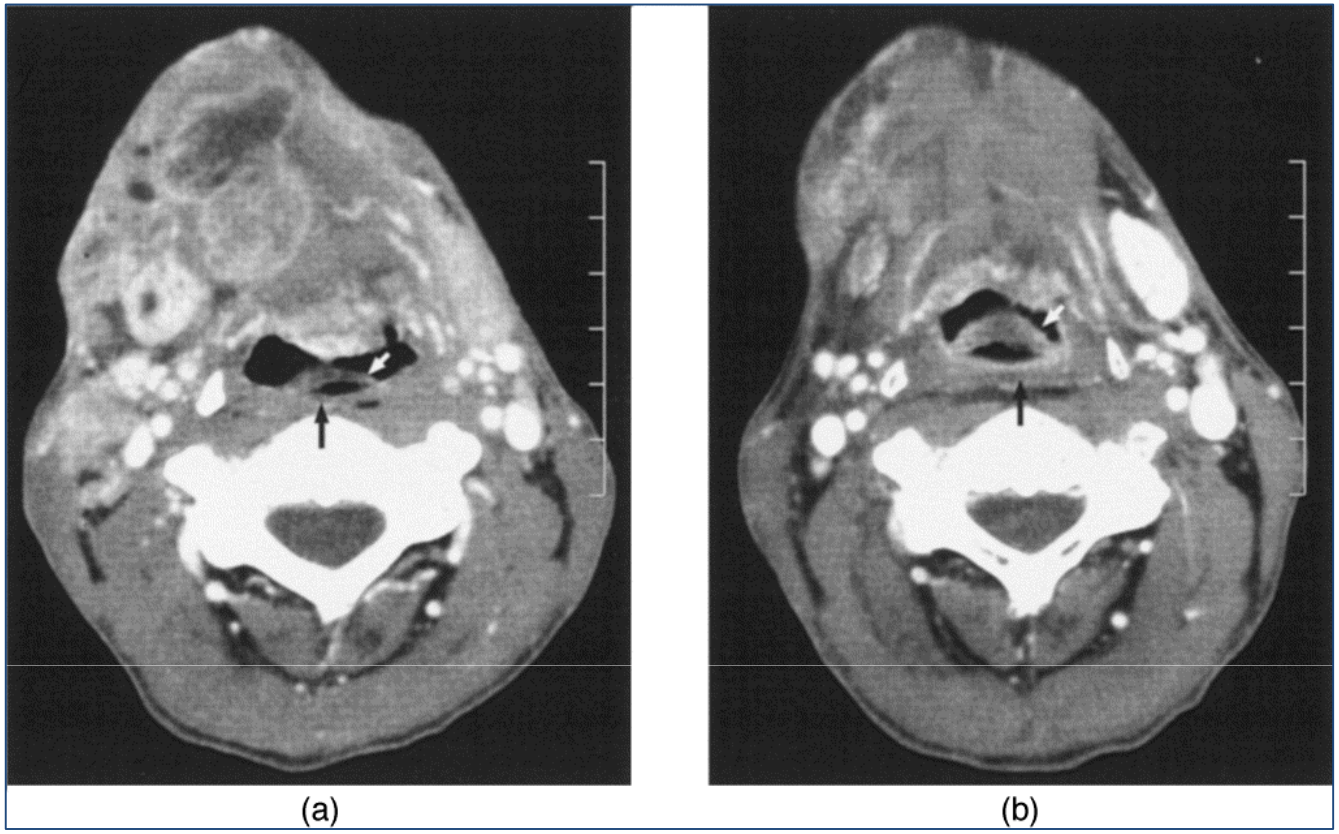
Rancati et al *IJROBP 2009*

Larynx is parallel for edema



Laryngeal edema:

- Large volume effect
  EUD<30-35 Gy (n=0.45)
- V50≤27%;
  mean dose ≤44 Gy



Black arrow, middle pharyngeal constrictor

white arrow, epiglottis….

before (a) and 3 months after treatment (b)

Eisbruch *et al* 2003

DYSPHAGIA

- Organs: supraglottic larynx and constrictor muscles
- Endpoints: aspiration and deglutition
- **Feng et al, 2006 (ASTRO):** evidence of a quantitatively assessed **dose-volume effect** for disphagia & aspiration (36 pts)
- **Aspiration**: **mean dose & V50-V65 to pharingeal constrictors**, supraglottic larynx - correlated.

Most predictive: V65(PC)<50%

Validation of QUANTEC guidelines for dysphagia

- Anderson NJ *et al,* Acta Oncologica 2014
- 76 pts, advanced squamous cell ca,
- **QUANTEC larynx** recommendations: **V50< 27 Gy**, **D mean< 44 Gy**
- Acute dysphagia toxicity, weekly measurements, prospectively scoring

- V50<27 Gy, Dmean>40 Gy, Dmax<66Gy predicted for grade 3 dysphagia
- no clinical risk factors significantly predicted for gr. 3 dysphagia

Usefulness of QUANTEC criteria in predicting acute toxicity

Xerostomia and disphagia after IMRT

Morbidity of head and neck RT

Late dysphagia after IMRT for head and neck cancer and correlation with dose–volume parameters

Hanna R. Mortensen [a,*], Kenneth Jensen [a], Karin Aksglæde [b,c], Marie Behrens [d], Cai Grau [a]

Prospective study, 294 pts, IMRT 2006-2010

EORTC QoL-C30, H&N 35 questionnaires
65 pts: also objective measurements

- QoL data: low degree of disphagia compared to objective measures
- Both subjective and objective measurements of late disphagia correlated with **dose to PCM**, QoL points correlated with **DVH parameters in the glottis/supraglottic larynx**

Both xerostomia and disphagia reduced after introduction of IMRT

PHARYNX irradiation - QUANTEC

Table 3. Organs at risk and dose–volume relationship above which swallowing dysfunction increases significantly

		Dose–volume data						
Investigator/patients (*n*)	Critical organs	Mean dose (Gy)	Median dose (Gy)	V_{50}	V_{60}	V_{65}	Endpoint	Evaluation method
Eisbruch *et al.* (13),	Larynx	60		50%	—	—	Aspiration	VF
Feng *et al.* (14)/36 patients	PC	66		80%	70%	50%	Aspiration	
IMRT + chemotherapy	PC			85%	70%	60%	Stricture	
Caglar (19)/96 patients	Larynx	48*		21%			Aspiration and stricture	VF
IMRT + chemotherapy	IC	54		51%

3D-CRT	sphincter						QOL	FEES
RT alone								

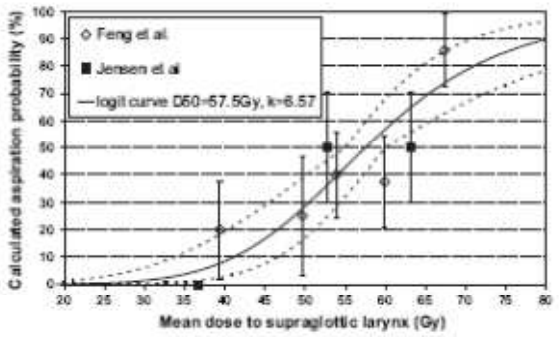

Fig. 1. Dose–effect relationship for dysphagia according to data from Feng *et al.* (14) and Jensen *et al.* (16). Solid line fit to combined data; dotted line fit to 68% confidence area for normal tissue complication probability-logit curve.

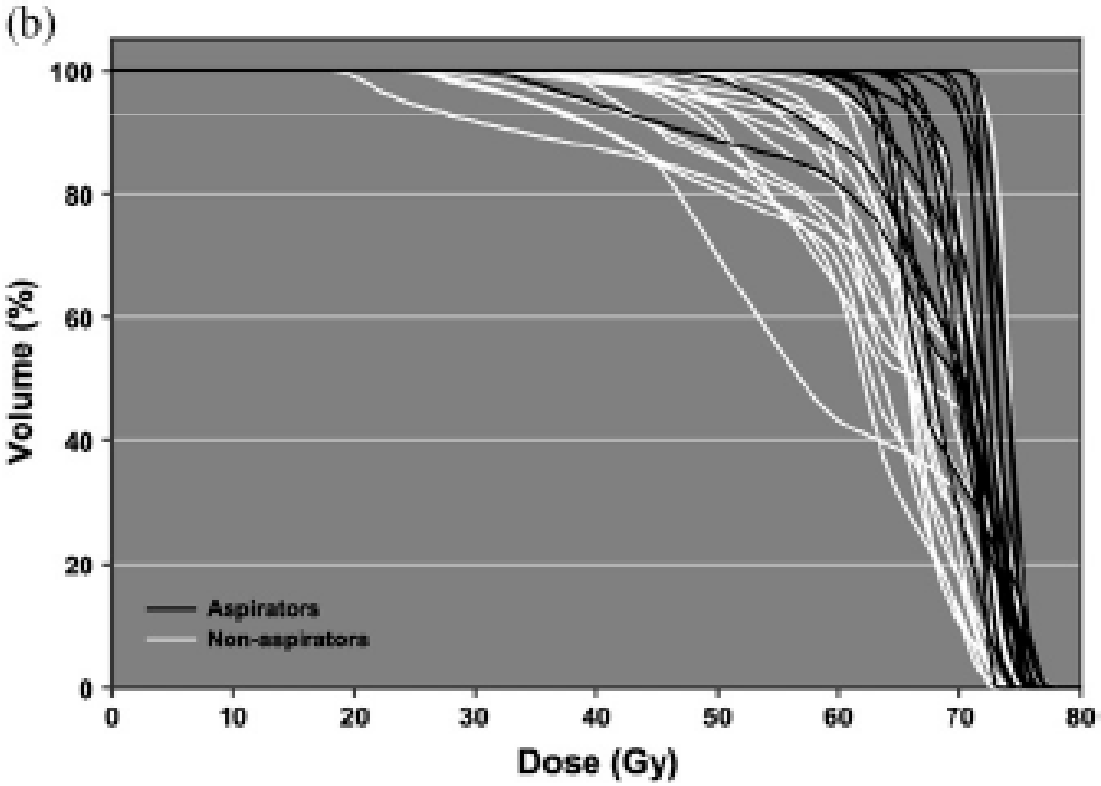
- **Data: Mean dose < 50 Gy < 20% incid.**
- Recommendations: **minimize volume of the constrictors >60 Gy**

  reducing volume receving > 50 Gy

SWALLOWING: **Pharingeal Constrinctors** and **Supraglottyx larynx**

IMRT of HN cancer aiming to reduce dysphagia: early dose–effect relationships for the swallowing structures

(Feng *et al*. IJROBP 2007)

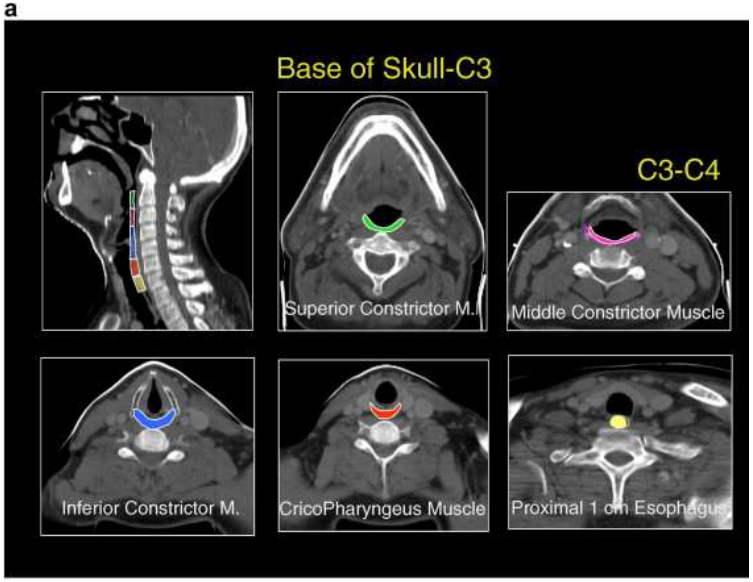


Superior PC most predictive

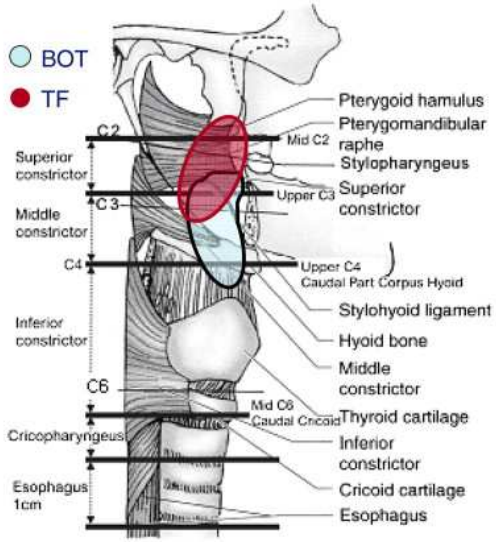
DVHs for the pharyngeal constrictor in patients with stricture (black) or without stricture (white).

SWALLOWING: dose to superior and middle constrictor muscles

a



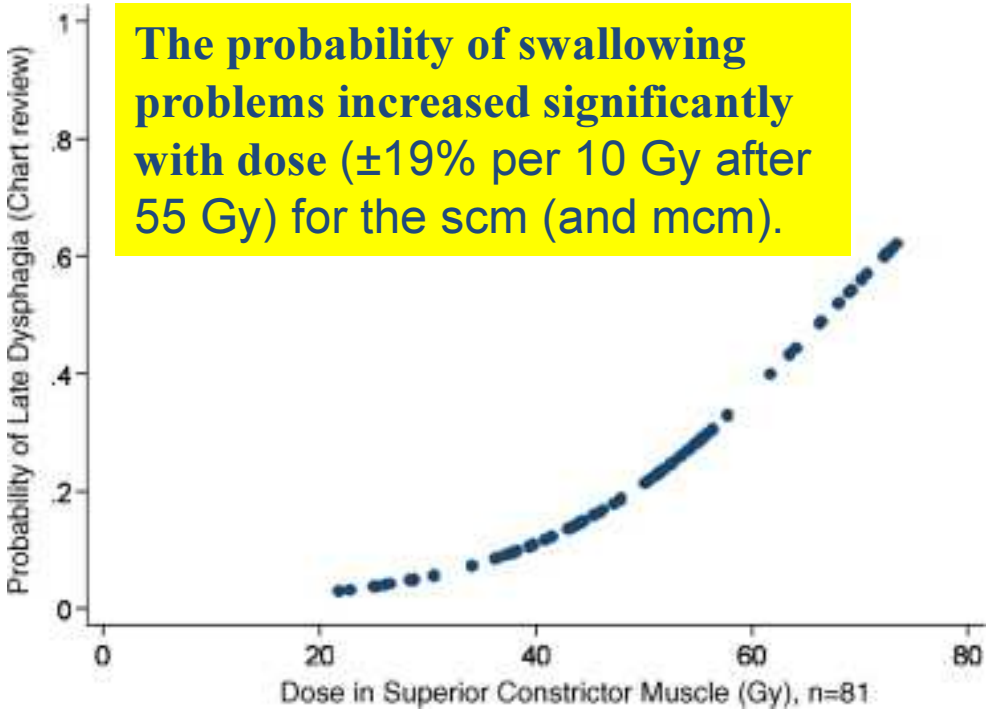
b



Dysphagia disorders in patients with cancer of the oropharynx are significantly affected by the radiation therapy dose to the superior and middle constrictor muscle: A dose-effect relationship

(Levendag, RO, 2007)

The probability of swallowing problems increased significantly with dose (±19% per 10 Gy after 55 Gy) for the scm (and mcm).

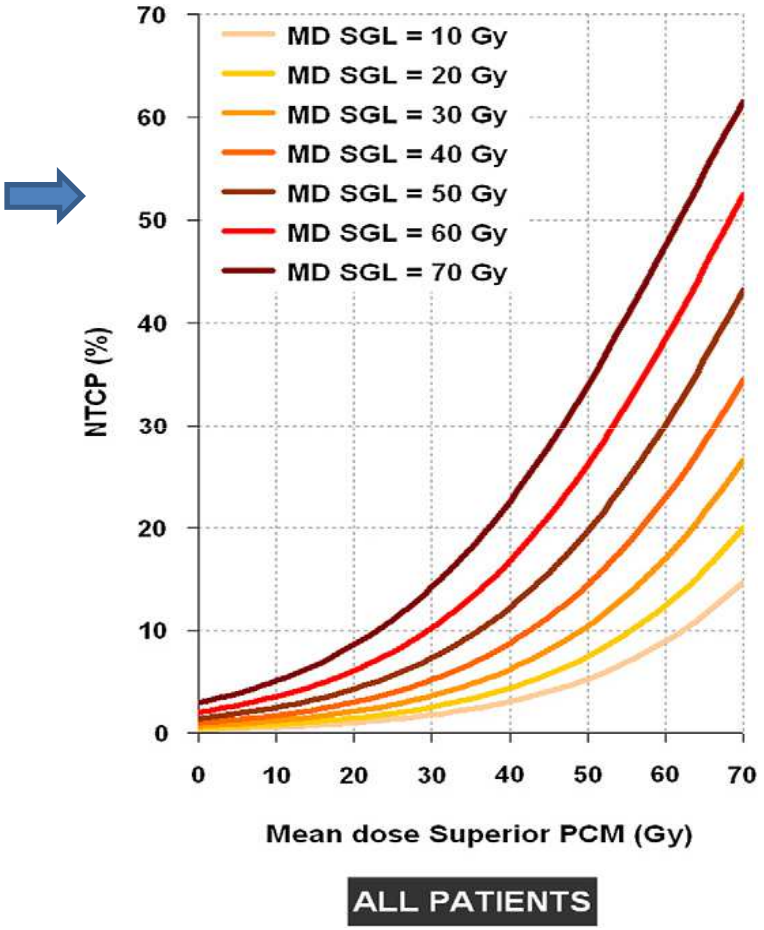


SWALLOWING: predictors

- Christianen *et al*, 2011, prospective study, 354 pts

- Toxicity related to mean dose to superior pharingeal constrictors and supraglottic larynx

- Age, previous symptoms, CHT
- **Oral mucosa irradiation** (Schwartz 2011, Sanguineti 2011)
- **PEG tube insertion** (Percutaneous endoscopic gastrostomic) (Caudell 2010, Sanguineti 2011)



NTCP curves for SWALM6 for each 10 Gy increase in dose to the supraglottic larynx.

SWALLOWING: oral mucosa irradiation/ risk of PEG (Sanguineti *et al*, 2011)

Cut off values:

V 9.5 Gy/week < 64 cm3
V10 Gy/week < 54 cm3

Multivariate analysis:
risk of PEG reduced when Oral Mucosa receives:
V 9.5 Gy/week < 64 cm3

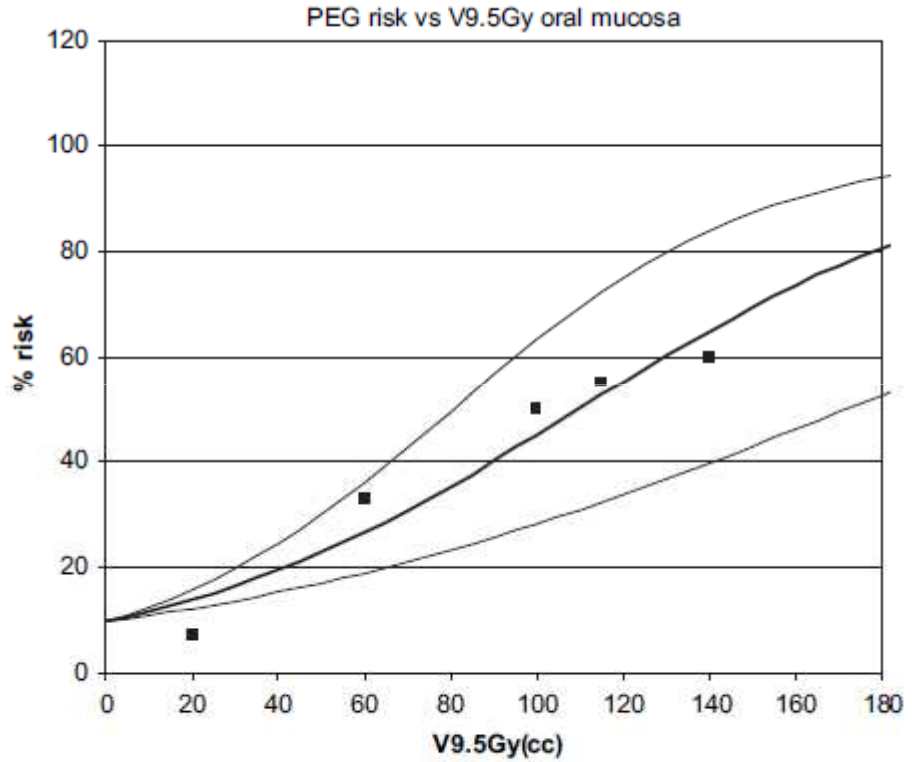


Fig. 3. Risk of percutaneous endoscopic gastrostomy (PEG) tube insertion vs. V9.5 Gy/week of oral mucosa is plotted with the 68% confidence intervals.

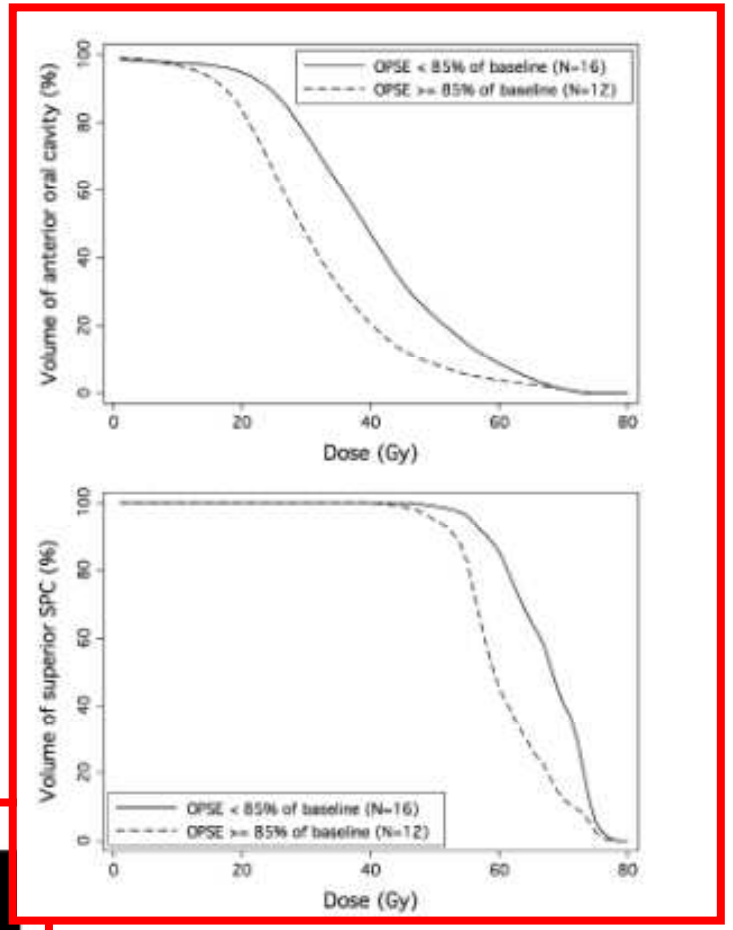
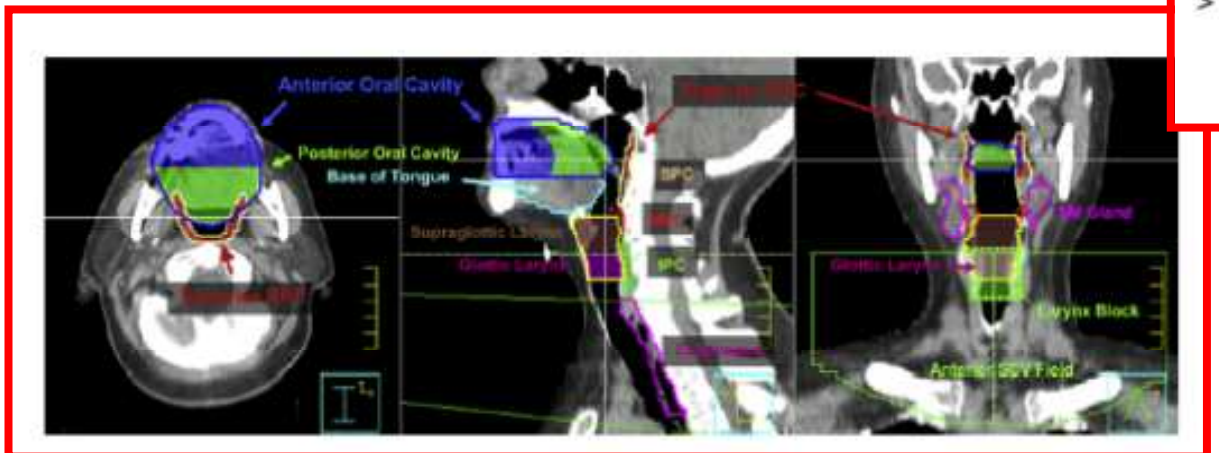
Confirming Oral Mucosa DVH related to late swallowing problems

- 31 IMRT pts, IV stage Oro cancer, no CHT (MDA)
- Prospective assessment of swallowing problems
- **Anterior and posterior oral mucosa DVHs as best predictors**
- Constrictors dose also correlated





Schwartz *et al*. 2011

Courtesy of C Fiorino

Summary: HN dose-volume relationships - Xerostomia

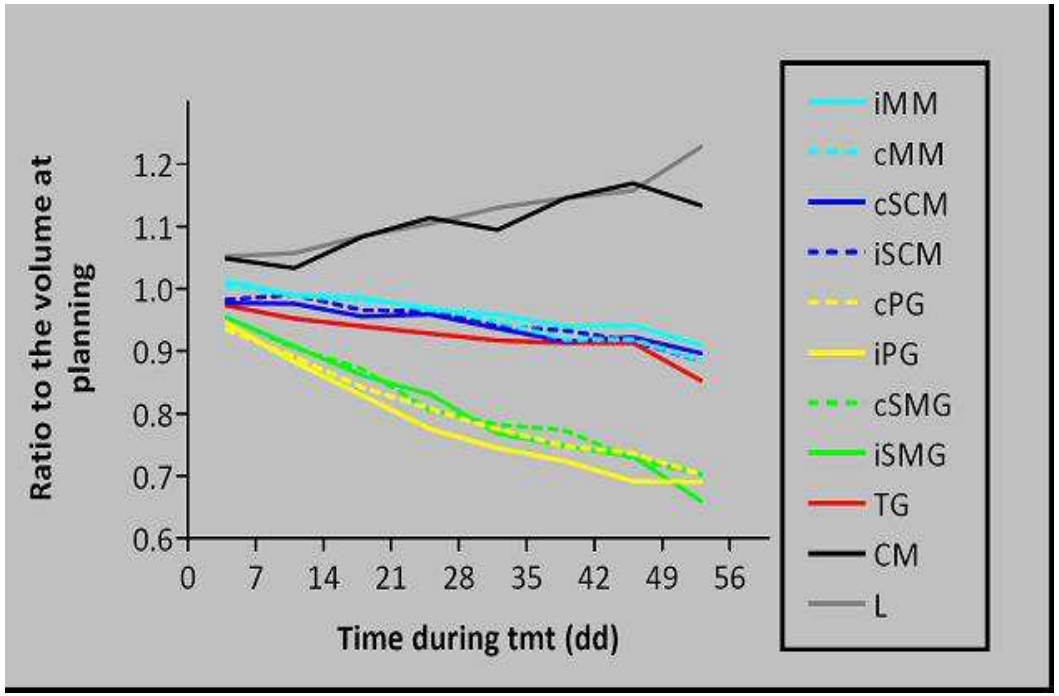
- Consensus : parotid as a parallel organ
- Mean dose, V20-40 best predictors
- Faster recovery of the damage with IMRT
- Different Mean dose vs xerostomia curves between 3DCRT and IMRT pts: spatial effects (?)
- Image-based assessment of early reactions (volumes, density, ….): high potential for better scoring and understanding radiation-induced parotid changes

Summary: HN dose-volume relationships – Disphagia, Larynx edema

- Increasing evidence of dose-volume effects for dysphagia (especially sup. constrictor, larynx)
- Dose-volume effect for Oral mucosa and constrictors in predicting PEG risk/swallowing problems
- Impact of CHT
- NTCP model available for laryngeal edema
- Conformal avoidance approach with IMRT may reduce toxicities (even without quantitative dose-volume relationship)

Volume changes during RT imaged by IGRT to assess normal tissue effects

- Volume variation of parotids and other organs during IMRT for HN cancer



PG: parotid glands
SMG: submandibular glands
TG: thyroid gland
CM: constrictor muscles
SCM:sternocleidomastoid muscles
MM: masticatory muscles
L: larynx

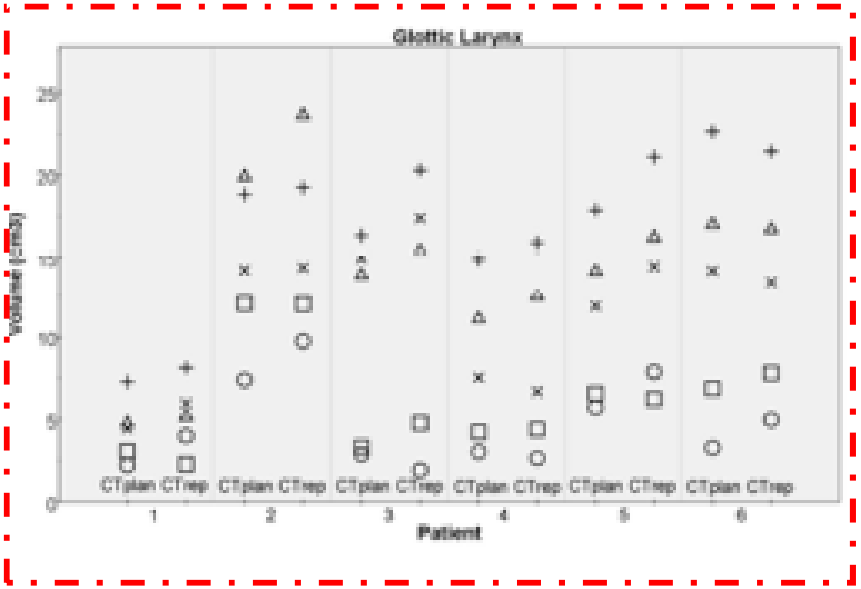
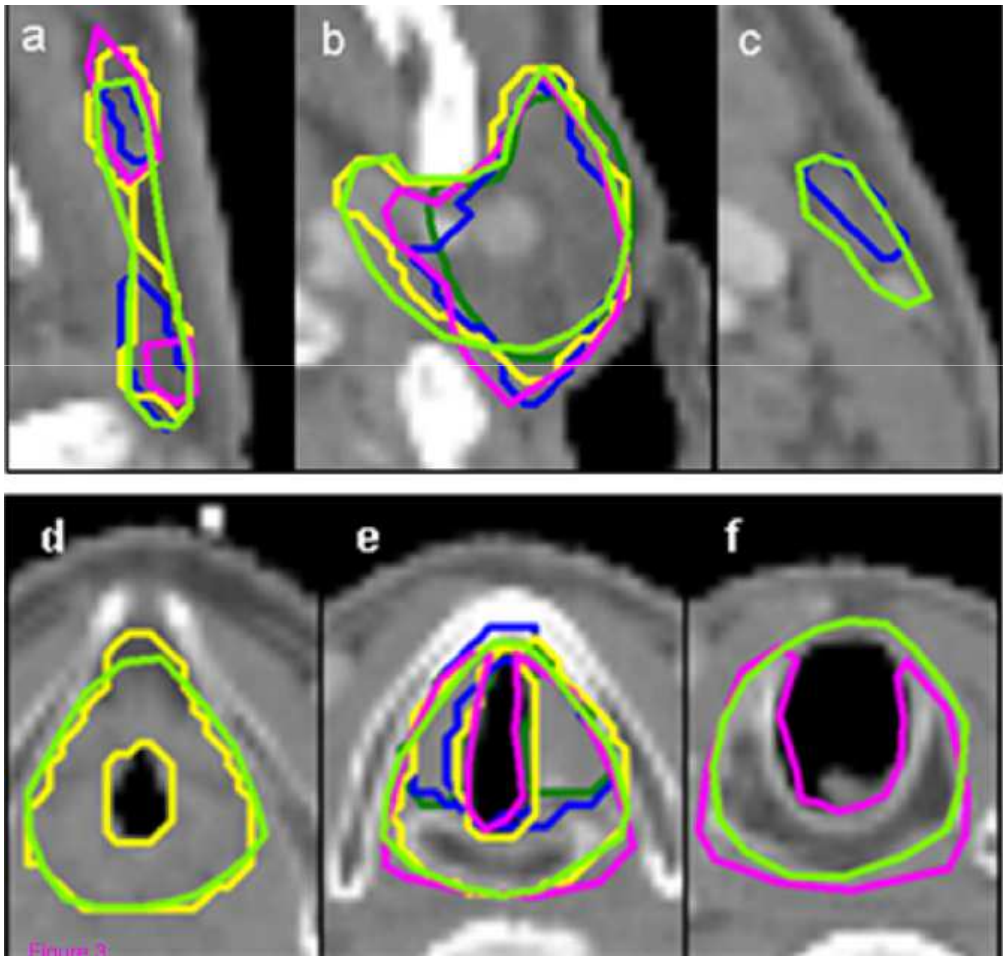
3D Variation in delineation of head and neck organs at risk

Radiation Oncology 2012, **7**:32 doi:10.1186/1748-717X-7-32

Brower et al

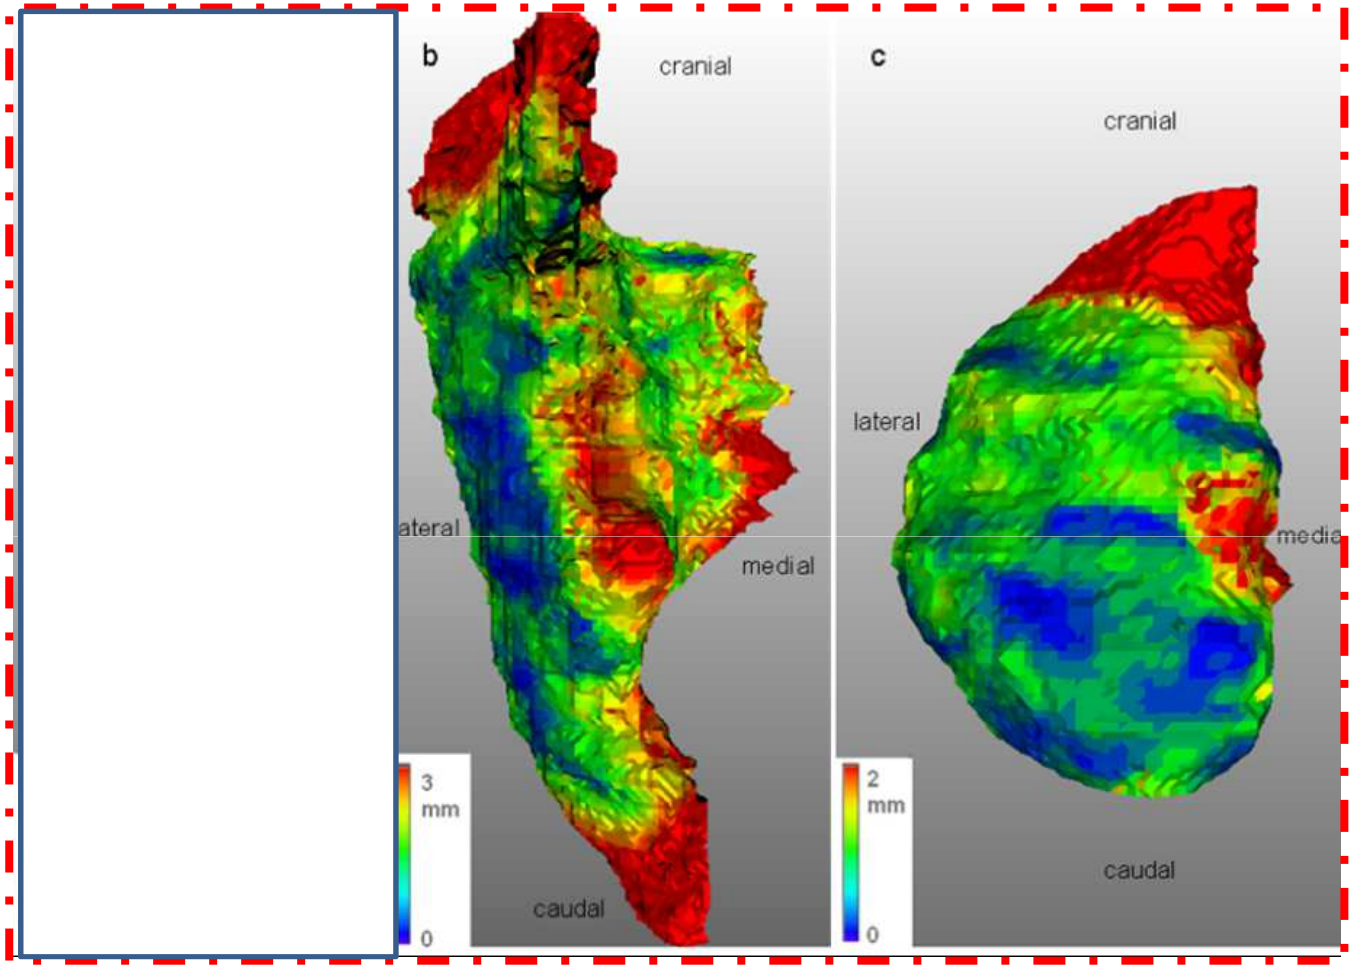
To study the magnitude and 3D localization of interobserver variability in the HN area





a) Larger interobserver variability for the glottix larynx

cranial, caudal and medial regions of the OAR showed larger interobserver variabilities



3D Standard Deviations for a patient

-Right parotid
-Right subman-dibular gland

- parotid glands: image resolution in cc direction
- submandibular gland: poor discrimination in contrast from adjacent tissues

Brower et al

Changes in anatomy over the course of treatment

- 10 H&N – oropharingeal ca pts, IMRT
- Three radiation oncologists delineating OARs, three contouring sessions one week apart
- Mean difference in total volume for each OAR was 1 cm3 for each OAR.
- Considerable spatial differences in contours, ipsilateral parotis and pharingeal constrictors showing most variability.
- **Despite substantial differences in OAR contours, optimization was barely affected with less than a 1 Gy difference in dose** (Feng *et al*, 2012)

Changes in anatomy over the course of treatment

- 10 H&N pts, IMRT
- CTVs and OARs delineated on CBCT at the10th, 15th, 20th, 25th treatment session and then compared with the planning CT
- A statistically significant increase of larynx volume at the 20th and 25th CBCT was observed
- The main benefit of replanning could be to preserve parotis, not to reevaluate the target

- **Check point at the 3rd week of radiotherapy in this pts cohort** (Cozzolino *et al*, 2014)

Changes in anatomy over the course of treatment

- 10 H&N – oropharingeal ca pts, IMRT
- CBCT prospectively acquired weekly, OARs dose/volume compared to the planned CT
- Evaluation of the use of KV CBCT for dose monitoring and examine if dosimetric impact of such changes on the parotid and OARs require replanning
- Patient weight loss (mean:7.5 kg) and parotid volume shrinkage was observed, but no significant excess dose to OAR
- **<u>No need for replanning in this patient cohort</u>** (Ho *et al* 2011)

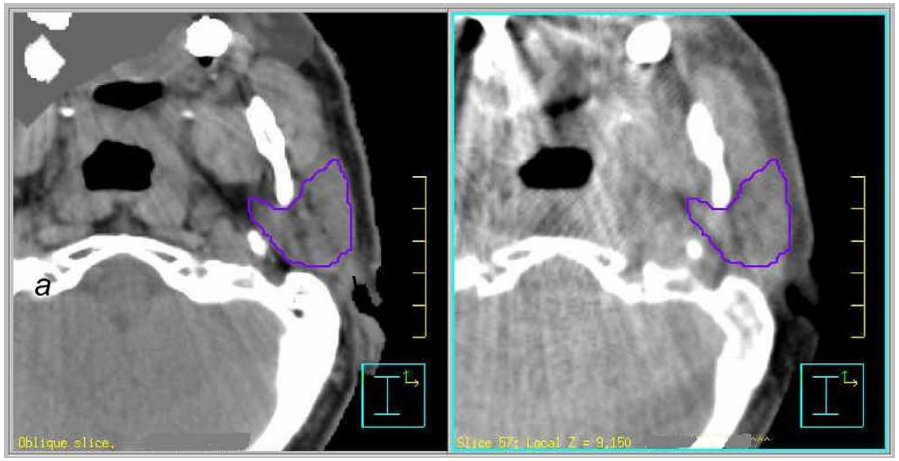


Fig. 1. Contouring parotid on cone beam computed tomography (CBCT) (b) using planning CT (a) as reference.

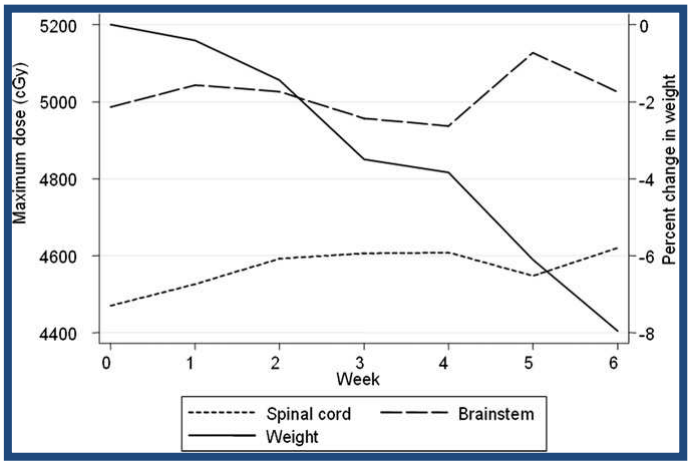
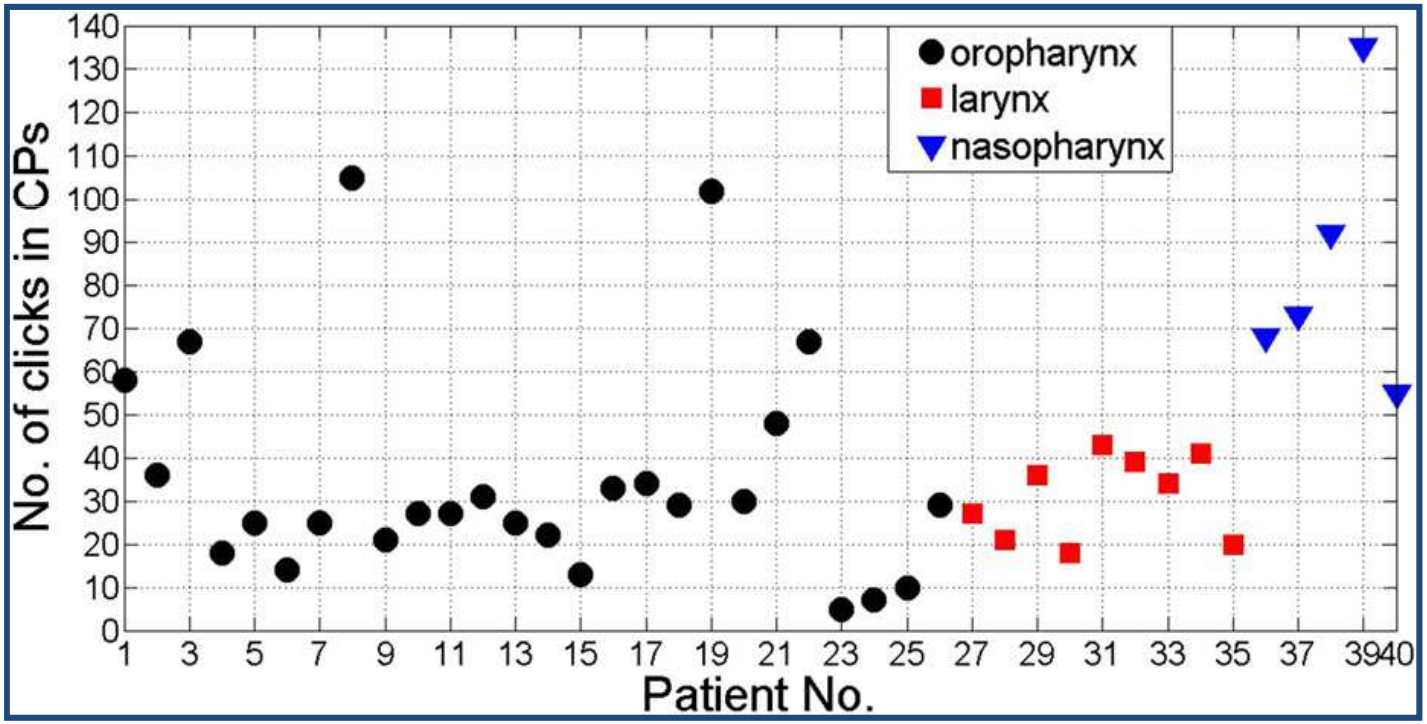


Automated VMAT planning

- Overlap volume histogram-driven automated planning optimization (Wu *et al*, 2012)
- Purpose: to prospectively determine whether it can be introduced in the clinical workflow
- 40 H&N SIB-IMRT consecutive pts, ; for each pt a fully automated plan (AP), was compared to the clinical plan (CP) used for the treatment.
- The study would show the non-inferiority of APs with respect to PTC coverage and secondary organ sparing (parotid, brachial plexus, esophagus, larynx, inner ear, oral mucosa).
- In APs, average doses to secondary organs were reduced by 1.16%, overall average PTV coverage was increased by 1.26%.

- According to the physician, APs were superior to CP in 27/40 cases
- **The dosimetric results of the APs were not inferior to routinely generated clinical plans.**



Distribution of the number of clicks of the “Start Optimization” button by dosimetrists in clinical planning. Average clicks in oropharynx, nasopharynx, and larynx planning is 35 (SD: 25.7), 84.6 (SD: 31.1), and 31 (SD: 9.7).

Clinical Application of IMRT

Most important indications and treatment philosophy

1. **Head and Neck Cancer**
   CNS

   Paranasal Sinus Tumors / Integrated Boost
   (Better Tumor coverage and shortening of overall treatment time)

   NPC and other ENT Tumors
   (Parotid sparing when possible, better tumor coverage for NPC)

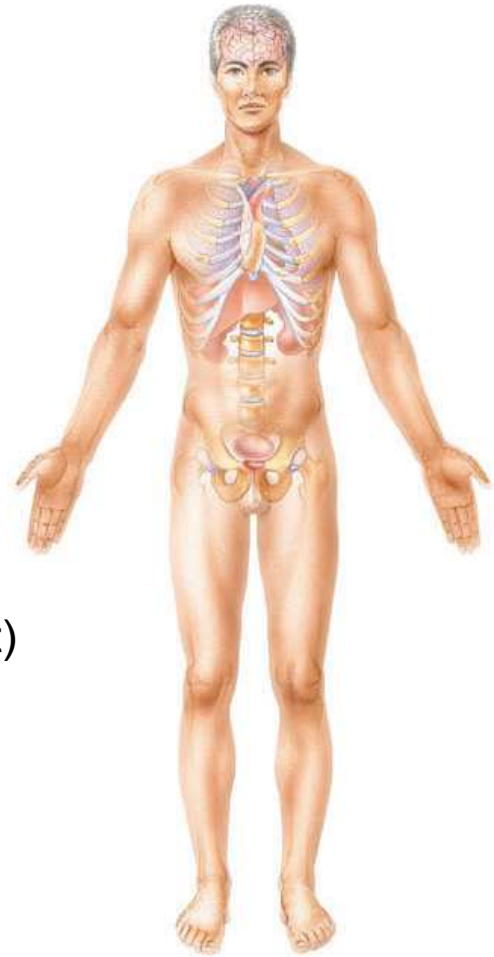
2. **Prostate / Integrated boost**
   (Potentially hypofractionation)

3. **Gastric cancer**
   (Better kidney sparing while treating the whole of the target)

4. **Breast Cancer**

5. **Lung Cancer**

6. **Metastases**



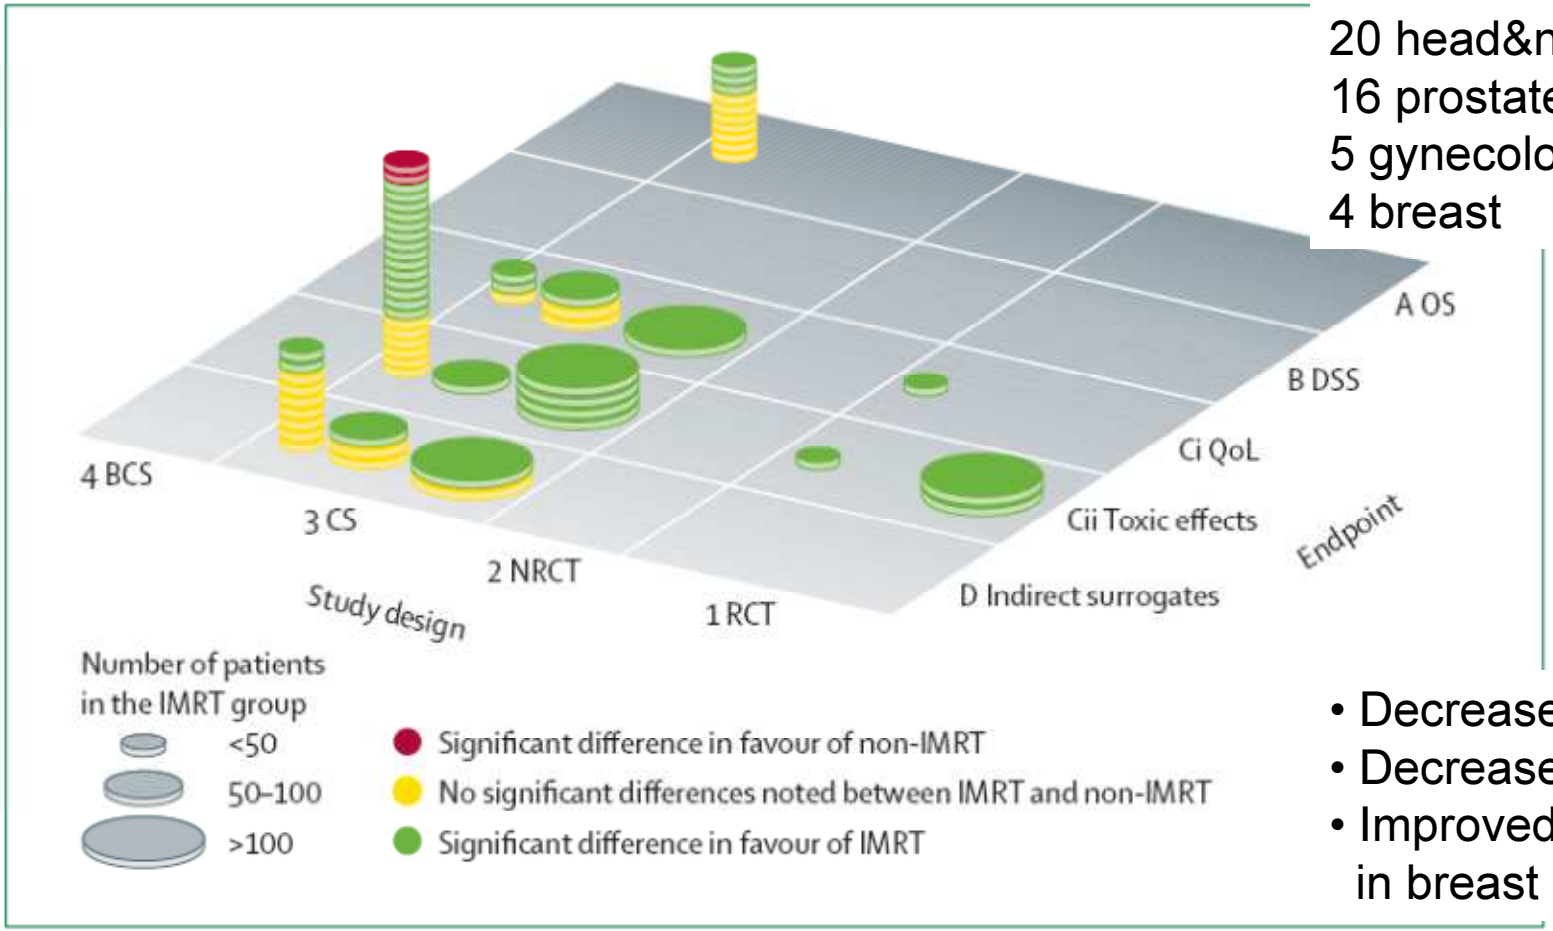
Evidence behind use of intensity-modulated radiotherapy: a systematic review of comparative clinical studies

Liv Veldeman, Indira Madani, Frank Hulstaert, Gert De Meerleer, Marc Mareel, Wilfried De Neve

Lancet Oncol 2008; 9: 367–375

56 studies/reports

20 head&neck	3 lung
16 prostate	5 GI
5 gynecological	3 CNS
4 breast	



- Decreased xerostomia
- Decreased rectal toxicity
- Improved cosmesis in breast cancer

Figure 3: **Evaluation tool for relevance of clinical statements reported in 56 studies of IMRT**
BCS=best case series. CS=case series. NRCT=non-randomised controlled trial. RCT=randomised controlled trial. OS=overall survival. DSS=disease-specific survival. QoL=quality of life.

IMRT clinical outcome

Factors influencing the rational use of IMRT for head-and-neck cancer

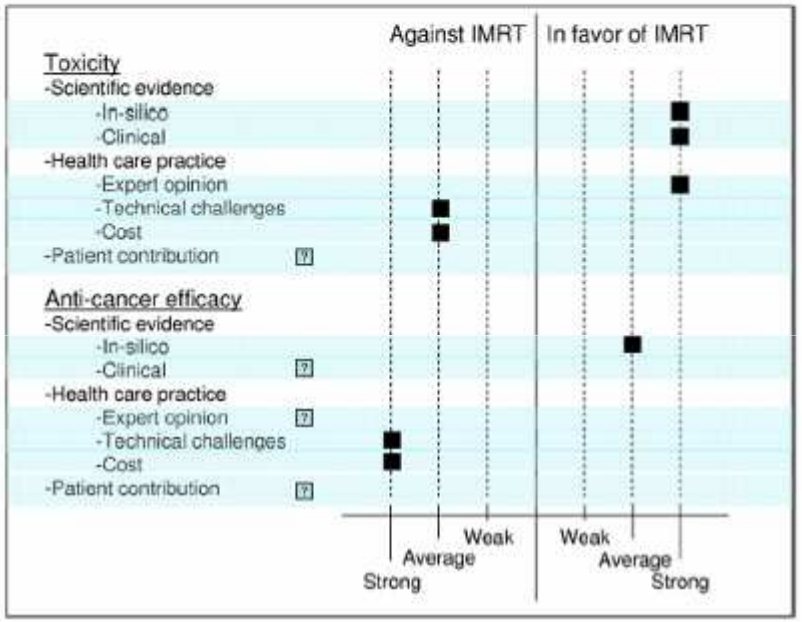


Figure 1 Factors in favor or against IMRT are represented by a rectangle on the right or on the left of the vertical solid line, respectively. A question mark inside a rectangle indicates too much uncertainty for using the factor in the graph.

Factors influencing the rational use of IMRT for whole breast irradiation

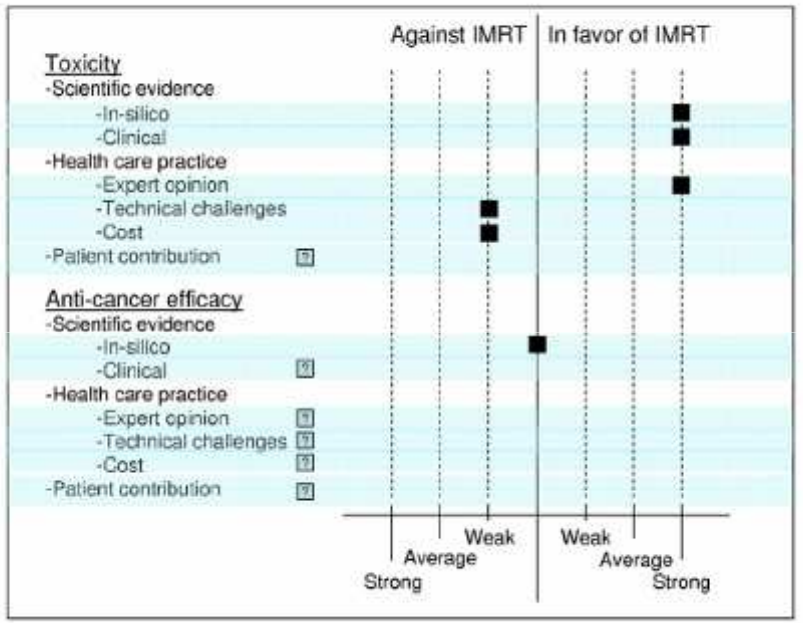

Figure 2 Factors in favor or against IMRT are represented by a rectangle on the right or on the left of the vertical solid line, respectively. A question mark inside a rectangle indicates too much uncertainty for using the factor in the graph.

De Neve et al. Sem Rad Onc, 2012

Canadian H&N IMRT-Review and Consensus

"The case for IMRT in head and neck cancer can be broadly outlined as follows:
1) The data identified in this review, as well as the earlier historical data described in the Introduction, support the contention that IMRT is, at worst, not inferior to two-dimensional CRT with respect to disease control.
2) The data identified in this review, as well as the earlier historical data, support the contention that with IMRT, there are clinically relevant and statistically significant differences in adverse event rates and quality of life compared with two-dimensional CRT."

O'Sullivan et al., Clin Oncol, 2012

Cost Effectiveness of IMRT

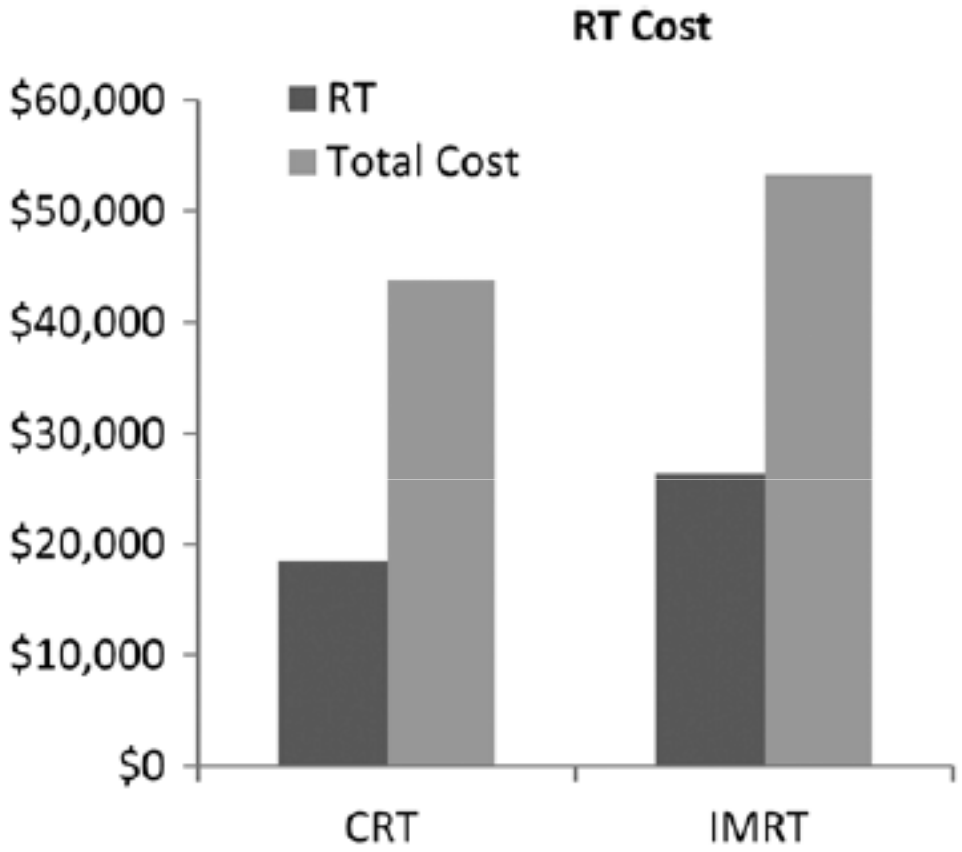

FIGURE 1. Radiation cost as a proportion of total cost from diagnosis through 1 year of follow-up.

-Exaggerated billing

-Cost F/u only recorded until 1 year after RT, therefore long term benefits not accounted for properly

Clinical Target Volumes in Conformal and Intensity Modulated Radiation Therapy
A Clinical Guide to Cancer Treatment

Table 3.10. Suggested guidelines for the treatment of patients with head and neck SCC

Location of primary tumor	Appropriate node levels to be treated	
	Stage N0–N1 (AJCC 1997)	Stage N2b (AJCC 1997)
Oral cavity	I, II[a], and III (+IV for anterior tongue tumors)	I, II, III, IV and V[c]
Oropharynx	II, III, and IV (+ retropharyngeal nodes for posterior pharyngeal wall tumors)	I, II, III, IV, V and retropharyngeal nodes
Hypopharynx	II[a], III, and IV (+ VI for esophageal extension)	I, II, III, IV, V and retropharyngeal nodes (+ VI for esophageal extension)
Larynx[b]	II[a], III, and IV (+ VI for transglottic and subglottic tumors)	(I), II, III, IV and V (+ VI for transglottic and subglottic tumors)
Nasopharynx	II, III, IV, V and retropharyngeal nodes	II, III, IV, V and retropharyngeal nodes

[a] Nodes in level IIb could be omitted for N0 patients
[b] T1 glottic cancer excluded
[c] May be omitted if only levels I–III are involved

V. Grégoire · P. Scalliet · K. K. Ang (Eds.)
Clinical Target Volumes in Conformal and Intensity Modulated Radiation Therapy
A Clinical Guide to Cancer Treatment

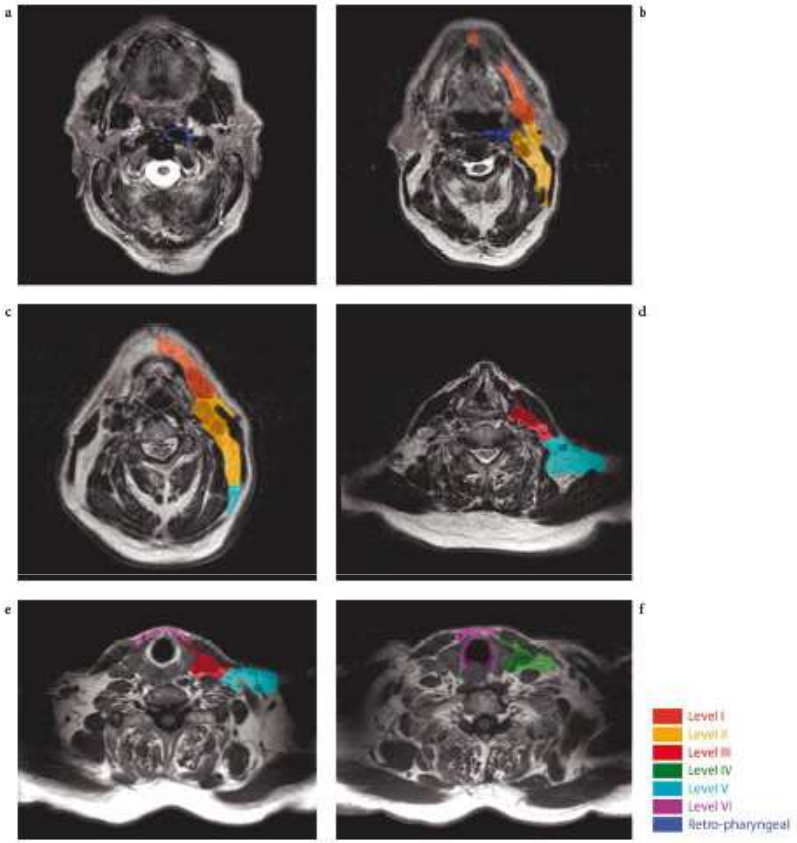

Fig. 3.3. MRI of the same patient with a T1N0M0 glottic SCC (see tumor in *panel d*). The examination was performed on a Gyroscan NT 1.5 T Philips Medical Systems (Eindhoven, the Netherlands) on an axial plane with a slice thickness of 4 mm, a gap of 2 mm, and a field of view of 240 mm. T2-weighted images (TR 7976 ms and TE 90 ms) are displayed in *panels a–d*. *Panels e and f* represent T1-weighted images (TR 500 and TE 12 ms). Sections were taken at the level of the bottom edge of C1 (*panel a*), the upper edge of C3 (*panel b*), mid C4 (*panel c*), the bottom edge of C6 (*panel d*), the bottom edge of C7 (*panel e*), and mid D1 (*panel f*). Neck node levels were drawn on each slice using the radiological boundaries detailed in Table 3.11. The slight difference in the shape of the various levels between Figs. 3.2 and 3.3 is explained by a difference in the positioning of the patient, leading to a slight difference in slice levels. Each node level corresponds to the CTV, and thus does not include a security margin for organ motion or set-up inaccuracy

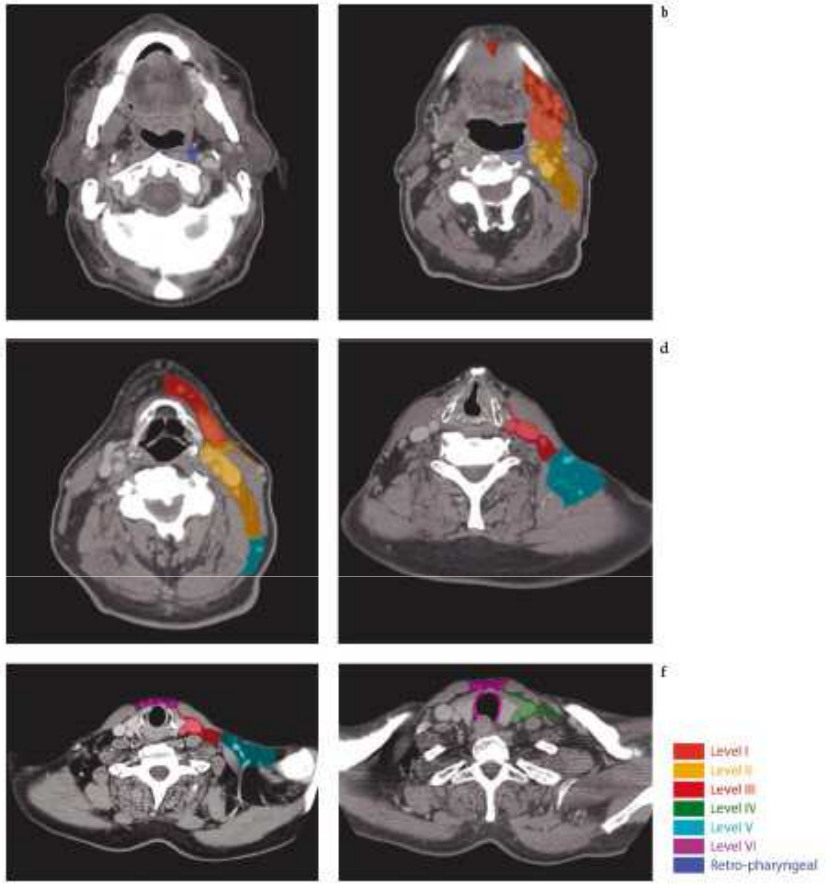

Fig. 3.2. CT imaging of a patient with a T1N0M0 glottic SCC (see tumor in *panel d*). The examination was performed on a dual-detector spiral CT (Elscint Twin, Haifa, Israel) using a slice thickness of 2.7 mm, an interval reconstruction of 2 mm and a pitch of 0.7. Contrast medium was injected intravenously at a rate of 2 ml/s with a total amount of 100 ml. Sections were taken at the level of the bottom edge of C1 (*panel a*), the upper edge of C3 (*panel b*), mid C4 (*panel c*), the bottom edge of C6 (*panel d*), the bottom edge of C7 (*panel e*), and mid D1 (*panel f*). Neck node levels were drawn on each CT slice using the radiological boundaries detailed in Table 3.11. Each node level corresponds to the CTV, and thus does not include a security margin for organ motion or set-up inaccuracy

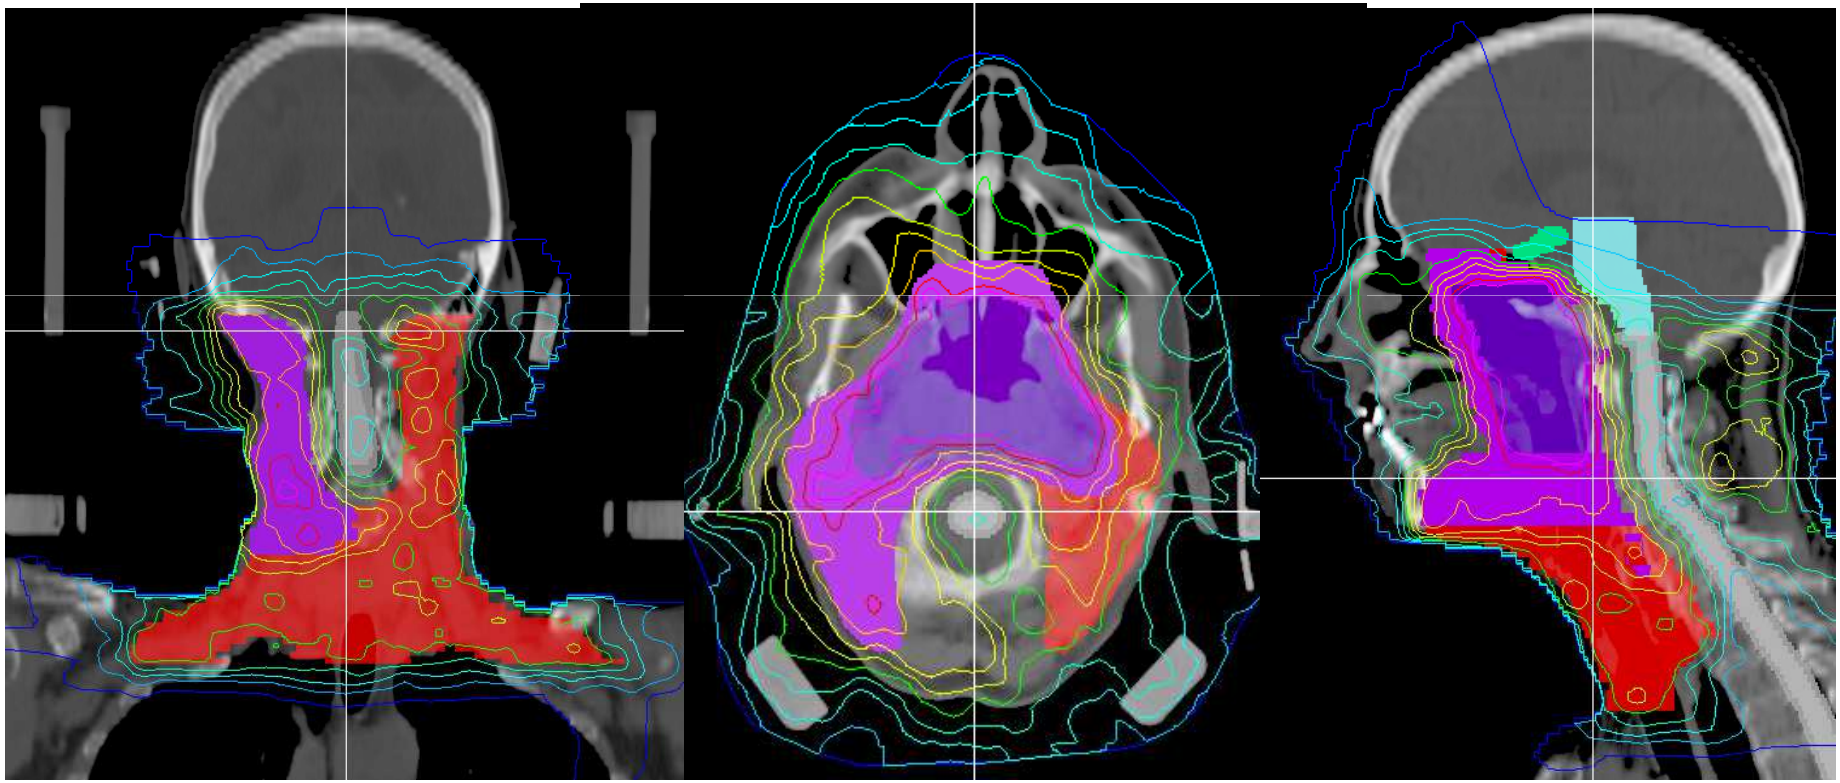
Clinical Target Volumes in Conformal and Intensity Modulated Radiation Therapy

A Clinical Guide to Cancer Treatment

Nasopharynx
Integrated Boost



Principles of using Integrated Boost

1. If working with several dose levels, try not to move too far away from single doses with which there is clinical experience (e.g. 1.6 to 2.5 Gy)

2. Keep the high-total-dose / high-single-dose volume small and away from (especially serial) critical structures

3. Start with IMRT as early as possible in the course of a patient‘s treatment to keep the single dose spread as low as possible

INTENSITY-MODULATED RADIATION THERAPY FOR HEAD-AND-NECK CANCER: THE UCSF EXPERIENCE FOCUSING ON TARGET VOLUME DELINEATION

NANCY LEE, M.D.,* PING XIA, PH.D.,* NANCY J. FISCHBEIN, M.D.,† PAM AKAZAWA, C.M.D.,* CLAYTON AKAZAWA, C.M.D.,* AND JEANNE M. QUIVEY, M.D., F.A.C.R.*

Departments of *Radiation Oncology and †Radiology, University of California-San Francisco, San Francisco, CA

Int. J. Radiation Oncology Biol. Phys., Vol. 57, No. 1, pp. 49–60, 2003

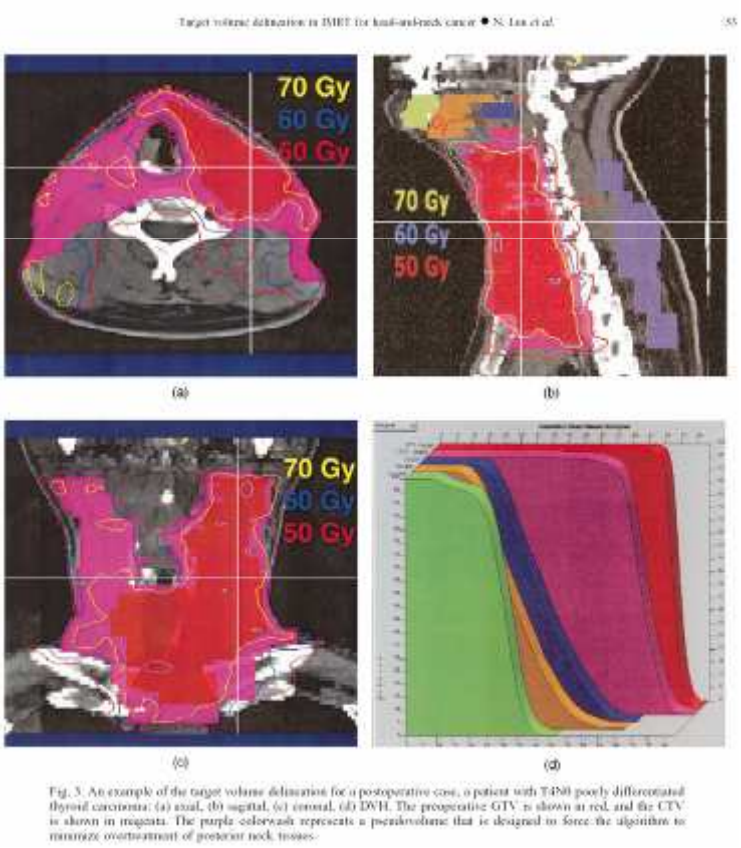


Fig. 3. An example of the target volume delineation for a postoperative case, a patient with T4N0 poorly differentiated thyroid carcinoma: (a) axial, (b) sagittal, (c) coronal, (d) DVH. The preoperative GTV is shown in red, and the CTV is shown in magenta. The purple colorwash represents a pseudovolume that is designed to force the algorithm to minimize overtreatment of posterior neck tissues.

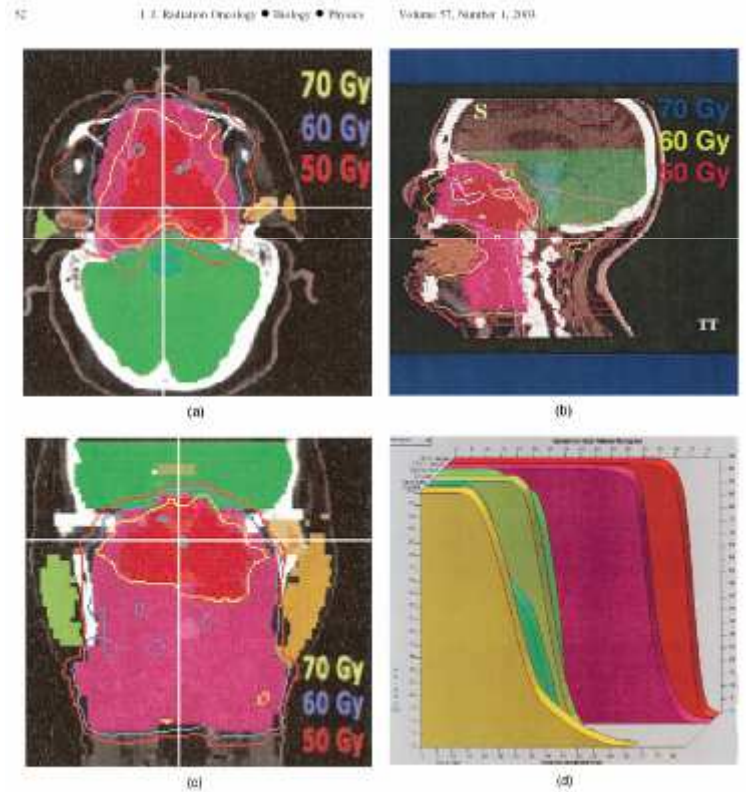

Fig. 2. An example of a target volume delineation for a definitive case, a patient with T3N0 nasopharyngeal carcinoma: (a) axial, (b) sagittal, (c) coronal, (d) DVH. The GTV is shown in red, and the CTV is shown in magenta.

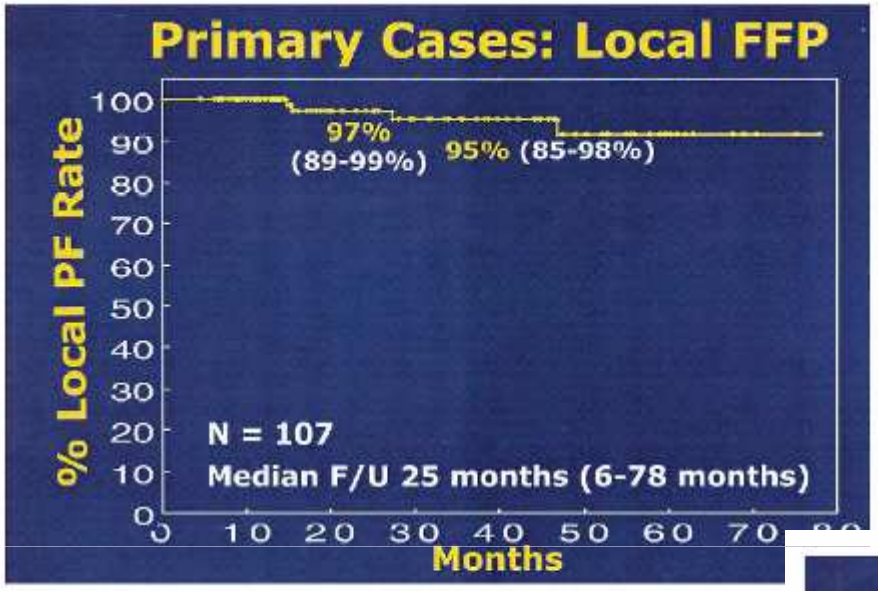

Fig. 4. Kaplan-Meier estimates of local freedom from progression rates for the definiti

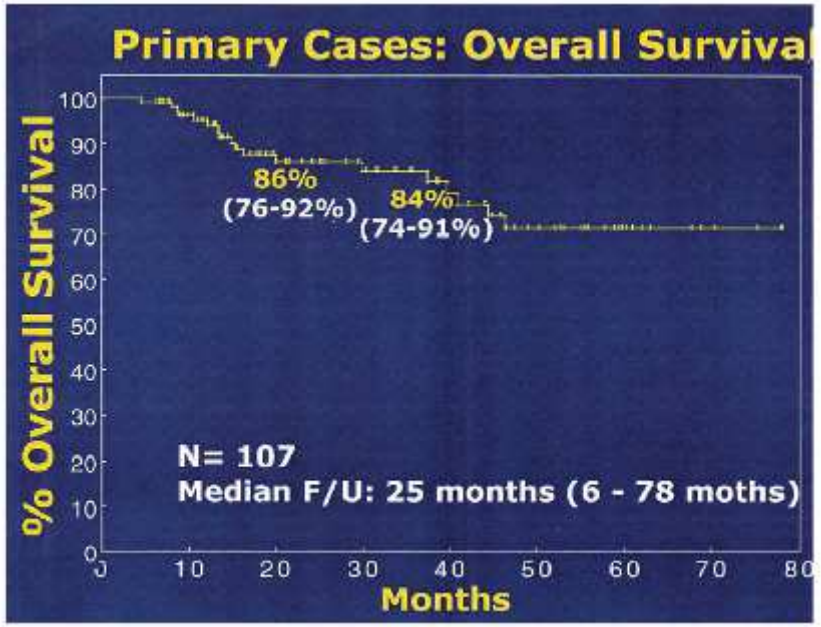

Fig. 5. Kaplan-Meier estimates of overall survival rates for the definitive cases.

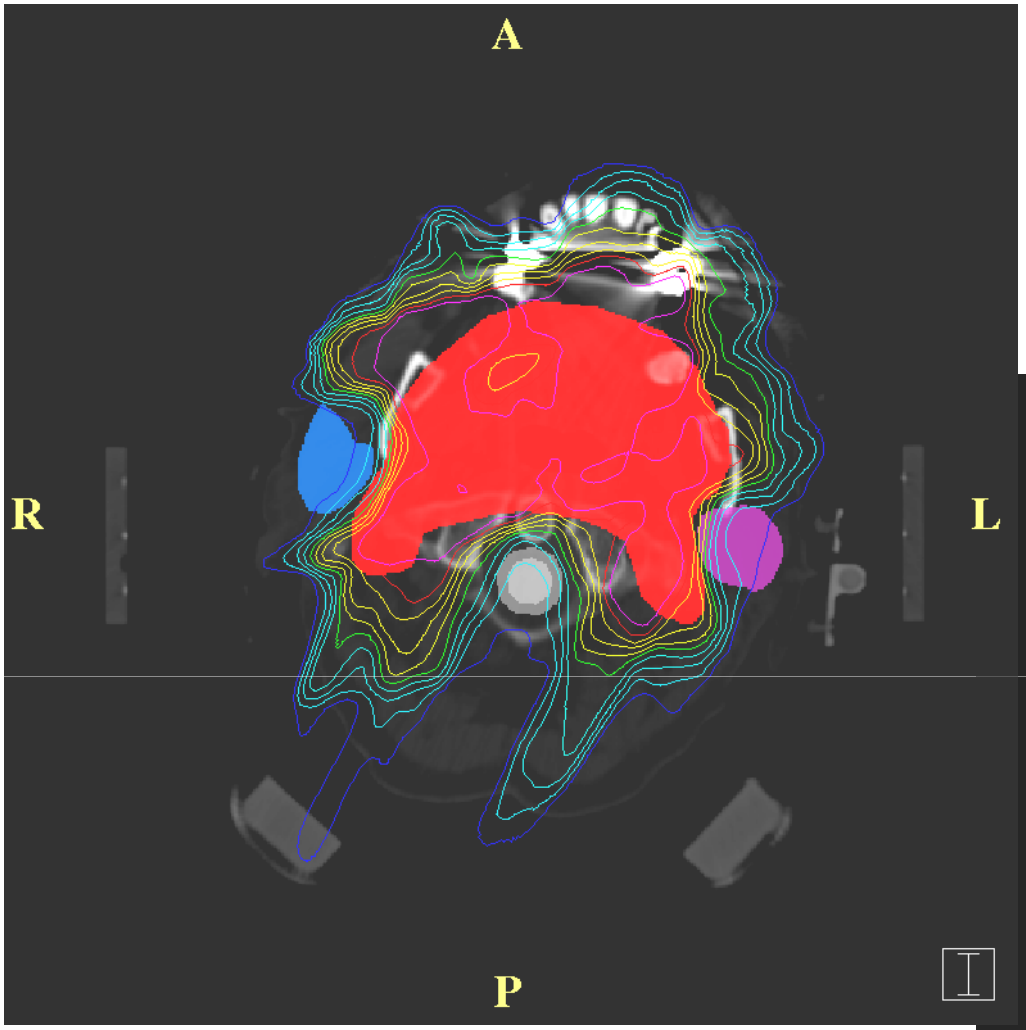
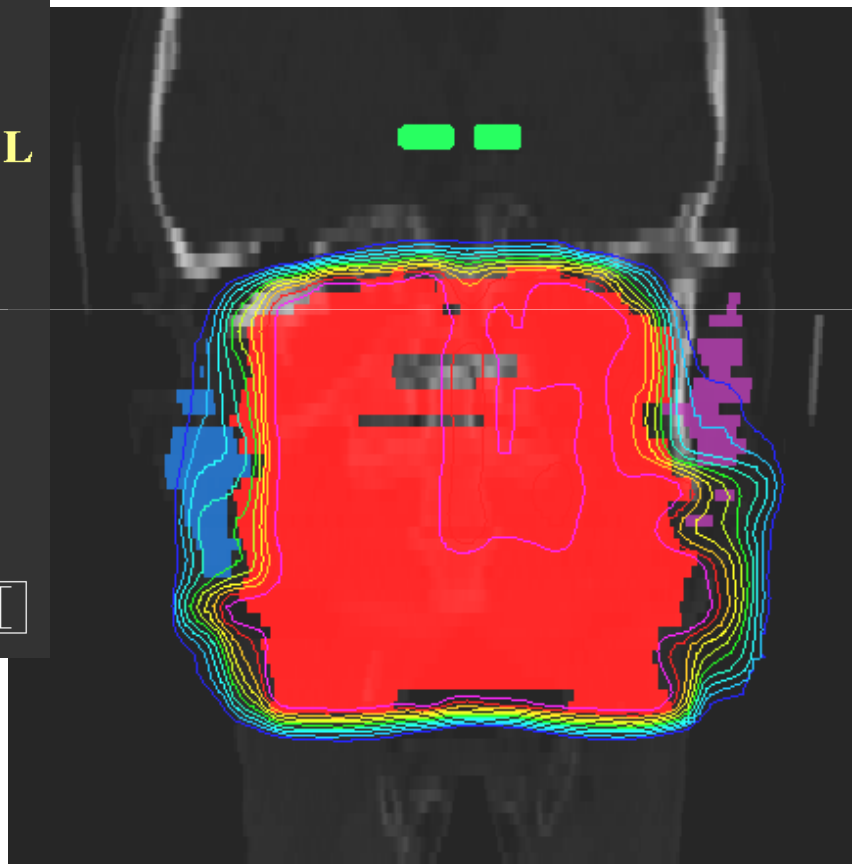
Oropharnynx (Tongue) T3N0 Bilateral Parotid Sparing





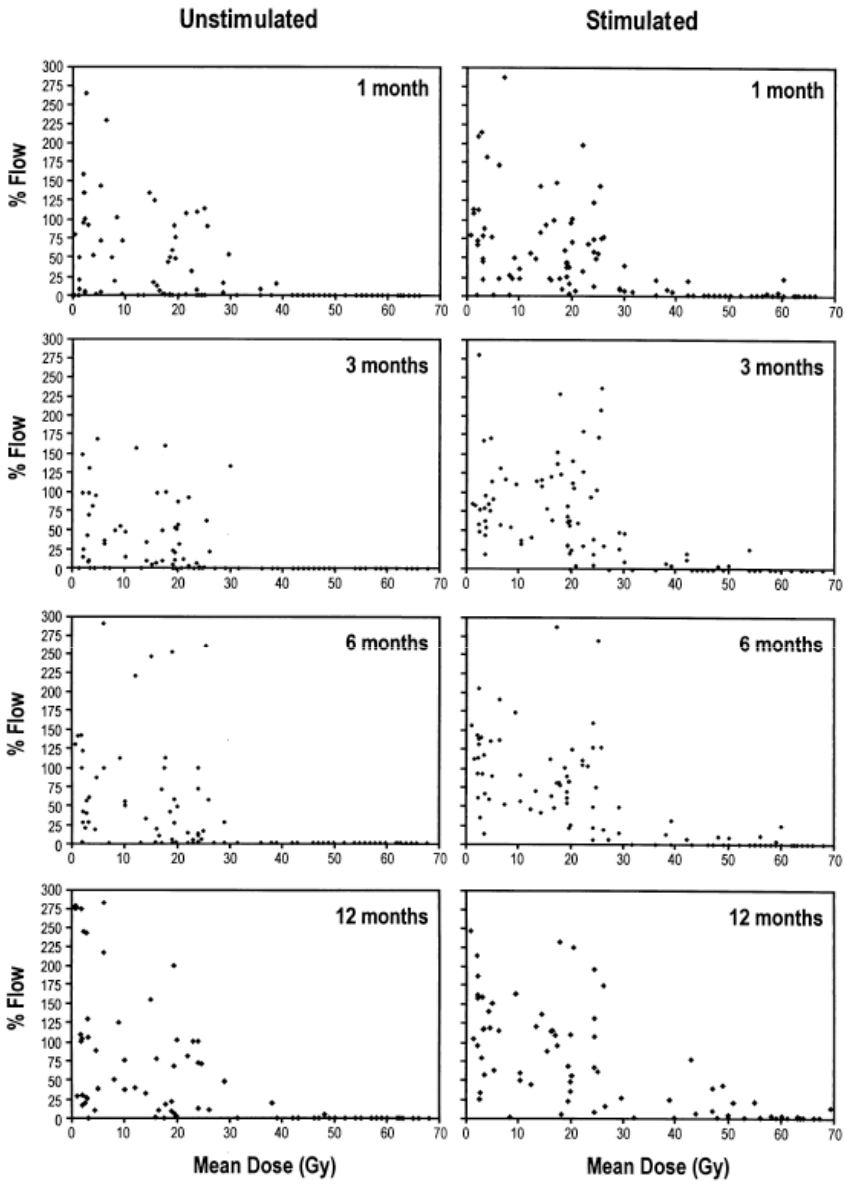


Fig. 2. Salivary flow rates, unstimulated and stimulated, vs. mean parotid gland dose at various time points after the completion of RT. The flows are expressed as the percentage of the pre-RT flow rates for each gland.

Parotid Sparing

–

Clinical Results

Eisbruch et al.,
IJROBP, 1999

-> Aim for a median parotid dose of <26 Gy

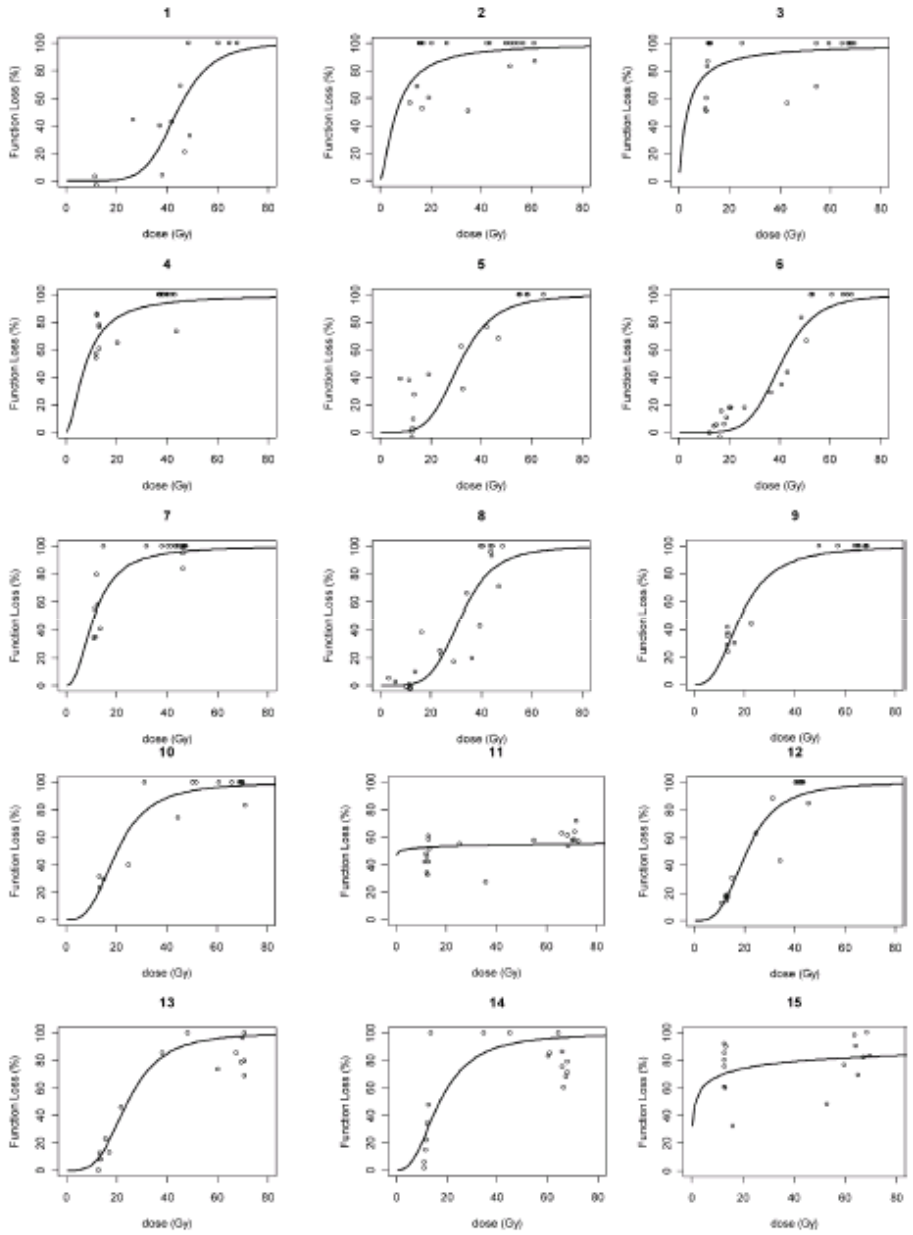

Fig. 5. The figure consists of the dose (Gy: *X*-axis) versus loss of function (dSEF: *Y*-axis) graphs for each of the 15 patients separately.

Parotid Sparing
–
Clinical Results

Bussels et al.,
R&O, 2004

-> Radiosensitivity of Parotid might be individual

->Parotid Tissue that is exposed to a dose that is lower than an individual threshold seems to remain functional

Parotid Tolerance -> The (almost) definitive data….

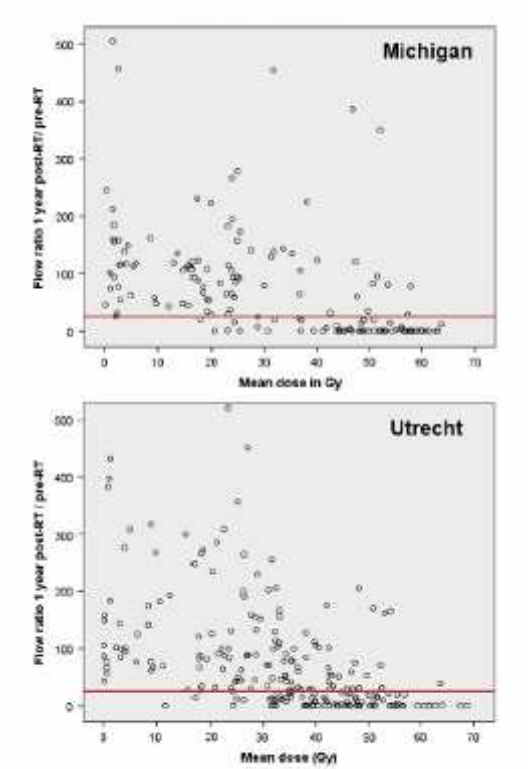

Fig. 1. Parotid flow ratio at 1 year after radiotherapy (RT) as a function of the mean parotid gland dose for Michigan (157 glands) and Utrecht (227 glands). The horizontal line indicates the complication threshold according to Radiation Therapy Oncology Group/European Organization for Research and Treatment of Cancer Grade 4 xerostomia (flow ratio <25% of pretreatment).

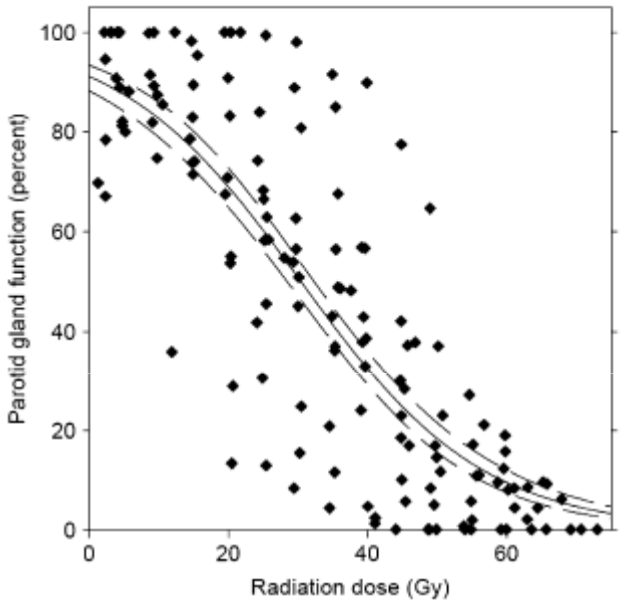

Fig. 4. Population-based dose vs. local function response (salivary function at rest) from imaging study by Buus *et al.* (2). Local functional decline in metabolic clearance of parotid salivary glands vs. local dose, according to voxel-by-voxel estimated time-activity curves of intravenously injected C11-methionine. Data points from 12 patients shown, along with best-fit curve and 95% confidence intervals of curve fit. Individual gland curves reported by Buus *et al.* (2) deviated significantly from this population average curve (reproduced from Buus *et al.* [2], used with permission.) This population curve demonstrated functional decline in salivary function even at low doses.

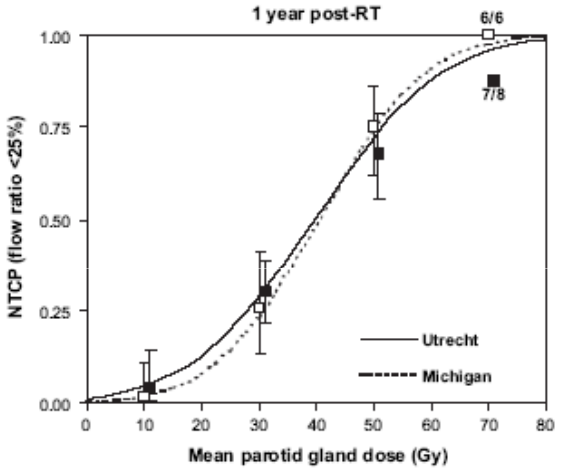

Fig. 2. Normal tissue complication probability (NTCP) curves as a function of the mean parotid gland dose for Michigan (dashed line) and Utrecht (solid line). Clinical NTCP values (using mean dose bins of 20 Gy) are shown for Michigan (open squares) and Utrecht (black squares), including 95% confidence intervals. RT = radiotherapy.

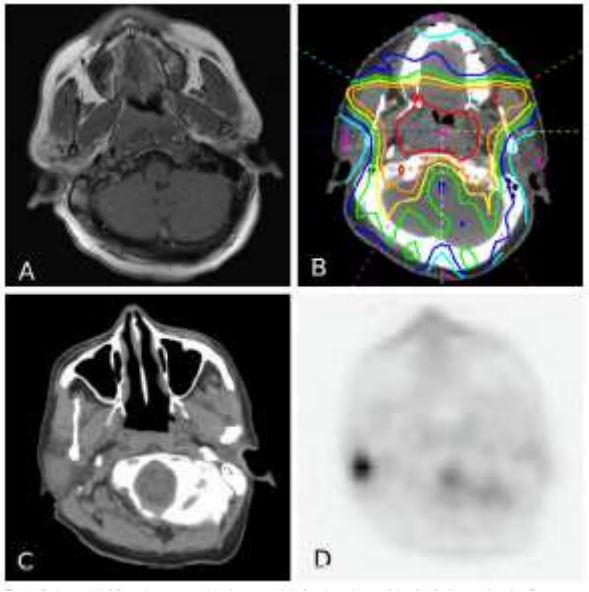
Recurrences after conformal parotid-sparing radiotherapy for head and neck cancer

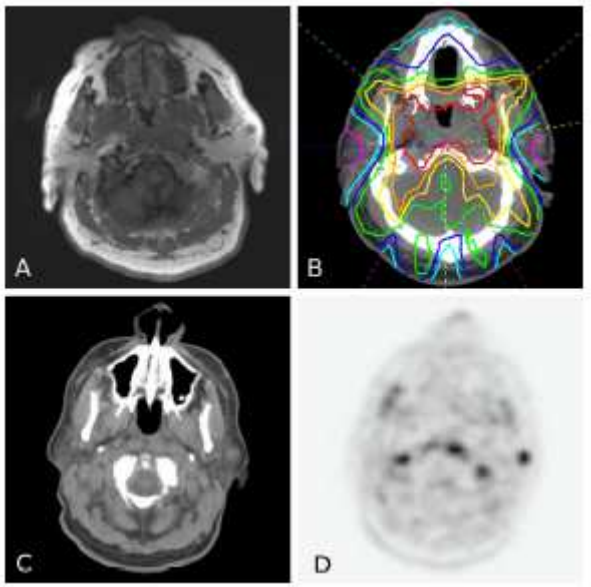
Barbara Bussels[a,*], Annelies Maes[b], Robert Hermans[c], Sandra Nuyts[a], Caroline Weltens[a], Walter Van den Bogaert[a]

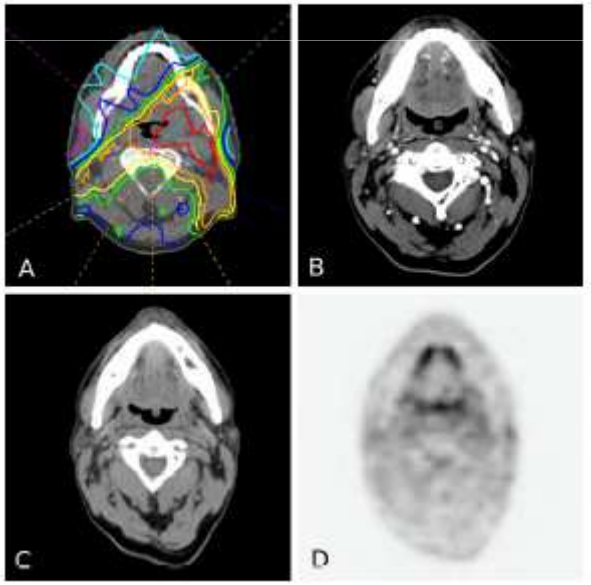
>95% in-field relapse

➢Parotid sparing with correct Patient selection does not seem to increase marginal misses

➢....is it?







„Our experience with the 2
NPC patients suggests that the presence of multilevel nodal disease and periparotid nodules on pretreatment imaging should raise the index of suspicion for subclinical disease, even if the nodules are not hypermetabolic on PET and do not meet radiographic or clinical criteria for possible gross disease. Additional evaluation such as FNA or CT-guided biopsy might be warranted in such situations before proceeding with definitive IMRT.“

Cannon, IJROBP, 2007

It usually is, but you gotta watch out!

Chen et al., IJROBP, 2011

90 Pts
11 In-Field Relapses
6 Marginal Misses

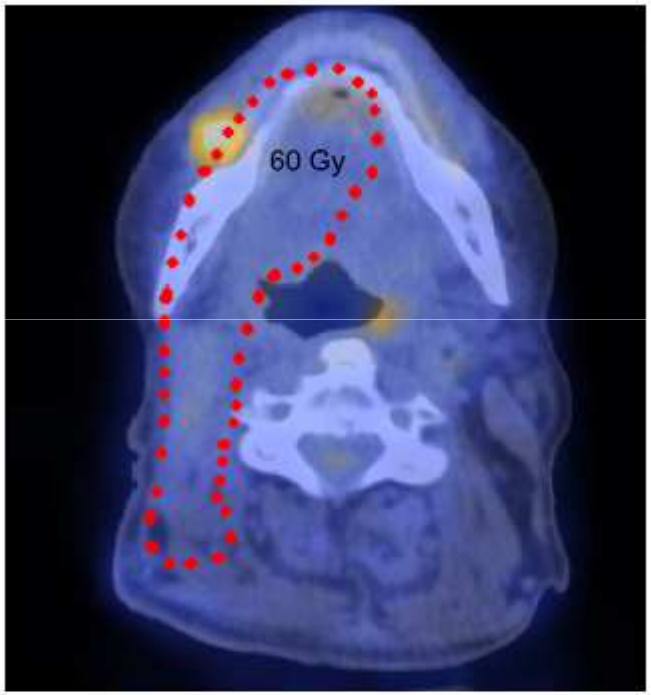


Fig. 4. Case illustration (marginal miss): This 69-year-old male underwent laser CO_2 excision for T1 squamous cell carcinoma of the right buccal mucosa and split-thickness skin grafting. Modified radical neck dissection on the ipsilateral side revealed six lymph nodes involved with malignancy at levels Ib and II with extracapsular extension. He subsequently completed postoperative IMRT with concurrent cisplatin chemotherapy. A dose of 60 Gy in 30 fractions was delivered to the primary tumor site and ipsilateral neck, with 54 Gy delivered to the contralateral left neck. Approximately, 9 months later, the patient presented with a subcutaneous nodule arising from the right anterior aspect of his mandible. PET/CT suggested LRR, which was confirmed by fine-needle aspiration biopsy.

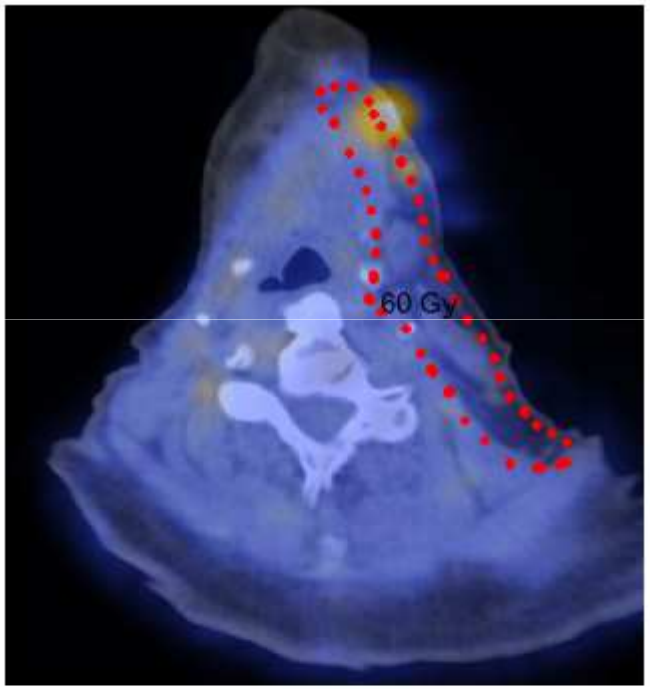

Fig. 5. Case illustration (marginal miss): This 70-year-old male underwent partial glossectomy for a 3.5-cm focus of squamous cell carcinoma involving the left oral tongue. Modified radical neck dissection on the ipsilateral side revealed 3 of 20 lymph nodes involved with disease at level Ib and II. There was no extracapsular extension. Postoperative radiation therapy was delivered to a dose of 60 Gy in 30 fractions to the primary site and ipsilateral cervical neck. The contralateral neck and supraclavicular fossae were treated to 54 Gy. Approximately 6 months after treatment, the patient presented with a suspicious erythematous lesion involving the left neck. PET/CT suggested LRR, which was confirmed by fine-needle aspiration biopsy.

It usually is, but you gotta watch out!

Chen et al., IJROBP, 2011

90 Pts
11 In-Field Relapses
6 Marginal Misses

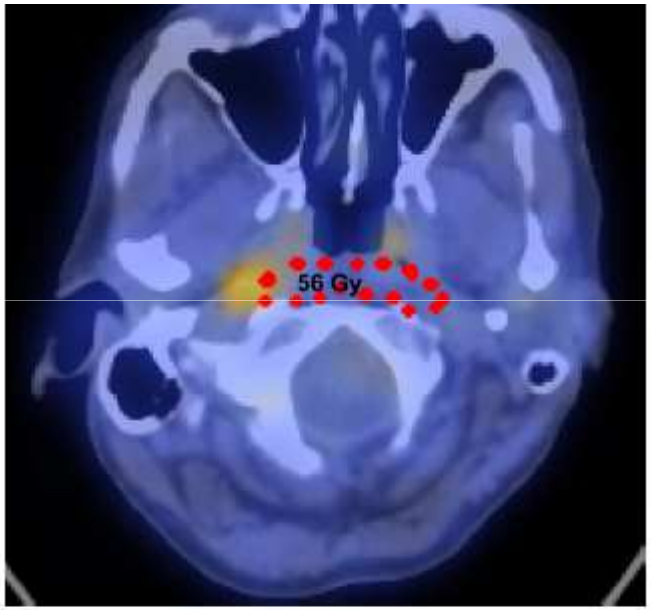

Fig. 2. Case illustration (marginal miss): This 70-year-old female underwent total laryngectomy and bilateral neck dissection for T4aN0 squamous cell carcinoma of the right pyriform sinus with extension through the thyroid cartilage. She subsequently completed postoperative IMRT at a dose of 63 Gy in 35 fractions to the primary surgical bed and 56 Gy (red outline) to the bilateral necks, including the retropharyngeal lymph nodes. A follow-up PET/CT scan performed approximately 12 months after completion of IMRT suggested regional recurrence in the retropharyngeal lymph nodes near the base of the skull. She also developed simultaneous lung metastasis. It should be noted that CTV delineation in this case was inadequate given that the consensus guidelines describe the lateral boundaries of the retropharyngeal nodal region as the medial edge of the internal carotid artery.

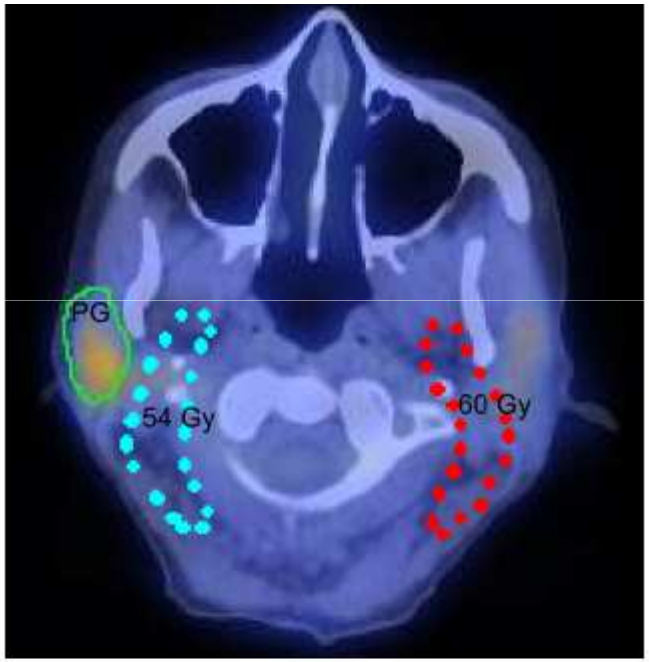

Fig. 3. Case illustration (marginal miss): This 67-year-old male underwent segmental mandibulectomy and open resection of a 3-cm squamous cell carcinoma of the left oral tongue. Modified radical neck dissection on the ipsilateral side revealed 4 of 15 lymph nodes involved at levels II and III. He subsequently completed postoperative IMRT with concurrent cisplatin chemotherapy. A dose of 60 Gy in 30 fractions (red outline) was delivered to the primary tumor site and ipsilateral neck. The contralateral right neck received a dose of 54 Gy (blue outline). Approximately 13 months later, the patient presented with fullness in the right parotid region. PET/CT scan suggested LRR near the region of the spared parotid gland (PG), which was confirmed by fine-needle aspiration biopsy.

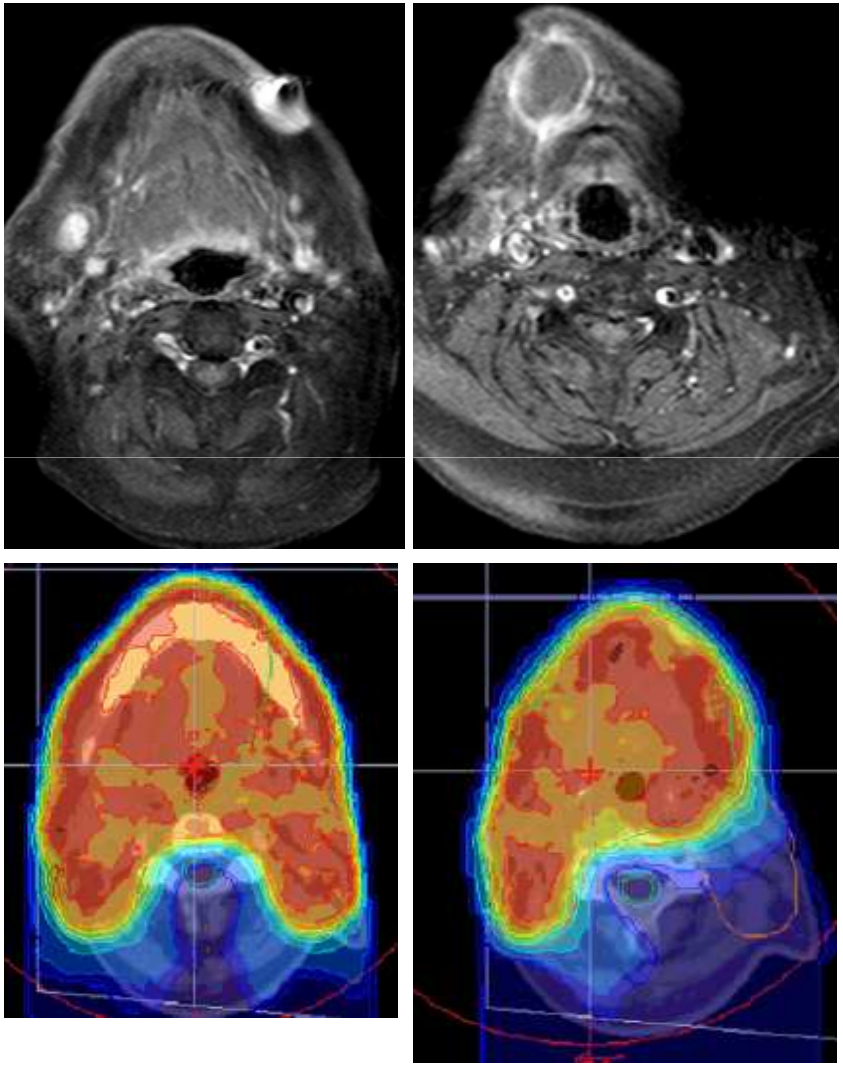
UMM example
– cancer of the lower lip



Relapse Pattern OCC - PMH

“Conclusions: Nearly a third (12/38) of LR recurrences were marginal or out-of-field following postoperative IMRT for OCSCC. Postoperative IMRT following gross total surgical resection requires careful and comprehensive target volume delineation, and larger volumes may be needed than the primary RT setting.”

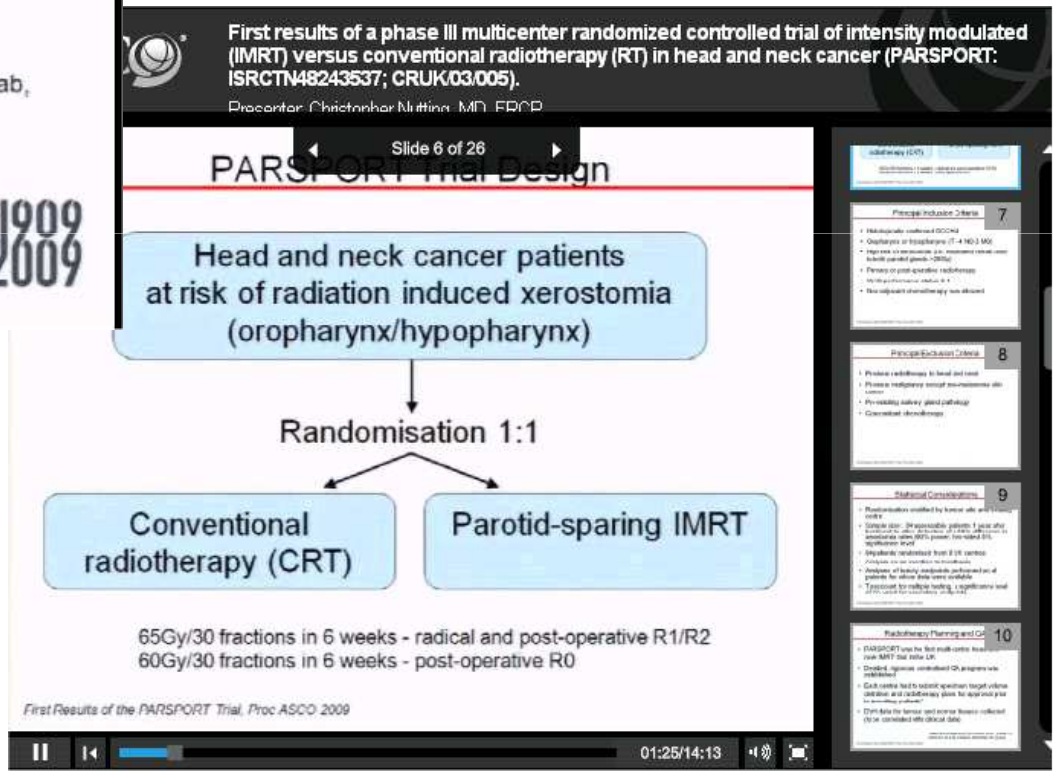
2009



First results of a phase III multicenter randomized controlled trial of intensity modulated (IMRT) versus conventional radiotherapy (RT) in head and neck cancer (PARSPORT: ISRCTN48243537; CRUK/03/005).
Slide 6 of 26
PARSPORT Trial Design
Head and neck cancer patients at risk of radiation induced xerostomia (oropharynx/hypopharynx)
Randomisation 1:1
Conventional radiotherapy (CRT)
Parotid-sparing IMRT
65Gy/30 fractions in 6 weeks - radical and post-operative R1/R2
60Gy/30 fractions in 6 weeks - post-operative R0
First Results of the PARSPORT Trial, Proc ASCO 2009
01:25/14:13

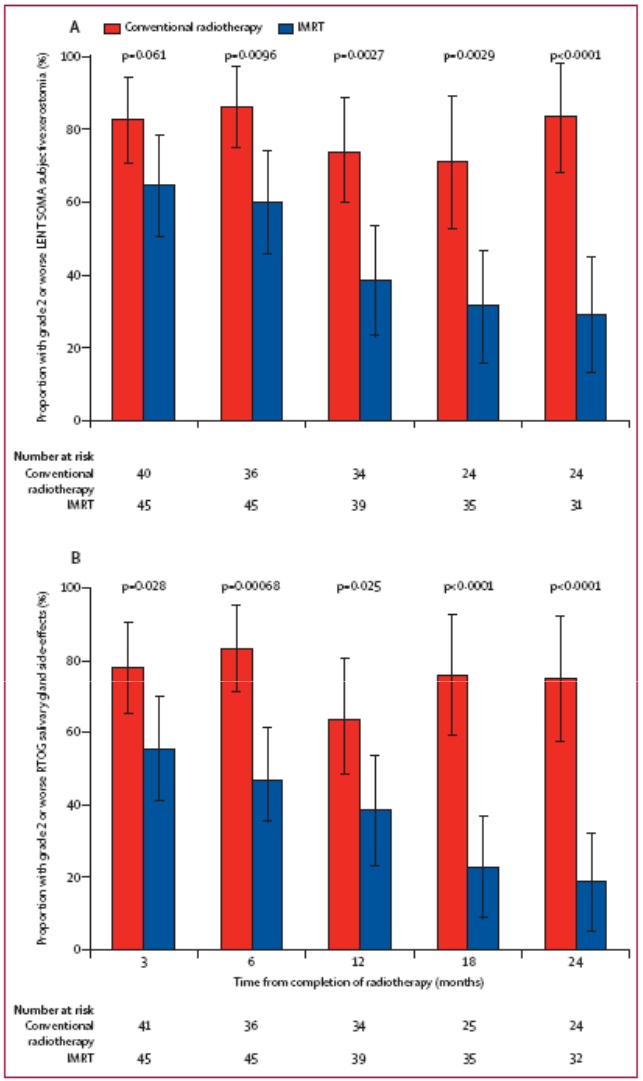


Figure 2: **Proportion of patients reporting grade 2 or worse LENT SOMA subjective xerostomia and RTOG salivary gland side-effects**
p values quoted compare proportions with grade 2 or worse side-effects in each group with a χ^2 test. Error bars represent 95% CIs. IMRT=Intensity-modulated radiotherapy. LENT SOMA=Late Effects of Normal Tissues Subjective-Objective Management Analytic. RTOG=Radiation Therapy Oncology Group.

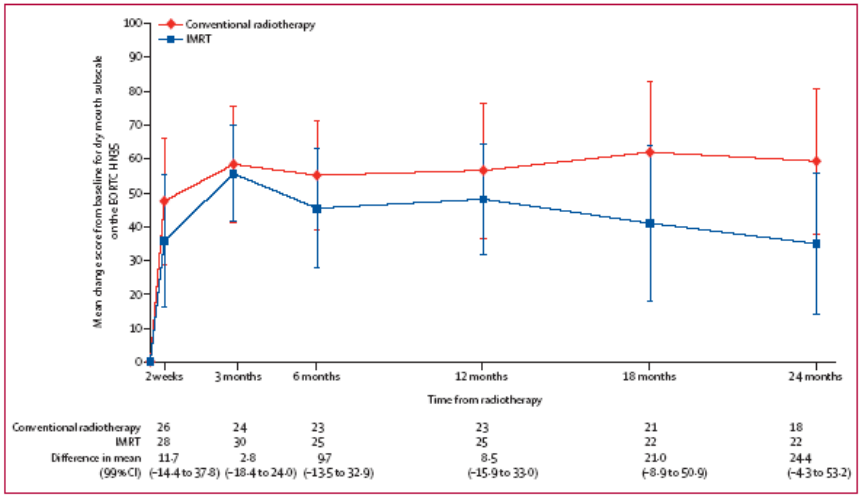

Figure 3: **Mean EORTC HN35 dry mouth subscale score changes from baseline**
IMRT=Intensity-modulated radiotherapy. EORTC HN35=European Organization for Research and Treatment of Cancer head and neck specific module HN35.

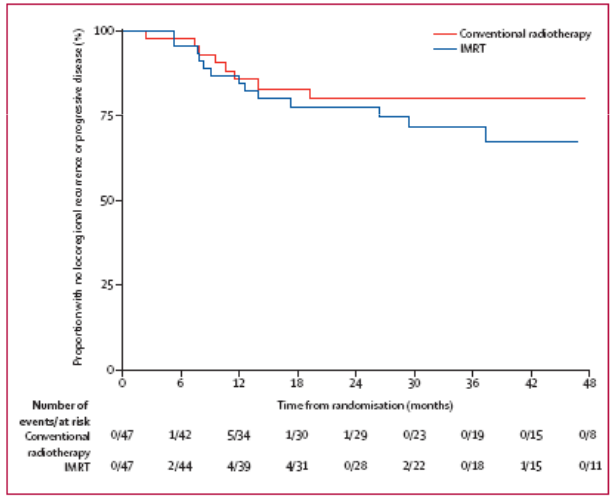

Figure 4: **Kaplan-Meier plot of locoregional progression-free survival by treatment group**
Hazard ratio 1·53 (95% CI 0·63 to 3·70). Log-rank test p=0·34. 2-year locoregional progression-free survival estimates for conventional radiotherapy 80% (95% CI 65 to 90) and for IMRT 78% (62 to 87); absolute difference 3% (−15 to 20). IMRT=Intensity-modulated radiotherapy.

„Unexpectedly, acute fatigue was greater in patients treated with IMRT, which could be due to the greater radiation dose to non-tumour tissues. In an unplanned dosimetry review in a subset of patients, mean radiation doses to the posterior fossa were 20–30 Gy in the patients treated with IMRT compared with about 6 Gy in patients treated with conventional RT“

Nutting et al., Lancet Oncol, 2011

Parsport – Parotid Dose Response Relationship

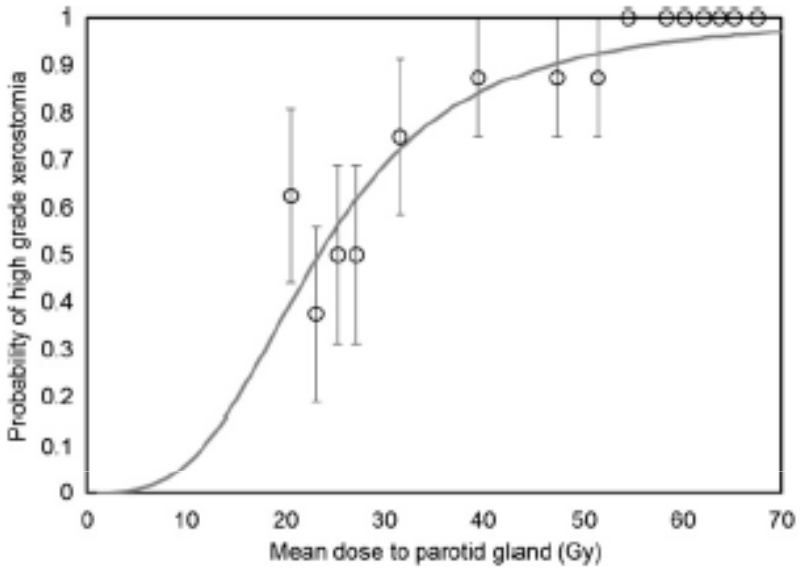

Fig. 3. Dose–response curve for probability of developing high grade xerostomia (no recovery of parotid saliva flow) at 12 months, error bars represent one standard error of mean. $D50 = 23.4$ (95% CI: 20.6–26.2) and $k = 3.2$ (95% CI: 1.9–4.5), line of best fit, $R^2 = 0.85$.

Rathod et al.,
Oral Oncol, 2013

Caveat:

At a median followup of 40 months (inter-quartile range 26-50 months):

The 3-year estimates of loco-regional control with 95% confidence intervals (95%CI) were
88.2%** (75.4–100%) for **3D-CRT
80.5%** (66.1–94.9%) for **IMRT
(p = 0.45).

And if you want everything in one publication…

go for the Metaanalysis

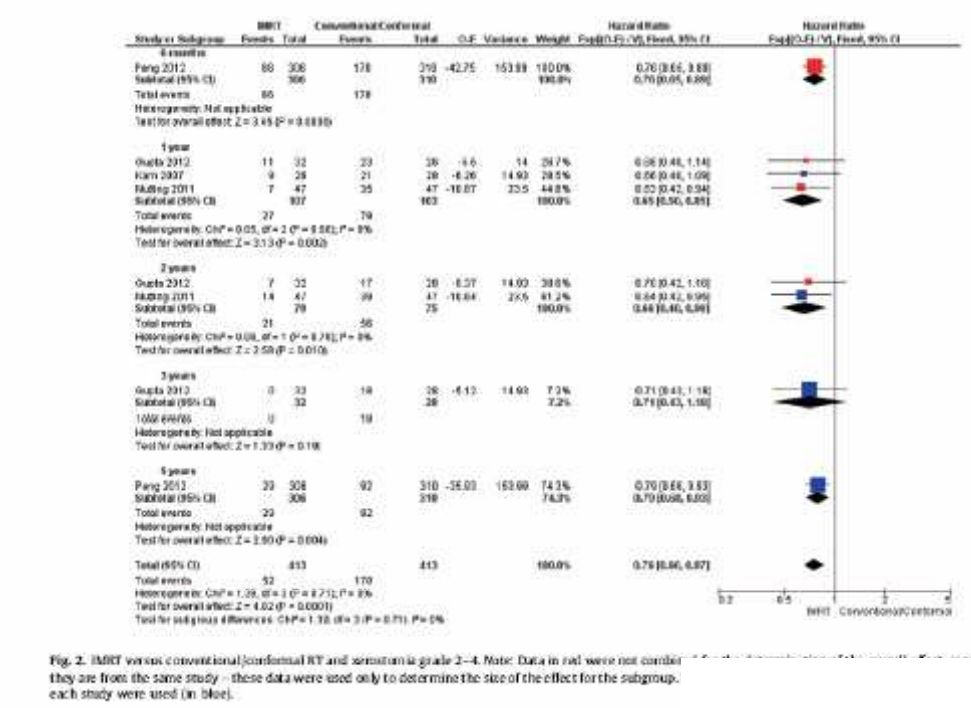

Fig. 2. IMRT versus conventional/conformal RT and xerostomia grade 2–4. Note: Data in red were not combi… they are from the same study – these data were used only to determine the size of the effect for the subgroup. each study were used (in blue).

Clinical Normal Tissue Toxicity

An excellent Reference just published:

Seminars in Radiation Oncology
Volume 26, No.2, April 2016

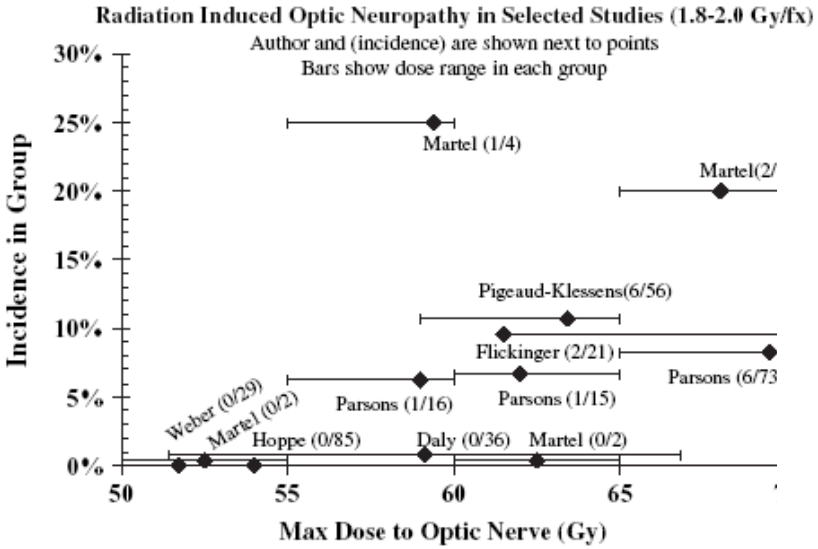
Normal Tissue Toxicity Modelling for SRS and SBRT

Optic Nerve Toxicity: Quantec

Mayo et al., IJROBP, 2010

Few studies have adequate data for dose–volume outcome modeling. The risk of toxicity increased markedly at doses **>60 Gy at >1.8 Gy/fraction** and at **>12 Gy for single-fraction** radiosurgery.

The evidence is strong that radiation tolerance is increased with a reduction in the dose per fraction.



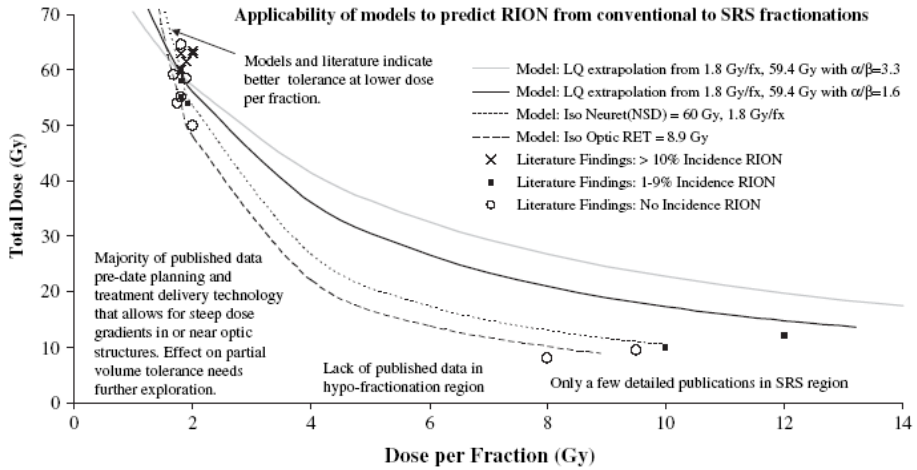


Fig. 2. Isoeffect linear-quadratic model extrapolations and alternative biologically effective threshold models (curves) compared with reported maximum optic nerve/chiasm doses detailing incidence of radiation-induced optic neuropathy (RION) (symbols) for full range of dose per fraction. Linear-quadratic model was unreliable for extrapolating from fractionated (1.8–2.0-Gy/fraction) dose range to single-fraction range. Detailed data needed for low (<1.8 Gy) and hypofractionated regions to better define organ response.

No Optic Neuropathy at <45/1,8 Gy in Nonfunctioning Pituitary Adenoma - High SD are problematic

Bold rows indicate patients in whom RON developed with "safe" radiation regimens.
F, female; M, male; Y, yes; N, no; VA, visual acuity; N/A, data not available.
*These references are also included in Table 1, because patient and treatment characteristics were available.
†In some cases, visual acuity was documented as "normal," or when not normal, as attributable to a cause other than RON; for simplicity, 20/20 has been used in all such cases.

No ON at Proton Doses of <55GyE

10% ON risk between 55 and 65GyE
(two of 20 patients in series developed ON at doses of 55 and 65GyE
at SD of <2Gy)

Habrand, IJROBP, 1989

Single Dose vs. Fractionated Tolerance for Meningeoma

Shrieve et al., J Neurosurg, 2004

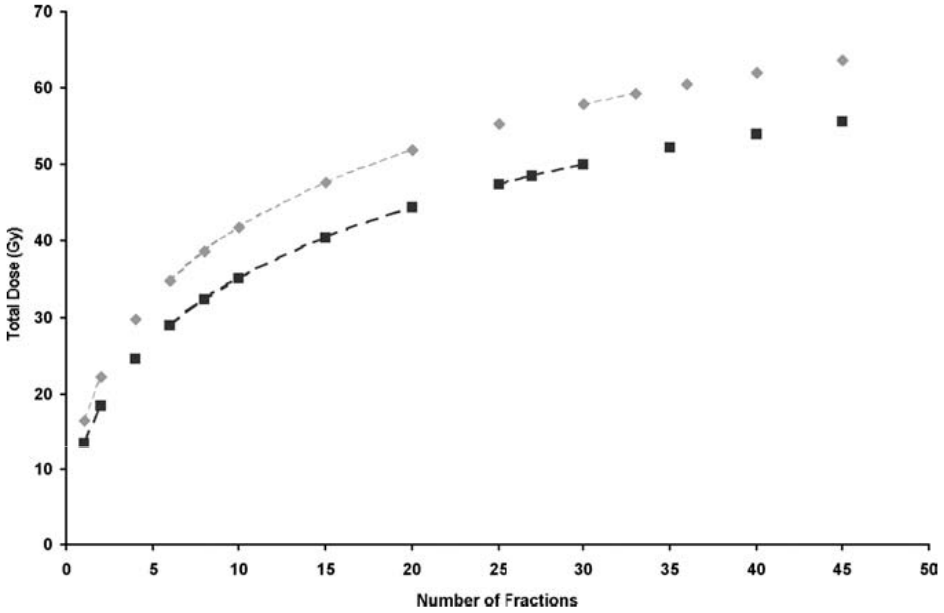

FIG. 4. Graph showing the range of total doses predicted to be associated with excellent control of meningioma *(dotted lines)* compared with the optic nerve tolerance for various equal daily doses *(solid line)*. The therapeutic range exceeds optic nerve tolerance until at least 20 fractions are used.

"Single doses of radiation required to treat benign meningioma optimally (13.5–16.5 Gy) clearly exceed the estimated and reported clinical tolerance of the optic nerves and chiasm. The application of equivalent biological doses in a small number of fractions continues to exceed optic tolerance until at least 25 fractions are applied."

Optic Neuropathy Risk after RS

The risk of developing a clinically significant RON was **1.1%** for patients receiving **12 Gy** or less with a median F/u of 40 months

Patients receiving prior or concurrent EBRT had a greater risk of developing RON after radiosurgery

Stafford et al., IJROBP, 2004

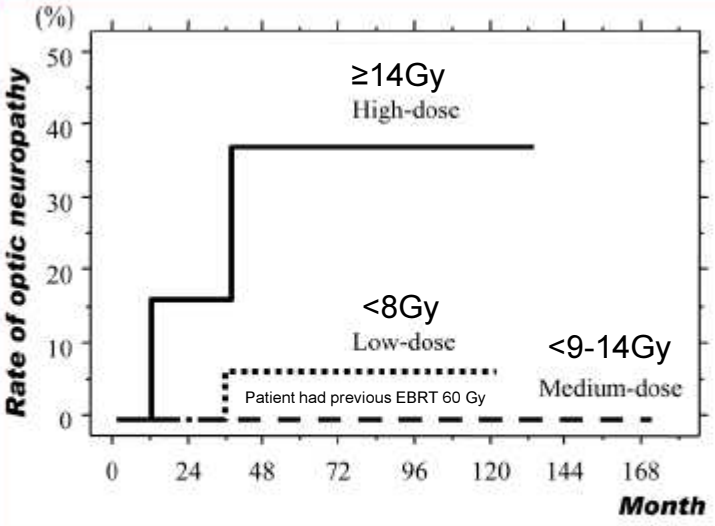

FIGURE 5. *Kaplan-Meier curves demonstrating radiation-induced optic neuropathy rates on the basis of dose groups.*

TABLE 3. Dose to Optic Chiasm (n = 53)

Maximum Dose, Gy	No. of Patients (%)
<5	13 (25)
5-6	13 (25)
7-8	14 (26)
9-10	11 (21)
11-12	1 (2)
13-14	0 (0)
15-16	1 (2)

Hasegawa et al., Nerurosurgery, 2010

Optic Neuropathy Risk - Synopsis

A TD of 45Gy/SD 1.8 Gy and RS with 1 x 8 Gy seem to be completely safe

At TD 50-60Gy/SD <2 Gy and RS with 1 x 10-12 Gy a low incidence of ON is reported

At TD>60Gy with SD < 2 Gy and TD>50 Gy with SD >2 Gy

as well as

RS with >12 Gy,

ON risk increases quickly with dose and SD

Plexopathy

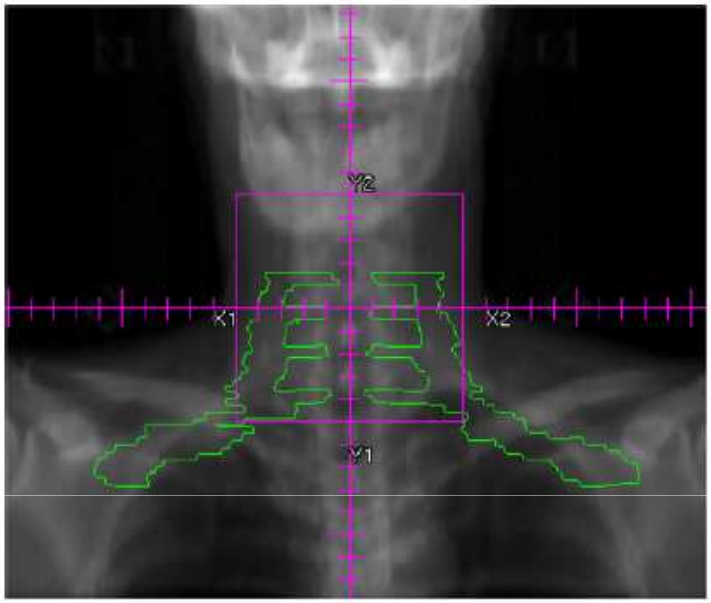

Fig. 3. Coronal section of the head and neck illustrating the anatomic location of the brachial plexus as depicted using the Radiation Therapy Oncology Group contouring atlas (available at www.rtog.org).

The brachial plexus begins at the ventral rami of nerve roots at the fifth cervical vertebrae and continues inferiorly to include the nerve roots exiting the neural foramen of the first thoracic vertebrae (Fig. 3). It then passes inferolaterally between the anterior and middle scalene muscles to innervate the cutaneous skin of the upper extremity and numerous muscles including the latissimus dorsi, pectoralis major and minor, levator scapulae, deltoid, and biceps brachii.

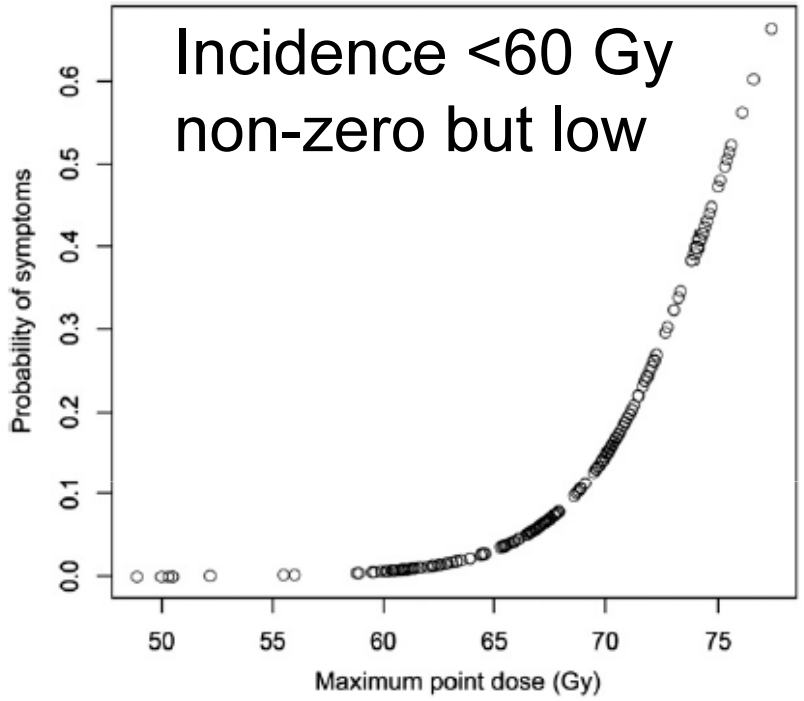

Fig. 2. Relationship between probability of developing neuropathic symptoms and maximum radiation point dose (Gy).

Chen et al., IJROBP, 2012

In this study cohort, at a minimum of two-years follow up, the mean dose of 68.7Gy, a median dose to 69.5Gy to ≤5% of ipsilateral BP, and a median Dmax of 72.96Gy did not result in BP injury when patients were treated with S-IMRT technique.

However, longer follow up is needed.

Spinal Cord Damage – Review 1

Fig. 1. Paraparésie sensitivomotrice, cinq mois après irradiation en manteleet incomplet d'une adolescente ayant préalablement reçu une chimiothérapie (protocole OEPA/COPP, vincristine, procarbazine, etoposide, prednisone, adriamycine, cyclophosphamide). Dose délivrée : 20 Gy en 11 séances par faisceaux antéropostérieurs de photons de haute énergie. Aspect grêle et hyper T2 de la moelle cervicodorsale avec prises de contraste étagées, compatibles avec une myélite radique. Régression de la symptomatologie après bolus de corticoïdes. Tests de radiosensibilité négatifs (collection de l'institut Gustave-Roussy).

Spinal Cord Damage risk ~0,5%
for full cord exposure to 50 Gy

Habrand et al., Cancer Radiother, 2010

Spinal Cord Damage – Review 2

Dose–volume data for myelopathy in humans treated with radiotherapy (RT) to the spine is reviewed, along with pertinent preclinical data. Using conventional fractionation of **1.8–2 Gy/fraction** to the full-thickness cord, the estimated risk of myelopathy is **<1% and <10% at 54 Gy and 61 Gy**, respectively, with a calculated strong dependence on dose/fraction (a/b = 0.87 Gy.)

Reirradiation data in animals and humans suggest partial repair
of RT-induced subclinical damage becoming evident about 6 months post-RTand increasing over the next 2 years.

Reports of myelopathy from **stereotactic radiosurgery** to spinal lesions appear rare **(<1%)** when the maximum spinal cord dose is limited to the equivalent of **13 Gy in a single fraction or 20 Gy in three fractions**. However,long-term data are insufficient to calculate a dose–volume relationship for myelopathy when the partial cord istreated with a hypofractionated regimen.

Kirkpatrick et al., IJROBP, 2010

How much RT can I give after conventional RT?

Table 2. Risk score for development of radiation myelopathy

	Score									
Factor	0	1	2	3	4	5	6	7	8	9
Cumulative BED (Gy_2)	≤120	120.1–130	130.1–140	140.1–150	150.1–160	160.1–170	170.1–180	180.1–190	190.1–200	>200

50 Gy ~BED 100
-> low risk at 50+20Gy

Group	Score	Myelopathy (%)
Low risk	≤3	0/24 (0)
Intermediate risk	4–6	2/6 (33)
High risk	>6	9/10 (90)

Nieder et al., IJROBP, 2005

Maximum Doses to Spinal cord of 20 Gy in 1-3 SD
Lower than expected Tox – high parallelity of Spinal Cord

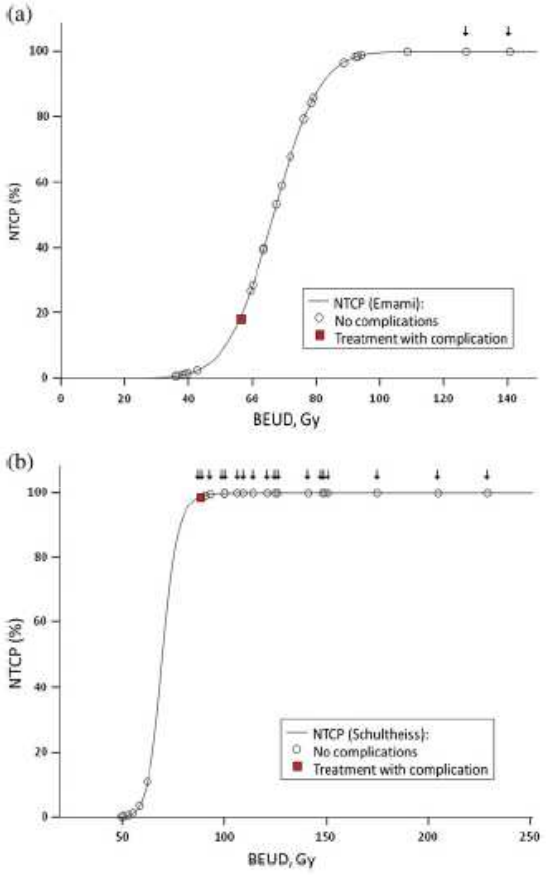

Fig. 1. a, Predicted normal tissue complication probability (NTCP) for spinal cord with NTCP modeling of clinical outcomes based on parameters of Emami (3). One cord toxicity was observed clinically (square) (with an NTCP of 19%). Seventeen other lesions with a higher NTCP, including two lesions with 100% NTCP (arrows), did not have toxicity. Therefore these modeling parameters were not predictive of the clinical outcomes. b, Predicted NTCP for spinal cord with NTCP modeling of clinical outcomes based on parameters of Schultheiss (5). One cord toxicity was observed clinically (square) (with an NTCP of 99.8%), whereas seventeen other lesions without toxicity had an NTCP of greater than 99% (arrows). These NTCP values overestimated the toxicity rates observed clinically. BEUD = biologically equivalent uniform dose.

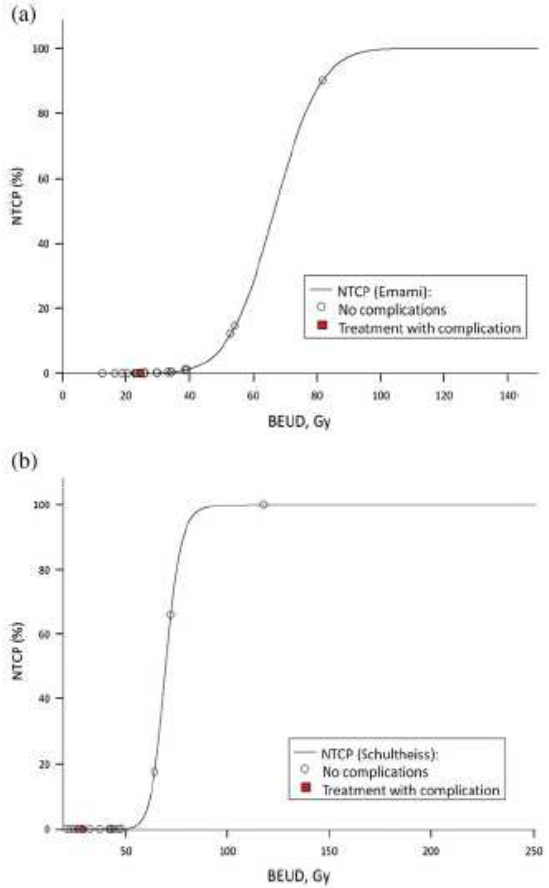

Fig. 2. a, Predicted normal tissue complication probability (NTCP) for spinal cord with NTCP modeling of clinical outcomes based on parameters of Emami (3), with optimization of the volume parameter ($n = 0.31$), assuming a greater degree of parallel organization of the spinal cord. Although this optimization provided a better fit of the NTCP to the clinical data, these NTCP parameters continued to overestimate the risk of complications. b, Predicted NTCP for spinal cord with NTCP modeling of clinical outcomes based on parameters of Schultheiss (5), with optimization of the volume parameter ($n = 0.43$), assuming a greater degree of parallel organization of the spinal cord. These modified parameters continued to overestimate the risk of complications observed clinically. BEUD = biologically equivalent uniform dose.

Table 2. Predicted and observed number of complications

Parameter used	No. of complications predicted	No. of complications observed
Emami	13	1
Schultheiss $n = 0.05$	18	1
Schultheiss $n = 0.43$	2	1
Emami with α/β of 13.2 Gy	0.7	1

Abbreviation: n = volume parameter.

How much SBRT can I give after conventional RT?

Table 6. Reasonable reirradiation SBRT doses to the thecal sac P_{max} following common initial conventional radiotherapy regimens

Conventional Radiotherapy (nBED)	1 fraction: SBRT dose to thecal sac P_{max}	2 fractions: SBRT dose to thecal sac P_{max}	3 fractions: SBRT dose to thecal sac P_{max}	4 fractions: SBRT dose to thecal sac P_{max}	5 fractions: SBRT dose to thecal sac P_{max}
0*	10 Gy	14.5 Gy	17.5 Gy	20 Gy	22 Gy
20 Gy in 5 fractions ($30\ Gy_{2/2}$)	9 Gy	12.2 Gy	14.5 Gy	16.2 Gy	18 Gy
30 Gy in 10 fractions ($37.5\ Gy_{2/2}$)	9 Gy	12.2 Gy	14.5 Gy	16.2 Gy	18 Gy
37.5 Gy in 15 fractions ($42\ Gy_{2/2}$)	9 Gy	12.2 Gy	14.5 Gy	16.2 Gy	18 Gy
40 Gy in 20 fractions ($40\ Gy_{2/2}$)	N/A	12.2 Gy	14.5 Gy	16.2 Gy	18 Gy
45 Gy in 25 fractions ($43\ Gy_{2/2}$)	N/A	12.2 Gy	14.5 Gy	16.2 Gy	18 Gy
50 Gy in 25 fractions ($50\ Gy_{2/2}$)	N/A	11 Gy	12.5 Gy	14 Gy	15.5 Gy

Abbreviations: N/A = not applicable; nBED = normalized biologically effective doses; SBRT = stereotactic body radiotherapy.

* These dose limits are based on our prior publication for spinal cord tolerance in patients treated with SBRT and no prior history of radiation (7).

Saghal et al., IJROBP, 2012

Daily vs. less frequent Imaging: Spinal cord dose

Duma et al., IJROBP, 2013

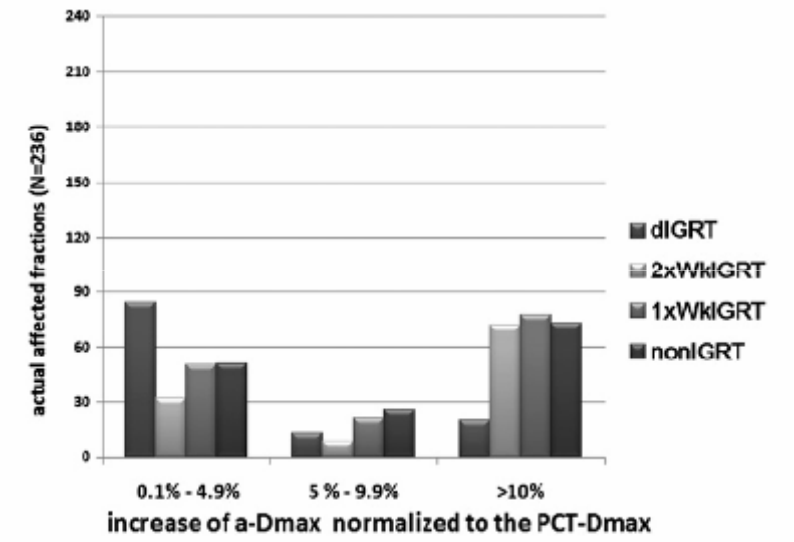

Fig. 2. The a-Dmax is higher than the planned Dmax. a-Dmax = actual delivered Dmax; plan-Dmax = Dmax on the planning kVCT.

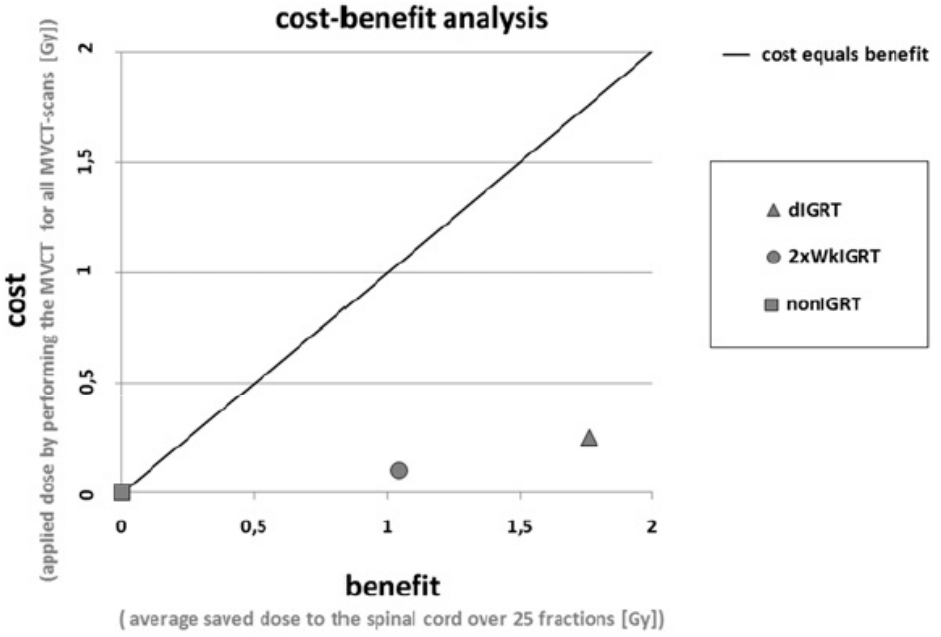

Fig. 4. Cost-benefit analysis of dIGRT and 2×WkIGRT compared to non-IGRT. Compared to the non-IGRT, the dIGRT and 2×WkIGRT scenarios save, on average, 1.76 and 1.04 Gy, respectively. That is calculated by the higher-than-planned Dmax for the non-IGRT (5.6%) minus the higher-than-planned Dmax for the dIGRT (1.2%); *e.g.*, 2.24 Gy − 0.48 Gy = 1.76 Gy; and for 2×WkIGRT, 2.24 Gy − 1.2 Gy = 1.04 Gy. The cost of one MVCT scan in the coarse mode is 0.01 Gy (dIGRT = 0.25 Gy; 2×WkIGRT = 0.12 Gy).

ART (IMRT) – Dosimetric Benefits

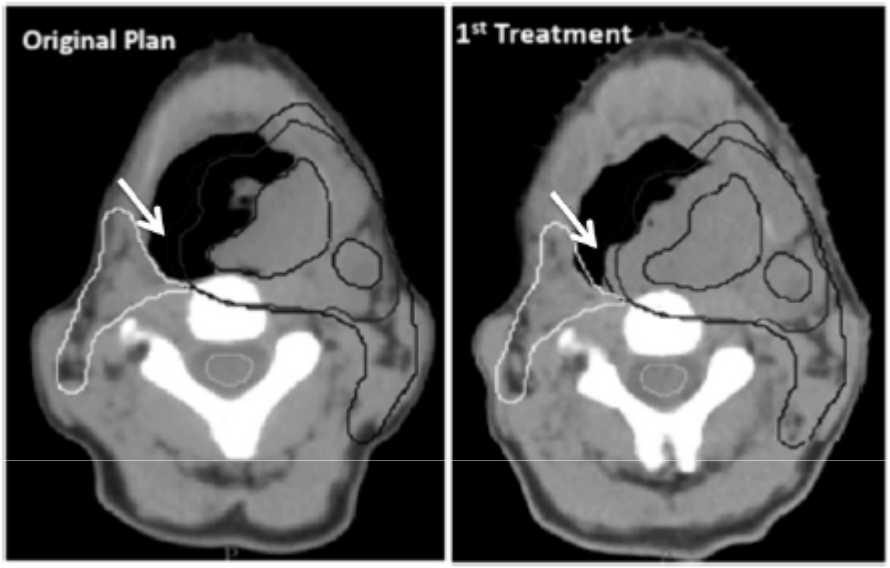

Fig. 1. Detection of rapid tumor progression prior to start of treatment. The original plan is shown to the left; patient's anatomy on first treatment day is shown on the right. Primary GTV progressed by >50%. Arrows designate site of geographic miss for CTV1.

Try to keep Interval between CT and 1st RT short (2-3 days is possible)

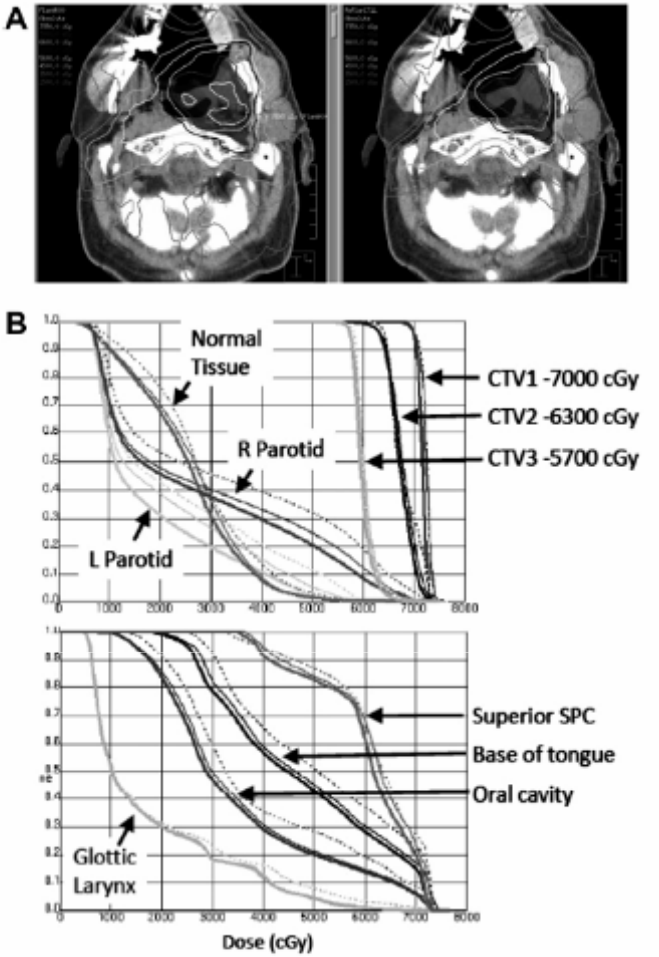

Fig. 3. (A) *Right:* Emergence of dose heterogeneity within high-risk CTV1 in a tonsillar carcinoma case at treatment fraction #11; *Left:* Restoration of intended dose distribution within CTV1 by adaptive replanning without PTV margin expansions. (B) DVH comparison for the original IMRT plan of this case (dotted lines), ART1 replan designed on treatment day 15 (thin solid lines), and the ART2 replan (thick solid lines), all re-calculated on CT anatomy obtained on 25th treatment day.

Schwartz et al., R&O, 2013

IMRT vs. Protons?

Table 1 Method to calculate toxicity for the *IMPT if efficient* strategy: Illustrated for xerostomia 6 months after radiation therapy

	Probability of xerostomia (%)		ICER	Preferred	Probability of xerostomia (%)
Patient	IMPT	IMRT	IMPT vs IMRT (€)	IMPT/IMRT	*IMPT if efficient**
1	25.5	41.3	93,302	IMRT	41.3
2	18.9	36.6	169,448	IMRT	36.6
3	23.6	55.2	44,358	IMPT	23.6
4	26.7	37.2	150,041	IMRT	37.2
↓	↓	↓	↓	↓	↓
25	25.8	45.1	89,593	IMRT	45.1
Mean probability of xerostomia for the IMPT if efficient strategy					37.1%

Abbreviations: ICER = incremental cost-effectiveness ratio; IMPT = intensity modulated proton radiation therapy; IMRT = intensity modulated radiation therapy with photons.

* Patients will only receive IMPT in this scenario if IMPT is expected to be cost-effective compared with IMRT (grey fields), thus if the ICER is below the threshold of 80,000 per QALY gained.

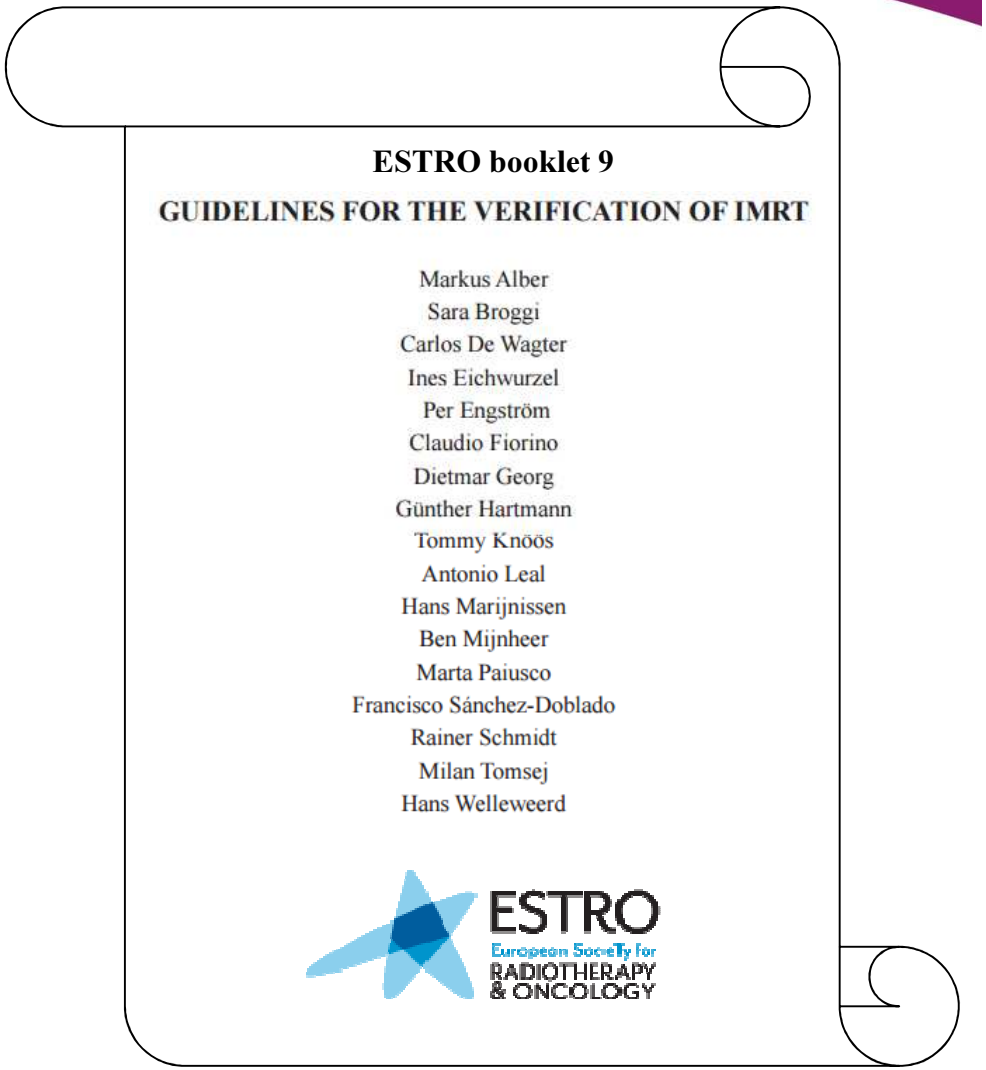
Contents

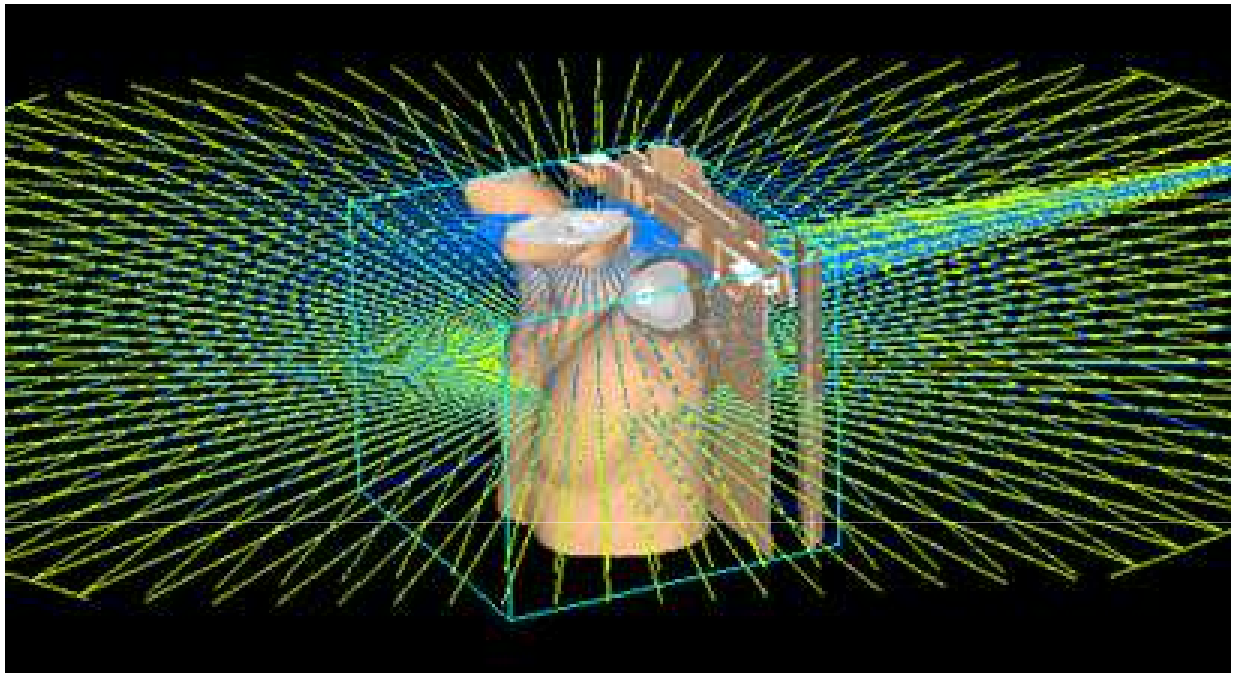
- What's special about IMRT?
- IMRT verification systems
- Data analysis: the gamma index
- The value of patient-specific QA



ESTRO School

QA in the 3D-CRT era

- Successful radiotherapy requires correct delivery of planned dose
- Achieved through commissioning of treatment-planning system (TPS) and treatment machines
- Stable performance of machines monitored through a quality assurance (QA) programme
  - Absolute and relative dose
  - Collimator positions
- Plan check routines make sure patients get correct treatment plans
- Patient-specific QA an option but not necessarily a requirement

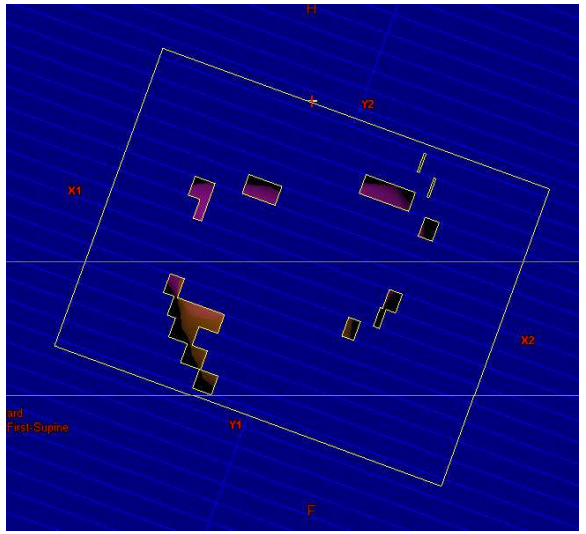


WHAT'S DIFFERENT ABOUT IMRT?

Modulation

Total dose delivered by multiple small beamlets

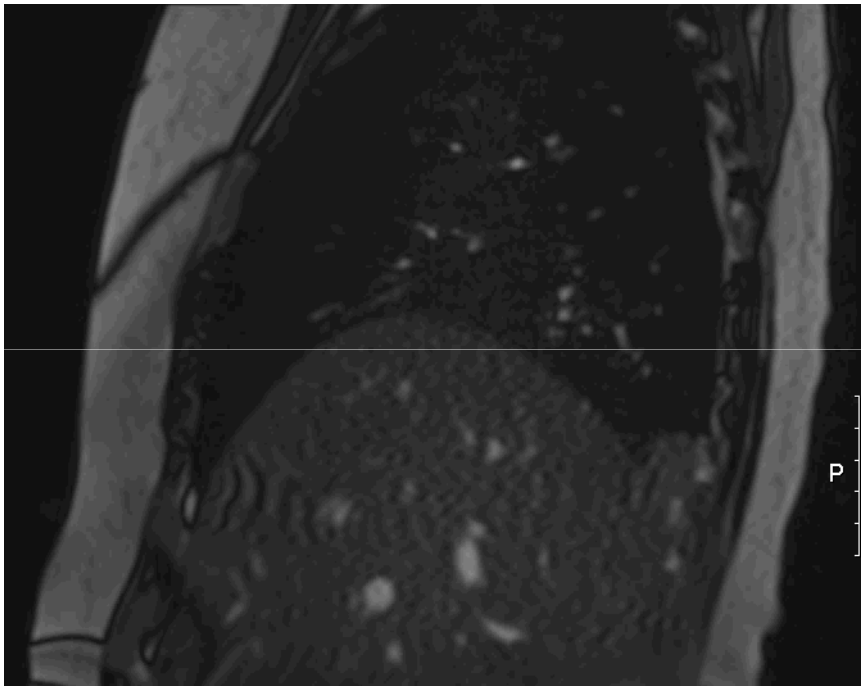
1. Output factor for very small fields difficult to measure/model
2. Field penumbra directly in the target
3. Inter-leaf leakage exposing the target
4. Secondary dose calculation complicated
5. Interplay effect

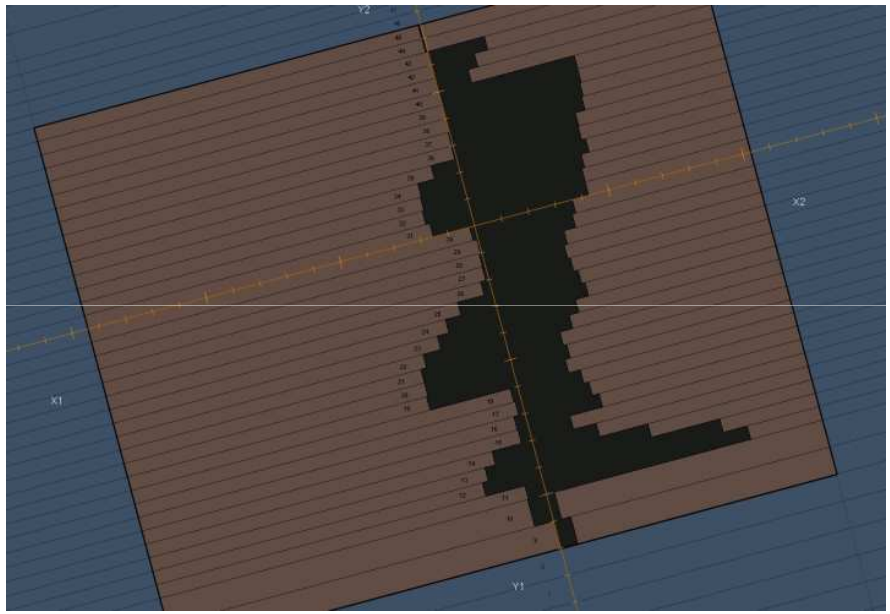


Limitations in beam modelling more important for IMRT.

Monte Carlo beam model could address 1-3 above.

Interplay effect



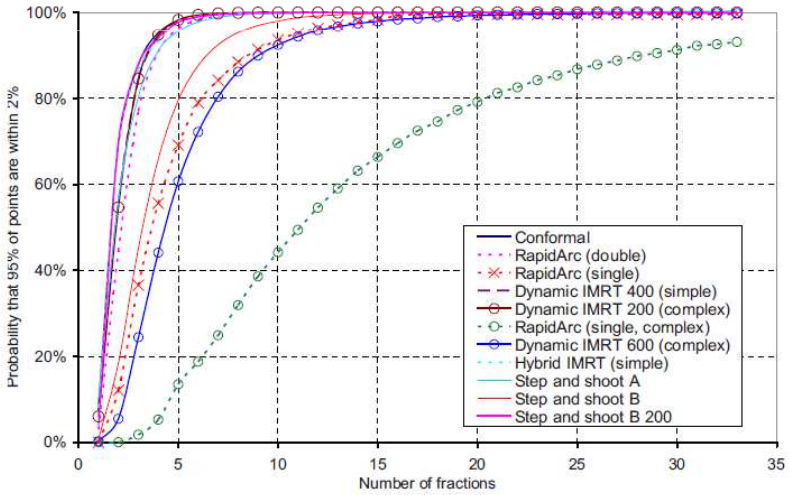


Interplay effect

- Total dose distribution relies on different areas of the target being selectively exposed at different times
- Intrafraction motion would lead to the dose accumulating in a different distribution than planned

In reality, the interplay effect is rarely a problem:

- Over many fractions the dose averages out
- SABR: few fractions but longer delivery times (e.g. more breathing cycles)
- Very heavily modulated plans, single-arc VMAT
- Avoid by limiting modulation



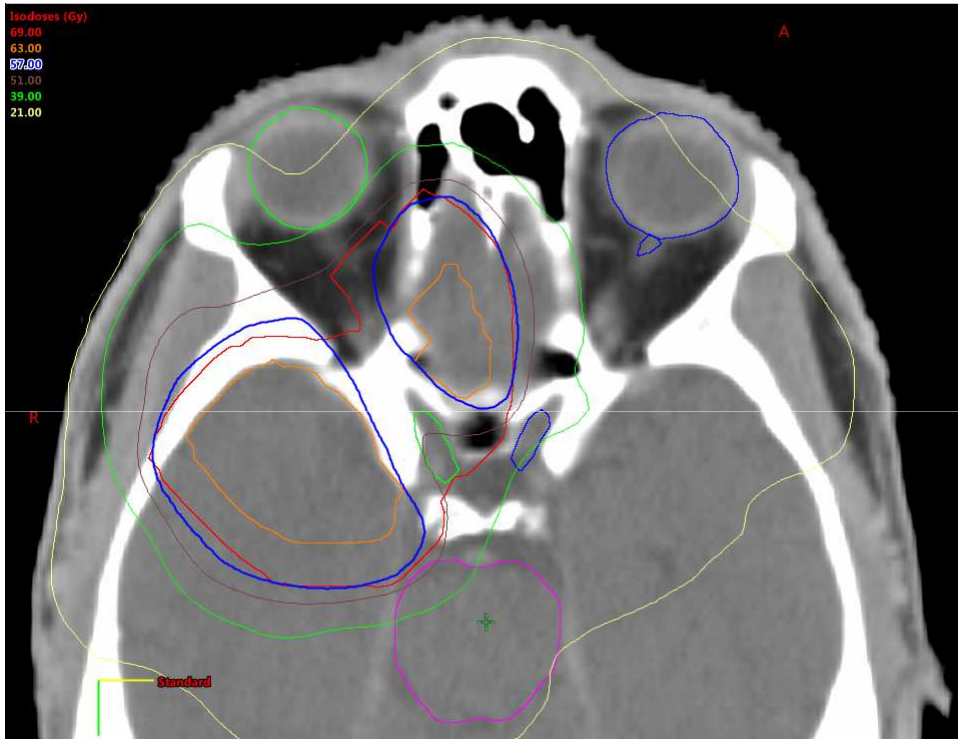
Court et al. MedPhys 2010

Static or dynamic delivery

- Step-and-shoot IMRT
  - Multitude of low-weighted beamlets
  - Quick ramp-up of accelerator performance required
- Sliding window IMRT and VMAT
  - Dose-rate, MLC motion and gantry motion need to be perfectly syncronised
  - Influence of gravity on MLCs
  - MLC QA, e.g. picket fence test
  - Analysis of MLC log files
- Standard IMRT/VMAT plan measured regularly on phantom/array

Complex modality

- Potentially high dose wrapping close around critical organs
- Sensitive to set-up errors
- High accuracy in delivery of planned dose *particularly* important for IMRT
- Difficult for treatment staff to discover mistakes



ESTRO School

IMRT audit results

- Dose determination audits with anthropomorphic phantoms show , in the target volume, an agreement between different centres of:
  - About 3% (1 standard deviation) for 3D-CRT
  - Up to 8% (1 standard deviation) for IMRT
- 30% of clinics failed to deliver correct IMRT H&N plans (7%/4mm) according to Ibbot et al. (IJROBP 2008), due to:
  - Incorrect output factors and percent depth dose data
  - Inadequate modeling of the penumbra at MLC leaf ends
  - Incorrect application of QA calculations or measurements
  - Inadequate QA of multileaf collimator
  - Incorrect patient positioning
  - Errors in treatment planning software

Why patient-specific QA?

The agreement between planned and delivered dose may depend on plan-specific parameters, like the level of modulation

Seems unavoidable at least until:

- Stable history of machine QC for dynamic MLC and gantry
- Monte Carlo dose calculation algorithm
- Convenient secondary dose calculation
- Extensive experience of high pass rates for patient-specific plan measurements
- New history of patient-specific QA needs to be aquired after new class solution is introduced

May be a legal requirement in your country

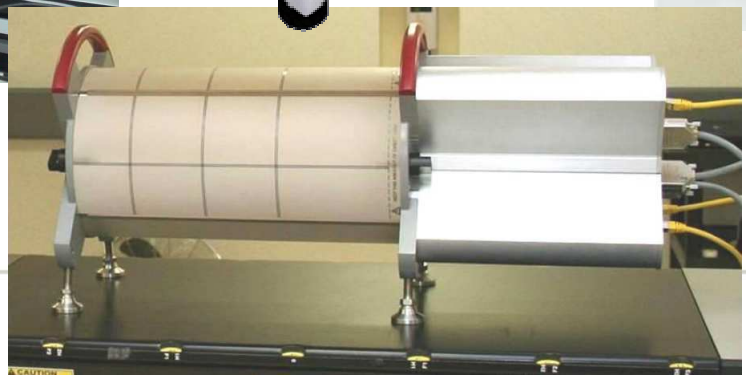
EURATOM directive 97/43

IMRT treatment plan verification strategies

- Single field- versus composite-field verification
  - Ease of evaluation and investigation
  - Both fill the purpose of plan verification
- 1D, i.e. point measurement: too simplistic
- 2D, i.e. film, detector arrays, EPID: most common
- 3D, i.e. gels and similar: less common
- Pre-treatment verification and/or in-vivo verification

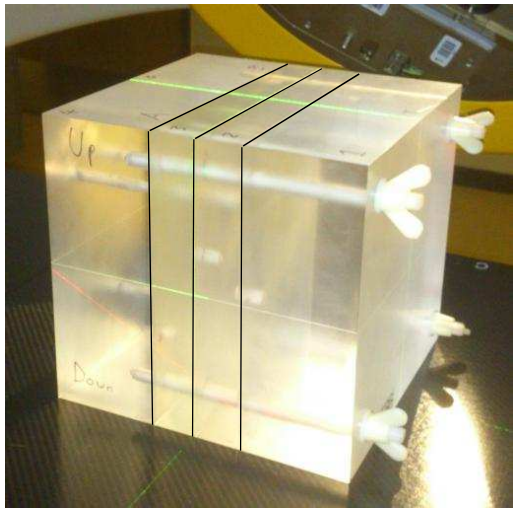
2D verification systems: detector arrays

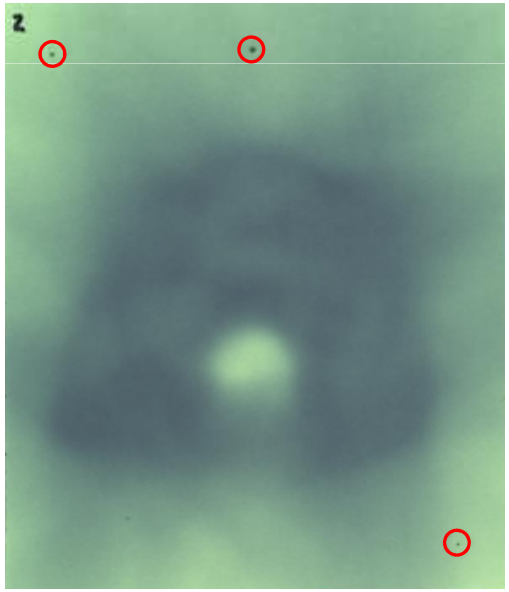
- Detector arrays can be integrated in a phantom or attached to the gantry
- Patient plan copied, unmodified, onto a phantom scan and the dose calculated. This 'hybrid' plan is compared to measurement.
- Convenient, large sample of measurement points

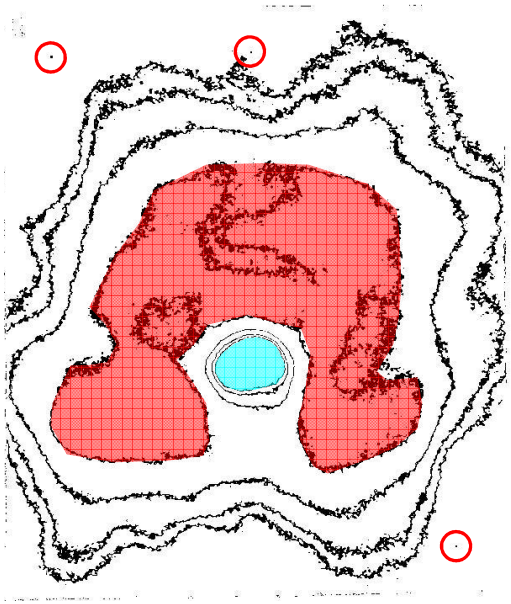


2D verification systems: Radiochromic film

- Radiographic film was used extensively at the dawn of IMRT
- Today radiochromic film more commonly used
- Great spatial resolution, less convenient than detector arrays
- Allows verification of steep dose gradients



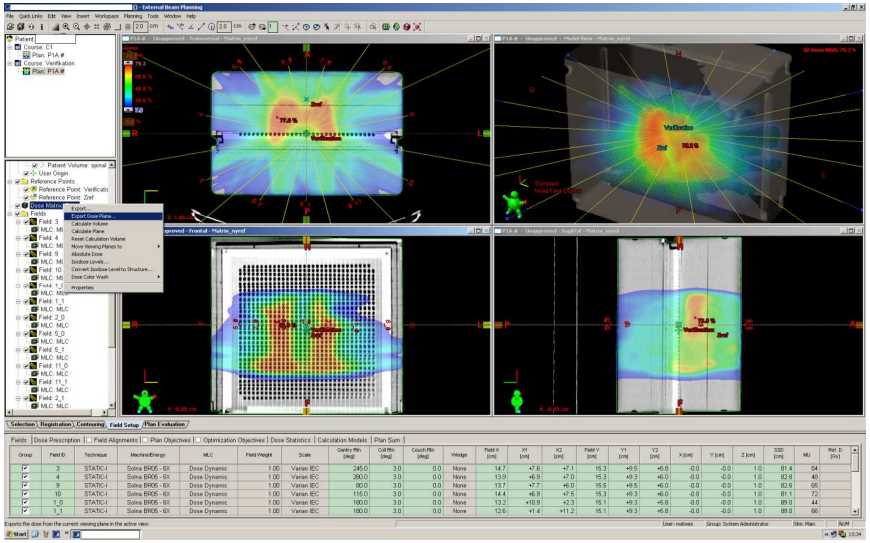


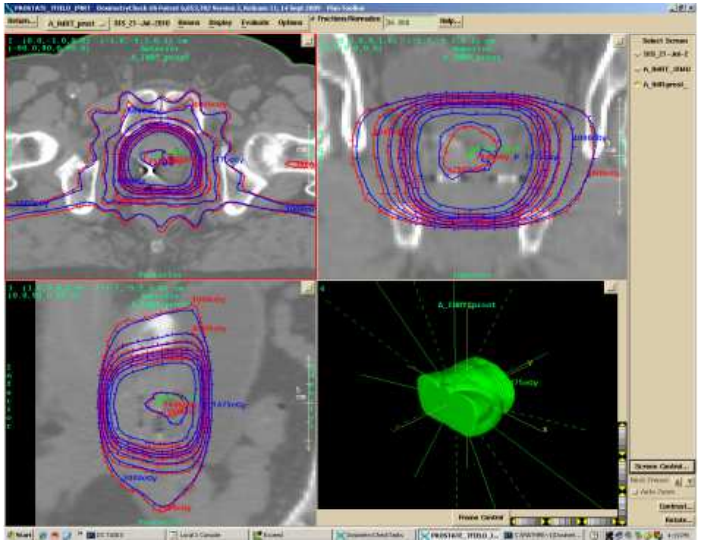


Courtesy Jonny Lee

2D verification systems: EPID

- The electronic portal imaging device (EPID) can be used for dose measurement, if correctly calibrated
- Higher resolution than detector arrays, not independent of gantry rotation
- Quick and convenient measurement, potentially integrated analysis tools
- Can also measure the exit dose during treatment: 3D in-vivo dosimetry





3D verification systems

A few 3D dosimetry systems available:

- Ferrous gel (Fricke)
- Polymer gels (PAG)
- Radiochromic plastics (Presage)

Read-out with MRI or optical CT

Takes time and requires specific equipent and expertise

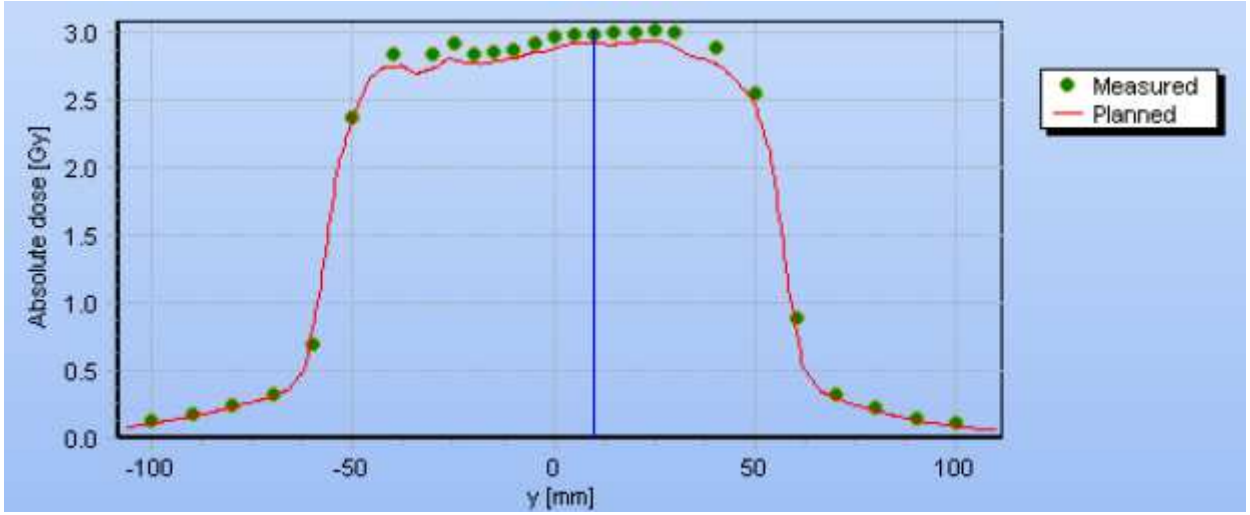
Suitable for commissioning/end-to-end tests rather than patient-specific QA

Vandecasteele PhysMedBiol 2013

ESTRO School

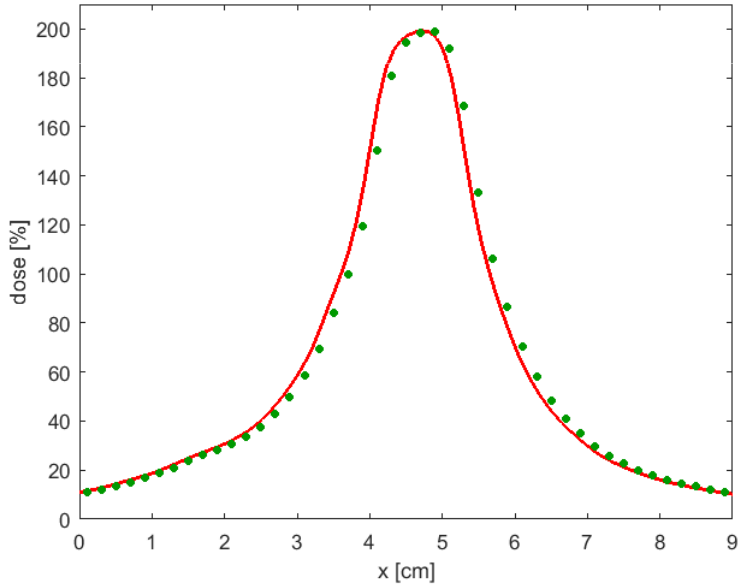
Data analysis: local dose difference

- IMRT verification measurements need to be compared to planned 3D dose distributions
- Agreement can be assessed qualitatively by overlaying isodose lines or comparing dose profiles
- Quantitative evaluation of many measurement points?



Data anlysis: DTA

- Dose difference can be large at steep dose gradients for realistic phantom set-up uncertainties
- Distance to agreement (DTA) between pixel/voxel values a more relevant measure



ESTRO School

Data analysis: gamma index

A gamma analysis compares each calculated value to all measured values, both in terms of dose deviation and DTA.

$$\Gamma(r_m, r_c) = \sqrt{\frac{r^2(r_m, r_c)}{\Delta d_m^2} + \frac{\delta^2(r_m, r_c)}{\Delta D_m^2}}$$

- r_m= point in measured distribution
- r_c= point in caculated distribution
- $r(r_m,r_c)$= distance between r_m and r_c
- $\delta(r_m,r_c)$= dose deviation in r_m to r_c
- Δd_m= DTA criterion
- ΔD_m= dose deviation criterion

For each r_m, the r_c with the lowest gamma value is identified.

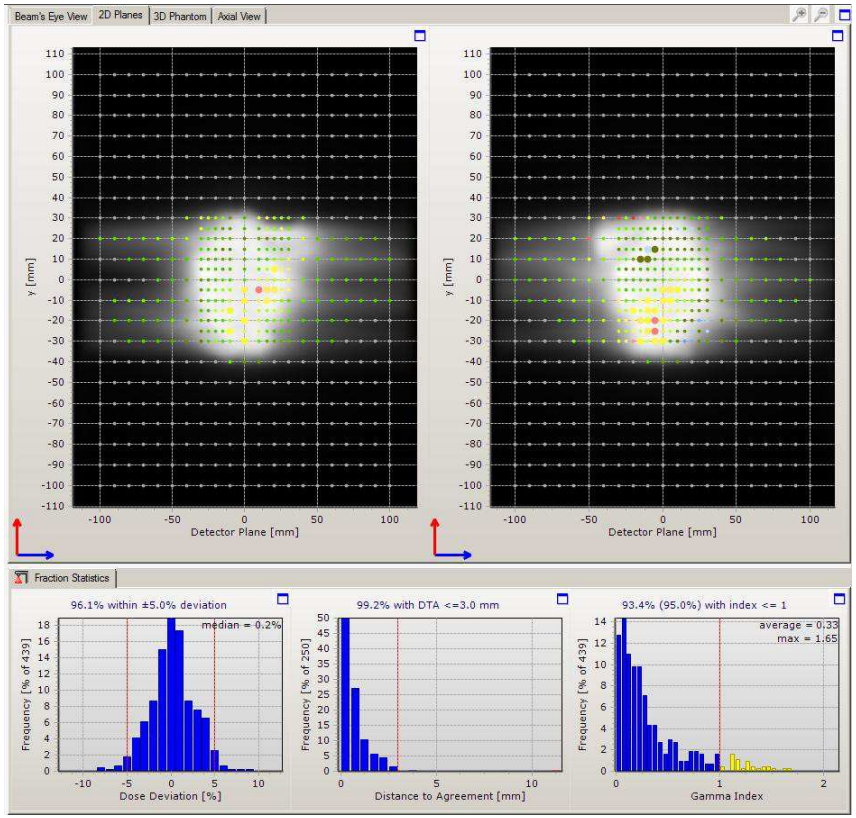
$$\gamma(r_m) = \min\{\Gamma(r_m, r_c)\} \forall \{r_c\}$$

All r_m with $\gamma \leq 1$ have passed the combined gamma criterion. The percentage of acceptable γ-values can be used as an over all agreement measure.

Gamma analysis considerations

- Local or global dose deviation can be used
  - Global: deviation expressed as percentage of maximum or prescribed dose
  - Local: deviation expressed as percentage of local dose
  - Global dose deviation more forgiving, especially in low-dose region
- Gamma analysis fails extensively in the low-dose region, but this may not be of interest: cut-off often applied
- Can be performed in 2D or 3D: slightly better pass rates with 3D
- Adjustment for the linac output of the day?
- Adjust spatial registration of dose distributions for best result?

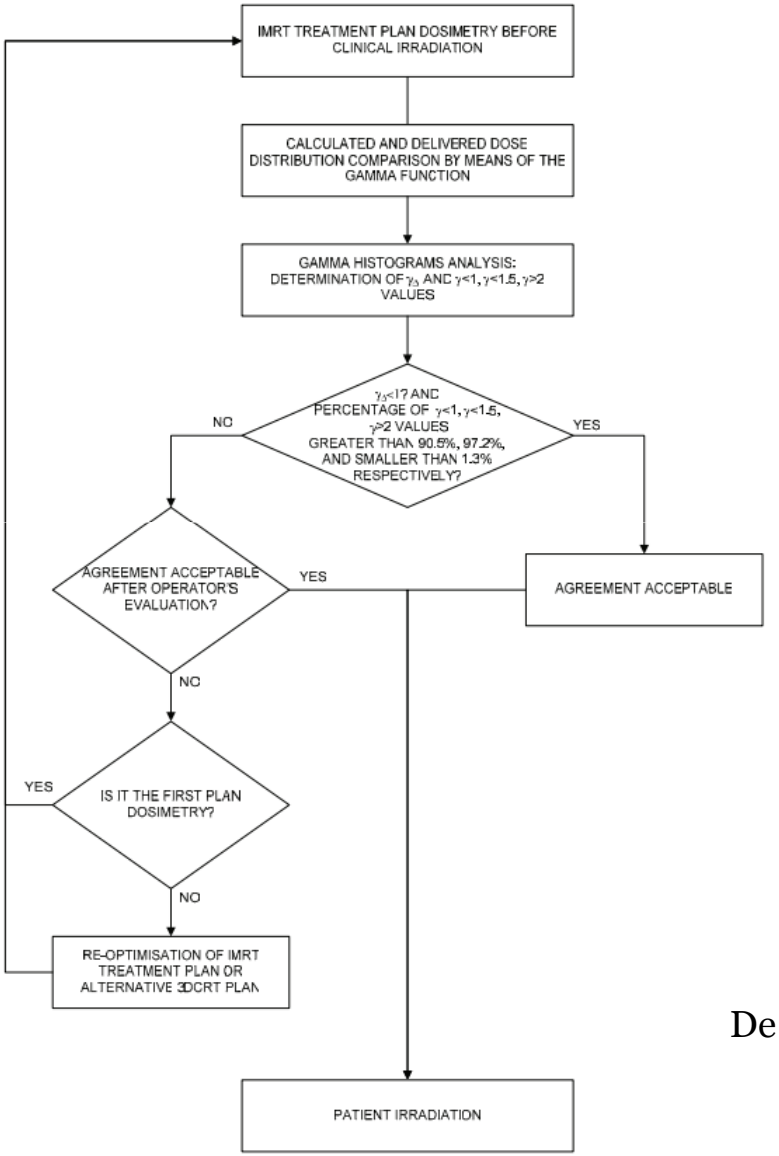
Example



- 5%/3mm gamma analysis of VMAT plan
- 2D analysis with the Delta4 system
- Low-dose cut-off
- Pass rate: 93.4%
- Failed the 95% limit of the clinic

ESTRO School

Decision protocol



De Martin et a. RadiotOncol 2007

Comparison between QA solutions

TABLE III. Comparison between calculated and measured dose distributions. Percentage of points satisfying Γ (3%, 3 mm) <1: Statistics for all plans and all dosimetric systems. The average pass-rate obtained over seven ERGO++ and seven Oncentra plans optimized for the same treatment cases is shown separately, and indicated as comparative study.

	ERGO++				Oncentra Vmat			
	All plans	Average (%) Comparative study	Max (%)	Min (%)	All plans	Average (%) Comparative study	Max (%)	Min (%)
EDR2	95.1	96.1	100.0	83.0				
EBT2	91.1	92.9	98.5	80.0	91.7	92.1	98.9	85.2
MAPCHECK	97.4	98.0	100.0	92.0	96.3	97.8	99.7	86.2
DELTA4	99.3	99.4	100.0	93.0	95.4	96.2	100.0	89.3
SEVEN29	99.6	99.8	100.0	99.1	98.0	97.5	100.0	88.0

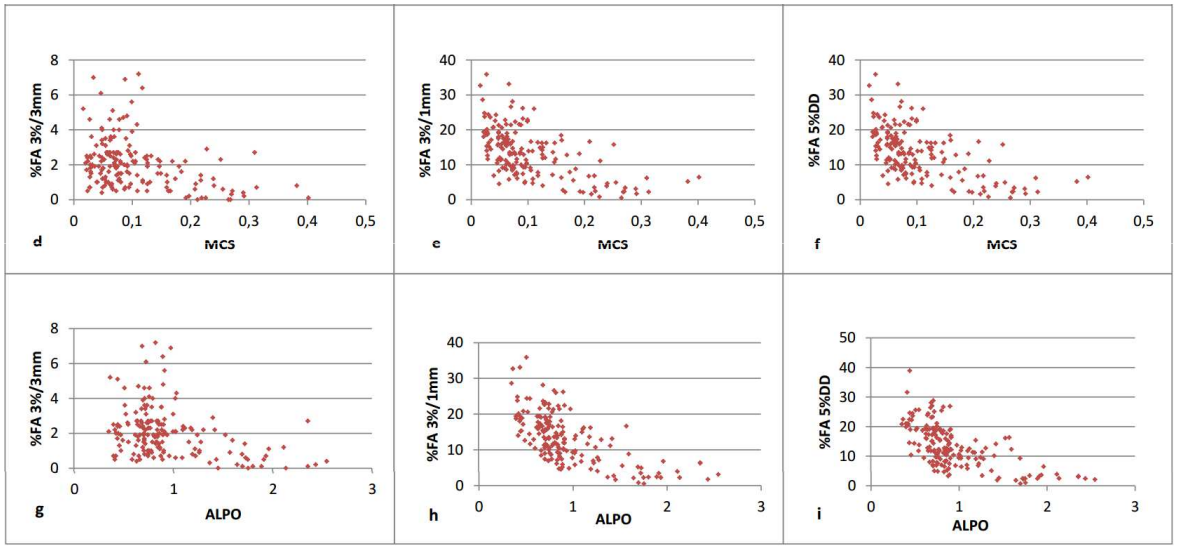
Masi et al. Medical Physics 2011

Gamma analysis physically relevant?

- What do we want to detect with patient-specific QA?
- Do we have confidence in our MLCs?
  - Perhaps better addressed with machine QA
  - Thourough commissioning of IMRT with challenging plans and several measurement systems
  - Constancy checks with challenging plan
- Do we have confidence in our dose calculation algorithm?
  - Aware of limitations
  - Impact depends strongly on the individual plan
  - The gamma index seems to correlate with plan complexity/modulation
  - Gamma pass rates can probably highlight challenging cases

Robust IMRT plans

- The Gothenburg group is looking at correlations of the gamma index to the modulation complexity score (MCS), and the average leaf pair opening (ALPO)



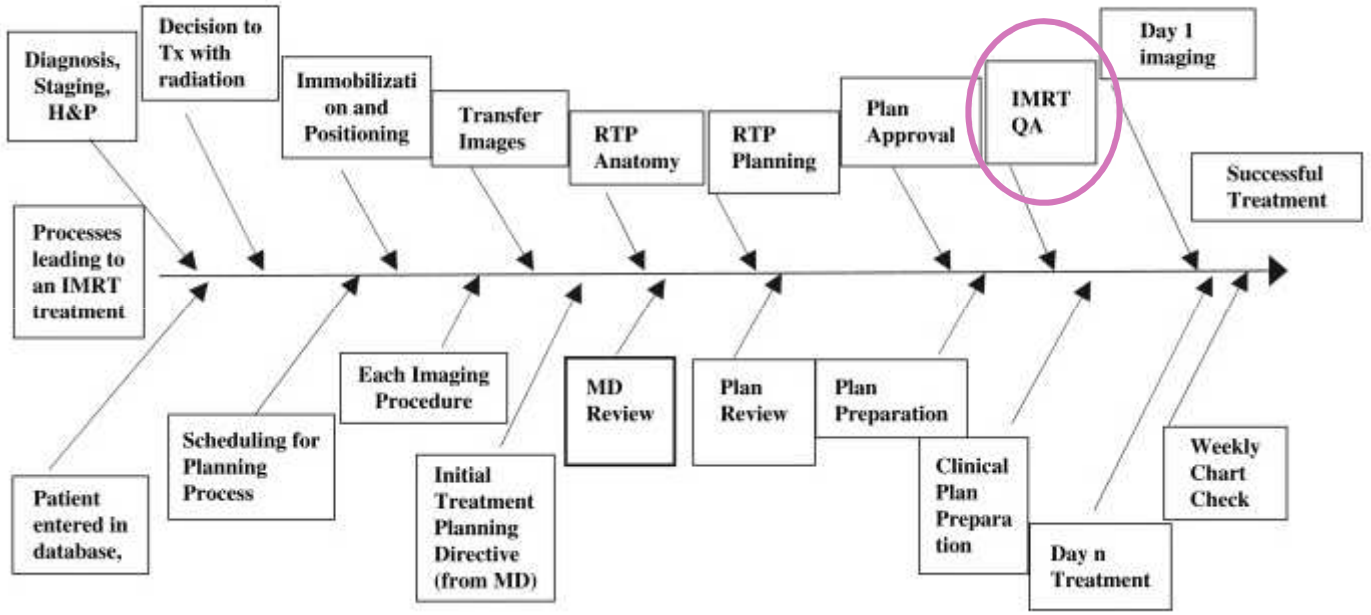
Olofsson, MSc thesis 2012

- For purposes of robustness, don't use more modulation than necessary
- Larger beamlets result in a better agreement between planned and delivered dose, and mitigates the interplay effect

Gamma analysis clinically relevant?

- Studies have shown that clinically relevant parameters do not correlate well with gamma pass rates (Nelms et al. MedPhys 2011, Carver et al. RadiatOncol 2011)
- Dose deviation tolerance usually at a few percent
- Tumour control probability depends strongly on the dose deviation
- Comparison of isodoses is important for critical organs at risk
- Not sensitive to small systematic differences

One piece of the puzzle

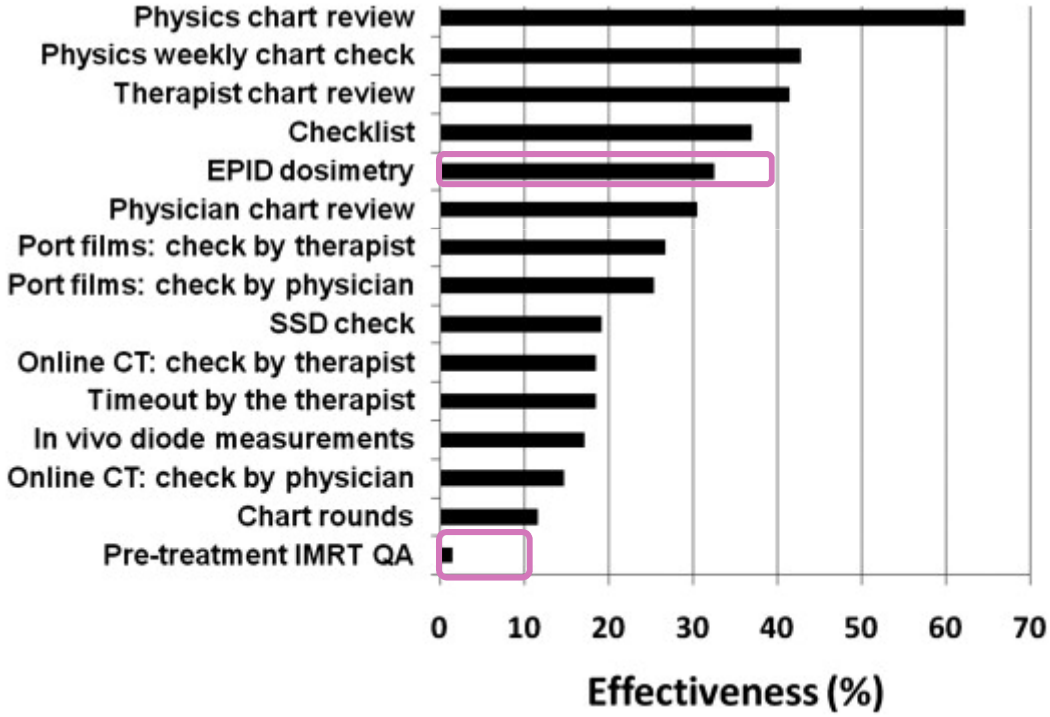


Huq et al. IJROBP 2008

Error-detection efficiency

Few errors are spotted using pre-treatment IMRT QA.

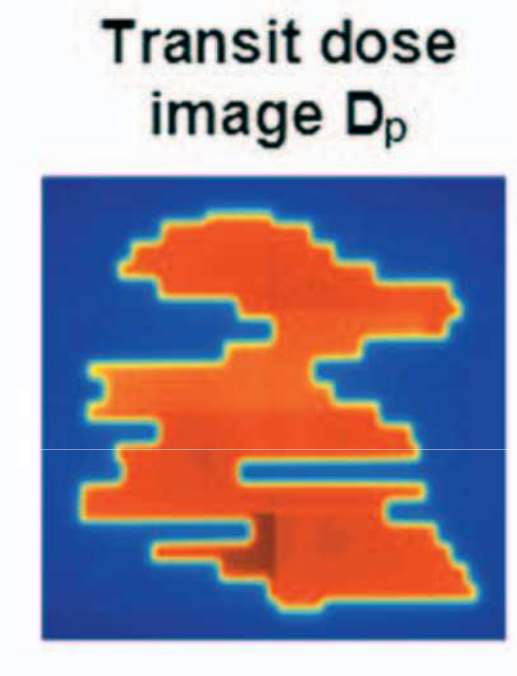
EPID-based in-vivo dosimetry ranks highly, on the other hand.



Ford et al. IJROBP 2012

Transit dosimetry

- Transit dose measurement with the electronic portal imaging device (EPID)
- 2D: model to convert gray scale image to portal dose
- 3D: Reconstruction of dose in 3D using CBCT
- In-vivo dosimetry using only the equipment integrated on the linac, using the treatment field itself
- Commercial solutions being developed
- Generates a huge amount of data to be analysed
- Do we know how to address discrepancies?



Nijsten MedPhys 2007

Conclusions

- Ideally, in-vivo plan verification should be performed for all techniques
- IMRT potentially pushes the delivery- and planning equipments to their limits
- Confidence in the whole chain should be built through, at least, patient-specific pre-treatment plan verification
- Convenient 'IMRT QA' systems exist
- Gamma analysis is useful for a high-throughput QA programme
- Limitations of the gamma index require attention to dose deviation in selected cases
- Consider patient-specific QA as one among several important components of the QA programme

Conclusions cont.

After initial successful learning phase, the QA programme might consist of:

- Regular machine QC, including dynamic MLC tests
- Monthly challenging standard plan measurement
- Secondary dose calculation of all plans
- Ideally, if possible, in-vivo dosimetry for all patients
- For new class solutions: patient-specific pre-treatment measurements for some time

Geometric uncertainties in IMRT

Koen Tournel - Physicist
Radiotherapy Department UZ Brussel

ESTRO School

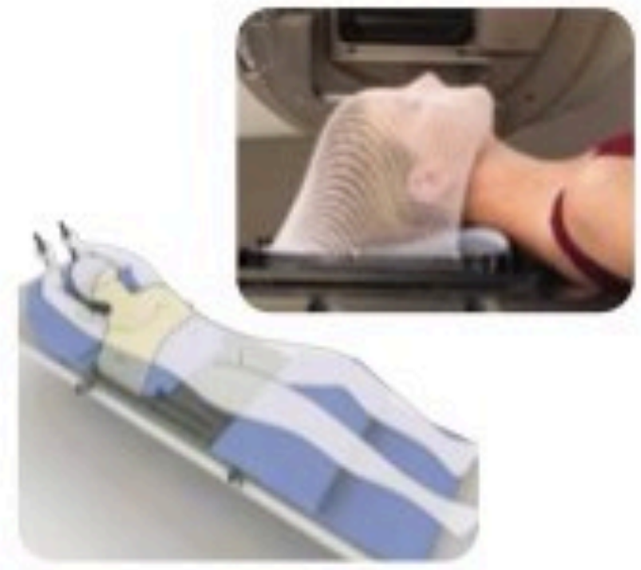
‘The snapshot paradigm’

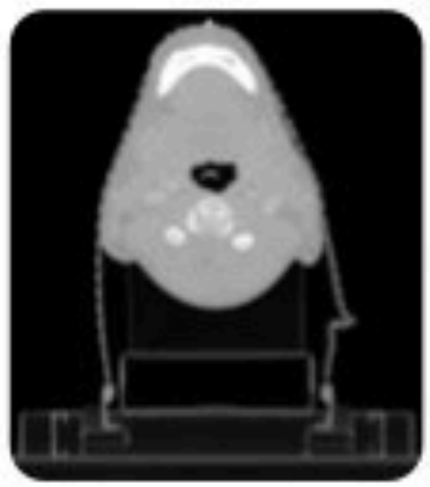
Simulation

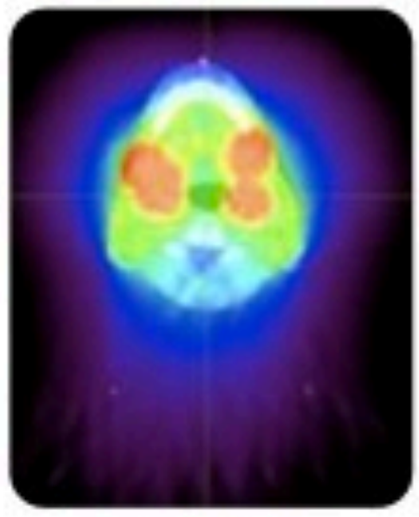
Planning CT

Treatment Planning

Treatment

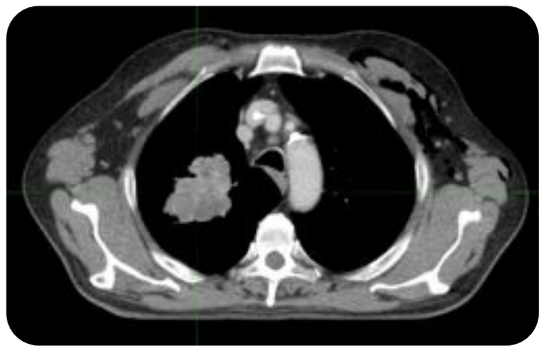


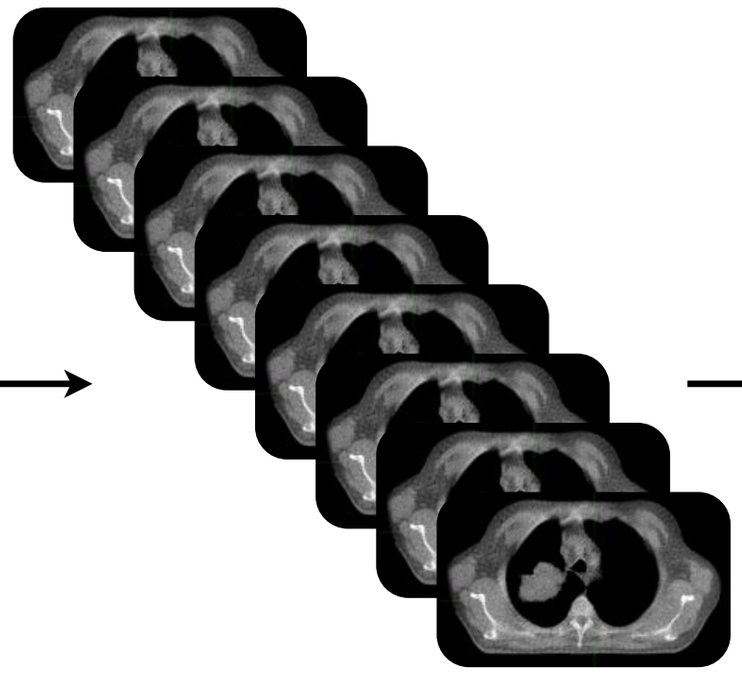




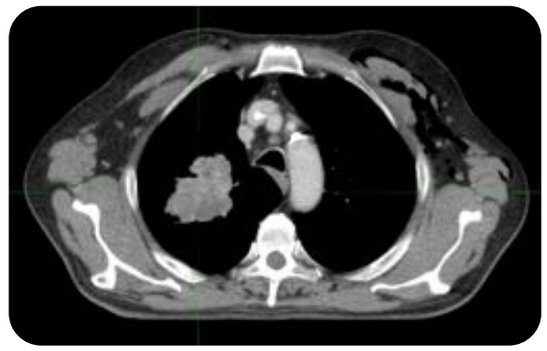
Treatment fractions

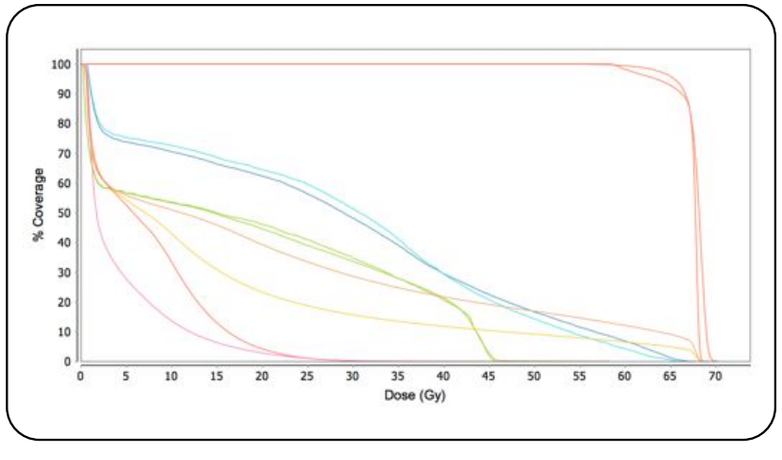
Start

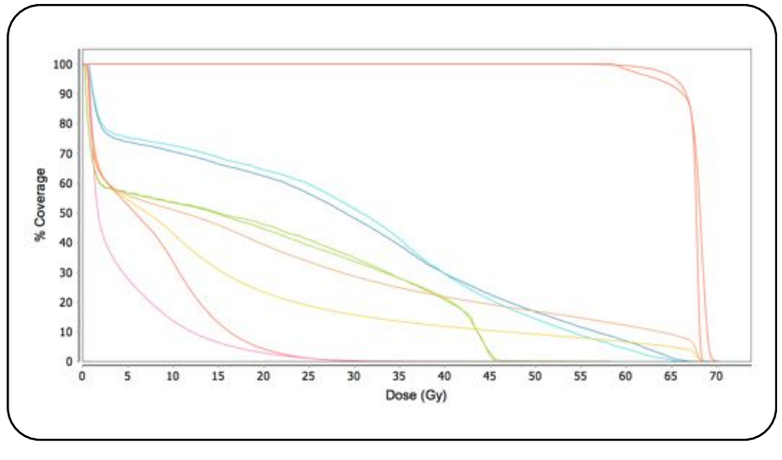




End





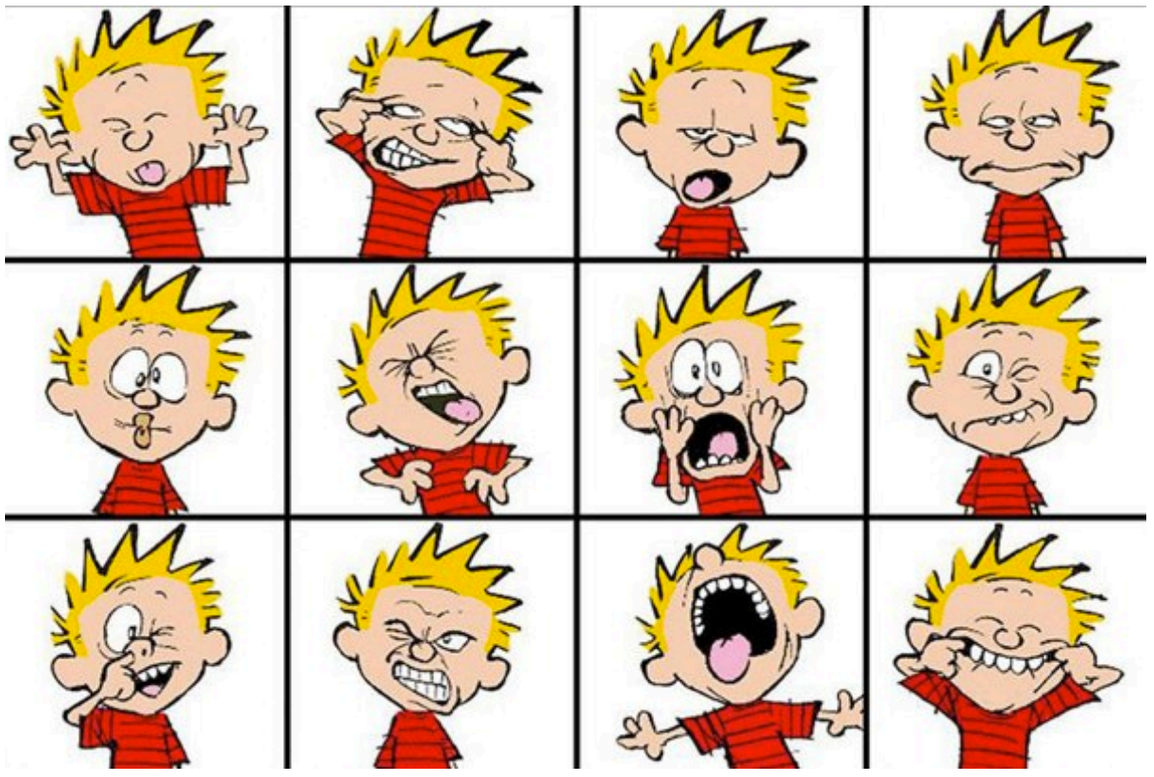


Problem

- IMRT planning is based on a -well defined and researched - snapshot of reality.
- This snapshot has to be reproduced during the entire treatment chain.
- This ain't just gonna happen....we can't be that lucky

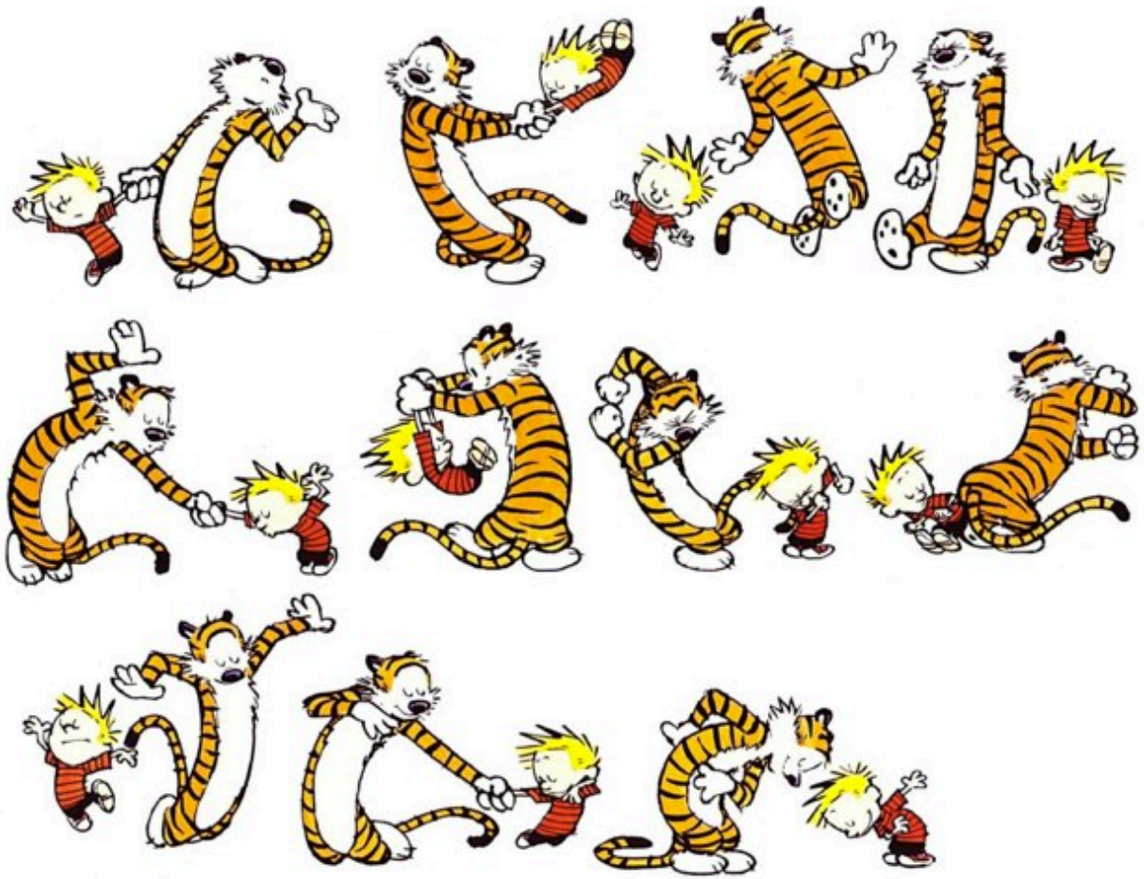
Types of uncertainties

- Movement
  - (Rigid)Interfractional (positioning errors)
  - The position/shape of our tumor will vary day by day



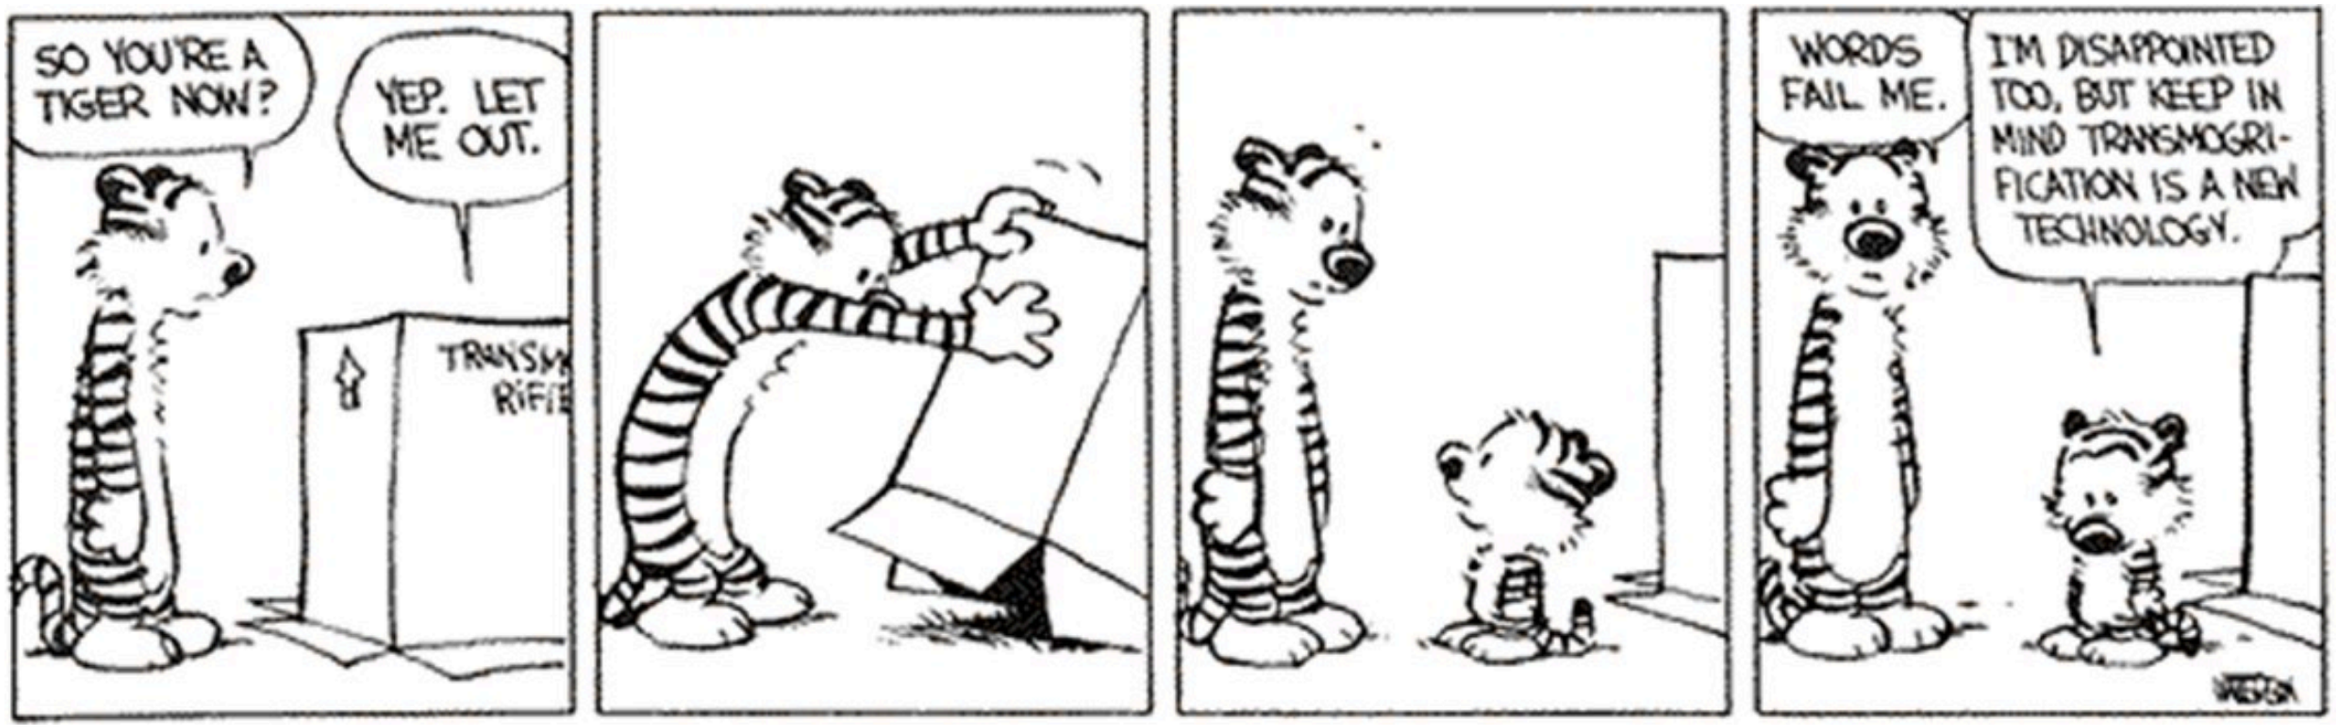
Types of uncertainties

- Movement
  - Intrafractional (periodic or non-periodic)
  - Tumor and OAR are moving while we are treating them

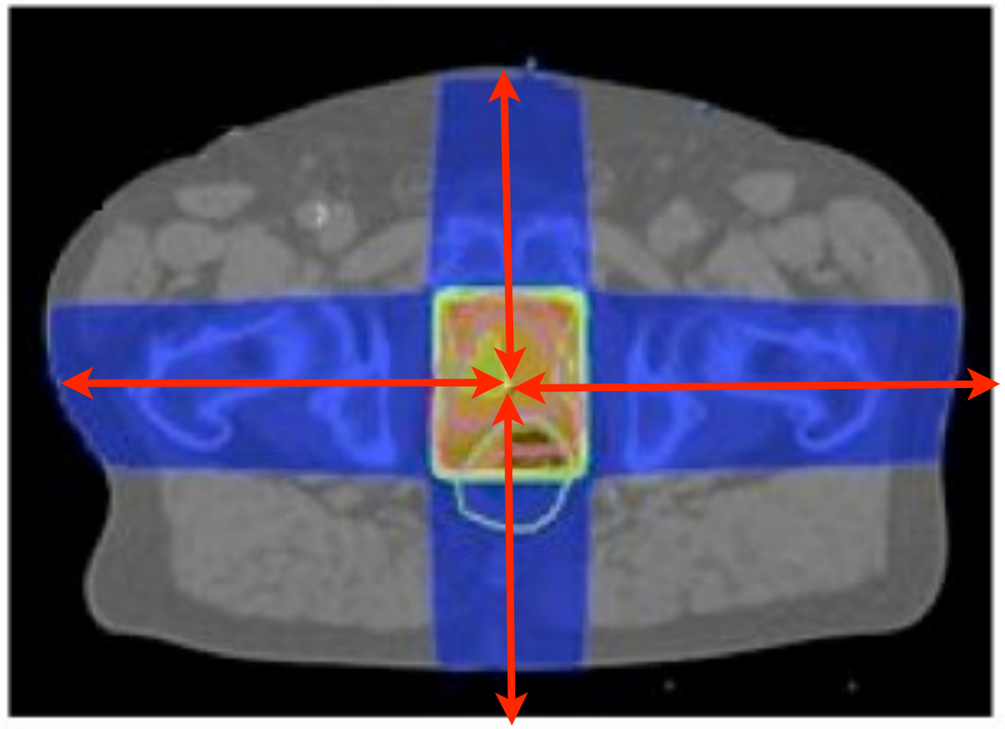


Types of uncertainties

- Deformation
  - Tumors and OARs will change shape



What do we do in normal conventional RT?



Open fields, normalized at isocenter, MU scaled on beam axis.

Conventional RT

- For movement there's the PTV concept.
- Minimization through movement management
  - IGRT, off-line/on line protocols
  - Gating/tracking
- Dose delivery will not change a lot when the radiological pathlength of the central axis does not change a lot
- Robustness of the dose

Patient geometric uncertainties: homogeneous dose distributions

$$\mathbf{m_{ptv}} = \alpha\Sigma + \beta\sigma - \beta\sigma_{\mathbf{p}}$$

Systematic errors

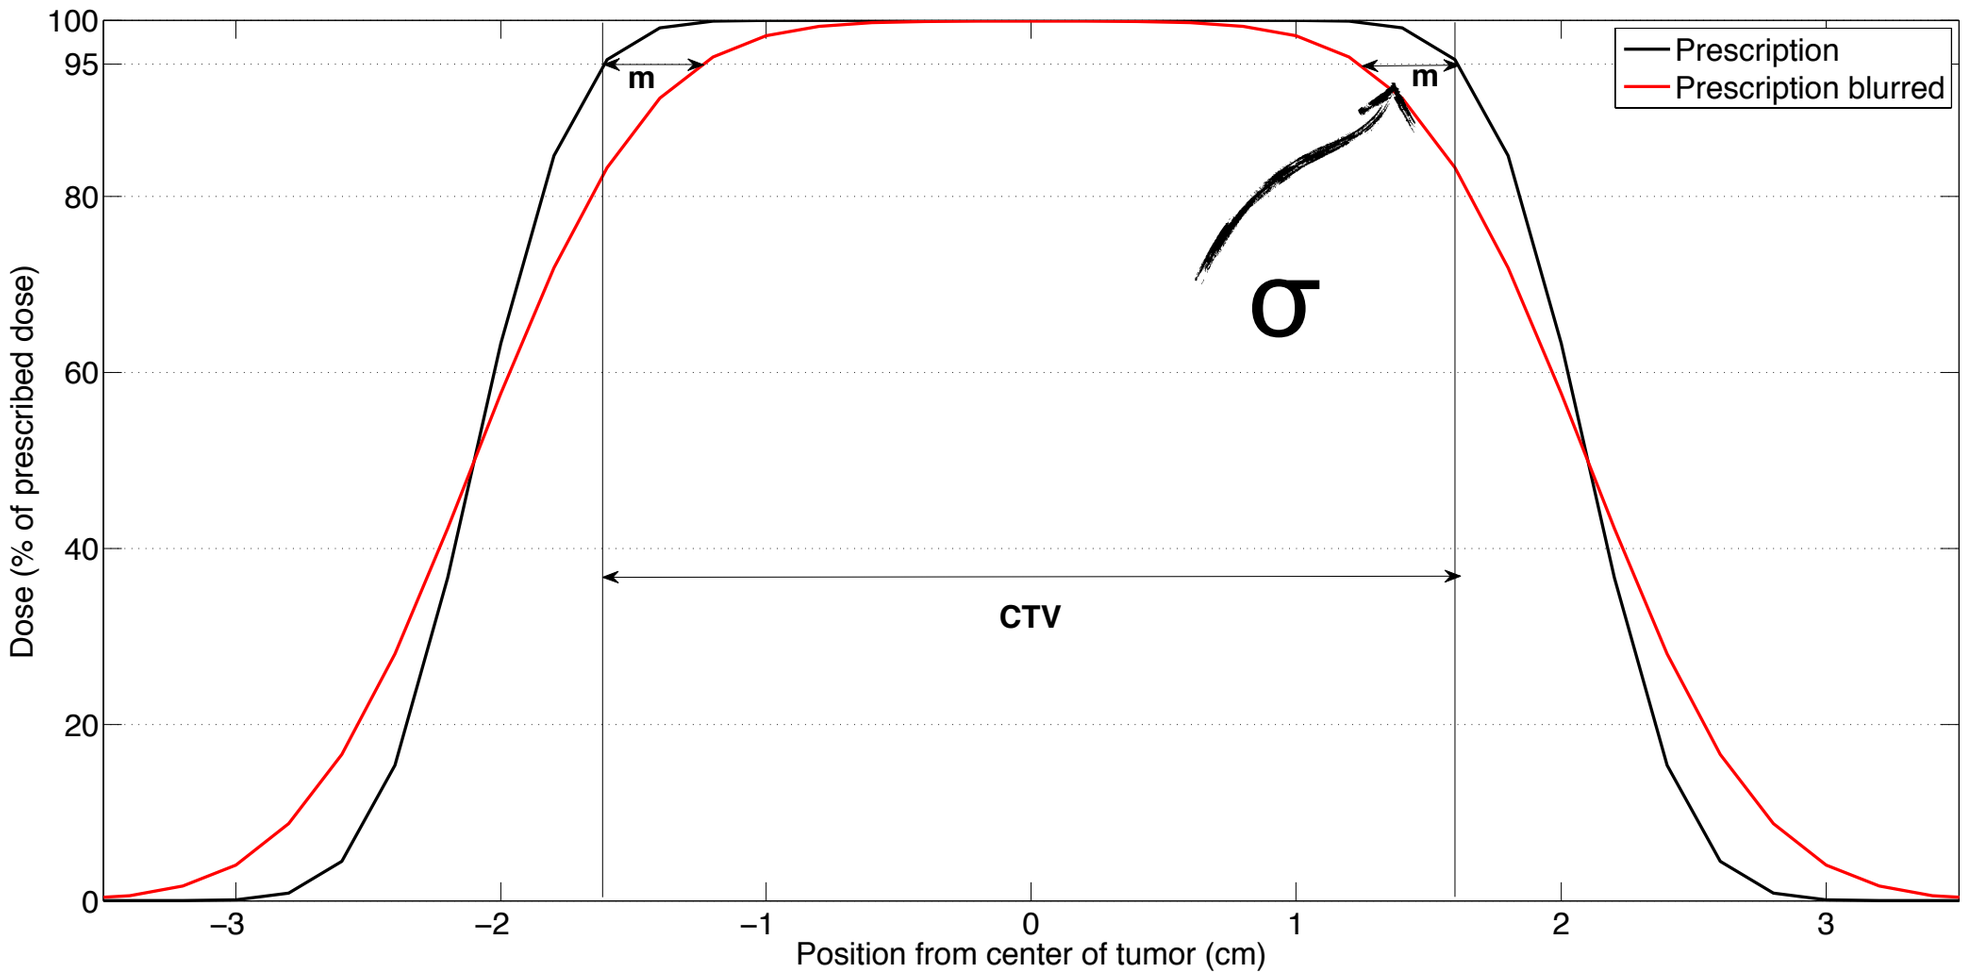
Random errors

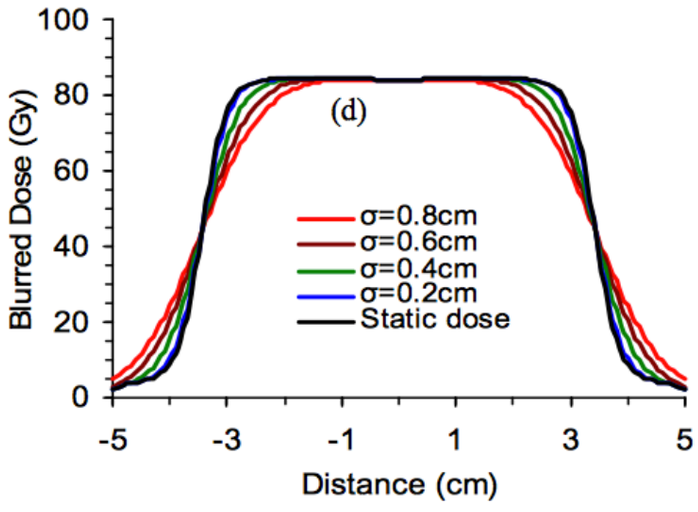
Shift

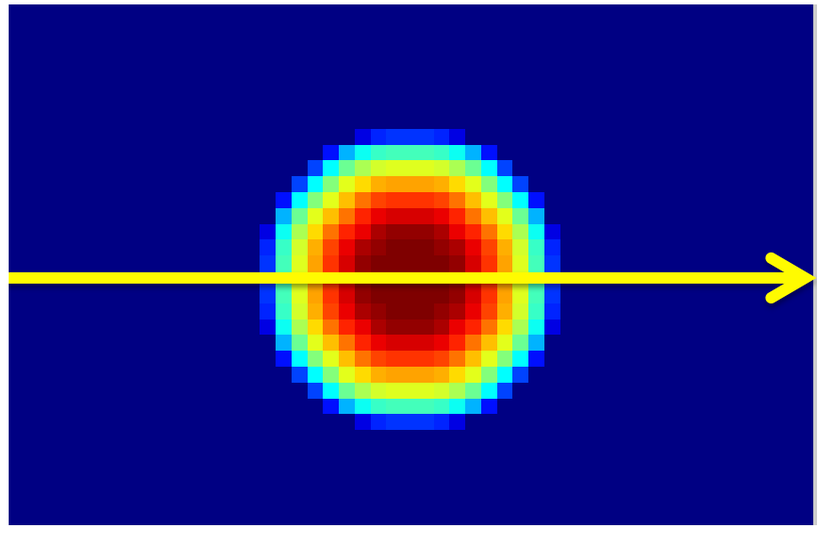
Smoothing

Assuming margins such that 90% of the population receives 95% of prescribed dose α=2.5 and β=1.64 (Van Herk et al)

effect of random errors - homogeneous precription

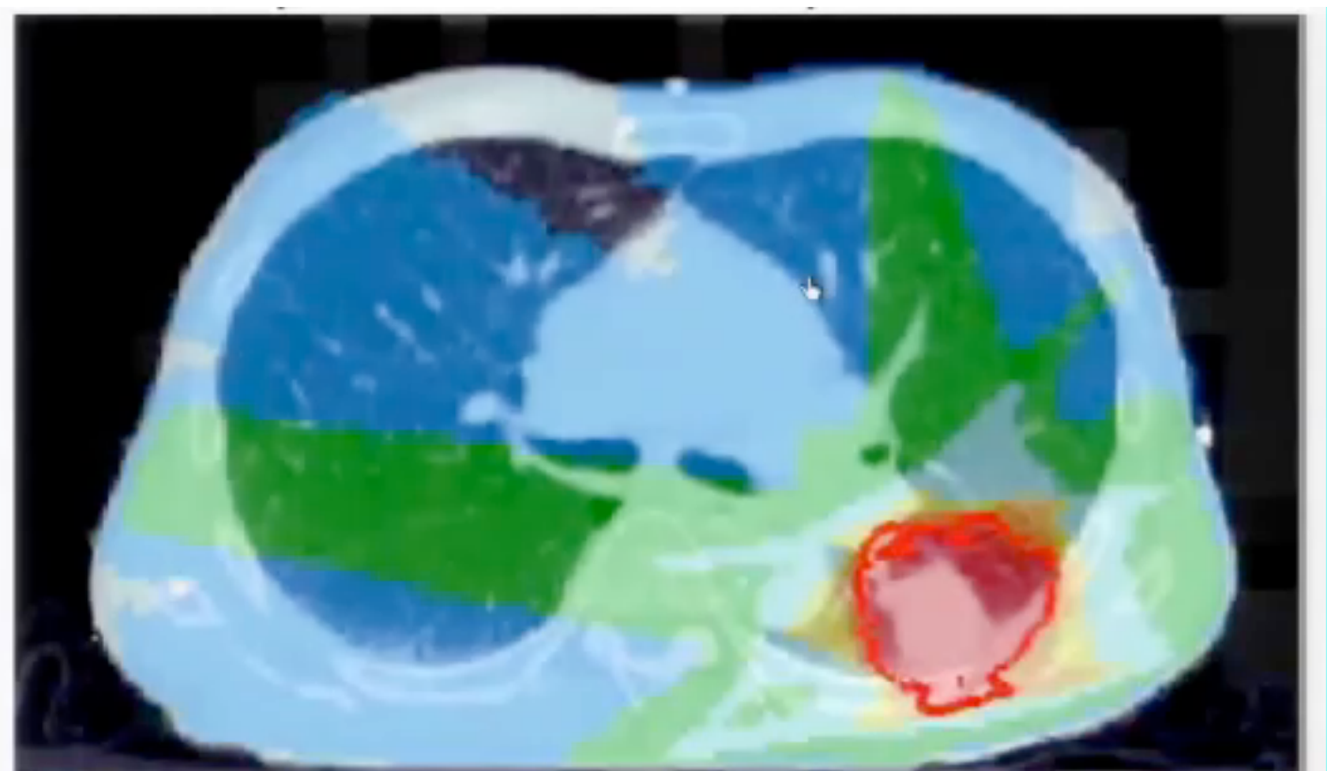






“Dose Cloud”

- Movement inside our nice, homogeneous dose region....robustness.
- In other phases dose will deform, but CTV will keep coverage



NO modulation

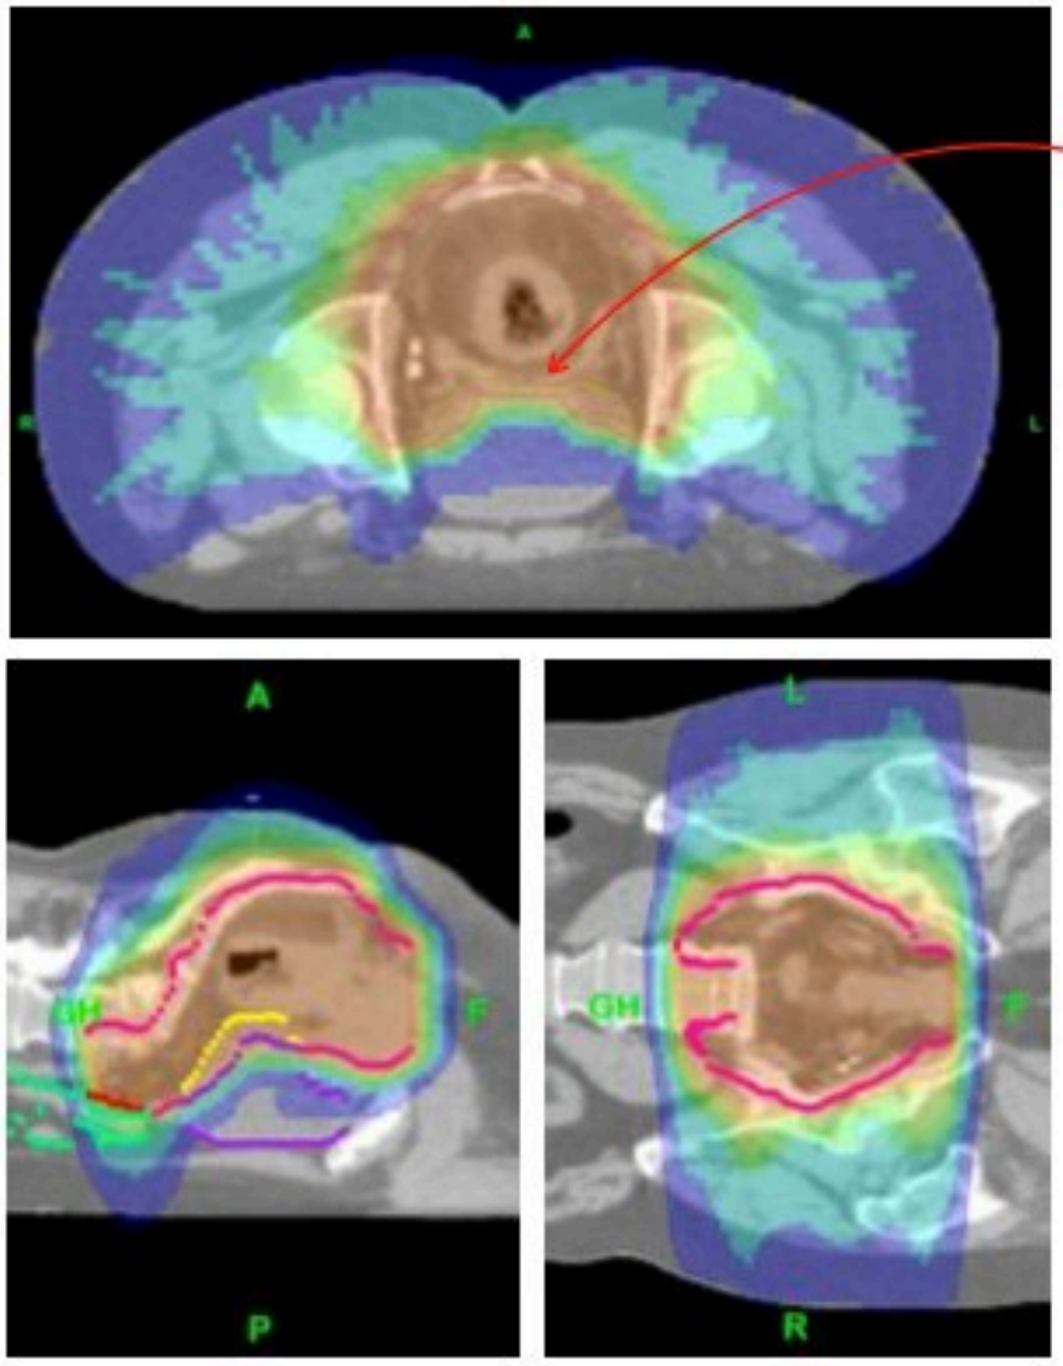
IMRT

- “More money, more problems”
- Beamlets are optimized on one particular pathlength, on particular scatter conditions

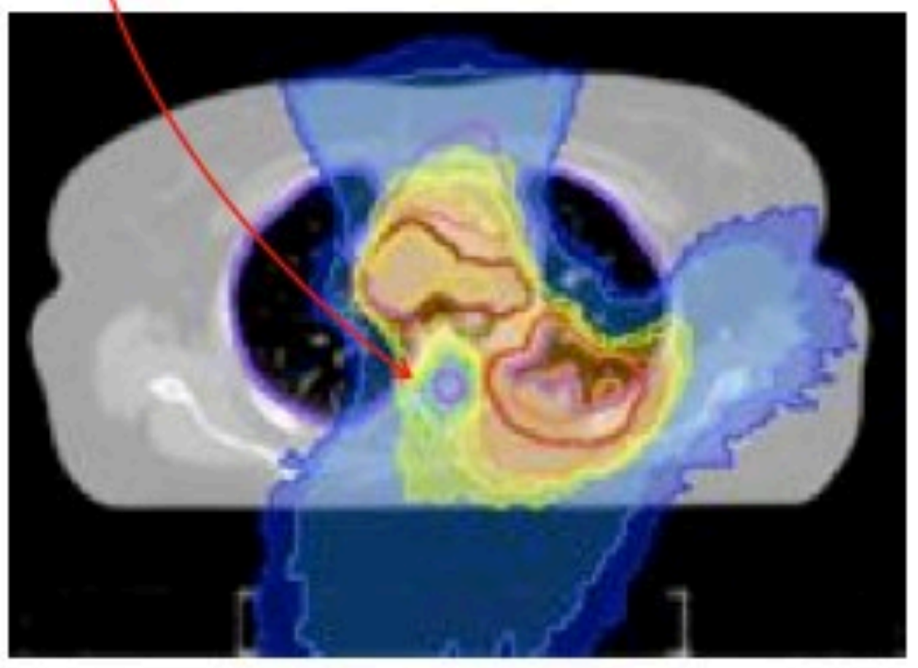
IMRT

- A lot of movement.
  - Tumor moves
  - OARs move
  - Leaves move (DMLC)
  - Gantry moves (VMAT/Tomo)
  - Table moves (Tomo/VMAT?)

All at different frequencies/speeds



Sharp gradients



(NO IMRT without IGRT)

The BIG question

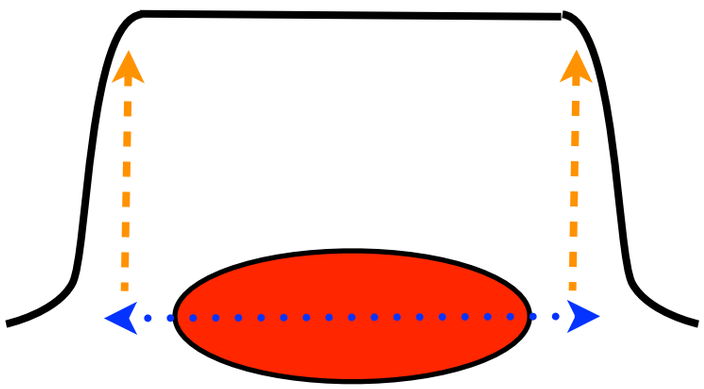
What is the effect of all of these geometric uncertainties on the IMRT dose distribution?

The answer

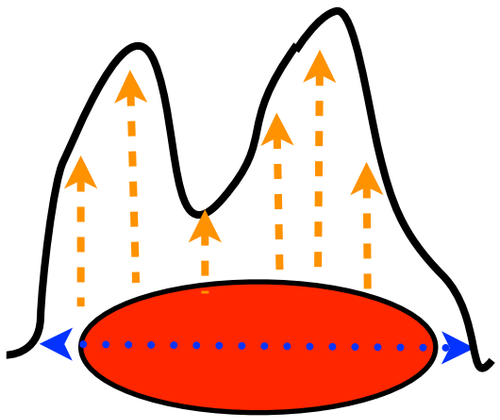
- ~~42~~
- Interfraction movement
- Intrafraction movement
- Deformation
- Robust Planning

PTV Margin?

Conventional



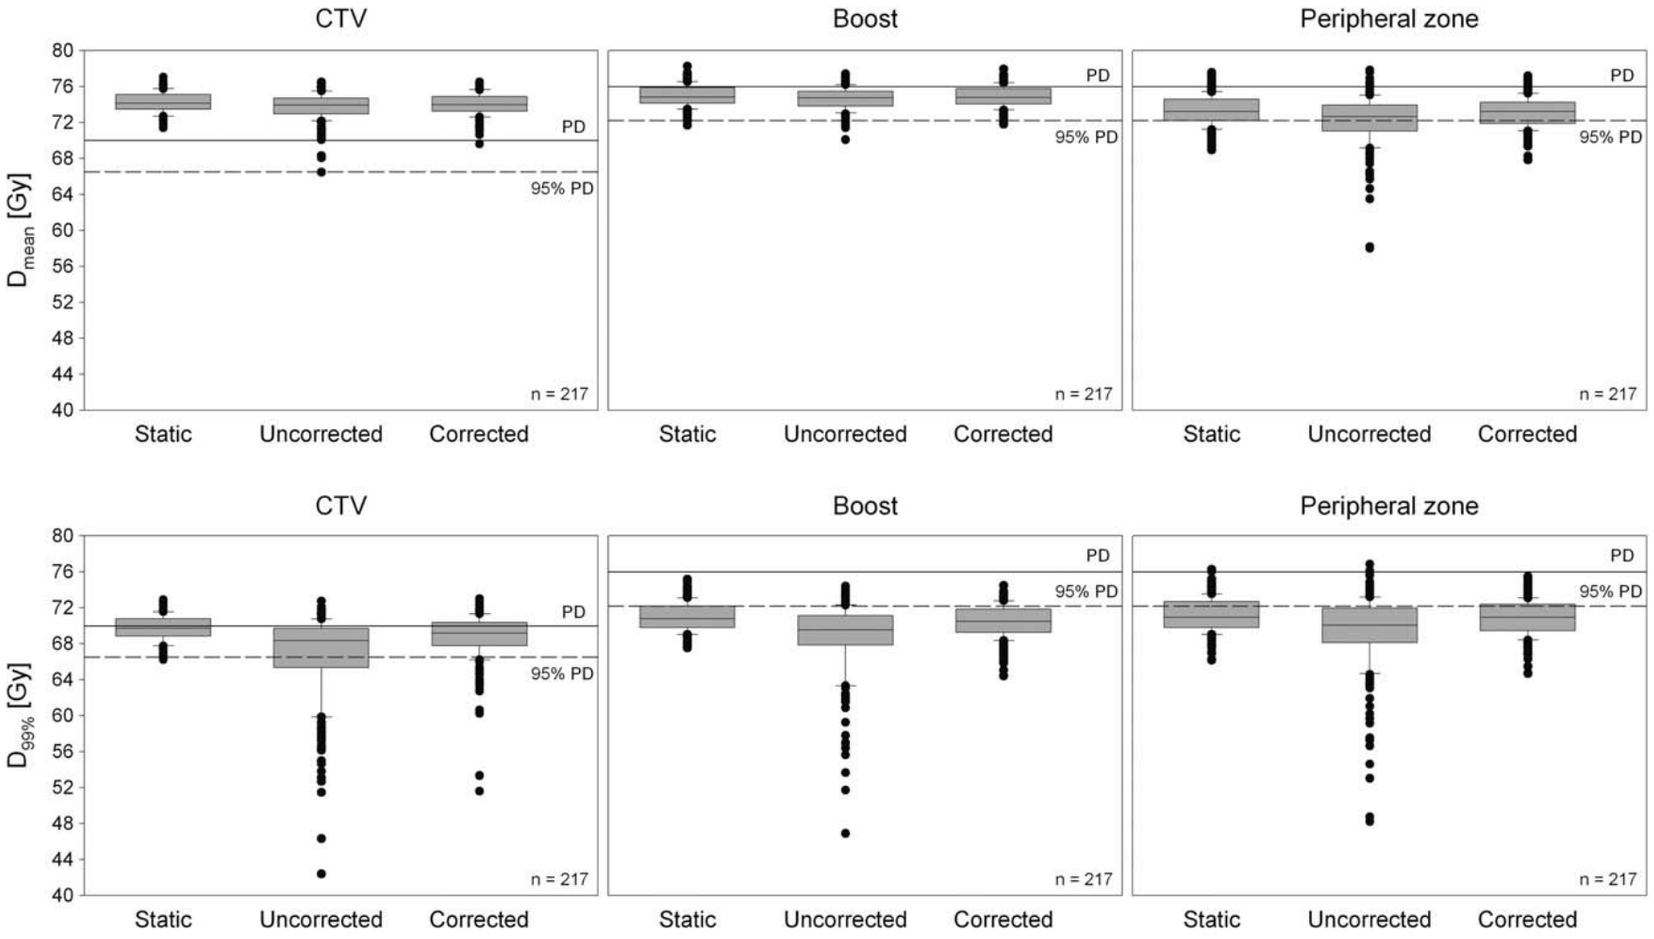
IMRT

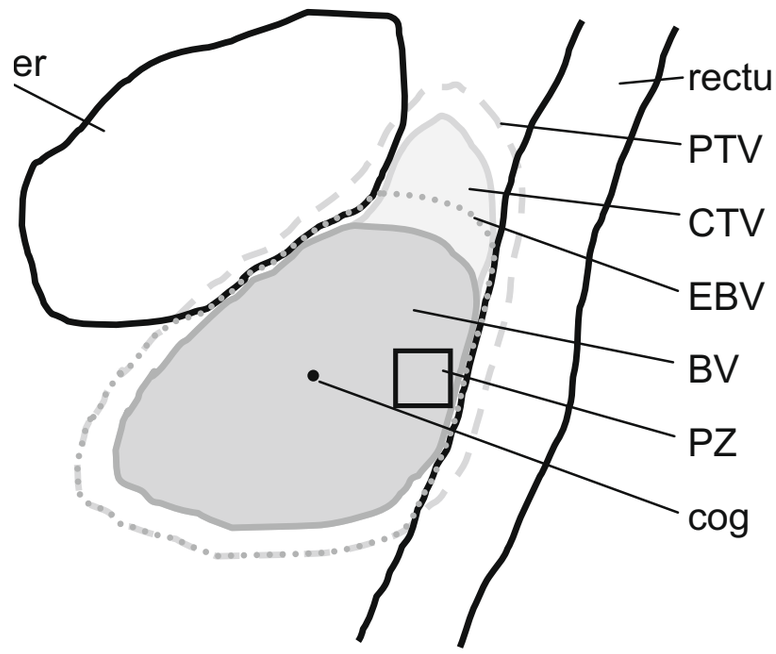


Interfraction Movement/setup errors

- NOT deformations
- Different effect of random and systematic errors
  - Systematic error : your gradient could end up somewhere else
  - random : averaging effect

Prostate





215 patients

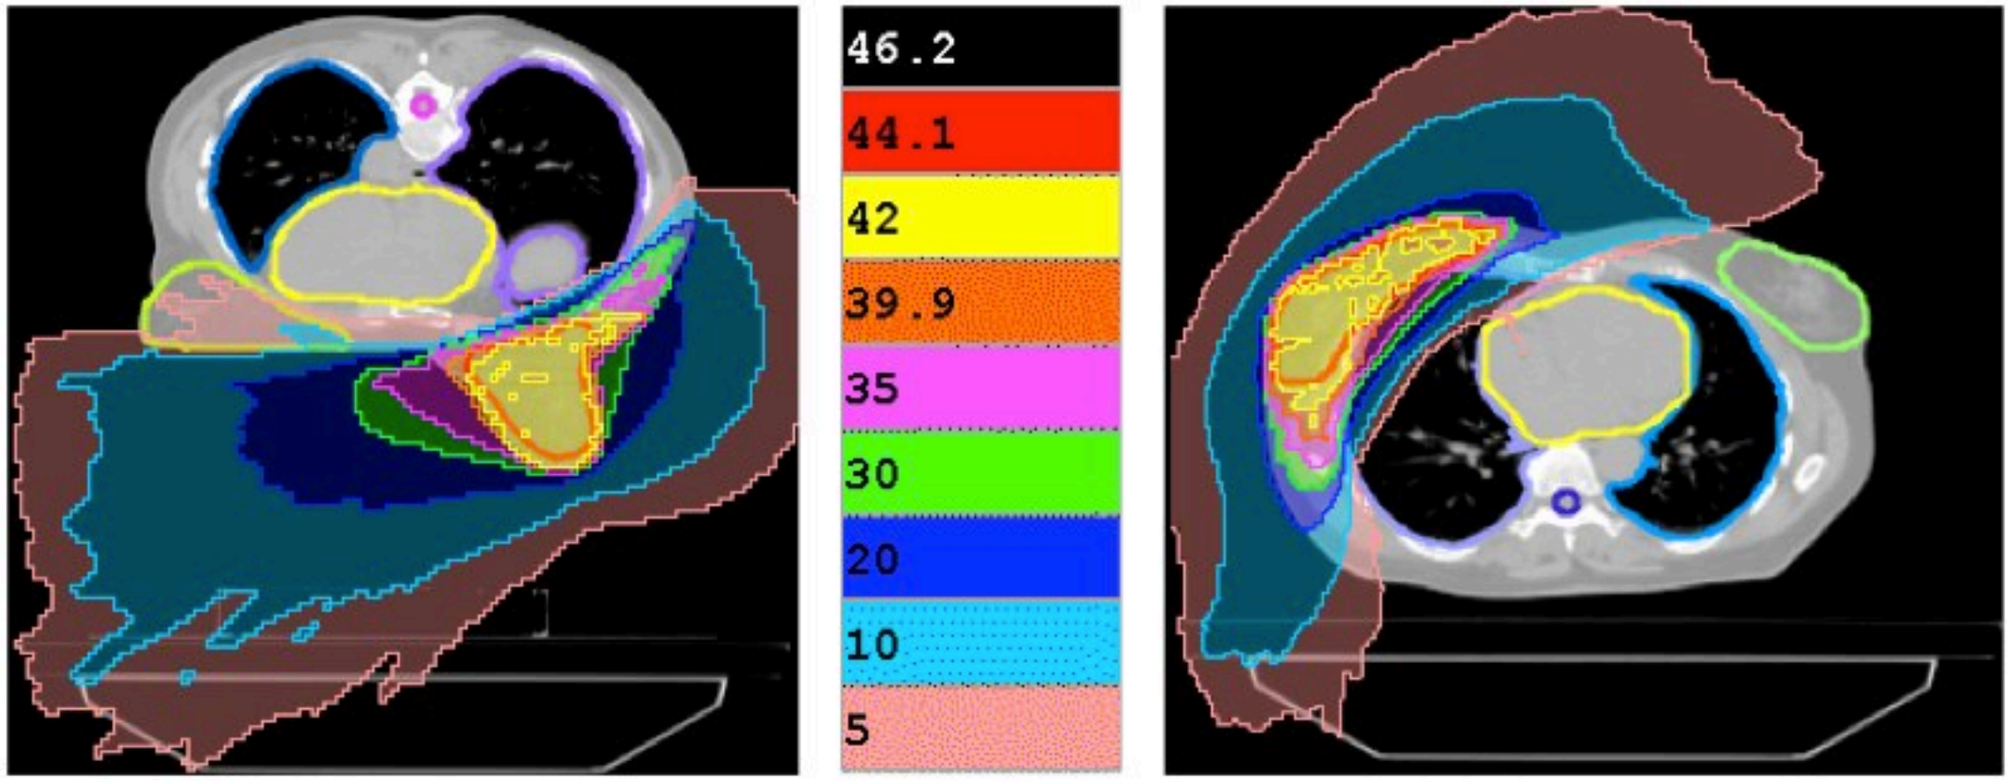
Changes can be accounted for by correction (IGRT) protocols or sufficient margins, when movement is limited <10mm

P.M.A. van Haaren et al./Radiotherapy and Oncology 90 (2009) 291–298

Prostate

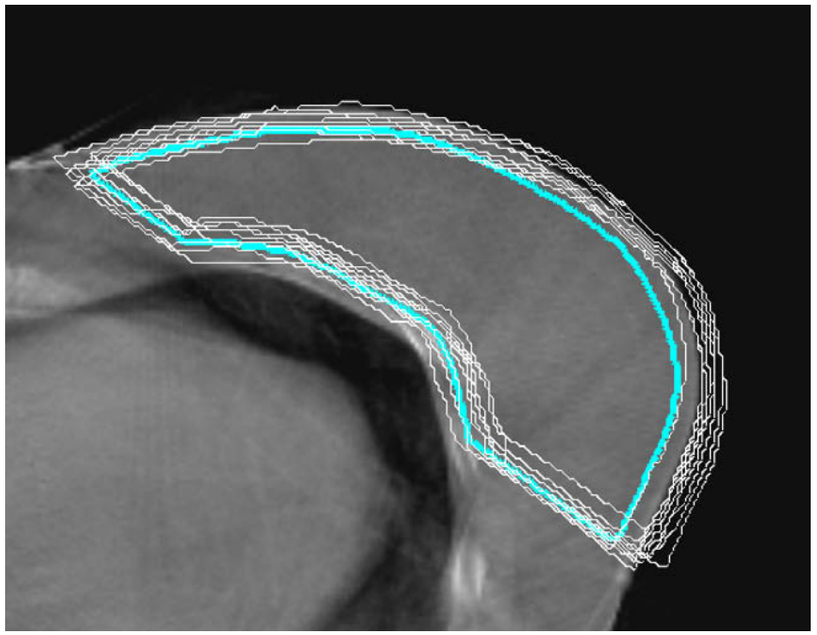
- "homogeneous region"
- Isodoselines are quite robust if the anatomy will not change.
- Watch out for systematic errors

Breast IMRT

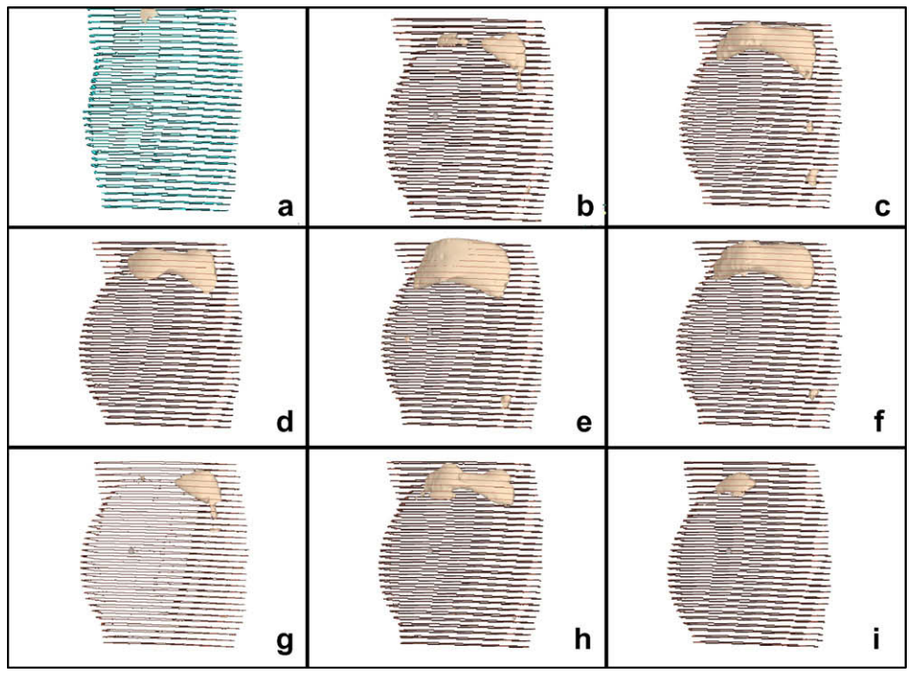


- Improves homogeneity
- You have to be sure that the extra few segments end up at the right place
- Susceptibility to movement?

Breast IMRT

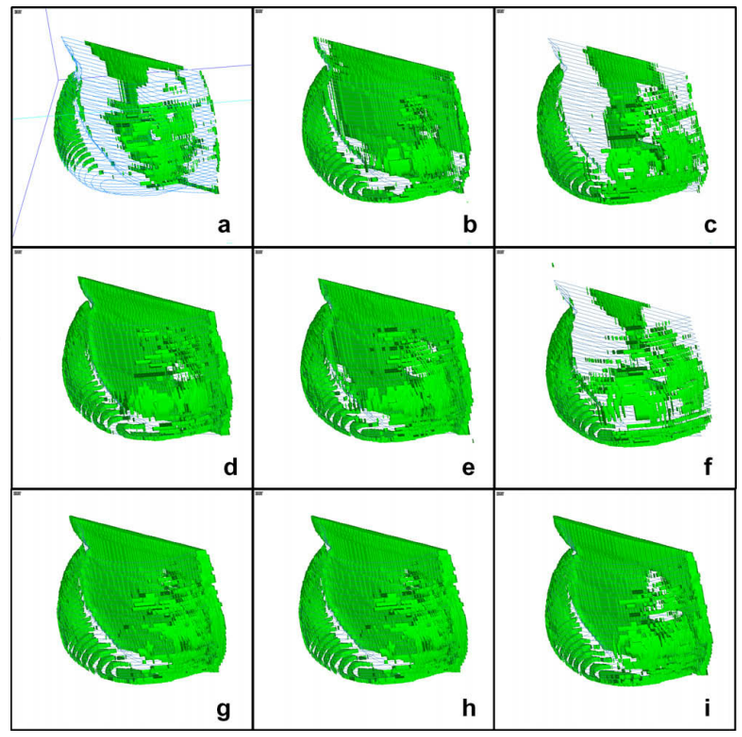


PTV position



High dose

Low Dose



Impact of daily PTV variations upon IMRT and conventional RT plans.

Isodose level	IMRT plan		Standard tangential RT plan	
	Mean planned volume (% PTV)	Mean delivered volume (% PTV)	Mean planned volume (% PTV)	Mean delivered volume (% PTV)
>107%	0.1	0.3 ± 0.6	4.0	4.4 ± 1.9
>105%	0.5	1.8 ± 2.0	15.7	15.6 ± 3.7
>95% <105%	96.7	89.5 ± 5.1	82.5	79.3 ± 5.1
<95%	2.7	8.6 ± 4.0	1.8	5.1 ± 2.6
<90%	0.3	2.7 ± 2.9	0.2	1.9 ± 2.0

P. Jain et al./Radiotherapy and Oncology 90 (2009) 93–98

Breast IMRT

Technique	D_{mean}, mean (SD), Gy	*p*	V_{95}, mean (SD), %	*p*	V_{107}, mean (SD), %	*p*
Wedge	-0.2 (± 0.1)	**<0.01**	-0.2 (± 0.2)	**<0.01**	-1.4 (± 0.9)	**<0.01**

Hybrid IMRT	-0.5 (± 0.3)	**<0.01**	-2.5 (± 3.7)	**<0.01**	0.0 (± 0.1)	0.65
Full IMRT	-0.6 (± 0.3)	**<0.01**	-4.3 (± 5.1)	**<0.01**	-0.1 (± 0.2)	0.38

Nakamura et al., 2010

Modulation vs. robustness to dose?

- Less is more?
- Max 20% modulation seems to preserve robustness
- Cave : internal mammary nodes
  - Sharon et al (IJROBP) : 28% change in V45 for M.I.
- What with SIB treatments?

Interfractional movement

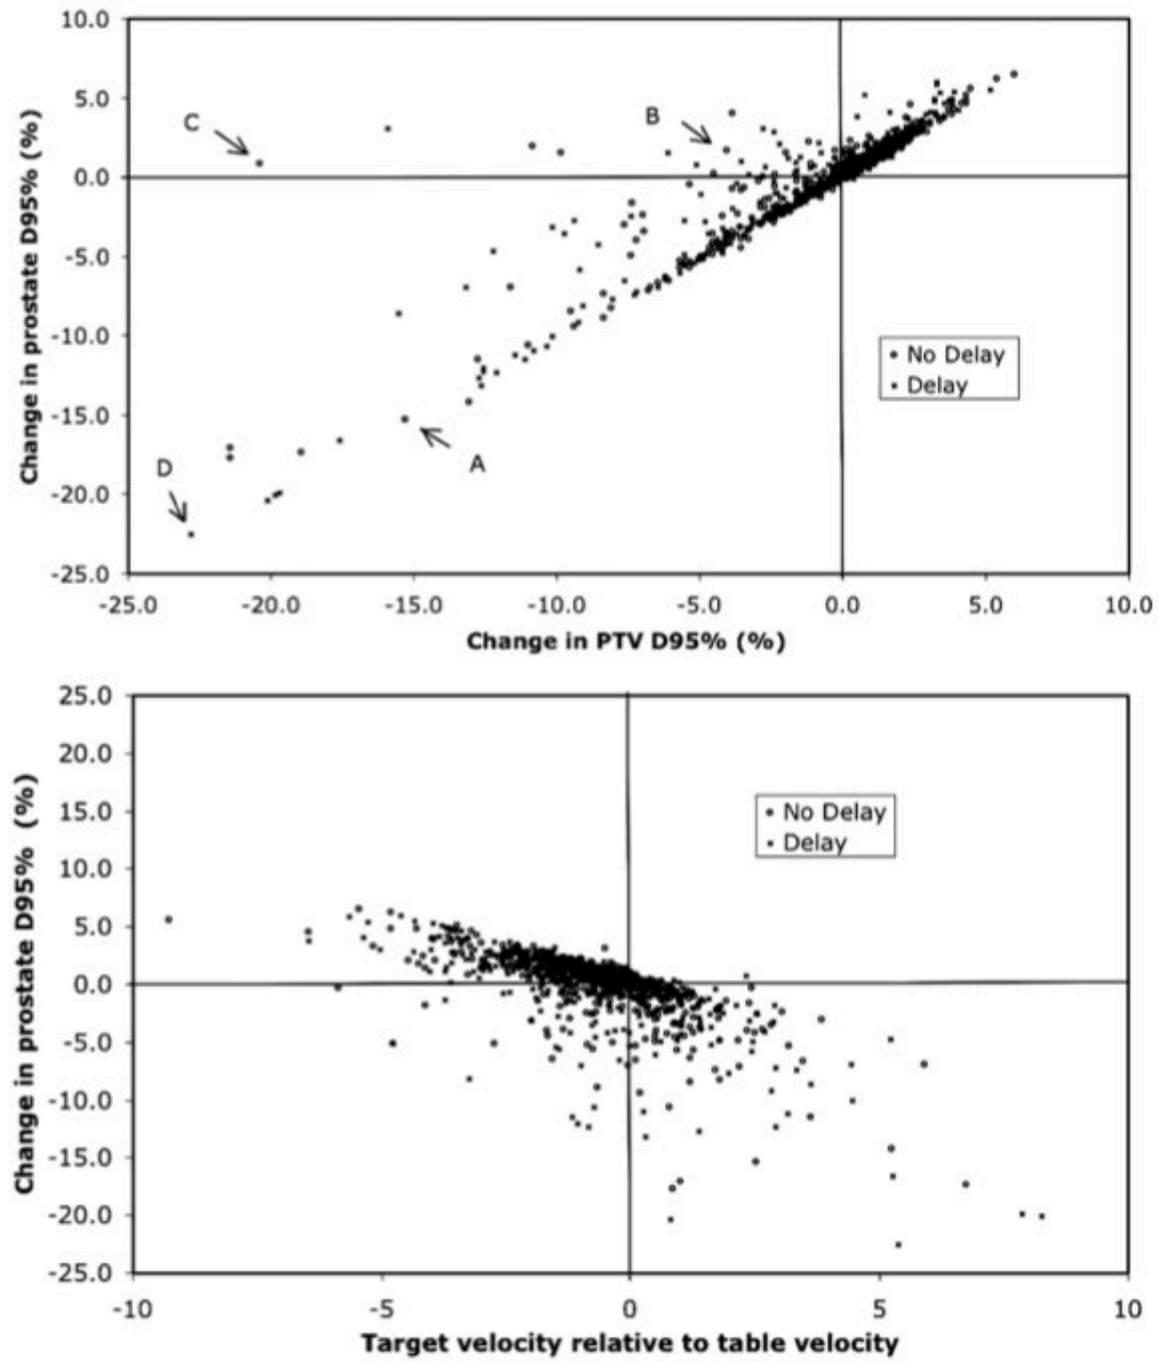
- As long as we are working in homogenous regions....
- or the modulation is not too large
- our concept of the robust dose cloud keeps up
- IGRT to the rescue

Intra-fraction movement

Prostate (tomotherapy)

Effect not limited to the periphery

Margins???



Relative movement table vs. target

Correlation between ampunt of motion and effect not straightforward (dep. direction...)

Phys. Med. Biol. **53** (2008) 7073–7086

"For prostate and HT, there CAN be a significant dosimetric effect in the cranio-caudal direction because table speed and tumor motion are of the same magnitude." However....

#fx	Movement	Impact (dose)
1/3	<3mm	5%
2/3	<5mm	10%

Correction schemes not feasible! We don't know when (which fraction and timing in the fraction) to interrupt an correct

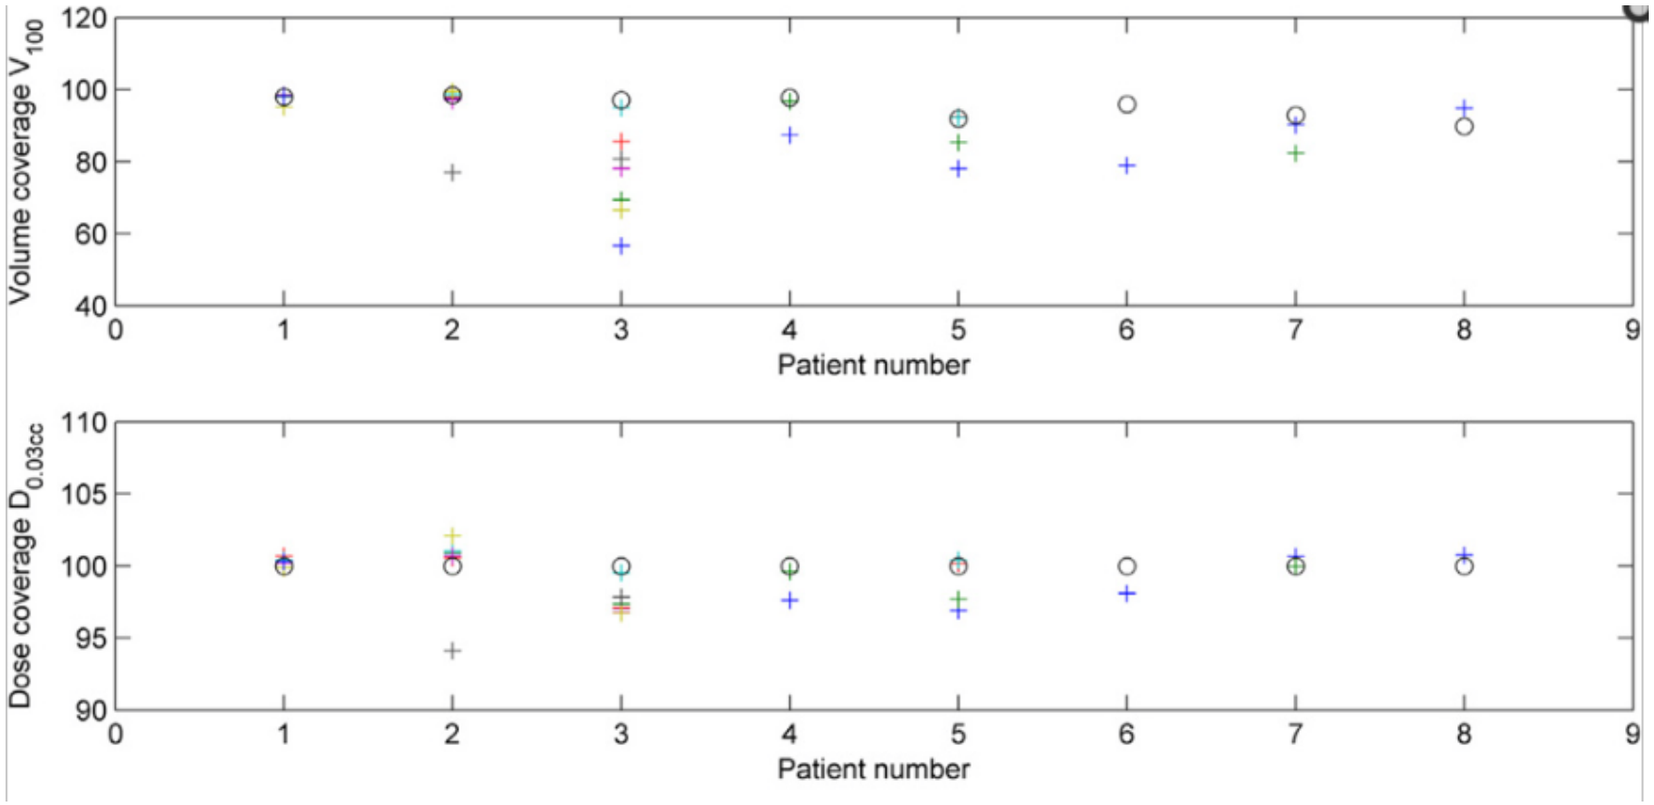
Prostate (S&S)

- 486 fractions
- Mean deviation at $D(95\%)_{CTV}$ =0.2+/- 0.5% (1SD)
- Poor correlation between movement parameters and $D(95\%)_{CTV}$
- No threshold possible

Langen et al , Int J Radiat Oncol Biol Phys. 2012 Dec 1;84(5):1220-5

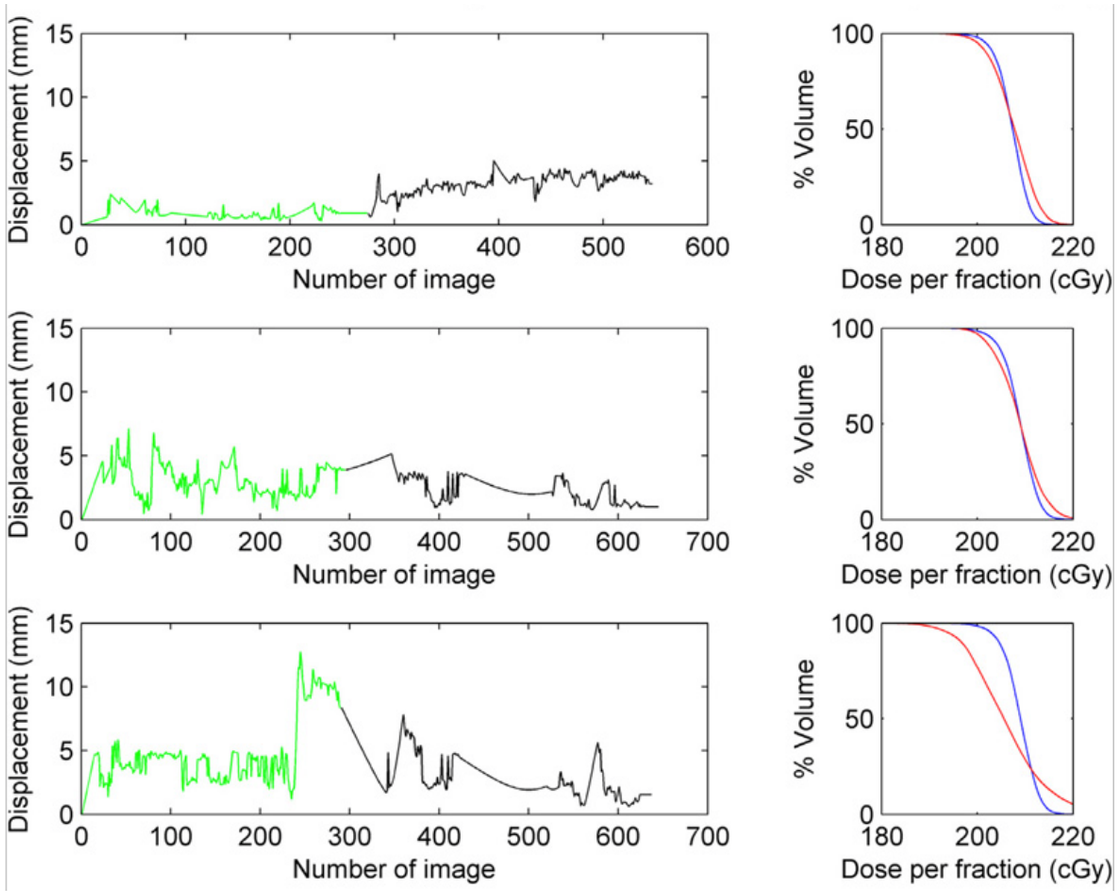
Intrafraction movement VMAT - prostate

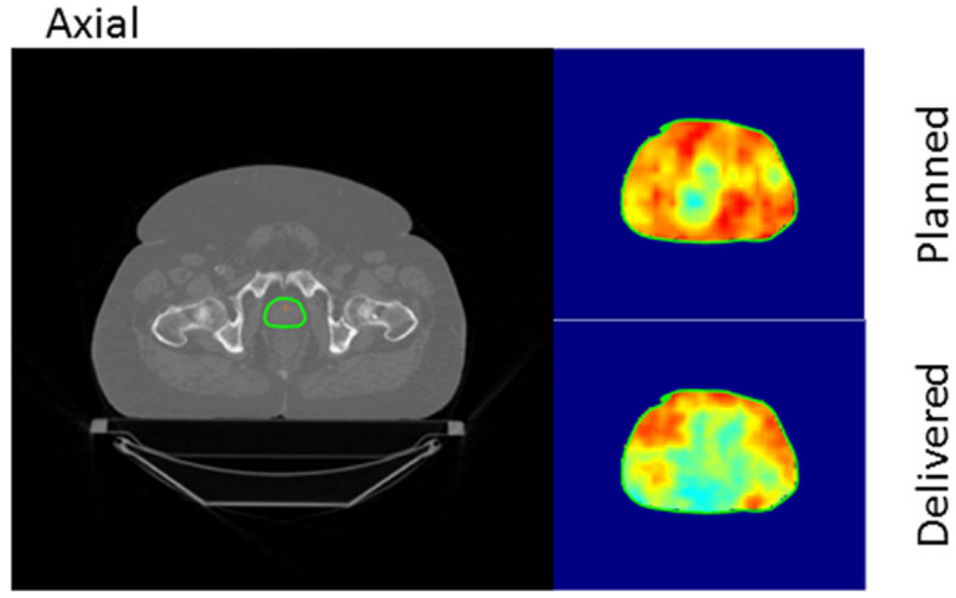
- Fiducial detection
- Linked to control points
- Recalculated using MC

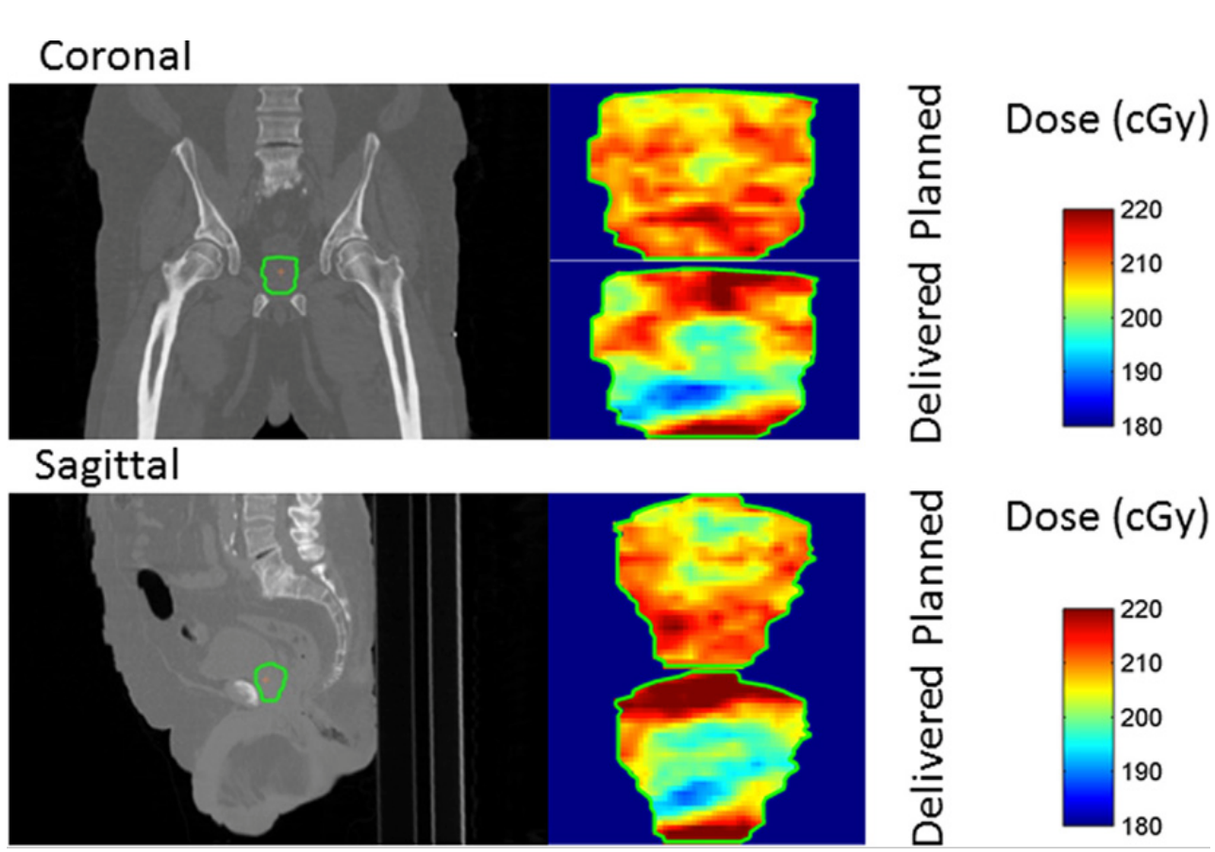


Azcona et al 2015

Intrafraction effect - VMAT prostate







- Possible large effects in single fractions
- Effect is reduced over 7-8 fractions
- Prostate tracking?

4D-PET SIB	-0.34% (-1.2, 2.6)	-0.29% (-2.4,2.1)
SBRT 3x18Gy	1.19% (-1.5,2.8)	1% (-2,2.8)

Sterpin et al.,Radiotherapy and Oncology 104 (2012) 173–180

Intrafraction movement in lung

- Dosimetric effects are linked to the relative frequencies of all the movements.
- There seems to be a possible problem with leaf/ movement interplay in DMLC techniques (VMAT/ DMLC) which can not be solved by PTV-margins.
- The size of this effect is dependent on the relative movement (size and speed).
- VMAT : depending on whatever your leaves are doing (can have low modulation)
- Possible solutions can be found in tracking, gating ...

In total…

- Effects on the dose distribution are not straightforward.
  - Depending on frequency, modulation, patient
  - Over all fractions things do not look that bad….
  - Are homogeneous phantom studies a good way to study these effects? There is no change of scatter conditions there.

Anatomical Deformations

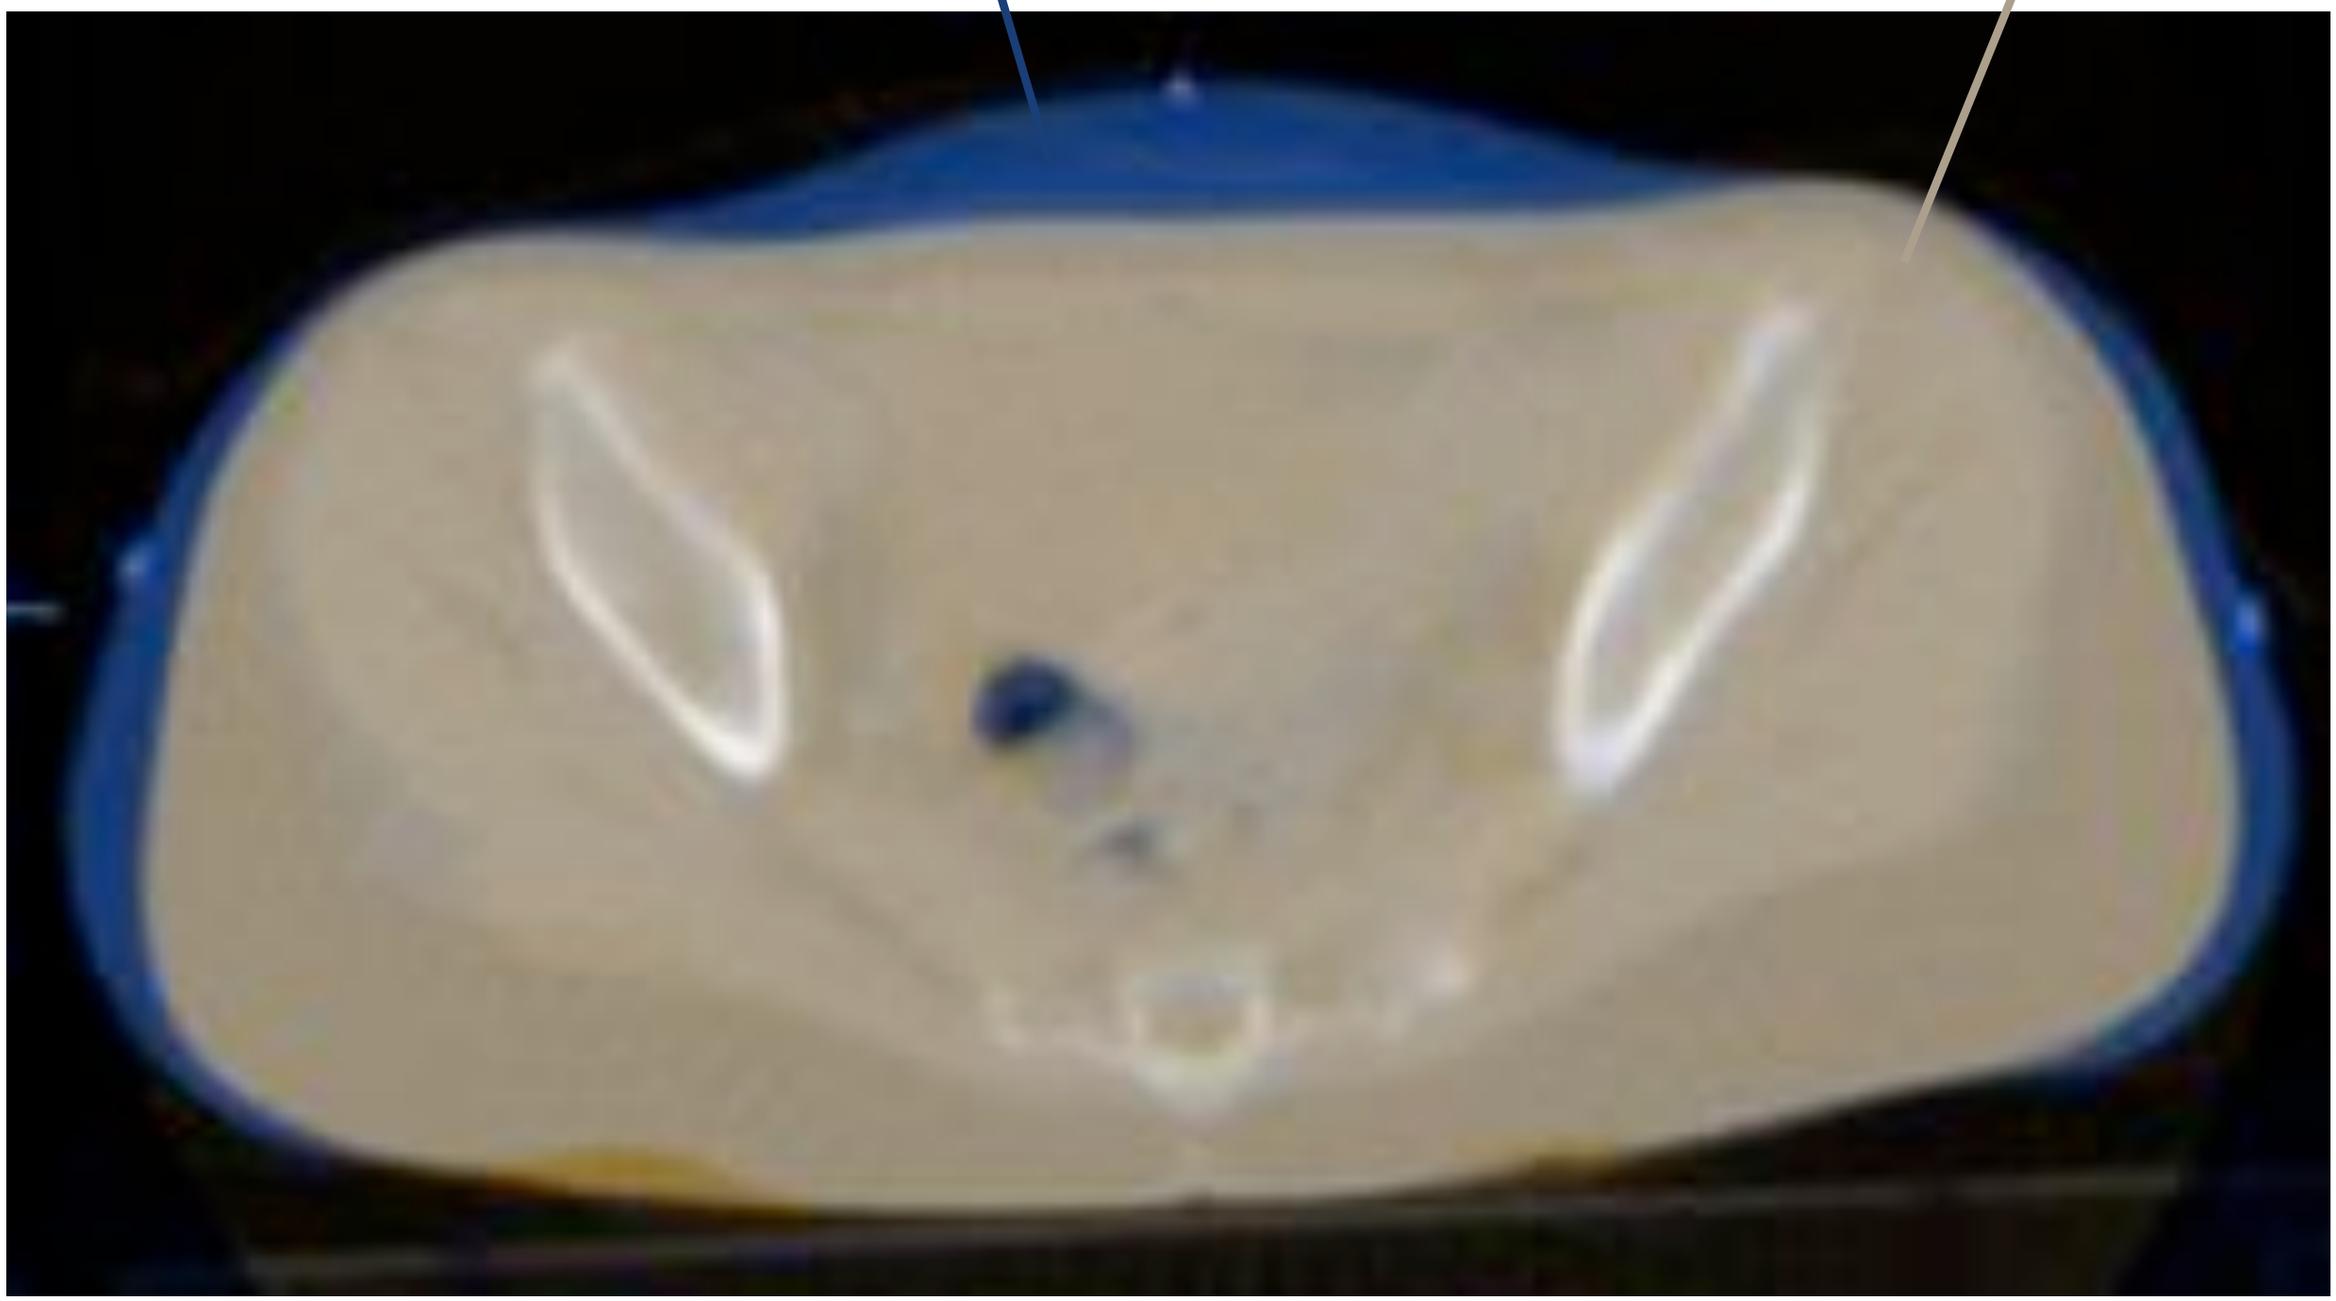
kV planning CT

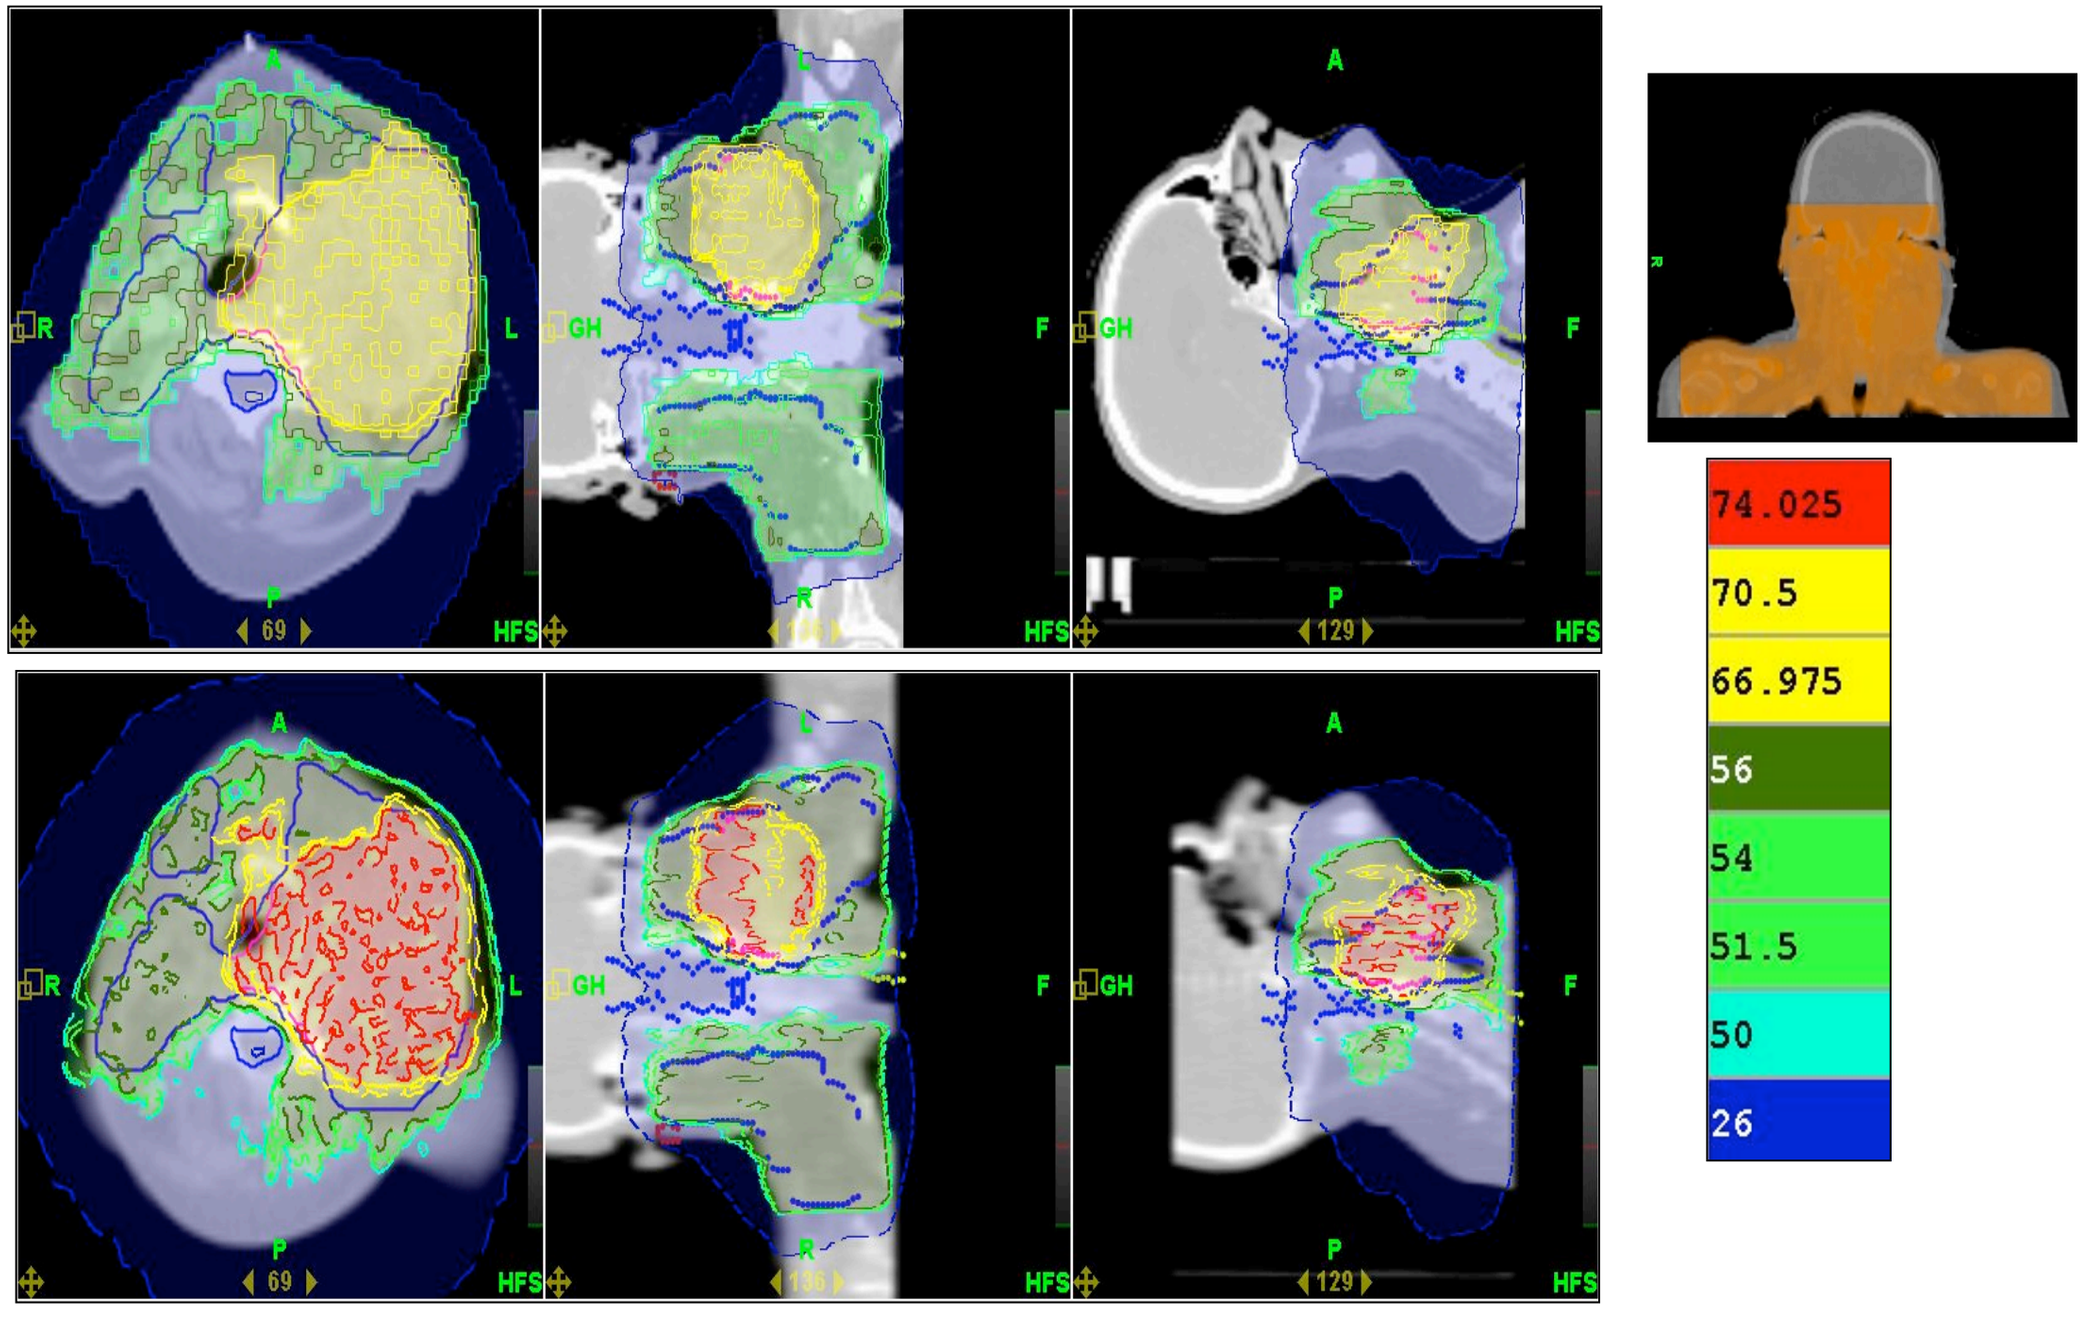
MVCT

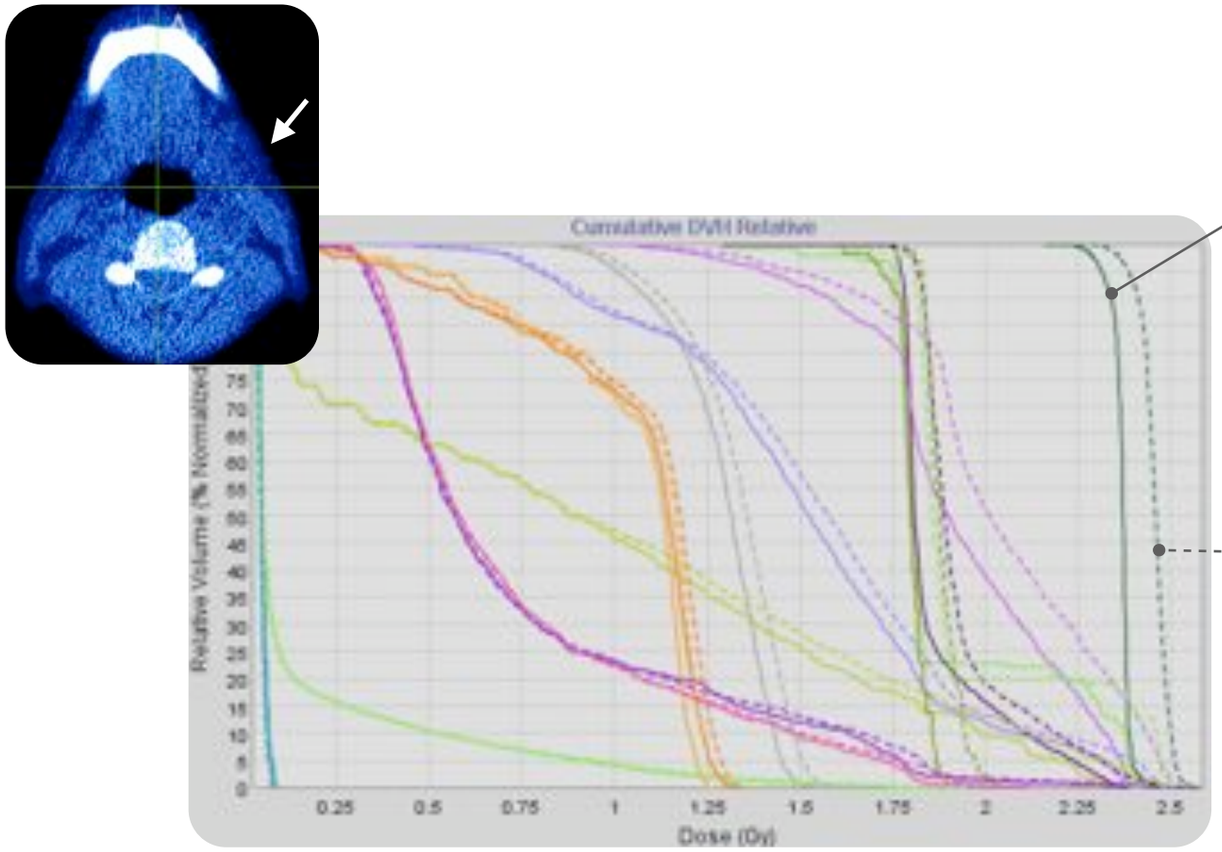


Toolbox

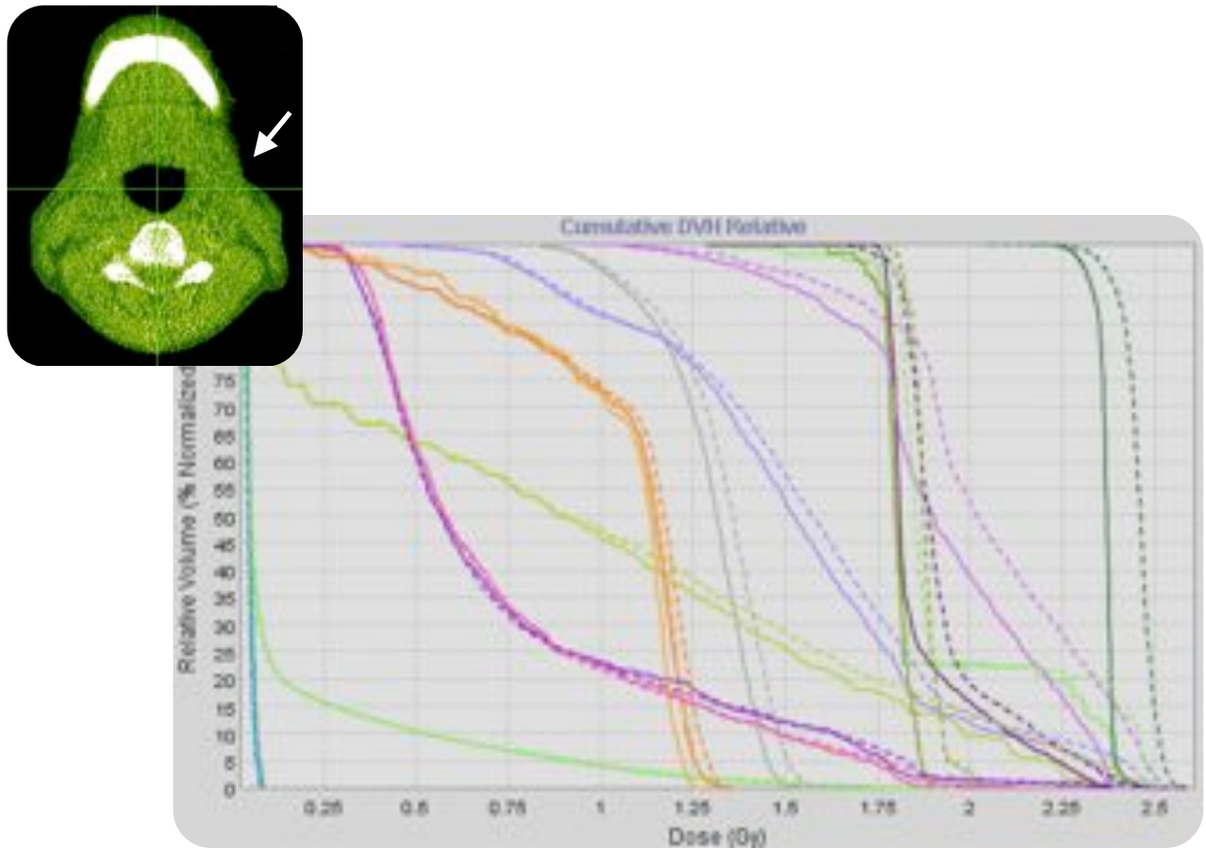
- Deformable registration
  - Volumes
  - Dose (NOT verified)
- ART
  - Dose Recalculation
  - Plan of the day-approach

Dose Recalculation





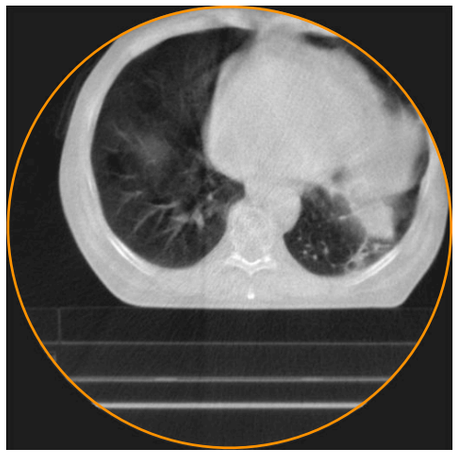
Cumulative DVH Relative
Relative Volume (% Normalized)
Dose (Gy)
kV calculated dose
MV calculated dose



Cumulative DVH Relative
Relative Volume (% Normalized)
Dose (Gy)

What's the catch?

- Adaptive strategies allow us to recalculate daily dose and see the immediate effect of deformations or geometrical uncertainties.
- Since this was a "buzzword" vendors were aching to have us spend our cash on these expensive options.
- Are they feasible in clinical routine?
  - MVCT : Duchateau *et al* 2010 *Phys. Med. Biol.* **55** N329
  - ConeBeamCT
    - Daily calibration
    - Check contouring
    - Missing information



Deformations : comment

ART will only work if there exists a clear, automatic workflow that is integrated in planning, imaging, treatment and follow-up.

Deformable registration

- The basis for a successful Adaptive Strategy
- The algorithm should be
  - usable in clinical routine
  - verified

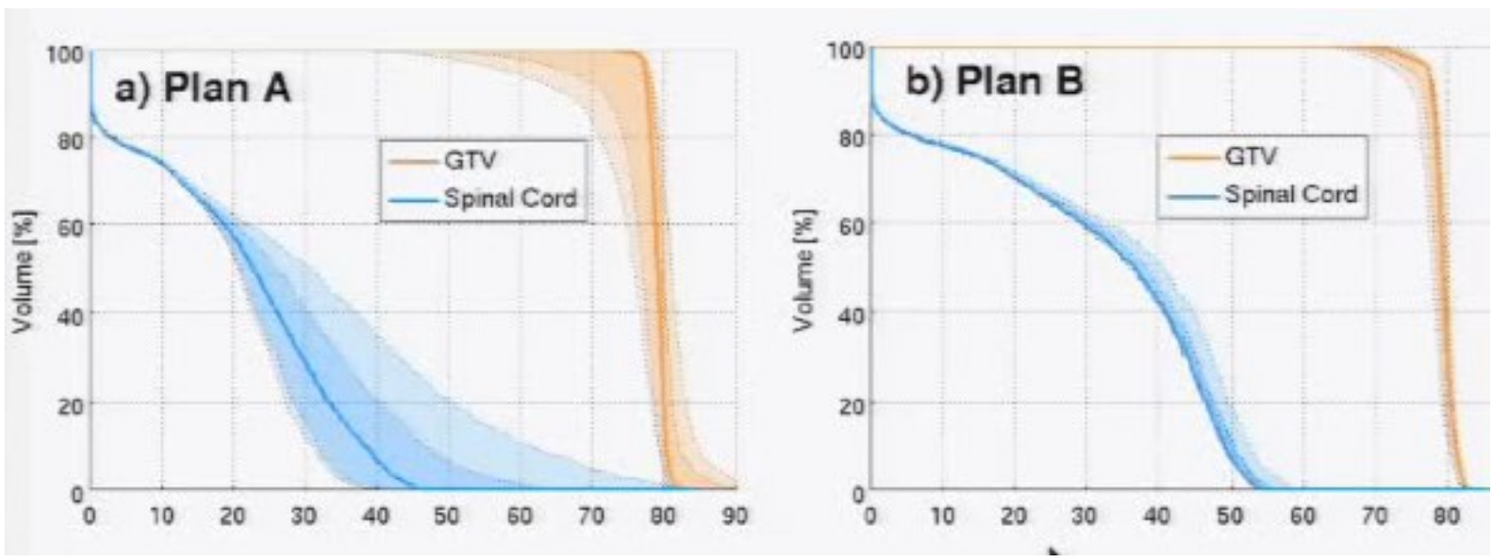
Robust Planning

Statistical models/Robust Planning

- Taking into account the possible geometric deviations (random and setup errors) at the planning stage.
- Creating a dose distribution that will be "robust" or "immune" against the "most likely" movements of the target volume



Trofimov, Phys Med Biol 2011

How can we achieve this?

- Stochastic programming : statistical method, using defined probability density functions for all uncertainty parameters (e.g. gaussian model for setup errors, breathin cycle...). Feed this to our IMRT objective function.
- Worst case approach : make sure that constraints are always fulfilled, obtain the best plan in the worst case.

Stochastic method

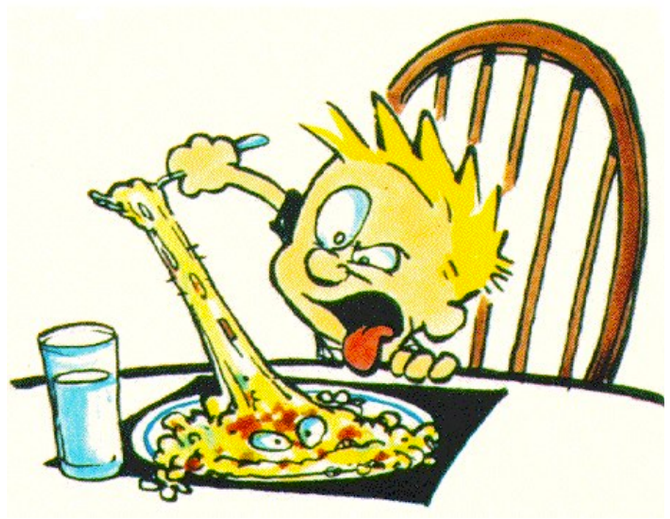
Normal Optimization

$$d_i(x) = \sum_j D_{ij} x_j$$

Dose in voxel i is a sum of the doses coming out of each bixel, weighed with the constraints

$$f(d(x))$$

Is our IMRT objective function which has to be minimized



Robust Optimization

$$d_i^s(x) = \sum_j D_{ij}^s x_j$$

Dose is calculate for all different scenarios = e.g. all possible positions

$$< f >= \sum_s p_s f(d^s(x))$$

The objective function is now minimized over all possible scenarios, weighed with the probability function

Worst case approach

$$d_i^s(x) = \sum_j D_{ij}^s x_j$$

Dose is calculate for all different scenarios = e.g. all possible positions

$$\left[\max_s f(d^s) \right]$$

Function is minimized for the WORST possible case

The plan that comes out will fit the worst patient situation, but is probably too strict

Example : Lung

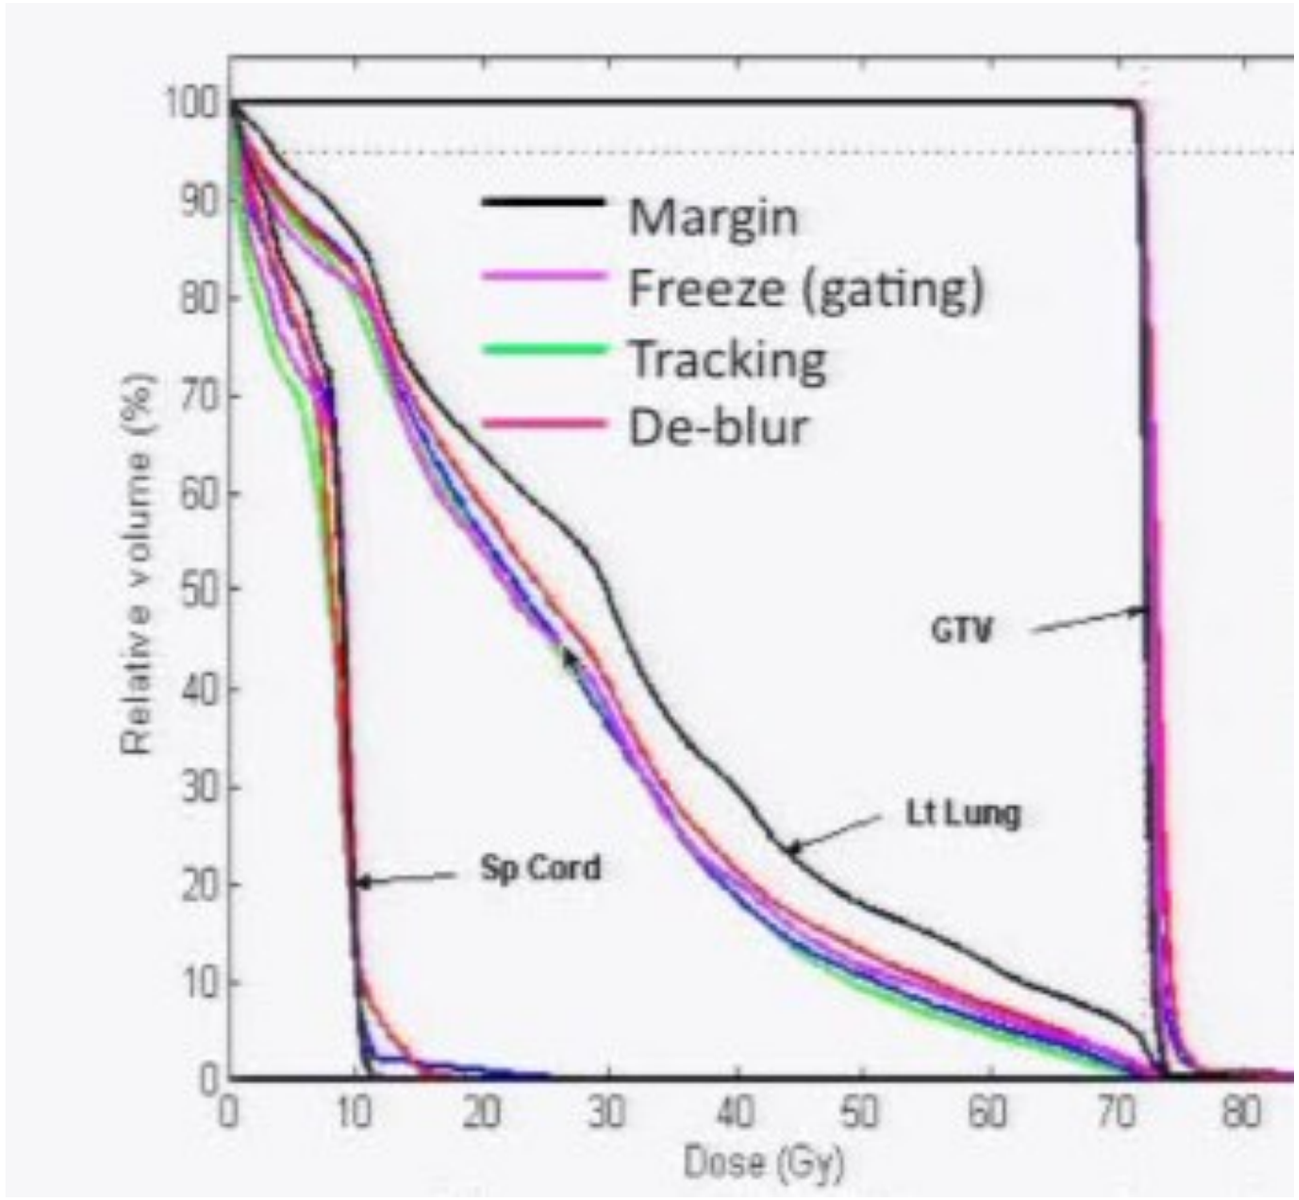
Dose Volume Histogram : lung case



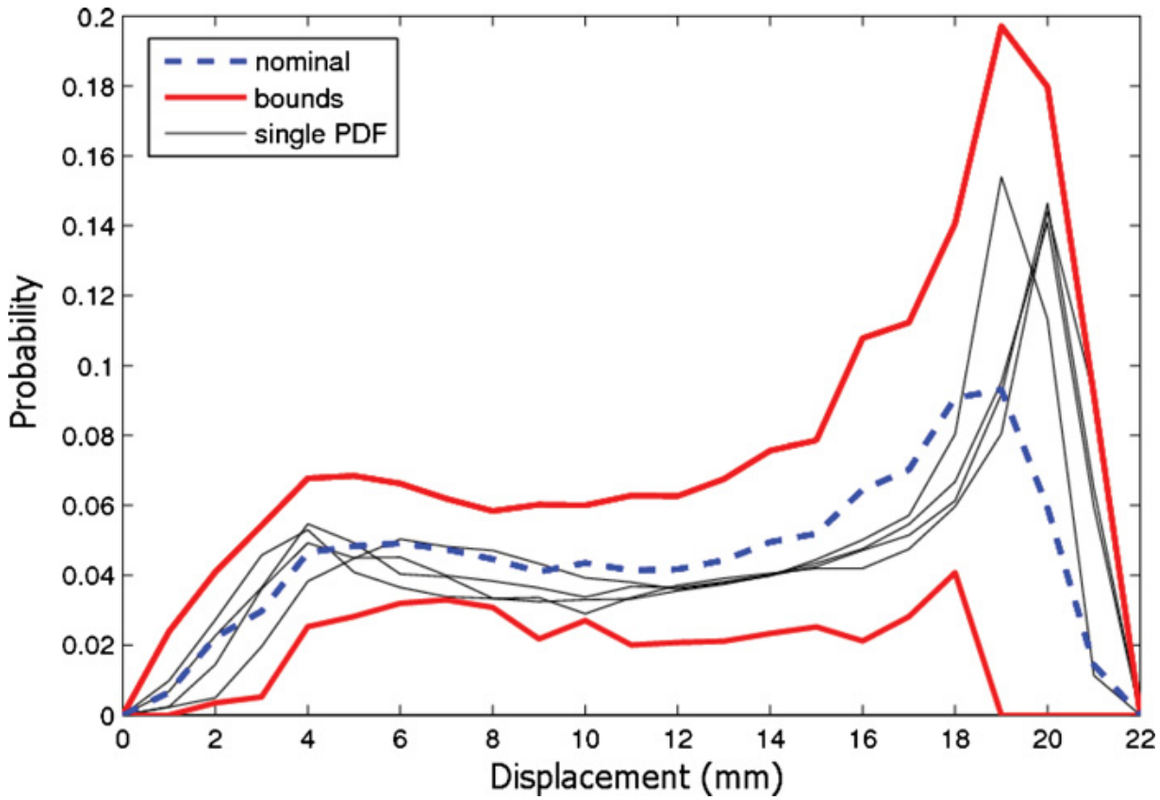
Mean dose to left lung is reduced by 20% a.r.t. adding margin

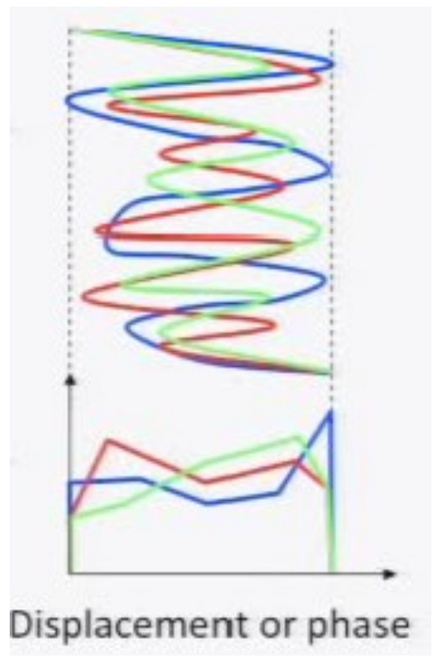
Trofimov et al., Phys Med Biol. 50:2779-98, 2005

Assumptions

- Based on probability functions for the breathing
- Has to be known perfectly
- Incorporation of this uncertainty

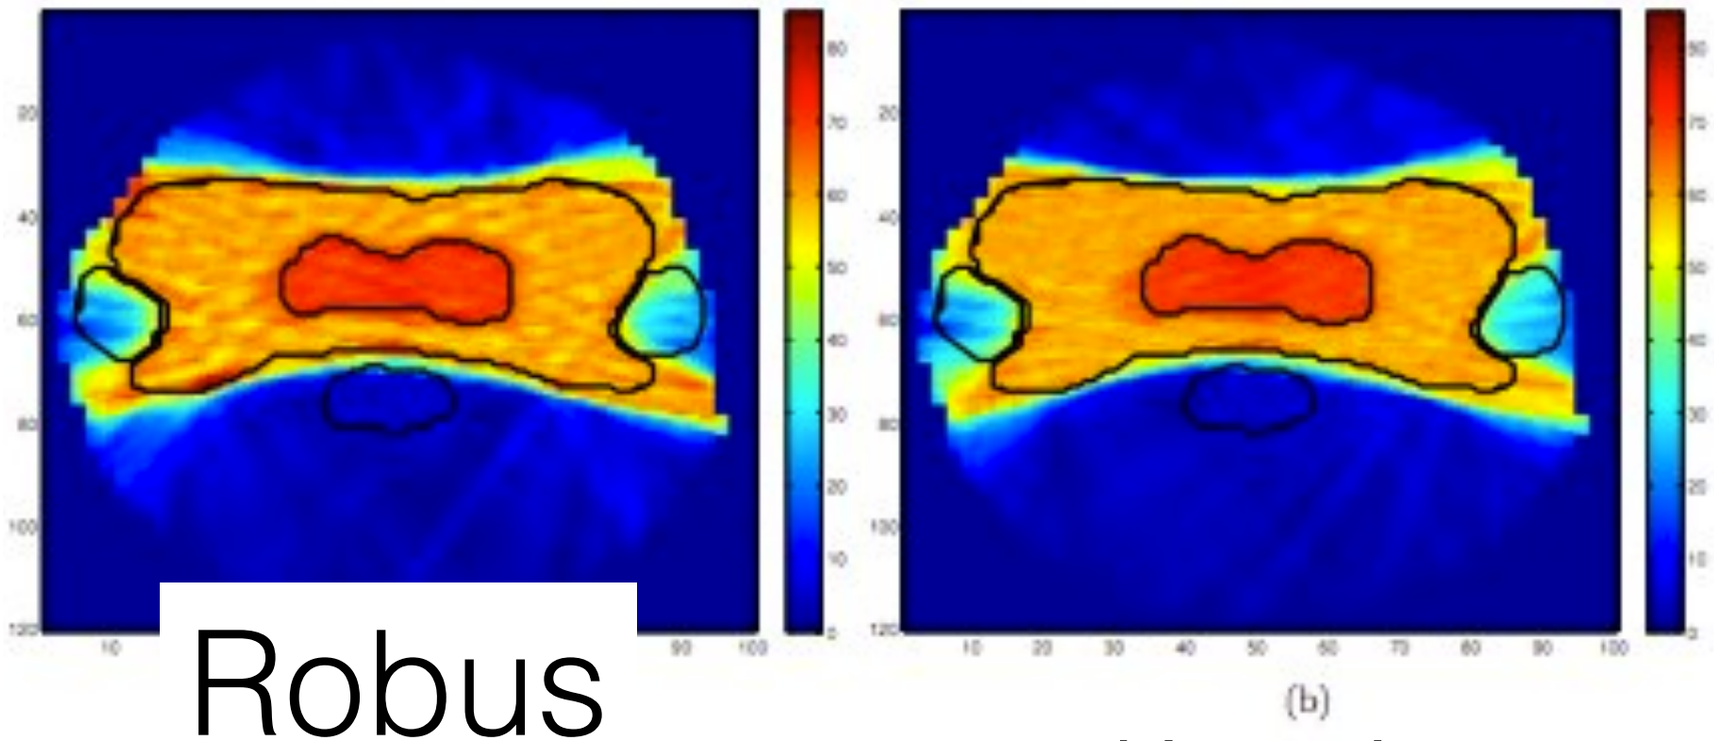
- Combination of horns and margins





Vrancic et al 2009 Phys. Med. Biol. 54 2901

Example H&N

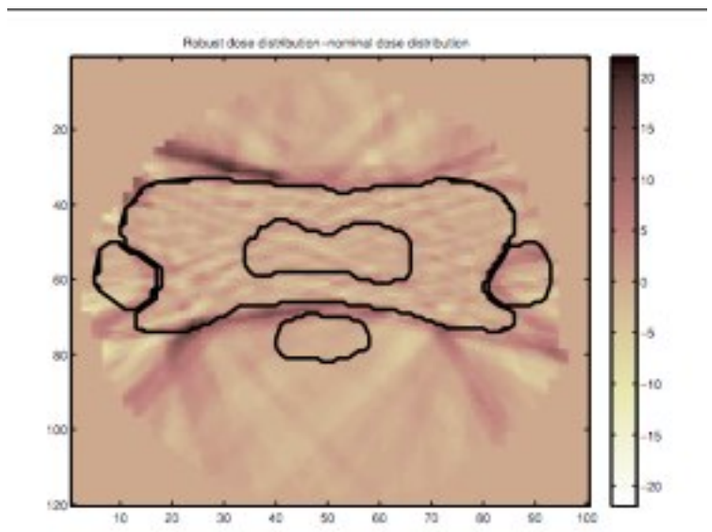


(b)

Robust

Non-robust

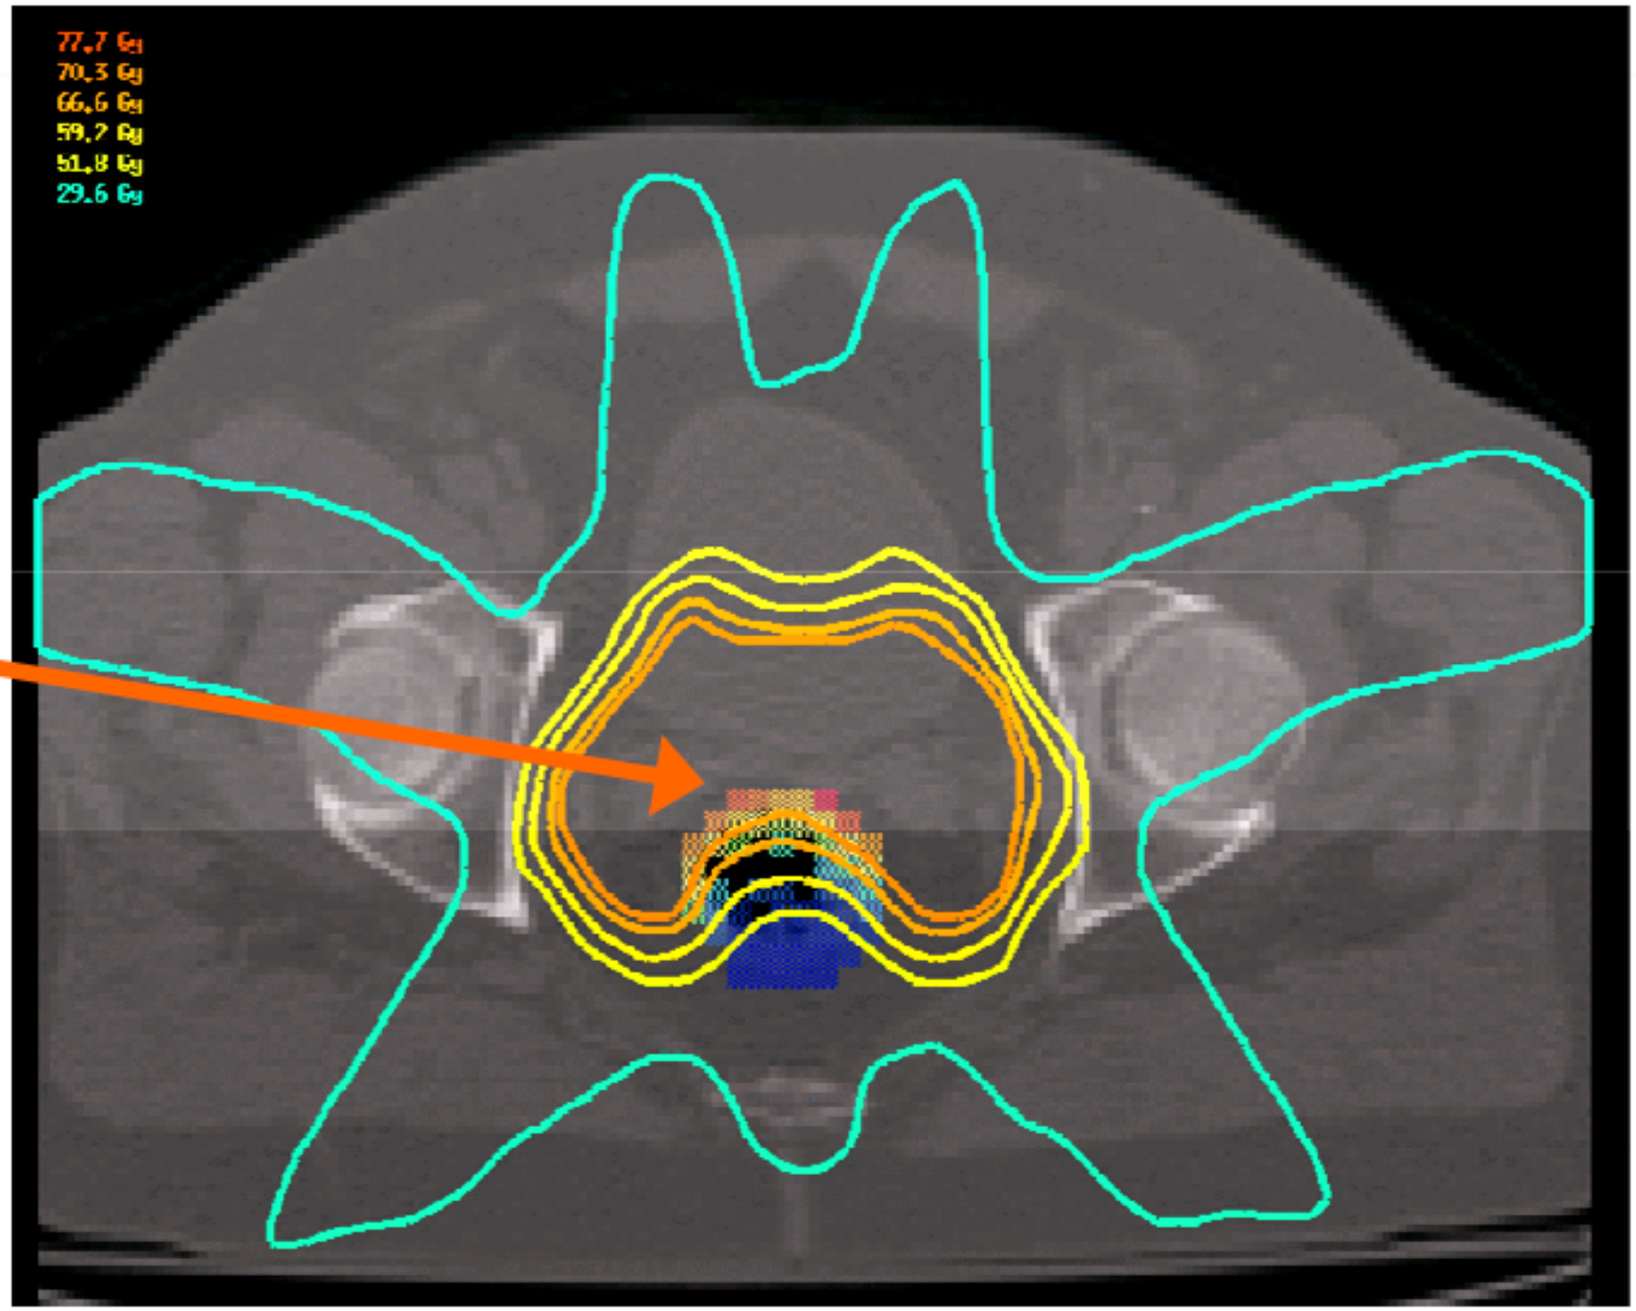
Difference



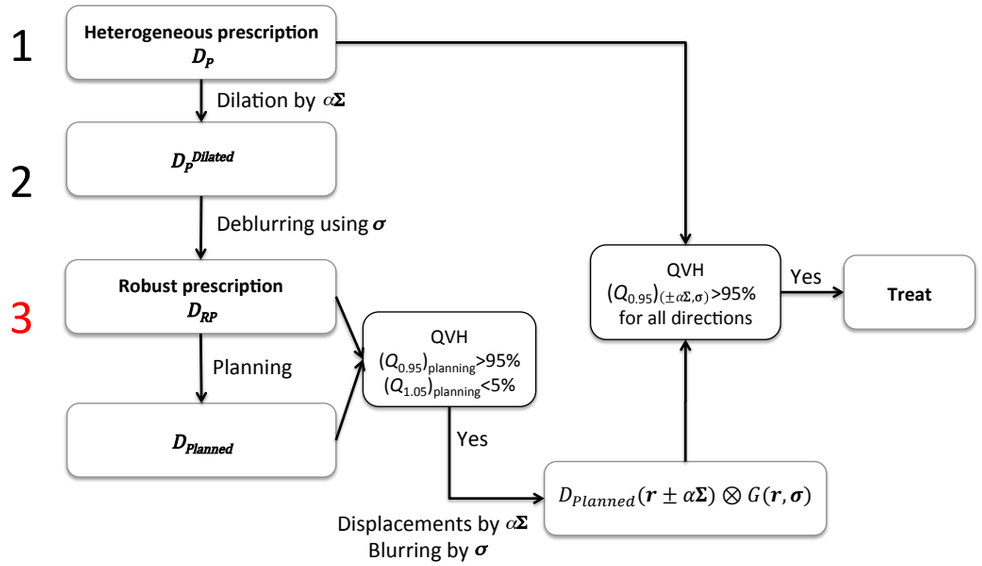
Olaffson et al,2006 Phys. Med. Biol. 51 5621

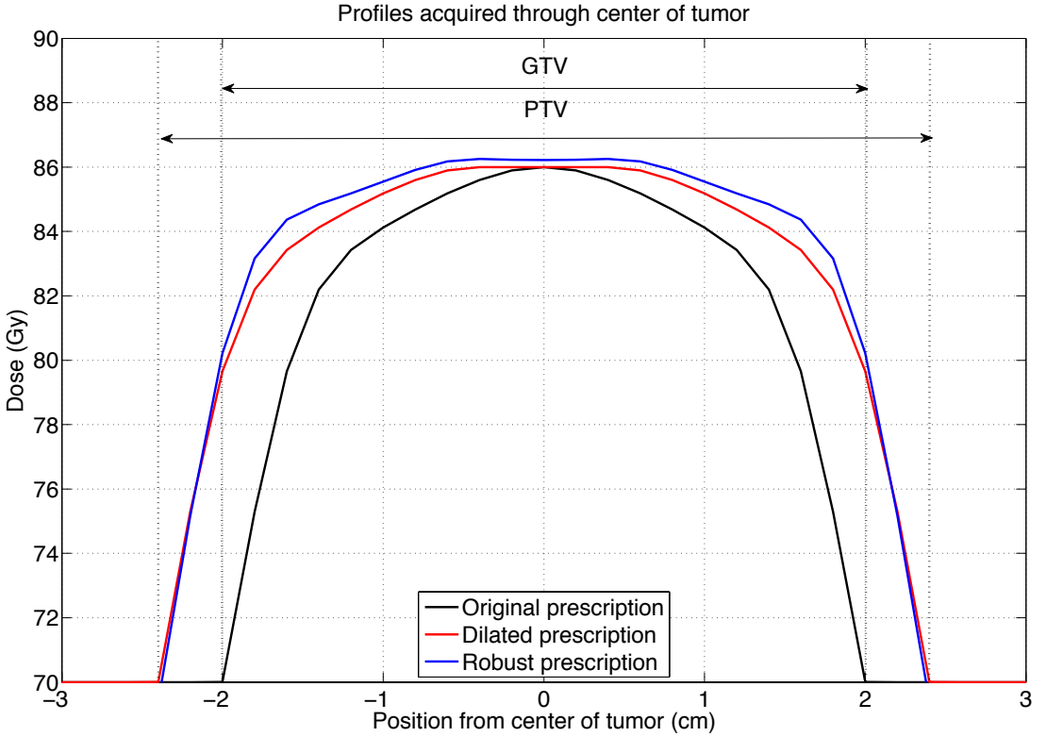
….look at the optimisation function!

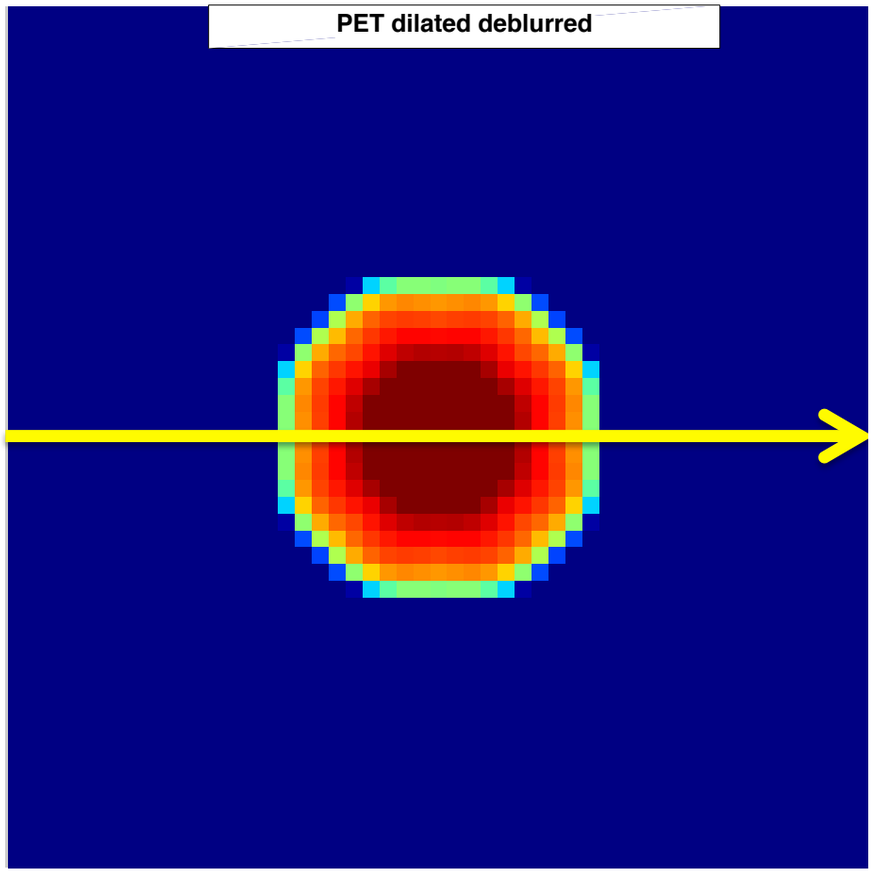
Volume of greatest weight in optimization



Alternative : robust prescription







Spherical tumor

Only dependent on σ and Σ
independant of TPS

Court. of E.Sterpin,

Conclusions

- In cases with small movements IGRT strategies will counter the effects on the dose distribution.
- In Other cases the PTV concept might not suffice in maintaining coverage
- Effects depend on interplay between the frequencies and amplitudes of the different processes
- Gating and tracking might be a possible countermove in selected cases.

Some wilder conclusions…

- Robust planning and optimisation could be the starting point of a new way of planning and evaluating dose distributions.
- Possibility of incorporating uncertainties into the planning phase (and very wild: dump the PTV notion?)
- To allow this uncertainties have to be known in a pretty high degree.
- to be continued…

A wise man's words…

"Simulating the effect of geometrical uncertainties on the individual patient plan should become part of the standard pre-treatment verification procedure."

Dose–volume effects for normal tissues in external radiotherapy: Pelvis

Claudio Fiorino [a,*], Riccardo Valdagni [b], Tiziana Rancati [b], Giuseppe Sanguineti [c]

RECTUM – main complications

- rectal bleeding
- foecal incontinence
- stool frequency

- ca. prostate /cervival ca

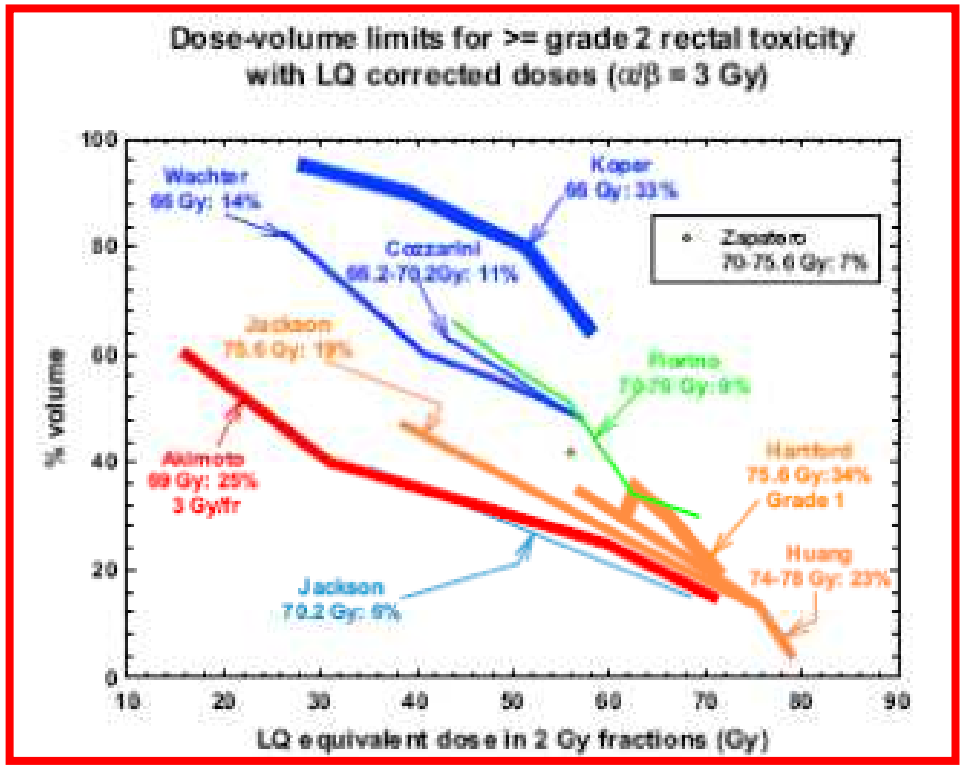
- acute: diarrhea, pain, superficial ulcerations, treatment for anemia, transfusion
- late (3-4 ys after RT): stricture, diminished rectal compliance, fecal incontinence

Rectal bleeding

- Grade 2: moderate diarrhea or colic, bowel movement, excessive rectal mucus, intermittent bleeding
- Grade 3: obstruction, bleeding requiring surgery

- **risk factors** for late rectal toxicity: hormonal therapy, diabetes, severe acute toxicity, advanced age, prior abdominal surgery

RECTUM, late rectal bleeding
DVH description



Thicker lines indicate
higher rates of overall toxicity

- Late rectal toxicity: doses $\geq$ 60 Gy
- Convergence at the high dose range < 70 Gy and volumes < 20%
- Uncertaint interpretation of the role of the intermediate doses?

Michalski *et al, IJROBP vol 76, n3, S123-S129, 2010*

RECTUM, late rectal bleeding
NTCP description

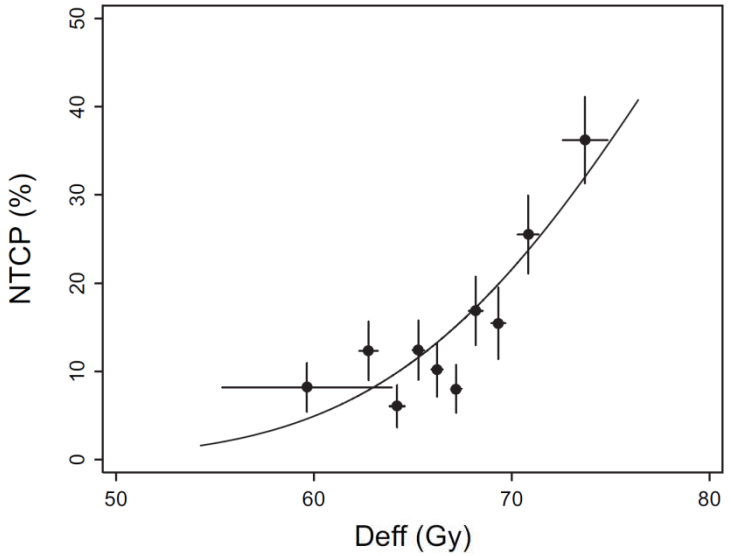
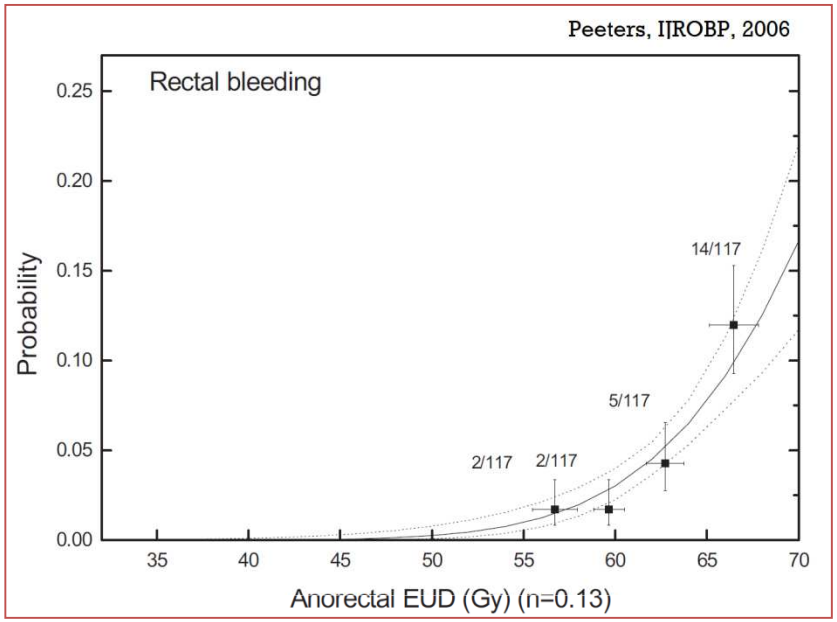
Tucker et al. IJROBP 2010

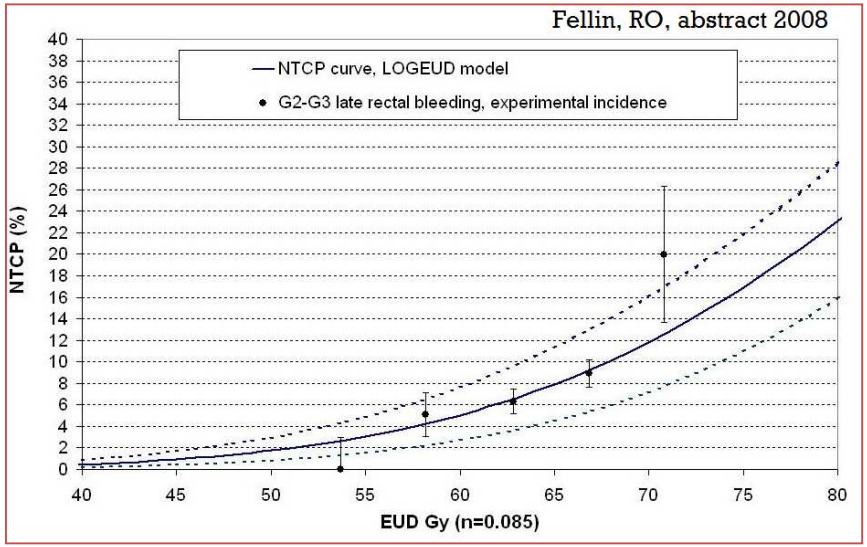


Incidence of Grade ≥2 late rectal toxicity at 8 years in each of 10 subgroups of 101 patients each, grouped by D_{eff} (equation 3), computed using $n = 0.077$. Points are plotted at the mean value of D_{eff} per subgroup. Horizontal error bars show ±1 standard deviation; vertical error bars show ±1 standard error.

Peeters, IJROBP, 2006

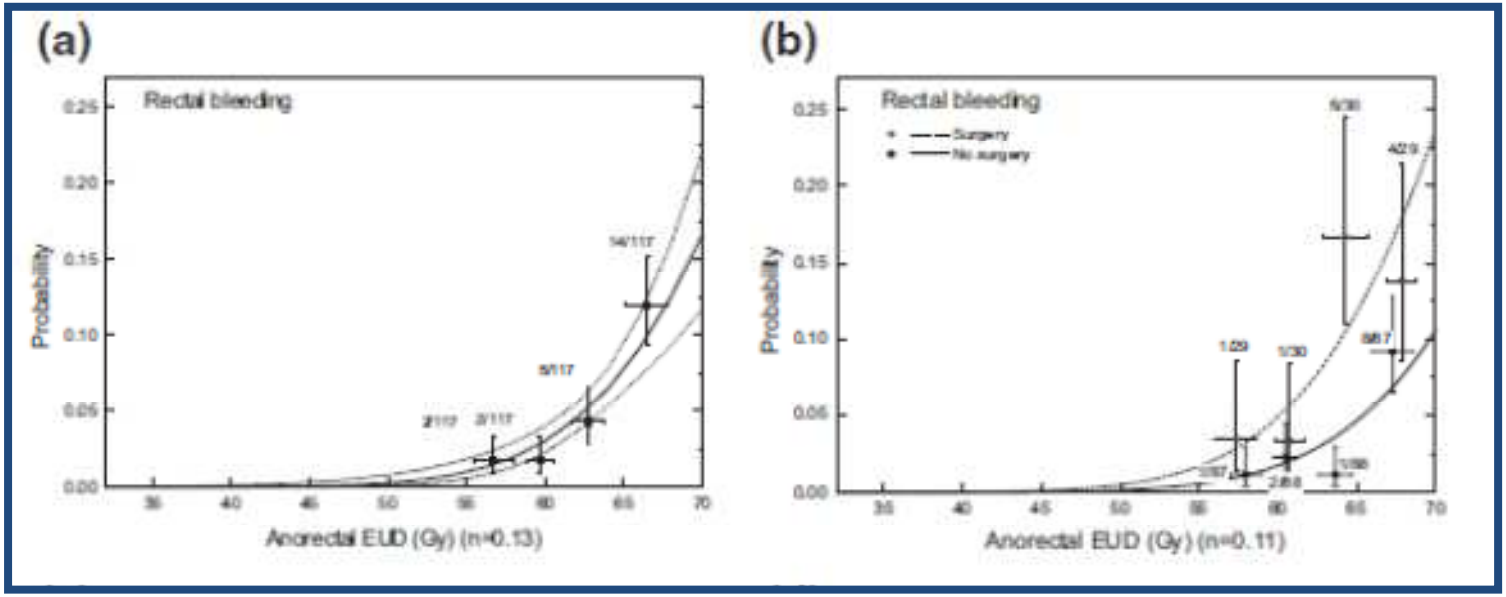


Fellin, RO, abstract 2008



Large data collections

RECTUM late rectal bleeding
DVH + clinical risk factors (abdom. surgery)

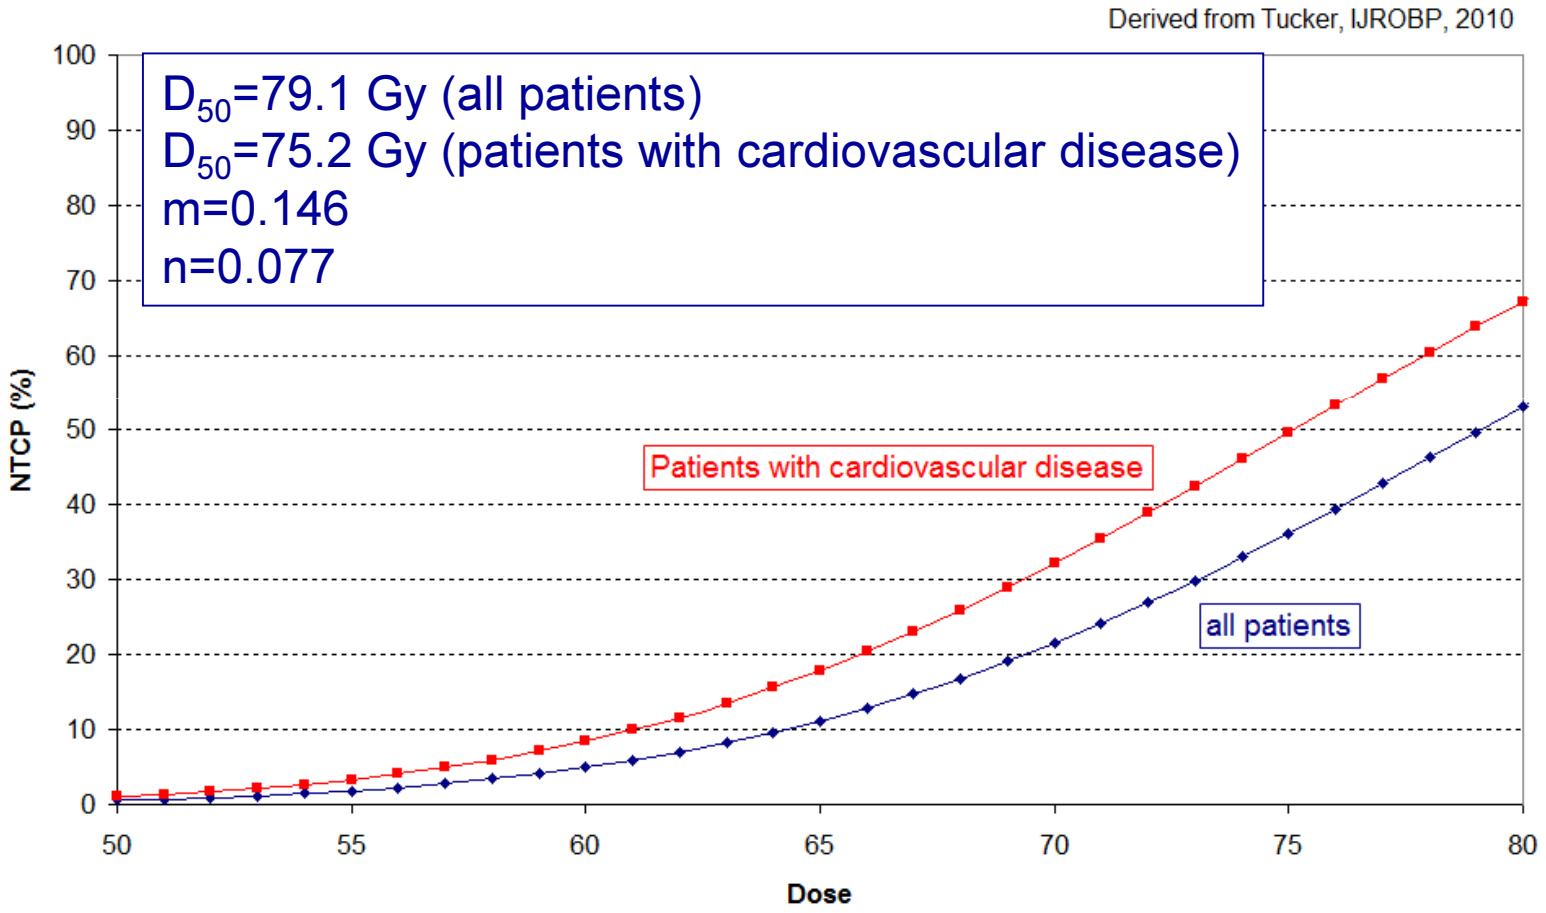


LKB	*TD50 (Gy)*	*m*	*n*
Observed	**81 (75-90)**	**0.14 (0.11-0.19)**	**0.13 (0.04-0.25)**
w/o previous abd. surgery	**85 (78-96)**	**0.14 (0.11-0.19)**	**0.11 (0.02-0.23)**
with previous abd. surgery	**78 (72-89)**		

Including clinical risk factor: lower tolerance to radiation (also for fecal incontinence)

Peeters *et al, IJROBP, 2006*

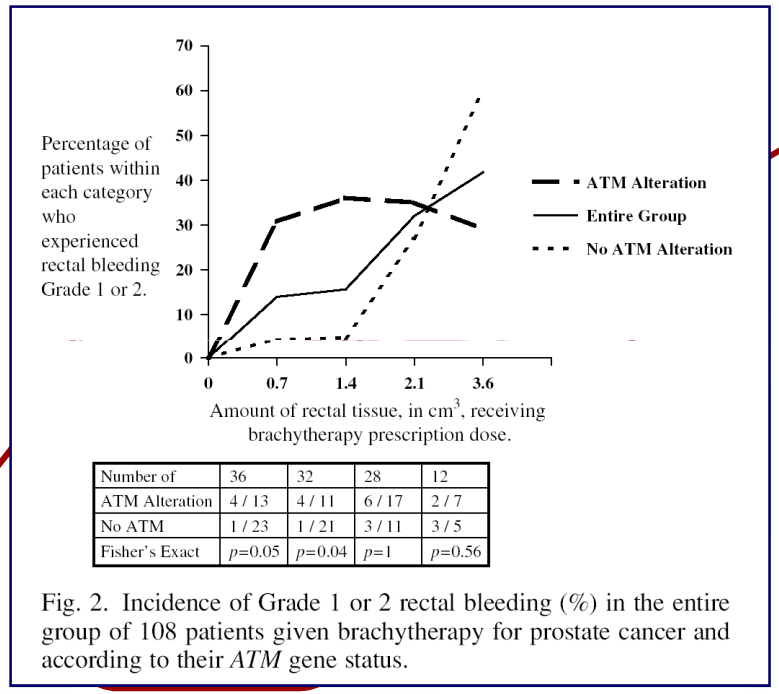
RECTUM: late rectal bleeding
DVH + clinical risk factors (cardiovascular disease)



Is there a genetic component in late rectal bleeding?

The data seem to confirm Cesaretti et al's findings (in brachytherapy) on the possible genetic component of rectal bleeding

Percentage of patients within each category who experienced rectal bleeding Grade 1 or 2



Number of	36	32	28	12
ATM Alteration	4 / 13	4 / 11	6 / 17	2 / 7
No ATM	1 / 23	1 / 21	3 / 11	3 / 5
Fisher's Exact	p=0.05	p=0.04	p=1	p=0.56

Fig. 2. Incidence of Grade 1 or 2 rectal bleeding (%) in the entire group of 108 patients given brachytherapy for prostate cancer and according to their *ATM* gene status.

EUD (Gy)

High-dose region: the genetic makeup plays a minor role and the dose the major role

LSM7 alteration

Entire population

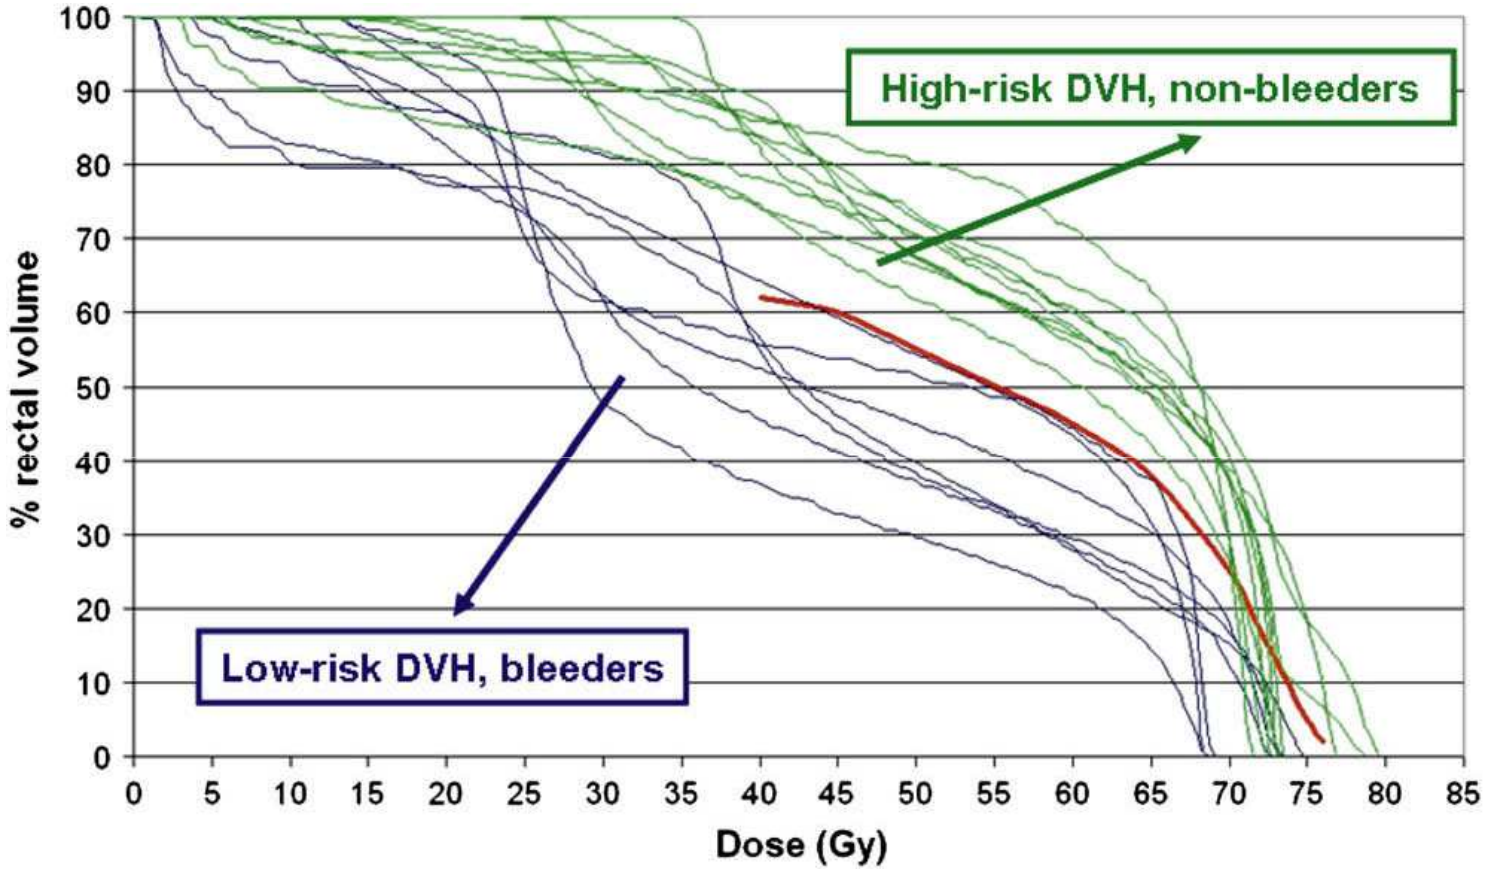
no LSM7 alteration

Low-dose region: the genetic makeup might play the major role

When more pts are available, it might be reasonable to unveil the double nature of the dose-response relationship also for external radiation

Courtesy of Riccardo Valdagni, Milan

TO BLEED OR NOT TO BLEED – Valdagni *et al*, Int.J Rad Onc Biol Phys, feb 2009



Dose–volume histograms (DVHs) for patients belonging to the low-risk bleeder (blue lines) and high-risk nonbleeder groups (green line). The red line is the cut-off DVH value that can be derived from literature-based dose–volume constraints.

			Grade ≥ 3 late rectal toxicity		<10	
	Whole organ	3D-CRT	Grade ≥ 2 late rectal toxicity,	V70 <20%	<15	
			Grade ≥ 3 late rectal toxicity		<10	
	Whole organ	3D-CRT	Grade ≥ 2 late rectal toxicity,	V75 <15%	<15	
			Grade ≥ 3 late rectal toxicity		<10	

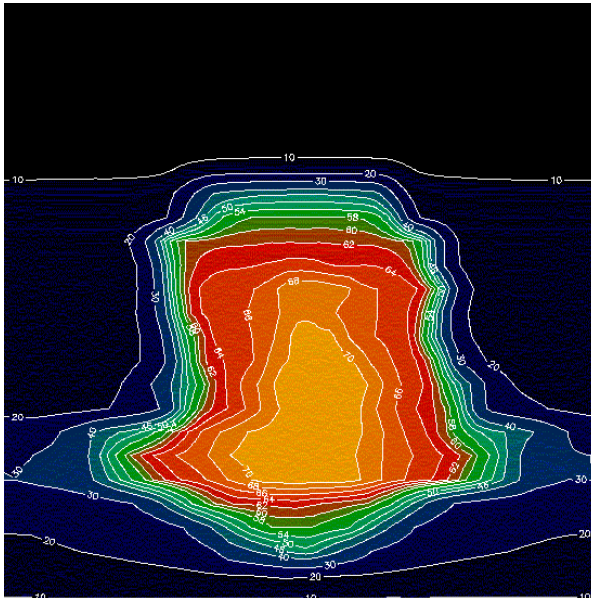
Recommendations:

- Organ definition, from above the anal verge to the turn in the sigmoid colon
- V_{50}<15%, V_{60}<35%, V_{65}<25%, V_{70}<20%, V_{75}<15%

  for $\leq$ 15% Gr.$\geq$ 2 late tox

  for <10% Gr. $\geq$ 3 late tox
- IMRT: intermediate (40-60 Gy) doses for pts <78Gy ?

Rectal bleeding: dose-volume, dose-surface or dose wall?



- Empty rectum: DWH ≈ DVH
- Full rectum: DWH ≈ DSH

Robust solutions:

Empty the rectum at plan CT scan and use DVH

Use DSH for distended rectum (rectal balloon)

Several prospective studies ongoing

Sanchez-Nieto B, Fenwick J F, Nahum A E *et al* 2001
Biological dose surface maps: evaluation of 3D dose data
for tubular organs *Radiother. Oncol.* **61** S52

FOECAL INCONTINENCE

- Volume(s) definition
- Quantification: need prospective studies/self reported toxicities/symptoms persistency
- Risk factors: age, baseline situation
- Complex anatomy and radiobiology

- Occur in ca 5% pts, but chronic symptoms
- V40< 80% (or mean rectal dose < 45-50 Gy)

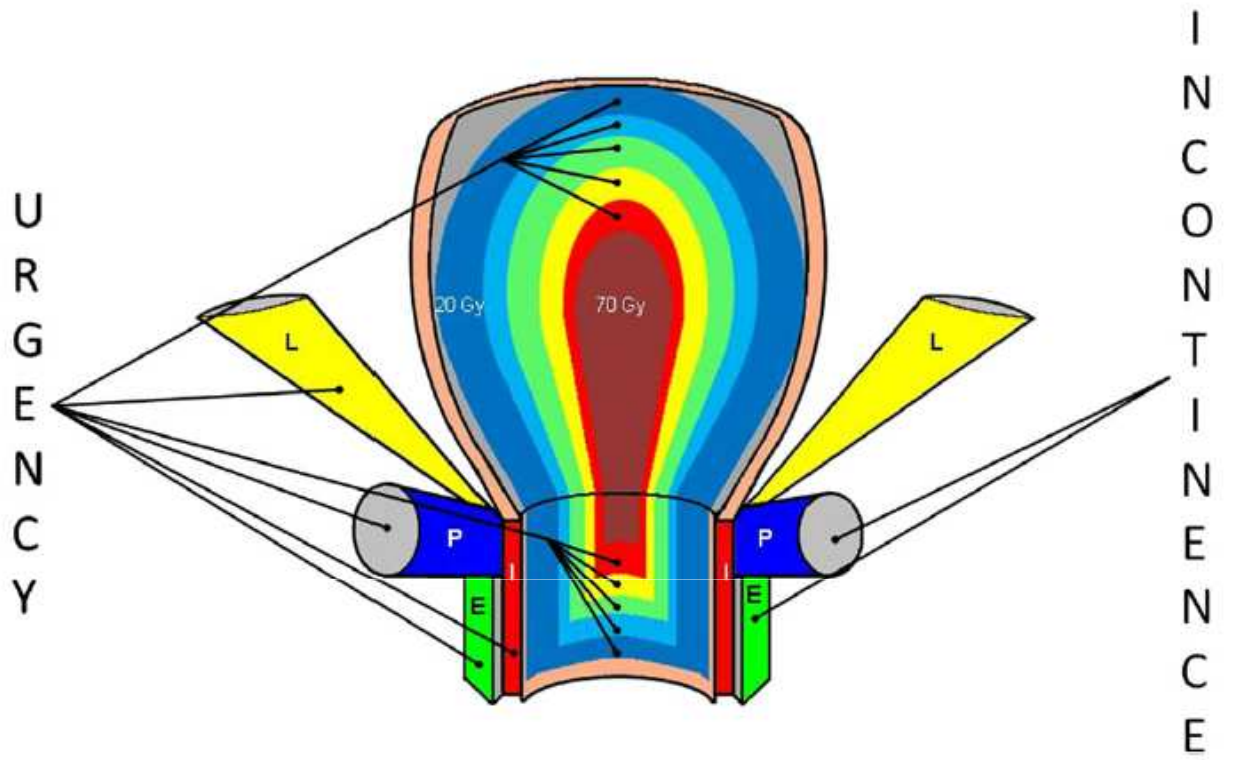


Fig. 2. Schematic image shows rectum, anal canal, and individual pelvic floor muscles. I = internal anal sphincter; E = external anal sphincter; P = puborectalis muscle; L = levator ani muscles. Lines represent associations between complaints and subsites.

- 48 pts, separate delineation of specific pelvic floor muscles
- Toxicity scale, scoring every 6 months
- EQD corrected doses

Smeenk *et al*, 2012

Foecal incontinence

- Occurrence of urgency correlated to incontinence and frequency
- No significant different toxicities with conv vs IRMT
- All mean doses higher in the group with urgency
- Mean dose ≤30 Gy to the internal anal surface,
  ≤10 Gy to the external anal surface
  ≤50 Gy to the puborectalis muscle
  ≤40 Gy to levator ani muscle

Constraints to **pelvic muscle floor** to reduce incontinence related complaints

- Endorectal balloon: fewer complaints in this group (28pts)

Smeenk *et al*, 2012

Foecal incontinence

- **Prospective** study **(> 500 pts**), self reported questionnaires
- Taking into account **severity** and **duration** of symptoms
- **V40>80%**: predictor of Mean Incontinence Score together with previous bowel symptoms, antiypertensive, surgery

- **Two patterns for occurrence of foecal incontinence after RT**:
  - 1: consequent to **acute effects** and mainly responsible for **peak events** (ca ½ pts recovering from symptoms)
  - 2: needs longitudinal analysis- it results form the irradiation of large fraction of the rectum at intermediate doses (V40), presence of pretreatment bowel symptoms, previous abdominal-pelvivc surgery for chronic incontinence
    - Vascular damage, more than damage to sacral nerve (hypertensive drugs work)

Fiorino *et al*, 2011

Summary RECTUM: dose-volume response relationships

- Late rectal bleeding: **serial** description
- DVH/NTCP description: consistent (10^3 pat)
- Abdominal/pelvic surgery- important predictor, modified dose-volume constraints and NTCP

- Foecal incontinence: seems parallel
- V40, D mean best predictors
- Clinical predictors important
- Longitudinal definitions of the endpoints
- Spatial aspects?

BLADDER

4. REVIEW OF DOSE–VOLUME DATA

To date, no studies have comprehensively reported the true three-dimensional (3D) bladder dosimetry in relation to toxicities. A single 3D image set (SimDVH) is of questionable validity. Data for whole-bladder RT vs. partial-bladder doses are discussed by cancer type.

QUANTEC, IJROBP, 2010

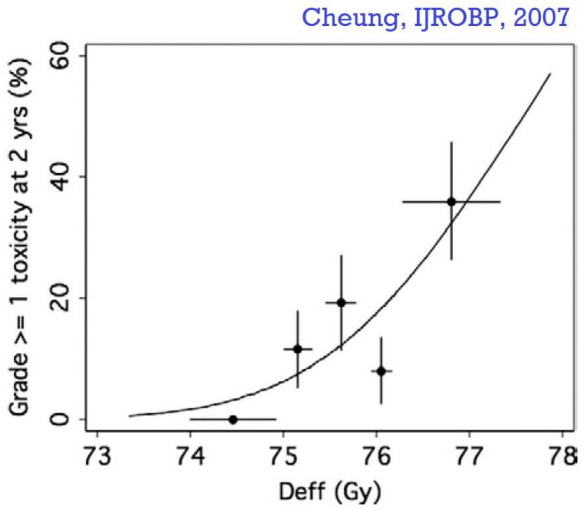
3-years GU (G2-3) toxicities correlated with both high and "low" dose if empty bladder (Harsolia, IJROBP, 2007)

V30Gy < 33.5 cc	2%	G3
V30Gy > 33.5 cc	20%	G3
V82Gy < 2.5 cc	2%	G3
V82Gy > 2.5 cc	12%	G3

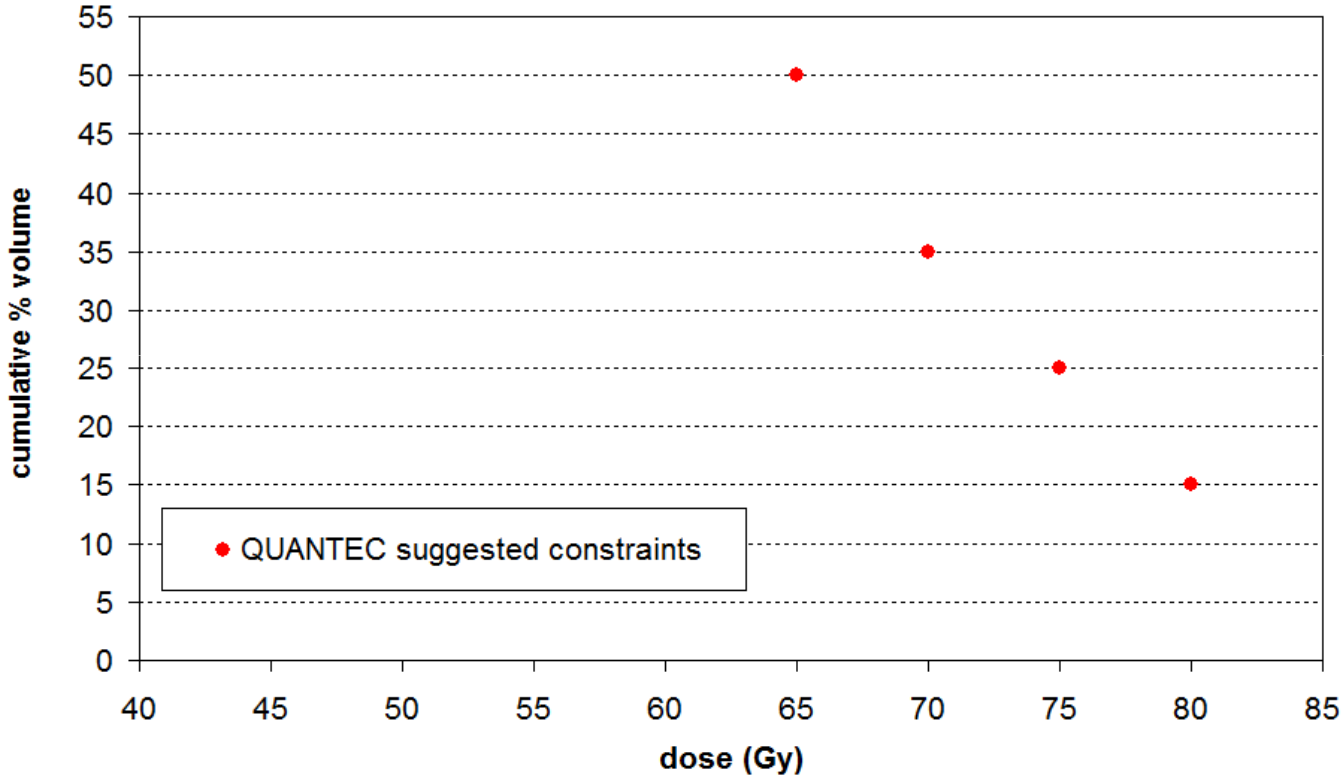
---

8 years GU (G1-3) toxicities correlated with "**hottest volume**"

V78Gy < 2.9 %	25 % 8-years risk
V78Gy > 2.9 %	50 % 8-years risk

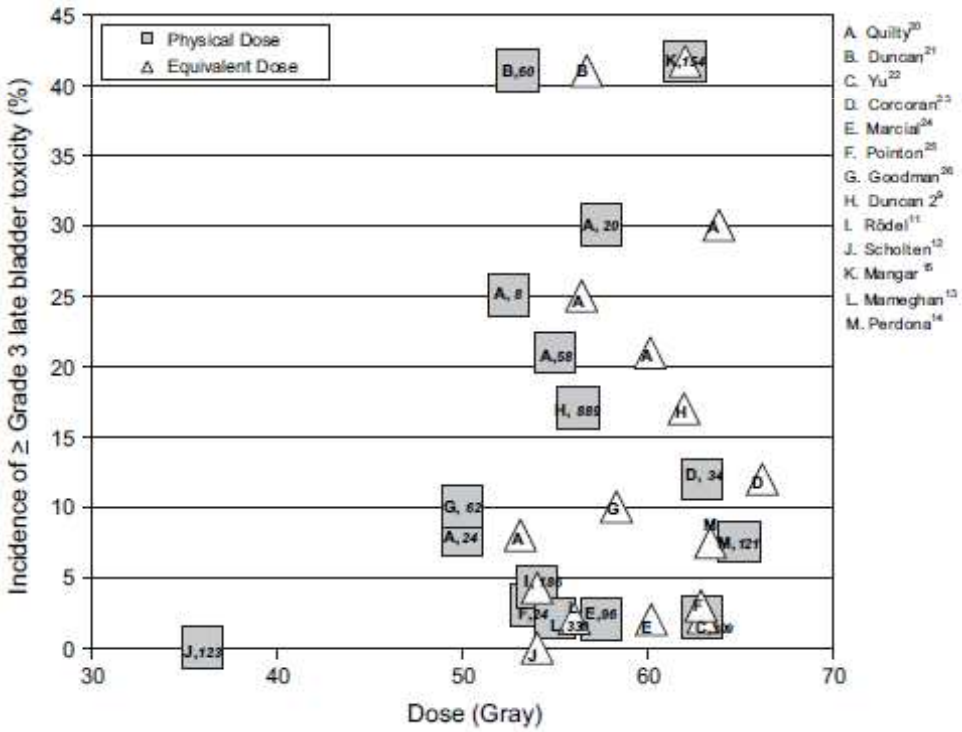


BLADDER: urinary toxicity
QUANTEC constaints (based on RTOG 0415)



GU toxicity- what do we know?

- Quantec summary: not much….
- Whole bladder irradiation: 55Gy threshold for late grade 3 RTOG tox
- Clinical factors hardly influence the outcome
- Variable filling?
- 8 ys fu: hottest volume
- 3 ys fu: both high and low dose



Quantifying Unnecessary Normal Tissue Complication Risks due to Suboptimal Planning: A Secondary Study of RTOG 0126

Moore *et al*, IJROBP, 2015

QC study on: a) treatment planning

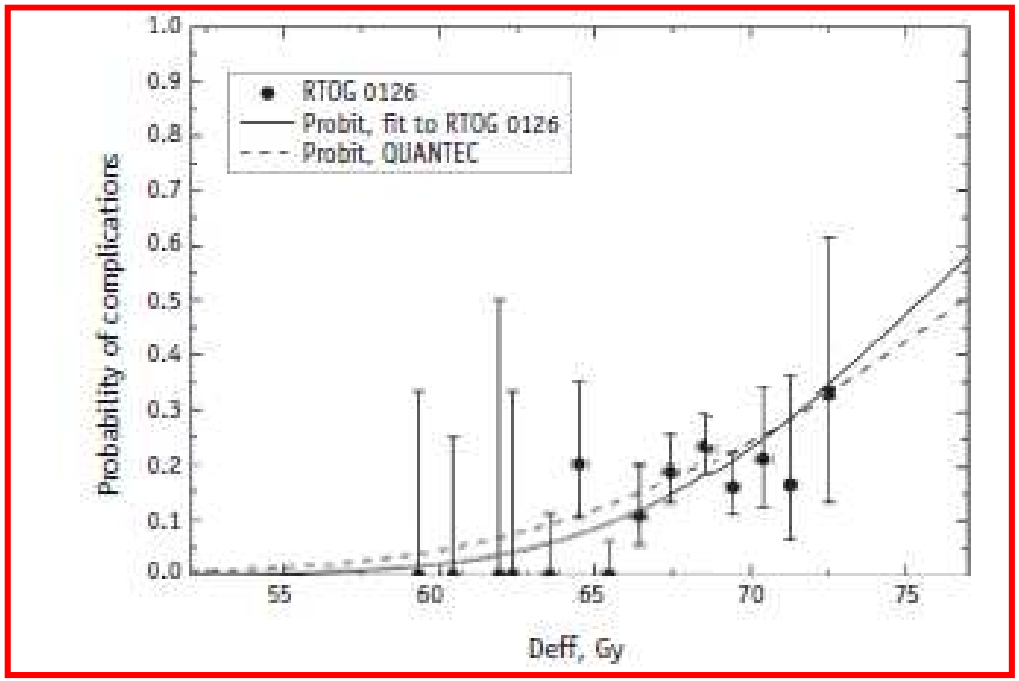
b) QUANTEC guidelines for rectal complications >2gr

- Purpose - Effect of suboptimal planning in IMRT (frequency and clinical severity of quality deficiencies)
- Material - RTOG 0126, 219 pts from the high dose arm (79.2 Gy in 44 frcs)

(RTOG0126: Phase 3 randomised study of High Dose 3D CFRT/IMRT vs Standard Dose 3D CFRT/IMRT)

- Plans analyzed with knowledge-based DVH predictions, based on differences (dose metrics and NTCP values) between the predicted ”best practice” plan and the clinical plan.

Plan quality deficiencies in RTOG 0126 exposed patients to substantial excess risk for rectal complications (less for bladder)



QUANTEC validation for rectal complication > gr 2: **ok!**

Fig. 2. Validation of QUANTEC LKB NTCP model. Observed grade ≥2 late GI toxicities agree with predictions based on QUANTEC (17) recommended LKB parameters (dotted line). Dose-response curve obtained with parameters fitted to RTOG 0126 data is shown for comparison (solid line). Vertical error bars are 68%

…more results from large studies!

Gastrointestinal Dose-Histogram Effects in the Context of Dose-Volume–Constrained Prostate Radiation Therapy: Analysis of Data From the RADAR Prostate Radiation Therapy Trial

Dataset: multicentral trial, **754 pts**, TROG 0304 RADAR LENT and SOMA **toxicity assessment**

- Anatomical dependence of specific GI toxicities
- Dose-volume constraints for different (parts of) OAR

Ebert *et al*, IJROBP, 2014

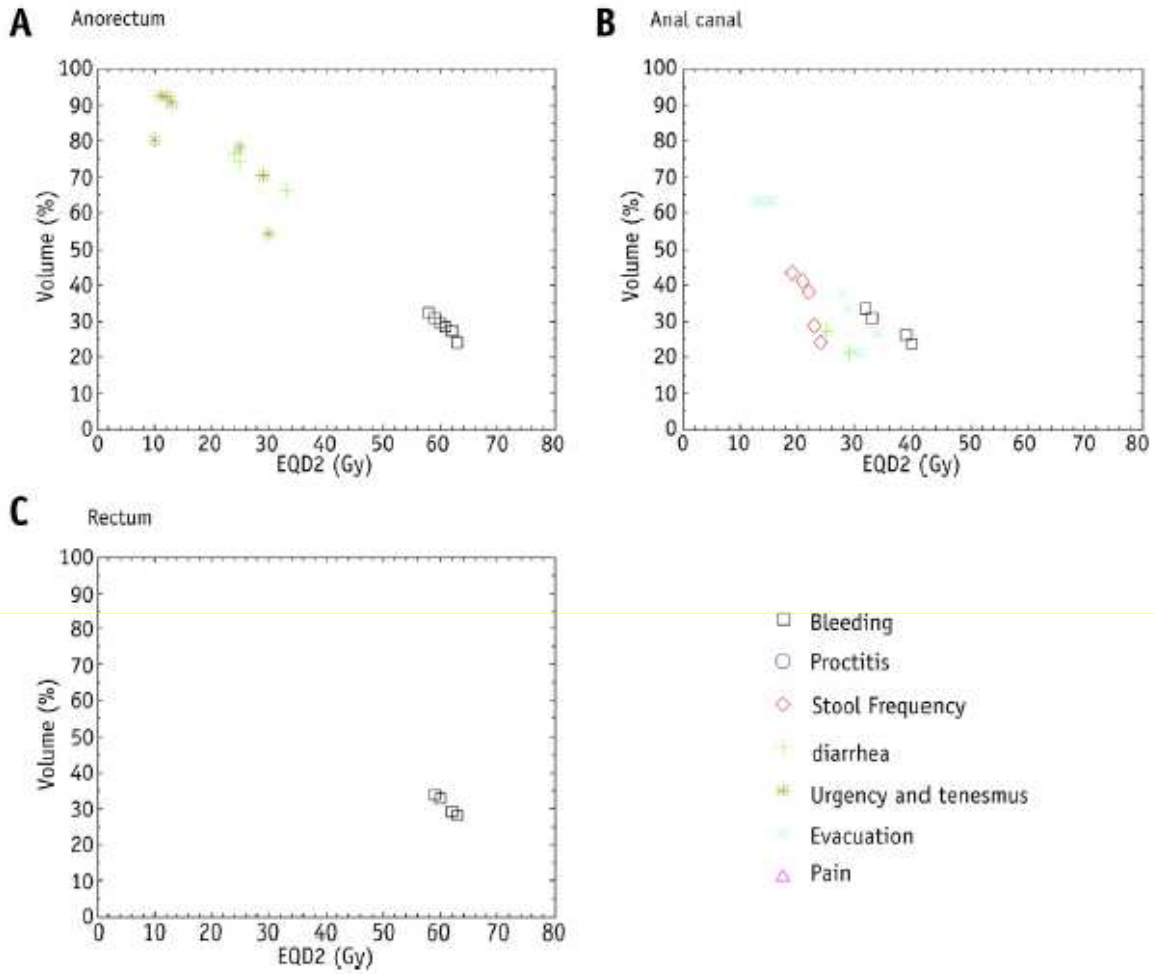


Fig. 5. Important relative dose-volume constraints identified by multivariate regression for 3 GI regions, (a) anorectum, (b) anal canal, and (c) rectum. All values are for peak toxicity and have an OR > 1. EQD2 is for $\alpha/\beta = 3.0$ Gy. EQD2 = equivalent dose in 2-Gy fractions; OR = odds ratio.

Ebert *et al*, IJROBP, 2014

BOWEL: dose-volume effect

Ref.	No. of pts	Doses[a]	Suggested constraints
Baglan [122]	40	45 Gy	Grade 3 CTC 3.0: V15Gy < 150 cc (V40Gy < 125 cc)
Roeske [123]	40	45 Gy	⩾ Grade 2 RTOG: V45Gy < 150–200 cc
Tho [126]	41	45 Gy	⩾ Grade 2 CTC 3.0: V15Gy < 100 cc (risk < 20%)
Huang [125]	80	39.6–45 Gy	⩾ Grade 2 diarrhoea CTC 3.0: V16–18Gy and V40–45Gy independently predictive for pts without/with previous surgery, respectively
Robertson [127]	91	45 Gy	Grade 3 diarrhoea CTC 3.0: V15Gy < 120 cc V25Gy < 105 cc V40Gy < 71 cc
Sanguineti [124]	149	0/54 Gy[b]	⩾ Grade 2 CTC 2.0: V15Gy < 1186 cc
Fiorino [128]	175	50.4–54 Gy	⩾ Grade 2 RTOG: Intestinal cavity outside PTV/Whole cavity V50Gy < 35 cc/100 cc V45Gy < 100 cc/250 cc V40Gy < 150 cc/350 cc V30Gy < 300 cc/500 cc

Fiorino, RO, 2009

DOSE–VOLUME RELATIONSHIPS FOR ACUTE BOWEL TOXICITY IN PATIENTS TREATED WITH PELVIC NODAL IRRADIATION FOR PROSTATE CANCER

CLAUDIO FIORINO, PH.D.,* FILIPPO ALONGI, M.D.,†‡ LUCIA PERNA, PH.D.,* SARA BROGGI, PH.D.,* GIOVANNI MAURO CATTANEO, PH.D.,* CESARE COZZARINI, M.D.,† NADIA DI MUZIO, M.D.,† FERRUCCIO FAZIO, PROF, M.D.,† AND RICCARDO CALANDRINO, PH.D.*

Table 1. Modified Radiation Therapy Oncology Group/European Organization for Research and Treatment of Cancer acute toxicity scoring criteria used to assess bowel symptoms in current study

Grade 0	1	2	3	4
No change	Increased frequency or change in habits not requiring medication	Diarrhea requiring drugs/mucous discharge not necessitating sanitary pads/abdominal pain requiring analgesic	Diarrhea requiring parenteral support/severe mucous discharge requiring sanitary pads	Acute or subacute obstruction/abdominal pain or tenesmus requiring surgery

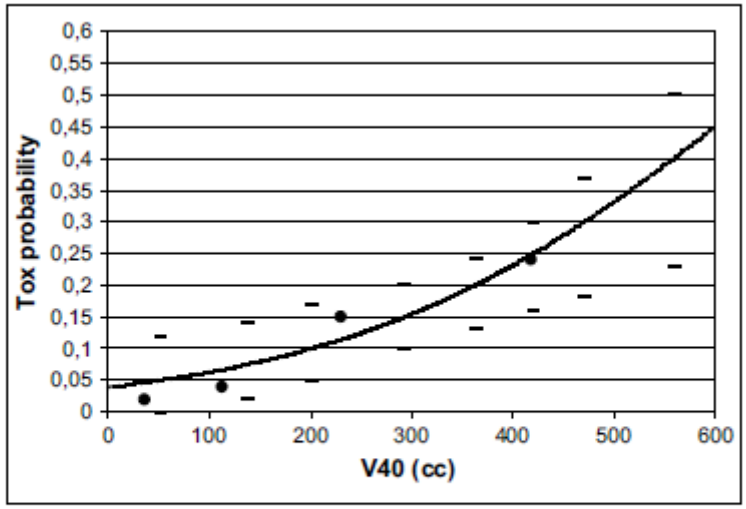

Fig. 1. The relationship between the V40 of the intestinal cavity (outside the planning target volume) and the risk of Grade 2–3 acute bowel toxicity is plotted, together with 95% confidence intervals (logistic curve).

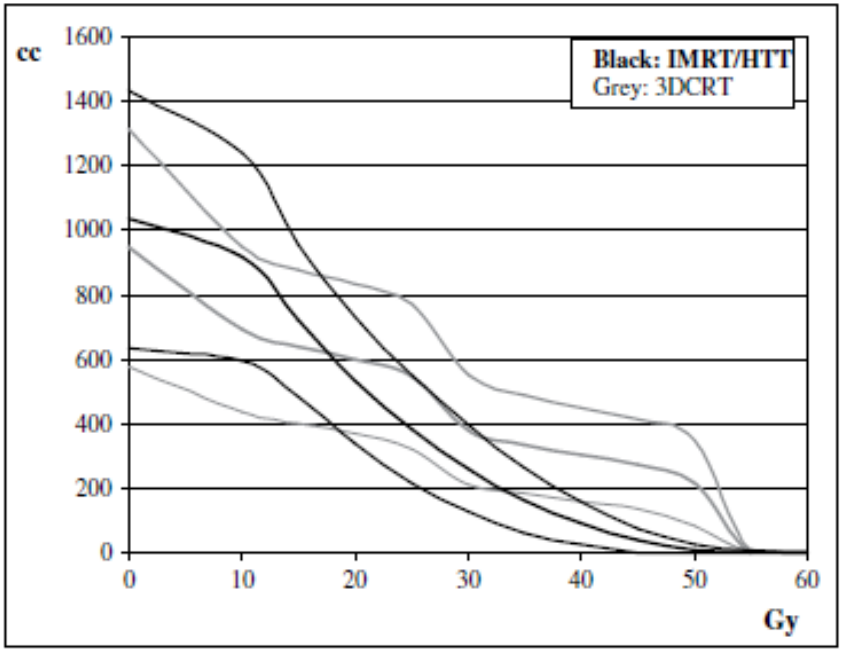

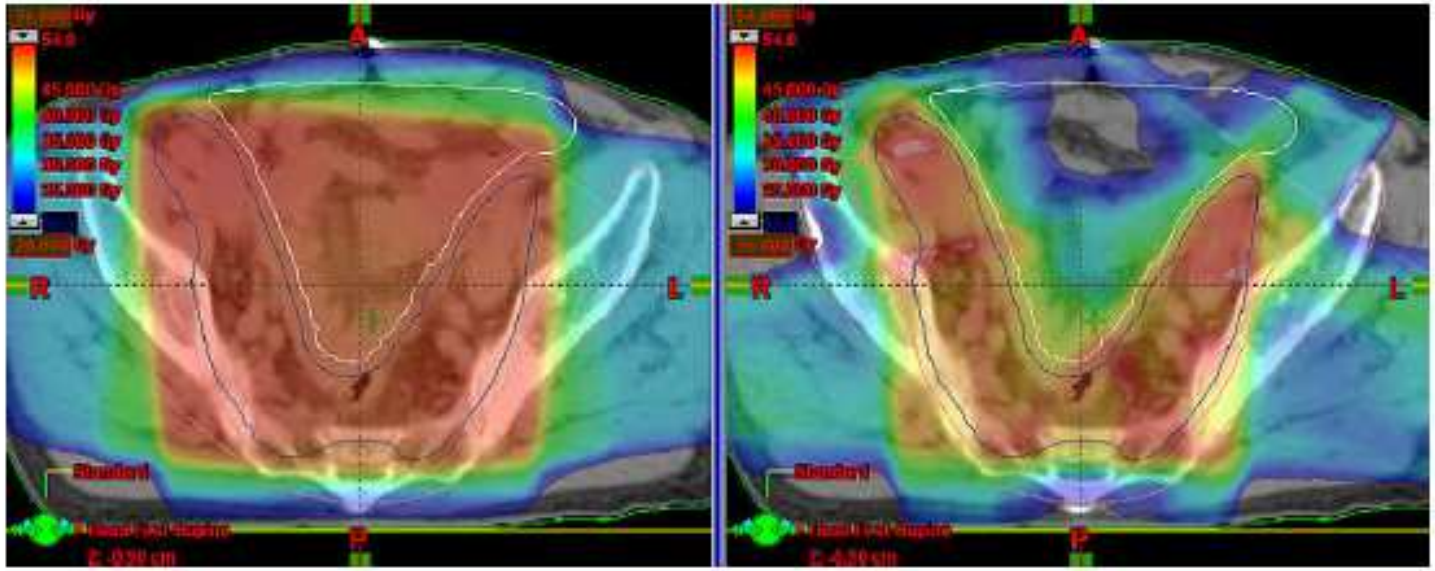

Fig. 5. An example of the dose distribution for three-dimensional conformal radiation therapy (3DCRT) and intensity-modulated radiation therapy (IMRT) on an axial slice passing through the pelvis: the 15- to 54-Gy dose range is shown in color wash. Dark contour = planning target volume (PTV); white contour = intestinal cavity outside PTV (IC).

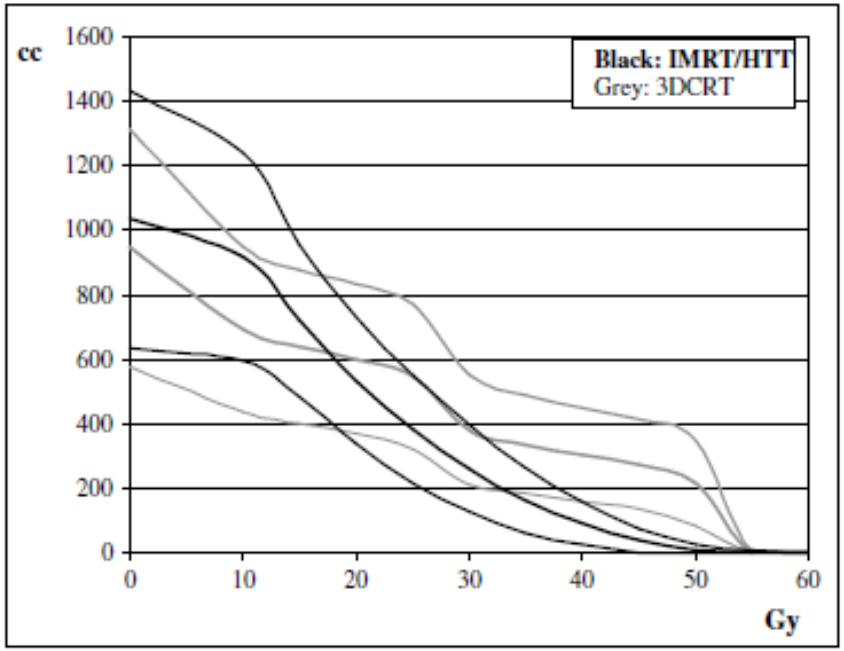
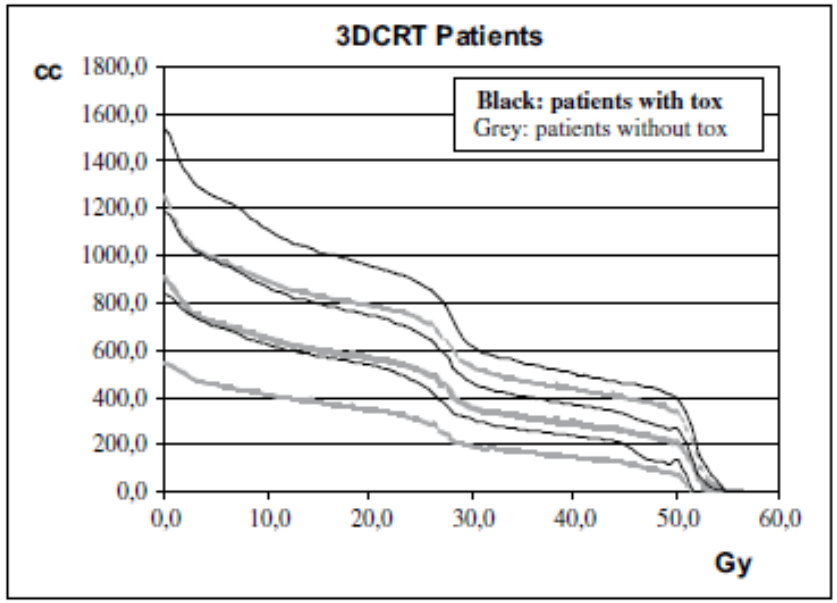
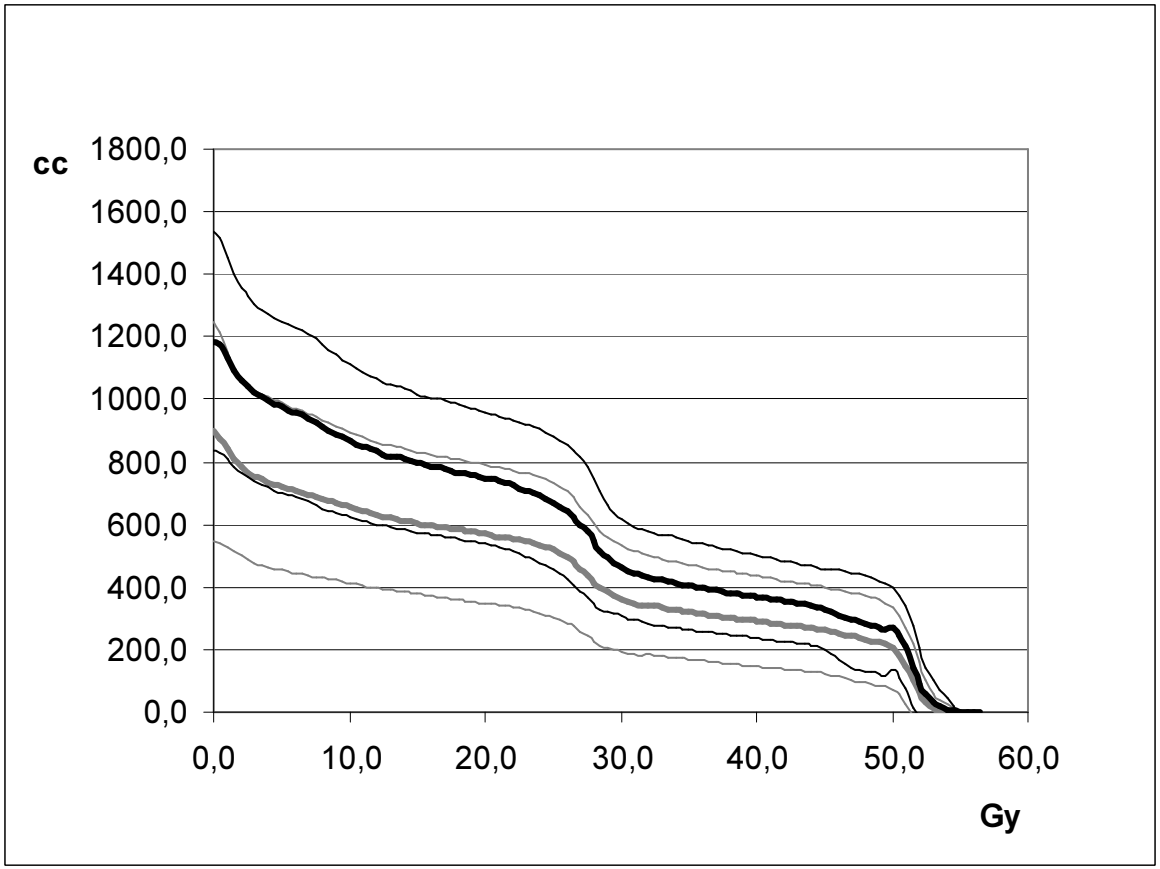






Black: pts with tox

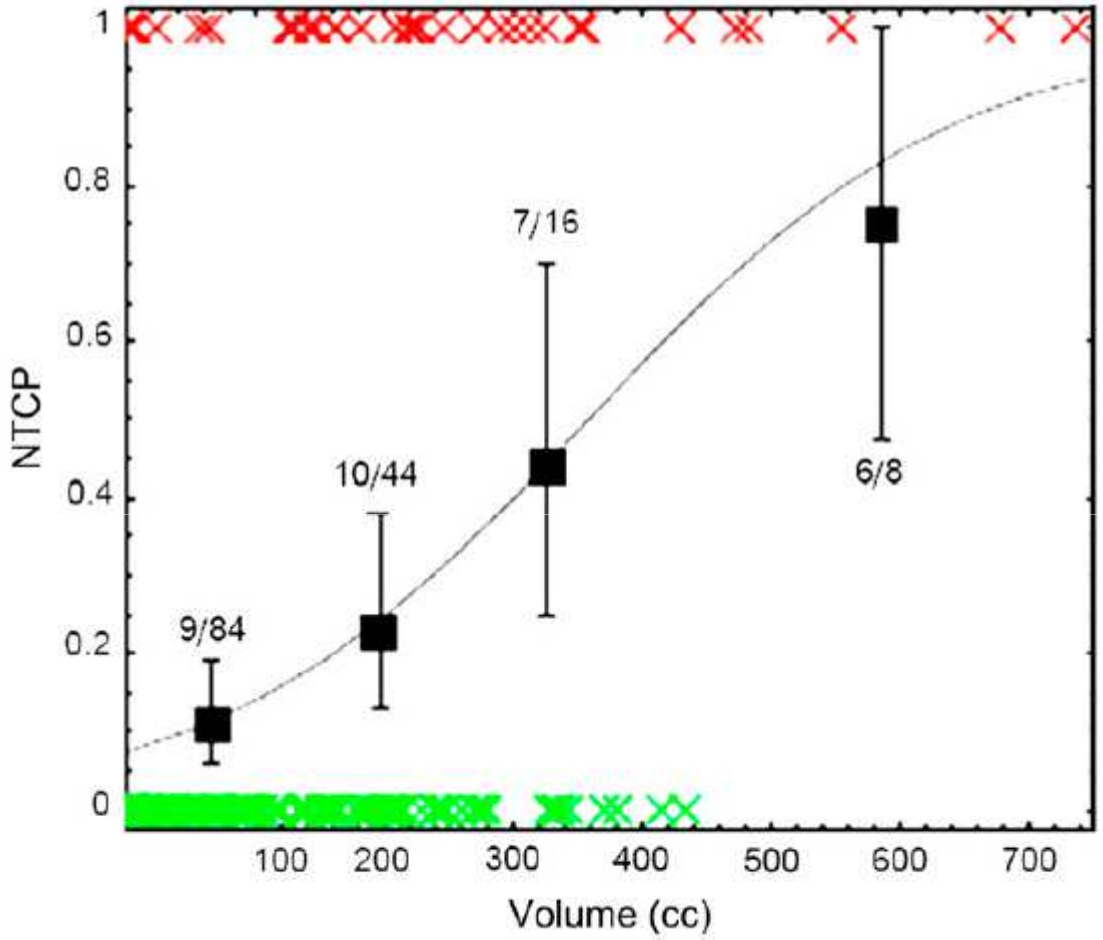
Grey: pts without tox

UVA: V15 best predictor compared to V40-V50…..due to larger differences at low doses (geometry…no biology !!!!)

V15 AS A SURROGATE OF THE HIGH-DOSE REGION IN THE BOX TECHNIQUE

NO BIOLOGICAL MEANING - DONT USE IT (ALONE) IN IMRT OPTIMIZATION…

BOWEL: dose-volume effect



V15Gy, rectal cancer patients, acute G3 diarrhea
Concomitant chemotherapy
Robertson IJROBP 2010

PENILE BULB: erectile dysfunction

Erectile dysfunction (ED), the consistent inability to attain or maintain an erection of sufficient quality to permit satisfactory sexual intercourse, is a common complication resulting from radiotherapy (RT) for prostate cancer (1). Many patients choose RT for their clinically localized prostate cancer because they believe there may be a lower risk of ED compared with radical prostatectomy (RP); however, this remains controversial. Posttreatment ED rates have been reported to be approximately 24% (brachytherapy alone), 40% (brachytherapy plus external RT), 45% (external RT alone), 66% (nerve-sparing RP), 75% (non–nerve-sparing RP), and 87% for cryosurgery, but physician-reported rates are known to be less reliable than patient-reported outcomes, so the optimal comparison studies have yet to be done (2).

QUANTEC 2010

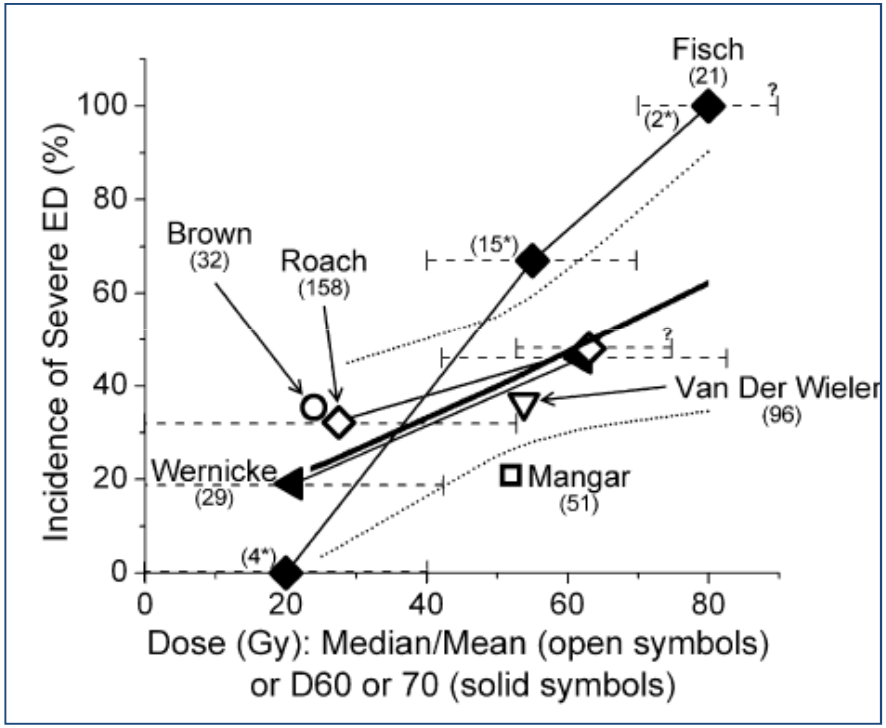
Table 1. Erectile dysfunction after external-beam radiotherapy and correlated parameters

First author, year (reference)	N	Assessment method*	Prescribed dose, treatment	OAR definition	Severe ED rate (%)	Correlated parameters	
						Dose–volume	Clinical
Fisch, 2001 (7)	21	Questionnaire†	65–72 Gy, 3D	Penile bulb	33‡	D70 ≥70 Gy§	No other endpoints analyzed
Roach, 2004 (10)	158	Patient report, (RTOG)‖	68.4 Gy, 73.8 Gy, 3D	Penile bulb¶	41	Median penile bulb dose ≥52.5 Gy¶	No other endpoints analyzed
Wernicke, 2004 (14)	29	Questionnaire†	66.6– 79.2 Gy, 3D	Penile bulb#	NS	D30 ≥67 Gy¶ D45 ≥63 Gy¶ D60 ≥42 Gy¶ D75 ≥20 Gy¶	Alcohol and smoking not significant, dose and volume significant
Selek, 2004 (11)	28	Questionnaire†	78 Gy, 3D	Penile bulb#	35.7% at 2 y	Mean dose to penile structure 38.2 Gy, no dose–volume effect was found#	Up to 68% may have had ED posttreatment? ED correlated with hypertension
Mangar, 2006 (8)	51	Questionnaire†	64 Gy, 74 Gy, 3D	Penile bulb, crura and cavernosum**	24	D15, D30, D50, D90 of penile bulb¶	Adjusted for age, bulb volume, hypertension, and previous pelvic surgery
Zelefsky, 2006 (15)	561	Patient report (NCI)††	81 Gy, IMRT	‡‡	49	Not evaluated	Hormone therapy
Brown, 2007 (5)	32	Questionnaire†	NS, IMRT	Penile bulb	34	No relationship noted	Hypertension, pre-RT erectile function
Cahlon, 2008 (6)	478	Patient report (NCI)††	86.4 Gy, IMRT	‡‡	30	Not evaluated	Age >70 y, diabetes, hormone therapy
van der Wielen, 2008 (13)	70	Questionnaire†	68 vs. 78 Gy	Penile bulb	36	No correlations between ED and dose–volume of crura, or the penile bulb#	Adjusted for diabetes and history of cardiovascular disease
Pinkawa, 2009 (9)	123	Questionnaire†	70.2–72 Gy, 3D	NS	73§§	Not evaluated	Age, diabetes

QUANTEC 2010

Suggestion: D>40-50 Gy to the whole bulb associated with increased toxicity,
Observe: several studies do **not** find any correlation with dose

Erectile dysfunction – dose response relationship?



8. RECOMMENDED DOSE/VOLUME LIMITS

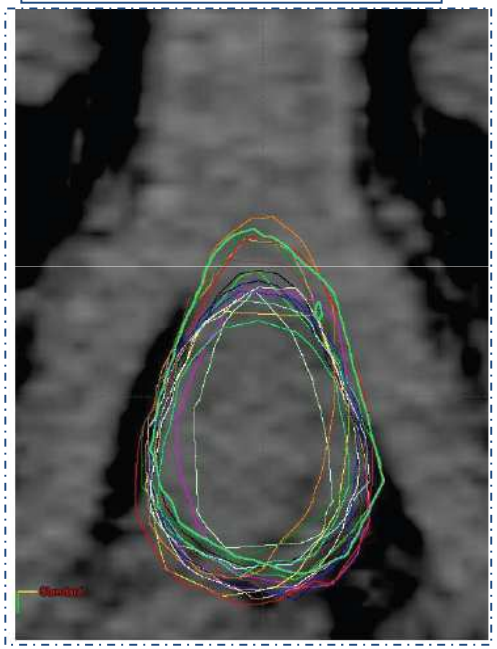
On the basis of the data available, it is prudent to keep the mean dose to 95% of the PB volume to <50 Gy. It may also be prudent to limit the D70 and D90 to 70 Gy and 50 Gy, respectively. It is acknowledged that the PB may not be the critical component of the erectile apparatus, but it seems to be a surrogate for yet to be determined structure(s) critical for erectile function for at least some techniques.

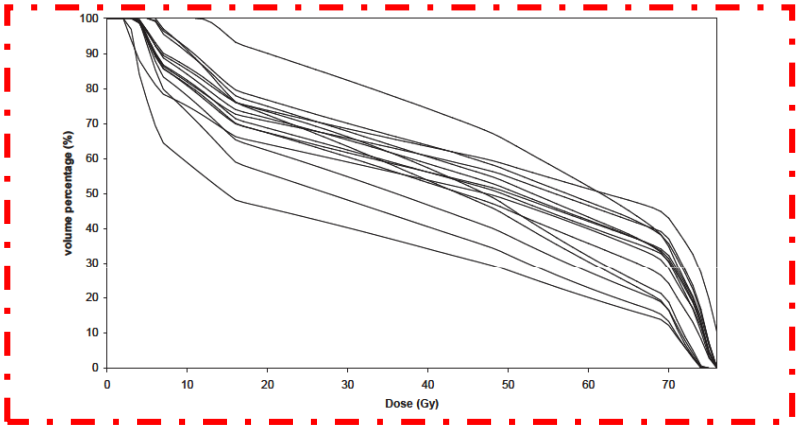
QUANTEC 2010

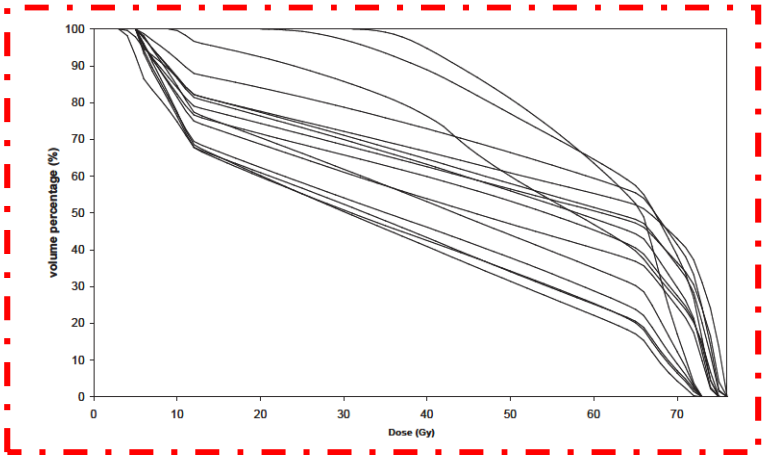
Inter-observer variability in contouring the penile bulb on CT images for prostate cancer treatment planning

Pema *et al. Radiation Oncology* 2011, **6**:123

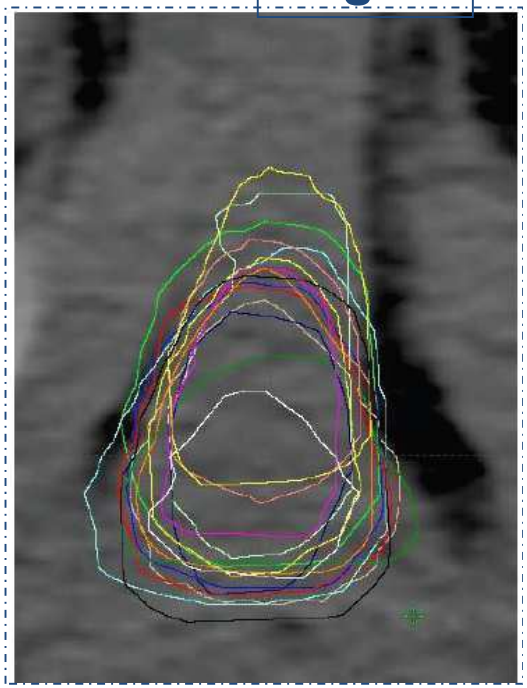
lowest







largest



•Penile bulb volume: 5-20cc

- Contouring: interobserver variability larger than interpatient variability
- Dose-metrics: interpatient variability larger than interobserver variability
- % DVH should be used, not absolute DVH in cc

Pema *et al. Radiation Oncology* 2011, **6**:123

	5yrs	10yrs
A	3%	3%
B	14%	26%
C	**26%**	**31%**

Improving the Results of RT

- PROBLEMS

1. Inadequate dose delivered so poor efficacy despite the fact that it was known that dose escalation beneficial – calculated that increasing the dose of radiation by 10% can increase local control by 20%

2. Inability to dose escalate without unacceptable toxicity to surrounding normal structures

3. High risk disease also recurrence at nodal and distant sites

Recent improvements in RT

- Innovative techniques allow dose escalation while sparing normal tissue:[1,2]

3D conformal RT (3D-CRT)
- Minimises organ damage
- Allows higher radiation dose

Image-guided RT (IGRT)
- Fiducial markers
- Cone-beam imaging
- Tomotherapy

High dose rate (HDR) brachytherapy boost

Cyberknife and Proton Boost under investigation

Intensity-modulated RT (IMRT)
- Optimised form of 3D-CRT
- Dose distribution shaped more precisely to target than 3D-CRT to spare organs at risk

Hypofractionation

Volumetric arc therapy

Combined RT and ADT
- Can delay progression and improve overall survival
- Concomitant and adjuvant ADT mandatory for RT of high-risk PCa[1]

: Androgen deprivation therapy, PCa: prostate cancer, RT: Radiotherapy

1. Heidenreich A, et al. Eur Urol 2011; 59:61–71; 2. Pinkawa M et al. Strahlenther Onkol 2011;187:479–484

3D-CRT and IMRT

- **3D-CRT:**
  - better targeting of RT using 3D imaging to define target volume and critical organs at risk (OAR); multiple beams conform to the 3D tumour shape and maximally avoid the OAR[1]
- **IMRT:**
  - optimized high-precision form of 3D-CRT
    - allows better dose distributions and improved ability to conform treatment volume to concave shapes
    - Individual beamlets allow varying doses to exploit differences in position of tumour vs. normal tissue[2]
- **IMRT +IGRT:**
  - IGRT may improve outcome by reducing set-up error and accounting for organ motion[2]

3D-CRT, 3-dimensional conformal RT ; IMRT, Intensity modulated RT; IGRT, image-guided RT

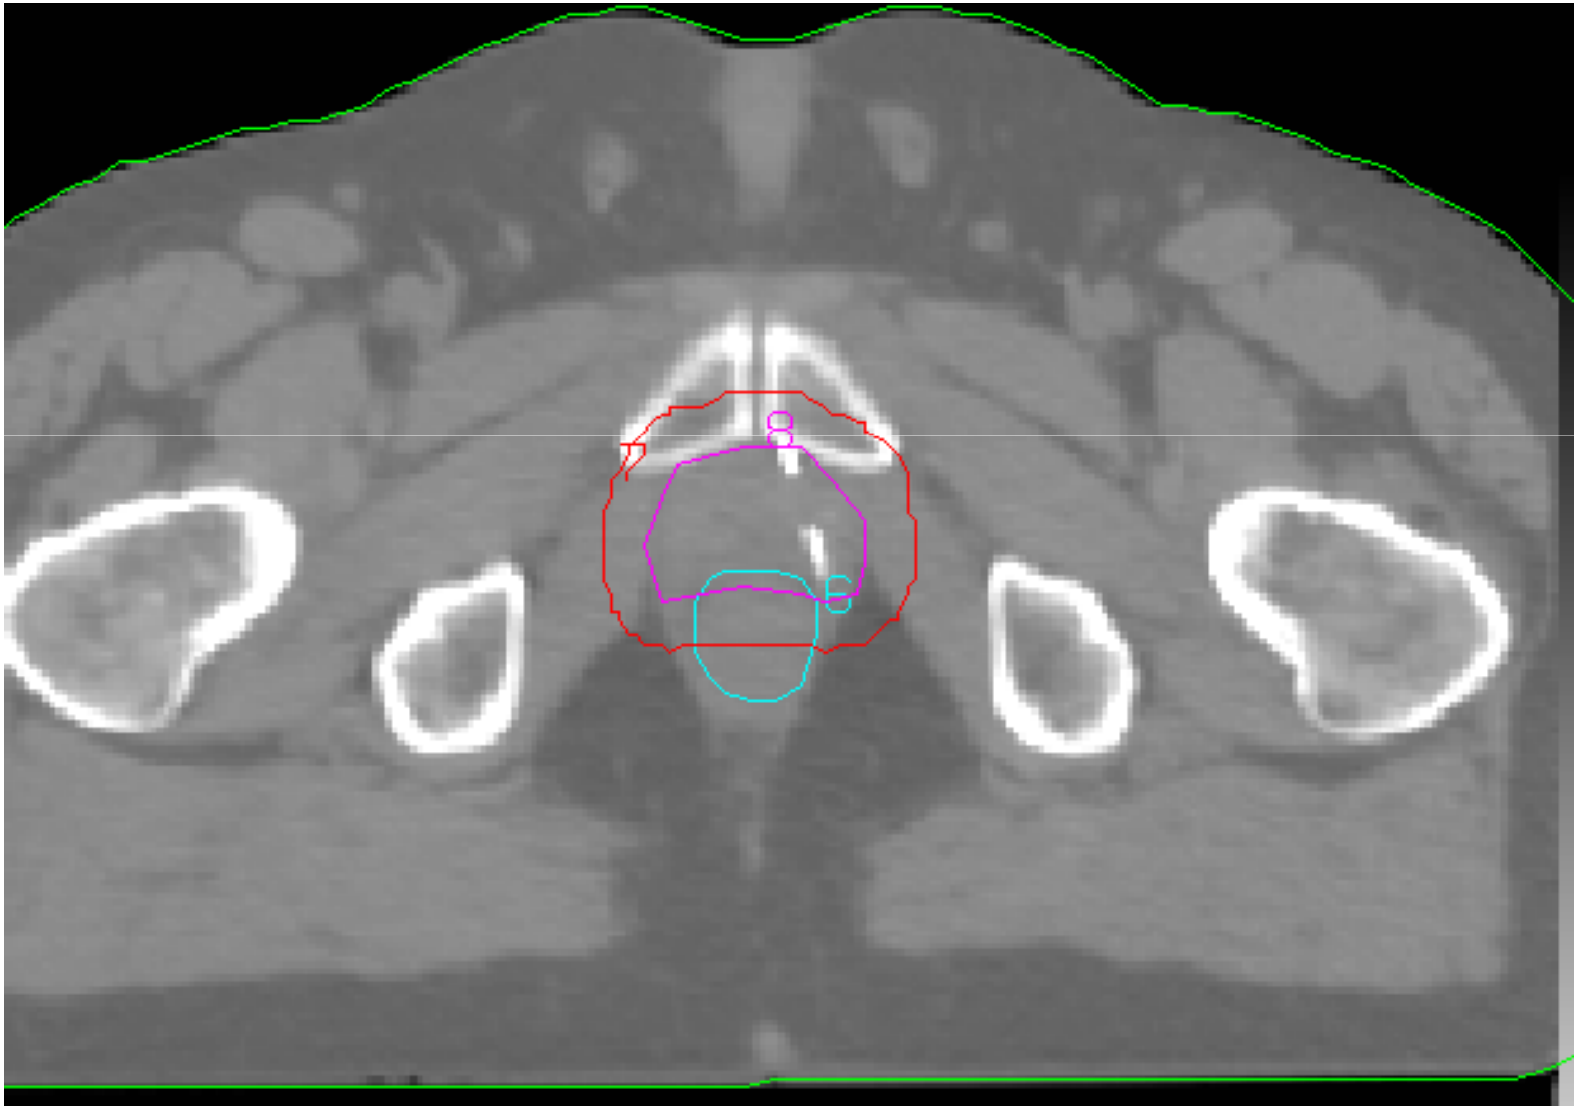
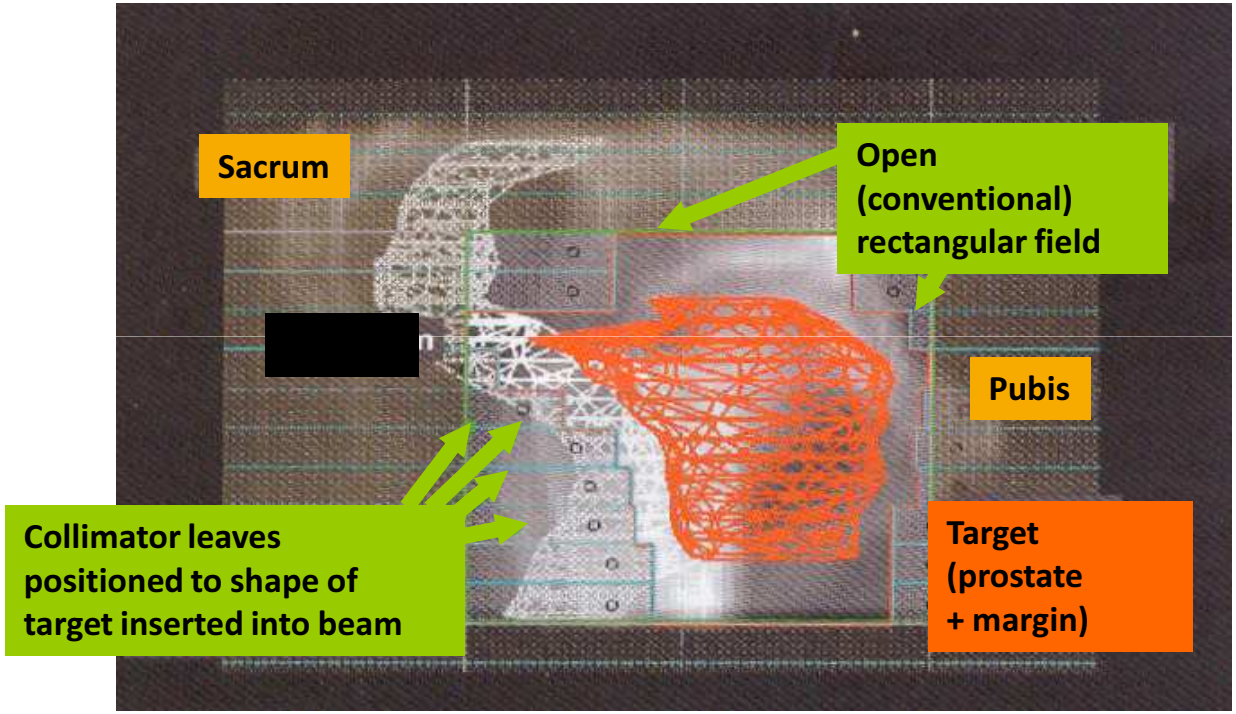
2. Wolff JM et al. BJU Int 2012; 109 (Suppl 6): 33–41

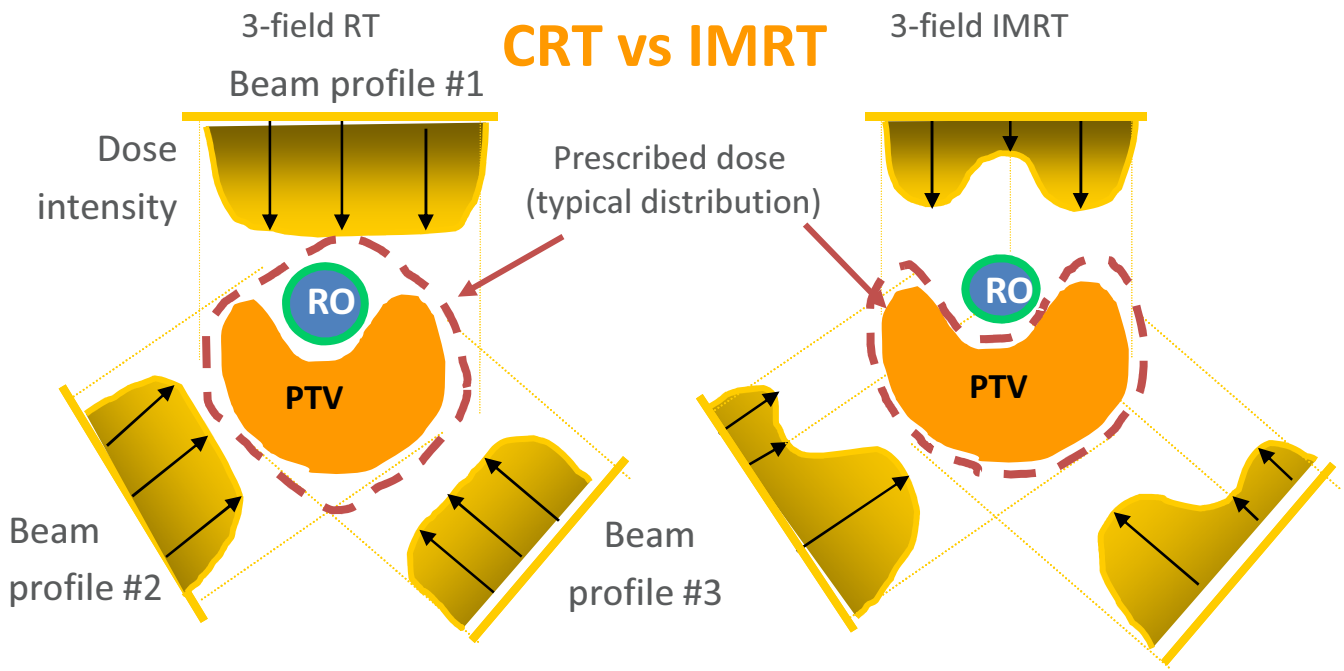
E



Conformal Radiotherapy



IMRT allows dose distribution to be shaped to the target, sparing at-risk organs



CRT: Conformal radiotherapy. IMRT: Intensity-modulated radiotherapy.
PTV: Panning target volume. RO: Risk organ

Volumetric modulated arc therapy (VMAT)

- Treatment of whole target volume using 1 or 2 arcs
- Simultaneous variation of 3 parameters:[1]
  - ➔ Gantry rotation speed
  - ➔ Treatment aperture shape via movement of multileaf collimators*
  - ➔ Dose rate
- Highly conformal dose distributions with improved target volume coverage and sparing of normal tissues vs. conventional RT techniques;
  - ➔ Potential to reduce treatment delivery time vs. conventional static field IMRT[1]

1. Teoh M, et al. British J Radiol 2011;84:967–996

* Each radiation beam is modulated by continuously moving multileaf collimators

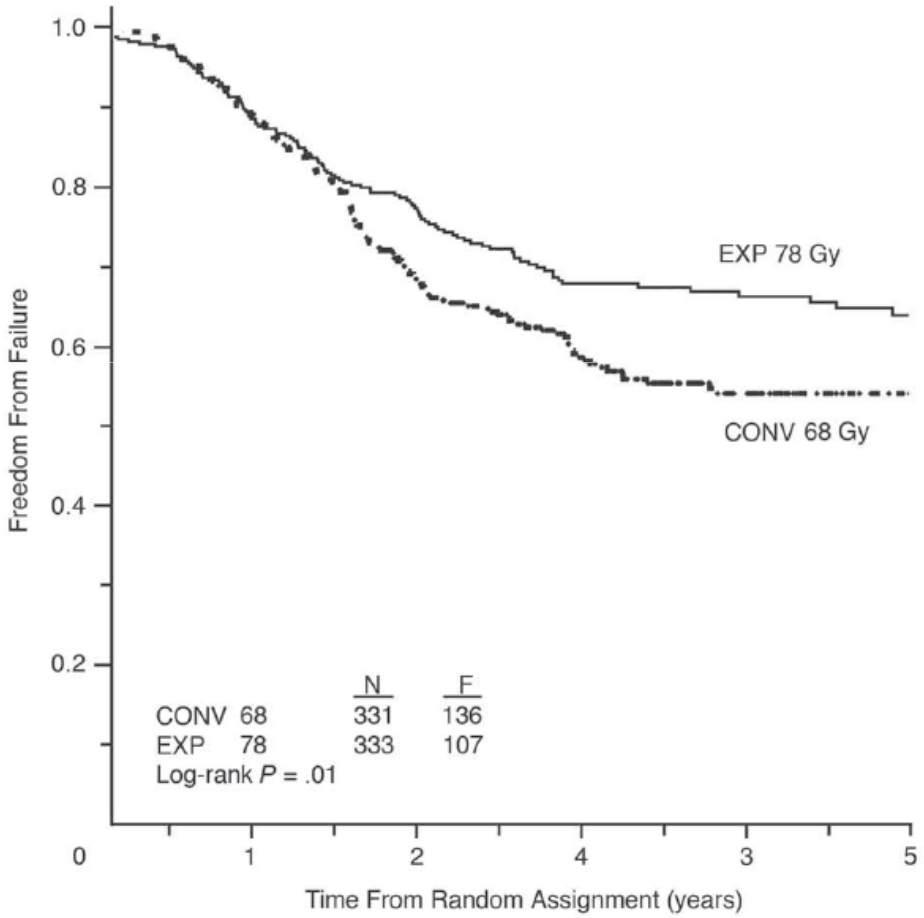
Netherlands Cancer Institute (NKI) study: Freedom from failure significantly better in dose-escalated arm

Freedom from failure*



Biochemical failure was defined according to the ASTRO definition with backdating
EXP, experimental; CONV, conventional; F, failures
Peeters ST, et al. J Clin Oncol 2006;24:1990–6

RT01 trial: 5-year follow-up: Improved bPFS with dose-escalation (44% high risk)

Median follow-up: 5 years	Standard dose CFRT 64 Gy/32 fractions (n=421)	Escalated-dose CFRT 74 Gy/37 fractions (n=422)	HR (95% CI)
bPFS at 5 years	60%	71%	0.67 (0.53-0.85) p<0.0007
bPFS events	149	108	
Clinical PFS	87%	90%	0.69 (0.47-1.02) p=0.064
Freedom from salvage androgen suppression	80%	84%	0.78 (0.57-1.07) p=0.12

At 5 years, using CFRT to increase RT dose from 64 Gy to 74 Gy had substantially improved prostate-cancer control in terms of bPFS

bPFS, biochemical progression-free survival; CFRT, conformal radiotherapy; HR, hazard ratio; all comparisons expressed relative to patients in standard group (i.e. HR <1・0 indicates decreased risk of event for escalated group)
Dearnaley DP et al. Lancet Oncol 2007;8:475–87

RT01 trial: 10-year follow-up: No improvement in long-term survival with dose-escalation (44% high risk)

Median follow-up: 10 years	Standard dose CFRT 64 Gy/32 fractions (n=421)	Escalated-dose CFRT 74 Gy/37 fractions (n=422)	HR (95% CI)
Deaths	120	119	
Overall survival at 10 years	70%	70%	0.99 (0.77-1.28) assumption of proportional hazards met: p=0.337
bPFS at 10 years	42%	54%	0.688 (0.56-0.84) p<0.0001
bPFS events	224	172	
Long-term HT	220 men overall: fewer men starting HT and later in escalated-dose group		0.77 (0.59-1.00) p=0.05

In the longer-term perhaps 74 Gy is not a sufficient dose escalation

No mandated IGRT

bPFS, biochemical progression-free survival; CFRT, conformal radiotherapy; HR, hazard ratio; all comparisons expressed relative to patients in standard group (i.e. HR <1・0 indicates decreased risk of event for escalated group); HT, hormone therapy

IMRT for Prostate Cancer

PATIENT SELECTION CRITERIA

Histologically confirmed non-metastatic prostate cancer

All patients referred for prostate +/- seminal vesicle radiotherapy +/- nodal therapy or prostate bed radiotherapy to be considered for inverse planned IMRT

WHO performance status 0 or 1

EXCLUSION CRITERIA

Previous pelvic radiotherapy

Inflammatory Bowel Disease?

Prior major pelvic surgery (e.g. Colectomy, colostomy, cystectomy)???

Significant bladder instability or urinary incontinence?????

Bilateral Hip Replacements????

IMRT for Prostate Cancer

PRE-TREATMENT ASSESSMENT

TNM stage
Pathology – Gleason Score
PSA at presentation

Neo-adjuvant androgen deprivation for 3- 6 months prior to RT
Discuss adjuvant androgen deprivation therapy according to risk category

Prostate fiducial marker implant 3-4 weeks prior to CT planning scan
Ciprofloxacin antibiotics to be prescribed in clinic and started by patient the evening before fiducial marker insertion.
Patients on anticoagulation require switching from warfarin to S/C heparin prior to fiducial marker insertion.

Bowel and bladder preparation appointment booked 1 week before planning scan

Consent form signed in clinic scanned onto CDR as a permanent record

IMRT for Prostate Cancer

Prostate and Seminal Vesicles

IMRT for Prostate Cancer

DECISION FOR TREATMENT VOLUME

Roach Formula: Seminal vesicle risk (%) = PSA + [(Gleason Grade – 6) x 10]

Seminal Vesicle Low risk group
Clinical stages T1b/c or T2a/b and with PSA + [(Gleason Grade – 6) x 10] <15

Seminal Vesicle Moderate/High risk group
Clinical stages T1b/c or T2a/b and with PSA + [(Gleason Grade – 6) x 10] >15
T2c or T3a

PATIENT RISK DEFINITION

Patients with **low risk disease** - T1-T2b, Gleason Grade ≤ 6, PSA ≤ 10

Patients with **intermediate risk disease** - T2c, Gleason Grade 7, PSA 10-20

Patients with **high risk disease** -T3a-T4 Gleason Grade ≥ 8, PSA ≥20

IMRT for Prostate Cancer

POSITIONING AND IMMOBILISATION

The patient will be immobilised head first supine on the combifix.

RADIOTHERAPY PLANNING

CT planning scan of the pelvis with 2.5 mm slice thickness

Bladder and rectal filling - Comfortably full bladder (350mls of water 30 minutes before scan) and empty rectum achieved using microlette enemas)

Rescan the patient if the bladder is empty or the rectum is >5cm. Consider rescan if rectum > 3.5cm and rectum is deforming prostate.

Scanning levels: From the top of the L3 vertebral space to 5cm below the ischial tuberosities.

IMRT for Prostate Cancer

VOLUME DELINEATION

The volumes will be delineated with the aid of CT images

The clinician will outline
Gross tumour volume (GTV)
Clinical tumour volume (CTV)
Planning target volume (PTV)

The normal tissue organs at risk of radiation exposure will be outlined- rectum, bladder, femoral heads, bowel, urethral bulb, penile shaft

IMRT for Prostate Cancer

PLANNING TARGET VOLUMES

Low and Intermediate Risk Patients:

GTVp	Prostate alone
GTVpb	Prostate and base of seminal vesicles
CTVpb	GTVpb+0.5cm (excluding rectum)
PTV74	GTVp + 0.5cm (excluding rectum)
PTV71	CTVpb + 0.5cm (isotropic)

High Risk Patients:

GTVp	Prostate alone +/- any involved disease
GTVpsv	Prostate and seminal vesicles
CTVpsv	GTVpsv+0.5cm (excluding rectum)
PTV74	GTVp+0.5cm (excluding rectum)
PTV71	CTVpsv+0.5cm (isotropic)

IMRT for Prostate Cancer

STRUCTURES TO BE OUTLINED AS ORGANS AT RISK

RECTUM

The circumference of the rectum should be outlined entirely. If the anterior-posterior diameter of the rectum is > 5cm at any level adjacent to the prostate, or is >3.5cm and deforming the prostate, the patient should be re-scanned. The outlining should extend to the bottom of the ischial tuberosities to the recto-sigmoid junction. At the recto-sigmoid junction, the rectum and the sigmoid will be outlined as different structures. The recto-sigmoid junction will be defined as the level at which there is an anterior inflection of the bowel.

IMRT for Prostate Cancer

STRUCTURES TO BE OUTLINED AS ORGANS AT RISK

BLADDER

The outside of the bladder wall should be outlined. The entire bladder should be included.

BOWEL (SMALL BOWEL AND COLON)

The small and large bowel should be outlined on all slices. The small and large bowel should be outlined as separate structures where possible. However, the combined structure will be used for the bowel dose constraint. The outlining will include the small bowel, large bowel and the sigmoid colon down to the level of the recto-sigmoid junction. The superior extent should be 3cm above the superior limit of the PTV.

FEMORAL HEADS

The femoral heads should be outlined to the bottom of the curvature of their heads.

PENILE SHAFT AND BULB

The penile shaft and penile bulb

IMRT for Prostate Cancer

RADIOTHERAPY TREATMENT

Inverse planned VMAT/IMRT using dynamic MLC, 6MV photons

VMAT: 1-2 Arcs

IMRT: 5-7 co-planar fields

Gantry: 0°, 52°, 100°, 157°, 203°, 260°, 308° (7 fields)

180, 91-100, 30, 330, 260-269 (5 fields)

Energy: 6 MV photons

IMRT for Prostate Cancer

RADIATION PRESCRIPTION

Low and intermediate risk patients

74Gy to MTD in 37# at 2Gy per # over 7.5 weeks

PTV74	74Gy in 37# to target mean (2.0)
PTV71	71Gy in 37# to target mean(1.92)

High risk patients

74Gy to MTD in 37# at 2Gy per # over 7.5 weeks

PTV74	74Gy in 37# to target mean (2.0)
PTV71	71Gy in 37# to target mean (1.92)

IMRT for Prostate Cancer

DOSE REQUIREMENTS

PTV 74

99% of the volume to be covered by 95-105% of prescribed dose (70.3 – 77.7Gy)

Median dose = 74Gy +/- 0.5Gy

Minimum dose to 99% volume = ≥ 95% (70.3Gy)

Maximum dose to 1% volume = <105% (77.7Gy)

PTV71

99% of the volume to be covered by 95% of 71Gy (67.45Gy)

Median dose = 71Gy +/ - 1Gy

IMRT for Prostate Cancer

MAXIMUM DOSE LIMITS FOR OAR

RECTUM

V30	80%
V40	70%
V50	60% (Should aim to achieve < 50%)
V60	50% (Should aim to achieve < 40%)
V65	30%
V70	15%
V74	3%

BLADDER

V50	50%
V60	25%
V74	5%

FEMORAL HEADS

V50	50%
Max	55Gy

IMRT for Prostate Cancer

BOWEL GRADE	0	(Grade1)
V45	78cc	158cc
V50	17cc	110cc
V55	14cc	28cc
V60	0.5cc	6cc
V65	0cc	0cc

Aiming to meet Grade 0 values

Urethral Bulb

V50	50%
V60	10%

DVH LIMITS FOR OAR

No hotspots (>103%) to occur in bowel

No dose > 105% to any OAR

Any hot spots outside the PTV should not to exceed 105%. Unexpected cold spots should be avoided.

RT Prostate

Morbidity

Acute

- Lethargy
- Proctitis
- Urethritis
- Cystitis
- Diarrhoea

Late

- Erectile Dysfunction– 40-50%
- Bowel Disturbance – 20%
- Surgery to Bowel – <1%
- Surgery to Bladder – <1%
- Risk Second Malignancy

EORTC GI Toxicity Scores

- 0 = None
- 1 = Mild diarrhoea, Mild cramping, Bowel movement 5 times daily, Slight rectal discharge or bleeding
- 2= Moderate diarrhoea and colic, Bowel movement >5 times daily, Excessive rectal mucus or intermittent bleeding
- 3 =Obstruction or bleeding requiring surgery
- 4= Necrosis/ Perforation Fistula

GI Toxicity

Dutch CKVO96-10 PMID 18718725 -- "Role of intensity-modulated radiotherapy in reducing toxicity in dose escalation for localized prostate cancer." (Al-Mamgani A, Int J Radiat Oncol Biol Phys

- Dutch randomized dose-escalation trial, subset treated at same institution to 78 Gy using 2 techniques: 3D-CRT and IMRT

- Outcome: 5-year bPFS IMRT 70% vs 3DCRT 61% (NS)

- Acute toxicity: G2+ IMRT 20% vs. 3DCRT 61% (SS)
  G3+ 0% vs 13%

- Late toxicity: G2+ IMRT 21% vs. 3DCRT 37% (NS); GI G3+ 0% vs 7%
  G3+ 0% vs 7%

  Conclusion: IMRT reduced toxicity without compromising outcomes

Hypofractionation

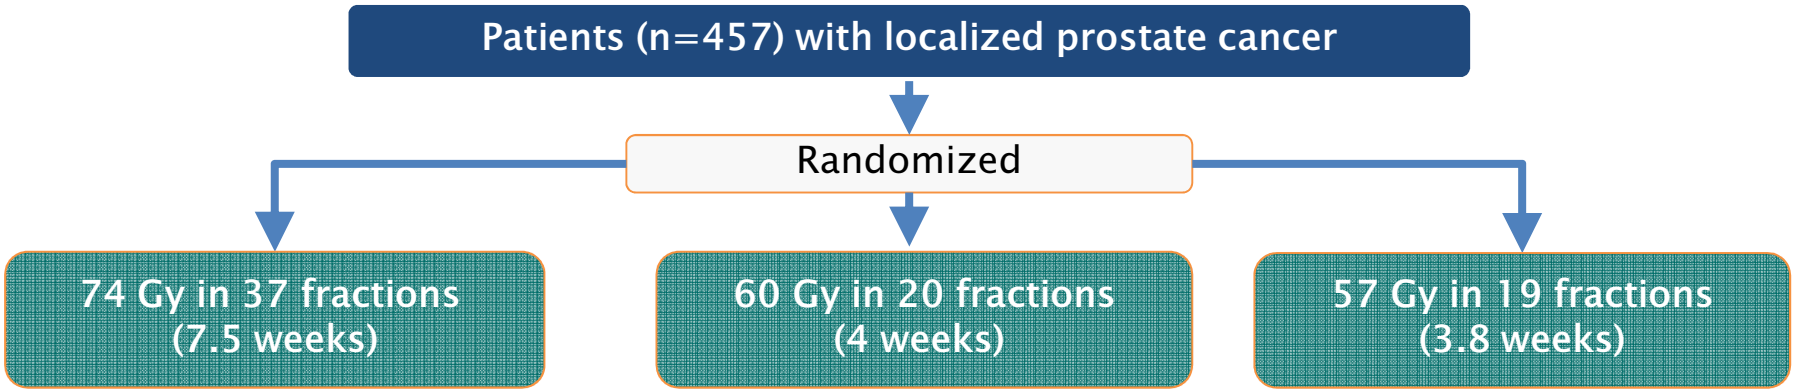
- Hypofractionation: delivery of larger doses of radiation (>2 Gy) per fraction to reduce the overall length of treatment[1]
- A lower alpha/beta ratio* in prostate cancer means that a larger dose of radiation per treatment may provide improved efficacy in terms of tumour control[1,2]
- Advantages include reduced health care costs and improved patient convenience[2]

1. Ritter M, et al. Cancer J 2009;15(1):1–6
2. Aneja S et al. Oncology: Perspectives on Best Practices 2012; 6:1-9

40

CHHiP Study

3 x RT dose fractionations combined with
3–6 months of neoadjuvant hormone therapy



- Safety results (median follow-up 50.5 months):

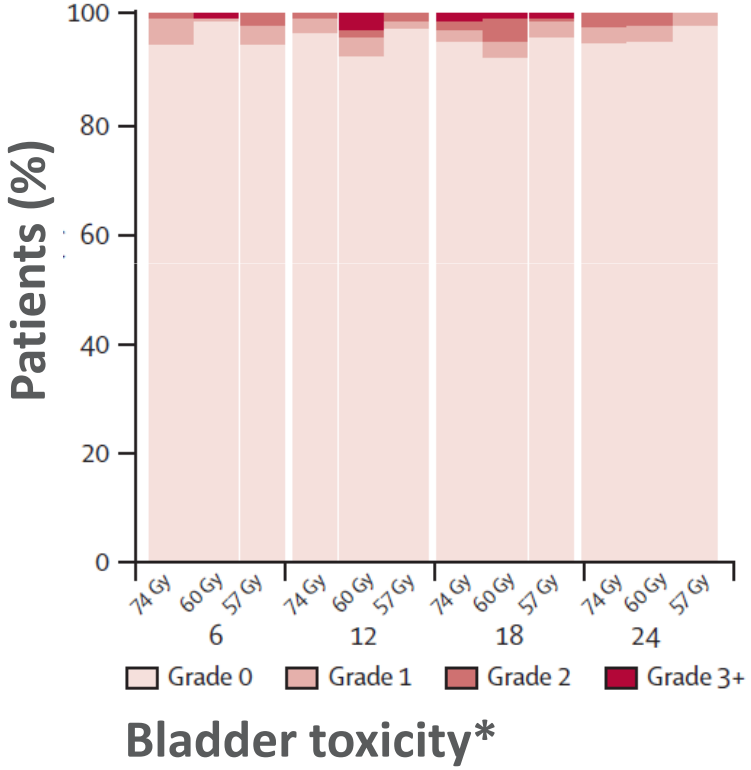
	RT dose		
	57Gy	60Gy	74Gy
Grade 2+ bowel toxicity	1.4%	3.6%	4.3%
Grade 2+ bladder toxicity	0%	2.2%	2.2%

- N

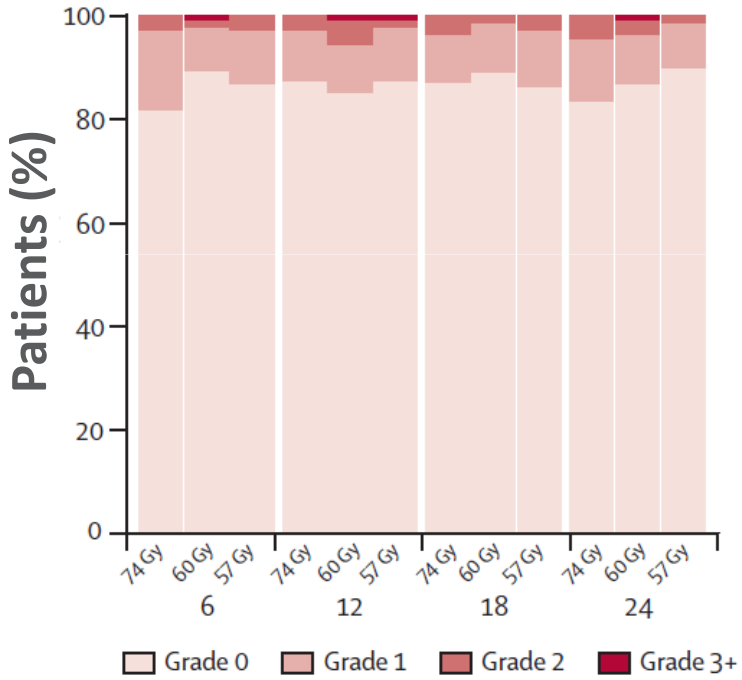
Dearnaley D, et al. Lancet Oncol 2012;13(1):43-54

CHHiP study comparing standard and hypofractionated RT+ADT

- No increased toxicity for hypofractionated regimes at 2 years – efficacy results awaited



Bladder toxicity*



Bowel toxicity*

CHHiP Study

3216 men randomised
Risk group 15% low, 73% intermediate, 12% high.
Median duration of hormone therapy was 5.6m.
Median follow up of 62.3m

5yr progression-free rate
74Gy: 88.3% (86.0%, 90.2%)
60Gy: 90.6% (88.5%, 92.3%)
57Gy: 85.9%(83.4%, 88.0%)

CHHiP Study

Late Toxicity

RTOG G2+ bowel toxicity at 2yr 74Gy (3.8%) 60Gy(2.9%) 57Gy (1.8%)

No significant difference at 5yr 74Gy (1.3%) 60Gy (2.3%) 57Gy (2.0%)

G2+ bladder toxicity showed NSD at 2yr or 5yr.

Analysis of LENT-SOM and PROs supported these results.

Conclusions: After 5 years follow-up treatment with 60Gy/20f is non-inferior to 74Gy/37f for PCa progression and is not associated with significant differences in late toxicity. 57Gy/19f has not been shown to be non-inferior to 74Gy/37f. All schedules had a low side effect profile using trial specified IMRT techniques. 60Gy/20f appears effective and safe and may be recommended as a new standard of care.

Neoadjuvant (NHT) and/or adjuvant (AHT) hormone therapy

- NHT, before definitive local treatment with curative intent, aims:
  - To reduce tumour bulk and prostate volume. Short-term ADT (3-4 m) reduces prostate size by 25-50%;[1] this may allow more focused RT
  - To treat micrometastatic disease and the primary lesion
- NHT responders may be candidates for AHT after surgery or RT
- NHT and/or AHT plus RT improves disease progression and/or overall survival vs. RT alone in high-risk localized and locally advanced PCa[2]
- Intermediate-risk patients may also benefit from combined RT and short-term ADT

Key trials of neoadjuvant HT plus RT

BM1

Trial	Follow-up	HT duration	Improved	Not improved
RTOG 86-10[1]	10 years	4 months	Disease-specific mortality, DFS, biochemical failure	OS, median survival time
TROG 96.01[2]	10 years	3 or 6 months	Local progression, event-free survival (3 and 6 months) All-cause mortality, prostate cancer mortality (6 months)	Prostate cancer-specific mortality, all-cause mortality (3 months)

DFS, disease-free survival; HT, hormone therapy
OS, overall survival; RT, radiotherapy

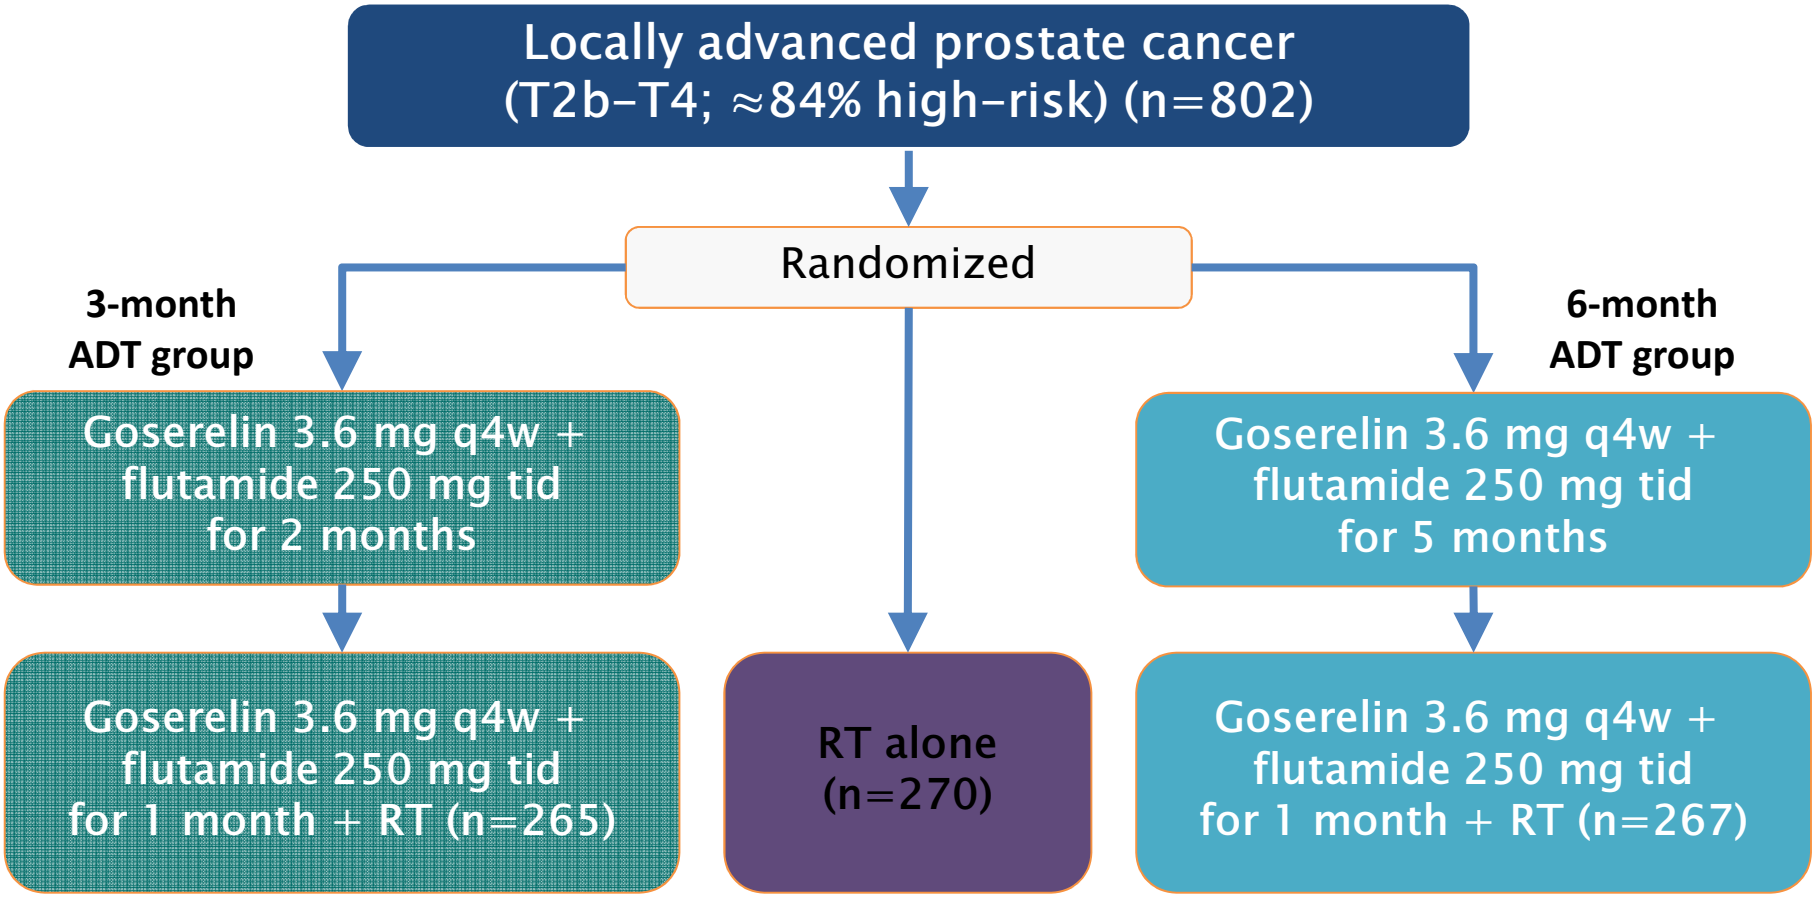
Bioscript Medical; 12-01-16

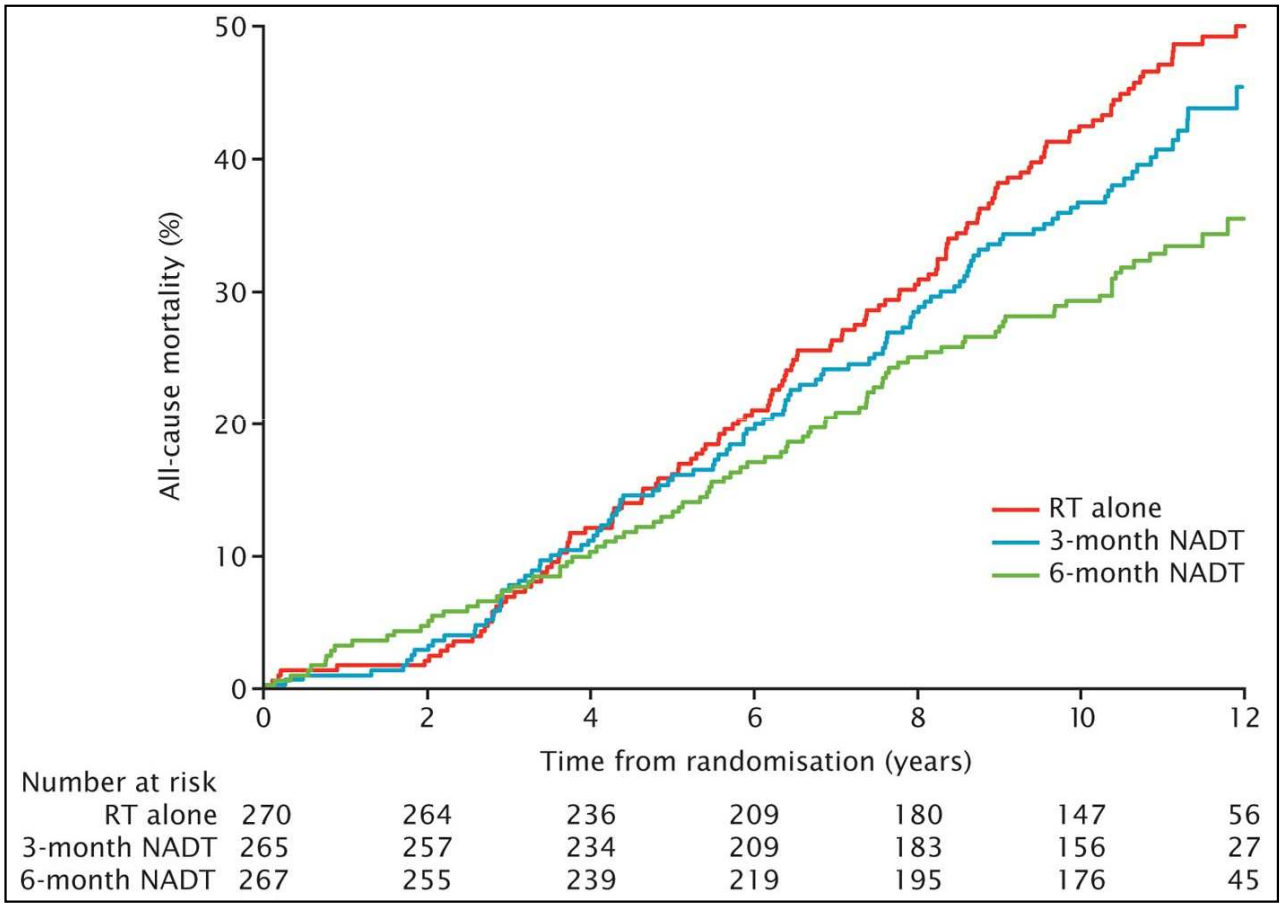
TROG 96.01: Neoadjuvant HT (3 or 6 months) plus RT vs RT alone



ADT, androgen deprivation therapy
HT, hormone therapy; q4w, every 4 weeks
RT, radiotherapy; tid, three times daily

Denham JW, et al. Lancet Oncol 2011;12:451-9

TROG 96.01: 10-year all-cause mortality



6-month ADT + RT vs RT alone: p=0.0008[a]

3- and 6-month ADT significantly reduced PSA progression, local progression and improved event-free survival

6-month ADT also significantly improved distant progression and prostate cancer mortality

[a]From multivariate model with covariates of treatment group, age, Gleason score, initial PSA and prostate cancer stage
NADT, neoadjuvant androgen deprivation therapy
PSA, prostate-specific antigen; RT, radiotherapy

Denham JW, et al. Lancet Oncol 2011;12:451-9

Adjuvant HT plus RT versus RT in high-risk PCa: 10-year results

- Significant reduction in most 10-year endpoints

Trial	Treatment groups	Local failure (%)	Distant metastases (%)	DFS (%)	OS (%)
EORTC 22863[1,2]	RT (n=208)	NR	70	23	40
	RT + goserelin for 36 months [+ AA for 1 month] (n=207)	NR	49‡	48‡	58†
RTOG 85-31[3]	RT (n=489)	38	39	23[a]	39
	RT + indefinite goserelin (n=488)	23‡	24†	37‡[a]	49**
RTOG 92-02[4,5]	Goserelin + AA for 4 months before and during RT, then:				
	– No further adjuvant HT (n=763)	22	23	23	52
	– Goserelin for 24 months (n=758)	12‡	15‡	13‡	54

[a]No evidence of disease survival: survival in absence of locoregional failure/distant metastases

**P<0.01; †P<0.001; ‡P<0.0001 vs RT alone

NR, not reported
DFS, disease-free survival
OS, overall survival

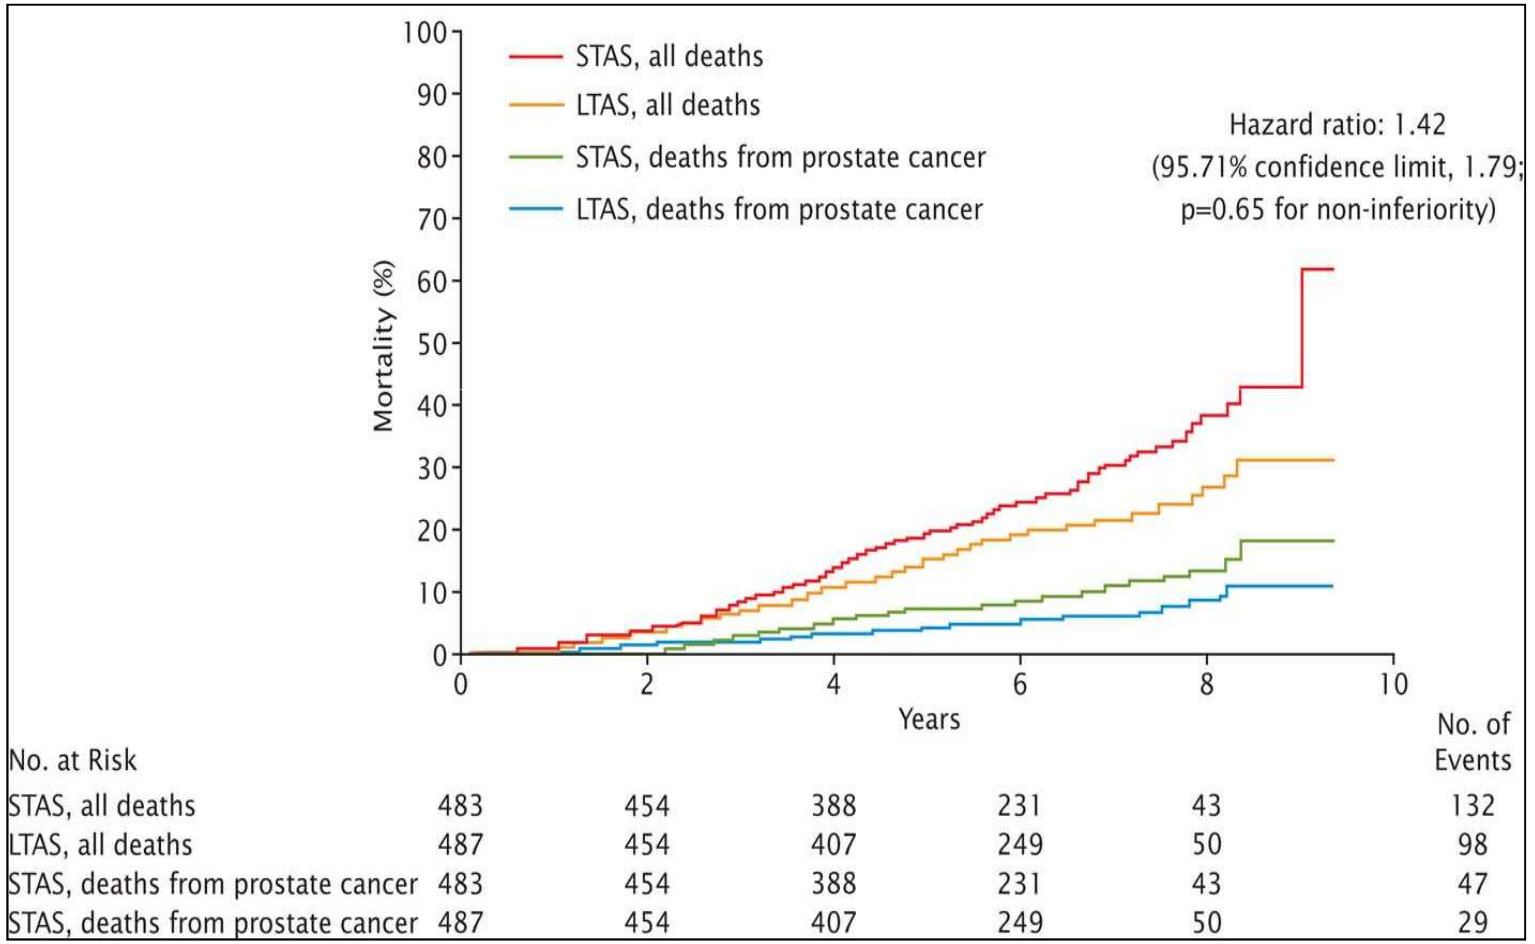
EORTC-22961: Increased overall survival and reduced prostate cancer mortality with long-term adjuvant HT

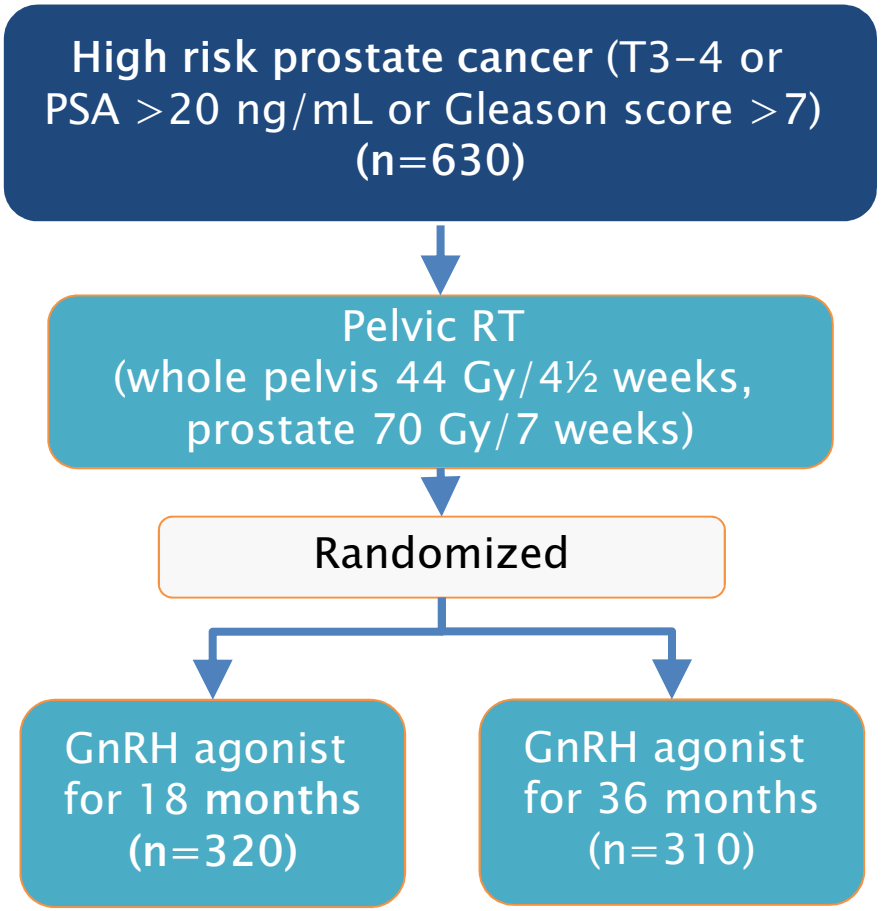


No. at Risk						No. of Events
STAS, all deaths	483	454	388	231	43	132
LTAS, all deaths	487	454	407	249	50	98
STAS, deaths from prostate cancer	483	454	388	231	43	47
STAS, deaths from prostate cancer	487	454	407	249	50	29

HT, hormone therapy; STAS: short-term androgen suppression LTAS: long-term androgen suppression

Bolla M, et al. NEJM 2009;360:2516–27

Adjuvant HT: 18 vs 36 months (PCS IV trial)



- Median follow-up 77 months
- 10 year overall survival
  - 63.6% (18 months) vs 63.2% (38 months), p=0.429
- 10 year disease-specific survival
  - 87.2% (18 months) vs 87.2% (36 months), p=0.838
- No significant differences in biochemical, regional or distant failure between arms

HT, hormone therapy; RT, radiotherapy

Nabid A, et al. ASCO GU 2013; Abstract 3

Conclusions

- The benefits of EBRT can be enhanced by dose escalation:

  Improves biochemical and/or clinical failure in localized or locally advanced PCa, with acceptable genitourinary and rectal safety[1-]

- The benefit of adding ADT to RT is established

  The exact timing and duration of ADT is still under investigation

  It remains to be established whether combining these approaches improves Prostate Cancer outcomes further

		PORT	52	NA		29 (5 years)	

Dirix et al. Radiother Oncol 2006;79(1):1-14

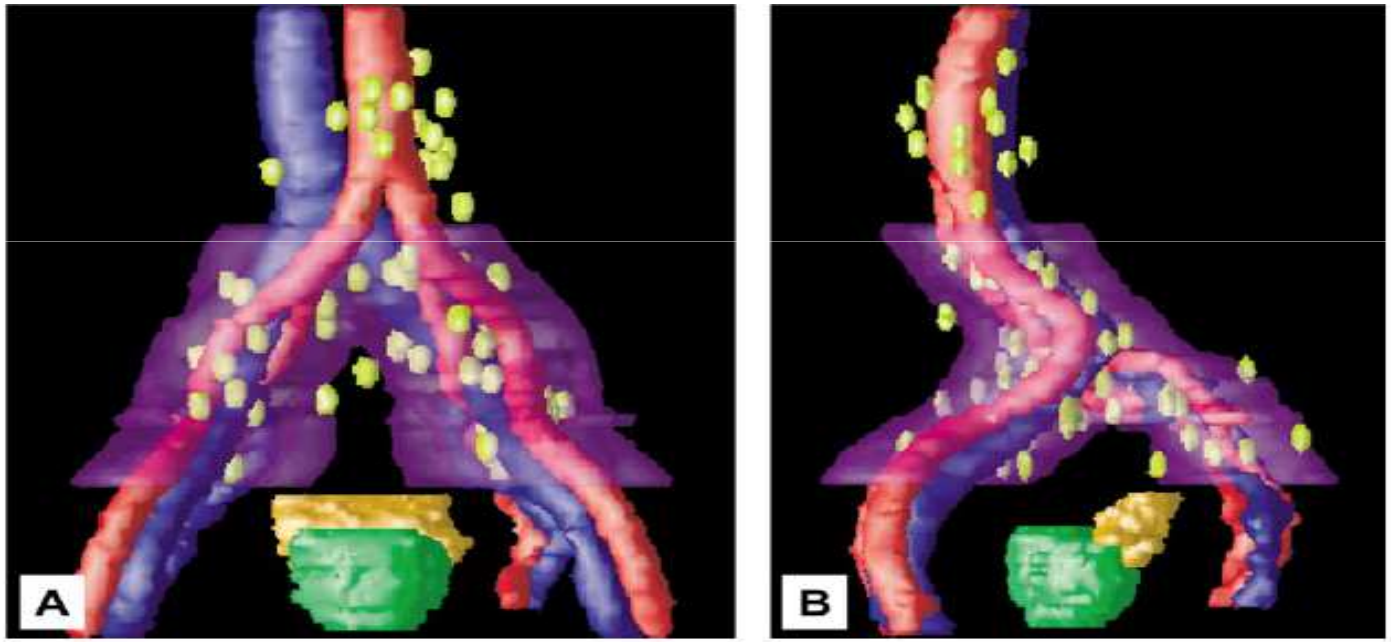
What were the problems with these trials ?

- Recruitment of patients with low risk of LN mets (GETUG)
- Low doses of RT to prostate and pelvis approx. 66-70GY and 46-48Gy
- Inadequate treatment of some LN groups
- Interaction with scheduling of hormone treatment (RTOG)
- Some favourable subgroup analyses for LN RT

N0/N1 – non metastatic prostate cancer

- Evidence unclear for concomitant RT to whole pelvis to treat pelvic LN for N0/N+ - studies N0 with different dose and RT techniques
- Historically associated with high toxicity
- Inadequate dose
- N0 to N+ - detection and imaging utilised
- N+ to N0 with neoadjuvant ADT= treat microscopic disease
- No RCT has assessed the role of RT N+ M0 patients and none are planned.

Target volume for Treatment of pelvic lymph nodes



Metastatic nodes referenced to pelvic vessels with a 2.0-cm clinical target volume expansion to the region

STAMPEDE

- Recruits men from 4 groups starting long-term ADT:
  1. High-risk localised (T3/4, PSA >40 or Gleason 8-10)
  2. Node-positive (N+) prostate cancer
  3. Newly-diagnosed metastatic (M1)
  4. High risk recurrence post surgery or RT

- Tests addition of further treatments to standard care

- Radical radiotherapy in standard care:
  - N0M0 patients; optional Oct 2005 – Nov 2011, mandatory from Nov-2011
  - N+M0 patients; optional

Impact of node status and radiotherapy on failure-free survival in patients with newly-diagnosed non-metastatic prostate cancer: Data from >690 patients in the control arm of the STAMPEDE trial (MRC PR08, CRUK/06/019)

Nicholas James , MR Spears, NW Clarke, MR Sydes, CC Parker, DP Dearnaley, JM Russell, AWS Ritchie, G Thalmann, JS De Bono, G Attard, C Amos, MK Parmar, MD Mason and the STAMPEDE Investigators

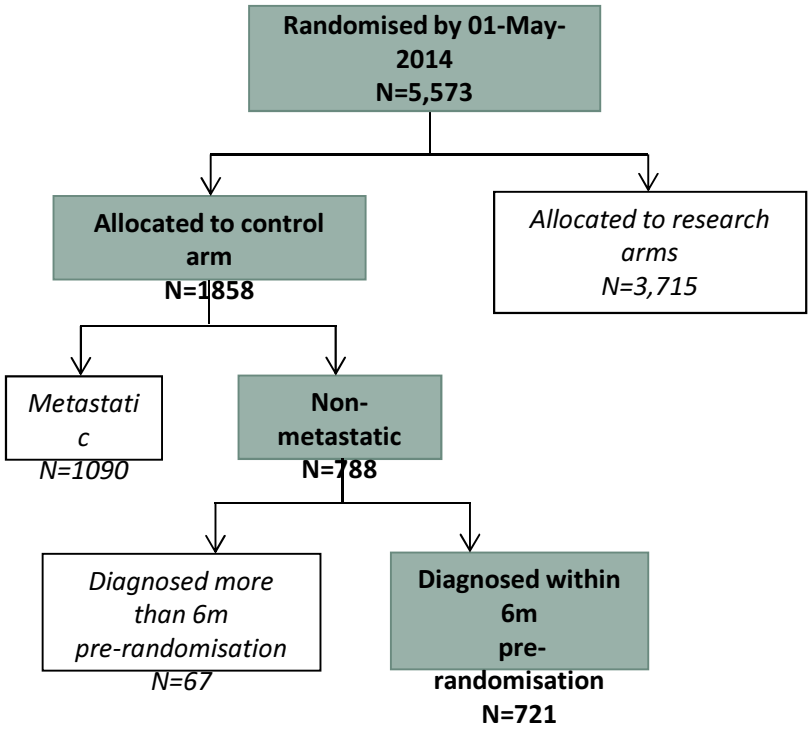
Aims

1. Describe prognosis for men with newly-diagnosed high-risk M0 disease

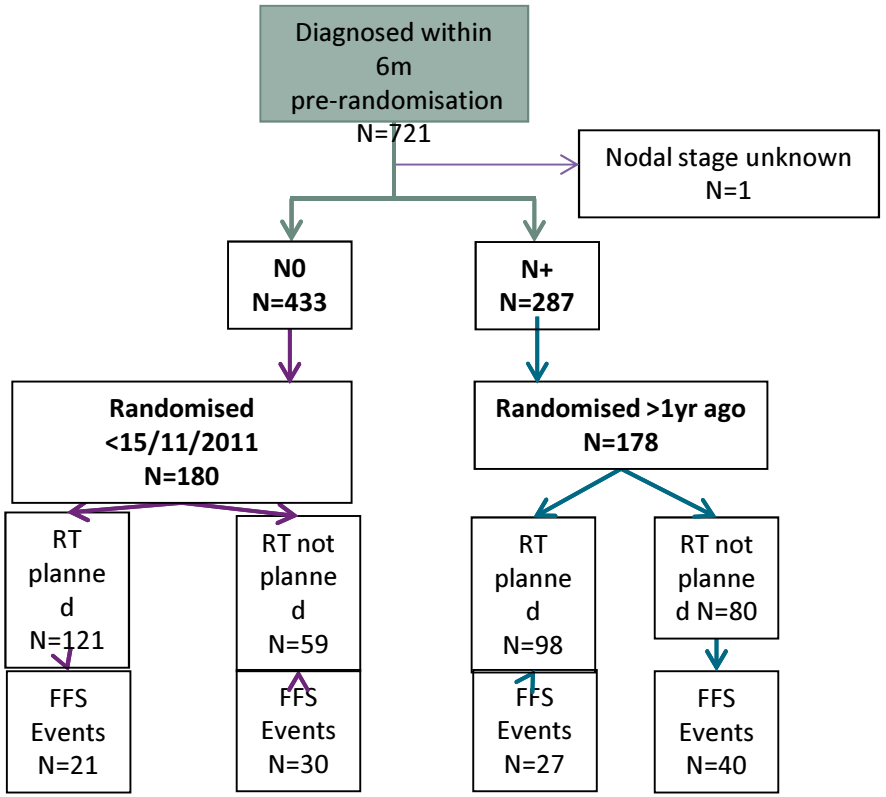
2. Describe impact of planned radical RT (6-9 months from randomisation) on time to progression
   - split by nodal status N0/N+

Results

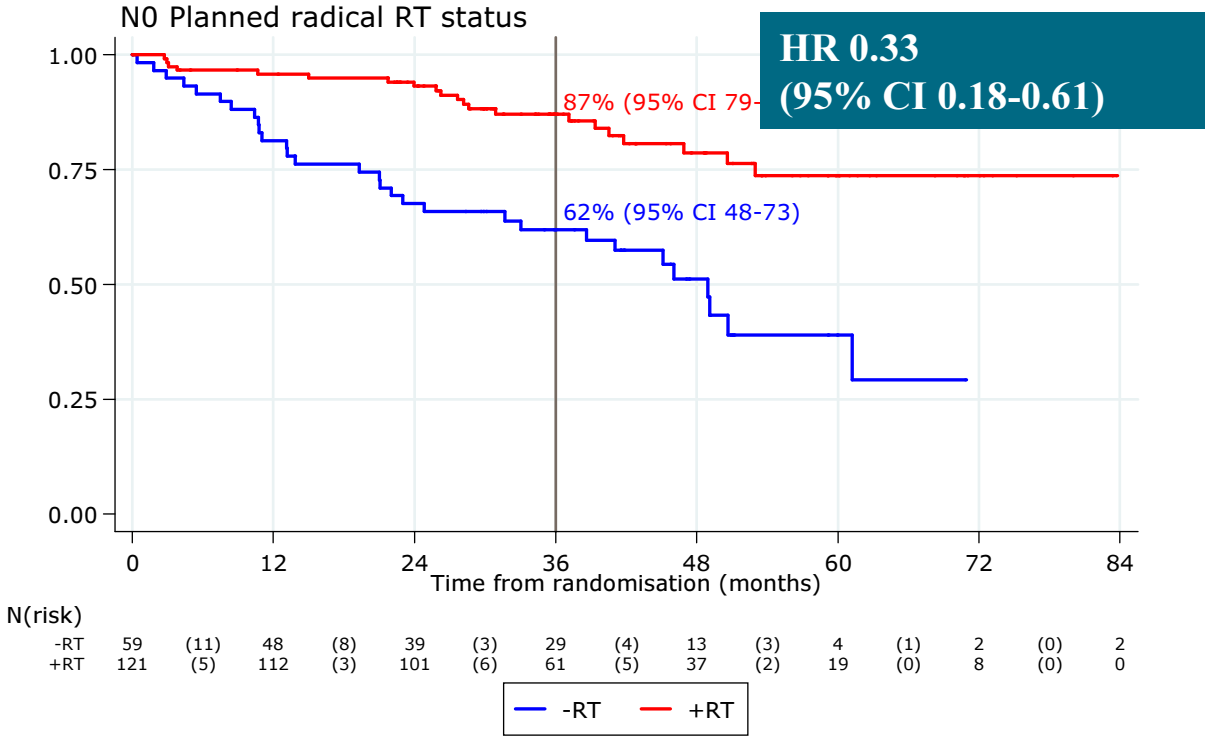
- Prognosis of newly-diagnosed high-risk M0 disease
- Cohort selection:



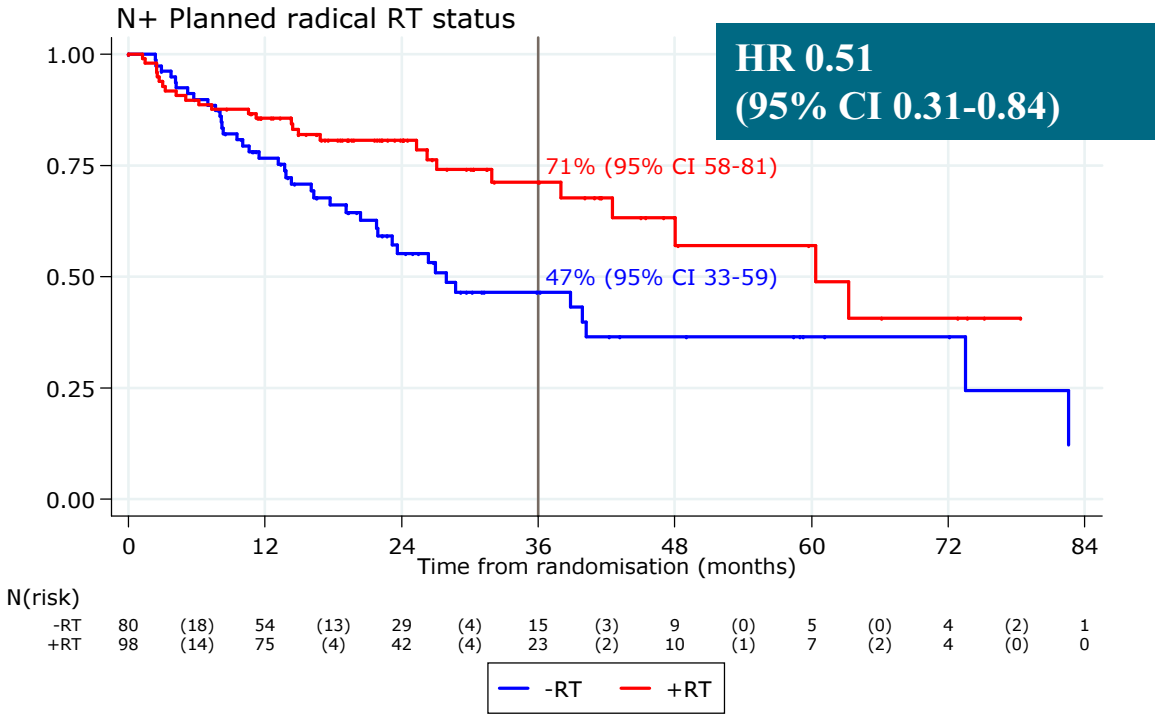
Nodal Subgroups



FFS by RT status: Node-negative cohort



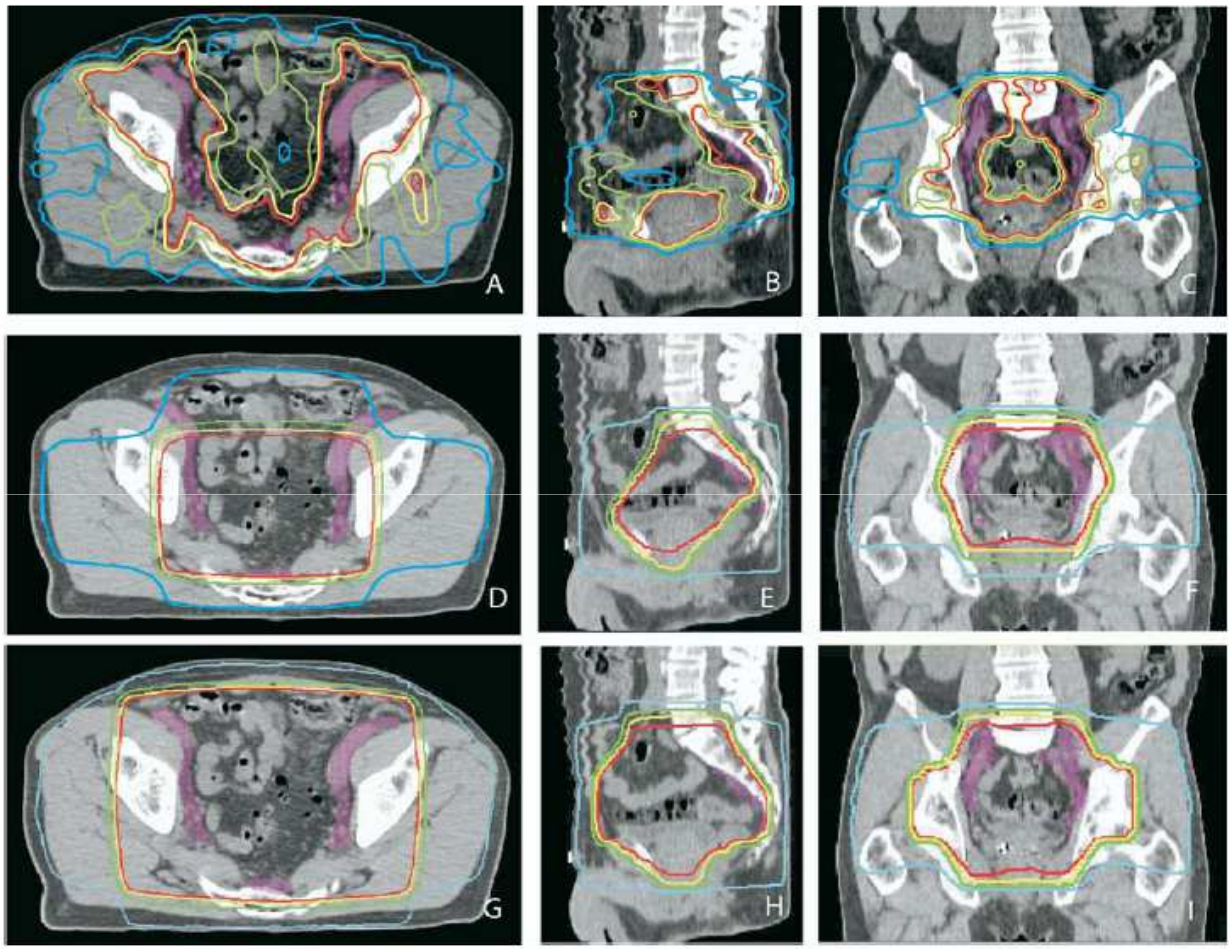
FFS by RT status: Node-positive cohort



Conclusions

- Survival better than anticipated at trial inception in 2005
  - In M0, control arm patients
- Effect of RT in N0M0 patients consistent with effect seen in previous large RCTs
- Effect of RT in N+ patients similar to effect in N0 patients
- Strongly supports routine use RT in node-positive prostate cancer
  - How best to administer?

ND James et al Proc ASTRO 2014.



Pagliarullo et al. JCO 2006; 24: 2735 - 2742

IMRT to Pelvic Lymph Nodes

- PLANNING TARGET VOLUMES

- GTVnodes GTV nodes - vessels
-
- CTVnodes GTVnodes + 0.7cm with trim for muscle and bone. Superiorly CTV extends to lower border of L5,as seen on the sagital view of the planning CT; inferiorly to the obturator nodes at superior extent of seminal vesicles.

- PTV55 = CTVnodes+ 0.5cm-0.7cm (to be specified on planning note)

CONCLUSIONS

- RT to N+ pelvic lymph nodes – emerging data but no RCT – extrapolation of data
- Neoadjuvant ADT to reduce LN – treat microscopic disease
- EBRT can now be given with reduced toxicity
- Role of chemotherapy
- Role of Surgery

Thank You

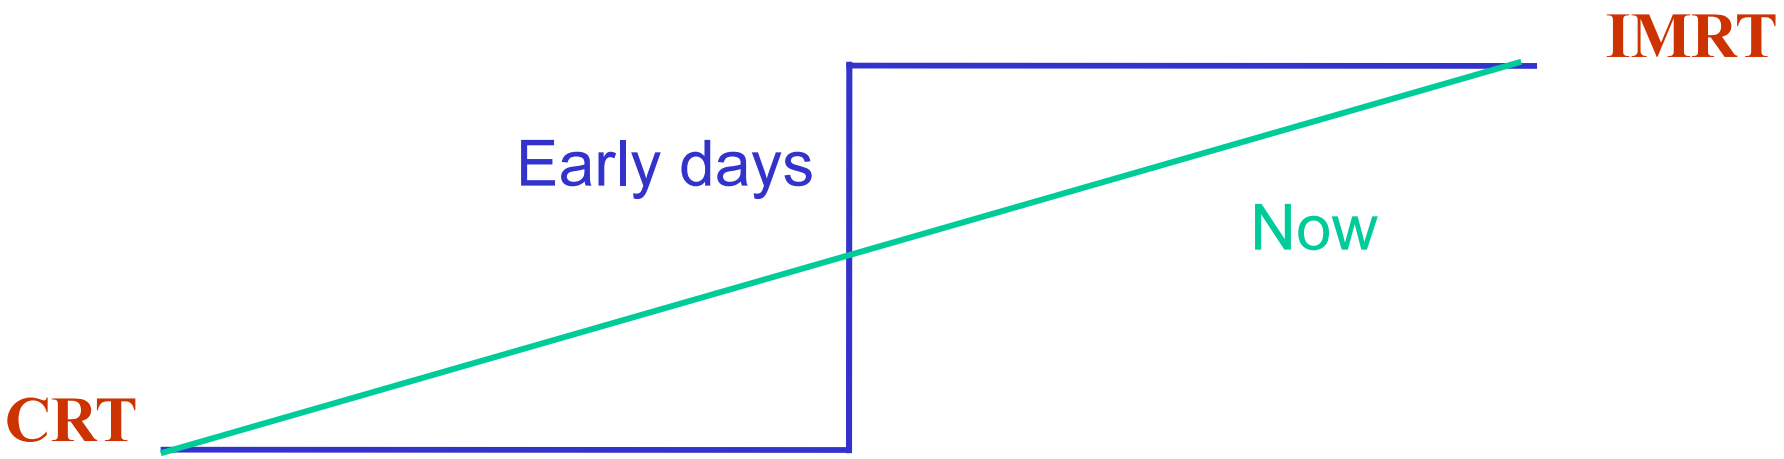
Practical IMRT planning and 'biological optimization'

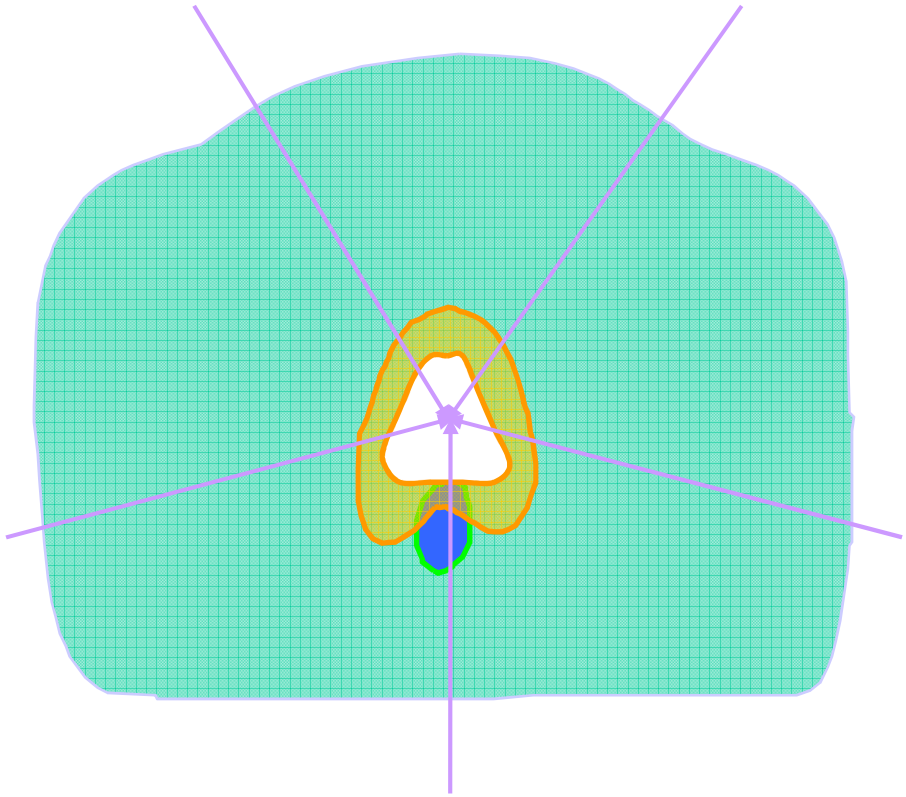
Marco Schwarz
Marco.schwarz@apss.tn.it

‘IMRT’: one word for a number of different approaches



Choosing where to stay on this line will make quite some difference also in terms of treatment planning

IMRT to solve simple problems

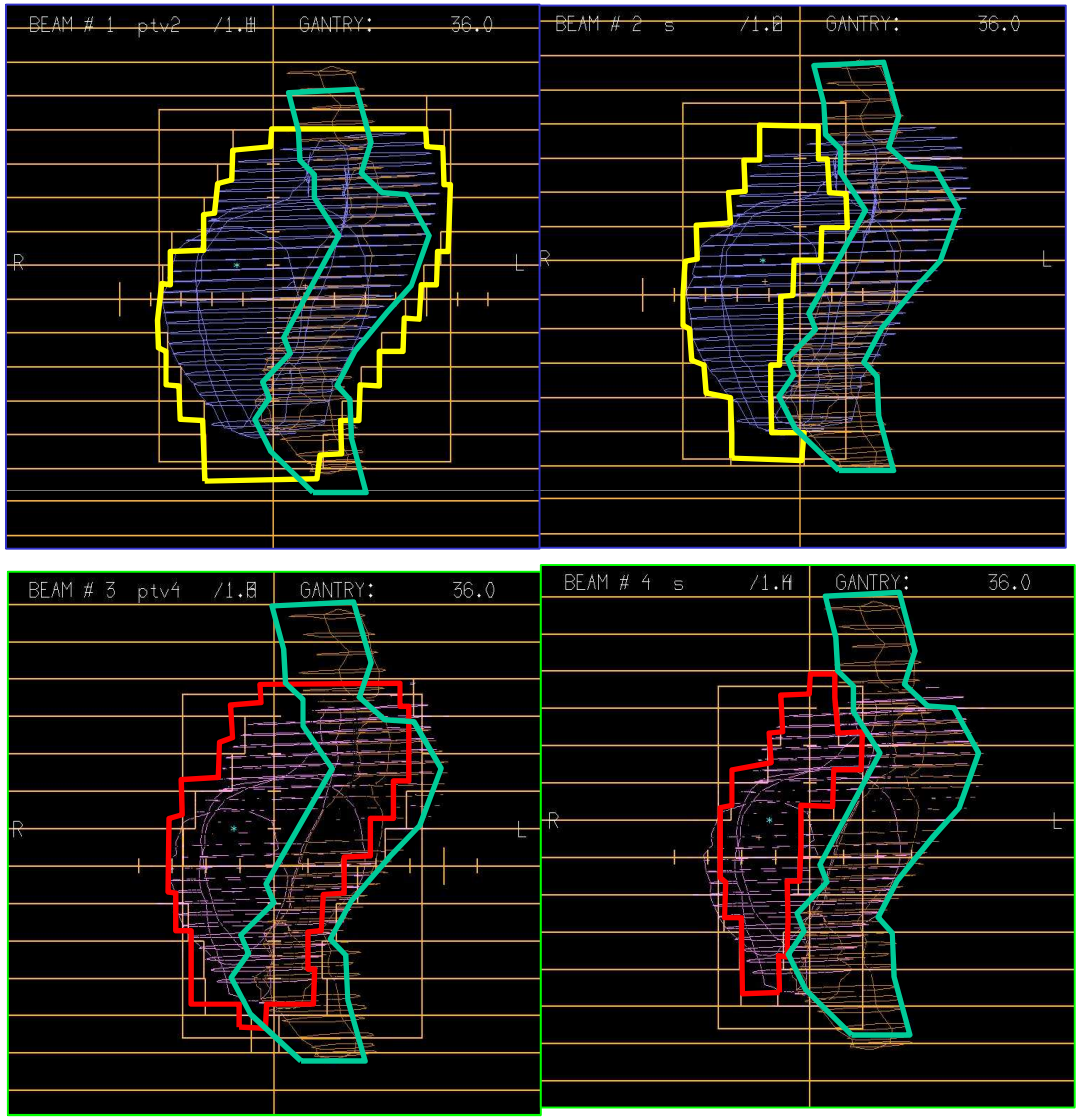


The problem:

Deliver 78 Gy to prostate (± SV) + margin

CRT too risky for the rectal wall

1 conflict to deal with
(PTV minimum dose vs high doses in the rectum)



Possible solution:

‘Forward planning’ does work

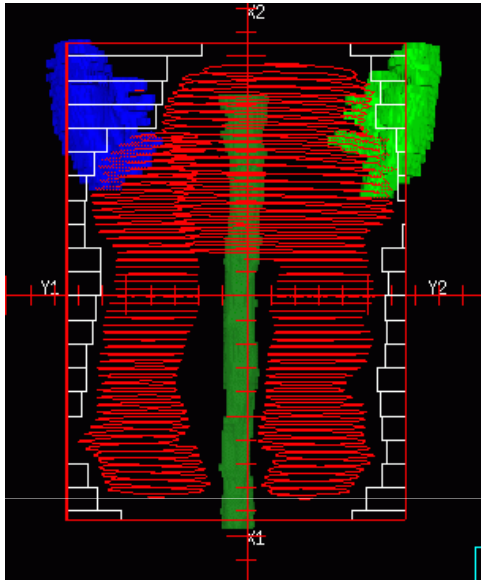
Class solution for beam direction and segment shape

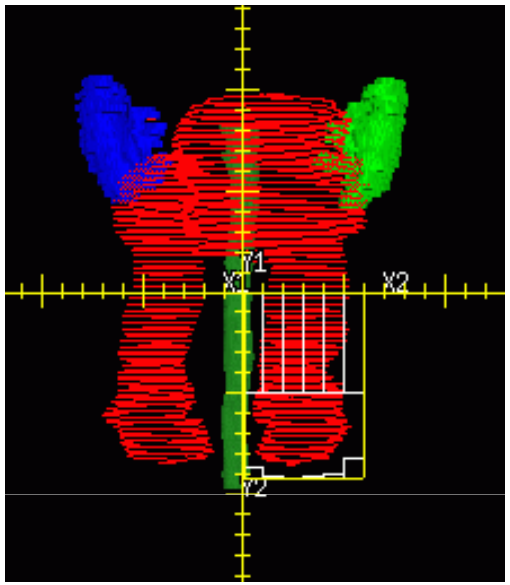
Simple cost function

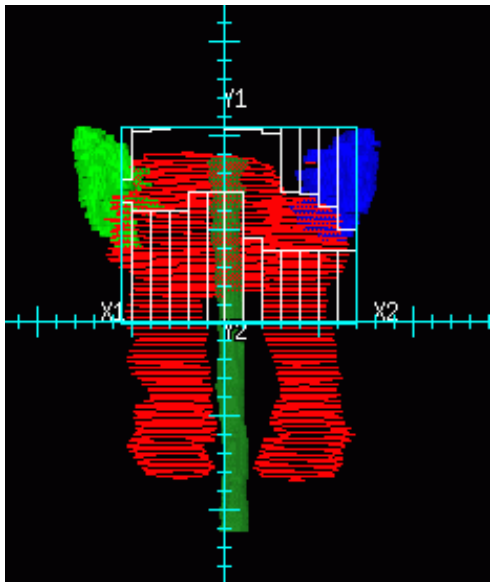
12-18 segments overall

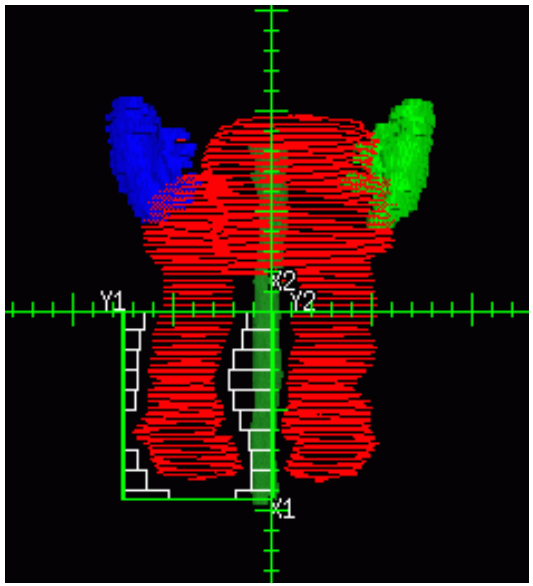
Simple plan verification

… more complex problems









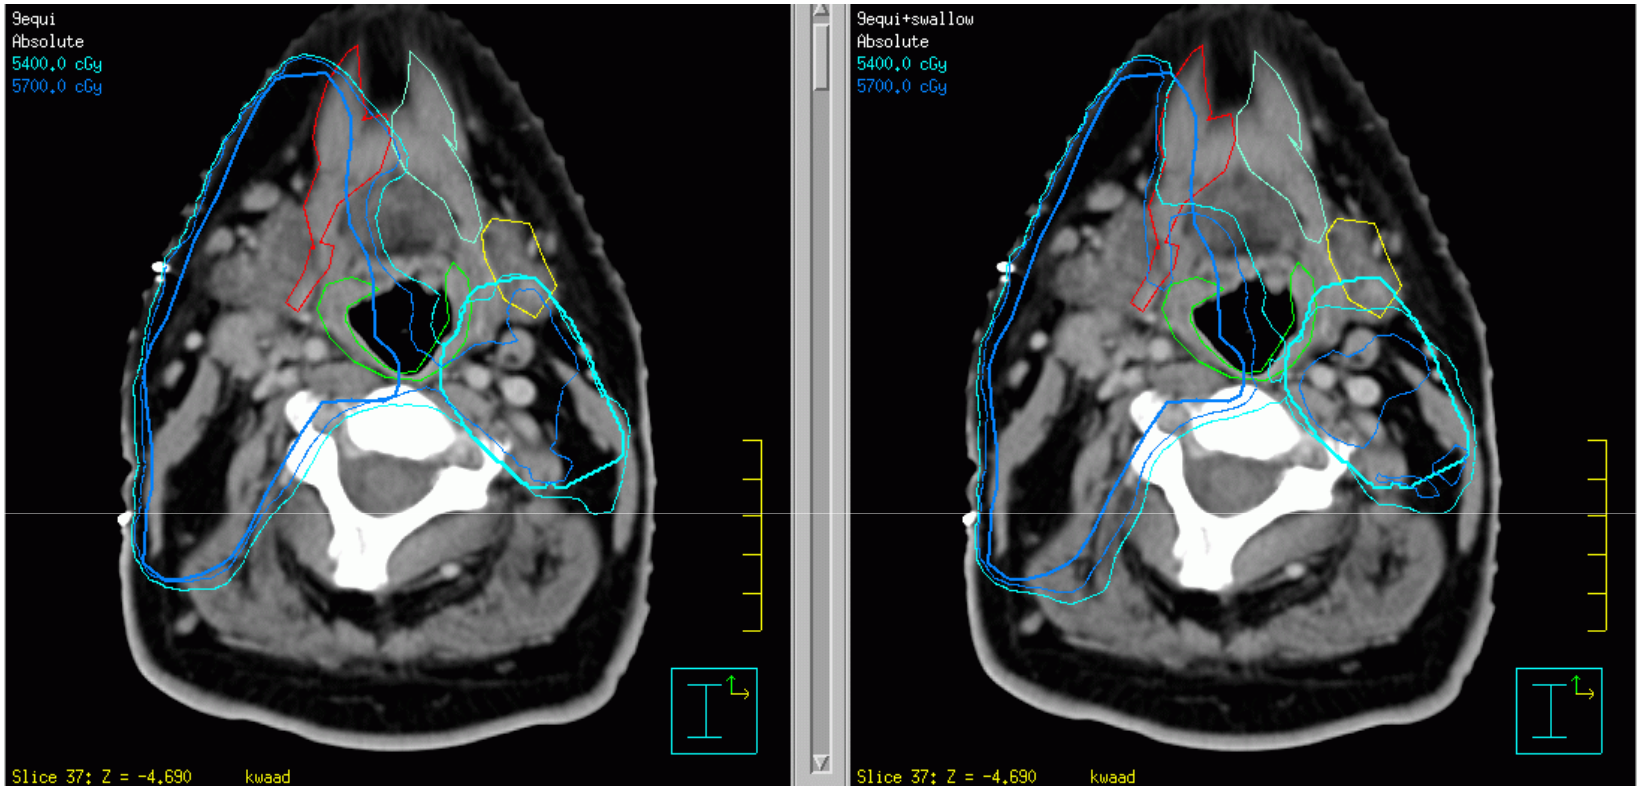
'forward planning' sort of works, but tricky without

automatic segment definition

and

segment shape optimisation

… even more complex problems



Complex IMRT cases require

- Elaborate cost functions,
- Efficient optimisation and segmentation techniques,
- Segment shape optimisation and
- Tools for sensitivity analysis.

Defining the treatment goals - Cost function

One should define a cost function …

1. Specific enough

To define the boundaries of the search space.

Example: Define the dose limits for the OAR over the whole dose range.

2. General enough

Not to artificially restrict the solution space

Example: if you want to obtain a specific OAR mean dose, do not set objectives for this OAR with DVH points.

Common sense and implicit knowledge must be made explicit

Cost function vs. plan evaluation

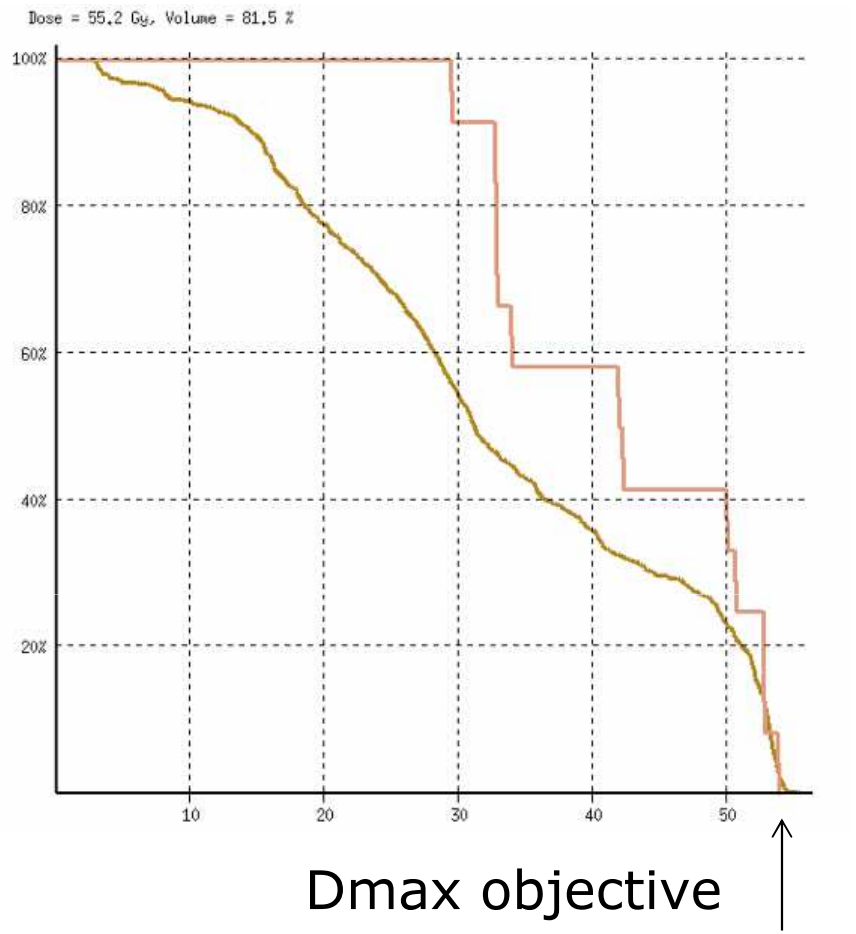
The dose distribution resulting from (unconstrained) optimisation typically contains

- Features you requested and you obtained
- Features you requested and you did not obtain

!!!!!!!

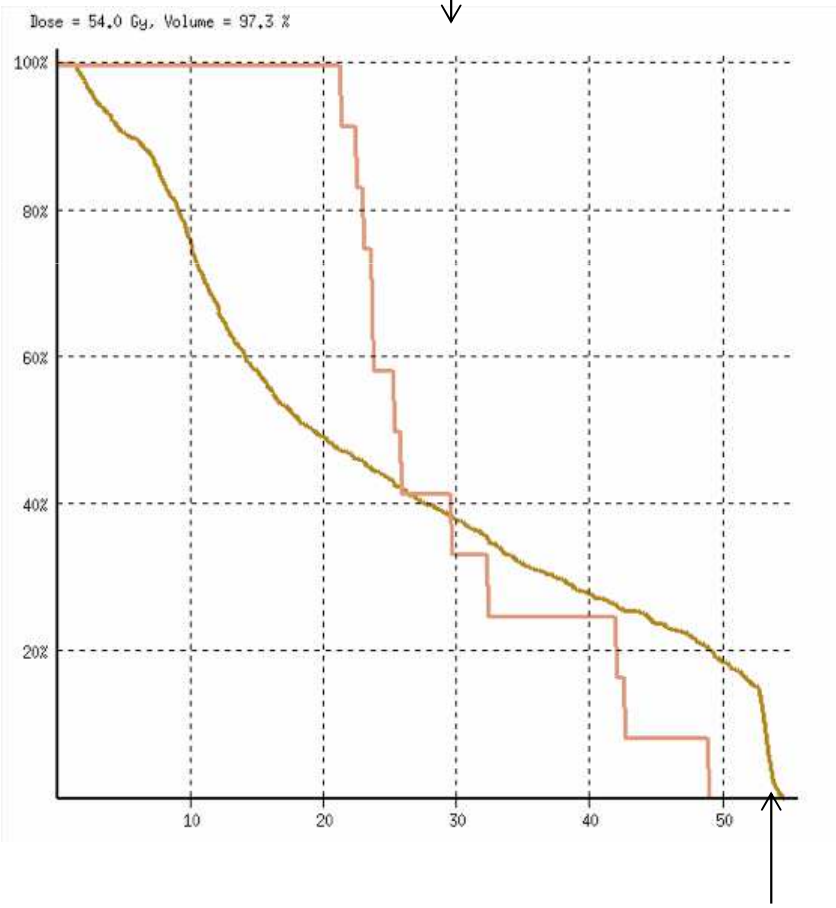
- Features you did **not** request
  - Neutral features
  - Negative features (you left a ‘hole’ in the cost function, and the optimisation took advantage from it)
  - Positive features (you got them ‘for free’, as a byproduct of other features)

?????



Dmax objective

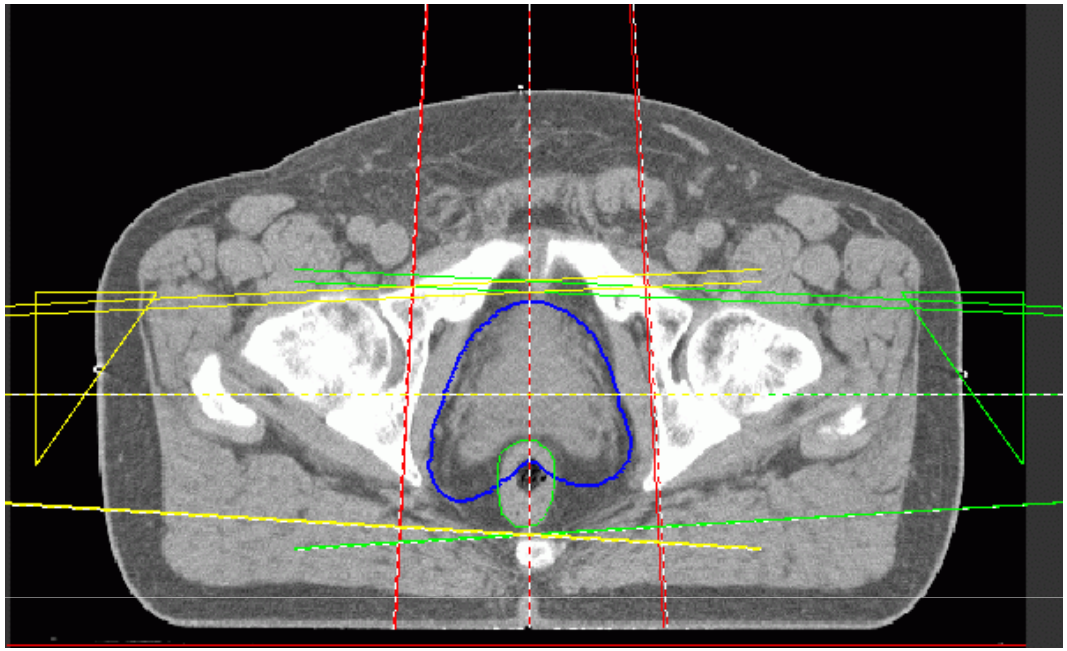
Dmax + Dmean objective



Think about this problem when you read paper on treatment planning studies

Defining the treatment goals - VOI definition

PTV: advantages



Forced people to incorporate geometrical uncertainties into treatment planning

ICRU concepts quite rapidly became a standard

Very appropriate tool for CRT: not too simple, not too complex.

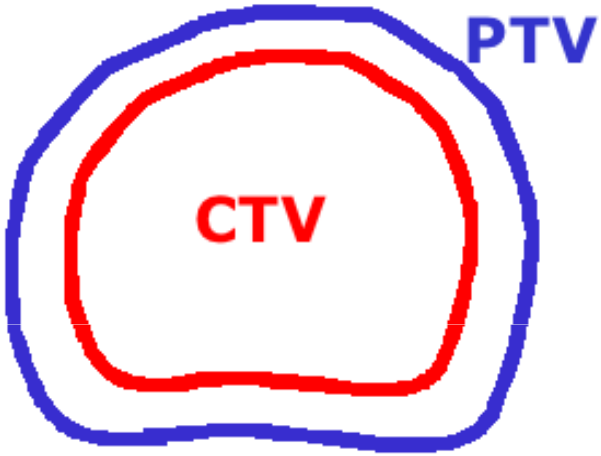
PTV: disadvantages

The PTV concept works only when

a)The dose is homogeneous

b)The dose is invariant after translations/rotations

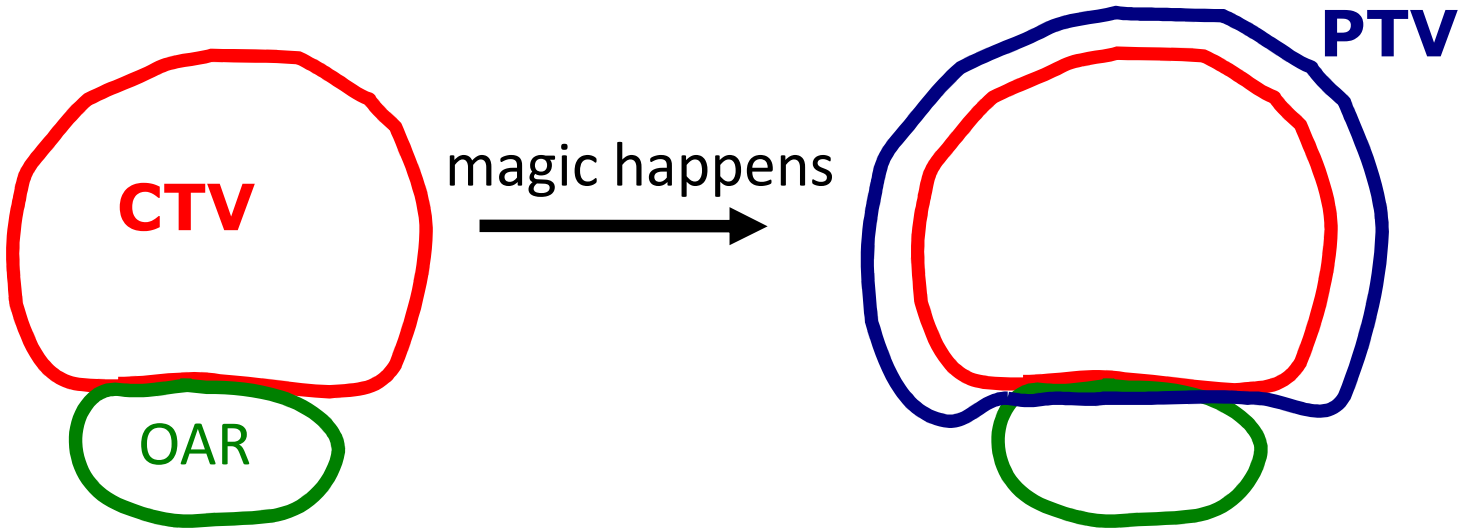
c)Margins are defined correctly w.r.t. the geometrical uncertainties



The tradeoff between target coverage and OAR sparing is unbalanced

N.B. IGRT aims at reducing PTV margins but does not address the shortcomings of PTV-based RT

To compensate for the unbalance between target coverage and OAR sparing, we often cheat



As if one should prefer
homogeneous doses in the wrong PTV instead of
heterogenous doses in the right PTV

We just shift the problem from planning to dose delivery and dose reporting

Reduced local control in prostate XRT with 3mm margin and daily IGRT (Engels IJROBP 2009)

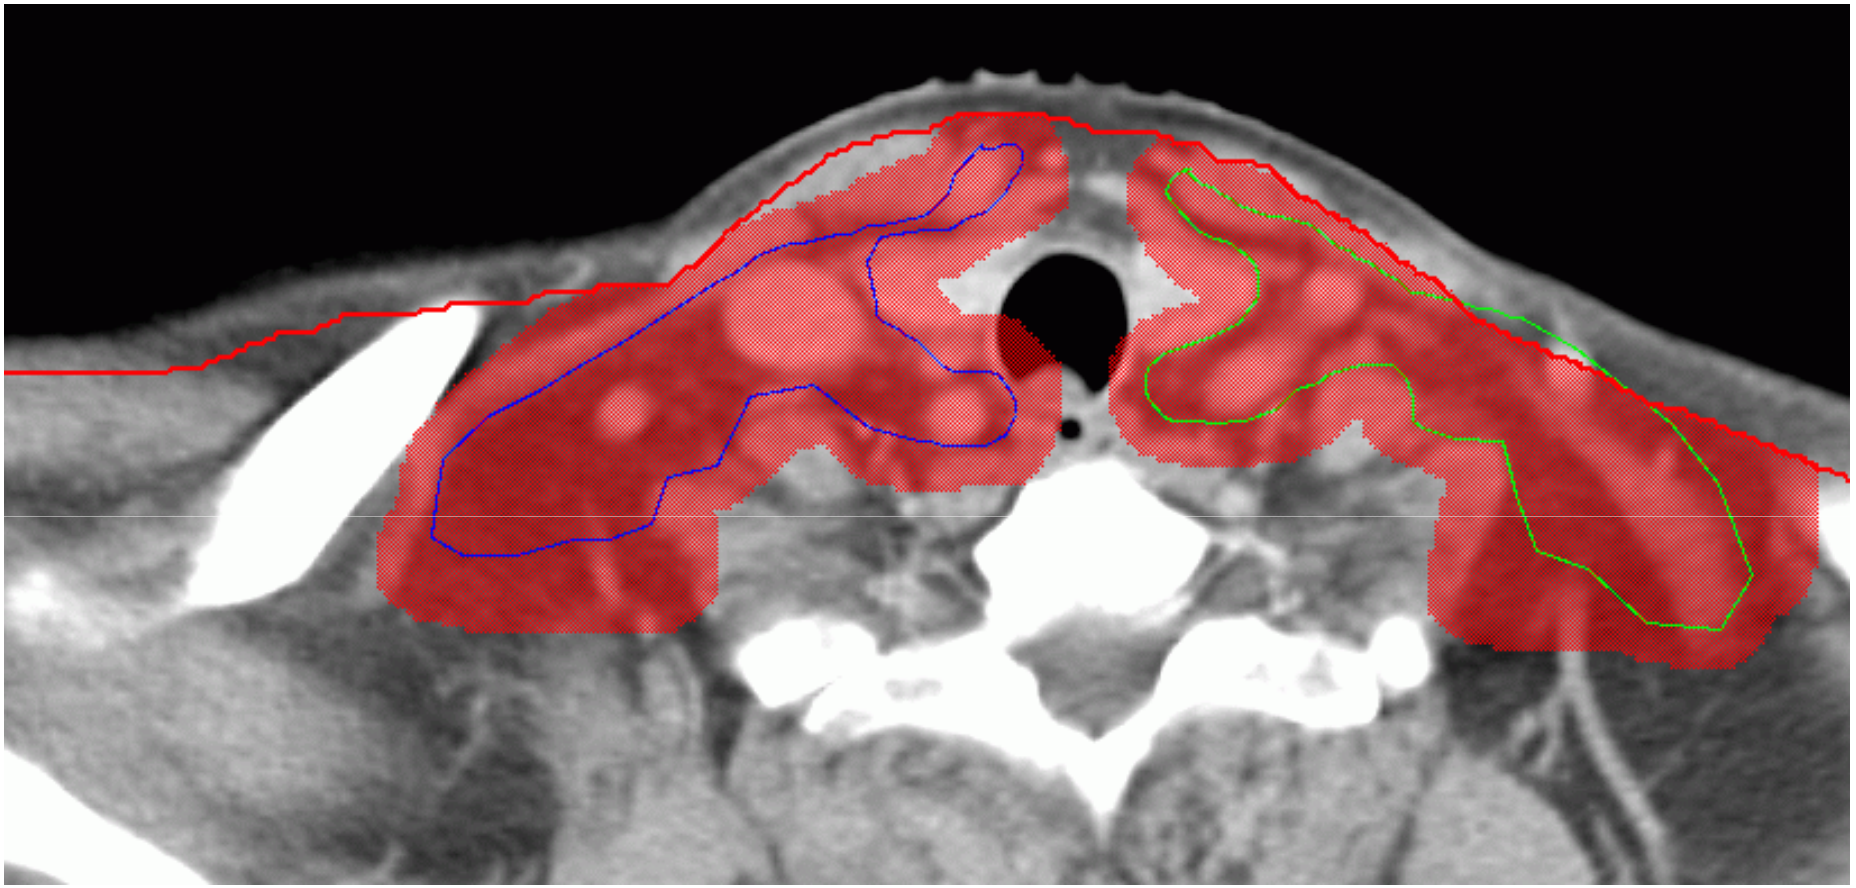
CLINICAL INVESTIGATION **Prostate**

CONFORMAL ARC RADIOTHERAPY FOR PROSTATE CANCER: INCREASED BIOCHEMICAL FAILURE IN PATIENTS WITH DISTENDED RECTUM ON THE PLANNING COMPUTED TOMOGRAM DESPITE IMAGE GUIDANCE BY IMPLANTED MARKERS

BENEDIKT ENGELS, M.D., GUY SOETE, M.D., PH.D., D. VERELLEN, PH.D., AND GUY STORME, M.D., PH.D.

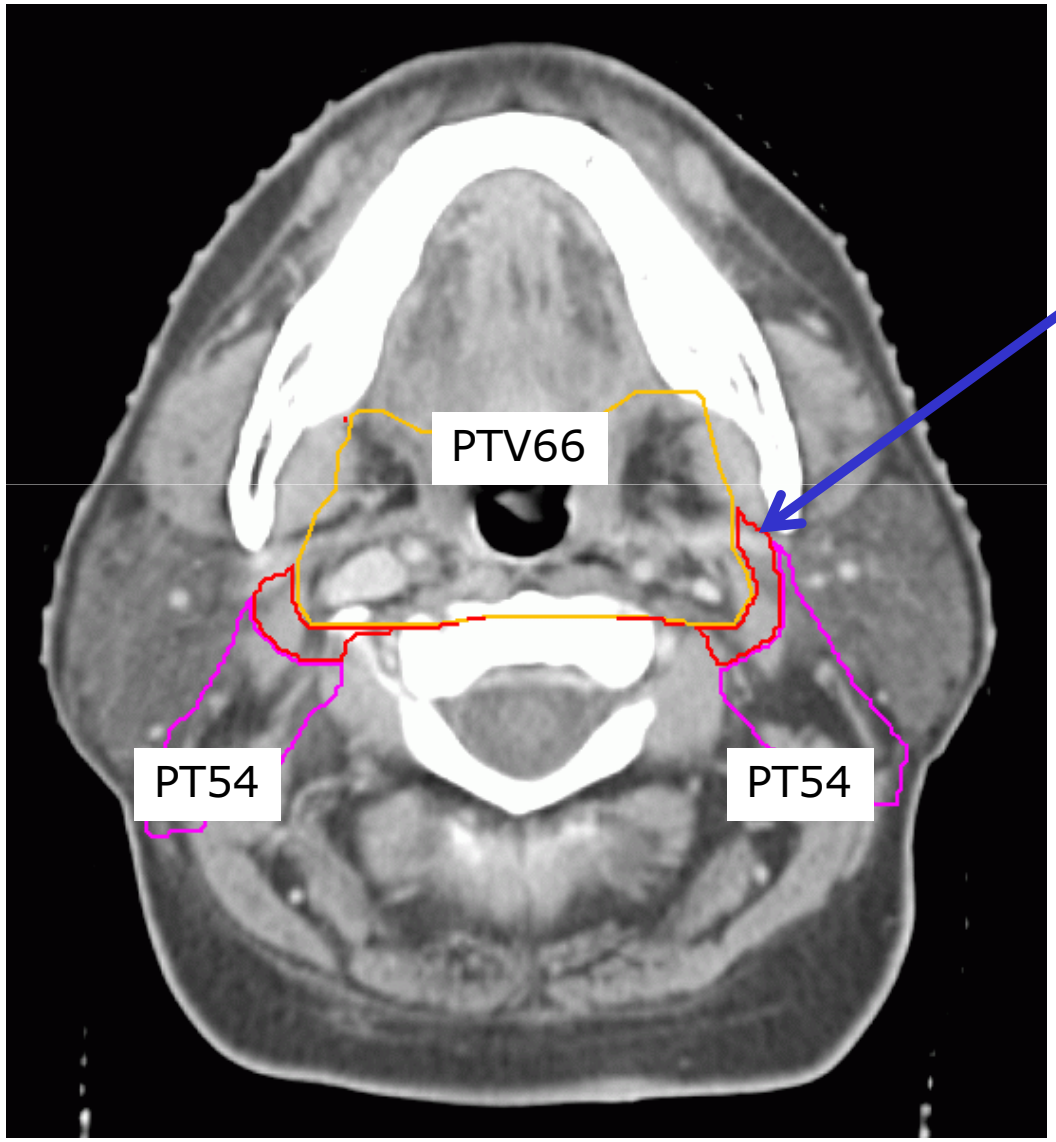
Department of Radiotherapy, University Hospital Brussels, Brussels, Belgium

VOI definitions & c.f. – build up region



When the PTV is shallower than the depth of Dmax, defining an ad-hoc volume + using the ‘skin flash’ feature of your TPS will help defining better plans

SIB & dose gradients in the PTV



IF

You want to control the Dmax in PTV 54

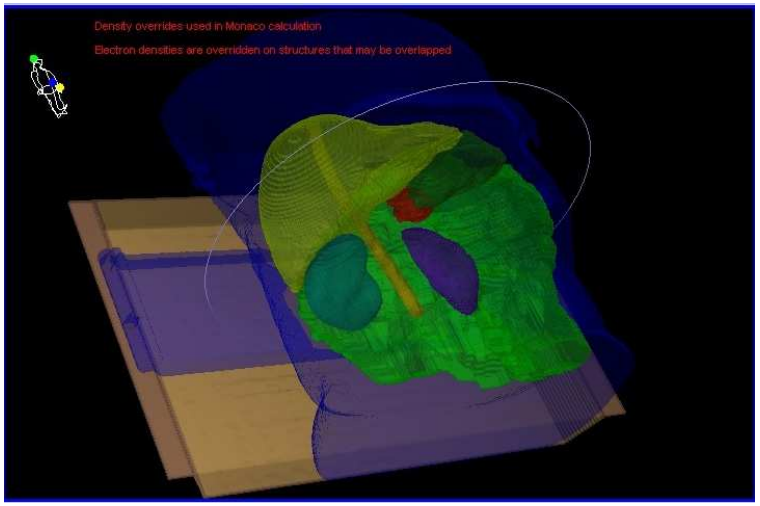
AND

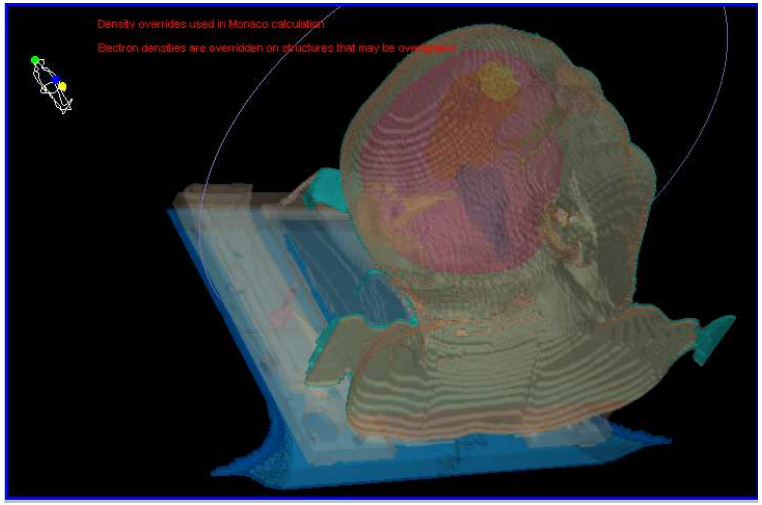
Dmin in PTV66

THEN

You need to make room for the dose gradient

Treatment couch modelling





With VMAT there is an increased need in accounting for the couch top (attenuation, increased skin dose, and target coverage effects).

Dosimetric effects caused by couch tops and immobilization devices: Report of AAPM Task Group 176

Arthur J. Olch[a)]

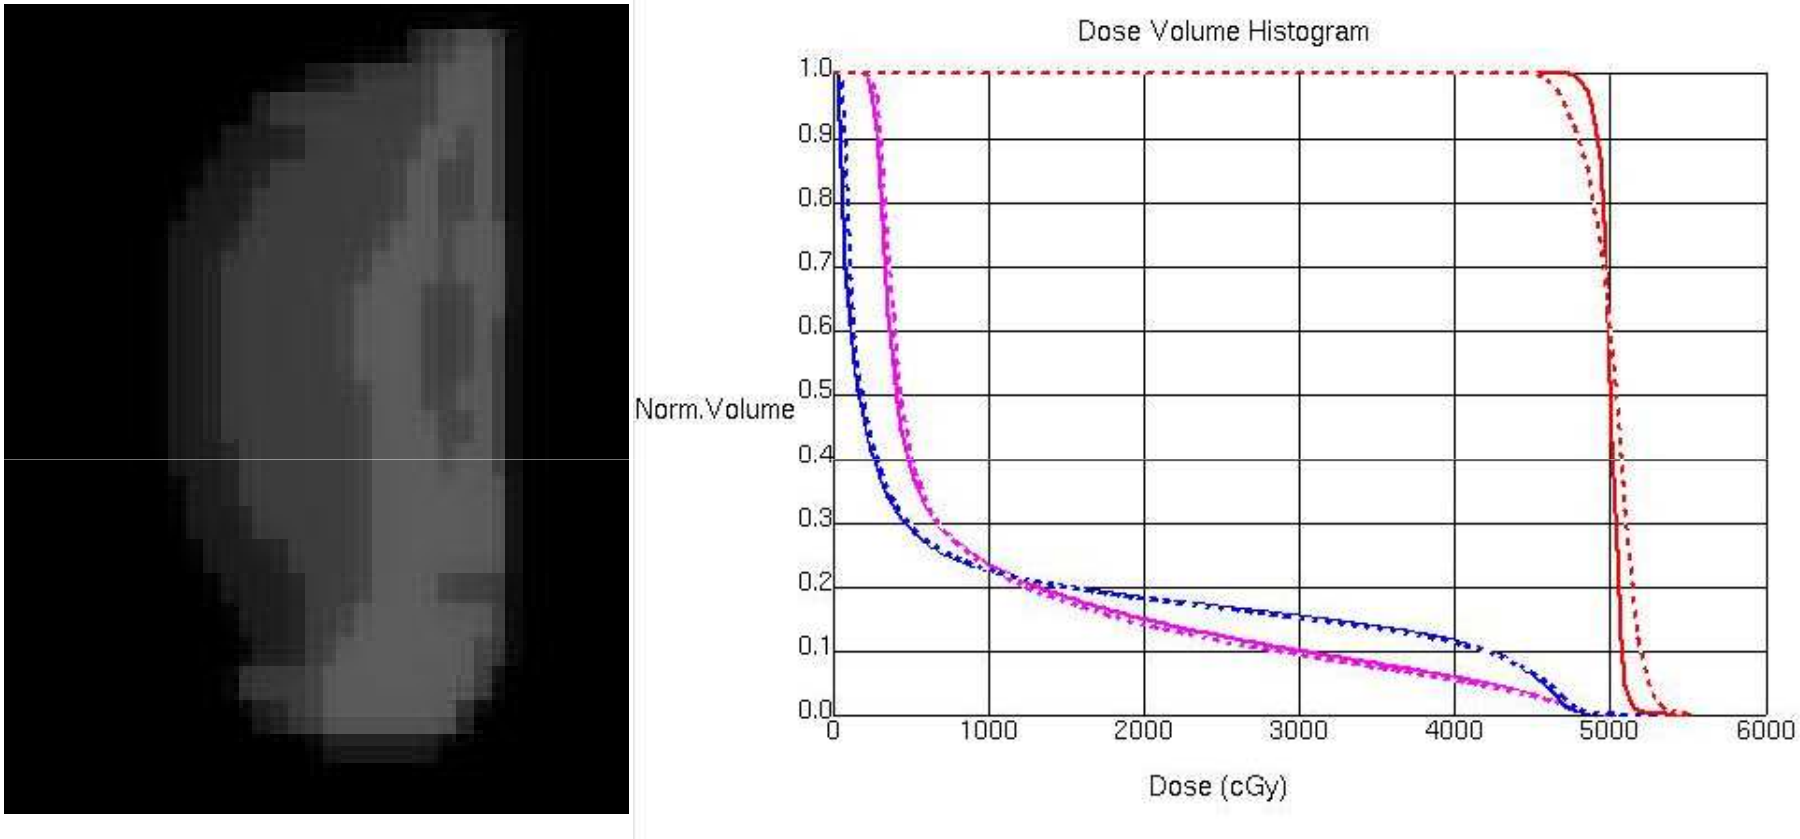
Urban legends on IMRT /1

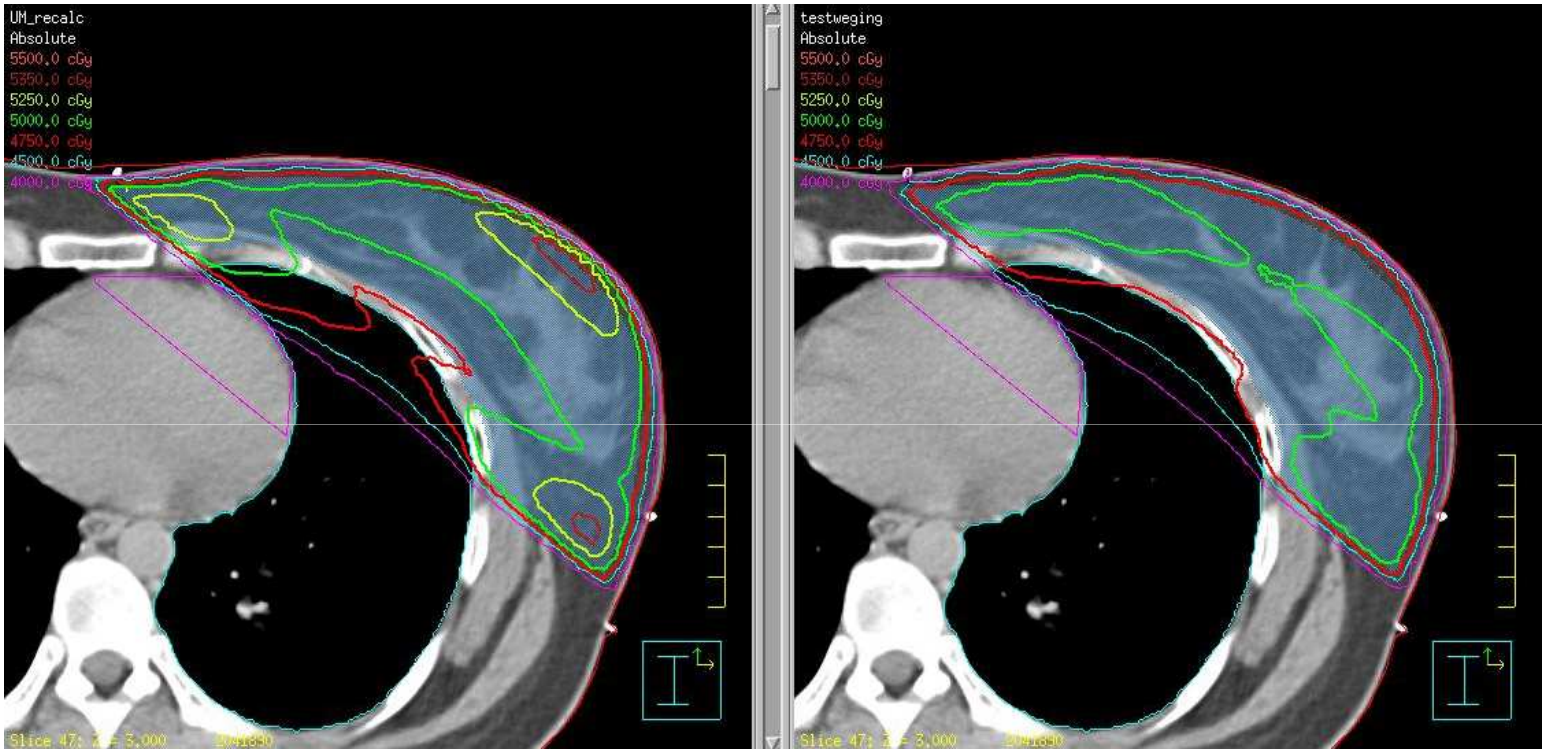
"IMRT = dose heterogeneity in the PTV. Live with that."

IMRT to increase PTV dose homogeneity



B. van Asselen

IMRT to increase PTV dose homogeneity

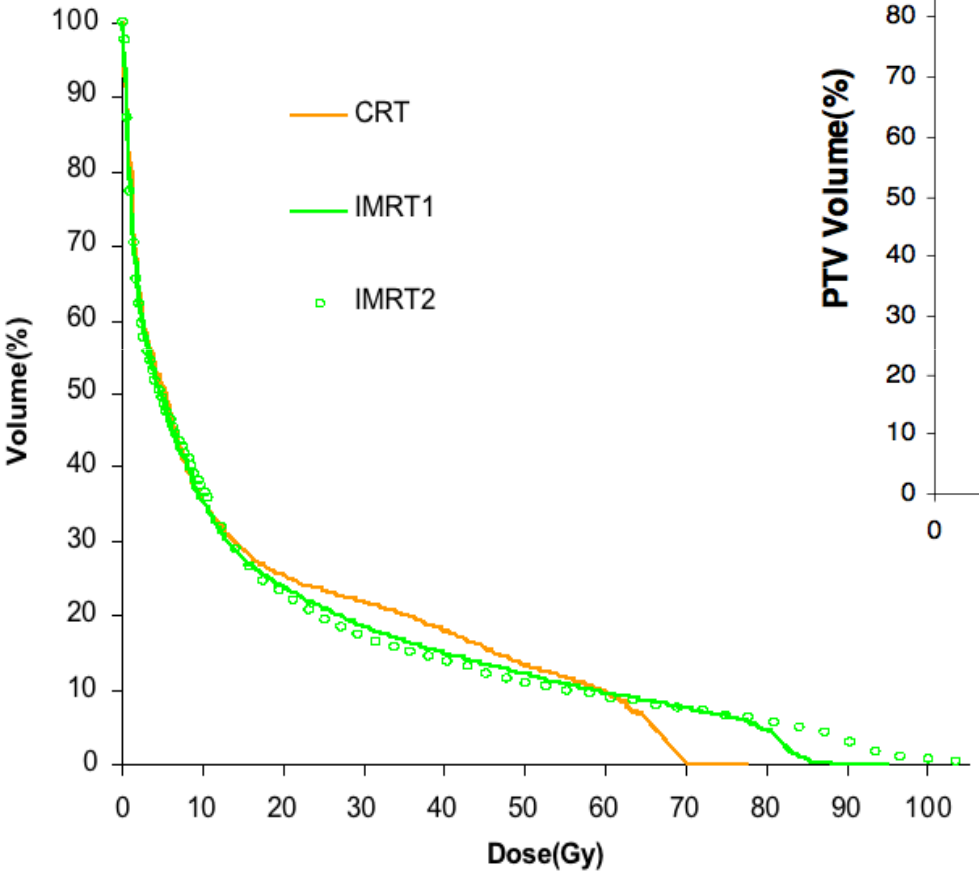


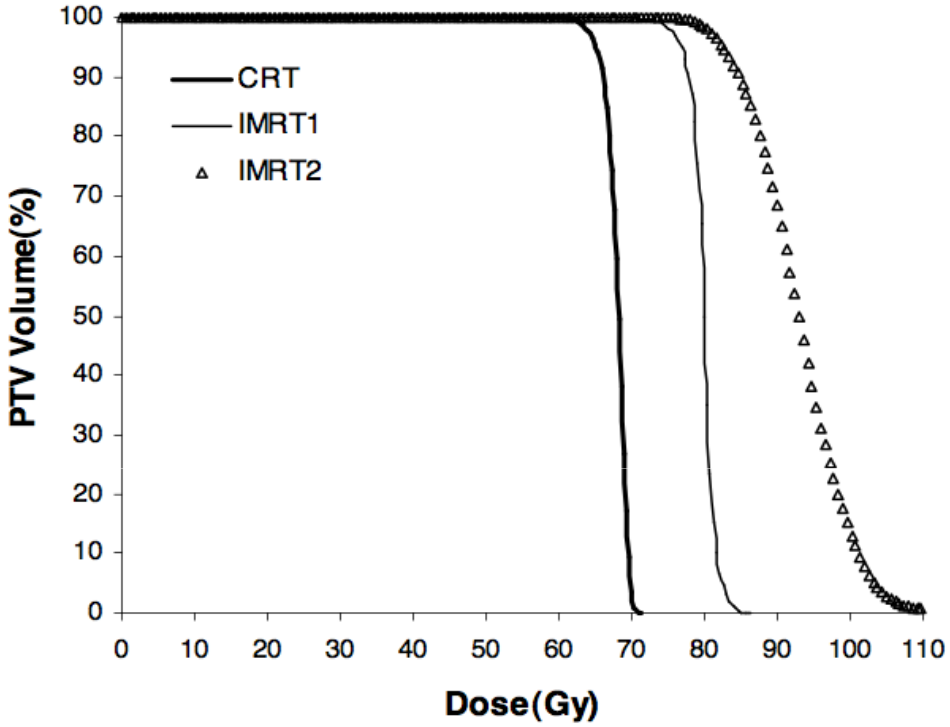
CRT

IMRT

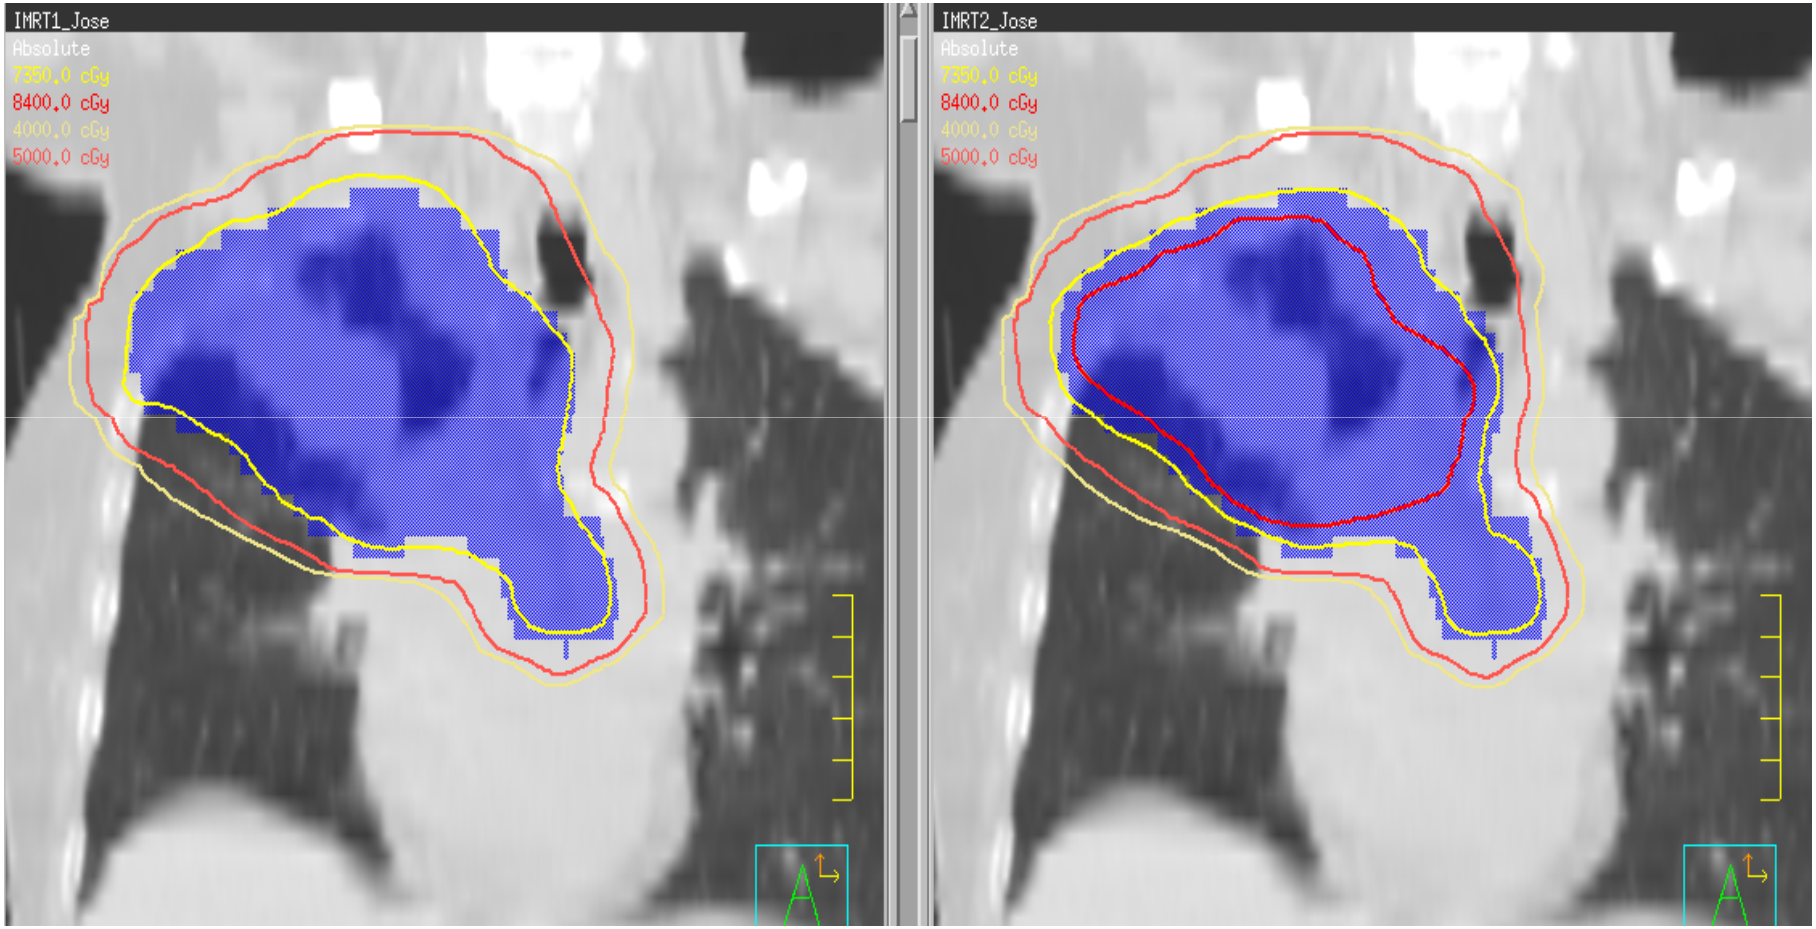
van Asselen et al, R&O 2006

Dose heterogeneity is a feature, not a bug





IMRT & dose heterogeneity in the PTV



"IMRT = dose heterogeneity in the PTV. Live with that."

Quite the contrary.

IMRT allows excellent dose homogeneity as long as you are willing to pay the price for it, so ask for homogeneity only if you actually need it.

Urban legends on IMRT /2

"We are not yet ready for EUD/'biological' optimisation in the clinical practice"

For some OARs the estimates for the volume effect parameter is consistent

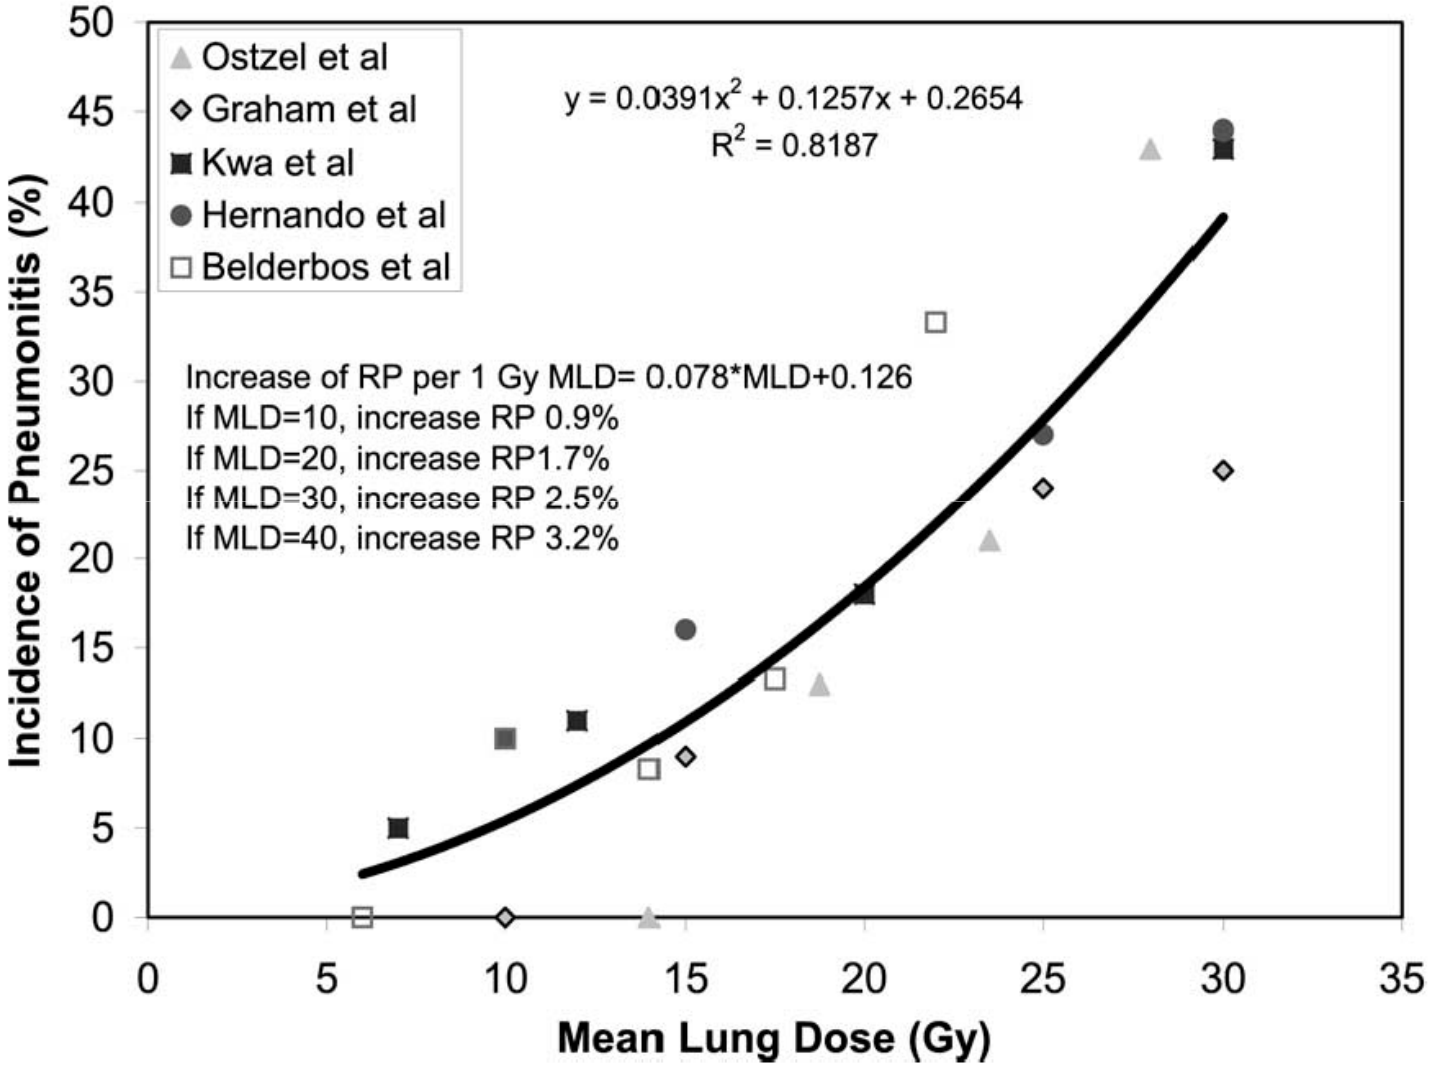
Rectum NTCP parameters with the LKB model

Mean lung dose model



Kong et al, Sem. Rad. Oncol 2005

Generalized EUD (gEUD)

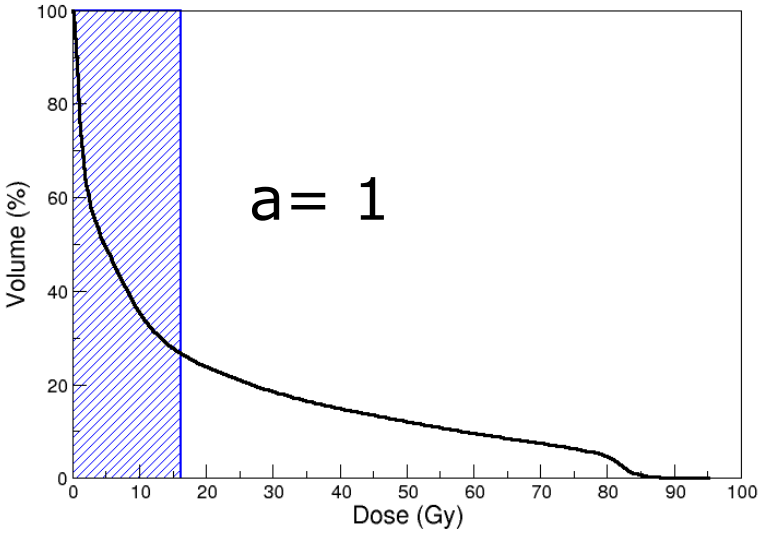
$$gEUD(Gy) = \left(\sum_{i=1}^{n} v_i D_i^a \right)^{1/a}$$

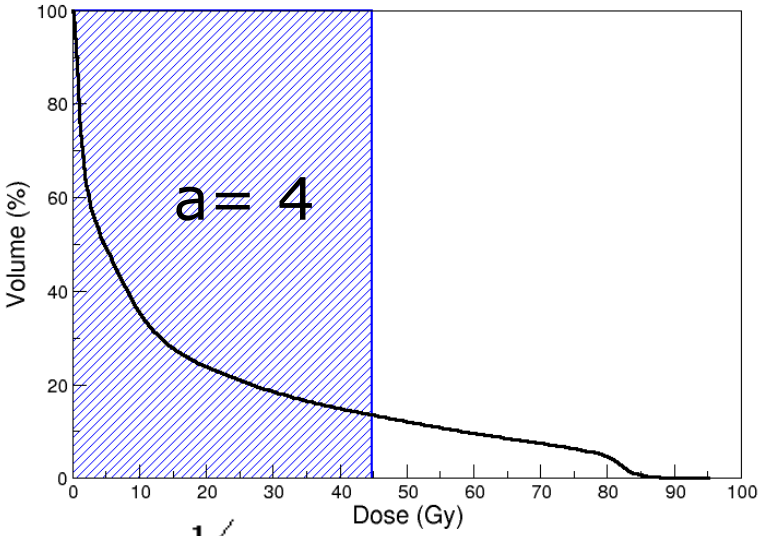
Niemierko 2000

a = 1	EUD = Dmean
a --> -∞	EUD --> Dmin
a --> +∞	EUD --> Dmax

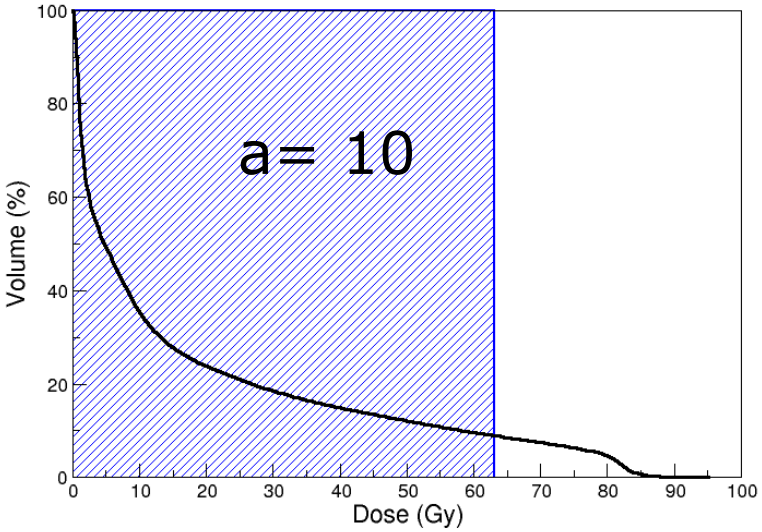
gEUD : phenomenological description
of the biological response to the radiation

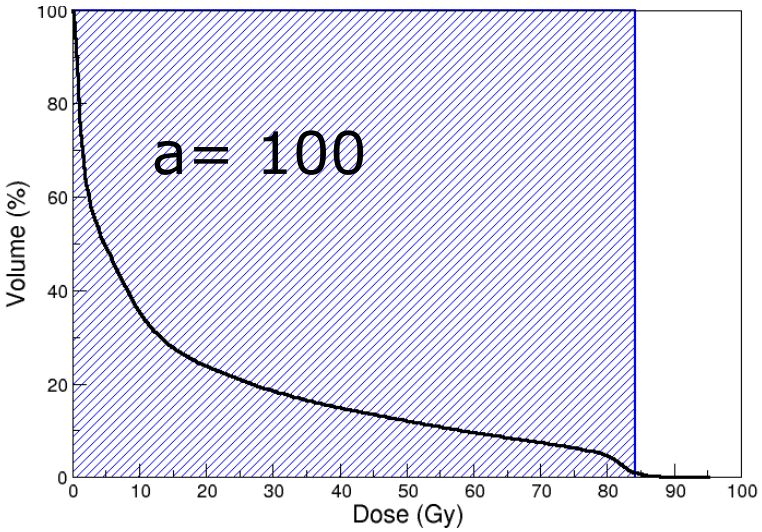
In principle applicable to target volumes and OARs

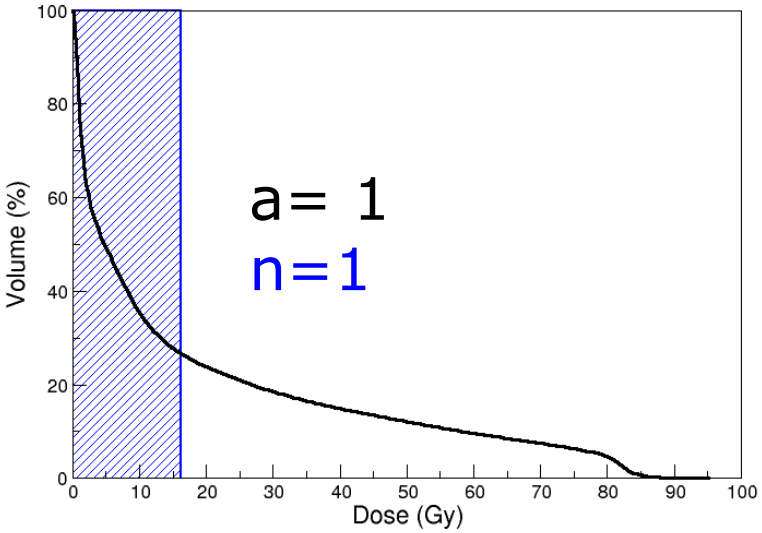


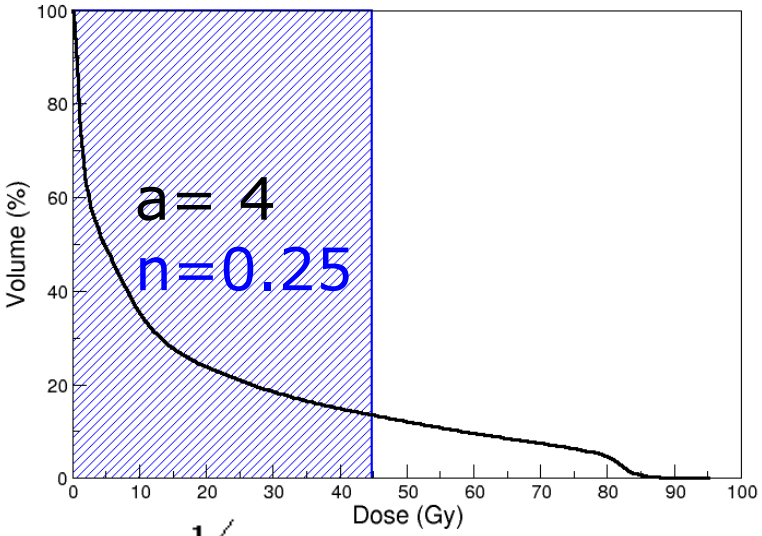


$$gEUD(Gy) = \left(\sum_{i=1}^{n} v_i D_i^a \right)^{1/a}$$

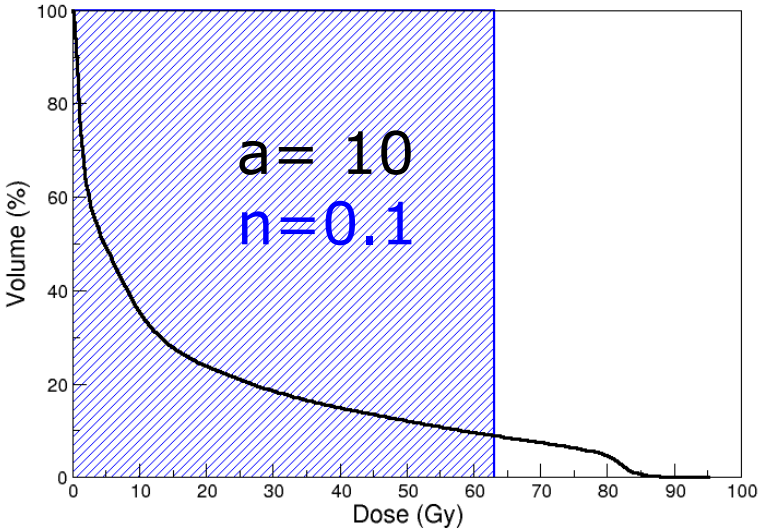


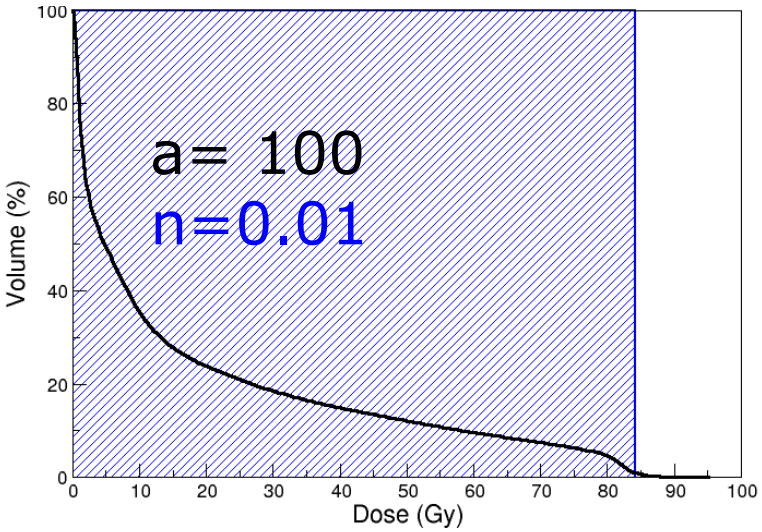




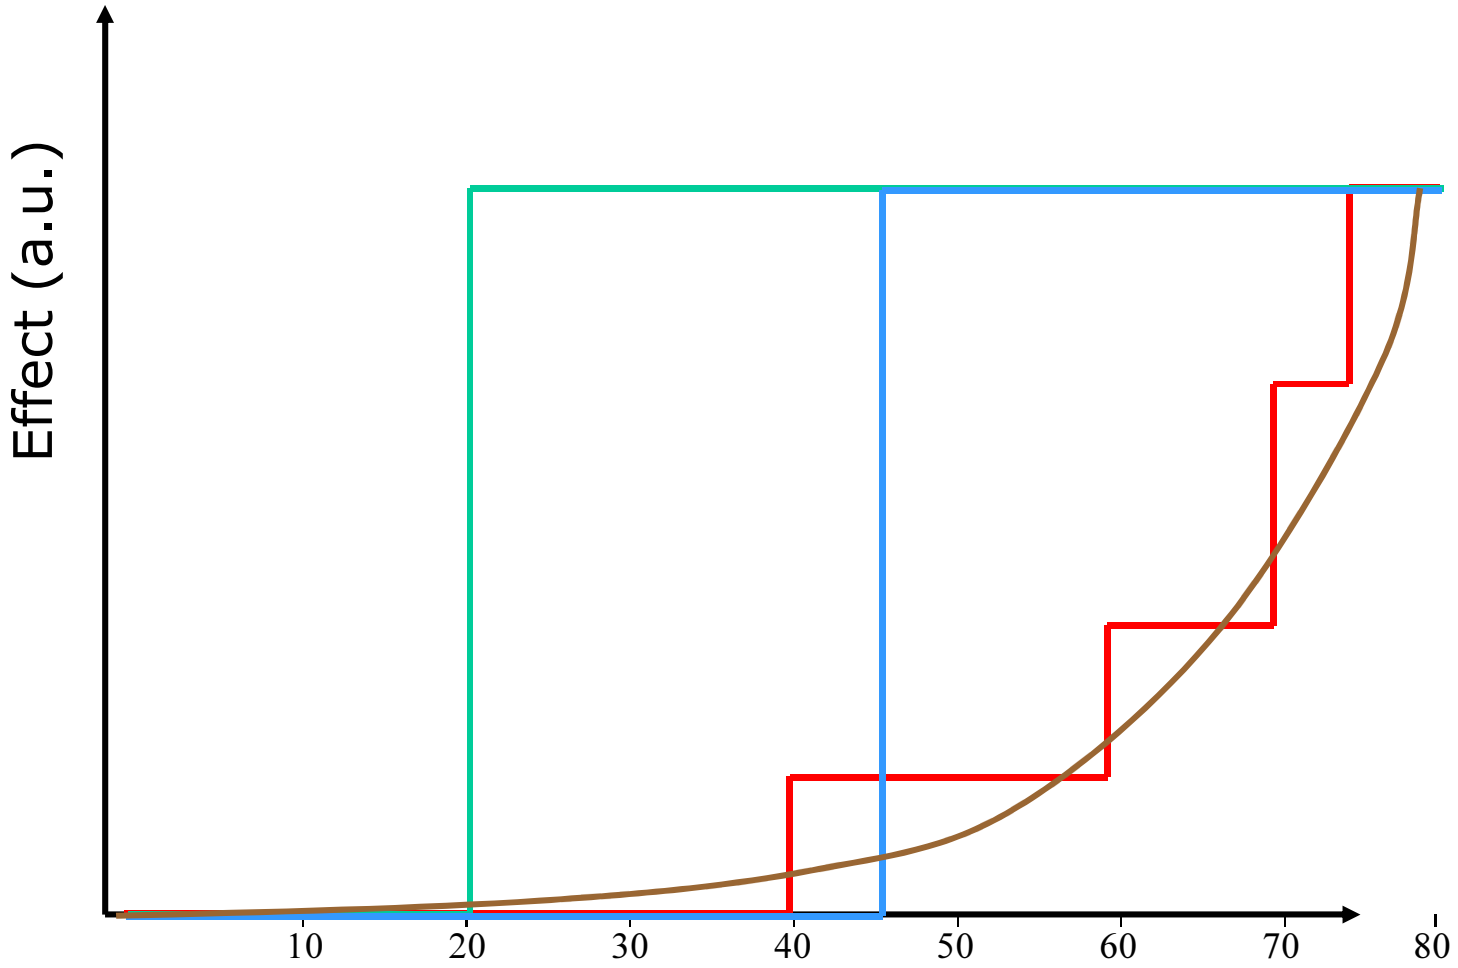


$$gEUD(Gy) = \left(\sum_{i=1}^{n} v_i D_i^a \right)^{1/a}$$





gEUD as a way to lock the relation between different DVH points (and getting rid of weigths!)



Commercial implementations - 1 (Philips/Raysearch/(Varian?))

(g)EUD optimisation for target and OARs as an add-on to DVH-based optimisation

$$F(\mathrm{E}UD)=\Theta(\mathrm{E}UD\text{-}\mathrm{E}UD_0)\left(\frac{\mathrm{E}UD\text{-}\mathrm{E}UD_0^2}{\mathrm{E}UD_0}\right)$$

Unconstrained optimisation

Evaluation tool including TCP, NTCP & P+

Commercial implementations - 2 (Elekta-Monaco)

EUD_{target}= Poisson EUD,

Serial model=gEUD,

Parallel model $$Isoeffect=\frac{1}{n}\sum_{i=1}^{n}\left(1+\left(\frac{d_0}{d_i}\right)^k\right)^{-1}$$

Constrained (OAR) or multicriteria (target) dose optimisation

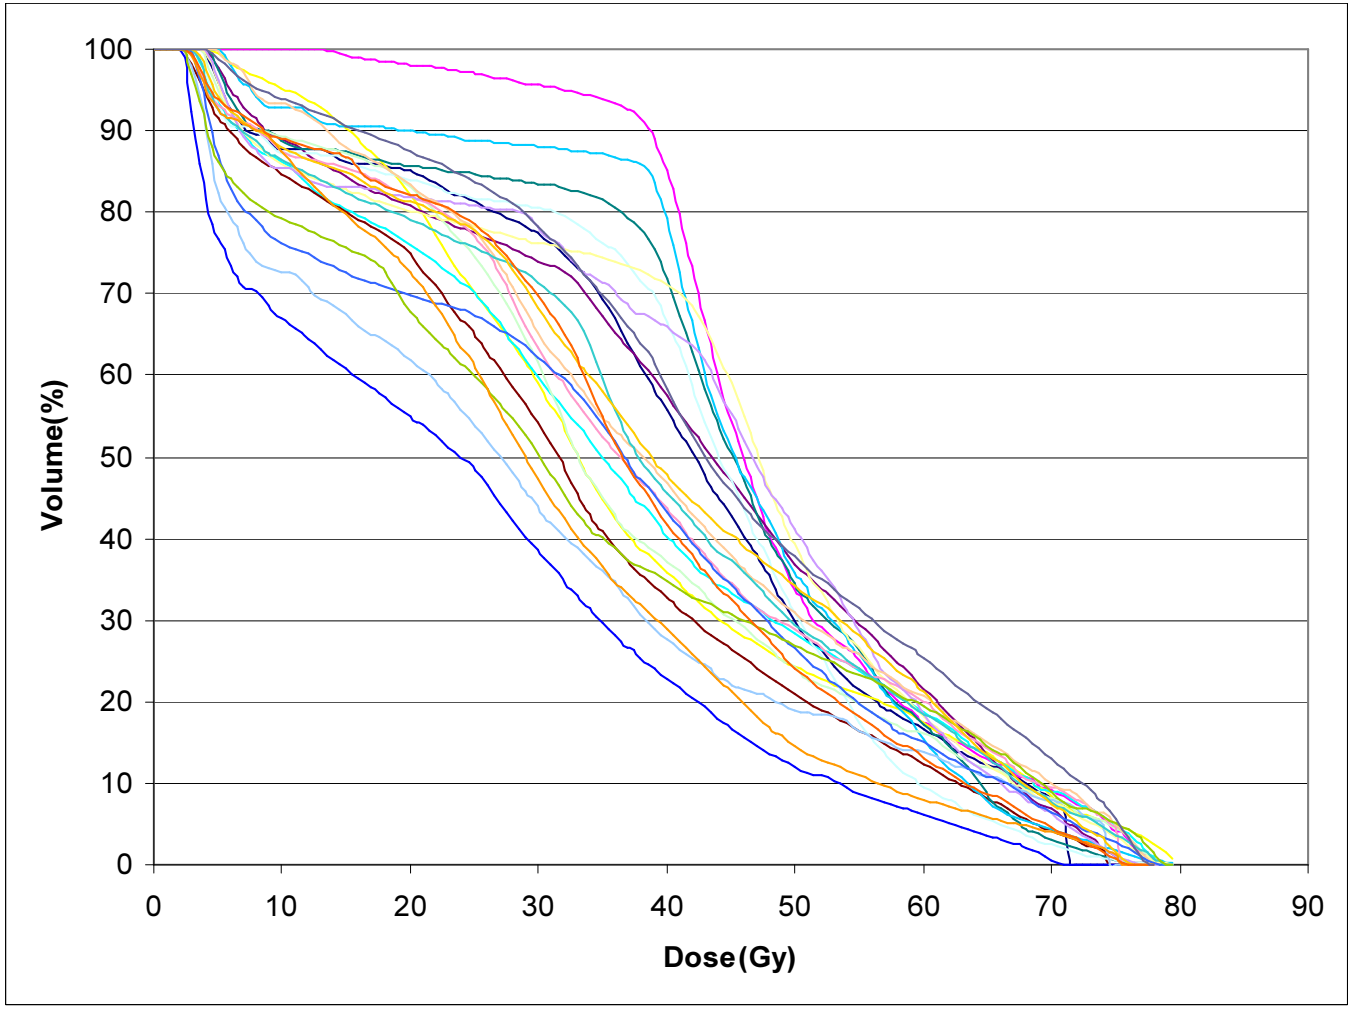
Tool for sensitivity analysis

(DVH constraints are available too.)

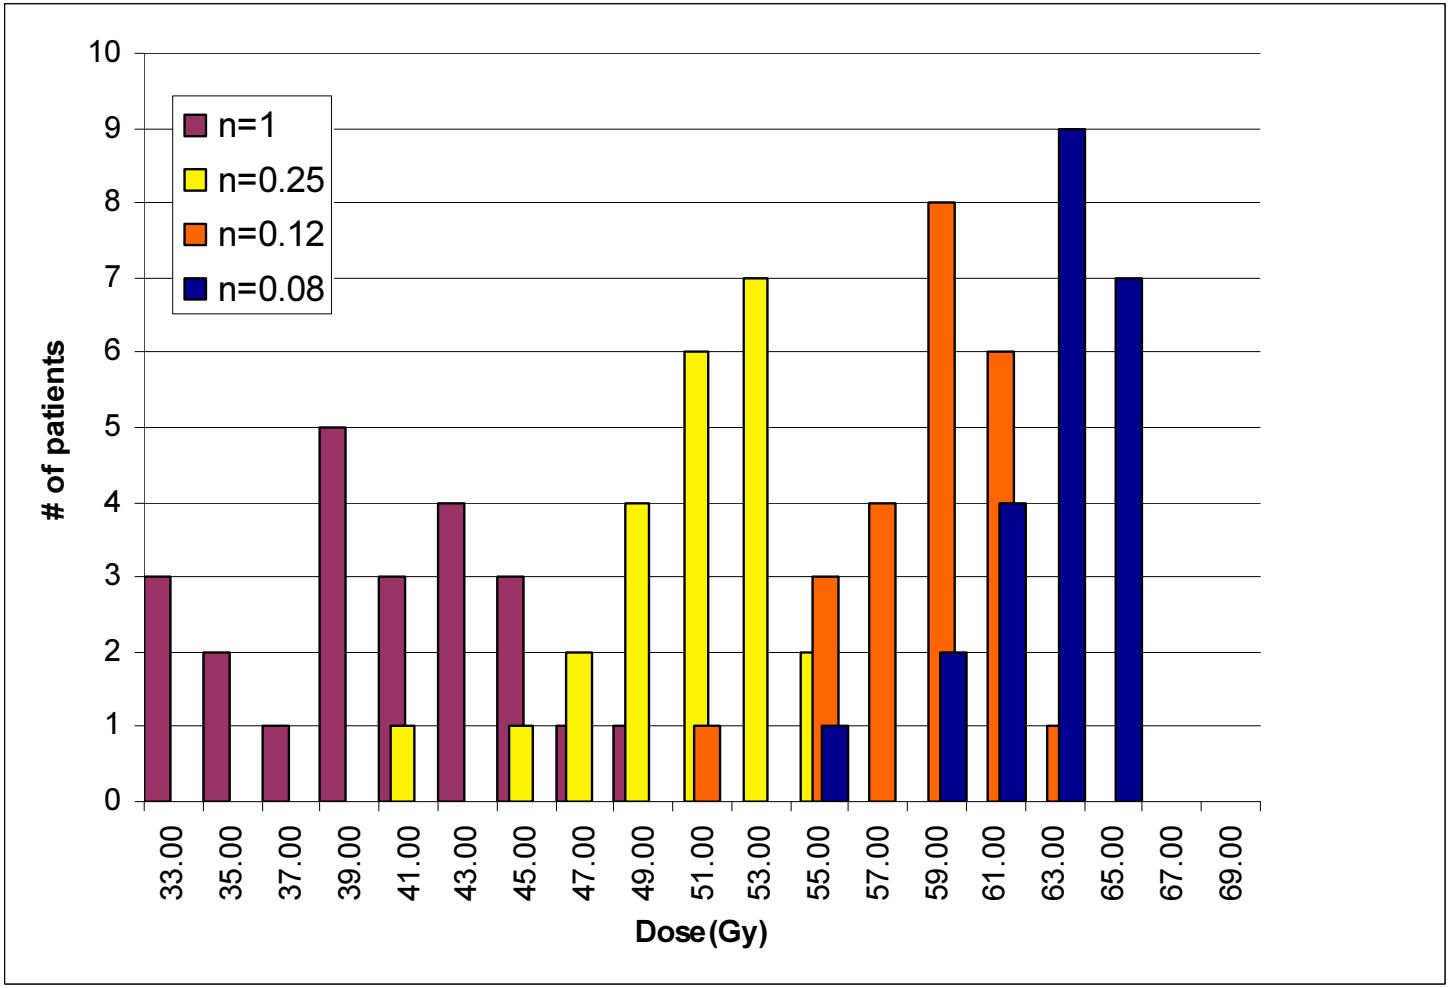
Fine, let’s try EUD optimisation.

Where should I start?

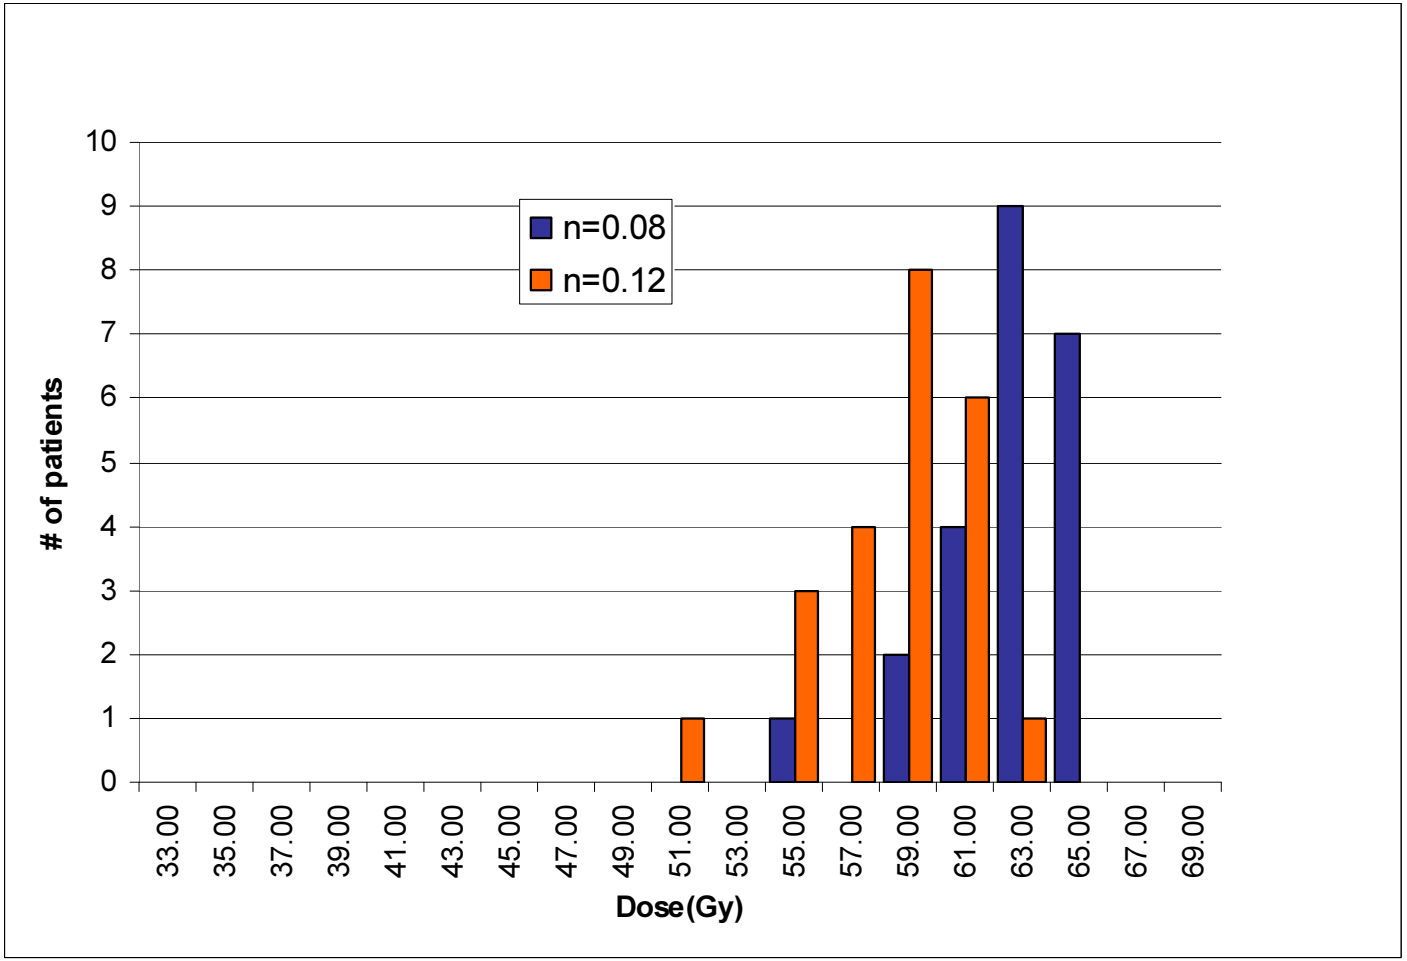
Start from your existing clinical practice.



Calculate EUD values for your plans



Do the n *values suggested in the literature make sense ?*



Run a sensitivity analysis

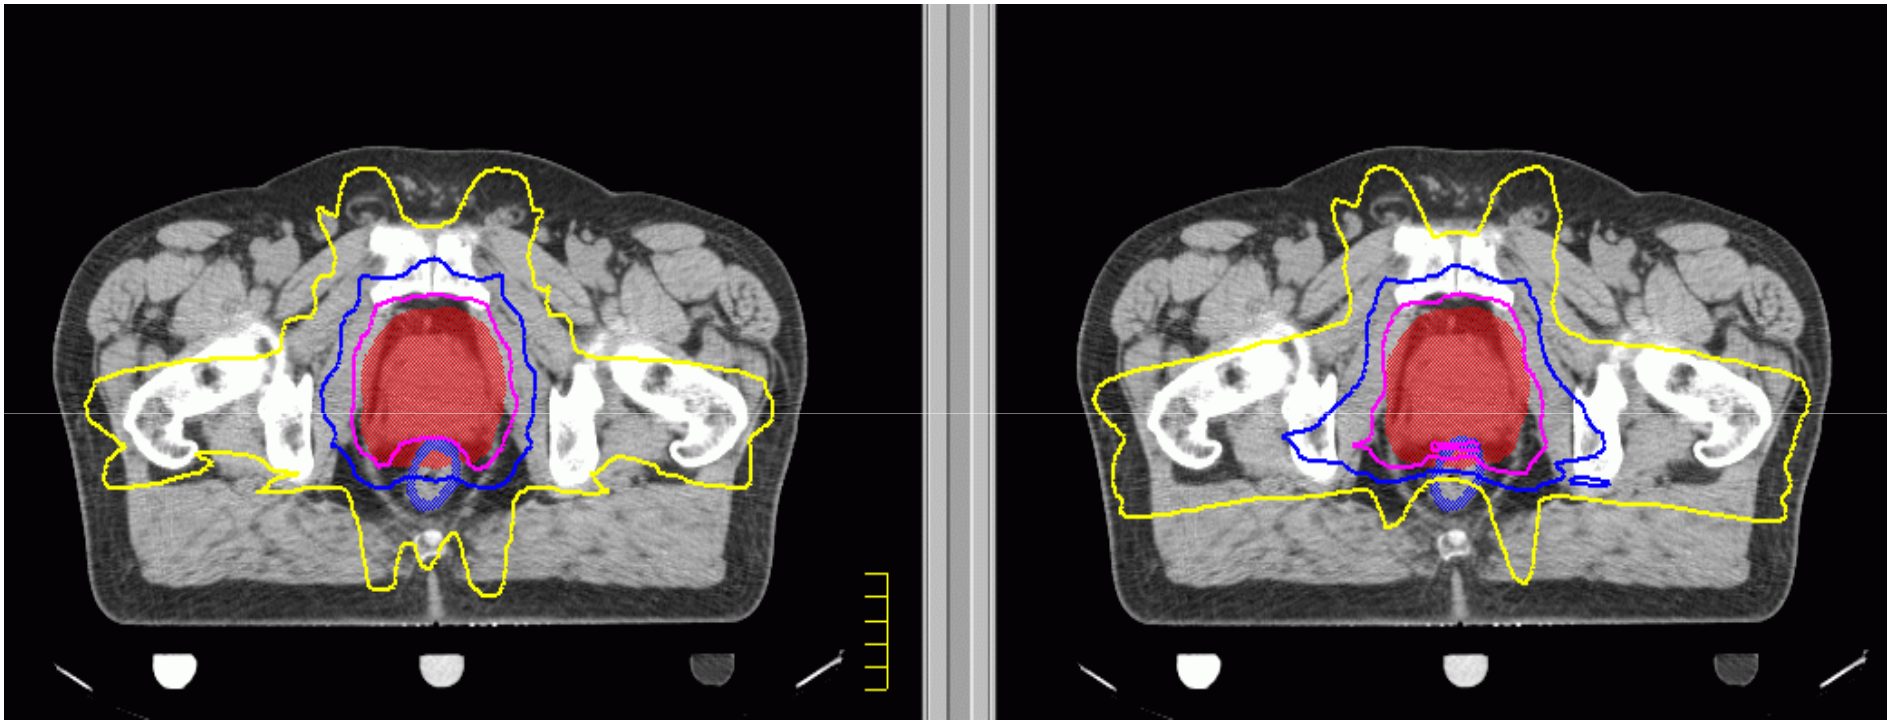
Dose(Gy)

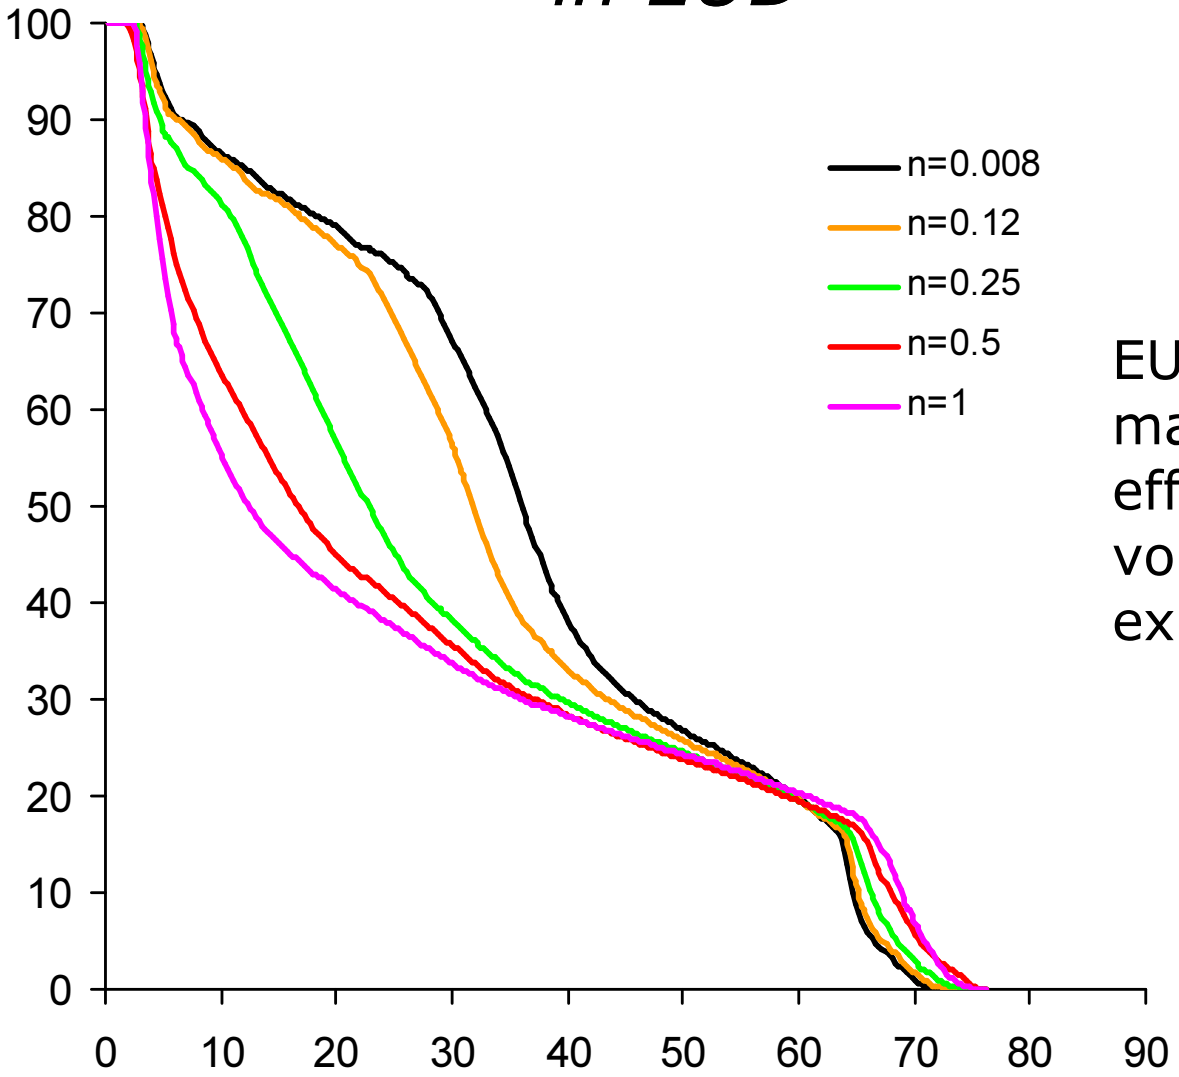
2D dose distributions



***n* = 0.08**

***n* = 1**

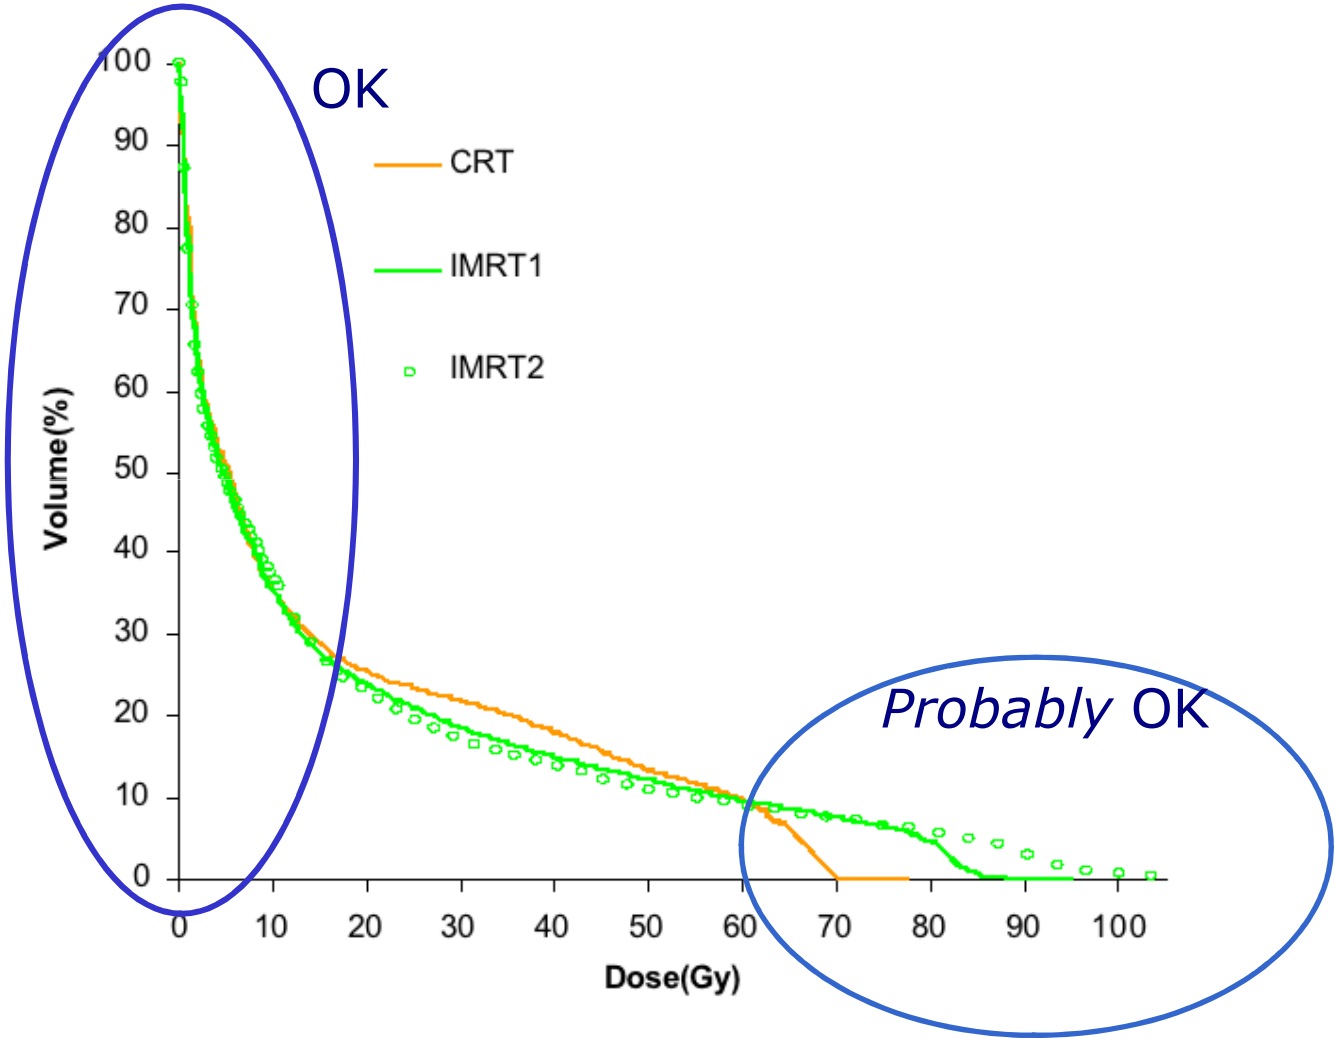
There's no magic in EUD



EUD it's all about making volume effects (i.e. dose-volume tradeoffs) explicit

“IMRT optimisation can not be based on data obtained in the 3D-CRT era.”

Don't make the dose-response models break



... but don't get stuck either

1. One uses IMRT to create plans as similar as possible to CRT

2. CRT-like dose distributions are delivered to patients

3. The follow up will provide further data on the effect of ... CRT-like dose distribution

The smaller the dose effect for a complication, the least you should be worried about potentially undue extrapolations

... And then you learn about puzzling results

Med Phys 2012

Plan reporting

Current plan reporting (e.g. recent ASTRO recommendation) does not include ‘error bars’.

If there are uncertainties in the planning procedure, they should be reflected in plan reporting.

E.g., reporting the PTV dose is correct only if

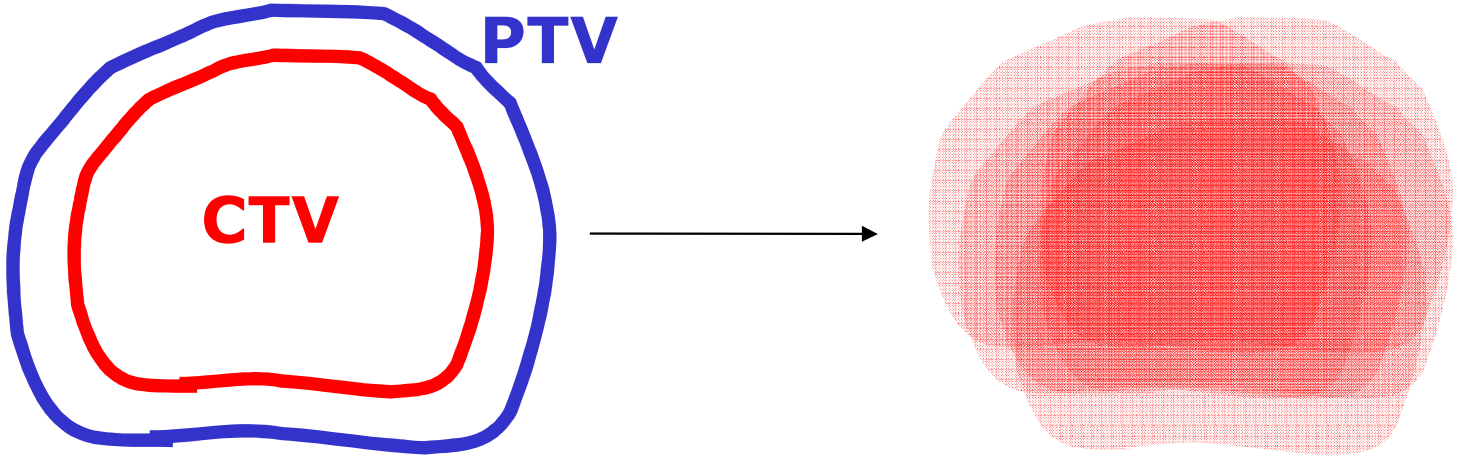
- The margins are correct
- The dose distribution is invariant for traslations/rotations
- The dose in the PTV is homogeneous

The same holds for ‘biological planning’:

- Uncertainty in the optimisation parameters (e.g. ‘a’) should result in a robustness analysis of the results.

Current and future developments

IMRT planning & geometrical uncertainties



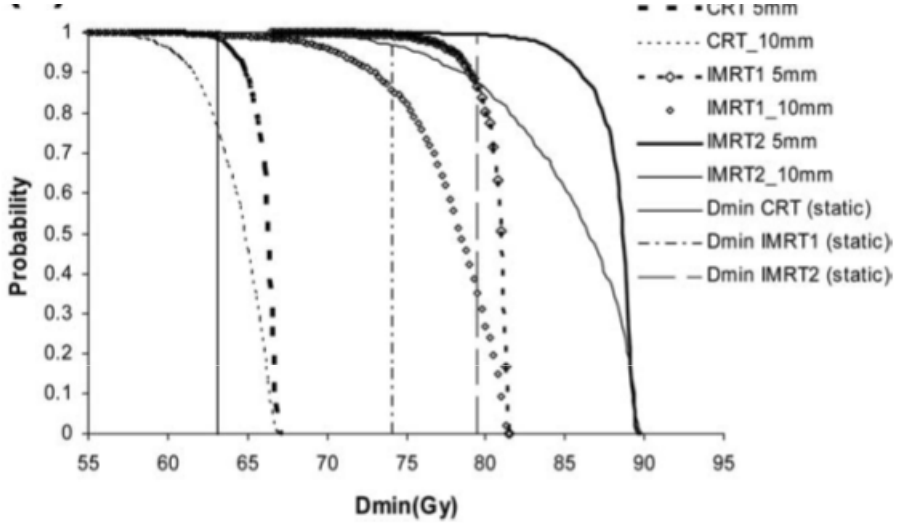
The PTV is an appropriate tool for CRT, but in IMRT one can do better than that.

'Robust optimisation' is an emerging field

Alternatives to the PTV particularly needed for charged particle therapy (e.g. p+).

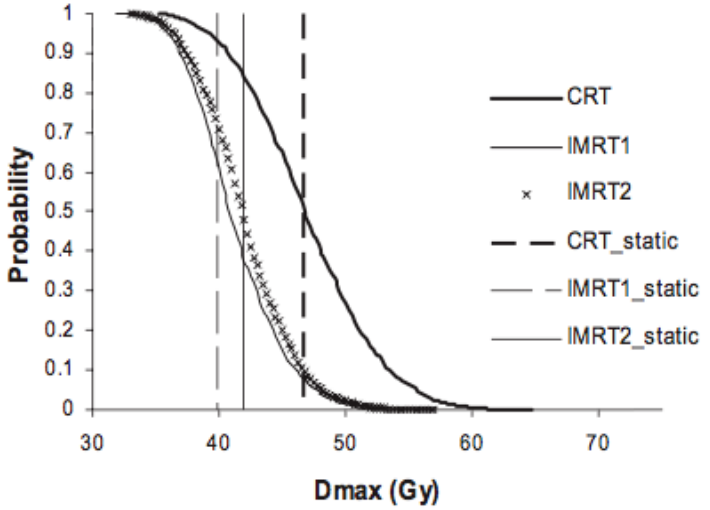
Current target dose reporting assumes homogeneous dose distributions in the appropriate PTV.

If **either** of the two is missing, we should report the dose differently.



Probabilistic dose reporting?

In the meantime, report the dose for the correct volumes



Schwarz et al IJROBP 2006

Conclusions

Class solutions ± 'forward planning' might facilitate a gradual transition to IMRT

Appropriate cost function and VOI definition are critical in 'steering' the optimisation in the desired direction.

‘Biological’ planning can be incorporated in everyday practice

Automatic planning is coming. Fast.

Dose Calculation in Static and Rotational IMRT

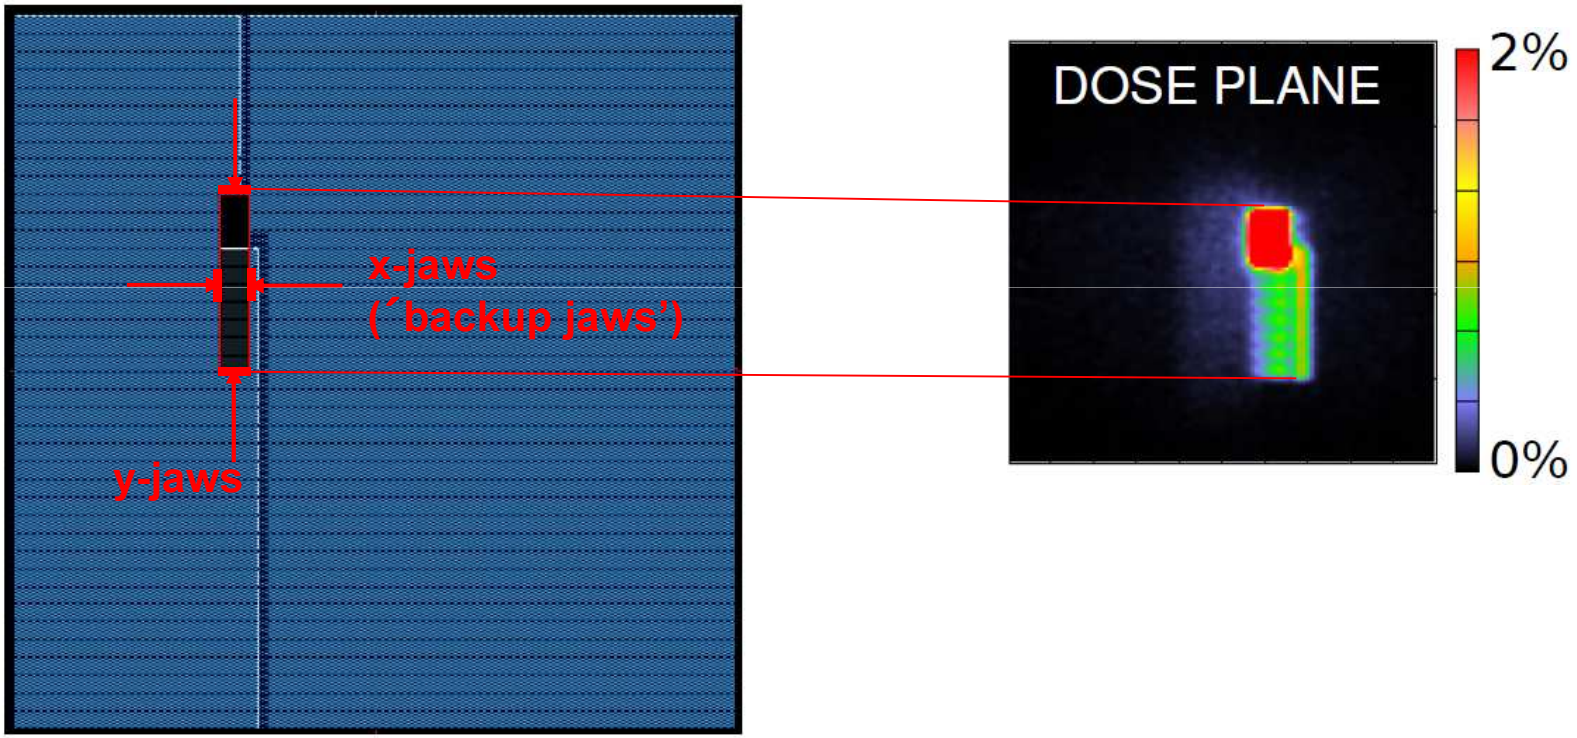
Leaf and jaw transmission, inter-leaf leakage

courtesy M. Sikora

3 x 1 cm off-axis segment



Effects of the beam modulating elements that need to be modeled for high-precision dose calculation

- leaf transmission, (jaw transmission)
- inter-leaf leakage
- leaf/jaw tip factors (influence on penumbra shapes)
- tongue-and-groove
- systematic leaf offsets
- correction factors for MLC/jaw backscatter into Monitor chamber

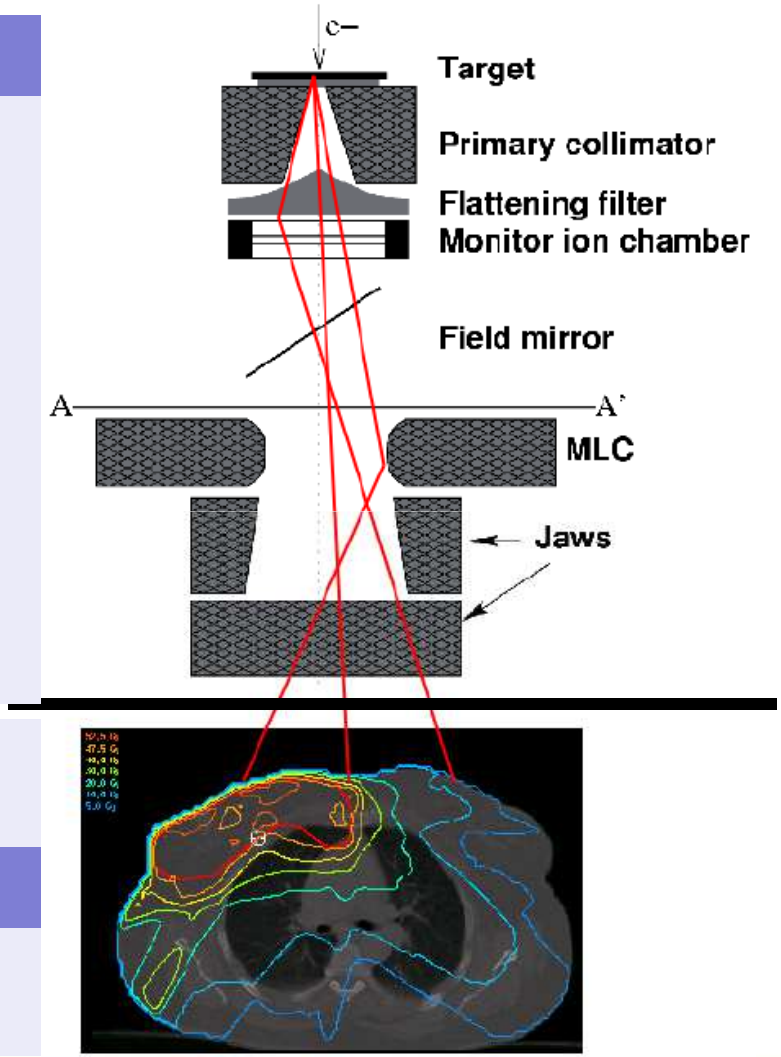
→ *most of these effects were discussed in the presentations of Marco Schwarz:*
"IMRT delivery techniques"
"TPS commissioning"

Where are we now?

accelerator head

particle source

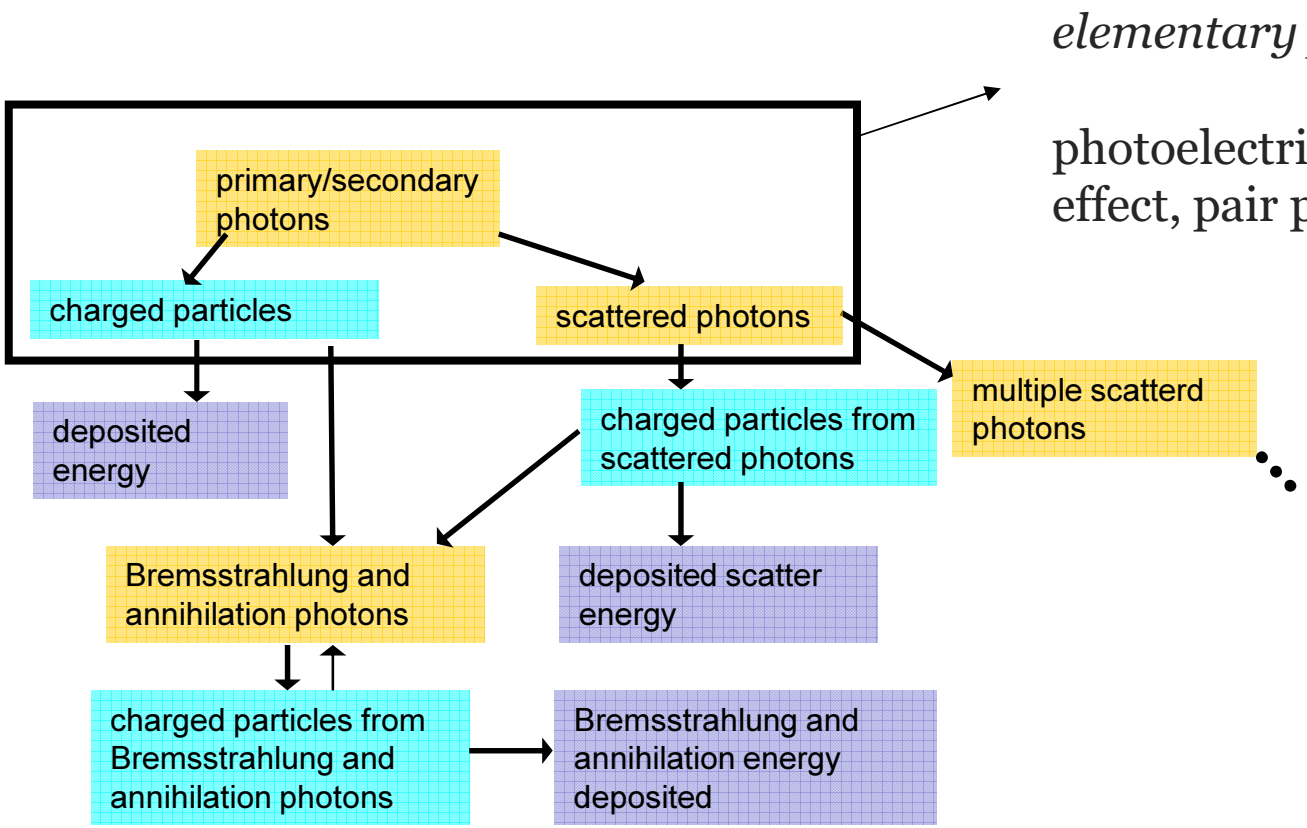
beam modulators



Patient

‘Beam phase space’

What happens in the patient…



elementary physical processes:

photoelectric effect, Compton effect, pair production

Modelling particle transport in the patient: Dose calculation methods

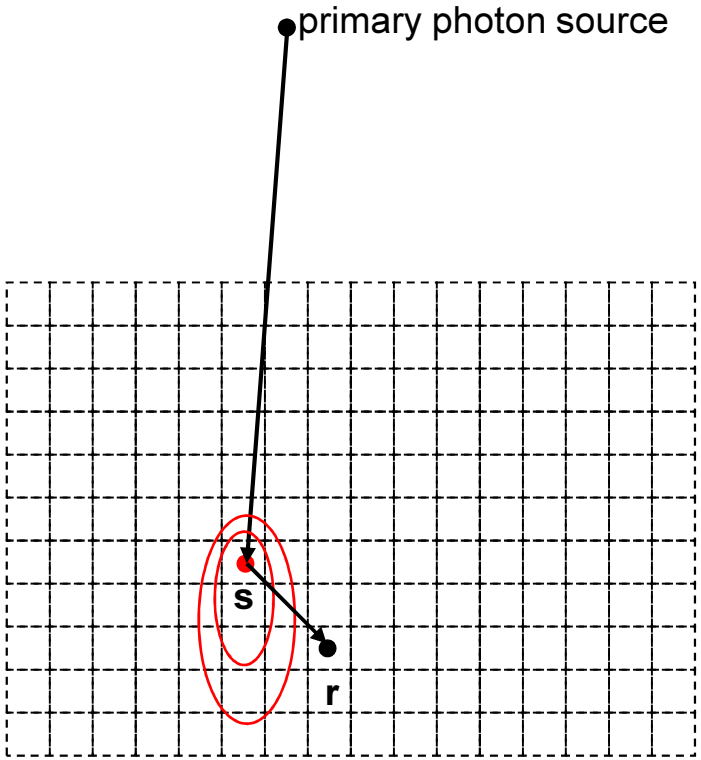
Implicit, Kernel-based methods:

- Collapsed Cone Convolution Superposition
- Pencil Beam

Explicit methods:

- stochastic particle transport modelling: Monte Carlo
- deterministic particle transport modelling: Boltzmann Transport Equation (LBTE) Solvers

Kernel-based methods: Separation of Photon-fluence and energy deposition



TERMA~photon fluence

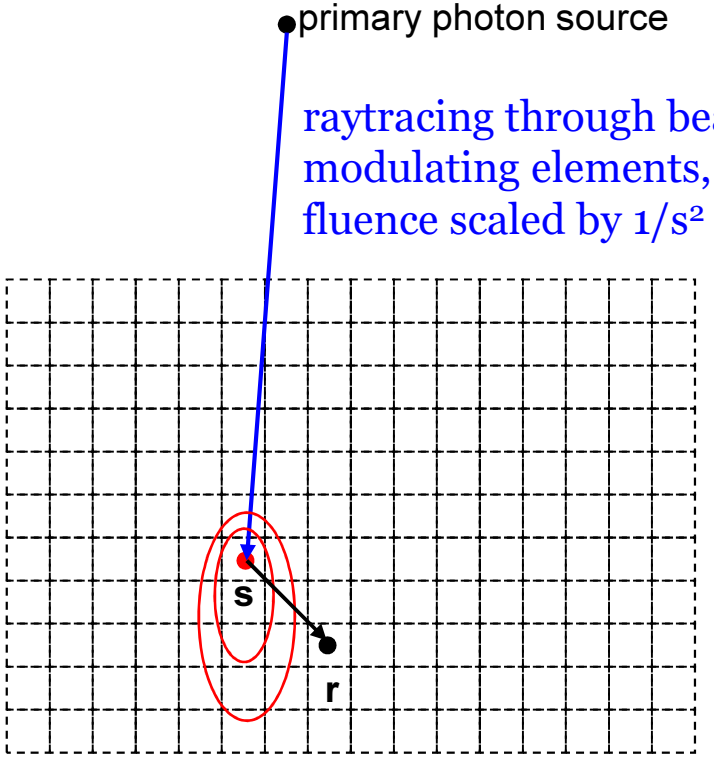
Photon transport from the primary photon source (or a secondary source) to an interaction point *s*

Energy release through physical interactions in medium

Energy transport from *s* to point *r* through secondary particles (photons and electrons)

KERNEL

Kernel-based methods: The TERMA concept



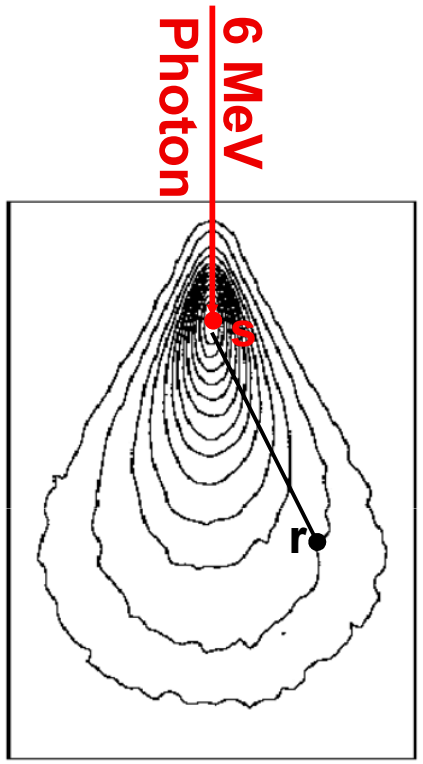
$$T(E,\vec{s}) = \underbrace{\frac{\mu(E,s)}{\rho(\vec{s})}}_{\text{mass attenuation coefficient}} \cdot \underbrace{E \cdot \Phi^{prim}(E,\vec{s})}_{\text{primary fluence}}$$

TERMA:
Total **E**nergy **R**eleased per **MA**ss

all energy released at *s* through physical interactions of the ***primary*** photon with the medium: *photons, electrons, (positrons)*

Neglected in most commercial dose calc. algorithms

Kernel-based methods: Energy deposition *point kernel*



$$h^{water}\left(E,\vec{r},\vec{s}\right) = h^{water}\left(E,\vec{r}-\vec{s}\right)$$

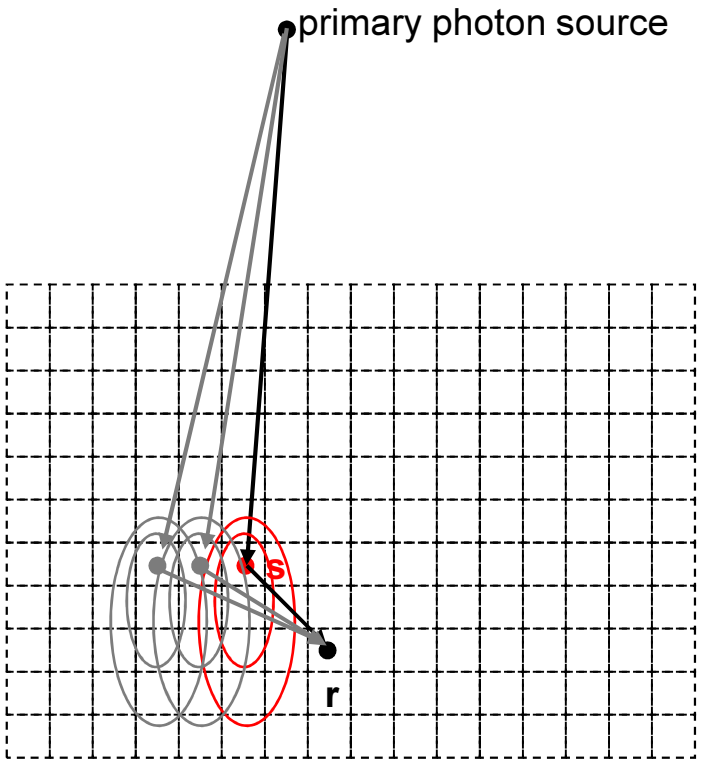
homogeneous medium (water)
→ symmetrical PSF!

The *point kernel* - also called *point spread function* (PSF)- summarizes energy deposition of all physical interaction processes:

- pre-calculation e.g. with Monte Carlo dose calculation in water
- parameterization for efficient use

Kernel-based methods: Convolution/Superposition

Simplest possible situation:
Monoenergetic incident photons,
Homogeneous medium



Dose in point *r*...

$$D(\vec{r}) = \int d^3 s \; T(\vec{s})\, h(\vec{r} - \vec{s})$$

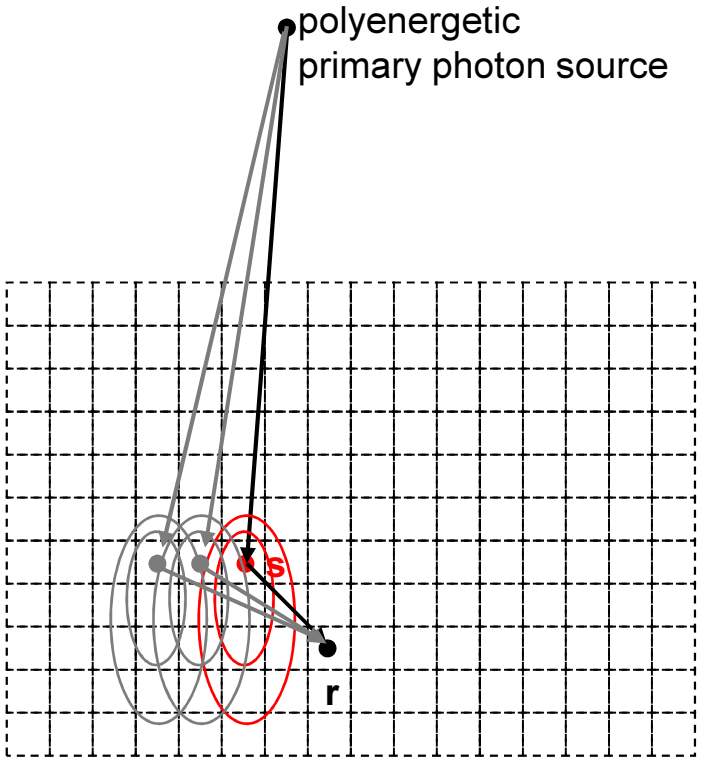
...*superposition* of all point kernels originating around all possible points *s*

mathematically: 3D-*convolution integral*

→ very efficient numerical implementation via fast fourier transform!
BUT necessary condition: point kernel independent of location (homogeneous medium)

Kernel-based methods: Convolution/Superposition

more realistic situation:
***Poly*energetic** incident photons,
Homogeneous medium (water)



Dose in point *r*...

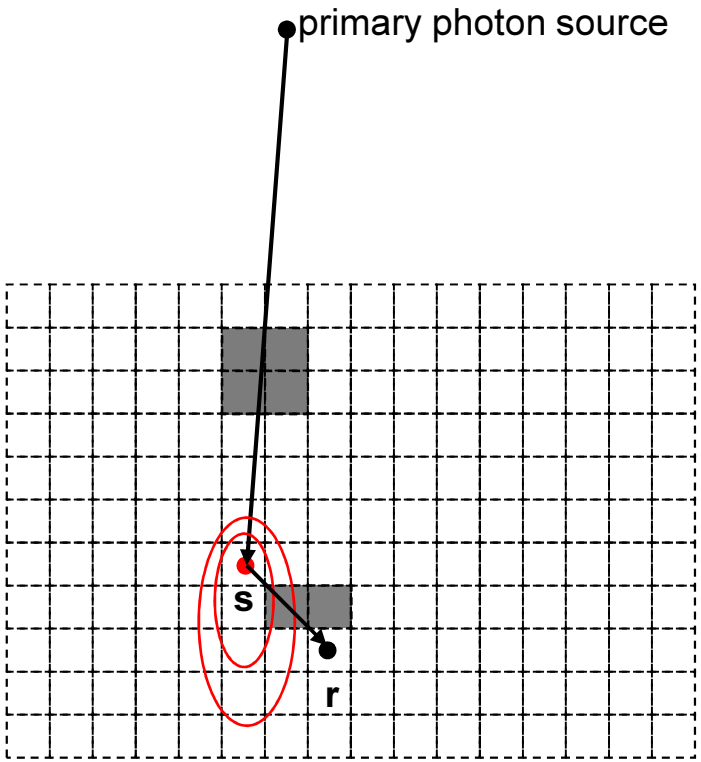
$$D(\vec{r}) = \int dE \int d^3s \; T(E,\vec{s})\, h(E,\vec{r}-\vec{s})$$

3+1D-*superposition:*

weighted superposition of dose contributions for different energies

→ numerical less expedient than the previous idealized situation

Kernel-based methods:
Dose calculation in inhomogeneous media



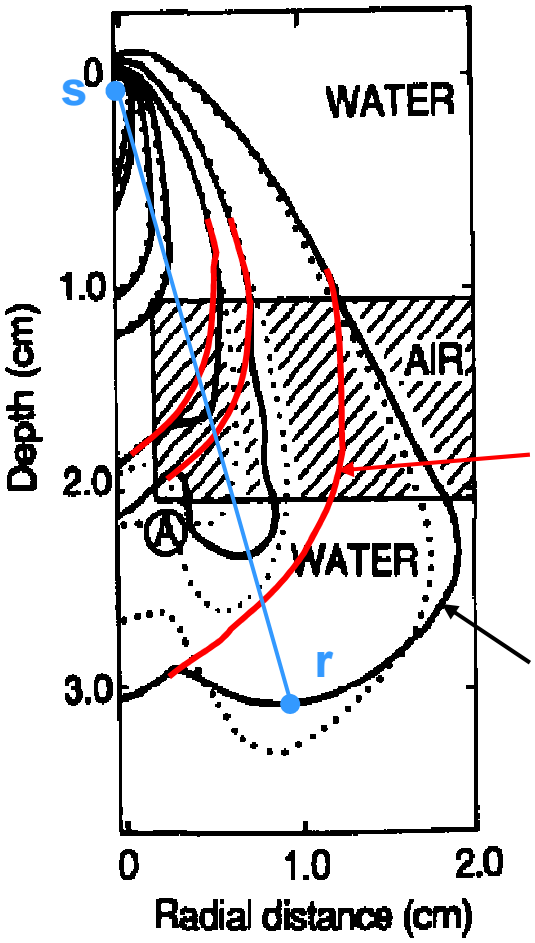
How to handle inhomogeneous media in the kernel formalism?

(1) rescale fluence according to the *effective pathlength* corrected by densities-along-the-way of raytracing

(2) 'rectilinear' density rescaling of kernel

Kernel-based methods: Rectilinear density rescaling of the kernel

adapted from Woo and Cunningham 1990 (Med. Phys. 17(2))



$$h(E,\vec{r},\vec{s}) = \frac{\rho(\vec{r})}{\rho_{water}} \cdot \bar{\rho}^{2}{}_{rel}(\vec{r},\vec{s}) \cdot h^{water}\left(E, \bar{\rho}_{rel}(\vec{r},\vec{s}) \cdot (\vec{r}-\vec{s})\right)$$

this would be the kernel dose in a homogeneous medium: h^{water}!

...and after rectilinear rescaling

'Rectilinear' rescaling with the *mean relative density* along the path between s and r:

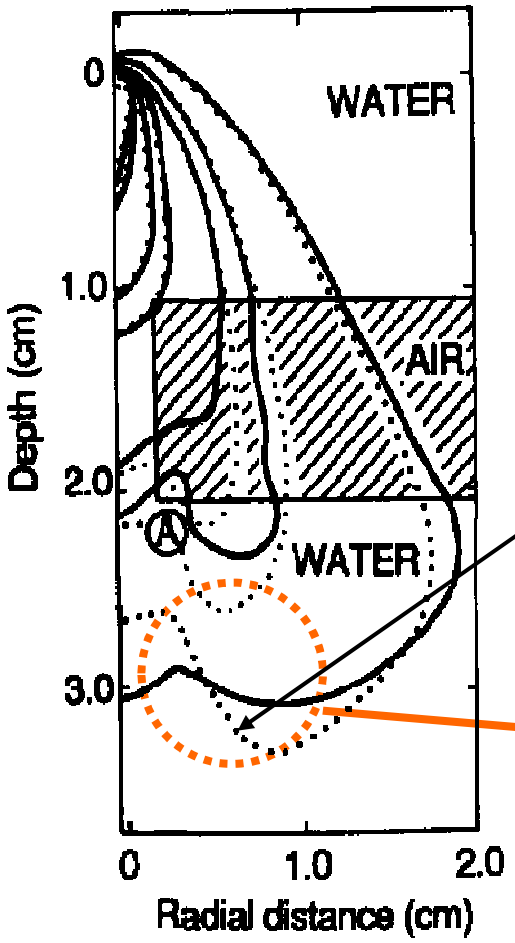
$$\bar{\rho}_{rel}(\vec{r},\vec{s}) = \frac{1}{|\vec{r}-\vec{s}|}\int_{\vec{r}}^{\vec{s}} d\vec{s}' \, \frac{\rho(\vec{s}')}{\rho_{water}}$$

→ The point kernel dose *is dependent on location* inside of inhomogeneous media (patient!)

→ efficient numerical dose calculation w. fast fourier transform not possible without further approximations

Kernel-based methods: Rectilinear density rescaling of the kernel

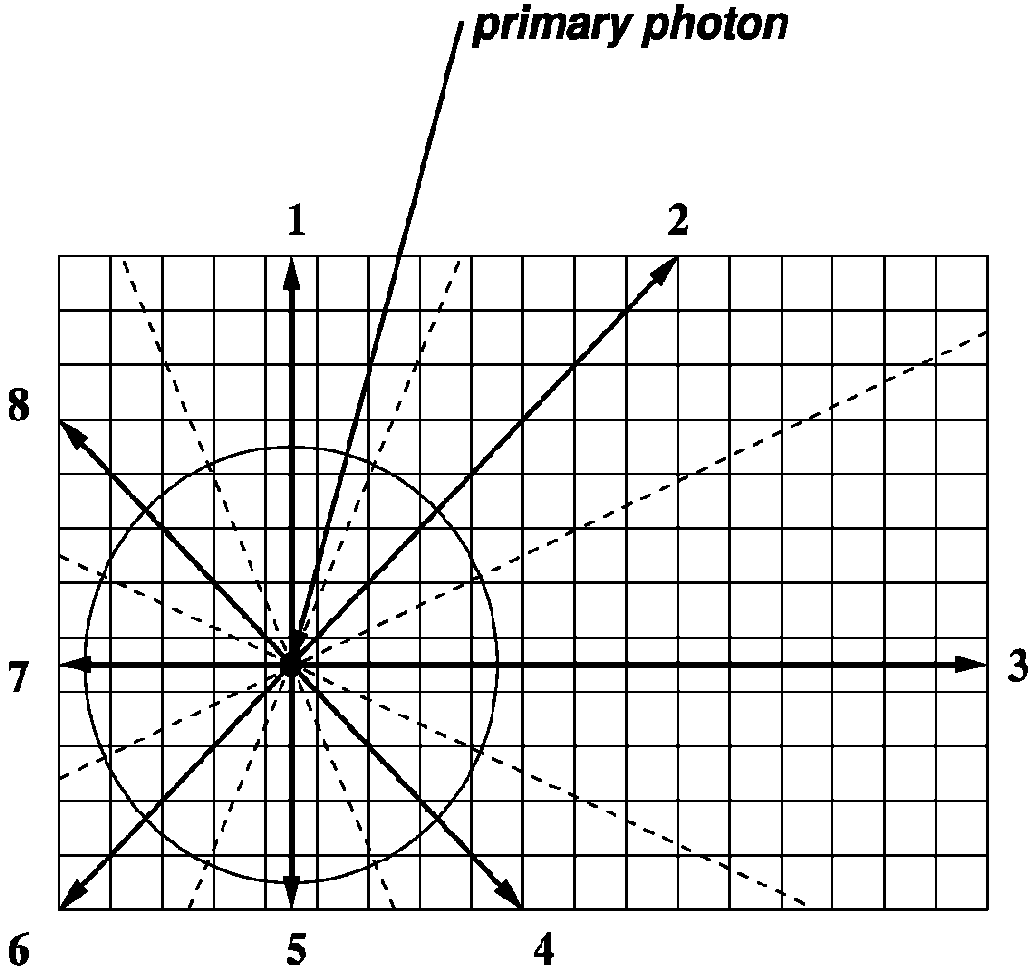
Woo and Cunningham 1990 (Med. Phys. 17(2))



…dotted isodose lines: 'exact' point kernel dose from Monte Carlo calculations

Electrons do not move linearly on straight tracks!
Multiple scattering effects not exactly handled

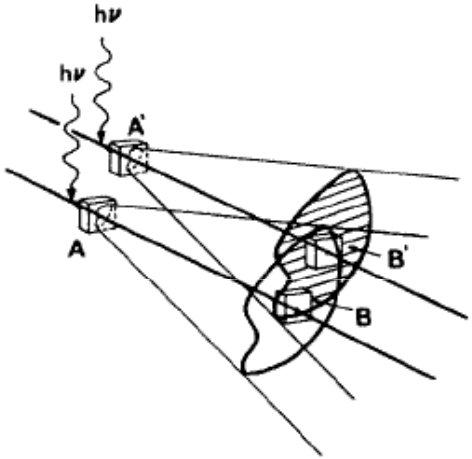
Kernel-based methods:
'Collapsed Cone' approximation for efficient density rescaling

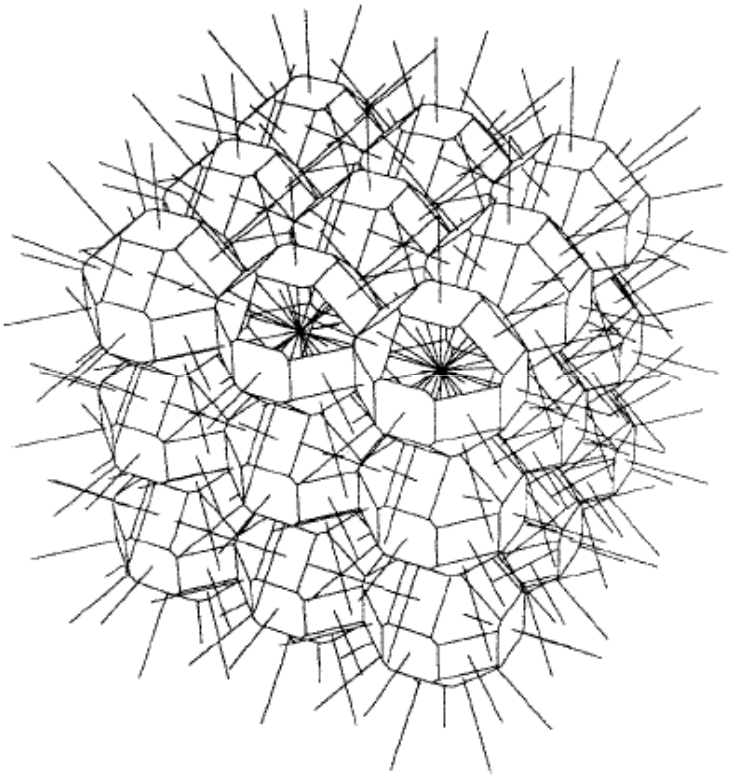


- Discretization of the point kernel into angular sectors ('cones')
- density rescaling only done for voxels on the central cone axis, i.e. the cones are 'collapsed' to their central axis
- precision and calculation time depend on resolution

Kernel-based methods:
'Collapsed Cone' approximation for efficient density rescaling

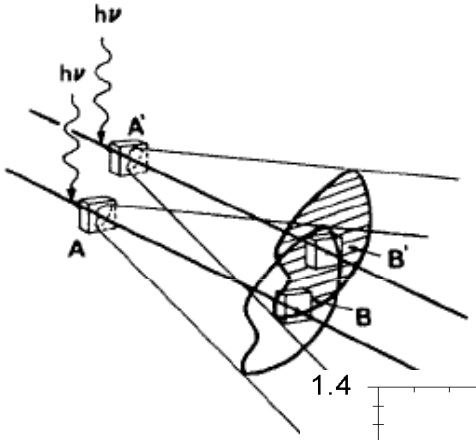
Ahnesjö and Aspradakis
1999 (PMB 44(11))

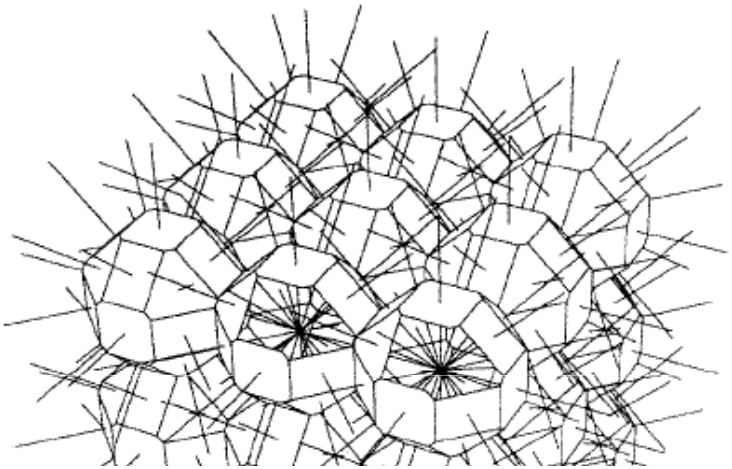


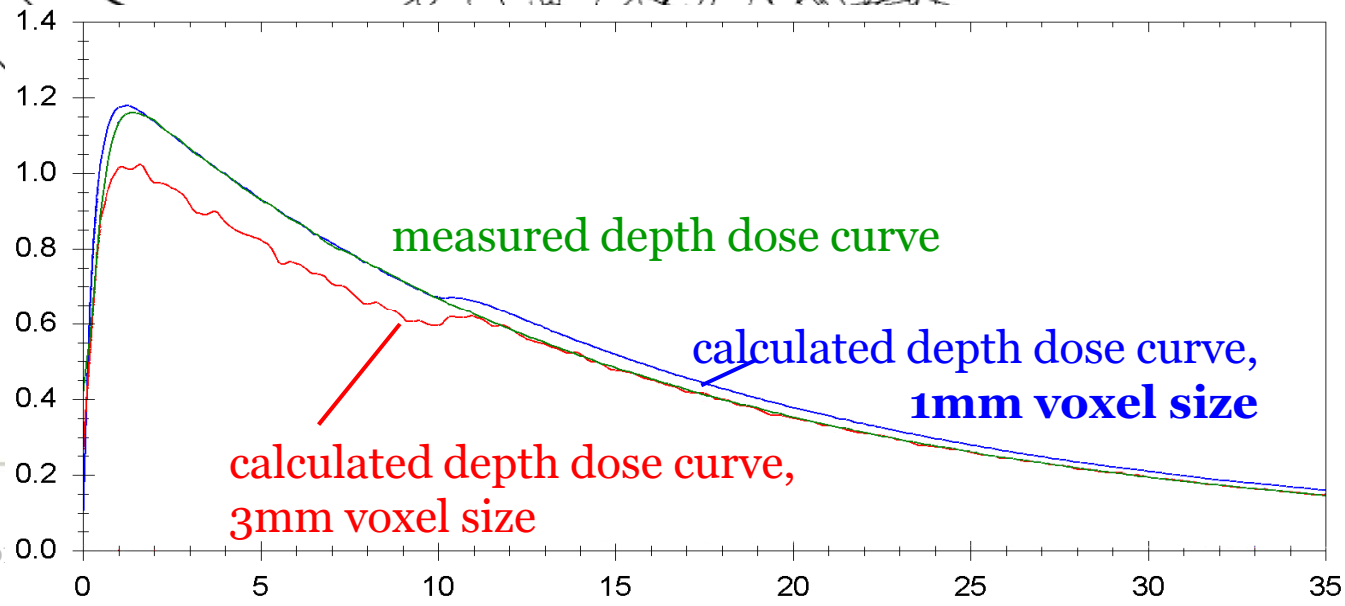


Kernel-based methods:
'Collapsed Cone' approximation for efficient density rescaling

Ahnesjö and Aspradakis
1999 (PMB 44(11))





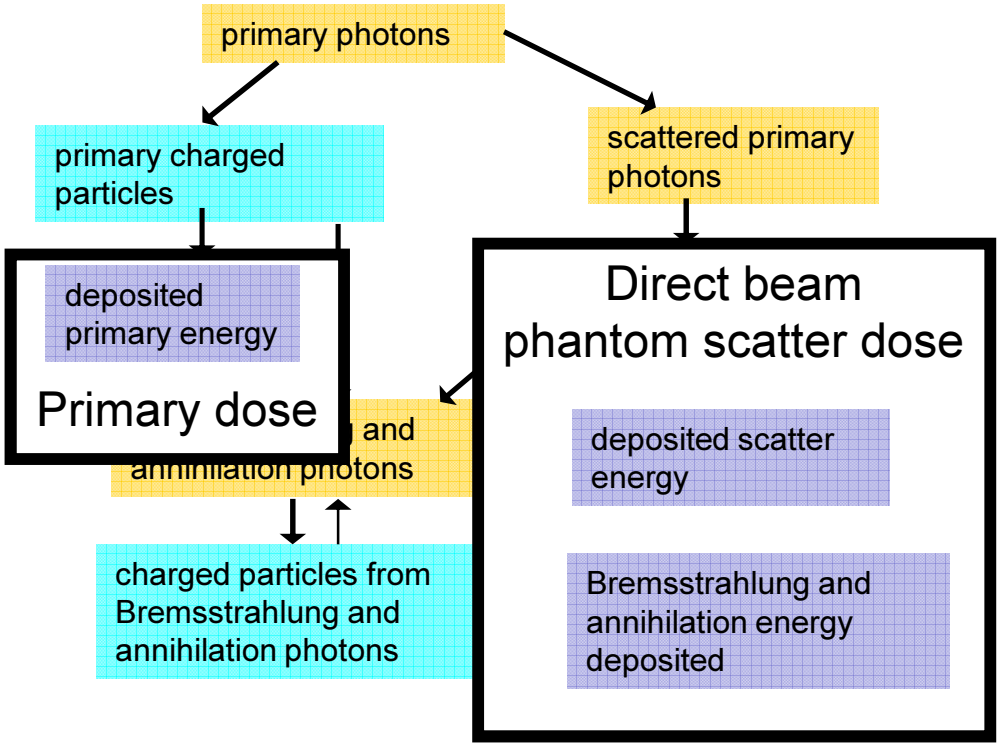


Kernel-based methods:
'Collapsed Cone' approximation for efficient density rescaling

Further 'smart' approximations for efficient numerical implementation:

- separate treatment of deposited primary enery and deposited phantom scattered dose

- further approximations for polyenergetic photon beams (details depend on implementation): Energy-averaged TERMA and point kernel; approximate or no modelling of beam hardening; ...



More details: Ahnesjö and Aspradakis 1999 (PMB 44(11))

Important to realize:
There is not >>THE<< Collapsed-Cone algorithm

The specific accuracy of different *implementations* of Collapsed Cone algorithms does vary!

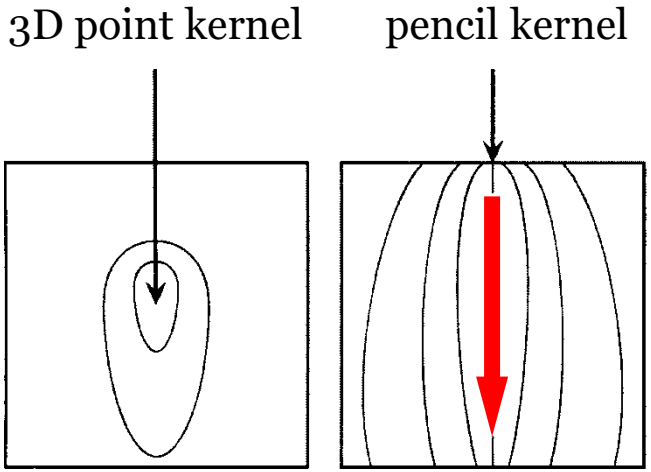
In fact, this is also true for Pencil Beam, and – to some extent (esp. head model) – for Monte Carlo…

Further readings e.g…

- Vanderstraeten et al. 2006: Accuracy of patient dose calculation for lung IMRT: A comparison of Monte Carlo, convolution/superposition, and pencil beam computations. Med. Phys. 33(9), 3149-3158

- Huang et al. 2013: Investigation of various energy deposition kernel refinements for the convolution/superposition method. Med. Phys. 40, 121721

Kernel-based methods:
2D-superposition methods: Pencil Kernel algorithms



Integrate 3D point kernels along beam direction ('pre-convolution'):

→ patient-specific *local* lateral scatter cannot be modelled well!

Dose calculation becomes a 2D-integration (superposition integral):

$$D(\vec{r}) = \int d^2s \; \Psi(\vec{s}) \; p(\vec{r}, \vec{s})$$

$\Psi(\vec{s})$: Fluence on the patient surface

$p(\vec{r}, \vec{s})$: Pencil Beam kernel

Kernel-based methods:
2D-superposition methods: Pencil Kernel algorithms

As for 3D point kernel methods, the superposition integral is a convolution integral, if the pencil kernel in spatially invariant (**homogeneous media**)

→ **very fast dose calculation** using Fast Fourier Transformation

approx. ***dose deposition in the patient***

Approximate methods to handle **inhomogeneous media:**

- density corrections: mainly effective path length rescaling along beam direction
- simplified modelling of phantom scatter: local *lateral scatter* effects not modelled correctly
- neglect energy spectrum changes
- simplified modelling of head scatter: requires *correction factors for the output-factor*

...and approximations to the ***head model***

Modelling particle transport in the patient: Dose calculation methods

about
Monte Carlo…

sources the most demanding candidate for direct use of Monte Carlo dose calculations. Long calculation times are a pronounced problem in conformal therapy where optimization of dose distributions using iterative algorithms requires the dose to be recomputed many times during the planning procedure. Hence, it is likely that for another decade photon Monte Carlo will be used for beam characterization, benchmarking and other special studies rather than routine treatment planning. Nevertheless, a very ambitious Monte Carlo treatment planning

Anders Ahnesjö and Maria Mania Aspradakis 1999:
Dose calculations for external photon beams in radiotherapy
Phys. Med. Biol. **44**(11), R99-R155

…and LDPE
Solvers…

number of iterations is proportional to the number of interactions. Hence, to completely solve the dose deposition in photon beams numerically by purely deterministic methods the electron transport must be solved by a more suitable method such as the phase space evolution originally developed for dose calculation in electron beams (Huizenga and Storchi 1989, McLellan *et al* 1992, Janssen *et al* 1997). The complexity and computational burden for such a complete deterministic approach would probably exceed that of the Monte Carlo approach (Börgers 1998).

Summary and Conclusions

- As clinical **users**, we don't have to know all details of dose calculation algorithms

The few things you should know and be aware of:

- Major effects happen in the accelerator head already
  – importance of a good head model!
- Pencil beam algorithms are very fast, but have major problems with accuracy in regions of the body with large density inhomogenieties (lung/thorax!, head-and-neck)
- thus, the final dose calculation should be done with Collapsed Cone algorithms, Linear Boltzmann Transport Equation Solvers or Monte Carlo algorithms
- be aware: There is not "THE" Pencil Beam or "THE" Collapsed Cone algorithm
  – accuracy and performance depend on vendor-specific implementational details
- finally, and most importantly: *Always keep a critical eye on what is calculated!* (Appendix)

Appendix

Dose calculation issues ‚in practice‘

Dose calculation issues ‚in practice‘

Even when using allegedly ‘precise’ dose calculation algorithms:

DON’T TRUST YOUR DOSE TOO MUCH!

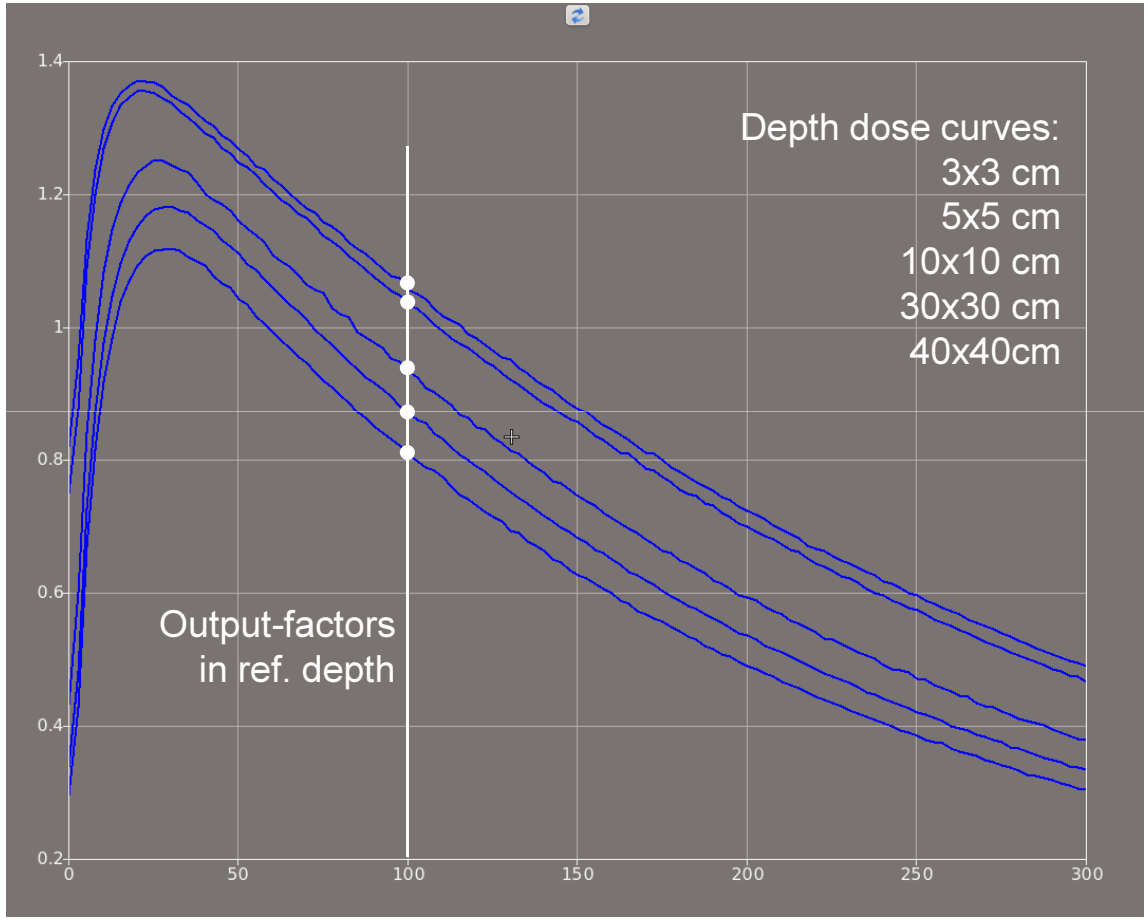
[i.e. always keep a critical eye on what is calculated]

Some examples for situations which need special care:

- small fields, irregular shaped fields (esp. off-axis), …
- potential systematic errors in measured base-data
- air in rectum
- dose calculation in lung in presence of breathing motion (‘4D’ dose)
- dose absorption in the patient table/couch
- dose calc in presence of CT artifacts: dental&hip implants
- HU errors in CT-calibration

Base-data for dose-calculations algorithms

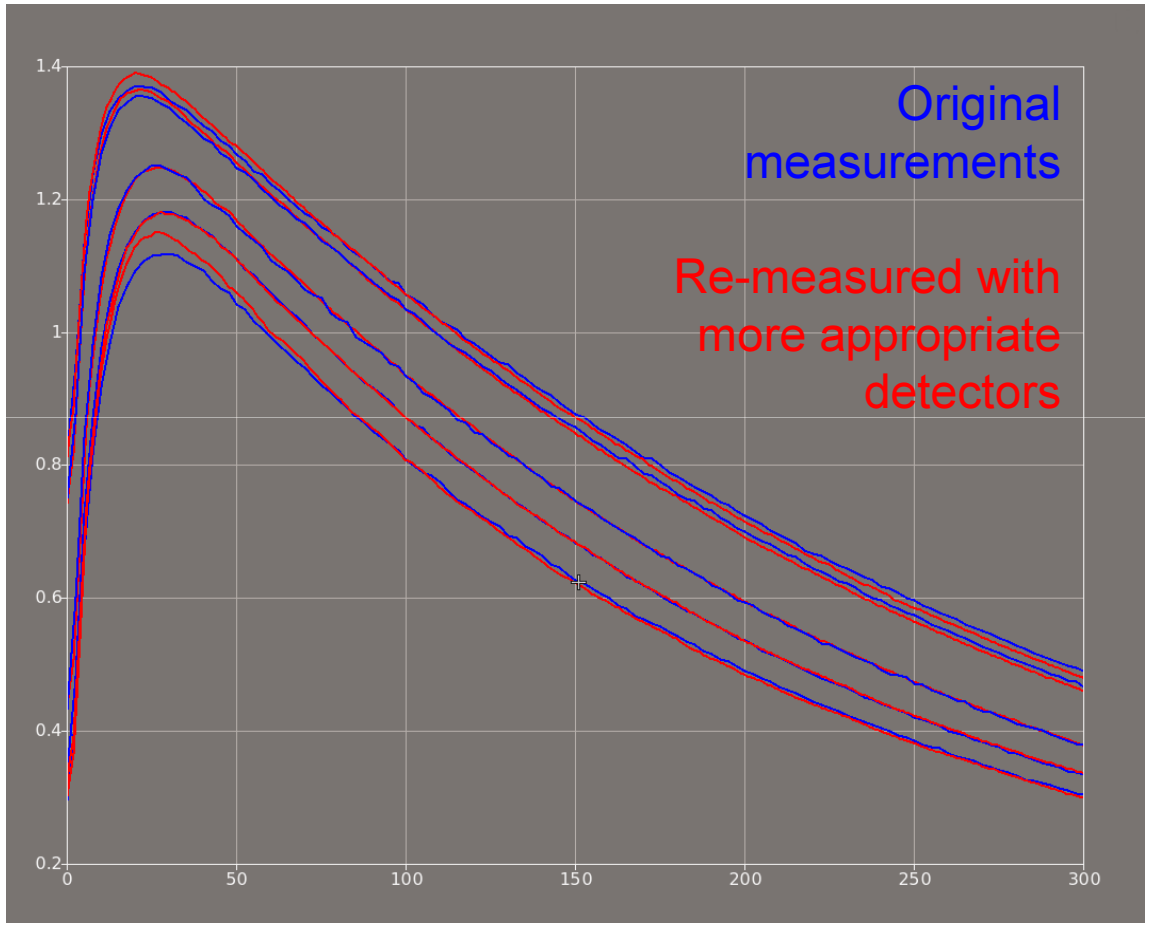
Key-input for all types of dose-calculation algorithms: DDCs, OFs…



ESTRO School

Base-data for dose-calculations algorithms

...a classical *garbage-in garbage-out* problem:



...non-trivial optimal choice of detector(s) (ionisation chamber, diode, diamond, ...):

- Energy-dependence
- Field size
- DDC vs. cross-profile
- ...

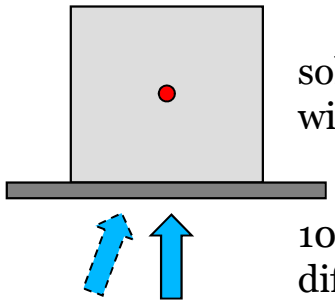
Monte Carlo vs. Pencil Beam Based Optimization of Stereotactic Lung IMRT

• related -- highly recommended -- reading: Static (3D-)dose-to-GTV representative for actual 4D-dose (based on Collapsed Cone dose calculation):

Guckenberger et al. 2007 (IJROBP 69(1)):
Four-Dimensional Treatment Planning For Stereotactic Body Radiotherapy

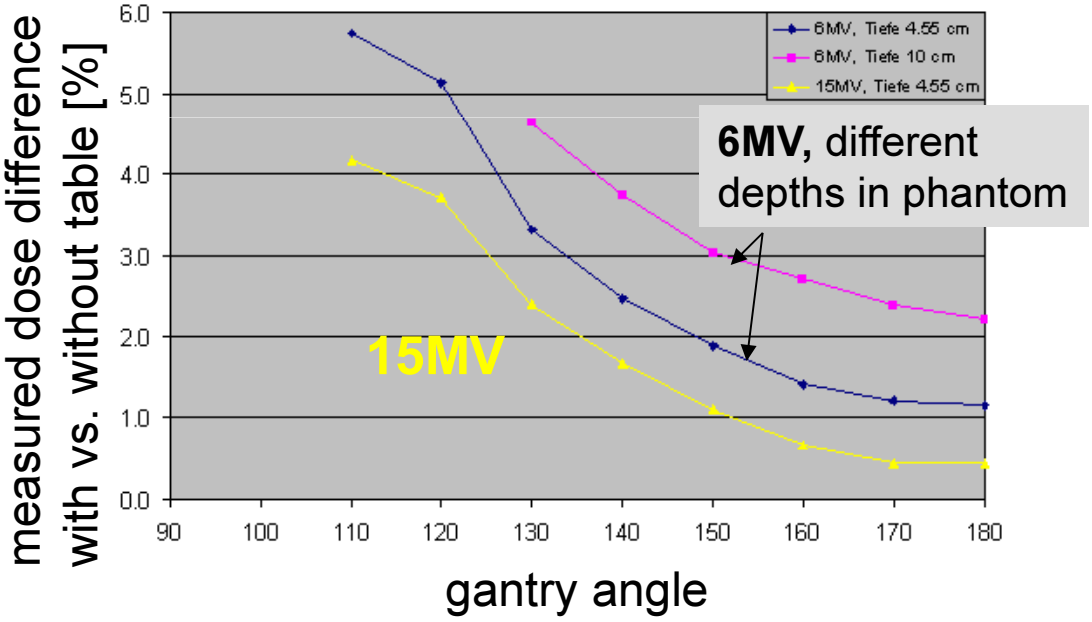
Dose calculation issues ‚in practice‘: Dosimetric effects of the treatment table/setup devices

Reiner et al., DEGRO 2013



solid water phantom
with ionisation chamber

10x10 cm field,
different beam angles

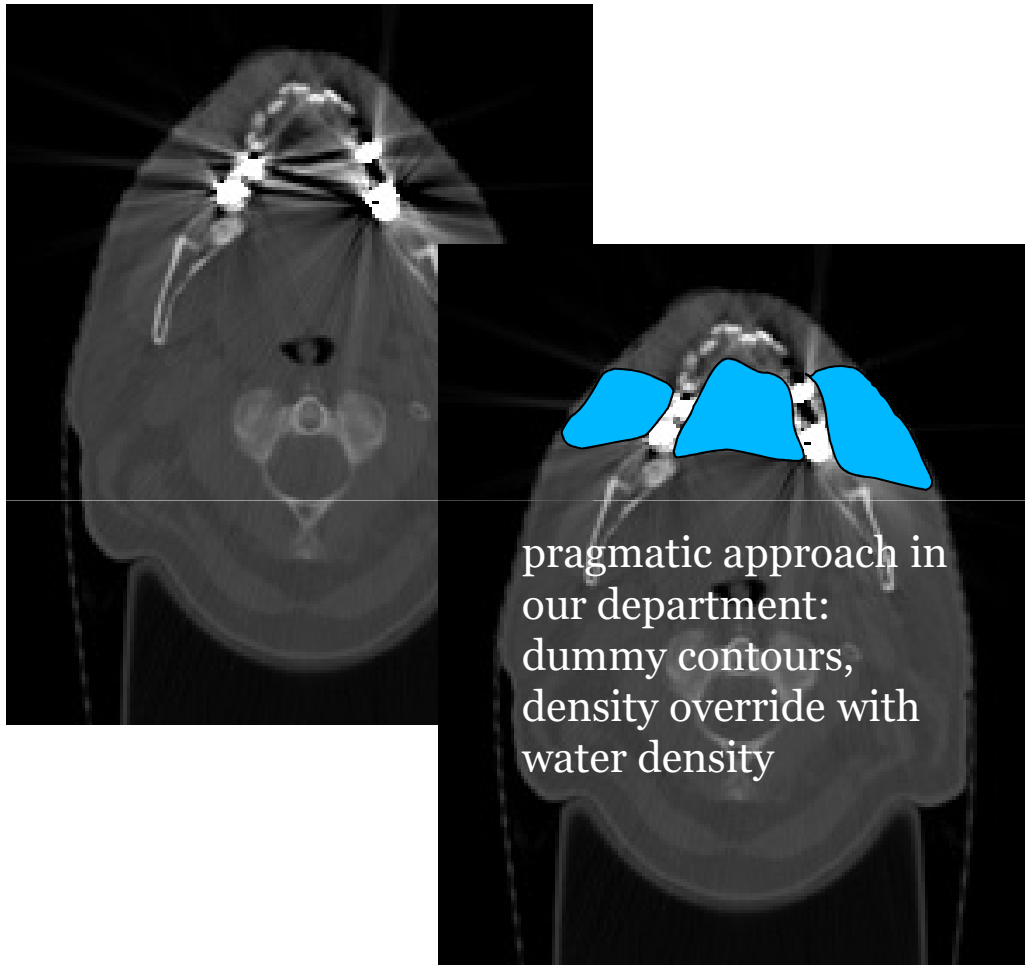


- depending on the vendor/model, treatment tables can have a water-equivalent thickness of ~1 cm w.r.t dose absorption
- depending on beam angle, dose absorption of several percent

→ should be explicitly considered for dose calculation, especially for rotational techniques (VMAT), where oblique angles through the table cannot be avoided

- Methods: Dose calculation with table/setup devices ‘as in CT’, or dummy contour with water density override. MIND: evaluate optimal method for your TPS/dose calculation algorithm!

Dose calculation issues ‚in practice‘: Dose calculation in presence of CT artifacts



- typical cases in RT: dental metal implants, hip implants
- significant dose calculation errors possible in soft tissue artifact regions due to wrong Hounsfield (CT-) values
- Hounsfield values of metal structures itself wrong as well AND usually dose calculation algorithms do not model radiation transport through metal correctly

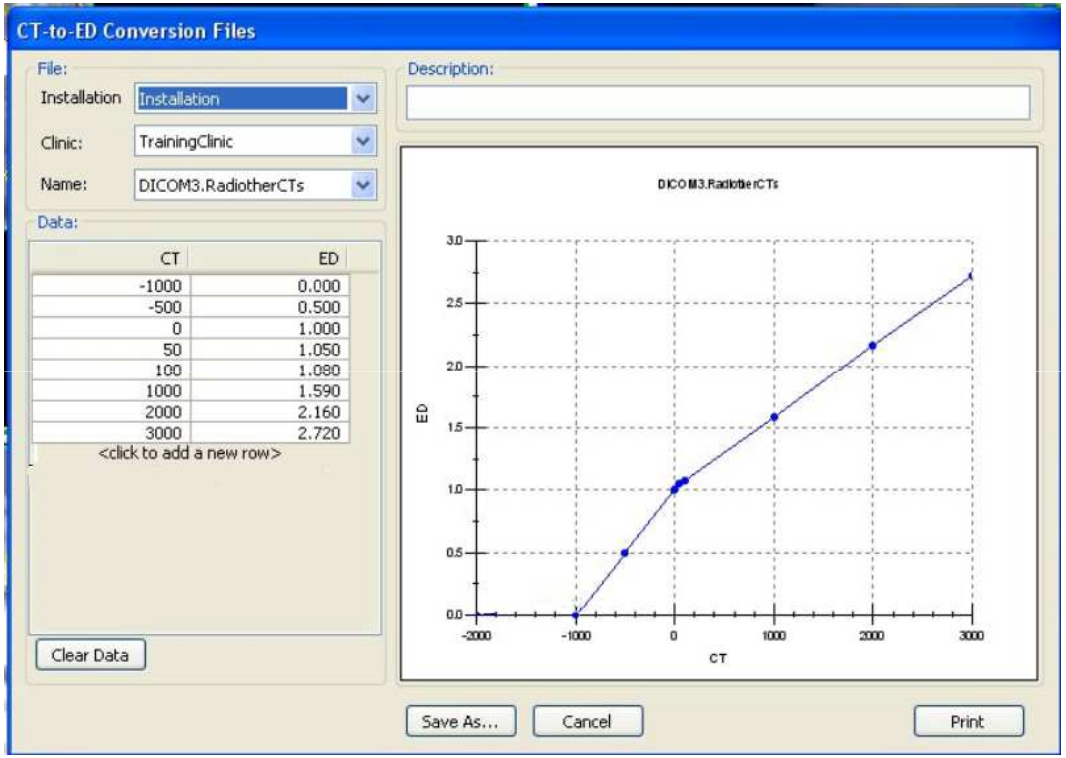
→ do not trust your dose ‘behind’ metal structures!

→ if possible (hip implants), try to avoid beam directions passing metal structures

further reading e.g. Kim et al. 2006 (Radiother. Oncol. 79(2))

Dose calculation issues ‚in practice‘: Hounsfield (CT-) value calibration

...a sometimes (!?) underrated issue!



- input for clinical dose calculation algorithms: local *electron or mass densities* in the patient
- these are typically determined based on the Hounsfield (CT-) values via calibration curves

→ MIND potential errors in calibration curve, or Hounsfield stability problems of CT hardware

Related issue: Dose calculation based on Cone Beam CTs!

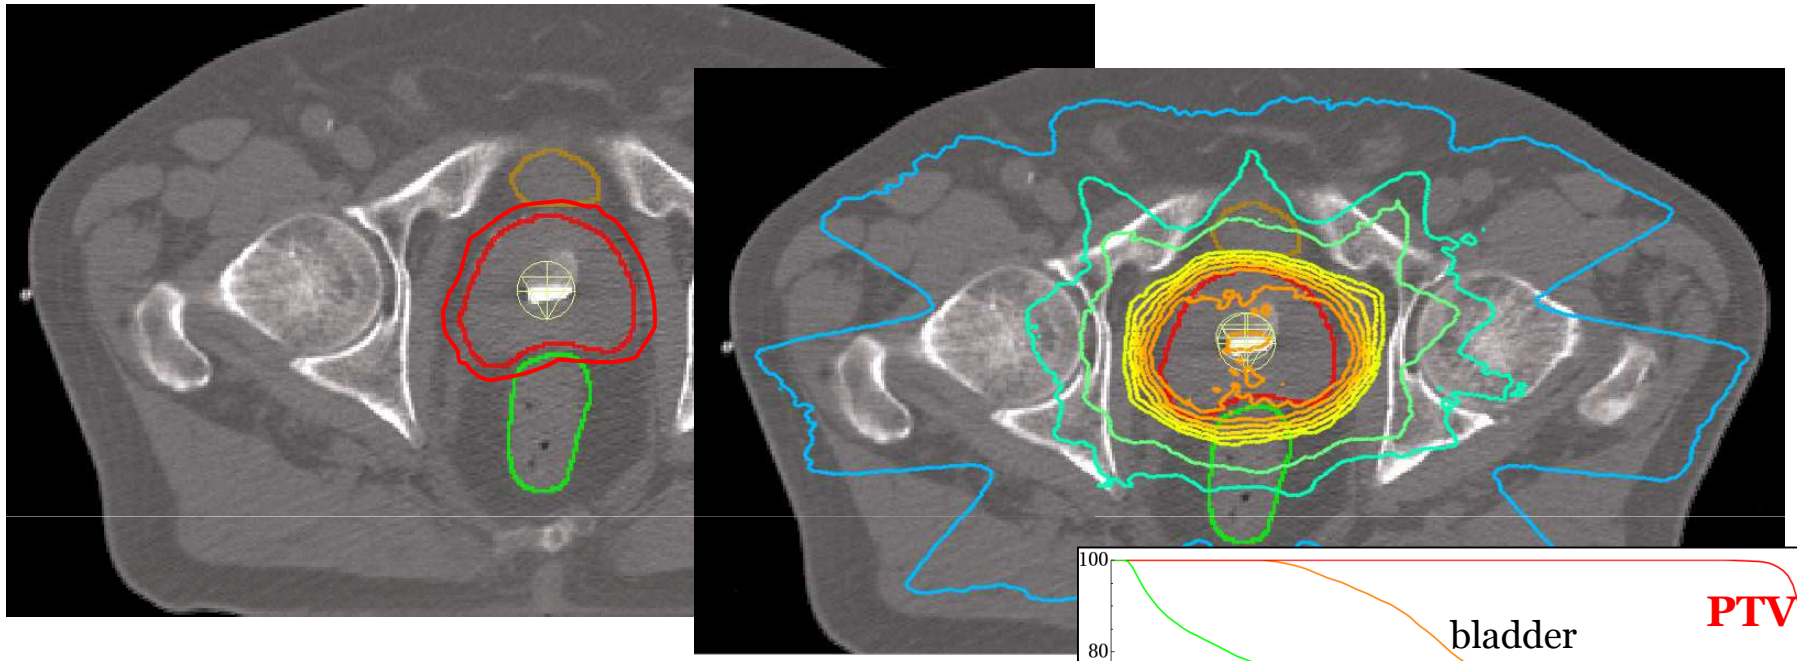
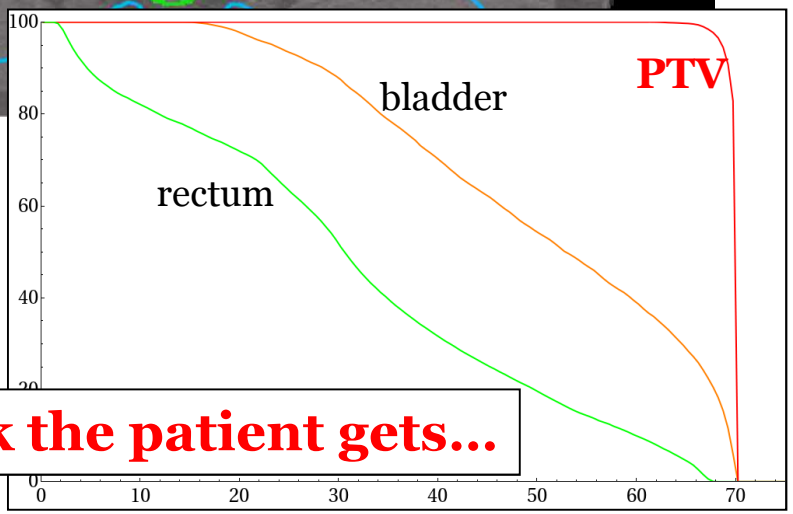
The common planning approach





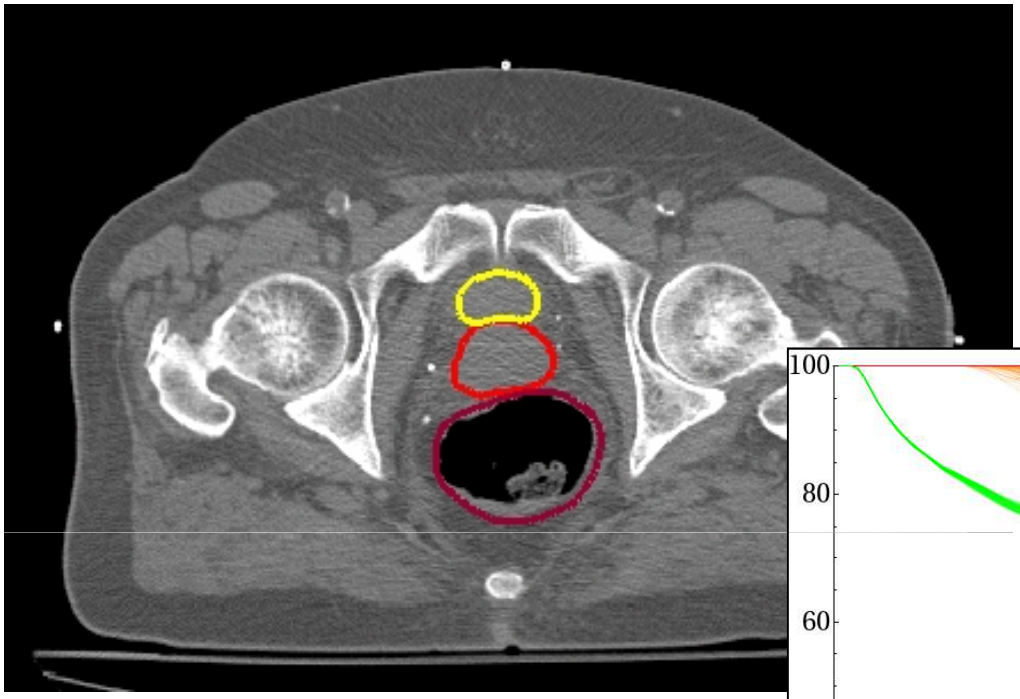
(1) planning CT

(2) add a margin

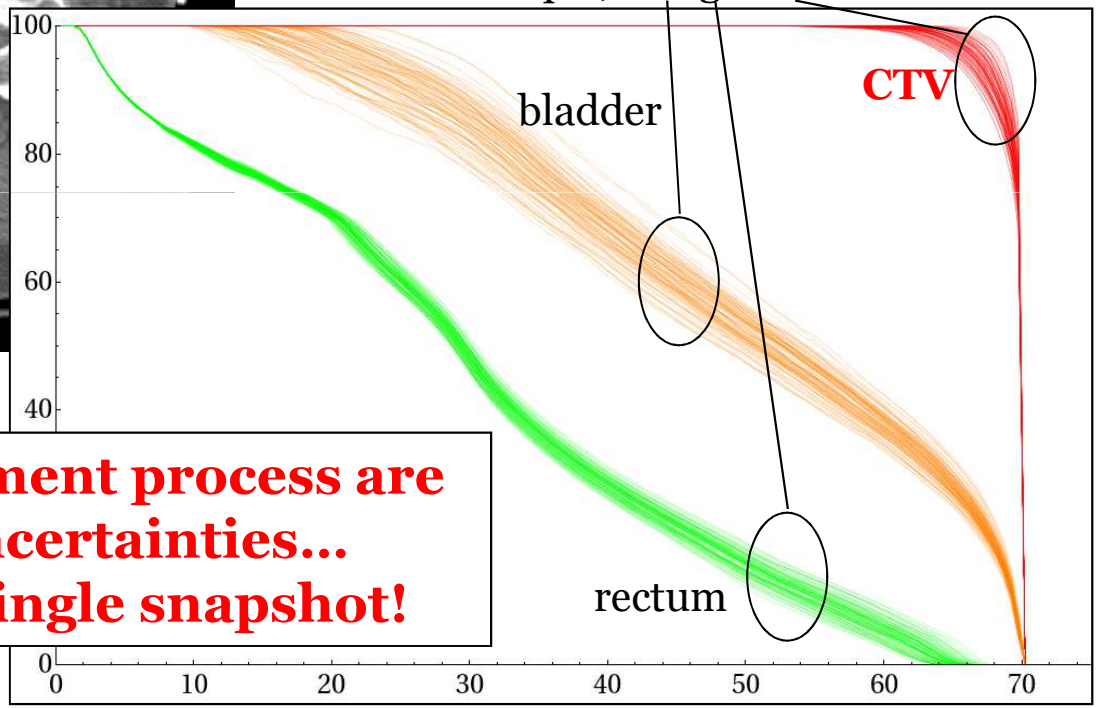
(3) make a plan!

This is the dose we may think the patient gets…

This is what actually happens!



Uncertainties depend on patient, treatment technique, margin size…



Reason: Patient and treatment process are not a *static*, all kinds of uncertainties…
The planning CT is just a single snapshot!

Classification of errors&uncertainties according to their *stochastic* nature

Systematic errors:

most deleterious!

Imaging, segmentation, planning, application, patient-setup, organ-motion&deformation, …

Random errors:

Application, patient-setu… motion&deformation, …

Most of this: patient-dependent!

Non-stationary ('trending') errors:

anatomic changes, functional changes, …

‘Adaptive RT’: How it all started

Phys. Med. Biol. **42** (1997) 123–132. Printed in the UK PII: S0031-9155(97)67292-9

Adaptive radiation therapy

Di Yan†, Frank Vicini, John Wong and Alvaro Martinez
Department of Radiation Oncology, William Beaumont Hospital, Royal Oak, MI 48073, USA

Received 11 August 1995, in final form 29 August 1996

Abstract. Adaptive radiation therapy is a closed-loop radiation treatment process where the treatment plan can be modified using a systematic feedback of measurements. Adaptive radiation therapy intends to improve radiation treatment by systematically monitoring treatment variations and incorporating them to re-optimize the treatment plan early on during the course of treatment. In this process, field margin and treatment dose can be routinely customized to each individual patient to achieve a safe dose escalation.

Adaptive RT:
The fundamental, yet abstract picture…

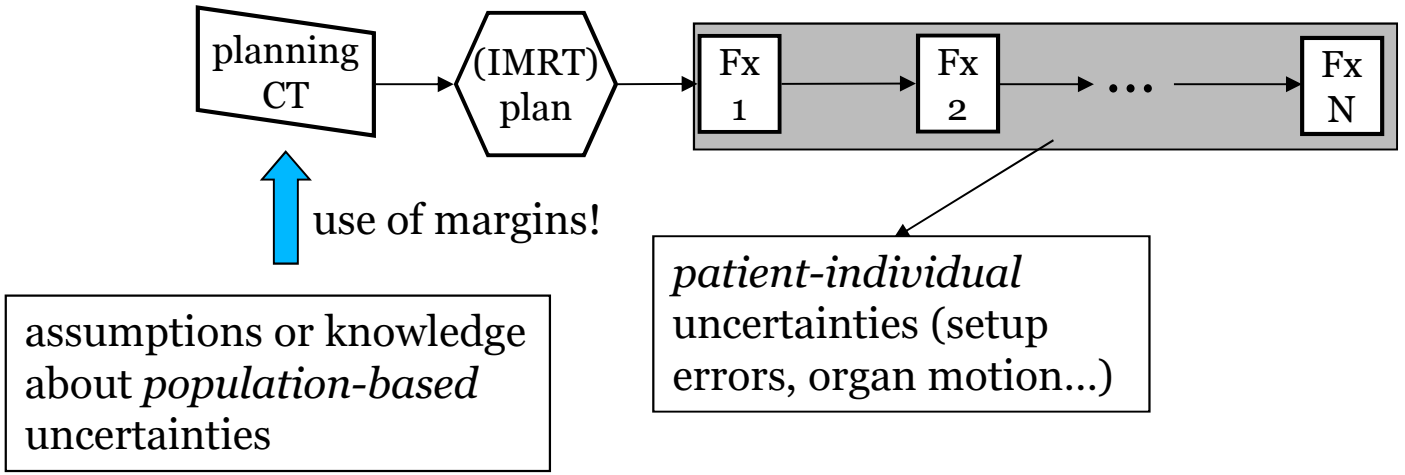
Adaptive radiotherapy:

- explicitly acknowledge that radiotherapy treatment as a whole is a **process**
- this process is performed in presence of all kinds of **uncertainties**
- the uncertainties can be strongly **patient-dependent**
- uncertainties are understood as – stationary or non-stationary – random processes

⇒ new understanding of an *radiotherapy treatment process* as
'feedback control strategy'

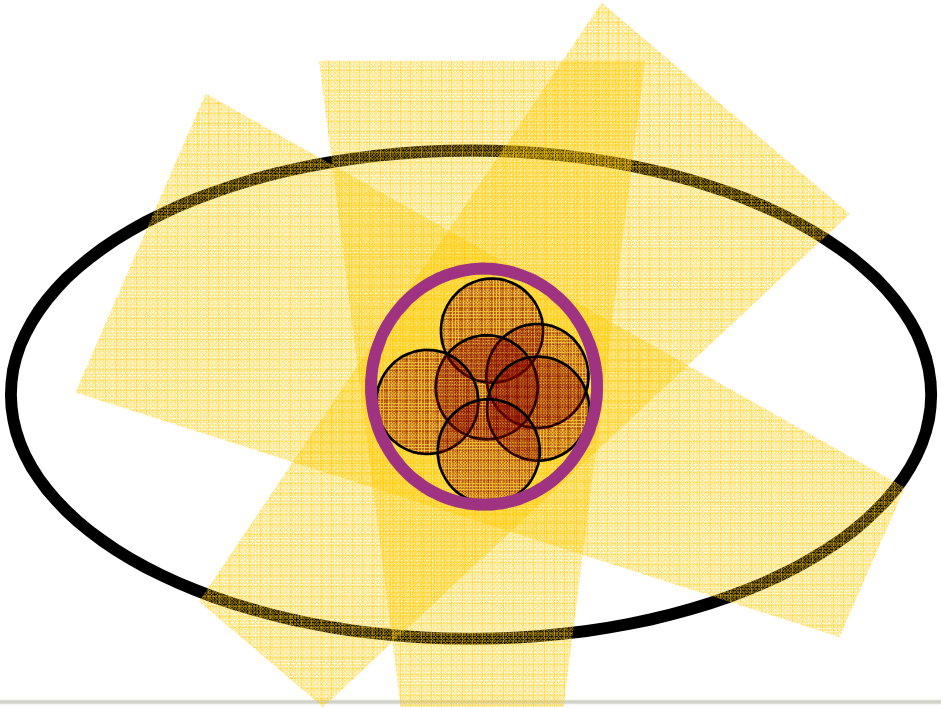
…versus the conventional approach:
single planning in the beginning without further actions/corrections later

The simplest, non-adaptive planning approach as *process*



Margins: The PTV-concept

Irradiate a volume, which is large enough, such that the CTV will (almost) always stay inside!



How large does the margin have to be?

A typical 'margin recipe'...:

systematic errors are more deleterious than random errors!

$$R = 2.5\,\Sigma + 0.7\,\sigma$$

Σ systematic setup errors

σ random setup errors

M. van Herk et al. 2000: The probability of correct target dosage: dose-population histograms for deriving treatment margins in radiotherapy. IJROBP 47(4)

Which assumptions are behind this formula?

$$R = 2.5\,\Sigma + 0.7\,\sigma$$

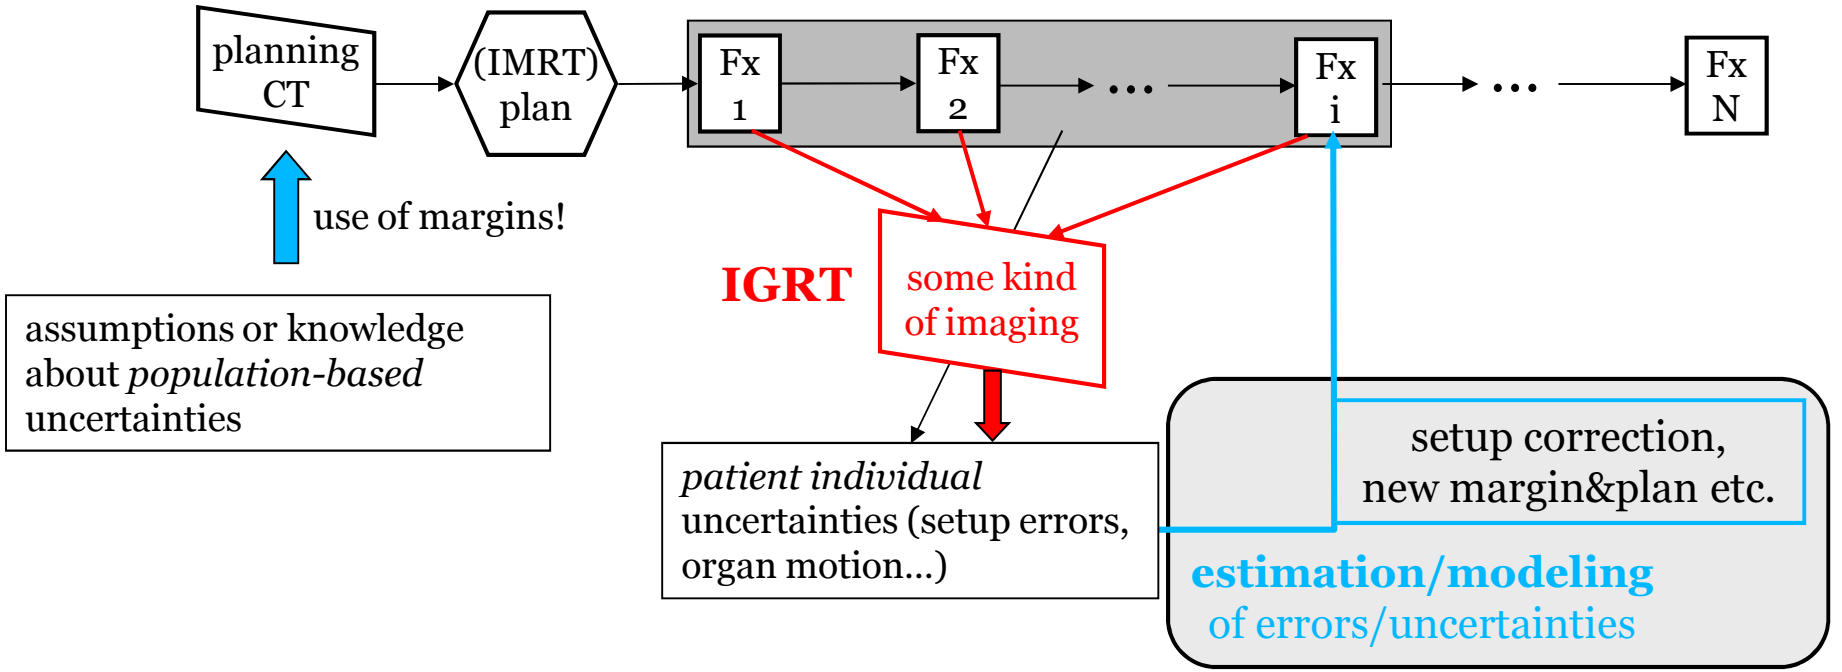
Σ systematic setup errors

σ random setup errors

- round CTV moves around within idealized round dose distribution with idealized penumbra, which drops to zero to all sides
- **population-based uncertainties**, effect quantized as TCP of a population

For the individual patient, the margin will be either too large, or too small…

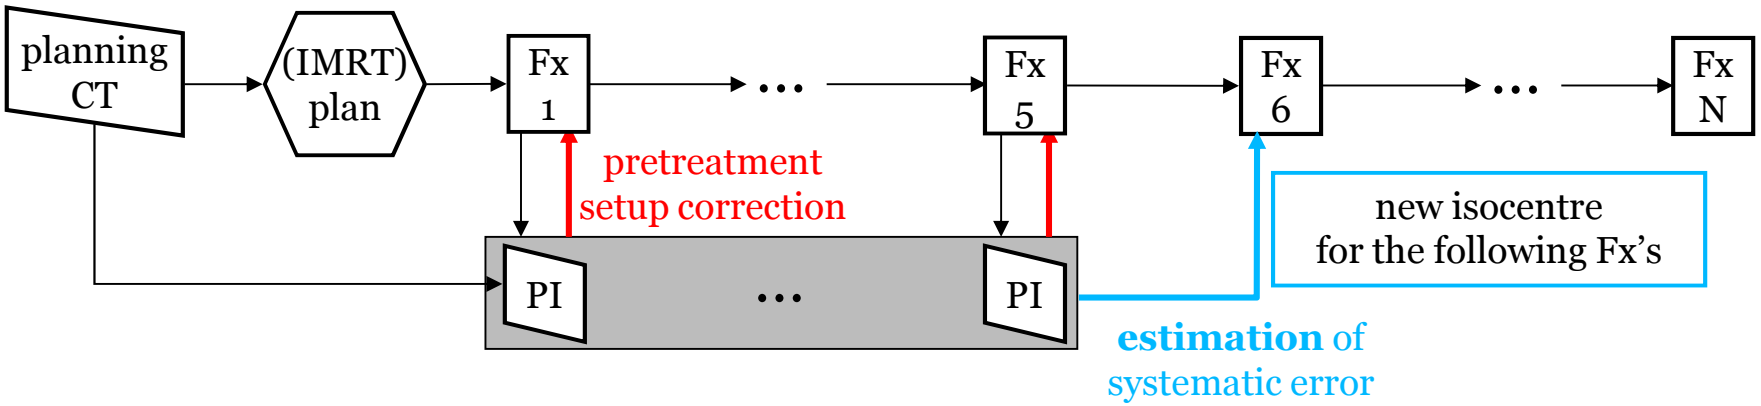
This is where adaptive RT comes in!



"Feedback-loop"!
This makes it 'adaptive RT'!

Adapting the isocentre: Setup correction protocols

An early adaptive RT workflow:
Patient-individual reduction of systematic and random setup errors via portal imaging!

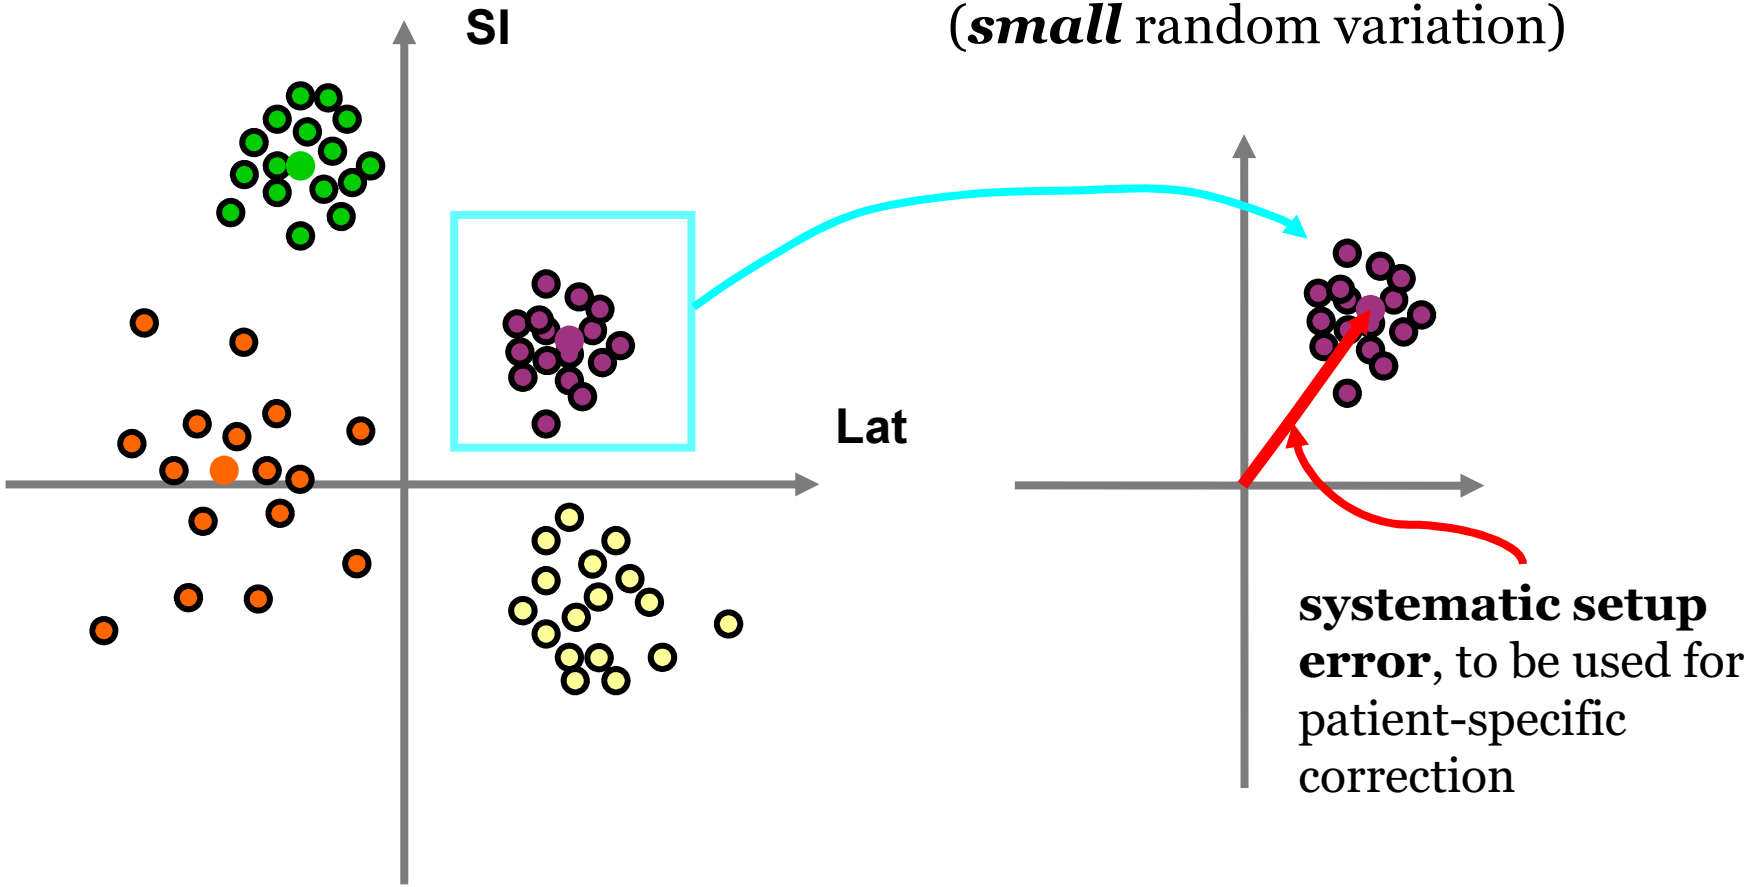


courtesy D. Lockman/D. Yan (WBH)

Estimation of the patient-individual setup error

Population distribution of setup errors

Patient-specific distribution (***small*** random variation)

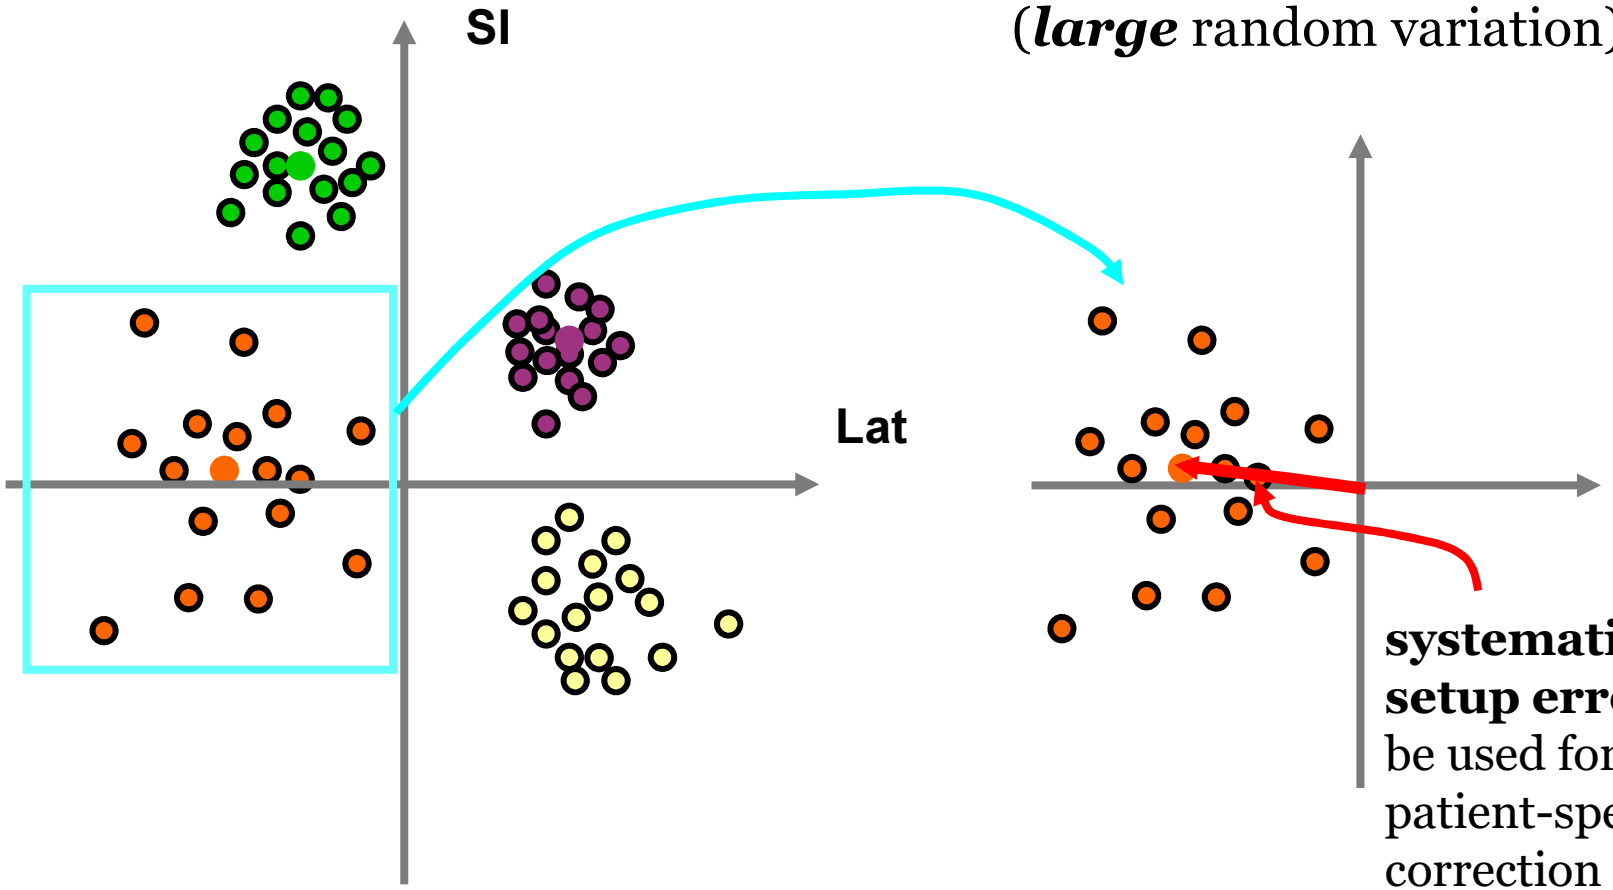


courtesy D. Lockman/D. Yan (WBH)

Estimation of the patient-individual setup error

Population distribution of setup errors

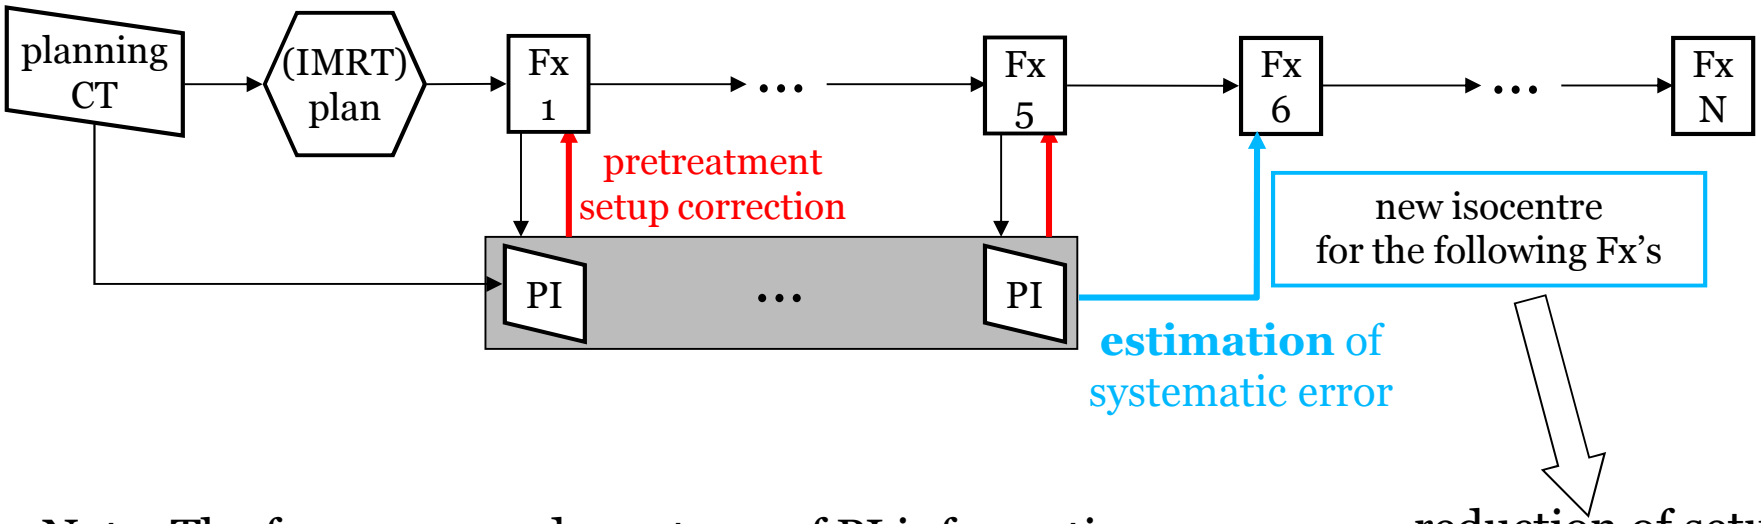
Patient-specific distribution (***large*** random variation)



systematic setup error, to be used for patient-specific correction

Adapting the isocentre: Setup correction protocols

An early adaptive RT workflow:
Patient-individual reduction of systematic and random setup errors via portal imaging!



Note: The frequency and exact use of PI information depends on the **setup protocol** used!

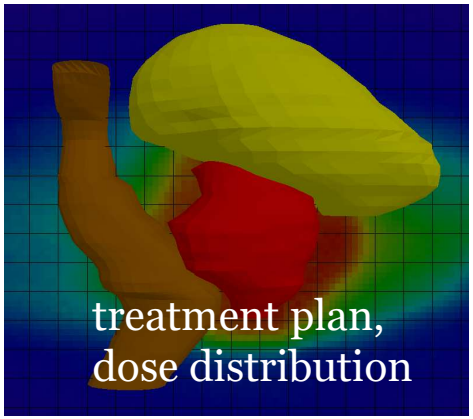
Some proposed setup protocols…

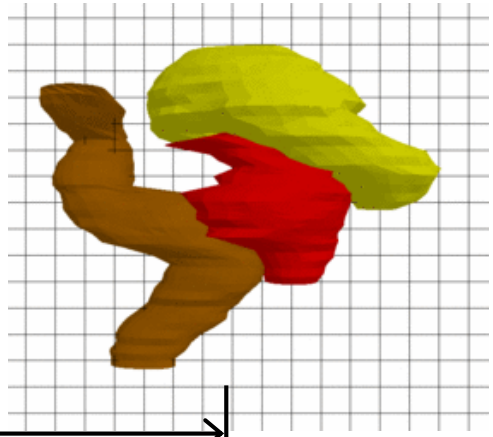
Offline setup protocols (e.g. DRR-PI match):

no action level:	correct setup by the average setup error after n days
shrinking action level:	correct setup by the average setup error after n days, if above a threshold S(n)
Newcastle:	correct setup by the average setup error after n days, if the assumption of 'zero' error is not in confidence interval of estimated error distribution

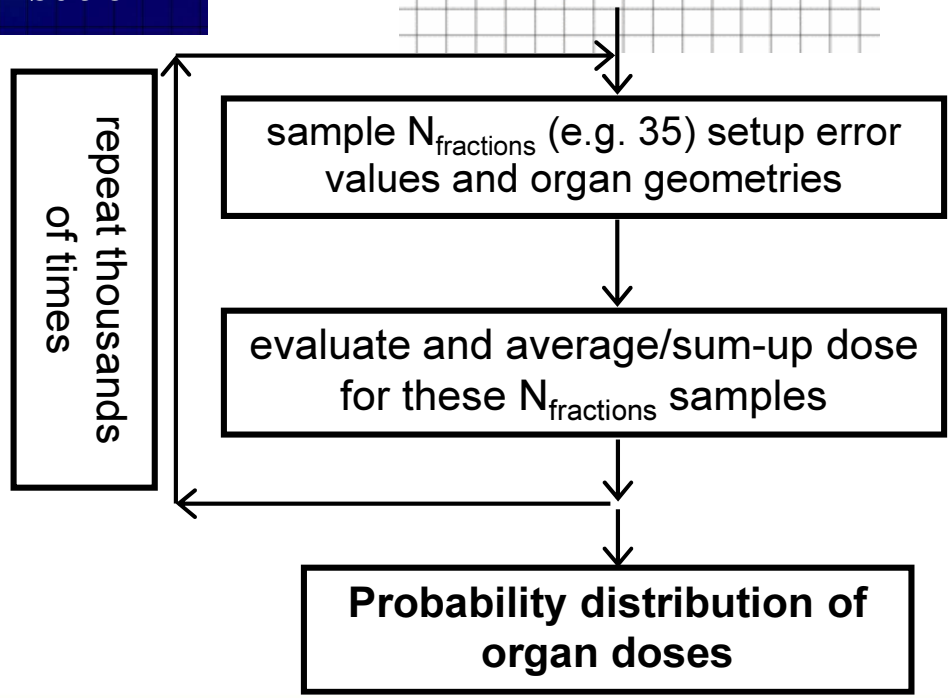
…

How to evaluate and find the best strategy?: Treatment course simulation approaches





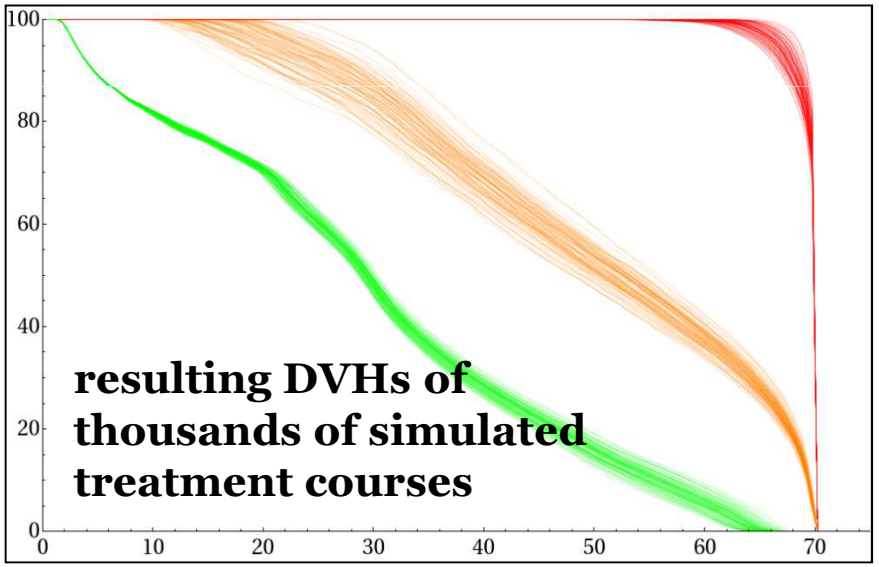
multiple organ contours and setup errors values
- either measured in a patient study
- and/or simulated based on *motion model*

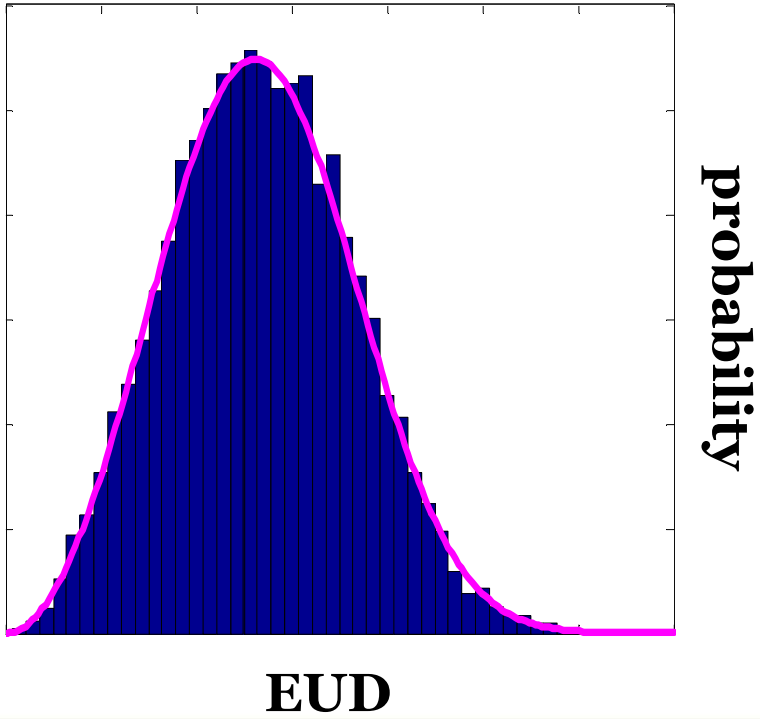


How to evaluate and find the best strategy?: Treatment course simulation approaches

Every treatment course realizes a dose distribution with a certain probability.

Purpose of treatment course simulations: Estimate the probability distribution for a given plan and given uncertainties!





Treatment course simulations for use of different setup protocols

C. Baum et al. 2005: Dosimetric consequences of the application of off-line setup error correction protocols and a hull-volume definition strategy for intensity modulated radiotherapy of prostate cancer.
Rad. Onc. 76(1)

→ Almost all setup correction protocols are similarly efficient in ensuring CTV coverage in presence of setup errors!

Important conclusion for clinical practice:
No need to do especially sophisticated and complicated corrections, but instead implement a workflow with a few simple corrections in a thorough way!

no correction

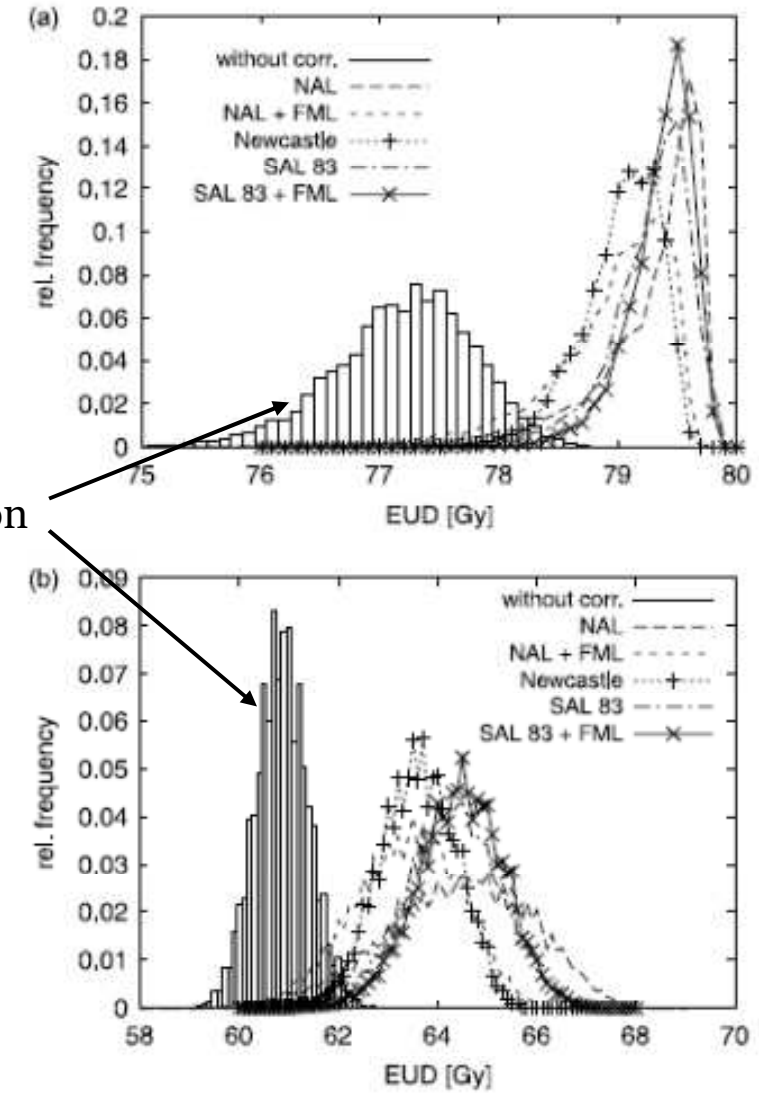


Fig. 4. Distribution of EUD of (a) CTV_hull and (b) Rectum_hull for artificial patient A6 of treatment simulations with and without setup correction.

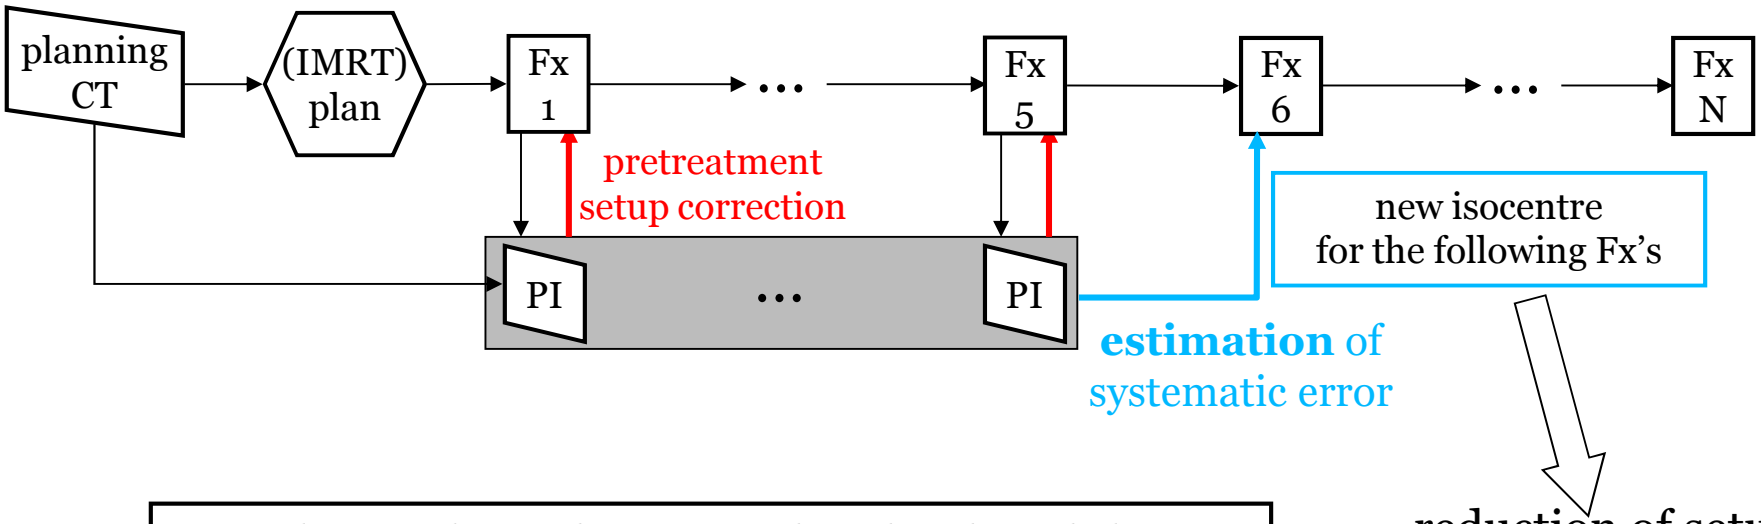
The ‘Toolbox’ of Adaptive RT

- IGRT – imaging!
- prediction methods/models
- evaluation approaches: prospective studies on real (and realistic!) patient data of a study cohort, treatment course simulations, motion models

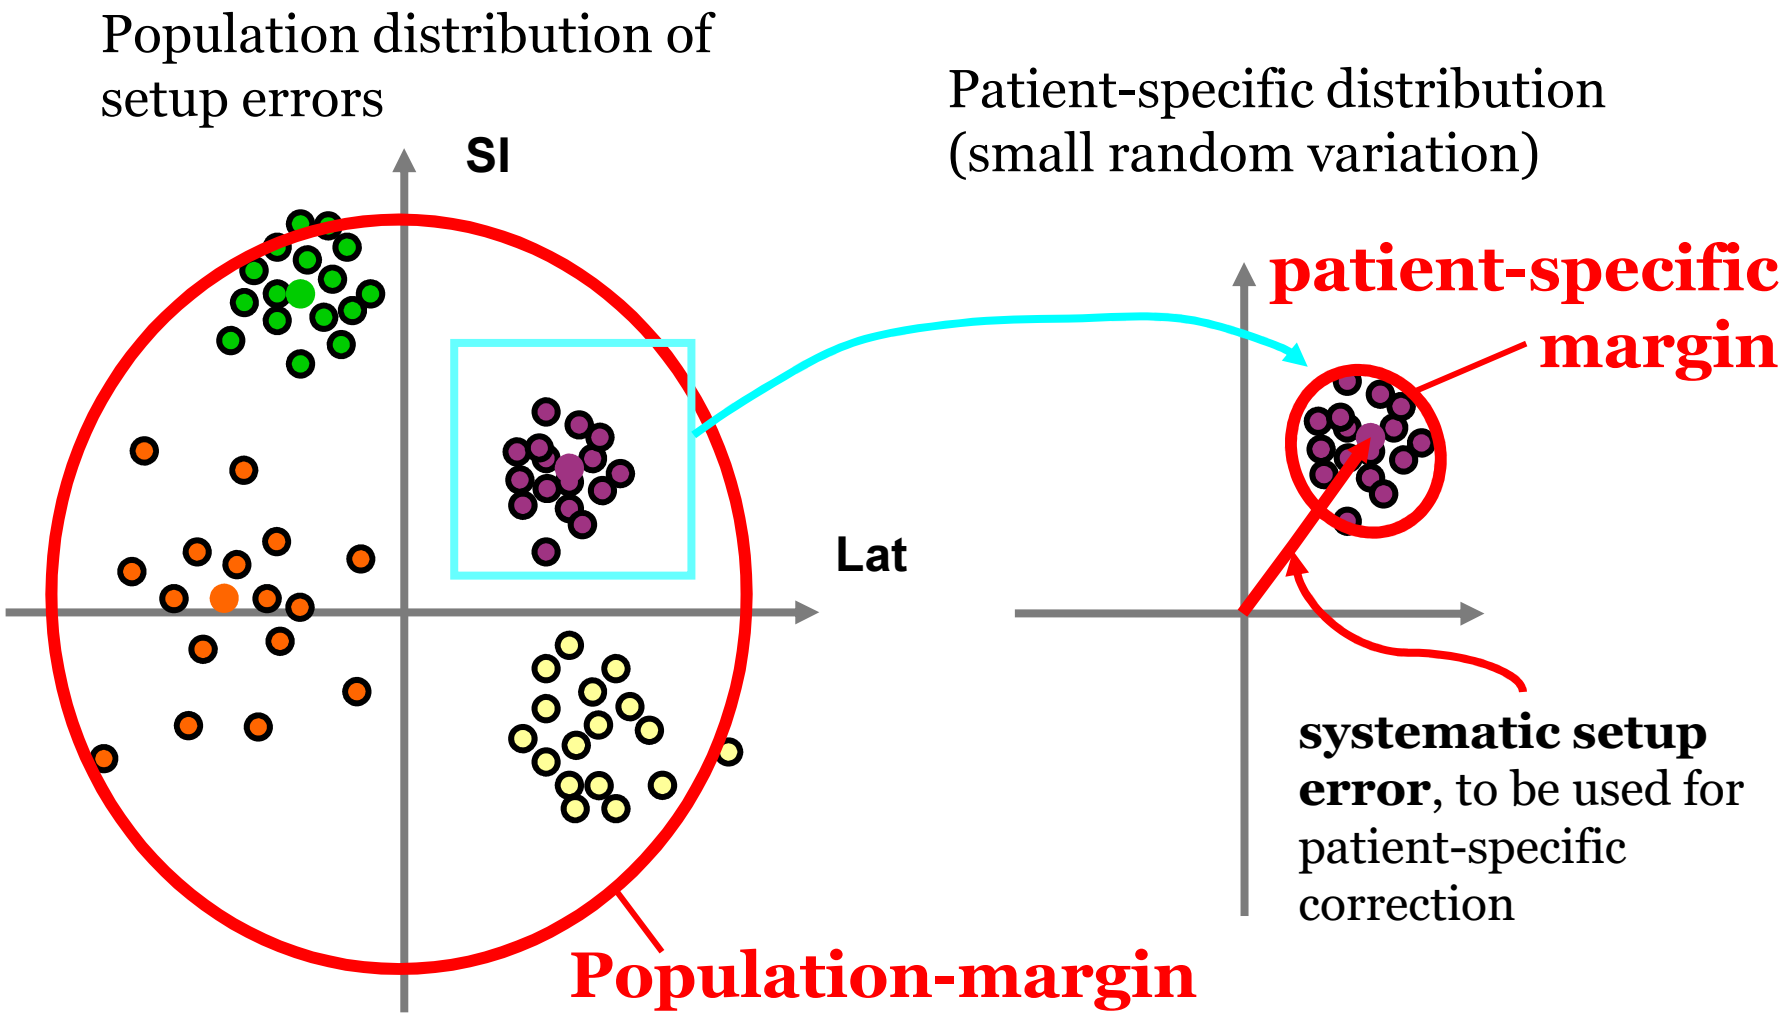
One step further: Margin adaption



Now that we have determined and reduced the patient-individual systematic error:
Why not also reduce/adapt the margin???

Margin adaptation 'visually'

courtesy D. Lockman/D. Yan (WBH)

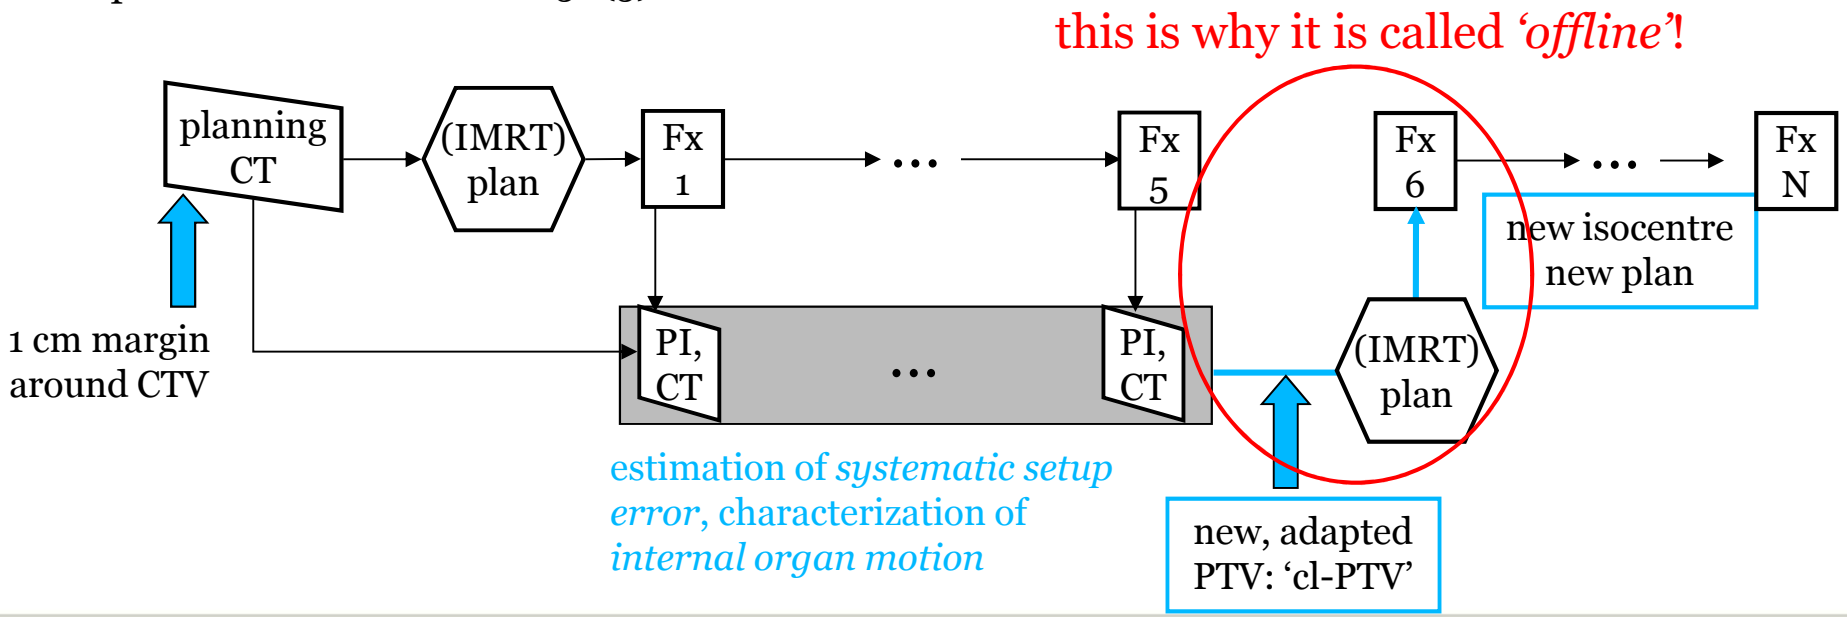


The Beaumont offline adaptive RT approach

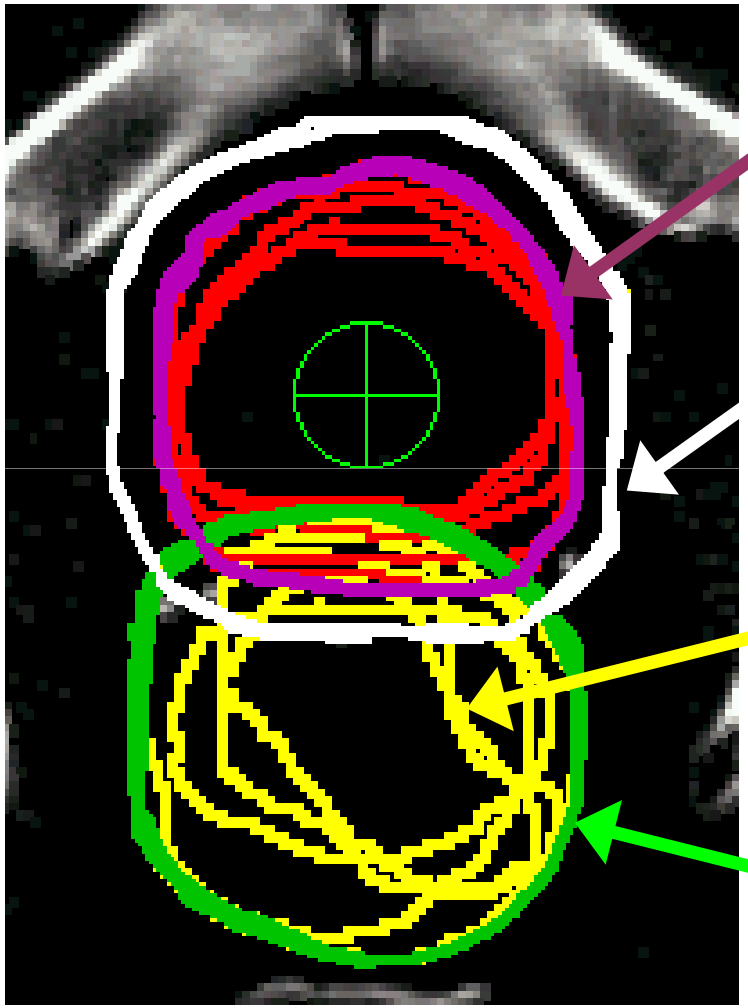
First systematic clinical adaptive RT implementation
at Beaumont Hospital, Royal Oak, Michigan: since 1997!

Yan et al. 2000: An off-line strategy for constructing a patient-specific planning target volume in adaptive treatment process for prostate cancer. IJROBP 48(1)

Martinez et al. 2001: Improvement in dose escalation using the process of adaptive radiotherapy combined with three- dimensional conformal or intensity-modulated beams for prostate cancer. IJROBP 50(5)



The Beaumont offline adaptive RT approach: Eliminate systematic errors of the organ geometry!



CTV_hull = hull of 3-5 prostate contours (planning CTV and first days of treatment)

PTV = CTV_hull + patient-individual margin, adapted according to setup errors measured during first 5 fractions (~5mm)

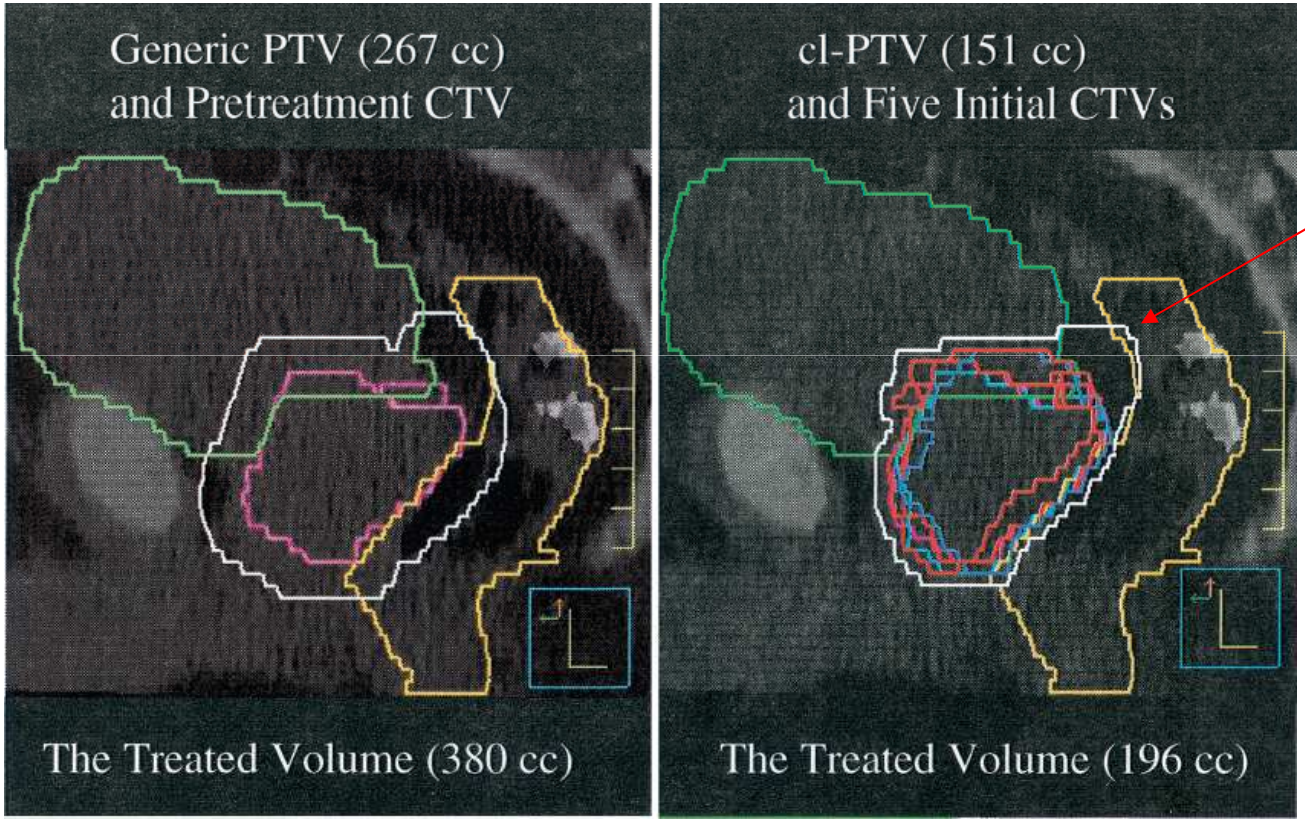
corresponding rectum contours of the first 3-5 treatment days;
Beaumont approach: dose constraint to rectal-wall structure as in planning CT

alternative approach:
constraints to Rectum_hull = hull of 3-5 rectum contours, no PRV margin

The Beaumont offline adaptive RT approach

Martinez et al. 2001 (IJROBP 50(5))

average PTV volume reduction (150 patients): 24%



BUT:
may also be larger
- locally
- or for 'large mover' patients!

=> adaptation to the patient-individual interfractional 'motion pattern'

What are the clinical benefits?

NKI-AVL dose escalation study, **no margin adaptation** (1cm, 0-5mm for boost):

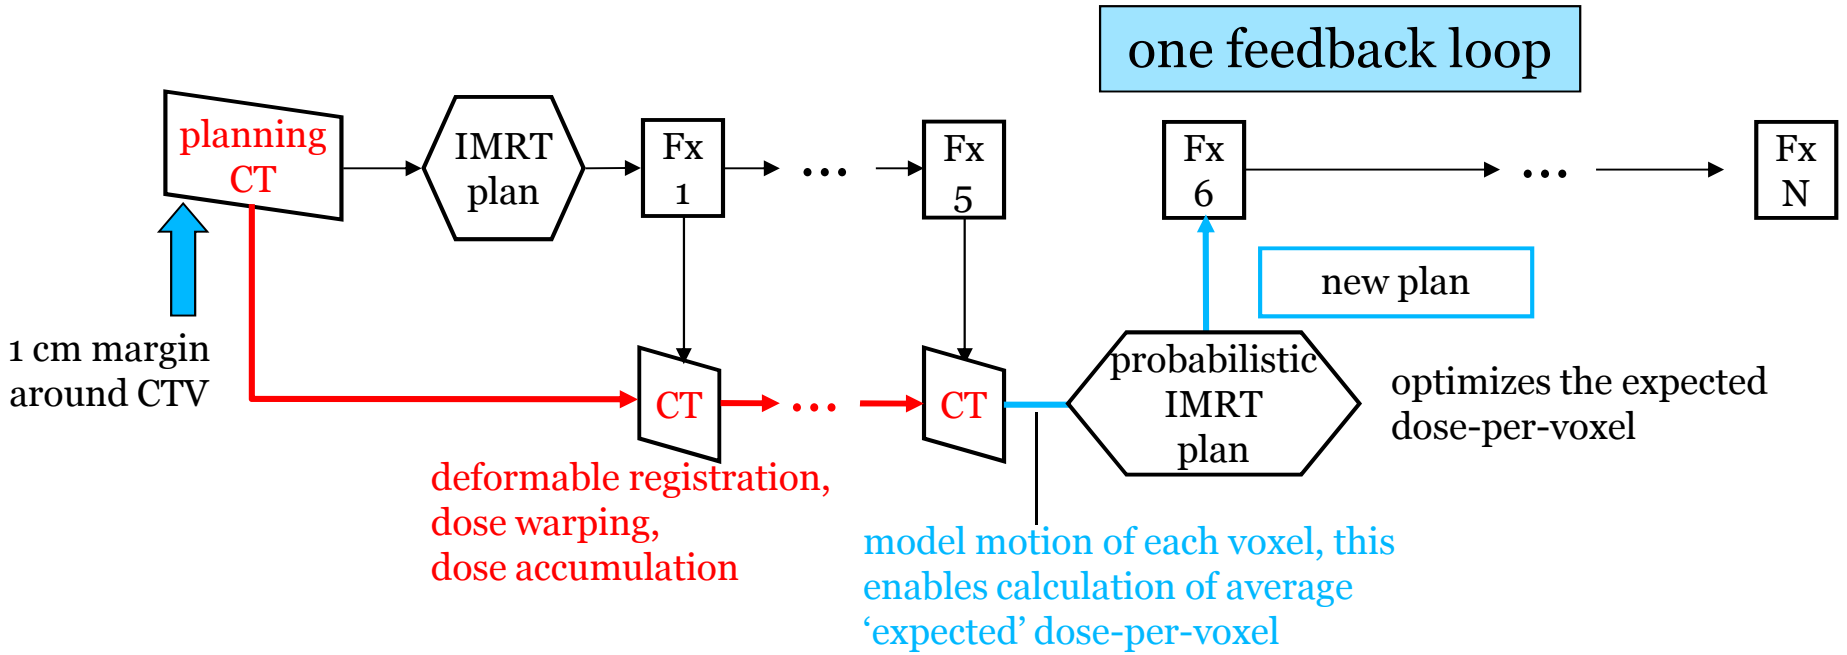
W. Heemsbergen et al. 2007: Increased risk of Biochemical and clinical failure for prostate patients with a *large rectum at radiotherapy planning*: results from the dutch trial of 68 Gy versus 78 Gy.
IJROBP 67(5)

...versus clinical long-term follow-up results of Beaumont offline ART:

S. S. Park et al. 2012: Adaptive Image-guided Radiotherapy (IGRT) Eliminates the Risk of Biochemical Failure Caused by the *Bias of Rectal Distension* in Prostate Cancer Treatment Planning: Clinical Evidence.
IJROBP 83(3)

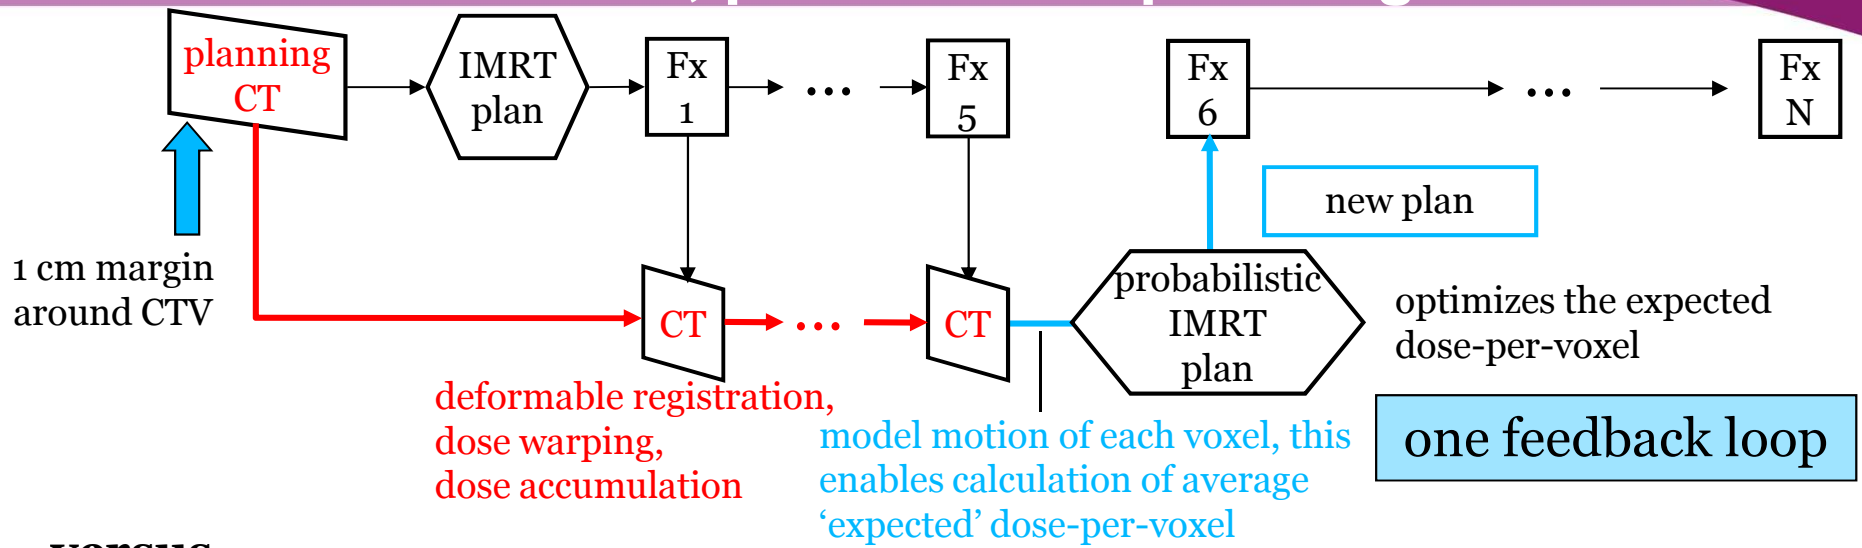
The next step: more than one re-optimization, dose accumulation, probabilistic planning

M. Birkner et al. 2003: Adapting inverse planning to patient and organ geometrical variation: algorithm and implementation.
Med. Phys. 30(10)

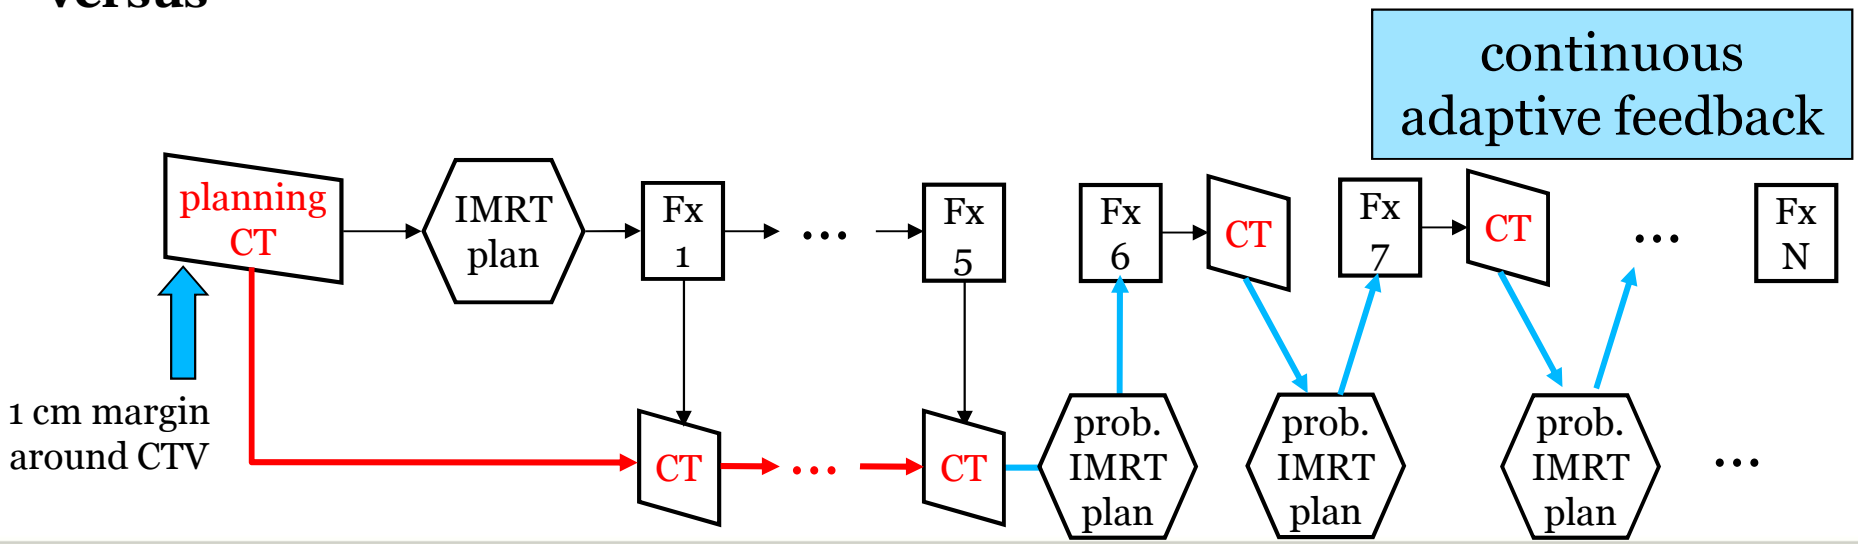


The next step: more than one re-optimization, dose accumulation, probabilistic planning

Birkner et al. 2003 (Med. Phys. 30(10))



versus



The next step: more than one re-optimization, dose accumulation, probabilistic planning

Birkner et al. 2003
(Med. Phys. 30(10))

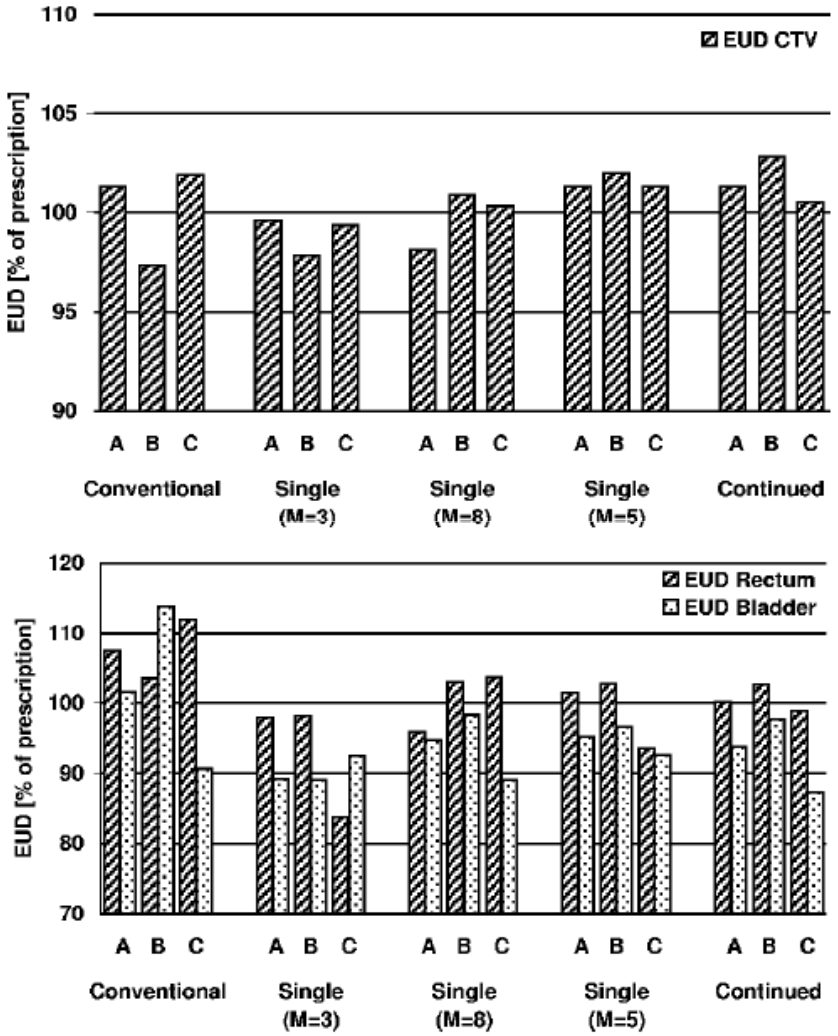


FIG. 4. Comparison of treatment prescription and treatment outcome for treatment strategies: Conventional IMRT planning (PTV=CTV+1 cm) without feedback, single adaptive feedback re-optimization after 3, 8, and 5 fractions, and continued adaptive feedback from fraction 6 to final fraction. All three patients (A, B, C) show a similar trend of convergence of CTV coverage with increasing number of feedbacks (top). For the critical structures (bottom), treatment outcome comes closer to the prescribed 100% EUD level with any adaptive feedback strategy, while at the same time inter-patient variability is reduced. Differences between single re-optimiztion after $M=5$ fraction and continued feedback strategies are marginal.

→ one plan adaptation after 5 fractions almost 'does the full job',
no significant additional benefits from more than one re-planning

The 'Toolbox' of Adaptive RT

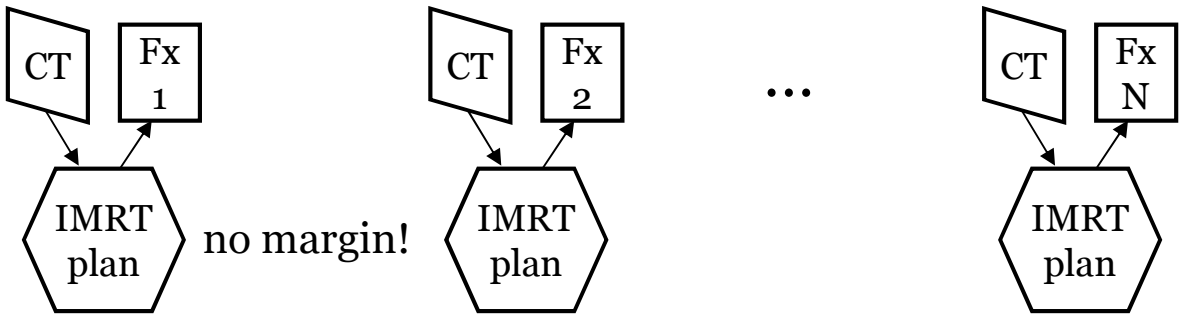
- IGRT – imaging!
- prediction methods/models
- evaluation approaches: prospective studies on real (and realistic!) patient data of a study cohort, treatment course simulations, motion models
- deformable registration, dose warping, dose accumulation
- probabilistic and robust planning approaches

This was all offline ART…
Now: Online Adaptive Re-Planning

M. Ghilezan et al. (2004): Online image-guided intensity-modulated radiotherapy for prostate cancer: How much improvement can we expect? A theoretical assessment of clinical benefits and potential dose escalation by improving precision and accuracy of radiation therapy. IJRPBP 60(5)

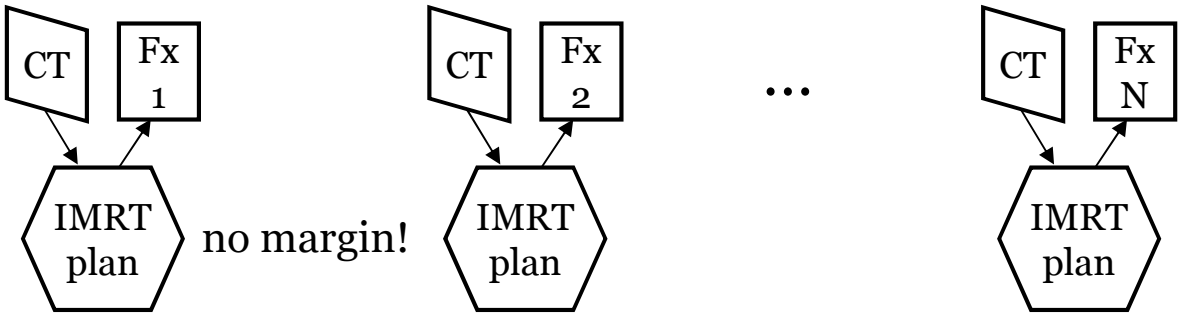
Idealized assumptions to investigate a 'gold-standard' benchmark online ART scheme:

- daily pre-treatment imaging and online IMRT replanning
- no intrafractional or other uncertainties => no PTV-margin necessary
- evaluation using deformable dose accumulation of multiple CTs of 18 patients



This was all offline ART…
Now: Online Adaptive Re-Planning

Ghilezan et al. 2004
(IJROBP 60(5))



Results (in short):

- average dose escalation by 13% possible, but with large interpatient variation (5-41%).
- 27% of the patient would have only minimal benefit (<5% dose escalation), 32% would have significant benefit (>15% dose esc.)

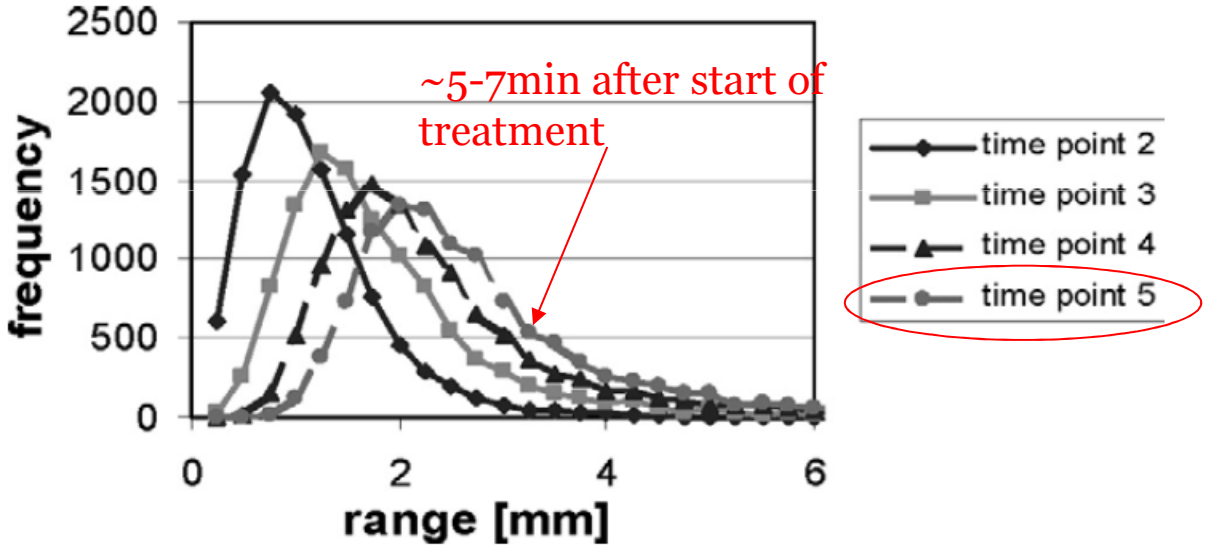
Note!:

- comparison relative to non adaptive standard IMRT (1 cm margin), not to offline adaptive IMRT.
- no margin, intrafraction motion and all other uncertainties neglected

Zero Margins in daily online ART/IGRT?
Intrafraction motion: prostate

A. N. T. J. Kotte et al. 2007: Intrafraction motion of the prostate during external-beam radiation therapy: Analysis of 427 patients with implanted fiducial markers. IJROBP 69(2)

Motion of implanted fiducial markers as seen with PIs:
11426 fractions of 427 pts.



- intrafraction motion range >2mm in 66% of all fractions, >3mm in 28%
- conclusion of the authors: lower limit of 2 mm for margins

Zero Margins in daily online ART/IGRT?
Intrafraction motion: prostate

D. Skarsgard et al. 2010: Planning target volume margins for prostate radiotherapy using daily electronic portal imaging and implanted fiducial markers. Radiat Oncol. 5:52

RESULTS:
Without image guidance, margins of 0.57 cm, 0.79 cm and 0.77 cm, along the left-right, superior-inferior and anterior-posterior axes respectively, are required to give 95% probability of complete CTV coverage each day. With the above image guidance strategy, these margins can be reduced to 0.36 cm, 0.37 cm and 0.37 cm respectively. Correction of all isocenter placement errors, regardless of size, would permit minimal additional reduction in margins.

Zero Margins in daily online ART/IGRT?
Intrafraction motion: prostate

...this was all portal-image based visualization of implanted fiducial markers.
*Improvements by daily **Cone-Beam-CT**-based setup?*

J. Adamson et al. 2011: Dosimetric effect of intrafraction motion and residual setup error for hypofractionated prostate intensity-modulated radiotherapy with online cone beam computed tomography image guidance. IJROBP 80(2)

CONCLUSIONS:
For protocols with CBCT guidance, RL, AP, and SI margins of 2, 4, and 3 mm are sufficient to account for translational errors; however, the large variation in patient-specific margins suggests that adaptive management may be beneficial.

Note: This is not resulting from geometric considerations (CTV appropriately covered by PTV), but from dosimetric considerations: coverage by 95% isodose line.
→ Influence of planning strategy and TPS!

Further limitations of daily rigid isocentre adaptations: Deformable uncertainties

again: prostate…

G. J. van der Wielen et al. 2008:Deformation of prostate and seminal vesicles relative to intraprostatic fiducial markers. IJROBP 72(5)

CONCLUSION:
Although prostate deformation with respect to implanted fiducial markers was small, the corresponding deformation of the seminal vesicles was considerable. Adding marker-based rotational corrections to on-line translation corrections provided a limited reduction in the estimated planning margins.

Further limitations of daily rigid isocentre adaptations: Deformable uncertainties

Head-and-neck…

S. van Beek et al. 2010: First clinical experience with a multiple region of interest registration and correction method in radiotherapy of head-and-neck cancer patients. Radiother. Oncol. 94(2)

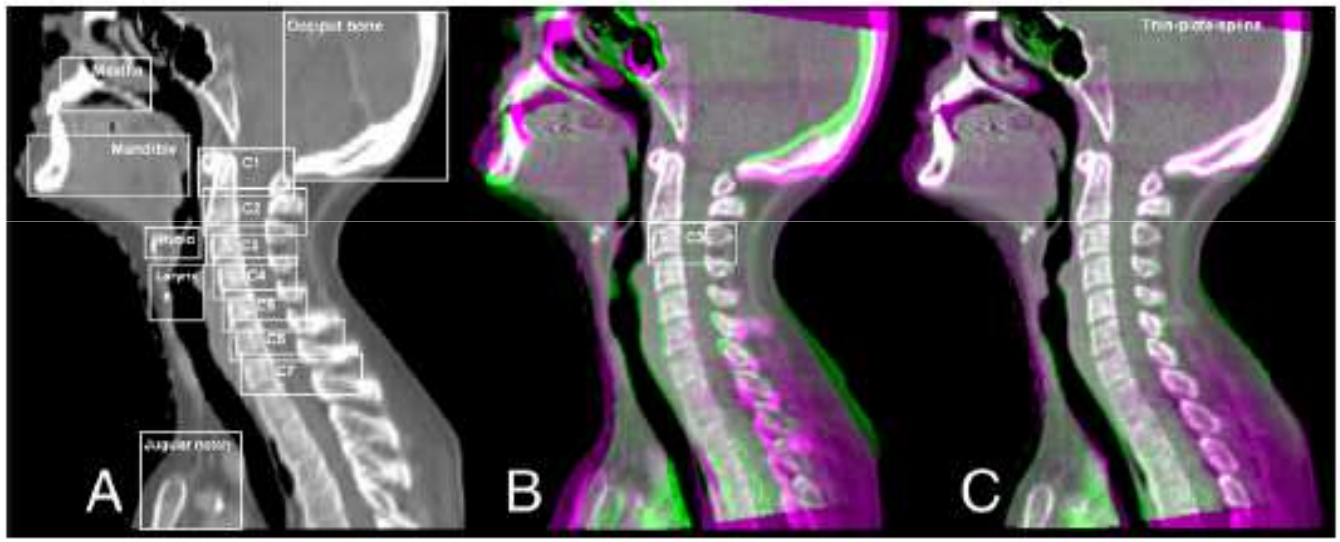


Fig. 1. Multiple regions of interest registration method on bony structures. (A) Definition of 13 regions of interest in the sagittal view. (B) Example registration of vertebrae C3 in green/purple overlay, note that other bony structures are not aligned. (C) Single assessment of all registration with a thin-plate-spline-based deformation.

In 40% of the CBCTs scans the errors in one or more subregions exceeded 5mm / 5°!

Daily rigid isocentre adaptations/IGRT: Conclusions

- Daily online adaptive concepts further *reduce* uncertainties, but *do not remove uncertainties completely*
- *there is still a lower limit for margin size* – treatment with 'zero margin' is not safe even with online imaging efforts
- too much margin reduction might be dangerous for other reasons as well: extra-capsular extension, see Chao et al. 2006 (IJROBP 65(4))

My personal opinion:
Even with advanced daily IGRT possibilities, there is still a need for 'smart' *probabilistic and robust planning approaches* – beyond the margin approach – due to the remaining uncertainties.

Treatment of targets with large interfractional deformations: Plan-selection strategies

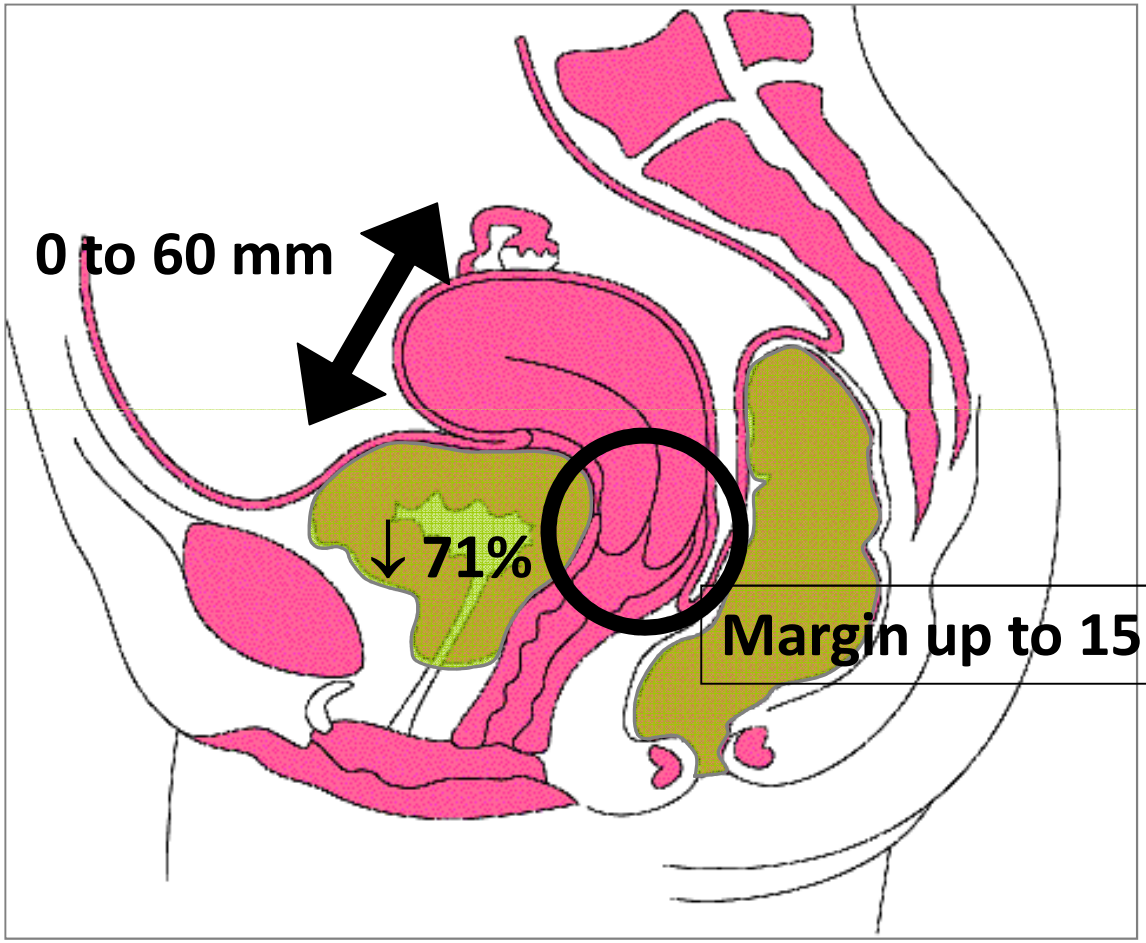
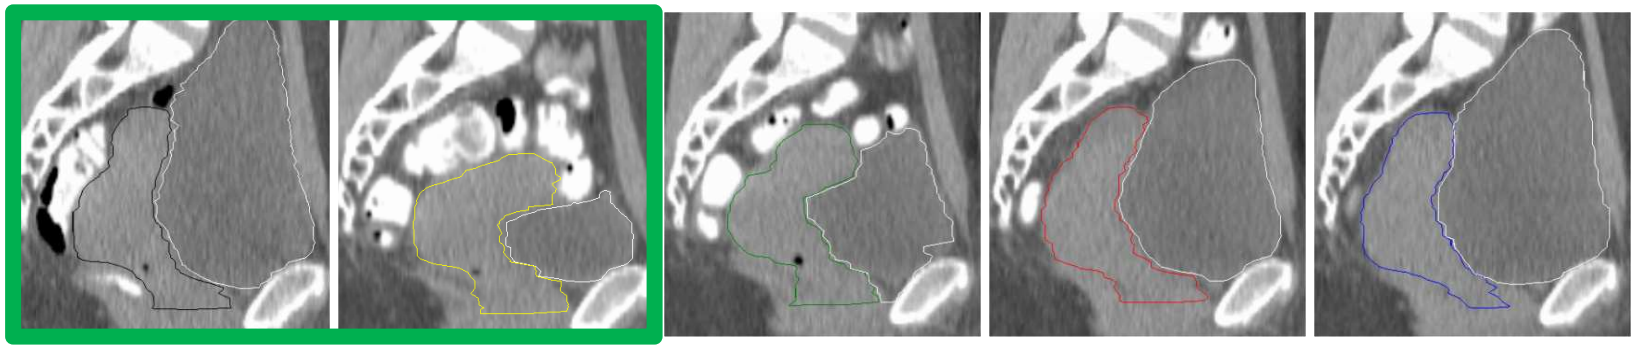
Example: female pelvis



Langerak et al.

Treatment of targets with large interfractional deformations: Plan-selection strategies

Example: female pelvis



Bondar et al. 2011 (Rad. Onc. 99(2)); courtesy M. Hoogeman (Erasmus MC)

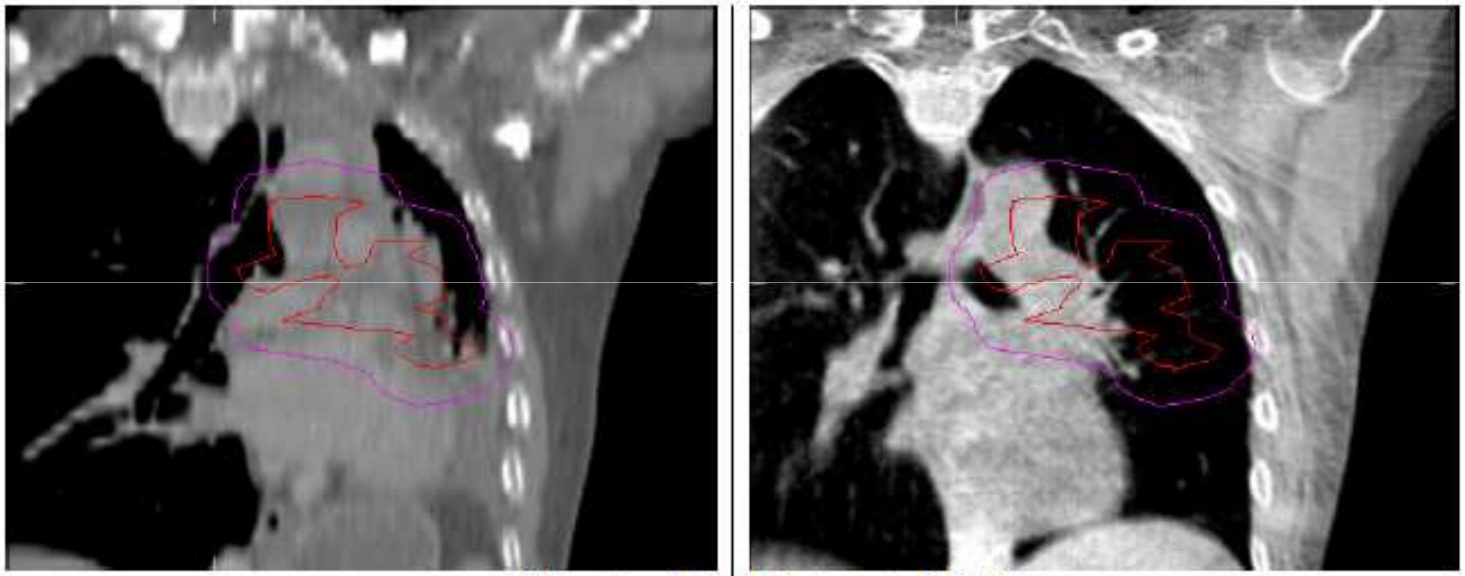
- ART for cervical cancer: For 90% of pts. with CTV coverage of >=95%...
  * non-ART population based **CTV-PTV volume 1702±274ml** (38mm margin)
  * online-adaptive 2-plan library: **CTV-PTV volume 764 ±165ml** (7mm margin)
  (Bondar et al. 2012, IJROBP 83(5))

- ART for bladder cancer, online adaptive 3-plan library:
  compared to non-ART, **V_{57Gy} of body tissue reduced by 34%**
  (Vestergaard et al. 2013, Rad. Onc. 109(3))
  and **median PTV volume reduction by 30%**
  (Vestergaard et al. 2014, Acta Oncol. 53(8))

Anatomical changes of trending nature

Sonke and Belderbos 2010
(Sem. Rad. Onc. 20(4))

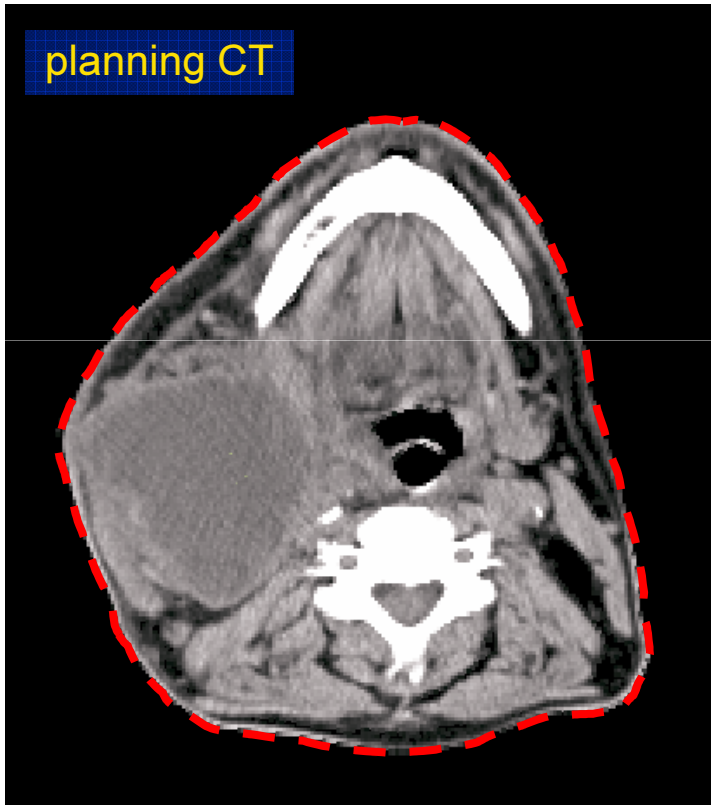
example: lung

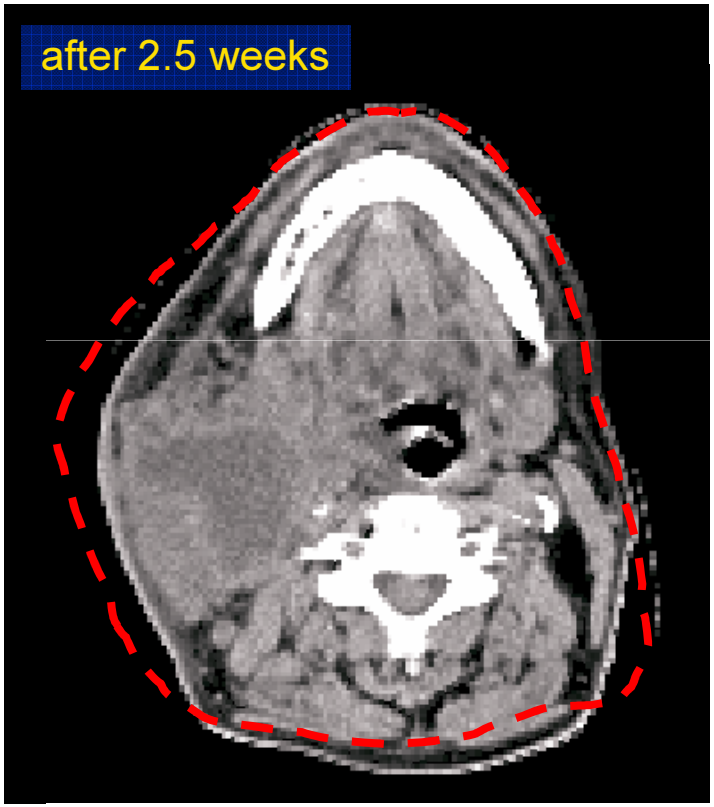


Planning CT | First week CBCT

Anatomical changes of trending nature

example: head-and-neck

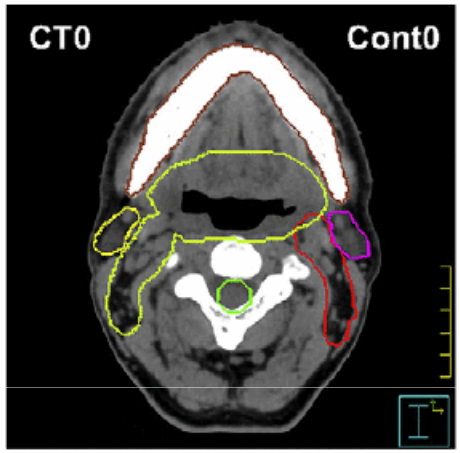


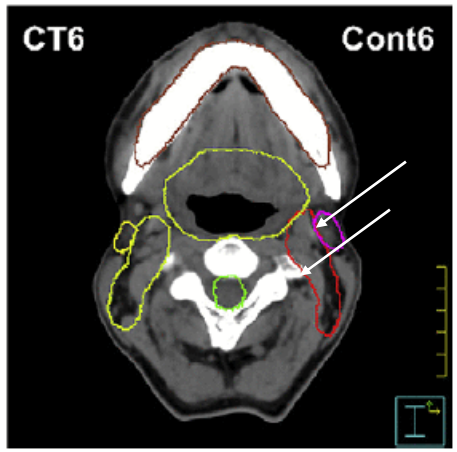


Anatomical changes of trending nature

Wu et al. 2009
(IJROPB 75(3))

example:
planning CT and 6 weeks later…





- systematic shrinkage of tumor/parotid volumes during treatment course, OARs move into high dose
- overdosage of OARs as compared to planning, and potential partial misses of CTVs
- more serious esp. for IMRT due to steep dose gradients

My personal opinion:
High(est) potential for clinical improvements by repeat imaging and multiple replanning/adaptation.

Wishful for the future: 'flag'/red light identifying patients who benefit most from one or multiple adaptations

Biologically Adapted Radiotherapy

Å. Søvik et al. 2010
(Sem. Rad. Onc. 20(4))

- adaptation by patient-individual biological/functional feedback

- **tumor:** changes in perfusion, hypoxic areas/re-oxigenation, tumor cell metabolism
- early predictive discrimination between 'responders' and 'non-reponders'
- **normal tissues:** e.g. lung perfusion changes, early detection of potential radiation-induced toxicity

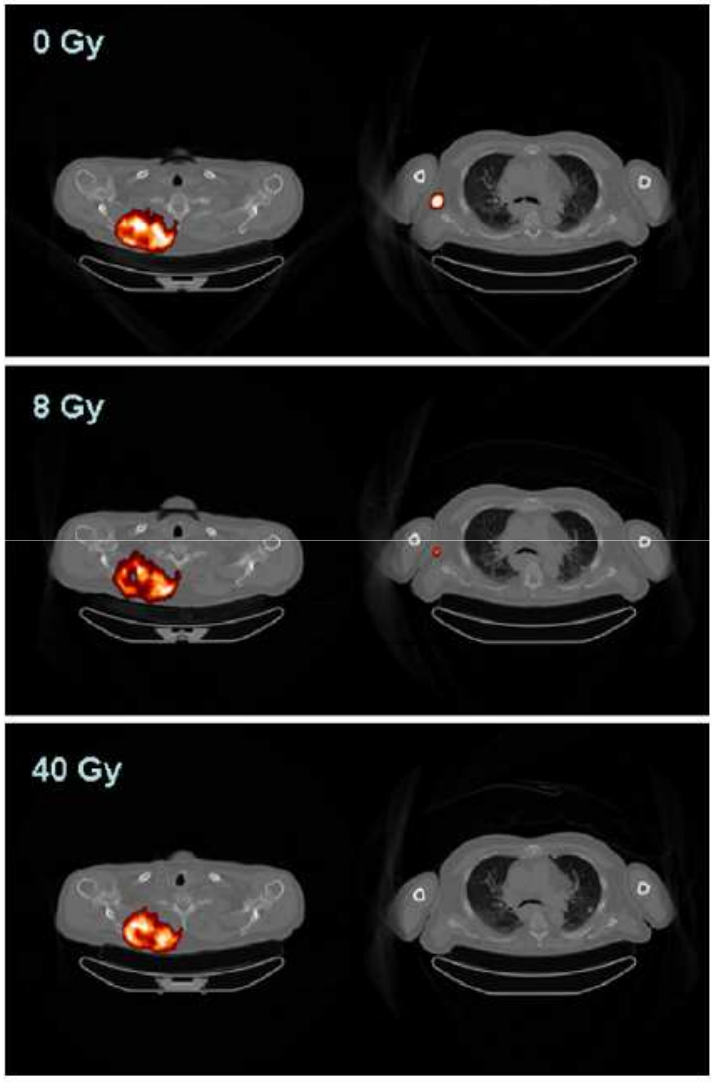


Figure 1 ^{18}F-FDG-PET/CT images of a patient with a sarcoma in the right scapula and a lymphoma in the right axillary lymph node. Images were taken before the start of radiotherapy, after 8 Gy (early treatment) and after 40 Gy (late treatment). PET/CT images courtesy of Jan Rødal.

- Liver cancer
- Bladder cancer
- Cervical Cancer
- Prostate Cancer

Conclusions

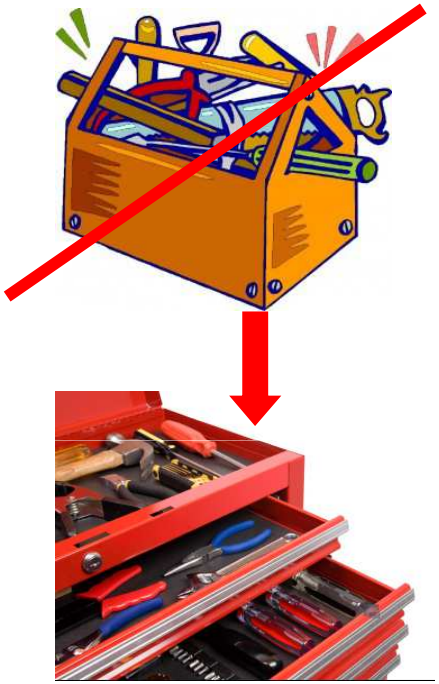
- *offline adaptive* setup correction and margin adapting protocols with clinically proven benefits and high efficiency to reduce systematic errors

- *online adaptive* schemes can further reduce uncertainties for the price of more frequent imaging, but there is a lower limit for margin reduction

provocative thought: a single adaptation – if well implemented and its effects evaluated thoroughly – is better than some 'latest' complex IGRT/ART scheme with daily imaging and repeat adaptations
– unless its benefits are clearly proven with treatment simulation approaches/patient data.

Conclusions [2]

- A real broad, clinical implemention of full adaptive schemes probably won't happen before vendors provide easy, yet robust and mature software solutions for meaningful adaptive workflows



Finally: Some (more) words of caution

The ‘latest-and-greatest’ ART schemes use methods from the ‘toolbox’, that start to find its way into commercial products and thus into clinical practice.

BUT be aware…

- Deformable registration errors => dose warping errors!
  Deformable registration is especially challenging for prostate/rectum
- Thus: Are hot/cold spots in an accumulated dose real? Should these be actively compensated for?
- Dose calculation on cone beam CT data: no high-precision dose calculation possible, thus dose-of-the-day calculation is subject to errors

Errors and Margins in Radiotherapy

Marcel van Herk

Clinical radiotherapy procedures aim at high accuracy. However, there are many error sources that act during treatment preparation and execution that limit the accuracy. As a consequence, a safety margin is required to ensure that the planned dose is actually delivered to the target for (almost) all patients. Before treatment planning, a planning computed tomography scan is made. In particular, motion of skin with respect to the internal anatomy limits the reproducibility of this step, introducing a systematic setup error. The second important error source is organ motion. The tumor is imaged in an arbitrary position, leading to a systematic organ motion error. The image may also be distorted because of the interference of the scanning process and organ motion. A further systematic error introduced during treatment planning is caused by the delineation process. During treatment, the most important errors are setup error and organ motion leading to day-to-day variations. There are many ways to define the margins required for these errors. In this article, an overview is given of errors in radiotherapy and margin recipes, based on physical and biological considerations. Respiration motion is treated separately.

Sem Rad Onc, 2004

„Will positioning errors ever be zero?“

Well, for photons we are getting sufficiently close to zero…

4D-CBCT

Sweeney et al., Radiation Oncol, 2012

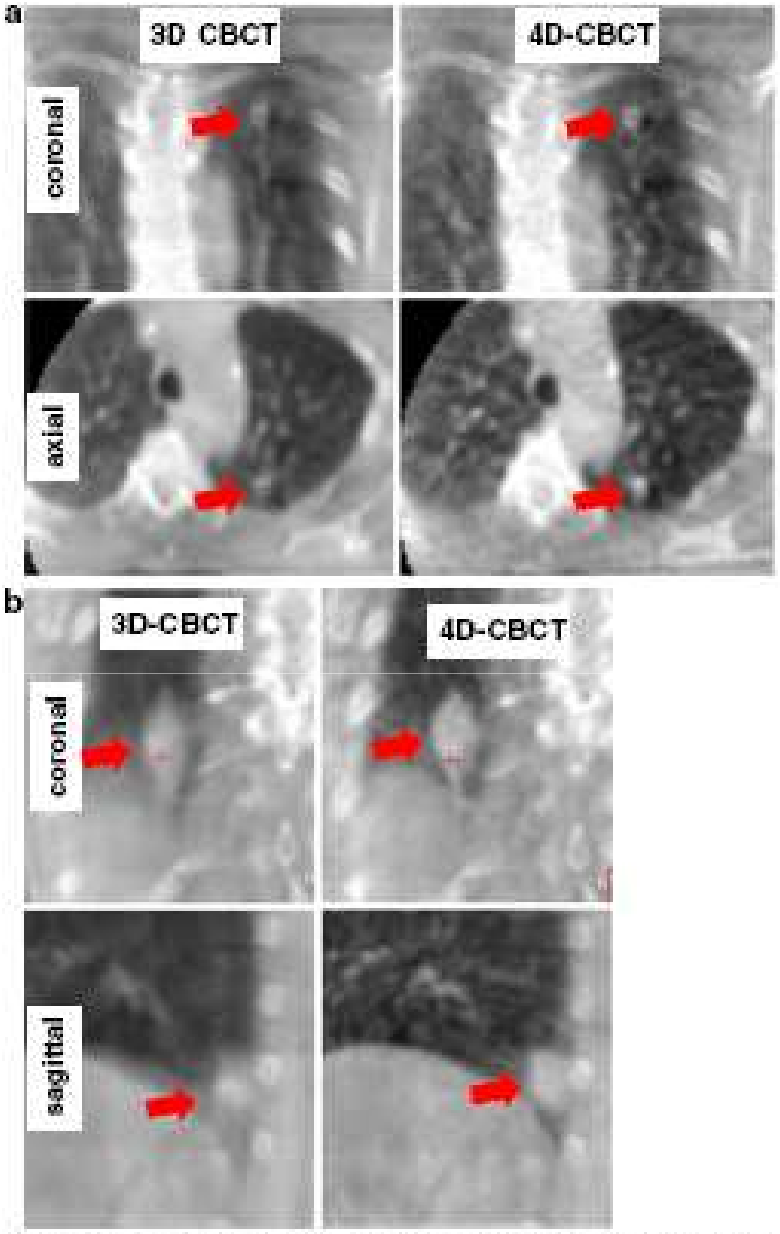

Figure 4 Examples of image quality in 3D-CBCT and 4D-CBCT. The arrow indicates the position of the target. a) Small target in the upper lobe with a 3D motion amplitude of 9.3 mm, where averaged image quality was 3.0 and 1.8 in 3D-CBCT and 4D-CBCT, respectively. b) Target in the lower lobe immediately superior to the diaphragm with a 3D motion amplitude of 16.6 mm, where averaged image quality was 3.0 and 1.3 in 3D-CBCT and 4D-CBCT, respectively.

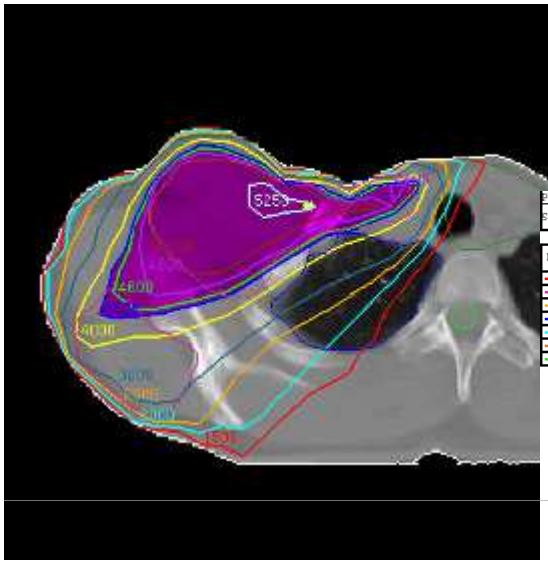
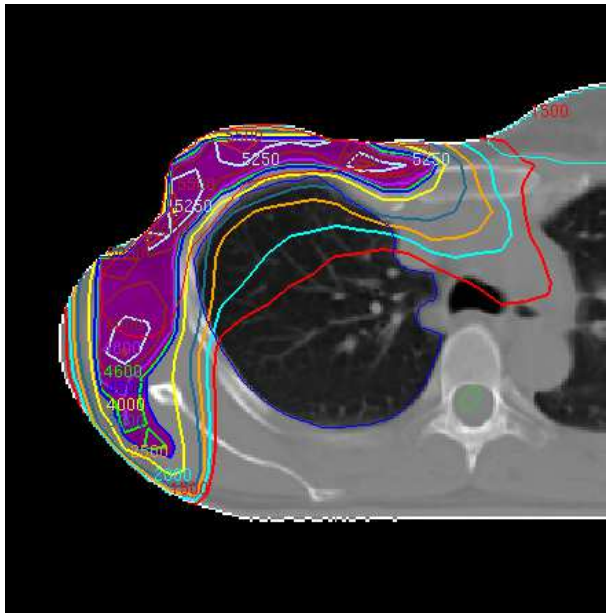
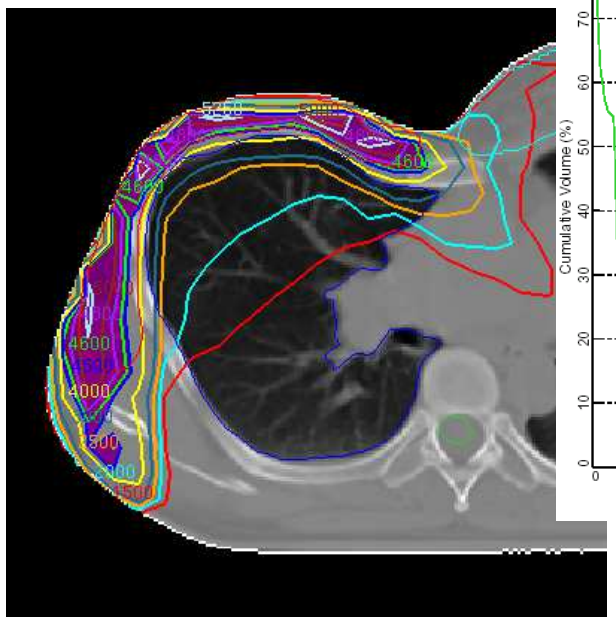
Thoracic Wall IMRT

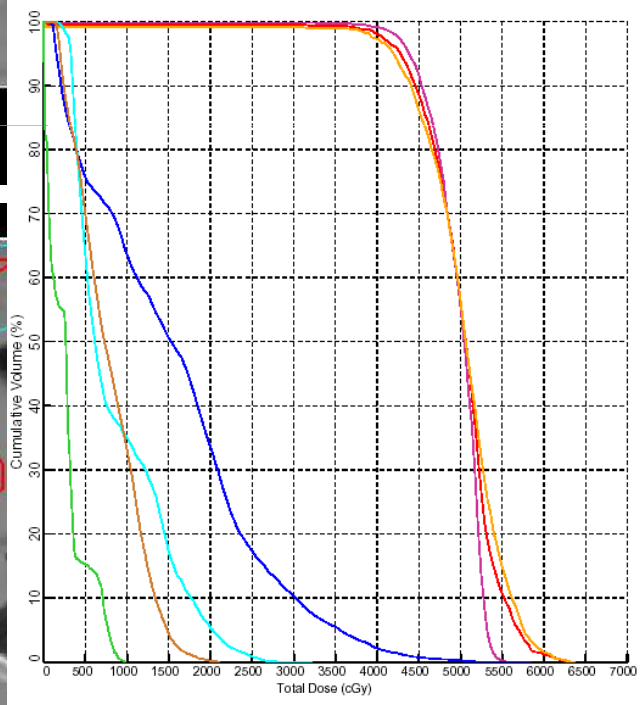




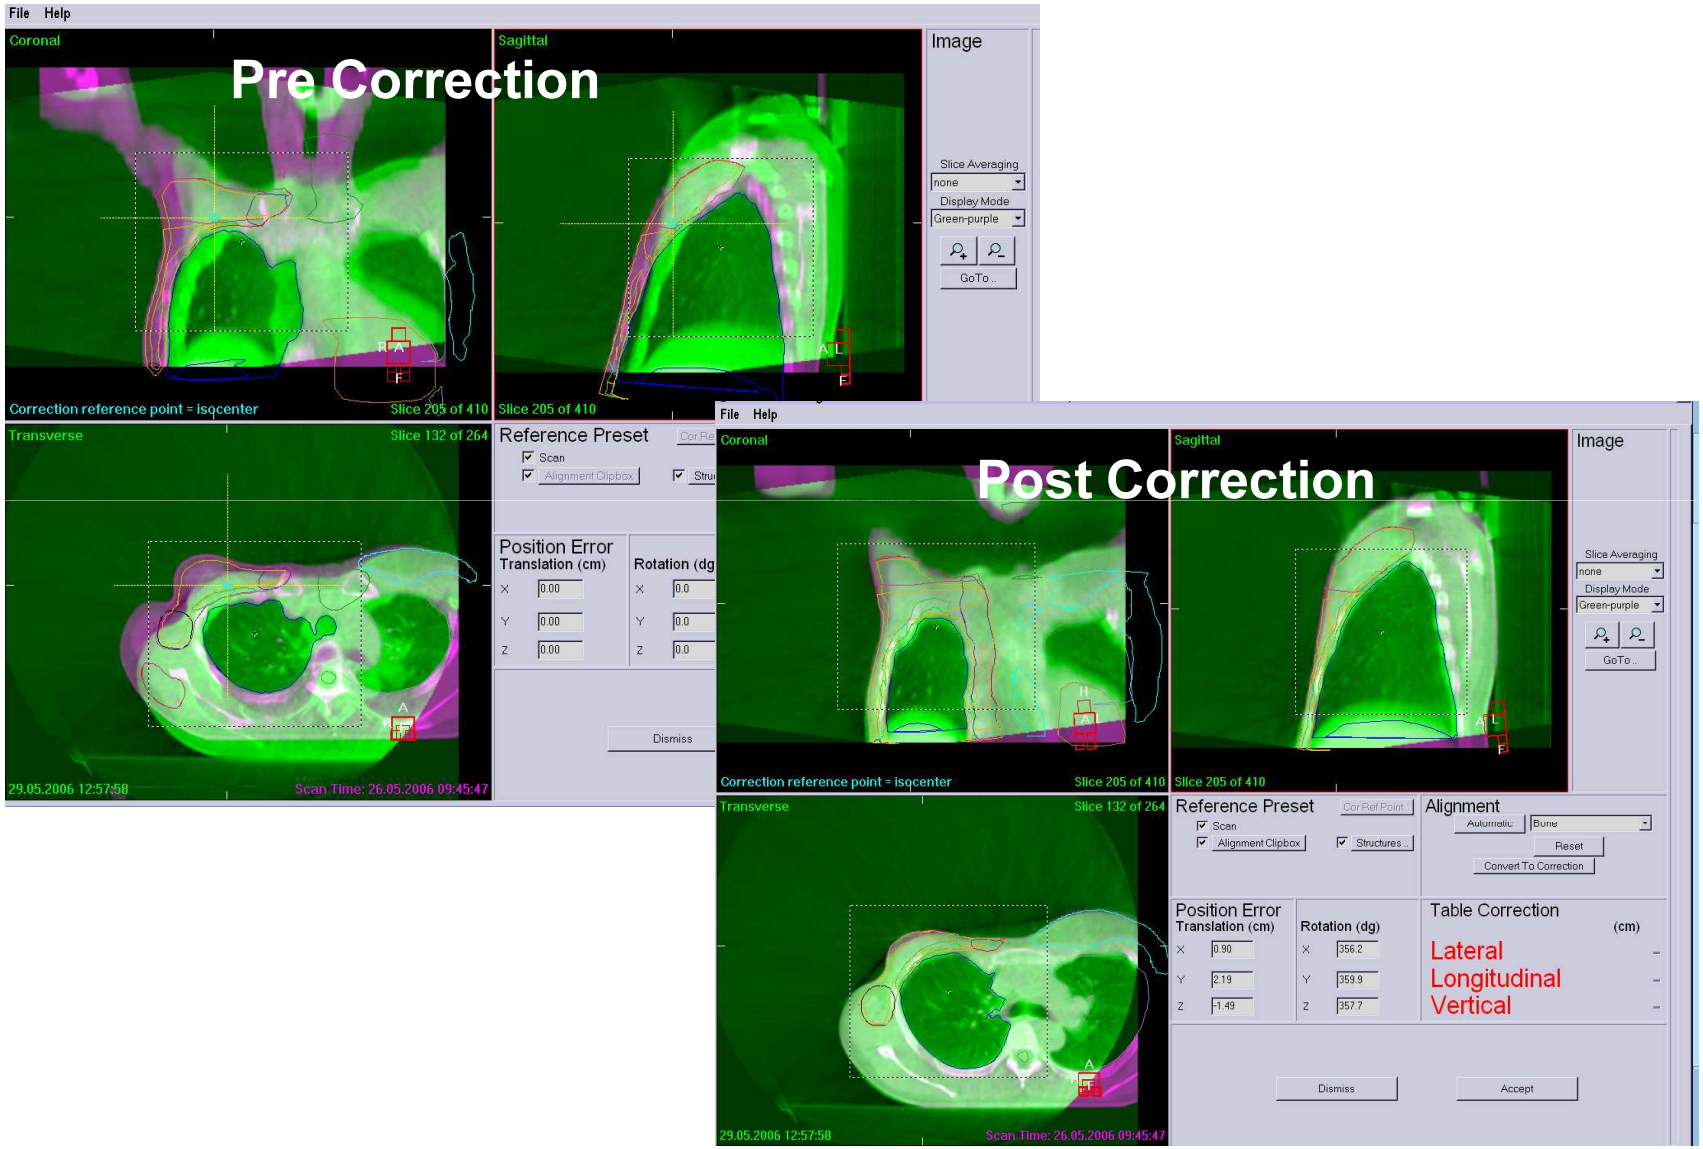


Plan: 37	plan 36 - hot spots out	Plan Date	23-MAY-2006 22:54
Signature	8 Beams - 35 segments - purged for <3 MUs - Flash region added		

Key	Structure	Plan	Min Dose[cGy]	Max Dose[cGy]	Mean Dose[cGy]	Total Vol [cc]
	PTV	Renken Heike(37) Whole PTV	0	6288	5800	774.4
	SCLN	Renken Heike(37) Supraclavicular LNs	0	5545	4962	261.3
	PTV 2	Renken Heike(37) Chest Wall	0	6336	5800	461.1
	Lunge re	Renken Heike(37) Ipsilateral Lung	107	5775	1552	1635.0
	L Breast	Renken Heike(37) Contralateral Breast	0	3186	886	632.5
	Herz	Renken Heike(37)	141	2090	785	409.3
	RM	Renken Heike(37)	0	963	258	60.8

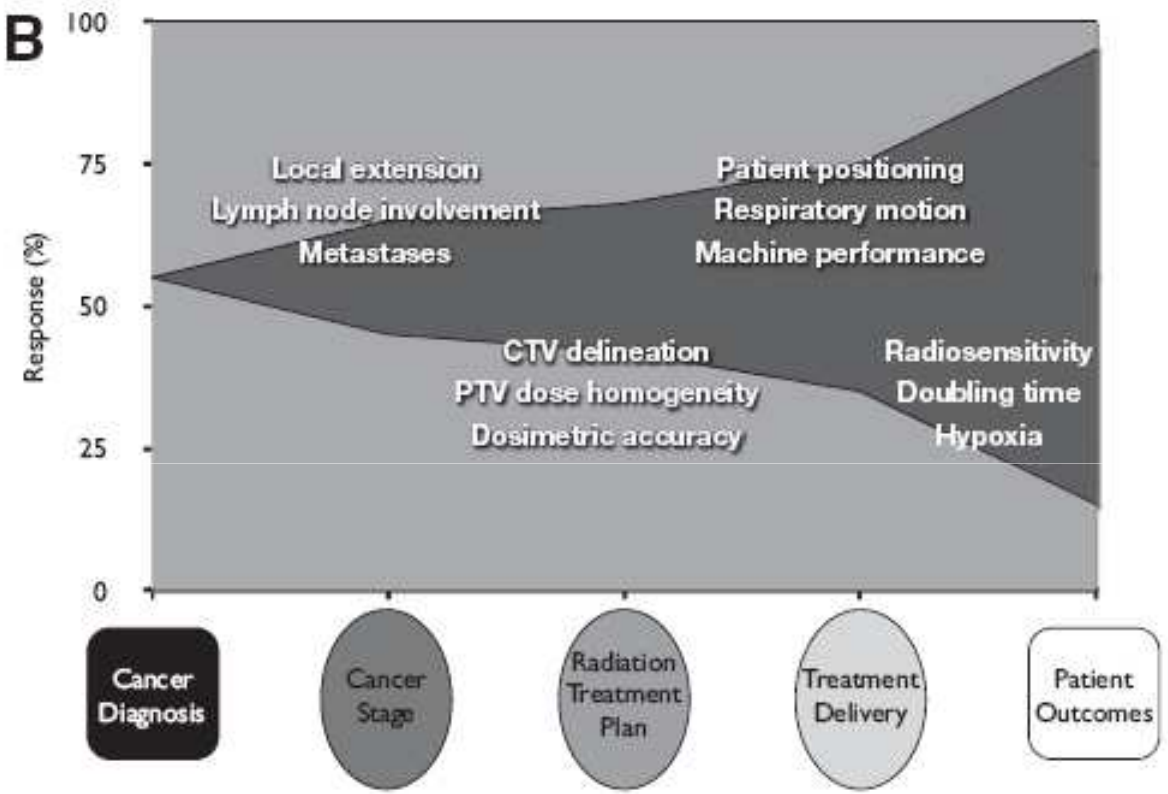


Positioning for Thoracic Wall IMRT



Influence of IGRT on clinical outcome

„Although it may be difficult to directly evaluate the limited evidence for IGRT it is possible to examine improved clinical outcomes that have been enabled by IGRT“

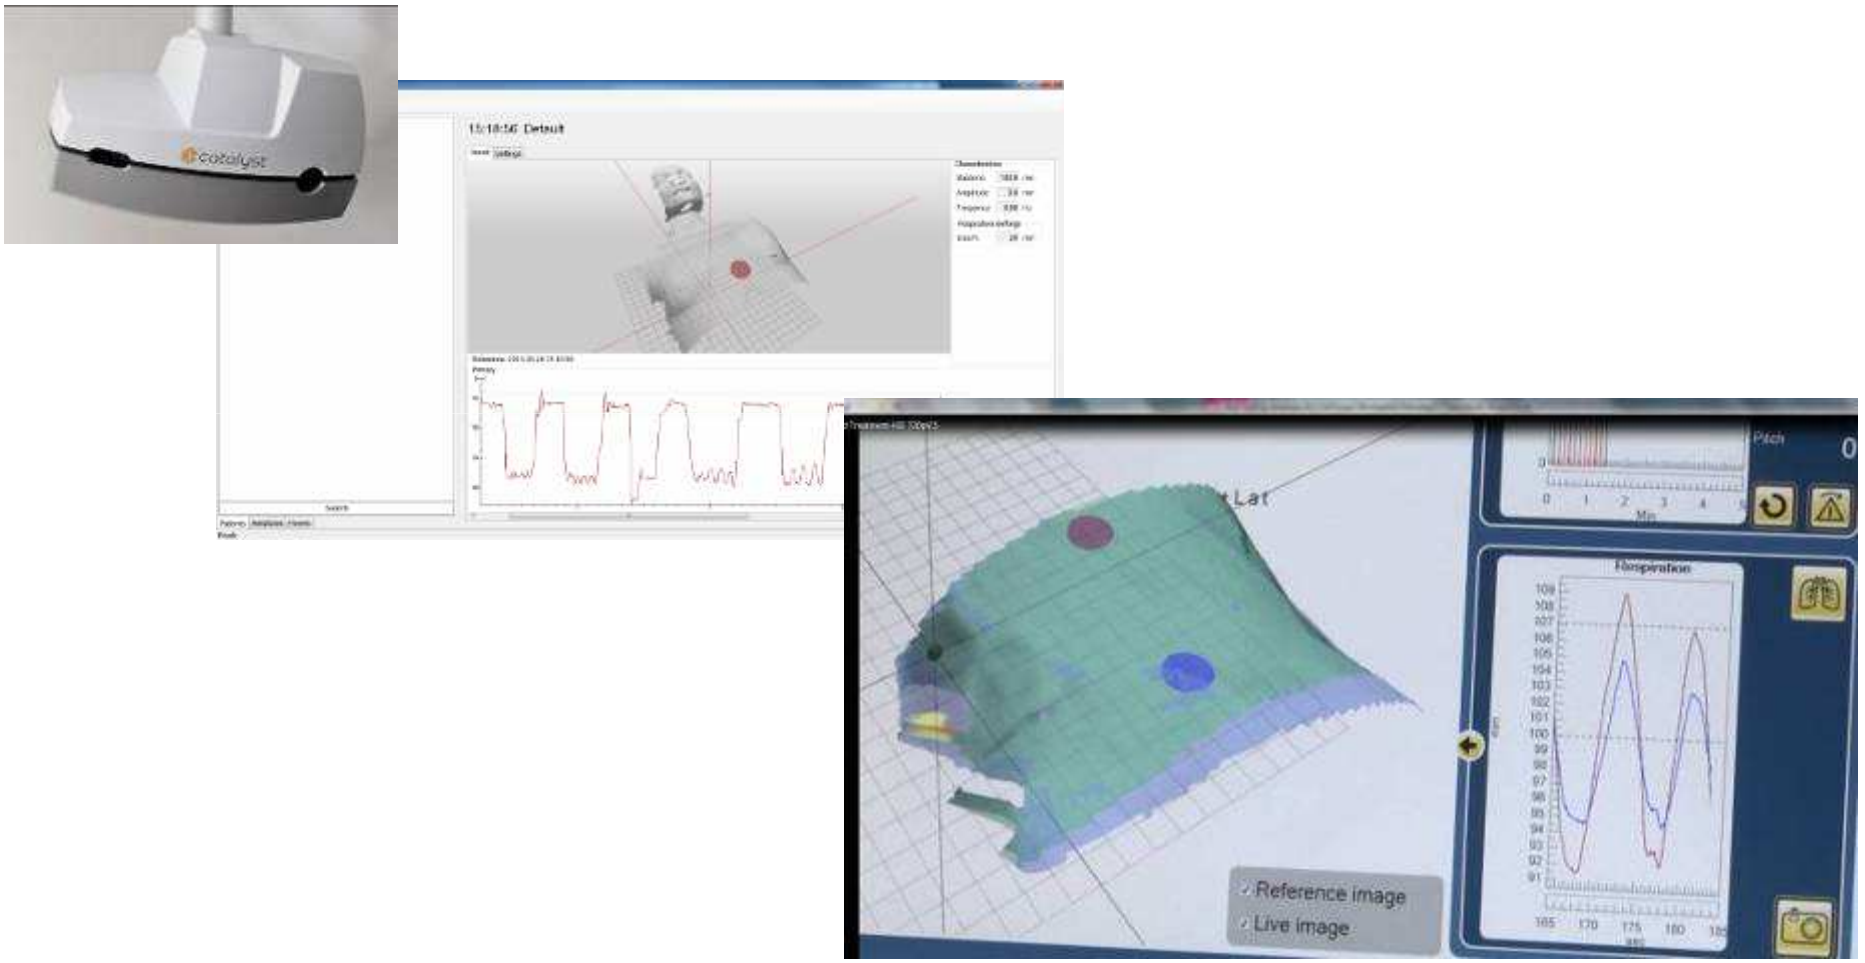


Bujold, Craig, Jaffray, Dawson, Sem Rad Onc, 2012

“Although there are many guidelines for the quality assurance of IGRT equipment, there are few that specifically highlight the role of IGRT as quality assurance or the potential of IGRT to reduce patient treatment incidents”

Bujold, Craig, Jaffray, Dawson, Sem Rad Onc, 2012

Surface-based Surveillance



Catalyst Characteristics

Stieler et al., submitted

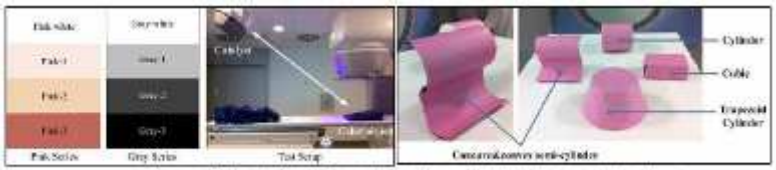


Figure 2a,b: Left: colour test setup. Right: shape test setup

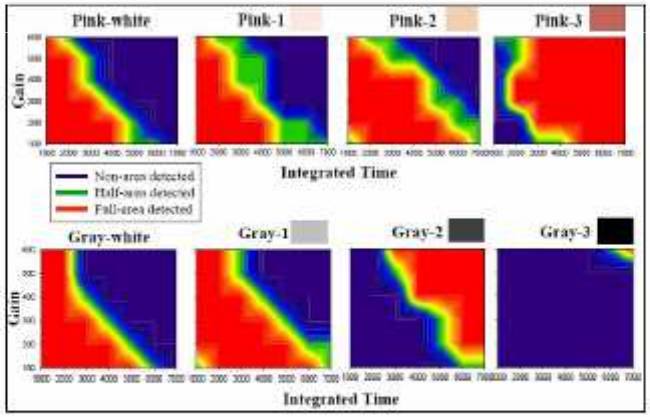

Figure 3: Plots of the color tests depending on gain and IT. Scans with settings that result with values in the blue area are not visible; scans with results in the red area are full visible.

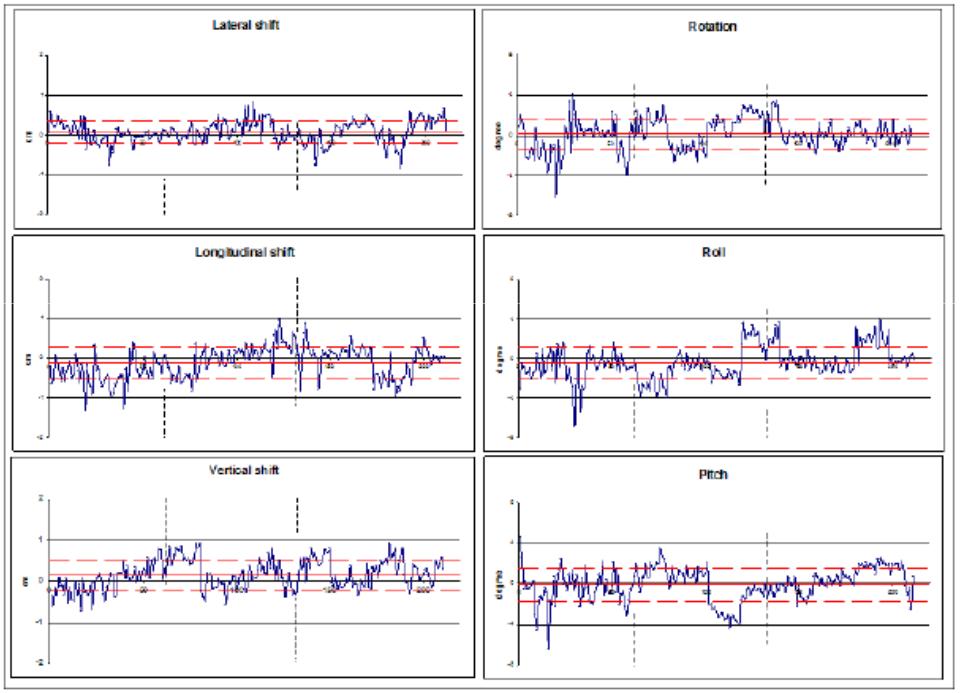

Figure 6: Shift vector in cm respectively degree for the 224 fraction for 3 translation directions (lateral, longitudinal and vertical) and 3 rotational directions (rotation, roll and pitch). First block: head-and neck targets, second block pelvic targets and third block thoracic targets.

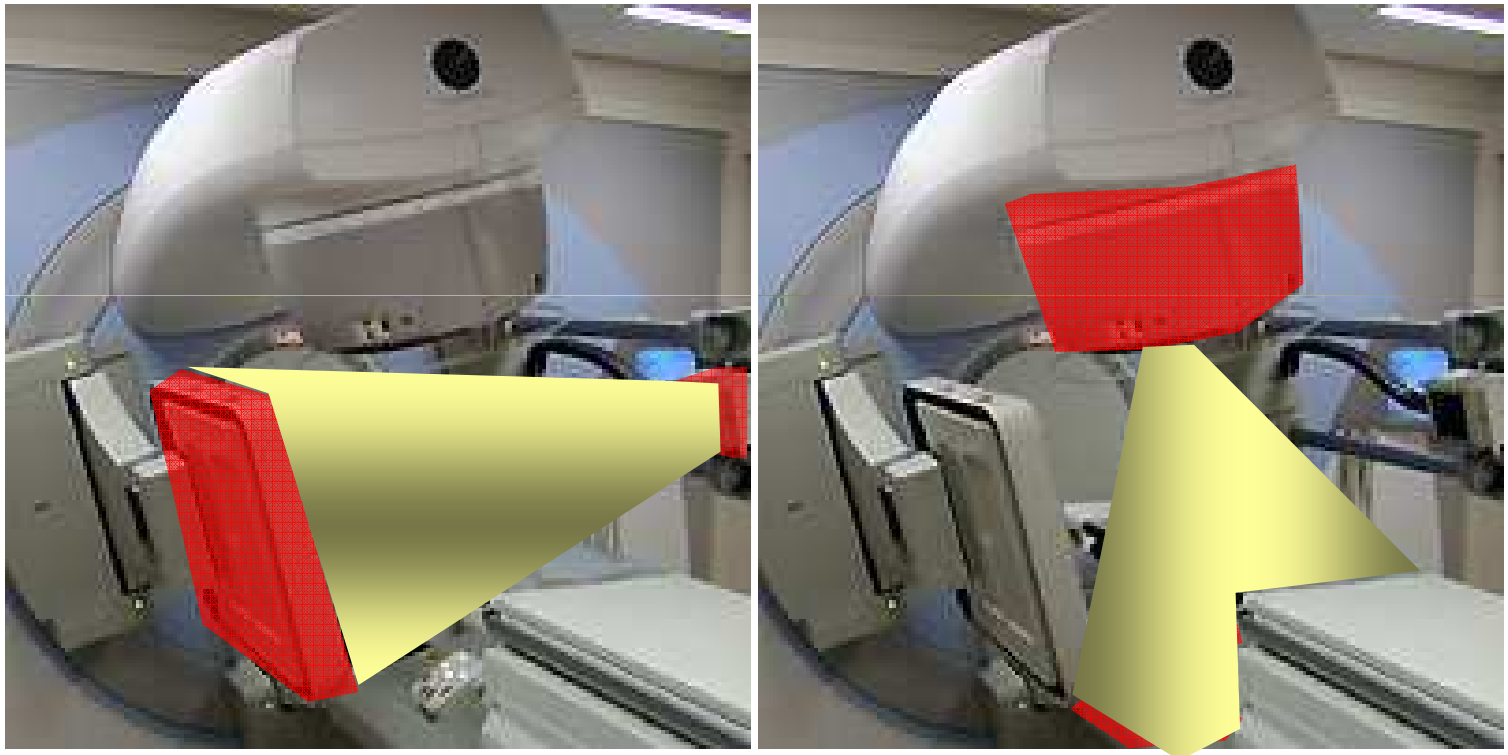
Ansatz kV+MV-Rekonstruktion

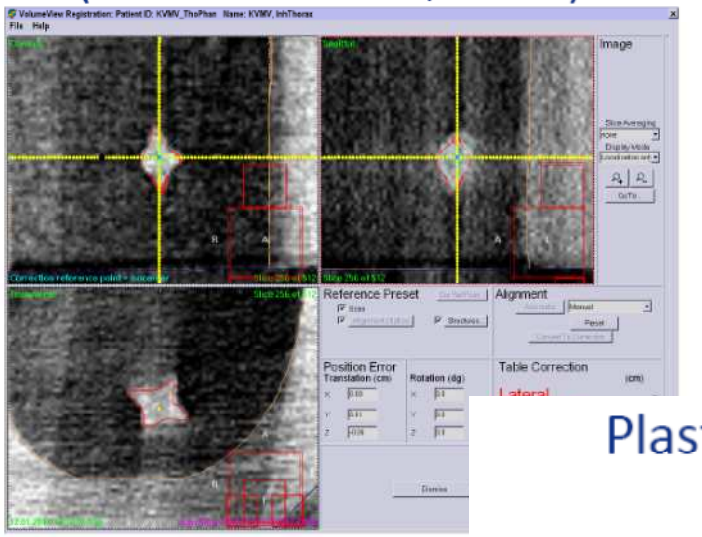
kV

MV

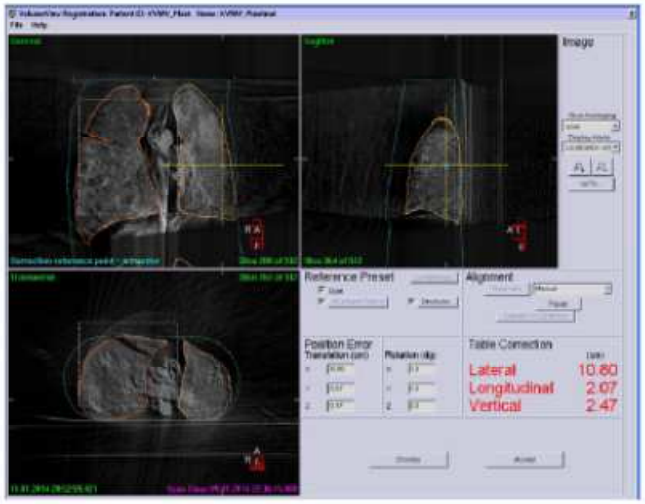


http://www.elekta.com/healthcare_international_beaumont_work_results_breakthrough.php

Thorax phantom: star shaped inlay
(15s kV-MV scan, 5 MU)



Plastinated Thorax (15s kV-MV mode, 5MU)
different level/window settings



Beispiel: Tumor shape Star10, after registration of iso-shift 1
(automatic registration with in-house developed software - Matlab)

	pCT	kV-Chest CBCT * (360°) (*clinical preset)	kV-only CBCT (180°)	MV-only CBCT (180°)	Combined kV-MV CBCT (90°)
Full Phantom (registered)					Full phantom registration overlay	pCT CBCT				Full tumor registration overlay	pCT CBCT				
NOTE: kV-only, MV-only and combined kV-MV CBCT were simultaneously acquired → MV-scatter in kV-contribution
