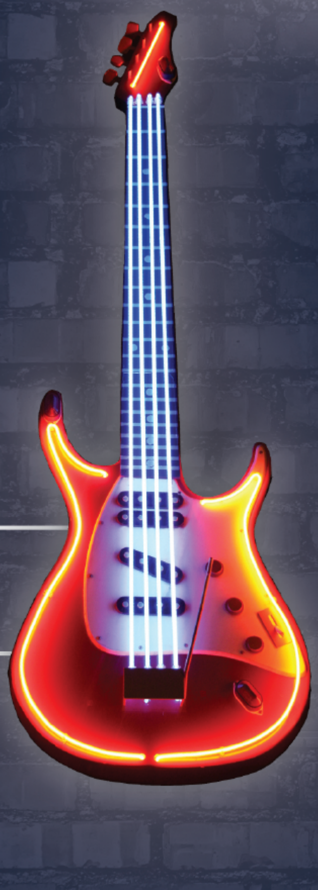
Fine Tuning Decisions in Music City



http://meetings.informs.org/nashville2016

ORGANIZING COMMITTEE

General Chair
Chanaka Edirisinghe
Rensselaer Polytechnic Institute

Program Chair
Bogdan Bichescu
University of Tennessee

Invited Sessions Chair
Shabbir Ahmed
Georgia Institute of Technology

Sponsored Sessions Chair
James Ostrowski
University of Tennessee

Tutorials Chairs
Aparna Gupta
Rensselaer Polytechnic Institute

Agostino Capponi
Columbia University

Contributed Sessions Chairs
Scott Mason
Clemson University

Justin Yates
Francis Marion University

Practice Program Co-Chairs
Mingzhou Jin
University of Tennessee

Sean Willems
University of Tennessee

Plenary/Keynote Chair
James Primbs
California State University

Poster Sessions Co-Chairs
Melissa Bowers
University of Tennessee

Oleg Shylo
University of Tennessee

Arrangements Co-Chairs
Christine Vossler
University of Tennessee

Anahita Khojandi
University of Tennessee

Copies of papers abstracted in the meeting program are available only from the authors. Requests for papers should be sent to the authors at the addresses shown in the program. Published annually prior to the meeting by INFORMS. Individual issues of the program are available upon request. Please contact the INFORMS office for additional information, 800.446.3676. Orders must be prepaid.

GENERAL CHAIR'S RECEPTION

Lally School of Management
Rensselaer Polytechnic Institute (RPI)
110 8th Street, Troy, NY 12180, U.S.A.

Dear INFORMS Friends and Colleagues,

Welcome to the 2016 INFORMS Annual Meeting in Nashville, the capital city of the state of Tennessee and the second most populated. In addition to being a major music production center, Nashville's economy is powered by the healthcare industry along with other important industries such as automotive, financial, insurance and publishing industries. The conference theme, "Fine-Tuning Decisions in the Music City," reflects the broad scope of what will be covered in the conference, from applications in industries such as healthcare, finance and risk, entertainment, and supply chains to methodologies and analysis in advanced computing, big data, and new challenges in the optimization of systems.

An intriguing blend of topics from academics and practitioners fill the plenary and semi-plenary presentations. Guruduth Banavar, VP and Chief Science Officer at IBM, is the distinguished speaker for the opening plenary on Sunday, presenting an overview of cognitive computing, the technology breakthroughs, and the practical applications that are transforming every industry.

Margaret L. Brandeau, Professor of Engineering and Professor of Medicine at Stanford University, delivers a Monday plenary on effective public health preparedness and national security implications with a view to answering very complex questions using operations research. A Tuesday plenary is offered jointly by Professors Suvrajeet Sen and Gareth James, University of Southern California, on big data and big decisions.

Omega Rho's 40th Year Anniversary is celebrated with a Monday plenary lecture given by an expert panel consisting of Professors Alfred Blumstein (Carnegie Mellon University), John Birge (University of Chicago), Ralph Keeney (Duke University), and John Little (MIT). Moreover, the IFORS Distinguished Lecture is given by Professor Rolf H. Möhring, Beijing Institute for Scientific and Engineering Computing. The winners of the Franz Edelman, UPS George D. Smith, and Daniel H. Wagner Prizes will present their accomplishments in separate keynote presentations.

The lineup of keynote lectures also includes: Jeff Nichols, Director, Oak Ridge National Laboratory, on creating the Exascale ecosystem for science; Jason Murray, Vice President of World wide Retail Systems, Amazon, on optimizing supply chains; Edmund Jackson, Chief Data Scientist, Hospital Corporation of America, on analytics in healthcare; Stephen Prather, on sports analytics and the pursuit of usefulness; and Gerald Brown, Naval Postgraduate School, on what the goals of analysis should be.

Please take advantage of the many opportunities to network, including the Welcome Reception on Sunday evening, the General Reception on Tuesday evening, and the gathering areas at the conference exhibits and the Career Center. Also, do not forget to indulge yourself in the "The Coolest, Tastiest City in the South" food offerings from southern fare to haute cuisine to quite literally everything in between.

I am grateful to the INFORMS Meetings Committee for their support, and to the highly professional and efficient INFORMS staff members for their dedication to success. I am indebted to the organizing committee members for their unwavering support and hard work to put together a high quality program. The Program Chair, Bogdan Bichescu, University of Tennessee, has been my right-hand person persevering for success for over two long years, along with James Primbs, California State University, who served as Plenary and Keynote chair. Tutorial co-chairs, Aparna Gupta and Agostino Capponi; Invited sessions chair, Shabbir Ahmed; Poster sessions co-chairs, Melissa Bowers and Oleg Shylo; Contributed sessions co-chairs, Scott Mason and Justin Yates; Sponsored sessions chair, James Ostrowski; Practice program co-chairs, Mingzhou Jin and Sean Willems; and Arrangements co-chairs, Christine Vossler and Anahita Khojandi, all contributed immensely to the meeting's success. Organizing this event would not have been possible without their creative spirit and steadfast support.

I would also like to thankfully acknowledge the generous support received from our sponsors for the success of this conference. My special thanks go to the Platinum sponsor, Haslam College of Business, University of Tennessee; Gold sponsors, AIMMS, Caterpillar, IBM, and Industrial and Systems Engineering, University of Tennessee; Bronze sponsors, The Hong Kong Polytechnic University and SAS; and various Contributor sponsors, a long list that includes Rensselaer-Lally School, UT Dallas-Jindal School, Georgia Tech-ISyE, Lehigh-Engineering, PennState, Northwestern-Engineering, SUTD-Singapore, UTenn-Business Analytics, UT Austin-Engineering, GAMS, AMPL, and LINDO Systems.

It is my great pleasure and privilege to welcome you to INFORMS 2016! I hope you will enjoy the conference.

Chanaka Edirisinghe, General Chair
Professor, Lally School of Management,
Rensselaer Polytechnic Institute

MCC - Music City Center | **Omni** - Omni Hotel

FRIDAY, NOVEMBER 11

Combined Colloquia		
Registration	Omni - Legends D, 2nd Floor	5:30–6:30pm
Dinner	Omni - Legends ABC, 2nd Floor	6–8pm

SATURDAY, NOVEMBER 12

Combined Colloquia	Omni - Cumberland 1-6	7am–6pm
CIST	Omni - Legends B,C,D	7:30am–6pm
ISR Editors Meeting	Omni - Music Row 2	8am–2pm
Organization Science Dissertation Competition	Omni - Legends A, 2nd Floor	8am–5pm
Data Mining & Analytics Workshop	Omni - Music Row 3,4,5	8am–7pm
Visit Music City	MCC - Exhibit Hall A, Level 3	9am–5pm
INFORMS Registration	MCC - Exhibit Hall A, Level 3	7am–5:30pm
Executive Committee Meeting	Omni - Gibson Boardroom, 3rd Floor	10am–12noon
INFORMS Board Meeting	Omni - Legends EF, 2nd Floor	12noon–4:30pm
Technology Workshops		
SAS - GAP/EDU	MCC - 201A, Level 2	9–11:30am
Optimization Direct	MCC - 201B, Level 2	9–11:30am
AIMMS	MCC - 201A, Level 2	12noon–2:30pm
FICO	MCC - 201B, Level 2	12noon–2:30pm
SAS - JMP	MCC - 202A, Level 2	12noon–2:30pm
Bayesia	MCC - 202B, Level 2	12noon–2:30pm
SAS Institute	MCC - 201A, Level 2	3–5:30pm
GAMS	MCC - 201B, Level 2	3–5:30pm
GUROBI	MCC - 202B, Level 2	3–5:30pm
IBM Analytics	MCC - 205A, Level 2	3–5:30pm
SIMIO	MCC - 202C, Level 2	3–5:30pm
MathWorks	MCC - 202A, Level 2	3–5:30pm
Neusrel	MCC - 208B, Level 2	3–5:30pm
LINDO Systems	MCC - 208A, Level 2	3–5:30pm
Frontline Systems	MCC - 205B, Level 2	3–5:30pm
INFORMS Member Meeting	Omni - Broadway GHJK, 2nd Floor	5–6:30pm
Roundtable Reception	Omni - Acoustic, 4th Floor	5–6pm
Roundtable Dinner	Omni - Electric, 4th Floor	6–7pm
ISS Awards & *ISR* Editors Reception	Omni - Legends G, 2nd Floor	6:30–8pm

SUNDAY, NOVEMBER 13

INFORMS Registration	MCC - Exhibit Hall A, Level 3	7am–5pm
New Member Breakfast (invite only)	Omni - Broadway F, 2nd Floor	7–8am
MNSC Editorial Board Meeting (invite only)	Omni - Broadway K, 2nd Floor	7:30–9am
ITED Editorial Board Meeting (invite only)	Omni - Broadway H, 2nd Floor	7:30–9am
Career Center Breakfast & Meeting	Omni - Broadway E, 2nd Floor	7:30–9am
Technical Sessions (SA)	**Music City Center & Omni**	**8–9:30am**
INFORMS Board	Omni - Legends EF, 2nd Floor	8am–5pm
CIST	Omni - Legends B,C,D	8am–5:15pm
Visit Music City	MCC - Exhibit Hall A, Level 3	9am–5pm
Coffee Break	MCC - Level 2 / Omni - 2nd Floor	9:30–10am
Welcome & Plenary: Guru Banavar	**MCC - Davidson Ballroom, Level 1M**	**10–10:50am**
Technical Sessions (SB)	**Music City Center & Omni**	**11am–12:30pm**
QSR Student Intro. & Interactive	Omni - Mockingbird 2	11am–12:30pm
Exhibits, Career Center, Technology Center	MCC - Exhibit Hall A, Level 3	12noon–5pm
INFORMS Center, Networking Lounge	MCC - Exhibit Hall A, Level 3	12noon–5pm
CIEADH	Omni - Legends A, 2nd Floor	12noon–6pm
Junior Faculty Interest Group Lunch (ticketed event)	Omni - Broadway E, 2nd Floor	12:30–1:30pm
Lunch Break (on your own)		12:30–1:30pm
M&SOM Associate Editors Lunch (invite only)	Omni - Broadway A, 2nd Floor	12:30–2:30pm
Technical Sessions (SC)	**Music City Center & Omni**	**1:30–3pm**
Keynote: UPS George D. Smith Reprise	**MCC - Davidson Ballroom A, Level 1M**	**3:10–4pm**
Keynote: Jeff Nichols, ORNL	**MCC - Davidson Ballroom B, Level 1M**	**3:10–4pm**
Keynote: IFORS Distinguished Lecture	**MCC - Davidson Ballroom C, Level 1M**	**3:10–4pm**
Coffee Break	MCC - Exhibit Hall A, Level 3 / Omni - 2nd Floor	4–4:30pm
Technical Sessions (SD)	**Music City Center & Omni**	**4:30–6pm**
INFORMS Community Meetings	See p. 6	
INFORMS Connect & Social Networking Reception	Omni - Broadway AB, 2nd Floor	6:30–7:30pm
Welcome Reception - Exhibits Open	MCC - Exhibit Hall A, Level 3	7:30–9pm
Minority Issues Forum Reception	Omni - Broadway K, 2nd Floor	7:30–9pm
Awards Ceremony & Dessert	Omni - Broadway EF, 2nd Floor	8:30–9:45pm

MONDAY, NOVEMBER 14

INFORMS Registration	MCC - Exhibit Hall A, Level 3	7am–5pm
ACORD Breakfast & Meeting	Omni - Broadway H, 2nd Floor	7:30–9am
Engagement with Organization Committee Meeting	Omni - Broadway B, 2nd Floor	8–9am
Technical Sessions (MA)	**Music City Center & Omni**	**8–9:30am**
Service Science Editorial Board Meeting (invite only)	Omni - Broadway D, 2nd Floor	8–10am

Interfaces, EIC Orientation	Omni - Broadway A, 2nd Floor	8am–12noon
Chapters/Fora Committee	Omni - Broadway J, 2nd Floor	8:30–9:30am
Exhibits, Career Center, Technology Center	MCC - Exhibit Hall A, Level 3	9am–5pm
INFORMS Center, Networking Lounge	MCC - Exhibit Hall A, Level 3	9am–5pm
Visit Music City	MCC - Exhibit Hall A, Level 3	9am–5pm
Section/Societies Committee	Omni - Broadway J, 2nd Floor	9:30–10:30am
Coffee Break	MCC - Exhibit Hall A, Level 3 / Omni - 2nd Floor	9:30–10am
Amazon Fulfillment Center Plant Tour	MCC – 6th Ave Exit, Near Rooms 210-214	9:30–12:30pm
Plenary: Philip McCord Morse Lecture	**MCC - Davidson Ballroom, Level 1M**	**10–10:50am**
Technical Sessions (MB)	**Music City Center & Omni**	**11am–12:30pm**
Education Committee Meeting	Omni - Broadway D, 2nd Floor	11am–12noon
Lunch Break (on your own)		12noon–1:30pm
Sections/Societies Officers Lunch (invite only)	Omni - Broadway J, 2nd Floor	12noon–1:30pm
Bonder Scholarship Lunch	Omni - Broadway A, 2nd Floor	12:30–1:30pm
COIN-OR Members & Users	Omni - Broadway H, 2nd Floor	12:30–1:30pm
PSOR Business Meeting	Omni - Legends E, 2nd Floor	12:30–1:30pm
MOOR Editorial Board Meeting (invite only)	Omni - Broadway K, 2nd Floor	12:30–2pm
Poster Session & Competition	MCC - Exhibit Hall A, Level 3	12:30–2:30pm
Publications/Editors-in-Chief Meeting	Omni - Broadway C, 2nd Floor	12:30–3:30pm
Fellows Lunch (invite only)	Omni - Legends D, 2nd Floor	12:45–2:30pm
Technical Sessions (MC)	**Music City Center & Omni**	**1:30–3pm**
Subdivisions Council	Omni - Broadway D, 2nd Floor	2:30–4:30pm
Analytics Program Director Meeting	MCC - Executive Boardroom, Level 3	3–4pm
Plenary: Omega Rho – 40th Year Anniversary Panel	**MCC - Davidson Ballroom, Level 1M**	**3:10–4pm**
Coffee Break	MCC - Exhibit Hall A, Level 3	4–4:30pm
Omega Rho Reception (invite only)	MCC - Davidson Ballroom A, Level 1M	4:30–6pm
Technical Sessions (MD)	**Music City Center & Omni**	**4:30–6pm**
INFORMS Community Meetings	See p. 6	
Interfaces Editorial Board Meeting (invite only)	Omni - Broadway B, 2nd Floor	6:15–7:15pm
International Activities Reception	Omni - Broadway G, 2nd Floor	7:30–9pm
Student Awards Reception	Omni - Broadway EF, 2nd Floor	7:30–9:30pm
WORMS Networking/Dessert Reception	Frothy Monkey (off-site)	8–10pm

TUESDAY, NOVEMBER 15

INFORMS Registration	MCC - Exhibit Hall A, Level 3	7am–5pm
Chapters/Fora Officers Breakfast	Omni - Broadway F, 2nd Floor	7–8am
IFORS Members Societies Representatives Breakfast	Omni - Broadway J, 2nd Floor	7–8am
Transportation Science Associate Editors (invite only)	Omni - Broadway K, 2nd Floor	7:30–9am
Student Chapter Officers Meeting	Omni - Broadway F, 2nd Floor	8–8:45am
Technical Sessions (TA)	**Music City Center & Omni**	**8–9:30am**
Exhibits, Career Center, Technology Center	MCC - Exhibit Hall A, Level 3	9am–5pm
INFORMS Center, Networking Lounge	MCC - Exhibit Hall A, Level 3	9am–5pm
Visit Music City	MCC - Exhibit Hall A, Level 3	9am–5pm
Coffee Break	MCC - Exhibit Hall A, Level 3 / Omni - 2nd Floor	9:30–10am
Smyrna Vehicle Assembly Plant Tour (ticketed event)	MCC - 6th Ave Exit, Near Rooms 210-214	9:30–11:30am
Plenary: Suvrajeet Sen & Gareth James, Univ. of Southern Calif.	**MCC - Davidson Ballroom, Level 1M**	**10–10:50am**
Technical Sessions (TB)	**Music City Center & Omni**	**11am–12:30pm**
Lunch Break (on your own)		12noon–1:30pm
IJOC Editorial Board Meeting (invite only)	Omni - Broadway G, 2nd Floor	12:30–1:30pm
Women in OR/MS Lunch (ticketed event)	Omni - Broadway F, 2nd Floor	12:30–1:30pm
Poster Session & Competition	MCC - Exhibit Hall A, Level 3	12:30–2:30pm
Technical Sessions (TC)	**Music City Center & Omni**	**1:30–3pm**
Keynote: Wagner Prize Winner Reprise	**MCC - Davidson Ballroom A, Level 1M**	**3:10–4pm**
Keynote: Jason Murray, Amazon	**MCC - Davidson Ballroom B, Level 1M**	**3:10–4pm**
Keynote: Edelman Reprise: UPS	**MCC - Davidson Ballroom C, Level 1M**	**3:10–4pm**
Coffee Break	MCC - Exhibit Hall A, Level 3 / Omni - 2nd Floor	4–4:30pm
Technical Sessions (TD)	**Music City Center & Omni**	**4:30–6pm**
Exhibitor & Organizing Committee Reception	Omni - Broadway JK, 2nd Floor	5–6pm
INFORMS Community Meetings	See p. 6	
General Reception	MCC - Grand Ballroom, Level 4	7:30–9:30pm

WEDNESDAY, NOVEMBER 16

INFORMS Registration	MCC - Exhibit Hall A, Level 3	7am–4:30pm
Technical Sessions (WA)	**Music City Center & Omni**	**8–9:30am**
Exhibits, Career Center, Technology Center	MCC - Exhibit Hall A, Level 3	9am–3pm
INFORMS Center, Networking Lounge	MCC - Exhibit Hall A, Level 3	9am–3pm
Coffee Break	MCC - Exhibit Hall A, Level 3 / Omni - 2nd Floor	9:30–10am
Keynote: Edmund Jackson, HCA	**MCC - Davidson Ballroom A, Level 1M**	**10–10:50am**
Keynote: Gerald Brown, Naval Postgraduate School	**MCC - Davidson Ballroom B , Level 1M**	**10–10:50am**
Keynote: Stephen Prather, SportSource Analytics	**MCC - Davidson Ballroom C, Level 1M**	**10–10:50am**
Technical Sessions (WB)	**Music City Center & Omni**	**11am–12:30pm**
Technical Sessions (WC)	**Music City Center & Omni**	**12:45–2:15pm**
Coffee Break	MCC - Exhibit Hall A, Level 3 / Omni - 2nd Floor	2:15–2:45pm
Technical Sessions (WD)	**Music City Center & Omni**	**2:45–4:15pm**
Technical Sessions (WE)	**Music City Center & Omni**	**4:30–6pm**

MCC - Music City Center | **Omni** - Omni Hotel

SUNDAY, NOVEMBER 13

Information Systems	Omni - Legends D, 2nd Floor	5:15–6:15pm
Aviation Applications	MCC - 107A, Level 1	6:15–7:15pm
Decision Analysis Society Council	Off-Site	6:15–7:15pm
ENRE Section	MCC - 101D, Level 1	6:15–7:15pm
Forum on Education (INFORM-ED)	MCC - 211, Level 2	6:15–7:15pm
Location Analysis Section	MCC - 107B, Level 1	6:15–7:15pm
Manufacturing & Service Operations Society	MCC - Davidson B, Level 1M	6:15–7:15pm
Minority Issues Forum	MCC - 105A, Level 1	6:15–7:15pm
Military Applications Society Board	MCC - 108, Level 1	6:15–7:15pm
Multiple Criteria Decision Making	MCC - 105B, Level 1	6:15–7:15pm
Optimization	MCC - Davidson A, Level 1M	6:15–7:15pm
Railway Applications	Off-Site	6:15–7:15pm
Revenue Management & Pricing	MCC - 207D, Level 1	6:15–7:15pm
Telecommunications Section	MCC - 110A, Level 1	6:15–7:15pm
Transportation Science & Logistics Society Board	MCC - 110B, Level 1	6:15–7:15pm
Simulation	MCC - 209A, Level 2	6:15–7:15pm
Women in OR/MS	MCC - 212, Level 2	6:15–7:15pm
Revenue Management & Pricing Board Meeting	MCC - 207D, Level 2	7:15–8:15pm

MONDAY, NOVEMBER 14

PSOR	Omni - Legends E, 2nd Floor	12:30–1:30pm
DM, QSR, & Artificial Intelligence	MCC - Davidson B, Level 1M	6–8pm
Analytics	MCC - 104D, Level 1	6:15–7:15pm
Applied Probability	MCC - 207A, Level 2	6:15–7:15pm
Computing	MCC - 106B, Level 1	6:15–7:15pm
CPMS Isolated Practitioners Workshop	MCC - 109, Level 1	6:15–7:15pm
Decision Analysis	MCC - 208A, Level 2	6:15–7:15pm
e-Business	MCC - 107A, Level 1	6:15–7:15pm
Financial Services	MCC - 207C, Level 2	6:15–7:15pm
Health Applications	MCC - Davidson C, Level 1M	6:15–7:15pm
Military Applications Society	MCC - 108, Level 1	6:15–7:15pm
Social Media Analytics	MCC - 210, Level 2	6:15–7:15pm
Tech., Innovation Mgmt., & Entrepreneurship	MCC - 107B, Level 1	6:15–7:15pm
TSL	MCC - Davidson A, Level 1M	6:15–7:15pm
Behavioral Operations Management	MCC - 109, Level 1	7:15–8:15pm
Military Applications Reception	MCC - 108, Level 1	7:15–10:15pm

TUESDAY, NOVEMBER 15

SpORts	Baileys Sports Grille (off-site)	6:00–7:00pm
CPMS Section Membership Reception	Palm Restaurant (off-site)	6:15–7:15 pm
Service Science	MCC - 107A, Level 1	6:45–7:30pm

UNIVERSITY RECEPTIONS

MONDAY, NOVEMBER 14

Texas A&M University	Omni - Legends A, 2nd Floor	5:30–7:30pm
Princeton University	Omni - Broadway H, 2nd Floor	TBA
Tepper School of Business - Carnegie Mellon University	Omni - Legends E, 2nd Floor	6–8pm
University of Florida	Omni - Legends F, 2nd Floor	6–7:30pm
University of Texas at Austin (Sponsored by: IROM & ORIE)	Omni - Broadway D, 2nd Floor	7–9pm
University of Notre Dame	Omni - Broadway A, 2nd Floor	7–9pm
Cornell University	Omni - Legends C, 2nd Floor	7:15–8:15pm
Northwestern University	Omni - Broadway C, 2nd Floor	7:30–9:30pm

All Technology Tutorials will take place in the Music City Center, 5th Avenue Lobby.

AIMMS 48
www.aimms.com

AIMMS is an innovative technology company with offices in Europe, the U.S. and Asia. Half of the global Fortune top 20 corporations rely on AIMMS because of our unique analytics, modeling and optimization platform that supports both strategic and daily operational challenges such as supply chain optimization, strategic sourcing, pricing, workforce optimization, portfolio optimization and production planning and scheduling.

Amazon 54
www.amazon.com

Amazon's mission is to be Earth's most customer-centric company where people can find and discover anything they want to buy online. Amazon's evolution from website to e-commerce and publishing partner to development platform is driven by the pioneering spirit that is part of the company's DNA. The world's brightest technology minds come to Amazon to research and develop new technologies that improve the lives of our customers: shoppers, sellers, content creators, and developers around the world. Because that's what being Earth's most customer-centric company is all about, and it's still Day 1 at Amazon.

AMPL Optimization Inc. 32
www.ampl.com

AMPL's modeling language and system give you an exceptionally powerful and natural tool for developing and deploying the complex optimization models that arise in diverse business applications. AMPL lets you formulate problems the way you think of them, while providing access to the advanced algorithmic alternatives that you need to find good solutions fast. It features an integrated scripting language for automating analyses and building iterative optimization schemes; access to spreadsheet and database files; and application programming interfaces for embedding within larger systems. AMPL works with over 30-powerful optimization engines including all of the most widely used large-scale solvers.

Monday, November 14, 5:15–6pm

***Technology Tutorial:** AMPL in the Cloud: Using Online Services to Develop and Deploy Optimization Applications through Algebraic Modeling Robert Fourer, President AMPL Optimization Inc., 4er@ampl.com. Optimization modeling systems first appeared online almost 20 years ago, not long after web browsers came into widespread use. This presentation describes the evolution of optimization alternatives in what has come to be known as cloud computing, with emphasis on the role of the AMPL modeling language in making models easy to develop and deploy. We start with the pioneering free NEOS Server, and then compare more recent commercial offerings such as Gurobi Instant Cloud; the benefits of these solver services are readily leveraged through their use with the AMPL modeling tools. We conclude by introducing QuanDec, which creates web-based collaborative applications from AMPL models. Robert Fourer, an authority on the design and implementation of computer software to support large-scale optimization, studied at MIT and Stanford and was a professor of Industrial Engineering and Management Sciences for over 30 years. He is a founder and is currently President of AMPL Optimization Inc. and is co-author of a popular book on modeling in the AMPL language.*

AnyLogic North America, LLC 27
www.anylogic.com

AnyLogic Software–the first and only tool that brings together System Dynamics, Process-centric (Discrete Event), and Agent Based methods within one modeling language and one model development environmentis–the leading provider of dynamic simulation tools, technologies and consulting services for business applications. The language of AnyLogic has unmatched flexibility enabling modelers to capture the complexity of business, economy and social systems at any level of detail to gain deeper insight into interdependent processes inside and around an organization.

Artelys 47
www.artelys.com

Artelys is a global provider of decision-support solutions through numerical optimization and analytics technologies, with offices in France, United States, Canada and UK. The organization is particularly active in the energy & environment, logistics & transportation, telecommunications, finance and defense sectors with half of their clients coming from the top French stock market index (CAC 40). Artelys offers a superior level of expertise to help governments and commercial entities with highly qualified consultants. The company also develops and supports a comprehensive portfolio of efficient and robust optimization tools such as Artelys Kalis, FICO Xpress Optimization suite, Knitro and AMPL. In addition, many of our customers are professional who use the Artelys Crystal suite, a set of user-friendly software dedicated to the optimization of energy and transportation systems. Artelys offers comprehensive and flexible solutions that range from functional analysis and organizational architecture design to implementation of solutions and operational tools.

Monday, November 14, 8:45–9:30am

***Technology Tutorial:** Solving Large Least-Squares Models with the Artelys Knitro Nonlinear Optimization Solver. Presenting Author: Richard Waltz, Senior Scientist, Artelys Corp, richard.waltz@artelys.com. Artelys Knitro is the premier solver for nonlinear optimization problems. This software demonstration will highlight the latest Knitro developments, including a new specialized API, as well as enhanced algorithms, for large-scale nonlinear least-squares models. We will demonstrate how to solve least-squares models using Knitro through a variety of interfaces such as R, MATLAB and C/C++, and also provide some benchmarking results. In addition, we will summarize some of the other recent developments in Knitro.*

Bayesia, USA 33
www.bayesialab.com

Bayesian Networks & BayesiaLab: Artificial Intelligence for Research, Analytics, and Reasoning. The objective of this workshop is to show that "Artificial Intelligence" should not be perceived as a quasi-magic technology that is mostly incomprehensible to normal mortals. We want to illustrate how scientists in any field of study—rather than only computer scientists—can employ AI to explore complex problems. For this purpose, we present Bayesian networks as the framework and BayesiaLab as the software platform. In this context, we demonstrate BayesiaLab's supervised and unsupervised machine learning algorithms for knowledge discovery in high-

All Technology Tutorials will take place in the Music City Center, 5th Avenue Lobby.

dimensional, unknown domains. Also, while AI is commonly associated with another buzzword, "Big Data", we wish to prove that AI can be useful for dealing with problems for which we possess little or no data. Here, expert knowledge modeling is critical, and we describe how even a minimal amount of expertise can serve as a basis for sound reasoning aided by AI.

Sunday, November 13, 11:45am–12:30pm

Technology Tutorial: *AArtificial Intelligence in Marketing Science: Marketing Mix Modeling and Optimization with Bayesian Networks & BayesiaLab , "Half the money I spend on advertising is wasted; the trouble is I don't know which half." Various versions of this quote have been attributed to John Wanamaker, Henry Ford, and Henry Procter, yet 100 years after these marketing pioneers, in this day and age of big data and advanced analytics, the quote still rings true. The current practice is often "more art than science." The lack of a well-established marketing mix methodology has little to do with the domain itself. Rather, it reflects the fact that marketing is yet another domain that typically has to rely on nonexperimental data for decision support. Marketing mix modeling is a causal problem, which means we are not looking for a prediction of an outcome based on the observation of marketing variables, but attempting to manipulate the marketing variables to optimize the outcome. Thus, we must simulate interventions, not observations, and switch from observational to causal inference. This brings us to deriving causal inference from observational data. We introduce the fundamental concepts of graphical models and how they can help us perform causal identification, i.e., determine whether it is possible to estimate causal effects from observational data, which requires causal assumptions about the domain plus a decision criterion, e.g., the Adjustment Criterion. However, the complexity of the marketing domain limits the practical application of this criterion. We introduce the Disjunctive Cause Criterion, which reduces the number of assumptions required for causal identification and, thus, confounder selection. Proceeding from causal identification to estimation requires an "inference engine." In the simplest case, we could use a regression, but with dozens of interacting variables, that is not practical. Instead we use Artificial Intelligence by employing BayesiaLab's machine-learning algorithms, which builds a high-dimensional Bayesian network model that represents the joint probability distribution of all variables. This causal inference engine plus BayesiaLab's Target Optimization algorithm enable us to search efficiently for the ideal marketing mix.*

Cambridge University Press 34
www.cambridge.org/academic

Cambridge University Press' publishing in books and journals combines state-of-the-art content with the highest standards of scholarship, writing and production. Visit our stand to browse new titles, available at 20% discount, and to pick up sample copies of our journals. Visit our website to find out more about what we do.

Clemson University/COIN-OR Foundation 23
www.coin-or.org

The Computational Infrastructure for Operations Research publishes high quality, free, open-source tools for OR professionals and students, suitable for commercial, educational, and personal use. COIN-OR is the place to go when you need a "white box" for algorithm research and development. COIN-OR is a strategic partner of the INFORMS Computing Society.

Cornell Tech 7
http://tech.cornell.edu

At Cornell Tech, students across programs learn and work side-by-side, spending one-third of their experience together working on a studio-based core curriculum. They collaborate with the tech industry and postdoc-level researchers to build start-up companies and new products. By bringing these talents together at the start, there is enormous potential for better, more impactful and ultimately more successful companies and products. Programs offered: Master of Engineering in Computer Science, Master of Engineering in Electrical and Computer Engineering, Master of Engineering in Operations Research and Information Engineering, Technion-Cornell Dual Degree in Connective Media, Technion-Cornell Dual Degree in Health Tech, Johnson Cornell Tech MBA, and Master of Laws in Law, Technology and Entrepreneurship.

Darden Business Publishing 16
http://store.darden.virginia.edu

Darden Business Publishing markets case-based educational materials written by the renowned faculty at the University of Virginia Darden School of Business. Darden maintains a catalogue of student-centered learning materials that energize classrooms around the world with dynamic interactive simulations and thought-provoking paper cases.

Dynamic Ideas, LLC 49
www.dynamic-ideas.com

Dynamic Ideas, LLC is a publisher of scientific books that have quality and originality in the areas of Operations Research and Applied Mathematics. The key objective of our titles is to "educate the next generation." Many of our books are currently being used as the main textbook in academic courses in some of the finest universities and research institutions in the world.

Elsevier 26
www.elsevier.com/decisionsciences

Elsevier publishes leading journals in OR/MS and Decision Sciences, including *European Journal of Operational Research*, *Computers & Operations Research*, and *Omega-International Journal of Management Science*. Elsevier journals occupy 7 of the Top 10 Impact Factor positions in the Thomson Reuters 'Operations Research & Management Science' category. Come to the booth to find out more, including how to use Elsevier's researcher centric tools to develop your research.

FDA/Center for Drug Evaluation and Research 38
www.fda.gov/drugs

The Center for Drug Evaluation and Research (CDER) performs an essential public health task by making sure that safe and effective drugs are available to improve the health of people in the United States.

All Technology Tutorials will take place in the Music City Center, 5th Avenue Lobby.

FICO 5

www.fico.com

FICO is a leading analytics software company, helping businesses in 90+ countries make better decisions that drive higher levels of growth, profitability and customer satisfaction. The company's groundbreaking use of Big Data and mathematical algorithms to predict consumer behavior has transformed entire industries. FICO provides analytics software and tools used across multiple industries to manage risk, fight fraud, build more profitable customer relationships, optimize operations and meet strict government regulations. Many of our products reach industry-wide adoption. These include the FICO® Score, the standard measure of consumer credit risk in the United States. FICO solutions leverage open-source standards and cloud computing to maximize flexibility, speed deployment and reduce costs. The company also helps millions of people manage their personal credit health.

Tuesday, November 15, 4:30–5:15pm

Technology Tutorial: *How to deploy your analytic models to empower non-technical business users. You have a team with great analytics background. They have developed advanced analytical tools using SAS, Python, R, or with your current traditional optimization solver. They have derived crucial insights from your data, and figured out how your decisions shape your customers' behaviors. Now it's time to put these critical analytical insights in the hands of your non-technical business users. In this tutorial, we will cover how FICO's Optimization Suite (including Xpress and Optimization Modeler) make it possible to embed your analytic models in user-friendly business-user facing applications. Learn how you can supercharge your analytic models with simulation, optimization, reporting, what-if analysis and agile extensibility.*

Frontline Systems, Inc. 39

www.solver.com

Frontline Systems is democratizing analytics, enabling business analysts and developers to get results quickly with just a browser, spreadsheet, or programming language, instead of expensive enterprise software with steep learning curves. See how easily you can solve optimization, simulation/risk analysis, forecasting and data mining problems–starting for free, and scaling up easily to the largest models, using AnalyticSolver.com, Analytic Solver® for desktop Excel, and our RASON® modeling language and REST API. Use our Solver and XLMiner® SDKs for C#, Java, C++, R and Python to create your own analytics applications. Find your fastest path to real analytics results.

Tuesday, November 15, 8–8:45am

Technology Tutorial: *AnalyticSolver.com: Data Mining, Simulation and Optimization in Your Web Browser. AnalyticSolver.com is the new, simple, point-and-click way to create and run analytic models using only your web browser – that also works interchangeably with your spreadsheet. Whether you need forecasting, data mining and text mining, Monte Carlo simulation and risk analysis, and conventional and stochastic optimization, you can "do it all" in the cloud. We'll show how you can upload and download Excel workbooks, pull data from SQL Server databases and Apache Spark Big Data clusters, solve large-scale models, and visualize results – without leaving your browser. If you're more comfortable working on your own laptop or server, we'll show how you can do that, too.*

GAMS Development Corp 4

www.gams.com

The General Algebraic Modeling System (GAMS) is a high-level modeling system for mathematical programming and optimization. It consists of a language compiler and a stable of integrated high-performance solvers. GAMS is tailored for complex, large-scale modeling applications, and allows you to build large maintainable models that can be adapted to new situations. Come to our booth to learn more about GAMS or ask for an evaluation license. Visit our technology workshop or software demo.

Monday, November 14, 1:30–2:15pm

Technology Tutorial: *We demonstrate many of the capabilities of the GAMS software as we start with a simple optimization model and build it out by adding nonlinear and integer variables to the model and connecting it with a GUI in a sample application.*

Gurobi Optimization 21

www.gurobi.com

Gurobi Optimization is dedicated to helping our users succeed with optimization. We provide the leading math programming solvers, offering best-in-class performance as well as a broad array of tools for developing and deploying optimization applications on top of these solvers. We support all of the most popular programming languages, as well as client-server architectures, cloud computing, and distributed optimization. We also provide outstanding, easy-to-reach support and transparent, no-surprises pricing.

Monday, November 14, 4:30–5:15pm

Technology Tutorial: *Advanced Python Modeling with Gurobi. Are you looking for an environment that combines the expressiveness of a modeling language with the power and flexibility of a programming language? The Gurobi Python interface allows you to build concise and efficient optimization model, using high-level modeling constructs. This tutorial will provide an overview of these capabilities, including an introduction to new modeling features that significantly enhance the expressiveness of our environment.*

IBM 35

www.ibm.com

Critical business decisions can be made with ease when you know what is likely to happen in the future and how you should respond. IBM is paving the way to the next generation of analytics solutions and platforms by combining descriptive, predictive and prescriptive analytics with the power of cloud and cognitive insights. These advanced analytics capabilities provide robust; user friendly platforms aimed at helping you solve even the most complex business and research problems. Visit the IBM Advanced Analytics booth to learn more

Monday, November 14, 11:45am–12:30pm

Technology Tutorial: *IBM Decision Optimization: Performance gains and New features in CPLEX and CP Optimizers. In this tutorial, you will learn about the new CPLEX and CP Optimizer engine features in the upcoming IBM CPLEX Optimization Studio release, including how to use the new features, how they can help you during the development of your model, and how they can speed up the resolution of your models.*

All Technology Tutorials will take place in the Music City Center, 5th Avenue Lobby.

IFORS 11
www.IFORS.org

The International Federation of Operational Research Societies (IFORS) is an umbrella organization comprising the national Operations Research societies of over 45 countries from four geographical regions: Asia Pacific, Europe, North America, South America. Total membership is over 30,000 persons. IFORS' mission is to promote Operations Research as an academic discipline and a profession.

Ivey Publishing 9
www.iveycases.com

Ivey Publishing is the leader in providing business case studies with a global perspective. With over 35,000 products in our library, Ivey Publishing adds more than 350 classroom-tested case studies each year. Virtually all Ivey cases have teaching notes. Clear, concise, and current, Ivey cases are lauded by the academic community as meeting the rigorous demands of management education by responding to the ever changing needs of business and society. Meet with one of our case experts on how to publish with us and how you can integrate world-class cases into your curriculum.

LINDO Systems, Inc. 29
www.lindo.com

Operations Research professionals across nearly every industry for over 30 years. LINDO offers a full range of solvers to cover all your optimization needs. The Linear Programming solvers handle million variable/constraint problems fast and reliably. The Quadratic/SOCP/Barrier solver efficiently handles quadratically constrained problems. The Integer solver works fast and reliably with LP, QP and NLP models. The Global NLP solver finds the guaranteed global optimum of non-convex models. The Stochastic Programming solver has a full range of capabilities for planning under uncertainty.

Get all the tools you need to get up and running quickly. LINDO provides a set of versatile intuitive interfaces to suit your modeling preference. What's best is an add-in to Excel that you can use to quickly build spreadsheet models that managers can use and understand. LINDO has a full featured modeling language for expressing complex models clearly and concisely, and it has links to Excel and databases that make data handling easy. LINDO API is a callable library that allows you to seamlessly embed the solvers into your own applications. You can pick the best tool for the job based upon who will build the application, who will use it, and where the data reside. Technical support at LINDO is responsive and thorough - whether you have questions about the software or need some guidance on handling a particular application.

Monday, November 14, 2:15–3pm

Technology Tutorial: *Optimization Modeling Made Easy. Presenter: Mark Wiley, VP Marketing, mwiley@lindo.com. Come and learn how easy it is to: quickly build linear, nonlinear, quadratic, conic and integer optimization models; incorporate uncertainty into optimization models; easily access data from Excel and databases; seamlessly embed a solver into your own application. Come and see a demonstration of the power and flexibility of the new releases of: LINDO API – a callable solver engine, LINGO – an integrated modeling language and solvers, for Excel.*

MathWorks 8
www.mathworks.com

The MATLAB and Simulink product families are fundamental applied math and computational tools at the world's educational institutions. Adopted by more than 5,000 universities and colleges, MathWorks products accelerate the pace of learning, teaching, and research in engineering and science. MathWorks products also help prepare students for careers in industry worldwide, where the tools are widely used for data analysis, mathematical modeling, and algorithm development in collaborative research and new product development. Application areas include data analytics, mechatronics, communication systems, image processing, computational finance, and computational biology.

Monday, November 14, 8–8:45am

Technology Tutorial: *Data Analytics with MATLAB. Mary Fenelon, Product Manager, MathWorks, mary.fenelon@mathworks.com. Using data analytics to turn large volumes of complex data into actionable information can help you improve engineering design and decision-making processes. However, developing effective analytics and integrating them into business systems can be challenging. In this session you will learn approaches and techniques available in MATLAB to tackle these challenges through an example showing steps of data access, exploration, predictive and prescriptive model development, and deployment.*

Military Operations Research Society 10
www.mors.org

MORS is a professional society of nearly 1,000 operations researchers and national security analysts. Since 1966 MORS' mission has been to enhance the quality of analysis to address real world national security interests through the advancement of the operations research profession. Today MORS services include the Annual MORS Symposium with 500+ classified and unclassified sessions, year-round communities of practice, geographic chapters, an annual Education and Professional Development Colloquium for students and young analysts, classified and unclassified special meetings/workshops, tutorials and CEU Courses, *Phalanx* the magazine of national security analysis and a catalog of original books, reports and republished historical manuals.

MIT Sloan 52
www.mitsloan.mit.eduu

MIT Sloan is a mission-driven organization. We develop principled, innovative leaders who improve the world and generate ideas that advance management practice. Our diversified, specialized, and action-oriented curriculum exemplifies our commitment to balancing innovative ideas and theories with hands-on, real-world application. The coursework at MIT Sloan is markedly rigorous and further distinguished by emphasis on real-world engagement that turns innovative ideas into practical solutions to the world's problems. MIT Sloan School offers a variety of degree programs to help you advance your career. The two-year full time MBA program allows you to customize your curriculum to focus on specific areas of interest. Optional tracks and certificates in Enterprise Management, Entrepreneurship & Innovation, Finance, Healthcare, and

Sustainability help you dive more deeply into your career interests. For students interested in careers in finance or data analytics, MIT Sloan has innovative programs to help them succeed. The new one-year Master of Business Analytics (MBAn) program is tailored for graduating college seniors and early-stage professionals. This innovative program features Action Learning labs, collaboration with other MIT Sloan programs, a Summer Capstone project, career support, and tailored electives in statistics, finance, economics, and operations research. The program answers the industry's demand for a skilled pool of graduates who can apply data science to solve business challenges. The 12-month and 18-month Master of Finance (MFin) program is designed for students who want to become leaders in the field of finance. The MFin program combines in-depth study of quantitative techniques with practical problem solving and the 18-month pilot allows time for a summer internship. MIT Sloan is about invention. It's about ideas that are made to matter. At MIT Sloan, we discover tomorrow's interesting and important challenges and opportunities. We go where we want to have impact. And then, we invent the future.

MOSEK ApS 46

https://mosek.com

MOSEK ApS provides optimization software to help clients making better decisions. It specializes in creating advanced software for solution of mathematical optimization problems. In particular, the company focuses on solution of large-scale linear, quadratic, and conic optimization problems. MOSEK ApS was established in 1997 by Erling D. Andersen and Knud D. Andersen. Our customer base consists of financial institutions and companies, engineering and software vendors, among others.

Neusrel/Success Drivers 19

www.neusrel.com

NEUSREL is the leading software for exploring cause-effect networks using the Universal Structure Modeling approach. Because it leverages machine learning techniques it is a self-learning system and the only methodology to explore previously not hypnotized nonlinearities (of any form) or interactions (of any type). It is the first system meeting the need of researcher to explore success factors instead of just falsifying a given set of hypothesis. It bridges the largely relevant gap between qualitative exploration and statistical testing/modeling. NEUSREL Causal Analytics is dedicated to provide software as well as training and statistical consulting to the academic community.

Tuesday, November 15, 2:15–3pm

Technology Tutorial: NEUSREL is a self-learning causal analysis software and leverages Advanced Machine Learning techniques. It builds cause-effect networks (path models) in order to understand the impact and role of success factors. The software is the only solution worldwide that is able to explore unexpected nonlinearities and unexpected interactions – a capability that not only led to largely increased explanation power but turned out to be crucial when understanding true key drivers of outcomes. The software is applied in all fields where many factors drive a particular outcome and therefore it is not clear how important those are and how they interact.

North Carolina State University 51

www.ise.ncsu.edu

Within NC State's renowned College of Engineering, the Edward P. Fitts Department of Industrial and Systems Engineering (ISE) is among the top ranked programs in the country by *US News & World Report*. The department has created a legacy of success by partnering with industry, government and universities while producing engineers with cutting edge ingenuity, interpersonal skills and business acumen. The College ranks ISE #1 in student satisfaction, job placement and job placement in their field of study. Currently, there are more companies looking to hire our students than there are candidates to fill those positions.

Now Publishers 30

www.nowpublishers.com

Now Publishers publishes a suite of reference journals called *Foundations and Trends* including *Information Systems, Machine Learning, Operations Management, Optimization*, and *Systems and Control*, academic journals including the *DEA Journal* and *Review of Behavioral Economics*, and scholarly books in the fields of business and technology. We will also represent World Scientific who publishes about 600 new titles a year and 130 journals in various fields. Started in 1981, it has established itself as one of the leading scientific publishers in the world, and the largest international scientific publisher in the Asia-Pacific region.

Optimization Direct Inc. 24

www.optimizationdirect.com

Optimization Direct Inc., markets IBM® ILOG® CPLEX Optimization Studio®, the world's leading software product for modeling and optimization. CPLEX Optimization Studio solves large-scale optimization problems and enables better business decisions and resulting financial benefits in areas such as supply chain management, operations, healthcare, retail, transportation, logistics and asset management. It has been applied in sectors as diverse as manufacturing, processing, distribution, retailing, transport, finance and investment.

Monday November 14, 11–11:45am

Technology Tutorial: *Recent advancements in Linear and Mixed Programing give us the capability to solve larger Optimization Problems. CPLEX Optimization Studio solves large-scale optimization problems and enables better business decisions and resulting financial benefits in areas such as supply chain management, operations, healthcare, retail, transportation, logistics and asset management. In this tutorial using CPLEX Optimization Studio, we will discuss modeling practices, case studies and demonstrate good practices for solving Hard Optimization Problems. We will also discuss recent CPLEX performance improvements and recently added features.*

All Technology Tutorials will take place in the Music City Center, 5th Avenue Lobby.

Palgrave Macmillan — 6

www.palgrave.com

Palgrave Macmillan is proud to publish a unique cross-section of high-quality research work fundamental to understanding contemporary issues and developments in operations research and information technology. Our growing portfolio in this area includes the journals of the OR Society and the OR Essentials series. With offices in London and New York, and sales teams across 50 countries, we have a global reach, and as part of Springer Nature, are proud to uphold an unbroken tradition of over 170 years of academic publishing.

Palisade Corporation — 53

www.palisade.com

Palisade Corporation is the maker of the market leading risk and decision analysis software @RISK and the DecisionTools® Suite. Virtually all Palisade software adds in to Microsoft Excel, ensuring flexibility, ease-of-use, and broad appeal across a wide range of industry sectors. Free trial downloads at www.palisade.com.

Sunday, November 13, 11–11:45am

Technology Tutorial: *Introduction to Risk and Decision Analysis using @RISK and The DecisionTools Suite. This software presentation is designed to provide an entry-level introduction into probabilistic analysis and will show how Monte Carlo simulation and other techniques can be applied to your everyday business analyses. Using Monte Carlo simulation, @RISK will analyze many different scenarios all at once, giving you more insight into what could happen. We'll look at example models including a basic revenues/cost/profits model, an NPV model, and a Cost Estimation model, to give you an idea of how quickly you can get started in probabilistic modeling in Excel. If you build models in Excel then Palisade solutions can almost certainly help you to make more informed decisions, right from your desktop. For more than 30 years, Palisade software and solutions have been used to make better decisions. Cost estimation, NPV analysis, operational risk registers, portfolio analysis, insurance loss modeling, reserves estimation, schedule risk analysis, budgeting, sales forecasting, and demand forecasting are just some of the ways in which the tools are applied. This presentation will demonstrate how easy – and necessary – it is to implement quantitative risk analysis in any business.*

Princeton Consultants — 20

www.princeton.com

Founded in 1980, Princeton Consultants blends advanced analytics, data science, software development and management consulting to help industry leaders and fast-growing innovators transform performance. Based on our track record of developing and implementing critical operational systems, we review and improve optimization and predictive analytics models through our quality assurance service. We are a member of the INFORMS Roundtable.

Provalis Research — 28

www.provalisresearch.com

Provalis Research is a leading developer of text analytics software with groundbreaking qualitative and quantitative analysis programs, such as QDA Miner, an innovative mixed-methods qualitative data analysis software; WordStat, a powerful add-on module for computer assisted content analysis and text mining; and Simstat, an easy yet powerful statistical software. One of the most distinctive features of these tools is their interoperability, allowing researchers to integrate numerical and textual data into a single project file and to seamlessly move back and forth between quantitative and qualitative data analysis, as well as to easily explore relationships between numerical and textual data.

Sunday, November 13, 1:30–2:15pm

Technology Tutorial: *Provalis Research will showcase its integrated collection of text analytics software.*
QDA Miner is an easy-to-use qualitative and mixed methods software that meets the needs of researchers performing qualitative data analysis and would like to code more quickly and more consistently larger amounts of documents. It offers high level computer assistance for qualitative coding with innovative text search tools that help users speed up the coding process as well as advanced statistical and visualization tools. Users with even bigger text data can also take advantage of WordStat. This add-on module to QDA Miner can be used to analyze huge amounts of unstructured information, quickly extract themes, find trends over time, and automatically identify patterns and references to specific concepts using categorization dictionaries.

Responsive Learning Technologies — 18

www.responsive.net

Responsive Learning Technologies provides compelling business simulations to teach Operations Management and Supply Chain Management in a dynamic context and adaptive self-study software to help students prepare for beginning a degree program. Our software has enriched courses at the undergraduate, graduate, and executive levels for thousands of students at hundreds of institutions in dozens of countries. Our products are developed with leading scholars, to achieve well-defined learning objectives.

RPI, Lally School of Business — 45

https://lallyschool.rpi.edu

At the Lally School of Management at Rensselaer Polytechnic Institute in Troy, NY, we develop aspiring business leaders who have a passion for innovation with the ability to work across business functions. Our programs are built around innovation, technology, and entrepreneurship in the global economy. The Lally School offers eight undergraduate concentrations including: Accounting, Business Analytics, Entrepreneurship, Finance, International Management, Management Information Systems, Marketing, and Supply Chain Management. It also offers an MBA; MS degrees in business analytics, supply chain management, technology commercialization and entrepreneurship, quantitative finance and risk analytics, or management; and a PhD in management.

All Technology Tutorials will take place in the Music City Center, 5th Avenue Lobby.

SAS - GAP/EDU 2

www.sas.com

SAS is the leader in analytics. Through innovative analytics, business intelligence and data management software and services, SAS helps customers at more than 80,000 sites make better decisions faster. Since 1976, SAS has been giving customers around the world THE POWER TO KNOW®.

Tuesday, November 15, 8:30–9:30am

Technology Tutorial: *Analysis of a Presidential Debate Using SAS Text Analytics. Presenter: Andre de Waal. During the last year of a presidential term in the United States of America, the race to the White House has everybody excited. News channels and newspapers provide "expert" analysis of day to day events. However, many of the expert opinions are biased and reflect a commentator's political viewpoint or affiliation. Can text mining be used to look at the data objectively and cut through the political rhetoric? In this talk, a script of one of the 2016 presidential debates is analyzed with SAS Text Miner. An attempt is made to look at the data "objectively" and to let the data speak. Words are counted and stemmed, documents are grouped into clusters, topics are identified and candidates are analyzed while trying to determine what separates one candidate from the rest of the field. Although it is impossible to predict using text mining alone who will win the presidential election, text mining could provide some insight into the election process (of which the debates are an integral part) that is not generally available to the general populace and might influence their choice of presidential candidate.*

SAS Institute Inc. 1

www.sas.com

The effective use of analytics is more important than ever for today's organizations. The most effective analytics are coordinated, and the best and most complete set of coordinated analytic capabilities comes from SAS. Data integration, statistics, data and text mining, econometrics, and forecasting integrate deeply with operations research features like optimization, simulation, and scheduling. SAS helps organizations around the world build analytic models, populate them with relevant data and insights, communicate recommended decisions effectively, and surface these capabilities within accessible, business-oriented interfaces. See how SAS can help you understand the past and present, anticipate the future, and make better decisions.

Tuesday, November 15, 11–11:45am

Technology Tutorial: *"Solving Business Problems with SAS Analytics and OPTMODEL." Abstract: SAS provides a diverse array of analytics, including data integration, statistical analysis, data/text mining, forecasting, and reporting, all integrated with operations research capabilities in optimization, discrete-event simulation, and scheduling. The most prominent SAS optimization component is the OPTMODEL procedure. OPTMODEL incorporates an algebraic optimization modeling language that provides unified support for LP, MILP, QP, NLP, CLP, and network-oriented models and methods, including an expanding suite of standard solvers and support for customized algorithms. We'll demonstrate OPTMODEL's power and versatility in building and solving optimization models, noting the significant improvements resulting from recently added features. We'll emphasize integration with SAS data, analytic, and reporting capabilities, focusing primarily on case studies drawn from our successful work with customers across a broad range of industries.*

SAS JMP Division 3

www.jmp.com

JMP® statistical discovery software from SAS is the tool of choice for scientists, engineers and other data explorers worldwide. JMP links dynamic data visualization with powerful statistics, in memory and on the desktop. Interactive and visual, JMP reveals insights that raw tables of numbers or static graphs tend to hide. JMP simplifies data access, cleanup and processing, and makes it easy to share results. It includes comprehensive capabilities for: Statistical analysis, design of experiments, multivariate analysis, quality and reliability analysis, scripting, graphing and charting, and more.

Tuesday, November 15, 11:45am–12:30pm

Technology Tutorial: *SAS Institute, JMP Division: Interactive Data Analysis and Modeling with JMP 13 Pro Mia Stephens, JMP Academic Ambassador JMP® Statistical Discovery Software is dynamic and interactive desktop software for data exploration, visualization, analysis, and modeling. In this workshop we'll use case studies to illustrate how to interactively build, compare and deploy predictive models using the newly release JMP 13 Pro. We use the Graph Builder®, data filter and other tools to get to know and prepare our data. Then, we explore a variety of predictive models (decision trees, regression, neural networks, and penalized regression), and use the Prediction Profiler and the Solution Path to interactively explore parameters and select potential models. Finally, we compare a variety of competing models using Model Comparison, and use the Model Depot to easily deploy these models.*

SIAM 44

www.siam.org

Visit the Society for Industrial and Applied Mathematics booth to check out our new publications, including recent titles in the MOS-SIAM Series on Optimization such as *Minimum-Volume Ellipsoids: Theory and Algorithms* (Todd) and *Electrical Transmission System Cascades and Vulnerability: An Operations Research Viewpoint* (Bienstock), plus other bestselling SIAM books, all available at a conference discount. You'll also find sample issues of SIAM's renowned journals, including SIOPT, along with information and applications for anyone interested in becoming a SIAM member. And don't forget to pick up a copy of SIAM News for the road.

SIMIO LLC 41

www.simio.com

Simio Simulation and Scheduling Software is the most advanced solution on the market. With simulation, it is the only software that is fully object oriented with process and objects being defined graphically with no programming. Unlike other scheduling software, Simio allows you to introduce risk into your production schedule with its patented Risk Based Planning and Scheduling. This dual function in Simio not only helps you improve your business performance from a facility design perspective, but also helps you maximize business results by optimizing the use of critical resources and assessing the risk associated with operational decisions.

All Technology Tutorials will take place in the Music City Center, 5th Avenue Lobby.

Tuesday, November 15, 1:30–2:15pm

Technology Tutorial: *Simio now leverages the cloud computing power of Microsoft Azure to support your most demanding applications; compatibility with Schneider Electric's Wonderware to allow detailed production scheduling with real-time data and risk analysis; and healthcare and other capabilities in the services field. Outside our immense technology partner advances, we have great new features, application areas and capabilities! Come explore an overview of the new Simio experience and see why we are always "Forward Thinking."*

SIMUL8 17
www.SIMUL8.com

For over 20 years SIMUL8 Corporation has been producing powerful simulation software. SIMUL8's Educational Software is used in universities worldwide and gives tutors the ability to teach simulation, not software thanks to its intuitive interface. When teaching simulation, the purpose is not for students to learn software; it's to get them understanding the benefits that simulation can bring to decision making. SIMUL8 was created with this in mind and as a result our software allows students to build and run their first simulation in less than an hour and see the results.

Springer 42 & 43
www.springer.com

Looking to publish your research? Discover Springer's print and electronic publication services, including open access! Get high-quality review, maximum readership and rapid distribution. Visit our booth or springer.com/authors. You can also browse key titles in your field and buy ebooks at discount prices. With Springer you are in good company.

Taylor & Francis Group 25
http://taylorandfrancis.com

Taylor & Francis boasts a first-class journal portfolio publishing Manufacturing and Operational Engineering articles as well as a wide range of scholarship from related disciplines. Our journals are edited by some of the most prominent academics in the world and offer a variety of accommodating options for our authors. Our prominent journals include *International Journal of Production Research*, *Production & Manufacturing Research: An Open Access Journal* and *INFOR: Information Systems and Operational Research*.

University of Illinois at Urbana-Champaign 50
www.ise.illinois.edu

The Department of Industrial and Enterprise Systems Engineering at the University of Illinois at Urbana-Champaign, innovates the engineering discipline with leading-edge research and scientific discoveries; educates a new generation of leaders in systems, industrial and financial engineering; and serves education, industry, & society.

University of TN, College of Engineering 22
www.ise.utk.edu

Department of Industrial & Systems Engineering (ISE) at UTK offers graduates and scientific professionals a Master of Science (MS) degree, a MS in Reliability and Maintainability Engineering, a dual-degree option (MS and MBA), a PhD with a major in IE, and a concentration in Engineering Management. Located in the recently dedicated John D. Tickle Building, the ISE Department has about 163 undergraduate and 130 graduate students enrolled. The ISE department has been active in the research areas of Operations Research, Management Systems, Lean, Statistics, and Human Factors with applications in manufacturing, healthcare, service, transportation, energy, finance, entertainment, and logistics.

University of TN, Haslam College of Business 31
http://haslam.utk.edu

The Haslam College of Business at the University of Tennessee, Knoxville, was founded in 1914 and consists of approximately 5,500 undergraduate and graduate students, 130 faculty and 125 staff members. Our departments, centers, institutes, forums and graduate and executive education programs reach across the profit, not-for-profit and governmental sectors of business, with a heavy emphasis on practical research. From our top-notch supply chain management and highly regarded accounting programs to our renowned business analytics and Physician EMBA programs, Haslam students and faculty create the change that changes our world for the better."

www.wiley.com

Wiley is a global provider of knowledge and knowledge-enabled services that improve outcomes in areas of research, professional practice, and education.

Sunday, November 13, 2:15–3pm

Technology Tutorial: *Interested in publishing for the Wiley Series in Operations Research and Management Science? The Wiley Series in Operations Research and Management Science is a broad collection of books that meet the varied needs of researchers, practitioners, policy makers, and students who use or need to improve their use of analytics. The workshop will include presentations on the following: The Mission of the Series for the Betterment of the Community, The Proposal Process: Maximizing your Success, What's Next: The Writing, Review, and Publishing Process, Q&A. In addition to the presentation, you will be able to meet with Founding Series Editor James J. Cochran and Wiley Editor Susanne Steitz-Filler to discuss any further questions or potential book ideas you may have."*

infORmational SESSIONS

INFORMS CENTER is located in Exhibit Hall A in the Music City Center. InfORmational Q&A sessions with INFORMS members are listed below.

SUNDAY, NOVEMBER 13

CAP/aCAP 3:30–5pm
Ever wonder what this thing called CAP is? And now there's an aCAP to boot. Find out what they are, why they're important to you and get answers to any other questions about the certification program.

2017 Houston 3:30–5pm
Learn about many exciting things to see and do next year at the INFORMS Annual Meeting in Houston. Stop by for info and a giveaway while supplies last.

Service Science 3:30–5pm
Service Science publishes articles about various aspects of service and service systems. Come chat with the Editor-in-Chief and Area Editors to learn more about the journal and the service science community at INFORMS.

Transactions on Education 3:30–5pm
The Editor-in-Chief and Area Editor for classroom games will provide suggestions to authors who wish to submit their work to *ITE*. What material should be included in a case study or classroom game? To what extent should my approach be classroom tested? What are the main criteria to accept or reject a paper for *ITE*?

Meet the Board 7:30–8:30pm

MONDAY, NOVEMBER 14

CAP/aCAP 9–10:30am

2017 Houston 9–10:30am

Volunteering Opportunities 9–10:30am
No matter how much (or little) time you have to give, INFORMS offers opportunities to get involved, make a difference, and build your network. Come chat with staff about current volunteer opportunities.

Management Science 9–10:30am
Management Science is ranked among the top journals in the area of O.R. The journal's submission rate has grown steadily over the years. In 2015, the journal received 150% more original articles as compared to 2011. Teck Ho, editor-in-chief, will be present to share the journal's selection criteria.

CAP/aCAP 3:30–5pm

2017 Houston 3:30–5pm

Editor's Cut 3:30–5pm
Come learn about multimedia collections, INFORMS *Editor's Cut*, speak with series editor Anne Robinson, and volume editors. See what INFORMS is publishing on hot topics like Big Data Analytics and Elections, and learn how you can use *Editor's Cut* in your research or classroom. There is also a unique giveway!

SpORts 3:30–5pm
The mission of the Section on OR in Sports is to promote and disseminate research and applications among professionals interested in theory, methodologies, and applications of ORMS to sports problems. Basically have fun with sports analytics.

TUESDAY, NOVEMBER 15

Volunteering Opportunities 9–10:30am

2017 Houston 9–10:30am

ProBono Analytics 9–10:30am
Interested in volunteering your analytical skills to help underserved communities? Come learn about recent projects we have undertaken, and discover how you can join your colleagues who have already signed up to be a Pro Bono Analytics volunteer!

CAP/aCAP 3:30–5pm

What's New @ INFORMS 3:30–4:30pm
Stop by and visit with Executive Director Melissa Moore to learn more about what we are doing to promote the OR & Analytics professions, our members, and more.

WEDNESDAY, NOVEMBER 16

CAP/aCAP 9–10:30am

Initiative Proposals 9–10:30am
Do you have an idea for a special project for INFORMS? Attend this special discussion about the initiatve proposal process to learn how to get visibility, support, and funding to bring your idea to fruition.

MICRO-VOLUNTEERING OPPORTUNITY

INFORMS Pro Bono Analytics has paired with Safe Haven of Nashville to help measure the impact of the organization's education support program for school-age children. It involves assessing the social and cognitive levels of children before and after enrolling in the program by assisting with the design and implementation of a survey, and conducting analysis of the survey data.

As a special aside, we invite all Annual Meeting attendees to visit the INFORMS Center to create cards of encouragement or to wish happy holidays for program families who have recently moved from the shelter to housing. It's just one more way for us to give back, and we hope you'll take a moment to stop by the INFORMS Center to help us make a difference. And be sure to keep an eye out in INFORMS Connect and in the Center for more ways to help.

How to Navigate the Technical Sessions

There are four primary resources to help you understand and navigate the Technical Sessions:

- This Technical Session listing, which provides the most detailed information. The listing is presented chronologically by day/time, showing each session and the papers/abstracts/authors within each session.
- The Author and Session indices provide cross-reference assistance (pages 518-560).

Quickest Way to Find Your Own Session

Use the Author Index (page 518) — the session code for your presentation will be shown along with the room location. You can also refer to the full session listing for the room location of your session.

The Session Codes

TA01

Room number. Room locations are also indicated in the listing for each session.

The day of the week

Time Block. Matches the time blocks shown in the Program Schedule.

Time Blocks

Sunday - Tuesday

8:00am -9:30am

11:00am – 12:30pm

1:30pm – 3:00pm

4:30pm – 6:00pm

Wednesday

8:00am -9:30am

11:00am – 12:30pm

12:45pm -2:15pm

2:45pm – 4:15pm

4:30pm- 6:00pm

Rooms and Locations /Tracks

All tracks / technical sessions will be held in the Music City Center and Omni Hotel. Room numbers are shown on the Quick Reference and in the Technical session listing.

Sunday, 8:00AM - 9:30AM

Temporal Data Mining and Pattern Discovery

Sponsored: Data Mining

Sponsored Session

Chair: Mustafa Gokce Baydogan, Bogazici University, Bebek, Istanbul, 34342, Turkey, baydoganmustafa@gmail.com

1 - Discovering Distinct Features Using Deep Learning For Arrhythmia Detection

Seho Kee, Arizona State University, Tempe, AZ, United States, skee4@asu.edu, Phillip Howard, George Runger

Although domain knowledge-based features have been widely adopted in anomaly detection studies, they still suffer from the limitations of the insufficient known features or unavailability in practice. To address these problems, we propose an autoencoder model that is able to discover useful features that identify anomaly patterns in temporal heartbeat data without assuming any prior knowledge. The results show that the discovered features obtained from just a two-dimensional projection layer can effectively distinguish abnormal beats from normal beats without training on pre-labeled data.

2 - Process Control For Time-varying Situations

Seoung Bum Kim, Korea University, sbkim1@korea.ac.kr, Seulki Lee

In modern manufacturing systems containing the complexity and variability of processes, appropriate control chart techniques that can efficiently handle the nonnormal and nonlinear processes are required. In this talk, I will present some recently developed multivariate control charts to handle both nonnormal and time-varying process situations.

3 - On The Use Of Support Vectors For Time Series Pattern Discovery

Mustafa Gokce Baydogan, Bogazici University, Istanbul, Turkey, mustafa.baydogan@boun.edu.tr, Mehmet R Kamber, Erhun Kundakcioglu

Similarity search and classification on time series (TS) databases has received great interest over the past decade. The definition of similarity between TS is a major problem in this context. Nearest-neighbor (NN) classifers are widely used for TS classification but these approaches compute the similarity over the whole TS which might be problematic with the long TS and relatively short features of interest. Moreover, these classifiers are not directly interpretable as they do not describe why a TS is assigned to a certain class. This study utilizes margin maximization to discover the regions of the time series that have potentially representative patterns related to the classification task.

4 - Machine Learning For Predicting Heart Failure Readmission

Wei Jiang, Research Assistant, Johns Hopkins University, 3400 N Charles St, Baltimore, MD, 21218, United States, wjiang1990@gmail.com, Scott R Levin, Lili Barouch, Frederick Korley, Sauleh Ahmad Siddiqui, Diego A. Martinez, Matthew Toerper, Sean Barnes, Eric Hamrock

Predicting risk of heart failure (HF) readmission has gained increasing attention, with existing studies mainly using administrative data. We will focus on using clinical data from EMR for predicting HF readmission by doing pattern recognition with time series clinical data. We will then use classification models for predicting the drivers of readmission.

Healthcare Analytics and Medical Decision Making

Sponsored: Data Mining

Sponsored Session

Chair: Hasan Kartal, University of Massachusetts Lowell, One University Avenue, Lowell, MA, 01854, United States, Hasan_Kartal@uml.edu

1 - PPMF: A Patient-based Predictive Modeling Framework For Early ICU Mortality Prediction

Mohammad Amin Morid, The David Eccles School of Business, University of Utah, 130 University Village, Salt Lake City, UT, United States, amin.morid@business.utah.edu, Olivia R. Liu Sheng, Samir Abdelrahman

This paper presents a patient based predictive modeling framework (PPMF) to improve the performance of early ICU mortality prediction. PPMF consists of three main components. The first component captures dynamic changes of patients' status in the ICU using their time series data. The second component is a local approximation algorithm that classifies patients based on their similarities. The third component is a Gradient Decent wrapper that updates feature weights according to the classification feedback. Experiments show that PPMF significantly outperforms: (1) the severity score systems, (2) the aggregation based classifiers, and (3) baseline feature selection methods.

2 - The Emergency Response Community Effectiveness Modeler: A Simulation Modeling Tool To Analyze EMS vs. Smartphone-based Samaritan Response

Michael Khalemsky, Graduate School of Business Administration, Bar Ilan University, Ramat Gan, Israel, khalemsky@gmail.com, David G. Schwartz

Smartphones and location-based social networking technologies present an opportunity to re-engineer certain aspects of emergency medical response by establishing Emergency Response Communities (ERC). The ERC Effectiveness Modeler (ERCEM) estimates the efficacy of smartphone-based Samaritan response for given medical condition and geographic region. The ERCEM uses parameters such as population density, prescription adherence, smartphones penetration etc. and performs Monte Carlo simulation to compare potential ERC response to traditional EMS response. We present the modeler and show how it assessed effectiveness of ERC for anaphylaxis in the USA based on data from the NEMSIS project.

3 - Public Health Data Sharing With Privacy Protection

Hasan Kartal, Manning School of Business, University of Massachusetts Lowell, Lowell, MA, 01850, United States, hasan_kartal@uml.edu

This study examines privacy disclosure risks in health data when patients have multiple records in a dataset. Existing data privacy approaches typically assume that each individual in a dataset corresponds to a single record, which tends to underestimate the disclosure risks in the multiple-record problems. We propose a new privacy measure, called g-balance, and develop an efficient algorithm based on the g-balance measure to protect against the multiple-record linkage attacks. The effectiveness of the proposed approach is demonstrated in an experimental study using real-world data.

Nicholson Student Paper Prize I

Invited: Nicholson Student Paper Prize

Invited Session

Chair: Maria Esther Mayorga, North Carolina State University, 400 Daniels Hall, Raleigh, NC, 27695, United States, memayorg@ncsu.edu

1 - Nicholson Student Paper Prize

Maria Esther Mayorga, North Carolina State University, Dept. of Industrial & Systems Engineering, Raleigh, NC, 27695, United States, memayorg@ncsu.edu

This session highlights the finalists for the 2016 George Nicholson Student Paper Competition.

2 - A Necessary and Su cient Condition for Throughput Scalability of Fork and Join Networks with Blocking

Yun Zeng, Ohio State University, Columbus, OH, United States, zeng.153@buckeyemail.osu.edu, Augustin Chaintreau, Don Towsley, Cathy Xia

3. Household-level Economics Of Scale In Transportation

Mehdi Behroozi, Northeastern University, Boston, MA, 02115, United States, behro040@umn.edu

4. Online Decision-Making With High-Dimensional Covariates

Hamsa Bastani, Stanford University, Stanford, United States, bayati@stanford.edu

Big data has enabled decision-makers to tailor choices at the individual-level in a variety of domains such as personalized medicine and online advertising. This involves learning a model of decision rewards conditional on individual-specific covariates. In many practical settings, these covariates are high-dimensional; however, typically only a small subset of the observed features are predictive of a decision's success. We formulate this problem as a multi-armed bandit with high-dimensional covariates, and present a new efficient bandit algorithm based on the LASSO estimator. Our regret analysis establishes that our algorithm achieves near- optimal performance in comparison to an oracle that knows all the problem parameters. The key step in our analysis is proving a new oracle inequality that guarantees the convergence of the LASSO estimator despite the non-i.i.d. data induced by the bandit policy. Furthermore, we illustrate the practical relevance of our algorithm by evaluating it on a real-world clinical problem of warfarin dosing.

5 - Distributionally Robust Stochastic Optimization With Wasserstein Distance

Electricity Markets and Contract Design

Sponsored: Energy, Natural Res & the Environment, Energy I Electricity

Sponsored Session

Chair: Edward James Anderson, University of Sydney, H70 - Abercrombie Building, Sydney, NSW 2006, Australia, edward.anderson@sydney.edu.au

1 - Retail Equilibrium With Switching Consumers In Electricity Markets

Carlos Ruiz Mora, Universidad Carlos III de Madrid, Madrid, Spain, caruizm@est-econ.uc3m.es, F. Javier Nogales, F. Javier Prieto

We consider a game theoretical model where asymmetric retailers compete in prices to increase their profits by accounting for the utility function of switching consumers. Consumer preferences for retailers are uncertain and distributed within a Hotelling line. We analytically characterize the equilibrium of a retailer duopoly, establishing its existence and uniqueness conditions for a wide class of utility functions. The duopoly model is extended to a multiple retailer case.

2 - Flow-based Market Coupling In The European Electricity Market

Mette Bjørndal, Professor, NHH Norwegian School of Economics, Bergen, Norway, Mette.Bjorndal@nhh.no

From May 2015, the Flow-Based Market Coupling (FBMC) model replaced the Available Transfer Capacity (ATC) model in parts of the European power market. The FBMC model aims to enhance market integration and to better monitor the physical power flow, and it is expected to lead to increased social welfare in the day-ahead market and more frequent price convergence between different market zones. This paper gives a discussion on mathematical formulations of the FBMC model and the procedures of market clearing. We examine the FBMC model in two test systems and show the difficulties of implementing the model in practice.

3 - Negotiating Forward Contracts With Private Information

Edward James Anderson, University of Sydney, edward.anderson@sydney.edu.au

We consider the use of forward contracts to reduce risk for firms operating in a spot market. Firms have private information on the distribution of prices in the spot market. We discuss different ways in which firms may agree on a forward contract (offers to a broker and direct bargaining). We also discuss an equilibrium in which two firms each offer a supply function and the clearing price and quantity for the forward contracts are determined from the intersection. In this context a firm can use the offer of the other player to augment its own information about the future price. It is interesting that these sophisticated strategies are likely to produce worse outcomes for both firms.

101E-MCC

Power System Resilient Design and Optimization

Sponsored: Energy, Natural Res & the Environment, Energy I Electricity

Sponsored Session

Chair: Seyedamirabbas Mousavian, Clarkson University, 8 Clarkson Avenue, Potsdam, NY, 13699-5790, amir@clarkson.edu

1 - Self-healing Attack-resilient PMU Network For Power System Operation

Chen Chen, Argonne National Laboratory, Lemont, IL, United States, morningchen@anl.gov, Hui Lin, Jianhui Wang, Junjian Qi, Dong Jin

We propose a self-healing PMU network by exploiting the features of programmable configuration in a software-defined networking (SDN) to achieve resiliency against cyber-attacks. After a cyber-attack, by changing the configuration of the network switches, the disconnected yet uncompromised PMUs will be reconnected to the network to "self-heal" and thus restore the observability of the power system. Specifically, we formulate an integer linear programming (ILP) model to minimize the overhead of the self-healing process, while considering the constraints of power system observability, hardware resources, and network topology.

2 - Minimum Risk-maximum Availability Response To Electric Vehicle-initiated Smart Grid Attacks

Seyedamirabbas Mousavian, Clarkson University, amir@clarkson.edu, Melilke Erol-Kantarci, Thomas Ortmeyer

Malware pose a significant threat to the power grid and the connected electric vehicle infrastructure. Penetration and propagation of cyber attacks including worms and viruses vary depending on the nature of the connected systems. Electric vehicles (EVs) being the mobile portion of the smart grid may easily spread worms and viruses in a large geographic area. We propose a probabilistic model for the worm propagation in EV to Electric Vehicle Supply Equipment (EVSE) networks, formulate threat levels and then, we propose a Mixed Integer Linear Programming (MILP) model as a protection scheme that relies on isolating infected nodes.

3 - Storage And Generation Expansion Problem Considering Primary Response

Hrvoje Pandzic, University of Zagreb, Zagreb, Croatia, hrvoje.pandzic@fer.hr, Yury Dvorkin, Miguel Carrion

A sustainable and efficient generation and storage expansion program needs to consider both the capacity needs and short-term operational requirements of a power system. A generation expansion formulation considering frequency regulation using both generators and storage units will be presented.

4 - Optimal Resilient Grid Design Distribution And Transmission Systems

Russell Bent, Los Alamos National Laboratory, rbent@lanl.gov Emre Yamangil, Harsha Nagarajan, Pascal Van Hentenryck

Modern society is critically dependent on the services provided by engineered infrastructure networks, particularly distribution and transmission grids. When natural disasters (e.g. Hurricane Sandy) occur, the ability of these networks to provide service is often degraded. However, well-placed upgrades to these grids can greatly improve post-event network performance. Hence, we pose the optimal electrical grid resilient design problem as a two-stage, stochastic mixed-integer program with damage scenarios and propose decomposition-based algorithms to solve and analyze medium-sized networks.

102A-MCC

Joint Session DM/Optimization: Discrete Optimization and Machine Learning

Sponsored: Data Mining

Sponsored Session

Chair: Berk Ustun, Massachusetts Institute of Technology, Cambridge, MA, United States, ustunb@mit.edu

1 - A Multi-group Discrete Support Vector Machine – Theory And Computation

Eva Lee, Georgia Tech, evakylee@isye.gatech.edu

We describe a general-purpose machine learning framework, DAMIP, for discovering gene signatures that can predict vaccine immunity and efficacy. DAMIP is a multi-group 'concurrent' classifier that offers unique features not present in other models: a nonlinear data transformation to manage the curse of dimensionality and noise; a reserved-judgment region that handles fuzzy entities; and constraints on the allowed percentage of misclassifications.Computational results for biological and medicine problems will be discussed.

2 - Optimized Risk Scores

Berk Ustun, MIT, Massachusetts Institute of Technology, Sloan School of Management, Cambridge, MA, 02142, United States, ustunb@mit.edu, Cynthia Rudin

Risk scores are simple models that let users quickly assess risk by adding, subtracting, and multiplying a few small numbers. These models are widely used in healthcare and criminology, but difficult to create because they need to be risk-calibrated, use small integer coefficients, and obey operational constraints. We present a new approach to learn risk scores from data by solving a discrete optimization problem. We formulate the risk score problem as a MINLP, and present a cutting-plane algorithm to efficiently recover the optimal solution by solving a MIP. We demonstrate the benefits of our approach by creating risk scores for real world problems.

3 - Supersparse Integer Regression Model For Nonparametric Failure Time Analysis

Keivan Sadeghzadeh, MIT Sloan School of Management, Cambridge, MA, United States, keivan@mit.edu, Cynthia Rudin

Analysis of failure time data has an inevitable role in predicting events occurrence. We develop an integer-based predictive model that is accurate and also interpretable, in order to determine effective features and predict potential failures. The strategy is to select appropriate covariates for censored large-scale and high-dimensional failure time data in a regression model. Our approach is to design robust algorithm to find the optimal integer solution for supersparse linear model. This optimal solution is reached by using machine learning techniques over a high-dimensional closed quadric hypersurface.

4 - Nested Clustering On A Graph

Gokce Kahvecioglu, Northwestern University, 2145 Sheridan Road Room C210, Evanston, IL, 60208, United States, gokcekahvecioglu2014@u.northwestern.edu David P. Morton

We study a clustering problem defined on an undirected graph with weight function defined on the edges, which denotes the importance of the connection between vertices. We remove a set of edges in order to maximize the number of clusters in the residual graph while minimizing the weight of deleting edges. Solving this graph clustering problem parametrically identifies the solutions that lie on the concave envelope of efficient frontier and the breakpoints on this envelope have a nested structure. We propose to solve this parametric model in polynomial time by solving a sequence of parametric maximum flow problems, which yields the family of nested clusters on the efficient frontier.

102B-MCC

Undergraduate OR Prize – I

Invited: Undergraduate Operations Research Prize

Invited Session

Chair: Pavithra Harsha, IBM Research, 1101 Kitchawan Road, Room 34-225, Yorktown Heights, NY, 10598, United States, pharsha@us.ibm.com

1 - Car Sharing Fleet Location Design With Mixed Vehicle Types For CO2 Emission Reduction

Joy Chang, University of Michigan, Ann Arbor, MI, United States, joychang@umich.edu. Siqian Shen, Ming Xu

As carsharing companies integrate electric vehicles to reduce CO_2 emissions, we optimize a mixed-integer linear program to study a carsharing fleet location design problem with mixed vehicle types. We create a minimum cost flow formulation on a spatial-temporal network to model round-trip and one-way vehicle flows. We test different one-way trip demands, and provide a model that ensures the first-come first-serve principle while satisfying CO_2 restrictions. Via testing instances from the Boston Zipcar fleet, we provide insights on carsharing fleet location and vehicle-type composition.

2 - Collaborative Decision Making For Air Traffic Management

Hale Erkan, Bilkent University, Ankara, Turkey, hale.erkan@bilkent.edu.tr, Nesim K. Erkip, Ozge Safak

We propose a model which can be utilized within a collaborative decision making (CDM) framework for rescheduling of flights. The proposed mathematical program is expected to be utilized by major stakeholders, airlines and air navigation service providers. After providing the constraints, we list possible equity and efficiency performance measures that will make-up the objective function to be used by a stakeholder. We suggest guidelines to utilize the model for any stakeholder within CDM. Finally, a case study is prepared using publicly available data to demonstrate possible benefits.

3 - A Reformulation Of The Appointment Scheduling Problem With Customer Choice Behavior And Multiple Customer Types

Cem Aydin, Koc University, Dept of Industrial Engineering, Istanbul, Turkey, cemaydin@ku.edu.tr, Alp Aribal, Cansu Erol, Begum Tuglu

In this paper, we propose a new formulation to the appointment scheduling problem with customer choice behavior and multiple customer classes. Using this new formulation and an approximation of the state space, we find an upper bound to the total expected revenue. We exploit the special structure created by our new formulation to present an efficient algorithm that can find this upper bound. We test methods commonly used in practice using our upper bound to rate their performance and show that performances of traditional methods decay as problem size increases.

Balancing Water Use for Food and Energy

Sponsored: Energy, Natural Res & the Environment I Environment & Sustainability

Sponsored Session

Chair: Hayri Onal, University of Illinois, 305 Mumford Hall, 1301 W. Gregory Dr., Urbana, IL, 61801, United States, h-onal@illinois.edu

1 - A Robust Planning Decision Model For Smart Water System

Mengqi Hu, University of Illinois at Chicago, 842 W. Taylor St., 3023 ERF, Chicago, IL, 60607, United States, mhu@uic.edu, Afshin Ghassemi

Water is a critical resource for different sections and people's everyday life. In this research, we propose a robust planning decision model for smart water system including sources, water plants, end users and waste water systems. In the smart water system, the concepts of dynamic pricing and onsite inventory and 3rd-party water plant are explored. Various levels of uncertainties from both water demand and pipeline efficiencies are considered. Three sets of experiments are developed to test the effectiveness of the proposed decision model. It is concluded that our proposed model provides a platform to transform novel smart grid concepts to renovate the existing water infrastructure.

2 - Assessment Of Ecosystem Services In A Semi-arid Agriculture-dominant Area: Framework And Case Study

Yihsu Chen, University of California, Santa Cruz, Yihsu Chen, Ramesh Dhungel, Rudy Maltos, Kumar Sivakumaran, Andres Aguilar, Thomas Harmon

Evaluating ecosystem services is difficult as the services are not traded at an open market. In this study, we developed a framework that allows for assessing the effectiveness and implied costs of ecosystem services provided by a restored SJR (San Joaquin River) in a semi-arid agriculture-dominant area. This is done by explicitly linking economics-based farmers' model with a reduced-form hydrological model that is loosely coupled to a physical-based stream-temperature model. We quantify the lower bound of the short-run economic costs and show that current mandated flows are unlikely to have a meaningful impact on restoring fish population.

3 - Predictive Analytics For Sustainable Water Consumption

Ellen Wongso, Student, Purdue University, West Lafayette, IN, 47906, United States, ewongso@purdue.edu, Zijian He, Roshanak Nateghi

According to a recent report by the EPA, 40 states will experience water shortages in the coming decade. Climate change and increased consumption trends will likely exacerbate the current water scarcity issues. Access to clean water is a basic human right and is an essential element is ensuring energy and food security. There is therefore a critical need to identify the main drivers of consumption to promote sustainable use. Previous research on water sustainably has been local in scope and mostly from a management science perspective. In this research we will leverage advanced statistical learning methods to identify the main drivers of water usage in the US.

4 - Scheduling Water Reuse In The Food Industry: Theory And Application

Renzo Akkerman, Technical University of Munich, Munich, 80333, Germany, renzo.akkerman@tum.de
Sai Jishna Pulluru

Water considerations are increasingly relevant in the planning and scheduling of production activities in the food industry. This includes the reuse of various water streams and their possible treatment or regeneration. We develop a model for production scheduling that integrates water flows and their possible treatment for reuse. We perform a numerical study to analyze the performance of the modelling approach, and also apply the model in a case application from the dairy industry. Overall, the results demonstrate the relevance of the modelling approach and its computational performance. Furthermore, the work provides managerial insights for increased water efficiency in the food industry.

Optimizing Distributed Energy Generation I

Sponsored: Energy, Natural Res & the Environment, Energy II Other

Sponsored Session

Chair: Alexandra M Newman, Colorado School of Mines, 1, Golden, CO, 1, United States, anewman@mines.edu

1 - Hybrid Energy System Dispatch Strategy For A Forward Operating Base

Mark Husted, Colorado School of Mines, mhusted@mines.edu

Given a set of systems (i.e., batteries, diesel generators, and photovoltaics), we determine a dispatch strategy for a forward operating base, isolated from the grid. This cost-minimizing strategy subscribes to minute-level fidelity over a 24-hour time horizon given the expected demand profile and the anticipated solar generation. Operational constraints include (i) ramp-up and ramp-down and minimum up and down times of the generators, (ii) spinning reserve levels, and (iii)other interoperability requirements among the systems. We show how our model results improve over traditional rules of thumb used for real-time dispatch.

2 - A Capacity Expansion Model For Energy Planning For Turkey

Muhammed Sutcu, Assistant Professor, Abdullah Gul University, Sumer Campus, Erkilet Bulvari, Kayseri, 38060, Turkey, muhammed.sutcu@agu.edu.tr, Tugba Degirmenci

There has been a considerable effort to raise the share of their renewable energy (RE) sources in the total sum to reach an environmental sustainability. This study addresses the question of what level of each type of RE should actually be provided year by year to maximize the total productions by minimizing the associated costs for RE policies of Turkey. With this goal on mind, a multistage optimization model for years 2016-2023 is constructed and solved with the interpretation of the results throughout the study.

3 - Integrated Model For Power Interruption Contracts

Lakshmi Palaparambil Dinesh, University of Cincinnati, 601 Mc Alpin Avenue, Apartment 5, Cincinnati, OH, 45220, United States, lakshmi603@gmail.com, Uday S Rao, Jeffrey D. Camm, Kenneth Skinner

Demand response is changing electricity usage based on a change in price of electric power. We study a demand response program where residential customers participate. Each customer has to sign up for a contract to enroll in the program. We develop a model that helps to decide which power unit to turn on or off, which customers to cut power during peak demand hours, and what contract parameters to use while designing contracts between the supplier and residential customers. The proposed model leads to higher overall costs savings for the power supplier compared to the current model used in practice.

4 - Optimal Sizing Of An EV Parking Facility Within A Microgrid

Ebrahim Mortaz, Auburn University, 115 N. Debardeleben St. Apt 29, Auburn, AL, 36830, United States, emortaz@auburn.edu
Jorge F Valenzuela

Integrating the provided energy and storage capacity by the electric vehicles into the microgrid reduces the cost of electricity supply. In this talk, we assume that a grid-connected microgrid is set to transform an EV parking facility into a large energy storage resource by investing on the V2G technology. We propose a mathematical model that aims to determine the optimal number of V2G stations in the parking facility by minimizing the total cost of the microgrid. The results show that the investment in the V2G technology is an enhancement to the long-term economics of microgrids.

Cliques and Clique Relaxations

Sponsored: Optimization, Network Optimization

Sponsored Session

Chair: Eugene Lykhovyd, Texas A&M University, College Station, TX, United States, lykhovyd@tamu.edu

1 - Exact Algorithms For The Minimum S-Club Partitioning Problem

Oleksandra Yezerska, Texas A&M Univeristy, Fort Worth, TX, United States, yaleksa@tamu.edu

Graph clustering (partitioning) is a helpful tool in understanding complex systems and analyzing their structure and internal properties. An s-club is a distance-based relaxation of a clique and is formally defined as a subset of vertices inducing a subgraph with a diameter of at most s. We study the minimum s-club partitioning problem, which is to partition the graph into a minimum number of s-club clusters. Integer programming techniques and combinatorial branch-and-bound framework are employed to develop exact algorithms to solve this problem. We also compare the computational performance of the proposed algorithms for the special case of $s=2$ on a test-bed of real-life graphs.

2 - High Communication Efficiency Subgraphs

Vladimir Stozhkov, University of Florida, Gainesville, FL, United States, vstozhkov@ufl.edu, Alexander Veremyev, Oleg A Prokopyev

We introduce a new clique relaxation model which is based on the notion of communication efficiency. The communication efficiency is assumed to be a non-increasing function of pair-wise distances in a graph. We prove that the corresponding maximization problem is NP-hard and present effective exact algorithms to solve it.

3 - Approximating The Maximum Edge Weight Clique Problem Using A Continuous Formulation

Seyedmohammadhossein Hosseinian, Texas A&M University, 2027 Emerging Technologies Building, Mail stop 3131, College Station, TX, United States, hosseinian@tamu.edu, Dalila B M M Fontes, Sergiy Butenko

The Maximum Edge Weight Clique (MEWC) problem, defined on an undirected and weighted graph, is to find a clique whose sum of edge weights is maximized. This work presents a continuous formulation for the MEWC problem, along with a heuristic based on solving the continuous form over a n dimensional hypersphere, where n is the number of vertices of the graph. Results of the algorithm on some benchmark instances are also presented.

Sponsored Session

Chair: Swati Gupta, Massachusetts Institute of Technology, Cambridge, MA, United States, swatig@mit.edu

1 - Algorithms For Stable Matching With Imperfect Transfer Of Utility (ITU)

Rajan Harish Udwani, Massachusetts Institute of Technology, rudwani@mit.edu, James B Orlin

The classical stable matching and utility transfer problems (also the dual of the assignment problem), are two extreme cases of the imperfect utility transfer problem, where we wish to find a stable matching in a bipartite graph, while allowing imperfect/lossy transfer of utility across matched pairs. In case of complete loss (or no transfer), we recover the former and in absence of loss we get the latter. We develop a novel combinatorial algorithm for this generalized stable matching problem under imperfect transfer of utility, when the loss function is linear. The model was inspired by a recent paper of Galichon et al. (2016).

2 - Polyhedral Study Of A Generalization Of The Continuous Mixing Set

Haochen Luo, Texas A&M University, College Station, TX, United States, hcluo@tamu.edu, Kiavash Kianfar

We report our progress on polyhedral study of a generalization of the continuous mixing set. We provide facet-defining valid inequalities and discuss how they can be used to generate cuts for well-known problems such as lot-sizing.

3 - Learning Combinatorial Structures

Swati Gupta, Massachusetts Institute of Technology, Cambridge, MA, United States, swatig@mit.edu, Michel X Goemans, Patrick Jaillet

To find optimal strategies for dueling algorithms, we consider two online learning methods: multiplicative weights update (MWU) and online mirror descent (OMD). We first show how to simulate MWU over vertices of polytopes in R^m (e.g. spanning trees, bipartite matchings), in time poly(m) under fast generalized counting oracles (even if approximate). Next, we solve a well-known computational bottleneck of computing projections for the OMD by giving novel algorithms for separable convex minimization over base polymatroids (e.g. for spanning trees, truncated permutations, subset of experts). These results extend to applications in stochastic optimization, game theory and machine learning.

Global Optimization: Algorithms and Applications

Sponsored: Optimization, Global Optimization

Sponsored Session

Chair: Emily Speakman, University of Michigan, MI, United States, eespeakm@umich.edu

1 - Strong Relaxations For Optimal Power Flows

Pascal Van Hentenryck, University of Michigan, pvanhent@umich.edu, Carleton Coffrin, Hassan Hijazi

This talk reviews recent progress in convex relaxations of the power flow equations, which combines the SDP relaxation, the QC relaxations, bound tightening, and valid inequalities. Computational results on state-of-the-art benchmarks are presented.

2 - Branching Point Selection For Trilinear Terms

Emily Speakman, University of Michigan, 2222 Fuller Court, Apt 702A, Ann Arbor, MI, 48105, United States, eespeakm@umich.edu, Jon Lee

The case of having three or more expressions multiplied together (each expression being possibly complex itself) occurs frequently in global-optimization models. For these “trilinear terms,” we present some analytic results regarding the choice of branching point and branching variable in the context of spatial branch-and-bound, and we compare our results to common practice in software. In obtaining the “best” branching point or variable we use n-dimensional volume as a comparison measure. Using volume as a measure gives a way to analytically compare formulations and corresponds to a uniform distribution of the optimal solution across a relaxation.

3 - Virtuous Smoothing For Global Optimization.

Daphne Skipper, US Naval Academy, daphne.skipper@gmail.com, Jon Lee

Virtually all exact solvers for global-optimization (GO) rely on NLP solvers, both to generate good feasible solutions and to solve relaxations. Convergence of most NLP solvers requires that functions be twice continuously differentiable. Yet many models naturally utilize functions with some limited non-differentiability. One approach to handle limited non-differentiability is via smoothing. We propose a method, mostly aimed at (concave) root functions ($f(x)=x^p$, with $0<p<1$) that provides a tighter lower bound than the obvious shift ($g(x)=(x+\epsilon)^p-\epsilon^p$), and is smooth and globally concave, so it works well with local and global solvers.

Operations Research Approaches to Plant Breeding

Invited: Agricultural Analytics

Invited Session

Chair: Lizhi Wang, Iowa State University, Ames, IA, United States, lzwang@iastate.edu

1 - Resource Allocation In Trait Introgression – A Markov Decision Process Approach

Ye Han, Iowa State University, yeh@iastate.edu
Lizhi Wang, William D Beavis, John N Cameron

Plant breeding companies continuously improve their cultivars through trait introgression projects, which are usually constrained with budgets and deadlines. In this presentation, we formulate the optimal allocation of money and time resources as a Markov decision process, in which the breeder incurs a cost for each progeny produced and receives a reward for producing an ideal progeny by the deadline. We will share preliminary results on a hypothetical trait introgression project and discuss future research opportunities.

2 - Maximizing Quantitative Traits In The Mating Design Problem

Susan R Hunter, Purdue University, West Lafayette, IN, United States, susanhunter@purdue.edu, Benjamin McClosky

We consider a version of the mating design problem in which breeders allocate a breeding budget to a set of parent pairs to maximize the expected maximum trait observed in the progeny population. In this context, the only parent pairs that receive nonzero breeding budget at optimality in the mating design problem lie on a Pareto set. Since the performance of each parent pair is assessed through Monte Carlo simulation, identifying the Pareto set is a bi-objective simulation optimization problem. We derive an asymptotically optimal simulation budget allocation to estimate the Pareto set of parent pairs. This estimated Pareto set is used as an input to the mating design problem, which is an integer program.

3 - Response Surface Methodology In Plant Breeding

Reka Howard, University of Nebraska – Lincoln, NE, rekahoward@gmail.com, William Beavis, Alicia Carriquiry

We introduce Response Surface Methodology (RSM) as a strategy to find the combination of attribute levels that results in accurate predictions for a given genomic prediction (GP) method, and compare GP methods. We illustrate RSM with a simulated example where the response we optimize is the difference between prediction accuracy using the parametric best linear unbiased prediction (BLUP) and the nonparametric support vector machine (SVM). The greatest impact on the response is due to the genetic architecture of the population and the heritability. When epistasis and heritability are highest, the advantage of using the SVM versus the BLUP is greatest.

4 - A New Genomic Selection Approach

Lizhi Wang, Iowa State University, lzwang@iastate.edu, Matthew Goiffon, Guiping Hu, Aaron Kusmec, Patrick Schnable

Conventionally, plant breeders make selection decisions based on phenotype observations and intuitive judgement. The advent of genotyping techniques provides breeders with much more informative genomic data. However, the enormous volume and complexity of the genomic data also present great challenges in extracting the useful information deeply buried in the mountains of data. We present a new approach for genomic selection and demonstrate its improvement over previous methods using computer simulation with realistic genomic data.

Big Data in the E-Commerce Deliveries

Invited: Modeling and Methodologies in Big Data

Invited Session

Chair: Chung-Yee Lee, HKUST, IELM Dept. HKUST, Clear Water Bay, Hong Kong, 0000, Hong Kong, cylee@ust.hk

1 - The Benefits Of Randomization In Warehousing And Logistics

John Carlsson, University of Southern California, jcarlsso@usc.edu

A recent innovation in warehousing and logistics has been the use of randomization, such as Amazon's random stow, in which warehouse items are scattered throughout the floor map as opposed to being concentrated in one area. We use a continuous approximation model to describe how such a policy is beneficial in the long run.

2 - Resource Allocation With Unmanned Aerial Vehicle

Siyuan Song, University of Southern California, siyuanso@usc.edu, John Gunnar Carlsson

Unmanned aerial vehicles, commonly known as drones, have become more widely utilized in delivery nowadays. We study the efficiency of a so-called 'horsefly' delivery system, in which drones are used in conjunction with truck. We propose a mathematical formulation of a 'horsefly' problem followed by some general properties of optimal solutions. Then some approximation results, including an approximation algorithm, are given to illustrate the benefit of horsefly system on a large scale. Lastly, we compare some practical heuristic algorithms in different scenarios for best choice in each case.

3 - The Last Mile Rush

Song Zheng, Cainiao Network, Hang Zhou, China, zhengsong.zs@alibaba-inc.com, Lijun Zhu

As e-commerce keeps its impressive growth, a large percentage of express orders are generated by e-commerce. In China, for example, it is over 60 percent. Increasing investments rush into China's express delivery industry, which now has thousands of delivery companies and millions of delivery workers. Alibaba group and Cainiao Network are building China Smart Logistics Network and developing a huge ecosystem with all major logistics companies in China. We will present an optimal solution to the last mile delivery, more specifically, arranging thousands of courier to delivery all kinds of packages in cities including online e-commerce packages and offline O2O packages.

Inverse Optimization: Theory

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Taewoo Lee, Rice University, #217, 7010 Staffordshire Street, Houston, TX, 77030, United States, taewoo.lee@utoronto.ca

Co-Chair: Timothy C.Y. Chan, University of Toronto, Toronto, ON, Canada, tcychan@mie.utoronto.ca

1 - Goodness-of-fit In Multi-point Inverse Optimization Optimization

Rafid Mahmood, University of Toronto, Toronto, ON, Canada, rafid.mahmood@mail.utoronto.ca, Timothy Chan, Taewoo Lee, Daria Terekhov

Inverse optimization is a model fitting technique that uses observed points to impute the cost function of an unknown optimization problem. Applications of inverse optimization often rely on ad-hoc or informal methods to evaluate the fit quality of the inverse solution to the data. A previous work introduced a general formulation for inverse optimization with a single observation and a measure for the goodness-of-fit. We extend both of these results to the case of multiple observed points. Our techniques are capable of comparing different models and identifying outliers that do not fit well with the remaining points.

2 - Inverse Optimization For Determining Constraint Parameters

Neal Kaw, University of Toronto, Toronto, ON, Canada, neal.kaw@mail.utoronto.ca, Timothy Chan

Most inverse optimization literature has focused on determining the objective function of an optimization problem, given an observed solution. In this work, we develop inverse optimization models that additionally determine unspecified parameters of the feasible set. First, we propose an inverse linear programming model to determine all problem data. Second, we propose inverse robust linear programming models to determine a cost vector and unspecified parameters of the uncertainty set, for two types of uncertainty: interval uncertainty and cardinality constrained uncertainty.

3 - Robust Inverse Optimization

Kimia Ghobadi, MIT, Cambridge, MA, United States, kimiag@mit.edu, Daria Terekhov, Houra Mahmoudzadeh, Taewoo Lee

In this talk, we explore the robustification of inverse optimization. Our work is motivated by problems in which the observation of the solution is partial, noisy, or uncertain. We build an uncertainty set around the observation and derive an inverse model that finds a cost vector that protects against the worst case scenario in the given uncertainty set. Our model generalizes previous work on single-observation inverse models. It can also be seen as more general than inverse optimization with multiple points, since the points can be thought of as a sample from the uncertainty set.

Optimal Statistical Learning

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Nana Kwabena Aboagye, Princeton University (ORFE), 1 Nassau Hall, Princeton, NJ, 08544, United States, aboagye@princeton.edu

1 - Uncertain Date Envelopement Analysis

Allen Holder, Rose-Hulman Institute of Technology, holder@rose-hulman.edu

We motivate an inverse optimization problem that calculates a decision making unit's maximum efficiency within the context of uncertain data envelope analysis. One of the sub-problems is a robust linear program, but unlike a traditional robust model that sacrifices the objective to hedge against uncertainty, the data envelope model leverages uncertainty to promote efficiency. We apply the method to a set of prostate radiotherapy treatments to help discern appropriate treatments.

2 - Optimal Learning Of Expensive Quadratic Functions

Nana Kwabena Aboagye, Princeton University, aboagye@princeton.edu

We study the problem of learning the unknown parameters of an expensive function where the true underlying surface can be described by a quadratic polynomial. We present a previously studied Bayesian optimization algorithm known as the knowledge gradient for the parametric belief model. Originally established in the limited context of drug discovery (see Negoescu et al. (2011), the knowledge gradient for the parametric belief model remains under-studied with regards to its behavior. We seek to understand the behavior of this algorithm and exploit this understanding to derive a simple heuristic that performs just as well as the knowledge gradient for the parametric belief model.

3 - Dueling Bandits With Dependent Arms

Bangrui Chen, Cornell University, bc496@cornell.edu

We consider online content recommendation with implicit feedback through pairwise comparisons. We study a new formulation of the dueling bandit problems in which arms are dependent and regret occurs when neither pulled arm is optimal. We propose a new algorithm, Comparing The Best (CTB), appropriate for problems with few arms, and a variation of this algorithm for problems with many arms. We show both algorithms have constant expected cumulative regret. We demonstrate through numerical experiments on simulated and real dataset that these algorithms improve significantly over existing algorithms in the setting we study.

4 - Asymptotic Optimality In Finite Horizon Multi-armed Bandits With Multiple Pulls Per Period

Weici Hu, Cornell University (ORIE), wh343@cornell.edu

We view the finite horizon multi-arm bandit problem with multiple pulls per period (MABMP) as a special case of a weakly coupled dynamic program (WCDP). A WCDP is a class of optimal control problems for which the complexity can be reduced by Lagrangian Relaxation. We propose an index-based policy that utilizes the Lagrange multiplier in the relaxed problem, and give a proof that this index-based policy is asymptotically close to the optimal policy as the problem size gets larger. We also use simulation to show that this index policy performs better than state-of-art heuristics in various problem sizes.

High-Performance Computing for Stochastic Optimization

Invited: High Performance Computing

Invited Session

Chair: Jean-Paul Watson, Sandia National Laboratories, P.O. Box 5800, MS 1326, Albuquerque, NM, 87185, United States, jwatson@sandia.gov

1 - Parallel Branch-and-bound Based On PH For Stochastic MIPS

David Woodruff, University of California Davis, dlwoodruff@ucdavis.edu, Jason Barnett

Progressive hedging (PH), though an effective heuristic for stochastic mixed integer programs (MIPs), is not guaranteed convergence in the integer case. Here, we describe BBPH, a branch and bound algorithm that uses PH within each node that, given enough time, will always converge to the optimal solution. In addition to providing a theoretically convergent wrapper for PH applied to MIPs, computational results are given that demonstrate that for some difficult problem instances branch and bound can find improved solutions within a few branches.

2 - Schuripopt: A Parallel Optimization Package For Structured Nonlinear-programming Problems

Gabriel Hackebeil, University of Michigan, Ann Arbor, MI, United States, hackebeg@umich.edu, Jose Santiago Rodriguez, Jean-Paul Watson, Carl Laird

In this work, we develop SchurIpopt, a parallel extension to Ipopt that solves structured NLP problems efficiently on shared memory and distributed memory parallel architectures. Our implementation uses a Schur-complement decomposition strategy to exploit the structure of NLP problems arising in multi-scenario and dynamic optimization applications. The implementation achieves high parallel efficiency by parallelizing the solution of the KKT system and related vector-vector and matrix-vector operations. We interface SchurIpopt with PySP — a Python-based software package for modeling stochastic programming problems, which is an extension of the open-source AML Pyomo (pyomo.org).

3 - Parallel Solution Of Large-scale Stochastic Economic Dispatch And Unit Commitment Problems

Jean-Paul Watson, Sandia National Laboratories, jwatson@sandia.gov

We consider the solution of large-scale, industrially relevant economic dispatch and unit commitment problems, for systems with large renewables penetration levels, using parallel scenario-based decomposition methods. We discuss both lower and upper bounding performance, in the context of CAISO and other realistic data sets. We will detail tuning and implementation issues that impact and in some cases limit scalability of scenario-based decomposition (in particular, progressive hedging) on these problems.

Chair: Guzin Bayraksan, The Ohio State University, The Ohio State University, Columbus, OH, United States, bayraksan.1@osu.edu

1 - Reconfigurable Optimization

Prateek Raj Srivastava, Graduate Research Assistant, The University of Texas at Austin, 204 East Dean Keeton Street, Engineering Training Center II (ETC), Austin, TX, 78712, United States, prateekrs@utexas.edu, Nedialko Dimitrov, David L. Alderson

We develop a modeling framework for a class of optimization problems in which operational decisions need to be altered as a system transitions stochastically between states of the world. Our framework addresses the multi-objective problem of minimizing reconfiguration costs associated with changing the operational decisions and ensuring good quality solutions in each individual state. We compare and contrast our model solutions with those obtained from other modeling frameworks like Stochastic and Robust Optimization.

2 - Variance Reduction For Sequential Sampling In Stochastic Optimization

Jangho Park, The Ohio State University, Columbus, OH, United States, park.1814@osu.edu, Rebecca Stockbridge, Güzin Bayraksan

We investigate Antithetic Variates (AV) and Latin Hypercube Sampling (LHS) for sequential sampling in stochastic optimization. We assume a sequence of solutions is given and employ AV or LHS to assess the quality of these solutions in a sequential sampling framework. The sequence of solutions can be given by any method satisfying some convergence properties. Therefore, the sequential framework can be used by a variety of methods to find high-quality solutions with a desired probability. We present theoretical justification and update the theory especially for LHS. Computational results indicate that the use of AV and LHS can lead to tighter confidence intervals on the quality of solutions obtained.

3 - A Tractable Stochastic Program For The Operation Of A Hydroelectrical Complex With Uncertain Inflows

Charles Gauvin, École Polytechnique de Montréal, 2900 Boul. Édouard-Montpetit, Montréal, QC, H3T 1J4, Canada, charles.gauvin@polymtl.ca, Erick Delage, Michel Gendreau

This talk considers the operation of a real multireservoir hydroelectrical complex. We focus on the uncertainty surrounding inflows and explicitly capture the serial correlation though well-known time series. We then consider affine decision rules to quickly obtain solutions to this multistage stochastic program. Finally, we evaluate the quality of these policies by embedding our approach into a rolling horizon simulation.

4 - Distributionally Robust Newsvendor Problem With Variation Distance

Hamed Rahimian, PhD Candidate, The Ohio State University, 1971 Neil Ave., Columbus, OH, 43215, United States, rahimian.1@osu.edu, Guzin Bayraksan, Tito Homem-de-Mello

We study a general class of newsvendor models where the underlying demand distribution is unknown. An ambiguity set of distributions is formed by the variation distance centered around a nominal continuous distribution. We characterize the optimal solution to the resulting distributionally robust problem. Then, we examine which demand levels are more critical to the optimal cost than others. Finally, we show the sets of critical demands are decreasing and converge to a set of measure zero as the level of robustness increases. Numerical results show that the optimal decision to the risk-neutral model plays an important role to characterize the most critical demands.

Storage and Read-Optimized Data Placement Structures for High Performance Analysis

Invited: Tutorial

Invited Session

Chair: Edmon Begoli, University of Tennessee-Knoxville, Joint Institute for Computational Sciences (JICS),, Knoxville, TN, 37831, United States, ebegoli@utk.edu

1 - Storage And Read-Optimized Data PlacementStructures For High Performance Analysis

Edmon Begoli, University of Tennessee-Knoxville, Joint Institute for Computational Sciences (JICS), Knoxville, TN, 37831, United States, ebegoli@utk.edu, Pragnesh Patel, J. Blair Christian

We present state-of-art structures and methods for efficient data preparation, and representation for analysis. Our intent is to introduce the data science and analytics communities to open source data placements, structures, and methods. These practices can make the foundational processes of data preparation and access dramatically more efficient than typical raw file or database representations and use more conservative storage. To illustrate this, we introduce two highly efficient data placement structures. We then present a tutorial, supported by step-by-step examples, of how to create, use and access data, structured by Parquet or ORC, using Apache Spark. Finally, we illustrate the benefits of using these structures with computational and storage volume benchmarks.

1 - Optimization-based Scheduling Tools For Hospital Staff

Fei Li, Hennepin County Medical Center, Fei.Li@hcmed.org

Clinics and hospital units hope to staff more accurately to demand patterns, but many have trouble doing so, because of multiple difficulties. We try to understand the difficulties in real practice and offer optimization-based solutions.We propose a solution that is both easier to use and more personalized. Our solution includes a one-stop web-based access to our CPLEX server for any model, and a customized user-friendly tool for each team. They gain users' acceptance, and we reach better schedules that both the department and staff are happy with.Continued effort cannot be saved in making the tool fit the team's need. Including modeling skill in supporting staff is recommended.

2 - A Target Discharge Strategy For Inpatient Discharge Planning

Nicholas Ballester, PhD Candidate, Wright State University, 1555-A Sudbury Lane, Faiborn, OH, 45324, United States, ballester.2@wright.edu, Pratik Parikh, Nan Kong

Ineffective inpatient discharge planning may cause discharge lateness and upstream patient boarding. Working with a local hospital, we propose a novel target discharge strategy, the n-by-T strategy. We demonstrate the effectiveness of this strategy via a simulation study, which suggests nearly 2 hr of advancement in the mean discharge time and nearly 15% reduction in upstream boarding. The sensitivity of this strategy for varying unit's occupancy rates and findings from a trial implementation at this hospital unit will also be discussed.

3 - Enhancement and Validation Of Outpatient Blood And Marrow Transplant Practice Using Time Driven Activity Based Costing (TDABC)

William J Hogan, Mayo Clinic-Rochester, NY, United States, hogan.william@mayo.edu

Mayo Clinic has developed an infrastructure to permit the performance of a complex procedure, Blood and Marrow Transplant (BMT), as an outpatient. Using a combination of Standardize to Value (STV) and Time Driven Activity Based Costing (TDABC) approach a number of strategies were developed to converge the practice across multiple sites resulting in greater standardization, consistency, quality of care and cost containment. The value of performing BMT as an outpatient was interrogated using TDABC, which effectively demonstrated enhanced resource utilization and cost containment while maintaining excellent clinical outcomes. These principles are generalizable to other practices involving complex care.

4 - Anesthesiology Practice Redesign

Michael J Brown, Mayo Clinic-Rochester, NY, United States, Brown.Michael3@mayo.edu

The Department of Anesthesiology led perioperative practice redesign initiative improved the quality and increased the value of perioperative care. Utilizing an analytical approach to identify, prioritize, assimilate, and interpret impactful information, multiple high-value strategies were implemented that optimized Mayo Clinic's perioperative facilities, human resources, workflows and clinical outcomes. The majority of interventions were perioperative specialty specific, however others were generalizable to the entire practice. "

1 - Optimal Patient And Provider Incentives In Funding-constrained Humanitarian Healthcare Service Settings

Karthik Natarajan, University of Minnesota, Minneapolis, MN, United States, knataraj@umn.edu, Mili Mehrotra

We analyze how a budget-constrained humanitarian organization managing a healthcare service program should design incentives to the provider and patients to maximize program coverage. We explore how the incentives change with the service offered and operating environment. We also compare the optimal incentive scheme to incentive schemes used in practice.

2 - Competing For Donations In The NPO Sector

Milind Sohoni, Indian School of Business, milind_sohoni@isb.edu, Sripad K Devalkar, Neha Sharma

We study the impact of competition under two fund-raising models, commonly observed in the non-profit sector, when donors and non-profit organizations face challenges due to information asymmetry and outcome (benefit) uncertainty. We also analyze implications on benefits delivered from a social planner's perspective.

3 - Discharge Decision In Emergency Departments: Impact Of Operational Measures And Pay-for-performance Incentives

Eric Park, University of Hong Kong, 1, Hong Kong, ericpark@hku.hk

We study how operational measures in the emergency department such as number of patients waiting to be seen and physician's patient load affect patient discharge decisions. We also analyze the impact of a provincial government level pay-for-performance incentive scheme on discharge decisions. We empirically study several major hospitals in the metro Vancouver, Canada area.

Evaluating Health Policy Decisions

Sponsored: Health Applications

Sponsored Session

Chair: Zhaowei She, Georgia Institute of Technology, 755 Ferst Drive, NW, Atlanta, GA, 30332, United States, zhaowei@gatech.edu

1 - Positive Externalities In Disease Intervention: A Study Of Mosquito Borne Viruses

Anneke Claypool, Stanford University, annekecl@stanford.edu Jeremy Goldhaber-Fiebert

Health interventions often result in positive externalities that are not captured in traditional cost-effectiveness analysis. This study uses a dynamic transmission model to analyze the cost-effectiveness of Chikungunya prevention measures. We compare a potential Chikungunya vaccine to vector control methods that result in fewer Chikungunya, Zika and Dengue cases. By using this model, the additional health benefits of interventions that impact multiple diseases can be captured.

2 - Modeling Health Insurance Marketplaces

Zhaowei She, Georgia Institute of Technology, zhaowei@gatech.edu

As part of the Affordable Care Act, Health Insurance Marketplaces (HIX) has significantly reduced the number of uninsured in the United States. However, concerns exist about quality and accessibility of services in HIX. Motivated by these concerns, we propose a theoretical framework to understand the current state of HIX, and make projections about its future and sustainability. Our analysis shows that the current design of HIX may unintentionally incentivize health plans to ration services to attract low risk enrollees, leading to adverse selection and narrow-network phenomena in HIX. Moreover, HIX's limitations in addressing upcoding behavior can lead to an unraveling of the market.

3 - Balancing Functional And Technical Quality In Health Services Under Provider Consolidation And Shifts In Payment Structure

Aaron H Ratcliffe, University of North Carolina at Greensboro, 438 Bryan Building, University of North Carolina at Greensboro, Greensboro, NC, 27402-6165, United States, aaron.ratcliffe@uncg.edu, Ann Marucheck, Wendell G Gilland

We develop a competitive queueing model to study how health service providers balance investments in functional quality (experiential elements of service) against investments in technical service quality (positive service outcomes). Our analytical derivations measure the impact of provider consolidation and alternative payment structures on the equilibrium technical quality and functional quality efforts and equilibrium wait times for health service.

Dynamics of Scope and Innovation

Invited: Strategy Science

Invited Session

Chair: Brian Wu, University of Michigan, Tappan Street, Ann Arbor, MI, 48109, United States, wux@umich.edu

1 - Adaptation On Multiple Landscapes: Relatedness, Complexity And Dynamic Coordination Costs

Aseem Kaul, University of Minnesota, Minneapolis, MN, United States, akaul@umn.edu, Mo Chen, Xun Wu

We introduce and explore the concept of dynamic coordination costs, i.e. the reduction in a diversified firm's ability to adapt within its businesses resulting from the coordination of activities across them. Using a modified NK simulation, we show that a combination of rigidity and learning means that these costs are highest at moderate levels of relatedness across business, with the level of interdependency within businesses moderating this effect. We also show that diversifying entrants in new markets experience a short-term learning advantage, but a long-term rigidity disadvantage. Our study speaks to work on organizational adaptation and strategic renewal in multi-business firms.

2 - Innovation In Ecosystems

Gwendolyn K Lee, University of Florida, 2822 SW 94th Drive, Gainesville, FL, 32608, United States, gwendolyn.lee@cba.ufl.edu, Martin Ganco, Rahul Kapoor

We consider the context for innovation to comprise of interdependent industries within an ecosystem. Using a simulation model, we explore how the structure of interdependencies shapes the pattern of innovation across industries. The notion is that an industry's close proximity to end-use provides firms with a larger pool of components to combine but also more complex objective function to solve. A larger pool presents more choices and covers a wider variety of choices. However, certain architectural configurations impose heavy constraints on downstream firms. We show innovation outcomes depend on the architecture of interdependencies across and within the different industries in an ecosystem.

3 - Effect Of Competitor Investments On Established Firms' Redeployment Entry Into Nascent Markets: Evidence From The U.S. Electric Utilities' Adoption Of Solar Energy

Shaohua Lu, Tulane University, Freeman School of Business, New Orleans, LA, 70118, United States, slu4@tulane.edu
Jay Anand

This paper examines the effect of competitor investments on established firms' entry into an emerging, uncertain market. To understand information effect, we shift attention to the "flow" of recent competitor investments rather than analyzing the "stock" of cumulative investments. We further postulate that this information effect interacts with a competition effect in oligopolistic market competition. We construct formal models and predict a U-shaped relationship. We further examine how competitor similarity and existing capacity affect this U-shaped relationship. Using data on investor-owned utilities' entry into the solar market, we find supporting evidence for our predictions.

4 - Stock Market Undervaluation Of Resource Redeployability

Arkadiy Sakhartov, University of Pennsylvania, Wharton School of Business, 3620 Locust Walk, Philadelphia, PA, 19104, United States, arkadiys@wharton.upenn.edu

The study uses three steps to establish the applicability of the strategic factor market theory to acquisitions of firms in stock markets. First, the study reviews literature on resource valuation and finds a likely source of the undervaluation, ambiguity about redeployability of resources to a new business. Second, the study compiles a case of Apple Inc., revealing a prolonged undervaluation of redeployability of the firm's resources to the smartphone business. Third, the study builds a valuation model deriving the undervaluation as a function of observable resource properties.

Capacity Allocation and Scheduling Issues

Invited: Project Management and Scheduling

Invited Session

Chair: Zhixin Liu, University of Michigan-Dearborn, 19000 Hubbard Dr, Dearborn, MI, 48126, United States, zhixin@umich.edu

1 - Coordination Mechanisms For Several Scheduling Game Problems

Guo-Qiang Fan, Northwestern Polytechnical University, Xi'an, China, pacpos.gqfan@gmail.com, Jun-Qiang Wang

We consider two scheduling problems in the non-cooperative game setting. Each job is owned by a selfish agent whose strategy is to minimize its completion time. (P1) For the scheduling game problem Q||max wjCj, we design the Greatest-Weight-First Coordination Mechanism and show that the price of anarchy is equal to 2-1/m for identical parallel machines and is not greater than 1+(m-1)smax/ms for uniform parallel machines. (P2) For the scheduling game problem Q|p-batch,b<n|Cmax, we design the FBLPT coordination mechanism and show that the price of anarchy is not greater than 2-2/(3b)-1/(3max{m,b}) for identical parallel-batching machines and 1+smax(1-1/max(m,b)) for uniform parallel machines.

2 - Disruption Recovery For Berth Allocation

Li Chen, Assistant Professor, Tianjin University, College of Management and Economics, Tianjin University, Tianjin, China, cliad@connect.ust.hk, Xiangtong Qi

A major disruption to a container terminal may cause a substantial delay to the vessels waiting for services. When the terminal makes the berth allocation decision after the hit of a major disruption, the possibility of missing container transshipment becomes a new issue that does not exist in conventional berth allocation models. We study the berth allocation problem under such a scenario to balance the operational efficiency of the terminal and lose of misconnected containers.

3 - Fixed Factor Allocation For Capacity Allocation With Demand Competition

Zhixin Liu, University of Michigan-Dearborn, Dearborn, MI, United States, zhixin@umich.edu, Jianbin Li, Xueyuan Cai

We consider a supply chain consisting of a supplier and two retailers. The supplier sells a single product to the retailers, who in turn retail the product to customers. The supplier has limited production capacity, and the retailers compete for the supplier's capacity and are duopolists engaged in Cournot competition for their customers. We propose a new capacity allocation rule, fixed factor allocation, which incorporates the ideas of proportional and lexicographic allocations: it prioritizes retailers as in lexicographic allocation, but guarantees only a fixed proportion of the total available capacity to the prioritized retailer. We show desirable properties of the fixed factor allocation.

Procurement Auctions and Bidding

Invited: Auctions

Invited Session

Chair: Kartikeya Puranam, La Salle University, 1900 West Olney Ave, Philadephia, PA, 19141, United States, puranam@lasalle.edu

1 - Behavioral Analysis Of A + B Sealed Bid Procurement Auctions

Bernardo F. Quiroga, Assistant Professor, Clemson University, Clemson, SC, 29634, United States, bquirog@g.clemson.edu
Brent Moritz, Xiaosong Wu

Using a laboratory experiment, we study the effect of complexity in multidimensional bidding in A+B governmental procurement auctions. Varying the number of bidders and the dimensionality of the bid, we offer an explanation for over/underbidding, and suggest potential solutions to the welfare implications of the observed biases. In our analyses, we evaluate several different explanations to rationalize this behavior, including risk attitudes, bounded rationality, loss aversion, quantile response equilibria measures, and structural estimation of the implied private value of the contracts.

2 - Score Auction Bidding Under Quality Uncertainty: Effort, Risk And Agency Considerations

Daniel Nielubowicz, Clemson University, dnielub@g.clemson.edu
Bernardo F. Quiroga

In a price-and-quality score procurement auction setting, we model the effect of quality uncertainty on bidding behavior under the presence of moral hazard, using a sealed-bid-first-score mechanism. In our scenario, bidders submit prices and target quality levels, and are subject to a failure-to-deliver penalty from deviations below said target. We present our analytical model and offer policy implications in presence and absence of default risk/renegotiation, and offer light to a dynamic extension of this model (in which credibility plays a fundamental role).

3 - Bidding With Learning In Repeated Auctions

Kartikeya Puranam, La Salle University, puranam@lasalle.edu,
Michael N Katehakis

We consider the problem of a firm that procures items in a sequence of auctions by bidding against the “market.” The firm has two bid levels available (High and Low). The firm and the “market” learn from each winning bid. We study bidding strategies for the firm when the objective of the firm is to minimize the expected total cost of acquiring items to meet demand.

Behavioral Operations

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Javad Nasiry, Hong Kong University of Science and Technology-HKUST, Hong Kong, nasiry@ust.hk

Co-Chair: Xiaoyang Long, Hong Kong University of Science and Technology, Hong Kong, xlongaa@connect.ust.hk

1 - Trust, Social Networks, And Information Sharing Among Executives

Ozalp Ozer, The University of Texas at Dallas, Richardson, TX, 75080, United States, oozer@utdallas.edu, Emily Choi,
Yanchong Zheng

We experimentally study how trust and social networks influence forecast information sharing behavior among executives with an average 17 years of professional experience. We demonstrate how trust preconditioned by prior experiences and trust measured from social network jointly influence information sharing behavior and the resulting supply chain efficiency.

2 - A Behavioral Study On Abandonment Decisions In Multi-stage Projects

Xiaoyang Long, Hong Kong University of Science and Technology, Hong Kong, Hong Kong, xlongaa@connect.ust.hk
Javad Nasiry, Yaozhong Wu

We experimentally investigate continuation/abandonment decisions in a multi-stage project under two conditions: when the project is reviewed at every stage and when review opportunities are limited. We find systematic deviations from the optimal solution: subjects may wrongly continue or abandon the project, and their decisions are path dependent. We propose a behavioral model which explains the behavioral regularities.

3 - Newsvendor Problem In The Presence Of Strategic Customers: Theory And Laboratory Evidence

Yang Zhang, Tsinghua University,
yangzhanguser@mail.tsinghua.edu.cn, Benny Mantin,
Yaozhong Wu

How would a newsvendor react to strategic customers who may delay their purchase until a price discount to take place? In theory, the newsvendor should optimally order less than the conventional critical fractile, in order to signal a shortage of products so that strategic customers herd into purchases at full price. In the laboratory however, retailers tend to psychologically overreact to the strategic customer behavior, which produces the so-called pull-below-center bias. We develop a behavioral model based on reference dependence to explain the observed ordering patterns, comparative statics, and the presence and asymmetry of pull-below-center bias across treatments.

4 - Competitive Dynamic Pricing Under Capacity Constraints: An Experimental Study

Bahriye Cesaret, Ozyegin University, Istanbul, Turkey,
bahriye.cesaret@ozyegin.edu.tr, Elena Katok

We present an experimental study of a stylized competitive dynamic pricing model for a duopoly. We designed a set laboratory experiments to investigate how human decision makers price their fixed units of capacity over a multiple-period selling season when they face a competition in the market. We report on the results of four experiments. The results show that our laboratory participant tends to underprice (i.e., price over-competitively) at the beginning of a selling season, and as the selling deadline gets closer she tends to overprice (i.e., price not competitive enough) her units.

Dynamic Mechanism Design

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Peng Sun, Duke University, Durham, NC, United States, peng.sun@duke.edu

1 - Dynamic Mechanism Design With Budget Constrained Buyers Under Limited Commitment

Omar Besbes, Columbia University, ob2105@columbia.edu, Santiago Balseiro, Gabriel Weintraub

We study the dynamic mechanism design problem of a firm repeatedly selling items to budget-constrained buyers when the seller has limited commitment power. We argue that this problem is generally intractable. Thus motivated we introduce a fluid model that allows for a tractable characterization of the optimal mechanism. We leverage our characterization to provide insights into the dynamic structure of the optimal mechanism and show that the proposed mechanism is a good approximation in large markets.

2 - Dynamic Short-term Contracts Under Hidden Inventory And Backlog

Hao Zhang, University of British Columbia, Vancouver, BC, Canada, hzhang01@sauder.ubc.ca
Lifei Sheng, Mahesh Nagarajan

We study a supply chain consisting of a supplier and a retailer faced with random demand over multiple periods. At the beginning of each period, the supplier offers a one-period contract and the retailer chooses order quantity before the demand is realized. The retailer carries leftover inventory or backlogs unmet demand, which is unobservable by the supplier. We find that in the infinite-horizon setting with exponentially distributed demand, for a large parameter set, the optimal sequence of short-term contracts is a generalized base-stock policy, where the base-stock level weakly increases with the beginning inventory.

3 - Dynamic Mechanism Design Without Money

Huseyin Gurkan, Duke University, Duke University, Durham, NC, 27707, United States, huseyin.gurkan@duke.edu, Santiago Balseiro, Peng Sun

We consider a principal repeatedly allocating a single resource in each period to one of multiple agents without relying on monetary payments over an infinite horizon. Agents' private valuations are independent and identically distributed. We show that as the discount factor approaches 1, the optimal dynamic mechanism without money achieves the first-best allocation (the welfare maximizing allocation when valuations are public). As part of the proof, we provide an incentive compatible dynamic mechanism that asymptotically achieves the first-best.

4 - Optimal Contract To Induce Continued Effort

Peng Sun, Duke University, Durham, NC, psun@duke.edu, Feng Tian

We consider a principal incentivizing an agent to exert effort in order to raise the arrival rate of a Poisson process. The effort is costly to the agent, unobservable to the principal, and affects the instantaneous arrival rate. Each arrival yields a constant revenue to the principal. A contract involves payments and a potential stopping time in order to motivate the agent to always exert effort. Although payments can take general forms contingent upon past arrival times, the optimal contract has a simple and intuitive structure, which depends on whether the agent is less patient than the principal.

Revenue Management: Algorithms and Applications

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Retsef Levi, MIT, Cambridge, MA, United States, retsef@mit.edu

1 - Assortment Optimization Under A Mallows Distribution Over Permutations

Antoine Desir, Columbia University, 601 W 113th Street, Apt 3J, New York, NY, 10025, United States, ad2918@columbia.edu, Vineet Goyal, Srikanth Jagabathula, Danny Segev

We study assortment optimization under Mallows distribution over permutations model that is specified by a central permutation and a decay parameter. The probability of any permutation decays exponentially in the (Kendall-Tau) distance from the central permutation. We present an efficient procedure to compute exact choice probabilities for any assortment even with exponential size distribution. Our procedure crucially exploits the symmetries of the Mallows model and leads to a compact IP formulation for assortment optimization. We also give an efficient near-optimal approximation for the IP.

2 - Auctions In The Online Display Advertising Chain: A Case For Transparency

Amine Allouah, Columbia University, 520 W 122nd Street Apt 24, New York, NY, 10027, United States, mallouah19@gsb.columbia.edu
Omar Besbes

In the online display advertising market in which auctions are run to sell impressions in real time, advertisers most often bid for impressions through intermediaries. We investigate the impact of the active role such intermediaries take on the selling mechanism that sellers should use and on the performance metrics of the different agents in the advertising chain.

3 - Fast Provably Near-optimal Algorithms For Dynamic Assortment Optimization

Ali Aouad, Massachusetts Institute of Technology, aaouad@mit.edu
Retsef Levi, Danny Segev

We study the dynamic assortment planning problem, where the demand is stochastic, and retailers' decisions need to be robust (revenue-wise) to stock-out events, elicited by the inventory limitations. While being key to revenue management, particularly in retailing and airlines, the computational aspects of such problems are still wide open. We devise the first efficient algorithms with provable performance guarantees, under several common modeling primitives, including the widespread Multinomial Logit choice model. In practical comparisons against incumbent heuristics, our algorithms improve the revenue by 9% to 35%, with better computational efficiency and robustness in most cases.

Sponsored Session

Chair: Arun Chockalingam, Eindhoven University of Technology, Den Dolech 2, Eindhoven, 5612 AZ, Netherlands, a.chockalingam@tue.nl

1 - The Optimal Hedging Strategy In A Competitive Supply Chain With Substitutable Commodities

Ehsan Bolandifar, Chinese University of Hong Kong, ehsan@baf.cuhk.edu.hk, Zhong Chen

This paper studies two risk-neutral processors procure two substitutable commodities from spot markets to process and sell through a retailer. First, we characterize the optimal index-based contracts for processors that indicates the processor's optimal contract consists of a processing margin which is independent of its financial hedging decisions and a hedge ratio which is a function of commodity price volatility. Next, we characterize conditions under which, the retailer prefers to be exposed to commodity price risks. We show that processors can benefit from market pricing, when these prices are linked to input commodity prices and index-based contracts are a means to achieve it.

2 - Integrated Risk Management In Commodity Markets

Fehmi Tanrisever, Bilkent University, tanrisever@bilkent.edu.tr

In this paper, we examine the integrated operating and financial hedging decisions of a value maximizing firm, in the presence of capital market imperfections. Our results show that the working capital and the hedging polices of the firm interact with each other in a multi-period dynamic inventory model. In particular, looser working capital policies lead the managers to take relatively more speculative positions in the market to maximize firm value.

3 - Production Planning With Shortfall Hedging Under Partial Information And Budget Constraint

Liao Wang, Columbia University, lw2489@columbia.edu, David D Yao

We study production planning integrated with risk hedging by considering shortfall (from a pre-specified target) as the risk measure. The optimal hedging strategy is identified via a dual lower-bound problem, and takes the form of a digital option combined with a put option; and optimizing the production quantity, given the optimal hedging, is shown to be a convex minimization problem. With both production and hedging optimized, we provide a complete characterization of the efficient frontier, and an explicit quantification of the shortfall reduction achieved by hedging.

4 - Dual Sourcing: Optimal Procurement Policy With Option Hedging Against Freight Rate Risk

Arun Chockalingam, Eindhoven University of Technology, Hoog Gagel 62, Eindhoven, 5611BG, Netherlands, a.chockalingam@tue.nl, Taimaz Soltani, Jan C Fransoo, Chung-Yee Lee

Raw materials cost less to procure on offshore markets as opposed to domestic markets. However, offshore procurement requires ocean shipping, the price of which is highly volatile, and firms usually have to charter ships, even if they do not use the whole capacity of ships. We consider a commodity processor with two sourcing choices and develop models to determine the firm's optimal sourcing policy. The models allow for three sources of uncertainty: demand, commodity spot price and freight rate. Using option contracts as hedging tools against freight rate risk, we develop a model that integrates a firm's optimal sourcing decision with the integer constraint on hiring ships.

Scheduling I

Contributed Session

Chair: Neil Desnoyers, Saint Joseph's University, 133 Green Valley Rd, Upper Darby, PA, 19082, United States, ndesnoye@sju.edu

1 - A Bicriteria Scheduling Problem With Two Competing Agents

Shudong Sun, Northwestern Polytechnical University, 127 Youyi West Road, PO Box 554, Xi'an, 710072, China, sdsun@nwpu.edu.cn

Single machine scheduling with two competing agents is studied. Cost function of the machine and agent 1 must be minimized simultaneously, while cost function of agent 2 is keeped below a determined value Q. Total completion time and maximum lateness of the machine, and most regular cost functions of the agents are consided. The model of multiagent scheduling has been enlarged to including the goal of both machine and agents. Some polynomial and pseudo-polynomial algorithms are presented.

2 - Scheduling Student Volunteers For The Informs Annual Meeting

Neil Desnoyers, Adjunct Instructor, Saint Joseph's University, 5600 City Avenue, Philadelphia, PA, 19131, United States, ndesnoye@sju.edu

The 2015 INFORMS Annual Meeting in Philadelphia required the assistance of 59 student volunteers. Each student volunteer was required to serve two half-day shifts out of the eight shifts available over four days (AM and PM shift each day). Via a web survey, student volunteers indicated five of eight shifts they were available to work. Between 12 and 14 student volunteers were required for each shift, and student volunteers were assigned to 9 or 10 locations/roles each shift. The problem was set up and solved as a binary integer programming problem. The problem provides lessons for volunteer scheduling in general.

Simulation and Optimization I

Contributed Session

Chair: Tomas Ignacio Lagos, Masters Degree Student, University of Chile, 2017 - Pozuelo, Santiago, 7640031, Chile, tomas.lagos.gonzalez@gmail.com

1 - An Integrated Multi-criteria Decision Making And Simulation-optimization Framework For Supplier Selection

Mohammad Dehghanimohammadabadi, Teaching Assistant Professor, Northeastern University, 360 Huntington Ave, MIE Department, Boston, MA, 02115, United States, mdehghani@neu.edu, Emanuel Melachrinoudis

A wide spectrum of criteria have been introduced by researchers to evaluate the suppliers' performance; however, measuring and employment of all of these criteria is impractical. In this study, a two-fold integration of MCDM and Simulation-Optimization is developed to select the most effective criteria for the supplier selection process. In this framework, the MCDM module incorporates a combination of criteria to select the suppliers. Then, the simulation model evaluates the performance of the Supply Chain (SC) considering the selected suppliers. Based on the simulation results, a metaheuristic algorithm finds the best/good combination of the criteria that maximizes the SC performance.

2 - Cloud-based Collaborative Application Development

Susanne Heipcke, Principal Engineer, FICO, FICO House, Starley Way, Birmingham, B37 7GN, United Kingdom, susanneheipcke@fico.com, Oliver Bastert

Integrated development environments are critical for efficient development but tooling for algebraic modeling languages has been lacking adoption of the latest technologies, no single tool covering the whole application development process so far. FICO Optimization Designer provides a novel approach for collaborative web-based development of optimization solutions. It supports model development in Xpress-Mosel, add-in predictive models implemented in R, deployment as on premises or cloud applications, and debugging of models run from a FICO Optimization Modeler application GUI.

3 - Adaptive Sampling Trust-region Optimization For Derivative-based And Derivative-free Simulation Optimization Problems

Sara Shashaani, PhD, Purdue University, Lafayette, IN, 47901, United States, sshashaa@purdue.edu, Raghu Pasupathy

We present ASTRO and ASTRO-DF – adaptive sampling trust-region optimization algorithms – or solving derivative-based and derivative-free continuous simulation optimization problems. Sampling in ASTRO and ASTRO-DF is done adaptively in an attempt to keep stochastic and structural errors in lock-step as the algorithm iterates evolve through the search space. We show consistency and discuss finite-time performance for a set of low to moderate dimensional optimization problems.

4 - Designing Resilient Electric Networks Under Natural Hazards

Tomas Ignacio Lagos, Masters Degree Student, University of Chile, 2017 - Pozuelo, Santiago, 7640031, Chile, tomas.lagos.gonzalez@gmail.com

We present an optimization framework for the problem of designing a resilient electric grid under high impact and low probability events, such as earthquakes. We use an Optimization via Simulation approach to solve this discrete decision problem, where the measure of resilience is the expected Energy Not Supplied and its evaluation uses an existing simulator with historical earthquake data, information of fragility curves of the components provided by FEMA, and an Optimal Power Flow model. We use this framework to evaluate the effect of different resilience measures and algorithms.

Sponsored Session

Chair: Carolyn Queenan, University of South Carolina, 1014 Greene St, Columbia, SC, 29208, United States, carrie.queenan@moore.sc.edu

1 - The Impact Of Call Rotations And Geographic Localization Of Patients On Hospital Performance

Douglas Morrice, University of Texas-Austin, Austin, TX, United States, douglas.morrice@mccombs.utexas.edu, Ying Chen, Jonathan F Bard, Luci Leykum

We study the impact of an on-call rotation of teaching teams for admissions and geographic localization of patients on hospital performance using patient-level data from a Texas teaching hospital and simulation. Performance is measured by length of stay in the Emergency Department, patient hand-offs, and bed availability. The results of this study inform admission decision-making including patient allocation to medical teams and admission capacity planning.

2 - Complementarities Or Substitutes Of Physician Employment For Managing Patient Care: Effects Of Focus, Experience, And Technology

David Zepeda, Northeastern University, Boston, MA, 02115, United States, d.zepeda@neu.edu, Gilbert N. Nyaga, Gary J. Young

A dramatic change in the health care industry is the increasing emphasis on linking provider payment to clinical quality performance metrics. This is one of several considerations leading hospitals to vertically integrate by acquiring physician practices and employing physicians directly. Yet, there is little evidence regarding whether this form of vertical integration leads to better performance on clinical quality performance metrics. We empirically evaluate the relationship between hospital employment of physicians and hospital performance on clinical quality performance metrics. We also consider several hospital operational considerations as potential moderators.

3 - Analyzing The Impact Of Surgical Process Changes On Patient Flow

Justin Kistler, University of South Carolina, Columbia, SC, United States, justin.kistler@grad.moore.sc.edu
Ramkumar Janakiraman, Vikram Tiwari, Subodha Kumar

Leveraging unique patient level encounter data through econometric techniques, we examine the impact of two process changes on surgical operations at a medical center. Building on management and operations literature, we posit that a process change, and a subsequent intra-operative IT enabled process change, will significantly improve surgical operations flow time. Given the high opportunity cost of resources associated with surgical procedures, this finding has important implications for surgical process owners and participants.

Co-Chair: Rachel Rong Chen, University of California-Davis, Graduate School of Management, Davis, CA, 95616, United States, rachen@ucdavis.edu

1 - Exploring The Rational Behind Outlet Stores

Jiaru Bai, University of California, Irvine, jiarub@uci.edu, Haresh Gurnani, Shuya Yin

Outlet stores have been both complementary to and competing with the main stores. In this project, our goal is to understand the tradeoffs involved in offering outlet stores. In particular, we study how much differentiation should be kept between the main and outlet stores from three perspectives: price, product and location.

2 - Fit-revelation Sampling And Advertising: Complementary Or Substitutable?

Rachel Rong Chen, University of California-Davis, Davis, CA, United States, rachen@ucdavis.edu, Shiming Deng, Lingli Wu

Buyers are often uncertain about how a product fits their individual preferences. In such situations, fit-revelation sampling can be offered to allow consumers to resolve such uncertainties before purchase. When advertising is jointly offered, fit-revelation sampling may have a correction effect that could enhance or weaken the valuation added by advertisements. This paper studies the profit implications of the interactions between advertising and fit-revelation sampling.

3 - Replenishment Strategies For Micro-retailers In Developing Countries

Sean Zhou, Chinese University of Hong Kong, Hong Kong, Hong Kong, zhoux@baf.cuhk.edu.hk, Christopher S. Tang, Kairen Zhang

When formal distribution channels are absent in developing countries, micro-retailers travel long distances to replenish their stocks directly from key suppliers. We examine a model where multiple competing retailers collectively determine the replenishment strategy among three possible strategies: informal, formal, and hybrid. We show that when the stores engage in quantity competition, the hybrid strategy maximizes the retailers' total welfare when either the travel cost is sufficiently high or the fixed operating costs are sufficiently low.

1 - An Empirical Investigation Of Network Effect In Automobile Sales

Tianjun Feng, Fudan University, tfeng@fudan.edu.cn, Fuqiang Zhang, Peiwen Yu

This paper investigates the network effect in automobile sales by using a unique dataset from a large city in China. We demonstrate the existence of a positive but diminishing marginal effect of the local owner base on the sales of automobiles.

2 - The Operational Value Of Social Media Information

Dennis Zhang, Northwestern University, 1500 Chicago Avenue, Apt.712, Evanston, IL, 60201, United States, j-zhang@kellogg.northwestern.edu, Antonio Moreno-Garcia, Ruomeng Cui, Santiago Gallino

This paper empirically studies whether using publicly available social media information can improve the accuracy of daily sales forecasts. We collaborated with an online apparel retailer to implement a variety of machine learning methods to create daily sales forecasts. We find that using social media information results in statistically significant improvements in the out-of-sample accuracy of the forecasts, with relative improvements ranging from 12.85 percent to 23.23 percent over different forecast horizons.

3 - When You Work With A Super Man, Will You Also Fly? An Empirical Study Of The Impact Of Coworkers On Performance

Serguei Netessine, INSEAD, serguei.netessine@insead.edu
Fangyun Tan

We examine a large operational data set in a casual restaurant setting to study how coworkers' sales ability (measured as servers' sales premium) affects workers' performance in terms of service speed and service quality. We find that servers react non-linearly to their coworkers' ability. In particular, when coworkers' overall sales ability is low, increasing this ability may trigger servers to redouble both upselling and cross-selling efforts at the expense of slower service speed. Our empirical findings imply that managers should mix servers having heterogeneous ability levels during the same shift.

4 - Ceo Overconfidence And Inventory Management

Fuqiang Zhang, Washington University in St. Louis, zhang@olin.wustl.edu, Tianjun Feng, Qing Zhang

Using the data of the US-listed companies in the manufacturing industry during 1999-2011, this study empirically investigates the relationship between CEO overconfidence and firms' operations efficiency. Specifically, we focus on inventory turnover, a widely used operations efficiency measure for inventory management. We find that firms with overconfident CEOs are associated with higher inventory turnover.

1 - Impact Of Physical Retail Channel On Customers' Online Purchase Behavior

Anuj Kumar, University of Florida, akumar1@ufl.edu
Amit Mehra, Subodha Kumar

We use customer-level data of a large apparel retailer to estimate the treatment effect of store openings on the online purchase behavior of its existing customers. The retailer's store openings resulted in a 29 percent increase in annual online purchase revenue of the existing customers. The increase in online purchases of existing customers after store opening could be attributed to: (1) higher engagement with the retailer from their higher store interactions and (2) availability of a low cost option of returning their online purchases in store if it does not fit their needs. The effect of store opening was found to be higher for customers who experience higher reduction in their store distances.

2 - When The Bank Comes To You: Branch Network And Custsomer Multi-channel Banking Behavior

Vibhanshu Abhishek, Carnegie Mellon University, vibs@cmu.edu
Beibei Li, Dan Geng

Customers today increasingly interact with their banks using digital channels, lifting the necessity for banks to rethink the distribution of physical branches and customer behavior in a multi-channel environment. Using approximately 1.2M anonymized individual-level data from a large commercial bank in US over 6 years, our paper investigates the traditional channel - bank branches - and the impact of its network change (branch opening or closure) on customer multi-channel preferences and other banking behavior. Our results show that both branch opening and closure are associated with decreasing transactions through offline channels and increasing transactions in online banking.

3 - Inventory Management In An Omnichannel Environment

Yong-Pin Zhou, Professor, Foster School of Business, University of Washington, Seattle, Seattle, WA, 98195-3226, United States, yongpin@uw.edu, Elnaz Jalilipour Alishah

We consider a single newsvendor-type product that is sold both online and offline. We present two models where each channel is used as a backup for the other channel, and derive structural and qualitative results on effective inventory management policies. Specifically, we consider inventory positioning, inventory level, and real-time inventory rationing decisions. When it is possible to shift some customer demand using discounts, we also investigate the level of discount and customer reaction.

4 - The Omni-channel Fulfillment Dilemma

Santiago Gallino, Dartmouth College, Dartmouth, NH, United States, santiago.gallino@tuck.dartmouth.edu, Antonio Moreno-Garcia, Robert P. Rooderkerk

Using transaction level data from a multi-channel retailer we explore how customer interact with the retailer over time. We study the underlying patters of customer's interactions and discuss the implications for retailers that have both an online and a brick and mortar presence.

Product Development and Competition

Invited: New Product Development

Invited Session

Chair: Morvarid Rahmani, Georgia Institute of Technology, Atlanta, Atlanta, GA, 30308, United States, morvarid.rahmani@scheller.gatech.edu

Co-Chair: Karthik Ramachandran, Georgia Institute of Technology, Atlanta, GA, 30308, United States, karthik.ramachandran@scheller.gatech.edu

1 - Knowledge Search In Mobile App Development

Nilam Kaushik, PhD Candidate, UCL School of Management, London, United Kingdom, uceikau@ucl.ac.uk, Bilal Gokpinar

The process of search, identification, and acquisition of new knowledge is essential for the success of new products. We explore how firms search for ideas in sequential product development through the highly competitive and dynamic setting of mobile application development. Using novel text-mining techniques, we derive measures of similarity between a focal app's update and updates made by competitor apps and study performance implications thereof. We also explore the performance implications of the distance of an app's update with respect to its past updates.

2 - Decision Options At Project Gate Reviews: Beyond The Go/ Kill Model

Alison Olechowski, Massachusetts Institute of Technology, Cambridge, MA, United States, alisono@mit.edu Steven D Eppinger, Nitin Joglekar

Most current academic models of project gate reviews represent the gate decision as a simple choice between go and kill. In reality, product developers often reach the gate with incomplete or unacceptable deliverables, and managers consider more than just the kill option if a go is not appropriate. We have created a simple model which adds options of: waiver, waiver with re-review, delay and switch to back-up plan. This decision tree model compares the value of this more realistic set of options based on costs, payoffs and confidences. We demonstrate the application of this model to complex product development gate decisions via multiple case examples from industry.

3 - Capacity Investment For Product Upgrades Under Competition

Ram Bala, Santa Clara University, ram.bala@gmail.com, Milind Sohoni, Sumit Kunnumkal

Firms often introduce a vertical line extension of an existing product to consolidate their market position after loss of monopoly status. However, introducing a line extension is fraught with uncertainty as it may fail to be technically feasible as originally intended. We analyze a two stage competitive game between an incumbent and an entrant where the firms make capacity investment decisions before uncertainty resolution and then set production quantities. We uncover conditions on innovation level which determine whether the incumbent will continue to offer the existing product once the new product succeeds. We also determine the innovation level beyond which competitive entry is deterred.

4 - Institutional Design And The Creative Process: An Experimental Study

Lakshminarayana Nittala, University of California San Diego, La Jolla, CA, 92037, United States, lnittala@ucsd.edu Sanjiv Erat, Viswanathan Krishnan

The process of Innovation often takes the form of problem solving and requires creative insights for achieving success. In an experimental setting we use tasks that are representative of such problems and study the role of institutional design on the creative output and the underlying search process.

A/B Testing, Experiments, and Learning

Sponsored: Applied Probability

Sponsored Session

Chair: Ramesh Johari, Stanford University, Stanford, CA, United States, ramesh.johari@stanford.edu

Co-Chair: David Walsh, Stanford University, Department of Statistics, Stanford, CA, 94305, United States, dwalsh@stanford.edu

1 - Using Simulation To Improve Statistical Power In Switchback Experiments At Uber

Peter Frazier, Cornell University, Ithaca, NY, 14850, United States, pf98@cornell.edu

We consider A/B testing of systemic changes with time-varying effects, such as changes to the algorithm used to dispatch cars at Uber. Testing such changes is made difficult by correlations in outcomes across dispatches, and by seasonal and autocorrelated random variation in riders' demand for trips. One standard A/B testing method is a switchback experiment, which applies the treatment and control on alternating days over two weeks. We show how to combine simulation-based predictions of a change's effects with data from a switchback experiment to improve statistical power, and make analysis robust to missing data.

2 - A/B Testing In A Changing World

David Walsh, Stanford University, dwalsh@stanford.edu

The purpose of A/B testing is to let any technology company iterate on its products quickly and stay ahead of a rapidly changing market. Given this dynamic context, it is odd that the existing statistical approaches to A/B testing view the environment as static. The outcome: inferences that do not generalize beyond the life of the experiment, which then lead to actions that perform substantially worse than expected. I present new methodology that anticipates temporal variation, generating the right inferences to support dynamic product optimization.

3 - Simple Bayesian Algorithms For Identifying The Best Arm In A Multi-armed Bandit

Daniel Russo, Northwestern University, Evanston, IL, United States, Dan.Joseph.Russo@gmail.com

This talk considers the optimal adaptive allocation of measurement effort for identifying the best among a finite set of options or designs. An experimenter sequentially chooses designs to measure and observes noisy signals of their quality with the goal of confidently identifying the best design after a small number of measurements. I propose three simple Bayesian algorithms for adaptively allocating measurement effort. Each is shown to have strong performance in numerical experiments, and a unified analysis establishes each satisfies a strong asymptotic optimality property.

4 - Sequential A-B Testing With Constraints

Vivek Farias, Massachusetts Institute of Technology, Cambridge, MA, United States, vivekf@mit.edu, Ciamac Cyrus Moallemi

We consider the problem of sequential A-B testing when the impact of a treatment is marred by a large number of covariates. Our main contribution is a tractable algorithm for the online allocation of test subjects to either treatment with the goal of maximizing the efficiency of the estimates treatment effect under a linear model, which due to a surprising state space collapse, reduces to solving a low dimensional dynamic program. Our approach is robust and covers many variations of the problem, including cases where there are budget constraints on individual treatments, where the number of trials is to be endogenously decided, and where the objective is to balance a tradeoff between efficiency and bias.

Applications in Efficiency Analysis

Invited: Data Envelopment Analysis

Invited Session

Chair: Kankana Mukherjee, Babson University, 231 Forest Street, Babson Park, MA, 02457, United States, kmukherjee@babson.edu

1 - Malmquist Productivity Analysis With The Stoned Method

Endre Bjørndal, Norwegian School of Economics, Endre.Bjorndal@nhh.no, Xiaomei Cheng, Mette Bjorndal

We construct a Malmquist productivity index based on the Stochastic Non-parametric Envelopment of Data (StoNED) method, and we discuss how the distributional assumptions in the second StoNED stage affect estimates of productivity change and its decompositions. Our results are also valid for similar methods, such as COLS and MOLS, where a best-practice frontier is obtained from an average-practice frontier. Data on Norwegian electricity distribution companies is used to illustrate our discussion.

2 - Determinants Of Energy Efficiency In Indian Manufacturing

Kankana Mukherjee, Babson University, kmukherjee@babson.edu

This paper takes a production perspective and utilizes Data Envelopment Analysis to examine the major determinants of the traditional index of energy efficiency in the Indian manufacturing industry. The roles of technical efficiency of production, capacity utilization, and the adoption of energy efficient technology in determining energy efficiency is specifically addressed.

3 - Implicit Estimation For Stochastic Frontier Model

Mohamed Nejib Ouertani, Sfax University, n_ouertani@yahoo.fr

In this paper, a novel approach has been proposed to estimate stochastic frontier models; namely the Implicit approach. As we reckon, to our limited knowledge this method steel has not been applied to the stochastic frontier approach. For this purpose, the Markov Chain Monte Carlo (MCMC) techniques are used and implemented for both approaches subject of our study. As matter of fact, our new approach has been illustrated by means of a data pertaining to a sample of Saudian insurers.

4 - Inward Internationalization And Performance: An Application Of The Bootstrapped Truncated Regression Model

Yi-Chun Liu, National Taiwan University, Taipei, Taiwan, d02724003@ntu.edu.tw, Yang Li, Homin Chen

This study is the first to study the influence of the breadth of inward internationalization (BII) on the performance of internationalization of international tourists (ITHs). We employ the bootstrapped truncated regression model and takes into account the property of quasi-fixed inputs to analyze how BII influences the operational performance of Taiwan's ITHs. The data set consists of 70 Taiwanese ITHs and 208 observations for the period 2011-2013. The empirical results show that the BII contributes positively to ITHs' efficiency, benefits independent ITHs greater than it does for chain ones, and moderates the relationship between core revenue and operational performance.

Control and Optimization in Finance

Sponsored: Financial Services

Sponsored Session

Chair: James Primbs, Cal State Fullerton, Fullerton, CA, United States, jprimbs@fullerton.edu

1 - Order Book Dynamics And Price Sensitivity At Nasdaq: Part 1

James Primbs, California State University Fullerton, Fullerton, CA, 92831, United States, japrimbs@live.com
Scott Condie, Sean Warnick

The order book is a rich source of information detailing trading dynamics in equity markets. Recent concerns with algorithmic trading activities suggest that high frequency traders have unfair advantages compared with nominal traders. The first part of this talk will introduce the order book and explore the data set used in the analysis. Public concerns related to high frequency trading and Siren orders will also be discussed.

2 - Order Book Dynamics And Price Sensitivity At Nasdaq: Part 2

James Primbs, California State University Fullerton, 925 Berenice Dr, Brea, CA, 92821, United States, japrimbs@live.com
Scott Condie, Sean Warnick

The order book is a rich source of information detailing trading dynamics in equity markets. Recent concerns with algorithmic trading activities suggest that high frequency traders have unfair advantages compared with nominal traders. The second part of the talk will explore differences in market dynamics over different time scales and price sensitivity to the shape of the order book. Efforts to find evidence for the concerns detailed in Part I will be explained.

3 - On A New Class Of Pairs-trading Strategies

Atul Deshpande, University of Wisconsin, Madison, WI, United States, adeshpande4@wisc.edu, B. Ross Barmish

The starting point for this paper is a new class of pairs-trading strategies which have rather weak requirements on the underlying stocks. We allow the user to define a rather arbitrary spread function to relate the two stock prices under consideration. Moreover, when this function, in conjunction with the price processes, satisfies a certain mean-reversion condition, we deem the stocks to be a tradeable pair. For such a case, we prove that our trading strategy results in positive expected growth in the account value. For a limited number of backtests using popular spread functions from literature, we see robust growth while avoiding huge drawdowns.

4 - Robust Empirical Optimization Is Almost The Same As Mean-variance Optimization

Jun-ya Gotoh, Chuo University, jgoto@indsys.chuo-u.ac.jp

We consider a robust optimization problem. Our main finding is that a large class of robust empirical optimization problems are essentially equivalent to an in-sample mean-variance. With this insight, we suggest a robust version of cross-validation which can be beneficial to high-dimensional-small-data situation such as portfolio optimization.

Quantitative Methods in Finance

Sponsored: Financial Services

Sponsored Session

Chair: Richard Sowers, University of Illinois, Champaign, Urbana, IL, 61801, United States, r-sowers@illinois.edu

1 - Measures Of Financial Network Complexity: A Topological Approach

Mark Flood, Office of Financial Research, Mark.Flood@ofr.treasury.gov

We present a general definition of complexity appropriate for financial counterparty networks, and derive several topologically based implementations. These range from simple and obvious metrics to others that are more mathematically subtle. It is important to tailor a complexity measure to the specific context in which it is used. This paper introduces measures of the complexity of search and netting in dealer markets. We define measures of line graph homology and collateral line graph homology that are sensitive to network interactions, such as collateral commingling and interdependent chains of obligations, that can be difficult or intractable to unwind.

Military Applications of Decision Analysis

Sponsored: Decision Analysis

Sponsored Session

Chair: Gregory S Parnell, University of Arkansas, University of Arkansas, Fayetteville, AR, 72701, United States, gparnell@uark.edu

1 - Stakeholder Requirements For Engineered Resilient Systems Decision Support Tools

Christina Rinaudo, Operations Research Analyst, USACE Engineer Research and Development Center (ERDC), Vicksburg, MS, 39180, United States, christina.h.rinaudo@usace.army.mil,
Randy Buchanan

Engineered Resilient Systems (ERS) seeks to improve engineering and design development to generate adaptive, effective, and trusted systems in a physics model-based environment. The ERS program strives to incorporate decision analysis tools that enable customization of analytical tools. Through a collaborative workshop held with ERS stakeholders, researchers gained an understanding of multiple perspectives for decision analysis methods in a physics model-based environment. This presentation explores the stakeholder requirements identified by the workshop and proposes next steps to incorporate decision analysis into the ERS tradespace analytical tool suite.

2 - Tradespace Tools For Engineering Resilient Systems

Valerie B. Sitterle, Senior Research Engineer, Georgia Tech Research Institute, Atlanta, GA, United States, valerie.sitterle@gtri.gatech.edu, Santiago Balestrini-Robinson, Dane F. Freeman, James Arruda, Simon R. Goerger, Tommer R. Ender

Engineered Resilient Systems (ERS) is a U.S. Department of Defense (DoD) program focusing on effective, efficient development of complex engineered systems across their lifecycle and different future operational needs and mission contexts. This presentation will describe the ERS TRADESPACE toolset being collaboratively developed for the DoD Acquisitions community to support the end-to-end set of integrated processes necessary to specify stakeholder needs and create tradespaces for exploration in synergy with decision analysis methods. We will also discuss how traditional decision analysis may be a foundation from which to explore additional questions relevant to key decision makers.

3 - Decision Analysis In The Engineering Body Of Knowledge

Gregory S Parnell, University of Arkansas, gparnell@uark.edu

We review the definitions of decision analysis and list the decision analysis articles in the body of knowledge for the following professional societies: INFORMS, the Society for Decision Professionals, the Military Operations Research Society (MORS), The International Council on Systems Engineering (INCOSE), and the American Society for Engineering Management (ASEM).

4 - Evaluating Stakeholder Requirements To Assess Resiliency For Engineered Resilient Systems

Christina Rinaudo, USACE Engineer Research and Development Center (ERDC), Vicksburg, MS, United States, Christina.H.Rinaudo@usace.army.mil, Randy K Buchanan

Engineered Resilient Systems (ERS) research focuses on identifying methods and incorporating processes to enable model-based systems engineering analysis early in the acquisition life cycle. ERS research efforts include defining, quantifying, and developing a methodology to analyze system resiliency. Previous research described an aspect of resilience as robustness and proposed a workflow to quantify robustness using Multi-Attribute Utility Theory (MAUT). This presentation describes the application of the robustness workflow to evaluate design alternatives using the system requirements generated during the development of the Mine Resistant Ambush Protected (MRAP) vehicle.

Applications of Decision Analysis to Natural Resource Management

Sponsored: Decision Analysis

Sponsored Session

Chair: Karen Jenni, US Geological Survey, DFC, MS 939, Denver, CO, 80225, United States, kjenni@usgs.gov

Co-Chair: Michael Runge, US Geological Survey, Patuxant Wildlife Research Center, Laural, MD, 20708, United States, mrunge@usgs.gov

1 - Optimal Design Of Protection Zones For Wildlife.

Julien Martin, US Geological Survey, julienmartin@usgs.gov

The establishment of protection areas to reduce mortality risk of wildlife is a common management action, yet implementation of these zones can be contentious. We apply optimization approaches to determine optimal configuration of protection zones that meet management objectives under various costs and constraints scenarios. One key management objective is to minimize risk of deadly collisions. We apply encounter rate theory to quantify the relative risk of lethal collisions between marine mammals and watercraft.

2 - Managing A Long-term Tidal Estuary Restoration: An Adaptive Framework For Decisions Under Uncertainty And Risk

David R Smith, Researcj Statistician, US Geological Survey, Leetown, WV, 25430, United States, drsmith@usgs.gov
Jill Gannon, Mitchell J Eaton

In collaboration with NPS, we developed a decision framework to help guide restoration of an ecologically degraded estuary, restricted from tidal influence for 100+ years. Decisions involve the timeframe under which restored tidal exchange will occur via modified water control structures, and implementation of secondary actions to address specific concerns. Decision complexity is magnified by multiple objectives, a long restoration horizon, high uncertainty about ecosystem response to hydrologic changes and low risk tolerance by numerous stakeholders. Although leaning is anticipated to occur rapidly, problem complexity limits the application of formal adaptive management principles.

3 - Models And Tools To Support Decision Making On Multiple, Future, As-yet Unclear Management Issues

Karen Jenni, US Geological Survey, kjenni@usgs.gov

The USGS is developing a set of approaches and tools for conducting multi-resource analyses. These tools are intended to support decision making on a variety of future issues related to landscape-scale resource management. The tools can be used to consider multiple natural resources and sources of change and to address the relationships among resources and the social and economic impacts of resource change over time. We will discuss some of the unique challenges in scoping, defining, and building such models, focusing on the benefits a decision analysis approach brings even to problems without a clearly defined issue or specifically identified decision-makers.

4 - Casting Endangered Species Recovery As A Budget Allocation Problem

Michael C Runge, USGS Patuxent Wildlife Research Center, Laurel, MD, 20708, United States, mrunge@usgs.gov, Leah R. Gerber, Jeff Newman, Lynn A. Maguire, Richard F. Maloney, Deborah T. Crouse

The U.S. Fish and Wildlife Service (FWS) is charged with managing recovery programs for species listed under the Endangered Species Act. At an agency level, this can be seen as the allocation of scarce resources to a portfolio of individual recovery efforts, taking into account the potential synergies among programs, as well as the opportunity to motivate additional funding from external partners. We are working with FWS to frame such decisions, using combinatorial optimization to explore solutions. Initial results suggest recovery outcomes could be improved with strategic budget allocation. Further, this framework provides a way to clearly articulate the benefits of increased funding.

Pricing and New Product Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Nur Sunar, UNC, Chapel Hill, NC, United States, nur_sunar@kenan-flagler.unc.edu

1 - Optimal Subscription Pricing For Free Delivery Services

Chinmoy Mohapatra, PhD Student, The University of Texas at Austin, McCombs School of Business, Austin, TX, 78712, United States, chinmoym@utexas.edu, Anant Balakrishnan, Shankar Sundaresan

We study the subscription pricing problem of a retailer that offers its consumers two delivery choices: a pay-per-delivery option and a subscription option with free delivery. The retailer balances the “loss” incurred in covering the shipping costs of subscribers against the increase in revenue from the “lift” in their purchase quantity. We develop a model based on a novel utility-based framework that captures consumer heterogeneity, both in terms of their utility and preference across different firms, characterize the retailer’s optimal subscription pricing policy, and develop interesting insights.

2 - Optimal Dynamic Product Development And Launch For A Network Of Customers

Nur Sunar, UNC, nur_sunar@kenan-flagler.unc.edu
John Birge, Sinit Vitavasiri

We consider a firm that dynamically chooses its effort to develop a product for a network of customers represented by a general connected graph. In addition to dynamically choosing its development effort, the firm chooses when to launch or abandon the product. If the firm launches the product, the firm also chooses a selling price, a promotional price and a target customer to offer promotion. Once the target customer adopts the product, the product dynamically diffuses over the customer network based on the topology of the graph and the selling price. In a continuous-time setting, we explicitly solve the firm's jointly-optimal development, launch and post-launch strategies for any connected network.

3 - Quantity Pre-commitment And Cournot Equivalence

Amr Farahat, Washington University-St. Louis, Campus Box 1133, 1 Brookings Drive, St. Louis, MO, 63130, United States, farahat@wustl.edu, Woonghee Tim Huh, Hongmin Li

We study a two-stage oligopolistic competition game, called the Quantity Pre-Commitment game, in which firms compete on quantity in the first stage and then compete on price in the second stage. This game is compared to a single-stage Cournot game, in which firms compete on the quantity only and the prices are set to clear the market. We show an equivalence result that an equilibrium of the Quantity Pre-Commitment game coincides with an equilibrium of the Cournot game, under certain conditions. The conditions that we identify are more general than those of specific models used in the seminal papers in the literature.

4 - A Stochastic Model For Pricing In Reverse Supply Chains

Elif Akcali, University of Florida, Dept of Industrial and Systems Engineering, 303 Weil Hall PO Box 116595, Gainesville, FL, 32611-6595, United States, akcali@ise.ufl.edu, Sila Cetinkaya, Yi Zhang

We address channel coordination issues in a two-echelon reverse supply chain that consists of a collector and a manufacturer. We develop stochastic models to maximize the manufacturer's and collector's profits in a game-theoretic framework. We develop an effective mechanism to coordinate manufacturer's and collector's decisions.

Topics in Assortment Planning and Consumer Choice

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Kris Johnson Ferreira, Harvard Business School, Boston, MA, United States, kferreira@hbs.edu

1 - A Data-driven Approach To Customer Segmentation

Ashwin Venkataraman, New York University, 719 Broadway, 7th Floor, New York, NY, 10003, United States, ashwin@cs.nyu.edu
Srikanth Jagabathula, Lakshminarayanan Subramanian

We propose a new "model-based" projection technique for segmenting customers based on partial observations for each customer. We suppose that data are available in the form of categorial responses for on a collection of n variables for each customer. This unified representation allows one to combine diverse signals (clicks, demographics, purchases, etc.) to obtain accurate segmentation. Our method relies on a combination of model-based projections and matrix completion techniques to obtain the clusters. We theoretically and empirically show how our method is superior to existing benchmarks.

2 - Analysis Of Choice Models: A Welfare-based Framework

Xiaobo Li, University of Minnesota, Minneapolis, MN, 55414, United States, lixx3195@umn.edu, Guiyun Feng, Zizhuo Wang

We propose a framework for discrete choice models through a welfare function. The framework provides a new way of constructing choice models. It also provides great analysis convenience for establishing connections among existing choice models. We define a new property in choice models: substitutability/complementarity and study conditions for a choice model to be substitutable. We show that our framework is flexible in this property, which is desirable in capturing practical choice patterns.

3 - A Dynamic Clustering Approach To Data-driven Assortment Personalization

Fernando Bernstein, Duke University, fernando@duke.edu
Sajad Modaresi, Denis R. Saure

A retailer faces heterogeneous customers with initially unknown preferences. The retailer can personalize assortment offerings based on available profile information; however, users with different profiles may have similar preferences, suggesting that the retailer can benefit from pooling information among customers with similar preferences. We propose a dynamic clustering approach that adaptively adjusts customer segments and personalizes the assortment offerings to maximize cumulative profit.

4 - Assortment Rotation And The Value Of Concealment

Kris Johnson Ferreira, Harvard Business School, kferreira@hbs.edu, Joel Goh

The frequency at which retailers change their assortment varies widely across fashion retailers. Some retailers choose to sell products simultaneously throughout the season, whereas others choose to sell products sequentially, requiring that the consumer make a purchase decision before seeing the subsequent products for sale. By offering products sequentially, retailers can introduce uncertainty in consumer choice that affects purchase decisions. We develop a consumer choice model and finite-horizon stochastic dynamic program to study when this uncertainty is advantageous for a retailer: a phenomenon we refer to as the retailer's value of concealment.

Social Media Analysis I

Invited: Social Media Analytics

Invited Session

Chair: Chris Smith, Air Force Institute of Technology, 2950 Hobson Way, 2950 Hobson Way, Wright-Patterson AFB, OH, 45433, United States, cms3am@virginia.edu

1 - User Reward Programs In Online Social Media

Fouad H Mirzaei, Santa Clara University, Unit 3, 559 Alviso St, Santa Clara, CA, 95050, United States, fhm.phd@ivey.ca, Fredrik Odegaard, Xinghao Yan

Online social media (OSMs) have become a popular and growing Internet phenomenon, as exemplified by the millions of followers of websites like YouTube, Twitter, and Facebook. Given the Internet's ease of access and the high degree of competition to attract users to these sites, a question arises as to whether OSMs should develop revenue-sharing programs as a way to reward their contributing users. We present an ex ante asymmetric duopoly OSM game, where heterogeneous users are either active or passive with respect to each OSM. In this study, we explore how online users' actions and perspectives impact the outcome of the competition among OSMs.

2 - Research On The Influence Of Microblog Advertising Of Theatre Chain On Its First Week Box Office Revenue

Jiayin Qi, Shanghai University of International Business and Economics, Shanghai, 100876, China, qijiayin@139.com, Jiaqi Liu

With the participation of enterprise in social network, a question arises of how enterprise can gain more real profit from social network advertising. This article analyzes the relationships among contents of enterprise's online post, consumer's participation on microblog, and short-term product sales. Taking movie market as research set, this research finds that short-term product sales is positively influenced by the information quantity of enterprise's post, and the influence is mediated by the "repost" of other users of Sina microblog. The mechanism examined in this research on the influence of microblog advertising on short-term sales can be guidelines of social network advertising.

3 - Social Media Use And New Product Development Performance

Debasish N Mallick, Associate Professor, University of St. Thomas, Opus College of Business, 1000 La Salle Avenue # TMH 443, Minneapolis, MN, 55403, United States, dnmallick@stthomas.edu

Use of social media is becoming increasingly popular in new product development (NPD). Yet, the performance impact of social media use in NPD remains inconclusive. Using a cross industry survey of new product development projects, we explore the factors affecting the relationship between social media use and NPD performance.

Case Competition I

Sponsored: Education (INFORMED)

Sponsored Session

Chair: Palaniappa Krishnan, University of Delaware, Newark, DE, United States, baba@udel.edu

1 - Wine Of Kings, King Of Wines

David Kopcso, Babson College, Wellesley, MA, United States, kopcso@babson.edu

It is a cool October morning and Borbála Bodnar is faced with a dilemma. The harvest at her northeast Hungary vineyard is finishing. Her hopes for a harvest of botrytis-affected, aszu (dried) grapes is waning. The seasonally rainy days are approaching. Bodnar must decide if she should harvest the grapes immediately for a modest profit or wait with the hope of a Botrytis infection. A heavy downpour would swell the already ripe grapes with water producing an inferior wine with little profit while a shower or even just a high humidity day followed a day later by a drop in humidity would be ideal for the development of the Botrytis cinerea fungus needed to produce the very profitable, complex, sweet Tokaji wine.

2 - Risks and Rewards in Professional Tennis

Fredrik Odegaard, Western University, London, ON, Canada. fodegaard@ivey.uwo.ca

The case centers on the professional tennis tour ATP, and the world-famous and prestigious Grand Slam tournament Wimbledon.Depending on the instructor's use of the case, the case is suitable in both an introductory and as well as intermediate/advanced management science/analytics course. Although the main target audience is under-graduate business and engineering students, the case is also suitable for Masters students (including MBA). The case has been used both as a casebased final exam and as material for in-class case discussion.

3 - Optimizing Promotions For Supermarkets Using Data Analytics

Maxime Cohen, New York University, Stern School of Business, New York, NY, United States, maxcohen@nyu.edu, Georgia Perakis

In this case, we expose the students to the issues faced by a supermarket manager seeking to optimize price promotions for a category of products. The students will learn: how to handle data, demand modeling and forecasting, business rules and mathematical modeling, optimization formulation, solving linear programs, and how to measure the practical impact of the approach. The case includes data sets so that the students can experience handling data. The approach encompasses the entire process behind promotion planning, from data collection to optimizing promotion decisions.

4 - Ingenuity Technology-From Chaos To Structured Data

William Schmidt, Cornell University, Ithaca, NY, United States, wschmidt@cornell.edu

This case will familiarize students with the process of merging together and analyzing data from multiple files. Students will (1) conduct a data integration effort similar to what they may encounter it in a practical setting and (2) perform an analysis on the combined data set. The case is designed such that the tasks can be conducted using a variety of platforms. The setting is a recently founded technology firm that has experienced rapid growth in its first 2 years of operations. The protagonist must decide whether a new sales process has improved the performance of the sales organization.

Gender and Diversity-based Research

Sponsored: Women in OR, MS

Sponsored Session

Chair: Sarah G Nurre, University of Arkansas, 4207 Bell Engineering, Fayetteville, AR, 72701, United States, snurre@uark.edu

1 - Evaluations At Every Corner A Discussion Of Bias In The Evaluation Process

Tristan Botelho, MIT Sloan School of Management, Cambridge, MA, United States, tbotelho@mit.edu

Evaluations were traditionally handled by experts (e.g., critics, experts, judges), however, over the past 10-15 years, platforms have emerged to facilitate the evaluation process in nearly every domain. Now, any individual or firm has an outlet that they can use to evaluate a candidate, good, or service with a click of a button. Further, the prevalence of these evaluation processes has led to organizations utilizing similar rating systems to evaluate workers, ideas, and strategy. In this talk I review some work on how biases can enter into different stages of the evaluation process affecting evaluation outcomes. I will specifically focus on issues related to social influence, gender, and expertise.

2 - It's A Man's Job: Income And The Gender Gap In Industrial Research

Myriam Mariani, University, 1, Bocconi, Italy, myriam.mariani@unibocconi.it

This study examines differences in income and job performance between women and men in creative jobs tasked with achieving technological inventions. By building on data pertaining to 9,692 inventors from 23 countries, this study shows that female inventors represent only 4.2% of total inventors, and they earn 14% less than their male peers. The gap persists after controlling for sources of heterogeneity, the selection of inventors into types of jobs and tasks, and potential parenthood, instrumented by exploiting religious practices. The income gap is not associated with differences in the quality of the inventions.

3 - An Agenda For Diversity And Inclusion-related Research within OR/MS/Analytics

Michael P Johnson, University of Massachusetts Boston, 100 Morrissey Blvd, M-3-428A, Department of Public Policy and Public Affairs, Boston, MA, 02124, United States, michael.johnson@umb.edu

Diversity and inclusion have been widely studied and debated, most often within the social sciences. What contributions can operations research, management science and analytics make to this domain of inquiry? This talk will critically examine assumptions and practices within the decision sciences that may support as well impede diversity- and inclusion-related research, and propose a research agenda that can challenge yet enrich our profession.

4 - Bridging The Gap: Optimal Responses To Equal Pay Legislation

Margret Bjarnadottir, University of Maryland, R H Smith School, College Park, MD, 20, United States, margret@rhsmith.umd.edu, David Anderson

We study how firms can reduce any measured demographic based pay-gap (such as the gender pay gap), in the most cost efficient way possible. We show that by prioritizing wage increases and targeting workers that will have the greatest impact, a manager can meet the Equal Pay for Equal Work standard for less than half the cost of the naive methods. We further formulate a trade-off optimization model that balances the need to close a pay gap with employee fairness, given a fixed budget during the annual review cycle.

Applied Humanitarian Operations Management

Sponsored: Public Sector OR

Sponsored Session

Chair: Alfonso J Pedraza-Martinez, Indiana University, 1309 E. 10th Street, Room HH 4100, Bloomington, IN, 47405, United States, alpedraz@indiana.edu

1 - Dynamic Allocation Of NGO Funds Among Program, Fundraising, And Administration

Telesilla Kotsi, Indiana university, Bloomington, IN, United States, tkotsi@umail.iu.edu, Goker Aydin, Alfonso Pedraza Martinez

NGOs report three types of spending: program spending to deliver services directly to beneficiaries; fundraising spending; and administrative spending. Watchdog organizations give higher ratings to NGOs that allocate more of their budget to the program. However, fundraising and administrative spending are also necessary. Fundraising helps to increase the NGO's future budget, while administrative spending helps to make future program spending more impactful. We model this trade-off in a dynamic program. One of our results is that NGOs with tight budgets should prioritize fundraising and administration now, so that they are in a better position to make impactful program spending in the future.

2 - Supporting Hurricane Inventory Management Decisions With Consumer Demand Estimates

Douglas Morrice, University of Texas Ausitn, Douglas.Morrice@mccombs.utexas.edu, Paul Cronin, Fehmi Tanrisever, John Butler

We consider inventory allocation issues faced by a retailer during a hurricane event and provide insights that can be applied to humanitarian operations during slow-onset events. We start with an empirical analysis using regression that triangulates three sources of information: a large point-of-sales data set from a Texas Gulf Coast retailer, the retailer's operational and logistical constraints, and hurricane forecast data from the National Hurricane Center (NHC). Using the results of the empirical analysis and the NHC forecast data, we construct a demand model and develop an inventory management model to satisfy consumer demand prior to a hurricane making landfall.

3 - Information Dissemination Through Social Media In Humanitarian Operations

Eunae Yoo, Arizona State University, Tempe, AZ, United States, eunae.yoo@asu.edu, Elliot Rabinovich, Bin Gu, William Rand, Mahyar Eftekhar

For humanitarian operations, the distribution of information is critical to support the effective and efficient delivery of goods and services. Since social media facilitates real-time information sharing, humanitarian organizations have started leveraging these platforms to communicate with their stakeholders. Our research examines information diffusion patterns on social media during disasters, taking into account the underlying social network among users. From our results, we identify how humanitarian organizations can improve information propagation on social media in emergencies.

4 - Disaster Cycle Management: Matching Supply And Demand Of Social Support Through Social Media.

Alfonso Pedraza-Martinez, Indiana University, alpedraz@indiana.edu, Lucy Yan

We study information management during the disaster cycle. This research investigates the match of social support supply provided by organizations and social support demand from social media users during the stages of preparedness, response and early recovery. Using the case of Hurricane Sandy, 2012 we find a mismatch between supply and demand for social support and provide discussions on alleviating the mismatch. Moreover, we study how actionable operations management content posted by organizations affects their interaction with users through social media.

Prevailing Issues in Public Sector OR

Sponsored: Public Sector OR

Sponsored Session

Chair: Ebru Bish, Virginia Tech, Dept of Industrial and Systems Engineering, Blacksburg, VA, 24061, United States, ebru@vt.edu

1 - The Probabilistic Independence Of Mass Killings In The United States

Douglas M King, Lecturer, University of Illinois at Urbana-Champaign, 117 Transportation Building, 104 S Mathews Avenue, Urbana, IL, 61801, United States, dmking@illinois.edu, Sheldon Jacobson

As mass killings are increasingly visible in media coverage, understanding patterns in their occurrence becomes increasingly important. This talk finds that the 300 mass killings taking place in the United States from 2006 to 2016, as documented by USA Today, have a temporal distribution indistinguishable from a homogeneous Poisson process. This result suggests that these events are independent in that the occurrence of one mass killing does not indicate whether another is imminent.

2 - Adaptive Array-based Screening For Heterogeneous Populations

Hrayer Aprahamian, Virginia Tech, 250 Durham, Blacksburg, VA, 24061, United States, ahrayer@vt.edu, Ebru Korular Bish, Douglas R Bish

Group (pooled) testing has seen many applications, especially in the context of public health, blood screening, and genetics. We consider a special form of group testing called “array-based testing,” which takes advantage of overlapping pools. We model an adaptive and informative testing scheme that considers important test and population characteristics, including imperfect tests, dilution effect, and heterogeneity in the population, and determine the structure of the optimal testing design and optimal assignment of the heterogeneous subjects to the pools. Our case study indicates that the proposed optimization-based model leads to a substantial improvement over current practices.

3 - Prevalence Estimation Through Pooled Testing

Ngoc Nguyen, Virginia Tech, ntn@vt.edu, Ebru Korular Bish, Douglas R Bish

Surveillance studies often rely on pooled testing in order to estimate the unknown prevalence rate of an infection or a genetic disorder. Utilizing larger pools reduces testing costs, but also leads to a loss of accuracy due to dilution effects. We develop a mathematical model that considers this trade-off and determines the optimal pool size as well as the optimal number of pools under resource constraints. Our case study shows that this optimization-based approach improves upon the accuracy of the prevalence rate estimate over current approaches.

4 - Production And Distribution Capacity Planning For Mitigating Urban Delivery Risk Of E-commerce

Mu Du, Dalian University of Technology, 509 School of Management, No.2 Linggong Road, Dalian, 116023, China, dumu.dlut@gmail.com, Nan Kong

The integrated production and distribution capacity planning is vital to the supply chains of perishable commodity B2C e-commerce, which are keen on reducing production makespan and delivery lateness. However, significant challenge lies in the uncertain delivery workload caused by traffic control and adverse weather (e.g., smog) in Chinese urban areas. We formulate a two-stage stochastic programming model and propose a stochastic branch and bound algorithm. We report the impact of traffic control and adverse weather on the capacity planning decisions, confounded by other factors.

1 - Retaining Capable New Employees: Role Of Strategic Interaction And The Learning Rate

Onesun Steve Yoo, University College London, London, United Kingdom, onesun.yoo@ucl.ac.uk, Dharma Kwon

We study a two-sided game involving a firm and a newly hired employee whose capability is not initially known to either party. As the employee performs, both players learn and are presented with an option: the firm can terminate an incapable employee, and a capable employee can leave the firm for greater financial remuneration elsewhere. We examine the Markov perfect equilibrium (MPE) termination strategies and payoffs that unfold. We report a counterintuitive result: slower learning can increase the equilibrium payoff for both parties. Our result identifies a nonfinancial way for firms to improve retention of highly capable employees and create a win-win situation for both parties.

2 - The Impact Of Valuation Heterogeneity And Network Structure On Equilibrium Prices In Supply Networks

Alper Nakkas, Nova School of Business and Economics, Campus de Campolide, VAT - 506030636, Lisbon, 1099-032, Portugal, alper.nakkas@novasbe.pt, Yi Xu

We study how valuation heterogeneity and network structure on equilibrium prices in supply networks by identifying the main factors that influence the equilibrium prices, trading pattern and surplus allocation in such networks. We also show what types of links can be added into a supply network to improve its competitiveness and/or efficiency.

3 - Signaling Product Quality Through A Trial Period

Gulru Ozkan-Seely, University of Washington – Bothell, Bothell, WA, 98033, United States, gulru@uw.edu, Shouqiang Wang

We evaluate a firm’s pricing and timing strategies when launching via a time-locked trial period a new product that has privately observable product quality. While the trial period allows consumers to learn about the product quality (a phenomenon we term a learning effect), a longer trial period increases the heterogeneity of consumers’ willingness-to-pay for the firm (a phenomenon we term a dispersion effect). The dispersion effect exacerbates the firm’s pricing difficulty and generates an informational cost, warranting a longer trial period as a credible signal of the firm’s superior product quality. In a key finding, we show that a firm can use the price and the trial length as dual signals.

4 - An Experimental Study Of Idea Evaluation Process

Zhijian Cui, IE Business School, Zhijian.cui@ie.edu

With an online experiment, this study compares the efficacy of two idea evaluation processes commonly observed in practice: ranking and scoring. We find that the scoring process has a higher evaluation accuracy than the ranking process. In addition, providing more information and domain-specific expertise could improve the evaluation accuracy of scoring process, but not the ranking process.

1 - Analytics Framework For Higher Education

Roger Gung, University of Phoenix, Phoenix, AZ, United States, roger.gung@phoenix.edu

We present an end-to-end anlytics framework for adult learning/higher education industry that covers solution methods with using big data analytics for the management of marketing, enrollment service, learning platform, academic performance and institutional finance.

2 - Big Data And FinTech Programs at Asia University

Grace Lin, Institute for Information Industry, 1F, No. 133, Sec. 4, Minsheng E. Rd., Taipei, Taiwan, gracelin.ny@gmail.com

Asia University in WuFeng, Tahchung, Taiwan recently established a Big Data Research Center and a FinTech and Blockchain Research Center. We will present an overview of our research projects including precision medicine, IOT-enabled healthcare, and FinTech Innovation. ORMS opportunities related to these projects will also be discussed.

3 - Integrating Physical And Social Sensing To Enable Smart Services

Robin Qiu, Penn State, robinqiu@psu.edu, Youakim Badr, Lawrence Qiu

The Internet of Things (IoT) allows objects to be sensed and managed over the networks, which creates opportunities for more direct integration between the physical world and computer-based systems. People-centric sensing or social sensing transforms how we sense the world. Today, social sensing (e.g., mobile apps) complements physical sensing (e.g., IoT) by substantially extending the horizon we know about the world in real time. This talk mainly discusses how we can integrate physical and social sensing to enable better and smarter services. An example will be provided.

Chair: Jie Zhang, The University of Vermont, The University of Vermont, Burlington, VT, 05405, United States, jz@bu.edu

1 - Hotel Performance Impact Of Socially Engaging With Consumers

Saram Han, Cornell University, Ithaca, NY, United States, sh2322@cornell.edu, Chris K Anderson

This study examines three aspects of the online interaction based on customer reviews using TripAdvisor data. First, the study found that simply encouraging reviews was associated with an increase in a hotel's ratings. Second, the fact that management responds to reviews leads to improved sales and revenue. Finally, the study found that revenue improvements based on review responses are limited in two ways. First, revenue levels increase as the number responses increases, but only to a point. Second, consumers seem to be most appreciative of responses to negative reviews, rather than positive reviews.

2 - The Impact Of Marketing Expenditures On Outlet Performance In Franchised Channels

Ben Lawrence, Cornell University, benlawrence@cornell.edu

This study contributes to a greater understanding of marketing expenditures in the context of franchising by empirically examining the effects of different types of advertising expenditures including loyalty programs, local sales force, and e-commerce on unit level profitability. Examining the profit and loss statements of over 4,500 franchised hotel properties in the U.S between 2007 to 2013 we find a direct positive effect of advertising on unit level performance. We also find differential effects of advertising for units with varying levels of dependence on the franchisor.

3 - Introduction To Wellness-inspired Service Operations Strategies

Min Lee, Clemson University, minl@g.clemson.edu
Aleda Roth, Rohit Verma

The design and the specific features of buildings can have a meaningful impact on building occupants health, productivity, and mental state as well. This research focuses on the unstudied area of human sustainability in terms of their health and wellness. This research presents a conceptual framework and research agenda that explores wellness-inspired service operations strategies.

4 - Exploring The Synergy Between Online Reviews And Structured Surveys

Jie Zhang, University of Victoria, jz@bu.edu

Service organizations have relied on guest surveys to assess satisfaction and identify opportunities for operational improvement. Increasingly, online reviews presents opportunities to collect real-time feedback. In this study, we describe a study that explores how to use the insights from online reviews to adapt survey questions for more focused performance evaluation.

1 - Visualizing The Dynamics Of Multivariate Time-series Data From Social Media During Emergency Management And Disaster Response

Dave Yates, Assistant Professor, University of Denver, Denver, CO, 80208, United States, dave.yates@du.edu, Joe Ryan

This project develops visualization approaches for dynamic multivariate time-series data shared via social media during emergency and disaster response, a focus area in which decision making is of paramount importance. The data is similar to that shared on social media such as blogs or social networks for entertainment, personal connections, and many other purposes. In this research we discuss the nature of social media data and the particular challenges of visualizing it in ways that make sense for decision makers. Synergizing social theory with visualization techniques we present best practices, lessons learned, and a research agenda.

2 - Using Social Capital Theory In Social Network Sites To Improve Innovative Performance

Valerie Bartelt, Texas A&M University - Kingsville, TX, vbartelt@gmail.com, Murad Moqbel

Innovative performance has become increasingly essential for business success. This research compares how social capital through social network site (SNS) affects innovative performance. Survey research from 276 professionals found that work SNS use significantly increased innovative performance while social SNS use significantly decreased innovative performance. Structural capital significantly moderated the relational capital on innovative performance. These findings open new avenues for further research by identifying the type of SNS use that will cultivate innovation in businesses.

3 - Are Multi-listing Hosts Better Off? How Host Attributes Affect The Performance Of Airbnb Listings

Karen Xie, University of Denver, Karen.Xie@du.edu

This study investigates the relationship between Airbnb hosts' attributes, in terms of both the quality of host services and the quantity of host listings. Our unique sample included 5,805 active listings of 4,608 hosts in Austin, of which 12.26% or 565 hosts had more than one listing. We found that the host may make a tradeoff between quantity and quality as he/she manages more listings. Such research into Airbnb hosts will unveil important business and policy strategies for Airbnb to improve and grow its business more strategically.

4 - User Engagement In Social Media: Evidence From A Field Experiment

Jane Tan, University of Washington, xuetan@uw.edu
Yingda Lu, Yong Tan

User engagement in charitable campaigns over social media environment is critical for raising awareness, which is key to the success of fundraising. In this study, we analyze the impacts of different solicitation approaches. Specifically, we evaluate the effect of adding compassionate followers to prospective users and the effect of adding prospective users into a charitable list. Using a randomized field experiment at Twitter, we find that adding compassionate followers positively affect users' propensity of engagement, while adding them to a charitable list has negative effect.

Sponsored Session

Chair: Ruth Beer, Indiana University, Kelley School of Business, Bloomington, IN, United States, ruthbeer@indiana.edu

1 - An Experimental Investigation Of Managing Quality Through Monetary And Relational Incentives

Andrew M. Davis, Cornell University, adavis@cornell.edu, Kyle Hyndman

We investigate indirect and direct incentives for managing the quality of a product in a two-tier supply chain. In our study, a retailer pays a supplier for a product, where the supplier can choose to exert high effort, which is costly but guarantees high quality, or low effort, which does not assure high quality. We consider scenarios where the retailer pays the supplier a fixed fee, or a combination of a fixed fee and conditional bonus, which is only paid to the supplier when high quality is received. We evaluate these scenarios in both one-shot and repeated environments and find that different incentives can significantly influence the quality of a product.

2 - The Supplier's Dilemma: Buyback Contracts In A Competitive Setting

Anna Devlin, University of Alabama in Huntsville, agd0008@uah.edu

This research studies the performance of buyback (BB) and wholesale price (WP) contracts when a single newsvendor retailer purchases products from two suppliers competing for retailer effort. We determine that a profit-maximizing retailer's effort allocation differs by contract pair offered by the suppliers, impacting supplier profits and equilibrium decisions. If demand uncertainty is low the difference in retailer effort across contract pairs minimally impacts profits and both suppliers offer BB contracts in equilibrium. However if demand uncertainty is high this effort allocation disparity creates a "prisoner's dilemma" for the suppliers and both will offer WP contracts in equilibrium.

3 - Stagnant Leader Or Fast Improver? The Impact Of Transparency On Consumers' Purchase Behavior

Yanchong Zheng, Massachusetts Institute of Technology, yanchong@mit.edu
Ryan Buell, Shwetha Mariadassou

We study how consumers' purchase behavior may be influenced by a company's information transparency in its sustainability performance. We consider interaction between transparency and two types of information: current performance level and changes in performance. Our results yield important insights about a company's transparency strategy in the marketplace.

4 - How Negotiatons Improve Performance In The Buyback Contract

Elena Katok, University of Texas at Dallas, 800 W. Campbell Rd., Jindal School of Management (SM30), Richardson, TX, 75080, United States, ekatok@utdallas.edu, Michael Becker-Peth, Ulrich Thonemann

We conduct a lab experiment to analyze how negotiations affect performance of a buyback contract. We show that adding a negotiation phase in a human-human setting improves performance significantly if negotiation agreements are reached. These Agreements result in almost full SC efficiency (0.97) and the profit split is fairly equal (0.54 to 0.46). We analyze the underlying drivers of successful negotiations which are both, personal and procedural.

1 - Modeling The North American NGL Market In A Low Oil And Gas Price Environment

Robert Brooks, Founder, RBAC Inc, 14930 Ventura Boulevard, Suite 210, Sherman Oaks, CA, 91403, United States, rebrooks@rbac.com

The last decade's "shale gas revolution" recreated the US natural gas and oil industry. It also revitalized the natural gas liquids business and promised to do the same for petrochemicals. But runaway production combined with slowed demand growth has resulted in a collapse of prices for all of these commodities world-wide. How can one make rational predictions about the future of the North American NGL market under these conditions? NGL-NA is a model of the North American market for natural gas liquids. The presentation will describe the model and results from recently run scenarios.

2 - Fuel Procurement Strategy With Inventory Consideration For Electric Power Utilities

Chung-Hsiao Wang, LG&E and KU, 102 Spruce Lane, Louisville, KY, 40207-1701, United States, chunghsiao@hotmail.com, K Jo Min

In recent years, natural gas combined cycle power plants have started to replace aging and less efficient coal power plants. Furthermore, due to cheap natural gas prices, economic dispatching has resulted in high coal inventory levels. Under these circumstances, in this paper, we develop mathematical models for structured and analytical guidelines on fuel procurement strategies for a utility owning both natural gas and coal generation units.

3 - Modeling And Analysis Of Remote, Off-grid Microgrids

Sreenath Chalil Madathil, Doctoral Candidate, Clemson University, 110 Freeman Hall, Clemson, SC, 29634, United States, schalil@g.clemson.edu, Emre Yamangil, Harsha Nagarajan, Arthur K Barnes, Russell Bent, Scott Backhaus, Scott J. Mason, Salman Mashayekh, Michael Stadler

We develop a mixed-integer, quadratically-constrained quadratic program for minimizing total installation and operation costs of remote off-grid microgrids with renewable and non-renewable energy sources under N-1 contingencies and one day time horizon. We compare various relaxations for this NP-Hard problem and present efficient decomposition algorithms for our problem. We model the nonlinear efficiency curves associated with these devices using a piecewise linear approximations and demonstrate the efficiency of proposed relaxation and decomposition methods using benchmark test problems.

4 - An Empirical Study On A Demand Response Program With Battery Storage Systems

Arnab Roy, PhD Student, University of Louisville, 2719 South 4th Street, Apt. #2, Louisville, KY, 40208, United States, arnab.roy@louisville.edu, Prajwal Khadgi, Lihui Bai

Demand response (DR) in smart grid aims to reduce peak load, thus the needs for ancillary services in generation. On the other hand, any DR programs must be implemented with incentives to ensure consumers' active engagement. In this paper, we investigate the effects of the DR implementation measures by one utility company on the load consumption of approximately 300 homes. The DR measures include the introduction of an innovative residential rate structure, direct load control, installation of efficient heat pump water heaters, and reliable utility-grade power storage systems.

1 - Network Design For In-motion Wireless Charging Of Electric Vehicles In Urban Areas

Mamdouh Mubarak, Southern Methodist University, mmubarak@smu.edu, Halit Uster, Khaled Abdelghany, Mohammad Esmaeil Khodayar

We present a model to optimize the location and power capacity of in-motion electric charging stations. We formulate the problem as a MIP and we propose a Benders-decomposition-based algorithm to solve it efficiently. We present the computational results of testing the algorithm on large-scale grid networks.

2 - Deployment Of Stationary And Dynamic Charging Infrastructure For Electric Vehicles Along Traffic Corridors

Zhibin Chen, University of Florida, Gainesville, FL, United States, zhibinchen@ufl.edu, Yafeng Yin, Wei Liu

This paper optimizes a deployment plan of dynamic and stationary charging facilities along a traffic corridor to serve the charging need of electric vehicles with the minimum social cost. The deployment plan will specify the number of charging stations, the number of chargers installed at each station, the lengths of dynamic charging lanes, and charging prices of charging stations and lanes.

3 - Modeling Plug-in Electric Vehicles Driving And Charging Behavior Using Real-world Connected Vehicles Data

Kuilin Zhang, Assistant Professor, Michigan Technological University, Houghton, MI, 49931, United States, klzhang@mtu.edu
Shuaidong Zhao

We propose to investigate driving and charging behavior of Plug-in Electric Vehicles using real-world connected vehicles data. We use a data-driven approach to estimating 24-hour activity-travel dynamics of individual drivers from connected vehicles data collected in real-world. Based on this real-world driver's activity and mobility pattern, we formulate an optimization model to address driving and charging behavior of Plug-in Electric Vehicles to better understand the battery performance of electric vehicles under real-world conditions.

4 - Operation Of Electricity And Transportation Networks With Ev Wireless Charging

Mohammad Khodayar, Southern Methodist University, mkhodayar@smu.edu, Saeed D Manshadi, Khaled Abdelghany, Halit Uster

This research presents the coordinated operation of wireless electric vehicle charging stations (WECS) in electricity and transportation networks. The traffic flow pattern in transportation network is assumed to follow the user equilibrium (UE) traffic assignment, where the cost of utilized electricity is incorporated in the total traveling cost. The presented formulation leverages consensus optimization to address the unit commitment in the electricity network as well as user equilibrium traffic assignment in the transportation network.

Chair: Hai Wang, Singapore Management University, Singapore Management University, Singapore, Singapore, Singapore, haiwang@smu.edu.sg

1 - Matching Problem For A Stochastic And Dynamic Online Vehicle Sharing System

Hai Wang, Singapore Management University, haiwang@smu.edu.sg, Chiwei Yan

We study a stochastic and dynamic matching problem for online vehicle sharing platform: match the spatial and temporal changing demand (ride request) with supply (vehicle). We propose an algorithm to determine the pairings of drivers to riders' requests. At any decision epoch, we consider the set of known available drivers and potential available drivers, as well as the set of known existing passengers and potential passengers. We use an iterative procedure which calls a static and deterministic matching problem as a sub-routine. The objective is to minimize the average waiting time until picked-up for ride requests. We demonstrate the advantages of our algorithm by testing in real world data sets.

2 - Estimating Primary Demand In One-way Vehicle Sharing Systems

Chiwei Yan, Massachusetts Institute of Technology, Cambridge, MA, United States, chiwei@mit.edu, Chong Yang Goh

Observed trip data for one-way vehicle sharing systems do not always correspond to true demands for the service due to varying vehicle and parking availability. For example, in bike sharing systems, passengers arriving at an empty pickup station may either leave the system or spill over to nearby stations. We propose efficient methods to estimate the true origin-destination demands in a one-way vehicle sharing system using observed trip data. Our approach models a customer's station substitution behavior based on a ranking-based choice model. We demonstrate the effectiveness of our approach using data from a bike-sharing system in Boston.

3 - The Learning Curve Of Taxi Drivers In an Urban Area: An Empirical Analysis

Youngsoo Kim, Singapore Management University, Singapore, Singapore, yskim@smu.edu.sg

This study aims to better understand the dynamic change of individual taxi drivers' performance on both an aggregated output level (e.g., revenue and trips) and process level (e.g., occupancy rate and zone selection decision). We also conduct counterfactual policy experiments that capture the change derived through knowledge sharing of demanding zone on both individual and company levels. The implications of our findings for both theory and practice are discussed.

4 - Stochastic Ride-matching In Peer-to-peer Ridesharing Systems

Neda Masoud, University of Michigan, 2350 Hayward St., 2124 GG Brown Bldg., Ann Arbor, MI, 48109, United States, nmasoud@umich.edu, R. Jayakrishnan

We formulate the multi-hop peer-to-peer stochastic ride-matching problem as a binary program, and propose an efficient algorithm to solve the problem. We use a forecast of passenger arrivals, and take into consideration the possible future states of the ridesharing system when routing drivers. The multi-hop property of the system allows passengers to transfer between different vehicles/modes of transportation.systems.

1 - Facility-level Item Allocation Problem In Ship-from-Store Environment

Seyed Shahab Mofidi, Rensselaer Polytechnic Institute, 110 8th Street, RPI ISE Department, CII 5015, Troy, NY, 12180, United States, mofids@rpi.edu, Jennifer A Pazour

Leading retailers are using their brick-and-mortar stores to fulfill online order requests, which results in ambidextrous stores that use inventory to serve both in-store and on-line shoppers. We develop a novel multi-product optimization model that captures the tradeoff between applying resources in advance when the demand is unknown or applying resources after the demand realizes. A case study illustrates how our model can be used to recommend item allocation policies for omni-channel supply chains.

2 - Parallel Algorithms For Large Assignment Problems On Graphics Processing Unit Clusters

Rakesh Nagi, University of Illinois, Urbana-Champai, 117 Transportation Building, MC-238, 104 South Mathews Avenue, Urbana, IL, 61801, United States, nagi@illinois.edu, Ketan Date

We discuss efficient parallel algorithms for solving large instances of the Linear Assignment Problem (LAP) and the Quadratic Assignment Problem (QAP). Our parallel architecture is comprised of CUDA enabled NVIDIA Graphics Processing Units (GPUs) on a computational cluster. We propose novel parallelization of the Hungarian algorithm on the GPUs, which shows excellent parallel speedup for large LAPs. We also propose a novel parallel Dual Ascent algorithm on the GPUs, which is used for solving the RLT2 linearization of the QAP, which also utilizes our parallel Hungarian algorithm. We show that this GPU-accelerated approach is extremely valuable in a branch-and-bound scheme.

Spatial Multicriteria Decision Making: Challenges and Current Developments

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Valentina Ferretti, London School of Economics and Political Science, Houghton Street, London, WC2A 2AE, United Kingdom, V.Ferretti@lse.ac.uk

1 - Geographically Weighted Multi-attribute Decision Making For Taxi Assignment

Ali Esmaeeli, University of California, Irvine, Irvine, CA, United States, esmaeeli@uci.edu, L Robin Keller

Taxi assignment problem is usually considered as one part of the more general vehicle routing problem (VRP) with a known value function. In this work, we extend this viewpoint to match the problem more with the real world conditions. We consider a map with weighted regions and propose a method to find the best option for each taxi request based on two different attributes. These attributes are the average response time for each region and the rate of accepted requests for each region. We show how to combine these attributes and how to include the region weights into the main value function. Moreover, we present a method for finding the best assignment option based on our defined value function.

2 - Spatial Multi Criteria Decision Analysis In The Energy Sector: A Preliminary Application To Deep Geothermal Energy Systems

Matteo Spada, Risk Analyst, Paul Scherrer Institut, OHSA/D19, Villigen PSI, 5232, Switzerland, matteo.spada@psi.ch Peter Burgherr

This study presents the preliminary application of a spatial MCDA to the energy sector. In particular, Deep Geothermal Energy (DGE) systems are considered in the analysis. DGE is gaining quite some interest as new renewable energy system, since it offers the prospect of supplying base-load power in a decentralize fashion and a theoretically large resource potential. The proposed approach will combine spatial information from both explicit data (e.g., heat flow) and calculated ones (e.g., risk indicators, environmental impact indicators, etc.) for specific a priori defined capacity plants. The results will be presented for different hypothetical stakeholders for the case study of Switzerland.

3 - Case Studies With Gear, A New Tool For Geospatial Multi-Criteria Decision Analysis

Matthew Bates, Research Engineer, US Army Corps of Engineers, Concord, MA, United States, matthew.e.bates@usace.army.mil Michelle Hamilton, Jeffrey Cegan, Cate Fox-Lent, John Nedza

GEAR (the Geospatial Environment for Analysis and Reasoning) is a new, state-of-the-art geospatial multi-criteria decision analysis (GIS-MCDA) tool developed by the Engineer Research & Development Center of the US Army Corps of Engineers. GEAR has a friendly and intuitive user interface, accepts diverse web-service and file data inputs, and guides users through data exploration, criteria development, value function and weight specification, and running the analysis. It is designed for both practiced analysts and non-expert users. In this presentation, we introduce the GEAR functionality through a series of spatial decision case studies.

4 - Behavioural Issues In Spatial Decision-making Processes

Valentina Ferretti, London School of Economics and Political Science, V.Ferretti@lse.ac.uk

Behavioral decision research has demonstrated that judgments and decisions of ordinary people and experts are subject to numerous biases. While these biases have already been extensively discussed in several disciplines, e.g. economics, game theory, finance, and risk analysis, to name the most relevant, there is now a need to pay more attention to behavioral and cognitive effects in spatial environmental decision-making processes. Within this context, this talk explores which biases are relevant in the field and proposes a first behavioral experiment focusing on the weights elicitation step

5 - Landscape Multi-methodological Evaluations: Approaches For Collaborative Spatial Decision-making Processes

Maria Cerreta, University of Naples,, cerreta@unina.it

The paper, starting from the evolution of the landscape's concept and related evaluative approaches, focuses on the management of its complexity in transformation processes included in the dynamic context of landscape's values and in its local development strategies. A multi-methodological synergistic evaluations framework for a Collaborative Spatial Decision-Making Process has been tested in some case-studies for context-aware planning strategies and scenarios of local sustainable policies, combining Multi-Criteria Analysis (MCA), Multi-Group Analysis (MGA) and Geographic Information Systems (GIS).

1 - E-commerce In The Manufacturing Supply Chain: An Empirical Analysis

Patricia Angle, Georgia Institute of Technology, Patricia.Angle@scheller.gatech.edu, Christopher M Forman, Kristina Steffenson McElheran

In this paper, we explore the value of e-commerce technologies on the total factor productivity (TFP) of manufacturing plants. We find that, on average, e-selling adoption is associated with a 1.4% increase in TFP. However, these returns differ significantly between small and large plants. For large plants, those above the 25th percentile in number of employees, the increase in TFP is 2%. For plants below that size threshold, the returns to e-selling are statistically indistinguishable from zero. We further find that plants with prior experience with enterprise IT realize greater productivity gains from their e-selling investments.

2 - Piracy-induced Competition In Information-good Supply Chains

Antino Kim, Indiana University, Bloomington, IN, United States, antino@iu.edu, Debabrata Dey, Atanu Lahiri

In an otherwise monopolistic information goods market, piracy presents itself as a "shadow competition" to the legal product by providing consumers with other means to use the product, albeit at a lower quality. In this work, we analyze the effect of this shadow competition by comparing it to competition in a manufacturer-retailer setting.

3 - Impact Of Promoting Free Wi-fi On Mobile Data Usage: Evidence From A Field Experiment

Karthik Babu Nattamai Kannan, Georgia Institute of Technology, KarthikBabu.NK@scheller.gatech.edu, Jeffrey Hu, Sridhar Narasimhan

With the rapid proliferation of free Wi-Fi hotspots in public locations such as restaurants, shopping malls, airports etc., mobile users have the choice of accessing Internet either via paid mobile data plans or through the free Wi-Fi hotspots. We conduct a field experiment in July 2015 to study the impact of promoting free Wi-Fi service on mobile data usage. We work with a leading national mobile carrier in the USA to randomly choose 500,000 subscribers who receive a promotional text message about the availability of free Wi-Fi hotspots and compare them with a control group made of 500,000 customers who do not receive any promotional message.

4 - Strategic Intellectual Property Sharing: Competition on an OpenTechnology Platform Under Network Effects

Marius Niculescu, Georgia Institute of Technology, marius.niculescu@scheller.gatech.edu, D. j. Wu, Lizhen Xu

This study explores when an incumbent software developer might find it optimal to utilize the open business model to share its intellectual property with entrants in markets for software products with network effects.

High-Dimensional Functional Data Analysis

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Hao Yan, Georgia Institute of Technology, yanhao@gatech.edu

Co-Chair: Kamran Paynabar, kpaynabar3@gatech.edu

1 - Difference Detection Between Two Images For Image Monitoring

Peihua Qiu, University of Florida, pqiu@ufl.edu

Comparison of images is a fundamental task in image-based quality control. This problem, however, is complicated because 1) observed images often contain noise, and 2) the related images need to be geometrically matched up first because images of different products could be geometrically mismatched. In this paper, we propose effective methods for detecting difference between two images of products, and our proposed methods can accommodate both noise and geometric mismatch mentioned above.

2 - Online Adaptive Sampling And Estimation For Clustered Anomaly Detection

Hao Yan, Georgia Institute of Technology, yanhaopku@gmail.com

In point-based sampling and sensing system, adaptive exploration in complex sampling space can dramatically reduce the sampling time. Most of the existing techniques focus on reducing the overall fitting error for the entire sampling space. However, in many application, such as anomaly detection, only sparse clustered anomalous regions are important. In this paper we develop two adaptive sampling strategies together with estimation methods to recover the clustered region and discuss their properties to balance the space filling property and focus sampling near the anomalous region. Finally, the proposed methodology is validated by simulation study and real datasets in Guided Wave Experiment.

3 - A Penalized (log)-Location-Scale Tensor Regression Model For Residual Useful Lifetime Prediction

Xiaolei Fang, Georgia Institute of Technology, xfang33@gatech.edu
Kamran Paynabar, Nagi Gebraeel

We develop a penalized prognostic model whose covariates are tensor-based degradation signals. To address the ultrahigh dimensionality challenge, the coefficient tensor is decomposed as a product of some basis matrices (CP decomposition) or a product of a core tensor and some factor matrices (Tucker decomposition) . Instead of estimating the coefficient tensor itself, we estimate these basis matrices or core tensor and factor matrices, which have far much smaller dimensionalities. Two algorithms with global convergence property are developed for model estimation. The effectiveness of our models is validated using a simulation study and an infrared image-based degradation signal dataset.

4 - Multivariate Profile Monitoring Based On Sparse Multichannel Functional Principle Component Analysis

Chen Zhang, National University of Singapore, zhangchen@u.nus.edu, Hao Yan, Jianjun Shi

This paper presents a new monitoring framework for multi-channel profile data. In particular, we first propose a sparse multichannel functional principle component analysis (SMFPCA) to model multiple profiles, SMFPCA on one hand can capture the auto-correlation structure of profile data well, and on the other can allow flexible cross-correlations of multiple or even high-dimensional profiles with different features. Then using SMFPCA scores, we further propose a monitoring scheme that can detect sparse out-of-control changes efficiently. Numerical studies together with a real example in the semiconductor manufacturing demonstrate the application and effectiveness of our methods.

1 - Bayesian Life Test Planning For Log-Location-Scale Family Of Distributions

Yili Hong, Virginia Polytechnic Institute, yilihong@vt.edu

This paper describes Bayesian methods for life test planning with censored data from a log-location-scale distribution. We use a Bayesian criterion based on the estimation precision of a distribution quantile. A large-sample normal approximation gives a simplified, easy-to-interpret, yet valid approach to this planning problem, where in general no closed-form solutions are available. We present numerical investigations using the Weibull distribution with type II censoring. We also assess the effects of prior distribution. A simulation approach of the same Bayesian problem is also presented.

2 - Multivariate Exponentially Weighted Moving-average Chart For Monitoring Poisson Observations

Nan Chen, National University of Singapore, isecn@nus.edu.sg

In this talk, we develop a feasible multivariate monitoring procedure based on the general multivariate exponentially weighted moving average (MEWMA) to monitor the multivariate count data. The multivariate count data is modeled using Poisson log-normal distribution to characterize their interrelations. We systematically investigate the effects of different charting parameters and propose an optimization procedure to identify the optimal charting parameters. To further improve the efficiency, we integrate the variable sampling intervals (VSI) in the monitoring scheme. We use simulation studies and an example to elicit the application of the proposed scheme.

1 - An Optimum Design Of Laser-based Additive Manufacturing Experiments by Leveraging Analogous Prior Data

Amir Massoud Aboutaleb, Mississippi State University, 139 A, Park Circle, Starkville, MS, 39759, United States, aa1869@msstate.edu
Linkan Bian

Most of Lase-Based Additive Manufacturing studies do not use a systematic approach for optimizing process parameters for desired part properties. Existing design-of-experiment methods require two stages of experiments: a large batch of initial experiments and multiple smaller batches of sequential experiments. Our method directly utilizes experimental data from previous studies to guide the sequential optimization experiments of the current study.

2 - Model Transfer via Equivalent Effects Of Lurking Variables

Arman Sabbaghi, Purdue University, West Lafayette, IN, 47907, United States, sabbaghi@purdue.edu
Qiang Huang

The transfer of a model across different settings of lurking variables is addressed with a novel framework that fuses the Rubin causal model with the effect equivalence concept. A Bayesian methodology for model transfer is developed and applied to transfer deformation models across additive manufacturing environments

3 - Residual Useful Lifetime Prediction Using a Degradation Image Stream

Xiaolei Fang, Georgia Institute of Technology, 1546 Woodlake Dr NE, Apt F, Atlanta, GA, 30329, United States, xfang33@gatech.edu, Kamran Paynabar, Nagi Gebraeel

This paper proposes a new methodology for RUL prediction of a system using a sequence of degradation images. The methodology integrates tensor linear algebra with traditional location-scale regression widely used in reliability and prognosis. Two optimization algorithms with a global convergence property are developed for model estimation.

4 - Statistical Modeling For Spatio-Temporal Degradation Data

Xiao Liu, IBM, 1101 Kitchwan Road, Room 29-252, Yorktown Heights, NY, 10598, United States, liuxiao@us.ibm.com
Kyongmin Yeo, Jayant Kalagnanam

This paper investigates the modeling of an important class of degradation data, which are collected not only over time but also from a spatial domain. Like many traditional degradation models which rely on stochastic processes, a space-time random field is constructed, through a novel approach, for modeling the spatio-temporal degradation process.

1 - Operations Research Transforms The Scheduling Of Chilean Soccer Leagues And South American World Cup Qualifiers

Andres P Weintraub, Universidad de Chile, Dept De Ingenieria Industrial, Republica 701 Casilla 86-D, Santiago, Chile, aweintra@dii.uchile.cl, Fernando Alarcon, Guillermo Duran, Luis Ramirez, Hugo Munoz, Mario Ramirez, Denis R. Saure, Sebastian Souyris, Rodrigo Wolf-Yadlin, Gonzalo Zamorano, Matias Siebert, Jaime Miranda, Mario Guajardo

For the past 12 years, we have applied OR techniques to schedule soccer leagues in Chile. Using integer programming-based methods, it is decided which matches are played in each round, taking into account various objectives. We have scheduled more than 50 tournaments using this approach, resulting in an estimated economic impact of about $59 million. Because of the high portability of these techniques, we have used them successfully to schedule sports leagues in other countries and the South American qualifiers for the 2018 Soccer World Cup. Furthermore, the methods used in this application have been disseminated widely, helping to promote OR as an effective tool for addressing practical problems.

1 - Stacking Containers In An Automated Terminal

Amir Hossein Gharehgozli, Texas A&M University at Galveston, P.O. Box 1675, Galveston, TX, 77553, United States, gharehga@tamug.edu

We study temporary stacking of containers in an automated terminal. In such terminals, containers to be transported the hinterland or other terminals are stacked in compact stacks with multiple piles of containers. Transfer zones located at both ends of each stack are used to stack and retrieve containers. We propose a mathematical model to stack containers.

2 - An Economical, Reliable And Sustainable Transport Strategy: Synchromodality From Shipper's Perspective

Chuanwen Dong, Kuehne Logistics University, Grosser Grasbrook 17, Hamburg, 20457, Germany, chuanwen.dong@the-klu.org Robert Boute, Alan Mckinnon, Marc Verelst

In order to cut the GHG emission by 60-80% by 2050, innovation is needed to shift more volume from trucks to trains. We argue that the current standstill of modal split is due to a lack of holistic understanding of the supply chain changes driven by modal split. Building on a literature review, we broaden the conventional focus of multimodal transport to a supply chain viewpoint and propose a new concept: synchromodality from shipper's perspective. We apply our approach to a case of an FMCG firm and quantitatively demonstrate that the shipper can significantly reduce its emission without sacrificing cost or service level.

3 - Design Of Truck Appointment System

Mohammad Torkjazi, University of South Carolina, Columbia, SC, 29205, United States, torkjazi@email.sc.edu, Nathan Huynh

The truck appointment system can adjust the length of queue at the gate of the marine container terminals. This adjustment affects the terminal operations as well as trucking companies' schedule. This study proposes a new mathematical formulation for the truck appointment system which optimizes terminal operations as well as trucking companies' schedule.

1 - Bus Service Design Under Demand Diversion And Dynamic Roadway Congestion Based On Aggregated Network Models

Antoine Petit, Research Assistant, U of Illinois at Urbana-Champaign, 205 N Mathews Avenue, # B156, Urbana, IL, 61801, United States, apetit@illinois.edu, Mehmet Yildirimoglu, Nikolas Geroliminis, Yanfeng Ouyang

This paper proposes an integrated methodological framework to design a spatial-dependent bus route network and time-dependent headways to serve travel demand that varies over time and space. Travelers choose transit or driving mode (as well as travel paths) that minimizes its equilibrium travel cost in the multi-modal network. Numerical experiments are used to demonstrate the applicability of the proposed modeling framework and provide managerial insights on the influence of the demand pattern, transit network design, and roadway congestion on the system performance.

2 - Evaluating Impacts Of Rainfall On Subway Ridership In Manhattan By Utilizing Bayesian Hierarchical Poisson Regression Model

Shirin Najafabadi, PhD Candidate, CCNY, 650 West 42nd Street, Apt 3014, New York, NY, 10036, United States, shirin.najaf@gmail.com, Ali Hamidi, Mahdieh Allahviranloo, Naresh Devineni

Impacts of rainfall on subway ridership in Manhattan was studied by using ridership and hydrology data for the year 2010-2011. Using Bootstrap technique, several hypothesis on ridership for different days of the week were constructed and tested. We present Bayesian Hierarchical Poisson Regression Model and incorporate Land-use characteristics as the influential factor in the estimation of ridership, as well as in estimating the sensitivity of the ridership to rainfall. A preliminary comparison between the Bayesian model and simple Poisson regression model supports the use of the former model.

3 - A Mixed Integer Programming Model For Dynamic Taxi Sharing Considering Provider Revenue

Yeming Hao, Research Assistant, University of Maryland-College Park, 8136 Paint Branch Dr., 0147C Engineering Laboratory, College Park, MD, 20742, United States, yhao@umd.edu, Ali Haghani

This paper proposed an optimization model for Dynamic Taxi Sharing(DTS), which allows two groups of taxi users to ride on the same taxi together. The significance of the taxi-sharing service was evaluated. A customized matching algorithm for taxi drivers and user pairs was developed to maximize taxi providers' revenue. We also designed a DTS fare calculation scheme which can automatically calculate the fare for each DTS user and self-adjust to balance the taxi occupancy rate in real time. A real world case was studied to demonstrate the DTS system is beneficial to taxi users, drivers and providers.

4 - Bike System Rebalancing In Omaha Nebraska

Betty Love, University of Nebraska - Omaha, Mathematics Department, Omaha, NE, 68182, United States, blove@unomaha.edu, Livvia Bechtold

Heartland B-cycle in Omaha, Nebraska is a bike sharing system that operates over 70 stations and 150 bikes. Rebalancing is done daily using one truck. We present the results of our work on the rebalancing problem using both integer programming and heuristic approaches.

1 - Modeling And Analysis Of Supply Chain Coordination Under The Crowd-funding Financing

Kuan Zeng, Dr, Huazhong University of Science and Technology, Wuhan, China, zk00315@126.com, Xianhao Xu

In this paper, we consider a supply chain which consists of a single manufacture and a single retailer with a single new product. The retailer designs a new product and posts it on the crowd-funding platform for financing. If the financing target is reached, the retailer will initiate cooperation with manufacture and decide the quantity of the mass production and the manufacture will decide the price accordingly. The target of the manufacture and retailer is to maximize their own profit. We also consider and analyze the situation in which manufacture will provide the retailer a quantity related trade credit.

2 - Swapping Inventory Between Competing Firms

Seung Jae Park, Assistant Professor, Ewha Womans University, Seoul, Korea, Republic of, park.s@ewha.ac.kr

We investigate how competing firms swap inventory. We first show that the firms would not swap inventory without a sophisticated method. However, under our proposed inventory swapping method, competing firms swap a positive amount of inventory. We also find that the swapped quantity increases as transportation costs decrease, and swapping inventory may not be beneficial if the transportation cost is either too low or too high. In addition, we show that firms may prefer to return the physical products to pay the value difference, especially if they are risk-averse.

3 - Manufacturers' Strategic Responses To Power Imbalance In Supply Chains

Zhexiong Tao, McGill University, 1001 Rue Sherbrooke O, Montreal, QC, H3A1G5, Canada, zhexiong.tao@mail.mcgill.ca Shanling Li, Saibal Ray

Our research presents a model of the manufacturer's strategic responses to the imbalance of power in supply chain relationships and empirically tests it using plant-level data. Analysis results show that in different contexts, the manufacturer will adopt different strategies and integration mechanisms to counteract the dominance of the strong actors.

4 - Debt Finanacing And Specific Capacity Investment

Qiaohai (Joice) Hu, City University of Hong Kong, AC-1, Room 7605, Dept of Management Science, Kowloon, Hong Kong, joice.hu@gmail.com

The supplier has to commit to building specific capacity for the buyer before demand uncertainty has been resolved. After uncertainty has been resolves, the parties engage in a bargaining game to decide whether or not to trade and at what price. We show that debt financing can improve supplier's bargaining position. However, this expanded capacity is still below the channel-efficient level because debt financing reduces the probability of trade. Surprisingly, the supplier's debt financing may also benefit the buyer and encourage the buyer to invest in value enhancement. Actually, the supplier's debt may result in Pareto improvement.

1 - Cognitive Computing: From Breakthroughs In The Lab To Applications on The Field

Guru Banavar, Vice President, IBM Research, Watson Research Center, Yorktown Heights, NY, United States, banavar@us.ibm.com

In the last decade, the availability of massive amounts of new data, the development of new machine learning technologies, and the availability of scalable computing infrastructure, have given rise to a new class of computing systems. These “Cognitive Systems” learn from data, reason from models, and interact naturally with us, to perform complex tasks better than either humans or machines can do by themselves. These tasks range from answering questions conversationally to extracting knowledge for discovering insights to evaluating options for difficult decisions. These cognitive systems are designed to create new partnerships between people and machines to augment and scale human expertise in every industry, from healthcare to financial services to education. This talk will provide an overview of cognitive computing, the technology breakthroughs that are enabling this trend, and the practical applications of this technology that are transforming every industry.

1 - Generalized Inverse Classification

Michael Lash, University of Iowa, Iowa City, IA, United States, michael-lash@uiowa.edu, Qihang Lin, Nick Street, Jennifer Robinson, Jeffrey W Ohlmann

Inverse classification (IC) is the process of perturbing a test point such that the predicted probability of a specific class is minimized. In previous work, we outlined an IC framework that incorporated a linear cost function and solved the problem by assuming the classifier was differentiable. In this talk we extend the framework to non-linear costs and relax our assumptions. We demonstrate that, using heuristic-based methods, the IC problem can be solved using arbitrary classifiers, about which only basic assumptions are made.

2 - On Difference Of Convex Optimization To Visualize a Word Storm

Dolores Romero Morales, Copenhagen Business School, drm.eco@cbs.dk, Emilio Carrizosa, Vanesa Guerrero

In this talk we address the problem of visualizing in a bounded region a set of individuals, which has attached a dissimilarity measure and a statistical value. This problem, which extends the standard Multidimensional Scaling Analysis, is written as a global optimization problem whose objective is the difference of two convex functions (DC). Suitable DC decompositions allow us to use the DCA algorithm in a very efficient way. Our algorithmic approach is used to visualize a dynamic linguistic real-world dataset.

3 - Consensus Based Modeling Using Distributed Feature Construction

Haimonti Dutta, University at Buffalo, haimonti@buffalo.edu

Inductive Logic Programming can be used as a tool for discovering relational features for subsequent use in a predictive model. However, such models often do not scale. In this paper, we address this computational difficulty by allowing features and models to be constructed in a distributed manner. There is a network of computational units, each of which employs an ILP engine to construct a small number of features and build a (local) model. Then a consensus-based algorithm is learnt, in which neighboring nodes share information to update local models. For a category of models (those with convex loss functions), it can be shown that the algorithm will result in all nodes converging to a consensus model.

1 - Single Stage Prediction With Text Data Using Dimension Reduction Techniques

Shawn Mankad, Cornell, spm263@cornell.edu

Text data is playing an increasingly important role within the business world for economic analyses and operations management. There are many ways to summarize and transform unstructured data into actionable insights. We compare several modern text analysis methods for prediction of economic outcomes to derive guidelines for researchers and practitioners.

2 - A Multi-response Multilevel Model With Application In Nurse Care Coordination

Bing Si, Arizona State University, Tempe, AZ, United States, bingsi@asu.edu, Jing Li

Nurse care coordination plays a vital role in promoting patient outcomes. The recently developed Nurse Care Coordination Instrument (NCCI) enables quantitative data to be collected on nurses' coordination activities, demographics, workload and practice environment. Driven by this, we propose a novel multi-response multilevel model with joint fixed/random effect selection across multiple responses and apply it to a dataset collected across four U.S. hospitals using the NCCI. Our study conducts the first quantitative analysis linking multiple care coordination metrics with multilevel predictors and thus provides important insight into how care coordination might be impacted or improved.

3 - Optimal Expert Knowledge Elicitation For Bayesian Network Structure Identification

Yan Jin, University of Washington, Seattle, WA, United States, yanjin@uw.edu, Cao Xiao

This talk is about a systematic approach that combines observational data and expert knowledge to better learn the influential relationships between variables for networked systems, as well as automates the expert elicitation process and collect the most informative expert knowledge, optimally matched to the observational data, to improve the learning of the BN structure.
Applications include event cascade modeling of Alzheimer's disease and human resource management key performance indicator measurement.

4 - Temporal Monitoring Of Dynamic Attributed Networks

Mostafa Reisi, Georgia Tech, mostafa.reisi@gmail.com

We consider the problem of change detection in dynamic attributed networks. First, networks are modeled through a generalized linear model (GLM). Then, a state-space model is built by considering a linear state model over the parameters of the GLM. Extended Kalman filter is used for estimating and predicting the parameters of the state-space model. For each upcoming network, a Pearson residual based on the actual network and its prediction is calculated. The Pearson residuals are monitored through an EWMA control chart. Comparison of this method with its static counterparts shows significant improvement in detecting changes.

1 - Optimizing Energy Flows For A Grid Connected Smart House Producing Renewable Energy

Luce Brotcorne, INRIA, luce.brotcorne@inria.fr
Ekaterina Alekseeva, Michel Gendreau, Mohammed Skiredj

We focus on optimizing energy flows for demand management of a grid connected smart house equiped with a system combining photovoltaic electricity and battery . The smartly scheduled way of using, storing, generating, buying and selling energy allows customers to reduce electricity payments, to be less dependent on the grid and avoid creating peak power demand in the grid. We propose a stochastic mathematical linear program to make an optimal decision with the lack of perfect information related to purchasing electricity prices and energy produced by PV generator.

2 - Capacity Expansion Modeling For Storage Technologies

Elaine Thompson Hale, Senior Engineer, National Renewable Energy Laboratory, Golden, CO, United States, elaine.hale@nrel.gov, Brady Stoll, Trieu Mai

The Resource Planning Model (RPM) is a capacity expansion model designed for regional power systems and high levels of renewable generation. Recent extensions capture value-stacking for storage technologies, including batteries and concentrating solar power with storage. After estimating per-unit capacity value and curtailment reduction potential, RPM co-optimizes investment decisions and reduced-form dispatch, accounting for planning reserves; energy value, including arbitrage and curtailment reduction; and three types of operating reserves. Multiple technology cost scenarios are analyzed to determine level of deployment in the Western Interconnection under various conditions.

3 - Optimizing Storage Operations In Transmission-constrained Networks For Medium And Long-term Operation

Diego Alejandro Tejada Arango, Universidad Pontificia Comillas, IIT, Madrid, Spain, Diego.Tejada@iit.comillas.edu
Sonja Wogrin, Efraim Centeno

The main objective is to present a new approach to model the storage operation in the context of Medium- and Long-Term Operational Planning (MLTOP). This approach is based on the system-state framework but including transmission constraints. A DC power flow approach is used to represent the transmission network. The methodology is related to clustering techniques using information such as demand and wind generation per node. Case studies are presented in order to compare the newly proposed methodology and the hourly approach. The results illustrate the computational time reduction without loss of accuracy in the solution.

4 - A Model Of Virtual Trading And The Forward Day Ahead Market

Gauthier De Maere D'Aertrycke, GDF Suez, Boulevard Simon Bolivar 34, Brussels, Belgium, gauthier.demaeredaertrycke@gdfsuez.com, Yves Smeers, Andreas Ehrenmann

The day ahead market plays an ambiguous role in restructured electricity markets. It is meant to help physical transactions such as the starting of machines in the unit commitment but is also intended to be a forward market capable of transferring the vagaries of real time prices into forward prices. Virtual trading was introduced for that purpose. We provide a model of virtual trading and give conditions for achieving the objective. We discuss what those conditions would imply in case of important penetration of decentralised energy. We also show some numerical experiment.

Chair: Stein-Erik Fleten, Norwegian University of Science & Technology, NO-7491 Trondheim, Trondheim, NO-7491, Norway, stein-erik.fleten@iot.ntnu.no

1 - Switching From Oil To Gas Production – Decisions In A Field's Tail Production Phase

Kristian Støre, Norwegian University of Science and Technology, Bodø, Norway, krm@uin.no, Verena Hagspiel, Stein-Erik Fleten, Claudia Nunes

We derive an optimal decision rule with regards to making an irreversible switch from oil to gas production. Assuming that both the oil and gas prices follow a geometric Brownian motion we derive a quasi-analytical solution for the exercise threshold. We also derive the related abandonment option.
When comparing the use of a static decision rule to the proposed option approach we show that the value loss can be substantial for the abandonment option. For the switching option we find that with low gas prices the value loss can be more substantial than for the abandonment option, while for high gas prices it may be optimal to switch even as oil production is still generating positive cash flows.

2 - Resilience And Investment Valuation Of A Microgrid: A Real Options Approach

Reinhard Madlener, Full Professor of Energy Economics and Management, RWTH Aachen University, E.ON Energy Research Center, FCN, Mathieustrasse 10, Aachen, Germany, RMadlener@eonerc.rwth-aachen.de, Lisa Goebbels

In this study, microgrids are discussed as a possible decentralized system approach to stabilize local power supply. Microgrids are a way to achieve a higher resilience for a whole energy supply system. We introduce and empirically apply a definition and quantification method for the resilience of a microgrid. Investment feasibility of the installation of different combinations of components is evaluated by adopting a real options approach for the optimal time to invest that takes the uncertainty about future developments into account.

3 - Real Options In Renewable Portfolio Standards

Ryuta Takashima, Tokyo University of Science, takashima@rs.tus.ac.jp, Makoto Goto

In order to promote renewable energy generation, the schemes as renewable portfolio standards have been introduced in various countries. Thus the power generators make investment decisions allowing not only for uncertain demands and competitors' strategies but also for the schemes. In this work we model an equilibrium investment strategy of generators to analyze an effect of the schemes on the investment in competitive electricity market. The market is composed of non-renewable and renewable sectors. We show how the uncertainty affects the investment timing for both generators with the scheme.

4 - Structural Empirical Analysis Of Hydropower Scheduling

Stein-Erik Fleten, Norwegian University of Science & Technology, stein-erik.fleten@iot.ntnu.no, Maren Boger, Jussi Keppo, Alois Pichler, Einar M Vestbøstad

Our goal is to study how price expectations are formed in an electricity market. In the context of a single hydropower producer in the Nordic market, we expect the forward curve to have a strong influence. The alternative we allow for is a seasonal autoregressive joint inflow and spot price model that takes dry- and wet year dynamics into account. Using observed time series of generation, reservoir trajectories and technical plant data, and a structural model of optimal releases, our initial findings indicate that forward prices have influence on price expectations. An important byproduct of the proposed procedure is estimates of marginal water values.

Data Mining in Decision Analytics: Predictive Modeling in Theory and Applications

Sponsored: Data Mining

Sponsored Session

Chair: Ali Dag, Auburn University, Auburn, AL, United States, azd0033@auburn.edu

1 - A Novel Sentiment Analytic Methodology For Multinomial Classification Of Product And Service Reviews

Ali Dag, Auburn University, azd0033@auburn.edu

The objective of this study is to classify the customer reviews (on a five-star scale) that were collected for 3 different product/service. To achieve this goal, a novel classification framework is built by constructing a unique predictor, which includes rich information gathered by using all of the extracted features. The results indicate that the proposed method outperforms the alternatives.

2 - Probabilistic Decision Analytic Risk Level Prediction Model For Kidney Transplants

Kazim Topuz, Wichita State University, Wichita, KS, United States, mktopuz@gmail.com, Mehmet B Yildirim, Ferhat Zengul, Ali Dag

The objective of this study is to define risk levels and offer additional insights into the factors affecting the short, medium and long-term success/failure of a kidney transplant from deceased donor by using machine learning techniques. We utilized an exhaustive variable selection algorithm to eliminate improper/noisy variables by combining medical knowledge and mathematical models on large pool of variables. Then we employed BBN to extract the hidden patterns and relations between predictor variables as well as multi-class response variable.

3 - Ensemble Model With Cluster Analysis For Short-term Stock Prediction

Bin Weng, Auburn University, Auburn, AL, 36849, United States, bzw0018@auburn.edu, Fadel Mounir Megahed, Chen Li

The stock market is one of the most important ways for companies and individuals to raise money due to the feature of publicity and high liquidity. Accurately predicting stock market is extremely difficult due to the non-linear, volatile and complex of the market. The purpose of this study is to develop a model to predict stock's short-term returns using disparate data sources from online data, economic data, technical indicators, and traditional history data. This study uses cluster analysis to cluster the trading days into different time periods and ensemble machine learning methods to develop the models for each period. As a result, the overall prediction performance has been increased.

Health Care, Modeling II

Contributed Session

Chair: Shenghai Zhou, Shanghai Jiao Tong University, 1954 Hua Shan Road, Shanghai, 200030, China, zshsjtu2014@sjtu.edu.cn

1 - Planning And Scheduling Of Operating Rooms And Personnel Under Uncertainty

Dominic Johannes Breuer, PhD Candidate, Northeastern University, 360 Huntington Ave, Boston, MA, 02115, United States, dbreuer@coe.neu.edu, Nadia Lahrichi, James C Benneyan

De-centralized decision-making in complex operating room (OR) environments leads to sub-optimal resource allocations. In this study, we consider operating room planning and patient sequencing as well as clinician scheduling to minimize the number of open rooms, overtime, and patient wait while maximizing shift preferences, urgent case accommodation, and OR utilization. Uncertainties such as case duration, surgeon lateness, and staff availability by specialty are incorporated in realistic-sized scenarios through robust optimization.

2 - Second-order Conic Robust Optimization With Radiation Therapy Treatment Planning Of Breast Cancer

Zengbo Zhang, Beijing Institute of Technology, 5 South Zhongguancun Street, Beijing, 10081, China, zhangzengbo_1999@163.com

We incorporate robust optimization into CVaR to formulate a loss distribution under uncertainty. We demonstrate an application of our model to the radiation therapy treatment planning problem of breast cancer. In this therapy process, the dose distribution dependented on each state is uncertain. Our framework generalize and develop this type of uncertainty and that the uncertainty set is ellipsoidal, then the formulation can be re-written as second-order conic programs. Monte Carlo simulation example are presented to illustrate the proposed approach. Our results increased dosimetric performance for former treatment planning methods and improved cardiac sparing.

3 - Patient Assignment And Operation Room Scheduling Under Uncertainty Of Patient Cancellation And Operation Duration

Bowen Pang, Tsinghua univ., Beijing, China, pzkaixin@foxmail.com, Xiaolei Xie, Li Luo, Yongjia Song

Considering the multistage decisions faced by hospital practitioners under the uncertainties of operation duration and patient no-show in multiple operation rooms, we develop a Stochastic Integer Programming (SIP) model, in which all the objectives from different stakeholders are unified into costs. Bender's Decomposition is applied to enhance the performance for solving the SIP. A case study of West China Hospital, SCU is presented.

4 - Using A Slotted Queuing Model To Predict Collaborative Emergency Center Operational Performance

Peter Vanberkel, Dahousie University, PO Box 1000, Halifax, NS, B3H 4R2, Canada, peter.vanberkel@dal.ca, Alix Carter, Ben Wedge

Nova Scotia has developed a novel way to manage Emergency Department (ED) patients in small communities. Staffed by a paramedic and a RN, and overseen by physician via telephone, Collaborative Emergency Centres (CECs) and able to manage the few patients who seek emergency care overnight in a cost effective manner. This work models the performance of CECs using a slotted queuing model in a number of different communities. Using the model, it is found that a CEC's success is related to the proportion of demand for primary care appointments compared with the supply of primary care appointments.

Renewable Energy Policies

Sponsored: Energy, Natural Res & the Environment I Environment & Sustainability

Sponsored Session

Chair: Sandra D. Eksioglu, Clemson University, Clemson, SC, United States, seksiog@clemson.edu

1 - Biomass Supply Contract Pricing And Environmental Policy Analysis: An Agent-based Modeling Approach

Shiyang Huang, Iowa State University, Ames, IA, United States, shuang@iastate.edu, Guiping Hu

This paper proposes an agent-based simulation model to study the biomass supply contract pricing and policy making in biofuel industry. Farmers' decision making is assumed to be profit driven and the biofuel producer's pricing decision is represented with a linear equation with an objective to maximize profits. A case based on Iowa has been developed to analyze the interactions between stakeholders. The impact of government environmental regulations on farmers' decision making and biomass supply has also been analyzed, and managerial insights have been derived.

2 - On The Effectiveness Of Tax Incentives To Support Biomass Co-firing

Hadi Karimi, Clemson University, hkarimi@clemson.edu, Sandra D. Eksioglu

We present models which capture the efficiency of renewable energy policies (such as, the production tax credit (PTC)) on biomass co-firing in coal-fired power plants. The efficiency measure assumed here is the sum of utilities (profits) obtained when power plants adopt biomass co-firing. The utilitarian approach identifies a PTC which maximizes this summation. We use the utilitarian solution as a basis for comparison with other PTC schemes, such as, flat tax rate and capacity based rate.

3 - A Game Theoretic Model Of Biomass Co-firing Policies

Sandra Eksioglu, Clemson University, seksiog@clemson.edu, Amin Khademi

We propose a bilevel optimization model for the optimal design of a production tax credit that optimizes renewable electricity production via biomass co-firing in coal-fired power plants. The policy maker identifies a tax credit scheme which minimizes the total tax credit necessary to meet GHG emission reduction standards at power plants. Power plants decide on biomass utilization in order to maximize their profits. We propose a solution algorithm and evaluate its performance on a case study.

4 - Evaluation Of A Wind Farm Project

Metin Cakanyildirim, The University of Texas at Dallas, metin@utdallas.edu

We discuss the evaluation of profit, revenues and costs of a wind farm. The revenue requires both wind energy generated and the sales price per unit of this energy. Generated energy is based on the wind speed and so is random. The price can also be random. Appropriate random variables for wind speed are introduced and their moments are evaluated. Costs are more predictable but government tax incentives can drastically affect profitability.

1 - Cooperative Management Of Invasive Species: A Dynamic Nash Bargaining Approach

Robert G Haight, USDA Forest Service Northern Research Station, St. Paul, MN, 55108, United States, rhaight@fs.fed.us Kelly Cobourn, Gregory Amacher

We use a Nash bargaining framework to examine scope for bargaining in invasive species problems where spread depends on the employment of costly controls. Municipalities bargain over a transfer payment that slows spread but requires an infested municipality to forgo nonmarket benefits from the host species. We find that when the uninfested municipality has a relative bargaining power advantage, bargaining may attain the first-best solution. However, in many cases a short-term bargaining agreement is unlikely to succeed, which suggests a role for higher levels of government to facilitate long-term agreements even when the details are left to municipalities to negotiate.

2 - Stochastic Programming Approaches To Surveillance And Control Planning For Emerald Ash Borer Infestations In Cities

Eyyub Yunus Kibis, Wichita State University, eykibis@wichita.edu, Esra Buyuktahtakin, Robert Haight

In this study, our objective is to maximize the net benefits of the ash trees on a landscape by applying surveillance to the ash population, followed by treatment or removal of trees based on the emerald ash borer (EAB) infestation level. Specifically, we propose a new multistage stochastic programming model which allows us to consider all possible scenarios for surveillance, treatment, and removal decisions over a planning horizon to control the invasion. Due to the model complexity, we use a decomposition technique to reach to optimal solutions for various initial scenarios. Results provide insights into surveillance and control policies, and provide an optimal strategy to reduce EAB infestation.

3 - Optimal Design Of A Nation-wide Surveillance System For Early Detection Of An Invasive Bark Beetle

Rebecca Epanchin-Niell, Resources for the Future, Epanchin-Niell@rff.org

Surveillance programs for early detection of new invaders can reduce long term costs by increasing the likelihood of successful eradication and reducing control and damage costs. We develop a model for allocating surveillance resources based on expected return on investment, in which resources are targeted first in areas with the highest expected benefits relative to costs. We define trapping benefits as the expected reduction in costs from active surveillance (i.e. trapping) relative to passive surveillance alone. We apply the approach to bark beetle detection programs in the U.S.

4 - Optimal Control Of Bio-invasions With Eradication Success Benchmarks And Management Of High Program Costs

Denys Yemshanov, Natural Resources Canada, Canadian Forest Service, Great Lakes Forestry Cente, Sault Ste. Marie, ON, P6A2E5, Canada, denys.yemshanov@canada.ca
Robert G Haight, Frank H. Koch, Robert Venette, Kala Studens, Ronald Fournier, Jean J Turgeon

We present a scenario-based model that incorporates uncertainty about the spread of an invasive pest and optimizes the deployment of survey and control measures to eradicate the outbreak. The model accounts for program success aspirations and controls the risk of high program costs. We apply the model to allocate surveys outside the quarantine area established following the discovery of Asian longhorned beetle in the Greater Toronto Area, Canada. Our approach is generalizable and helps support decisions on surveys and control of invasive pests when knowledge about a pest's spread is uncertain.

1 - Extreme-point Search Heuristics For Generalized Interval-flow Network Problems

Angelika Leskovskaya, Southern Methodist University, Dallas, TX, United States, aleskovs@lyle.smu.edu, Richard Barr

Generalized interval-flow networks are a new extension of the classic generalized network formulation that adds a conditional lower bound constraint on the arcs. An interval-pivoting heuristic that exploits the quasi-tree-forest basis structure to explore extreme points is developed and computational testing is presented.

2 - Detecting Central Clusters In Networks

Maciej Rysz, NRC, mwrysz@ufl.edu, Foad Mahdavi Pajouh

We propose a solution algorithm for identifying the most central clusters in graphs and examine its effectiveness when the centrality measure is defined by betweenness and the clusters represent cliques. Numerical experiments demonstrating the computational performance of the proposed method are conducted and compared with results obtained from solving an equivalent mixed integer programming representation.

3 - An Integrated Assignment Routing Network Representation For Solving The Multi Vehicle Routing Problem With Pickup And Delivery With Time Windows

Monireh Mahmoudi, Arizona State University, Tempe, AZ, 85283, United States, mmahmoudi@asu.edu, Chen Junhua, Xuesong Zhou

Generally, in the most commonly used exact approaches for solving the m-VRPPDTW, i.e., column generation and branch-and-cut, generating additional columns and cuts is an exhausting and time-consuming task. In this research, we intend to reach optimality for local clusters derived from a reasonably large set of passengers on real world transportation networks. In our proposed multi-vehicle state-space-time network, in order to keep only the non-dominated paths, we introduce the assignment-based hyper paths which embed passengers' cumulative service states. In addition, by the aid of our passengers' cumulative service patterns, we are able to take control of the symmetry issue.

1 - Approximating Min-cost Chain-constrained Spanning Trees: A Reduction From Weighted To Unweighted Problems

Chaitanya Swamy, Combinatorics & Optimization, University of Waterloo, 200 University Avenue West, Waterloo, ON, Canada, cswamy@uwaterloo.ca
Andre Linhares

We consider the problem of finding a min-cost spanning tree satisfying degree bounds for node-sets that form a chain. We give the first approximation algorithm for this problem that approximates both the cost and degree bounds by a constant factor. Our algorithm is based on a novel use of Lagrangian duality to simplify the cost structure of the underlying problem to obtain a decomposition into uniform-cost subproblems, and then using a known algorithm for the unweighted problem. We show that this Lagrangian-relaxation based idea is in fact applicable more generally and, for any cost-minimization problem with packing side-constraints, yields a reduction from the weighted to the unweighted problem.

2 - K-trails: Recognition, Complexity, And Approximations

Mohit Singh, Microsoft Research, mohitsinghr@gmail.com

Degree-constrained spanning hierarchies, also called k-trail, have been introduced to model network routing problems. Formally, they describe graphs that are homomorphic images of connected graphs of degree at most k. In this work, we show that computational aspects of k-trails can be analyzed using techniques from algorithmic matroid theory. Exploiting this connection, we resolve several open questions about k-trails raised by Molnar, Newman, and Sebo. The problems include the recognition of a k-trail and approximating the minimum weight k-trail in a graph.

3 - Stabilizing Unstable Graphs Through Minimum Modification

Karthik Chandrasekaran, UIUC, karthe@illinois.edu

An undirected graph G is stable if the max-fractional-matching LP (with degree and non-negativity constraints) has no integrality gap. Motivated by applications in cooperative game theory, we consider the optimization problem of achieving stability by modifying the graph to the smallest possible extent. We consider two modifications: min edge-deletion and min edge-weight-addition. We show that both these problems are NP-hard and develop approximation algorithms in certain families of graphs.

4 - Adaptive Submodular Ranking

Fatemeh Navidi, University of Michigan, navidi@umich.edu

We study a general adaptive ranking problem where we need to perform a sequence of actions on a random user, drawn from a known distribution, so as to satisfy the user as soon as possible. The user is said to be satisfied when its individual submodular function value goes above some threshold. We obtain a logarithmic factor approximation algorithm for this problem, which is the best possible. The adaptive ranking problem has many applications in active learning and ranking: it generalizes previously-studied problems such as optimal decision trees, equivalence class determination, decision region determination and submodular cover, for which our result matches the best known approximation ratio.

1 - Solving Standard Quadratic Programming By Cutting Planes

Andrea T. Lodi, École Polytechnique de Montréal, andrea.lodi@polymtl.ca

Standard quadratic programs are non-convex quadratic programs with the only constraint that variables must belong to a simplex. By a famous result of Motzkin and Straus, those problems are connected to the clique number of a graph. We propose cutting planes to obtain strong bounds: our cuts are derived in the context of Spatial Branch & Bound, where linearization variables represent products. Their validity is based on Motzkin-Straus result. We study the relation between these cuts and the ones obtained by the first RLT level. We present extensive computational results using the cuts in the context of the Spatial Branch & Bound implemented by the commercial solver CPLEX.

2 - Some Cut-generating Functions For Second-order Conic Sets

Asteroide Santana, Georgia Institute of Technology, Atlanta, GA, 30308, United States, asteroidemtm@gmail.com
Santanu Subhas Dey

In this paper, we study cut generating functions for conic sets. Our first main result shows that if the conic set is bounded, then cut generating functions for integer linear programs can easily be adapted to give the integer hull of the conic integer program. Then we introduce a new class of cut generating functions which are non-decreasing with respect to second-order cone. We show that, under some minor technical conditions, these functions together with integer linear programming-based functions are sufficient to yield the integer hull of intersections of conic sections in R2.

3 - Polynomial Dc Decompositions And Applications

Georgina Hall, Princeton University, Princeton, NJ, United States, gh4@princeton.edu, Amir Ali Ahmadi

Difference of Convex (DC) programming is a class of optimization problems where the objective and constraints are given as the difference of convex functions. Although several important problems (e.g., in machine learning) already appear in DC form, such a decomposition is not always available. We consider this decomposition question for polynomial optimization and present some new applications, primarily to distance geometry problems.

4 - A Second-order Cone Based Approach For Solving The Trust Region Subproblem And Its Variants

Nam Ho-Nguyen, Carnegie Mellon University, Pittsburgh, PA, United States, hnh@andrew.cmu.edu, Fatma Kilinc-Karzan

We study the trust region subproblem (TRS) of minimizing a nonconvex quadratic function over the unit ball with additional conic constraints. We follow a second-order cone based approach to derive an exact convex formulation of the TRS, and under slightly stronger conditions, give a low-complexity characterization of the convex hull of its epigraph without any additional variables. Our study highlights an explicit connection between the nonconvex TRS and smooth convex quadratic minimization, which allows for the application of cheap iterative methods to the TRS.

OR In Agriculture

Invited: Agricultural Analytics

Invited Session

Chair: Margarit Khachatryan, Monsanto, United States, margarit.khachatryan@monsanto.com

1 - Government Interventions In Promoting Sustainable Practices In Agriculture

Duygu Akkaya, Stanford Graduate School of Business, Stanford, CA, United States, duygug@stanford.edu, Hau Lee, Kostas Bimpikis

Sustainable practices in agriculture such as organic farming have attracted immense attention lately due to the increase in environmental and health concerns. Government support is often used to incentivize producers to convert to sustainable practices. We investigate the effectiveness of government interventions including tax, subsidy and hybrid policies in terms of their impact on sustainable practice adoption, producers' profits, consumer welfare, and return on government spending using a setting in which producers with traditional and sustainable production options serve consumers that have a high valuation for sustainable production.

2 - Accelerating Digital Agriculture Through Automated R&D Trial Placement Into Field Zones

Qinglin Duan, Monsanto, St. Louis, MO, United States, qinglin.duan@monsanto.com, David Ciemnoczolowski

The trend towards Digital Agriculture requires increasing information on conditions within fields and corresponding decisions about product selection and management. To provide placement and management prescriptions, products must be tested across differing conditions within fields. We formulate the zone mapping problem as a 2D bin-packing model with trials of known dimensions and operational constraints. The model is integrated into Monsanto's geospatial field platform with analytics relating climate, soils, and topography to crop performance. Optimized placement has enabled representative testing across environments and set the foundation for advancements in digital agriculture.

3 - Combining Expert Estimates With Data To Obtain Hybrid Yield Distributions

Saurabh Bansal, Penn State University, sub32@psu.edu, Genaro J Gutierrez

We discuss a Copula based approach to combine expert judgments for yield distributions with data, and illustrate its application for the seed corn business.

4 - A Mathematical Model For Farm Scale Land Management Considering Uncertainty

Qi Li, Iowa State University, qili@iastate.edu, Guiping Hu

Farmers make decisions on types of crops to plant and irrigation frequency and pattern on an annual basis. This is often done under various uncertainties, such as precipitation amount, crop prices, and soil profile. In the study, a farm level precision farmland management model based on stochastic programming is proposed. The model focuses on the uncertainties in weather, yield and market prices. Advanced statistical methods such as time series analysis and spatial analysis are also investigated to generate representative realizations for the uncertainties.

Building Better Models: Innovations in Predictive Analytics

Invited: Modeling and Methodologies in Big Data

Invited Session

Chair: CP Teo, NUS, 1 Business Link, Singapore, 598727, Singapore, bizteocp@nus.edu.sg

1 - Multi-product Pricing Problem Using Experiments

Zhenzhen Yan`, National University of Singapore, Singapore, Singapore, a0109727@u.nus.edu, Cong Cheng, Karthik Natarajan, Chung-Piaw Teo

We study the multi-product pricing problem using pricing experiments. In particular, we develop a data driven approach to this problem using the theory of marginal distribution. We show that the pricing problem is convex for a large class of discrete choice models, including the classical logit and nested logit model. Our model remains convex as long as the marginal distribution is log-concave. More importantly, by fitting data to optimize the selection of choice model, we develop an LP based approach to the semi-parametric version of the pricing problem. Preliminary tests using a set of automobile data show that this approach provides near optimal solution, even with random coefficient logit model.

2 - Disruption Risk Mitigation In Supply Chains – The Risk Exposure Index Revisited

Sarah Yini Gao, NUS, 1, Singapore, Singapore, yini.gao@nus.edu.sg, Chung-Piaw Teo, David Simchi-Levi

We proposed a new method to integrate probabilistic assessment of disruption risks into the REI approach, and measure supply chain resiliency by analyzing the Worst-case CVaR of total lost sales under disruptions. We show that the optimal emergency inventory positioning strategy in this model can be fully characterized by a conic program. Moreover, the optimal primal and dual solutions to the conic program can be used to shed light on comparative statics in the supply chain risk mitigation problem.

3 - Provably Data-Driven Approximation Schemes For Joint Pricing And Inventory Control Models

Hanzhang Qin, Massachusetts Institute of Technology, Cambridge, MA, United States, hqin@mit.edu, Davis Simchi-Levi, Li Wang

We propose a data-driven algorithm to solve the joint inventory and pricing problem for a single-product, multi-period model under independent demand. Our algorithm provides a near-optimal solution under any degree of accuracy and pre-specified confidence probability and requires polynomial number of sample data and is polynomial in the number of time periods. This algorithm differs from other online data-driven counterparts in the sense that we make all decisions based on past data only.

4 - Lockers Network: A Solution To Last Mile Delivery Problem

Guodong Lyu, National University of Singapore Business School, #B1-01, BIZ2 Building, 1 Business Link, Singapore, 117592, Singapre, 117592, Singapore, guodong.lyu@u.nus.edu
Chung-Piaw Teo

Lockers (Parcel Collection Point) are convenient for parcels collection. To maximize the coverage of failed delivery by using lockers, a novel locker location model is introduced and customer choice is considered as an input. We provide the mobile flow from stations to residence blocks, and use the mobility data to locate lockers. The mobile delivery flow is calculated based on the transportation data and failed delivery data. Customers' parcel collection behavior is estimated from locker usage data. Furthermore, lockers location data from an Express are provided to validate our model. We demonstrate that the value of using mobility date for failed delivery coverage maximization is significant.

Algorithms for Stochastic Programming

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Natashia L Boland, Georgia Institute of Technology, 755 Ferst Drive, NW, Atlanta, GA, 30332, United States, natashia.boland@isye.gatech.edu

1 - Scenario Set Partition Dual Bounds For Multi-stage Stochastic Programming

Ilke Bakir, PhD Candidate, Georgia Institute of Technology, Atlanta, GA, 30309, United States, ilkebakir@gatech.edu
Natashia Boland, Brian Dandurand, Alan Erera

We propose expected partition (EP) bounds, a hierarchy of bounds based on partitions of the scenario set into subsets of (nearly) equal cardinality. Additionally, using the fact that solution of group subproblems for all subsets in a single partition also yields a dual bound, we establish that the best of even a very small number of such single partition bounds is likely to be better than the corresponding EP bound. By sampling partitions of the scenario set, we obtain an algorithm that computes confidence intervals for an EP bound, while also providing exact dual bounds. The practical value of these ideas is illustrated on benchmark problems, and the approach is compared to Sample Average Approximation.

2 - AMPL Representation And Solution Of Multiple Stochastic Programming And Robust Optimization Formulations

Christian Valente, OptiRisk Systems, One Oxford Road, Uxbridge, UB9 4DA, United Kingdom, christian@optirisk-systems.com,
Gautam Mitra, Christiano Arbex Valle, Robert Fourer

Paradigms of 'Uncertainty Models', namely, recourse, chance constrained, integrated chance constrained, and robust optimization models, are introduced and represented through use case exemplars. Through our continued research and close collaboration with AMPL Optimization we have now developed AMPL templates and frameworks which can describe these classes of models and connect them to respective solvers, making them readily available to industry-based analysts and to the academic research community. We also describe an E-book (in preparation) which captures the use cases that underpin our goal to make these modelling and solving capabilities widely available to the OR community.

3 - Combining Progressive Hedging And Frank-Wolfe To Solve The Lagrangian Dual Of a Multistage Stochastic Integer Program

Natashia Boland, Georgia Institute of Technology, natashia.boland@isye.gatech.edu, Jeffrey Christiansen, Brian Dandurand, Andrew Eberhard, James Luedtke, Jeffrey Linderoth, Fabricio Oliveira

We present a new primal-dual algorithm for computing the value of the Lagrangian dual of a stochastic mixed-integer program (SMIP) formed by relaxing its nonanticipativity constraints. The algorithm relies on the progressive hedging method, but unlike previous progressive hedging approaches for SMIP, it converges to the optimal Lagrangian dual value. The key improvement is an inner loop of optimized linearization steps, as in the classical Frank-Wolfe method. Numerical results show that the new algorithm outperforms the standard progressive hedging approach.

4 - First Order Approximation Methods For Estimating Decision Covariance In Stochastic Optimization

Sriram Sankaranarayanan, Johns Hopkins University, 3400, N. Charles St, Baltimore, MD, 21218, United States, ssankar5@jhu.edu, Felipe A Feijoo, Sauleh Ahmad Siddiqui

We use first order methods to efficiently approximate the covariance matrix of the optimal solution vector. The idea is extended for the covariance of the solution to a complementarity problem by posing the complementarity problem as an unconstrained minimization problem using the Fischer Burmeister merit function. Having done this, we estimate the variability in the estimated Market equilibrium of a Natural gas model, owing to uncertainty in the parameters of the demand function.

Optimization Challenges in Modeling

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Leobardo Valera, University of Texas El Paso, 500 W. University Ave, El Paso, TX, 79968, United States, lvalera@miners.utep.edu

1 - Problem Of Moments Over Log-concave Measures

Christopher Thomas Ryan, The University of Chicago, Chicago, IL, United States, chris.ryan@chicagobooth.edu, Simai He, Bo Jiang, Teng Zhang

We explore the classical discrete problem of moments in a setting where the underlying distribution are discrete log-concave. This situation arises in applied problems such as reliabilit The challenge is that with log-concavity constraints, the problem of moments becomes a non-convex optimization problem. Nonetheless, we are able to characterize optimal extreme point solutions to such problems. Our approach gives rise to improved bounds over the existing literature, as well as analytical insight into the structure of extreme point optimal solutions as geometric distributions.

2 - Interval Constraint Solving Techniques And Model Order Reduction To Enhance The Solution Of Dynamic Systems

Leobardo Valera, The University of Texas at El Paso, lvalera@utep.edu, Martine Ceberio

Many natural phenomena are dynamic systems, which can often be modeled as nonlinear systems of equations. Major issues with solving such nonlinear systems are that their dimension can be very large and that uncertainty, often present, is tricky to handle. Reduced-Order Modeling (ROM) can address dimension issues, via Proper Orthogonal Decomposition (POD) in particular. On the other hand, interval constraint-solving techniques (ICST) allow to handle uncertainty and ensure reliable results. In this presentation, we show how ICST can be embedded into POD to address dimension and uncertainty.

HPC in Optimization 1

Invited: High Performance Computing

Invited Session

Chair: Kibaek Kim, Argonne National Laboratory, 9700 South Cass Avenue, Building 240, Lemont, IL, 60439, United States, kimk@anl.gov

Co-Chair: Geoffrey Malcolm Oxberry, Lawrence Livermore National Laboratory, P. O. Box 808, Livermore, CA, 94551, United States, goxberry@gmail.com

1 - Asynchronous Parallelization Of Decomposition Methods

Kibaek Kim, Argonne National Laboratory, kimk@anl.gov

We present an approximate and incremental bundle method based on dual decomposition for stochastic mixed-integer programming (SMIP), where the Lagrangian dual function is incrementally updated by approximate subgradients as well as exact ones. We implemented the method in an open source parallel solver DSP, taking advantage of asynchronous communications on HPC cluster using MPI library. We present our computational results on several SMIP problem instances.

2 - Parallel Branch And Bound Revisited

Lluis-Miquel Munguia, Georgia Institute of Technology, lluis.munguia@gatech.edu, Geoffrey Malcolm Oxberry, Deepak Rajan

Branch and Bound (B&B) is a widely used algorithm for solving Mixed Integer Programs (MIPs). Despite its straightforward parallelization, current B&B implementations have shown to scale inconsistently. In this talk, we propose a new decentralized and lightweight implementation of parallel Branch & Bound for PIPS-SBB, a distributed-memory parallel stochastic MIP solver. In this work, we exploit parallelism at two levels of the optimization process with the objective of increasing parallel efficiency. We present computational results to evaluate the effectiveness of our approach.

3 - Scalable Strategies Exploited by Parallel Nonlinear Solver PIPS-NLP

Nai-Yuan Chiang, United Technology Research Center, chiangn@utrc.utc.com

We present PIPS-NLP, a software library for the solution of large-scale structured nonconvex optimization problems on high-performance computers. We focus on linear algebra parallelization strategies and discuss how such strategies influence the choice of algorithmic frameworks, while all the proposed approaches guarantee global convergence. Small examples about using parallel solver PIPS-NLP via AMPL or StructureJuMP are given, to illustrate how to exploit the problem structures. Numerical studies from large-scale security-constrained ACOPF and line-pack dispatch in natural gas networks also demonstrate the robustness and efficiency of PIPS-NLP.

Bilevel Programming: Methodology and Applications

Sponsored: Computing

Sponsored Session

Chair: Juan S. Borrero, University of Pittsburgh, 1012 Benedum Hall, Pittsburgh, PA, 15261, United States, jsb81@pitt.edu

Co-Chair: M. Hosein Zare, University of Pittsburgh, 1012 Benedum Hall, Pittsburgh, PA, 15260, United States, moz3@pitt.edu

1 - A Sampling-based Exact Approach For The Bilevel Mixed Integer Programming Problem

Leonardo Lozano, Clemson University, llozano@g.clemson.edu Cole Smith

We examine bilevel mixed integer programs which are difficult to solve because the leader feasible region is defined in part by optimality conditions governing the follower variables, which are difficult to characterize because of the nonconvexity of the follower problem. We propose an exact finite algorithm for these problems based on an adaptive sampling scheme, and demonstrate how this algorithm can be tailored to accommodate either optimistic or pessimistic assumptions on the follower behavior. Computational experiments demonstrate that our approach outperforms existing algorithms that are tailored to problems in which all functions are assumed to be linear.

2 - On Bilevel Progams With Inexact Follower

M. Hosein Zare, University of Pittsburgh, moz3@pitt.edu

We consider classes of bilevel programs, where the upper-level decision-maker (i.e., the leader) needs to consider the uncertain behavior of the lower-level decision maker (i.e., the follower). We derive some theoretical properties of the proposed models, and illustrate our results with numerical illustrations.

3 - Reliable Vehicle Sharing Program Network Design

Ran Zhang, University of South Florida, ranzhang@mail.usf.edu, Bo Zeng

This talk develops a bi-level optimization model to achieve a reliable vehicle sharing program network design. A set of numerical study will be presented to demonstrate our design model.

4 - Sequential Max-min Bilevel Programming With Incomplete Information And Learning

Juan S. Borrero, University of Pittsburgh, jsb81@pitt.edu Oleg A Prokopyev, Denis R. Saure

We consider an adversarial bilevel problem where the leader and follower interact repeatedly. At each period the leader implements an upper-level solution after which the follower reacts by solving the lower-level problem. The leader has incomplete information about the variables, constraints, and data of the follower's problem, and learns about them from observing his reaction to her actions. Given that the leader's objective is to maximize the costs the follower incurs across all periods, we study a set of greedy and robust decision policies that are able to find an optimal solution to the full-information bilevel problem in finite time periods, and moreover, are worse-case optimal.

Methods and Applications of Network Sampling

Invited: Tutorial

Invited Session

Chair: Mohammad Al Hasan, Indiana University/Purdue University, Department of Computer Science, Indianapolis, IN, 46202, United States, alhasan@iupui.edu

1 - Methods And Applications Of Network Sampling

Mohammad Al Hasan, Indiana University/Purdue University, Indianapolis, IN, 46202, United States, alhasan@iupui.edu

Network data appears in various domains, including social, communication, and information sciences. Analysis of such data is crucial for making inferences and predictions about these networks, and moreover, for understanding the different processes that drive their evolution. However, a major bottleneck to perform such an analysis is the massive size of real-life networks, which makes modeling and analyzing these networks simply infeasible. Further, many networks, specifically, those that belong to social and communication domains are not visible to the public due to privacy concerns, and other networks, such as the Web, are only accessible via crawling. Therefore, to overcome the above challenges, researchers use network sampling overwhelmingly as a key statistical approach to select a sub-population of interest that can be studied thoroughly. In this tutorial, we aim to cover a diverse collection of methodologies and applications of network sampling. We will base the discussion of network sampling in terms of population of interest (vertices, edges, motifs), and sampling methodologies (such as Metropolis-Hastings, random walk, and importance sampling). We will also present a number of applications of these methods.

Applications in Healthcare

Sponsored: Health Applications

Sponsored Session

Chair: Sarah Kadish, Dana-Farber Cancer Instititue, 450 Brookline Ave, Boston, MA, 02215, United States, sarah_kadish@dfci.harvard.edu

1 - Determining The Optimal Schedule For Premixing Chemotherapy Drugs

Donald Richardson, University of Michigan, 2753 IOE Building, 1205 Beal, Ann Arbor, MI, 48109-2117, United States, donalric@umich.edu, Amy Cohn

In collaboration with the University of Michigan Comprehensive Cancer Center, we have developed an optimization-based approach to improve make-ahead policies for chemotherapy drugs for infusion patients. We first present our optimization model. Then we present our proposed user interface to aid our collaborators with interpreting the solutions.

2 - Operations Research Applications At A Comprehesive Cancer Center

Victoria Jordan, University of Texas MD, vsjordan@mdanderson.org

Industrial and Systems Engineering is an emerging field in healthcare. The University of Texas MD Anderson Cancer Center has Healthcare Systems Engineers working in the Office of Performance Improvement. This session will provide a high level overview of OR applications to improve patient flow and the patient experience, reduce costs, and improve safety. Also presented will be more clinical applications to improve delivery of care and the care itself.

3 - Factors That Predict Discharge Disposition At Admission For Veterans

Nicholas Ballester, Wright State University, 207 Russ Center, 3640 Col Glenn Hwy, Dayton, OH, 45435, United States, ballester.2@wright.edu, Pratik J Parikh

Discharge delays reduce inpatient quality of care and reverberate back through the health care system, tying up valuable resources needed by incoming patients. Discharge disposition, in particular, has a significant effect as different dispositions require vastly different procedures for insurance and transportation coordination. We have developed model to predict discharge disposition upon admission for veterans admitted to a general internal medicine unit. This model considers patient factors known at admission such as demographics, medical history, and living status. Preliminary findings from a trial implementation will also be discussed.

4 - Applications Of Real Time Locating Systems In Ambulatory Oncology

Sarah Kadish, Dana-Farber Cancer Instititue, Boston, MA, United States, sarah_kadish@dfci.harvard.edu, Constance Barysauskas, Ryan Leib, Avishai Mandelbaum, Petar Momcilovic, Arik Senderovich, Nikolaos Trichakis, Craig Bunnell

Real Time Locating Systems (RTLS) implementations have increased in the healthcare industry despite few studies supporting efficacy. In addition, the potential applications of RTLS as a tool for improving hospital operations management remains relatively unexplored. We sought to measure the improvement in quality of care and patient experience immediately after RTLS implementation. Furthermore, we explored the utility of RTLS in providing unbiased data to improve accuracy for chemotherapy scheduling. Finally, we demonstrate the ability for RTLS to assess impacts of large organizational changes such as the implementation of an Electronic Health Record on patient time in clinic.

Panel: Challenges of Implementing OR in the Healthcare Industry

Invited: ORinformed Healthcare Policies

Invited Session

Moderator: Michael W Carter, University of Toronto, Toronto, ON, Canada, carter@mie.utoronto.ca

Implementing OR/MS in healthcare poses major challengers to practical researchers. The problems and the corresponding solutions are similar to those in industry and other service industries. So why is it so difficult? This panel brings together a group of researchers who have been successful in overcoming the challenges.

1 - The Challenge Of Lean; Working With Health Professionals Who Think O.R. Means Operating Room

Panelist: Martin L Puterman, University of British Columbia, martin.puterman@sauder.ubc.ca

2 - Developing Good Collaborations And Avoiding Bad Ones

Panelist: Brian T Denton, University Of Michigan, btdenton@umich.edu

3 - The Good, The Bad, And The Ugly Of Publishing Operations Research Work In Medical Journals

Panelist: Sheldon H Jacobson, University Of Illinois, shj@illinois.edu

4 - Struggles In Getting Data For Healthcare Research

Panelist: Amy Cohn, University Of Michigan, amycohn@umich.edu

5 - Moving The Needle In Public Health Decision Making

Panelist: Margaret L Brandeau, Stanford University, brandeau@stanford.edu

Joint Session MIF/HAS: Modeling and Optimization for Advanced Stage Liver and Kidney Disease Patients

Sponsored: Health Applications

Sponsored Session

Chair: Anahita Khojandi, University of Tennessee Knoxville, 521 John D. Tickle Building, 851 Neyland Drive, Knoxville, TN, 37996, United States, khojandi@utk.edu

Co-Chair: Murat Kurt, Merck Research Labs, 351 N. Sumneytown Pike, North Wales, PA, 19454, United States, murat.kurt7@gmail.com

1 - Optimal Liver Cancer Surveillance In Hepatitis C Infected Population

Qiushi Chen, Georgia Institute of Technology, Atlanta, GA, United States, chenqiushi0812@gatech.edu, Turgay Ayer, Jagpreet Chhatwal

Liver cancer is the fastest growing cause of cancer deaths in the United States. Although early diagnosis through can improve survival, the optimal surveillance policy remains unknown. We develop a mixed-integer programming-based framework to identify the most cost-effective surveillance policy. Our framework allows a formulation of practical policy structures. Our numerical results find that (1) the optimal surveillance interval should depend on patient's stage of hepatitis C and age, and (2) expanding surveillance to earlier stage of hepatitis C improves the cost-effectiveness of HCC surveillance.

2 - The Changing Etiology Of End Stage Liver Disease And The Implicationsfor The Liver Transplant Waitlist

Maria Mayorga, North Carolina State University, memayorg@ncsu.edu
Zinan Yu, Stephanie B Wheeler

Changes in the epidemiology of end stage liver disease will impact future liver transplant (LT) waitlist. We performed a discrete event simulation model to forecast both regional and national LT waitlist size, number of transplants, and hazard of waitlist drop out, while considering patient arrivals, demographic and clinical attributes, waiting time and liver availability.

3 - Investigating Steroid Withdrawal Strategies For Kidney Transplant Recipients

Yann B. Ferrand, Clemson University, Clemson, SC, United States, yferran@clemson.edu, Vibha Desai, Christina M. Kelton, Teresa M. Cavanaugh, Jaime Caro, Jens W. Goebel, Pamela C. Heaton

We evaluate various steroid withdrawal strategies for kidney transplant recipients. The goal is to minimize major complications resulting from these complex drug regimens over the long term. We develop a model calibrated with an econometric study of patient data from a national registry to simulate the long-term course of these patients. We report on the frequency and timing of adverse events and identify trade-offs in the steroid withdrawal strategies.

4 - Eliciting Patients' Revealed Risk Perceptions Of Dialysis And Death In Preemptive Living-donor Kidney Transplantation

Masoud Barah, University of Tennessee, Knoxville, TN, United States, mbarah@vols.utk.edu, Anahita Khojandi, Murat Kurt

When kidneys can no longer function at the level needed, patients must undergo either dialysis or transplantation to survive. Given empirical patterns in timing of pre-dialysis living donor transplantation, we investigate the behavioral dynamics behind patients' risk-averse behavior. We develop an inverse MDP model to elicit the perceived life-year loss associated with kidney failure or death due to delaying transplantation. We calibrate the model using clinical literature and publicly available datasets and provide insights on patients' perceptions of kidney failure and risk of death.

Ecology of Innovation: Sources of Knowledge and Complements

Invited: Strategy Science

Invited Session

Chair: Daniel Levinthal, University of Pennsylvania, Wharton School, Philadelphia, PA, 189, United States, levinthal@wharton.upenn.edu

1 - Intra-firm Spillovers? The Stock And Flow Effects Of Collocation

Evan Rawley, Columbia Business School, New York, NY, United States, erawley@columbia.edu, Robert Seamans

We study how intra-firm collocation—geographic clustering of establishments owned by the same parent company—influences performance, decomposing collocation effects to learn about the mechanisms behind intra-firm agglomeration. Using Census micro data on the population of U.S. hotels and restaurants 1977-2007, we find that doubling the intensity of intra-firm collocation is associated with a productivity increase of about 2%. Further analyses reveal that a significant component of the productivity gains persist after an establishment ceases to be collocated, suggesting that proximity to other establishments owned by the same parent firm facilitates the transfer of knowledge.

2 - Waste Reduction Strategies: Less Is More

Luca Berchicci, Erasmus University, Rotterdam School of Business, Rotterdam, Netherlands, Berchicci @erasmus.edu
Nilanjana Dutt, Will G Mitchell

Manufacturing firms seek to develop and implement techniques to improve production efficiency by obtaining information from various knowledge sources. Examining a greater number of knowledge sources should help firms find a viable solution to improve production efficiency, but it also raises the costs of collecting and using new information, which may ultimately hinder performance. Due to these tradeoffs, a key initial choice is how many knowledge sources to search. Based on U.S. manufacturing facilities that seek to improve production efficiency by reducing their annual toxic waste output, our results indicate that examining one knowledge source is the best approach.

3 - Reload And Relaunch: Strategic Governance Of Platform Ecosystems

Joost Rietveld, Erasmus University, Burgemeester Oudlaan 50, Mandeville (T) Building, Room 7-41, Rotterdam, 3072AP, Netherlands, rietveld@rsm.nl, Melissa A Schilling, Christiano Bellavitis

Platforms have a number of levers for managing their ecosystems. However, they must use them carefully: how and by whom value is captured is shaped by the dynamics between complementors and the platform itself. We develop a framework of value creation and value capture yielding implications for whether and when platforms should selectively promote complements. We analyze data from seventh generation video games, assessing both how games are selected for promotion, and how promotion affects sales. Platform owners do not promote best in class complements; they invest in underappreciated ones where there is more marginal value to be unlocked, and with whom the platform has greater bargaining power.

4 - Value-Based Outsourcing

Joaquín Poblete, Pontificia Universidad Catolica de Chile, s, s, Chile, joaco.poblete@gmail.com, Jorge Martabit

Using a value-based approach we analyze make-or-buy choices in settings in which value created by activities depend on the set of activities being performed. We show that when activities are complements, optimal make or buy choices tend to follow a common pattern, i.e., they are all insourced or outsourced, whereas firms tend to choose different governance modes when activities are substitutes. We also found that coordination advantages of insourcing are more important when activities are complements, while cost advantages of outsourcing are more important when activities are substitutes.

Improving Efficiency of Supply Chains through Scheduling

Invited: Project Management and Scheduling

Invited Session

Chair: Chelliah Sriskandarajah, Texas A&M University, College Station, TX, United States, chelliah@mays.tamu.edu

Co-Chair: Yunxia Peter Zhu, Assistant Professor, Rider University, Sweigart Hall 358, 2083 Lawrenceville Road, Lawrenceville, NJ, 08648, United States, yuzhu@rider.edu

1 - Provider Selection Framework For Bundled Payments In Healthcare

Seokjun Youn, Texas A&M University, College Station, TX, United States, syoun@mays.tamu.edu, Anupam Agrawal, Subodha Kumar, Chelliah Sriskandarajah

Well-designed incentive system can lead to the successful operation of bundled payment program. Focusing on provider selection and evaluation problems, we develop a framework that aims to select better providers than existing method while balancing cost reduction, quality of care, and efficiency measures.

2 - A Framework For Analyzing The U. S. Coin Supply Chain

Yiwei Huang, Visiting Assistant Professor, The Pennsylvania State University, State College, PA, United States, yuh201@psu.edu

This is the first study that addresses operational issues within a Coin Supply Chain (CSC) and presents a framework, an optimal/near-optimal operating policy, and a robust planning system for the Federal Reserve System and Depository Institutions to increase their efficiency and effectiveness of coin ordering, producing, packaging, distribution, and inventory management by treating the U.S. CSC as a closed-loop supply chain from both supply and demand-side perspectives.

3 - Recent Results In Scheduling Dual Gripper Robotics Cells

Kyung Sung Jung, University of Florida, ksjung@ufl.edu, Harry Neil Geismar, Michael L Pinedo, Chelliah Sriskandarajah

We focus on the problem of finding 1-unit cyclic sequence of robot movements in dual-gripper buffer-less robotic cells designed to produce identical parts under the free-pickup criterion. We establish conditions where the problem of finding an optimal cycle is NP-hard. The remaining cases can be shown to be polynomial solvable.

4 - Cross-dock Terminal Scheduling

Yunxia Zhu, Rider University, yuzhu@rider.edu
Harry Neil Geismar, Chelliah Sriskandarajah, Inna Drobouchevitch

We study various scheduling problems encountered in cross-dock terminals. In a general cross-dock scheduling problem, a set of inbound trucks are assigned to a fixed number of unload docks. Items are first unloaded from these trucks then are transferred to outbound trucks to be dispatched to customers. The typical objective is to minimize the total time spent to perform such unloading and loading operations for a planning horizon. We also study other objective functions under various cross-dock terminal environments (e.g., with no-wait processing and with the presence of temporary storage).

110B-MCC

Procurement Auctions

Invited: Auctions

Invited Session

Chair: Martin Bichler, Technische Universitat Munchen, Munich, Germany, bichler@in.tum.de

1 - Trust In Procurement Interactions

Nicolas Fugger, ZEW Mannheim, L7, 1, Mannheim, 68161, Germany, nicolas.fugger@zew.de, Elena Katok

We investigate the observation that auctions in procurement can be detrimental to the buyer-seller relationship. Poor relationship can result in a decrease in trust by the buyer during the sourcing and an increase in opportunistic behavior by the supplier after the sourcing. We consider a setting in which the winning supplier decides on the level of costly quality to provide to the buyer, and compare a standard reverse auction and a buyer-determined reverse auction in the laboratory. We find that buyer-determined auctions result in higher prices but also improve cooperation between the buyer and the selected supplier.

2 - An Optimal Procurement Mechanism With Post-auction Cost-reduction Investigations

Qi (George) Chen, University of Michigan, Ann Arbor, MI, United States, georgeqc@umich.edu, Damian Beil, Izak Duenyas

This paper studies the optimal mechanism design problem of a buyer who needs to procure from a pool of qualified suppliers in a setting where she can choose to investigate the suppliers to identify cost-reduction opportunities which reduce their costs after the bids are collected, and then awards the contract. We fully characterize the optimal mechanisms and show that for symmetric suppliers, our mechanisms create ex ante win-win situations for everyone compared to the optimal mechanism without investigations. The win-win situation may break down when suppliers are sufficiently asymmetric, but no supplier has the incentive to unilaterally block investigation.

3 - Linear Pricing In Large-scale Combinatorial Exchanges

Vladimir Fux, Technical University of Munich, vladimir.fux@tum.de, Martin Bichler

Linear and anonymous competitive equilibrium prices are desirable in multi-object auctions, but unfortunately such prices typically do not exist in combinatorial exchanges. We discuss the market design of a large-scale combinatorial exchange for fishery access rights where linear and anonymous prices is a requirement and minor efficiency loss can be tolerated. We analyze the trade-offs of different payment rules relevant for an auction designer, in particular with respect to the welfare loss they incur. Via analytical models and numerical simulations, we show that these losses can be up to 100% in worst-case scenarios, but that these losses are small on average in larger markets.

4 - Equilibrium Bidding Strategies In Ex-post Split-award Auctions With Diseconomies Of Scale

Gian-Marco Kokott, Technical University of Munich, Munich, Germany, gian.marco@dss.in.tum.de, Martin Bichler, Per Paulsen

Ex-post split-award auctions are a wide-spread form of combinatorial procurement auctions. We focus on markets with diseconomies of scale, which is practically relevant and strategically challenging, since bidders have to coordinate on the efficient outcome. We show that the first-price sealed-bid and the Dutch ex-post split-award auction are not strategically equivalent. The first-price sealed-bid format exhibits a coordination problem for bidders, whereas the Dutch has a unique and efficient equilibrium. We also analyze a combination of both formats and compare all three auctions with respect to efficiency and costs. In lab experiments, we find support for the theoretical results.

Diagnosis Under Uncertainty

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Sarang Deo, Indian School of Business, Hyderabad, India, sarang_deo@isb.edu

Co-Chair: Tinglong Dai, Johns Hopkins University, Baltimore, MD, United States, dai@jhu.edu

1 - False Diagnosis And Overtreatment In Services

Senthil Veeraraghavan, University of Pennsylvania, senthilv@wharton.upenn.edu

In many services, consumers must rely on experts to identify the type of service they need. In such service, diagnosis is a crucial step in which the expert identifies the problem and provides the corresponding treatment. The information asymmetry leads to inefficiencies in the form of overtreatment. Overtreatments are expensive but also require more service capacity and time, and thus result in longer delays and higher waiting costs for services. However, we find that such delays act as a natural "fraud cost" and mitigates expert cheating and induce honesty. Experts high capacity utilization are less prone to overtreat.

2 - Conspicuous By Its Absence: Diagnostic Expert Testing Under Uncertainty

Tinglong Dai, Assistant Professor, Johns Hopkins University, 100 International Drive, Baltimore, MD, 21202, United States, dai@jhu.edu, Shubhranshu Singh

Diagnostic experts, such as medical doctors, are crucial for evaluating the state of the world. All diagnostic experts are not equally competent, and even the best experts are imperfect. We model the decision-making process of a diagnostic expert, who is altruistic but concerned about reputation. Our paper presents interesting insights about the expert's test-ordering behavior primarily driven by reputation concerns.

3 - Incentizing Less-than-Fully-Qualified Providers For Early Diagnosis Of Tuberculosis In India

Sarang Deo, Indian School of Business, sarang_deo@isb.edu
Milind Sohoni, Neha Jha

A major driver of TB epidemic in India is delay in diagnosis by less-than-fully-qualified providers (LTFQs), who are typically the first point of contact for patients. This work is motivated by pilots funded by international donors to provide monetary incentives to LTFQs to induce earlier referral and diagnosis. Using a game-theoretic model, we show that the optimal structure of the incentive referral contract (whether to pay for all referrals or only for confirmed referrals) depends on the quality of diagnosis of the provider. We calibrate our model results using realistic parameter estimates obtained from primary and secondary data sources.

4 - Medical Guideline Making When Litigation Is A Concern: The Role Of Ubiquitous Health Information

Mehmet U Ayvaci, University of Texas-Dallas, 800 W. Campbell Rd. SM33, Richardson, TX, 75080, United States, Mehmet.Ayvaci@utdallas.edu, Yeong In Kim, Srinivasan Raghunathan, Turgay Ayer

We examine the optimal formulation of guidelines in a generic health screening with consideration for the physician's increased liability risk under ubiquitous health information and information technologies. We find that under the litigation concern, the social planner strategically provides imprecise guidelines with vague recommendations regarding which patients should undergo the test while providing precise guidelines regarding the physician's decisions based on test results. Strategic vagueness in guidelines balances the trade-off between the reduction of defensive medicine and supply of the health service.

Abstract to come

3 - Online Decision-Making with High-Dimensional Covariates

Hamsa Bastani, Stanford University, Stanford, CA, bayati@stanford.edu

Big data has enabled decision-makers to tailor decisions at the individual-level in a variety of domains such as personalized medicine and online advertising. This involves learning a model of decision rewards conditional on individual-specific covariates. In many practical settings, these covariates are high-dimensional; typically only a small subset of the observed features are predictive of a decision's success. We formulate this problem as a multi-armed bandit with high-dimensional covariates, and present a new efficient bandit algorithm based on the LASSO estimator. Our regret analysis establishes that our algorithm achieves near-optimal performance in comparison to an oracle that knows all the problem parameters. The key step in our analysis is proving a new oracle inequality that guarantees the convergence of the LASSO estimator despite the non-i.i.d. data induced by the bandit policy. Furthermore, we illustrate the practical relevance of our algorithm by evaluating it on a real-world clinical problem of warfarin dosing.

Innovations in the Operations-Marketing Interface

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Jose A Guajardo, University of California-Berkeley, Berkeley, CA, United States, jguajardo@berkeley.edu

1 - Does Online Learning Work In Retail?

Serguei Netessine, INSEAD, serguei.netessine@insead.edu
Marshall L Fisher, Santiago Gallino

We partnered with Experticity, a firm that provides online training modules for retail Store Associates, and Dillard's, a leading department store chain whose more than 50,000 Store Associates had access to the Experticity product training modules. We found that as Store Associates engaged in training over time, their sales rate increased by 1.8 percent for every module taken. We also found that willingness to engage in voluntary training was an indicator of raw talent; those Store Associates who engaged in training were 20 percent more productive prior to any training, and 46 percent more productive after training, than those who took no training.

2 - Business Models In The Sharing Economy: Manufacturing Durable Goods In The Presence Of Peer-to-peer Rental Markets

Zhe Zhang, Carnegie Mellon University, 4800 Forbes Avenue, Pittsburgh, PA, 15213, United States, zhezhang@cmu.edu
Vibhanshu Abhishek, Jose A Guajardo

Business models focusing on providing access to assets rather than on transferring ownership of goods have become an important recent industry trend. Motivated by this trend, this research analyzes the interaction between a manufacturer of durable goods and a peer-to-peer marketplace, characterizing market outcomes under alternative market structures.

3 - When The Bank Comes To You: Branch Network And Custsomer Multi-channel Banking Behavior

Vibhanshu Abhishek, CMU, vibs@andrew.cmu.edu
Beibei Li, Dan Geng

Customers today increasingly interact with their banks using digital channels, lifting the necessity for banks to rethink the distribution of physical branches and customer behavior in a multi-channel environment. Using approximately 1.2M anonymized individual-level data from a large commercial bank in US over 6 years, our paper investigates the traditional channel - bank branches - and the impact of its network change (branch opening or closure) on customer multi-channel preferences and other banking behavior.

Social and Environmental Considerations in Retailing

Sponsored: Manufacturing & Service Oper Mgmt
Sponsored Session

Chair: Xiajun Amy Pan, University of Florida, Gainesville, FL, United States, amy.pan@warrington.ufl.edu

Co-Chair: Dorothee Honhon, University of Texas at Dallas, Richardson, TX, United States, dorothee.honhon@utdallas.edu

1 - Social Labeling: Leaderboard Or Threshold Policy?

Xiajun Amy Pan, University of Florida, amy.pan@warrington.ufl.edu, Quan Zheng, Asoo Vakharia

Labeling, as a way to certify corporate social performance, is widely adopted in practice. However, little attention has been paid to the endogenous choice of a labeling policy. Should the label be awarded to manufacturers based on absolute performance (threshold policy) or relative performance (leaderboard policy)? We address this question through a mechanism design perspective. Our findings are that an impact-motivated third-party organization should confer the label on the best manufacturer provided it meets a threshold. On the other hand, a profit-maximizing retailer should select a certain number of manufacturers who outperform the others in the set without setting a threshold.

2 - The Impact Of Supply Chain Contracts On Inventory Shrinkage: Inference From Packaged Food Products

Min Choi, Arizona State University, mchoi9@asu.edu
Elliot Rabinovich, Timothy Richards

This paper examines the effect of supply chain contracts on inventory shrinkage using a data set from a packaged bakery manufacturer in the U.S. We find that the amount of inventory shrinkage tends to be higher under scan-based (SBT) contracts compared to vendor-managed inventory (VMI) contracts when measured in terms of both explicit and non-explicit shrink. We attribute this effect to retailers' moral hazard under SBT contracts. Our findings highlight a potential loss in efficiency in food supply chains reflected in higher inventory shrinkage under SBT contracts. Our study calls for a careful reexamination of emerging contractual forms in light of their potential impact on inventory waste.

3 - Online Grocery Retail: Revenue Models And Environmental Impact

Elena Belavina, The University of Chicago, ?, chicago, IN, 6, United States, elena.belavina@chicagobooth.edu

We compare the financial and environmental performance of two revenue models for the online retailing of groceries: the per-order and the subscription model. We find that subscription incentivizes smaller and more frequent orders, which reduces food waste and results in higher retailer revenues. These advantages are countered by greater delivery-related travel and expenses. Subscription leads to lower food waste-related emissions but to higher delivery-related emissions. Geographic and demographic data indicate that the subscription model is almost always environmentally preferable because lower food waste emissions dominate higher delivery emissions.

4 - Incorporating Consumer Attitudes To Minimise Waste And Out-of-stock Situations In Food Retail

Emel Aktas, Senior Lecturer, Cranfield University, Cranfield, United Kingdom, emel.aktas@cranfield.ac.uk
Soroosh Saghiri, Zeynep Topaloglu, Tamara van 't Wout, Akunna Oledinma, Zahir Irani, Amir Sharif, A. K. Samsul Huda

Inventory management of perishable food products is not straightforward since the demand volatility for these products is usually high. Consumer behavior is influenced by many factors, particularly the product availability and the expiry date of the product. Product inventory is to meet the customer demand and due to short shelf life it cannot act as a buffer against demand fluctuations. We study the optimal inventory policies to minimize food waste and stock-out situations based on the expiry dates and consumer preferences. Implications for the environment follow from reduced food waste.

Empirical Research in Supply Networks

Sponsored: Manufacturing & Service Oper Mgmt, iFORM
Sponsored Session

Chair: Vishal Gaur, Cornell University, 321 Sage Hall, Ithaca, NY, 14850, United States, vg77@cornell.edu

Co-Chair: Yasin Alan, Vanderbilt University - Owen Graduate School of Management, 401 21st Avenue South, Nashville, TN, 37203, United States, yasin.alan@owen.vanderbilt.edu

1 - Evolution Of Supply Networks

Nikolay Osadchiy, Emory University, nikolay.osadchiy@emory.edu, Vishal Gaur, Maximiliano Udenio

Using a large panel of firm-level buyer-supplier relationships, we study evolution of supply networks over time.

2 - Inaccurate Durations And Supply Chain Disruptions

William Schmidt, Cornell University, wschmidt@cornell.edu, Mili Mehrotra

We use supply chain and production data from a division of a Fortune 500 multinational manufacturer to examine the operational performance impact of inaccurate supply chain disruption duration estimates. We find that such inaccuracies can materially increase the cost of the disruption. This effect (1) persists after controlling for the actual length of a disruption and (2) can occur regardless of whether the disruption duration is initially over-estimated or under-estimated. We identify several factors that contribute to the impact of inaccurate estimates.

3 - Using Delay Forecasting To Correct Airline Turn Time Misallocation

Yannis Stamatopoulos, McCombs School of Business, Austin, TX, United States, yannis.stamos@mccombs.utexas.edu, Jun Li, Carlos Carvalho

Achieving good on time performance (OTP) is a challenging task for airlines. At the center of this challenge is the tradeoff between utilization and resilience. For example, longer turn times increase network resilience by reducing propagated flight delay, but at the same time keep airplanes away from flying and generating revenues. In this work, using proprietary data from a large US airline, we examine how an airline can manage turn times smartly from a network perspective. We find evidence for a potential significant improvement in OTP without hurting revenues.

4 - Shock Propagation In Supply Chain Networks

Jing Wu, University of Chicago, jwu7@chicagobooth.edu

Firms do not exist in isolation but are linked to each other through supply chain relationships. How do firm-level information transmits in the supply chain networks empirically? In this talk, we show both average shock propagation as reflected in stock returns, and extreme shock propagation as reflected in credit default swaps. The results are supported by supply chain theory and also have practical value in investment.

Scheduling II

Contributed Session

Chair: Mauricio G. C. Resende, Amazon.com, Inc., 2483 Birch Ave N, #512, Seattle, WA, 98109, United States, resendem@amazon.com

1 - Online Lazy Bureaucrat Scheduling With A Machine Deadline

Ling Gai, Shanghai University, Shanghai, 201444, China, lgai@shu.edu.cn

The lazy bureaucrat scheduling problem was first introduced by Arkin et al. in 1999. Since then, a number of variants have been addressed. However, very little is known on the online version. In this note we focus on the scenario of online scheduling, in which the jobs arrive over time. The bureaucrat (machine) has a working time interval. Namely, he has a deadline by which all scheduled jobs must be completed. A decision is only based on released jobs without any information on the future. We consider two objective functions of [min-makespan] and [min-time-spent]. Both admit best possible online algorithms with competitive ratio of 1.618.

2 - A Model For Scheduling Practical Lessons And Selecting Teaching Assistants At Universities

Cristian D Palma, Assistant Professor, Universidad del Desarrollo, Avda. Sanhueza 1750, Pedro de Valdivia, Concepcion, 4040418, Chile, cristianpalma@ingenieros.udd.cl, Pablo Gonzalez, Pamela Riffo

Most of the courses at universities includes practical sessions taught by teaching assistants (TA), which are also students. These sessions are usually scheduled as part of the courses, so the day and time when they are taught are known when students register their courses. Since TAs have to attend their own courses, they apply for teaching only in courses that match their own schedules rather than courses they are good at. We propose a framework in which practical sessions are scheduled after course registration, and show a model that schedules practical sessions and simultaneously selects the TAs for each course. We discuss the advantages of using this approach and present results of its application.

3 - Scheduling Virtual Network Embeddings

Frank Fischer, University of Kassel, Heinrich-Plett-Str. 40, Kassel, 34132, Germany, frank.fischer@mathematik.uni-kassel.de, Andreas Bley

The virtual network embedding problem aims to embed several virtual network (VN) requests, each consisting of several node and connection services that require certain CPU, memory and bandwidth resources, into a shared physical substrate network in such a way that the resources available in the substrate network are not exceeded.

We consider the dynamic version of this problem, where VN requests have time windows and durations specifying when and how long they should be embedded. We discuss several mixed integer and constraint programming approaches for this combined embedding and scheduling problem. Our computational results show that a combination of both techniques performs best.

4 - An Improved Genetic Algorithm For Job-shop Scheduling

Mauricio G. C. Resende, Principal Research Scientist, Amazon.com, Inc., 333 Boren Ave N, Seattle, WA, 98109, United States, resendem@amazon.com
José F. Gonçalves

We present a local search, based on a new neighborhood for the job-shop scheduling problem, and its application within a biased random-key genetic algorithm. Schedules are constructed by decoding the chromosome supplied by the genetic algorithm with a procedure that generates active schedules. After an initial schedule is obtained, a local search heuristic, based on an extension of the 1956 graphical method of Akers, is applied to improve the solution. The new heuristic is tested on a set of 205 standard instances taken from the job-shop scheduling literature and compared with results obtained by other approaches. The new algorithm improved the best-known solution values for 57 instances.

Simulation and Optimization II

Contributed Session

Chair: Ryan Lawhead, Research Assistant to Dr. Gosavi, Missouri University of Science and Technology, 223 Engineering Management Building, Rolla, MO, 65409, United States, rjlm97@mst.edu

1 - A Study on The Operations Analysis Using Big Data Developed by Simulations

Hongseon Park, University of Central Florida, Orlando, FL, United States, gauss1211@naver.com, Won Il Jung, Yong Bok Lee, Gakgyu Kim, Gene Lee, Rabelo Luis

The operations analysis is analyzed under simulation circumstances. A lot of assumptions and limited environments are included and, thus, the results have a bias. To overcome this problem, we proposed a new methodology for the operations analysis using Big Data developed by Virtual and Constructive (VC) simulations. The VC simulations can produce a large volume and variety of data since many variables are used for analyzing the operations close to reality by using 6 Degrees of Freedom models. More than terabytes of data including structured and unstructured types are applied to the current techniques of Big Data. Then we will build the probability map and index to help the commanders make decisions.

2 - Cloud Based Collaborative Information Sharing In Supply Chains

Cigdem Kochan, Assistant Professor, Ohio Northern University, Dicke College of Business Administration, 525 S Main St, Ada, OH, 45810, United States, cigdem.kochan@gmail.com, David R. Nowicki

This research develops system dynamics models to simulate the effect of cloud based collaborative information sharing in a supply chain. The results suggest that the use of the cloud based information sharing in supply chain reduces inventory levels, reduces actual lead time through demand and inventory visibility, and reduces delivery delays while increasing overall performance of the supply chain.

3 - A Fully Exploratory Reinforcement Learning Algorithm For Solving Semi-Markov Decision Processes

Angelo Encapera, Research Assistant, Missouri University of Science & Technology, Rolla, MO, 65409, United States, amet3b@mst.edu, Abhijit Gosavi

We study the development of a fully exploratory Reinforcement Learning (RL) algorithm for solving Semi-Markov Decision Processes (SMDPs). Existing RL algorithms, such as R-SMART, for solving SMDPs require gradual decay of exploration. The latter adds a tuning parameter to the algorithm, and indeed its success depends on how the exploration-decay parameter is tuned. Our algorithm uses a "reflective" update that accompanies the main update, based on relative Q-Learning, to estimate the average reward without decaying the exploration. Our algorithm delivers encouraging empirical behavior.

4 - A Bounded Actor Critic Algorithm For Reinforcement Learning

Ryan Lawhead, Research Assistant to Dr. Gosavi, Missouri University of Science and Technology, 223 Engineering Management Building, Rolla, MO, 65409, United States, rjlm97@mst.edu, Abhijit Gosavi, Susan Murray

Actor-critic algorithms are amongst the oldest reinforcement learning algorithms that can be used to solve Markov decision processes (MDPs) via simulation. Unfortunately, the values of the "actor" in the classical version of this algorithm get unbounded in practice. In practice, the actor's values are artificially constrained to obtain solutions. Boltzmann action selection is used for this algorithm in which a temperature is used, but the convergence of the algorithm is guaranteed only when the temperature equals 1. We propose a new actor-critic algorithm in which the actor's values are bounded even when the temperature is set to 1. Our algorithm delivers encouraging numerical behavior.

Data-Driven Decisions in Healthcare

Sponsored: Manufacturing & Service Oper Mgmt, Healthcare Operations

Sponsored Session

Chair: Vishal Ahuja, Southern Methodist University, Dallas, TX, United States, vahuja@smu.edu

1 - Optimizing Cancer Prevention Strategies For BRCA1/2 Mutation Carriers

Elisa Frances Long, Assistant Professor, UCLA Anderson School of Management, Los Angeles, CA, United States, elisa.long@anderson.ucla.edu, Eike Nohdurft, Stefan Spinler

BRCA1/2 mutation carriers face significantly elevated lifetime risks for breast and ovarian cancer. Prophylactic surgery (bilateral mastectomy, oophorectomy, or both) can reduce the risk of cancer but may impact health utility. We developed a Markov decision process model to determine the optimal age to undergo surgery to maximize quality-adjusted life years or survival. Key state variables include age, mutation type, breast cancer stage and sub-type, ovarian cancer stage, and preventive surgery status. We solve the model with linear programming and compute the optimal policy for different parameter settings reflecting varying mutation carrier's preferences.

2 - Predictive Models For Making Patient Screening Decisions

Michael Hahsler, Southern Methodist University, Dallas, TX, United States, mhahsler@lyle.smu.edu, Vishal Ahuja, Michael Bowen

A critical dilemma that clinicians face is when and how often to screen patients who may suffer from a disease. The stakes are heightened in the case of chronic diseases that impose a substantial cost burden. We investigate the use of predictive modeling to develop optimal screening conditions and assist with clinical decision-making. We use electronic health data from a major U.S. Hospital and apply our models in the context of screening patients for type-2 diabetes, one of the most prevalent diseases in the U.S. and worldwide.

3 - Belief Perseverance And Experience

Bradley R Staats, University of North Carolina at Chapel Hill, bstaats@unc.edu, Diwas S KC, Francesca Gino

Many models in operations management involve dynamic decision making that assumes optimal updating in response to information revelation. However, behavioral theory suggests that rather than updating their beliefs, individuals may persevere in their prior beliefs. We examine how individuals' prior experiences and the experiences of those around them alter their belief perseverance in operational decisions after the revelation of negative news using a field experiment and two lab experiments.

4 - Being On The Productivity Frontier: Identifying “Triple Aim Performance” Hospitals

Sriram Venkataraman, University of South Carolina, sriram.venkataraman@moore.sc.edu
Aleda Roth, Anita L Tucker, Jon A Chilingerian

Hospital decision makers may face tradeoffs that make it difficult to achieve relatively high performance simultaneously on cost, clinical quality and patient experience. We empirically examine the association between having high performance on any of the three criteria on the probability of being a U.S. News & World Report honor roll hospital. Surprisingly, we find a significant negative relationship exits between being an honor roll hospital and achieving high performance outcomes on any of the three TAP criteria. Furthermore, we find that the percent of physicians employed by the hospital has a positive and significant effect on being a TAP hospital.

Behavioral Models in Service Operations

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Guillaume Roels, UCLA, Anderson School of Management, Los Angeles, CA, 90095, United States, groels@anderson.ucla.edu

1 - Pricing With Consumer Optimism And Quality Perception: From Experiment To Theory

Rim Hariss, Massachusetts Institute of Technology, 254Windsor Street, Apt 2L, Cambridge, MA, 02139, United States, rhariss@mit.edu, Georgia Perakis, Wichinpong Sinchaisri, Yanchong Zheng

We study how consumers’ optimism about future markdowns and their quality perceptions influence a firm’s optimal markdown pricing strategy. We experimentally elicit the relationship between consumers’ perceived quality of a product and the product’s price information (e.g., initial price, discount, final selling price). We estimate a functional relationship from the data and incorporate this relationship into consumers’ purchase behavior. We then characterize the firm’s optimal policy given that consumers form price-based quality perceptions and may hold inaccurate expectation of the level of future markdown.

2 - Impact Of Server Behavior On The Performance Of Queueing Systems

Masha Shunko, University of Washington, mshunko@gmail.com

Multi-server single-queue (SQ) systems may outperform multi-server parallel-queue (PQ) systems due to the pooling effect. We model and analyze the impact of human server behaviors (namely, slowdown due to free riding and workload-dependent service rate) on the performance of SQ and PQ systems and derive how large the behavioral impacts should be to outweigh the benefits of pooling.

3 - Pooling Queues With Work Averse Servers

Guillaume Roels, UCLA, groels@anderson.ucla.edu, Mor Armony, Hummy Song

Contrary to the classical theory of operations management, recent case studies in retail, call centers, and healthcare indicate that pooling queues may not necessarily result in less expected work in process. In this paper, we propose that this phenomenon may arise when servers are work averse and have some discretion over their choice of service capacity. We distinguish two types of work aversion, namely workload aversion and busyness aversion, and show that dedicated configurations yield less expected work in process than pooled configurations when servers exhibit high degrees of workload aversion or low degrees of busyness aversion.

Incentives and Risk in Supply Chains

Sponsored: Manufacturing & Service Oper Mgmt, Supply Chain

Sponsored Session

Chair: Karan Girotra, INSEAD, Fontainebleau, France, karan.girotra@insead.edu

Co-Chair: Simone Marinesi, Wharton, Philadelphia, PA, United States, marinesi@wharton.upenn.edu

1 - Fleet Management For Healthcare Delivery In Africa: Vehicle Ownership And Contracting Models

Sang-Hyun Kim, Associate Professor, Yale University, New Haven, CT, United States, sang.kim@yale.edu, Li Chen, Hau Leung Lee

In this paper we study an innovative healthcare product delivery system that Riders for Health, a nonprofit organization based in UK, has implemented in a number of African nations. Health products are delivered to rural areas via motorcycles in difficult transportation conditions, and therefore it is critical to run an effective vehicle maintenance program. Riders for Health experimented with different contractual agreements with government agencies. We build a model based on reliability theory and contract theory that captures the essence of the problem that Riders faced, and discuss managerial insights that the model predicts.

2 - Learning (or Not) From Precursors To Disasters

Heikki Peura, Imperial College, London, United Kingdom, hpeura@london.edu, Nitin Bakshi

Disasters are invariably preceded by more frequent precursor events. These events embed valuable information about the likelihood of the root cause of a disaster, and thereby facilitate risk assessment. But to learn from precursors, a managing firm typically relies on the reports of a contractor, who is often also responsible for mitigating the occurrence of these incidents. We show how firms may fail to learn from precursor events due to the resulting intertwined problems of moral hazard (on risk mitigation) and hidden information (on reporting precursors).

3 - Supply Disruptions And Optimal Network Structures

Kostas Bimpikis, Stanford, kostasb@stanford.edu, Ozan Candogan, Shayan Ehsani

We study multi-tier supply chain networks in the presence of disruption risk. Firms compete in one of K production stages and prices of intermediate goods are set so that markets clear. We characterize equilibrium prices, profits, and sourcing decisions and explore how they are affected by the network structure. Also, we identify the network structures that maximize aggregate profits, welfare, and consumer surplus. Interestingly, these networks can be ranked in terms of how “balanced” the supply chain is. Finally, we consider endogenous chain formation and argue that it leads to inefficiencies both in terms of the number of firms that enter and in terms of the structure of the resulting networks.

Sponsored Session

Chair: Robert Bray, Kellogg School of Management, 830 Hinman Ave. Apt. 2S, Evanston, IL, 60202, United States, robertlbray@gmail.com

1 - Buyer Intermediation In Supplier Finance

Tunay Tunca, Professor, Unversity of Maryland, College Park, MD, 20910, United States, ttunca@rhsmith.umd.edu, Weiming Zhu

We analyze the role and the efficiency of buyer intermediation in supplier financing (BIF). We theoretically demonstrate that BIF can significantly improve the supply chain surplus over traditional financing. Using data from a large Chinese online retailer, we estimate model parameters, empirically verify the theory, and predict efficiency gains.

2 - Shock Spillover And Financial Response In Supply Chain Networks: Evidence From Firm-Level Data

Andrew Wu, Assistant Professor of Tech, Operations, Finance, Ross School of Business, University of Michigan, Ann Arbor, MI, United States, andydiwu@umich.edu, Jun Li

Using machine learning methods on firm-level textual disclosures, this research studies the propagation of firm-specific production shocks through supply chain relationships, and the stock market reactions to such propagated shocks.

3 - Unbundling Of Ancillary Service: How Does Price Discrimination Of Main Product Matter?

Yao Cui, Cornell University, Ithaca, NY, United States, yao.cui@cornell.edu, Izak Duenyas, Ozge Sahin

We consider a setting where the firm sells a main service and an ancillary service. We study how the firm's ability to charge discriminatory main service prices affects the decision of whether to separately charge for the ancillary service, both for the firm and for the industry.

4 - Centralized Vs. Decentralized Platform Markets

Daniela Saban, Stanford GSB, dhs2131@columbia.edu, Yash Kanoria

We consider a two-sided matching market with search frictions, and study the impact of the matching technology and platform design on the efficacy of the marketplace in serving its users. We find that a few different designs may be optimal in different settings, with the best choice of design depending crucially on the agents' selectivity — likelihood that a potential match on the opposite side of the market will be acceptable— and their cost of search —cost of discovering the value of a potential match.

Innovation: Choices and Constraints

Invited: New Product Development

Invited Session

Chair: Pascale Crama, Singapore Management University, Singapore, Singapore, pcrama@smu.edu.sg

1 - The Role Of Form In Product Evolution: An Analysis Of Styles

Tian Chan, Emory University, Atlanta, GA, 3, United States, tianheong.chan@insead.edu, Jurgen Mihm, Manuel Sosa

Styles are groupings of product designs of similar form. We leverage on a recently introduced database of styles among the more than 350,000 US design patents granted from 1977 through 2010 to study how styles evolve over time. We study and theorize how the interactions between design, technology, and organizations lead to the emergence, growth, and decline of styles. We discuss the implications of our results in furthering the understanding of how products evolve.

2 - Implementing Corporate Entrepreneurship With Contests

Lakshminarayana Nittala, University of California San Diego, La Jolla, CA, 92037, United States, lnittala@ucsd.edu, Sanjiv Erat, Viswanathan Krishnan

We analyze the use of Innovation contests by firms as processes to implement corporate entrepreneurship. The cost benefit analysis of such internal contests brings forth interesting insights on the relation between the institutional features and profitability of such contests.

3 - Contracts With Reciprocal Buyout Options

Pascale Crama, Singapore Management University, pcrama@smu.edu.sg, Niyazi Taneri

Joint research and development (R&D) allows firms to combine complementary capabilities, but is difficult to organize in the face of uncertainties surrounding the future product and skills needed to bring it to market. We analyze how contracts with reciprocal buyout options can help to organize joint R&D to mutual advantage when the parties to the contract can invest in capability-building.

Mean Field Models and Economic Applications

Sponsored: Applied Probability

Sponsored Session

Chair: Ramesh Johari, Stanford University, Stanford, CA, United States, ramesh.johari@stanford.edu

1 - Mean Field Models For Economic Applications

Ramesh Johari, Stanford University, ramesh.johari@stanford.edu

This session will survey the use of mean field methods for analysis of strategic interactions in dynamic markets. Dynamic markets can be viewed as a significant special class of dynamic stochastic games; these are generally difficult to analyze, and these difficulties are only exacerbated when the number of players is large. We will discuss the use of large system asymptotics to simplify equilibrium characterization and market design. A significant emphasis will be on discussion of open applied directions for such methods. It will not be assumed that attendees are experts in dynamic games or economic modeling; the goal is to introduce applied probabilists to an exciting area of application.

Applications of Data Envelopment Analysis

Invited: Data Envelopment Analysis

Invited Session

Chair: Daiki Wakayama, Komazawa University, 1-23-1-2409 komazawa, Setagaya-ku, Tokyo, 154-8525, Japan, dwakayam@komazawa-u.ac.jp

1 - Transmission Congestion And Eco-technology Innovation In U.S. Electric Power Industry Measured by DEA Environmental Assessment

Daiki Wakayama, Komazawa University, Tokyo, 3510021, Japan, dwakayam@komazawa-u.ac.jp, Mika Goto, Toshiyuki Sueyoshi

This study discusses a new use of DEA environmental assessment to measure a possible occurrence of congestion in U.S. coal-fired power plants. The congestion is classified into two categories: Undesirable Congestion (UC: indicating a transmission limit) and Desirable Congestion (DC: indicating eco-technology innovation). The identification of UC is important to avoid a cost increase and a shortage of electricity, while investigating of DC can be effectively used to reduce the amount of air pollution. This study finds that UC may occur on most of power plants. In contract, DC may occur on a limited number of power plants.

2 - Study Of Capital Requirement And Bank Operating Efficiency

Yang Li, National University of Kaohsiung Kaohsiung, yangli@nuk.edu.tw

Following the 2008 financial tsunami, the Bank of International Settlements proposed Basel III in 2010, in which banks need to raise their capital adequacy ratio in order to make them sound and safe. This study employs the two-stage bootstrapped truncated regression model, proposed by Simar and Wilson (2007), and takes into account undesirable outputs to investigate how the increases in core, tier I, and total capital adequacy ratios influence the efficiency of Chinese commercial banks. The data set is obtained from Bankscope for the period 2012-2014. Empirical results are consistent with the schedule and intention set by Basel III.

3 - Statistical Measure Of Goodness On Quantitative Models Of Efficiency And Effectiveness

Abbas Attarwala, University of Waterloo, Waterloo, ON, Canada, aattarwa@uwaterloo.ca, Stanko Dimitrov, Amer Obeidi

We propose a statistical measure of goodness on quantitative models of efficiency and effectiveness. Our measure is used in a financial setting based on the Efficient Market Hypothesis. Using information criterion we find the best fit model in a family of functions. The goodness of fit of a model is traded against the number of parameters required to achieve this approximation. We apply the developed statistical measure on four models using two case studies of U.S and Indian bank data.

4 - The Group And Individual Evaluation Using Fuzzy Dea

Hiroshi Morita, Osaka University, Suita, Japan, morita@ist.osaka-u.ac.jp, Rui Dai, Minghao Chen

We use the fuzzy DEA to evaluate the performance based on the evaluators' scores, which come from the evaluation questionnaire and considered as fuzzy DMUs. We suppose the situation of teachers' evaluation by students' score. The fuzzy DEA model is used to analyze the group evaluation of the performance effectiveness. The DEA model is firstly used to analyze the scores for every DMU, where the evaluators' ambiguity or bias may bring the fuzziness of DMU. It also compares the group evaluation and individual evaluation on efficiencies. This approach is more objective and fair by avoiding the effect of the directly counting scores which is easily affected by negative or positive attitude of evaluators.

Spectral Methods in Finance: Option Pricing and Econometrics

Sponsored: Financial Services

Sponsored Session

Chair: Lingfei Li, Assistant Professor, The Chinese University of Hong Kong, 608 William M.W.Mong Engineerng Building, Shatin, N.T., none, Hong Kong, lfli@se.cuhk.edu.hk

1 - Error Analysis Of Finite Difference And Markov Chain Approximations For Option Pricing With Non-smooth Payoffs

Gongqiu Zhang, PhD Candidate, The Chinese University of Hong Kong, ERB 802, Hong Kong, gqzhang@se.cuhk.edu.hk, Lingfei Li

We provide error analysis for finite difference and Markov Chain approximations in option pricing when the payoff function is non-smooth. We assume the asset price is a one-dimensional diffusion or a jump process constructed from a diffusion by subordination. We show that the spatial discretization error is second order for call and put-type payoffs and first order for digital-type payoffs. Furthermore, averaging discontinuous payoffs can restore second order convergence.

2 - Long Forward Probabilities, Recovery And The Term Structure Of Bond Risk Premiums

Likuan Qin, Northwestern University, Evanston, IL, 60016, United States, likuan.qin@gmail.com, Vadim Linetsky

We show that the martingale component in the long-term factorization of the stochastic discount factor due to Alvarez and Jermann (2005) and Hansen and Scheinkman (2009) is highly volatile, produces a downward-sloping term structure of bond Sharpe ratios, and implies that the long bond is far from growth optimality. In contrast, the long forward probabilities forecast an upward sloping term structure of bond Sharpe ratios and implies that the long bond is growth optimal. Thus, transition independence and degeneracy of the martingale component are implausible assumptions in the bond market.

3 - Parametric Inference Of Discretely Observed Subordinate Diffusions

Weiwei Guo, The Chinese University of Hong Kong, wwguo@se.cuhk.edu.hk

We develop a two-step procedure to estimate a class of jump processes known as subordinate diffusions from discrete-time data. The first step identifies the diffusion parameters using estimating functions only involve diffusion parameters and the second step identifies the subordinator parameters using martingale estimating functions based on eigenfunctions. Under regularity conditions, our estimators are consistent and asymptotically normal. Numerical examples show that our method is statistically and computationally efficient. Analysis of VIX index indicates that a pure jump subordinate diffusion model significantly outperforms diffusion models in modeling the VIX index.

Sponsored Session

Chair: Changle Lin, Princeton University, Jersey City, NJ, United States, changlel@princeton.edu

Co-Chair: Woo Chang Kim, Associate Professor, KAIST, KAIST 291, Daehak-ro, Yuseong-gu, Daejeon, 34141, Korea, Republic of, wkim@kaist.ac.kr

1 - Goal-based Investment Via Multi-stage Stochastic Programming For Robo Advisor Service

Woo Chang Kim, KAIST, wkim@kaist.ac.kr

Robo-advisors aim to attract non high-net-worth individual investors by significantly lowering the entry barrier to professional wealth management industry. Unfortunately, existing schemes of robo-advisors have not been sophisticated enough to provide fully personalized investment advices. However, it surely is challenging to ask clients, who might lack financial literacy, to provide their detailed financial situation through online platform. Therefore, we propose a goal-based investment model that only requires the input of wealth, income, and consumption goals with priorities via multi-stage stochastic programming approach.

2 - How to Train Your Lawyer

Ephrat Bitton, Future Advisor, ephratb@gmail.com

For better or worse, Robo Advisors operate in a highly regulated industry. Folks may roll their eyes at the mention of compliance, but it is a crucial process for ensuring that we protect the end client. As a mathematician at FutureAdvisor, one of my greater challenges is adequately describing to our compliance officer how we manage portfolios using optimization. MILP can be immensely powerful for solving complex decision problems, but it is notoriously difficult to pinpoint the reasons for different outcomes. This talk follows my story on automating portfolio management, ensuring the quality of our results, and finally, explaining how it all works to someone who reads legal settlements for fun.

3 - Pricing And Hedging Guaranteed Minimum Withdrawal Benefit With High Water Mark Benefit Base

Peiqi Wang, Princeton University, Princeton, NJ, United States, peiqiw@princeton.edu, Patrick Cheridito

We consider pricing and hedging of Guaranteed Minimum Withdrawal Benefit (GMWB) rider on a variable annuity (VA) contract. We price the VA+GMWB contract by considering the optimal withdrawal strategy of the policyholder. We show that policyholder's payoff resulting from the optimal withdrawal strategy corresponds to the super-replication cost of the contract and we provide a hedging strategy. Our numerical results show that it is sometimes optimal for the policyholder to aggressively withdraw and ruin the account. Further analysis on the numerical results suggests how the insurer should determine the fee structure and minimal deposit requirement.

4 - About Holistic Robo-advice Engine

Dan Dibartolomeo, Northfield Information, dan@northinfo.com

Robo-advisors aim to attract non high-net-worth individual investors by significantly lowering the entry barrier to professional wealth management industry. Unfortunately, existing schemes of robo-advisors have not been sophisticated enough to provide fully personalized investment advices. However, it surely is challenging to ask clients, who might lack financial literacy, to provide their detailed financial situation through online platform. Therefore, we propose a goal-based investment model that only requires the input of wealth, income, and consumption goals with priorities via multi-stage stochastic programming approach.

1 - Value-focused Thinking For Engineering Resilient Systems

Greg Parnell, University of Arkansas, gparnell@uark.edu

DoD's requirements analysis identifies Key Performance Parameters to meet the system goals. The acquisition documents identify the thresholds and objectives for each parameter that are supported by mission analysis that considers mission needs, technical maturity, affordability, and schedule. Multiple objective decision analysis and Value-Focused Thinking can provide a mathematical framework for evaluating the resilience of systems in mission scenarios under uncertainty and the adaptability of the platform to future missions.

2 - The Systems Engineering Approach To Setting Design Targets

Robert Bordley, Booz Allen Hamilton, bordley_robert@bah.com

Systems engineering is a value-focused process aimed at defining feasible component-level design targets for a system which, when designed and assembled, will best meet the needs of system stakeholders. To reach this goal, systems engineering first defines targets at the system level, then at the subsystem level, the assembly level etc down to the component level. At each level, informed trade-offs are made about what is most appealing to stakeholders given beliefs about what is technically possible. Making these tradeoffs involves specifying alternative solutions, investigating each solution and constructing an optimal hybrid of the solutions.

3 - A Bayesian Method For Selecting Elite Varieties Of Soybean

Jack Kloeber, Kromite, LLC, 82 Nelson Drive, Churchville, PA, 18966, United States, jkloeber@kromite.com, Joseph Byrum, Tracy Doubler, Greg Doonan, Craig Davis, Peiran Zhao

In agriculture R&D, a new variety's genetic contribution to higher yield is difficult to separate from factors of soil, insects, weather, or agronomic practices. Varieties are grown at multiple locations, downselecting over 4 years. Syngenta developed a generalizable method which helps soy breeders find the genetic winner using Bayesian Updating. The increased accuracy leads to better decision-making and higher yield.

Decision Analysis, Game Theory, and Homeland Security

Sponsored: Decision Analysis

Sponsored Session"

Chair: Jun Zhuang, University at Buffalo, SUNY, Buffalo, NY, United States, jzhuang@buffalo.edu

Co-Chair: Jing Zhang, University at Buffalo, SUNY, University at Buffalo, SUNY, Buffalo, NY, 14228, United States, jzhang42@buffalo.edu

1 - Defensibility - A New Concept In Risk Analysis

Vicki Bier, University of Wisconsin-Madison, vicki.bier@wisc.edu
Alexander Gutfraind, Ziyang Lu

We define a system as defensible if modest investment of resources can significantly improve the outcome to the defender. After quantifying defensibility, we use empirical examples and stylized examples to show that some systems that appear highly vulnerable are actually highly defensible.

2 - Using The Concept Of Multidimensional System Resilience In Decision And Risk Analysis

Dante Gama Dessavre, Stevens Institute of Technology, dgamades@stevens.edu, Jose Emmanuel Ramirez-Marquez

Resilience is generally understood as the ability of an entity to recover from an external disruptive event. Systems such as cities, face the challenge of each of their subsystems being vulnerable to multiple threats. This work analyzes the compilation of subsystem and multiple measurements in order to have more accurate description of system resilience. The object of this work is to introduce the use of this multidimensional system resilience model in the disciplines of decision and risk analysis, showing how it allows creating more comprehensive and intuitive tools for decision makers.

3 - Behavioral Experiments On Deterrence

Richard John, USC, richardj@usc.edu

When evaluating potential countermeasures, emphasis is often placed on interdiction over deterrence because the impact of interdiction focused countermeasures are easier to identify and quantify compared to the impact of countermeasures designed to deter. Resource allocation decision often focus on measures of interdiction enhancement only, even though the involve countermeasures are expected to improve both interdiction and deterrence. I will focus on innovative methods to characterize and quantify the deterrent effects of countermeasures. I will also include methods and findings drawn from decision and risk analysis, game theory, and behavioral research on deterrence.

4 - A Robust Optimization Approach For Electric Power Grid Protection

Alberto Costa, NUS, Singapore, Singapore, isealc@nus.edu.sg
Alberto Costa, Future Resilient Systems (FRS) - ETH Zurich, Singapore, Singapore, isealc@nus.edu.sg

We study the problem of the optimal allocation of protection resources in an electric power grid with the aim of maximizing its robustness against attacks to the lines. This problem can be seen as a game between two players, i.e., the system operator and the attacker. Given a budget for protecting the lines and a performance threshold, i.e., the maximum value of load shed tolerated by the system operator, the attacker wins the game if the load shed after the attack is above the threshold. We propose an algorithm to find the allocation of the system operator's budget to the lines of the grid which maximizes the amount of budget needed by the attacker to win the game.

Model Uncertainty, Risk, & Compliance

Invited: Risk and Compliance

Invited Session

Chair: Ricky Rambharat, Lead Statistician, Office of the Comptroller of the Currency, 400 7th SW, Mail-stop 6E-2, Washington, DC, 20219, United States, ricky.rambharat@occ.treas.gov

1 - Missing Data Inference With Application To The Home Mortgage Disclosure Act

Andrew Porter, Office of the Comptroller of the Currency, Washington, DC, United States, andrew.porter@occ.treas.gov
Tong-yob Nam

The Home Mortgage Disclosure Act (HMDA) mandates financial institutions to report protected class information such as race and ethnicity for each mortgage applicant when available. However, a significant proportion of these data is missing which impairs regulatory ability to determine whether a financial institution provided fair access to its mortgage products. We use a multinomial logit with spatial data analysis coupled with a multiple imputation methodology to infer the missing HMDA data and mitigate the effect of model uncertainty. Our empirical analysis concerns varied institutions with different levels of missing protected class data including a large bank and a non-bank lender.

2 - Prudential Policies And Their Impact On Credit In The United States

Paul Calem, FRB of Philadelphia, paul.calem@phil.frb.org

We analyze impacts on bank lending of two supervisory policies. We find that banks reduced their share of jumbo mortgage originations following the stress test in 2011, but not in later years when they were better capitalized. We find little initial impact of the 2013 Leveraged Lending Guidance, but follow-up FAQs issued late in 2014 marked a significant drop in leveraged lending. Thus, measureable risk and capital appear to have a more immediate impact on lending. Model governance can still have compliance implications—exemplified by banks failing the stress tests on qualitative grounds. Our findings for the 2013 Guidance and FAQ suggest that clarity of regulatory communications also play a role.

3 - Forecast Combination Of Machine Learning Models With Application To Camels Early-warning Systems

Lewis Gaul, Office of the Comptroller of the Currency, lewis.gaul@occ.treas.gov

This paper uses forecast combination methods to predict future CAMELS bank ratings assigned by the Office of the Comptroller of the Currency. We use several individual algorithms and statistical models to forecast future CAMELS ratings with information on lagged financial statement ratios and macroeconomic variables. We then analyze whether combinations of multiple forecasts provide more accurate out-of-sample forecasts of future CAMELS ratings than any individual forecast model. Results indicate that the out-of-sample forecast performance of most individual models varies over time, and that combinations of forecasts generally perform better than any individual model.

Sharing Economy, Mechanism Design and Networks I

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Santiago Balseiro, Duke University, Durham, NC, United States, sbalseiro@gmail.com

Co-Chair: Ozan Candogan, University of Chicago, Durham, NC, United States, ozan.candogan@chicagobooth.edu

1 - Matching Markets With Search Frictions

Nicholas A. Arnosti, Stanford University, narnosti@stanford.edu

We consider a model in which sellers compete by posting prices and buyers visit sellers sequentially. We show that there is a unique equilibrium outcome, which is constrained efficient.
We then study the consequences of reducing search costs. This benefits buyers, but may either increase or decrease seller revenue. If there are sufficiently many buyers, sellers benefit from lower search costs. Otherwise, the effect on seller revenue depends on the shape of the distribution of buyer values. If it is heavy-tailed (has a decreasing hazard rate), then sellers benefit from lower search costs. If it is light-tailed (has an increasing hazard rate), then seller revenue falls as search becomes easier.

2 - Dynamic Mechanisms With Martingale Utilities

Santiago Balseiro, Duke University, srb43@duke.edu, Vahab Mirrokni, Renato Paes Leme

We study the dynamic mechanism design problem of a seller who repeatedly sells independent items to a buyer with private values under two practically relevant business constraints: (i) a periodic individual rationality constraint, which limits the mechanism to charge at most the buyer's value in each period and (ii) a martingale utility constraint, which imposes that from the perspective of the buyer, the next item's expected utility is equal to the present one's. Our main contribution is the design of a dynamic auction that asymptotically achieves full extraction of buyer surplus as agents become more patient.

3 - Ridesharing Networks

Ozan Candogan, University of Chicago, 7449 9th Street, Unit 472, Durham, NC, 27705-1084, United States, ozan.candogan@chicagobooth.edu, Daniela Saban, Konstantinos Bimpikis

We consider the problem faced by a revenue optimizing ride-sharing platform, which must decide on how to price the rides as well as how to compensate the drivers. These decisions will impact both the entry of customers and the actions of the drivers. We study the impact that the underlying network structure has on the pricing strategy.

4 - Tractable Equilibria For Sponsored Search With Budget Optimizing Bidders

Dragos Florin Ciocan, INSEAD, florin.ciocan@insead.edu, Krishnamurthy Iyer

We examine a model of sponsored search markets where bidders strategically choose their budgets and bids, while the ad network can throttle bidders to optimize its own revenues. We show the equilibria in this market take a simple form and that for these equilibria the network's optimal throttling policy is greedy.

New Topics in Revenue Management and Pricing

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: So Yeon Chun, McDonough School of Business, Georgetown University, Washington, DC, United States, sc1286@georgetown.edu

1 - Worker Poaching In A Supply Chain: Enemy From Within?

Gad Allon, Northwestern University, g-allon@kellogg.northwestern.edu, Achal Bassamboo, Evan Barlow

Poaching workers has become a universal practice. We explore worker poaching between firms linked in a supply chain. We show that the classical intuition from labor economics is insufficient in explaining poaching between supply chain partners. We also show how and under what conditions worker poaching can actually improve supply chain performance. Finally, we show how the equilibrium identity of the supply chain bottleneck depends on the interaction between hiring, poaching, and productivity.

2 - The Revenue Impact Of Dynamic Pricing Policies In Major League Baseball Ticket Sales

Joseph Xu, University of Pennsylvania, Philadelphia, PA, United States, jiaqixu@wharton.upenn.edu, Senthil Veeraraghavan, Peter Fader

We study RM implementation of multiproduct dynamic pricing by a Major League Baseball franchise for their single game tickets. We develop a comprehensive customer choice model to calibrate and design a dynamic pricing policy for the franchise. Our model also incorporates external factors that drive customer valuation of sports tickets, such as the effect of the home team's on-field performance and the effect of overall attendance level. Our counterfactuals show potential revenue improvement of up to 15% through the effective use of dynamic pricing. We also find that a properly calibrated fixed pricing policy can achieve similar levels of performance as the optimal dynamic pricing policy.

3 - Designing Rewards-based Crowdfunding Campaigns For Strategic Contributors

Soudipta Chakraborty, Duke University, Durham, NC, 27708, United States, sc390@duke.edu, Robert Swinney

We study a model of rewards crowdfunding with the all or nothing funding mechanism. The creator of a crowdfunding campaign sets a target funding level and the campaign is successful only if the funding it receives meets this target. A creator can have two possibly competing objectives: maximize the likelihood of success and maximize the expected total funding. The contributors incur a transaction cost while pledging to a campaign. As a result, they behave strategically and decide whether to pledge at the beginning or to wait till the target is met. We analyze how a creator, who encounters such strategic behavior, can achieve her objectives by optimally using the operational parameters of her campaign.

4 - Setting The Optimal Value Of Loyalty Points

So Yeon Chun, McDonough School of Business, Georgetown University, sc1286@georgetown.edu, Dan Andrei Iancu, Nikolaos Trichakis

A loyalty program introduces a new currency—the points—through which customers transact with a firm. We study the problem of optimally setting the monetary value of points, i.e., pricing in this new currency, in a multi-period setting. We first show that point pricing is different from cash pricing primarily due to the way points are accounted for, as liabilities on the firm's balance sheet, and then we characterize the optimal cash and point pricing policies.

Social Media Analytics for Businesses

Invited: Social Media Analytics

Invited Session

Chair: Panagiotis Adamopoulos, New York University, School of Business, New York, NY, 11111, United States, padamopo@stern.nyu.edu

1 - Monetizing Sharing Traffic Through Incentive Design: Evidence From A Randomized Field Experiment

Tianshu Sun, University of Southern California, 3330 Van Munching Hall, Los Angeles, CA, 20742, United States, tianshu.sun@gmail.com, Siva Viswanathan, Elena Zheleva

Using a large-scale randomized field experiment, we examine whether and how firms can engage customers involved in online social sharing, through the design of novel incentive mechanisms. We find evidence that incentive design has a significant impact on both sender's purchase and referrals, but in a different ways. Specifically, compared to the senders who receive non-shareable promotional code, senders who receives shareable code are less likely to make purchases themselves, but much more likely to make further referrals. We further leverage variation in incentive design to untangle three motives underlying the sender's sharing:self-regarding, other-regarding, group-regarding motive.

2 - Realizing The Activation Potential Of Online Communities

Marios Kokkodis, Boston College, kokkodis@bc.edu

In this work we present a data-driven stochastic framework that identifies which users and when are more likely to become heavy contributors in an online community.

3 - Word Of Mouth Vs. Word Of Health Inspectors: Evidence From Restaurant Reviews

Chenhui Guo, University of Arizona, 1130 E Helen St, McClelland Hall 430, Tucson, AZ, 85721, United States, chguo@email.arizona.edu, Paulo B Goes, Mingfeng Lin

Prior to purchase, consumers are naturally exposed to multiple sources of quality information. We study whether and how consumer word of mouth of restaurants—both volume and valence—is influenced by co-presence of information from health inspectors. We build a simple analytical model and conduct an empirical study using data from a leading consumer review site, showing that the availability of official information has a significant dampening effect on the volume of reviews generated by consumers. Moreover, the effect on valence is significantly positive, with a very small magnitude.

4 - The Role Of Dimensionality Reduction In Binary Classification For Social Network Data

Jessica Clark, New York University, jclark@stern.nyu.edu, Foster Provost

Dimensionality reduction is regarded as a key part of the predictive analytics process. We take a design-science approach to analyzing the role of dimensionality reduction via matrix factorization for binary classification using large, sparse social network data. The experiments in this work (which span a variety of data sets, modeling techniques, and DR methods) find that DR at best provides little advantage in terms of classification performance, and at worst can significantly negatively impact performance. The results emphasize the need for caution when utilizing DR in predictive modeling, which should serve as a guideline for applied data science researchers and industry practitioners.

Case Competition II

Sponsored: Education (INFORMED)

Sponsored Session

Chair: Palaniappa Krishnan, University of Delaware, Newark, DE, United States, baba@udel.edu

1 - Dynamic In-Game advertising: Managing Complex High-Stakes Operations

Alan Scheller-Wolf, Carnegie Mellon University, Pittsburgh, PA, United States, awolf@andrew.cmu.edu, John Turner

Dynamic in-game advertising is an advanced form of advertising in which ads are displayed on electronic billboards, stadium walls, or in other visually appealing spots within the 3D worlds of video games. This case teaches students not only about the economics of online advertising and how to solve complex multi-objective ad planning problems using goal programming, but also covers broader modeling concepts, practical modeling considerations, and discusses relevant strategic issues from the fast-growing and fast-changing online advertising industry.

2 - Shipment Consolidation And Dispatching Problem At Ekol Logistics

Sinem Tokcaer, zmir University of Economics, Izmir, Turkey, sinem.tokcaer@ieu.edu.tr, Ozgur Ozpeynirci, Muhittin H. Demir, Irem Celik

The case considers international freight forwarding operations in Ekol Logistics of Turkey; a leading international logistics company. Less-than-truckload orders are routed either directly to destination, or through a cross dock. Currently, the consolidation and dispatching plan is done manually. The case has two phases: first, students analyze the cost structure to determine the total cost for a given plan and suggest a better one. The second phase involves the construction of the mathematical programming formulation to identify an optimal plan. Students are also required to identify alternative feasible routes to be fed into the formulation, in search for an improved optimal plan.

3 - Inventory Optimization For Rent The Runway

Vincent Slaugh, Cornell University, Ithaca, NY, United States, vslaugh@cornell.edu, Sridhar Tayur

The choice of how many rental dresses to procure in advance of each fashion season plays a critical role in the success of Rent the Runway, an online high-fashion dress rental business. The case leads students through this inventory optimization decision for a single dress style using both queueing and Monte Carlo simulation models implemented in a spreadsheet. Students are encouraged to consider the strengths and weaknesses of each modeling approach and how to incorporate additional model features such as nonstationary demand and the random loss of rental units.

4 - The Safe Birth Clinic

Milind Dawande, The University of Texas at Dallas, Richardson, TX, United States, milind@utdallas.edu, Tim Huh, Ganesh Janakiraman, Mahesh Nagarajan, Yang Bo

The effective utilization of capacity is an important operational goal that managers strive to achieve. Most textbooks use the following simple “bottleneck formula” to calculate process capacity: the capacity of each resource is first calculated by examining that resource in isolation; process capacity is then taken as the smallest (bottleneck) among the capacities of the resources. The main goal of this case is to alert students that, for processes in which activities share resources, the use of the bottleneck formula brings the potential danger of reaching incorrect conclusions about process capacity and may eventually lead to erroneous decisions with significant financial impact.

Decision Making in Healthcare

Sponsored: Minority Issues

Sponsored Session

Chair: Shannon Harris, Ohio State University, 600 Fisher Hall, Columbus, OH, 43210, United States, harris.2572@osu.edu

1 - Simulation Optimization To Inform Decision Making In Birth

Karen T Hicklin, University of North Carolina, Chapel Hill, NC, United States, kthickli@ncsu.edu, Julie Ivy

Of the nearly 4 million births that occur each year in the U.S., almost 1 in 3 is a cesarean section (C-section). Due to the various increased risks associated with C-sections and the potential major complications in subsequent pregnancies, a re-evaluation of the C-section rate has been a topic of major concern. We present a discrete event simulation model of women undergoing a trial of labor with the goals to: (1) model the natural progression of labor for spontaneous and induced laboring patients and (2) optimally decide when an intervention is needed, such as augmentation or C-section, in order to reduce the number of C-sections due to a “failure-to-progress” diagnosis.

2 - Dynamic Control Of A Single Server System When Jobs Change Status

Gabriel Zayas-Caban, University of Michigan, gzayasca@umich.edu

Many systems must contend with allocating resources to jobs whose initial service requirements or costs change when they wait too long. We present a new queueing model for this scenario and use a Markov decision process formulation to analyze assignment policies that minimize holding costs. We provide sufficient conditions under which simple priority rules hold and for when switching curve structures hold. In general, we find that allowing service and/or cost requirements to change changes the structure of optimal controls for resource allocation in queueing systems.

3 - Online Overbooking Strategies In Outpatient Specialty Clinics With No-shows And Advance Cancellations

Shannon Harris, Ohio State University, harris.2572@osu.edu
Jerrold H May, Luis G Vargas

Patient behavior, such as no-shows and cancellations, can lead to issues that heighten outpatient clinic access issues. In this paper, we develop strategies to determine if and when to overbook patients, over a finite horizon, in an online scheduling environment. We incorporate clinic parameters, no-shows, and cancellations to inform the overbooking decisions. We find that the optimal overbooking strategies are a function of both no-shows and cancellations, and that a clinic can, under certain conditions, achieve a greater service reward by overbooking patients than it can by not overbooking. Our work is motivated, in part, by our observations of scheduling at a VHA specialty clinic.

4 - Modeling For The Equitable And Effective Distribution Of Food Donations Under Stochastic Capacities

Irem Sengul Orgut, Quality Analytics Project Manager, Lenovo, Raleigh, NC, United States, isengul@ncsu.edu, Julie Ivy, Reha Uzsoy

Food insecurity is an increasing threat to people’s health status and quality of life. In partnership with the Food Bank of Central and Eastern North Carolina, which distributes donated food to a 34-county service area, our objective is to achieve equitable and effective food distribution among the population at risk for hunger. Counties’ capacities are the main source of uncertainty in this system as they constrain the total food distribution due to the need to distribute food equitably. We develop stochastic models for optimal food distribution and prove structural results. We illustrate our results and perform an extensive numerical study using historical data from our collaborating food bank.

Emergency Response, Recovery, and Resilience

Sponsored: Public Sector OR

Sponsored Session

Chair: Laura Albert McLay, University of Wisconsin-Madison, 3218 Mechanical Engineering Building, 1513 University Avenue, Madison, WI, 53706, United States, laura@engr.wisc.edu

1 - Resilience-based Component Importance Measures For Interdependent Infrastructure Networks

Yasser Almoghathawi, University of Oklahoma, Norman, OK, United States, moghathawi@ou.edu
Kash Barker

Interdependent infrastructure networks are subjected to disruptions due to different disruptive events. Consequently, a failure in one network could lead to a failure in another network. We propose two resilience-based component importance measures to quantify the impact of the disrupted components on the resilience of the interdependent infrastructure networks and rank them according to their criticality to focus on preparedness efforts.

2 - An Integrated Network Design And Scheduling Problem For Network Recovery And Emergency Response

Suzan Afacan, Graduate Student, University of Wisconsin-Madison, Madison, WI, 53705, United States, iloglu@wisc.edu, Laura Albert McLay

Infrastructure recovery is important for delivering time-sensitive services and commodities after a disaster while also repairing network damage. To examine this issue, we present an extension of the p-median problem in the case of extreme events. In the model, we coordinate two types of service providers: (1) recovery crews who repair disrupted roads and (2) emergency responders who deliver services and commodities. The objective is to minimize the cumulative weighted distance between the emergency responders and the calls for service over the time horizon. We also present a new backup coverage model with the same extension. The models are illustrated with the computational examples.

3 - Dynamic Programming For Ambulance Fleet Management

Amir Rastpour, Postdoctoral Fellow, University of Western Ontario, Ivey Business School, 1255 Western Road,, London, ON, N6G0N1, Canada, arastpour@ivey.uwo.ca, Mehmet A. Begen, Armann Ingolfsson, Greg Zaric

We use dynamic programming to model ambulance systems. Our model can potentially assist ambulance dispatchers to proactively take actions to avoid high operational costs, lost calls, and the proportions of urgent calls that are not covered timely, or a weighted sum of these performance measures. Possible actions that we consider are: Calling in additional ambulances from neighboring cities, expediting the service, and repositioning available ambulances following a desired compliance table. We use a detailed simulation model to validate our results.

1 - A Forecast Driven Model For Prepositioning Supplies In Preparation For A Hurricane

Gina Galindo, University of Del Norte, ggalindo@uninorte.edu.co Rajan Batta

We present a forecast-driven dynamic model for prepositioning relief items in preparation for a foreseen hurricane. The decisions in our model are based on real-time updated information from periodic forecast advisories issued by the National Hurricane Center (NHC). Our approach, which combines Decision Theory and stochastic programming, determines the time to start prepositioning, and the units to be prepositioned at each selected supply point. It also accounts for the possible re-positioning of already prepositioned supplies. Our results show that our model outperforms the alternative wait-and-see approach.

2 - Modeling Proactive Surgery Cancellation With Weather Forecast Updates

Mahsa Ghanbarpour Mamaghani, Northeastern University, Boston, MA, 02148-8208, United States, ghanbarpourmamagh.m@husky.neu.edu, Ozlem Ergun

Severe weather such as hurricanes and snowstorms can dramatically disrupt the delivery of many essential services within a community, including healthcare services. This research introduces proactive surgeries cancellation planning due to snowstorms with considering weather forecast updates. Since the snowstorms can be predicted more accurate in the last steps of planning horizon the problem is formulated as an evaluation of the tradeoff between more accurate forecasts and cost of late cancellations for determining optimal surgeries cancellation.

Emerging Trends in Business Innovation

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Fangyun Tan, Southern Methodist University, 6212 Bishop Blvd, Dallas, TX, 75275, United States, ttan@cox.smu.edu

1 - Impact Of Tabletop Technology On Restaurant Performance

Fangyun Tan, Southern Methodist University, ttan@cox.smu.edu, Serguei Netessine

We analyze a large data set of transactions in a casual restaurant chain to understand the effect of implementing a tabletop technology on service performance (measured in sales and meal duration). We find the technology directly increases sales and significant reduces the meal duration. We provide insights on how to manage technology in restaurant operations.

2 - The Role Of Surge Pricing On A Service Platform With Self-scheduling Capacity

Kaitlin Daniels, Assistant Professor, Olin Business School, Washington University in St. Louis, St Louis, MO, United States, k.daniels@wustl.edu

Platforms like Uber use dynamic pricing policies to manage a workforce of “self-scheduling” providers who decide for themselves how often to work. We show that the optimal dynamic pricing policy substantially increases the platform’s profit relative to contracts with a fixed price or fixed wage (or both) and although surge pricing (which pays providers a fixed percentage of a dynamic price) is not optimal, it generally achieves near optimal profit. Furthermore, we find that providers and consumers are generally better off with surge pricing because providers are better utilized and consumers benefit both from lower prices during normal demand and expanded access to service during peak demand.

3 - Team Leadership And Performance: Combining The Roles Of Direction And Participation

Morvarid Rahmani, Georgia Institute of Technology, 800 West Peachtree Street, NW, Atlanta, GA, 30308-1149, United States, morvarid.rahmani@scheller.gatech.edu, Uday Karmarkar, Guillaume Roels

One of the challenges that project team leaders face is how to combine their roles as individual contributors and managers. In this paper, we propose a model of team leadership and study how a contributor leader should adjust her managing effort over time and with respect to the project characteristics (e.g., team members’ incentives and team size).

4 - Sole Inventor Vs Team Of Inventors: What’s Best?

Tian Chan, Emory University, Atlanta, GA, United States, tianheong.chan@insead.edu, Jurgen Mihm, Manuel Sosa

Should a team of inventors outperform individual inventors in creating groundbreaking innovations? The empirical evidence that examines into scientific papers and technology patents (representing millions of inventive work) suggests that the answer is an unqualified “yes”. However, in this work we use design patent data to show that “teams are better than individuals” is not true in the context of design innovation. While so, we find that collaboration yields future dividends—designers who has collaborated extensively in the past but currently operates alone outperforms either teams or sole designers. We discuss the implications of our results in the organization of innovative work.

1 - Impact Of Future Wind Power Scenarios On The Distributionally Robust Operation And Cost Of Reserves

Bita Analui, Post Doctoral Scholar, Ira A. Fulton Schools of Engineering, Arizona State University, Tempe, AZ, 85287-9309, United States, Bita.Analui@asu.edu, Anna Scaglione

The increasing share of renewable energy and its intermittency have led to new challenges in modeling and optimization of power system operations. In this work, we present the distributionally robust extension of multistage stochastic optimization of reserves operations under stochastic wind power generation. In this setting, the reference probability model is a scenario tree based on the direct quantization of wind power trajectories. Constructing the alternative scenario trees in the epsilon-neighborhood of the reference tree forms the ambiguity set P, wherein an iterative algorithm determines the minimax solution and identifies the worst case probability model.

2 - The Quest For Zero-carbon Supply Chain: An Onsite Generation Approach

Tongdan Jin, Texas State University, tj17@txstate.edu

Is it feasible to deploy a zero emission production-logistics system using intermittent renewable energy? If so, how to design such eco-friendly supply chain system in a distributed generation environment? In this talk we present a wind- and solar-based onsite generation system to achieve carbon-neutral performance for a multi-facility production-distribution network with affordable cost.

3 - Robust Transmission Planning Under Uncertain Generation Investment And Retirement

Lizhi Wang, Iowa State University, lzwang@iastate.edu, Bokan Chen

We present a new robust optimization model for transmission planning. This model considers the addition of new renewable generation and the retirement of existing generation capacity as sources of uncertainty, anticipates for each transmission plan the worst scenario that would result in the highest investment and operational cost, and identifies the most robust transmission plan with the least costly worst case scenario. We demonstrate this approach with a case study on the WECC 240-bus test system. Results will be illustrated with novel quantification and visualization techniques.

4 - Data-driven Stochastic Unit Commitment For Integrating Wind Generation

Chaoyue Zhao, Oklahoma State University, chaoyue.zhao@okstate.edu

In this talk, we propose a data-driven risk-averse stochastic unit commitment model, where risk aversion stems from the worst-case probability distribution of the renewable energy generation amount, and develop the corresponding solution methods to solve the problem. Given a set of historical data, our proposed approach constructs a confidence set for the distributions of the uncertain parameters using statistical inference and solves the corresponding risk-averse stochastic unit commitment problem. The computational results numerically show how the risk-averse stochastic unit commitment problem converges to the risk-neutral one, which indicates the value of data.

Chair: Yonghua Ji, University of Alberta, School of Business, Edmonton, AB, T6G2R6, Canada, yji@ualberta.ca

1 - Announcing Privacy Threshold In Mobile Platform Competition

Zixuan Meng, University of Washington, zxmeng@uw.edu

Smartphones are increasingly necessary for everyday life and consumers find it important to prevent from privacy violations through Apps on mobiles. Android and iOS, two of the most popular App platforms, are different in App privacy levels. IOS, known to have a higher privacy level, chooses to make privacy requirement public. Using vertical differentiation model, we find that when market is fully covered, publicizing privacy threshold motivates both firms lowering privacy level. This helps both firms generate more profit by hurting consumers. This finding contradicts with common belief and calls for awareness of potential harm from a policy that seems protective to consumers.

2 - How Much To Open, How Fast To Fix And Develop? Impacts Of Openness On Software Development And Maintenance

Rakesh R Mallipeddi, Texas A&M University, College Station, TX, 77840, United States, rmallipeddi@mays.tamu.edu
Emre Muzaffer Demirezen, Ram Gopal, Subodha Kumar

Proprietary software vendors have recently begun to emulate the open source software community in opening up part of their software. We analyze the impact of software openness in the context of resource allocation between bug fixing and new version development, an important operations issue that many software vendors face in light of prevalence of software defects. We formulate optimal control models to examine the effects of making the software code open (fully or partially) on the overall quality of the software and the development efforts of its next version.

3 - Crowdfunding Mechanism Design And Its Effect On Fundraising

Aravinda Garimella, University of Washington, aravinda.garimella@gmail.com

Our study examines how entrepreneurs' choices of Funding Type and Rewards Types jointly impact the outcome of crowdfunding campaigns. We begin by providing a conceptual framework that distinguishes between Mechanism and Non-Mechanism aspects of campaign design. We then focus on two mechanisms at play in Reward-Based Crowdfunding platforms. First, entrepreneurs may opt for one of two Funding Types, Fixed Funding or Flexible Funding. Second, entrepreneurs are also heterogeneous in the mix of Reward Types they choose to offer to their backers. Using a rich data set of daily funding information on Indiegogo, we study how these two mechanisms influence funding outcomes and trajectories.

4 - Dynamics And Efficiency Of a Mobile Platform

Ruibing Wang, University of Science and Technology of China, Hefei, China, ruibing@mail.ustc.edu.cn, Qinglong Gou, Yonghua Ji

A mobile platform serves as a multi-sided market which connects users, app developers and advertisers. Different from the traditional multi-sided market, the cross-side network effects between different groups are different. It makes the decision process on advertising investments of platform owners and app developers more challenging. We develop a dynamic model, capturing these impacts, to offer suggestions on their advertisement strategy. We found that platform owners should offer app developers incentives according to the size of their user base or their advertising expenditure. We also Investigate the impact of different kinds of incentive on the system efficiency.

Behavioral Research on Inventory and Pricing

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Elena Katok, University of Texas at Dallas, Richardson, TX, United States, ekatok@utdallas.edu

1 - Negotiating Transshipments Prices For Improving Supply Chain Coordination

Sebastian Villa, University of Los Andes, Bogotá, Colombia, villabes@usi.ch, Elena Katok

When retailers face stochastic demand, it is often beneficial for retailers in the same industry to buy or sell product from one another in order to better match supply and demand. This exchange of product at the retailer level is called transshipment. Appropriate ordering decisions and transshipment prices can improve supply chain coordination. We create some experiments to evaluate how subjects decisions deviate (or not) from the theoretical channel-coordinating benchmarks. Initially, we automate the ordering decision, to evaluate how the transshipment prices are negotiated, and then we evaluate retailers' decisions when they do both, negotiate transshipment prices and place orders.

2 - Newsvendors' Decisions Revisited

Tobias Stangl, University of Cologne, tobias.stangl@uni-koeln.de
Elena Katok, Ulrich Thonemann

In our study we revisit most of the proposed explanations for the pull-to-center effect in newsvendor experiments. We conducted an experimental study with 620 students from a core course in operations management. Our newsvendor study comprises two frames and seven critical ratios. In addition we collected data on anchoring, cognitive reflection, overconfidence, and risk aversion. In our data we find no support for assuming that context matters nor for assuming (different) psychological costs of leftovers and stock-outs. We find a risk and gender effect and additional evidence that low cognitive reflection and over-precision increases the pull-to-center effect.

3 - Procurement In The Presence Of Supply Disruptions

Elena Katok, University of Texas at Dallas, ekatok@utdallas.edu

We consider a setting with a supply disruption that may occur after a contract is negotiated. If the disruption can be corrected at a cost, and it is more efficient for the supplier, rather than for the buyer, to correct the disruption, a contract that does not include the disruption contingency leads to inefficient outcome. We examine the effect of communication and the ability to renegotiate in the laboratory. The main finding is that informal commitments improve efficiency a great deal.

4 - Profit-sharing Or Target-with-bonus? A Behavioral Investigation

Kay-Yut Chen, University of Texas at Arlington, UTA, Arlington, TX, 1, United States, kychen@uta.edu
Shan Li, Ying Rong

We experimentally study the profit sharing and the target-with-bonus mechanism in a setting with a principal setting the parameters of the mechanism, and an agent choosing his effort level (moral hazard) and managing a newsvendor store. We find the presence of fairness concerns under both mechanism, and the principal yields higher profit under target-with-bonus mechanism. A behavioral model is constructed to explain the findings.

Energy II

Contributed Session

Chair: Alberto J Lamadrid, Assistant Professor, Lehigh University, 621 Taylor Street, R451, Bethlehem, PA, 18015-3120, United States, ajlamadrid@ieee.org

1 - Optimal Transmission Line Switching Under Geomagnetic Disturbances

Mowen Lu, Clemson University, Industrial Engineering Department, 801 7th St. Apt 21B, Los Alamos, NM, 87544, United States, mlu87@g.clemson.edu, Russell Bent, Scott Backhaus, Harsha Nagarajan, Emre Yamangil

Geomagnetically-induced current (GIC) flows induced by geomagnetic disturbances (GMDs) can cause transformer hotspot heating and reactive power losses that can severely impact power grid reliability. We present an optimal transmission line switching model for a power grid experiencing a GMD. We show how convex quadratic relaxations and improved bilinear function relaxations can be used to obtain tight lower bounds. A case study based on a modified single area of the IEEE RTS-96 system demonstrates our model's operating decisions with respect to GMD direction.

2 - Management Of Electric Vehicles Participation In Smart Grids For Demand Response

Nasim Nezamoddini, Ms., State University of New York - Binghamton, 222 Main Street, Apt 1, Binghamton, NY, 13905, United States, nasim.nezam@gmail.com

Electric vehicles (EVs) are potential distributed energy resources that support both the grid-to-vehicle and vehicle-to-grid modes in the smart grid. Their participation in the time-based and incentive-based demand response (DR) programs helps improve the stability and reduce the potential risks to the grid. This research proposes a novel stochastic model from the Independent System Operator's perspective for risk management and participation planning of EVs in the smart grid for DR. The effectiveness of the model in response to various settings such as the area type (residential, commercial, and industrial), the EV penetration level, and the risk level has been investigated.

3 - A Computationally Efficient Branch-and-cut Method For Robust Unit Commitment

Narges Kazemzadeh, Iowa State University, 3004 black engineering, Ames, IA, 50011-2164, United States, narges.kazemzadeh@gmail.com, Sarah M Ryan

Unit commitment seeks the most cost effective generator commitment decisions to meet net load while satisfying operational constraints. Robust optimization is a widely studied approach for optimizing under uncertainty in the load less variable generation. We adopt a branch-and-cut approach to solve a Benders decomposition for the robust formulation with different forms of uncertainty sets. Its improved efficiency relative to the naïve Benders algorithm is demonstrated with numerical experiments.

4 - Modeling And Computation Of Reliable Grid Expansion

Bo Zeng, University of Pittsburgh, Department of Industrial Engineering, Pittsburgh, PA, 15260, United States, bzeng@pitt.edu, Hossein Haghighat

Different from existing capacity expansion model, we consider the non-cooperative market clearing results in bilevel capacity expansion scheme. Numerical results will be presented to demonstrate this novel scheme in practice.

5 - Interdependencies In The Communications And Electrical Networks

Alberto J Lamadrid, Assistant Professor, Lehigh University, 621 Taylor Street, R451, Bethlehem, PA, 18015-3120, United States, ajlamadrid@ieee.org, Basel Alnajjab, Lawrence V. Snyder, Rick Blum, Shalinee Kishore

Managing an electric grid in a reliable and economic manner requires collecting information for grid operators. Part of this information is collected through sensors and a supervisory control and data acquisition (SCADA) system, as well as from data provided by market players in the market clearing process. Therefore, the operation of the system requires three interdependent networks: the electric grid, the communication network and the control network.
This paper presents a model that explicitly connects these three networks, considering the probabilistic nature of possible disruptions and changes in any of the networks.

TSL Keynote Address

Keynote Session

Chair: Stephen D Boyles, The University of Texas at Austin, 301 E. Dean Keeton St. Stop C1761, Austin, TX, 78712, United States, sboyles@gmail.com

1 - City Logistics: Challenges And Opportunities

Martin W P Savelsbergh, Georgia Institute of Technology, School of Industrial and Systems Engineering, Atlanta, GA, 30332-0205, United States, martin.savelsbergh@isye.gatech.edu
Tom Van Woensel

Today, around 54% of the world's population lives in urban areas. By 2050, this share is expected to go up significantly. As a result, city logistics, which focuses on the efficient and effective transportation of goods in urban areas while taking into account the negative effects on congestion, safety, and environment, is critical to ensuring continued quality of life in cities. We review and discuss a variety of current and anticipated challenges and opportunities of city logistics. We hope this helps shaping an appropriate research agenda and stimulates more researchers to enter this exciting field.

Advances in Traffic Equilibrium and Network Loading Models

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Yang Liu, National University of Singapore, National University of Singapore, Singapore, 00000, Singapore, iseliuy@nus.edu.sg

1 - Time-based Equilibrium For Staggered Bottleneck Congestion With Heterogeneous Commuters

Yang Liu, National University of Singapore, iseliuy@nus.edu.sg

This paper develops a time-based dynamic user equilibrium (DUE) model with heterogeneous users under the flexible work hour scheme. We first prove that, given the identical work start time, the equivalent traffic assignment can be formulated as a symmetric and convex problem for time-based DUE, which admits unique solution. At short-run DUE, i.e., the staggered work hour scheme is predetermined, DUE is formulated as variational inequality, and the unique solution cannot be guaranteed. At long-run DUE, where commuters have the flexibility to choose work start time, the equivalent convex optimization is formulated. We prove that both DUE solution and commute cost are uniquely determined.

2 - Price Of Satisficing: Bounding The Performance Of Boundedly Rational User Equilibrium

Mahdi Takalloo, University of South Florida, Tampa, FL, United States, mtakalloo@mail.usf.edu
Changhyun Kwon

Due to the lack of full information and personal preferences, network users are mostly satisficing decision makers instead of perfectly rational decision makers. This satisficing behavior results in a traffic pattern, which attains a boundedly rational user equilibrium (BRUE) instead of perfectly rational equilibrium (PRUE). This research uses a perception error model to describe BRUE, and also quantifies how bad the system total travel delay in BRUE can be compare to PRUE.

3 - Path Based Formulations For Generalized Bounded Rationality And Multi-commodity Network Design

Changhyun Kwon, University of South Florida, 4202 E. Fowler Ave. ENB118, Tampa, FL, 33620, United States, chkwon@usf.edu
Longsheng Sun, Mark H Karwan

The route choices of network users could be uncertain when they are satisficing with sub-optimal routes or there are errors in each individual's perception of the route's utility. By modeling perception error, the notion of generalized bounded rationality was recently proposed, providing a unified framework for the two sources of uncertainty in route choices. In this paper, we design path based formulations for route choice uncertainty represented by generalized bounded rationality. We show how to incorporate them into multi-commodity network design problems.

4 - Node Modeling For Congested Urban Road Networks

Saif Eddin G Jabari, New York University Abu Dhabi, sej7@nyu.edu

Node models are responsible for capturing the propagation of traffic dynamics through networks (e.g., spillback dynamics). Holding-free solutions for node models are formally defined. Flow maximization is only a sufficient condition for holding-free solutions. A greedy algorithm is shown to produce holding-free solutions while also respecting the invariance principle. Staging movements through nodes in a manner that prevents conflicting flows from proceeding through the nodes simultaneously is shown to simplify the node models considerably and promote unique solutions.

Advances in Railway Research

Sponsored: Railway Applications

Sponsored Session

Chair: Shantih Marie Spanton, CSX, 31 West Adams Street, Apt 607, Jacksonville, FL, 32202, United States, shantihs@gmail.com

1 - CSX Line-of-Road Simulation

Yu Wang, CSX, Jacksonville, FL, United States, yu_wang@csx.com Jagadish Jampani, Lray Rahn

CSX Line-of-road simulation model implements a heuristic algorithm which can efficiently generate a meet-and-pass plan to dispatch trains through a division in a conflict-free manner. In order to accurately capture the speed variation, a data-mining module was implemented to predict the speed of any train during its trip based on selected attributes of the train at that time. The model has been validated and used for multiple case studies such as impact of train profile change, sub-division capacity analysis, and curfew planning.

2 - Crew Caller Districting With Consideration Of Workload Balance And Geographic Compactness

Siyang Xie, U of Illinois at Urbana-Champaign, Urbana, IL, United States, sxie13@illinois.edu, Yanfeng Ouyang, Kamalesh Somani

Railroads companies everyday receive a large amount of customer calls. These calls are handled by the crew callers distributed in various crew calling desks. Each of these desk is in charge of the calls from a particular region. To improve service quality and save costs, the region assigned to each desk is designed to be compact and the workload of desks are balanced. We formulate the problem as a network-flow based graph partitioning model and design a specialized heuristic to effectively solve the model. We demonstrate the feasibility of our methodology by applying it to the CSX's call center design problem.

3 - Scheduling Preventive Grinding For Railway Maintenance

Masoumeh Taslimi, Operations Research Manager, CSX Transportation, Jacksonville, FL, United States, masoumeh_taslimi@csx.com, Kamalesh Somani, Siyang Xie, Yanfeng Ouyang

Railway is the one of the most valuable assets at railway industries. Periodic grinding has been used to protect railway from deterioration and to prolong the life of existing rail infrastructure. Rail grinding smooths the rail to minimize the impact of rail wear, fatigue, and defects. The grinding schedule is usually determined manually on required frequencies. It is desirable to both maximize the total track miles smoothed by grinding, and also minimize the grinder's total travel distance. In this study, we propose a variant of Vehicle Routing Problem with Time Window to create the grinder's target frequencies at CSX Transportation.

4 - Scheduling Training Activities For Engineers And Conductors

Grigory Pastukhov, CSX, grigoriypas@gmail.com

CSX Transportation constantly hires engineers and conductors to operate trains. In order to make sure that these people are qualified to fulfill their duties, they have to complete extensive training program. We present fully automated scheduling system that creates detailed training plan for each trainee in the system for the whole duration of training.

Chair: Jee Eun Kang, University at Buffalo, 409 Bell Hall, Buffalo, NY, 14260, United States, jeeeunka@buffalo.edu

Co-Chair: Changhyun Kown, University of South Florida, 4202 E. Fowler Ave. ENB118, Tampa, FL, 33620, United States, chkwon@usf.edu

1 - Economic Analysis On Adopting Strategies Of Electric Vehicles For Urban Parcel Delivery Industry

Nan Ding, University at Buffalo, Nanding@Buffalo.edu, Changhyun Kwon, Rajan Batta

Most existing works of electric vehicles (EVs) address travel distance cost of EVs as the only objective and implement the strategy of replacing an entire fleet of conventional vehicles (CVs) with EVs. Few works consider other costs of EVs or alternative strategy. To fill this gap, this work conducts economic analysis of four different strategies of adopting EVs. The objective of all strategies is to minimize the total cost including distance cost, ownership cost, energy cost, as well as infrastructure and maintenance cost for both CVs and/or EVs. These strategies are implemented and solved by heuristics. Secondly, simulation analysis is conducted under various uncertainties for comparison.

2 - Incorporating Demand Dynamics In Multi Period Capacitated Recharging Location Planning For Electric Vehicles

Anpeng Zhang, University at Buffalo, Buffalo, NY, United States, anpengzh@buffalo.edu, Jee Eun Kang, Changhyun Kwon

We develop a multi-period capacitated flow refueling location problem for electric vehicles (EVs) as EV market responds to the charging infrastructure. We present two market dynamics (sensitive to path specific and general charging opportunities) with two objective of charging location problem (maximizing flow coverage and maximizing electric vehicle demand). A case study on US Northeastern network is presented.

3 - Long-term Planning Of Inter-city Battery Electric Vehicle Fast Charging Stations For The State Of California

Fei Xie, Oak Ridge National Laboratory, Knoxville, TN, United States, xief@ornl.gov, Changzheng Liu, Shengyin Li, Yongxi Huang, Zhenhong Lin

This study focuses on the long-term planning of battery electric vehicle (BEV) inter-city fast charging stations for the state of California in response to the increasing market share of BEVs. Genetic algorithm will be used to solve this large scale problem. We will investigate the trade-off between the high investment cost in the BEV infrastructure and the growing BEV intercity travel demand with higher BEV fleet size.

4 - Intercity Network Of Refueling Stations For Plug-in Electric Vehicles

Mehrnaz Ghamami, Assistant Professor, Michigan State University, 428 S. Shaw Lane, Room 3502, East Lansing, MI, 48824, United States, ghamamim@msu.edu

This study aims at finding the optimum location of charging stations in an intercity network of roads, considering multiple routes and multiple OD pairs on each route. It also captures the optimal routes for various classes of vehicles considering not only refueling time, but also travel time, subject to change by link flows, along the routes. It is worth noting that the location of charging stations affects the route selection of electric vehicle users and the route selection affects the energy consumption, traffic on road, and the optimum location of charging stations as a result. Thus, this study considers these codependent variables.

Applications and Methodological Issues on MCDM

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Danielle Morais, Universidade Federal de Pernambuco, Recife - PE, Brazil, daniellemorais@yahoo.com.br

Co-Chair: Adiel Teixeira De Almeida Filho, Universidade Federal de Pernambuco, Management Engineering Department, Recife, Brazil, adieltaf@cdsid.org.br

1 - A Navy Weapon Selection Throughout Fitradeoff

Adiel Teixeira De Almeida Filho, Assistant Professor, Universidade Federal de Pernambuco, Recife, Brazil, adieltaf@cdsid.org.br, Leonardo A Pessoa, Rodrigo Ferreira, Adiel Teixeira de Almeida

This work presents a multiple criteria decision model for selecting a weapon to be incorporated in a navy ship using the FITradeoff method. A numerical application is presented based on realistic data with regard to the real problem faced by a Brazilian Navy.

2 - A Multicriteria Model For Supplier Selection Based On A Multilinear Utility Function

Felipe Macedo de Morais Pinto, Universidade Federal de Pernambuco, felipe_mmp94@hotmail.com, Adiel Teixeira De Almeida Filho

This work presents an MCDM model based on a multilinear utility function for selecting a maintenance service supplier. Depending on the context, maintenance activities may need to consider other criteria besides cost, which are detailed in the reference Multicriteria and Multiobjective Models for Risk, Reliability and Maintenance Decision Analysis.

3 - Computing Interval Weights For Incomplete Pairwise Comparison Matrices Of Large Dimension – A Weak Consistency Based Approach

Jana Krejcí, PhD Student, University of Trento, Via Sommarive 9, Povo, Trento, 38123, Italy, jana.krejci@unitn.it
Jana Krejcí, PhD Student, University of Bayreuth, Universitat sstr. 30, Bayreuth, D-95440, Germany, jana.krejci@unitn.it, Vera Jandova, Jan Stoklasa, Michele Fedrizzi

We present a novel interactive algorithm for large-dimensional pairwise-comparison problems based on the sequential optimal choice of the pairwise comparisons (PCs) to be provided by the decision maker and the concept of weak consistency. The proposed solution significantly reduces the number of needed PCs by providing sets of feasible values for all missing PCs after each input of a new PC. Interval weights of objects covering all possible weakly consistent completions of the incomplete PCMs are then computed from the resulting incomplete weakly consistent PCM. The algorithm is capable of reducing the number of PCs required in PC matrices of dimension 15 and greater by more than 60% on average.

Learning Analytics of Massive Open Online Courses (MOOCs)

Sponsored: Information Systems

Sponsored Session

Chair: Sang Pil Han, Arizona State University, Arizona State University, Tempe, AZ, 85281, United States, sangpil78@gmail.com

1 - Cohort Size And User Engagement: A MOOC Field Experiment

Jiye Baek, Boston University, jiyebaek@bu.edu
Jesse C Shore

MOOCs have the potential to transform how people access knowledge, but they face substantial difficulties in keeping users engaged. We conduct a field experiment on the edX platform to identify factors that promote student engagement in MOOC discussion forums, focusing on cohort size. While most prior work show that users in smaller groups participate more per person, our results show that in the MOOC, the students in larger size cohorts interact more per person and that this greater interaction in turn increases student retention and performance. We theorize that larger cohorts produce more forum content and thus increase the resources available to draw marginal students into an engaged state.

2 - Towards Improved Education For Students Of Low Socioeconomic Status: Learning Analytics Of Massive Open Online Courses (MOOCS)

Sang Pil Han, Arizona State University, Main Campus, PO Box 874606, Office:BA 301D, Tempe, AZ, 85287-4606, United States, sangpil78@gmail.com, Mi Hyun Lee, Sunghoon Kim, Sungho Park

Although the new era of free, online learning unfolds, the claim of 'education for all' appears to be overshadowed by the concern over the unequal use of Massive Open Online Courses (MOOCs). MOOCs may not be a viable solution to students across all levels of socioeconomic status (SES). Using learner outcome and demographic data at a MOOC, we examine the effectiveness of two intervention strategies to improve engagements among low SES learners: (1) course verification which allows learners to earn an official credit later and (2) mobile media which enable learners to attend MOOCs anytime/anywhere. From the findings, we draw implications that can help expand access to education to everyone through MOOCs.

Sponsored Session

Chair: Chiwoo Park, chiwoo.park@eng.fsu.edu

Co-Chair: Shiyu Zhou, shiyuzhou@wisc.edu

1 - Structural Damage Growth Prediction Via Integration Of Finite Element Method And Bayesian Estimation Approaches

Yuhang Liu, Graduate Student Research Assistant, University of Wisconsin–Madison, 1513 University Ave., Madison, WI, United States, liu427@wisc.edu, Shiyu Zhou

Damage diagnosis and prognosis play an important role in ensuring the safety of mechanical and civil structures. Existing works are limited to estimation of the damage magnitude at the current time instance. Revealing the evolving path of structural damage is highly desirable for prognosis and remaining useful life prediction. In this paper, we propose a dynamic data-driven hierarchical Bayesian degradation model, which takes advantage of both the physical finite element model and the data driven Bayesian framework, to tackle the structural damage growth prediction. The damage growth trend can be efficient and accurately estimated by Gibbs sampling. Numerical and case studies are presented.

2 - Dynamic Data Driven Visual Surveillance Via Cooperative Unmanned Aerial/ground Vehicles

Sara Minaeian, University of Arizona, Systems and Industrial Engineering, Tucson, AZ, 85721, United States, minaeian@email.arizona.edu, Jian Liu, Young-Jun Son

Unmanned vehicles (UVs) with onboard sensors have recently shown promising performance in various applications such as autonomous surveillance, compared to the fixed sensors. However due to the uncertain and dynamically changing environment, the complex problem of autonomous crowd control requires robust, multi-scale and effective algorithms to be applied in real-time. In this work, we propose an autonomous visual surveillance system based on dynamic data-driven adaptive multi-scale simulation (DDDAMS) for crowd control in a border area. The experimental results reveal effectiveness of the proposed system in accomplishing assigned missions under dynamic conditions.

3 - Efficient Multi-fidelity Decision Making For Dynamic Data Driven Application Systems

Jie Xu, George Mason University, jxu13@gmu.edu
Chun-Hung Chen, Edward Huang

Dynamic data driven application systems enable real-time simulation-based decision making. However, existing simulation optimization algorithms lack the computational efficiency required for real-time decision making. In this talk, we present a Bayesian framework that makes use of data and models of multiple fidelity levels to achieve the computational efficiency necessary for decision support in the context of dynamic data driven application systems.

4 - Dynamic Data Driven Modeling Of Nanoparticle Self-assembly Processes

Xin Li, Florida State University, 2525 Pottsdamer St, Building A, Suite A231, Tallahassee, FL, 32310, United States, xl12d@my.fsu.edu, Chiwoo Park, Yu Ding, Tao Liu

We present a dynamic data-driven modeling strategy, capable of tracking and predicting the transient dynamics of nanoparticle production processes. The proposed methodology is built upon two emerging multi-resolution instruments. The methodology regularly triggers cheap low resolution measurements while triggering expensive high resolution measurements when model predictions fail. The proposed strategy would provide crucial clues to understand nanoparticle productions as well as powerful insights to control the production of nanoparticles for yielding desirable morphology.

1 - Reordering Of Spare Parts Experiencing Two Phase Onshelf Deterioration

Haitao Liao, University of Arkansas, liao@uark.edu

We study maintenance and inventory policies for a system carrying spare parts that experience two-phase on-shelf deterioration. Based on the parts' degradation states, we introduce two different replacement strategies for the spare consumption, i.e., the Degraded-First strategy and the New-First strategy.

2 - A Model Of System Limiting Availability Under Imperfect Maintenance

Suzan Alaswad, Zayed University, suzan.alaswad@zu.ac.ae
Charles Richard Cassady, Edward A Pohl

In this paper, we explore the impact of Kijima Type II imperfect repair model on equipment availability. Our specific interest is in the system steady-state availability. Since the derivation of a closed form expression for the limiting availability is extremely difficult, we use simulation modeling and analysis to estimate the system limiting availability. Next, we develop a meta-model to convert the system reliability and maintainability parameters into the coefficients of the limiting availability estimate without the simulation effort. Lastly, we identify an optimal age-based preventive maintenance policy that maximizes the system's steady-state availability.

3 - Predictive Maintenance For A Multi-unit System

Yisha Xiang, Lamar University, yxiang@lamar.edu
Zhicheng Zhu, David W Coit

Preventive maintenance has been extensively studied. Time-based PM and condition-based maintenance (CBM) are two major approaches for PM. However, time-based PM is often associated with high occurrence of system breakdowns, and CBM might incur more-than-necessary inspections. Recently, predictive maintenance has become popular since it aims to pinpoint when a failure is about to occur and prolong the operational time. However, only a few predictive models consider a multi-unit system. In this paper, we develop an opportunistic predictive maintenance structure for a multi-unit system. Numerical examples are provided to illustrate the proposed predictive maintenance policy.

4 - Reliability Of System With Clusters Of Dependent Degrading Components

Sanling Song, Rutgers University, Busch Campus, Core Building Room 201, Piscataway, NJ, 08854, United States, sanling@scarletmail.rutgers.edu, David W Coit, Qianmei Feng, Yisha Xiang

A reliability model is developed for complex multi-component system with each component subject to multiple failure processes. Degradation paths for certain components are stochastically dependent with clusters of dependent components. Gamma process is used to model the stochastic process of component deterioration. In this new model, two failure processes within each component are dependent due to simultaneous shared exposure to shock process. Furthermore, degradation paths among certain components are considered to be dependent. Components sharing dependent degradation can be determined by the MLE of model parameters.

1 - Commodity-based Econometric Empty Trip Models

Carlos Alberto Gonzalez-Calderon, Research Associate, Rensselaer Polytechnic Institute, 4 25TH ST, APT 5, Troy, NY, 12180, United States, gonzac8@rpi.edu, Jose Holguin-Veras, Ivan Dario Sanchez-Diaz, Ivan Sarmiento, Johanna Amaya

This paper estimates econometric models of empty trips of different commodities and vehicle types. In doing this, panel models with time-dependent parameters and fixed effects are used to assess how parameters change over time considering different commodities, and to detect the presence of time effects not captured by the other parameters. The performing of the formulation for the different commodities is tested in Colombia.

1 - On The Unique Features Of On-demand Peer-to-Peer Logistics Systems

Jennifer A Pazour, Assistant Professor, Rensselaer Polytechnic Institute, 110 8th street, CII 5217, Troy, NY, 12180, United States, pazouj@rpi.edu

On-demand peer-to-peer logistics systems use a business model for the movement and storage of goods that matches independent supply resources (warehouse space, truck space, delivery services) to demand requests on demand. These systems are part of the growing sharing economy and gig economy. We identify the unique features of these systems, comparing and contrasting them with traditional logistics systems. By mapping the characteristics to supply chain principles, we identify challenges with designing and operating, as well as using these systems for the movement and storage of goods.

2 - The Impact Of U. S. Chassis Supply Models On Drayage Productivity

Samaneh Shiri, Research Assistant, University of South Carolina, 101 pickens st. APt. G2, Columbia, SC, 29205, United States, shiri@email.sc.edu, Nathan Huynh

The U.S. container chassis supply market is changing and new models are emerging recently. Supply chain stakeholders such as drayage companies could be affected by evolving models. To study this effect on drayage operation productivity, drayage problem is formulated as an extension of the multiple traveling salesman problem with time window. The proposed solution method is based on tabu search.

1 - The Simultaneous Vehicle Scheduling And Passenger Service Problem With Flexible Dwell Times

Allan Larsen, Associate Professor, Technical University of Denmark, DTU, Building 115 Room 003, Lyngby, DK-2800, Denmark, alar@dtu.dk, Joao F Fonseca, Evelien van der Hurk, Roberto Roberti, Stefan Røpke

In the SVSPSP-FDT the original timetables of the trips can be changed (i.e., shifted and stretched) in order to minimize a new objective function that aims at minimizing the operational costs plus the waiting times of the passengers at transfer points. The SVSPSP-FDT establishes the possibility of changing trips' dwell times at important transfer points based on expected passenger flows. A compact mixed integer linear formulation of the SVSPSP-FDT capable a solving small instances as well as a meta-heuristic approach to solve medium/large instances are presented. The proposed solution methods are tested on a set of real-life instances from the greater Copenhagen area.

2 - A Static Repositioning Problem With Two Commodities For Bike-sharing Systems

Tiantian Zhu, Nanyang Technological University, 50 Nanyang Avenue, Singapore, 639798, Singapore, zhut0003@e.ntu.edu.sg Xiaofeng Nie

In order to handle the issue of static repositioning for bike-sharing systems, a novel integer optimization model is formulated, defining repositioning activities as transferring both bikes and lockers. To handle larger-scale cases, a new cluster-first route-second heuristic is proposed. Based on a set of modified instances from the literature, the heuristic is tested to show its efficiency.

3 - Impact Of Carpool Lane Availability And Traffic Conditions On Peer-to-peer Ridesharing Demand

Sara Masoud, University of Arizona, 1300 E Fort Lowell Road, # A214, Tucson, AZ, 85719, United States, saramasoud@email.arizona.edu, Neda Masoud, Young-Jun Son

This research examines the impact of carpool lane availability and traffic conditions on ridesharing demand using an agent-based simulation model. The proposed work uses a many-to-one ride-matching algorithm in which each rider can travel by means of transferring between multiple drivers' vehicles. A ride-matching algorithm is embedded in the agent-based microscopic traffic simulation software AnyLogic®. Trip tables derived from a real travel demand data set of Los Angeles, California have been used to calibrate the simulation model. The results of this research will shed light on the types of urban settings that are more receptive towards ridesharing services.

Supply Chain Mgt II

Contributed Session

Chair: Mojtaba Mahdavi, PhD Student, University of Auckland, 12 Grafton Road, Auckland, New Zealand, m.mahdavi@auckland.ac.nz

1 - Optimal Procurement Design For A National Brand Supplier In The Presence Of Store Brand Competition

Xiang Fang, Associate Professor, University of Wisconsin-Milwaukee, 3202 North Maryland Avenue, Milwaukee, WI, 53211, United States, fangx@uwm.edu, Xinyan Cao

We consider a supply chain consisting of a national brand supplier and a retailer which intends to develop its own store brand. We develop a game-theoretic framework to analyze the strategic interaction between the two players in the presence of asymmetric information.

2 - Optimizing Array Of Shipping Cartons For Ecom DCS

Manjeet Singh, Research Manager, DHL Supply Chain, 570 Polaris Parkway, Westerville, OH, 43082, United States, manjeet.singhin@dhl.com

Dimensional weight charges previously restricted to large packages are now applied to all packages. This has a large impact on Ecom DCs, we found that even in a small piece pick and pack operation on an average over 50% of shipments are now subjected to dimensional weight. Therefore, optimizing the array of shipping cartons can have a huge impact in combating dimensional weight charges. This study puts a special focus on large shipments, which are subjected to more severe charges. Additionally, it also makes recommendations on when to utilize made to order packaging.

3 - How To Design Effective Supply Chain Strategies Based On The Product And Demand Characteristics

Mojtaba Mahdavi, PhD Student, University of Auckland, 12 Grafton Road, Auckland, New Zealand, m.mahdavi@auckland.ac.nz, Tava Olsen

This paper analyzes how different characteristics of product and demand impact the capacity of supply chain strategies for efficiency and responsiveness. In our modeling work, we particularly discuss the impact of product life cycle, demand variability, contribution margin, and stock-out rate on both inventory and lead-time decisions.

JFIG Paper Competition II

Sponsored: Junior Faculty JFIG

Sponsored Session

Chair: Andrew Schaefer, Rice University, 6100 Main Street - MS 134, Houston, TX, 77005, United States, andrew.schaefer@rice.edu

1 - JFIG Paper Competition II

Andrew Schaefer, Rice University, 6100 Main Street - MS 134, Houston, TX, 77005, United States, andrew.schaefer@rice.edu

The 2016 JFIG paper competition features paper submissions from a diverse array of talented junior faculty members. The prize committee evaluated submissions based on the importance of the topic, appropriateness of the approach, and significance of the contribution. After careful review, the prize committee selected a group of finalists to present their research in one of the two JFIG sessions. For information on the finalists and their papers, please refer to the online program.

2 - Simple Bayesian Algorithms For Identifying The Best Arm In A Multi-armed Bandit

Daniel Russo, Northwestern University, Evanston, IL, Dan.Joseph.Russo@gmail.com

This talk considers the optimal adaptive allocation of measurement effort for identifying the best among a finite set of options or designs. An experimenter sequentially chooses designs to measure and observes noisy signals of their quality with the goal of confidently identifying the best design after a small number of measurements. I propose three simple Bayesian algorithms for adaptively allocating measurement effort. Each is shown to have strong performance in numerical experiments, and a unified analysis establishes each satisfies a strong asymptotic optimality property.

3 - Recovering Statistical Guarantees Via The Empirical Robust Optimization

Henry Lam, the University of Michigan, khlam@umich.edu

We investigate the use of distributionally robust optimization (DRO) in recovering the statistical guarantees provided by the best benchmark that is in line with the central limit theorem, for the feasibility of expected value constraints. We show that the divergence ball, suitably empirically defined, and with its size calibrated by the quantile of a chi-square process excursion, amounts to such guarantees. The construction of this ball deviates from the standard mechanism of DRO in that the ball can have low, or even zero probability of covering the true distribution. Rather its performance is explained by connecting the dual of the DRO with a generalization of the empirical likelihood method.

4 - Staffing to Stabilize the Tail Probability of Delay in Service Systems with Time-Varying Demand

Yunan Liu, North Carolina State University, Raleigh, NC, yliu48@ncsu.edu

Manufacturing II

Contributed Session

Chair: Gourav Dwivedi, Doctoral Student, Indian Institute of Management, Indian Institute of Management, IIM Road, off Sitapur Road, Lucknow, 226013, India, fpm14013@iiml.ac.in

1 - A Lagrangian Relaxation Approach For A Multiproduct Stochastic Production Planning Problem

Reha Uzsoy, North Carolina State University, Dept. of Industrial & Systems Engg, 300 Daniels Hall Camps Box 7906, Raleigh, NC, 27695-7906, United States, ruzsoy@ncsu.edu, Erinc Albey, Karl Kempf

We model a single-stage multi item capacitated production-inventory system with stochastic demand. We present a chance-constrained production planning model that considers forecast evolution, which is solve using Lagrangian relaxation. Computational results show that the proposed approach outperforms previous myopic capacity allocation procedures.

2 - Order Scheduling For A Class Of Electronic Ceramic Manufacturers In Make To Order Environments

Zhongshun Shi, Peking University, Haidian Chengfu Road 298, Founder Building Room 512, Beijing, 100871, China, zhongshun@pku.edu.cn, Hongqiang Gao, Leyuan Shi

Motivated by the applications for a class of electronic ceramic manufacturers, we study the order scheduling on sintering operations in make-to-order environments, where sintering furnaces are modeled as batch processing machines. The order consists of multiple types of jobs with specific demand quantity. We consider the total weighted order completion time as objective function and prove the problem is strongly NP-hard. Efficient heuristics with worst-case analysis and asymptotic performance analysis are also developed. Numerical results demonstrate that the proposed heuristics can give near-optimal solutions for different production scenarios.

3 - A Lagrangian Approach For Coordinating Capacity Negotiations In A Semiconductor Firm

Reha Uzsoy, North Carolina State University, Dept. of Industrial & Systems Engg, 300 Daniels Hall Camps Box 7906, Raleigh, NC, 27695-7906, United States, ruzsoy@ncsu.edu, Ankit Bansal, Karl Kempf

We model the negotiations between a product development organization and a production organization for access to manufacturing capacity for product development activities in the semiconductor industry. We develop a negotiation framework based on Lagrangian decomposition that maximizes overall firm contribution subject to the resource constraints of both organizations. The approach aims to achieve coordinated decisions between the two organizations, and provides a benchmark for alternative models of negotiations.

4 - Modeling And Solution For Supply Chain Scheduling In Cold Rolling

Shengnan Zhao, PhD Candidate, Northeastern University, Shenyang, China, zhaoshengnan_neu@163.com, Lixin Tang, Qingxin Guo

This paper studies a supply chain scheduling problem which is derived from steel production. The problem is to make coil schedules with the aim of balancing the capacity of each production line, and minimizing the total setup cost. To describe the problem, we formulate a MILP model with consideration of practical technological requirements. Then we develop an improved discrete differential evolution (DE) algorithm to solve it. The computational experiments show that the proposed DE algorithm outperforms the compared DE algorithms for solving this problem. In addition, the proposed algorithm is also competitive in comparison with the commercial optimization solver CPLEX.

5 - Analysis Of The Barriers To Implement Additive Manufacturing Technology In The Indian Automotive Sector: A Fuzzy-ISM Approach

Gourav Dwivedi, Doctoral Student, Indian Institute of Management, Indian Institute of Management, IIM Road, Off Sitapur Road, Lucknow, 226013, India, fpm14013@iiml.ac.in, Rajiv K Srivastava, Samir K Srivastava

This paper analyzes the interaction among barriers to implement additive manufacturing (AM) technology in the Indian automotive sector. We use Fuzzy-Interpretive Structural Modeling (Fuzzy-ISM) method to derive hierarchy and direction and to measure the strength of relations among these barriers. Dominant barriers are identified using this approach. The findings may be useful for managers to develop suitable mitigation strategies. This study contributes to AM literature by the structured presentation of the barriers.

Technologoy Tutorial: Palisade Corporation/Bayesia

1 - Palisade: Introduction To Risk And Decision Analysis Using @RISK And The Decision Tools Suite

José Raúl Castro, Palisade Corporation, Ithaca, NY, raul.castro.gc@gmail.com

This software presentation is designed to provide an entry-level introduction into probabilistic analysis and will show how Monte Carlo simulation and other techniques can be applied to your everyday business analyses. Using Monte Carlo simulation, @RISK will analyze many different scenarios all at once, giving you more insight into what could happen. We'll look at example models including a basic revenues/cost/profits model, an NPV model, and a Cost Estimation model, to give you an idea of how quickly you can get started in probabilistic modeling in Excel. If you build models in Excel then Palisade solutions can almost certainly help you to make more informed decisions, right from your desktop. Palisade software and solutions have been used to make better decisions. Cost estimation, NPV analysis, operational risk registers, portfolio analysis, insurance loss modeling, reserves estimation, schedule risk analysis, budgeting, sales forecasting, and demand forecasting are just some of the ways in which the tools are applied. This presentation will demonstrate how easy - and necessary - it is to implement quantitative risk analysis in any business.

2 - Bayesian Networks & BayesiaLab: Artificial Intelligence for Research, Analytics, and Reasoning

Stefan Conrady, BAYESIA USA, Franklin, TN, Contact: stefan.conrady@bayesia.us

The objective of this workshop is to show that "Artificial Intelligence" should not be perceived as a quasi-magic technology that is mostly incomprehensible to normal mortals. We want to illustrate how scientists in any field of study—rather than only computer scientists—can employ AI to explore complex problems. For this purpose, we present Bayesian networks as the framework and BayesiaLab as the software platform. In this context, we demonstrate BayesiaLab's supervised and unsupervised machine learning algorithms for knowledge discovery in high-dimensional, unknown domains. Also, while AI is commonly associated with another buzzword, "Big Data", we wish to prove that AI can be useful for dealing with problems for which we possess little or no data. Here, expert knowledge modeling is critical, and we describe how even a minimal amount of expertise can serve as a basis for sound reasoning aided by AI.

Supervised and Unsupervised Methods

Sponsored: Data Mining

Sponsored Session

Chair: Wenjun Zhou, University of Tennessee, 916 Volunteer Blvd, 255 Stokely Management Center, Knoxville, TN, 37996-0525, United States, wzhou7@gmail.com

1 - Group-wise Sufficient Dimension Reduction: With Applications In Forecasting The Equity Risk Premium

Haileab Tesfe Hilafu, University of Tennessee, hhilafu@utk.edu

When there is prior domain knowledge concerning a grouping structure of the predictors, two different approaches of dimension reduction exist: carry out dimension reduction of predictors in each group separately which ignores the inter-dependence among the groups; ignore the grouping structure and reduce the dimension of the predictors jointly. We present a method that bridges these two approaches in the sense that it, simultaneously, utilizes the prior domain knowledge and accounts for potential inter-dependence among the groups of predictors. The proposed method is applied to forecast the equity risk premium from a set of well known macroeconomic and a set of technical variables.

2 - Sufficient Dimension Reduction For Treatment Effect Estimation

Craig Anthony Rolling, Saint Louis University College for Public Health and Social Justice, 1 North Grand Boulevard, Saint Louis, MO, 63103, United States, rollingca@slu.edu, Wenbo Wu

For nonparametric methods of estimating the treatment effect, if the dimension of the baseline covariates is large, implementation becomes difficult and sometimes infeasible due to the curse of dimensionality. Hence, sufficient dimension reduction of baseline covariates can be useful before estimating the treatment effect. We refer to such a dimension reduction subspace as a central treatment effect subspace (CTES). We propose methods to estimate the CTES and its structural dimension, investigate the theoretical properties of these estimators, and demonstrate their effectiveness with numerical studies.

3 - Load Forecasting Using Support Vector Machine With Optimized Parameters

Olufemi A. Omitaomu, Oak Ridge National Laboratory, omitaomuoa@ornl.gov

Load forecasting is central to most of the energy transaction decisions in power systems planning and energy markets. Until now, most approaches for forecasting energy demand rely on monthly electrical consumption data. The emergence of smart meters is changing the data landscape for electric utility companies, and creating opportunities for utility companies to collect and analyze energy consumption data at a much finer temporal resolution. To enhance the estimation of energy demand at the household and network levels, we present an on-line accurate support vector regression technique that uses optimized regression parameters for forecasting real-time energy demand using smart meters data.

4 - Catch Me If You Can: Detecting Pickpocket Suspects From Large-scale Transit Records

Chuanren Liu, Drexel University, chuanren.liu@drexel.edu

Massive data collected by automated fare collection (AFC) systems provide opportunities for studying both personal traveling behaviors and collective mobility patterns in the urban area. We creatively leverage such data for identifying thieves in the public transit systems. We develop a thief active tracking system that identifies pickpocket suspects based on their daily transit records. We first extract a number of features from each passenger's daily activities in the transit systems. Then, we exploit a combination of outlier detection and classification models to identify thieves, who exhibit abnormal traveling behaviors.

Quality and Statistical Decision Making in Health Care Applications

Sponsored: Data Mining

Sponsored Session

Chair: Cao Xiao, University of Washington, 3900 Northeast Stevens Way, MEB, Seattle, WA, 98195, United States, xiaoc@uw.edu

Co-Chair: Shuai Huang, University of Washington, Seattle, WA, United States, shuaih@uw.edu

1 - Modeling And Analysis Of The Waiting Time Of Rapid Response Process In Acute Care

Nan Chen, Tsinghua University, Room 615, Shunde Building, Tsinghua University, Haidian District, Beijing, 100084, China, chenn618@gmail.com, Xiaolei Xie, Li Zheng

Improving the efficiency of rapid response process in acute care plays a significant role to ensure patient safety. We develop an analytical method to evaluate the waiting time and its variability. We discussed the structural properties and continuous improvement by adding care providers. A bottleneck indicator is introduced and a simple approximation formula is obtained. Case study is introduced to illustrated the application of the method.

2 - Modeling And Prediction Of The Mental Health Conditions Of Web Users

Qingpeng Zhang, City University of Hong Kong, 1, Hong Kong, brianzqp@gmail.com

The digital footprints of Web users left on the Web presents important proxies of their health conditions. In this research, we propose novel machine learning algorithms to model and predict the mental health conditions of Web users based on their online activities on social media. The preliminary results show the potential of using the open source social media data to infer the mental health conditions of people, and help health providers make better decisions.

3 - Learning Semantics Behind Health Status Disclosure On Twitter

Zhijun Yin, Vanderbilt University, Nashville, TN, 37203, United States, zhijun.yin@vanderbilt.edu, Bradley Malin

User generated content in social media is increasingly acknowledged as a rich resource for research into health problems. We in this talk present a framework to investigate how semantics are related with disclosure routines for 34 health issues. Our findings show that health issues related with family members, high medical cost and social support (e.g., Alzheimer's Disease, cancer, and Down syndrome) lead to tweets that are more likely to disclose another individual's health status, while tweets with more benign health issues (e.g., allergy, arthritis, and bronchitis) with biological processes (e.g., health and ingestion) and negative emotions are more likely to contain self-disclosures.

4 - Hospital Operational Health Monitoring: Enabling Organizational Communication Of Key Indicators And Analytics

Diego A. Martinez, Scott R. Levin, Matthew F. Toerper, Johns Hopkins University School of Medicine, Baltimore, MD, dmart101@jhmi.edu

Most hospitals have adopted electronic medical records, yet leveraging these data to optimize hospital operations remains a challenge. Grounded in human-computer interaction and visualization theory, we built a web app to facilitate data exploration and trend analysis. The app allows users to directly explore big data and scientifically assess whether or not an intervention is impacting hospital performance. Keeping clinicians and hospital leadership informed about practice operations can help align them with organizational goals, ultimately leading to better financial performance.

1 - The Operational Challenges Of Sharing-Economies: An Optimal Re-balancing Mechanism For The Bike-Sharing Industry

Pantelis Loupos, Department of Operations Management, Kellogg School of Management, Northwestern University, Evanston, IL 60208, Can Urguny

Bike-sharing programs have been gathering momentum, but their expansion poses operational challenges. We propose a novel solution to the bike re-balancing problem, that is centered around the actions of the riders instead of utilizing trucks for re-balancing. Our findings indicate great promise, whose adoption by bike sharing operators could have a positive impact on the industry.

2 - The Humanitarian Pickup And Distribution Problem

Ohad Eisenhandler, Department of Industrial Engineering, Tel Aviv University, Tel Aviv, Israel, ohadeis@gmail.com, Michal Tzur

We address the logistic challenges of food banks, which collect donated food from suppliers and distribute it to welfare agencies. We model the problem as a routing – resource allocation problem. Motivated by the activity of Israeli and American organizations, we introduce an innovative objective function, which balances equity and effectiveness in this operation, and propose exact and heuristic solution methods.

3 - Data Analytics For Optimal Detection Of Metastatic Prostate Cancer

Christine Barnett, Department of Industrial & Operations Engineering, University of Michigan, 1205 Beal Avenue, Ann Arbor, MI 48109, clbarnet@umich.edu, Selin Merdan

We used data-analytics approaches to develop, calibrate, and validate predictive models to help urologists make prostate cancer staging decisions. These models were used to design guidelines that weigh the benefits and harms of radiological imaging. The Michigan Urological Surgery Improvement Collaborative implemented these guidelines which miss less than 1% of metastatic cancers while reducing unnecessary imaging by more than 40%.

Gas-Power Market Integration

Sponsored: Energy, Natural Res & the Environment, Energy I Electricity

Sponsored Session

Chair: Robert Brooks, President, RBAC Inc, 14930 Ventura Blvd. Ste. 210, Sherman Oaks, CA, 91403, United States, rebrooks@rbac.com

1 - Analysis Of Gas / Electric Integration And Coordination In The Eastern Interconnection Of The United States And Canada

Sara Wilmer, Levitan & Associates, Inc., sw@levitan.com

Levitan & Associates has conducted recent analyses of gas-electric integration and coordination on behalf of the Eastern Interconnection Planning Collaborative and the Department of Energy. These analyses examined whether future electric sector demand for natural gas will be able to be accommodated by the available natural gas infrastructure as renewable penetration expands and coal-fired resources are retired. This case study will describe the modeling tools and integrated modeling framework used to conduct the work, and challenges faced both in the representation of real-world gas and electric systems in the selected modeling tools and in the integration of the different modeling tools.

2 - Gas & Power Markets: Forecasting Prices In An Evolving Energy Landscape

Connie S. Trecazzi, Tennessee Valley Authority, cstrecazzi@tva.gov

Environmental regulations in the energy sector paired with a tsunami of shale gas have changed power and natural gas market operations. The shift in regional gas supply is driving infrastructure changes. Lower renewable costs are impacting capacity decisions and affecting reliability requirement decisions. Electricity demand has gone through a paradigm shift as steps taken to improve energy efficiency are realized, changing views on how to model future growth. In this environment, having tools to evaluate the impact of changes in both the electricity and gas markets and pass detailed information between the models is essential to understanding how each assumption impacts both markets.

3 - The Clean Power Plan: The Art And Science Of Quantifying Its Impacts Using Integrated Gas-power Modeling

Rahul Dhal, Developer, EPIS, LLC, 13535 72nd Ave., Ste. 165, Tigard, OR, 97223, United States, rahuldhal@epis.com

Energy policies are, by nature, complex. The mechanisms through which policies attempt to bring about changes in the market regularly involve a large number of stakeholders. Given the decentralized and interconnected nature of U.S. energy sectors, it is very important to develop methods for evaluating the impact of the complex energy policies. In this talk we present a method for evaluating energy policies. Our methodology that integrates industry-standard modeling frameworks for gas and power markets. The integrated gas-power framework allows for evaluation of a wide-range of energy policies. We employ this framework to quantify the impact of the Clean Power Plan on both power and gas markets.

4 - Integrated Natural Gas And Electricity Modeling With RBAC GPCM And GE Maps

Leah Kaffine, Senior Engineer, GE Energy Consulting Group, Schenectady, NY, United States, Leah.Kaffine@ge.com

Natural gas has seen a steady increase in its market share as a fuel for power generation, with continued growth expected. GE Energy Consulting has integrated Multi Area Production Simulation Software (MAPS) with Gas Pipeline Competition Model (GPCM) in order to provide a more detailed spatial and dynamic understanding of the gas-power interaction. While existing models can capture some market dynamics in isolation, the integration of MAPS with GPCM allows for a comprehensive approach to understanding interdependent issues. Ultimately Energy Consulting's integrated modeling allows for a consistent view of the future natural gas demand for power between the two models.

Power Transmission Planning under Uncertainty

Sponsored: Energy, Natural Res & the Environment, Energy I Electricity

Sponsored Session

Chair: Rodrigo Moreno, University of Chile, Av. Tupper 2007, Santiago, 8370451, Chile, rmorenovieyra@ing.uchile.cl

1 - A Comparison Of Stochastic And Adaptation Programming Methods For Electric Infrastructure Planning

Patrick Maloney, Iowa State University, Ames, IA, United States, patrickm@iastate.edu, Ali Jahanbani-Ardakani, James McCalley

In this work a recently developed mathematical programming formulation called adaptation is compared with traditional stochastic programming methods in the context of electric infrastructure expansion planning. While the adaptation formulation structure resembles that of a generic stochastic program it deviates from the temporal conventions of traditional expansion planning formulations. Structural comparisons and simulations are investigated to better understand differences in the methods.

2 - Value Of Model Sophistication On Transmission Expansion Planning

Qingyu Xu, Johns Hopkins University, Baltimore, MD, 21218, United States, qxu25@jhu.edu, Saamrat Kasina, Benjamin Field Hobbs

A set of transmission expansion plans for the western North America interconnection are optimized based on several variants of a 300-bus co-optimization model with a range of levels of sophistication, including DC optimal power flow, unit commitment and stochastic planning. The economic benefits of increasing model realism are estimated. The results show consistent impacts of sophistication upon transmission and generation investments, with load flow representations mattering most.

3 - A Five-level Milp Model For Flexible Transmission Network Planning Under Uncertainty: A Min-max Regret Approach

Alexandre Moreira, Imperial College London, a.moreira14@imperial.ac.uk
Goran Strbac, Rodrigo Moreno, Alexandre Street, Ioannis Konstantelos

The benefits of network planning solutions have to be explicitly considered in the context of uncertainty in future realizations of generation infrastructure. Hence this talk presents a novel five-level model to determine optimal transmission expansion plans under generation expansion uncertainty in a min-max regret fashion, when considering flexible network options and n-1 security. In order to solve the five-level model on large-scale networks, we propose an effective outer algorithm.

4 - Uncertainty In Strategic Network Investment: Stochastic vs. Robust Min-max Approaches

Rodrigo Moreno, University of Chile, Santiago, Chile, rmorenovieyra@ing.uchile.cl, Goran Strbac

Benefits of transmission network planning significantly depend on deployment patterns of electricity generation that are characterized by severe uncertainty. In this context, this talk presents various approaches to solve the transmission expansion planning problem under generation expansion uncertainty. In particular, we compare robust and stochastic methods, and discuss about their suitability to properly balance benefits of economies of scale against risks of stranded assets.

Joint Session DM/AI: Data Mining for Decision Making

Sponsored: Data Mining

Sponsored Session

Chair: Iljoo Kim, Saint Joseph's University, Philadelphia, PA, United States, ikim@sju.edu

1 - Studying Agenda Setting Influence Of Online Newspaper Comments

Iljoo Kim, Saint Joseph's University, ikim@sju.edu

In this continued work, we study online comments and their influence in online news articles. Using text-mining techniques, we attempt to explain and/or predict influence of online newspaper comments on the context of the original article or even on creating a new agenda through the discussions among commenters. This is done based on the textual signals embedded within comments as well as news articles.

2 - Crowdiq: Aggregating Crowd Opinions For Stock Price Predictions

Qianzhou Du, Virginia Tech, 100 Otey Street, Room 301, Blacksburg, VA, 24061, United States, qiand12@vt.edu
Hong Hong, Alan Wang, Weiguo Fan

The Wisdom of Crowds (WoC) theory explains how crowd opinions should be aggregated in order to improve the performance of decision making. Diversity, independence, decentralization, and aggregation are important factors to crowd wisdom. Existing opinion aggregation methods fail to collectively consider all the factors of crowd wisdom. We propose a new opinion aggregation method, namely CrowdIQ, to evaluate crowd wisdom using all four factors. We apply CrowdIQ to a stock prediction task using user-generated stock tweets. The result shows that CrowdIQ outperforms baseline methods.

3 - Data Mining For Result Prediction In Sports

Kyuhan Lee, Seoul National University, Seoul, Korea, Republic of, kyuhanlee0119@gmail.com
Jinsoo Park, Buomsoo Kim

The expansion of sports betting has extensively contributed to the increase of public interest on sports result prediction. In academia, as statistical data respecting sports games are readily accessible, abounding research has been conducted regarding the subject. In this paper, unlike the past studies focusing on limited types of data, we use a comprehensive set of data, including statistical data as well as text data, to enhance the accuracy of sports result prediction. We expect that our prediction model produces a preferable outcome comparing to the models of previous research.

4 - Predicting Users' Continuous Participation In Online Health Virtual Community: Demographic And Content Cues

Yanyan Shang, Dakota State University, Madison, SD, United States, yshang@pluto.dsu.edu, Jun Liu, Iljoo Kim

Online health community (OHC) is a platform where people with similar health conditions gather virtually to ask questions, share experiences, provide support, and exchange healthcare knowledge. To be effective, the OHCs have to maintain active continuance participation from their users. The purpose of this study is to identify factors that affect the users' continuance participation. Specifically, we attempt to use data analytics techniques to identify the demographic and content cues that affect the users' continuance participation. The findings of our research help community managers deploy various strategies to encourage the continuance participation of different types of members.

1 - Hot Sales Logistics Optimization For ET

Ba ak Erman, Bilkent University, Ankara, Turkey, basakerman@gmail.com
Zeynep Yaprak Be ik, Deniz Berfin Karakoç, Umut Müdüro Lu, Yekta Jehat Mizrakli, Egehan Yanik

ET is one of the leading food manufacturer in Turkey. Additonal to standard distribution system, ET has a local distribution system that enables trucks to visit smaller retailers and pursue hot sales. The aim of the project is to increase the efficiency of hot sales where demand by the retailers are better satisfied. The delivery route is divided into two: route from the main depot, which is far from customers, to the customers, and the route between customers. This project aims to maximize the utility of time spend in routes by assigning customers to trucks and identifying depot locations.

2 - Regularized Linear Regression via Robust Optimization Lens

Hari Bandi, Massachusetts Institute of Technology, Cambridge, MA, United States, hbandi@mit.edu, Garud Iyender, Vineet Goyal

There has been research in recent years to understand why regularized linear regression methods work well in the presence of noise. This problem has been approached by establishing relationship between robust optimization and regularized linear regression methods. In this work, we seek to understand the same for general loss functions used widely in Statistics, Machine Learning and Econometrics literature and we propose principled approaches to select regularization functions in order to optimally balance the bias-variance trade-off in regularized regression.

3 - On Comprehensive Mass Spectrometry Data Analysis For Quality Assessment Of Biological Samples

Sameer Manchanda, Purdue University, West Lafayette, IL, United States, Mikaela Meyer, Nan Kong, Qianqian Li, Yan Li

Mass spectrometers have become promising instruments to acquire proteomic information, creating a need for a data analysis platform for classification of mass spectra and identification of important biomarkers. To meet this need, we present a comprehensive pattern recognition platform for spectrum preprocessing and classification. In a case study, the platform achieves higher than 90% sensitivity and specificity in distinguishing rat blood samples stored for different amounts of time and derives fingerprint patterns of serum proteins that are strongly associated with the sample classification.

4 - Allocating Countermeasures To Defend Water Distribution Systems Against Terrorist Attack

Jacob Monroe, North Carolina State University, Raleigh, NC, United States, jgmonroe@ncsu.edu
Elizabeth Ramsey, Emily Zechman Berglund

An agent-based model is developed to simulate the attack and defense of a water distribution system to analyze security resource allocation strategies for protecting against chemical contamination events. A single period attacker-defender game is simulated, in which an attacker seeks to contaminate a system node, and a group of defenders seek to minimize the public health impact from attack. Terrorist decisions are simulated using a multi-attribute utility function. The utility manager assigns personnel and security equipment to nodes using one of three security resource allocation strategies.

1 - The Cost Of Reaching Mexicos Climate Change Goals

Rodrigo Mercado Fernandez, UMass, Amherst, MA, rodmerfdez@gmail.com

This paper analyzes the cost of Mexico reaching its climate change emissions goals, using integrated assessment models, and looks at how this will affect the electricity generation portfolio. These results are compared with the predicted impacts that Mexico's current policies will have on emissions and generation. Lastly this paper identifies policy changes that could help Mexico reach its long-term emissions goals for 2030 and 2050.

2 - On The Inefficiencies Of The US Federal Clean Power Plan

Duan Zhang, University of California Santa Cruz, Santa Cruz, CA, United States, dzhang33@ucsc.edu, Yihsu Chen, Makoto Tanaka

The performance-based standard under the US federal Clean Power Plan relies on trading the emission rate credits (ERCs), which represent the equivalent MWh of energy generated or saved with zero associated CO2 emissions, to equating marginal abatement costs across generating units. We show theoretically the equivalence between the ERCs and the traditional mass-based trading when states are subject to their own performance-based standards. We also identify the conditions under which the inefficiency of the performance-based standard might arise, leading to a divergence of permit prices across states. A numerical 3-node model was built to illustrate our findings.

3 - Feed-in Tariffs Vs. Renewable Portfolio Standards: The Effect Of Market Power

Mari Ito, Tokyo University of Science, Noda, Japan, mariito@rs.tus.ac.jp, Ryuta Takashima, Makoto Tanaka, Yihsu Chen

Recently policies for promoting renewable energy, e.g., feed-in tariffs (FIT) and renewable portfolio standards (RPS) have been introduced in various countries. In this work, we examine an effect of market power in the electricity market on FIT and RPS by bi-level model. For lower level, generation outputs for renewable and non-renewable generators are decided by maximizing their profits whereas for upper level, the fixed price of FIT and the RPS requirement are derived by maximizing a social welfare. In addition, we show how the number of firms affects the fixed price and the requirement.

4 - Tradable Performance-based Co2 Emissions Standards: Walking On Thin Ice?

Yihsu Chen, University of California Santa Cruz, yihsuchen@ucsc.edu, Afzal Siddiqui, Makoto Tanaka

US federal Clean Power Plan (CPP) stipulates a state-specific performance-based CO2 standard and offers considerable flexibility to the states in achieving the target. We analyze the tradable performance standards and related mass-based standard when they are subject to imperfect competition by formulating them either as a complementarity problem or a mathematical program with equilibrium constraints (MPEC). The MPEC is solved as mixed integer problems with a binary expansion. We show that while the cross-subsidy inherent in the performance-based standard that might effectively reduce power prices, it could in inflate energy demand, thereby rendering permits scarce.

1 - Plug And Abandonment Of Offshore Oil And Gas Fields.

Steffen J. Bakker, Norwegian University of Science and Technology, steffen.bakker@iot.ntnu.no

At the end of a wells life-cycle, the well has to be permanently abandoned. This process is called plug and abandonment (P&A). Decisions in the P&A process depend heavily on uncertain factors such as oil and gas prices, rig rates or well states. Moreover, these decisions have to be taken at different levels. In this presentation we discuss a classification of the P&A process into an operational, tactical and strategic level. For each of these levels we present a corresponding model, where we make use of real options theory and the frameworks of integer and stochastic programming.

2 - Trading Off Demand Side Flexibility Vs. Supply Side Flexibility And Storage In The Electricity System

Hector Maranon-Ledesma, Norwegian University of Science and Technology, hector.maranon-ledesma@iot.ntnu.no

Demand Side Management (DSM) permits a reduction in peak load consumption, a more adaptable demand of electricity, allowing shuting down high emission power plants, and the intermittent renewable resources to be better exploited by the use of flexibility mechanisms.
The EMPIRE electricity sector model is a long-term investment stochastic model. This model has been improved by including DSM at the operational level. The contributions of this work are including DSM in a large scale electric system and highlighting the importance that DSM might acquire in the future European power system.

3 - The Effect Of Drivers Elasticity On The Optimal Pricing And Management Of Electric Vehicles Charging

Chiara Bordin, Norwegian University of Science and Technology, Trondheim, Norway, chiara.bordin@iot.ntnu.no, Stig Ødegaard Ottesen, Asgeir Tomasgard, Siri Bruskeland Ager-Hanssen, Siri Olimb Myhre

The increasing demand for Electric Vehicles (EV) charging puts pressure on the power grids as in some situations the power consumption can exceed the grid capacity. We propose a mathematical model for the indirect control of EV charging that finds an optimal set of price signals to be sent to the drivers according to their flexibility. The objective is to satisfy the demand when there is a capacity lack by minimizing the curtailment of loads and prioritizing the loads shifting. The key contribution is the use of the elasticity concept to forecast the drivers reactions to the price signals. Sensitivity analyses are presented to investigate the elasticity effect on prices and loads management.

4 - Risk Aversion In Imperfect Natural Gas Markets.

Rudolf Gerardus Egging, Norwegian University of Science & Technology, ruud.egging@iot.ntnu.no

We consider risk aversion by natural gas supply companies considering investment in conventional and shale gas resources in a stochastic multi-period mixed complementarity problem. Uncertainty considered includes political risk and resource sizes. We consider shale gas investment in Poland and Ukraine in a realistic market setting in Europe. We discuss investment decisions and profits for varying levels of risk aversion.

Dense Clusters in Network Optimization

Sponsored: Optimization, Network Optimization

Sponsored Session

Chair: Vladimir Stozhkov, University of Florida, 2330 SW Williston Rd, Apt 2826, Gainesville, FL, 32608, United States, vstozhkov@ufl.edu

1 - Relative Clique Relaxations In Complex Networks

Vladimir Boginski, University of Central Florida, Vladimir.Boginski@ucf.edu

Real-world complex networks exhibit clustered structure: certain groups of nodes (vertices) form “cohesive” or “highly connected” clusters (can also be referred to as “communities”), which can be rigorously characterized using graph-theoretic concepts. In this presentation, we will focus on so-called relative clique relaxation models, which are obtained by relaxing certain metrics that attain their maximum possible values on a clique: edge density, minimum vertex degree, and vertex connectivity. We will discuss optimization problems of identifying such clusters in networks, as well as related asymptotic results on phase transitions in random graphs.

2 - Robust Network Clusters With Small-world Property

Jongeun Kim, University of Florida, Gainesville, FL, United States, kje0510@ufl.edu, Alexander Veremyev, Vladimir Boginski, Oleg A Prokopyev

Networks are popular and effective tools for analyzing real-world systems, such as telecommunication, transportation, and social networks. Network robustness is one of the important issues, because some undesired failures may affect connectivity and functionality of a network. The ideal robust cluster in a network is a clique and clique-relaxation research have been developed in recent decades. In this talk we will address small-world clusters that are robust but also have certain natural properties.

3 - Detecting Essential Proteins Using A Novel Star Centrality Metric

Mustafa Can Camur, North Dakota State University, Fargo, ND, United States, mcancamur@gmail.com

In this talk, we propose a new centrality metric (referred to as star centrality), which aims to incorporate information from the closed neighborhood of the node, rather than strictly from the node itself. More specifically, we turn our focus to degree centrality and show that in the complex protein-protein interaction networks it is a naive metric that can lead to misclassifying importance in the network. We portray the success of the new metric using protein-protein interaction networks, and investigating the significant difference in the importance of individual nodes we observe when transitioning from node degree centrality to star degree centrality.

4 - Estimating The Maximum IUC Using SDP Relaxations

Eugene Lykhovyd, Texas A&M University, lykhovyd@tamu.edu, Sergiy Butenko

If you have a simple, undirected graph, the Independent Union of Cliques (IUC) problem is to find the maximum subset of vertices, in which every connected component is a clique. It is known that this problem can be formulated on 3-uniform hypergraphs as the maximum weak independent set. We propose the estimates for IUC problem based on different SDP relaxations, extending the Lov\'asz estimate for the maximum stable set. The comparison of different approaches is also presented.

Chair: Daniel Bienstock, Columbia University, 116th and Broadway, New York, NY, 10027, United States, dano@columbia.edu

1 - LP And SOCP-based Algebraic Relaxations For Polynomial Optimization

Amir Ali Ahmadi, Princeton University, a_a_a@princeton.edu

We present ongoing work on solving polynomial optimization problems using linear and convex relaxations based on a number of ideas, including separation from the set of rank-1 psd matrices, and, in particular, the method of approximate representation of continuous variables as weighted sums of binary variables. We will discuss theory and computational practice. Joint work (Gonzalo Munoz, Chen Chen and Daniel Bienstock).

2 - Online First-order Framework For Robust Convex Optimization

Fatma Kilinc-Karzan, Carnegie Mellon University, fkilinc@andrew.cmu.edu, Nam Ho-Nguyen

We present a flexible iterative framework to approximately solve robust convex optimization problems. Our results are based on weighted regret online convex optimization and online saddle point problems. A key distinguishing feature of our approach from prior literature is that it requires access to only cheap first-order oracles for each constraint individually and does simple online updates in each iteration while maintaining the same convergence rate. For strongly convex functions, we also establish a new improved iteration complexity. As a result, our approach becomes much more scalable and hence preferable in large-scale applications from machine learning and statistics domains.

3 - New And Old Results On Polynomial Optimization

Daniel Bienstock, Columbia University, dano@columbia.edu

We present ongoing work on solving polynomial optimization problems using linear and convex relaxations based on a number of ideas, including separation from the set of rank-1 psd matrices, and, in particular, the method of approximate representation of continuous variables as weighted sums of binary variables. We will discuss theory and computational practice, and attempt to relate our work to earlier results by Renegar and Barvinok. Joint work (Gonzalo Munoz, Chen Chen and Daniel Bienstock).

1 - Exploiting Permutation Invariance To Construct Tight Relaxations

Mohit Tawarmalani, Purdue University, West Lafayette, IN, United States, mtawarma@purdue.edu, Jinhak Kim, Jean-Philippe P. Richard

We construct the convex hull for a set that does not change when the variables are permuted. We illustrate the technique by developing (1) convex hull of matrices with bounded rank and spectral norms, (2) convex envelopes of multi-linear functions over certain domains, and (3) a novel reformulation and relaxation for sparse principal component analysis.

2 - Intersection Cuts And S-free Sets For Polynomial Optimization

Chen Chen, Columbia University, New York, NY, United States, chen.chen@columbia.edu, Daniel Bienstock, Gonzalo Munoz

We develop an intersection cut for generic problems with closed sets. The cut relies on a violation distance oracle and it can be computed in polynomial time in the special case of polynomial optimization. Additional cuts are presented based on S-free sets or convex forbidden zones; for polynomial optimization we adopt the specialized term of outer-product-free sets. We provide some insight into the nature of maximal outer-product-free sets and present two classes of such sets. These two classes give intersection cuts that can be computed in polynomial time. Furthermore, the associated intersection cuts can be strengthened in the case of intersections at infinity.

3 - On The Strength Of Linear Approximations For Multilinear Monomials

Yibo Xu, Clemson University, Clemson, SC, United States, yibox@clemson.edu, Warren P Adams, Akshay Gupte

We analyze worst-case errors associated with approximating multi-linear terms over bounded variables when using linear functions. The error associated with a linear function at a given point is the absolute difference between the actual and functional values. These errors turn out to be dependent on the variable bounds. We identify "best" linear functions that yield the smallest worst-case errors for various sets of bounds, and identify those points at which these errors are realized. The errors favorably compare with those obtained by convex hull representations.

4 - Iterative LP And SOCP-based Approximations To Semidefinite Programs

Georgina Hall, Princeton University, Princeton, NJ, United States, gh4@princeton.edu, Amir Ali Ahmadi

We develop techniques for approximating SDPs with LPs and SOCPs. Our algorithms iteratively grow an inner approximation to the PSD cone using a column generation scheme and/or a change of basis scheme involving Cholesky decompositions.

1 - Hierarchical Modeling Of Soybean Variety Yield And Decision Making For Future Planting Plan

Huaiyang Zhong, Stanford University, hzhong34@stanford.edu, Xiaocheng Li, David J Lovell

We introduce a novel hierarchical machine learning mechanism for predicting soybean yield that can achieve a median absolute error of 3.74 bushels per acre in five-fold cross-validation. Further, we integrate this prediction mechanism with a weather forecasting model, and propose three different approaches for decision making under uncertainty to balance yield maximization and risk.

2 - Balancing Weather Risk And Crop Yield For Soybean Variety Selection

Ling Tong, University of Iowa, Iowa City, IA, United States, ling-tong@uiowa.edu, Bhupesh Shetty, Samuel Burer

We propose an optimization-based method to assist a farmer's choice of soybean varieties to plant in order to maximize expected yield while also managing risk, where the primary uncertainty faced by the farmer is due to seasonal weather patterns. By solving a sequence of MIPs, we calculate the efficient frontier between the two competing objectives of maximizing expected yield and guaranteed yield over all possible season types. The coefficients of the MIPs are estimated using a multiple-linear-regression model and a Bayesian-updating scheme applied to the training and evaluation data. Using the efficient frontier, the farmer may choose an optimal solution that fits his/her risk-reward profile.

3 - Decision Assist Tool For Seed Variety To Provide Best Yield In Known Soil And Uncertain Future Weather Conditions

Mehul Bansal, Robert Bosch Engineering and Business Solutions, Bengaluru, Karnataka, India, Mehul.Bansal@in.bosch.com Nataraj Vusirikala

The gap between agriculture produce and demand is ever increasing due to growing world population. There is an urgent need for utilizing all possible methods and technology solutions to bridge this gap. One of the key challenges to increase the agricultural produce is the ability to take right decisions under uncertain climate and weather conditions. In this paper we discuss a method to provide decision assist to the farmer on the best variety of soybean seed to be sown at the start of a season. In order to optimize the yield under uncertain conditions, we use a combination of crop yield modeling, weather forecasting and portfolio optimization techniques to suggest best combination of soybean seed variety. The data used in this method is the historical soybean produce data and the corresponding soil and weather conditions under which the yield was produced, day-wise weather data (temperature, precipitation and solar radiation) at farm sites from 2008 to2014. We recommend planting the following varieties with the given percentages at site 2290 for year 2016: (i) 10% of Variety V107, (ii) 35% of Variety V179, (iii) 10% of Variety V189, (iv) 10% of Variety V193, and (v) 35% of Variety V46.

1 - Latent Graphical Models For Mixed Data

Yang Ning, Princeton University, Princeton, NJ, United States, yning@exchange.Princeton.EDU, Jianqing Fan, Han Liu, Hui Zou

Graphical models are commonly used tools for modeling multivariate random variables. While there exist many convenient multivariate distributions such as Gaussian distribution for continuous data, mixed data with the presence of discrete variables or a combination of both continuous and discrete variables poses new challenges in statistical modeling. In this talk, we propose a semiparametric model named latent Gaussian copula model for binary and mixed data.

2 - Hierarchical Knowledge-gradient With Stochastic Binary Feedbacks With An Application In Personalized Health Care

Yingfei Wang, Princeton University, Princeton, NJ, United States, yingfei@cs.princeton.edu, Warren B. Powell

Motivated by personalized health care problems, we consider the problem of sequentially making decisions that are rewarded by ``successes" and ``failures" which can be predicted through an unknown relationship that depends on a partially controllable vector of attributes for each instance. The learner takes an active role in selecting samples from the instance pool. The goal is to maximize the probability of success. Our problem is motivated by healthcare applications where the highly sparsity makes leaning difficult. With the adaptation of an online boosting framework, we develop a knowledge-gradient (KG) policy to guide the experiment by maximizing the expected value of information.

3 - Approximate Newton-type Methods With Cubic Regularization

Saeed Ghadimi, Princeton University, Princeton, NJ, United States, sghadimi@princeton.edu, Tong Zhang, Han Liu

In this talk, we consider a class of second order methods for solving convex optimization problems. In particular, we propose Newton-type methods with cubic regularization when hessian of the objective function is not completely available. Convergence analysis of these methods under different conditions like stochastic setting are also presented.

Sponsored Session

Chair: Jikai Zou, Georgia Tech, 225 North Ave, Atlanta, GA, 30332, United States, jikai.zou@gatech.edu

1 - New Linear Algebra Strategies For Stochastic Programming

Nai-Yuan Chiang, United Technologies Research Center, 611 Silver Ln, East Hartford, CT, 06118, United States, chiangn@utrc.utc.com, Yankai Cao, Victor Zavala

We present a clustering-based preconditioning strategy for stochastic programs within an interior-point framework on distributed memory machines. This approach is unique in that the scenario clustering is applied at the linear solver level, not at the outer NLP level, allowing for scenario clusters to change from iteration to iteration. This approach allows one to build a small and sparse pre-conditioner with fewer clusters, and then solve the full KKT system in parallel using GMRES. We also describe the features of our implementation in C++, demonstrate that high scenario compression rates of up to 94% can be obtained, and that speedups of an order of magnitude are achievable.

2 - Optimization Driven Scenario Grouping

Kevin C Ryan, Georgia Institute of Technology, Atlanta, GA, United States, kryan31@gatech.edu, Shabbir Ahmed, Santanu Subhas Dey, Deepak Rajan

Scenario decomposition algorithms for stochastic programs compute bounds by dualizing all nonanticipativity constraints and solving individual scenario problems. We develop an optimization problem that selects a set of nonanticipativity constraints to re-enforce, placing scenarios into `groups'. We show that the proposed grouping problem is NP-hard in general, identify a polynomially solvable case, and present a mixed integer programming formulation. Its effectiveness is demonstrated on a set of standard test instances for two-stage 0-1 stochastic programs. The idea is extended to propose a finitely convergent algorithm for two-stage stochastic programs with a finite feasible region.

3 - MIDAS: A Mixed Integer Dynamic Approximation Scheme

Andy Philpott, University of Auckland, Auckland, New Zealand, a.philpott@auckland.ac.nz, Faisal Wahid, Frederic Bonnans

Mixed Integer Dynamic Approximation Scheme (MIDAS) is a sampling-based algorithm for solving finite-horizon stochastic dynamic programs with monotonic Bellman functions. MIDAS approximates these value functions using step functions, leading to stage problems that are mixed integer programs. We provide a general description of MIDAS, and illustrate it on some instances of revenue maximization problems for hydroelectricity generators.

4 - Nested Decomposition Of Multistage Stochastic Integer Programs With Binary State Variables

Jikai Zou, Georgia Institute of Technology, Atlanta, GA, United States, jikai.zou@gatech.edu, Shabbir Ahmed, Andy Sun

We propose a valid nested decomposition algorithm for multistage stochastic integer programming problems when the state variables are binary. We prove finite convergence of the algorithm as long as the cuts satisfy some sufficient conditions. We discuss the use of well known Benders' and integer optimality cuts within this algorithm, and introduce new cuts derived from a reformulation of the problem where local copies of state variables are introduced. We propose a stochastic variant of this algorithm and prove its finite convergence with probability one. Numerical experiment on a large-scale generation expansion planning problem will be presented.

1 - Tight Formulations For Value-at-Risk Minimization Problems

Konstantin Pavlikov, University of Florida, Gainesville, FL, 32611, United States, kpavlikov@ufl.edu, Alexander Veremyev, Eduardo Pasiliao

The problem of minimization of Value-at-Risk via MIP formulations with big M constants is considered. Special emphasis is put to setting the tightest big M for every scenario where it should be positive. We show that the problem of setting the tightest possible M is equivalent to solving another instance of VaR minimization problem. Moreover, we propose a specialized branch-and-bound algorithm to solve the problem that dynamically updates big Ms during its execution. Computational experiments are provided and discussed.

2 - A Two-stage Stochastic Program With Joint-chance Constraints For A Hybrid Wind-conventional Generator System

Bismark Singh, The University of Texas at Austin, Austin, TX, bismark.singh@utexas.edu, David Morton, Surya Santoso

We consider an application of a two-stage joint chance constrained stochastic program with recourse to power generation. As a first stage decision we promise an hour-by-hour firm energy output to the system operator. The conventional generator serves as a recourse option which can be used if the uncertain wind output is not large enough. We seek to ensure that with high probability our promised energy output is met by this generator and wind combination. We computationally investigate this joint-chance constrained model with recourse, using data from Texas

3 - An Integer L-shaped Approach To A Stochastic Program With Endogenous Uncertainty And Chance-constrained Recourse

Gabriel Lopez Zenarosa, Assistant Professor, University of North Carolina at Charlotte, 9201 University City Blvd., Cameron Hall 242, Charlotte, NC, 28223, United States, gzenaros@uncc.edu Oleg A. Prokopyev, Andrew J. Schaefer

We present a stochastic integer program with chance-constrained recourse for the surgery scheduling and one-time rescheduling problem. Our goal is to provide an approach for creating initial surgery schedules that afford agility in day-of-surgery rescheduling so as to minimize the total expected operating-room underutilization under probabilistic overutilization constraints. We use the integer L-shaped method to iteratively refine the initial surgery schedule to enable subsequent rescheduling of surgeries under the scenarios the initial schedule induces.

4 - Solving 0-1 Semidefinite Programs For Distributionally Robust Allocation Of Surgery Blocks

Yiling Zhang, University of Michigan, Ann Arbor, MI, United States, zyiling@umich.edu, Siqian Shen, Ayca Erdogan

We consider surgery allocation in operating rooms (ORs) under random surgery durations. We minimize the cost of opening ORs and surgery assignments, while restricting OR overtime risk via a distributionally robust (DR) chance constraint, built on a moment-based ambiguous set. Following the conic duality, the DR chance-constrained model is equivalent to a 0-1 semidefinite program, solved by a cutting-plane algorithm. Alternatively, we optimize a less conservative 0-1 second-order conic program approximation. We test outpatient treatment instances, and compare different approaches.

1 - Updates To PIPS-SBB: Distributed-memory Structure-aware Presolve And Cut Generation

Geoffrey Malcolm Oxberry, Lawrence Livermore National Laboratory, Livermore, CA, United States, oxberry1@llnl.gov Lluis-Miquel Munguia, Cosmin G Petra, Pedro Sotorrio, Thomas Edmunds, Deepak Rajan

Deterministic equivalent formulations of stochastic MIPs from applications such as unit commitment (UC) can exceed available memory on a single workstation. To overcome this issue, we have developed PIPS-SBB, a distributed-memory parallel stochastic MIP solver based on the distributed-memory parallel stochastic LP solver PIPS-S. Our initial work focused on implementing a distributed-memory B&B algorithm that parallelizes LP solves. To further improve performance, we discuss implementing structure-aware variants of presolve methods and cuts, and how these methods improve performance. Based on these results, we discuss a path forward to solving large UC problem instances.

2 - Generating And Solving The Large Scale AC-security Constrained Optimal Power Flow Problems In Parallel

Feng Qiang, Argonne National Laboratory, Lemont, IL, 60439, United States, fqiang@anl.gov, Cosmin G Petra, Joseph A Huchette, Miles Lubin, Mihai Anitescu

In this talk, we present an integrated approach for the modelling and solution of the AC-SCOPF problems using StructJuMP, a newly developed parallel extension of JuMP for modelling large scale optimization problems in Julia and PIPS optimization solver for HPC platforms. We will present a thorough study of the the parallel performance of StructJuMP and PIPS for large scale AC-SCOPF instances on hundreds of nodes.

3 - Paraxpress: A Massively Parallelized MIP Solver Designed To Run On The Largest Supercomputers

Yuji Shinano, Zuse Institute Berlin, Takustrasse 7, Berlin, 14195, Germany, shinano@zib.de, Timo Berthold, Stefan Heinz

The Ubiquity Generator (UG) is a framework for the external parallelization of MIP solvers. It was used to develop ParaSCIP, a distributed memory, massively parallel version of the open source solver SCIP, that runs on up to 80,000 cores in parallel. In this talk, we introduce ParaXpress, for which one of the fastest commercial MIP solvers, the FICO Xpress-Optimizer, has been parallelized by UG. Combining the internal shared-memory parallelization of Xpress and the external parallelization of UG, we aim at a new order of magnitude for supercomputer core-usage in MIP solving.

1 - Models And Algorithms For Maximum Proportional Flow Problems With Semicontinuous Restrictions

Robert Mark Curry, Clemson University, Clemson, SC, United States, rmcurry@g.clemson.edu, Cole Smith

We consider a variation of the multi-source, multi-sink maximum flow problem in which flow must emanate from the source nodes according to a prescribed rate, while flow arrives to the sink nodes at another given rate. Additionally, we restrict flow variables to be semicontinuous, in which the flow must either be 0 or no less than some lower bound. We call this problem the semicontinuous maximum proportional flow problem (SC-MPFP) since the amount of outgoing flow must leave the source nodes and arrive at the sink nodes according to a given proportional pattern. To solve the SC-MPFP, we decompose the formulation and employ a Branch-and-Price algorithm.

2 - Enumeration Algorithms For Infrastructure Resilience Analysis

W Matthew Carlyle, Naval Postgraduate School, mcarlyle@nps.edu, David Alderson

We propose a functional definition of infrastructure resilience based on parametric analysis of two-stage (attacker-defender) and three-stage (defender-attacker-defender) models that require enumeration of a potentially enormous number of optimization problems. We present computational techniques that use bounding arguments to significantly limit the enumeration while still providing useful measures of infrastructure resilience and support the use of faster heuristic algorithms for the most difficult of these problems.

3 - Faster Algorithms For The Time-cost-tradeoff Problem And Minimum Cost K-flow Problems With A New All-min-Cuts Procedure

Dorit S. Hochbaum, University of California, Berkeley, Berkeley, CA, United States, hochbaum@ieor.berkeley.edu

We explore surprising links between the time-cost-tradeoff (TCT) problem in project management and the minimum cost flow problem (MCF) leading to faster algorithms for both problems. The algorithm relies on a new procedure all-min-cuts procedure, which for a given maximum flow, is capable of generating all minimum cuts of equal value very efficiently. This results in faster strongly polynomial algorithms for unit capacity MCF, the K-MCF problem and uniform costs TCT and match the complexity of the fastest algorithm for the assignment problem.

Novel Dimension Reduction Techniques for High Dimensional Data Using Information Complexity

Invited: Tutorial

Invited Session

Chair: Hamparsum Bozdogan, University of Tenneesse-Knoxville, Oper and Mgmt Sci, Knoxville, TN, 37996, United States, bozdogan@utk.edu

1 - Novel Dimension Reduction Techniques For High Dimensional Data Using Information Complexity

Hamparsum Bozdogan, University of Tennessee-Knoxville, Oper and Mgmt Sci, Knoxville, TN, 37996, United States, bozdogan@utk.edu, Esra Pamukcu

This tutorial introduces and develops two computationally feasible intelligent feature extraction techniques that addresses the potentially daunting statistical and combinatorial problems. First part of the tutorial employs a three-way hybrid between: Probabilistic Principal Component Analysis (PPCA) to reduce the dimensionality of the dependent variables; Multivariate regression (MVR) models that account for misspecification of the distributional assumption to determine a predictive operating model for glass composition for automobiles; and uses the genetic algorithm (GA) as the optimizer along with the misspecification-resistant form of Bozdogan's ICOMP as the fitness function. Second part of the tutorial is devoted to dimension reduction via a novel Adaptive Elastic Net (AEN) regression model to reduce the dimension of a Japanese stock index called TOPIX as the response to build a best predictive model when we have "large p, small n" problem. Our results show the remarkable dimension reduction in both of these real-life examples of wide datasets, which demonstrates the versatility and the utility of the two proposed novel statistical data modeling techniques.

1 - Optimal Pooling Strategies For Nucleic Acid Testing Of Donated Blood Considering Viral Load Growth Curves And Donor Characteristics

Hadi El-Amine, Virginia Tech, Blacksburg, VA, United States, hadi@vt.edu, Hadi El-Amine, George Mason University, Fairfax, VA, 22030, United States, hadi@vt.edu, Ebru Korular Bish, Douglas R Bish

Blood product safety, in terms of being free of transfusion-transmittable infections (TTIs), is crucial. Nucleic Acid Testing (NAT) technology enables earlier detection of infections but is more expensive, hence, most blood centers administer NAT to pools of blood samples from multiple donors. Since some donor characteristics are uncertain, we develop a chance-constrained model that determines the optimal NAT pool sizes for various TTIs, considering both non-universal (where first-time donors undergo more extensive screening), and universal (i.e., common testing for all donors) strategies, so as to minimize the TTI risk, while remaining within the testing budget with a high probability.

2 - Infection Control In Outpatient Clinics: The Risk- Efficiency Tradeoff

Cory Stasko, Massachusetts Institute of Technology, cstasko@mit.edu,

As HAIs remain a major problem and U.S. healthcare shifts towards outpatient, understanding the risk of HAIs in this environment is important. For a particular clinic, we simulate the potential impacts of two interventions: 1) improving hand hygiene, and 2) separating likely infectious patients from other patients. By creating an integrated discrete event and agent based model to simulate patient flow and the spread of infections, we examine how these two domains interact, testing 891 intervention combinations in terms of wait time, infection exposures, and implementability. Interdependent effects and the tradeoff between risk reduction and operational efficiency are discussed.

3 - Social Desirability Bias In Self-reported Compliance With Hand-hygiene Regulations

Reidar Hagtvedt, University of Alberta School of Business, 2-43 Business Building, Edmonton, AB, T6G 2R6, Canada, hagtvedt@ualberta.ca, Kenneth L. Schultz, Sarah Forgie

We posit Social Desirability Bias (SDB) as an explanation for why self-reported compliance with hand-hygiene (HH) regulations is so much higher than observed compliance. SDB breaks down into self-deception and image management. Using data gathered at a large teaching hospital over six years, we first show that in spite of the two measures being nearly uncorrelated, respondents do know something of their own compliance rate, and secondly, that image-management is a greater effect than self-deception.

4 - Reducing Surgical-site Infections For Coronary Artery Bypass Graft Patients

Eva Lee, Georgia Tech, evakylee@isye.gatech.edu

This is joint with Grady Health Systems. A system-approach is designed to reduce surgical site infection (SSI) which takes into account the inter-dependency of preoperative, intraoperative and postoperative processes. A decision tree model and a simulation-optimization model are developed to identify critical infection factors. Changes involve pre-op sterilization, nasal cleaning, hair-clipping, and optimized antibiotics prophylaxis timing and dosage. E-alerts are also implemented for compliance. The hospital realized a drop of 65% in SSI (from 23% to 8%) in the first six months. It achieved zero percentage thereafter and sustained that rate for 18 months.

Joint Panel Session: ORHP/HAS/MSOM-Hlth: Challenges and Lessons Learned from Influencing National Policy Change in Organ Transplant

Invited: ORinformed Healthcare Policies

Invited Session

Moderator: Sanjay Mehrotra, Northwestern University, 2145 Sheridan, Evanston, IL, 60208, United States, mehrotra@iems.northwestern.edu

1 - Challenges And Lessons Learned From Influencing National Policy Change In Organ Transplant

Sanjay Mehrotra, Northwestern, mehrotra@northwestern.edu

Policy changes are being debated nationally to reduce disparity and improve efficiency in organ allocation. These issues are contentious within the transplant community as such policy changes impact patient lives lost and finances at the regional and national level. Operations research models have been used to help arrive at recommendations in the past, but get questioned. This session will focus on lesson learned from discussions with the transplant community that would be helpful for policy related research in other areas of work in healthcare. The panelists have worked closely with the transplant community as joint researchers, advisors and reviewers of proposed changes.

2 - Panelist

Andrew J Schaefer, Rice University, andrew.schaefer@rice.edu

Risk Management in Global Food Supply Chains

Sponsored: Health Applications

Sponsored Session

Chair: Retsef Levi, MIT, 100 Main Street, Building E62-562, Cambridge, MA, 02142, United States, retsef@mit.edu

1 - A Data-Driven Approach To Managing Food Safety In Global Supply Chains

Amine Anoun, Massachusetts Institute of Technology, aanoun@mit.edu

Economically motivated adulteration poses a serious threat to public health. Prevention is achieved by sampling food shipments. However, the sampling resources are limited. In an effort to mitigate risk in the shipping supply chains, we develop a data-driven approach to identify risky manufacturers. We obtained over 850,000 shipment records of shrimp to the U.S. from the FDA. We determine structural features of shipping supply chains that correlate with risk of adulteration, at the global scale and in China. We use a Bayesian approach to model both the risk of adulteration, and the sampling procedure of the FDA, and show that our model predicts high risk manufacturers with high accuracy.

2 - Economically Motivated Adulteration In Agriculture Supply Chains

Somya Singhvi, Massachusetts Institute of Technology, Cambridge, MA, United States, ssinghvi@mit.edu, Retsef Levi, Yanchong Zheng

We study how dispersion and quality uncertainty affect adulteration risk in agriculture supply chains. Our model captures the effects of testing accuracy and traceability on adulteration decisions by suppliers. We characterize conditions under which adulteration risk increases with dispersion or quality uncertainty. Further, we also analyze quality assurance policies for manufacturers in the presence of a risk threshold.

3 - The Role Of Farming Supply Chain Structure In Driving Economically Motivated Food Adulteration

Shujing Wang, Massachusetts Institute of Technology-ORC, shujing@mit.edu

We investigate how the structure of farming supply chains and regulatory measures are correlated with the risk of economically motivated adulteration of food products.We define the dispersion of a farming supply chain, which measures how distributed a food manufacturer's farming sources are. We collect farm-level data on over 1,000 Chinese manufacturers in the honey, pork, poultry, egg, and seafood industries to quantify the dispersion of their farming supply chains. Combining farm-level data and quality data, we show that a more dispersed farming supply chain is more prone to the risk of economically motivated adulteration.

Dynamics of Competition

Invited: Strategy Science

Invited Session

Chair: Daniel Levinthal, Wharton School, University of Pennsylvania, Philadelphia, PA, 19104, United States, dlev@wharton.upenn.edu

1 - Changes In Persistence Of Performance Over Time

Claudine Gartenberg, New York University, Stern Business School, New York, NY, 1, United States, cgartenb@stern.nyu.edu
Victor Bennett

One of the central puzzles of strategy is the persistence of superior performance. About a decade ago a stream of research emerged looking at changing persistence over time and finding a trend toward a new "age of temporary advantage". We extend the time series from these analyses and introduce new tools from the literatures on social mobility and economic growth. We find that the trend reversed itself and the beginning of the 21st century has been characterized by increasing persistence of superior performance. This trend is not due to changes in industry composition or newly public listings. Instead we report this reversal both within and across industries and primarily within established firms.

2 - Markets For Technology And The Technological Trajectories Of Entrepreneurial Startups

Mahka Moeen, University of North Carolina, Chapel Hill, NC, 03, United States, mahka_moeen@kenan-flagler.unc.edu
Seth Carnahan

This paper focuses on how entrepreneurial startups shape their opportunity set for participation in the market for technology, by pursuing investments that increase their attractiveness as a technology seller. Because startups in technological proximity to a technology buyer may be considered favorable technology sellers, we suggest that investment by potential buyers in a technical domain is likely to spur investments by startups in the same or proximate domains. We further examine the moderating effects of the direction of scientific progress, commercial applicability, and density of the buyer's alliance portfolio. The empirical context is plant biotechnology field experiments.

3 - The Entrepreneurial Process: Evidence From A Nationally Representative Survey

Aaron Chatterji, Duke University, Faqua School of Business, 100 Fuqua Drive, Durham, NC, 27708, United States, ronnie@duke.edu, Victor Bennett

Using data from a new nationally representative survey of Americans, we document patterns in the process of firm entry via entrepreneurship. Only 1/3 of our respondents have even considered starting a business, motivated in the vast majority of cases by non-pecuniary concerns rather than the pursuit of significant market opportunities. Fewer than half of those who considered starting a business take even the lowest cost steps, like searching the Internet for potential competitors or speaking with a friend. This surprising lack of progress is evident in comparison to nationally representative evidence on job search activities.

4 - Venture Capital Investment Strategies Under Financing Constraints: Evidence From The 2008 Financial Crisis

Annamaria Conti, Georgia Institute of Technology, Atlanta, GA, 30332, United States, annamaria.conti@scheller.gatech.edu
Stuart Graham, Nishant Dass

Employing the 2008 financial crisis as an empirical setting, we examine the investment strategies of venture capitalists (VCs) in response to liquidity supply shocks. While predictably VCs reduce investment, we show that VCs reposition by increasing their share of, and per-round funding to, startups operating in the VCs' core sectors. These effects are driven by more-experienced VCs, and are strongest in early-stage portfolio startups. Consistently, we find superior ex-post performance among crisis-funded portfolio startups operating in more-experienced VCs' core sectors. Our findings point to more-experienced VCs possessing information advantages, especially in their core sectors.

Latest Developments in Scheduling Research

Invited: Project Management and Scheduling

Invited Session

Chair: Zhi-Long Chen, Professor, University of Maryland, Van Munching Hall, College Park, MD, 20742, United States, zchen@rhsmith.umd.edu

1 - A Polyhedral Study Of The Physician Scheduling Problem With Equalization Constraints

Pelin Damci-Kurt, Lightning Bolt Solutions, South San Francisco, CA, United States, pelin@lightning-bolt.com, Minjiao Zhang

We study a physician scheduling problem in which the goal is to minimize the penalties associated with different requirements over a finite horizon. The problem is divided and solved in two phases according to penalty values. We focus on a relaxation including assignment demand and equalization constraints. We present a class of valid inequalities, and report preliminary computational experiments with them in a branch-and-cut algorithm on our client data sets.

2 - Models For Workforce Scheduling In A Union Shop

John Mittenthal, The University of Alabama, Tuscaloosa, AL, 35487, United States, jmittent@cba.ua.edu, Minjiao Zhang

We develop an assignment problem model for worker to job assignments that deviates as little as possible from a shift supervisor's allocation of these workers. These deviations occur due to worker absences. In addition to validating the model over four weeks of data, we investigate a number of what-if questions.

3 - An Integrated Production Scheduling And Outbound Vehicle Routing Problem

Kunpeng Li, Huazhong University of Science and Technology, likp@hust.edu.cn

In this integrated production scheduling and vehicle routing problem, there is a single machine for production and limited vehicles with capacity constraints for transportation. The objective is to determine the decisions about production scheduling, transportation batching and vehicle routing, to minimize the maximum order delivery time. Based on an optimal property for production scheduling and transportation batching, backward and forward batching methods are developed, which are embedded into an improved genetic algorithm. The results show that the genetic algorithm can provide high quality solutions, compared with a two-stage algorithm and a published genetic algorithm.

4 - Integrated Production, Inventory And Distribution Problems

Zhi-Long Chen, University of Maryland, zchen@rhsmith.umd.edu
Feng Li, Lixin Tang

We consider several integrated production, inventory and delivery problems that arise in practical settings where customer orders have pre-specified delivery time windows and are first processed in a plant and then delivered to the customers by transporters that have fixed delivery departure times. The objective is to find an integrated schedule for processing the orders, keeping finished orders in inventory if necessary, and delivering them to the customers such that the total inventory and delivery cost is minimum. We study complexity and propose algorithms for various problems. For the two most general problems, we propose combined column generation and tabu search heuristic algorithms.

Auction Design Topics

Invited: Auctions

Invited Session

Chair: Sasa Pekec, Duke University, 100 Fuqua Drive, Durham, NC, 27708-0120, United States, pekec@duke.edu

1 - Stable Matchings With Proportionality Constraints

Thanh Nguyen, Purdue University, nguye161@purdue.edu, Rakesh Vinay Vohra

In designing two sided markets, a stable matching is often desired to satisfy certain additional side constraints. Current literature has mainly focused on constraints where the relevant "right hand sides" are absolute numbers specified a-priori; before agents on the "proposing" side make their participation decisions. There is a danger, then, of over constraining the problem. It is sometimes more natural to express the relevant constraints as proportions. We develop a framework to obtain stable matchings that almost satisfy floor and ceiling proportional side constraints. Our results are based on a generalization of Scarf's lemma, which is of independent interest.

2 - Budget-constrained Procurement

Alexandre Belloni, Duke University, abn5@duke.edu
Giuseppe Lopomo, Leslie Marx, Roberto Steri

We consider a setting where a buyer procures up to D units of a homogeneous good (e.g. a medical drug) but needs to satisfy a hard budget constraint of spending at most B in total payments. Furthermore, the buyer faces suppliers with privately known costs. We characterize the optimal procurement mechanism as well as new simple mechanisms (which are at least as good as the second price auction with reservation price) that are easy to implement via a sequential auction. In particular we highlight how the budget constrain fundamentally alters the structure of the optimal mechanism.

3 - Robust Bidding Policies

Sasa Pekec, Duke University, pekec@duke.edu

We study the best-response decision problem of an auction bidder who wants to maximize her worst-case payoff, while facing uncertainty about rivals' objectives and bids. The information about rivals is modeled via an uncertainty set consisting of all possible realizations of rivals' bids. Maximizing the bidder's worst-case payoff over this set yields robust bidding policies that do not depend on distributional assumptions. Robust bidding policies are constructed for several multi-item auction formats, depending on how supply (homogeneous or heterogeneous items) and demand (unit-demand or multiple-demand bidders) is handled.

Panel: Emerging Themes in Innovative Operations

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Moderator: Nitin Joglekar, Boston University School of Management, 595 Comm Ave, Boston, MA, 02215, United States, joglekar@bu.edu

Co-Moderator: Stylianos Kavadias, University of Cambridge, Trumpington Street, Cambridge, CB2 1AG, United Kingdom, s.kavadias@jbs.cam.ac.uk

1 - Innovative Operations

Nitin Joglekar, Boston University School of Management, joglekar@bu.edu

We draw upon an expert panel to discuss emerging innovation research themes in the manufacturing and service operations context by raising the following “when, what and how” questions: (i) Are operations essential for creating innovation (e.g. in terms of product and services)? (ii) Are operations essential to compete in innovative ways (e.g. through business model innovations and/or through supply chain innovations)? (iii) Are operations based innovations critical in establishing new businesses (e.g. through entrepreneurship)?

Empirical Research in Operations Management

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Nathan C. Craig, Ohio State University, 630 Fisher Hall 2100 Neil Avenue, Columbus, OH, 43210, United States, craig.186@osu.edu

1 - Dynamic Optimization Of Multichannel Advertising Campaigns In An Online Advertising Supply Chain

Changseung Yoo, The University of Texas at Austin, Austin, TX, United States, csyoo@utexas.edu, Anitesh Barua, Genaro Gutierrez

We examine channel structures and pricing models in an online advertising supply chain using a proprietary dataset. The supply chain consists of two channels - a network and an exchange - from which an ad agency buys advertising inventory and sells them to an advertiser. We design a nonlinear Kalman filter to estimate an extension of the Sethi advertising model and derive the optimal closed-loop strategies for the advertising agency. We then compare them to the approximate solutions based on the Nerlove-Arrow model and derive managerial insights. Our analyses furnish strong support for the synergy effects between the channel structures due to strategic complementarities between the channels.

2 - Variability In Labor Schedules: Effects On Store Performance And Employee Turnover

Hyun Seok Lee, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, Hyunseok_Lee@kenan-flagler.unc.edu, Saravanan Kesavan, Camelia Kuhnen

Millions of employees face work schedules that are changed frequently by firms trying to match labor to demand. Prior work has shown that unstable schedules have negative consequences on worker life quality. Here, using detailed personnel records from the retail industry, we find that variability in labor schedule negatively affects store performance metrics such as sales, number of transactions, and employee turnover.

3 - Reference Points In Replacement Purchases

Mahdi Mahmoudzadeh, Georgia Institute of Technology, mahdi.mzh@scheller.gatech.edu

We study reference-points in replacement purchases, trade-ins and upgrades, wherein customers replace their in-use product with its newer version. Through an experimental study, we find that with trade-ins, irrespective of the new version’s innovation level, the secondary market price is the reference-point. With upgrades, however, depending on the innovation level and the manufacturer’s decision on co-production of successive versions, the new version’s price, the current selling price the old version, or the original price of the old version is the reference-point. We also find that the manufacturer can always frame a replacement purchase to induce the same reference-point as in buy-backs.

4 - Rewarding Service And Serving Rewards: Strategic Complications To Order Management

Somak Paul, Doctoral Student, The Ohio State University, 600 Fisher Hall, 2100 Neil Avenue, Columbus, OH, 43202, United States, Paul.865@osu.edu, Nathan C. Craig, Elliot Bendoly

We conduct laboratory experiments to identify how order complexities including strategic-level factor relating to demand management affect the ordering behavior of those in purchasing management roles and thus induce variation in upstream orders. We further investigate how the backorder and surplus cost structure moderates the relationship between the service-dependent demand and order variation. We finally recommend strategic directions for the purchasing manager and suggest personality traits to look for while choosing purchasing managers.

MSOM Energy and Sustainability

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Yangfang Zhou, Singapore Management University, Singapore, Singapore, helenzhou@smu.edu.sg

1 - Strategic Forward Trading And Technology

Heikki Peura, London Business School, hpeura@london.edu, Derek W Bunn

We analyze how operational factors of production, such as its flexibility and reliability, can influence market prices indirectly through altering the balance of spot and forward trading. As a result, increasing the capacity of intermittent renewable electricity generation, despite its lower marginal cost, may not necessarily reduce prices.

2 - Repositioning Operations In One-way Vehicle Sharing Systems

Long He, National University of Singapore, longhe@nus.edu.sg Zhenyu Hu, Meilin Zhang

We study the repositioning problem in one-way vehicle sharing systems, in order to balance the fleet and meet the demands. We formulate the problem as a dynamic program and also discuss the optimal policy.

3 - Merchant Operations Of An Aluminium Smelter

Selvaprabu Nadarajah, College of Business, University of Illinois at Chicago, Chicago, IL, United States, selvan@uic.edu, Stein-Erik Fleten, Denis Mazieres, David Pisinger, Alessio Trivella

Motivated by an Aluminium producer, we consider the merchant operations of a smelter facing predictable Aluminium demand and volatile electricity prices. This smelter endows a merchant with flexibility to (i) choose between the production, mothballs, and shutdown operating states; and (ii) procure electricity needed for operations using forward contracts with different maturities and underlying currencies. We formulate the management of these flexibilities as a stochastic optimization problem. We overcome the intractability in computing optimal operating and sourcing policies by combining least squares Monte Carlo with stochastic programming. Preliminary findings will be discussed.

Empirical Studies in Operations Management

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Suresh Muthulingam, The Pennsylvania State University, University Park, PA, United States, suresh@psu.edu

1 - Are Patients Patient? The Role Of Time To Appointment On Patient Flow

Diwas S KC, Emory University, diwas.kc@emory.edu

We examine the effect of wait to appointment on patient flow - specifically, on a patient's decision to schedule an appointment and arrive for that session. Contrary to previously-reported findings, our results suggest that some wait can be beneficial for reducing no-shows.

2 - Product Complexity, Network Position, And Product Innovation

Yingchao Lan, PhD Candidate, The Ohio State University, 2100 Neil Avenue, Fisher Hall 252C, Columbus, OH, 43210, United States, lan.63@osu.edu, John Gray, Aravind Chandrasekaran, Brett Massimino

Despite a consensus that a firm's extended product development network plays a critical role in its innovation performance, empirical evidence linking network position, product complexity, and product innovation performance is scarce. We provide a longitudinal study employing secondary data to investigate these relationships.

3 - Managerial Attention, Reminders And The Energy Efficiency Gap

Enno Siemsen, University of Wisconsin-Madison, esiemsen@wisc.edu, Suvrat Dhanokar

Reminders have been shown to at the individual level increase adherence to medical prescriptions and savings goals. We demonstrate that reminders also help to increase environmental project implementation at the organizational level. Using data from a state technical assistance program, we also demonstrate the contextual effects that make reminders more effective.

4 - Does Learning From Inspections Affect Environmental Performance? - Evidence From Unconventional Oil And Gas Wells

Suresh Muthulingam, The Pennsylvania State University, State College, PA, United States, suresh@psu.edu
Vidya Mani

Manufacturing firms increasingly face environmental inspections that determine whether their operations comply with environmental regulations. We investigate how firms learn from their own inspection experiences as well as from the experiences of other firms. We identify the characteristics of the inspection experience that enable firms to improve their environmental performance.

Chair: Panos Kouvelis, Washington University in St. Louis, One Brookings Drive, Box 1156, Saint Louis, MO, 63130, United States, kouvelis@wustl.edu

Co-Chair: Wenhui Zhao, Associate Professor, Shanghai Jiao Tong University, 1954 Huashan Road, Shanghai, 200030, China, zhaowenhui@sjtu.edu.cn

1 - Optimal Monitoring In Collateralized Lending

Dan Andrei Iancu, Stanford University, Stanford, CA, United States, daniancu@stanford.edu, Nikolaos Trichakis, Do Young Yoon

Collateralized lending agreements critically rely on the lender's ability to monitor the value of a borrower's pledged assets, and to decide when these are sufficient to cover the outstanding loan. To further complicate matters, lenders often have to take such decisions under limited information concerning the assets' future value. Our work focuses on the problem of choosing a monitoring and liquidation policy for a lender when a finite number of monitoring times are possible during the life of the loan. We develop a robust optimization model and provide characterizations for the optimal choices involved.

2 - Financial Pooling In A Supply Chain

Alex Song Yang, London Business School, London, United Kingdom, sayang@london.edu, Ming Hu, Qu Qian

Trade credit is common in supply contracts. We find the embedded stretch option of trade credit (i.e., buyers paying suppliers after the agreed due day) allows supply chain partners to pool their liquidity. As such, even as the supplier's financing costs are strictly higher than the buyer's, the buyer may still demand for trade credit. In addition, trade credit is more efficient when the supplier's cost for collecting trade credit is low (e.g., when the retailer trusts the supplier), when the supplier's financing cost is high when facing liquidity shocks, or when the buyer has a more diversied supplier portfolio. Finally, reverse factoring further enhances this pooling benefit.

3 - Effective Donor Fund Allocation For Health Product Procurement

Iva Petrova Rashkova, Washington University in St Louis, irashkova@wustl.edu, Jeremie Gallien

Motivated by Global Fund grant recipients, we study the procurement of health products subject to an uncertain funding schedule. Such schedule includes either periodic lump-sum disbursements or per-unit subsidy agreements, or both. The objective is to minimize expected health costs in the presence of random demand and lost sales inventory dynamics. We design near-optimal financing mechanisms for the allocation of donor funds, characterize their theoretical and computational performance, and discuss managerial insights.

4 - Who Should Finance The Supply Chain: Impact Of Credit Ratings on Supply Chain Decisions

Wenhui Zhao, Associate Professor, Shanghai Jiao Tong University, 1954 Huashan Road, Antai College of Economics and Management, Shanghai, 200030, China, zhaowenhui@sjtu.edu.cn, Panos Kouvelis

We study the impact of credit ratings on supply chain decisions. The retailer can use bank loans and/or trade credits, while the supplier can use bank loans and/or retailer's early payment. The bank's risk premium decreases in the borrower's credit rating. We show if the supplier's credit rating is above a threshold, she will offer zero interest rate trade credits and the retailer will use trade credits only. Otherwise, she will set positive rate so that the retailer uses bank loans only or combines them with trade credits. While a supplier always benefits by working with good credit rating retailers, it may not be necessarily true for the retailer, who may benefit by working with low credit rating suppliers.

Scheduling III

Contributed Session

Chair: Sangoh Shim, Hanbat National University, Dept of Business Administration, Deokmyung-Dong, Daejeon, 305-719, Korea, Republic of, mizar0110@gmail.com

1 - Integrated Pricing And Production Scheduling Under Make-to-order Strategy

Guohua Wan, Professor, Shanghai Jiao Tong University, 1954 Huashan Road, Antai College of Economics and Management, Shanghai, 200030, China, ghwan@sjtu.edu.cn, Qing Yue, Zhi-Long Chen

we consider a joint pricing and production scheduling problem where the manufacturing firm produces a number of customized products from a base product. At the beginning of each period in a planning horizon, the firm sets the price of the base product as well as the prices for the customized products, and processes the accepted orders on a single production line, so as to maximize the total profit of the orders over the planning horizon. Three specific problems with different order acceptance and processing modes are studied, and computational complexity and solution algorithms are presented.

2 - Optimal Course Scheduling For United States Air Force Academy Cadets

Christopher D. Richards, Colorado School of Mines, Golden, CO, United States, capt.soup@gmail.com

The United States Air Force Academy spends months scheduling approximately 1,500 courses and 4,000 cadets. By building alternatives based on department preferences, we develop an integer program to generate course and cadet schedules which fulfill registration, department and institution needs. Specifically, we observe enrollment and staffing limits, military time requirements, and athletic commitments. Efficient formulation and solution methods including heuristics provide quick turnaround for an iterative process between departments and the registrar. Easily resolving scheduling conflicts ensures all cadets meet crucial commissioning deadlines.

3 - Minimizing The Total Number Of Late Multi-task Jobs On Identical Machines

Hairong Zhao, Purdue University Calumet, 2200 169 Street, Hammond, IN, 46323, United States, hairong@pnw.edu
Lingxiang Li, Haibing Li

We consider scheduling multi-task jobs on identical machines in parallel. Each job consists of one or more tasks that can be processed by any machine. The tasks of a job can be processed concurrently. Preemptions are not allowed. Each job has a release date and a due date. The completion time of a job is the time when all of its tasks have been completed. We focus on the problem of minimizing the number of late jobs. We show that while some special cases are solvable, the general problem is NP-hard and admits no constant approximation algorithm unless =NP. We then present a framework of a general algorithm for the problem and derive from it six heuristics whose performance is evaluated by experimental results.

4 - An Improvement In NSGA II For Resource Constrained Project Scheduling Problem

Fikri Kucuksayacigil, Iowa State University, 610 Squaw Creek Drive, Unit 18, Ames, IA, 50010, United States, fksayaci@iastate.edu

Resource constrained project scheduling problem has been extensively studied. For multi-objective form of this problem, since finding an optimum solution is nearly impossible, several metaheuristic methods have been proposed and implemented. Non-dominated sorting genetic algorithm (NSGA II) has been one of the most effective algorithms in this respect. In this study, we develop a hybrid simulated annealing / NSGA II algorithm to find more diverge and better quality results. The results show that our algorithm visits more solutions in the solution space.

5 - Production Scheduling Of Jobs With Fixed Processing Property On Parallel Machines

Sangoh Shim, Hanbat National University, Dept of Business Administration, Deokmyung-Dong, Daejeon, 305-719, Korea, Republic of, mizar0110@gmail.com

One of the important things for smart factory is an intelligent production scheduling, how to schedule jobs effectively and efficiently. This problem is for scheduling jobs on parallel machines with the fixed processing property in which a group of specific jobs can be processed on the predetermined machine. Usually, even though parallel machines can process various types of jobs, fixed processing are preferred not to deteriorate products' quality. Also, in this problem, when changing process of different groups of jobs, operations for changing type of groups, called as setup, are necessary. To minimize makespan of jobs, several heuristic algorithms are devised.

Simulation and Optimization III

Contributed Session

Chair: Prasanna Kumar Ragavan, Virginia Tech, Durham Hall, Blacksburg, VA, 24061, United States, rpkumar@vt.edu

1 - Managing Escalations: Equipment Failure And Response Capacity Allocation

Marc Christiaan Jansen, PhD Candidate, Cambridge Judge Business School, Downing College, Regent Street, Cambridge, CB2 1DQ, United Kingdom, mcj32@cam.ac.uk
Nektarios Oraiopoulos, Daniel Ralph

Failure of medical equipment represents a cause of downtime for hospitals and may lead to life-threatening circumstances for patients. At the onset of such failure, the scale of the disruption is typically unknown. This paper examines how contracting decisions between a maintenance service provider and multiple clients can enable efficient allocation of response capacity under imperfect and asymmetric information on the true nature of the disruption.

2 - Illusion Of Control In Resource Allocation Decision Making

Howard Charles Ralph, Visiting Assistant Professor, Western Carolina University, 201 Edgemont Avenue, Liberty, SC, 29657-1110, United States, r_11l1f@hotmail.com

Resource allocation decisions drive the managerial function of control and are basic to business school curricula. Decision problems, deterministic or probabilistic, seek to equip future managers with mathematical tools for optimized solutions, and flexibility to operate under uncertainty. But, "illusion of control" or cognitive biases giving the decision-maker unwarranted confidence, interferes with learning. An exercise has inexperienced decision-makers prioritize a set of realistic allocation problems and explores recorded rationales for features of illusion of control biases.

3 - Flexible High Density Puzzle Storage System

Ehsan Shirazi, West Virginia University, 1204, Van Voorhis Road, Unit B, Morgantown, WV, 26505, United States, ehshirazi@mix.wvu.edu

A puzzle-based storage system has been introduced to replenish and retrieve items from the top and bottom of a highly dense storage system. Each cell of the puzzle storage is considered as a grid. Each grid is able to store an item and or to move items in the south direction. We describe a high density storage system that can retrieve and replenish items from all sides. A puzzle storage with this characteristic is a lot more flexible than what has been introduced before. We will illustrate how this puzzle storage scheme affects replenish and retrieve time based on different network policies, distributions of replenishing and retrieving items, and number of free spaces on the puzzle network.

4 - The Use Of Simulation For Evaluating Forecast Models

Sanjeewa Naranpanawe, Sr Analytical Consultant, SAS Institute, 100 SAS Campus Drive, Cary, NC, 27513, United States, sanjeewa.naranpanawe@sas.com

The normal process of evaluating forecast models are by fitting the model using historical data, evaluating using holdout samples to select the model. However, this single point evaluation of forecast accuracy may not be good at predicting how the model is going to perform in the future. This presentation examines how simulation can be use to evaluate different forecast models.

5 - Adaptive-spline For Integer-order Simulation Optimization

Prasanna Kumar Ragavan, Virginia Tech, Durham Hall, Blacksburg, VA, 24061, United States, rpkumar@vt.edu
Raghu Pasupathy, Michael Taaffe

We present Adaptive-SPLINE to solve simulation optimization (SO) problems where the decision variables are integer-ordered, and the objective function can only be estimated through "noisy" observations from a simulation. Adaptive-SPLINE iterates between a line search and an enumeration procedure, and adaptively determines sampling effort by trading-off stochastic error with structural error. We will discuss consistency and finite-time performance.

Joint Session HAS/MSOM-HC: Analytics in Drug Development

General Session

Chair: Elisa Frances Long, UCLA Anderson School of Management, Los Angeles, CA, United States, elisa.long@anderson.ucla.edu

1 - Continuity In Gatekeepers: Quantifying The Impact Of Care Fragmentation

Vishal Ahuja, SMU Cox School of Business, vahuja@smu.edu
Bradley R Staats,

Care coordination is increasingly being recognized as an criticla aspect of overall patient care. We attempt to establish a quantitative measure of care coordination and study its impact on patient health outcomes. Further, we investigate the mechanism by which coordination affects these outcomes. We use data on patients with diabetes, a chronic condition.

2 - Flexible FDA Approval Thresholds: A Dynamic Programming Approach

Taylor Corcoran, University of California-Los Angeles, taylor.corcoran.1@anderson.ucla.edu, Elisa Frances Long, Fernanda Bravo

Current FDA approval standards require drug companies to demonstrate the efficacy of their product by presenting statistically significant results from clinical trials. Traditionally, this significance level is set to 0.05 or 0.01, but this choice ignores the complexity of the drug approval process. In particular, the current approval threshold does not incorporate the severity and prevalence of the disease being treated, the level of research and development taking place, and the quantity of existing drugs available for the disease. We develop a continuous time dynamic programming model to study how the optimal significance level should depend on characteristics of the drug pipeline.

3 - Is The FDA Too Conservative Or Too Aggressive?: A Bayesian Decision Analysis Of Clinical Trial Design

Andrew W Lo, Charles E. and Susan T. Harris Professor, MIT, 100 Main Street, E62-618, Cambridge, MA, 02142, United States, alo-admin@mit.edu, Andrew W Lo, Charles E. and Susan T. Harris Professor, MIT, 32 Vassar Street, Cambridge, MA, 02139, United States, alo-admin@mit.edu, Leah Isakov, Vahid Montazerhodjat

We explore the application of Bayesian decision analysis (BDA) to minimize the expected cost of drug approval, where the relative costs of Type I and Type II errors are calibrated using burden of disease data. For terminal illnesses with no existing therapies such as pancreatic cancer, the standard Type I error threshold of 2.5% is substantially more conservative than the BDA-optimal threshold of 23.9% to 27.8%. We compute BDA-optimal sizes for 25 of the most lethal diseases and show how a BDA-informed approval process can incorporate all stakeholders' views in a systematic, transparent, internally consistent, and repeatable manner.

4 - A Comparison Between The Robust Risk-aware And Risk-seeking Managers In R&D Portfolio Management

Aurelie Thiele, Associate Professor, Southern Methodist University, Dallas, TX, United States, aurelie@alum.mit.edu
Shuyi Wang

We analyze via simulation two mathematical modeling frameworks that reflect different managerial attitudes toward upside risk in R&D portfolio selection. The manager seeks to allocate a development budget between low-risk, low-reward projects, called incremental projects, and high-risk, high-reward projects, called innovational projects. We study the differences in strategy and portfolio's risk profile that arise between a risk-aware manager, who takes upside risk because he has to for the long-term competitive advantage of his company, and a risk-seeking manager, who will take as big a bet as allowed by the model.

Frontiers of Supply Chain Research

Sponsored: Manufacturing & Service Oper Mgmt, Supply Chain Sponsored Session

Chair: Karen Zheng, MIT Sloan School of Management, Cambridge, MA, 02142, yanchong@mit.edu

1 - Dual Co-product Technologies: Implications For Process Development And Adoption

Brian Tomlin, Tuck School of Business, brian.tomlin@tuck.dartmouth.edu, Ying-Ju Chen, Yimin Wang

Many industries operate technologies in which multiple outputs (co-products) are jointly produced. Three important attributes of a co-product technology are its production cost, its overall yield, and its co-product split. Process development often wrestles with an inherent trade-off: improvement in one attribute comes at the expense of another. In this talk, we first explore production and pricing decisions for a firm with two technologies and then use this foundation to examine implications for process development and process adoption.

2 - Impact Of Grocery Store Density And Market Structure On Food Waste

Elena Belavina, University of Chicago Booth School of Business, elena.belavina@chicagobooth.edu

Food waste is one of the major contributors of greenhouse gas emissions. If food waste was a country, it would be third largest polluter shortly after US and China. About $1 trillion dollars of food is wasted every year, which is equivalent to 1% of GDP globally. This study explores the impact of store density and market structure on consumer food waste.

3 - Self-policing In A Supply Chain Under Threat Of Public Disclosure

Sang-Hyun Kim, Associate Professor, Yale University, New Haven, CT, United States, sang.kim@yale.edu, Saed Alizamir

We study incentive dynamics among supply chain members and an external stakeholder (e.g., NGO) that impact environmental performance. A buyer inspects a supplier's production in its supply chain to detect and correct environmental compliance violations. The buyer's primary motive is to deter the NGO from discovering the violation first and publicize it, from which the buyer incurs a reputational penalty. The buyer and the NGO engage in a game to competitively set their inspection intensities, which influence the supplier's decision to restore compliance. Together, the actions made by all parties determine the environmental outcome and and social welfare.

4 - Increasing Retail Sales Via Improved Store Staffing: An Empirical Study With Implemented Results

Santiago Gallino, Dartmouth College, santiago.gallino@tuck.dartmouth.edu, Marshall L Fisher, Serguei Netessine

We analyzed 30 months of a retailer's history on store-month sales and potential sales drivers to measure the impact of store selling staff level on revenue. We identified a third of the stores where our analysis indicated that increasing staffing would increase sales. The retailer confirmed this finding via a 16 store test which showed that a 10% increase in sales staff resulted in a 9.9% sales increase, and was highly profitable. The retailer is now implementing our finding in other stores.

205B-MCC

Information and Risk in Supply Chain Networks

General Session

Chair: Kostas Bimpikis, Stanford Graduate School of Business, 650 Knight Way, Stanford, CA, 94305, United States, kostasb@stanford.edu

1 - Inventory Management With Censored Demand Data: The Adversarial Case

Michail Markakis, Universitat Pompeu Fabra, mihalis.markakis@upf.edu

We consider a repeated newsvendor problem where the demand distribution is unknown ex ante and has to be learned from sales/censored data. To shed light to scenarios where the demand may be non-stationary, e.g., exhibiting trends or seasonalities, we model the problem as a game between the inventory manager and an oblivious opponent, who prior to the game decides a sequence of demands for the different periods arbitrarily. We propose randomized inventory management policies that perform well with respect to the regret criterion, i.e., the difference between a policy's cumulative cost and the cumulative cost of the best fixed action/ordering decision in hindsight, for any given demand sequence.

2 - Optimizing Local Content Requirements Under Technology Gaps

Shiliang Cui, Georgetown University, shiliang.cui@georgetown.edu, Lauren Xiaoyuan Lu

We study the optimal Local Content Requirements (LCR) and innovation policies of a developing economy in which a foreign Original Equipment Manufacturer (OEM) produces and sells a final product. We find that as the domestic component supply base becomes more cost efficient, surprisingly, the OEM's profit could decrease.

3 - Take-rate Crowdsourcing Contracts

Yun Zhou, University of Toronto, Toronto, ON, Canada, yzhou.zj@gmail.com, Ming Hu

Motivated by the surge pricing strategy by the ridesharing platforms, we consider the pricing problem in a two-sided market. The total amount of supply is an increasing function of the wage and the amount of demand depends on the price. We model supply and demand uncertainty by a number of different scenarios, and show that the take-rate price contract is optimal for maximizing the platform's profit or the total utility of the platform and the supply side when only the market size is scenario dependent. In more general cases, we derive performance bounds for the take-rate contract.

205C-MCC

Revenue Management, Assortments and Choice Models

Sponsored: Manufacturing & Service Oper Mgmt, Supply Chain Sponsored Session

Chair: Ozge Sahin, Johns Hopkins University, Brooklyn, NY, United States, ozge.sahin@jhu.edu

1 - Consumer Choice Under Rational Inattention And Implications For Assortment Planning

Tamer Boyaci, ESMT Berlin, Berlin, 10178, Germany, Tamer.Boyaci@esmt.org, Frank Huettner, Yalcin Akcay

We study the choice behavior of rationally inattentive customers who optimally acquire information about available options with ex-ante uncertain values through potentially different channels with different costs. Customers trade-off the benefits of better information obtained by asking questions with the associated cost. We quantify acquired information and its cost through a novel function based on conditional mutual information. We solve the consumer's choice problem and analytically characterize the resulting optimal choice behavior. We illustrate some properties of the choice behavior and discuss implications for assortment planning.

2 - Assortment Optimization For Choosy Customers

Jake Feldman, Washington University in St. Louis, jbfeldman@wustl.edu

We study two different choice models that capture the purchasing behavior of customers who only consider purchasing one of two substitutable products. We refer to these customers as choosy. The first choice model captures substitution behavior through probabilistic transitions between products. The second choice model that we study assumes each customer is characterized by a ranking of the products. An arriving customer will purchase her highest ranked product that is offered. Since we model choosy customers, we assume that these rankings contain at most two products. This paper focuses on the assortment optimization problem under these two choice models.

3 - Learning Consumer Tastes From Dynamic Assortments: A Nonparametric Bayesian Model

Canan Ulu, Georgetown University, cu50@georgetown.edu
Dorothee Honhon

We study dynamic assortment decisions of a firm learning about consumer tastes by observing sales. Each period, the firm offers an assortment to maximize expected total profits over a finite horizon given its beliefs on consumer tastes. The consumers then choose a product that maximizes their utility and the firm updates its beliefs on consumer tastes after having observed sales. We model consumer tastes as locations on a Hotelling line and develop a nonparametric Bayesian learning model using Polya tree priors. We develop upper bounds on the firm's total profit based on information relaxations and study the performance of various heuristic policies with respect to these upper bounds.

4 - The Price Of Flexibility

Hoda Bidkhori, Swanson School of Engineering, University of Pittsburgh, Pittsburgh, PA, United States, bidkhori@pitt.edu
Dimitris Bertsimas, Albert Dunning

Process flexibility is a popular operations strategy that has been employed in many industries to help firms respond to uncertainty in product demand. Additional flexibility comes at a cost that firms must balance against the reduction of risk it can provide. We reduce the price of flexibility by taking an optimization approach to the process flexibility design problem. Unlike many approaches in the literature, we consider systems that may have nonhomogenous parameters and unbalanced capacity and demand. We formulate the problem as a robust adaptive optimization model, and propose a computationally tractable method for solving this model using standard integer optimization software.

Collaborative New Product Development

Sponsored: New Product Development

Sponsored Session

Chair: Niyazi Taneri, Singapore University of Technology and Design, Singapore, Singapore, na, Singapore, niyazitaneri@sutd.edu.sg

1 - The Role Of Operations In Alliances For New Product Development

Niyazi Taneri, Singapore University of Technology and Design, niyazitaneri@sutd.edu.sg, Arnoud De Meyer

We review contract theory and hypothesize its implications for the choice between collaborative alliances (where both parties exert joint efforts) and sequential alliances (where, for the most part, the partner takes over going forward). We test these hypotheses through the analysis of a dataset of over 2000 biopharmaceutical alliances.

2 - Optimal Sequential Investments In Product Development With Exogenous Technologies And Learning

Shantanu Bhattacharya, Singapore Management University, shantanub@smu.edu.sg, Stylianos Kavadias, Sameer Hasija

We determine the optimal investments for a firm when the product development opportunities come over time from two distinct exogenous technologies. Upfront investment in a product platform from a technology that is currently available gives higher returns from opportunities based on the platform technology in the future, due to the associated learning effects. We formulate the resource allocation problem and characterize the optimal development investments that determine the firm product development roadmap. We show that the firm's optimal resource investment in platform development has a nuanced relationship with the relative speed of arrival of the new technology.

3 - Business Model For Technology-intensive Supply Chains

Junghee Lee, University of California, San Diego, junghee.lee@rady.ucsd.edu
Krishnan Vish, Hyoduk Shin

In technology licensing, controversy has swirled among firms and policymakers about royalty base choice between subsystem and full system. We study the impact of royalty base on innovator's business model decisions from R&D investment to manufacturing integration in Technology Intensive Supply Chain. We identify the key drivers, market heterogeneity and production cost, for the controversy and provide managerial and political implications. Interestingly, the innovator can be better off with a strong competitor when market inequality is low or the competitor is strong enough.

Market Microstructure and Optimal Trading

Sponsored: Applied Probability

Sponsored Session

Chair: Costis Maglaras, Columbia University, New York, NY, United States, c.maglaras@columbia.edu

Co-Chair: Ciamac Cyrus Moallemi, Columbia University, New York, NY, United States, ciamac@gsb.columbia.edu

1 - Trading The Close — Market Impact And Optimal Execution

Costis Maglaras, Columbia University, c.maglaras@columbia.edu

The "close" concentrates a significant amount of daily liquidity for various market structure reasons. In this talk I will describe a market impact model for "Market-On-Close" (MOC) orders, and its consequences on optimal execution profiles.

2 - Portfolio Liquidity Estimation And Optimal Execution

Kai Yuan, Columbia University, kyuan17@gsb.columbia.edu

We develop a tractable model to estimate portfolio liquidity costs through a multi-dimensional generalization of the optimal execution model of Almgren and Chriss. Our model allows for the trading of standardized liquid bundles of assets (e.g., ETFs or indices). We show that in a "large universe" asymptotic limit, where the correlations across a large number of assets arise from relatively few underlying common factors, the liquidity cost of a portfolio is essentially driven by its idiosyncratic risk. Moreover, the additional benefit of trading standardized bundles is roughly equivalent to increasing the liquidity of individual assets.

3 - Optimal Execution In Hong Kong Given A Market-on-close Benchmark

Christoph Frei, University of Alberta, Edmonton, AB, Canada, cfrei@ualberta.ca, Nicholas Westray

For stocks traded on the Hong Kong Exchange, the median of five prices taken over the last minute of trading is currently chosen as the closing price. We introduce a stochastic control formulation to target such a median benchmark in an empirically justified model which takes the key microstructural features into account. We solve this problem by providing an explicit and efficient algorithm which can be used for the dynamic linear approximation of any square-integrable random variable. Implementing the algorithm on the stocks of the Hang Seng Index, we find an average improvement of around 6% in standard deviation of slippage compared to an average trader's execution.

4 - Mean Field Games Of Singular Control With Applications

Joon Seok Lee, UC Berkeley, 2938 McClure Street, # A207B, Oakland, CA, 94609, United States, ljshope@berkeley.edu
Xin Guo

We introduce a mean field game framework with singular controls. To solve this singular control problem with multiple agents, we derive the Kolmogorov forward equation for the singular control, which is a generalization of the mean fi eld game with regular controls. Both single controls with a bounded velocity and singular controls with a finite variation will be analyzed. Finally, we will present some applications to real options and systemic risk.

Computational Issues in Productivity and Efficiency Measurement

Invited: Data Envelopment Analysis

Invited Session

Chair: Jose Dula, Virginia Commonwealth University, Snead Hall, 301 W. Main Street, Richmond, VA, 23284, United States, jdula@vcu.edu

1 - Validating DEA As A Rating Tool: The Case Of CMS's Nursing Home Compare.

Jose Dula, Virginia Commonwealth University, jdula@vcu.edu
Marie-Laure Bougnol

The US government's CMS agency rates more than 15000 nursing homes nationwide using a star system. The outcomes are disseminated in various ways including a user friendly and informative web page. We report on a study comparing the government's ratings with classifications obtained with DEA using the same model and data. We answer the question: How would DEA fare as a tool to rate complex entities such as nursing homes?

2 - Dea Computation For The Big Data – A Proactive Approach

Wen-Chih Chen, National Chiao Tung University, Hsinchu, Taiwan, wenchih@faculty.nctu.edu.tw, Yueh-Shan Chen

This talk presents a computation strategy to determine the DEA efficiencies of a massive data set. The strategy proactively searches for the references of a data point under evaluation by solving small-size linear programs (LPs). The size of each individual LP solved is controlled within a guarantee upper bound. The approach does not rely on the data density, and can improve the computational performance significantly.

3 - Segmented Concave Least Squares: An Automatic Classification Method With An Application To The Analysis Of The Room Rates Of Hotels In Finland

Abolfazl Keshvari, Aalto University School of Business, Helsinki, Finland, abolfazl.keshvari@aalto.fi

In this paper, segmented concave least squares estimator is introduced. It estimates a piecewise linear concave function, wherein the number of linear segments (k) is pre-specified. Two extreme cases of this problem are ordinary least squares (k=1) and concave least squares (k=n, the number of observations). The estimator is used to analyze the room rates of hotels in Finland and to classify them into three groups based on their pricing strategies.

1 - Robust Versus Sparse Portfolio Selection: Insights And Alternatives

Yufei Yang, Singapore University of Technology and Design, Singapore, Singapore, eeyufei@gmail.com
Selin Damla Ahipasaoglu, Jingnan Chen

In this talk, we will provide an in-depth discussion on the robustness and sparsity trade-off in finding the mean-variance portfolio. We extend the classical mean-variance framework by incorporating an ellipsoidal uncertainty set and fixed transaction costs. We demonstrate that the optimal portfolio can be approximated by a linear combination of three benchmark portfolios, and discuss how the number of traded assets changes with respect to uncertainty level and transaction cost.

2 - Portfolio Liquidity Estimation And Optimal Execution

Kai Yuan, Columbia Business School, Broadway, New York, NY, 10027, United States, kyuan17@gsb.columbia.edu

We develop a tractable model to estimate portfolio liquidity costs through a multi-dimensional generalization of the optimal execution model of Almgren and Chriss. Our model allows for the trading of standardized liquid bundles of assets (e.g., ETFs or indices). We show that in a “large universe” asymptotic limit, where the correlations across a large number of assets arise from relatively few underlying common factors, the liquidity cost of a portfolio is essentially driven by its idiosyncratic risk. Moreover, the additional benefit of trading standardized bundles is roughly equivalent to increasing the liquidity of individual assets.

3 - Spectral Portfolio Theory

Shomesh E Chaudhuri, Massachusetts Institute of Technology, Cambridge, MA, 0, United States, shomesh@mit.edu
Andrew W Lo

Economic shocks can have diverse effects on financial market dynamics at different time horizons, yet traditional portfolio management tools do not distinguish between short- and long-term components in alpha, beta, and covariance estimators. In this paper, we apply spectral analysis to quantify stock-return dynamics across multiple time horizons. Using the Fourier transform, we decompose asset-return variances, correlations, alphas, and betas into distinct frequency components. These decompositions allow us to identify the relative importance of specific time horizons in determining each of these quantities, as well as to construct mean-variance-frequency optimal portfolios.

4 - Long Term Risk: A Martingale Approach

Likuan Qin, Northwestern University, Evanston, IL, 60208, United States, likuan.qin@gmail.com

This paper extends the long-term factorization of the stochastic discount factor introduced and studied by Alvarez and Jermann (2005) in discrete time ergodic environments and by Hansen and Scheinkman (2009) and Hansen (2012) in Markovian environments to general semimartingale environments. The transitory component discounts at the stochastic rate of return on the long bond and is factorized into discounting at the long-term yield and a positive semimartingale that extends the principal eigenfunction of Hansen and Scheinkman (2009) to the semimartingale setting. The permanent component is a martingale that accomplishes a change of probabilities to the long forward measure, the limit of T-forward measures. The change of probabilities from the data generating to the long forward measure absorbs the long-term risk-return trade-off and interprets the latter as the long-term risk-neutral measure.

Stochastic Systems in Finance

Sponsored: Financial Services

Sponsored Session

Chair: Alexandra Chronopoulou, Assistant Professor, University of Illinois, Urbana-Champaign, 117 Transportation bldg. MC-238, 104 S. Mathews Ave., Urbana, IL, 61801, United States, achronop@illinois.edu

1 - Statistical Inference For Long Memory Stochastic Volatility Models

Alexandra Chronopoulou, University of Illinois, Urbana-Champaign, achronop@illinois.edu

Long memory stochastic volatility (LMSV) models have been used to explain the persistence of volatility in the market, while rough stochastic volatility (RSV) models have been shown to reproduce statistical properties of low frequency financial data. In these two classes of models, the volatility process is often described by a fractional Ornstein-Uhlenbeck process with Hurst index H, where H>1/2 for LMSV models and H<1/2 for RSV models. The goal of this talk is to propose a general methodology for the estimation of the parameters of the above models, the filtering of the volatility process, and the calibration of the Hurst index, H, which will then be applied to the option pricing on the S&P 500 index.

2 - Optimal Randomized Unbiased Monte Carlo Simulation Of Discounted Costs

Zhenyu Cui, Stevens Institute of Technology, zcui6@stevens.edu

In this talk, we consider the problem of estimating the expected infinite-horizon cost of running a stochastic system with stochastic fluctuations using Monte Carlo simulation. We propose a randomized unbiased estimator based on truncating the simulation horizon at an independent random time. The problem of determining the optimal randomization distribution of the truncation random variable is formulated as minimizing the “work-variance product” proposed by Glynn and Whitt (1992). We solve this optimization problem explicitly and prove that it is always optimal to use a “shifted” distribution. Numerical experiments illustrate our findings. (This is joint work with Lingjiong Zhu).

3 - Monte Carlo Estimation Of Sensitivities From Analytic Characteristic Functions

Runqi Hu, University of Illinois, Urbana-Champaign, runqihu2@illinois.edu, Liming Feng

Sensitivity analysis is transformed into simulating a probability expectation through the likelihood ratio method (LRM). In this paper, we apply Hilbert transform inversion in evaluating a cdf on a uniform grid from its characteristic function and provide explicit bound for estimation bias. In one dimension cases, the bound allows one to determine the size and fineness of the grid and numerical parameters for the inversion. For multidimensional cases, the parameters can be determined by a procedure that will be proved to converge, and work well practically. In the numerical experiments part, the method is applied in estimating both European and Asian option deltas under CGMY model.

4 - Sensitivity Of The Eisenberg-Noe Network Model To The Relative Liabilities

Mackenzie Wildman, University of California, Santa Barbara, CA, United States, mackenzie.wildman@gmail.com
Zachary Feinstein, Weijie Pang, Birgit Rudloff, Eric Schaanning, Stephan Sturm

The Eisenberg-Noe algorithm gives a clearing payment vector for a system of interconnected financial institutions in which some banks are unable to fulfill their obligations to other banks in full. The network model takes as input a relative liability matrix which gives the liabilities owed from each bank to its counterparties. In practice, these liabilities are generally unknown and must be estimated. We perform sensitivity analysis on this relative liability matrix and obtain a worst-case scenario in terms of the payoff to a “society” node. We illustrate our results on an EBA dataset of European banks.

Spatial Risk and Decision Analysis

Sponsored: Decision Analysis

Sponsored Session

Chair: Gilberto Montibeller, Loughborough University, Loughborough, United Kingdom, g.montibeller@lboro.ac.uk

1 - Spatial Risk Analysis In Emergency Management

Nikolaos Argyris, Loughborough University, Loughborough, United Kingdom, n.argyris@lboro.ac.uk, Simon French

In any emergency, there is a great deal of uncertainty, often geographical or spatio-temporal uncertainty. For instance, an industrial accident may lead to a plume of contamination, putting populations at risk downwind. The path of a hurricane provides another example that is of obvious concern to emergency managers. We consider how analysts can communicate spatio-temporal uncertainty to those handling the crisis. We review the somewhat limited literature on the representation of spatial uncertainty on maps. We note that many cognitive issues arise and that the potential for confusion is high. We then make some suggestions based upon the idea of presenting multiple scenarios.

2 - Spatial Preference Functions For Risk Analysis

Jay Simon, American University, jaysimon@american.edu, L Robin Keller

When outcomes are defined over a geographic region, measures of spatial risk regarding these outcomes can be more complex than traditional measures of risk. One of the main challenges is the need for a cardinal preference function that incorporates the spatial nature of the outcomes. We explore preference conditions that will yield the existence of spatial measurable value and utility functions, and discuss their application to spatial risk analysis.

3 - Multi-criteria Spatial Risk Analysis For Resource Allocation Decisions

Gilberto Montibeller, Full Professor of Management Science, Loughborough University, Loughborough, United Kingdom, g.montibeller@lboro.ac.uk, Valentina Ferretti

There is a broad literature on spatial multi-criteria evaluation in the environmental domain and some attempts of conducting risk analysis in this context. Most of these attempts neither employ a proper decision analytical framework nor provide a clear conceptualization for allocating resource on mitigating actions. To address these weaknesses we conceptualize a multi-criteria spatial risk analysis assessment, which may support spatial decision-making processes. The framework employs expected multi-attribute utility and portfolio decision analysis concepts in a spatial context. A case study on flooding evaluation and defense building illustrates its application in practice.

Modeling of Uncertainty and Preference in Decision Analysis

Sponsored: Decision Analysis

Sponsored Session

Chair: Christopher Hadlock, Austin, TX, United States, cchadlock@gmail.com

Co-Chair: Robert Hammond, Chevron, Houston, TX, United States, robertkh@gmail.com

1 - Johnson Quantile-parameterized Distributions

Christopher Hadlock, The University of Texas at Austin, cchadlock@gmail.com, J. Eric Bickel

It is common practice in decision analysis to elicit quantiles of continuous uncertainties, and then fit a continuous probability distribution to the corresponding probability-quantile pairs. This process is inconvenient because it requires access to a curve-fitting process, and the best-fit distribution will often not honor the assessed points. By strategically extending the Johnson Distribution System, we design the new J-QPD distribution system, which is directly parameterized by and honors any symmetric percentile triplet of low-base-high assessments in conjunction with known support bounds, eliminating the need to apply a fit procedure.

2 - The Metalog Distributions

Thomas Keelin, Keelin Reeds Partners, 770 Menlo Avenue, Suite 230, Menlo Park, CA, 94025, United States, tomk@keelinreeds.com

The metalog distributions constitute a new system of continuous univariate probability distributions designed for flexibility, simplicity, and ease of use. The system includes quantile-parameterized unbounded, semi-bounded, and bounded distributions, each of which offers shape flexibility that compares favorably with Pearson distributions and others. Applications in fish biology and hydrology show how metalogs enable unprecedented insight into CDF data. A decision analysis application shows metalogs aided a decision that would have been made wrongly based on traditional discrete methods.

3 - Reexamining The Viability Of Scoring Rules

Zachary Smith, The University of Texas at Austin, zack.smith@utexas.edu, J. Eric Bickel

There are a number of widely used proper scoring rules used to elicit and rank expert opinions. However, not all rules have the property of being additive, in the sense that the score for marginal distributions and joint distributions are comparable. Scoring rules without this property are sensitive to the presentation of information as well as the information itself. We characterize scoring rules that are additive, and consider practical implications for some commonly-used rules.

Dynamic Pricing with Substitution, Learning and Reference Price Effects

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Candace Arai Yano, University of California-Berkeley, IEOR Dept. and Haas School of Business, Berkeley, CA, 94720, United States, yano@ieor.berkeley.edu

1 - Optimal Use And Replenishment Of Substitutable Raw Materials In Non-Stationary Capacitated Systems With Dynamic Price

Izak Duenyas, University of Michigan-Ann Arbor, duenyas@umich.edu

We consider a make-to-order setting where a firm can use either of two kinds of materials (or their mixture) to produce an end product using a shared production line with stochastic capacity. The materials are substitutable but one has a higher conversion rate and the other is cheaper, and their availability is uncertain. We show that a Use-down-to/Balancing Production Policy and modified Order-up-to Ordering Policy is optimal. Although the optimal policy is hard to compute using brute-force due to curse of dimensionality, we use its structure to develop an algorithm that solves for it efficiently. We also conduct sensitivity analysis of the optimal policy and find counter intuitive results.

2 - A Squared-coefficient-of-variation Rule For Learning And Earning

N. Bora Keskin, Duke University, Durham, NC, United States, bora.keskin@duke.edu

Consider a price-setting firm that sells products over a continuous time horizon. The firm is uncertain about the sensitivity of demand to price changes and updates its prior belief on an unobservable sensitivity parameter by observing demand responses. We derive and solve a PDE to show how the value of learning should be projected onto prices in an optimal fashion.

3 - Dynamic Pricing With Stochastic Reference Price Effects

Xin Chen, UIUC, xinchen@illinois.edu, Zhenyu Hu, Yuhan Zhang

We study a dynamic pricing problem of a firm facing stochastic reference price effect. Randomness is incorporated in the formation of reference prices to capture exogenous factors that affect consumers' memory processes. We derive an explicit expression for the optimal pricing strategy which allows us to obtain the distribution of the steady state reference price. We compare the expected steady state reference price to the steady state reference price in a deterministic model and we find that the former one is always higher. A transformation technique is presented to show how one can extend the analysis to higher dimensional problems in which consumers have heterogeneous reference prices.

4 - Hidden City Travel And Its Impact On Airfare: The Case With Competing Airlines

Jaelynn Oh, University of Utah, jaelynn.oh@business.utah.edu
Tim Huh

We study the impact of hidden-city ticketing on airfare pricing in a setting where two airlines compete on a hub-and-spoke flight network.

New Topics in Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Stefanus Jasin, University of Michigan, Ann Arbor, MI, United States, sjasin@umich.edu

1 - Managing Dynamic Mobile Push Advertisements At Alibaba

Van Anh Truong, Columbia IEOR, vt2196@columbia.edu

In recent years, e-commerce companies are seeing an increasing amount of transactions completed via mobile platforms, such as apps in iOS and Android systems. In China, the e-commerce market share of a mobile app developed by Alibaba Group, which has been installed on several hundred million devices, is rapidly replacing that of traditional e-commerce markets hosted on webpages. We study the problem of managing the allocation of push notifications sent to users by this app which recommends products tailored to every user.

2 - Efficient Algorithms For Dynamic Pricing Problem With Reference Price Effect

Zhenyu Hu, National University of Singapore (NUS), bizhuz@nus.edu.sg

We analyze a dynamic pricing model in which demand at each period depends on not only the current price but also past prices through reference prices. A unique feature but also a significant challenge in this model is the asymmetry in reference price effect which implies the underlying optimization problem is non-smooth and no standard optimization methods can be applied. We identify a few key structural properties of the problem, which enable us to develop strongly polynomial time algorithms to compute the optimal prices for several plausible scenarios. We further conduct numerical experiments to study the optimal price path and demonstrate the value of dynamic pricing when demands are seasonal.

3 - Optimal Stopping And Worker Selection In Crowdsourcing: An Adaptive Sequential Probability Ratio Test Framework

Xi Chen, Stern, NYU, xchen3@stern.nyu.edu

In this talk, we propose an adaptive sequential probability ratio test (Ada-SPRT) that obtains the optimal experiment selection rule, stopping time,and final decision rule under a single Bayesian decision framework. Our motivating application comes from binary labeling tasks in crowdsourcing, where the requestor needs to simultaneously decide which worker to choose to provide the label and when to stop collecting labels to save for budget. We characterize the structure of the optimal adaptive sequential design that minimizes the Bayes risk through log-likelihood ratio statistic and develop dynamic programming based algorithms for both non-truncated and truncated tests.

4 - Dynamic Joint Pricing And Order Fulfillment For E-commerce Retailers

Yanzhe Lei, University of Michigan, Ann Arbor, MI, United States, leiyz@umich.edu, Stefanus Jasin, Amitabh Sinha

We consider a dynamic joint pricing and order fulfillment optimization problem in the e-commerce retailing context, where a retailer sells a catalog of products to customers from different locations and fulfills orders through multiple fulfillment centers. The objective is to maximize the total expected profits, defined as revenues minus shipping costs. We propose two heuristics that are easily implementable, and show both theoretically and numerically their good performances compared to reasonable benchmarks.

Social Media in Marketing and Talent Management

General Session

Chair: Fujie Jin, Indiana University, 1309 East Tenth Street, Suite 4100, Bloomington, IN, 47405, United States, jinfujie@wharton.upenn.edu

1 - Social Media Marketing In Product Harm Crisis

Shu He, University of Connecticut, shuhe@utexas.edu

We conceptualize the dual roles of a firm's social media strategy—-offensive and defensive marketing strategies—-and study how non-focal firms adjust these two components of strategy in response to a product-harm crisis. We use daily social media activity of 56 major airlines on Twitter around the time of an airplane crash to study how non-focal airlines harness these two functions before and after the crisis. We find that a non-focal airline increases its defensive marketing effort but decrease its offensive marketing effort after the crash. The adjustment of offensive marketing decrease is significantly attenuated by whether the non-focal airline directly competes with the focal airline.

2 - Influence Of Social Media On Flash Sales: An Empirical Analysis

Karthik Kannan, Georgia Tech, karthikbabu.nk@scheller.gatech.edu, Jeffrey Hu, Sridhar Narasimhan

The emergence of e-commerce platforms has democratized both the production and consumption of goods and services. While anyone can offer their services through these platforms, sellers with little brand recognition have to overcome high search cost faced by prospective buyers in order to succeed in these markets. We study two mechanisms - flash sales and social media - used by sellers to promote their products by collecting sales and social media data from 24,446 products sold in a popular e-commerce platform.

3 - Does Reputation Management On Social Media Boost Career? Evidence From The Market For Executives

Yanzhen Chen, University of Texas at Austin, Austin, TX, United States, yanzhen@utexas.edu, Huaxia Rui, Andrew Whinston

Our paper studies the impact of reputation management (RM) on executives' careers gathering evidence from their Twitter usage. Our structural model, which is based on a Two-Sided Matching Model, is able to exploit the characteristics of all of the candidates so as to identify separate RM's influences in bargaining power as well as sorting during the hiring process. The results show that in the recruiting process of CEO and CMO markets, both out-/underperformed applicants benefit from RM. However, in compensation bargaining, RM is profitable only for outperformed candidates. RM can help more than 40% of CEOs and may increase their compensation by more than $10 million per year.

4 - Gravity In Open Source Software Production

Xuan Ye, New York University, New York City, NY, United States, xye@stern.nyu.edu, Prasanna Tambe

Using data on over 2 million hourly contributions contributed over eight years to GitHub.com, this paper investigates how the geographic organization of contributors influences open source production in corporate sponsored projects. Specifically, we test the extent to which time zones play a role in open source software contribution. We find strong evidence of such a bias in open source software production. Concentration of contributors within the same time zone is correlated with greater contribution levels, and this is robust to user fixed-effects.

Social, Political, and Economic Applications of Social Media Analysis

Invited: Social Media Analytics

Invited Session

Chair: Amanda Andrei, MITRE Corporation, 7515 Colshire Dr, Mclean, VA, 22102, United States, aandrei@mitre.org

1 - Characterizing Traffic Accident Detection Through Twitter And Open Data

Jared Mowery, MITRE Corporation, jmowery@mitre.org

Several recent studies have shown that Twitter can be used to detect traffic disruptions with high precision. This study builds on those results by incorporating open data including real-time traffic speed sensor measurements and weather data, measuring the recall of traffic accident detection against New York City police records, and by characterizing the probability of detection as a function of the severity of the accident.

2 - Assessing Patient Abuse At Nursing Homes Via Classification Of Online Reviews

Jing Jian, MITRE Corporation, jjian@mitre.org

This study demonstrates a correlation between a maximum entropy classifier's assessment of indications of patient abuse in online reviews for nursing homes and the results of Medicare facility inspections. Over 8,000 reviews were analyzed, representing over 4,000 facilities. Aggregating reviews for nursing homes with similar numbers of deficiencies from the inspections indicates the Pearson correlation coefficient approaches approximately 0.65 as the number of reviews increases.

Analytical Research in Humanitarian Service Delivery

Sponsored: Public Sector OR

Sponsored Session

Chair: Mahyar Eftekhar, Arizon State University, Arizon State University, Tempe, AZ, 00, United States, eftekhar@asu.edu

1 - Leading Diverse Teams In Humanitarian Aid Field Offices: A Case For Intergroup Leadership

Mojtaba Salem, Kuehne Logistics University, Hamburg, Germany, Mojtaba.Salem@the-klu.org, Maria Besiou, Niels Van Quaquebeke, Louisa Meyer

The humanitarian system struggles sometimes with adequate operational leadership. We study, via an online survey with 123 humanitarian practitioners, how operational leadership can effectively work with the unique challenges of having multiple and highly diverse teams in the humanitarian field offices. We focus on the improvement of intergroup relations and reduction of potential tensions between international and local staff in the same field office. It is shown statistically that group orientated leadership has a positive impact on the operational excellence of response.

2 - Policies For Fleet Operations And Procurement In Humanitarian Development Programs

Milad Keshvari Fard, ESSEC Business School, Av Bernhard Hirsch BP 50105, Cergy Pontoise Cedex, 95021, France, milad.keshvarifard@essec.edu, Felix Papier, Mahyar Eftekhar

Fleet management is known as a pivotal component of humanitarian service delivery. Considering essential constraints (e.g. budget uncertainty, and environmental conditions at the field), we design a heuristic to identify the optimal fleet sizing and mission fulfillment over time. The objective of our model is to minimize the social cost.

3 - Models And Metrics To Assess Humanitarian Response Capacity

Jason Acimovic, Penn State University, acimovic@psu.edu

The race to meet vital needs following sudden onset disasters leads response organizations to establish stockpiles of inventory that can be deployed immediately. Even though the value of one organization's stock deployment is contingent on others' decisions, decision makers lack evidence regarding sector capacity to assess the marginal contribution (positive or negative) of their action. To our knowledge, there exist no metrics describing the system capacity across many agents to respond to disasters. To address this gap, our analytical approach yields new humanitarian logistics metrics based on stochastic optimization models.

4 - Supply Management Strategies In Emergency Relief Operations

Mahyar Eftekhar, Arizona State University, BA 433, Main Campus, P.O. Box 874706, Tempe, AZ, 85287, United States, eftekhar@asu.edu, Jeannette Song, Scott Webster

To fulfill beneficiaries' demands, humanitarian organizations should design a cost-efficient and time-effective procurement policy. We consider and analyze two common supply management policies: pre-positioning and local-purchasing. Our analysis takes demand characteristics, supply uncertainty, and budget limitations into account.

Public Policy for Energy and the Environment

Sponsored: Public Sector OR

Sponsored Session

Chair: Zana Cranmer, University of Massachusetts - Amherst, 160 Governors Drive, Amherst, MA, 01003, United States, acranmer@umass.edu

Co-Chair: Erin Baker, University of Massachusetts - Amherst, 160 Governors Drive, Amherst, MA, 01003, United States, edbaker@ecs.umass.edu

1 - Benefit Cost And Distributional Effects Analysis For Solar PV In The United States

Parth Vaishnav, Carnegie Mellon University, Pittsburgh, PA, United States, parth.vaishnav@gmail.com, Ines Azevedo

Solar irradiance varies by location and time, as do the private benefits of solar PV. The health, environmental and climate change (HECC) benefits of displacing a unit of grid electricity production, which stem from reduced emissions of CO2, NOx, SOx and PM also vary by time and location. We present a location-specific cost-benefit analysis that quantifies the county-level costs, benefits, and distribution of benefits for residential solar PV in the continental United States, emphasizing an environmental justice perspective.

2 - Expert Elicitation Of The Proliferation Resistance Of Using Small Modular Reactors For The Expansion Of Civilian Nuclear Systems

Jonas Siegel, University of Maryland, College Park, MD, United States, jsiegel@umd.edu, Elisabeth A Gilmore, Nancy Gallagher, Steve Fetter

SMRs could allow for more proliferation resistant designs, manufacturing arrangements and fuel cycle practices at widespread deployment compared to large reactor designs. Here, we conduct an expert elicitation involving the pairwise comparison of future nuclear energy systems that may be feasibly deployed in 2050. The experts do not consistently judge the SMR deployment scenario to have greater overall proliferation resistance than those that rely on larger nuclear generation options. The experts identify two features that are facilitated by SMRs, specifically international safeguards and the operation of multinational fuel cycle facilities, as improving proliferation resistance.

3 - Power Plants Compliance With Co2 Emissions Regulations: The Effect Of Policy Mechanisms, And Technological And Fuel Price Uncertainty

Dalia Patino Echeverri, Duke University, dalia.patino@duke.edu

Under and Alternative Compliance Payment mechanism regulators set a CO2 emissions rate target, a fee (the ACP) to be paid for every ton of emissions in excess of the target, and a deadline to permanently reduce emissions (by installing controls, improving efficiency, reducing generation, or replacing with low carbon technologies). We explore the effects of an ACP policy through the use of a Stochastic Mixed Integer Linear Program representing the investment decision of a regulated electric utility under different ACP designs, and fuel price, and technology uncertainty.

4 - Valuing Offshore Wind Energy

Zana Cranmer, University of Massachusetts Amherst, MA, acranmer@umass.edu, Erin Baker

Much attention has been paid to the environmental costs of offshore wind, such as bird mortality. We are addressing the environmental benefit of offshore wind in the context of climate change. Measuring this value is complex, as it depends importantly on the policy environment and the energy system. We propose a model for the environmental value of offshore wind and show that the policy context determines whether that value is derived from reducing the cost of abatement or reducing the damages associated with emissions. We use a global integrated assessment model, GCAM, to estimate the value, with a focus on the Atlantic coast of the US.

Advances in Research Exploring the Link between Learning and Innovation

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Onesun Steve Yoo, University College London, One Canada Square, London, E14 5AB, United Kingdom, o.yoo@ucl.ac.uk

1 - Design Of Resource Competitions For R&D Projects

Pascale Crama, Singapore Management University, pcrama@smu.edu.sg

Academic research is funded by governments as well as by university administered research funds (UARF) at research universities. Government funding is based on arm's length, competitive peer reviews of project proposals, whereas UARF funding is more relationship-based. We evaluate the impact of these two funding sources and their differing funding rules on the novelty of the projects being funded and social welfare creation. Our research points to the importance of an appropriate design of the two-stage funding system to increase social welfare.

2 - Staged Ideation In Crowdsourced Problem Solving

Nilam Kaushik, University College London, uceikau@ucl.ac.uk

Crowdsourcing ideation platforms are increasingly gaining traction and are being used by firms to tap into the wisdom of crowds to generate ideas and to solve problems. Some such platforms are based on a multi-staged ideation paradigm where ideas are elicited from the user community for an open problem. A few ideas are selected for further refinement which involves updating the idea based on feedback from the user community. Refined ideas are subsequently evaluated and a subset is chosen for winning. Using a novel dataset from a crowdsourcing innovation platform, we investigate factors that affect the selection of an idea into the refinement stage and further into the winning stage.

3 - Research And Development Competition With Spillovers And Uncertain Completion Times

Wenxin Xu, University of Illinois at Urbana-Champaign, wxu9@illinois.edu

Dharma Kwon, Jovan Grahovac

We examine a game-theoretic model of two firms that are competitively engaged in R&D projects and address two questions: (1) What is the impact of natural spillover upon innovative firms' payoffs? (2) Does an innovative firm have an incentive to unilaterally increase the spillover to its competitor? To answer these questions, we investigate the impact of natural spillover on R&D investment strategies when the R&D completion times are uncertain and either firm can receive spillover from the other. We characterize the Nash equilibrium of the model and find that natural spillover may or may not diminish the profit of the more efficient firm.

4 - A Theoretical Analysis Of The Lean Startup's Agile Product Development Process

Onesun Steve Yoo, University College London, onesun.yoo@ucl.ac.uk, Tingliang Huang, Kenan Arifoglu

We provide a theoretical foundation for the lean startup's agile product development process. It helps us better understand why lean start-up works, and also predict when it does not work. We discuss the implications of our results to research and practice.

1 - Analyzing The Predictive Power Of Early Warning Systems In Healthcare

Nasibeh Azadeh-Fard, Visiting Professor, Rochester Institute of Technology, Industrial and Systems Engineering Department, Rochester, NY, 14623, United States, azadehfard@gmail.com, Navid Ghaffarzadegan, Jaime Camelio

Early warning systems have been widely used in healthcare to predict adverse outcome. The prediction power of early warning systems, however, is an empirical question. The objective of this study is to assess the predictive power of early warning systems and prognostic risk indicators in predicting different outcomes in health such as mortality, disease diagnosis, adverse outcomes, care intensity, and survival.

2 - Reverse Bullwhip Effect In Pricing In Retail Industry

Ziaul Haq Adnan, University of North Carolina at Charlotte, Charlotte, NC, United States, zadnan@uncc.edu

Ertunga Ozelkan

Bullwhip effect in pricing refers to the amplified variability of prices. If the variability is amplified towards downstream (upstream), we refer to it as reverse (forward) bullwhip effect in pricing. In this paper, we consider both simultaneous and sequential (e.g. wholesale and retail leading) game structures. We show analytical results and parametric examples for concave, linear, and convex demand functions. We conclude that forward bullwhip effect in pricing occurs for all concave and linear demand functions, and reverse bullwhip effect in pricing occurs for some convex demand function. The rate of amplification of variability in prices varies for different game structure.

3 - A Simulation Approach To Plan DesignV&V Activities For The New Product Reliability Improvement

Mohammad Sadegh Mobin, Western New England University, 1215 Wilbraham Road, Springfield, MA, 01119, United States, mm337076@wne.edu", Zhaojun Li, Mohammad Dehghanimohammadabadi

Product failure modes, their effects, and a set of verification and validation (V&V) activities are outputs of conducting the design failure modes and effect analysis (DFMEA) in the early stages of developing a new product. A robust method for planning V&V activities is needed to mitigate all critical design failure modes by considering cost and timeframe constraints. In this paper, an integrated simulation-DEA (Data Envelopment Analysis) model is proposed to provide the efficient product design V&V activities' plans by considering the uncertainty of V&V process parameters.

4 - Design Of Coordinating Contracts In Volume Discount Group Purchasing

Abdollah Mohammadi, University of North Carolina - Charlotte, 532 Lex Dr., Charlotte, NC, 28262, United States, amoham17@uncc.edu, Ertunga Ozelkan

This study investigates supply chain coordination using contracts in the context of group purchasing (GP), where there is a supplier, a GP agent and multiple customers. In GP the underlying contract between a supplier and the GP agent is quantity discount, while between the agent and the customers it can be a different type of contract. In this study, we specifically investigate revenue sharing or buyback contracts and discuss how and when they coordinate and align objectives of all members of the supply chain.

1 - Vertical Opaque Selling Under Demand Uncertainty

Rachel Chen, UC Davis, rachen@ucdavis.edu

This paper studies opaque selling with vertically differentiated products when demand is uncertain. The quality of the product a consumer receives depends on the realization of the random demand. We show that it is more profitable to offer an opaque product of the vertically differentiated products than to offer a transparent product line.

2 - When Prospect Theory Meets Consumer Choice Models

Ruxian Wang, Johns Hopkins Carey Business School, Baltimore, MD, 21202, United States, ruxian.wang@jhu.edu

According to prospect theory, when the price is higher or lower than a reference point, customers perceive a utility loss or gain. We incorporate the extra utility changes into popular choice models. An empirical study shows that the new choice models can better characterize customer choice behavior.

3 - Price Formation And Efficiency In Ride Sharing Services

Yi Xu, University of Maryland, yxu@rhsmith.umd.edu, Liu Ming, Tunay Tunca, Weiming Zhu

Using data obtained from a leading company, we construct a structural model to estimate price formation in ride-sharing services based on operational characteristics such as the number of consumers and the utilization of drivers. Further, we conduct counterfactual analysis to examine efficiency and welfare implications.

4 - When Do Financial Firms Relocate? A Stochastic View

Michael Pinedo, New York University Stern School of Business, 44 West 4th St. KMC8-152, New York, NY, United States, mpinedo@stern.nyu.edu, Yuqian Xu, Lingjiong Zhu

We consider a financial firm makes the relocation decision based on two perspectives: i) higher expected utility in relocation, and ii) higher probability in achieving certain utility. In this paper, we use the hiring lead time which is a random variable to capture the difficulty in hiring, and thus how this factor impact the relocation decision. At the same time, we integrate in our model the uncertainty and variation in employee capability as well as the uncertainty in their willingness to relocate.

1 - Do Ride Sharing Services Affect Traffic Congestion? An Empirical Study Of Uber Entry

Yili Hong, Arizona State University, Tempe, AZ, United States, ykhong1@asu.edu, Ziru Li, Zhongju Zhang

Sharing economy, which leverages information technology to re distribute unused or underutilized assets to people who are willing to pay for the services, has received tremendous attention in recent years. Its creative business model has disrupted many traditional industries by fundamentally changing the mechanism to facilitate the matching of demand with supply. In this research, we investigate how Uber affects traffic congestion in the urban areas of the United States. Findings from this research provide evidence on the potential effect of ride sharing services in the transportation industry, contributing to the understanding of the sharing economy and government policy decisions.

2 - Room Sharing Economy And Destination Tourism

Wei Chen, University of Arizona, 3750 E Via Palomita, Apt 23103, Tucson, AZ, 85718, United States, weichen@email.arizona.edu, Lijia Xie

While significant debate has surrounded the entry of room-sharing services, limited empirical work uncovers the impact of such services to traveler activity, particularly, tourism flow and satisfaction at local destinations. We exploit a set of natural experiments, the entry of two major room-sharing services, Tujia.com and Xiaozhu.com, into markets of China between 2011 and 2015. The study underscores the connection of peer-to-peer accommodation availability to relocation of traveler spending, extended stays and improved experience which are critical to the local tourism industry gains. Important implications of theory, practice, and policy making will be provided.

3 - The Role Of Syndication In Democratizing Capital Flow In Online Equity-crowdfunding

Qiang Gao, City University of New York, New York, NY, 85719, United States, qiangg@email.arizona.edu, Mingfeng Lin

Equity crowdfunding provides opportunities for startups to raise funds from large number of online potential investors. However, the issue of information asymmetry not only remains as the major barrier for financing these early stage companies but is actually exacerbated by the “virtual” nature of these marketplaces. This paper examines whether syndication, a group of investors who collaborate to pool resources and share risks, in online equity crowdfunding, can alleviate this issue and democratize the access to capital and investment opportunities. We further investigate the drivers for the formation of such syndicates.

4 - “Release Early, Release Often”? The Impact Of Release Frequency In Open-source Software Co-creation

Wei Chen, University of Arizona, weichen@email.arizona.edu Vish Krishnan, Kevin Zhu

A central virtue of OSS is the contributions from the communities, yet our knowledge of how to coordinate and maximize the benefit of such contributions for market success is limited. In this paper, we uniquely formalize, analyze, and validate the impact of product release frequency as a coordinating mechanism in the adoption of open-source products. We build a dynamic structural model to characterize the optimal release strategy from the project owner’s perspective. The theoretical and empirical results have important implications for managing technology-enabled collaboration in open-source communities and for research on open-source software, open innovation, and software adoption.

Consumer Behavior and Pricing Optimization

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Nikolay Osadchiy, Emory University, Atlanta, GA, United States, nikolay.osadchiy@emory.edu

1 - Pricing Under Anticipation

Javad Nasiry, Hong Kong University of Science and Technology-HKUST, nasiry@ust.hk, Ioana Popescu

We model the purchase behavior of consumers by accounting for anticipatory feelings triggered by the prospect of buying at a discount, as well as for the disappointment when anticipated outcomes fail to materialize. We show that sales policies can outperform uniform pricing when a monopolist sells to anticipating customers.

2 - Mental Accounting, Reference Price Adaptation, And The Pricing Of Flat-rate Contracts

Manel Baucells, University of Virginia, 100 Darden Blvd, Charlottesville, VA, 22903, United States, baucellsm@darden.virginia.edu, Woonam Hwang

We propose a model where consumers possess a mental account that stores the worth of items purchased and yet to be consumed. Reference prices act as the book values of these items, and are determined by a psychological process of adaptation to the price evoked by the trade. The model is integrative, in that it explains a wide array of observed anomalies such as sunk-cost effects, payment depreciation, reluctance to trade, preference for pre-payment, and the flat-rate bias. We explore the pricing implications of the model when it comes to flat-rate pricing.

3 - Tell Me What I Want: A Study Of Personalized Assortment Planning For Learning Consumers

Yulia Vorotyntseva, University of Texas at Dallas, Richardson, TX, 7508, United States, yxv120230@utdallas.edu Dorothee Honhon, Canan Ulu

We model retailer’s and consumer’s simultaneous learning about the consumer’s idiosyncratic preferences. In each period the retailer chooses an assortment of products to offer the consumer and learns about her preferences by observing the choice. The consumer picks one product, gets a noisy signal about its utility and updates her beliefs in Bayesian fashion. We use this model to study structural properties of the firm’s optimal assortment policy and to quantify the value of information about the consumer’s experience, such as feedback surveys.

4 - Optimal Dynamic Upgrade

Xiao Zhang, PhD Candidate, The University of Texas at Dallas, 800 West Campbell Rd, Richardson, TX, 75080, United States, xiao.zhang@utdallas.edu, Metin Cakanyildirim, Ozalp Ozer

Upgrade, a strategy used in travel industry to balance supply-demand mismatches among products of different quality levels, is usually implemented either at the booking time or at the consumption time. We study a revenue management problem of a firm which sells two products and offers upgrade option anytime when necessary. The optimal policy specifies the timing of the upgrade option and how many customers should be offered this option.

1 - Modelling Electricity Balancing Market Prices And Premiums

Ezgi AVCI-SURUCU, Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands, avcisurucu@rsm.nl, Wolfgang Ketter, Gerhard-Wilhelm Weber

In smart electricity markets, the increased penetration of renewable sources reveals the need for decision support systems. For developing reasonable bidding strategies, market participants need intelligent agents to make informed decisions about the trade-off between sales in the day-ahead market or in the balancing market. In this paper, by considering a detailed system-level data; firstly we examine the market efficiency by fractal analysis to understand the level of price predictability. Further, due the invalidity of normality and linearity assumptions, we propose non-parametric non-linear models to provide strategic tools for policy makers and market participants.

2 - A Game Theoretic Approach For Load-shifting In The Smart Grid With Storage Capacity

Murat Erkoc, Associate Professor, University of Miami, 1251 Memorial Drive, Eng. Building. Room 282, Coral Gables, FL, 33146, United States, merkoc@miami.edu, Eeyad Al-Ahmadi

We study the load-shifting problem within the context of smartgrid demand response for an electricity market composed of a single energy provider and multiple consumers. We consider the case where the energy provider has the option of installing and managing client storage devices at consumer sites. The provider acts as the leader and decides on price discounts and storage decisions across a finite time horizon. The consumers, acting as followers, respond by deciding if and how they shift their consumption from their nominal demand. We investigate the joint impact of price discounts and storage option on player incentives and peak-to-average ratios.

3 - Essential Aspects Of Power System Resource Planning In Developing Community Of Microgrid

Aida Khayatian, PhD Student, University of Houston, 4722 Calhoun Rd, E206 Engineering Bldg 2, Houston, TX, 77204, United States, akhayatian@uh.edu, Masoud Barati, Gino J Lim

This paper addresses Microgrid expansion planning problem which helps Community Microgrid companies to decide whether or not they invest on Microgrid installation in a competitive electricity market. Integrated resource planning, demand-side management, environmental issues, the competitiveness of power investors, energy efficiency, rural electrification, future load growth and possible power outage in the face of uncertainty and reliability are challenges faced by power system planners. This paper develops a model and policy for Microgrid expansion planning in a competitive electricity market under uncertainty by considering these challenges.

4 - Technology-push, Demand-pull, And Strategic R&D Investment

Benjamin D. Leibowicz, Assistant Professor, University of Texas at Austin, 204 E. Dean Keeton St., Stop C2200, Austin, TX, 78712, United States, bleibowicz@gmail.com

A bilevel modeling framework is constructed to determine the optimal combination of technology-push and demand-pull interventions for a given technology policy application. The inner agents are profit-maximizing firms who solve a two-stage stochastic decision problem with product and process R&D investments. The outer agent is a welfare-maximizing policymaker. Findings illustrate how the optimal technology policy combination varies with the primary motivation for innovating and the relative strengths of three important market failures (incomplete appropriability of R&D, a negative production externality, and imperfect competition).

1 - Understanding The Integration Of Freight Supply Chain By Integrating Pairwise Decision Mechanism

Dapeng Zhang, Hyperloop Tech Inc., dapeng@hyperlooptech.com

This paper develops an innovative econometric model to understand joint response. The first part explains the matching process in a many-to-one matching structure; The second part characterizes the joint decision making process of mutually-selected decision makers. The two parts are integrated by recognizing their dependency that is essentially a sample selection process: a joint response is only observed for matched decision makers. The proposed model is estimated using a Bayesian Markov-Chain Monte-Carlo approach. The likelihood functions and posterior distributions are derived and followed by simulation studies to test parameter recovery capability.

2 - Spatial Optimization For Designing Public Water Supply Systems

EunSu Lee, New Jersey City University, elee3@njcu.edu

To supply safe and clean water is critical for urban life. The objective of this study is to provide spatial and optimization approach for public water supply. The model considers existing and potential water sources to design public water supply network. This study concerns demand-supply balance and age and safety of the existing and network.

1 - Towards Calculating Realistic Walking Paths In Warehouses: A New Approach

Sabahattin Gokhan Ozden, Graduate Research Assistant, Auburn University, Shelby Center 3333, Auburn, AL, 36849, United States, gokhan@auburn.edu, Alice E. Smith, Kevin Gue

We consider a visibility graph as a new way of routing order pickers in traditional and fishbone layout warehouses.. The traditional method of calculating distances is not realistic for many warehouse designs, especially those with non-traditional aisle structures. By using a visibility graph we not only consider paths that are more realistic for non-traditional layouts but can also make unbiased comparisons between traditional and non-traditional layouts for order picking operations.

2 - Retail Layouts For Maximal Exposure

Pratik J. Parikh, Wright State University, 3640 Colonel Glenn Highway, 207 Russ Engineering Center, Dayton, OH, 45435-0001, United States, pratik.parikh@wright.edu, Corinne H. Mowrey

Industry practice suggests that over 70% of purchase decisions are made in the store, and that store design influences shoppers' buying decisions. Arguably one of the most important attributes of store design is product exposure; i.e., what the customer sees. We seek to optimize the design of a store section in order to maximize exposure to a traveling shopper while accounting for bi-directional traffic flow. Results from our approach suggest that layouts that combine both acute (or obtuse) and 90° rack orientations generate substantially higher exposure than traditional layouts for given floor-space and minimum rack-display constraints.

3 - A Multi-objective Intermodal Network Design Considering The Effect Of Carbon Tax

Sunderesh S Heragu, Oklahoma State University, sunderesh.heragu@okstate.edu, Xiaoren Duan

In this paper, we analyze a real world coal transportation intermodal network across 15 states in US including highway, railway and inland waterway. With a motivation to minimize the economic cost and environment cost simultaneously, we propose multi-objective optimization models to analyze intermodal transportation with economic, time performance and environmental considerations. A time penalty parameter is introduced to simulate the real coal transportation behavior through the mathematical model. The breakeven point for tax rate is 13 dollars per ton, which can provide minimum carbon emission without increasing the transportation cost.

Fleet Sizing Models

Sponsored: Railway Applications

Sponsored Session

Chair: Dharma Acharya, President, KOSU Services LLC, 241 Auburndale Dr., Ponte Vedra, FL, 32081, United States, acharya.dharma@gmail.com

Co-Chair: Michael Gorman, Prof., University of Dayton, Dayton, OH, 12345, United States, mgorman1@udayton.edu

1 - Fleet Sizing Model Overview

Michael Gorman, University of Dayton, mgorman1@udayton.edu

Appropriate fleet sizing is critical for rail asset utilization and service. I will discuss the basic trade-offs for the fleet sizing decision, discussing both deterministic and stochastic approaches. I will present rail fleet sizing and other literature, and discuss approaches taken in practice. Key discussion points surrounding the fleet sizing decision will be raised.

2 - Fleet Sizing Model Case - Freight Railroad Perspective

Clark Cheng, Senior Director Operations Research, Norfolk Southern Railway, 1200 Peachtree Street NE, Atlanta, GA, 30309, United States, Clark.Cheng@nscorp.com, Andy Yoon, Xin Zhang

We will present a freight car fleet planning tool that evaluates the long-term impact of fleet management decisions based on demand forecast, budget and costs. The tool has been in use at Norfolk Southern for the last 10 years to assist with decision making in freight car acquisitions to maximize long-term profits in the future years.

3 - Intermodal Equipment Fleet Sizing

Bruce Patty, Veritec Solutions, bpatty@veritecsolutions.com

This presentation will review approaches used to determine the number of both containers and chassis needed to support projected volumes. Models used to estimate chassis demand by location will be discussed based on the experience of the author as AVP-Equipment Strategy at Pacer Stacktrain. Offhire and onhire planning will also be included in the session.

4 - Fleet Sizing Model: Railroad And Shipper Perspective

dharma acharya, KOSU Services LLC, acharya.dharma@gmail.com

In this session, we will present how some railroads and shippers perform fleet sizing of their rail car fleet to move the forecast shipments. We will also discuss issues associated with uncertain demand forecast and cycle times. Additional functionality requirements to meet the future business needs will also be presented.

Network Design and Maintenance in Transportation

Sponsored: TSL, Intelligent Transportation Systems (ITS)

Sponsored Session

Chair: David Rey, UNSW Australia, School of Civil and Environmental Engineering, UNSW, 2072, Australia, d.rey@unsw.edu.au

1 - Scheduling Work Zones In Networks Of Service Vehicles

Dening Peng, Arizona State University, 699 South Mill Avenue, Tempe, AZ, 85281, United States, dening.peng@asu.edu, Pitu B Mirchandani

A mixed integer linear programming model is developed to schedule work zones in transportation networks of service vehicles (e.g. trucks). For links with active work zones, the available capacity of that link is reduced. The origin-destination flow demands are given, and they route through the network based on available capacities on the links to achieve the total minimum cost. The goal is to schedule the work zones so that all maintenance work can be completed before a given completion date while the total flow cost over the project period is minimized. An innovative randomized fix-and-optimize heuristic is developed to solve the problem with much better efficiency than commercial solvers like CPLEX.

3 - Optimal Deployment Of Autonomous Vehicle Lanes With Endogenous Market Penetration

Zhibin Chen, University of Florida, 1, Gainesville, FL, 32603, Lihui Zhang, Yafeng Yin, Fang He

This paper first models the evolution of autonomous vehicle (AV) market penetration on a multimodal transportation network that includes conventional vehicles (CVs) and AVs. A time-dependent mathematical approach is then proposed to optimize the deployment plan of AV lanes such that the social cost is minimized. The AV lanes are exclusive lanes for AVs, and the deployment plan will dictate when and where, and how many AV lanes to be deployed.

4 - Road Extension Prioritization And Scheduling Problem

Mersedeh Tariverdi, University of Maryland, College Park, Washington, DC, 20009, United States, mercedeh@umd.edu, David Rey, Saeed Asadi Bagloee

Budget scarcity as well as limited resources in road construction may have a significant toll on the completion of the projects. Therefore it is of highest importance to arrive at a knowledge based decision support system for projects prioritization and scheduling. We represent this problem as a bi-level program where the objective function maximizes the return of projects' completion defined as the total savings derived from traffic improvement. The interconnections among the projects as well as prerequisites requirements are imposed using mixed integer constraints. An efficient solution algorithm is developed based on an outer approximation approach.

5 - A Branch And Price Algorithm For The Work-zone Scheduling Problem

David Rey, University of New South Wales, School of Civil and Environmental Engineering, Sydney, Australia, d.rey@unsw.edu.au, Hillel Bar-Gera, Vinayak Dixit, S. Travis Waller

We address the work-zone scheduling problem which consists in finding the optimal schedule for the coordination of road occupancy projects in a transport network over a planning period. Road works and maintenance operations which require partial or total road closures over a period of time may considerably impact network performance and result in significant delays. In addition, the effects of conducting multiple work-zone projects simultaneously may be non-additive, hence increasing the difficulty to anticipate congestion effects. We present a new branch and price algorithm for the work-zone scheduling problem which relies on the enumeration of work-zone project combinations.

DAAD Special Session on Multiobjective Optimization for Improved Modeling of Complex Systems

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Stefan Ruzika, University of Koblenz-Landau, Universitätsstraße 1, Koblenz, 56070, Germany, ruzika@uni-koblenz.de

1 - Efficient Computation Of The Search Region In Multi-objective Optimization

Kerstin Daechert, Chair of Management Science and Energy Economics, University of Duisburg-Essen, Germany, kerstin.daechert@uni-due.de

Multi-objective optimization methods often proceed by producing new solutions in an iterative way. For this purpose it is important to determine and update the search region. It can be described by a set of so-called local upper bounds whose components are defined by already known nondominated points. In this talk we concentrate on how to design this update efficiently with the help of a specific neighborhood structure among local upper bounds. Thanks to this structure we can quickly identify all local upper bounds that have to be updated with respect to a new nondominated point. Besides, the neighborhood structure provides new theoretical insight into the search region for more than two objectives.

2 - A General Approximation Method For Bicriteria Minimization Problems

Stefan Ruzika, Department of Mathematics/Natural Sciences University of Koblenz-Landau Universitätsstraße 1 56070 Koblenz (Germany), ruzika@uni-koblenz.de

We present a general technique for approximating bicriteria minimization problems with positive-valued, polynomially computable objective functions. Given 0 < ≤ 1 and a polynomial-time -approximation algorithm for the corresponding weighted sum problem, we show how to obtain a bicriteria (· (1 + 2), · (1 + 2/))-approximation algorithm for the budget-constrained problem whose running time is polynomial in the encoding length of the input and linear in 1/ . Moreover, we show that our method can be extended to compute an (· (1 + 2), · (1 + 2/))-approximate Pareto curve under the same assumptions.

3 - Bicriteria Analysis Of The Fixed-charge Network Flow Problem - Separating Fixed Costs And Flow Costs

Michael Stiglmayr, University of Wuppertal, Wuppertal, Germany, stiglmayr@math.uni-wuppertal.de

The fixed-charge network flow problem is an inherently biobjective optimization problem: Minimize fixed (design) costs and minimize flow costs. In its classical form the sum of these two objectives is minimized which corresponds to the weighted-sum scalarization of the associated biobjective problem.
However, design costs and flow costs are not directly comparable, since design costs occur once, while flow costs are due periodically. In this talk we present heuristic and exact solution approaches based on the two-phase method and ranking algorithms.

4 - Multi-objective Optimization Of Coupled Systems

George Fadel, Mechanical Engineering Department Fluor Daniel Engineering Building Clemson University, Clemson SC 29634 USA, fgeorge@clemson.edu

An engineering problem consists of two multi-objective problems that must be coordinated. The top level focuses on the optimal placement of components under the hood of a car, with design variables which specify the location of the various non-convex components in a non-convex volume, and non-overlap constraints. Then, the optimization of shape and size of a battery pack that is one of the components placed under the hood is conducted. We show how the two problems can be assigned to separate teams, and their optimizations can be coordinated, enabling the chief designer to allow the sub-problem or the upper level design team to be driving the solution.

1 - Modeling User Engagement In Mobile Content Consumption With Tapstream Data

Yingjie Zhang, Carnegie Mellon University, yingjie2@andrew.cmu.edu

Low engagement rate and high attrition rate have been major challenges for the success of mobile apps. To date, little is known towards how companies can improve user engagement and business revenues through designing effective in-app pricing strategies. We propose a structural model by accounting for time-varying nature of engagement and consumer forward-looking behavior. We analyze mobile tapstream data from a popular mobile reading app. Our results enable us to tailor optimal pricing strategy to each consumer based on their engagement status. Interestingly, we found such engagement-specific pricing strategy leads to lower average price for consumers and higher overall business revenues.

2 - Examine Large Scale App Usage Structure By Graphical Model

Jinyang zheng, University of Washington, Seattle, zhengjy@uw.edu

Identifying an app which generates usage to other app(s) is not only a crucial task for industrial practitioner, but also challenging for researchers given the larger scale of App network. With a state of art graphical model method, we overcome the limitation of traditional econometric causal inference models and examine the causal relationship in emerging App market among Chinese users. Our model generates a causal diagram displaying usages of what app would that of each specific app leads to. Spillover effects of certain app and sequential causal effects can be easily identified, suggesting significant role of graphical model in business analytics and big data related research.

3 - Airbnb And Hotel Latent Quality

Uttara Ananthakrishnan, Carnegie Mellon University, uttara@cmu.edu

Sharing economy has empowered consumers to communicate their needs with one another and thus has helped them to assume the role of both suppliers and producers seamlessly. In this paper, using a natural experiment set up and a novel dataset, we analyze how Airbnb has impacted the traditional way of conducting the hotel business. We study if the hotels have responded to the increasing number of Airbnbs by increasing their quality and whether this response varies across different types of hotels. We analyze the hotel industry's response across different dimensions in quality by not only considering star ratings, but also user sentiments and latent quality expressed in textual content of reviews.

4 - How Much Is An Image Worth? An Empirical Analysis Of Property's Image Aesthetic Quality On Demand At Airbnb

Shunyuan Zhang, Carnegie Mellon University, Pittsburgh, PA, United States, shunyuaz@andrew.cmu.edu
Dokyun Lee, Param Vir Singh, Kannan Srinivasan

Sharing economy platforms such as Airbnb are challenged with product quality uncertainty. To solve the issues, Airbnb has implemented strategies such as professionally taking high quality photos for hosts and calling them verified. This paper studies the impact of having verified photos. To assess the aesthetic quality of images, we use machine learning techniques. Employing Difference-in-Difference method we find rooms with verified photos are on average 9% more frequently booked. We separate the effect of photo verification from photo quality and find an extra $2,455 in yearly earnings brought by high photo quality. We find asymmetric spillover effects across rooms in the same neighborhood.

Additive Manufacturing

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Prahalad Krishna Rao, Assistant Professor, Binghamton University, P.O. Box 6000, Binghamton, NY, 13902-6000, United States, prao@binghamton.edu

1 - Accelerated Process Optimization For Laser-based Additive Manufacturing By Leveraging Similar Prior Studies

Amir M Aboutaleb, Mississippi State University, Industrial & Systems Engineering Department, Mississippi State University, MS, 39762, United States, aa1869@msstate.edu, Linkan Bian

Manufacturing parts with target properties and quality in Laser-Based Additive Manufactured (LBAM) parts is crucial towards enhancing the "trustworthiness" of this emerging technology. We propose a novel process optimization method by directly utilizing experimental data from previous studies as the initial experimental data to guide the sequential optimization experiments of the current study. We conduct a real-world case study that optimizes the relative density of parts manufactured using a Selective Laser Melting system. A combination of optimal process parameters is achieved within 5 experiments.

2 - Online Detection For Cyber Attacked Additive Manufactured Parts By Real-time Sensing And Analysis

Chenang Liu, Virginia Tech, Blacksburg, VA, 24061, United States, lchenang@vt.edu, Tomilayo Komolafe, Zhenyu Kong, Jaime Camelio

Cyber security of additive manufacturing (AM) is important for some critical applications such as defense industry. This work focuses on the online detection of attacked AM parts by real-time sensing using network analysis based data fusion techniques. Using the effective features extracted from multiple sensor data, the discrepancy between normal and attacked AM parts can be detected effectively. The case study show that the proposed method can successfully detect the attacked parts, but does not cause false alarm for the sample normal part.

3 - Laplacian Eigen Compressive Sensing For Dimensional Integrity Classification In Additive Manufacturing

Prahalad Rao, Binghamton University, prahalad.k.rao@gmail.com

This work relates the effect of parameters, namely, infill and extrusion temperature in fused filament fabrication (FFF) additive manufacturing (AM) process on pre-selected geometric dimensioning and tolerancing (GD&T) features. Next, a method is proposed to classify the part quality in terms of the geometric integrity using minimal number of laser-scanned point cloud data. The proposed method combines spectral graph theory with compressive sensing, as a means of supervised classification of part geometric integrity.

1 - Self-organizing Network For Variable Clustering And Predictive Modeling

Hui Yang, Penn State University, huy25@engr.psu.edu

Rapid advancement of sensing and information technology brings the big data, which presents a gold mine of the 21st century to advance knowledge discovery. However, big data also brings significant challenges for data-driven decision making. In particular, it is common that a large number of variables (or predictors, features) underlie the big data. Complex interdependence structures among variables challenge the traditional framework of predictive modeling. This paper presents a new methodology of self-organizing network for variable clustering and predictive modeling.

2 - Forecasting Of Weather-driven Damage In A Distribution System Of Electric Power

Zhiguo Li, IBM, hardthinking@gmail.com

Electric utilities spend a large amount of resources and budget on managing unplanned outages, the majority of which are driven by weather. A major ongoing effort is to improve their emergency preparedness process, in order to reduce outage time, reduce repair costs, and improve customer satisfaction. This paper proposes a method for forecasting the number of damages of different types that will result from a weather event in a power distribution system. The proposed method overcomes practical issues with sparsity of historical damage and weather records, and its performance is evaluated on real utility data. This work is the core of an approach called Outage Prediction and Response Optimization.

3 - Prognostics Of Surgical Site Infections Using Dynamic Health Data

Yan Jin, University of Washington - Seattle, yanjin@uw.edu, Shuai Huang

Surgical Site Infection (SSI) is a national priority in healthcare research. To achieve better SSI risk prediction models, there have been emerging mobile health (mHealth) apps that can closely monitor the patients and generate continuous measurements of many wound-related variables and other evolving clinical variables. Since existing predictive models of SSI have quite limited capacity to utilize the evolving clinical data, we develop the corresponding solution to improve these mHealth tools with decision-making capabilities for SSI prediction. We derive efficient algorithms and demonstrate the advantage of our new predictive model on a real-world dataset.

4 - Spatiotemporal Model With Dirichlet Process Mixing For Nonnormal And Nonstationary Data

Jia Liu, Virginia Tech, jliu@vt.edu

In real-life, sensor data often violate assumptions of normality and stationarity required by many prevalent statistical methods. In order to acquire accurate prediction and interpolation by sensor data, a nonparametric spatiotemporal model is proposed, which takes non-normality and non-stationarity of data into account. In this model, spatial correlation is captured by Dirichlet process mixture model using particle filter. Moreover, temporal correlation is incorporated into this model by using recurrent Dirichlet process. This model can be used in various fields with data exhibiting non-normality and non-stationarity to achieve accurate interpolation and prediction.

Transportation, Freight III

Contributed Session

Chair: Carlos Alberto Gonzalez-Calderon, Rensselaer Polytechnic Institute, 4 25th St, Apt 5, Troy, NY, 12180, United States, gonzac8@rpi.edu

1 - A Multi-commodity Intermodal Traffic Assignment Between Rail And Truck

Lokesh Kumar Kalahasthi, Rensselaer Polytechnic Institute, 22 College Ave, Troy, NY, 12180, United States, kalahl@rpi.edu Trilce Marie Encarnacion, Jose Holguin-Veras, John E Mitchell

The goal of the paper is to obtain an optimization model that gives a freight traffic assignment on a combined network of road and rail; that could be used to assess the freight modal split including vehicle types and intermodal transfers. Authors of this paper have conducted In-Depth-Interviews (IDI) with shippers, carriers and receivers regarding the factors influencing their mode choice. The challenge is to incorporate the findings from these IDIs into a mathematical model. Major findings include commodity type, backhaul, shipment limit, transfer time, reliability in transit time restrictions. The model also incorporates the variation in the rail pricing based on origin and destination.

2 - Reliable Routing Of Multicommodity Road-rail Intermodal Freight Under Uncertainty

M. Majbah Uddin, University of South Carolina, 300 Main Street, Civil and Environmental Engineering, Columbia, SC, 29208, United States, muddin@cec.sc.edu, Nathan Huynh

A reliable routing model for multicommodity shipments on a road-rail intermodal freight transport network, where network elements are subject to uncertainty, is proposed. A stochastic mixed integer program is formulated which minimizes not only operational costs but also penalty cost associated with unsatisfied demand. This study provides a novel distribution-free approach to ensure probabilistic guarantees on the resulting routing plan. Case study on a small network reveals the key characteristics of the proposed model.

3 - Shipment Consolidation And Dispatching With Cross-docks

Sinem Tokcaer, Izmir University of Economics, Fevzi Cakmak Mh, Sakarya Cd No:156, Izmir, 35330, Turkey, sinem.tokcaer@ieu.edu.tr, Ahmet Camci, Ozgur Ozpeynirci

Freight forwarders dealing with long haul transportation establish their own consolidation systems in order to reduce costs by economies of scale and efficient use of owned or rented vehicles. Such consolidation systems usually include cross-docking terminals to provide additional services and reduce the travelling time of the vehicles. We propose a shipment consolidation and dispatching problem with cross-docks, and develop a mathematical programming model. The model suggests the consolidation and transportation plans. We propose lower and upper bounds, develop a Variable Neighborhood Search algorithm, and test the performances of develop methods on randomly generated instances.

4 - Freight Trip Generation (FTG), Freight Generation FG) And Service Trip Attraction (STA) In New York City (NYC) And Capital Region

Carlos Alberto Gonzalez-Calderon, Rensselaer Polytechnic Institute, 4 25th St, Apt. 5, Troy, NY, 12180, United States, gonzac8@rpi.edu, Jose Holguin-Veras, Shama Campbell, Lokesh Kumar Kalahasthi

This paper presents a thorough analyses and econometric models explaining the Freight Trip Generation (FTG), Freight Generation (FG) and the Service Trips Attraction (STA) in the New York City and Capital Region. The team conducted a detailed survey including the number of deliveries (received), shipments (sent), type of cargo, weight of shipment, industry sector, truck type, who transports the cargo (vendor or receiver). This study serves as a tool for transportation planners in understanding the freight patterns in urban areas.

1 - Developing an Integrated Approach To Optimize Vehicle And Driver Scheduling Problem With Equilibrium Constraint

Bisheng He, Southwest Jiaotong University, 111#, 1st Section, Northern 2nd Ring Road, Chengdu, 610031, China, bishenghe@home.swjtu.edu.cn, Xiaobo Liu, Gongyuan Lu, Wei Xiao

We optimized vehicle and driver scheduling problem considering equilibrium constraint to maintain their equal workload. An integer programming model was established and solved by integrating a heuristic algorism and a commercial solver. Comparison results indicated that this method could effectively improve the scheduling efficiency and equilibrium based on a real world case from Ji'nan Transit Company.

2 - How Tight Capacity Constraints Invoke Bounded Rationality And How To Consider Bounded Rationality In Designing Dynamic Capacitated Transit Service Network

Jiangtao Liu, Arizona State University, 2026 S Hammond Drive, Apt 205, Tempe, AZ, 85282, United States, jliu215@asu.edu, Xuesong Zhou

This talk will discuss how tight capacity constraints invoke bounded rationality and how to address bounded rational decision rules of travelers in a dynamic transit service network with tight capacity constraints. Within a space-time network, we propose an agent-based single-level integer linear programming model, which can be further decomposed as two efficiently solvable subproblems through Lagrangian decomposition.

3 - Study on The Taxi Fleet Of Electric Vehicles With Battery Swapping

Lei Li, Zhejiang University, 866 Yuhangtang Rd, West Lake District, Hangzhou, 310058, China, lilei.simon@gmail.com, Qingwei Jin

In this paper, we consider that a company is using electric vehicles with battery swapping to satisfy the urban taxi traveling demand. We construct a choice model based on the utility of the taxi drivers which reflects the adoption model of electric taxi vehicles. Based on the adoption model, the company is trying to maximize its profit based on the optimal decisions of battery capacity and service price. We set up a revenue model to find these optimal decisions and consider the impacts of technology advancements. We also extend this model to a mixed case in which the swapping stations serves both taxis and private vehicles.

4 - Pricing Analysis And Optimization Of Mobility On Demand Service

Hao Zhou, Research Scientist, Ford Motor Company, 2101 Village Road, Dearborn, MI, 48124, United States, haozhou@umich.edu

Mobility On Demand (MoD) is a new transportation system that allows users to make on demand ride request using devices such as smartphone or tablet. The MoD back-end service tries to dynamically schedule these requested rides to maximize ride-sharing while minimizing waiting time. This research tries to analyze 1) under what conditions such MoD system can be functioning efficiently, and 2) what would be the right pricing scheme for this kind of MoD system.

5 - An Integrated Priority Optimization And Intelligent Traffic Signal Control Model

Mehdi Zamanipour, University of Arizona, 7415 Seneca Ridge Dr, McLean, VA, 22102, United States, zamanipour@email.arizona.edu, Govind Vadakpat

In this research, an integrated priority and adaptive signal control model is developed that can intelligently consider connected vehicles and priority eligible vehicles at both intersection level and section level in a low connected vehicles penetration rate environment. Fundamentals of shockwave theory and queue estimation techniques are used in the mathematical model. Standard traffic control methods including coordinated-actuated operation are taken in to consideration. The study also conducts a sensitivity analysis on the Dedicated Short Range Communication (DSRC) by virtually extending the range.

1 - An Empirical Analysis Of Supply Chain Finance Adoption

David Wuttke, EBS University, Burgstr. 5, Oestrich-Winkel, 65375, Germany, david.wuttke@ebs.edu, Eve Rosenzweig, H. Sebastian Heese

We empirically test hypotheses derived, in part, from the literature on adoption of Supply Chain Finance (SCF) by buyers and their suppliers. We identify payment terms, payment terms extensions, and annual spend as important drivers of adoption speed. We also examine the ways in which the institutional environment of a supplier influences the speed of SCF adoption. In doing so, we provide a fairly comprehensive set of insights for buyers who seek to implement SCF with their suppliers.

2 - Models For Evaluating And Monitoring Supply Chain Network Design Efficiency

Hakan Yildiz, Assistant Professor, Michigan State University, Department of Supply Chain Management, 370 N Business Complex, East Lansing, MI, 48824, United States, yildiz@broad.msu.edu, Sri Talluri, Jiho Yoon, John M Wassick

In order to evaluate and monitor the real life effectiveness of a new supply chain network design, we employ a statistical control chart that monitors an integrated performance index generated from data envelopment analysis (DEA), which effectively considers multiple performance measures and the relationships between them. In addition, this methodology is used to trigger the re-evaluation of the network design. Moreover the clustering methods used can help management focus on improvement strategies and resource allocations.

3 - Supply Chain Performance With A Target Oriented Retailer

Qinshen Tang, National University of Singapore, Business School, I Business Link, Singapore, Singapore, tang@u.nus.edu, Gongtao Lucy Chen, Melvyn Sim

We study a supply chain with one supplier and one target-oriented retailer, who decides the order quantity to maximize his ability to reach a target profit, which is evaluated by a CVaR satisficing measure. We investigate how the retailer's target-oriented preference affects the supply chain performance. With a linear target formation model, the supplier can significantly benefit from the retailer's target-attaining behavior. The supply chain can also perform better with a target-oriented retailer than with a risk-neutral retailer. More interesting is, the target-oriented retailer can sometimes help the supply chain achieve the same efficiency level as in a centralized system.

1 - Strategic Nurse Allocation Policies For A Pediatric Intensive Care Unit

Osman Tuncay Aydas, University of Wisconsin-Milwaukee, 3202 N Maryland Avenue, S466, Milwaukee, WI, 53202, United States, otaydas@uwm.edu, Anthony D. Ross, Kaan Kuzu

We study integrated nurse staffing and scheduling in Pediatric Intensive Care Units. Feasible nurse schedules are generated using algorithms for the mixed-integer programming models developed in this work. Main objective is to reduce nurse staffing costs while balancing the under- and over staffing risks. We include a novel methodology for estimating nurse workloads by considering patient acuity and activity in the unit.

2 - Wait Time Announcements At Hospital Emergency Departments

Marco Bijvank, University of Calgary, 2500 University Dr. NW, Calgary, AB, T2N 1N4, Canada, marco.bijvank@haskayne.ucalgary.ca, Zhankun Sun

A number of Canadian hospitals have started publishing live emergency department (ED) wait times online in an effort to provide patients with expectations on how long they will have to wait to be seen for non-urgent care after initial assessment by a triage nurse. We accurately predict the state-dependent wait times at emergency departments based on a busy-period analysis for a multi-class, multi-server priority queue with delayed feedback. We illustrate the robustness and impact of the predictor on patient flow and patient care with a case study at four major hospitals in the Calgary area.

3 - Allocation Of Medical Interventions In Outbreak Control: The Case Of Ebola Virus

Farbod Farhadi, Roger Williams University, 1 Old Ferry Road, Bristol, RI, 02809, United States, ffarhadi@rwu.edu

The outbreak of Ebola in 2014 in western Africa is one of the fastest and deadliest outbreaks in history of viral diseases, causing a reported 28 thousand suspected cases and over 11 thousand deaths, according to WHO, leading to over 70% fatality rate. Further outbreaks of the disease may occur in the future and fast and effective containment strategies to control the spread is vital. In this study a model for efficient allocation of medical interventions for outbreak containment is presented.

5 - Cyclic Physician Scheduling Using Goal Programming

Hamoud Sultan Bin Obaid, PhD Student, University of Oklahoma, 1027 E Brooks St., Apt E, Norman, OK, 73071, United States, hsbinobaid@gmail.com, Theodore B Trafalis

A two-phase approach to construct a three-month schedule for physicians at an outpatient clinic is proposed. The goal of the proposed model is to minimize the variability of clinic and surgery sessions over the three-month period and utilize resources. From mathematical point of view, the goal is to reduce the complexity of solving this problem. The data used in this problem is obtained from King Khaled Eye Specialist Hospital in Saudi Arabia.

1 - Minimum Cost Allocation Of Quality Improvement Targets: The Effects Of Forgetting And Knowledge Decay

Didun Peng, Purdue University, 610 Purdue Mall, West Lafayette, IN, 47906, United States, peng67@purdue.edu Weijia Wang, Robert Plante, Jen Tang

This paper incorporates knowledge depreciation in two dimensions of learning: forgetting in autonomous learning and induced learning. We first present a comprehensive quality cost progress function to account for both learning and forgetting effects, where the forgetting effects are imbedded in the progress function components of accumulated production and induced learning. Within the context that a manufacturer allocates quality improvement targets to its suppliers, an optimization model is developed to allocate induced learning activities that minimize the total system cost. A numerical examples of an internal supplier process is used to demonstrate the model.

2 - Sustainability and Changeability In Manufacturing System

Shima Ghanei, University of Minnesota -Duluth, 105 Voss Kovach Hall,1305 Ordean Court, Duluth, MN, 55812, United States, ghane009@d.umn.edu, Tarek Al Geddawy

Changeable Manufacturing Systems (CMS) are designed to quickly adapt to changing market requirements by transition from a configuration to the next. Not only is the reconfiguration cost dependent on degree of system convertibility and scalability, but also dependent on what time of the year during which it is performed, since energy pricing changes within and between seasons. This paper presents a new linear mixed integer mathematical model to maximize sustainability of CMS on the tactical level. It is solved by CPLEX solver in GAMS software to analyze influence of volatile energy pricing and variable demand on system convertibility and scalability which can affect layout configuration selection.

3 - Printing The Future: Using Analytics To Advance Additive Manufacturing

Sarah Powers, Oak Ridge National Laboratory, One Bethel Valley Rd., P.O. Box 2008, Oak Ridge, TN, 37831, United States, powersss@ornl.gov

Recent advances in additive manufacturing have led to many success stories of large 3D printed objects and leave the industry poised for rapid growth. This work describes a multi-pronged approach for data discovery, engaging multiple analytic tools as well as a framework to ingest and house the data itself in an effort to identify areas for process improvement and promote the potential for advanced defect detection.

4 - A Short Note On The Effect Of Sample Size On The Estimation Error In Cp

Zahra Sedighi Maman, Auburn University, Auburn, AL, 36849, United States, zzs0016@auburn.edu, William Murphy, Saeed Maghsoodloo, Fatemeh HajiAhmadi, Fadel Megahed

Process Capability indices such as Cp are used extensively in manufacturing industries. In practice the parameter for calculating Cp is rarely known and is frequently replaced with estimates from an in-control reference sample. This study explores the optimal sample size required, with some practical tools to achieve a desired error of estimation using absolute percentage error of different Cp estimates.

Optimizing the Kiel Canal – Online Routing of Bidirectional Traffic

Keynote Session

Michael Trick, IFORS President, Carnegie Mellon University, Pittsburgh, PA 15213-3890, trick@cmu.edu

1 - Optimizing The Kiel Canal – Online Routing Of Bidirectional Traffic

Rolf H Mohring, Beijing Institute of Scientific and Engineering Computing, Beijing, China, rolf.moehring@me.com

We introduce, discuss, and solve a hard practical optimization problem that deals with routing bidirectional traffic on the Kiel Canal, which is the world's busiest artificial waterway with more passages than the Panama and Suez Canal together. The problem arises from scarce resources (sidings) that are the only locations where large ships can pass each other in opposing directions. This requires decisions on who should wait for whom (scheduling), in which siding to wait (packing) and when and how far to steer a ship between sidings (routing), and all this for online arriving ships at both sides of the canal. The lecture is based on joint work with Elisabeth Lübbecke and Marco Lübbecke.

Creating the Exascale Ecosystem for Science

Invited: Plenary, Keynote

Invited Session

Bogdan Bichescu, The University of Tennessee, Knoxville, TN 37996-0525, bbichescu@utk.edu

1 - Creating The Exascale Ecosystem For Science

Jeff Nichols, Oakridge National Laboratory, Oak Ridge, TN, United States, malonelt@ornl.gov

The way we tackle grand challenge science questions at the national scale has changed over the past two decades with the advent of both modeling and simulation (M&S) and "big data" becoming more recognized and supported discovery paradigms. In fact, most large scientific problems today are solved as integrated solutions of experiment, theory, M&S, and data analytics. The past several decades of high performance computing have focused on delivering compute intensive systems and their performance measured by how fast they can accomplish a simple matrix multiply (e.g., high performance linpack). Today's complex workflows require not only compute intensive capabilities, but also capabilities that target data analytics approaches such as deep learning, graph analytics, or map reduce. In this talk I will describe several scientific areas that require an integrated approach and discuss the ecosystem [ORNL's Leadership Computing Facility (OLCF) and its Compute and Data Environment for Science (CADES)] that we have created. We continue to invest in the evolution of this ecosystem to enable successful delivery of important scientific solutions across a broad range of disciplines.

Analytic + IT + Deployment = Real World Impact

Keynote Session

Robin Lougee, IBM TJ Watson Research Center, Yorktown Heights, NY 10598, rlougee@us.ibm.com

1 - Analytic + IT + Deployment = Real World Impact

Ramayya Krishnan, Carnegie Mellon University, Pittsburgh, PA, United States, rk2x@cmu.edu

The Heinz College is home to two highly ranked graduate schools: 1) Information Systems and Management and 2) Public Policy and Management, a deliberate structure which exists only at Carnegie Mellon University (CMU). Founded by noted Management Scientist W. W. Cooper to educate "men and women capable of intelligent action", the unique structure of the college gives its educational programs a holistic focus on societal problem solving. This focus translates into teaching cutting-edge information technologies and analytic methods and providing students with multiple opportunities to apply them to solve real world problems that matter. This focus also means an emphasis on structuring unstructured problems and an education in the skills required to be effective at that structuring and at decision making, and engendering change through deployment. In this keynote, I will provide an overview of our award winning analytics program and describe how we combine industry-funded research centers and their partner ecosystems to provide students with multiple opportunities to learn an array of analytic skills and problem-solving expertise in order to be effective in the real world.

Interpretable Machine Learning in Social Science

Sponsored: Data Mining

Sponsored Session

Chair: Tong Wang, MIT, Cambridge, MA, United States, tongwang@mit.edu

1 - Interpretable Decision Sets: A Joint Framework For Description And Prediction

Himabindu Lakkaraju, Stanford University, himalv@cs.stanford.edu

One of the most important obstacles to deploying predictive models is the fact that humans do not understand and trust them. In this talk, I will present interpretable decision sets, a framework for building predictive models that are highly accurate, yet also highly interpretable. We formalize decision set learning via an objective function that simultaneously optimizes for accuracy, conciseness, and meaningfulness of the rules. We prove that our objective is a non-monotone submodular function, and efficiently optimize it with a 2/5 approximation guarantee. Our experiments demonstrate that interpretable decision sets help humans understand their data better than other interpretable models.

2 - Exploring Complex Systems Using Semi-parametric Graphical Models

Mladen Kolar, University of Chicago, mkolar@chicagobooth.edu

Extracting knowledge and providing insights into the complex mechanisms underlying noisy high-dimensional data sets is of utmost importance in many scientific domains. Networks are an example of simple, yet powerful tools for capturing relationships among entities over time. For example, in social media, networks represent connections between different individuals and the type of interaction that two individuals have. Unfortunately the relationships between entities are not always observable and need to be inferred from nodal measurements. I will present a line of work that deals with the estimation and inference in high-dimensional semi-parametric elliptical copula models.

3 - Causal Rule Set For Subgroup Identification

Tong Wang, University of Iowa, tongwang@mit.edu

We propose an interpretable classifier for causal analysis, Causal Rule Set (CRS), that discriminates between two types of subgroups, one that benefits from the treatment (Effective Class), and one does not (Ineffective class). CRS uses a set of interpretable rules to present and characterize an Effective class. We present a Bayesian framework with priors that favor simple models, and a Bayesian logistic regression that models the relation between outcomes and a set of observed (attributes) and inferred objects (subgroup membership). The simulation studies and experiments on real data sets show that distributing treatment according to a CRS model enhances the average treatment effect.

Data Analytics and Modeling for Medical Prognosis and Decision Making

Sponsored: Data Mining

Sponsored Session

Chair: Shouyi Wang, University of Texas-Arlington, Arlington, TX, United States, shouyiw@uta.edu

1 - Disgnosis Of Posttraumatic Stress Disorder Using Functional Near Infrared Spectroscopy (fNIRS) signals And Data Mining Techniques

Rahil Hosseini, University of Texas at Arlington, rahilsadat.hosseini@mavs.uta.edu

In this paper we extract various feature groups from FNIRS records that are from the experiment about digits memorizing and recalling; it includes three phases in each trial; encode, maintain and recall; we show the discovered patterns between two classes for some selected features. Specifically the results show that the last phase which is when the subject tries to recall the digits, is the most significant part and with extracted features from Statistics, Autocorrelation and SVDNorm; it is enough for highly accurate classification.We discuss a new proposed feature derived from SVD (Singular Value Decomposition) of raw data in channels. It demonstrated promising results in classification. Third contribution is comparison of feature selection methods to reduce the dimension of the feature matrix. We compare the performance through number of selection and sensitivity and specificity and their average. The proposed method includes Mutual Information (MI) guided sparse models that outperform the existing features selection techniques. The existing models are ''minimum Redundancy and Maximum Relevancy" (mRMR), and ''Sparse Group Lasso" (SGL). We propose ''Mutual Information and Least Absolute Selection and Shrinkage Operator" (MILASSO) ''Mutual Information Sparse Group Lasso" (MISGL). All these techniques are applied to classify PTSD veterans and healthy controls using ''Support Vector Machines" (SVM). Last contribution is finding the Region of Interest (ROI), we conclude that two specific areas on brain are the most significant ones which are directly related to memorizing

2 - Pattern Classication And Analysis Of Memory Processing In Depression Using Eeg Signals

Kin Ming Puk, University of Texas at Arlington, bookbook0089@gmail.com

An automatic, EEG-based approach of diagnosing depression with regard to its effect on memory is presented. EEG signals are extracted from 15 depressed subjects and 12 normal subjects during experimental tasks of reorder and rehearsal. After pre-processing noisy EEG signals, seven groups of mathematical features are extracted and classification with SVM is conducted under a five-fold cross-validation, with accuracy of up to 70% - 100%. The contribution of this paper lies in illustrating the usefulness of the classification framework in facilitating the analysis and visualization of the difference of EEG signals between depressed and control subjects in memory processing.

3 - Discriminating Parkinson's Disease (pd) Using Functional Connectivity And Brain Network Analysis

Shouyi Wang, University of Texas at Arlington, shouyiw@uta.edu

In this study, we explored the use of functional connectivity patterns in fMRI data to classify subjects on the basis of Parkinson's disease. We explore various brain networks and features. We partition our fMRI data in 5 filtered frequency ranges. We use a proximal support vector machine paired with a minimum-redundancy and maximum-relevance feature selection method on each frequency range. We use a majority voting ensemble classification method on the results of the proximal support vector machine classification results. Our results indicate that the ensemble method is effective compared to a single broad frequency range, and that Bonferroni correction may enhance classification results.

Optimizing Urban Infrastructure Resilience Under Climate Change

Sponsored: Energy, Natural Res & the Environment I Environment & Sustainability

Sponsored Session

Chair: Mohammad Ramshani, University of Tennessee, 524 John D. Tickle Building, Knoxville, TN, 37996, United States, mramshan@vols.utk.edu

1 - Optimizing Green Roof Integrated Photovoltaics Placement Under Climate Change

Mohammad Ramshani, University of Tennessee, mramshan@vols.utk.edu, Xueping Li, Anahita Khojandi, Olufemi A Omitaomu

We develop a two-stage stochastic model to optimally place green roofs and/or Photovoltaic panels under climate change uncertainty, with the aim of improving urban system resilience. Different climate forecasts from different climate models are taken into account as different scenarios. The interaction between green roofs and Photovoltaic panels in terms of efficiency is considered. An efficient L-shaped algorithm is developed. Computational studies along with sensitivity analysis are conducted.

2 - Optimal Planning Of Green Infrastructure Placement Under Precipitation Uncertainty

Masoud Barah, University of Tennessee, mbarah@vols.utk.edu, Anahita Khojandi, Xueping Li, Jon Hathaway

Green Infrastructures (GIs) are low cost, low regret strategies that can dramatically contribute to stormwater management. We develop a multi-objective stochastic programming model to determine the optimal placement of GIs across a set of candidate locations in a watershed to minimize the excess runoff under short-term and medium-term precipitation uncertainties. We calibrate the model using precipitation projections and stormwater system's hydrologic responses to them. We obtain the optimal GI placement for a watershed and perform sensitivity and robustness analyses to provide insights.

3 - Optimal Placement Of Green Infrastructure Under Uncertainty

Anahita Khojandi, University of Tennessee, 603 W Main St., Apt 801, Knoxville, TN, 37902, United States, anahitakhojandi@gmail.com, Mohit Shukla, Xueping Li, Mohammad Ramshani

Despite the environmental and societal benefits of Green Infrastructure (GI), they are mostly planned and established in response to an existing problem rather than being actively incorporated into the early stages of urban planning. In this paper, we present a stochastic model that would allow urban planners to incorporate uncertainties in population and climate predictions, land use and budgetary constraints and the 'connectivity' between GIs into the decision making process of GI placement on a county or city scale land area. The proposed approach is tested on data from a real county to evaluate its utility.

Sponsored Session

Chair: Xi Wang, University of Iowa, S210 John Pappajohn Business Building, Iowa City, IA, 52242-1000, xi-wang-1@uiowa.edu

1 - Link Prediction In Multi-relational Networks For Online Health Communities

Xi Wang, The University of Iowa, xi-wang-1@uiowa.edu Kang Zhao

Online Health Communities (OHCs) are a popular resource for those with health problems to exchange information and support. Users often interact via multiple communication channels, such as online discussions, blogs, and private messages. Connections among users via different channels form a multi-relational social network. Using data from a smoking cessation network, this study aims to predict links between users in one sub-network based on information from other sub-networks. Our findings regarding tie formation will inform the development and ongoing management of online health communities.

2 - Purchase Prediction Based On Multilevel Association Rule Mining

Xinxue Qu, College of Business, Iowa State University, Ames, IA, 50010, United States, quxinxue@iastate.edu, Zhengrui Jiang

Recommender systems are one of the most widely deployed applications in E-commerce. The goal of this study is to improve existing association-rule-based methods to increase the quality of product recommendations. There are two important factors in our method. First, due to the huge number of products in stores, market basket data is often sparse. Second, competing products are often highly substitutable, and consumers may be open to alternatives. The method we propose infers the level of similarity/substitutability between pairs of products from product category information. Experimental results show multilevel association rules can lead to a higher accuracy of purchase predictions.

3 - Risk Information Disclosure And Project Success Rate

Yang Pan, University of Maryland, ypan@rhsmith.umd.edu

Since information asymmetry between funders and creators is a critical issue in crowdfunding platform, many policies are introduced to improve the information transparency and make markets more efficient. One of the mechanisms is mandatory disclosure imposed by platform. We aim to understand how disclosed risk information has an effect on project outcomes. We study this question on a popular crowdfunding site requiring project creators disclose potential risk information about projects. We analyze the detail content of the disclosed risk information with text mining techniques and test the association between self-disclosed risk information and successful rate of crownfunding projects.

Sponsored Session

Chair: Alexander Nikolaev, Assistant Professor, University at Buffalo, 312 Bell Hall, Buffalo, NY, 14260, United States, anikolae@buffalo.edu

1 - Optimal Seed Activation Scheduling For Influence Maximization In Social Networks

Mohammadreza Samadi, Operations Research Consultant, American Airlines, Fort Worth, TX, United States, Mohammadreza.Samadi@aa.com, Alexander Nikolaev, Rakesh Nagi

Influence maximization problem selects a set of influential nodes, called seeds, in a social network to spread the influence over the network maximally. We critique the basic assumption of influence maximization problem in the literature on controlling cascades only through the early starters and present Seed Activation Scheduling Problem (SASP) in two-level networks. The SASP is a sequential seed selection problem that results in optimal budget allocation over the campaign time horizon. The problem is modeled as a mixed-integer program for blogger-centric marketing campaigns and an efficient heuristic algorithm is presented using column generation method.

2 - From Local To Global Connections: A New Random Graph Model To Explain The Structural Properties Of Real-world Networks

Rakesh Nagi, U of Illinois at Urbana-Champaign, Department of Industrial & Enterprise Systems, 117 Transportation Building, MC-238, Urbana, IL, 61801, United States, nagi@illinois.edu Sushant Khopkar, Alexander Nikolaev

Online Social Network (OSN) data are hard to interpret. Many OSN users have lots of connections, easily surpassing 150 - the Dunbar number. We present a random graph formation model that explains social tie formation by bridging the gap between the Watts-Strogatz and scale free networks. It shows how the information about "talented" individuals may propagate from their friends towards the masses, with a power law in degree emerging via the mechanism fundamentally different from preferential attachment (PA): while PA assumes full visibility, our model relies on local information exchanges. We report and interpret the model parameter estimates for several real-world networks.

3 - Constrained Sparse Optimization For Tensor Based Modeling Of Student Learning In Collaborative Environments

Alireza Farasat, University at Buffalo, afarasat@buffalo.edu

Educational systems have witnessed a substantial transition from traditional educational methods mainly using text books, lectures, etc. to newly developed systems which are artificial intelligent-based systems personally tailored to the learners. In this study, a constrained sparse tensor-based factorization approach is proposed for modeling of student learning in collaborative environments. The main challenge of modeling students learning is the fact that learning occurs over time therefor. We develop a probabilistic, constrained based approach to the tenser factorization model which enables capturing the underlying dynamics of students learning over time.

4 - Generalized Cascade Model And Seed Bounds For Disease Spread In Social Networks

Arash Ghayoori, U of Illinois at Urbana-Champaign, Urbana, IL, 61801, United States, ghayoor2@illinois.edu, Rakesh Nagi

In this talk, we introduce a new diffusion model for social networks, which generalizes most of the previously introduced diffusion models. We establish its relevance in disease spread (epidemiology) as well as viral marketing. An upper bound on the size of the influential set ("seed" set of nodes that if become infected, will eventually result in making the entire network becoming infected) is also obtained for a special case of this model. We show this bound to be tight by providing a simple algorithm that outputs an influential set with size nearly equal to this upper bound.

Chair: Sercan Yildiz, Carnegie Mellon University, 5000 Forbes Ave, Pittsburgh, PA, 15213, United States, syildiz@email.unc.edu

1 - Sparse Pseudoinverses Via LP And SDP Relaxations Of Moore-Penrose

Jon Lee, University of Michigan, jonxlee@umich.edu

Pseudoinverses are ubiquitous tools for handling over- and under-determined systems of equations. For computational efficiency and also in the context of identifying Gaussian models having a sparse precision matrix, sparse pseudoinverses are desirable. Recently, sparse left and right pseudoinverses were introduced, using 1-norm minimization and linear programming. We introduce new sparse pseudoinverses by developing tractable convex relaxations of the wellknown Moore-Penrose properties. In the end, we have several new sparse pseudoinverses that can be calculated via linear and semi-definite programming.

2 - Optimal Truss Topology Design By Mixed Integer Conic Optimization

Tamas Terlaky, Lehigh University, terlaky@lehigh.edu, Mohammad Shahabsafa, Ali Mohammad-Nezhad, Luis F Zuluaga

We present novel models, including Mixed Integer Linear Optimization (MILO) and Mixed Integer Second Order Cone Optimization (MISOCO) models, for Truss Topology Design Optimization. We discuss how classes of non-convex models can be reformulated as MILO and MISOCO models. We present our approach to solve the MISOCO models through adding Disjunctive Conic Cuts in a BCC framework. Additionally, we present an efficient line search method developed to solve the original non-convex model. Preliminary computational results indicate the effectiveness of our novel approaches.

3 - Low-complexity Relaxations And Convex Hulls Of Disjunctions On The Positive Semidefinite Cone And General Regular Cones

Sercan Yildiz, Postdoctoral Researcher, Statistical and Applied Mathematical Sciences Institute, Durham, NC, United States, syildiz@email.unc.edu, Fatma Kilinc-Karzan

This talk concerns two-term disjunctions on a regular cone K. The resulting disjunctive sets provide fundamental non-convex relaxations for mixed-integer conic programs. We develop a family of structured convex inequalities which together characterize the closed convex hull of such a set in the original space. Under certain conditions on the choice of disjunction, a single inequality from this family is enough for a closed convex hull description. In the case where K is the positive semidefinite cone, we show that these inequalities can be represented in conic form for a class of elementary disjunctions. For more general disjunctions, we present tight conic relaxations.

New Algorithms for Global Optimization and MINLP I

Sponsored: Optimization, Global Optimization

Sponsored Session

Chair: John W Chinneck, Carleton University, Ottawa, ON, Canada, chinneck@sce.carleton.ca

1 - Nonlinear Objective Decomposition By Binary Decision Diagrams

David Bergman, University of Connecticut, david.bergman@business.uconn.edu, Andre Augusto Cire

In recent years the use of decision diagrams for discrete optimization has grown in popularity, with a focus on linear integer optimization. In this talk, an expansion to nonlinear objective functions will be discussed. The work proposes the use of decision diagrams to model the objective function, which are then linked together through a network flow linearization. Experimental results on problems arising in revenue management, portfolio optimization, and healthcare exhibit orders-of-magnitude improvement in solution times compared with state-of-the-art nonlinear solvers.

2 - Identifying And Exploiting Special Features In Mixed Integer Nonlinear Programs

Linus E Schrage, LINDO Systems, Inc., linus.schrage@chicagobooth.edu

Most MINLP problems have the following features to varying degrees: convexity, linearizability, conic representability, common expressions, monotonicity, decomposability, and symmetry. We describe methods for identifying these features and performance improvements possible by exploiting these features.

3 - A Fast Heuristic For Global Optimization

John Chinneck, Carleton University, chinneck@sce.carleton.ca, Mubashsharul Shafique

Our CCGO multistart heuristic trades off some accuracy to gain speed. It generally finds good quality solutions quickly. The main steps are a scatter of initial points, rapid movement towards feasibility via Constraint Consensus, clustering, simple point improvement, and local solver launch. Much of the work is done concurrently. Recent work improves the initial point scatter to provide better exploration of useful areas of the variable space. Our results are very promising in comparison to several existing global optimizers, especially for larger nonconvex models.

4 - A Dantzig-Wolfe Decomposition With Nonlinear Subproblems For Recursive Circle Packing

Ambros Gleixner, Zuse Institute Berlin, Takustr. 7, Berlin, 14195, Germany, gleixner@zib.de
Stephen John Maher, Benjamin Müller, Joao Pedro Pedroso

A large fraction of the total costs in tube industry arises from delivery inside rectangular containers. The problem of minimizing the number of containers to transport a set of different tubes can be modeled as a nonconvex MINLP: the recursive circle packing problem (RCPP), which is practically unsolvable for any state-of-the-art MINLP solver.

We present a branch-and-price algorithm that handles recursiveness in the master problem and solves nonconvex MINLPs for column generation. Our computational results using the MINLP solver SCIP show that this algorithm solves small-sized instances to proven optimality and produces better solutions than the best known heuristic for larger RCPP instances.

Sponsored Session

Chair: Linwei Xin, U of Illinois at Urbana-Champaign, Urbana, IL, 12345, United States, lxin@illinois.edu

1 - A Nonparametric Sequential Test For Online Experiments

Vineet Abhishek, @WalmartLabs, Sunnyvale, CA, United States, vineet.abhishek@gmail.com, Shie Mannor

We propose a nonparametric sequential test that aims to address two practical problems pertinent to online randomized experiments: (i) how to do hypothesis test for complex metrics; (ii) how to prevent type 1 error inflation under continuous monitoring. The proposed test does not require knowledge of the underlying probability distribution generating the data. We use the bootstrap to estimate the likelihood for blocks of data followed by mixture sequential probability ratio test. We validate this procedure on data from a major online e-commerce website and show that the proposed test controls type 1 error at any time, has good power, and allows quick inference in online randomized experiments.

2 - Implementing Tailored Base-surge Inventory Policies At Walmart.com

Linwei Xin, U of Illinois at Urbana-Champaign, lxin@illinois.edu
John Bowman, Huijun Feng, Zhiwei Qin, Long He, Jagtej S Bewli

We consider the following dual-sourcing inventory problem: one supplier is reliable but has a longer lead time; the other one is not always reliable but has a shorter lead time. The objective is to minimize the inventory cost. We propose a so-called Tailored-Base Surge policy. Under such a policy, a constant order is placed at the slow supplier in each period, while the order placed at the fast supplier follows an order-up-to rule. We test Tailored-Base Surge using data from Walmart.com, where lead time differences of many import items could be as large as 12 periods. Our result shows that Tailored-Base Surge outperforms other heuristics such as dual-index and single-sourcing base-stock policies.

1 - Optimal Classification Trees

Jack Dunn, Operations Research Center, MIT, jackdunn@mit.edu

Decision trees are widely used to solve the classical statistical problem of classification. We introduce a new method for constructing optimal decision trees using Mixed-Integer Optimization, and develop high-performance heuristics for these formulations that offer significant improvements over traditional greedy approaches and run in comparable times. We show in a large and diverse collection of synthetic and real-world instances that our Optimal Classification Trees improve substantially over CART and related methods such as Random Forests.

2 - Sparse High-dimensional Regression: Exact Scalable Algorithms And Phase Transitions

Bart van Parys, Operations Research Center, MIT, vanparys@mit.edu

We present a new binary convex reformulation and duality perspective to the sparse regression problem. We devise a novel cutting plane method and provide evidence that it can solve exact sparse regression problems for problem sizes in the 100,000s. Our sparse regression formulation has the property that as the number of samples increases its exact solution recovers the true signal very fast (faster than the Lasso in fact), while for small sample sizes, our approach takes a large amount of time to solve the problem, but most importantly the optimal solution does not recover the true signal.

3 - Compressed Sensing Via A Modern Optimization Lens

Lauren Berk, Operations Research Center, MIT, lberk@mit.edu

We develop tractable algorithms that provide provably optimal solutions to compressed sensing problems. These methods include new first order methods and a cutting planes method that operates in a reduced variable space, preserving tractability as problem sizes grow.

4 - Sparse Convex Regression

Nishanth Mundru, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, nmundru@mit.edu, Dimitris Bertsimas

Given data (xi, yi) (d+1), i=1,..,n, the problem of convex regression finds a convex function f: d   that minimizes the error ∑i (yi - f(xi))2. We propose a cutting plane algorithm that scales to (n,d) = (10^4,10) in minutes and (n,d) = (10^5,10^2) in hours. Sparse convex regression finds the best k out of d features, and solves for the optimal convex function on that subset. Using Mixed integer optimization methods and first order convex optimization based heuristics, we extend our algorithm to model sparsity, and solve the problem to provable optimality for (n,d,k) = (10^4,10^2,10) in minutes.

Buffered Probability of Exceedance and Applications

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Matthew Norton, University of Florida, 355 Tigert Hall, Gainesville, 32611, United States, mdnorton@ufl.edu

1 - Buffered Probability Of Exceedance And Applications To Machine Learning

Matthew Norton, University of Florida, mdnorton@ufl.edu

We present a new characterization of uncertainty, called Buffered Probability of Exceedance (bPOE), specifically addressing its application to machine learning. Using ideas from Robust Optimization, we show that Robust bPOE minimization provides a highly flexible framework for binary classification which encompasses support vector machines (SVM's), including SVM variants which utilize Robust Optimization and various convex/non-convex regularization schemes. While also providing a more concrete interpretation for various SVM formulations, the proposed framework reveals a fundamental connection between many regularization schemes and Robust Optimization principals.

2 - Buffered Probability Of Exceedance: Methodology And Applications

Stan Uryasev, University of Florida, uryasev@ufl.edu

This paper investigates a new probabilistic characteristic called buffered probability of exceedance (bPOE). With bPOE, it is possible to count outcomes similar to a threshold value, rather than only outcomes exceeding the threshold. To be more precise, bPOE counts tail outcomes averaging to some specific threshold value. bPOE can be considered as an important supplement to POE. We will discuss the Cash Matching problem for a Portfolio of Bonds. We minimize bPOE that assets exceed liabilities.

3 - Smoothed Buffered Probability Of Exceedance: A New Class Of Probability-like Uncertainty Measures

Alexander Mafusalov, University of Florida, mafusalov@ufl.edu

Buffered probability of exceedance (bPOE) is a risk-averse alternative to probability of exceedance and cumulative distribution function. Minimization of bPOE is reduced to convex programming or even LP for a wide class of problems. However, being a non-smooth function, bPOE is not always well suited for gradient optimization. In addition, bPOE reverses the curve of CVaR values, while another family of risk measures might be preferable in a given application. This paper introduces a new class of smooth probability-like uncertainty measures, which are based on bPOE. Dual representations and other mathematical properties, along with advantages in optimization, are studied.

4 - Approximation Of A Distribution With A Finite Mixture Of Some Other Distributions Using Cvar Norm

Giorgi Pertaia, University of Florida, Gainesville, FL, United States, georgepertaia@gmail.com

CVaR norm is applied to approximate a distribution with a finite mixture of some other distributions. A finite mixture is a weighted sum of simple distributions (such as normal or triangular). Despite the simplicity of underlying distributions, the finite mixture can model a wide variety of distributions with heavy tails. Classical approach of fitting the mixture relies on Maximum Likelihood estimation, which, in general, leads to a nonconvex optimization problem (with many local minima where the optimization algorithms might get trapped). In contrast, procedures using CVaR norm minimization lead to convex programming, which can be reduced to linear programming problems.

Polyhedral Methods in Integer Programming under Uncertainty

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Weijun Xie, Georgia Institute of Technology, 225 North Ave, Atlanta, GA, 30332, United States, wxie33@gatech.edu

1 - Decomposition Methods For Solving Distributionally Robust Two-stage Stochastic Integer Programs

Sanjay Mehrotra, Northwestern University, mehrotra@northwestern.edu, Manish Bansal, Kuo-Ling Huang

We present a cutting surface L-shaped method for solving 2-stage distributionally robust mixed integer programs. We show the finite convergence of the algorithm under suitable conditions. Wasserstein and moment based uncertainty sets are considered. Numerical results will be presented that demonstrate the performance of our approach and illustrate its ability to perform distributional sensitivity analysis.

2 - An Integer Programming Approach For Two-sided Chance-constrained Programs

Xiao Liu, The Ohio State University, liu.2738@osu.edu Simge Kucukyavuz, Fatma Kilinc-Karzan

We study two-sided chance-constrained programs with a finite probability space. We reformulate this class of problems as a mixed-integer program. We study the key substructure of the reformulation and propose valid inequalities that define the convex hull of this substructure. Finally, we propose polynomial optimization and separation algorithms for the optimization problem over this substructure.

3 - A Polyhedral Approach To Online Bipartite Matching

Alfredo Torrico, Georgia Institute of Technology, Atlanta, GA, United States, atorrico3@gatech.edu, Alejandro Toriello, Shabbir Ahmed

We study the i.i.d. online bipartite matching problem, a dynamic version of the classical model where one side of the bipartition is fixed and known in advance, while nodes from the other side appear one at a time as i.i.d. realizations of a uniform distribution, and must immediately be matched or discarded. We consider various relaxations of the polyhedral set of achievable matching probabilities, introduce valid inequalities, and discuss when they are facet-defining. Several of these relaxations correspond to ranking policies and their time-dependent generalizations.

4 - On Risk Averse Submodular Minimization

Weijun Xie, Georgia Institute of Technology, Atlanta, GA, United States, wxie33@gatech.edu, Shabbir Ahmed

This paper studies a risk averse submodular minimization problem (RASMP) under a knapsack constraint. Many problems can be reformulated as RASMP (e.g., chance constrained problems, mean-risk models, optimization with conditional-value-at-risk, etc). Approximation algorithms are proposed for RASMP by rounding an optimal solution to a suitable convex relaxation. We also propose new valid inequalities by partitioning binary variables into groups, and their separation.

Contributed Session

Chair: Gary Chao, Kutztown University, 888 Kingston Ln, Breinigsville, PA, 18031, United States, chao@kutztown.edu

1 - Product Life Cycle Among Different Generations

Gary Chao, Kutztown University, PO Box 730, Department of Business Administration, Kutztown, PA, 19530, United States, chao@kutztown.edu, Maxwell Hsu

The launch of a new product needs a larger commitment in time, money, and managerial resources. The new product introduction requires careful planning to ensure the expected market success of a new product. We would like to study how frequently and when an automaker introduced the new models, how an automaker designed their product line, what factors influence the diffusion. We attempt to fit longitudinal data across brands to the Bass diffusion model and examine the generation change within the same model from different automakers in order to identify the factors influencing car sales.

Parallel Computing for Optimization and Data Analysis

Sponsored: Computing

Sponsored Session

Chair: Jonathan Eckstein, Rutgers University, Rutgers University, Piscataway, NJ, 00000, United States, jeckstei@rci.rutgers.edu

1 - The Rectangular Maximum Agreement Problem And Its Data Analysis Applications

Ai Kagawa, Rutgers University, ai.kagawa@gmail.com

The NP-hard rectangular maximum agreement (RMA) problem finds a "box" that best discriminates between two weighted datasets. Its data analysis applications include boosting classification methods and boosted regularized regression. We describe a specialized parallel branch-and-bound method for RMA.

2 - Object-parallel Solution Of Lasso Problems

Gyorgy Matyasfalvi, Rutgers University, 100 Rockafeller Road, Piscataway, NJ, 08854, United States, matyasfalvi@gmail.com Jonathan Eckstein

We describe an "object-parallel" C++ approach to implementing first-order optimization methods. As an example application, we solve large-scale Lasso problems on a distributed-memory supercomputer with the spectral projected gradient (SPG) method. We can efficiently accommodate highly unbalanced sparsity patterns.

3 - Asynchronous ADMM-like Optimization Algorithms

Jonathan Eckstein, Rutgers University, jeckstei@rci.rutgers.edu

Drawing on some recent work on asynchronous decomposition methods for monotone inclusions, this talk develops a class of parallel convex optimization algorithms that resembles the alternating direction method of multipliers (ADMM) but operates asynchronously. Unlike prior work on asynchronous variants of the ADMM, the new algorithm's convergence theory does not rely on either restrictive assumptions on the problem instance or on random invocation of subproblems. Instead, it needs only a basic "fairness" restriction that there be some upper bound on the ratio of the longest and shortest possible subproblem solution times. Stochastic programming applications may also be discussed.

A Unified Framework for Optimization under Uncertainty

Invited: Tutorial

Invited Session

Chair: Warren B Powell, Princeton University, 230 Sherrerd Hall, Dept of Operations Research and Financial Eng, Princeton, NJ, 08544, United States, powell@princeton.edu

1 - A Unified Framework For Optimization under Uncertainty

Warren B Powell, Princeton University, 230 Sherrerd Hall, Dept Of Operations Research And Financial Eng, Princeton, NJ, 08544, United States, powell@princeton.edu

Stochastic optimization, also known as optimization under uncertainty, is studied by over a dozen communities, often (but not always) with different notational systems and styles, typically motivated by different problem classes (or sometimes different research questions) which often lead to different algorithmic strategies. This resulting "jungle of stochastic optimization" has produced a highly fragmented set of research communities which complicates the sharing of ideas. This tutorial unifies the modeling of a wide range of problems, from dynamic programming to stochastic programming to multiarmed bandit problems to optimal control, in a common mathematical framework that is centered on the search for policies. We then identify two fundamental strategies for finding effective policies, which leads to four fundamental classes of policies which span every field of research in stochastic optimization.

Chair: Julie Lynn Hammett, Texas A&M University, 301 Holleman Dr E, Apt 728, College Station, TX, 77840, United States, jhammett@tamu.edu

1 - Analysis Of Physician Productivity In Emergency Departments

Krista Foster, University of Pittsburgh, Mervis Hall, Roberto Clemente Drive, Pittsburgh, PA, 15260, United States, kmf88@pitt.edu, Jennifer S Shang

We present our analysis of a cohort of U.S. emergency departments. We use visit-level data to analyze hospital processes and develop models for physician productivity.

2 - A Review And Extension Of Clinically Significant, Automated Estimation Of End Systolic And End Diastolic Volumes In Cardiac MRIs

Michael Kim, Booz Allen Hamilton, 3930 Valley Ridge Drive, Fairfax, VA, 22033, United States, mikeskim@gmail.com

We review the winning methods in Kaggle's Second Annual Data Science Bowl. The top three algorithms automatically measure endsystolic and enddiastolic volumes in cardiac MRIs using data from more than 1000 patients. The results were found to be clinically significant. An analysis of the winning solutions is presented with a focus on extension through ensembling and transfer learning. In particular, we architect a machine learning pipeline to extend the top algorithms to the case of cancer detection given a time series of prostate MRIs.

3 - The Risks Of Risk Adjusted Mortality Rates And A Proposed Alternative Measure

Thomas Raymond Sexton, Professor, Stony Brook University, 317 Harriman Hall, Stony Brook, NY, 11794-3775, United States, Thomas.Sexton@StonyBrook.edu, Christine Pitocco

We consider the widespread use of the risk-adjusted mortality rate (RAMR) to evaluate hospital performance. We demonstrate that the RAMR, as currently employed, has significant methodological flaws. We propose an alternative to the RAMR that is based on standard statistical theory and methods. Applying our measure yields a more complete and accurate evaluation of hospitals.

4 - Effects Of Artificial Agents Based Ordering On The Supply Chain Of Perishables

Harshal Lowalekar, Assistant Professor, Indian Institute of Management-Indore, Prabandh Shikhar, Rau-Pithampur Road, Indore, 453331, India, lwlherschelle@gmail.com, Raghu Santanam, Ajay Vinze

We develop a blood bank game which contains a mix of human and computer based hospital blood banks who order blood at regular intervals from a regional bank. The objective of all the agents is to minimize their total inventory costs. The computer agents use a near-optimum policy to determine their order sizes. We show that presence of a large number of computer based agents in the supply chain leads to a systematic increase in the order sizes of the hospital banks which leads to a severe perceived blood shortage in the region. The performance of the supply chain worsens when the computer agents have the capability to learn from their past performance.

5 - Remote Patient Monitoring System Framework: A User Perspective

Julie Lynn Hammett, Texas A&M University, 301 Holleman Dr E, Apt 728, College Station, TX, 77840, United States, jhammett@tamu.edu, Michelle M. Alvarado, Mark Alan Lawley

Healthcare providers are facing an increasing number of patients requiring long-term care, introducing new challenges to providing fast and affordable care. We present ongoing research to create a framework for the design, development, and implementation of remote patient monitoring (RPM) for chronic care. We highlight the stakeholder needs, system requirements and component interdependencies. We describe RPM's need for automated solutions that support clinical decisions and deliver interventions. This technology must be interchangeable to suit the varied needs and characteristics of many patients. We show that these solutions can improve chronic care management.

1 - Pre-positioning Emergency Relief Items Before A Typhoon With An Uncertain Trajectory

Joline Uichanco, University of Michigan, Ross School of Business, jolineu@umich.edu

We describe a collaborative work with the Philippine government on a pre-positioning model in preparation for an oncoming typhoon. Pre-positioning relief aid before a typhoon is challenging due to the uncertainties in locations and quantities of future demand. We develop a prediction model for the number of affected population by fitting a dataset of typhoon effects to a hierarchical linear model. Our model reveals a significant relationship between wind speed and affected population. We propose a bi-objective stochastic pre-positioning model which balances fairness and effectiveness of the pre-positioning strategy.

2 - Ecuador Earthquake Relief Support: Observations From Fieldwork Research

Johanna Amaya, Rensselaer Polytechnic Institute, Troy, NY, United States, amayaj@iastate.edu, Johanna Amaya, Iowa State University, Ames, IA, 50011, United States, amayaj@iastate.edu, Cinthia Perez Siguenza, Jose Holguin-Veras

This talk presents an overview of the disaster response logistics that took place after the earthquake in Ecuador. The talk discusses the preliminary results of the fieldwork research conducted by the authors in the aftermath of the disaster.

3 - Objectives' Misalignment In Humanitarian Operations: The Role Of Earmarking

Laura Turrini, Kuehne Logistics University, laura.turrini@the-klu.org, Maria Besiou

Effectiveness of humanitarian programs depends both on the donors' willingness to support the program and on the program implementation by the international humanitarian organization (IHO). Donors donate with the aim of reaching as more beneficiaries as possible. IHOs also have the same objective, but face constraints on how they can use the available funds. A big constraint comes from the donors themselves, who often earmark their funding. In this paper, we analyze the donors' and IHOs' decision-making in an effort to shed more light on how decisions for earmarking are taken. The aim is to give recommendations to the IHOs on how to align donors' objectives to theirs.

4 - Willingness-to-pay Models On Post-disaster Environments

Diana Ramirez-Rios, Research Assistant, Rensselaer Polytechnic Institute, Troy, NY, 12180, United States, ramird2@rpi.edu Jose Holguin-Veras, Johanna Amaya, Trilce Marie Encarnacion, Shaligram Pokharel, Victor Cantillo, Luk Wassenhove

This paper introduces an economic valuation for the level of anxiety of an individual under deprivation conditions as anxiety is well-known measure of psychological distress in a community. More specifically, this research estimated the willingness-to-pay for water of individuals who have been affected by disasters, under different scenarios of deprivation and expectation. The level of anxiety is measured by the effect that the expected time to normality introduces to WTP, and results indicate that that as the time to recover increases, the level of suffering increases. "

Applications in Physician Scheduling

Sponsored: Health Applications

Sponsored Session

Chair: Andreas Fügener, Universität zu Köln, 123334, Germany, andreas.fuegener@uni-koeln.de

1 - Decision Support For Physician Rostering: Development Of Models And Implementation Of Software

Jens Brunner, University of Augsburg, jens.brunner@unikat.uni-augsburg.de, Andreas Fuegener

In order to cope with steadily increasing healthcare costs, hospitals try to schedule their physicians efficiently and effectively. We consider a scheduling problem at large teaching hospitals in Germany. We formulate mixed-integer linear programming models for duty- and workstation assignments subject to union contracts as well as individual agreements of the physicians. To promote for job satisfaction we take into account fairness and preferences. We present the status of the software development and discuss lessons learned from the project and highlight some barriers when it comes to implementation of decision support systems in practice.

2 - Neonatal Physician Scheduling At The University Of Tennessee Medical Center

Charles E Noon, University of Tennessee-Knoxville, Knoxville, TN, United States, cnoon@utk.edu, Melissa R Bowers, Wei Wu, Kirk Bass

The default approach for scheduling hospital coverage is to distribute the various types of shifts equally among the covering physicians. This "equality" approach insures that each physician works his/her fair share of overnights, weekends, etc. We present a new model that incorporates individual shift-type preference so that each physician attains a schedule that is equivalent or superior to his/her "equality" schedule. We formulate and solve the model as a mixed integer program. We demonstrate its benefits by using the approach to schedule hospital coverage for a neonatology group.

3 - Equitable Scheduling Of Resident Shifts

Hernan Abeledo, George Washington University, abeledo@gwu.edu, Anthony Coudert

Creating shift schedules for resident physicians is a notoriously difficult task that is typically done manually by the chief residents. Shift assignments need to observe a large number of rules while populating a complex schedule structure. A key goal is that the schedule be perceived as fair by all residents. We present an integer programming model used to schedule anesthesiology residents at the George Washington University Hospital. The fairness objective is addressed through a point system proposed by the residents.

4 - Re-scheduling Of Physicians In Case Of Unexpected Absences

Andreas Fügener, University of Cologne, andreas.fuegener@uni-koeln.de, Christopher Gross, Jens Brunner

Scheduling physicians is a complex task as legal requirements, levels of qualification, and preferences for different working hours should be considered. Unplanned absences, e.g. due to illness, additionally drive the complexity. In this study, we discuss an approach to deal with the following trade-off: Changes to the existing plan should be kept as small as possible. However, an updated plan should still meet the requirements regarding work regulation, qualifications needed, and employee preferences. We present a mixed-integer programming model to create updated plans following absences of scheduled personnel and apply it to real-life data from a German university hospital.

New Directions in Non-Market Strategies

Invited: Strategy Science

Invited Session

Chair: Jason Snyder, University of Utah, Eccles School, Salt Lake City, UT, 9, United States, Jason.snyder@eccles.utah.edu

1 - Locked In? Noncompete Enforceability And The Mobility And Earnings Of High-tech Workers

Jin Woo Chang`, University of Michigan, Ann Arbor, MI, United States, jinwooch@umich.edu, Natarajan Balasubramanian, Mariko Sakakibara, Jagadeesh Sivadasan, Evan Starr

We use matched employer-employee data from 30 U.S. states to examine how the enforceability of noncompete contracts affects the length of job spells and the level of wages. Exploiting inter-state variation in the degree of enforceability and controlling for worker-, job-, and state-level characteristics, we find that a unit standard deviation increase in enforceability is associated with a 3.6% increase in the length of job-spells for high-wage workers in technology industries. We also find persistent wage suppressing effects that last throughout their employment history. Together, these are consistent with noncompetes reducing the bargaining power of employees relative to their employers.

2 - On A Firm's Optimal Response To Pressure For Gender Pay Equity

David Ross, University of Florida, 55, Gainesville, FL, 32611, United States, David.Ross@warrington.ufl.edu David Anderson, Cristian Dezsö, Margret Bjarnadottir

We present a theory of how a firm would respond to pressure for gender pay equity by strategically distributing raises and adjusting its organizational structure. Using mathematical reasoning, simulations, and data from a real employer, we show that (a) employees in low-paying jobs and whose job-related traits typify men at the firm are most likely to get raises; (b) counterintuitively, some men will get raises and giving raises to certain women would increase the pay gap; (c) a firm can reduce the gender pay gap as measured by a much larger percentage than the overall increase in pay to women at the firm; and (d) "ghettoizing" women in select jobs can help a firm reduce its pay gap.

Managing Uncertainties in Projects

Invited: Project Management and Scheduling

Invited Session

Chair: Janne Kettunen, The George Washington University, Washington, DC, United States, jkettune@gwu.edu

1 - Zooming In On The Innovator's Bias Within Organizations

Fabian Sting, Erasmus University Rotterdam, Rotterdam School of Management, fsting@rsm.nl, Christoph Fuchs, Maik Schlickel

Firms in competitive industries strive for process innovations, and one source of such ideas is the firm's workforce. In the selection process, firms rely on input from ideating employees - input that might contain systematic errors (biases) and/or unsystematic errors (noise). We study such errors by analyzing the process innovation ideas considered by an automotive manufacturer. Our data set is unique in that it includes information on idea generation, employee evaluation, standardized value calculation, selection, and implementation. Overall, our findings contribute to a more differentiated yet theoretically coherent understanding of the innovator's bias in organizations.

2 - To Better Manage Risks In New Product Development Portfolio Selection – Be Risk Neutral

Janne Kettunen, Assistant Professor, The George Washington University, 2201 G Street, NW, Washington, DC, 20052, United States, jkettune@gwu.edu, Shivraj Kanungo

We investigate trade-offs between risk and return in multi-period new product development (NPD) portfolio selection problems, where new development projects become periodically available. Our analytical and computational results show that, paradoxically, a risk-neutral NPD portfolio selection approach provides higher return and lower risk than a risk-averse selection approach. This result can explain why leading innovators tend to employ a risk-neutral NPD selection approach. The risk of the NPD portfolio can be mitigated by (i) reviewing portfolios more frequently and (ii) increasing the proportion of derivative products instead of platform products.

3 - Project Portfolio Selection – A Behavioral Study

Sebastian Schiffels, Technical University of Munich, Munich, 80333, Germany, sebastian.schiffels@wi.tum.de, Thomas Fliedner, Rainer Kolisch

Choosing the right set of projects is a key driver of success and failure in new product development. We conducted experimental studies based on the knapsack problem to address the question which decision rules individuals apply to select a portfolio as well as how cognitive limitations influence their selection. Grounded in portfolio selection practice, we investigate subjects' adherence to four heuristics. Decision making is partially explained by adherence to two simple rules, but problem complexity limits the application of such rules as subjects apply a local search. Furthermore, decision maker prefer projects with low risk resulting in portfolios with few high risk high impact projects.

4 - Initiating Supplier New Product Development Projects: A Behavioral Investigation

David Wuttke, EBS University, Wiesbaden, Germany, david.wuttke@ebs.edu, Karen Donohue, Enno Siemsen

Using a combination of analytical models and laboratory experiments, we study the effectiveness of buyer contract mechanisms, including breach penalties and profit sharing, on incentivizing product innovation at the supplier level. Our results provide insight into how the mechanisms can be altered to better account for supplier-specific behavior.

Invited Session

Chair: Wolfgang Ketter, Rotterdam School of Management, Rotterdam, Netherlands, wketter@rsm.nl

1 - Using Optimal Grid Resources For Coordinating Electric Vehicle Charging

Konstantina Valogianni, IE Business School, Madrid, Spain, konstantina.valogianni@ie.edu, Alok Gupta, Wolfgang Ketter, Soumya Sen, Eric F Van Heck

We propose a social welfare maximization mechanism to optimally schedule EV charging, ensuring the lowest overall delay for the EV owners. At the same time, our mechanism creates electricity peak demand reduction which is important for improving sustainability in the grid. Our solution has lower computational complexity, compared to state of the art mechanisms, making it easily applicable to practice, where large numbers of EVs need to be charged. We prove the theoretical optimal conditions that must hold in order to have maximum social welfare in the grid. We validate our mechanism on real-world data and find both peak demand and delay reduction.

2 - Truthful Approximation Mechanisms for Knapsack Bidders

Martin Bichler, Soeren Merting, Technische Universitat Munchen, Munich, Germany. bichler@in.tum.de

In markets such as digital advertising markets, bidders want to maximize value for impressions subject to a budget constraint. This type of utility function is typically implemented in bidding agents, but it differs from quasilinear utility functions in important ways. We refer to such bidders as knapsack bidders. We study the offline mechanism design problem and analyze truthful approximation mechanisms to maximize social welfare. Serial dictatorship mechanisms are shown to be strategy-proof and Pareto-optimal, but they can have low welfare. We propose a randomized mechanism with an approximation ratio of 4. Our mechanism draws on a fractional deferred acceptance algorithm and randomized rounding, and it illustrates how the relax-and-round principle can be implemented in an important non-quasilinear environment.

3 - Modelling Electricity Balancing Market Prices And Premiums: A Non-parametric Non-linear Approach

Ezgi Avci-Surucu, PhD Student, Rotterdam School of Management, Rotterdam, Netherlands, avcisurucu@rsm.nl Wolfgang Ketter, Gerhard Wilhelm-Weber

In smart electricity markets, the increased penetration of renewable sources reveals the need for decision support systems. For developing reasonable bidding strategies, market participants need intelligent agents to make informed decisions about the trade-off between sales in the day-ahead market or in the balancing market. In this paper, by considering a detailed system-level data; firstly we examine the market efficiency by fractal analysis to understand the level of price predictability. Further, due the invalidity of normality and linearity assumptions, we propose non-parametric non-linear models to provide strategic tools for policy makers and market participants.

Sponsored Session

Chair: William Schmidt, Cornell University, United States, ws366@cornell.edu

1 - Optimal Timing Of Inventory Decisions Under Price Uncertainty

Nikolay Osadchiy, Emory University, nikolay.osadchiy@emory.edu, Vishal Gaur, Sridhar Seshadri, Marti Subrahmanyam

We study the problem of optimal inventory order timing when the selling price and demand are random and their forecasts improve with time. We show that the optimal timing of inventory ordering decision follows a simple threshold policy in the price variable with a possible option of non-purchasing, and is independent of the demand. Given this policy structure, we evaluate the benefits of timing flexibility using the best pre-committed order timing policy as the benchmark.

2 - Wisdom Of Crowds: Forecasting Using Prediction Markets

Ruomeng Cui, Kelley School of Business, Indiana University, Bloomington, IN, 47401, United States, cuir@indiana.edu Achal Bassamboo, Antonio Moreno-Garcia

Prediction markets are virtual markets created to aggregate predictions from the crowd. We examine data from a public prediction market and internal prediction markets run at three corporations. We study the efficiency of these markets in extracting information from participants. We show that the distribution forecasts, such as sales and commodity prices predictions, generated by the crowds are perfectly calibrated. In addition, we run a field experiment to study drivers of forecast accuracy.

3 - Linking Operational Performance To Financial Distress In The U.S. Airline Industry

Yasin Alan, Vanderbilt University, Nashville, TN, United States, yasin.alan@owen.vanderbilt.edu, Michael A Lapre

We study the impact of four areas of operational performance -revenue management, operational efficiency, service quality and operational complexity- on financial distress in the U.S. airline industry using quarterly data from 1988 through 2013. Our findings suggest that operational metrics convey useful information regarding future financial distress even after controlling for financial ratios that predict bankruptcies.

4 - Operational Transparency With Investors

William Schmidt, Cornell University, ws366@cornell.edu,
Ananth Raman

There is abundant evidence that operational disruptions are damaging to firm value. This depends not only on characteristics of the firm and its supply chain but also the level of operational transparency with investors. While the former has been widely studied, little is known about the implications of operational transparency. We examine this issue by taking advantage of an exogenous regulatory shock. A well-defined set of firms was excluded from fully complying with the new rules, creating a natural quasi-experiment which we exploit. Our research suggests that credible transparency with investors can alleviate over 50% of the loss in market value from operational disruption announcements.

Chair: Ozge Islegen, Kellogg School of Management, Evanston, IL, United States, o-islegen@kellogg.northwestern.edu

1 - The Economics Of Residential Solar PV Adoption

Ozge Islegen, Kellogg School of Management, o-islegen@kellogg.northwestern.edu, Basak Kalkanci

Given the new policies, federal and state incentives, we show how net metering rules, rate plans and options to finance solar projects affect the adoption of residential solar PV.

2 - Remuneration Of Flexibility Using Operating Reserve Demand Curves: A Case Study Of Belgium

Anthony Papavasiliou, CORE, UCL, tpapva@hotmail.com
Yves Smeers

We investigate an energy-only market design, referred to as operating reserve demand curves (ORDC), that rewards flexibility by adjusting the real-time energy price to a level that reflects the value of capacity under conditions of scarcity. We test the performance of the mechanism by developing a model of the Belgian electricity market. We verify that (i) none of the existing combined cycle gas turbines of the Belgian market can cover their investment costs, and (ii) the introduction of ORDC restores economic viability for most combined cycle gas turbines in the Belgian market.

3 - Robust Supply Function Equilibrium In Renewable Energy Markets

Yuanzhang Xiao, Northwestern University, Evanston, IL, United States, yuanzhang.xiao@northwestern.edu, Chaithanya Bandi, Ermin Wei

We consider a market where energy suppliers submit supply functions and bid to fulfill inelastic demand. Suppliers have renewable energy generation (with zero cost) and conventional energy generation (with variable costs). Each supplier performs robust optimization against worst-case realizations of its renewable energy generation and opponents' costs of conventional energy generation. We analyze the resulting robust supply function equilibrium and its efficiency.

4 - An Analysis Of Demand Response Programs In The Wholesale Electricity Market

Asligul Serasu Duran, Kellogg School of Management, Evanston, IL, 60208, United States, a-duran@kellogg.northwestern.edu, Baris Ata, Ozge Islegen

This project explores the impact of the participation and compensation of demand response (DR) providers in the wholesale electricity market on the generation portfolio, electricity prices and social welfare. Specifically, we model a supply function equilibrium for generators and DR providers. Then, we analyze the change in the generation portfolio, and in the welfare of the market participants due to varying compensation rates of DR providers.

Energy Resource Valuation, Investment and Management

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Owen Wu, Associate Professor, Indiana University, 1309 E. 10th Street, Bloomington, IN, 47405, United States, owenwu@indiana.edu

1 - Valuing Distributed Energy Resources In Electricity System Planning: Locational Benefits And Economies Of Unit Scale

Jesse Jenkins, Massachusetts Institute of Technology, jessedj@mit.edu

Distributed energy resources (DERs), including distributed generation, storage, and demand response, create new options for the provision of electricity services. Employing a new MILP formulation of the electricity capacity planning problem, this work evaluates the value of DERs and how they compete with conventional resources. Tradeoffs between "locational benefits" of DERs—e.g. loss mitigation, network capacity deferral, constraint mitigation—and economies of unit scale are considered, and cases where DERs are economically attractive contributors to a least-cost system mix are presented.

2 - Combined Heat And Power Production – Valuing Flexible Operation In An Uncertain Environment

Christoph Weber, University Duisburg-Essen, christoph.weber@uni-due.de

CHP provides an efficient means of converting fuels into power and heat. At the same time operation of CHP units is restricted by thermodynamical and technical constraints and subject to the double uncertainty of power prices and heat demand. The contribution explores the impact of operational flexibility both in the CHP unit (extraction condensing vs. backpressure turbines) and in the system configuration (back-up heat boiler). Analytical results are derived and a numerical application is presented.

3 - Economic Feasibility Of Compressed Air Energy Storage Under Market Uncertainty

Reinhard Madlener, Director FCN, Full Professor of Energy Econ & Mgt, RWTH Aachen University, Mathieustrasse 10, Aachen, 52074, Germany, RMadlener@eonerc.rwth-aachen.de, Eide Hammann, Christoph Hilgers

In light of increased levels of intermittent renewable electricity generation, energy storage is one option to balance supply and demand and thus to support the security of power supply. Compressed air energy storage (CAES) is a large-scale technology that has received considerable attention in recent years. As conventional CAES uses natural gas as an auxiliary fuel operators are exposed to price risks on two commodity markets. The more advanced adiabatic version, in contrast, features higher cycle efficiencies but at the downside of higher capital outlays. We apply real options analysis to investigate the economic viability of both technology variants in an uncertain market environment.

4 - Merchant Energy Trading In A Network

Selva Nadarajah, University of Illinois at Chicago, selvan@uic.edu, Nicola Secomandi

We formulate the merchant trading of energy on a network of storage and transport assets as a Markov decision problem. We overcome the intractability of this model by applying linear optimization in novel ways for approximate dynamic programming: (i) Iterative extensions of least squares Monte Carlo techniques based on value/continuation function approximations (V/CFAs) that are separable/non-separable and piecewise linear concave in the storage inventory levels; (ii) an extended reoptimization heuristic; and (iii) a perfect information dual bound based on a separable and linear VFA. We compare these methods on realistic natural gas instances, highlighting near-optimal methods.

Sponsored Session

Chair: Ryan Buell, Harvard Business School, Boston, MA, United States, rbuell@hbs.edu

1 - Managing Supplier Risks Via Diversification Versus Improvement: An Experimental Evaluation

Basak Kalkanci, Scheller School of Management, Basak.Kalkanci@scheller.gatech.edu

Using economic experiments, we evaluate the performance of supplier diversification versus improvement to mitigate supply chain risks of a buyer facing suppliers with different costs and risk profiles. We show that the buyers diversify their orders more than theory and the orders are artificially inflated to benefit from quantity hedging. We also demonstrate that sourcing commitment may hurt a buyer by reducing the buyer's supplier improvement effort, contrary to theory.

2 - Understanding And Managing Customer-induced Negative Externalities In Congested Self-service Environments

Hyun Seok Lee, University of North Carolina at Chapel Hill, Chapel Hill, NC, 27514, United States, Hyunseok_Lee@kenan-flagler.unc.edu, Saravanan Kesavan, Vinayak Deshpande

This paper identifies a new problem, i.e., the negative impact of congestion (using archival data at retailer A), demonstrates the mechanisms driving the problem (using observational data from field study at retailer B), proposes a solution to the problem, and discusses its implementation at two different retailers (using field experiments at retailers A and B). More importantly, we identify a new phenomenon called thwarting behavior, defined as a systematic change in customers' behavior when they experience congestion that imposes negative externalities on other customers.

3 - The Impact Of Decision Rights And Long Term Relationships On Innovation Sharing

Ruth Beer, Indiana University, Kelley School of Business, ruthbeer@indiana.edu, Hyun-Soo Ahn, Stephen Leider

We study a supplier's incentives to share an innovation with a buyer when sharing the innovation increases efficiency but makes the supplier vulnerable to the buyer sharing it with other suppliers. We show, both theoretically and experimentally, that the supplier's optimal decision depends on the length of the relationship and in particular, on how the buyer allocates decision rights among its employees.

Issues in Supply Chains, Risk Management and Finance

Sponsored: Manufacturing & Service Oper Mgmt, iFORM

Sponsored Session

Chair: Juan Camilo Serpa, McGill University, 1001 Rue Sherbrooke O, Montreal, QC, H3A 1G5, Canada, juan.serpa@sauder.ubc.ca

1 - Mitigating Disruption Cascades In Supply Networks

Nitin Bakshi, London Business School, London, United Kingdom, nbakshi@london.edu, Shyam Mohan

The losses from supply chain disruptions arise not only due to direct damage at firms, but also from the interruption of normal operations because of lack of supply; that is, due to disruption cascades from suppliers in the adjacent tiers and beyond. To curtail such losses, firms can make ex-ante investments in mitigation and recovery strategies. In this paper, we use a game-theoretic approach to study firms' equilibrium investments, and the associated efficiency (in comparison with the centralized benchmark), and its dependence upon network topology.

2 - Cancelability In Trade Credit Insurance

S. Alex Yang, London Business School, sayang@london.edu, Christopher J Chen, Nitin Bakshi

Trade credit insurance (TCI) is a risk management tool commonly used by suppliers to guarantee against buyers defaulting when purchasing on credit. In most TCI policies, the insurer can cancel this "guarantee" during the insured period. We explore the role of cancelability in TCI. We find that the utility of cancelability in TCI is linked to the insurer's monitoring role (tracking the buyer's continued creditworthiness during the insured period, which enables the supplier to make more efficient shipping decisions). Our findings help explain the historical dominance of cancelable contracts in TCI, and they also offer insight into the recent industry trend of offering non-cancelable TCI coverage.

3 - Trade Credit In Competition: A Horizontal Benefit

Heikki Peura, London Business School, hpeura@london.edu
S. Alex Yang, Guoming Lai

Prior research has focused on how trade credit benefits firms by improving vertical supply chain relationships. We offer a novel perspective by examining whether trade credit benefits suppliers through a horizontal channel. Under the classic Bertrand framework, we analyze two competing firms' price decisions with and without trade credit, and find that when the firms are financially constrained, trade credit allows them to soften horizontal price competition. Studying the firms' optimal contract choice, we further find that this horizontal benefit of trade credit may complement its vertical roles.

Scheduling IV

Contributed Session

Chair: Yumei Huo, Associate Professor, City University of New York, 2800 Victory Boulevard, 1N 215, Staten Island, NY, 10314, United States, yumei.huo@csi.cuny.edu

1 - An Improved Algorithm On Two-stage Scheduling With An Outsourcing Option

Kangbok Lee, City University of New York, York College, 94-20 Guy R Brewer Boulevard, Queens, NY, 11451, United States, kangbok.lee3@gmail.com, Xiaojuan Jiang, An Zhang, Yong Chen, Guangting Chen

We consider a two-stage scheduling problem with an outsourcing option where each operation can be outsourced. The objective is to minimize the sum of the makespan and the total outsourcing cost where the outsourcing cost of an operation is the product of the operation's processing time and the unit processing time cost of that stage. There was a study on Greedy algorithm with regard to the worst-case analysis. In this work, by reanalyzing the Greedy algorithm, we derive the tight worst-case performance ratio and proposed a new approximation algorithm with a better worst case performance ratio.

2 - Can Distance-driven Online Scheduling Be Better Than Order-driven?

KeLin Luo, Xi'an Jiaotong University, Xianning West Road 29, Xi'an, 710049, China, luokelin@stu.xjtu.edu.cn

Taxi arrangement, instance delivery, and intra-city express has been considered as a dispensable part of everyday life. The orders appear in real-time and in a certain area. The serving net is established by summarizing the order's properties, including time distribution, periodic distribution, and regional distribution. Then we can redefine the orders according their time and physical distances by special numbers, such as non-increasing numbers. We presented an online algorithm and verified the effectiveness and efficiency of this algorithm by comparing it with the order-driven scheduling. We refrain from the myopia of local optimum or global optimum accompanying with the substantial cost.

3 - A Dynamic Lot Sizing Based Discounted Cash Flow Model Considering Working Capital Requirement Financing Costs

Thomas G Yeung, Associate Professor, Ecole des Mines de Nantes, 4 rue Alfred Kastler BP 20722, La Chantrerie, Nantes, 44307, France, thomas.yeung@mines-nantes.fr, Yuan Bian, David Lemoine, Nathalie Bostel-Dejax, Jean-Laurent Viviani, Vincent Hovaleque

Companies always need free cash flow to efficiently react against uncertainty and ensure solvency. However, classical dynamic lot-sizing models only consider the physical flow of products. In this paper, we introduce a first link between the dynamic lot-sizing problem and financial aspects of working capital requirements (WCR). We propose a new generic WCR model along with a dynamic lot-sizing-based discounted cash flow model for single-site, single-level, single-product and infinite capacity cases. A polynomial algorithm is also presented with numerical tests in order to compare our approach with the traditional dynamic lot-sizing approach.

4 - Two Machine Scheduling Subject To Arbitrary Machine Unavailability

Yumei Huo, Associate Professor, City University of New York, 2800 Victory Boulevard, 1N 215, Staten Island, NY, 10314, United States, yumei.huo@csi.cuny.edu

We study two machine scheduling subject to arbitrary machine unavailability. The jobs are resumable. We consider both the single criterion and the bi-criteria problems concerning makespan and the total completion time. Liu and Sanlaville have shown that makespan minimization problem is solvable in polynomial time, leaving other three optimization problems still open: total completion time; total completion time subject to the constraint that the makespan is minimum; and makespan subject to the constraint that total completion time is minimum. In this research, we show all these three open problems are in P by giving optimal polynomial time algorithms.

Recent Advances in Simulation

Sponsored: Simulation

Sponsored Session

Chair: Jing Dong, Northwestern University, Evanston, IL, United States, jing.dong@northwestern.edu

Co-Chair: Jose Blanchet, Columbia University, New York, NY, United States, jose.blanchet@gmail.com

1 - On Calibrating Statistical Distances

Huajie Qian, University of Michigan, 2302 St Francis Drive, Apt B118, Ann Arbor, MI, 48104, United States, hqian@umich.edu Henry Lam

We present a general framework to calibrate the statistical distance dictating the size of the uncertainty sets for distributionally robust optimization used in stochastic or simulation optimizations under uncertainty. We discuss the implications on the statistical guarantees of the resulting objective values and feasibility. We also compare these guarantees to sample average approximation.

2 - Multi-resolution Gaussian Markov Random Fields For Discrete Optimization Via Simulation

Eunhye Song, Northwestern University, Evanston, IL, United States, EunhyeSong2016@u.northwestern.edu
Barry L Nelson, Jeremy C Staum

The Gaussian Markov Improvement Algorithm (GMIA), an optimization via simulation algorithm based on Gaussian Markov random fields (GMRF), has computational advantages in solving problems on a large discrete solution space. We extend GMIA to a multiresolution algorithm (MR-GMIA) to solve even larger problems. The solution space is divided into regions; each region becomes a “solution” in a region-level GMRF while solutions within each region are represented by a solution-level GMRF. Using complete expected improvement, MR-GMIA guides the search toward promising regions and promising solutions within the selected regions with global inference about the optimality gap for termination.

3 - Unbiased Monte Carlo Computations For Optimization And Functions Of Expectations

Yanan Pei, Columbia University, yp2342@columbia.edu, Jose Blanchet, Peter W Glynn

We present general principle for the design and analysis of unbiased Monte Carlo estimators for quantities such as functions of expectations. Our estimators possess finite work-normalized variance under mild regularity conditions. We apply our estimator to various settings of interest, such as optimal value estimation in the context of Sample Average Approximations, unbiased estimators for particle filters and conditional expectations.

4 - Estimation In The Tail Of The Gaussian Copula

Raghu Pasupathy, Purdue University, West Lafayette, IN, 47907, United States, pasupath@purdue.edu

We present ecoNORTA for efficient constrained random vector generation within the Gaussian and NORTA contexts. We propose three importance-sampling estimators for such settings, the first of which actively exploits knowledge of the local structure of the feasible region around a dominating point to achieve bounded relative error. The second and third estimators, for use in settings where information about the constraint set is not readily available, do not exhibit bounded relative error but are shown to achieve a slightly weaker form of efficiency. Numerical results on various example problems show promise.

Joint Session HAS/MSOM-HC: Models and Analytics in Healthcare Operations

Sponsored: Manufacturing & Service Oper Mgmt, Healthcare Operations

Sponsored Session

Chair: Joel Goh, Harvard Business School, Boston, MA, United States, jgoh@hbs.edu

1 - Accurate Prediction Of Case Duration

Amirhossein Meisami, University of Michigan, Ann Arbor, MI, United States, meisami@umich.edu, Nick Kastango, Christopher Thomas Borum Stromblad, Mark P Van Oyen

The primary goal of this study is to analyze the abundant data available prior to surgery and leverage this information to produce accurate case length predictions via novel statistical learning methodologies. We will be working with a rich database from Memorial Sloan Kettering Cancer Center to identify the essential features in defining case duration variability. The research also focuses on reducing the uncertainties and variations imposed by rare events that may arise in various procedures during a case.

3 - Admission Of Long Stay Patients In A Busy Pediatric ICU

Fernanda Bravo, Assistant Professor, UCLA Anderson School of Management, Los Angeles, CA, United States, fernanda.bravo@anderson.ucla.edu, Michael McManus

This work studies admission policies for complex patients in the ICU of a large pediatric academic hospital. There are four different patient types: medical, emergency, surgical, and transfers. Within these, long-stay-patients use a large amount of resources and limit the access to the unit. The ICU must always remain available for emergencies before accommodating elective admissions. As a result, many children are queued for complex surgeries and medical workups. We study policies to decide when to admit an long-stay-patient depending on the current ICU status, and future patients’ arrivals.

4 - Scheduling Work In Radiology

Maria R. Ibanez, Harvard Business School, mibanez@hbs.edu

Using detailed data on millions of radiological studies interpreted by physicians, we study the drivers of speed and quality of the interpretation, and identify implications for scheduling and allocation of work across workers.

1 - Queueing With Strategic Balking And System Design

Yichen Tu, University of North Carolina, Chapel Hill, NC, United States, yichen1@live.unc.edu, Nur Sunar, Serhan Ziya

We analyze a queueing system where customers decide whether to join or balk the system depending on the expected benefit they receive by joining a system. In this setting, we characterize the optimal choice of system design from the perspective of a social welfare optimizer. We also conduct numerical studies to shed light on the benefit of different system design choices.

2 - Risk/return Trade-off In Queues With A Nonlinear Waiting Cost Function

Hossein Abouee-Mehrizi, University of Waterloo, 200 University Avenue West, Waterloo, ON, N2L 3G1, Canada, haboueemehrizi@uwaterloo.ca, Ata G Zare, Renata Konrad

We consider an M/M/1 queueing system and assume that each customer receives a value by getting served and suffers from a waiting cost. To analyze customers’ behavior, we consider the risk/return trade-off and a nonlinear waiting cost function. Customers are impatient and have a mixed attitude with respect to the risk. Before reaching a certain point in time, customers are risk-seeking, but after that they become risk-averse. We assume that customers follow a joint balking and abandonment strategy. We fully characterize the equilibrium joint balking and abandonment strategy and show that three types of equilibria may exist: global, myopic, and farsighted.

3 - Optimal Information Disclosure In M/M/1 Queues

Shiliang Cui, Georgetown University, 548 Rafik B. Hariri Building, 37th & O Streets, NW, Washington, DC, 20057, United States, shiliang.cui@georgetown.edu, Jinting Wang

Queue length is a very important parameter for customers to make a joining decision or not. We study optimal information disclosure policies in M/M/1 queues.

4 - Want Priority Access? Refer Your Friend To Move Up In Line

Luyi Yang, University of Chicago, lyang6@chicagobooth.edu
Laurens G Debo

This paper studies the referral priority program, an emerging business practice adopted by a growing number of technology companies that manage a waitlist of customers. The program enables existing customers on the waitlist to gain priority access if they successfully bring in new customers. We find that the effectiveness of this novel mechanism as a marketing tool for customer acquisition and an operational approach for waitlist management depends crucially on the base arrival rate of the system. Referrals may not be generated when the base arrival rate is either too high or too low. Even when customer refer, the program could backfire (i.e., reduces the system throughput and customer welfare).

Economics of Operations Management

Sponsored: Manufacturing & Service Oper Mgmt, Supply Chain

Sponsored Session

Chair: Kenan Arifoglu, UCL, London, United Kingdom, k.arifoglu@ucl.ac.uk

1 - Money-back Guarantees When Physical And On-line Retailers Compete

Hang Ren, University College London, hang.ren.13@ucl.ac.uk Tingliang Huang, Ying-Ju Chen, Christopher S Tang

We study the pricing and product return policies when physical and on-line stores compete. We find that the on-line store offers money-back guarantees when its salvage advantage outweighs total return hassle. Interestingly, better service quality may hurt the on-line store. When consumers can showroom, i.e., buying online after trying the product offline, the on-line store should offer hassle-free money-back guarantees. Moreover, the showrooming behavior may benefit the physical store while harming the online store.

2 - Licensing Contracts In Conspicuous Markets

Prateek Raj, University College London, p.raj.12@ucl.ac.uk, Kenan Arifoglu

We study licensing decision of a brand owning firm that sells its primary product to conspicuous customers who value the brand exclusivity, and also licenses its brand name to a licensing firm. We compare efficiency of fixed-fee, royalty and mixed contracts and also explore the role of licensing under competition.

3 - Selling New Products Through Consumer Learning

Yufei Huang, University of Bath, y.huang@bath.ac.uk, Bilal Gokpinar, Christopher S. Tang, Onesun Steve Yoo

Due to uncertain valuation of a new product, consumers often seek to learn more about the product before making purchasing decisions. In general, consumers can learn from the firm directly, from making an individual effort to learn, or from other consumers indirectly (through social learning). In this paper, we present a unified framework of consumer learning in the context of rational and heterogeneous consumers. Our goal is to examine, from the firm's perspective, when and why (i) investing in firm-induced learning can be superior to variable pricing, (ii) subsidizing individual learning can be beneficial, and (iii) investing in social learning (e.g., online forums) can be harmful.

4 - Is Reshoring Better Than Offshoring Under Offshore Supply Dependence?

Hu Bin, University of North Carolina, Chapel Hill, NC, United States, bin_hu@unc.edu, Li Chen

We investigate offshore supply dependence's impact on the offshoring-reshoring comparison. We find that offshore supply dependence may hamper a reshoring manufacturer's responsiveness to demand information updates, such that reshoring may yield lower profits than offshoring in many cases, including when reshoring has no direct cost disadvantages. We then show that offshore supply dependence also affects how customs duties and shipping costs influence the offshoring-reshoring profit comparison. We further identify common-component designs as an approach to mitigate reshoring firms' offshore supply dependence and help promote reshoring in its presence.

1 - Retail Clusters In Developing Countries

Xuying Zhao, University of Notre Dame, Xuying.Zhao.29@nd.edu, Hong Guo, Chao Ding, Jing-Sheng Jeannette Song

A retail cluster refers to a collection of horizontally differentiated retailers of a particular business sector locating in close proximity. Retail clusters are commonly seen in developing countries. In this paper, we develop a game-theoretic model to explore why the retail cluster phenomenon is so popular in developing countries and how the governments in these countries can foster retail clusters and leverage them to improve social welfare.

2 - Achieving Sustainability Commitments In Commodity Supply Chains

Joann Francoise de Zegher, Stanford University, Stanford, CA, United States, jfdezegher@stanford.edu, Hau Leung Lee, Dan Andrei Iancu, Erica Plambeck

How can downstream companies in commodity supply chains incentivize small producers to mitigate deforestation while also improving farmer welfare? Motivated by field research in the palm oil industry, we propose an incentive based on early payments. The dynamics of this incentive are distinct from a price premium incentive, due to characteristics of small-farmer cash flow needs upstream and large discrepancies in borrowing abilities of different supply chain tiers. We build a theoretical model to analyze this setting and ground our analysis through empirical work in the complex palm oil supply chain originating in Indonesia.

3 - Effective Medical Surplus Recovery

Can Zhang, Georgia Institute of Technology, Atlanta, GA, 30309, United States, czhang2012@gatech.edu, Atalay Atasu, Beril L Toktay, Wee Meng Yeo

We analyze a Medical Surplus Recovery Organization (MSRO) that recovers and manages reusable medical products to fulfill the needs of under-served healthcare facilities in developing countries. Using a game theoretic analysis, we identify loss of effectiveness caused by competition among recipients in a recipient-driven model implemented by the MSRO. We then present operational mechanisms that can improve the MSRO's total value provision and we numerically validate our results using real life data.

Innovation and Entrepreneurship

Invited: New Product Development

Invited Session

Chair: Raul Chao, University of Virginia, UVA, Charlottesville, VA, United States, ChaoR@darden.virginia.edu

1 - Risk Aversion And Joint Problem Solving: Experimental Evidence

Marc Christiaan Jansen, Cambridge Judge Business School, Downing College, Regent Street, Cambridge, CB2 1DQ, United Kingdom, mcj32@cam.ac.uk, Nektarios Oraiopoulos, Niyazi Taneri

We examine the effect of risk aversion on collaborative problem solving between two partners. We design an experiment that measures subjects' risk aversion and allocates subjects to treatments accordingly. We show that subjects perform relatively well in sharing the risk between them, but underperform relatively to the optimal investments levels.

2 - Strategic Positioning In Global Entrepreneurship Ecosystems

Hyunwoo Park, Postdoctoral Fellow, Georgia Institute of Technology, Atlanta, GA, 30332, United States, hwpark@gatech.edu, Rahul C Basole, Raul Chao

Strategic positioning is particularly critical for entrepreneurial ventures, which face a difficult trade-off in balancing legitimacy through similarity versus innovativeness through differentiation. Using a computational approach based on data mining, text analytics, and network visualization, we seek to gain an understanding of the structure of strategic positioning of nearly 60,000 companies in 35 global entrepreneurial ecosystems.

3 - Won't Leave You At The Altar: Designing Alternative Mechanisms For Startup Supply Chain Development

Emre Guzelsu, Boston University, bguzelsu@bu.edu Brad Lee, Nitin Joglekar

Startup supply chain development spans two stages, early experimentation without revenue followed by production scale-up and revenue generation. Early experimentation involves single sourcing with another startup, while production offers dual sourcing opportunity. We explore alternative mechanisms for startup supplier alignment across both stages using a game theoretic framework.

4 - Optimal Supplier Allocation In Collaborative Product Development With Competing Internal Teams

Svenja Sommer, HEC Paris, 1, Rue de la Liberation, Jouy-en-Josas, France, sommers@hec.fr, Timofey Shalpegin, Christian Van Delft

To reduce the uncertainty inherent in development, manufacturers sometimes deploy competing internal teams, each working on a different technology or design. Often this development takes place in collaboration with key suppliers. We explore how manufacturers should allocate suppliers (with different capabilities) to these teams, considering the impact on supplier efforts.

Queueing Systems and Approximations

Sponsored: Applied Probability

Sponsored Session

Chair: John Hasenbein, University of Texas-Austin, Austin, TX, United States, jhas@mail.utexas.edu

1 - Optimal Routing To Remote Queues

Yunan Liu, NC State University, Raleigh, NC, United States, yliu48@ncsu.edu, Shucangchi He, Yao Yu

We develop optimal routing policies for remote queueing systems, in which each arrival, after being routed to join one of several single-server queues in parallel, will experience a pre-arrival delay. Motivated by service systems in which system state (e.g., queue length and waiting time) is available for routing decisions, we intend to use pre-arrival delays to model commute times of arrivals, such as patients' transportation times before arriving at clinics and data packets' transmission times to web servers. In order to minimize the delay, we propose a new state-dependent probabilistic routing policy.

2 - Complete Resource Pooling In Open Shop Networks

Shuangchi He, National University of Singapore, Singapore, heshuangchi@nus.edu.sg, Gideon Weiss, Hanqin Zhang

In an open shop network, each customer needs to go through all stations once, but the order of visiting each station is irrelevant. Can this flexibility in service order give us an edge in reducing customer waiting times? In this paper, we consider an open shop network consisting of two stations. We find routing and sequencing policies that are asymptotically optimal when the open shop network is operated in heavy traffic. We prove that under the obtained scheduling policies, customer waiting times in an open shop network are asymptotically close to the waiting times in a GI/GI/2 queue with the same traffic intensity.

3 - Stein Method And Moderate Deviations For Steady-state Diffusion Approximations

Jim Dai, Cornell University, jd694@cornell.edu, Fang Xiao

Service levels such as no more 5% of callers have to wait 3 minutes orlonger are common performance measures for many service systems. Iwill use the Erlang-C system to explain how Stein method can be used todevelop moderate deviations bounds for steady-state diffusionapproximations of these performance measures. This is the joint work with Xiao Fang at NUS and Chinese University of Hong Kong.

4 - Optimal Service Rate And Admission Control For A Queue

Levent Kocaga, Yeshiva University, kocaga@yu.edu

We study the joint service rate and admission control problem for a multi-server service system modeled as a G/M/N+GI queue. We consider the infinite horizon discounted cost criterion as well as the infinite horizon average cost criterion where costs are associated with customer waiting, customer abandonment, and service rate control. Instead of solving the potentially intractable original queueing control problem, we solve an approximating diffusion control problem (DCP) and show that the optimal control is of threshold and feedback type. We utilize the solution to the DCP to construct a control policy for the original queueing control problem.

1 - Simulation And Optimization For Reevaluating Order Fulfillment Plans In An Online Retail Environment

Amir Hossein Kalantari, University of Wisconsin Milwaukee, Milwaukee, WI, United States, kalanta2@uwm.edu, Matthew Petering

Online retailing has expanded dramatically in recent years and is expected to continue growing in the future. Online retailers typically operate a number of fulfillment centers that are located in different geographical regions. When an order is placed, it must be assigned to one or more fulfillment centers. The decision of choosing which fulfillment centers satisfy which orders is very critical and there is an opportunity for the retailer to significantly reduce shipping costs by making the right decisions. In our research, we use a combination of discrete event simulation and optimization to investigate the effects of different strategies and compare their effectiveness.

2 - The Value Of Aggregated Information Sharing In Supply Chains

Vladimir Kovtun, Yeshiva University Syms School of Business, New York, NY, vladimir.kovtun@yu.edu

We study a two-stage supply chain where the retailer's order is the aggregate of two stationary ARMA processes. We determine when there is value to sharing the individual processes and when there is additional value to sharing the shocks. We also determine the supplier's mean squared forecast error under no sharing, process sharing, and shock sharing. We find instances when process sharing has no value which are not present in earlier literature.

3 - Coordination Of The Supply Chain With Quality Improvement And Customer Returns

Xinghao Yan, Western University, London, ON, Canada. Contact: xyan@ivey.uwo.ca

We study a supply chain with both quality improvement and customer returns. We analyze the retailer's incentive for refund price and the supplier's incentive for quality improvement. We also design coordinating contracts for the supply chain, which is influenced by several factors: contract format, profit negotiation, and first-mover right.

1 - Simulating Risk Measures

Steven Kou, National University of Singapore, matsteve@nus.edu.sg

Risk measures, such as value-at-risk and expected shortfall, are widely used in risk management. We propose a simple general framework, allowing dependent samples, to compute these risk measures via simulation. The framework consists of two steps: In the C-step, we control the relative error in the simulation by computing the necessary sample size needed for simulation, using a newly derived asymptotic expansion of the relative errors for dependent samples; in the S-step, the risk measures are computed by using sorting algorithms. Numerical experiments indicate that the algorithm is efficient even at the 0.001 quantile level. This is a joint work with Wei Jiang.

2 - Valuation Of Path-dependent Equity And Credit Derivatives

Ning Cai, Hong Kong University of Science & Technology, ningcai@ust.hk

We study the pricing problems of path-dependent equity and credit derivatives within a general hybrid equity-credit framework, i.e., under generalized jump to default extended exponential Levy models with local volatilities. More precisely, under this general model, we propose a unified approach to pricing various equity derivatives and credit derivatives, including defaultable corporate bonds, European options, barrier options, CDS, and EDS. Numerical results indicate that our pricing methods are accurate, efficient, and easy to implement. This is joint work with Haohong Lin from HKUST.

3 - A Unified Framework For Options Pricing Under Regime Switching Models

Yingda Song, University of Science and Technology of China, Hefei, China, songyd@ustc.edu.cn

Regime changes are prevalent in the financial markets, yet it is challenging to price options in presence of regime switching. In this talk, we provide a unified framework for pricing options under a wide class of regime switching models. Based on our framework, we study the effects of regime switching on the prices and hedge parameters of various types of options, as well as the yield spread of a structural credit model.

The OTC Derivatives Market Reform and the Subsequent Interplay betwen Banks and CCPs

Sponsored: Financial Services

Sponsored Session

Chair: Ghamami Samim, Federal Reserve Board, 20th St and Constitution Ave NW, Washington, DC, 20551, United States, samim.ghamami@frb.gov

1 - OTC Derivatives Reform and the Subsequent Interplay Between Banks and Central Counterparties

Samim Ghamami, Federal Reserve Board, samim.ghamami@frb.gov

We first discuss the G-20 reform program in the over-the-counter (OTC) derivatives markets and the subsequent Basel risk capital, collateral, liquidity, and leverage regulation. Next and after a brief review of derivatives central counterparties (CCPs), we present the paper "Does OTC derivatives reform incentivize central clearing?" Ghamami and Glasserman [2016].

Values and Decision-Making

Sponsored: Decision Analysis

Sponsored Session

Chair: Johannes Siebert, University of Bayreuth, Universitätsstr. 30, Bayreuth, 95440, Germany, Johannes.Siebert@uni-bayreuth.de

1 - Identifying, Structuring, And Using Personal Strategic Life Objectives

Ralph L. Keeney, Duke University, San Francisco, CA, United States, keeneyr@aol.com

Most individuals desire a quality life, but have not articulated the objectives necessary to pursue and reasonably achieve such a life. This presentation discusses how to identify your personal strategic life objectives and how to use them to enhance the quality of your life.

2 - Identifying, Structuring, And Comparing Objectives Of Terrorists

Detlof von Winterfeldt, Center for Risk and Economic Analysis of Terrorism Events (CREATE), University of Southern California, Los Angeles, CA, CA 90089, United States, winterfe@usc.edu
Johannes Siebert, Richard S John, Gregory Keeney, Heather Rosoff

The risk of terrorism is of great concern to many countries and significant resources are spent to counter this threat. A better understanding of the motivation of terrorists and their reasons for selecting certain modes and targets of attack can help improve the decisions to allocate resources in the fight against terrorism. We develop methods using principles of decision analysis and value-focused thinking to identify, structure, and compare objectives of terrorists. We use our methods to provide the key decision makers in the Pentagon with a sound basis for fighting the terrorist groups.

3 - Enhancing Life Satisfaction By Improving Proactive Cognitve Skills

Johannes Siebert, University of Bayreuth, Johannes.Siebert@uni-bayreuth.de, Reinhard Kunz

The Proactive Decision Making scale, which is based on the concepts of value-focused thinking and decision quality, measures proactive personality traits and cognitive skills in decision-making. We show that proactive cognitive skills can explain up to 36% of life satisfaction, i.e. proactive decision makers are more satisfied with their decisions and with their lives. Furthermore, we provide empirical evidence that proactive cognitive skills can be trained in a course on decision-making. We recommend schools, colleges, and universities to offer more courses on decision-making to enhance student`s proactive cognitive skills and satisfaction with their decisions and lives.

Robust Decision Analysis

Sponsored: Decision Analysis

Sponsored Session

Chair: Erin Baker, Univ of Massachusetts-Amherst, Amherst, MA, United States, edbaker@ecs.umass.edu

1 - Robust Sensitivity Analysis In Climate Change Modelling

Emanuele Borgonovo, Bocconi University, emanuele.borgonovo@unibocconi.it, Max D. Morris, Elmar Plischke

In several situations, analysts are not able to assign a unique distributions to the inputs of a computer code. Especially when alternative opinions are received by experts, analysts may combine alternative assessments using a mixture. The removal of the unique distribution assumption creates several issues in global sensitivity analysis, which we address systematically in this work.

2 - Climate Informed Decision Analysis: Do We Need Probabilities?

Casey Brown, University of Massachusetts, Amherst, casey@engin.umass.edu

The projected impacts of climate change often include untenable implications for many infrastructure systems. Planners and policy makers seek the best possible sources of climate change projections and information to assist their decision making needs. However, the dominance of climate science oriented toward mitigation of greenhouse gas emission questions leads to a disorientation of research focused on adaptation to climate change impacts. A break from "impact analysis" methods is needed, and a climate informed decision analysis is proposed in response. The question of use of probabilities, in particular, is analyzed. <!—EndFragment—>

3 - Finding Common Ground When Experts Disagree: Robust Portfolio Decision Analysis

Erin Baker, Univ. of Massachusetts - Amherst, edbaker@ecs.umass.edu, Valentina Bosetti, Ahti Salo

We address the problem of choosing a portfolio of policies under "deep uncertainty." We introduce the idea of belief dominance as a way to derive a set of non-dominated portfolios and robust individual alternatives. The belief dominance concept allows us to synthesize multiple expert - or model - based beliefs by uncovering the range of alternatives that are intelligent responses to the range of beliefs. We illustrate our approach using an important problem in the climate change and energy policy context: choosing among clean energy technology R&D portfolios.

Quantitative Methods in Risk Management

Invited: Risk and Compliance

Invited Session

Chair: Agostino Capponi, Columbia University, 500 West 120th Street, New York, NY, 10027, United States, ac3827@columbia.edu

1 - Managing Systemic Risk In Inhomogeneous Financial Networks

Nils Detering, University of California Santa Barbara, Santa Barbara, CA, 93106, United States, detering@pstat.ucsb.edu, Thilo Meyer-Brandis, Konstantinos Panagiotou, Daniel Ritter

To quantify and manage systemic risk in the interbank market, we propose a weighted, directed random network model. The vertices in the network are financial institutions and the weighted edges represent credit exposures between them. Our model resembles the strong degree of heterogeneity observed in empirical data and generalizes earlier work based on the configuration model to inhomogeneous random graphs with unbounded variance of the degree sequence. We study the networks resilience to local shocks (only a few initially defaulted institutions) and derive capital charges, which ensure the networks resilience.

2 - Information Relaxation Bounds And The Dynamic Assortment Problem

David Brown, Duke University, dbbrown@duke.edu, Jim Smith

n this talk, we discuss the use of information relaxation bounds to generate performance bounds for dynamic programming problems. We focus on the dynamic assortment problem (Caro and Gallien 2007) and show how the information relaxation bounds improve upon Lagrangian relaxation bounds.

3 - Path-dependent And Randomized Strategies In Barberis' Casino Gambling Model

Xunyu Zhou, Columbia University, Manhattan, New York City, NY, United States, xz2574@columbia.edu

We consider the dynamic casino gambling model initially proposed by Barberis (2012) and study the optimal stopping strategy of a pre-committing gambler with cumulative prospect theory (CPT) preferences. We illustrate how the strategies computed in Barberis (2012) can be strictly improved by reviewing the betting history or by tossing an independent coin, and we explain that the improvement generated by using randomized strategies results from the lack of quasi-convexity of CPT preferences. Moreover, we show that any path-dependent strategy is equivalent to a randomization of path-independent strategies.

4 - Optimal Exit Time From Casino Gambling: Strategies Of Pre-committed And Naive Gamblers

Xuedong He, Chinese University of Hong Kong, xdhe@se.cuhk.edu.hk

We study the strategies of a pre-committed gambler, who commits her future selves to the strategy she sets up today, and of a naive gambler, who fails to do so and thus keeps changing plans at every time. We identify conditions under which the pre-committed gambler, asymptotically, adopts a stop-loss strategy, exhibits the behavior of disposition effect, or does not exit. When the utility function is piece-wise power and the probability weighting functions are concave power, we derive the optimal strategy of the pre-committed gambler in closed-form whenever it exists. Finally, we study the actual behavior of the naive gambler and highlight its marked differences from that of the pre-committed gambler.

Revenue Management: From Theory to Practice

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Georgia Perakis, Massachusetts Institute of Technology, Cambridge, MA, United States, georgiap@mit.edu

1 - The Role Of Vendor Funds In Promotion Planning

Lennart Baardman, MIT, Cambridge, MA, United States, Georgia Perakis, Kiran Venkata Panchamgam

Vendor funds are integral to promotion planning. Vendor funds are trade deals in which manufacturers offer discounts to retailers, encouraging them to promote their products, while demanding pass-through to the customers. We model the problem of selecting vendor funds to maximize profit while taking into account the impact on promotional pricing as a QIP. First, we use a strategic model to analyze the optimal strategies of both the manufacturer and the retailer. Additionally, to solve the tactical problem, we use Lagrangian relaxation to propose an approximation algorithm with analytical performance guarantees. Finally, computational results show near-optimal practical performance.

2 - Revenue Management For The Shipping Industry Under Limited Foresight

Max Biggs, Massachusetts Institute of Technology, Cambridge, MA, United States, maxbiggs@mit.edu, Georgia Perakis

We study a scenario where a shipping company has limited foresight into cargo availability in future periods. It is possible that a high valued cargo may discharge in unpromising region with scarce or low valued cargoes, thus jeopardizing profit in subsequent time periods. We model this situation using a finite horizon Markov Decision Process and present a ranking algorithm which solves optimally in polynomial time. We also explore fast heuristics, and test these algorithms on a simulation that uses real shipping data to evaluate their performance in a practical setting. We also show extensions for uncertain shipping rates.

3 - Submodular Batch Scheduling

Daniel Chen, MIT, Cambridge, MA, United States, dcchen@mit.edu, Retsef Levi, Georgia Perakis

Consider an online retailer shipping out orders from a warehouse. Multi-item orders take up capacity in a holding area until all items are picked. This holding area is often the cause of bottlenecks, so we formulate the submodular batch scheduling problem to maximize throughput. We wish to schedule jobs in batches to minimize the sum of job completion times. The processing time of each batch is given by a submodular cost function, and the completion time of each job is given by the completion time of the batch. We show this problem is strongly NP-hard, but propose several practical methods, including a 4-approximation algorithm.

4 - The Periodic Joint Replenishment Problem Is Strongly NP-hard

Tamar Cohen, MIT, tcohen@mit.edu, Liron Yedidsion

The Joint Replenishment Problem (JRP) deals with the prospect of saving resources through coordinated replenishments in order to achieve substantial cost savings. In the JRP it is required to schedule the replenishment times of numerous commodities in order to supply a constant demand per commodity. In this research we answer a long-standing open question regarding the computational complexity the periodic JRP. This problem received a lot of attention over the years and many heuristic and approximation algorithms were suggested. However, in spite of the vast effort, the complexity of the problem remained unresolved. In this research, we provide a proof that the problem is indeed strongly NP-hard.

Online Learning and Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Maxime Cohen, Google Research, Google, New York, NY, 10012, United States, maxccohen@google.com

Co-Chair: Ilan Lobel, New York University, New York, NY, United States, ilobel@stern.nyu.edu

1 - Dynamic Pricing And Learning With Online Retail Rankings

N. Bora Keskin, Duke University, Durham, NC, United States, bora.keskin@duke.edu, Arnoud V. den Boer

In online market environments such as Amazon or Google Shopping, firms receive advertisement space if they satisfy certain conditions. Beforehand, it is not clear if the benefits of this increased exposure outweigh the potential costs. We investigate this question in a dynamic pricing-and-learning setting.

2 - Dynamic Pricing With Demand Covariates

Sheng Qiang, Stanford University, sqiang@stanford.edu, Mohsen Bayati

We consider a generic problem that a firm sells products over T periods without knowing the demand function. The firm sets prices to earn revenue and learn the demand function. In each period before setting the prices, the firm observes some demand covariates, which may be predictive of the demand. Demand covariates can include marketing expenditure, consumer's attributes, weather, etc. We prove that in this setting the greedy policy achieves asymptotically optimal performance. We also show that inclusion of any set of demand covariates as potential variables for the demand estimation (even though they could be independent of the demand) would make greedy policy asymptotically optimal.

3 - Optimistic Gittins Indices

Vivek Farias, MIT, vivekf@mit.edu, Eli Gutin

We consider the multi-armed bandit problem in the Bayesian setting wherein one seeks to minimize expected regret. Gittins indices provide an optimal algorithm for the maximization of discounted, infinite horizon rewards (as opposed to regret minimization) in this very setting. So motivated, we propose an index rule we dub 'optimistic' Gittins indices. We show that this rule achieves logarithmic regret with an optimal constant, matching the Lai-Robbins lower bound for the problem — the strongest possible guarantee possible. The algorithm also offers excellent performance relative to recently studied approaches such as Thomspon and Information Directed Sampling.

4 - Feature-based Dynamic Pricing

Ilan Lobel, NYU Stern, New York, NY, 10012, United States, ilobel@stern.nyu.edu, Maxime Cohen, Renato Paes Leme

We consider the problem faced by a firm that receives highly differentiated products in an online fashion and needs to price them in order to sell them to its customer base. Products are described by vectors of features and the market value of each product is linear in the values of the features. The firm does not initially know the values of the different features, but it can learn the values of the features based on whether products were sold at the posted prices in the past. We propose an algorithm that combines ideas from contextual bandits and the ellipsoid method, and show that it has a worst-case regret that is quadratic in the dimensionality of the feature space and logarithmic in the time horizon.

Social Media Analytics for Competitive Advantage

Invited: Social Media Analytics

Invited Session

Chair: Vilma Todri, New York University, New York, NY, 11111, United States, vtodri@stern.nyu.edu

1 - Social Influence And Changing Circumstances In The Creation, Maintenance, And Disruption Of Habits In Global Health Behavior

Christos Nicolaides, Massachusetts Institute of Technology, chrisnic@mit.edu

In this research I analyze a unique, granular dataset of individual-level exercise data from more than 10 million users worldwide for about seven years to (a) measure the regularity of exercise behavior, (b) identify factors that predict a behavior continuing, (c) compare social influence in running for individuals with and without running habits, and (d) estimate the consequences of common disruptions to circumstances cues for habitual behaviors. I use modern causal inference techniques to address central questions in the psychology of habits with applications to interventions — especially social interventions — to influence exercise behavior and adoption of consumer exercise products.

2 - Location-based Advertising And Contextual Mobile Targeting

Dominik Molitor, New York University, dmolitor@stern.nyu.edu

Understanding how location-based advertising (LBA) can be utilized to increase sales in stores is important for offline retailers. LBA is a means to target users by making use of their location via GPS-enabled smartphones. Further, the ubiquitous nature of smartphones increases the importance of additional contextual factors such as time and weather. In particular, we analyze how contextual factors can be used to improve the prediction of responses to mobile promotions by applying unique GPS data. In particular, we examine the interplay between location, time, weather as well as co-location and users' responses to mobile promotions.

3 - The Effect Of Referral Source On News Article Readership And Sharing Patterns

Sagit Bar-Gill, Massachusetts Institute of Technology, Cambridge, MA, United States, sbargill@mit.edu, Shachar Reichman, Xitong Li

The ongoing transition to online and mobile news consumption is both a challenge and an opportunity to news providers. Readers are consuming more content online, and are increasingly relying on third-party aggregators and social media to find what content to read. We employ analytic tools and fine grained news consumption data to study the effect of online referral sources on readership and sharing patterns on the Christian Science Monitor website. We explore differences in traffic patterns coming from social media and news aggregators, and examine whether the effects of referral source differ for mainstream compared to niche content.

4 - Trade-offs In Digital Advertising: Modeling And Measuring Advertising Effectiveness And Annoyance Dynamics

Vilma Todri, New York University, vtodri@stern.nyu.edu
Anindya Ghose, Param Vir Singh

This study captures the trade-offs between effective and annoying digital advertising exposures. A hidden Markov model (HMM) is proposed that allows us to investigate the extent to which display advertising has an enduring impact on consumers' purchase decision and whether display advertising can stimulate annoyance to consumers; we provide a conceptual framework for understanding whether persistent digital display advertising exposures constitute a mechanism of annoyance. We also study the structural dynamics of the effective and annoying display advertising effects by allowing the corresponding effects to be contingent on the latent state of the funnel path consumers reside.

Text Analysis within Social Media

Invited: Social Media Analytics

Invited Session

Chair: Fay Cobb Payton, North Carolina State University, Campus Box 7229, Raleigh, NC, 27695, United States, fay_payton@ncsu.edu

1 - Text Analytics - The Power Of Storytelling

FayCobb Payton, Professor, Information Systems, NCSU, fay_payton@ncsu.edu

Numbers do not lie. This is a typical framework for positivists (often quantitative) researchable questions. This session will provide the introduction and a case study of why text analytics can be a powerful tool for complex, often unstructured data sources. A following session will provide insights into incorporating text analytics into organizational and research objectives.

2 - Unlocking Your 80%: Unearthing New Insights With Text Analytics

Christina Engelhardt, SAS Institute, Christina.Engelhardt@sas.com

How can your organization harness the staggering volumes of textual data coming from social & online media and your own proprietary systems? Join us as we explore some of the challenges and exciting opportunities these rich, yet complex, data sources provide us. Session topics include: • Why you should consider incorporating text analytics into your data science, research, and operational work streams• How to align technology, data sources, and the various text methods with your use case and objectives• Examples of how leading organizations are leveraging Text Analytics

3 - Hierarchical Machine Learning Approach To Detecting Anomalous Behavior In Online Social Media Forums

Naveen Kumar, University of Memphis, Memphis, TN, 38152, United States, nkumar7@memphis.edu, Deepak Venugopal, Robin Poston

The detection of anomalous behavior in online social media is a challenging problem due to complex interactions between several user characteristics such as review veracity, velocity, volume, and variety. We propose a novel two stage hierarchical machine learning approach that increases the likelihood of detecting anomalies by analyzing different actions of individual users and then characterizing their collective behavior. Specifically, we model user characteristics as univariate/multivariate distributions and then combine these distributions using mixture models to obtain a unified view of a user's behavior. We apply our approach to real-world reviews and obtain promising results.

Dr. William Massey: A Dynamic Legacy

Sponsored: Minority Issues

Sponsored Session

Chair: Jamol Pender, Cornell University, 206 Rhodes Hall, Ithaca, NY, 14853-3801, United States, jamol.pender@gmail.com

1 - Dynamic Rate Queues

Jamol Pender, Cornell University, jamol.pender@gmail.com

Inspired by healthcare and transportation systems, this talk will summarize the past, present, and future of dynamic rate queues and their impact on our society.

2 - Dr. William Massey: A Dynamic Legacy

Robert Hampshire, University of Michigan, hamp@umich.edu

In this talk we will explore the applications of time varying queues to problems in urban transportation. We show how Bill Massey's fundamental contributions to queueing theory and applied probability can be applied to smart parking systems, bike sharing and car sharing services

3 - The Dynamics 0f Queueing Transience With Dynamic Rates

William A Massey, Professor, Princeton University, ORFE Department, Sherrerd Hall, Princeton University, Princeton, NJ, 08544, United States, wmassey@princeton.edu

Inspired by communication and healthcare services, this talk summarizes the methods developed with many collaborators over the decades to understand the transient behavior of dynamic rate queues. This analysis is needed when confronted with the dynamic parameters found in time-inhomogeneous Markovian queueing models. The static equilibrium analysis for the steady state of constant rate queues no longer applies.
Constants summarizing the transient behavior for these steady state systems yield to the natural substitute of deterministic dynamical systems. We can then approximate the optimal behavior of these queues by controlling this related family of ordinary differential equations.

Decision-making Models for Public Health Systems

Sponsored: Public Sector OR

Sponsored Session

Chair: Chaitra Gopalappa, University of Massachusetts - Amherst, 120D Marston Hall, 160 Governors Drive, Amherst, MA, 01003, United States, chaitrag@umass.edu

1 - Estimating Disease Burden Of A Potential H7N9 Pandemic Influenza Outbreak In The United States

Walter Silva Sotillo, USF, silvasotillo@mail.usf.edu

Recent emergence of H7N9 influenza virus in China resulted in 571 laboratory-confirmed cases of human infections causing 212 deaths (37% fatality rate). Researchers have developed early estimates of some of the epidemiological parameters to characterize H7N9 virus in China. We use data from recent reports, an agent-based simulation model and stratified sampling to estimate disease burden of a potential H7N9 pandemic outbreak in the United States.

2 - Using The HIV Optimization And Prevention Economics (HOPE) Model For Evaluating HIV Interventions In The United States

Emine Yaylali, Centers for Disease Control and Prevention, wqq3@cdc.gov, Paul Farnham, Stephanie Sansom, Katherine A. Hicks, Amanda Honeycutt, Emily Tucker

The HOPE model is a detailed, dynamic compartmental model of HIV disease progression and transmission in the United States. We parametrized and calibrated the model to closely match the population of people living with HIV between 2006 and 2010, to project HIV transmission into the future. The population was stratified by age, sex, circumcision status, race/ethnicity, transmission group, and risk level. Outcomes included HIV incidence, prevalence, and care status. We employed the HOPE model to evaluate the cost-effectiveness of HIV interventions and explore HIV prevention policy questions.

3 - Access-to-Medicines (ATM) Vaccine Supply Chain Design: Astakeholder Framework

Nico Vandaele, KU Leuven, Naamsestraat 69, Leuven, 3000, Belgium, nico.vandaele@kuleuven.be
Catherine Jenny Decouttere, Mauro Bernuzzi, Stef Lemmens

Supply chains supportive of ATM, like vaccine supply chains, impose considerable additional challenges on the supply chain design process. We embed the modeling in a broader stakeholder based framework, which will substantially enhance the societal and human impact of the ATM supply chain service delivery. Our approach contains stakeholder mapping and system delineation, key performance indicator development, scenario generation including modelling, scenario ranking and final design selection.

4 - A Methodology For Parameterization Of State-transitions For Cancer Progression In Populations With Limited Longitudinal Cancer Database

Chaitra Gopalappa, University of Massachusetts, Amherst, chaitrag@umass.edu, Carel Pretorius, Jeremy Lauer

Economic analyses of cancer screening strategies specific to populations in low and middle income countries (LMICs) are limited. Barriers include absence of cancer progression models parameterized specific to these populations. This study addresses this gap.

Public Sector OR Problems with Geographic Considerations

Sponsored: Public Sector OR

Sponsored Session

Chair: Ronald G McGarvey, University of Missouri, E3437D Lafferre Hall, Columbia, MO, 65211, United States, mcgarveyr@missouri.edu

1 - Dynamic Decision Modeling For Inland Waterway Disruptions

Rachel Holmer, University of Arkansas, reholmer@email.uark.edu, Hueon Lee, Mahboubeh Madadi, Shengfan Zhang, Heather Nachtmann

There is much uncertainty associated with inland waterway transportation. Natural or man-made disruption on the inland waterway system can have widespread economic and societal impacts, and their consequences can be significant. In this research, a Markov decision process model was developed to identify optimal decisions in the event of a weather-related disruption to minimize the barge owner's loss, incorporating the uncertainty associated with the reopening of the waterway and deteriorating value of the cargo. Historical lock and dam unavailability data and related weather data were collected and analyzed to build a prediction model on lock and dam closure and reopening.

2 - Identifying Optimal Multi-state Collaborations For Reducing Co2 Emissions By Co-firing Biomass In Coal-burning Power Plants

Bayram Dundar, University of Missouri, Columbia, MO, 65201-3738, United States, Bd5zc@mail.missouri.edu
Ronald McGarvey, Francisco X Aguilar

EPA has recently proposed a rule that aims to achieve a total US carbon emission reduction of 32 percent below 2005 levels by 2030. An increase in co-firing woody biomass with coal is one approach electricity providers could take towards achieving these reductions. We develop a mixed integer linear programming model to identify min-cost approaches for reducing carbon emissions via biomass co-firing subject to spatially-explicit biomass availability constraints, utilizing a robust optimization approach to address uncertainties in power plant modification costs and emission rates. We apply this model to a set of 18 states in the northern US to identify optimal sets of multi-state collaborations.

3 - Estimates Of Successful Illegal Entry Across The U.S. Southwest Land Border

Brian Rieksts, Institute for Defense Analyses, brieksts@ida.org

We present a methodology to estimate successful illegal entry across the United States southwest land border. A repeated trials model based on repeated apprehensions was used to estimate these flows. Both administrative data and survey data were evaluated and used to construct these estimates.

4 - A Robust Optimization Evaluation Of The Potential For Reliance On Locally-produced Foods

Ronald G. McGarvey, University of Missouri, Columbia, MO, United States, mcgarveyr@missouri.edu, Bayram Dundar, Christine Costello

Strategies focused on local food production may generate new risks due to yield variability. We develop a robust optimization (RO) model to determine, for a given center C, the minimum radius R of a circle containing sufficient cropland and pasture to produce food items that satisfy the calorie and nutrient needs of the population residing within distance R of any point within that circle. We first run the model using historical yield averages for two US cities, assuming no variability. We then run our RO model using historical yield data over ten years to estimate variability. We compare the two model results to illustrate the impact of data uncertainty on meeting sustainable local food for communities.

1 - Business Start-up Operations

Nitin Joglekar, Boston University School of Management, joglekar@bu.edu

Evidence on operational innovations (OI), based on connectivity based analytics and low cost intelligent robotics, points to the co-evolution between business models and OI. We argue that this evolution offers opportunities to develop new types of decision support models.

2 - Communication, Incentives, And The Execution Of A Strategic Initiative

Jeremy Hutchison-Krupat, University of Virginia, krupatj@darden.virginia.edu

Senior leadership can influence a direct report through incentives and communication. Financial incentives are credible and precisely specified, but offer limited flexibility, whereas communication is flexible, but lacks precision and must be deemed credible to affect a direct report's actions. We study senior leadership who seeks to add an initiative to their portfolio. Early on, its potential to create value is not well-understood, however, senior leadership eventually obtains knowledge on its potential which they may communicate to their direct report.

3 - Relationship-specific Agreements Between The Service Provider And The Firm In The Gig Economy

Sinan Erzurumlu, Babson College, serzurumlu@babson.edu
Jonathan Sims

In this research we explore the interactions between the service providers and the firm in the gig economy. We analyze survey data to understand the relationship-specific norms and agreements between the service provider and the firm through the lens of psychological contracting.

4 - How Cost Reduction And Change Of Technology Significantly Changed The Demand Of A Product. Case Story Based On Daily Demand Data From 2012-2016

Eric Bentzen, Copenhagen Business School, eb.om@cbs.dk

Senior leadership can influence a direct report through incentives and communication. Financial incentives are credible and precisely specified, but offer limited flexibility, whereas communication is flexible, but lacks precision and must be deemed credible to affect a direct report's actions. We study senior leadership who seeks to add an initiative to their portfolio. Early on, its potential to create value is not well-understood, however, senior leadership eventually obtains knowledge on its potential which they may communicate to their direct report.

Simulation of Healthcare Service Systems

Sponsored: Service Science

Sponsored Session

Chair: Wai Kin Chan, Rensselaer Polytechnic Institute, 110 8th St., CII 5015, ISE Dept., RPI, Troy, NY, 12180, United States, chanw@rpi.edu

1 - Optimizing Hospital Service Levels Via Resource Allocation

Weiwei Chen, Assistant Professor, Rutgers University, 1 Washington Park, Newark, NJ, 07901, United States, wchen@business.rutgers.edu, Siyang Gao, Hainan Guo

This talk introduces a resource allocation problem typically encountered in hospitals. Service levels in a hospital will vary as the resources are allocated differently. These performance measures can be evaluated via simulation. We aim to find the optimal allocation that maximizes one service level while satisfying the other service level requirements. Such an optimization is subject to random noises in simulation and the limit on computing budget to run simulation. To this end, we formulate the problem as a simulation optimization problem, and derive the corresponding optimal computing budget allocation policy.

2 - Simulation Of Infectious Disease Propagation

Susan M Sanchez, Professor, Naval Postgraduate School, Monterey, CA, 93950, United States, ssanchez@nps.edu, Paul J. Sanchez

We explore the behavior of a new stochastic model of infectious disease propagation. The model tracks individual outcomes, but without creating connectivity graphs for all members of the population. Accordingly, it is readily scalable to large populations, while preserving the impact of variability during the critical early stages of an outbreak. Initial explorations show behaviors similar to the observed course of historical outbreaks: while many outbreaks fizzle out quickly, some flare into more widespread epidemics. Such results may better inform decision makers about risk.

3 - Association Between Staff Behavior And Patient Experience Of Care In Acute-care Hospitals

Eduardo Perez, Assistant Professor, Texas State University, San Marcos, TX, United States, eduardopr@txstate.edu David P. Dzubay, Anthony Stahl

This research proposes a new framework to assess the performance of hospitals across multiple domains of patients' experiences. We examine whether key systemic characteristics of hospitals are associated with a better experience for patients. In particular, we investigated the effects of nurses and hospitalists activities on patients' ratings of their care. A case study is presented that considers data from the intensive care units from multiple hospitals in Central Texas.

4 - Simulating The Size Distribution Of Hospital Service Systems

Wai Kin Chan, Rensselaer Polytechnic Institute, chanw@rpi.edu, Baojun Gao, Nancy Deng

This talk introduces an agent-based simulation model for simulating the growth process of a hospital service system. In this model, hospitals grow or reduce their size to react to (and compete for) patient demand. Patients, as another type of agents in the model, select a hospital to visit based on multiple factors. The objective of the agent-based model is to understand what factors influence the growth of hospitals in a way that the hospital size distribution converges to the size distribution consistent with the actual size distribution observed in a real hospital size dataset.

1 - Cross-sectional Surveys: Inferring Total Time In State Using Only Elapsed Time-to-date

Richard C Larson, Massachusetts Institute of Technology, rclarson@mit.edu

We survey populations whose members are in a temporary state, asking time already spent in the temporary state. Leveraging longevity bias, we derive distributions of total time spent in the state for: random & fixed times of surveying, random & fixed times of entering the state, and sampling only those who have already spent some minimal specified time in the state.

2 - Exploring The United States Behavioral And Social Science Research (BSSR) Workforce Through Dynamic Modeling

Julie Maurer, Ohio State University, maurer.99@osu.edu

The behavioral and social sciences research (BSSR) workforce in the United States is a segment of the STEM researcher workforce that is of growing concern. There is considerable interest in the health of the BSSR workforce as demonstrated by a recent Executive Order (EO 13707, 2015) recognizing the value of such research in informing effective policy creation. Given its complexity and the challenges of understanding the heterogeneity of its scientists, a hybrid model (combining system dynamics and agent based approaches) is developed in this study to explore and better understand the complex dynamics of the supply and demand in the BSSR workforce and the effects of various policy interventions.

3 - Different Modes Of Scientific Progress In HIV/AIDS

Arash Baghaei Lakeh, Virginia Tech, arashb@vt.edu Navid Ghaffarzadegan

There is a variation in research focus of scientific communities from different countries on various aspects of HIV/AIDS disease. In this research, we are employing topic finding methods to distinguish different trends of HIV/AIDS research over the past two decades. Our data includes the abstracts of more than 200,000 papers published over this period on HIV/AIDS. We then show differences of focus on HIV research in different countries and investigate the underlying reasons for such variation.

4 - Modeling And Analysis Of The Leaking Pipeline: Diversity In The United States Higher Education

Maryam Alsadat Andalib, Virginia Tech, Blacksburg, VA, United States, maryam7@vt.edu, Navid Ghaffarzadegan

Moving towards an equitable education system provides underrepresented groups with equal educational and economic opportunities. Many studies have attempted to identify the important causes of the existing gender and ethnicity gaps in higher education and the policy leverages with the goal of increasing equity. But the body of research investigating the effectiveness of different policy leverages is methodologically narrow. In this research, we specifically aim at identifying the important causes of disparities in the US higher education, and introduce policies to improve education equity as well as long term achievements of underrepresented minorities through a system dynamics approach.

1 - There's An App For That: Addressing The Handoff Problem In Healthcare Using Mobile

Idris Adjerid, Notre Dame University, iadjerid@nd.edu Corey M Angst, Ralph Gross

Healthcare and mobile technologies seem like a natural union with the potential for considerable value to providers and patients. With this in mind, we study a novel mobile application designed to address the handoff problem between the Emergency Department and inpatient units. Leveraging data on more than 145,000 Emergency Department visit over 4.5 years alongside detailed logs of app usage, we find that use of the app reduced patient length of stays in the ED by 4-6%, effectively eliminating the additional time that an admitted patient spends in the ED.

2 - CPOE Adoption Impacts On Medicare Reimbursements

Hilal Atasoy, Temple University, hilal.atasoy@temple.edu

Computerized Physician Order Entry (CPOE) systems allow physicians to seamlessly enter information in patient records compared to paper-based records, potentially leading to higher quality of care. On the other hand, the ease of capturing information into electronic medical records can be deliberately used by hospitals to inflate their reimbursement requests from Medicare by overstating the complexity of patients' diagnoses. We study the relationship between CPOE adoption and reported patient complexity of hospitals. We find that, on average, the adoption of CPOE systems is associated with an increase in the case mix index. This increase is significantly higher among for-profit hospitals.

3 - Not What The Doctor Ordered: Physician Mobility And Technology Adoption

Brad N Greenwood, Temple University, brad.n.greenwood@gmail.com, Corey M Angst, Kartik Krishna Ganju

In this work we investigate the relationship between EMR implementation and physician mobility. Strikingly, although significant anecdotal evidence would suggest that EMR implementation is associated with an exodus of physicians, we find that this reaction is strongly moderated by hospital characteristics, physician characteristics, and the type of EMR implemented.

4 - Detecting Anomalous Patterns Of Care Using Health Insurance Claims

Sriram Somanchi, University of Notre Dame, 344 Mendoza College of Business, Notre Dame, IN, 46556, United States, somanchi.1@nd.edu, Edward McFowland

Patient care data using health insurance claims can be used to improve clinical practice by analyzing patterns across patients and providing actionable insights. Our goal in this project is to analyze this complex patient care data in order to identify interesting patterns in patient care that have led to anomalous health outcomes. Specifically, we detect treatments in the outpatient patient care that have significantly deviated from the regular treatment process and have affected health outcomes either negatively or positively. This can further help both in terms of improving patient health and reducing health care costs.

Joint Session BOM/RMP: Consumer Behavior in Pricing and Loyalty

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Anton Ovchinnikov, Queen's School of Business, Kingston, ON, Canada, ao37@queensu.ca

1 - Impact Of Tiered Incentives On Behavior: Case Of The Airline Loyalty Programs

Tong Guo, University of Michigan, Stephen M Ross School of Business, 701 Tappan Street, Ann Arbor, MI, 48109, United States, tongguo@umich.edu, A. Yesim Orhun

This paper explores the impact of status incentives provided by a major U.S. airline on the purchasing behavior of its frequent flier program members. We leverage a database of complete transaction histories of more than six million members to study within-person changes in the distribution of price and route characteristics of tickets purchased from the airline as members progress towards a status goal. We present novel empirical manifestations of increased customer loyalty on market outcomes.

2 - Stockpile Or Redeem: How Do Consumers Value Loyalty Program Points

So Yeon Chun, McDonough School of Business, Georgetown University, sc1286@georgetown.edu, Rebecca Hamilton

Loyalty programs are designed to reward customers for buying more or buying more frequently from a firm. Typically, customers earn points for their purchases, which can then be exchanged for additional products and services. In a sense, these loyalty program points function as a currency that consumers can spend (redeem) on a purchase instead of money. We conduct a series of behavioral lab experiments to examine differences in the way customers think about loyalty points as compared to money, and how they choose whether to make a purchase with cash or points.

3 - Which Customers Are More Valuable In A Dynamic Pricing Situation?

Jue Wang, Queen's School of Business, Kingston, ON, Canada, jw171@queensu.ca, A. Yesim Orhun, Anton Ovchinnikov

We consider a firm that dynamically price its inventory and examine whether customers who purchase at higher prices indeed add higher marginal value to the firm. We present modeling and computational results which are calibrated on a unique data set from a major travel firm.

4 - Strategic Consumers, Revenue Management And The Design Of Loyalty Programs

Anton Ovchinnikov, Queen's School of Business, ao37@queensu.ca, So Yeon Chun

Several major firms recently switched their loyalty programs from quantity/'mileage'-based toward 'spending-based'. We study the impact of this switch on firm's profit and consumer surplus. We present a novel model of strategic consumers' response to firm's pricing and loyalty program decisions, incorporate such response into the firm's pricing and loyalty program design problem, compare several plausible loyalty-program designs, and discuss managerial implications.

Energy IV

Contributed Session

Chair: Byungkwon Park, Ph.D student, University of Wisconsin - Madison, 202 N Eau Claire Avenue, # 314, Madison, WI, 53705, United States, bpark52@wisc.edu

1 - Two-stage Multi-agent Stochastic Optimization In Power Systems

Shasha Wang, Clemson University, 107 Wyeth LN, Central, SC, 29630, United States, shashaw@g.clemson.edu
Harsha Gangammanavar, Sandra D Eksioglu, Scott J. Mason

We present a two-stage stochastic optimization framework for a multi-agent system in which the global objective function incorporates individual agents' objective functions. Our approach applies to the problem of managing energy in microgrids that contain integrated renewable energy resources. A sequential sampling-based, stochastic approach—stochastic decomposition—is used to analyze the problem. Computational experiments are conducted and demonstrate the effectiveness of our proposed methodology using real world case study data.

2 - Analysis Of Co2 Emission Performance And Abatement Potential For Municipal Industrial Sectors In Jiangsu, China

Jie Zhang, Hohai University, Nanjing, China, zhangjie_jie@126.com, Jigan Wang, Zhencheng Xing

As the main source of CO_2 emissions in China, industrial sector has been faced with the tremendous pressure of reducing emissions. Based on the analysis of SBM-Undesirable model, GIS visualization method, kernel density estimation and industrial abatement model, we find that there exists a significant spatial inequality of CO_2 emission performance across various regions in Jiangsu, the largest CO_2 emitter in China, but the regional disparity has been narrowing during our study period. Additionally, average annual industrial CO_2 emission reductions in Jiangsu can attain 15654.00 (10 thousand tons), accounting for 28.2% of its average annual actual emissions.

3 - Production Intermittence In Spot Electricity Markets

Olivier Massol, IFP School, 228-232 Avenue Napoleon Bonaparte, Rueil-Malmaison, 92852, France, olivier.massol@ifpen.fr, Albert Banal-Estanol, Augusto Ruperez-Micola

This paper analyses the influence of production intermittence on spot markets. We use both game theory concepts and an agent-based simulation approach derived from the Camerer and Ho (1999) behavioral model. Controlling for costs, we find that intermittent technologies yield lower prices when incumbents have individual market power, but higher when they do not have it. This happens when firms are risk-neutral and risk-averse, and also under different intermittence and ownership configurations. Replacing high-cost assets with low-cost ones results in higher prices than letting them co-exist.

4 - A Sparse Tableau Analysis Formulation For The Security-constrained Optimal Power Flow

Byungkwon Park, PhD Student, University of Wisconsin-Madison, 202 N Eau Claire Avenue, # 314, Madison, WI, 53705, United States, bpark52@wisc.edu, Christopher DeMarco

The nonlinear security-constrained optimal power flow (SCOPF) is computationally challenging, with difficulties in obtaining even feasible points due to the nonconvexity of power flow equations and the large dimension when many contingencies are considered. As illustrated in literature on semidefinite programming for OPF, a well-chosen formulation can yield better solutions, more efficiently. To this end, this work considers a range of SCOPF problems in new sparse tableau formulations that explicitly maintain port currents and voltages of all grid elements, and examines computational time and quality of solutions with different nonlinear solvers.

Advances in Transportation Modeling

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Tarun Rambha, University of Texas, Austin, TX, United States, tarun.1988@utexas.edu

1 - Throughput Analysis For Horizontal Traffic Queues under Safety Constraints

Mohammad Motie, University of Southern California, 1119 W 29th Street, Apt 7, Los Angeles, CA, 90007, United States, motiesha@usc.edu

We consider horizontal traffic queues (HTQ), where vehicle arrival and departure locations are sampled from spatial distributions. We consider first and second order car following models that guarantee no collision. HTQ is a state-dependent queuing system, where the service rate depends on the configuration of vehicles. We combine queuing- theoretic and dynamical systems tools, to provide novel insights into the service rate dynamics and busy period distribution for HTQ. These tools are used to compute bounds on throughput, which closely match simulations. Our throughput analysis illustrates the interplay between car-following behavior, road geometry, and arrival and departure statistics.

2 - Lost Demand And Redistribution In Bike Sharing Systems

Konstantina Mellou, Massachusetts Institute of Technology, Cambridge, MA, United States, kmellou@mit.edu, Patrick Jaillet

Spatial imbalances in bike sharing systems often lead to unavailability of resources (bikes or docks) and, as a result, lost customer demand. Our goal is to model redistribution operations that will allow the company to improve its level of service. An optimization approach is used, combined with decomposition and heuristics, and the performance of our methods is evaluated with tests on real datasets. Lost customer demand, which is often not considered since it cannot be registered in the system data, is also taken into account.

3 - A Destination-based Algorithm For User Equilibrium With Recourse Using Split Proportions

Tarun Rambha, University of Texas, Austin, TX, 6, United States, tarun.1988@utexas.edu, Stephen Boyles, Avinash Unnikrishnan

When travelers receive en route information and select routing policies that minimize expected cost, user equilibrium with recourse models can help predict the resulting network state. We propose a new destination based algorithm to solve such models using link proportions and compare its performance with existing methods.

4 - Optimal Patrol Planning For Urban Parking Enforcement Considering Driver's Parking Behavior

Chao Lei, University of Illinois at Urbana–Champaign, 2063 S. Orchard St. Apt A, Urbana, IL, 61801, United States, lei8785@gmail.com

In the aim of designing an effective parking patrolling scheme for the parking enforcement agency, we propose a bi-level optimization approach to help the agency determine the patrolling schedule and routing plan in the upper level while considering the drivers' parking payment decisions in the lower level. Both a mixed-integer formulation and a continuum approximation (CA) model are developed. The numerical study shows that, due to its advantage in computational performance, the CA approach provides a good alternative to handle the large scale problems.

Emerging Data Analytics in Transportation Modeling

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Xian-Biao Hu, Metropia, 1790 E. River Rd., Suite 140, Tucson, AZ, 85718, United States, xb.hu@metropia.com

1 - Contextual Driving Risks Analysis Using Individualized Dynamic Smartphone

Xian-Biao Hu, Metropia Inc., xb.hu@metropia.com

Traditional driving risk study is usually based on crash history data and can only be performed at aggregate level. Latest information and communications technology allows individualized data collection, but most researches rely solely on user GPS trajectories data but fail to consider other critical risk factors in the surrounding environment that also contribute to crash risk. To bridge this gap, a new approach that collects individualized driving behavior data from smartphone GPS module, combined with geographical network information and dynamic traffic conditions is presented to identify driving risk factors and evaluate driving behaviors under various contexts.

2 - Put Bluetooth Data In A Good Use: A Case Study In Tucson, Arizona

Shu Yang, University of Arizona, shuyang@email.arizona.edu
Yao-Jan Wu

A Bluetooth based traffic data collection and analysis system is developed and integrated into the regional transportation district network system. Fully utilizing the Bluetooth-based data requires comprehensive data quality assurance including data decomposition, imputation, and outlier detection. A case study is conducted in Tucson to demonstrate a one-stop solution for Bluetooth-based traffic performance measurement.

3 - Developing A Simulation Model Of A Tram Network By Using Historical RFID Data

Yong-Hong Kuo, The Chinese University of Hong Kong, Hong Kong, Hong Kong, yhkuo@cuhk.edu.hk, Janny M. Y. Leung, David S.W. Lai, Henry K.F. Cheung, Joshua Hiew

In this talk, we will present a real-world application that utilizes historical RFID data for the development of a simulation model of a tram network. The historical data about the tram locations are used to model the travel times of trams at different times of the day. Our simulation model allows the tram company to examine the impacts of different tram schedules on the service requirements and other performance measures.

4 - Accident Impacts on Traffic Mobility In Concern Of Network Features

Chenshuo Sun, Tsinghua University, Haidian District, Beijing, 100084, China, scs14@mails.tsinghua.edu.cn

It is hypothesized that there may be associations between intersection's accident-impact proneness and its location, as well as accident impacts and its origination. To substantiate such hypothesis, four topological measurements are assigned to intersections. Then, accident impacts specified in four aspects are quantified from both macroscopic and microscopic perspective. This study employs one macro-level model and three micro-level models. The results prove that intersection's accident-impact proneness is closely related to the network features of its location, also accident's infectiousness, network damage and delay are closely related to the network features of its origination.

1 - Metaheuristics For Efficient Aircraft Scheduling And Re-routing at Busy Terminal Control Areas

Marcella Sama, Roma Tre University, Rome, Italy, sama@ing.uniroma3.it

This work improves a state-of-the-art optimization solver for the real-time management of landing and take-off operations in a busy terminal maneuvering area. The solver computes a good initial solution for the aircraft scheduling problem with fixed routes, and then improves it by routing flexibility. Metaheuristics based on variable neighborhood search, tabu search and hybrid schemes are proposed. Experiments are performed on an Italian terminal maneuvering area to simulate various types of disturbances. Solutions of remarkable quality are computed within a short time.

2 - Customized Offers In Airline Revenue Management

Michael Witmann, Massachusetts Institute of Technology, Cambridge, MA, United States, wittman@mit.edu

I propose an approach for decoupling the customized offer generation problem from the well-studied airline revenue management (RM) problem. After generating a baseline assortment of fare products and observing a passenger's characteristics, an airline can choose to customize that passenger's offer by either adjusting the products in the assortment or changing the offered prices for those products. For implementation, heuristics are developed that are compatible with the airline RM methods and systems currently in use at large airlines.

3 - Optimization Models For Speed Control In Air Traffic Management

James Jones, University of Maryland, College Park, MD, United States, jonesjc1@umd.edu

We propose four sets of models that use speed control to enhance the level of coordination by FAA managers at the tactical and pre-tactical level to account for the uncertainty at the time of planning. The first approach, assumes control of all airborne flights 500 nm from the destination airport while assuming no control over flights originating less than 500 nm. The second assumes control over all flights. In the third and fourth approach we propose enhancements for equitably rationing airport access to carriers and new GDP control procedures and flight operator planning models.

4 - Modeling In Air Transportation: Cargo Loading And Itinerary Choice

Virginie Lurkin, University of Liege, Liege, Belgium, vlurkin@ulg.ac.be

We examine two problems as part of this presentation. The first is a cargo loading problem. The aim is to load a set of containers and pallets into a cargo aircraft that serves multiple airports. Our work is the first to model cargo transport as a series of trips consisting of several legs at the end of which pickup and delivery operations might occur. The second problem we examine involves the estimation of itinerary choice models that include price variables and correct for price endogeneity using a control function that uses several types of instrumental variables.

Dynamic Routing and Logistics

Sponsored: TSL, Freight Transportation & Logistics

Sponsored Session

Chair: Nicholas Kullman, University of Washington, Seattle, WA, United States, Nick.Kullman@gmail.com

1 - Dynamic Pickup And Delivery Problem With Transfers

Afonso H. Sampaio, Eindhoven University of Technology, Eindhoven, Netherlands, A.H.Sampaio.Oliveira@tue.nl, Lucas Petrus Veelenturf, Tom Van Woensel

We consider the Dynamic Pickup and Delivery Problem with Transfers (d-PDP-T) in which a set of transportation requests arrive in real-time and must be assigned to a fleet of vehicles. Unlike most variants of the PDP, the pairing constraint is not hard in the d-PDP-T and requests can be transferred from one vehicle to another at transfer locations. Our research focus is to address the operational issues and to evaluate costs/benefits when such transfers are introduced in a dynamic environment. It is especially relevant for transportation companies that provide on-demand services and that need to plan several service requests per day. We discuss some preliminary modelling and solution approaches.

2 - Anticipatory Preemptive Depot Revisits For A Dynamic Same-day Delivery Problem

Dirk Mattfeld, TU Braunschweig, Braunschweig, Germany, d.mattfeld@tu-bs.de, Marlin Wolf Ulmer, Barrett Thomas

We consider a single-vehicle stochastic and dynamic one-to-many pickup and delivery problem (SDPD) motivated by a same-day delivery application. An uncapacitated vehicle delivers goods from a depot to customers during a shift. Dynamic customer orders occur stochastically within the shift. Before serving these orders, the vehicle revisits the depot to pick up the according goods. Since the shift is limited, not every order can be assigned to the vehicle. Objective is to maximize the number of assigned orders. For the SDPD, we present an anticipatory preemptive depot revisit policy (APDR) based on approximate value iteration. We show how APDR significantly increases the number of assignments.

3 - Electric Vehicle Routing With Mid-route Recharging And Uncertain Charging Station Availability

Nicholas Kullman, University of Washington, nkullman@uw.edu Justin Goodson, Jorge E Mendoza

We consider the problem of routing a single electric vehicle (EV) and allow for mid-route recharging at stations with uncertain availability. The uncertainty in charging station availability complicates the planning of mid-route recharging, which is necessitated by EVs' restricted driving ranges; longer recharging times for EVs compound this difficulty. We present a stochastic dynamic programming approach to route planning that hedges against these uncertainties.

4 - Joint Capacity Logistics And Inventory Control Of Mobile Modular Production Systems

Satya Sarvani Malladi, Georgia Institute of Technology, mss@gatech.edu, Alan Erera, Chelsea C White III

Mobile modular production systems enable better response to spatial and temporal variations in demand. How should the logistics of such systems be planned taking into account uncertainty of demand? We try to evaluate value added by mobile modular production through several approaches.

Evolutionary Bilevel Multi-criterion Optimization Methods and Applications

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Kalyanmoy Deb, Professor, Michigan State University, 428 S. Shaw Lane, 2120 EB, Michigan State University, East Lansing, MI, 48824, United States, kdeb@egr.msu.edu

1 - Impacts Of Climate Uncertainty On A Bilevel Optimization Framework For Targeting Agricultural Conservation Policy

Moriah Bostian, Lewis and Clark College, mbbostian@lclark.edu

We characterize the problem of spatially targeting agricultural conservation practices to improve water quality as a multiobjective bilevel optimization problem, integrating a biophysical model of the watershed with an economic production model to estimate policy costs. Weather is an important driver of water quality and agricultural production. We solve for the Pareto frontier for water and production objectives under changing climate conditions, based on a range of leading climate projections. We use the solution values to assess the robustness of policy targets to climate uncertainty.

2 - Solving Optimistic Bilevel Programs By Iteratively Approximating Lower Level Optimal Value Function

Pekka Malo, Aalto University School of Buisness, pekka.malo@aalto.fi, Kalyanmoy Deb, Ankur Sinha

The difficulties in bilevel programming arise primarily from the nested structure of the problem. In this paper, we propose a metamodeling based solution strategy that attempts to iteratively approximate the optimal lower level value function.

3 - Optimal Allocation Of Restoration Practices Using Indexes For Stream Health

Brad Barnhart, U.S. EPA ORD/NHEERL/WED/EEB, bradleybarnhart@gmail.com

The optimal placement of agricultural and urban (i.e., green infrastructure) management practices in order to achieve both economic and environmental objectives is a commonly posed problem. However, the majority of studies seek to optimize objectives related to intermediary environmental outputs (e.g., N and P nutrient loadings, stream temperature, sediment concentrations) and do not address impacts on overall indexes of stream health. Therefore, we investigate on how best to include indexes within a bi-level optimization framework to better characterize objectives when targeting management practices.

4 - Robust And Reliability-based Bi-level Multi-criterion Optimization

Zhichao Lu, Michigan State University, mikelzc1990@gmail.com

Practical optimization and decision making problems involve uncertainties in decision variables and parameters. In this talk, we shall suggest robust and reliability based methods for bilevel problems using evolutionary methods. Results on two practical methods will be presented.

Chair: Zhe Zhang, University of Texas Dallas, University of Texas Dallas, Richardson, TX, 75080, United States, zxz145430@utdallas.edu

1 - Altruism or Shrewd Business? Implications Of Technology Openness on Platform Innovations And Competition

Hongyan Xu, Chongqing University, School of Economics & Business Admin, Chongqing, 400030, China, xuhongyan@cqu.edu.cn, He Huang, Geoffrey Parker, Yinliang Tan

There is a growing number of platforms that commit to open their technologies. In contrast to the previous literature focusing on the network effect, our study reveals a novel explanation on why firms are willing to open their technologies. The main intuition is due to the fact that technology openness can alleviate the unwarranted innovation competition caused by the uncertainty belonging to technology closeness. We also discuss the impact of technology openness on individual and total innovations and illustrate that this intuition is robust under several extended models.

2 - Share Your Health Information And Help Me Save Your Life: Effects Of Hie Use On Healthcare Outcomes – An Empirical Investigation

Emre Demirezen, School of Management, Binghamton University, Binghamton, NY, United States, edemirezen@binghamton.edu Eunho Park, Ramkumar Janakiraman, Subodha Kumar

In the last decade, the U.S. government has been aggressively promoting the use of electronic health records and the establishment of regional healthcare information exchanges (HIEs). HIEs facilitate the exchange of electronic health information among healthcare practitioners that is considered to be beneficial for the society. However, the real benefits of HIEs are not well understood. Hence, we work with an HIE provider based in the state of New York to investigate the benefits of HIEs.

3 - Platform Integration In The Age Of The Internet Of Things

Burcu Tan, Tulane University, btan@tulane.edu, Edward G Anderson, Geoffrey Parker

Many two-sided platforms (e.g., eBay, Google, iOS, Android, Twitter, Amazon) provide development tools, such as software development kits (SDKs) and application programming interfaces (APIs), to facilitate third party content development. While crucial to platform success, these tools are costly to create. We develop an analytic model to explore the key trade-offs behind investment in development tools and how that investment coordinates with pricing decisions in a two-sided market. We model these decisions under various scenarios including monopoly and competitive platforms as well as symmetric and asymmetric platforms.

4 - Interoperability, Organization Form And Cooperative Games In Public Safety Networks

Barrie R Nault, University of Calgary, nault@ucalgary.ca Hong Guo, Yipeng Liu

We analyze tradeoffs in the provision of public safety networks when network assets are distributed across districts, causing a district to value network assets in other districts as well as in its own district. Modeling centralized and decentralized organization forms we incorporate interoperability among distributed network assets. We find that the optimal/equilibrium interoperability increases in the cross-district spillovers from network assets. We show that the districts' incentive to adopt centralized provision depends on the sharing rule for the cost of interoperability effort, and we find that certain sharing rules have a corresponding cooperative game analogue.

Foundations of Accuracy for Additive Manufacturing

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Qiang Huang, University of Southern California, Los Angeles, CA, United States, qiang.huang@usc.edu

Co-Chair: Arman Sabbaghi, Purdue University, West Lafayette, IN, United States, sabbaghi@purdue.edu

1 - Deformation Model Transfer Via Equivalent Effects Of Lurking Variables In Additive Manufacturing

Arman Sabbaghi, Assistant Professor, Purdue University, 150 N. University Street, West Lafayette, IN, 47907, United States, sabbaghi@purdue.edu, Qiang Huang

The transfer of a deformation model across different settings of lurking variables in additive manufacturing is addressed with a novel framework that fuses the Rubin causal model with the effect equivalence concept. Model transfer in this general framework is formulated through the total equivalent amount of the lurking variables in terms of a base factor with respect to a key model feature. The weakest sufficient condition on the data-generating and assignment mechanisms in a new setting is identified that permits inference for its total equivalent amount with respect to the mean. Bayesian methodology for modeling the total equivalent amount are developed under this condition.

2 - Implications Of Assuming Incorrect Model Equivalence For Additive Manufacturing

Matthew Plumlee, University of Michigan, mplumlee@umich.edu

Additive manufacturing control is often limited by the few number of homogeneous parts produced. Thus purely data-driven approaches can fail to give anything but large uncertainty quantification bounds for producing a new part. One solution to this problem is to let additive manufacturing systems to learn from each other by assuming that they could produce exactly the same resulting parts. In this talk, some preliminary results are used to explain the potential ramifications of assuming that a model for one additive manufacturing system can produce similar results as another system under a specialized design plan.

3 - Prescriptive Analytics For Understanding Of Out-of-plane Deformation In Additive Manufacturing

Yuan Jin, University of Southern California, Los Angeles, CA, 90089, United States, yuanjin@usc.edu, Joe Qin, Qiang Huang

Geometric accuracy control is crucial to fulfill the promise of additive manufacturing (AM). We have been establishing a generic methodology to represent, predict and compensate 3D deformation of AM built products. Built upon our previous study, this work aims at 1) developing a prescriptive approach to understand the out-of-plane deformation due to complex inter-layer interactions; 2) establishing a Bayesian approach to infer the predictive deformation model for out-of-plane complex shapes. Experiments are conducted to validate the prescriptive model.

4 - Shape Deviation Modeling For Additive Manufacturing With Different Process Parameters

Longwei Cheng, HKUST, lchengae@connect.ust.hk

Reducing the dimensional error of the fabricated products is a critical quality issue for the wide application of additive manufacturing (AM) technologies in industry. Process parameters in fabrication significantly affect the shape deviation of products. In this work, we establish an in-plain shape deviation prediction scheme that predicts the final shapes of products with the information of both process parameters and 2D input shapes. The corresponding shape error compensation strategy is derived, which greatly improves the dimensional accuracy of products. The methodology is validated through experimental studies of fused deposition modeling (FDM) process.

Process Monitoring, Diagnosis, and Prognosis in Complex Systems

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Qiang Zhou, City University, 1, Kowloon, 1, Hong Kong, q.zhou@cityu.edu.hk

Co-Chair: Li Zeng, Texas A&M University, College Station, TX, United States, lizeng@tamu.edu

1 - High Dimensional Process Monitoring Using Sparse Principal Component Analysis

Mohammad Nabhan, Georgia Institute of Technology, nabhan@gatech.edu, Jianjun Shi

Dimension reduction techniques, such as PCA and PLS, have been used for process monitoring in statistical process control. However, in high dimensional settings they suffer from inconsistency and interpretability issues. Sparse principal component analysis (SPCA) has been shown to be more consistent in these settings. Due to its sparse nature, it allows for better interpretation. This article proposes a monitoring and diagnostics scheme utilizing SPCA to reduce the dimensionality of the data while improving interpretability. The method is effective under certain stipulations on the spatial structure of the data streams. The proposed method is validated through simulation and a case study.

2 - Monitoring Low-e Glass Manufacturing Using Optical Profiles

Qian Wu, Texas A&M University, College Station, TX, 77840, United States, hi_qianwu@tamu.edu, Li Zeng

In this study we develop a method for process monitoring using optical profiles collected from low-E glass products. The proposed method uses a piecewise polynomial mixed-effect model to characterize the complex shape of optical profiles and a T2 control chart to monitor the estimated random effects for change detection. We investigate a potential problem caused by high correlations of random effects in implementing this method and propose a remedy based on regressor transformation for this issue. A case study will be shown, indicating the proposed method fits the real optical profiles and performs well in process monitoring.

3 - Remaining Useful Life Prediction In Populations With Heterogeneity

Raed Kontar, University of Wisconsin - Madison, Madison, WI, United States, alkontar@wisc.edu

Degradation signal data used for prognosis are often imbalanced as most units are reliable and only few tend to fail at early stages of their life cycle. Such imbalanced data may hinder accurate remaining useful life (RUL) prediction especially in terms of detecting pre-mature failures as early as possible. . In this paper, we propose a degradation signal-based RUL prediction method to address the imbalance issue in the data. The proposed method introduces a mixture prior distribution to capture the characteristics of different groups within the same population and provides an efficient and effective online prediction method for the in-service unit under monitoring.

4 - Statistical Monitoring And Fault Diagnosis Of Vibration Signal Based On Wavelet Transform

Wei Fan, City University of Hong Kong, Kowloon, Hong Kong, weifan8-c@my.cityu.edu.hk, Qiang Zhou

To effectively monitor and detect the early fault of rolling bearing, a wavelet-based statistical process control method is proposed and studied. The vibration signal is decomposed by orthonormal wavelet transform. The generalized likelihood ratio test is taken into consideration to detect the shift of the wavelet coefficients. To increase the detection power of the small shift, the proposed control chart takes the exponentially weighted moving average of the logarithm of the likelihood ratio. Both the simulation studies and the experimental cases show the effectiveness of the proposed method.

Pierskalla II

Award Session

Chair: Baris Ata, University of Chicago, Booth School of Business

Co-Chair: Anton Skaro, Northwestern University, Feinberg School of Medicine

Co-Chair: Sridhar Tayur, Carnegie Mellon University, Tepper School of Business

1 - Pierskalla Award

Vikram Tiwari, Vanderbilt University Medical Center, Nashville, TN, Contact: vikram.tiwari@vanderbilt.edu

The Health Applications Society of INFORMS sponsors an annual competition for the Pierskalla Award, which recognizes research excellence in the field of health care management science. The award is named after Dr. William Pierskalla to recognize his contribution and dedication to improving health services delivery through operations research. The Pierskalla award information can be found on the website at: https://www.informs.org/Community/HAS/Pierskalla-Award

2 - Online Decision-Making with High-Dimensional Covariates

Hamsa Bastani, Mohsen Bayati, Stanford University, Stanford, CA, bayati@stanford.edu

Big data has enabled decision-makers to tailor treatment decisions based on their clinical information. This involves learning a model of decision rewards conditional on individual patient covariates. These covariates are high-dimensional; typically only a small subset of the observed features are predictive of a decision's success. We formulate this problem as a multi-armed bandit with high-dimensional covariates, and present a new efficient bandit algorithm based on the LASSO estimator. Our analysis establishes that our algorithm achieves near-optimal performance in comparison to an oracle that knows all the problem parameters. The key step in our analysis is proving a new oracle inequality that guarantees the convergence of the LASSO estimator despite the non-i.i.d. data induced by the bandit policy. We illustrate the practical relevance of our algorithm by evaluating it on a real-world clinical problem of warfarin dosing. A patient's optimal warfarin dosage depends on the patient's genetic and medical records. We show that our algorithm outperforms existing bandit methods as well as physicians to correctly dose patients.

3 - Do Mandatory Overtime Laws Improve Quality? Staffing Decisions and Operational Flexibility of NursingHomes

Lauren Xiaoyuan Lu, University of North Carolina, Chapel Hill, NC, lauren_lu@unc.edu, Susan Feng Lu

During the 2000s, over a dozen U.S. states passed laws that prohibit health care employers from mandating overtime for nurses. Using a nationwide panel dataset from 2004 to 2012, we find that these mandatory overtime laws reduced the service quality of nursing homes, as measured by an increase in deficiency citations. This outcome can be explained by two undesirable changes in the staffing hours of registered nurses: decreased hours of permanent nurses and increased hours of contract nurses per resident day. We observe that the increase in deficiency citations concentrates in the domains of administration and quality of care rather than quality of life, and the severity levels of the increased citations tend to be minor rather than major. We also find that the laws' negative effect on quality is more severe in nursing homes with higher percentage of Medicare-covered residents. These observations are consistent with the predictions of a stochastic staffing model that incorporates demand uncertainty and operational flexibility. Further, we rule out an alternative hypothesis that the quality decline is induced by an increase in nurse wages.

4 - Data-Driven Incentive Design in the Medicare Shared Savings Program

Anil Aswani, UC Berkeley, Berkeley, CA, aaswani@berkeley.edu, Zuo-Jun Shen, Auyon Saddiq

The Medicare Shared Savings Program (MSSP) was created to control escalating Medicare spending by incentivizing providers to deliver healthcare more efficiently. Providers that enroll in the MSSP earn bonus payments for reducing spending to below a risk-adjusted financial benchmark. To generate savings, a provider must invest to improve efficiency, which is a cost that is absorbed entirely by the provider under the current contract. This has proven to be challenging for the MSSP, with a majority of participating providers unable to generate savings. In this paper, we formulate the MSSP as a principal-agent model and take a data-driven approach to redesigning the MSSP contract. We propose a new type of contract that includes a performance-based subsidy that partially reimburses the provider's investment. We prove that there exists a subsidized contract that dominates the current MSSP contract by producing a strictly higher expected payoff for Medicare and the provider. We then present a maximum likelihood approach for estimating the parameters of the principal-agent model, using a dataset containing the financial performance of providers.

5 - Prioritizing Hepatitis C Treatment in U.S. Prisons

Turgay Ayer, Georgia Tech, Atlanta, GA, Boston, MA, ayer@isye.gatech.edu , Anthony Bonifonte, Can Zhang, Anne Spaulding, Jagpreet Chhatwal

High prevalence of HCV in prisons offers a unique opportunity to control the HCV epidemic. Newest HCV treatments drugs are effective but providing treatment is outrageously expensive. We propose a restless bandit modeling framework to support hepatitis C treatment prioritization decisions in U.S. prisons. From the interpretation of this closed-form expression, we anticipate the performance of Whittle's index would degrade as the treatment increases. Using a detailed agent-based simulation model, we show our proposed policy can significantly improve overall health outcomes compared with the current practice. Our results shed light on issues in hepatitis C prioritization: 1) considering remaining sentence length and injection drug use (IDU) status and liver health state in prioritization decisions can lead to a performance improvement; 2) when linkage-to-care rate outside prison is small while treatment capacity in prison system is relatively large, patients with shorter remaining sentence lengths should be prioritized; and 3) for patients with advanced liver disease, IDUs should not be prioritized unless their reinfection is very-well controlled.

1 - Solving The Privately Owned Automated Vehicles Assignment Problem

Theresia van Essen, Delft University of Technology, Mekelweg 4, Delft, 2628 CD, Netherlands, j.t.vanessen@tudelft.nl, Gonçalo Correia

We propose a new model to study how replacing privately owned non-automated vehicles with shared automated ones affects travel time, congestion and parking demand in an urban area. As automated vehicles will reduce the value of travel time, it is expected that travel time will increase. In addition, congestion is on the one hand expected to increase because of the empty trips, and on the other hand expected to decrease because of a reduction in the number of vehicles on the road. Parking demand is expected to decrease as the utilization of the vehicles will increase. The model is applied to a case study based on the city of Delft, the Netherlands.

2 - Developing Interrelated Airport Facilities under Uncertainty: A Network Flow Formulation

Yanshuo Sun, University of Maryland, 1173 Glenn Martin Hall, College Park, MD, 20742, United States, yssun@umd.edu, Paul Schonfeld

Interactions between user flows and facilities are quite complex in an airport system. Thus, capacity expansion decisions for these facilities are largely interrelated. A network flow formulation is proposed for coordinating such development decisions so that a balanced capacity configuration is likely to be obtained. The nonlinear congestion effect, which is common in most airport facilities, is considered and uncertainties in demand and aircraft mix are also included. The stochastic mixed integer nonlinear program is reduced to a deterministic mixed integer program and thus solved.

3 - From Trend Spotting To Trend Setting: Modeling The Impact Of Major Technological And Infrastructural Changes On Travel Demand

Feras El Zarwi, PhD Candidate, University of California at Berkeley, 2100 Channing Way, Apt 415, Berkeley, CA, 94704, United States, feraselzarwi@gmail.com

Transformative mobility will revolutionize travel and activity behavior but we should be cautious with how the future is going to play out. This research project proposes a methodological framework tailored to address impacts of technological innovation to understand and predict long-range trends in travel behavior. We integrate hidden markov and discrete choice models to predict long-range trends in travel behavior as a result of adopting new services. The model is estimated on a longitudinal travel diary dataset from Santiago, Chile. The proposed quantitative methods are critical in assessing how policies/strategies can influence trends of travel behavior to guide transformative mobility.

4 - Using Regression Tree Models To Improve Freeway Incident Duration Prediction A Comprehensive Case Study In Maryland Region

Xuechi Zhang, Graduate Research Assistant, University of Maryland, 0147C Engineering Lab Building, College Park, MD, 20740, United States, zhangxc90@gmail.com, Ali Haghani, Yeming Hao

Timely and accurate prediction of freeway incident duration is not only useful for providing travelers with re-routing strategies, but can also reduce their in-vehicle anxiety. This research proposed several regression tree based models to improve the incident duration prediction accuracy by fusing heterogeneous information, i.e. incident information, weather and traffic conditions. A comprehensive case study with real-world data in Maryland Region was conducted to evaluate and demonstrate the proposed models. Further, practical implications from the case study were given.

Transportation, Rail

Contributed Session

Chair: Emmanuel Martey, University of Delaware, 302 DuPont Hall, Newark, DE, 19716, United States, enmartey@udel.edu

1 - Optimization Techniques For Railways

Srinivasa Prasanna, Professor, IIIT-Bangalore, 26/C, Hosur Road, Electronics City, Opposite Infosys Technologies, Bangalore, 560100, India, gnsprasanna@iiitb.ac.in"

We present optimization techniques used in portions of the Indian Railway System, the largest in the world. We present techniques used for timetabling and investment planning, under large scale demand uncertainty. Many of these problems are at the scale of grand computational challenges (with 10'000 of trains and 1000's of control points), and the talk will present a few pieces of how portions of this problem can be simplified and made amenable to optimization techniques (convex/non-convex). Exemplary results will be discussed.

2 - Railway Capacity Analysis And Cyclic, Combined Train Timetabling And Platforming For A Single Track, Bidirectional Railway Line

Matthew Petering, University of Wisconsin-Milwaukee, Industrial and Manufacturing Engineering Dept, Ems E367, Milwaukee, WI, 53201, United States, mattpete@uwm.edu, Mojtaba Heydar

We present the literature's first mixed integer linear program for cyclic train timetabling and platforming on a single track, bi-directional railway line. There are T train types and one train of each type is dispatched per cycle. The decisions to be made include the sequencing of the train types on the main line and the assignment of train types to station platforms. Two conflicting objectives—minimizing cycle length and minimizing total train journey time—are considered.

3 - A MIP Model For High-speed Train Platforming Problem With Route Conflicts Constraints

Gongyuan Lu, Assistant Professor, Southwest Jiaotong University, 111#, 1st Section, Northern 2nd Ring Road, School of Transportation and Logistics, Chengdu, China, lugongyuan@swjtu.cn, Guangyuan Zhang, Yuan Wang

The biggest challenge in solving high-speed train platforming problem (HTPP) is to route trains without conflicts. Especially in a large multi-yard railway station, the conflicts between routes and platforms can easily make the scale increase dramatically. A MIP model aiming at minimize train delay is formulated to generate flexible train schedule without violating route conflicts. This research has been applied in largest high-speed train station in Asia.

4 - Predicting Cascading Effects Of Local Disruptions In A Large Scale Rail Network

Patrick Briest, McKinsey & Co, Kennedydamm 24, Dusseldorf, 40027, Germany, patrick_briest@mckinsey.com, Sebastian Albert, Robin Blöhm, Florian Brummer, Christian Gruß, Eike-Dennis Rausch

We propose a stochastic simulation model to determine network-wide effects of locally induced disruptions in a large scale rail system. We extend the model previously described by Berger et al. to include (A) dynamic diversion routing to mimic how traffic controllers will try to route trains around disrupted parts of the network and (B) track capacities and a load-dependent delay component. We present computational results based on detailed delay distributions extracted from multiple years of Deutsche Bahn's operations data and simulation runs using both current and historic schedules of regional, long-distance and cargo traffic in the Deutsche Bahn network.

5 - Probability Analysis Of The Severity Of Train Derailments Using Copula Models

Emmanuel Martey, University of Delaware, 302 DuPont Hall, Newark, DE, 19716, United States, enmartey@udel.edu, Nii Attoh-Okine

In spite of their relatively low occurrence, train derailments have been a major concern due to their high consequence. Derailment severity may depend on various factors such as speed, accident cause and residual train length. It is important to know the dependencies between these variables in order to better understand how to reduce derailment severity. This paper presents the copula approach as a technique for modeling dependencies between the various variables. Copulas link arbitrary marginal distributions to form a joint multivariate distribution with a particular dependence structure. Copulas are suitable for modelling multivariate data with non-normality, tail dependency or skewness.

1 - Upstream Supplier And Downstream Customer Networks: An Empirical Investigation

Marcus A Bellamy, Boston University, Rafik B. Hariri Building, 595 Commonwealth Avenue, Boston, MA, 02215, United States, bellamym@bu.edu, Soumen Ghosh, Manpreet Singh Hora

We examine the relationship dependence characteristics and structural configuration of a firm's supply chain as drivers of its performance using supply chain relationship data from the Bloomberg database. We demonstrate how firm performance may be influenced by the manner in which its cost is concentrated upstream as a customer, its revenue is concentrated downstream as a supplier, and its supply network is structured.

2 - Capacity Expansion Under Demand Uncertainty With Uncertain Probabilities

Heejung Kim, University of California- Berkeley, Berkeley, CA, 94720-1777, United States, kimheejung@berkeley.edu, Philip Kaminsky

Pharmaceutical industries make capacity investment decisions while clinical trials for products are running. The demands are highly dependent on the test results, and estimating exact probability distribution of the results is difficult. We focus on developing and understanding capacity expansion models that are robust to any possible probability distributions using multistage stochastic programming for different objectives - minimizing expected cost, value at risk and conditional value at risk.

3 - Supply Chain Partner Environmental Health And Firm Performance

Marcus A Bellamy, Assistant Professor, Boston University, Rafik B. Hariri Building, 595 Commonwealth Avenue, Boston, MA, 02215, United States, bellamym@bu.edu

We empirically examine the relationship between the environmental initiatives and outcomes of a firm's supply chain partners and firm performance. We draw from environmental, financial, and supply chain data to identify key mechanisms related to the environmental health of a firm's supply chain that influence its economic performance.

4 - Component Procurement And End Product Assembly In An Uncertain Supply And Demand Environment

Ramesh Bollapragada, San Francisco State University, School of Business, 1600 Holloway Avenue, San Francisco, CA, 94132, United States, rameshb@sfsu.edu, Saravanan Kuppusamy, Uday S Rao

In this paper, we examine a multi-product, multi-component, procurement and assembly problem with both supply and demand uncertainties. We explicitly model the uncertainty using a stochastic program that facilitates procurement and assembly decisions. We present a stochastic linear programming model of the problem which we solve using its deterministic equivalent with a finite number of scenarios. We identify the key cost drivers that need attention from managers in the manufacturing industry, when there is limited knowledge of future demand and component availability.

5 - Correlation Between Supply Networks' Strategic And Operational Risk Mitigation Strategies

Shabnam Rezapour, University of Oklahoma, 2248 Houston Ave. apt 2, Norman, OK, 73071, United States, shabnam_rezapoor@yahoo.com, Janet K. Allen, Farrokh Mistree

A supply network's performance is affected by two types of uncertainty: 1) disruptions distorting its topology; and 2) variations affecting its flow planning. We show that strategic risk mitigation strategies, such as robustness and resilience, and operational risk mitigation strategies, such as reliability, neutralizing impacts of disruptions and variations respectively are correlated. A model is developed to simultaneously determine robustness, resilience and reliability. Our findings show that the correlation between: i) robustness and resilience is negative; ii) robustness and reliability is positive; and iii) resilience and reliability is negative.

1 - Optimal Radiotherapy Treatment Policy Based On Tumor Biological Response: A Partially Observable Markov Decision Process Framework

Nasrin Nouri, PhD Student, University of Houston, 9701 Meyer Forest Dr., Apt 6207, Houston, TX, 77096, United States, nouri.nasrin@gmail.com

In radiotherapy treatment planning the prescribed dose is delivered in equal fractions of dose during 30 to 40 sessions to give healthy organs time to recover. Depending on tumor state, the tumor growth and its response to radiation will change, hence a dynamic treatment plan is required. It is not possible to observe the tumor before each session through CT images so we are faced to uncertainty of tumor state. In this study we develop a partially observable Markov decision process to provide optimal treatment policy when the density of tumor is uncertain. This approach provides the optimal policy determining when to choose a less effective, less harmful dose over a more effective, more harmful dose.

2 - Reserving Walk-in Times In Primary Care

Brigitte Werners, Professor, Ruhr-University Bochum, Fac. Management and Economics, Bochum, 44780, Germany, or@rub.de

For a primary care physician with varying workday demand, capacity reservation for walk-ins and scheduled appointment slots is optimized on a tactical level. Number and position of the scheduled appointments influence waiting times for patients, capacity for treatment and the utilization of PCPs. A multi-criteria mixed-integer linear programming model is suggested to find an acceptable compromise solution. Results are evaluated by an extensive stochastic simulation study.

3 - Econometric Model Of Critical Care Outreach Team And Intensive Care Unit

Ali Haji Vahabzadeh, The University of Auckland Business School, Private Bag 92019, Auckland, 1142, New Zealand, a.vahabzadeh@auckland.ac.nz, Valery Pavlov

To analyse the role and functionality of the critical care outreach team (CCOT) in hospitals, and particularly, its interactions with the ICU, we develop an econometric model of CCOT and ICU. This allows us to estimate the impact of CCOT intervention in detecting the critically ill patients in the ward on the ICU length-of-stay, potential ICU readmission and patient outcome.

1 - Setting Optimal Planned Leadtimes In A Configure To Order Manufacturing System

Sjors Jansen, PhD Candidate, Eindhoven University of Technology (TU/e), P.O. Box 513, Paviljoen E13, Eindhoven, 5600MB, Netherlands, s.w.f.jansen@tue.nl, Zumbul Atan, Ton de Kok, Ivo Adan

We study the production planning in Configure To Order (CTO) manufacturing systems. The system consists of multiple stages that converge to one final assembly stage. Leadtimes per stage are stochastic due to extensive testing at the end of each stage. Our goal is to determine optimal planned leadtimes for each stage such that the total expected production costs are minimized. We derive Newsvendor equations for each individual stage. This set of equations is solved and the exact optimal planned leadtimes for each stage are obtained. These equations give an important insight in the dynamics of the system, since they indicate to what extend a specific stage can be blamed for the lateness of the final product.

2 - Introduction Of A Motor Assembly Test Bed To Verify Manufacturing Technology

Jungryul Bae, Korea Institute of Industrial Technology (KITECH), Seoul, Korea, Republic of, somanythat@naver.com, SeHwan Ahn, YongJu Cho, Chul Kim, Hyunchul Tae

A Testbed is a place of verifying newly developed manufacturing technologies before apply it in practice. We built a motor-assembly Testbed that comprises seven connected facilities in a line. We have tested several manufacturing technologies including simulation, quality management, and IoTs on the Testbed. In this presentation, we aim to introduce our Testbed and share our experience. The final goal of the Testbed is to enhance the localization ratio of a convergence of the IoTs and manufacturing technology.Keywords: Connected Smart Factory (CSF), Testbed, IoTs, manufacturing technology.

3 - Modeling The Impact Of Product Variety On Inventory: Application To Strategic Assembly Sequencing And Supply Chain Design

Jeonghan Ko, University of Michigan; Ajou University, 1205 Beal Ave., Industrial & Operations Engineering, Ann Arbor, MI, 4810, United States, jeonghan@umich.edu, Heng Kuang

This paper models the impact of variety on assembly supply chain design when limited commonality exists between products. We derive theorems on the impact of product variety on safety inventory, and provide a measure to approximate the impact. The theorems and new measure are applied in two problems: optimal process sequencing and optimal assembly decomposition. We prove that to prioritize the process with a smaller number of variants will reduce the supply chain cost no matter the commonality is.

4 - Finite Capacity Material Requirement Planning System For Supply Chain Network

Benyaphorn Paopongchuang, Sirindhorn International Institute of Technology, Pathum Thani, 12121, Thailand, bp322@njit.edu
Benyaphorn Paopongchuang, New Jersey Institute of Technology, Newark, NJ, 07102, United States, bp322@njit.edu, Pisal Yenradee

Available Finite Capacity Material Requirement Planning (FCMRP) systems have some limitations. They are designed to determine production and purchasing plans in only one factory not in a multi-level supply chain network. Most systems lack of optimization capabilities. In addition, they do not manage bottleneck effectively. The proposed algorithm tries to develop FCMRP system that also considers finite capacity of some key suppliers and customers.

5 - Similarity Coefficient Model For Solving an Oil Global Facility Location Problem

Ali AlArjani, PhD Candidate, University of Wisconsin - Milwaukee, 4848 N lydell Ave, Milwaukee, WI, 53217, United States, alarjan2@uwm.edu

Solve an oil global facility location problem by a new similarity coefficient model for cluster analysis that model ranks multiple countries and cluster them in groups each group have similar attributes.

2 - An Analytics Approach To Designing Drug Therapies For Cancer

John M Silberholz, MIT, Cambridge, MA, 02139, United States, josilber@mit.edu, Dimitris Bertsimas

We present a data-driven approach to planning clinical trials and designing novel drug therapies for metastatic breast cancer (MBC). First, we describe construction of a large database of MBC clinical trial results and tools to help clinicians visualize the data. Next, we use statistical models to predict efficacy and toxicity outcomes of trials before they are run, with implications for selecting between multiple drug therapies for testing. Finally, we use optimization models to design novel therapies that strike a balance between maximizing patient outcomes and learning about new drugs; initial evaluation suggests these models may improve trial outcomes compared to current practice.

3 - Online Decision-making With High-dimensional Covariates

Hamsa Sridhar Bastani, Stanford University, 10 Comstock Circle, Apt 304, Stanford, CA, 94305, United States, hsridhar@stanford.edu, Mohsen Bayati

Big data has enabled decision-makers to personalize choices based on an individual's observed characteristics. We formulate this problem as a multi-armed bandit with high-dimensional covariates, and present a new efficient algorithm that provably achieves near-optimal performance. The key step in our analysis is proving convergence of the LASSO estimator despite non-iid data induced by the bandit policy. We evaluate our algorithm using a real patient dataset on warfarin dosing; here, a patient's optimal dosage depends on her genetic profile and medical records. Our algorithm outperforms existing bandit methods as well as physicians to correctly dose a majority of patients.

4 - Estimating Average Treatment Effects In High-dimensional Observational Studies

Stefan Wager, Stanford University, Stanford, CA, United States, swager@stanford.edu, Susan Athey, Guido Imbens

There are many studies where researchers are interested in estimating average treatment effects and are willing to rely on the unconfoundedness assumption, which requires that treatment assignment is as good as random conditional on pre-treatment variables. The unconfoundedness assumption is often more plausible if a large number of pre-treatment variables are included in the analysis, but this can worsen the finite sample properties of existing approaches to estimation. In this paper, we propose a new method for estimating average treatment effects in high dimensions that achieves the semi-parametric efficiency bound without requiring any modeling assumptions on the propensity score.

Sponsored Session

Chair: Neng Fan, University of Arizona, Engineering Bldg, Room 312, 1127 E. James E. Rogers Way, Tucson, AZ, 85721, United States, nfan@email.arizona.edu

1 - Multiclass Support Vector Machines With Labeling Uncertainty

Wanlu Gu, University of Arizona, wanlugu@email.arizona.edu

The multiclass support vector machines (SVMs) is an extension of the conventional SVM in machine learning, and it builds the classification hyperplanes based on a set of training data points. In practice, the real collected data may have noise or uncertainty. In this talk, we consider the observed data with noise on the labels, and construct models and algorithms to learn from this type of uncertain data. To model the uncertainty, the noise probability is assumed to the labeling noise from one class to the others. Then some novel optimization models are proposed and also validated through numerical experiments to check the difference with noise free models.

2 - Sparse Support Vector Machines With Data Uncertainty

Ammon Washburn, University of Arizona, wammonj@email.arizona.edu

Data with high dimensionality and uncertainty comes about when there are too many features and the data is unreliable, replicated or missing. Without taking these issues properly into account, classification models will overfit the training data. In order to deal with these two problems, sparse representations and chance-constrained programming have emerged separately. We will show how to implement both ideas by modifying Support Vector Machines in a way that is not overly conservative which we call Decoupled Margin-Moment SVM. Numerical experiments are performed on collected pancreatic cancer data.

3 - Graph Clustering Of Data With Uncertainties

Yujia Zhang, University of Arizona, yujiazhang@email.arizona.edu

In this talk, we will review models and algorithms for clustering of data with uncertainties. First, the methods to model data uncertainty will be reviewed. Second, we mainly concentrate on the graph models for clustering. Finally, algorithms for solving these models will be reviewed and compared.

4 - Constrained Clustering Of Uncertain Data

Derya Dinler, PhD Candidate, Middle East Technical University, ODTU Endustri Muhendisligi Bolumu, Cankaya, Ankara, 06800, Turkey, dinler@metu.edu.tr, Mustafa Kemal Tural

We consider a constrained clustering problem where the locations of the data objects are subject to uncertainty. Each uncertainty set is assumed to be either a closed convex bounded polygon or a closed disk. The final clustering is expected to be in accordance with a given number of instance level constraints. We propose a mixed-integer second order cone programming formulation for the considered clustering problem which is only able to solve small-size instances. For larger instances, approaches from the semi-supervised (constrained) clustering literature are modified and compared in terms of computational time and quality.

1 - Using Density To Identify Fixations In Gaze Data: Optimization-based Formulations And Algorithms

Andrew C Trapp, Worcester Polytechnic Institute, atrapp@wpi.edu

Eye tracking is an increasingly common technology with a variety of practical uses. Eye-tracking gaze data can be categorized into two main events: fixations, which represent attention, whereas saccades occur between fixation events. We propose a novel manner to identify fixations based on their density, which concerns both the fixation duration as well as its inter-point proximity. We develop two mixed-integer nonlinear programming formulations and corresponding algorithms to recover the densest fixations in a data set. Our approach is parameterized by a unique value that controls for the degree of desired density. We conclude by discussing computational results and insights on real data sets.

2 - Leveraging Longitudinal Healthcare Data For Inverse Classification

Michael Lash, University of Iowa, michael-lash@uiowa.edu, Nick Street

Inverse classification is the process of manipulating a test point to minimize the predicted probability of a specific class label. Such a process has been shown to be beneficial to healthcare-related problems such as lifestyle modification and treatment recommendations. Past work in this area has focused on single snapshots in time, which does not account for the history or behavioral changes of patients. In this work we incorporate longitudinal information into our inverse classification model and demonstrate its effectiveness in mitigating the long-term risk of cardiovascular disease.

3 - Stability And Performance Of Healthcare Access Supply-demand Systems Affected by Stochastic Time Delays

Sara Nourazari, California State University-Long Beach, Bellflower Boulevard, Long Beach, CA, 90840, United States, Sara.Nourazari@csulb.edu, Rifat Sipahi, James Benneyan

Time delays are an inevitable aspect of many healthcare supply-demand systems and can potentially lead to undesirable outcomes and decision making challenges. We propose an approach to characterize "expected" stability maps of healthcare access supply-demand systems affected by random time delays following a known probability distribution. This study aims to enable broader insight into the effects of random process delays, and across a wide range of test applications in healthcare queue management, demonstrates minimized undesirable oscillatory behaviors and improved system performance.

Daniel H. Wagner Prize Competition I

Invited: Daniel H. Wagner Prize Competition

Invited Session

Chair: C. Allen Butler, Daniel H Wagner Associates, Inc., 2 Eaton Street, Hampton, VA, 23669, United States, Allen.Butler@va.wagner.com

1 - Calibrated Route Finder – Social, Environmental And Cost-effective Truck Routing

Mikael Ronnqvist, Professor, Universite Laval, Pavillion Adrien-Pouliot, Bureau 3345, 1065 Avenue De La Medecine, Quebec, QC, G1V OA6, Canada, mikael.ronnqvist@gmc.ulaval.ca Gunnar Svenson, Patrik Flisberg, Lars-Erik Jönsson

Finding the best route with many conflicting objectives is very difficult. The online system Calibrated Route Finder has been developed in collaboration among many companies and organizations and successfully addresses the problem. A key component is an inverse optimization process that establishes more than 100 weights to balance social values, environmental impacts, traffic safety, stress, fuel consumption, CO2 emissions, and costs. In addition, methodological and analytic developments now enable measurement and inclusion of perceived hilliness and curviness as well as strict rules where to drive. The system has been in operations since 2009 and is today used by about 100 companies.

2 - Vungle Inc. Improves Monetization Using Data Analytics

Ioannis Fragkos, Erasmus University, Burgemeester Oudlaan 50, Rotterdam, Netherlands, fragkos@rsm.nl, Bert De Reyck, Yael S Grushka-Cockayne, Casey Lichtendahl, Hammond Guerin

Big data have enabled firms to customize their services to unprecedented levels of granularity. In mobile advertising, once a customer enters the network, the ad-serving decision must be made in milliseconds. In this work, we describe the design and implementation of an algorithm we developed for Vungle Inc., one of the largest global mobile ad networks, that incorporates machine learning methods to make personalized ad-serving decisions. When compared to the company's legacy algorithm, our algorithm generated a 23% lift, which represents a $1 million increase in monthly revenue.

Low-Carbon Power Sector: Policy and Technology Analysis

Sponsored: Energy, Natural Res & the Environment, Energy I Electricity

Sponsored Session

Chair: Afzal Siddiqui, University College London, Department of Statistical Science, London, WC1E 6BT, United Kingdom, afzal.siddiqui@ucl.ac.uk

1 - Strategic Offering Of A Flexible Producer

Tuomas Rintamäki, Aalto University, Espoo, Finland, tuomas.rintamaki@aalto.fi, Afzal Siddiqui, Ahti Salo

Imbalances caused by intermittent renewable generation may give an opportunity to a strategic producer to exert market power. We study offering strategies of a flexible producer in day-ahead and intraday markets using a bi-level model in which the upper-level represents the profit maximization of the producer and the lower-level problems clear both markets sequentially. Using data from the Nordic power market, we find that the flexible producer can increase its profit by withholding production and by causing transmission grid congestion in both markets. Moreover, we compare the welfare impacts of the strategies to those of perfect competition and the dispatch policies in Morales et al. (2014).

2 - Power And Heat Market Model

Vilma Virasjoki, Aalto University, Espoo, Finland, vilma.virasjoki@aalto.fi, Afzal Siddiqui, Behnam Zakeri, Ahti Salo

Power markets are changing, i.a. due to an increasing share of renewable energy. This will also have effects on combined heat and power (CHP) plants and further on the district heating (DH) sector. It is thus essential to understand the financial and technical interrelations of these asymmetrically regulated sectors. We use complementarity modelling to study this linkage and give a numerical example using the Nordic energy system. We model the power system as a mix of DC and DC load flow linearized AC lines. We formulate perfect competition and Cournot oligopoly models and use GAMS to solve the market equilibrium. The results provide insights e.g. into the market power impacts on CHP and DH operations.

3 - Market Power In Electricity Markets In South-east Europe

Verena Viskovic, PhD Student, UCL, 1-19 Torrington Place, 2 Cubitt Street, London, United Kingdom, verena.viskovic.13@ucl.ac.uk, Yihsu Chen, Afzal Siddiqui, Makoto Tanaka

We examine the effect of market power in electricity and permits markets via single and bi-level model. We analyse potential scenarios of ownership structure in the post-privatisation phase in South-East Europe. We expect producers with market power to be able to influence electricity prices through permits market. In addition, we study the effect of virtual divestitures in mitigating market power.

4 - Variability Management In Long-term Investment Models

Lina Reichenberg, Chalmers University of Technology, lina.reichenberg@chalmers.se, Sonja Wogrin, Afzal Siddiqui

Time representation in large-scale energy investment models has been typically governed by variability in demand. However, as CO2 abatement is becoming a stronger driving force, variability enters also on the generation side. As a response to this, two families of alternative time reduction methods have been developed: one based on representative days and the other on using time slices based on variable resources. We investigate the performance of these two families of methods, in terms of accuracy in predicting the system plant capacity mix and CPU time.

Sponsored Session

Chair: Anthony Papavasiliou, CORE, UCL, Voie du Roman Pays 34, Louvain la Neuve, B-1348, Belgium, tpapva@hotmail.com

1 - A Revenue Adequate, Cost Recovering, Uniform Pricing Scheme For Wind Generation

Golbon Zakeri, University of Acukland, g.zakeri@auckland.ac.nz Geoff Pritchard, Mette Bjorndal, Endre Bjorndal

In 2010, Pritchard et. al proposed a stochastic program that would accommodate absorbing electricity generation from wind into an electricity market. We will present a strict improvement over this mechanism which is based on uniform pricing, is revenue adequate in every scenario, recovers cost for each generator in expectation, is incentive compatible and displays a number of other desirable properties.

2 - Operating Reserve Demand Curves For Improved Pricing In Electricity Markets With Renewable Energy

Audun Botterud, Argonne National Laboratory, abotterud@anl.gov, Zhi Zhou, Todd Levin

We present a probabilistic method for determining operating reserve demand curves (ORDCs) in electricity markets, accounting for the uncertainty in wind power forecasts. We present case studies analyzing how ORDCs influence incentives for short-term operations as well as long-term generation expansion in electricity markets with increasing shares of renewable energy. Finally, we discuss to what extent ORDCs reward flexible resources through improved pricing of energy and reserves.

3 - Ramp Capability Pricing: Environmental, Economic And Reliability Outcomes In Markets With High Penetration Of Renewables And Flexible CCS Plants

Dalia Patino Echeverri, Assistant Professor, Duke University, 9 Circuit Drive, Box 90328, Durham, NC, 27708, United States, dalia.patino@duke.edu, Rubenka Bandyopadhyay

Ramp Capability (RC) pricing, recently implemented by MISO, is expected to improve economics and reliability by adequately compensating flexible ramping resources. Coal-fired power plants retrofit with flexible Carbon Capture and Storage (CCS) systems, would allow air emissions reductions and improved system ramping capability. This paper explores the effects of dispatching CCS in a market with RC products. A modified Unit Commitment/Economic Dispatch (UC/ED) with CO2 emissions constraint and RC pricing, simulates 10-minute, annual operations of a scaled version of the MISO power generation fleet, to estimate changes in generators revenue, systems costs, reliability and air emissions.

4 - Deterministic Market Designs With Efficient Scheduling Of Flexible Ramping Products

Stefanos Delikaraoglou, Technical University of Denmark, Elektrovej, Building 325, room 105, Kgs. Lyngby, 2800, Denmark, stde@dtu.dk, Yves Smeers, Anthony Papavasiliou, Pierre Pinson

The variable and uncertain nature of stochastic renewables calls for revised market designs to optimally allocate available flexibility between energy and ramping services. Unlike stochastic dispatch models that endogenously co-optimize these services, deterministic models require the explicit definition of ramping products, e.g., CAISO market design. However, these products pertain only to capacity and thus disregard the energy cost from the deployment of flexible resources. Contrary to existing penalty-based heuristics, we propose a systematic approach, using nested Benders decomposition, to bring the deterministic dispatch close to the stochastic ideal in terms of costs and prices.

Social Media Analytics

Sponsored: Data Mining

Sponsored Session

Chair: Julie Zhang, University of Massachusetts Lowell, One University Avenue, Lowell, MA, 01854, United States, Juheng_Zhang@uml.edu

1 - Challenging The Spatial Homogeneity Of Online Reviews

Theodoros Lappas, Stevens University of Technology, tlappas@stevens.edu

The popularity of online reviews has led to the emergence of large review-hosting platforms that rank businesses by aggregating their reviews. The standard aggregation approach naively considers only the review's text, stars, and date, while ignoring the reviewer's circumstances. In this work we hypothesize that the reviewer's role as a local or visitor has a significant effect on the content and valence of his review. Our study reveals significant differences between the two populations and provides strong evidence against spatial homogeneity. We provide a detailed analysis of our findings and discuss their implications for consumers, business owners, and review-hosting platforms.

2 - Aspect Mining For Discovering Demand-side Knowledge In Online Customer Reviews

Zhilei Qiao, Virginia Tech, qzhilei@vt.edu, G. Alan Wang

Online reviews provide important demand-side knowledge from customers to improve mobile app product quality. However, discovering and quantifying potential app product new feature requests and defects from large amounts of unstructured text is a nontrivial task. In this paper, we propose a Latent Domain-Side Knowledge Analysis (LDSKA) that identifies the most critical app product new features and corresponding product feature status, simultaneously. Experimental results demonstrate that our proposed model outperforms existing LDA model. Our research has significant managerial implications for app developers, app customers and app platform providers.

3 - Strategically Information Disclosure On Social Media

Julie Zhang, University of Massachusetts Lowell, Juheng_Zhang@uml.edu

With the prevalence of social media, more firms are using social media to disclose financial information. Unlike 10-k forms, firms have freedom to choose when and how to disclose "good" or "bad" news on social media. There are strategic behaviors of firms in information disclosure on social media. We investigate the strategic information disclosure of firms on social media.

4 - On Predicting Social Protest Using Social Media

Rostyslav Korolov, Doctoral Student, Rensselaer Polytechnic Institute, 110 Eighth street, Troy, NY, 12180, United States, korolr@rpi.edu, Di Lu, Jingjing Wang, Guangyu Zhou, Claire Bonial, Clare Voss, Lance Kaplan, William A Wallace, Jiawei Han, Heng Ji

We study the possibility of predicting a social protest based on social media messaging. We suggest that the frequency of text concerning the stages in the process of mobilization may be used to predict an imminent protest. We utilized several Natural Language Processing techniques to identify mobilization in social media. Our experiments with Twitter data collected before and during the 2015 Baltimore events show a correlation over time between volume of Twitter communications related to mobilization and occurrences of protest, thereby enabling estimation of the likelihood of a protest.

1 - Tree-based Models For Longitudinal Data

Peng Wang, University of Cincinnati, wangp9@ucmail.uc.edu Dan Liu, Brittany Green

Classification and regression tree (CART) has been broadly applied due to its simplicity of explanation, automatic variable selection, visualization and interpretation. Previous algorithms for constructing CART for longitudinal data suffer from the computational difficulties in estimation of covariance matrix at each node. We proposed to utilize the quadratic inference function (QIF) and developed a new criterion, named RSSQ, to select the best splits. The proposed approach incorporates correlation wihout estimating the correlation parameters. Therefore we could improve the efficiency of the partition results and prediction accuracy. This is joint work with Dan Liu and Brittany Green

2 - Mining Process Patterns Via Electronic Medical Record Audit Logs

He Zhang, University of South Florida, hezhang@usf.edu

Mining the process patterns in the access logs from information systems can provide useful insights for the workow patterns. One important issue in process mining is that the workow is usually highly dynamic and the access logs are noisy. We presenta framework to analyze process models with noisy data at an abstract level. We implement our approach using several months of data from a large academic medical center. Empirical results show that our framework can extract the process models effectively.

3 - Feature Selection For Quality Assessment Of Predicted Protein Structures

Shokoufeh Mirzaei, California State Polytechnic University - Pomona, CA, smirzaei@cpp.edu

In the context of computational biology a scoring function determines the quality of a predicted protein structure. The Goal of this paper is to find a subset of protein features that are critical in identifying native protein structures in order to develop a scoring function. In pursuit of this goal, our method of research consists of 1) identify a set of protein features suggested by the literature, 2) use a variety of feature selection methods to select the best subset of features 3) use deep learning techniques in machine learning to identify new features. The final Outcome of this research is a subset of protein features and a new scoring function which predicts the quality of protein models.

4 - Healthcare Fraud Analysis Using Sequential Data Mining

Babak Zafari, Babson College, Boston, MA, United States, zafari.babak@gmail.com

It is estimated that at least three percent of annual health care spending is lost to overpayments. However, the large size and complexity of the health care system make comprehensive auditing infeasible. This resulted in the use of data mining approaches to detect unusual payments. In this talk, we propose the use of pattern discovery methods to find the anamolies in the medical claims payment data.

Crowd-based Innovation

Invited: Business Model Innovation

Invited Session

Chair: Bilal Gokpinar, UCL, London, United Kingdom, b.gokpinar@ucl.ac.uk

1 - Experience Breadth And Problem-solving In Crowdsourcing Contests: An Empirical Investigation

Anant Mishra, George Mason University, Fairfax, VA, 22030, United States, amishra6@gmu.edu, Nirup M Menon, Shun Ye

Online crowdsourcing contests have become a popular mechanism for addressing challenging problems. In this study, we use a multi-dimensional classification scheme to represent a contestant's breadth of experience on a crowdsourcing platform, and examine how it impacts her performance in a contest. Using detailed archival data from TopCoder, a crowdsourcing platform that hosts contests across software development problem domains (e.g., architecture, design, testing), our results demonstrate that a contestant's breadth of experience has a nuanced relationship with her performance in a contest.

2 - Spatial Distribution Of Alternative Finance

Mingfeng Lin, University of Arizona, 1130 E. Helen St, Tucson, AZ, 85721, United States, mingfeng@eller.arizona.edu, Bryan Zhang

Will online alternative finance help reduce the geographical imbalance of capital that the literature has long documented of the traditional finance? Are funding distributions geographically more equitable online, and are there differences across different types of crowdfunding forms? We answer these questions by leveraging detailed transactions data from multiple major crowdfunding platforms in the UK. We compare the spatial flow in online debt crowdfunding to bank lending, and online equity crowdfunding to venture capital and private equity financing. We also compare the funding flow between different types of crowdfunding. Results show some surprising and interesting patterns.

3 - The Role Of Customer Investor Involvement In Crowdfunding Success

Philipp Cornelius, University College London, London, United Kingdom, philipp.cornelius.12@ucl.ac.uk, Bilal Gokpinar

Entrepreneurs and organisations increasingly use crowdfunding to fund innovation projects through a large number of customer investments. The growing literature on the topic has predominantly studied crowdfunding in terms of its financing mechanism. The involvement of customers during crowdfunding, however, goes beyond the provision of capital. As investors and prospective product customers, crowdfunders want to influence crowdfunding campaigns. Can project creators benefit from this or does an increased influence of the crowd push products into too many directions and deter other customers from funding?

Energy System Design and Optimization

Invited: Energy Systems Management

Invited Session

Chair: Kai Pan, University of Florida, 303 Weil Hall, Gainesville, FL, 32611, United States, kpan@ufl.edu

1 - An Asynchronous Dual Decomposition Algorithm For Stochastic Unit Commitment

Ignacio Aravena, PhD Student, Université catholique de Louvain, Voie du Roman Pays 34 bte L1.03.01, Louvain-la-Neuve, 1348, Belgium, ignacio.aravena@uclouvain.be, Anthony Papavasiliou

We present an asynchronous dual decomposition algorithm for solving transmission constrained stochastic unit commitment (UC) under multi-area renewable production uncertainty with a sub-hourly resolution. Dual iterations rely upon asynchronous subgradient methods, while primal candidates are recovered from dual subproblem solutions. The algorithm is implemented on a high performance computing cluster and its performance is compared to a deterministic UC model with exogenous reserve targets. The superior performance of stochastic UC in terms of expected cost, reliability, and run time is demonstrated on an industrial scale test case of the Central Western European region.

2 - Valid Inequalities For Hydro Genco Self-scheduling Optimization

Minseok Ryu, University of Michigan, Ann Arbor, MI, United States, msryu@umich.edu, Antonio J. Conejo, Ruiwei Jiang

We study on a self-scheduling optimization problem for a hydro generation company (GENCO) that manages a set of interconnected hydro reservoirs. We consider a class of key physical and operating characteristics of hydro reservoirs and generators in practical settings, including the minimum up/down time, the prohibited operating zones, and the nonlinear performance curves. We employ a mixed-integer linear programming (MILP) approach to formulate or approximate these characteristics. The MILP approach facilitates the use of many efficient computational tools, e.g., optimization solvers and valid inequalities. Finally, numerical experiments are conducted based on a real-world case study.

3 - A Bi-level Decision Dependent Stochastic Programming Model For Generation Investment Planning

Yiduo Zhan, University of Central Florida, yzhan@knights.ucf.edu Qipeng Zheng

A multistage bilevel decision dependent stochastic model is presented to tackle the generation investment planning problem. This model addresses both exogenous and endogenous uncertainties. The upper-level focuses on a long-term generation planning problem. The lower-level represents an electricity pricing problem that addresses the market clearing consideration with local transmission network. A linear reformulation solution approach is developed for nonlinear terms. The optimization model is implemented to CPLEX with C++. Real-world scenarios are tested.

4 - Optimal Bidding Strategy For Electricity Market Participants Considering Wind And Price Uncertainties

Kai Pan, University of Florida, 411 Weil Hall, Gainesville, FL, 32611, United States, kpan@ufl.edu, Yongpei Guan, Jean-Paul Watson

An optimal bidding strategy is derived for independent power producers (IPPs) by attending both day-ahead (DA) and real-time (RT) markets as a price taker. The IPP submits an offer of generation amounts to the DA market, for which a multistage adaptive optimization setting is explored for submitting RT market offers for each hour as a recourse by utilizing the more accurate forecasting of renewable output and RT price as the forecast range shrinks. This proposed strategy is theoretically justified of its significant advantages over existing alternative ones. The numerical studies show the promising future of adapting the proposed strategy and verify the effectiveness of the proposed cutting planes.

Chair: Laura Albert McLay, University of Wisconsin-Madison, 1513 University Avenue, Madison, WI, 53706, United States, laura@engr.wisc.edu

1 - A Modified Logistic Regression Markov Chain Model For Ranking College Basketball And Football Teams And Forecasting Game Outcomes

Laura Albert McLay, University of Wisconsin-Madison, laura@engr.wisc.edu

Selecting the teams for the College Football Playoff for NCAA Division IA men's football is a controversial process performed by the selection committee. We present a method for forecasting the four team playoff weeks before the selection committee makes this decision. Our method uses a modified logistic regression/Markov chain model for rating the teams, predicting the outcomes of the unplayed games, and simulating the unplayed games in the remainder of the season to forecast the teams that will be selected for the four team playoff. You can check out the methodology and results at http://bracketology.engr.wisc.edu/

2 - Sampling From The 9,223,372,036,854,775,808 Possible Brackets In The Ncaa Men's Basketball Tournament Using The Power Model

Arash Khatibi, University of Illinois, Urbana, IL, 61802, United States, khatibi2@illinois.edu, Douglas M King, Maryam Kazerooni, Sheldon H Jacobson

This paper proposes the Power Model to estimate the winning seed distribution out of 9,223,372,036,854,775,808 possible brackets for the NCAA basketball tournament. The Power Model incorporates both the possibility of upsets and the better performance of stronger seeds by quantifying the relative strength of each pair of teams as a power function of their seed numbers. The Power Model is assessed based on the aggregate performance of one million brackets, which are generated for the five most recent tournaments (2012-2016) and scored using the ESPN scoring system.

3 - Predicting The Other Bracket Analysis Of The Selection Process For The National Invitation Tournament

Stephen Hill, University of North Carolina - Wilmington, hills@uncw.edu

In this work the selection process for college basketball's National Invitation Tournament (NIT) is examined. Using historical selection data, models are constructed from variables that are shown to be strong predictors of NIT tournament selection. Model quality is also assessed.

Network Optimization Models and Applications I

Sponsored: Optimization, Network Optimization

Sponsored Session

Chair: Jorge A Sefair, Arizona State Univerity, 699 S. Mill Ave., BYENG 330, Tempe, AZ, 85281, United States, jorge.sefair@asu.edu

1 - Optimizing The Recovery Of Disrupted Multi-echelon Assembly Supply Chain Networks

Huy Q Nguyen, Rensselaer Polytechnic Institute, 110 8th Street, 5119 Center for Industrial Innovation, Troy, NY, 12180, United States, nguyeh7@rpi.edu, Thomas Sharkey, John E. Mitchell, William (Al) Wallace

We consider the problem of recovering multi-echelon assembly supply chain networks from large-scale disruptive events. Each supplier within this network assembles a component from a series of sub-components received from other suppliers. We show that scheduling rules applied locally at each supplier can optimize key recovery metrics including minimizing the maximum tardiness of any order of the final product of the supply chain network and minimizing the time to recover from the event. Our approaches are applied to a data set modeling an industry partner's supply chain.

2 - Network Level Traffic Management Through Selective Ramp Metering

Dening Peng, Arizona State University, Dening.Peng@asu.edu, Pitu B. Mirchandani

The vast literature on ramp metering has mostly focused on strategies for local traffic controls on an isolated freeway segment or freeway system, without considering integrated network-wide traffic diversions. The research presented investigates the coordinated ramp metering problem with the consideration of network-wide traffic diversions caused by ramp capacity changes from ramp metering. A nonlinear programming optimization model is developed to determine the optimal ramp metering rates for the entire traffic network and the corresponding user equilibrium traffic flow pattern. A gradient-based search algorithm is developed to solve the model efficiently.

3 - A New Methodology For Sewer Systems Design

Daniel Duque, Universidad de los Andes, d.duque25@uniandes.edu.co, Andres L Medaglia

The sewer network design problem consists of determining both the layout and the hydraulic design of the sewer system. In this work, we propose an iterative framework to design minimum-cost sewer networks. The layout selection is modeled as a variant of the Network Design Problem. Once the layout is defined, the hydraulic design is modeled as a Shortest Path Problem, in which the underlying graph resembles the diameter and slope of each pipe. Both procedures are solved iteratively to improve the objective function until a termination criterion is met. Our methodology compares favorably against traditional hydraulic-based techniques and commercial software.

4 - Dynamic Maximum Flow With Geographic Conflict Considerations

Navid Matin Moghaddam, Arizona State University, Tempe, AZ, United States, nmatinmo@asu.edu, Jorge A. Sefair

We study the problem of finding the maximum number of agents traveling between two known nodes in a network within a specified time horizon. Paths used by agents must not be conflicting, meaning that no two agents can be closer to each other than a given distance at any time. For this purpose, we need to find not only the path for each agent but also a schedule to traverse the network. Typical examples of this problem include the transportation of hazardous materials and transportation operations under geographic failures. Here, we present an exact solution method to solve this problem.

Integrated Methods and Decomposition Approaches

Sponsored: Optimization, Integer and Discrete Optimization

Sponsored Session

Chair: Joris Kinable, Carnegie Mellon University, Pittsburgh, PA, United States, jkinable@cs.cmu.edu

1 - Decomposition By Decision Diagrams

Andre Augusto Cire, University of Toronto - Scarborough, acire@utsc.utoronto.ca, David Bergman

Decision diagrams (DDs) have recently been applied to a variety of optimization problems, often closing long-standing instances from classical benchmarks. This success is primarily driven by a DD's ability to capture combinatorial structure. We exploit this characteristic and propose a novel solution method which decomposes a problem into highly-structured portions, where the solutions of each portion can be compactly represented using a DD. The DDs are then connected using mathematical programming, which represents a reformulation of the original problem. Preliminary results suggest that this new approach can improve upon both standard integer programming models and a single DD approach.

2 - Scalable Segment Abstraction Method For Advertising Campaign Admission And Inventory Allocation Optimization

Tuomas W Sandholm, Carnegie Mellon University, sandholm@cs.cmu.edu, Tuomas W Sandholm, Optimized Markets, Inc., Pittsburgh, PA, United States, sandholm@cs.cmu.edu, Fei Peng

Publishers enable advertisers to create increasingly targeted campaigns. This dramatically increases the publisher's complexity when optimizing campaign admission and inventory allocation to campaigns. We develop an optimal anytime algorithm for abstracting audience segments into coarser segments that are not too numerous for optimization. Compared to Walsh et al. [AAAI-10], it yields 45x to 142x speedup and significant improvement in quality. This stems from a quadratic-time (as opposed to doubly exponential or heuristic) algorithm for finding an optimal split of an abstract segment, a better scoring function for evaluating splits, and splitting time lossily like other attributes.

3 - A Branch-and-Check Approach To Solve A Wind Turbine Maintenance Scheduling Problem

Louis-Martin Rousseau, Professor, Ecole Polythechnique de Montreal, Montréal, QC, Canada, louis-martin.rousseau@polymtl.ca Louis-Martin Rousseau Froger, Michel Gendreau, Jorge E. Mendoza, Éric Pinson

The problem consist in finding a maintenance planning that maximizes the production of wind turbines while taking into account wind predictions, multiple task execution modes, and task technician assignment constraints. We introduce an exact method to solve this challenging problem. We first propose new integer linear programming formulations of this problem. Then, on this basis, we build up a Benders- based branch-and-cut approach making use of Benders cuts as well as problem-specific cuts. The results suggest that our method significantly outperforms the direct resolution of integer linear programming models and a previously developed hybrid metaheuristic approach.

4 - Branch And Price And Check For Vehicle Routing With Location Constraints

Pascal Van Hentenryck, University of Michigan, pvanhent@umich.edu

This paper considers a vehicle routing problem with pickup and delivery, time windows and location constraints. Locations can become congested if insufficient resources are available, upon which vehicles must wait until a resource becomes available before proceeding. This talk presents a branch-and-price-and-check model that uses a branch-and-price to solve the core vehicle routing problem and a constraint programming subproblem to check the feasibility of the location resource constraints. Combinatorial nogood cuts are added to the master problem when resource constraints are violated. Experimental results show the benefits of the approach.

Chair: Evrim Dalkiran, Wayne State University, 4815 Fourth St, Detroit, MI, 48202, United States, evrimd@wayne.edu

1 - Computational Experimentation With Cutting Planes For Convex-transformable Functions

Carlos Nohra, Carnegie Mellon University, Department of Chemical Engineering, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, cnohrakh@andrew.cmu.edu Nikolaos Sahinidis

Factorable relaxations of global optimization problems can be strengthened via the use of functional transformations. In this work, we consider a new method to strengthen factorable relaxations which exploits convex-transformability of intermediate expressions. We integrate recently developed relaxations into the software BARON and study their effect on the convergence of the branch-and-reduce algorithm. Our implementation relies on the generation of cutting planes corresponding to supporting hyperplanes of convex relaxations of convex-transformable functions. We present extensive computational results on problems from a collection of publicly available test sets.

2 - RLT And McCormick Relaxations For Polynomial Programming Problems

Evrim Dalkiran, Wayne State University, evrimd@wayne.edu

A polynomial programming problem can be equivalently formulated as a quadratically constrained quadratic program (QCQP) by introducing new variables that represent nonlinear monomials. In this talk, we discuss strength and tractability of the standard Reformulation-Linearization Technique (RLT) and J-set relaxations constructed for the original and quadrified formulations, and identify the superior relaxation depending on the problem characteristics. Extensive computational results are provided to demonstrate the effectiveness of the relaxations using problems from the literature and randomly generated test instances.

3 - Polyhedral Results For Combinatorially-constrained Network Flows

Jean-Philippe P. Richard, University of Florida, richard@ise.ufl.edu Danial Davarnia

Various problems that arise in railroad operations can be formulated as network flow problems with additional combinatorial constraints. In this talk, we describe two such requirements, and present mip formulations for them. We then show that valid inequalities can be derived for these combinatorial constraints in the space of original variables, limiting the need to introduce auxiliary binary variables. We report computational results that show that relaxation bounds obtained with these cutting planes are stronger, and faster to derive than those generated by commercial mip solvers on the problem natural mip formulations.

4 - New Formulation-based Methods In Distance Geometry

Leo Liberti, CNRS, Palaiseau, 91128, France, liberti@lix.polytechnique.fr

The fundamental problem of distance geometry asks to find a realization of a finite, but partially specified, metric space in a Euclidean space of given dimension. Unless some structure is known about the structure of the instance, it is notoriously difficult to solve these problems computationally, and most methods will either not scale up to useful sizes, or will be unlikely to identify good solutions. We propose a new heuristic algorithm based on a semidefinite programming formulation, a diagonally-dominant inner approximation of Ahmadi and Hall's, a randomized-type rank reduction method of Barvinok's, and a call to a local nonlinear programming solver.

1 - Discrete Choice Models In Airline Revenue Management Applications: Challenges And Opportunities.

Emmanuel Carrier, Delta Airlines, emmanuel.carrier@delta.com
Laurie A. Garrow

Although they are appealing as they reproduce the passenger's decision process, discrete choice models have failed to gain traction in airline RM applications. We examine the reasons for this lack of success despite significant academic research and successful applications in other industries. However, several trends are converging to make choice models more attractive. As RM techniques evolve in response to emerging data sources such as competitor fare data, the development of ancillary products and shifts to the distribution landscape, we discuss the relevance of choice models for new airline RM applications from dynamic pricing to ancillary products.

2 - New Developments In Airline Capacity Sharing Model With Movable Curtain

Ang Li, PROS, Inc., Houston, TX, United States, ali@pros.com, Darius Walczak

We present our new results on the single-leg capacity sharing model with a moveable curtain. In particular, these include structural properties of the model, and an algorithm rendered by these to solve the associated dynamic program. We also show a more general problem formulation where the curtain is only allowed at a few positions on the aircraft.

3 - Forecasting Hotel Room Sales By Utilizing Online User Reviews

Jian Wang, VP, R&D, The RainMaker Group, 4550 North Point Parkway, Alphretta, GA, 30022, United States, jwang@LetItRain.com, Sneha Bishnoi, Han Wu

In traditional hotel revenue management (RM), room sales are forecasted mostly based on transaction data. With the availability of "big data" such as online social reputation, hotel RM practitioners become more interested in improving room sales forecasting by utilizing these external data. In this talk, we present some empirical results of forecasting hotel room sales by using online reviews and scores of TrustYou and TripAdvisor along with transaction data. We then compare the results with some traditional forecasting models that use transaction data only.

Recent Advances in Optimization for Structured High-Dimension Problems

Invited: Modeling and Methodologies in Big Data

Invited Session

Chair: Mingyi Hong, Iowa State University, 118 Pearson Hall, Ames, IA, 50021, United States, mingyi@iastate.edu

1 - Improved Sampling Complexity For Non-convex Optimization And Learning

Guanghui Lan, Georgia Institution of Technology, Atlanta, GA, United States, george.lan@isye.gatech.edu

We present an improved complexity result on the number of samples required to find an approximate global solution to a general nonconvex stochastic optimization problem. We discuss the consequence of this result on machine learning based on nonconvex optimization models, e.g., for some of those arising from deep learning.

2 - Smart: The Stochastic Monotone Aggregated Root-finding Algorithm

Damek Davis, UCLA, damek@math.ucla.edu

We introduce the Stochastic Monotone Aggregated Root-Finding (SMART) algorithm, a new randomized operator-splitting scheme for finding roots of finite sums of operators. SMART is similar to the class of incremental aggregated gradient algorithms, which minimize finite sums of functions; the difference is that we replace gradients of functions with objects called operators. By replacing gradients with operators, we increase our modeling power, and we simplify the application and analysis of the resulting algorithms. Among other features, SMART incorporates block-coordinate and asynchronous parallel updates.

3 - A First Order Free Lunch For The Sort-Lasso Optimization: Linear Convergence Without A Price

Tuo Zhao, Johns Hopkins University, tour@cs.jhu.edu

Many machine learning techniques sacrifice convenient computational structures to gain estimation robustness and modeling flexibility. Here we study this fundamental tradeoff through SQRT-Lasso for sparse linear regression. We explain how novel optimization techniques address these computational challenges. Particularly, we propose a pathwise smoothing proximal algorithm for solving the SQRT-Lasso optimization problem. Theoretically, we provide a novel model-based perspective for analyzing the smoothing optimization framework, which allows us to establish R-linear convergence guarantee for our algorithm. This implies that solving SQRT-Lasso is almost as easy as solving Lasso.

4 - Fast Stochastic Methods For Nonconvex Optimization

Sashank Reddi, CMU, sjakkamr@cs.cmu.edu

We study stochastic methods for nonconvex finite-sum problems. Stochastic gradient descent (SGD) is the de-facto algorithm used for solving optimization problems of this form. However, SGD suffers from slow convergence due to the inherent variance in the stochastic gradients. To tackle this issue, we develop fast stochastic algorithms for the nonconvex finite-sum problem and show that they are provably faster than both SGD and batch gradient descent. We also analyze a subclass of nonconvex problems on which these methods attain linear convergence to the global optimum. Our methods are based on variance reduction techniques, that have recently surged into prominence for convex optimization.

Data Driven Optimization

General Session

Chair: Andrew Lim, National University of Singapore, 15 Kent Ridge Drive, Singapore, 119245, Singapore, andrewlim@nus.edu.sg

Co-Chair: Michael Jong Kim, University of Toronto, 5 King's College Road, Toronto, M5S3G8, Canada, mikekim@mie.utoronto.ca

1 - Solving The Dual Problems Of Dynamic Programs Via Regression

Enlu Zhou, Georgia Institute of Technology, enlu.zhou@isye.gatech.edu, Helin Zhu, Fan Ye

We develop a framework of regression approach to approximating the optimal dual penalties for the dual problems of general dynamic programs, by exploring the structure of the function space that consists of all the feasible dual penalties. The resulted approximations maintain to be feasible dual penalties, and thus yield valid dual bounds on the optimal value function. We further show that the proposed framework is computationally efficient, and the resulted dual penalties lead to numerically tractable dual problems.

2 - The Coherent Loss Function For Classification

Huan Xu, National University of Singapore, Singapore, isexuh@nus.edu.sg, Wenzhuo Yang, Melvyn Sim

Binary classification involves minimizing 0-1 loss, which is intractable. To address this, previous methods consider minimizing the *cumulative loss* - the sum of convex surrogates of the 0-1 loss of each sample. We revisit this paradigm and develop instead an *axiomatic* framework by proposing a set of salient properties on functions for binary classification and then propose the *coherent loss* approach, which is a tractable upper-bound of the empirical classification error over the *entire* sample set. We show that the proposed approach yields a strictly tighter approximation, while preserving the convexity of the underlying optimization problem, and links this approach with robust SVM.

3 - Inverse Optimization Of Convex Risk Functions

Jonathan Yu-Meng Li, University of Ottawa, Ottawa, ON, Canada, Jonathan.Li@telfer.uottawa.ca

The theory of convex risk functions has now been well established as the basis for identifying the family of risk functions that should be used in risk-averse optimization problems. Despite its theoretical appeal, the implementation of a convex risk function remains difficult, as there is little guidance regarding how a convex risk function should be chosen so that it also well represents one's own risk preferences. In this work, we present an inverse optimization framework that imputes a convex risk function based on solution data from some risk-averse optimization problems. Unlike classical inverse optimization, no parametric assumption is made about the risk function.

4 - Robust Empirical Optimization

Andrew Lim, National University of Singapore, Singapore, Singapore, andrewlim@nus.edu.sg, Jun-ya Gotoh, Michael Jong Kim

We analyze the out-of-sample performance of robust empirical optimization and show that it asymptotically optimizes the mean-variance reward under the data generating model. We also introduce the notion of robust cross-validation as a method of calibrating the empirical robust optimization problem. Theoretical and experimental comparison to empirical optimization is also provided.

Optimizing Power System Operations Under Uncertainty

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Yu Zhang, University of California, Berkeley, 200 California Hall, Albany, CA, 94720, United States, yuzhang49@berkeley.edu

1 - Unit Commitment Under Gas-supply Uncertainty And Gas-price Variability

Antonio J. Conejo, The Ohio State University, 1971 Neil Av., Columbus, OH, 43210, United States, conejonavarro.1@osu.edu Ramteen Sioshansi, Bining Zhao

We propose a two-stage stochastic optimization model to analyze the scheduling of power units under natural gas-supply uncertainty and natural gas-price variability. The first stage of this model represents the day-ahead scheduling stage, while the second stage represents real-time operations via scenarios. We use this model to analyze the effect of two types of gas-supply conditions. First, we analyze a case involving low-cost gas supply with gas-transmission issues. We then examine a case involving higher-cost gas supply, which is used solely to attain feasibility with fast ramping events.

2 - Stochastic Market Clearing With High-penetration Wind Power

Yu Zhang, University of California, Berkeley, yuzhang49@berkeley.edu, Georgios Giannakis

Integrating renewable energy into the modern power grid requires risk-cognizant dispatch of resources to account for the stochastic availability of renewables. Toward this goal, day-ahead stochastic market clearing with high-penetration wind energy is pursued in this work. The objective is to minimize the social cost, which consists of conventional generation costs, end-user disutility, and a risk measure of the system re-dispatching cost based on the conditional value-at-risk. The resulting convex optimization problem is solved via the sample average and the alternating direction method of multipliers. Numerical results corroborate the merits of the proposed approaches.

3 - Integrated Generator Maintenance And Operations Scheduling Under Uncertain Failure Times

Beste Basciftci, Georgia Institute of Technology, Atlanta, GA, United States, beste.basciftci@gatech.edu Murat Yildirim, Shabbir Ahmed, Nagi Gebraeel

In this study, we formulate an integrated generator maintenance and operations scheduling problem as a stochastic mixed integer program by considering unexpected failure times. We generate failure scenarios based on the remaining life time distributions of the generators. We adopt a scenario decomposition approach to solve this problem in a distributed framework that identifies and evaluates solutions by solving scenario subproblems. Finally, we present computational experiments demonstrating the effectiveness of the approach.

Theory of Integer Optimization

Sponsored: Optimization, Integer and Discrete Optimization

Sponsored Session

Chair: Alberto Del Pia, University of Wisconsin, Madison, Madison, WI, United States, delpia@wisc.edu

1 - Facet Separation With One Linear Program

Laurence Wolsey, Université catholique de Louvain, laurence.wolsey@uclouvain.be, Michele Conforti

Given polyhedron P and and a point x*, the separation problem for polyhedra asks to certify that x* in P and if not, to determine an inequality that is satisfied by P and violated by x*. This problem is central in cutting plane methods for Integer Programming and the “quality” of the violated inequality is an essential feature in the performance of such methods. In this talk we address the problem of finding efficiently an inequality that is violated by x* and either defines an improper face or a facet of P. We provide some evidence that our method works on structured and unstructured problems.

2 - Ellipsoidal Mixed-Integer Representability

Jeffrey Poskin, University of Wisconsin - Madison, Wisconsin, WI, United States, poskin@wisc.edu, Alberto Del Pia

Representability results for mixed-integer linear systems play a fundamental role in optimization since they give geometric characterizations of the feasible sets that can be formulated by mixed-integer linear programming. We consider a natural extension of mixed-integer linear systems obtained by adding just one ellipsoidal inequality. The set of points that can be described, possibly using additional variables, by these systems are called ellipsoidal mixed-integer representable. In this work, we give geometric conditions that characterize ellipsoidal mixed-integer representable sets. “

Evaluating the Performance of Optimization Solvers

Sponsored: Computing

Sponsored Session

Chair: Paul Brooks, Virginia Commonwealth Univ, Virginia Commonwealth Univ, Richmond, VA, 00000, United States, jpbrooks@vcu.edu

1 - IPET: Interactive Performance Evaluation Tools For Benchmarking Optimization Software

Gregor Hendel, ZIB, hendel@zib.de

The optimization community has recently seen an increasing number of non-standard benchmark measures for evaluating solver performance, which some data processing tools do not deliver. The benchmark evaluation starting from the parsing of raw solver log data until the preparation of publication-ready tables can be time-consuming and error-prone if done by hand. In this talk, we will first review some of the specialized benchmark measures used for optimization software. We will then present a Python tool named IPET to speed-up repetitive tasks during benchmarking. We will give an overview of the tool and show examples how automated benchmark scripts can be created using IPET.

2 - Surrogate Models For Algorithm Configuration

Meinolf Sellmann, IBM Research, Yorktown Heights, NY, United States, meinolf@us.ibm.com

Automatic algorithm configurators are important tools for improving program performance. Local search approaches in particular have proven very effective for tuning. We study the use of non-parametric models in the context of population-based algorithm configurators. We introduce a model designed specifically for the task of predicting high-performance regions in the parameter space. Moreover, we introduce the ideas of genetic engineering of offspring. Numerical results show that model-based genetic algorithms significantly improve our ability to effectively configure algorithms automatically.

3 - Tuning Of Optimization Software Parameters For Mixed Integer Programming Problems

Toni P Sorrell, Virginia Commonwealth University, Richmond, VA, United States, tpsorrel@vcu.edu, Paul Brooks, David Edwards

The tuning of optimization software is of key interested to researchers solving mixed integer programming (MIP) problems because the efficiency of the optimization software is can be greatly impacted by the solver’s parameter settings and the structure of the MIP. A designed experiment approach is used to fit a model that would suggest settings of the parameters that provided the greatest impact on the primal integral. Primarily, this research focuses on using classes of MIPs to not only obtain good parameter settings for a practitioner to use on future instances of the same class of MIPs, but to also gain understanding of why the settings work well for that class of MIPs.

4 - Deploying MPL Optimization Models With Google Web Services API’s

Bjarni Kristjansson, President, Maximal Software Inc., 2111 Wilson Boulevard, Suite 700, Arlington, VA, 22201, United States, bjarni@maximalsoftware.com

Over the past decade the IT has been moving steadfastly towards utilizing software on clouds using Web Services API’s. The old standard way of deploying software on standalone computers is slowly going away. Google has been one of the leading software vendors in this area and publishes several web API’s which can be quite useful for deploying optimization applications. In this presentation we will demonstrate several Google API’s, including the Google Sheets API, Google Maps API, and Google Visualization API and show how they can be integrated with the MPL OptiMax Library for deploying optimization to service both web and mobile clients.

Healthcare Analytics: Big Data, Little Evidence

Invited: Tutorial

Invited Session

Chair: Joris van de Klundert, Erasmus University, Institute of Health Policy & Management, 2983 HE Ridderkerk, Netherlands, vandeklundert@bmg.eur.n

1 - Healthcare Analytics: Big Data, Little Evidence

Joris van de Klundert, Erasmus University, Institute of Health Policy & Management, 2983 HE Ridderkerk, Netherlands, vandeklundert@bmg.eur.n

While the healthcare sector contributes more than ten percent of GDP in most developed countries and is approaching twenty percent in the US, it remains a relatively modest area in the field of Operations Research, Management Science, and Analytics. There is considerable room for a larger and more valuable contribution, especially in view of the important advancements in information technology taking place in healthcare across the globe, which are already contributing to reducing the global burden of disease. In order for Analytics professionals and scientists to reach the full contribution potential of their discipline, it is beneficial to understand the dominant research paradigms and results of clinical and health sciences research. These sciences are rooted in empirical evidence, in empirical data, thus offering connection opportunities. In this tutorial we review the current position of Analytics as covered in the Operations Research and Management Science literature, and outline a path for the science of Analytics to enlarge its contribution to the health of populations.

Applications of Health Systems Analytics

Sponsored: Health Applications

Sponsored Session

Chair: Muge Capan, Christiana Care Health System, Value Institute, 4755 Ogletown-Stanton Road, 2nd Floor, Suite 2E55, Newark, DE, 19718, United States, Muge.Capan@ChristianaCare.org

1 - Sepsis: Sepsis Early Prediction Support Implementation System

Nisha Nataraj, North Carolina State University, NC, United States, nnatara@ncsu.edu, Julie Ivy, Muge Capan, Ryan Arnold, James R Wilson

Sepsis can be broadly defined as an infection plus systemic manifestations of the infection. It remains the most expensive condition in hospitals as well as one of the leading causes of in-hospital mortality. Using a discrete-event simulation framework, this research aims to develop personalized intervention policies for patients with sepsis. Specifically, we focus on the toll comorbidities and pre-existing conditions take on the manner in which sepsis presents and the associated impact they have on decision making.

2 - Validation And Implementation Of Early Warning System To Synthesize Acuity, Clinical Judgment, And Workload

Stephen Hoover, Christiana Care Health System, Value Institute, Newark, DE, United States, Stephen.Hoover@ChristianaCare.org
Muge Capan, Justin M Glasgow, Susan Mascioli, Eric V. Jackson

We present the validation and implementation of a clinical early warning system. An analytical framework was developed to quantify physiological deterioration that results in adverse events by integrating a published Early Warning Score and a new Nurse Screening Assessment tool. Survival Analysis and Monte Carlo methods were used to validate our approach. Relevant system costs and workload implications were analyzed. Findings indicate potential for reduction in variation of care and prevention of unnecessary ICU transfers. Iterative implementation processes highlighted the importance of multidisciplinary teams and systemwide education when modifying complex healthcare systems.

3 - Patient Access To Specialty Endocrinology Care

Henry Ballout, University of Michigan, Ann Arbor, MI, United States, haballou@umich.edu, Pranjal Singh, Amy Cohn, Amy E. Rothberg

Recurrent patient visits add tremendous complexity to modeling capacity utilization for healthcare professionals. To assist an endocrinology clinic at the University of Michigan, we present a temporal database that takes prospective patient appointment and provider availability data and enables capacity analysis through a compilation of daily snapshots. Using this database, we investigate the clinics issues regarding access and adherence to the program's highly structured timeline.

4 - Robust Optimization Framework To Account For Prediction Errors For Cancer Diagnosis

Selin Merdan, University of Michigan, smerdan@umich.edu

Multiple diagnostic tests are often available for diagnosing diseases such as cancer; however, how best to use these tests to render a diagnosis is challenging because there is often a tradeoff between the benefits of diagnosis and the harms and costs associated with the diagnostic tests themselves. We present a robust optimization model for determining the optimal assignment of composite diagnostic tests based on individual patient risk factors to achieve an optimal balance between the benefits and harms of diagnostic tests. We further provide a specific example in the context of radiologic imaging to detect metastatic prostate cancer.

Healthcare Policy, Personalized Treatment, and Coalitions: Operations Research Approaches

Invited: ORinformed Healthcare Policies

Invited Session

Chair: Pooyan Kazemian, Harvard Medical School, 25 Shattuck Street, Boston, MA, 02115, United States, pooyan.kazemian@mgh.harvard.edu

Co-Chair: Mark P. Van Oyen, University of Michigan, Ann Arbor, MI, United States, vanoyen@umich.edu

1 - Depression Care Management: Personalized Assessment To Cost-effective Population Interventions

Shan Liu, Assistant Professor, University of Washington, Seattle, WA, 98195, United States, liushan@uw.edu
Shuai Huang, Ying Lin, Xuelu Yang, Jiaqi Huang, Weiwei Shang

Depression affects 1 out of 10 Americans. While electronic health record (EHR) provides an unprecedented information infrastructure, we need a system perspective and an associated computational platform, and a seamless integration with decision-analytic models to link the design of personalized disease interventions to cost-effective population management. We are developing methods to 1) analyze and predict the heterogeneous depression trajectories of a patient population from EHR, 2) characterize the hidden disease processes and design personal intervention schedules, and 3) evaluate their cost-effectiveness to monitor and treat depression across a range of care scenarios.

2 - National Policy Impact Of High-cost Biologics For Ophthalmologic Use

David W. Hutton, University of Michigan, dwhutton@umich.edu

In the last decade, high-cost biologics have taken center stage in the treatment of complex degenerative eye diseases. Biologics for ophthalmologic use consume one-sixth of Medicare's part B drug budget. We examine how OR-based tools can be used to forecast and evaluate the national policy impact of these therapies (on both outcomes and costs). We see how different parties frame the problems differently and make different modeling choices. We discuss how different ways of using OR-based tools can influence policy. We explore open challenges evaluating the value of information and understanding how to evaluate decisions made jointly between patients and providers.

3 - On Personalized Allocation Of Treatments

Mohsen Bayati, Stanford University, bayati@stanford.edu, Hamsa Sridhar Bastani, Khashayar Khosravi

Growing availability of data has enabled practitioners to tailor medical treatments at the individual-level. This involves learning a model of decision outcomes conditional on individual-specific covariates or features. Recently, "contextual bandits" have been introduced as a framework to study these online decision making problems. In this talk we discuss statistical challenges that arise in such data-driven allocation of treatments.

4 - From Incident To Inpatient: How Healthcare Coalitions Can Improve Community Response

Jonathan Helm, Indiana University, helmj@indiana.edu
Alex Mills, Andres Jola-Sanchez, Mohan V Tatikonda, Bobby Courtney

Healthcare coalitions are a new type of organization that can coordinate casualty distribution among available hospitals in a metropolitan area after a multiple casualty incident. Using data from a major metro area, we show the value of different types of coordination regarding hospitals' capacity information. We find that, while coalitions were initially create for large disasters, significant value comes in coordinate metropolitan area hospital resources on a much smaller scale. We also identify what types of information are most valuable for these organizations to collect and disseminate. This leads to interesting policy implication for the further funding and creation of such coalitions.

Human Resource Analytics in Anesthesia

Sponsored: Health Applications

Sponsored Session

Chair: Franklin Dexter, University of Iowa, 200 Hawkins Drive, 6-JCP, Iowa City, IA, 52242, United States, franklin-dexter@uiowa.edu

1 - Comparing Providers Based On An “obvious” Short-term Clinical Outcome: Pain Scores

Jonathan Porter Wanderer, Vanderbilt University, Nashville, TN, 37204, United States, jon.wanderer@Vanderbilt.Edu

In this presentation, we will review a “obvious” metric for comparing supervising anesthesiologists: their patients’ pain scores on admission to the recovery room. Using modeling, we will evaluate the appropriateness of this metric and analyze the degree to which these scores are useful in evaluating the performance of supervising anesthesiologists. Spoiler alert: this is not as useful a metric as it may first appear.

2 - Comparing Anesthesia Providers Based On Discrepancies In Their Controlled Substance Reconciliation Logs

Richard H. Epstein, University of Miami, repstein@med.miami.edu

Accurate accounting of controlled drugs is required in the US under the Controlled Substances Act. However, discrepancy rates of 15% between automated drug cart transactions and administration records in the anesthesia information management systems (AIMS) have been reported. We describe how we reduced our discrepancy rate from 15% to 3.5% through a sequential process involving daily, individualized email reports, a near real-time tool publicly showing the transaction balance compared to the AIMS, and involvement of the pharmacy to contact individuals with discrepancies. Although there were a few extreme outliers, discrepancies were widely distributed, requiring a system based approach.

3 - Comparing Faculty Anesthesiologists Based On Daily Evaluations Of Quality Of Supervision By The Resident Physicians

Franklin Dexter, University of Iowa, franklin-dexter@uiowa.edu

Since July 2013, resident physicians (and nurse practitioners) evaluate daily the anesthesiologists in our department based on quality of supervision. The uni-dimensional 9-item scale is valid and psychometrically dependable. Graduate students evaluate the faculty daily. In 9 papers, we have learned: what is being measured, achievable response rates, lack of important covariates, appropriate Bernoulli CUSUM analysis, role of feedback, minimum perceived acceptable scores, lack of correlation with individual productivity, lack of advantage to faculty specialization, and improvement over time. Textual analysis of resident comments showed behaviors associated with better scores.

4 - Privacy Policies For Protecting Human Resources

Liam O’Neill, University of North Texas, liam.oneill@unthsc.edu

The dominant paradigm of information privacy is based on de-identification. We calculated the percent uniqueness for hospital surgical patients from a database of 2.8 million hospital records. Only three attributes were considered: hospital name, fiscal quarter, and surgical procedures. For patients undergoing two or more procedures, 64.4% of records were found to be unique. For a patient selected at random, the probability of matching this record to state database was 42.8% (SE < 0.1%). Data sharing plans, as required by some journals and funding agencies, may place patient and clinician privacy at risk. Compliance with HIPAA alone is insufficient to protect health data from re-identification.

Organizational Structures and Innovation

Invited: Strategy Science

Invited Session

Chair: Todd Zenger, University of Utah, Eccles School of Business, Salt Lake CIty, UT, 9, United States, todd.zenger@eccles.utah.edu

1 - Organizational Structure, Attention Allocation Andinnovation In The Multidivisional Firm

John Joseph, University of California, Irvine, CA, 9, United States, john2@uci.edu, Alex Wilson

We propose that in order to understand how organizations develop inventions with greater impact, we must not only consider the formal divisionalization of the firm, but also its attention structure. We find that unit attention which is either highly specialized (distinct from other units) or highly integrated (similar to other units) yields higher quality inventions. We suggest that this U-shape relationship reflects the need for attentional coherence to product quality inventions. We test our theory using novel organizational structure and topic modeling of patent data from Motorola. Our findings have implications for theories of organizational design and innovation.

2 - Stage-gate Processes And Selection In Innovation

Ronald Klingebiel, Frankfurt School of Finance and Management, 1, Frankfurt, Germany, r.klingebiel@fs.de, Peter Esser

We examine resource allocation at stage gates of the innovation process at former handset manufacturer Sony Ericsson, illuminating project discontinuation behavior. We find that with financials unavailable early on, escalation can be unknowable as well as a bias. Further, the propensity to search and update financials declines as projects near completion, accompanying known self-justification and goal-substitution effects. Finally, projects, for which negative information does get translated into business case updates, are more likely to be continued than projects with stable or improving financials. This strong form of escalation suggests a counter-intuitive effect of attention.

3 - Intra-firm Collaboration Boundaries And The Efficacy Of Innovation

Andy Wu, Harvard Business School, Soldiers Field, Boston, MA, 02163, United States, awu@hbs.edu, David Hsu, Vikas Aggarwal

What are the implications of alternate approaches to organizing the inventive human capital of a knowledge-intensive firm? We empirically examine how the locus of technical experience diversity within a firm influences firm-level innovation output. Using a sample of biotechnology start-ups we find that organizing human capital so that there is greater indirect diversity (i.e., where technical experience diversity lies outside the locus of production) yields greater firm-level innovation benefits compared to organizing human capital so that there is greater direct diversity (i.e., where technical experience diversity lies inside production units themselves).

4 - How Do Pilots Work? Examining Pilot Use In New Practice Transfer?

Megan Lawrence, Vanderbilt University, Owen Graduate School of Management, Nashville, TN, 3, United States, megan.lawrence@vanderbilt.edu

This paper examines how the use of pilots influences new practice implementation. Using data from a Fortune 100 retail chain that implemented a new restocking process, I compare implementation performance in 280 stores. I propose and test that pilots enable learning from outside experiences. I find that stores only learn from the pilot store in their own district, even when closer to another district’s pilot. Stores’ prior performances relative to their pilot influence the extent to which they learn from their own experiences. Lastly, I provide evidence that the most likely alternative mechanism - peer effects - may also be present but that these effects do not eliminate the learning findings.

Modern Project Management

Invited: Project Management and Scheduling

Invited Session

Chair: Nicholas G Hall, Ohio State University, Columbus, OH, United States, hall.33@osu.edu

1 - Opportunities For Behavioral Research In Project Management

Enno Siemsen, University of Wisconsin, esiemsen@wisc.edu

Behavioral research in operations management is on the rise. The field of Project Management seems ripe for more applications of behavioral research. How do team members react to deadlines and reminders? How are projects selected and abandoned? What is the impact of multi-tasking, and how does assigning new resources change team dynamics? These are all important research topics, and I will both highlight past and current work in these areas, as well as opportunities for future research.

2 - Information Protection In New Product Development Projects

Xiaoqin Wen, Shanghai University, wenxq_8@163.com, Nicholas G Hall

Motivated by the threat of industrial espionage during new product development, a project company minimizes information leakage by using decoy work. The competitor validates the information it observes in a cost-effective way, based on three alternative prior assumptions about its validity. We model this problem as a two stage Stackelberg game, identify an equilibrium solution, and obtain managerial insights. Coordinated setting of the project deadline and budget is needed to protect the project. Counterintuitively, it benefits the project company to announce that it uses decoy work.

3 - Research Challenges In Project Management

Ted Klastorin, University of Washington, tedk@u.washington.edu

A great deal of previous project management research has focused on scheduling problems. But the research issues faced by project managers are far more complex and just as challenging as those faced by supply chain managers. In this talk, I will explore many of these issues and directions for future research studies, with an emphasis on problems associated with decentralized projects.

4 - Research Opportunities In Project Scheduling

Rainer Kolisch, Technical University of Munich, rainer.kolisch@tum.de

Operations Research has been applied in project scheduling for more than half a century. This talk summarizes achievements and outlines research opportunities.

Dynamic Matching

Invited: Auctions

Invited Session

Chair: John Dickerson, Carnegie Mellon University, 9219 Gates-Hillman Center, Pittsburgh, PA, 15213, United States, dickerson@cs.cmu.edu

1 - Dynamics Matching With Departures

Maximilien Burq, Massachusetts Institute of Technology, Cambridge, MA, United States, mburq@mit.edu
Vahideh Manshadi, Itai Ashlagi, Patrick Jaillet

We study dynamic matching in an infinite-horizon market with stochastic arrivals and departures, in which some agents are a priori more difficult to match than others. We analyze the effect of batching for policies that match agents through cycles of length 2 or 3. We show that if only cycles of length 2 are allowed, the benefit of batching is not significant. However for 3-cycles, batching can result in a considerable gain over greedy. Furthermore, using data from the National Kidney Registry, we provide simulations that confirm our theoretical results.

2 - Dynamic Matching In Over-the-counter Markets

Yu An, Stanford, Stanford, CA, United States, yua@stanford.edu
Zeyu Zheng

We model the dynamics of liquidity premium in an OTC market with heterogeneous assets. A monopolistic dealer matches supply and demand flows in order to maximize his profits. Inventory building by the dealer increases the average waiting time for those customers who rejected immediacy offers, and therefore helps the dealer extract rents via liquidity premium. The dealer's dual role of liquidity provision and matchmaking creates inefficient monopoly, and in equilibrium, he holds too much inventory compared to the first best. Our result helps explain the recent growth in all-to-all trading platforms in the corporate bonds market, as they circumvent these inefficiencies.

3 - Toward A Credit-based Mechanism For Dynamic Kidney Exchange

John Dickerson, Carnegie Mellon University, dickerson@cs.cmu.edu, John Dickerson, University of Maryland, College Park, MD, 20742, United States, dickerson@cs.cmu.edu

We discuss progress toward creating a credit-based matching mechanism for dynamic barter markets—-and kidney exchange in particular—-that is both strategy proof and efficient, that is, it guarantees truthful disclosure of donor-patient pairs from the transplant centers and results in the maximum global matching. We show that no such mechanism that supports cycles and chains of any length can be both long-term individually rational and economically efficient; we then give light assumptions under which such a mechanism can exist.

Empirical Research in Operations II

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Nils Rudi, INSEAD, 1 Ayer Rajah Avenue, Singapore, 138676, Singapore, nils.rudi@insead.edu

1 - Fitting, Clustering And Forecasting Product Life Cycles: Model And Empirical Validation

Jan A Van Mieghem, Harold Stuart Professor, Northwestern University, 1, Evanston, IL, 60209-2001, United States, vanmieghem@kellogg.northwestern.edu
Kejia Hu, Jason Acimovic, Douglas Thomas

We present an approach to fit product life cycle (PLC) curves from historical demand data and use them to predict/forecast demands of ready-to-launch new products. We propose three types of models to fit PLC: the BASS diffusion model, the polynomial model and the piecewise-linear model and compare their goodness-of-fit and complexity for fitting different categories of products. Using time-series clustering techniques, we cluster the fitted PLC curves into several representative patterns. Finally, we validate out-of-sample forecast accuracy using actual demand data of a computer company.

2 - Managing Multichannel Delivery Of Healthcare Services: Case Of Telemedicine In Rural India

Kraig Delana, London Business School, PhD Program Office, London, NW1 4SA, United Kingdom, kdelana@london.edu, Kamalini Ramdas, Sarang Deo

Telemedicine is a potent intervention to improve healthcare access for difficult-to-reach populations. We investigate the impact of the introduction of rural telemedicine facilities on access to eye care for patients in rural India using more than 4 million patient visit observations from the largest eye care system in the world. In particular, we exploit growth in the network of telemedicine centers over time and space to identify changes in where and how early patients seek care using a difference-in-differences methodology. Our results have implications for effective multichannel delivery of complex services such as healthcare.

3 - Forecasting Demand For New Products: Combining Subjective Rankings With Historical Data

Marat Salikhov, INSEAD, Boulevard de Constance, Fontainebleau, 77305, France, marat.salikhov@insead.edu
Nils Rudi

We combine subjective ranking inputs with historical data for new product demand forecasting. The methods yields good fit with data, both for order statistics of proportions of total demand and for predicting the actual demand.

1 - Probabilistic Selling For Vertically Differentiated Products: The Role Of Salience

Quan Ben Zheng, University of Florida, quan.zheng@warrington.ufl.edu, Xiajun Amy Pan, Janice E Carrillo

This paper studies probabilistic selling for vertically differentiated products, whereby consumers do not know the exact identity of a product until after making the purchase. Our work discovers the crucial role of consumers' salient thinking behavior: consumers focus on and overweight the salient attribute of a product in their perception. We show that probabilistic selling can improve the seller's profit with salient thinkers even when this strategy does not emerge with rational consumers. Consumers' salient thinking behavior enables the seller to utilize the probabilistic product to transform the consumers' choice context and direct their attention to quality.

2 - Maximizing Profitability In Online Retail Through Free Shipping Threshold

Jiaqi Xu, Carnegie Mellon University, 5000 Forbes Avenue, Pittsburgh, PA, 15217, United States, jiaqixu@wharton.upenn.edu, Gerard P Cachon, Santiago Gallino

We present a data-driven model to analyze the profit implication of an online retailer's free shipping threshold decision. A key component of our model derives from the empirical observation that customers often increase their basket size at checkout to qualify for free shipping (order padding). We find that a free shipping threshold policy is effective when the extra sales from order padding do not substantially reduce the total amount of future purchases, the retailer charges only a small portion of the fulfillment cost for orders that do not qualify for free shipping, and product handling costs for returns are low.

3 - Learning From Clickstream Data In Online Retail

Bharadwaj Kadiyala, PhD Candidate, The University of Texas at Dallas, Richardson, TX, United States, bharadwaj.kadiyala@utdallas.edu, Dorothee Honhon, Canan Ulu

We study the problem of an e-tailer who learns about consumer preferences from observing sales or clickstream data on his website in a Bayesian fashion. We use a ranking-based model to represent consumer choice for two types of products: basic products for which consumers have well-defined preferences and fashion products for which consumers discover their preferences via browsing. We prove that, when the e-tailer learns from clickstream data, it may be optimal to show products on the search page, but display them as unavailable later on their product information page. We also numerically estimate the value of learning from clickstream data versus learning from sales data only.

Improving Supply Chain Responsibility Through Regulation and External Actions

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Robert Swinney, Duke University, Durham, NC, United States, robert.swinney@duke.edu

1 - Pollution Regulation And Market Structure: Equilibria, Profits And Welfare Effects

Krishnan S Anand, University of Utah, 1655 E Campus Center Dr Rm 7211, David Eccles School Of Business, Salt Lake City, UT, 84112, United States, anand@eccles.utah.edu
Francois C. Giraud-Carrier

Opponents of pollution regulation claim that regulations choke businesses, hurt welfare and destroy economic growth. We model two popular regulations— Cap-and-Trade and Taxes— under imperfect competition, and prove that well-chosen regulation can simultaneously improve firms' profits, consumer surplus and welfare. Further, firms can be induced to perfectly internalize their pollution externalities, without being charged a penny in taxes. Our results suggest that the paramount factor in framing pollution regulations should be their impact on consumers rather than on producers.

2 - Extended Producer Responsibility (EPR) For Pharmaceuticals

Isil Alev, Boston College, isil.alev@bc.edu
Atalay Atasu, Beril L Toktay, Ozlem Ergun

Following their popularity for non-consumables, EPR-based implementation models have gained traction for managing pharmaceutical overage. We analyze the effectiveness of these models for pharmaceuticals, particularly Source Reduction (SR) and End-of-Pipe Control (EC), by developing a game-theoretic model of pharmaceutical chain with a focus on factors causing overage. We show that the pharmaceutical context may imply stronger preference for adopting the EC model as compared to non-consumables. We also show that an alignment of stakeholder preferences for the model choices can be achieved under a larger set of conditions for pharmaceuticals.

3 - Prevention Or Prosecution: An Analytical Approach To Modern Slavery In Supply Chains

Shawn Bhimani, Duke University, Durham, NC, United States, shawn.bhimani@gmail.com

We explore current human trafficking prevention schemes by modeling the interaction between a regulator and a business. By analyzing the incentive systems at play, we provide insights on how to effectively motivate integral stakeholders in the fight against corrupted supply chains.

Sustainable Operations I

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Basak Kalkanci, Georgia Institute of Technology, Atlanta, GA, United States, basak.kalkanci@scheller.gatech.edu

1 - Operational Challenges For Distributed Manufacturing In Developing Countries

Andre Du Pin Calmon, INSEAD, Fontainebleau, France, andre.calmon@insead.edu

We model and analyze a distributed manufacturing system set-up by a social enterprise that produces fashion accessories in Kenya. This company selects and works with a network of small artisan workshops with diverse characteristics in terms of quality and production capacity. Furthermore, when adding a new workshop to the network, there is uncertainty regarding that workshop's features and performance. We model the problem of allocating production orders to workshops as a stochastic learning problem. We also allow for "fairness" constraints, which encode the company's social objectives. We illustrate the performance of different allocation policies through numerical simulations.

2 - Sustainable Operations Versus Corporate Social Responsibility: A Cross – Country Analysis Of Value Chain Transparency

Ryan Buell, Harvard Business School, rbuell@hbs.edu
Basak Kalkanci

We study the differential impact of transparency into a company's sustainable operations relative to transparency into its "extracurricular" CSR activities. Through a series of cross-country experiments engaging participants in the US, India, China, Bangladesh, Mexico, and Turkey, we explore whether stakeholders respond more favorably to transparency that reveals sustainable operations (e.g. reducing water consumption or paying a living wage) than to transparency that reveals sustainable investments that fall outside the operation (e.g. donating an equivalent amount of drinking water or investing an equivalent amount in the community around a factory).

3 - A Dynamic Mechanism For Achieving Sustainable Supply Of High Quality Products

Fang Liu, Nanyang Technological University, Singapore, Singapore, Liu_Fang@ntu.edu.sg, Tracy Lewis, Jing-Sheng Jeannette Song

Several leading companies have realized the importance of sustainable quality supply and have initiated programs to achieve it. This paper investigates whether the guidelines in such programs provide the right incentives and information structures for all parties to participate in order to achieve the intended long-term goals.

4 - New Business Models For Industrial Park Operators

Ioannis Siskos, Kuhne Logistics University, ioannis.siskos@the-klu.org, Luk N Van Wassenhove

Industrial parks operators (IPOs) are interested in symbiotic projects developed in their parks. We use static monopoly and competition modelling in order to explore the cost and pricing conditions under which by-product synergies that are not realized by the candidate firms would be undertaken by the IPO.

Sponsored Session

Chair: Selvaprabu Nadarajah, College of Business, University of Illinois at Chicago, 601 S Morgan St, Chicago, IL, 60607, United States, selvan@uic.edu

1 - Risk Neutral And Risk Averse Approximate Dynamic Programming Methods For Bidding In The Energy Market

Daniel R. Jiang, University of Pittsburgh, Pittsburgh, PA, 15261, United States, drjiang@pitt.edu, Warren B Powell

In order to better assess the value of energy storage, we consider the problem of bidding into an hour-ahead market with the goal of "trading" physical energy, i.e., performing energy arbitrage. We describe an approximate dynamic programming method that exploits the monotone structure of the problem in order to obtain near-optimal bidding strategies for a risk-neutral formulation of the objective function. Additionally, in this application (and many others), it can be important to incorporate risk-aversion into the decision making process. We discuss a method that allows us to construct risk-averse bidding polices, optimized under dynamic quantile-based risk measures.

2 - Keeping Options Open When Just One Can Be Exercised: When To Pick A Winner

Daniel Ralph, University of Cambridge, d.ralph@jbs.cam.ac.uk
Rutger-Jan Lange

Given several, costly R&D projects for low carbon electricity, when should be any be abandoned to eventually pick the winner? We study parallel competing projects where the performance of each project is governed by a general Ito process, while opportunities to drop underperforming options (or select the winner) follow a Poisson process. We show how to construct the option value as the limit of an increasing sequence of lower bounds. This general multidimensional theory underlies many complex real-world stopping decisions, and offers the first opportunity to solve this class of problems optimally.

3 - Policy Uncertainty And Real Options On Switching Of Peak Power Plants

Stein-Erik Fleten, Norwegian University of Science and Technology, stein-erik.fleten@iot.ntnu.no, Marius Johansen, Alois Pichler, Carl J Ullrich

We examine empirically how economic factors, government policy, and strategic interactions a
ffect managers' decisions to switch between operating and stand-by states for peaking electric power generators. We model the switching decisions using a structural model of a dynamic optimal decision game. We focus on the power markets in the Northeastern United States, where annual observations of such decisions are available. The results indicate that regulatory uncertainty significantly increases firms' perception of switching costs, and that large power producers are noticeably more influenced by their economic environment in their decision-making than small firms.

Scheduling V

Contributed Session

Chair: Nermine Harraz, Associate Professor, Alexandria University - Faculty of Engineering, Alexandria, Egypt, nharraz@alexu.edu.eg

1 - Two Stage, Single Lot, Lot Streaming Problem For A 1 + M Hybrid Flow Shop

Sanchit Singh, Virginia Tech, 1206 University Terrace, Apt F, Blacksburg, VA, 24060, United States, sanchit@vt.edu

This paper considers a single lot, lot-streaming problem for a hybrid flow shop consisting of a single machine at Stage 1 and M identical machines at Stage 2. The aim is to find optimal number, sizes and allocation of sublots to the machines at Stage 2 for minimizing make span. An exact algorithm is developed with polynomial time search to obtain an optimal schedule when the sublot sizes are continuous. A branch-and-bound based method is also developed for the case of integer sublot sizes that employs tight bounds. Its performance is tested against the direct solution of the MIP formulation by CPLEX.

2 - Ideal Schedules

Kangbok Lee, City University of New York, York College, 94-20 Guy R Brewer Boulevard, Queens, NY, 11451, United States, kangbok.lee3@gmail.com, Joseph Leung, Michael L Pinedo

An ideal schedule is referred to as a schedule minimizing both maximum and total completion times simultaneously and an ideal problem is a problem where every instance of the problem has an ideal schedule. We identify the boundary between ideal and non-ideal problems and investigate the algorithms for ideal schedules under different job characteristics such as processing times, release dates, precedence constraints, and eligibility constraints.

3 - An Exact Model For Solving The Hybrid Flow Shop Scheduling Problem

Nermine Harraz, Associate Professor, Alexandria University - Faculty of Engineering, Alexandria, Egypt, nharraz@alexu.edu.eg

This work presents a model to solve the hybrid Flow Shop Scheduling problem. The developed Mixed Integer Programming model considers optimizing a dual criteria objective function to minimize a convex sum of makespan and the number of tardy jobs under various constraints. The constraints consider unrelated parallel machines, precedence relations, stage skipping, machine eligibility, operations lag time, machine release times, and sequence dependent anticipatory and non-anticipatory setup times. An exact solution is used to solve the model and to implement it in a real world packaging case. The output shows that the model is efficient and applicable easily under different conditions.

Simulation I

Contributed Session

Chair: Simon Mak, Graduate Student, Georgia Institute of Technology, North Ave NW, Atlanta, GA, 30332, United States, smak6@gatech.edu

1 - Dynamic Simulation Of Marine Port Resiliency

Henry Lester, University of South Alabama, PO Box 8172, Mobile, AL, 36689, United States, hlester@southalabama.edu, Raymond L Smith

Marine port system resiliency indicates the degree a port can resist and recover from a potential disruption. Essential measures of this port resiliency include operational factors subject to excessive burdens. This paper presents an approach to capturing marine port behaviors with respect to system operational factors. The procedure utilizes a system dynamic simulation model to analyze port operations under unpredictable and fluctuating loads to isolate significant critical port infrastructure components. The resultant critical components will provide a basis for future public policy decision analysis pertaining to marine port resiliency subject to extreme events.

2 - An Optimal Stopping Approach To Portfolio Risk Measurement

Kun Zhang, Mr, City University of Hong Kong, Tat Chee Avenue, Kowloon, Hong Kong, Hong Kong, 000, Hong Kong, kunzhang6-c@my.cityu.edu.hk, Guangwu Liu, Bingfeng Zhang

Portfolio risk measurement under the nested setting involving a two-level simulation procedure is a challenging computational problem. To reduce the computational burden, we propose an optimal stopping approach in which only one observation is required in the inner-level simulation for each outer-level scenario. In particular, we show that conditional value-at-risk (CVaR) of a portfolio can be represented as the solution to an appropriately constructed optimal stopping problem. Then the least squares method is employed to solve it, leading to a fast lower bound algorithm for portfolio CVaR. Numerical results show that this approach works well and produces accurate estimates of portfolio CVaR.

3 - A Simulation Model For Assessing Mitigation Strategies Against Cyber Attacks

Soumyo D Moitra, Senior Member of Technical Staff, Software Engineering Institute, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, smoitra@sei.cmu.edu

Defending information networks from cyber attacks is a major concern. We propose a simulation model that helps analyze the risks involved in different defense strategies. The model considers attack categories, vulnerabilities in target hosts and the probabilities of a negative impact as a function of attack categories and host states. The host states are modeled as functions of mitigation strategies. Thus the effectiveness of alternative mitigation strategies can be estimated. An illustrative example is presented and the advantages of this approach are discussed.

4 - Support Points: A New Method For Compacting Distributions

Simon Mak, Graduate Student, Georgia Institute of Technology, North Ave NW, Atlanta, GA, 30332, United States, smak6@gatech.edu

In this presentation, we introduce a new method for compacting a continuous distribution into a finite set of representative points, which we call support points. These points not only provide theoretical advantages over both Monte-Carlo (MC) and quasi Monte-Carlo (qMC) methods in integration, but can also be computed for any distribution in practice. To generate support points efficiently in high-dimensions, a blockwise coordinate descent algorithm is proposed which exploits closed-form majorization-minimization updates. Simulation studies and a real-world Bayesian example show that support points provide a sizable reduction in integration error compared to MC and qMC methods.

Networks in Healthcare

Sponsored: Manufacturing & Service Oper Mgmt, Healthcare Operations

Sponsored Session

Chair: Itai Gurvich, Kellogg School of Management, Evanston, IL, United States, i-gurvich@kellogg.northwestern.edu

1 - Network Effects In Epidemic Propagation

Kimon Drakopoulos, Massachusetts Institute of Technology, kimondr@mit.edu

In this paper we analyze data on the evolution and propagation of influenza across the United States and discover that compartmental epidemic models enriched with environment dependent terms have fair prediction accuracy, and that the effect of inter-state traveling is negligible compared to the effect of intra-state contacts.

2 - Distance, Quality, Or Relationship? Interhospital Transfer Of Heart Attack Patients

Lauren X Lu, Associate Professor, University of North Carolina, Chapel Hill, NC, United States, lauren_lu@unc.edu, Susan F Lu

We empirically investigate the pattern of where heart attack patients are transferred between hospitals. Our conditional logit analysis shows that the relationship of being affiliated with the same multihospital system plays a dominant role in the choice of transfer destinations, compared to distance and quality. When using 30-day readmission rate to evaluate the health outcome of transferred patients, we find that relationship-based transfers are associated with a much higher readmission rate than distance-based and quality-based transfers.

3 - Digital And Physical Team Interaction: How Team Size And Stability Determine Hospitalist Productivity

Jan A Van Mieghem, Northwestern University, vanmieghem@northwestern.edu, Itai Gurvich, Lu Wang, Nicholas D Soulakis

We present and empirically test a team evolution model of how team size and team stability determine the productivity of a focal member who acts as an information hub. In our healthcare field study, the focal member is a hospitalist that coordinates patient care among an extensive care team that comprises the patient's digital and the hospitalist's physical team. The physical team consists of care providers who interact directly (via phone, text, or face-to-face) with the hospitalist regarding the patient and whose activities we captured using a time and motion study. The digital team consists of providers that input information to the patient's Electronic Health Record (EHR).

4 - Market Failure in Kidney Exchange

Itai Ashlagi, Stanford University, Stanford, CA, iashlagi@stanford.edu

A market for kidney exchange has grown in recent years. Kidney exchange allows patient-donor incompatible pairs to swap donors. The number of transplants from kidney exchanges has grown to be 10% of live kidney donations in the U.S., but growth has stagnated in the last few years. Focusing on the U.S. market, we use administrative records to document that: (1) the market is fragmented across many competing exchange programs, (2) participants in the largest exchange program are adversely selected. (3) smaller exchange programs conduct inefficient exchanges. We propose a supply and demand model to explain how these outcomes can arise as equilibrium behavior, due to the social and private incentives of hospitals being misaligned. We use the model and data to develop simple and efficient alternative mechanisms.

Breakthroughs in Teaching Operations

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Ryan Buell, Harvard Business School, Soldiers Field Road, Boston, MA, 02163, United States, rbuell@hbs.edu

1 - The Use Of Technology To Improve Engagement Through Accountability

Gad Allon, Wharton School, Philadelphia, PA, 19010, United States, gadallon@wharton.upenn.edu

I will be discussing the use of technology to manage formative assessment before, during and after class, and improve learning in settings that encourage learning through discovery (case studies, exercises, etc). Specific attention will be given to teaching topics in operations management.

2 - Innovations In Teaching Operations Management At UCLA

Guillaume Roels, Anderson School of Management, UCLA, guillaume.roels@anderson.ucla.edu

In this presentation, I will review some recent innovations we have introduced at UCLA to make Operations & Technology Management one of the most popular courses in the core at UCLA. Some of these innovations are (i) striving to make the content more relevant to students, based on their job aspirations, (ii) structuring the class to deliver the best experience, and (iii) fostering student engagement.

3 - Architecting New Business Models (in the classroom)

Karan Girotra, INSEAD, karan.girotra@insead.edu

I will present a short summary of how we have redesigned MBA-level core and elective classes around the study of disruptive business models. These courses use traditional operations management tools to analyze and architect new business models. Pedagogically, we employ an experiential workshop format-participants identify and refine real-world disruptive business models.

4 - IDEO: Human-centered Service Design – Multimedia-enhanced Teaching And Learning

Ryan Buell, Harvard Business School, rbuell@hbs.edu

As technology matures, so does the demand for dynamic, media-rich educational content. "IDEO: Human-Centered Service Design" is a multimedia case study that focuses on the design thinking process at IDEO, one of the world's leading design firms. The case follows a team of IDEO designers as they reinvent the movie-going experience for the emerging middle class in Peru. During this session, I will demo the case, which can be successfully taught to undergraduates, MBA students, and executives. I will also discuss the lessons my colleagues and I have learned through teaching it, about how multimedia can enhance (or unwittingly detract from) the teaching and learning experience.

Emerging Issues in Supply Chain

General Session

Chair: Hyun-Soo Ahn", University of Michigan, Ann Arbor, MI, United States, hsahn@umich.edu

Co-Chair: Hakjin Chung, University of Michigan, 701 Tappan Avenue, Ann Arbor, MI, 48103, United States, hakjin@umich.edu

1 - On Multi-Attempt Approximation Of Choice Model And Its Application To Assortment Optimization

Hakjin Chung, University of Michigan, hakjin@umich.edu

It is known that any random-utility based choice model can be approximated to any degree of accuracy by a mixture of logits. We consider the problem of approximating an arbitrary mixture of logits with a series expansion. The degree of the expansion can be interpreted as the number of attempts that a customer is willing to make before leaving the system because his preferred product is not available. There are at least two benefits of using this approximation: the optimization problem becomes tractable and its parameters can be estimated using linear regression. We derive some bounds.

2 - Non-stationary Product Release Pattern

Lai Wei, University of Michigan, laiwi@umich.edu
Stefanus Jasin, Roman Kapuscinski

Companies continuously release new generations of products with new features to generate revenue and enlarge market share, especially in auto and software industry where customers are willing to pay for technology updates. One of the most widely adopted release strategy is a non-stationary mid-cycle strategy, where minor improvements follow a major improvement. Although people has been looking into the decisions in product release management, most of the works focus on trade-offs that do not lead to such non-stationary strategy. In this paper, we identify the main drivers to the non-stationary mid-cycle strategy and show the situations where such policy is optimal.

3 - Flexibility Design Of Unbalanced Supply Chains Via Extended Probabilistic Expanders

Hao Shen, Tsinghua University, Beijing, China, chenhao14@mails.tsinghua.edu.cn, Yong Liang, Zuo-Jun Max Shen

We study the design of flexible supply chains by finding sparse structures that perform almost as well as the fully flexible structure in unbalanced and symmetrical systems. We propose a class of sparse structures called extended probabilistic expanders, and show that our structures perform well in the expectation sense. We also present an efficient randomized algorithm to construct extended probabilistic expanders. We prove that for a mildly unbalanced system, our structure is the asymptotically sparsest design. Numerical results show that our design has good performance compared with varieties of known well-performing structures.

4 - Rationale For Supply Partnership With Downstream Rival: Information Asymmetry And Dual Sourcing

Seung Hwan Jung, Washingtn University in St. Louis, St. Louis, MO, United States, seunghwan.jung@wustl.edu

We consider the opportunities of horizontal cooperation at the component supply level between two firms that are rivals at the end-product market. We consider a two-echelon supply chain in which a vertically integrated (VI) firm sells a component to a component outsourcing (CO) firm that has private demand information. The VI firm has its own brand which competes with the CO firm's product. Under this circumstance, we characterize firms' sourcing and pricing decisions. We offer insights for supply partnership in horizontal outsourcing cases, with an emphasis on the complementary role of information asymmetry and dual sourcing.

Securing Sustainable Future

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Elena Belavina, University of Chicago Booth School of Business, Chicago, IL, United States, elena.belavina@chicagobooth.edu

1 - Grocery Access Market Structure And Food Waste

Elena Belavina, University of Chicago, elena.belavina@chicagobooth.edu

Access to grocery, or how dense is the network of retail stores in a neighborhood, varies extensively as a result of zoning laws and other city government initiatives. Similarly, some markets are dominated by one chain, while others have a high degree of competition with a lot of independent grocery stores. This paper studies how access to grocery stores, and the extent and nature of competition in the grocery retail market influences food waste.

2 - Pricing, Product Display, Inventory And Waste Management For Deteriorating Products.

Dorothee Honhon, University of Texas at Dallas, Richardson, TX, United States, dorothee.honhon@utdallas.edu Xiajun Amy Pan, Zumbul Atan

We consider the problem of a retailer managing the inventory and the prices of products whose quality deteriorates over time. We show that by appropriately displaying the most/least fresh products on the store shelves, the retailer can, in some cases, increase profits and reduce waste.

3 - The Impact Of Legislation on Food Waste

Alexandra Heeney, Stanford University, Stanford, CA, 9, United States, aheeney@stanford.edu, Warren H Hausman, Erica Plambeck

Worldwide, 30-40% of all food is wasted, which has a significant environmental impact: agriculture is responsible for 22% of all greenhouse gas emissions. This research explores whether California's AB32 and renewable energy legislation (that exempts farmers from carbon tax) increases the negative environmental impact of the food system (by preventing the true cost of food to propagate down the supply chain making food waste relatively inexpensive). Further, we study how the supply chain structure and design contribute to food waste and strategies for mitigating this.

4 - Design Implications Of Extended Producer Responsibility For Durable Products

Ximin (Natalie) Huang, Georgia Institute of Technology, 800 West Peachtree Street, NW, Atlanta, GA, 30308, United States, ximin.huang@scheller.gatech.edu, Atalay Atasu, Beril L Toktay

We consider a monopolist who has two product design options to manage the end-of-life costs/revenues associated with its products: making products more durable or recyclable. We explore how the recyclability and durability choices are affected by the requirements of take-back legislation.

Applied Probability and Machine Learning II

Sponsored: Applied Probability

Sponsored Session

Chair: Sewoong Oh, UIUC, 2011 Savanna Dr, Champaign, IL, 61822, United States, sewoong79@gmail.com

1 - Online Rules For Control Of False Discovery Rate

Adel Javanmard, Assistant Professor, University of Southern California, Bridge Memorial Hall, 3670 Trousdale Parkway, Los Angeles, CA, 90089, United States, ajavanma@marshall.usc.edu, Andrea Montanari

Multiple hypothesis testing is a core problem in statistical inference and arises in almost every scientific field. A common error criteria in this context is the false discovery rate (FDR). In this talk, we consider the problem of controlling FDR in an "online manner". Concretely, we consider an ordered, possibly infinite, sequence of null hypotheses where at each step the statistician must decide whether to reject current null hypothesis having access only to the previous decisions. We introduce a class of generalized alpha-investing procedures and prove that any rule in this class controls FDR in online manner. Time permitting, we will discuss applications for Ad click predictions and A/B testing.

2 - Newton Stein Method: An Optimization Method For Glms

Murat Erdogdu, Stanford University, erdogdu@stanford.edu

We consider the problem of efficiently computing the maximum likelihood estimator in Generalized Linear Models (GLMs) when the number of observations is much larger than the number of coefficients (n>>p>>1). In this regime, optimization algorithms can immensely benefit from approximate second order information. We propose an alternative way of constructing the curvature information by formulating it as an estimation problem and applying a Stein-type lemma, which allows further improvements through sub-sampling and eigenvalue thresholding. Our algorithm enjoys fast convergence rates, resembling that of second order methods, with modest per-iteration cost.

3 - Data-driven Rank Breaking For Efficient Rank Aggregation

Ashish Khetan, UIUC, Urbana, IL, United States, Khetan2@illinois.edu

Rank aggregation systems collect ordinal preferences from individuals to produce a global ranking. Rank-breaking is a common practice to reduce the computational complexity of learning the global ranking. The individual preferences are broken into pairwise comparisons and applied to efficient algorithm. However, naive rank-breaking approaches can result in inconsistent estimates. The key idea to produce accurate and unbiased estimates is to treat the pairwise comparisons unequally, depending on the topology of the collected data. In this paper, we provide the optimal consistent rank-breaking estimator. This allows us to characterize the trade-off between accuracy and complexity.

4 - On The Capacity Of Information Processing Systems

Kuang Xu, Stanford University, Stanford, CA, United States, kuangxu@gmail.com, Laurent Massoulie

We analyze a family of information processing systems, where a finite set of experts or servers are employed to extract information about a stream of incoming jobs, each associated with a hidden label. An inspection by an expert produces a noisy outcome that depends both on the job's hidden label and the type of the expert, and occupies the expert for a finite time duration. A decision maker's task is to dynamically assign inspections so as to accurately recover all job labels while keeping the system stable. Crowdsourcing, diagnostics and experiment designs are among our chief motivations. Our main result is an asymptotically optimal inspection policy that utilizes the fewest experts.

Supply Chain/ Inventory in Applied Probability I

Sponsored: Applied Probability

Sponsored Session

Chair: Yehua Wei, Duke University, Durham, Durham, NC, 27708, United States, yehua.wei@duke.edu

1 - Online Resource Allocation With Limited Flexibility

Arash Asadpour, NYU Stern, New York, NY, 10012, United States, aasadpou@stern.nyu.edu, Xuan Wang, Jiawei Zhang

We consider a class of online resource allocation problems in which there are n types of resources with limited initial inventory and n demand classes. In this paper, we focus on a special class of structures with limited flexibility, the long chain design, which was proposed by Jordan and Graves (1995) and has been an important concept in the design of sparse flexible processes. We show the effectiveness of the long chain design in mitigating supply-demand mismatch under a simple myopic online allocation policy. In particular, we provide an upper bound on the expected total number of lost sales that is irrespective of how large the market size is.

2 - Inventory Management For Assemble To Order Systems With General Bill Of Materials And Deterministic Lead Times

Qiong Wang, University of Illinois at Urbana - Champaign, qwang04@illinois.edu, Martin I Reiman, Haohua Wan

We study inventory management for minimizing the long-run average cost in Assemble-to-Order inventory systems. In our previous work, we have developed a stochastic programming based approach that gives rise to a lower bound on the cost objective, and for systems with identical lead times, asymptotically-optimal replenishment and allocation policies. Here we generalize our policies to prescribe a complete solution for systems with general Bill of Materials and general deterministic lead times. Our discussions focus on the design of a novel replenishment policy for the general case and asymptotic optimality of the entire approach.

3 - Managing Multi-period Production Systems With Limited Process Flexibility

Yuan Zhong, Columbia University, 500 W. 120th St., Mudd 344, New York, NY, 10027, United States, yz2561@columbia.edu Cong Shi, Yehua Wei

We develop a theory for the design of process flexibility in a multi-period production system. We propose and formalize a notion of “effective chaining” termed the Generalized Chaining Condition (GCC). We show that any partial flexibility structure that satisfies GCC is near-optimal under a class of policies called the Max-Weight policies. Furthermore, we show that GCC can be satisfied using just k arcs, where k is the equal to the number of products plus the number of plants.

4 - A Joint-replenishment System With Convex Purchase Costs

Paul H Zipkin, Duke University, Paul.Zipkin@Duke.edu

We consider the problem of replenishing inventories of several items facing stochastic demands, where the order cost is jointly convex, representing diseconomies of scale such as capacity limits. We want to find a good policy and also to understand the qualitative behavior of the system. To these ends, we show that the system enjoys a property called M-natural-convexity. This is a powerful analytical tool, but it poses some technical challenges.

Systemic Risk and Financial Networks

Sponsored: Financial Services

Sponsored Session

Chair: Agostino Capponi, Columbia University, New York, NY, United States, ac3827@columbia.edu

Co-Chair: Agostino Capponi, Columbia University, New York NY, United States, agcappo@gmail.com

1 - An Empirical Analysis Of The Centrally Cleared Credit Default Swaps Market

W. Allen Cheng, Columbia University, 500 W 120th st, 333 Mudd, New York, NY, 10027, United States, wc2232@columbia.edu

In this talk we present an empirical analysis of regulatory Credit Default Swaps data collected by the U.S. Commodity Futures Trade Commission according to Title 17 Chapter 1 part 39 of the Code of Federal Regulations. We discuss salient features of traded contracts, open positions, and margin posting. We also investigate feedback effects in price volatility and intraday margin calls.

2 - Systemic Risk And Liquidity Provision

Xu Sun, Columbia University, xs2235@columbia.edu, Agostino Capponi, David D Yao

We introduce an interbanking network model in which banks interact with each via borrowning/lending transactions, and can be assisted by a regulator who injects capital into the system to prevent insolvency. The regulated system follows a reflected multi-dimensional Ornstein-Uhlenbeck process with state dependent drift coefficient. We investigate how the concentration of interbanking activities affects the earliest intervention time as well as the market concentration, i.e the heterogeneity of asset value in the system.

3 - Systemic Risk Under Heterogeneous Beliefs

Benjamin Bernard, Columbia University, bb2794@columbia.edu Agostino Capponi

We consider an interbank network of bilateral exposures, where each bank only knows its own contracts but not the exposures between other pairs of banks. Defaults are costly and may lead to financial contagion that spreads through the network. We model this spread of insolvency as a dynamic game, where banks have the ability to intervene and join a rescue consortium to save the insolvent banks. Banks will do so only if an intervention is incentive compatible given their beliefs on the network. We analyze the set of sequential equilibria in these games with heterogeneous beliefs and contrast the results to the equilibrium outcomes with complete information.

4 - Model Risk In Financial Networks

Peng-Chu Chen, Purdue University, West Lafayette, IN, United States, chen621@purdue.edu, Agostino Capponi

We introduce a financial network model which accounts for uncertainty in the interbank liabilities. We define the systemic loss uncertainty as the difference between the maximum and minimum loss in the financial system. We investigate how the level of interbank intermediation in the financial system impacts systemic loss uncertainty. Our findings indicate the existence of a threshold above which higher intermediation reduces both systemic loss and the resulting uncertainty. When the intermediation level falls below, further increases reduce the minimum and maximum loss, but this comes at the expenses of higher uncertainty in the loss outcome.

Decision Analysis, Game Theory, and Disaster Management I

Sponsored: Decision Analysis

Sponsored Session

Chair: Jun Zhuang, University at Buffalo, SUNY, Buffalo, NY, United States, jzhuang@buffalo.edu

Co-Chair: Jing Zhang, University at Buffalo, SUNY, Buffalo, NY, United States, jzhang42@buffalo.edu

1 - Linear Programming Input Output Models For Energy Resilience

Adam Ng Tsan Sheng, National University of Singapore, isentsa@nus.edu.sg

We develop an approach to study the energy supply resilience of an economy using linear programming and economic input-output analysis. In particular, we propose an energy resilience index by examining the maximum level of energy supply reduction that the economy can endure without sacrificing domestic demands. A mixed integer model is developed to compute the resilience index efficiently. The methodology is applied to a case study using China data to study the energy resilience under different generation portfolio assumptions. We demonstrate how our models can be used to uncover important inter-sectoral dependencies. Extensions of the approach to include recovery effects are also presented.

2 - Agent-based Modeling For Resilience Of Disaster Recovery

Fei He, Texas A&M University, Kingsville, Kingsville, TX, United States, Fei.He@tamuk.edu, KumareshBabu Murugesan

Disaster recovery involves multiple stakeholders and various uncertainties associated with environment and community behaviors. This research use agent-based modeling and game theory to investigate the uncertainty and interdependence in the household and business for disaster recovery. The effects of disaster mitigation, and stake holders' learning capability to disaster recovery are investigated.

3 - Modeling Fire Risk And Resource Allocation For Fire Protection And Safety

Vineet Madasseri Payyappalli, PhD Student, University at Buffalo, SUNY, Buffalo, NY, United States, vineetma@buffalo.edu, Adam Behrendt, Jun Zhuang

Fire-related hazards are an everyday phenomenon, and firefighting in the United States owe to more than one million firefighters in about 30,000 fire departments across the country. The estimated total cost of fire was $329 billion in 2011, and yet there is little work in the literature about risk assessment, cost-benefit analysis, and resource allocation in fire protection. Using a data-driven study, we propose empirical and theoretical models to assess risk levels and develop risk-reduction strategies that include optimal resource allocation, optimal facility design, and optimal routing solutions.

4 - Crisis Information Distribution Among Official Users In Twitter Based On Hurricane Sandy

Bairong Wang, University at Buffalo, The State University of New York, 338 Bell Hall, Buffalo, NY, 14260, United States, bairongw@buffalo.edu, Jun Zhuang

Our study analyzes how crisis information about Hurricane Sandy is distributed from official Twitter accounts to the common Twitter users based on 6 social media key performance indicators (KPIs). Our results show that (a) the six KPIs are significantly different among governmental organizations (GOs), non-governmental organizations (NGOs) and news agent users; (b) the networks formed by mention and re-tweet are effective methods to reach more public members; (c) the information coverage could be expanded to more stakeholders in disaster scenario; (d) distributing speed is faster among networks formed by news agent users than GO and NGO users.

Chair: Melissa A Kenney, University of Maryland, College Park, MD, United States, kenney@umd.edu

1 - Robust Decision Making Methods For Water Resource Management Under Climate Change Uncertainty

Seth Guikema, University of Michigan, sguikema@umich.edu, Julie Shortridge, Ben D Zaitchik

Water resource systems must be managed under deep, long-run uncertainty about the impacts of climate change on water quantity and quality in a given basin. Standard approaches for decision making under uncertainty have limitations in this context. We summarize work done to further develop an alternative approach, based on the Robust Decision Making method (RDM). RDM seeks not to find the optimal solution to a given management problem but to find solutions that are robust in the sense of doing well under a wide range of future conditions. We demonstrate the method with an application to water resource management in the Lake Tana basin.

2 - Multi-criteria, Interactive Optimization For Design Of Watershed Plans

Andrew Hoblitzell, Indiana University Purdue University Indianapolis, Indianapolis, IN, 46202, United States, ahoblitz@umail.iu.edu, Meghna Babbar-Sebens, Snehasis Mukhopadhyay

Multi-objective optimization has yielded numerous algorithms for design of solutions to real-world planning problems. The inclusion of decision makers (DMs) within the optimization algorithm's search process, especially for planning problems with DM-specific, subjective, qualitative, and/or unquantifiable criteria, has gained interest recently. Our work focuses on modifications made to our existing watershed planning decision support system, called WRESTORE. Interactive genetic algorithms and reinforcement-based machine learning algorithms are used for search and optimization, while neural networks and other methods are utilized for the modeling of human users' criteria.

3 - Using Visualization Science To Diagnose And Improve Global Change Indicator Understandability

Michael D Gerst, University of Maryland, mgerst@umd.edu Melissa A Kenney

Indicators are variables that stakeholders believe summarize relevant trends. They have become an increasingly important part of continuous assessment of global environmental change. For indicators to be effective, they need to be understood by diverse audiences. Using visualization science, we have diagnosed and redesigned a set of global change indicators, showing how simple visual changes can lead to large improvements in understandability.

4 - Understanding Homeowner Decisions On System Configuration For Parcel Level Storm Water Management

Royce Francis, George Washington University, seed@email.gwu.edu, Domenico C Amodeo

A common problem faced by many older U.S. cities is the management of storm water to prevent the over flow of sewage and pollutants into local waterways. Many cities have addressed this problem through grey infrastructure improvements, as well as promoting low impact development (LID) on private and public property. Previous researchers have proposed models for assessing optimal LID installations and predicting consumer behavior in response to incentives. We explore what an optimal storm water management program would look like in light of these models, with the high level aim of learning best practices in system configuration from observing consumer choices.

1 - Agent-based Modeling And Simulation – Overview

Charles M Macal, Argonne National Laboratory, macal@anl.gov

Agent-based modeling and simulation (ABMS) is an approach to modeling systems comprised of autonomous, interacting agents. Applications are growing rapidly in fields ranging from modeling the stock market to predicting the spread of epidemics. Complex adaptive systems, emergent behavior, and self-organization are a few of the notions from ABMS. This session provides an overview of ABMS, covers its foundations, development toolkits and methods, practical aspects, and the relationship of ABMS to conventional OR. Key ABMS resources, publications, and communities are identified. It concludes by suggesting research challenges to advance the field of ABMS for the coming years.

Pricing, Revenue Management and Operations in Retailing

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Mehmet Sekip Altug, Assistant Professor, George Washington University, 2201 G. Street, NW, Washington, DC, 20052, United States, maltug@gwu.edu

1 - Assortment Optimization Under A Synergistic Version Of The Multinomial Logit Model

Venus Lo, Cornell University, Ithaca, NY, United States, vhl8@cornell.edu, Huseyin Topaloglu

We consider the revenue management problem of offering an optimal subset of goods when there are product synergies. The traditional multinomial logit choice model suffers from Independence of Irrelevant Alternatives and offering a larger subset must decrease each goods' choice probabilities. Our synergistic model has a similar structure but offering selected pairs of goods together can boost their choice probabilities. In the special case where synergy exists in a linear fashion, we provide an efficient dynamic program and show that the optimal subset can be found in one step by solving a simple linear program.

2 - Reining In Onion Prices By Introducing A Vertically Differentiated Substitute: Models, Analysis, And Insights

Muge Yayla-Kullu, Associate Professor, University of Central Florida, Orlando, FL, United States, mugeyayla@hotmail.com
Omkar D Palsule-Desai, Nagesh Gavirneni

We examine the pricing ordeal in India's onion markets caused by the fresh produce traders. As a remedy, policy makers have been proposing to establish processed produce competition in the market by either cooperatives or private firms. We formulate and analyze this situation in a mathematical model that captures (i) competition between non-profit and for-profit organizations, (ii) consumers' valuation discount for the processed produce, and (iii) perishability of the fresh produce. We identify and discuss the conditions under which (i) it is optimal to introduce the processed produce; and (ii) the processed onion should be managed by cooperatives instead of private firms.

3 - Impact Of Encroachment When Competing Manufacturers Sell Through A Common Retailer

Parshuram Hotkar, Doctoral Student, University of Texas, Austin, University Station, B6500, Austin, TX, 78712, United States, parshuram@utexas.edu, Steve Gilbert

We consider a setting in which two manufacturers sell partially substitutable products through a common retailer, and examine the impact of the development of a direct sales channel for one of the manufacturers. We find that the retailer's ability to purchase from another manufacturer can alter many of the results that have been obtained for how encroachment affects the interactions between a manufacturer and a retailer. In addition, we find that the non-encroaching manufacturer can benefit from his rival's direct channel.

4 - Effectiveness Of Targeted Return Management On Retailer's Profitability

Tolga Aydinliyim, Assistant Professor, Baruch College, CUNY, New York, NY, United States, Tolga.Aydinliyim@baruch.cuny.edu
Mehmet Sekip Altug

As retailers offer more flexible return policies, customer abuse and fraudulent returns are also on the rise. In order to combat that situation, instead of changing the return policies for everyone, retailers started to implement a tool that identifies those "renters". In a price-setting newsvendor framework, we first study the retailer's uniform return policy in which the retailer offers the same return policy to everyone; then we study a targeted return policy where the retailer identifies the renters segment and offers a different return policy to that segment. We argue how and when targeted return management leads to improvement in retailer's profitability.

Optimizing Pricing for Multiple Substitutable Products

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Candace Arai Yano, University of California-Berkeley, IEOR Dept. and Haas School of Business, Berkeley, CA, 94720, United States, yano@ieor.berkeley.edu

1 - Dynamic Pricing And Replenishment Of Vertically Differentiated Products With Customer Upgrades

Oben Ceryan, Drexel University, Philadelphia, PA, 19104, United States, oceryan@drexel.edu, Izak Duenyas, Ozge Sahin

We study the impact of product upgrades on a firm's pricing and replenishment policies by considering a multiple period, two-stage model where the firm first sets prices and replenishment levels, and after observing the demand, it decides whether to upgrade any customers to a higher quality product. We characterize the structure of the optimal upgrade, pricing, and replenishment policies and find that offering upgrades assists in preserving the vertical price differentiation between products.

2 - Dynamic Pricing Of Vertically Differentiated Products With Sales Milestones

Chi-Guhn Lee, University of Toronto, chi@mie.utoronto.ca, Sajjad Najafi

We study the dynamic pricing of multiple substitutable products over a finite horizon subject to sales milestone constraints. Customers are utility maximizer and consider the relative importance between the price and the quality of product. We formulate the problem as a Markov decision process with probabilistic constraints and relax the constraints following the Lagrangian relaxation to apply KKT conditions. The proposed model is specifically suitable for applications in which the achievement of sale targets plays a crucial role for managers such as residential real estate sales and penetration strategy.

3 - Optimizing Pricing For Multiple Substitutable Products

Kevin Li, University of California - Berkeley, kbl4ew@berkeley.edu

We address a retailer's problem of setting prices, including promotion prices, over a multi-period horizon for substitutable products within a category, considering the effects of reference prices on customers' strategic buying behavior, including stockpiling. We utilize an embedded model in which customers make purchasing and consumption decisions over multiple periods to maximize utility. We present structural results and examples that provide insights into the properties of optimal policies.

4 - Pricing Two Substitutable Products With Limited Demand Information

Zhi-Long Chen, Professor, University of Maryland, 691 Market Street East, College Park, MD, 20742, United States, zchen@rhsmith.umd.edu, Ming Chen

We consider a practical dynamic pricing problem with two substitutable products involving a number of business rules and constraints commonly seen in practice. There is limited demand information. A case with inter-product substitution only, and a case with both inter-product substitution and intertemporal substitution are studied. We propose DP algorithms for both cases, and for the latter, more general, case, we develop a fully polynomial time approximation scheme. We derive a number of managerial insights.

Social Media Analytics for Business Applications

Invited: Social Media Analytics

Invited Session

Chair: Yuheng Hu, University of Illinois-Chicago, 601 S Morgan St, Chicago, IL, 60607, United States, yuhenghu@gmail.com

1 - Content Complexity, Similarity, And Consistency In Social Media: A Deep Learning Approach

Gene Moo Lee, University of Texas at Arlington, Arlington, TX, United States, gene.lee@uta.edu
Donghyuk Shin, Shu He, Andrew B Whinston

We investigate the effect of social media content on customer engagement using company-generated posts from Tumblr. We employ state-of-the-art machine learning approaches to extract features from textual and visual sources that effectively capture their semantics. With such semantic representations, we develop novel complexity, similarity, and consistency measures of social media content. The results show that proper visual stimuli, complementary textual content, and consistent themes have positive effects on the engagement, and that content demanding significant concentration levels have the opposite effects. This work shows how unstructured data can be translated into insights.

2 - Does Twitter Sentiment Move Stock Prices: Evidence From An Event Study Of The Amsterdam Exchange

Yixin Lu, George Washington University, yixinlu@gwu.edu

The tremendous amount of information that accumulates and propagates via social media has profound impact on individual businesses as well as the entire market environment. This research focuses on the impact of twitter sentiment on leading stocks traded on the Amsterdam Exchange. By combining event study and sentiment analysis, we demonstrate that twitter peaks are strongly associated with abnormal returns. However, such association is asymmetric with respect to the valence of the sentiment.

3 - Patient Base And Price Premium For Online Health Consultations

Liwei Chen, University of Cincinnati, vivienclw@gmail.com, Arun Rai, Xitong Guo

Online health consultation communities (OHCCs) enable physicians to signal professional competence and compassionate care for patients, and allow patients to spread online reviews with peer patients. We examine the interactions between the signaling and online feedback mechanisms that explain how physicians build trust with patients and gain social and economic advantages in healthcare services. We scraped multilevel data and traced physicians biweekly over one year from an OHCC in China. Using mixed effects modeling, we find interesting interaction effects between trustworthiness signals and properties of feedback on online patient base and price premium.

1 - NLP, LDA, SMERT, k-Means And Efficient Estimation Methods

Zhenhuan Sui, Ohio State University, sui.19@osu.edu

We describe some of our recent advances in more efficient estimation for text-based clustering and topic discovery. Also, we illustrate the capability of VBA code for text processing and benchmark popular methods including k-means clustering and Latent Dirichlet Allocation in terms of computational efficiency and accuracy.

2 - Innovative Scheduling And Kriging-Based Optimization Methods In VBA

Sayak Roychowdhury, Ohio State University, rowchowdhury.6@osu.edu

A suite of techniques for scheduling and simulation optimization is described based on VBA and our own innovations. Results showing improved performance compared with alternatives for scheduling and inventory policy-making are described. Possible roles for the methods support social media analytics are also described.

3 - Cybersecurity Using Interdiction

Murat Karatas, University of Texas, Manor Road, Austin, TX, 78722, United States, mkaratas@utexas.edu, Nedialko Dimitrov

Recent cyber-attacks on private and public groups highlight the importance of a proper cybersecurity structure. Having well-structured cybersecurity decreases the vulnerability of the system. We present a network interdiction model to find the optimal strategy for a cyber physical network. Our model considers the specifics of the network structure.

New Models in Criminology

Sponsored: Public Sector OR

Sponsored Session

Chair: Lawrence Wein, Stanford University, 655 Knight Way, Stanford, CA, 94305, United States, lwein@stanford.edu

1 - Machine Learning For Crime Series Detection And Criminal Recidivism Prediction

Cynthia Rudin, Duke University, LSRC Building D101, 308 Research Drive Campus Box 90129, Durham, NC, 27708-0129, United States, cynthia@cs.duke.edu, Berk Ustun, Tong Wang

I will discuss machine learning algorithms for two problems: crime series detection, and recidivism prediction. In crime series detection, the goal is to identify crimes that were committed by the same individual(s). We cast this as a clustering problem with cluster-specific feature selection, in joint work with the Cambridge Police Department. The recidivism prediction problem is cast as a supervised classification problem, where the goal is to produce a scoring system, which is a sparse linear model with integer coefficients. This work was a finalist in the 2015 Doing Good with OR competition, and part of the winning entry of the 2016 Innovative Applications in Analytics Award.

2 - Optimizing Ballistic Imaging Operations

Can Wang, Stanford University, Stanford, CA, United States, canw@stanford.edu, Mardy Beggs-Cassin, Lawrence M Wein

Ballistic imaging can solve crimes by comparing images of cartridge casings to a database of images from past crimes. Many cities lack the capacity to process all of their images. Using data from Stockton, CA, we allocate limited capacity to maximize the hit rate. The hit rate can be doubled by giving crime scene evidence priority over test fires, and ranking cartridge types by their hit rate and processing evidence from only top-ranking cartridge types.

3 - Using Informed Heuristics For Pretrial Release

Jongbin Jung, Stanford University, jongbin@stanford.edu

We present a simple and intuitive strategy for creating statistically informed decision rules that are easy to apply and easy to understand, in the context of pretrial release. These simple informed heuristics take the form of a weighted check list and can be applied without the aid of a computer, but perform on par with state-of-the art machine learning methods. The rules can be readily constructed with moderate statistics knowledge using common and freely available software packages, facilitating adoption by practitioners in a wide array of fields.

4 - Assessing Risk-based Policies For Pretrial Release And Split Sentencing In Los Angeles County Jails

Lawrence Wein, Stanford University, lwein@stanford.edu Mericcan Usta

Court-mandated downsizing of the CA prison system has led to overcrowding in CA jails. We model the flow of individuals in the Los Angeles County jail system, from arraignment through post-sentence supervision. We optimize joint pretrial release and split-sentencing policies that are based on the type of criminal charge and the risk category as determined by the CA Static Risk Assessment tool. Policies that offer split sentences to all low-level felons optimize the trade-off between public safety and jail congestion.

Recent Developments in Humanitarian Logistics

Sponsored: Public Sector OR

Sponsored Session

Chair: Kezban Sokat, Northwestern University, 2145 Sheridan Road, Room C210, Evanston, IL, 60208, United States, kezban.yagcisokat@u.northwestern.edu

1 - The Vaccination Campaign Routing Problem

Melih Celik, Middle East Technical University, Ankara, Turkey, cmelih@metu.edu.tr, Bahar Cavdar, Haldun Sural

This study considers the routing of vaccination campaigns in developing country settings, where a team selects from a set of regions to visit and sequences these visits, subject to special time window constraints. The objective is to maximize the total number of people reached. A two-stage heuristic is proposed, where the first stage solves a b-matching problem to determine the regions to visit each day, whereas the second stage solves a modified orienteering problem to determine the routes.

2 - Cash, Vouchers Or In-kind Aid: A Game Theory Approach To Determine Optimal Aid Transfers

Christos Bitos, Kühne Logistics University, Hamburg, Germany, Christos.Bitos@the-klu.org, Maria Besiou

This research aims to determine the conditions for optimal aid transfers in the aftermath of a disaster or during a long-term development program. By using the principles of game theory, we consider the strategic interactions between Humanitarian Organizations (HO) and local markets, and discern how these interactions affect the distribution of aid to communities. We consider the effects of local market supply chain fluctuations, and how the market fluctuates in response to local and national crises. Ultimately, we hope to develop a framework to contextualize the intricacies of humanitarian relief distribution that can be applied broadly.

3 - An Agent-based Modeling Approach To Assess Coordination Among Humanitarian Relief Providers

Jessica Heier Stamm, Kansas State University, Manhattan, KS, United States, jlhs@k-state.edu, Megan Menth

Coordination between humanitarian organizations during disaster response may improve efficiency, reduce duplication of efforts, and lead to better outcomes for beneficiaries. We employ agent-based simulation to examine coordination strategies among humanitarian organizations that make post-disaster location decisions regarding temporary service facilities. For example, over 4,000 temporary learning facilities were needed after the 2015 Nepal earthquakes damaged or destroyed numerous school buildings. Our model is informed by data from the Nepal response and a survey of humanitarian professionals. We find that coordination strategies impact efficiency, effectiveness, and equity.

4 - Real-time Data In Humanitarian Response

Kezban Yagci Sokat, Northwestern University, kezban.yagcisokat@u.northwestern.edu, Irina Dolinskaya, Karen Smilowitz

State of the art humanitarian logistics models have been developed over the past decades. Most of these models assume availability of data. We study the impact of granularity in real time data on the humanitarian logistics models. We show that in the limited data environment higher granularity might lead better results.

Decision Analytics for Technology Management

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Tugrul Daim, Professor, Portland State University, Engineering and Technology Management Department, P.O. Box 751, Portland, OR, 972070751, United States, ji2td@pdx.edu

1 - GPS For Innovation

Jianxi Luo, Singapore University of Technology & Design, luo@sutd.edu.sg

Engineers, firms or governments continually explore innovation opportunities and roadmaps. However, related activities and decisions are traditionally based on intuition or experiences. InnoGPS is developed to provide scientifically-grounded and data-driven support for decisions regarding innovation directions. It integrates an empirical network map of technologies that represent the total technology space, and various map-based functions that allow users to navigate through the technology space, locate themselves, explore technologies within and across neighborhoods, and identify capability-building paths. InnoGPS is a "GPS for Innovation" in the technology space.

2 - Integrating Bibliometrics And Social Network Analysis For Identifying Knowledge Sources

Tugrul U Daim, Portland State University, ji2td@pdx.edu, Edwin Garces

At an era when technologies are developing rapidly, decision making becomes even more challenging. However data analytics have shown that data can be used effectively to help decision making in such environments. Several management strategies for technological innovations require expert judgments and thus making the expert identification very crucial. This paper integrates SNA and Bibliometric Analysis to determine the lead authors and their network. The main objective of this paper is to present cases from the power sector where this method was used to identify experts for applications such as technology roadmapping or forecasting.

3 - Evaluating Research Centers: Case Of NSF's I/URUC Program

Elizabeth Gibson, Portland State University, 14396 SW Pennywort Ter, Tigard, OR, 97224, United States, elgibson@pdx.edu

This research is focused on gaining deeper insights into US National Science Foundation (NSF) science and engineering research center challenges and motivated to develop a method that effectively measures the performance of these organizations. While research has addressed organizational performance at the micro, or single-actor level for universities or companies and at the regional or national macro level, the middle level where the NSF centers reside is largely missing. The bulk of the cooperative research center studies use either case-based methods or bibliometric data to measure traditional research outputs. Many are excellent studies; however, they only focus on a piece of the performance measurement problem. There is a need for more research to understand how to measure performance and compare performance of cooperative research centers formed in a triple-helix type partnership involving government, industry and academia.

4 - Design Support Of Salient Research Project By Integrated Approach Of Text And Citation Analysis

Yuya Kajikawa, Tokyo Institute of Technology, kajikawa@mot.titech.ac.jp

Bibliometrics has been a powerful tool to comprehend the current status and to analyze R&D trends but most of approach is descriptive. We proposed alternative approach to design salient research project by integrating citation analysis with text analysis. Explicit research cluster is extracted by citation relationships and implicit potential ones are by text analysis. This approach can help to find neglected opportunities between different research domains. This approach can also visualize plausible path how academic can contribute to development of industrial technology and to solve social issues. Efficiency and effectiveness of the approach are demonstrated in case studies.

Analytics and Operations Research for the IT Services Industry

Sponsored: Service Science

Sponsored Session

Chair: Aly Megahed, IBM Research - Almaden, 650 Harry Road - Office D3-428, San Jose, CA, 95120, United States, aly.megahed@us.ibm.com

1 - Maximum Accuracy Is Not Always Optimal

Ray Strong, IBM, San Jose, CA, United States, hrstrong@us.ibm.com, Aly Megahed, Janet Blomberg, Pablo Pesce, Yasuharu Katsuno, Sunhwan Lee

The optimal features of a machine learning classifier or prediction model depend on the users of the analytics results. When the users have responsibility for acting on the results, as in the case of a sales force for cloud services, it is often more important to produce simple, understandable, and credible rules than to optimize for best prediction accuracy.

2 - An Optimization Approach To Revenue Forecasting In Multi-Staged Sales Pipelines

Aly Megahed, IBM, San Jose, CA, United States, aly.megahed@us.ibm.com, Peifeng Yin, Hamid Reza Motahari Nezhad

Services organizations manage a pipeline of sales opportunities with variable engagement lifespans and contract values. Accurate forecasting of contract signings by the end of a time period (e.g., a quarter) is vital for such organizations to effectively manage the pipelines. We present a machine learning framework for this problem and introduce a novel nonlinear optimization approach for finding the optimized weights of a sales forecasting function. Our model also optimally determines the number of historical periods to use within the framework. We present a linear alternative model to the aforementioned model and present numerical results that show the superior performance of our method.

3 - Value Of Integrated Travel Data To The Organization Productivity

Pawan Chowdhary, Senior Research Engineer, IBM Research, 650 Harry Road, E3-238, San Jose, CA, 95120, United States, chowdhar@us.ibm.com, Guangjie Ren, Raphael Arar

In large enterprise, travel is integral part to meet customers, attend events and to deliver services. But travel data is fragmented from planning a trip to expense submission due to the sourcing from multiple vendors at each stage. We can derive greater value by learning from the booking and spend patterns, and leverage analytics for advanced booking, to negotiate better cost with vendors, identify market with short term demand forecast, etc. which can bring ten's of millions of cost savings. We will present our findings and analysis used to derive the savings and productivity enhancement.

1 - Resource Balancing In Intermodal Freight Networks

Amirali Ghahari, University of Arkansas, 4116 Bell Engineering Center, Fayetteville, AR, 72701, United States, aghahari@uark.edu, Edward A Pohl

Freight transportation networks provide a system to move containers that are filled with goods from one point to another. These movements are the main source of profit for companies. When each node in a network does not have equal number of incoming and outgoing containers, some nodes will have surpluses while shortages occur at others. This fact causes accumulation of containers at a few nodes in the network and shortages at others which would shut down the transportation network. To resolve this, operators should perform rebalancing moves. This research examines the planning problem to balance resources in an intermodal transportation network for one of the major transportation companies in the US.

2 - A Modified Age Replacement Model

Maryam Hamidi, University of Arizona, mhamidi@email.arizona.edu

The classical age replacement model is revisited when the scheduled arrival time of the replacement is also a decision variable in addition to the scheduled preventive replacement time. The equipment is replaced as scheduled unless it breaks down earlier, in which case replacement is performed immediately. If the replacement arrives before it is needed, then inventory cost arises, and if it is not available when needed then shortage cost of delayed production is the loss of the company. The production cycle is repeated without any change, therefore the expected net cost per unit time is computed by renewal theory. The existence of finite optimum is proved and the computer method is introduced to find it.

3 - Maximizing Availability In Operations And Maintenance Planning Of Airline Fleet

Javad Seif, Graduate Research Assistant, University of Tennessee-Knoxville, Tullahoma, TN, 37388, United States, jseif@utk.edu, Andrew Junfang Yu

In this paper, operations and maintenance planning (OMP) is modeled as a mixed-integer linear program with a case study in the airline industry. The objective is to maximize the availability of a fleet of aircraft over a planning horizon subject to their operations and maintenance requirements. An existing flight and maintenance planning (FMP) model is significantly extended by generalizing it to an OMP model, which makes the model more practical and suitable for a wider range of applications in both manufacturing and service industries.

Economics of IS in the Age of Big Data

Sponsored: EBusiness

Sponsored Session

Chair: Wael Jabr, Georgia State University, 35 Broad Street, Robinson College of Business, Atlanta, GA, 30303, United States, wjabr@gsu.edu

1 - Antecedents And Consequences Of Information Augmentation In Make-to-order Electronic Supply Chain

Ling Xue, Georgia State University, lxue5@gsu.edu
Arun Rai, Peijian Song, Cheng Zhang

In this study, we consider a phenomenon of information augmentation: in addition to passing the demand information from the consumers to the supplier, the retailer generates ad hoc coordination information to direct the order-fulfilment processes at the supplier side. Using transaction-level data from an international make-to-order supplier chain, we find that information augmentation is positively associated with product customization level and negatively associated with supplier relationship. We also find that information augmentation leads to higher fulfilment costs and lower probabilities of product return, and higher net profits for the retailer.

2 - Opening The Black Box: The Impact Of Telehealth And Latent Health Status On Patient Readmissions

Sezgin Ayabakan, The University of Baltimore, Baltimore, MD, 21201, United States, sayabakan@ubalt.edu
Indranil R Bardhan, Zhiqiang Eric Zheng

We investigate the effect of unobserved patient health status on patient readmission rates and the impact of telehealth on patient health status. We implement a hidden Markov model with a large, inpatient panel dataset of Congestive Heart Failure patient visits along with the American Hospital Association IT Supplement data. We reveal latent health states of patients and find that telehealth exerts a positive impact only on patients in less healthy states, while this impact diminishes as patients' health improves. These results suggest that focusing solely on readmission rates can be misleading, without regard to patients' health status.

3 - Leveraging Customer Feedback Through App Reviews

Kambiz Saffarizadeh, Georgia State University, Atlanta, GA, United States, ksaffarizadeh1@Student.gsu.edu, Wael Jabr, Mark Keil

Online app markets (e.g. Apple App Store) exhibit heavy customer engagement in the form of reviews that could help software developers adjust to user needs and become more competitive in crowded app markets. Using a panel dataset on 12,231 apps and document similarity methods, we develop a model that relates app success to developers' integration of user feedback.

4 - Crisis Management Of Customer Sentiments In Social Media: Empirical Study

Kyungsun Rhee, University of Washington, 4725 24th Avenue NE, # 405, Seattle, WA, 98105, United States, ksr22@uw.edu

In this paper, we will examine how firms strategically bundle news reports in order to intervene diffusion patterns of negative sentiments in social media after the event occur in companies. By conducting text mining and estimating unique data set on Twitter empirically, this paper will contribute to literature by providing managerial insights of ways to control social media.

Invited: The George B. Dantzig Dissertation Prize

Invited Session

Chair: Henri Groenevelt, University of Rochester, W. E. Simon Graduate School of Business Administration, Rochester, NY, 14627, United States, groenevelt@simon.rochester.edu

1 - Dynamic Monitoring And Control Of Irreversible Chronic Diseases With Application To Glaucoma

Pooyan Kazemian, Harvard Medical School, Boston, MA, United States, pooyan.kazemian@mgh.harvard.edu

To effectively manage chronic disease patients, clinicians must know (1) how to monitor each patient (i.e., when to schedule the next office visit and which subset of tests to take), and (2) how to control the disease (i.e., what levels of controllable risk factors will sufficiently slow disease progression). Our research addresses these questions simultaneously and provides the optimal solution to a novel linear quadratic Gaussian state space model. Glaucoma is discussed as a case study.

2 - Multiple Criteria Decision Engineering To Support Management In Military Healthcare And Logistics Operations

Nathaniel D. Bastian, Pennsylvania State University, 137 Arbor Bluff Drive, Pleasant Gap, PA, 16823, United States, nathaniel.bastian@fulbrightmail.org

The U.S. Military Health System (MHS) is a unique, complex health system with many healthcare and logistics challenges requiring effective management. We introduce multiple criteria decision engineering methods to assist strategic decision-making and to support the complex planning and management of MHS resources, personnel, logistics, and financial incentives. This contribution has helped senior military leaders make better, more informed, quicker, data-driven resource management decisions amongst conflicting objectives, along with the risks and uncertainties associated with those decisions.

3 - Smarter Tools For (Citi) Bike Sharing

Eoin O'Mahony, Uber, Itaca, NY, United States, eoin@uber.com

Bike-sharing systems are becoming increasingly prevalent in urban environments. These systems generally consist of stations where users can take out or drop off bikes, and may return a bike to a free dock at any station. New York City launched the largest bike sharing system in North America, Citibike, in May 2013 with over 300 stations and 5000 bikes. We have worked with Citibike since launch, using analytics and optimization to change how they manage the system. In this talk we will cover two areas of our work with Citibike; planning through data and rebalancing with optimization.

4 - Optimizing A Menu Of Multi-format Subscription Plans For Ad-Supported Media Platforms

Vamsi Krishna Kanuri, University of Miami, 501 Kosar Epstein Bldg, School of Business Administration, Coral Gables, FL, 33146, United States, vkanuri@bus.miami.edu

Media content distribution has changed extensively in the past decade. Content, which was once distributed through traditional formats such as television, radio and print, is now available through contemporary digital formats such as smartphone and tablet apps, with many possible versions (e.g., presence or absence of ads.) Consequently, many media firms facing markets comprised of heterogeneous consumers with varying content consumption preferences are now offering 'menus' of multi format-version subscription bundles for their consumers to choose from. Yet, little systematic model-based guidance exists for configuring and pricing menu options. Moreover, most media firms are 'audience-building platforms' that serve at least two distinct customer groups (content consumers and advertisers) with inter-related demands. Therefore, constructing a menu of content subscription bundles that maximizes total profit from both consumers and advertisers is a formidable challenge. This research proposes a theory-driven implementable model-based approach that can aid media platforms in addressing this challenge.

5 - Stochastic Models To Optimize Biomanufacturing Operations

Tugce Martagan, Eindhoven University of Technology, School of Industrial Engineering, Eindhoven, Netherlands, t.g.martagan@tue.nl

An interdisciplinary framework is developed to reduce costs and lead times in biomanufacturing operations. The proposed framework consists of Markov decision models that dynamically control and optimize the fermentation and purification operations. We characterize the structural properties of the optimal operating policies, and propose a new zone-based decision making approach to quantify the risks and costs in biomanufacturing operations. We provide guidelines that are easy to implement in practice, and develop approximation procedures to solve industry size problems.

1 - A New Computational Method For Rolling-horizon Stochastic Optimization In Power Systems

Site Wang, Clemson University, Freeman Hall, Fernow Street, Clemson, SC, 20634, United States, sitew@clemson.edu
Harsha Gangammanavar, Sandra D Eksioglu, Scott J. Mason

We investigate a multi-period, economic dispatch problem in a power system with high penetration of renewable resources. We propose a rolling horizon stochastic programming framework to analyze this problem. We solve this problem over a one-day horizon with sub-hourly intervals using novel warm-up techniques developed for the stochastic decomposition algorithm. We compare our stochastic approach with existing deterministic methods via extensive computational studies on real-scale systems.

2 - Greening The Vehicle Fleet: Evidence From Norway's Co2 Feebate

Shiyu Yan, Norwegian School of Economics, Bergen, Norway, shiyu.yan@nhh.no

To improve vehicle fuel efficiency and reduce CO_2 emissions, Norway linked vehicle registration taxes to CO_2 intensities, later adapted into feebate. We exploit a detailed vehicle registration dataset by econometric techniques. We find that the vehicle tax contributes to a purchase shift towards low-emitting cars. The results show that 1000NOK tax increase for a vehicle is associated with a 1.13%-1.58% registrations reduction. A pattern of rising CO_2 taxes across cars results in an elasticity (-0.06) of CO_2 intensities with respect to CO_2 prices. The estimated tax effect implies that the CO_2 differentiated vehicle registration tax explains 79% of the reduction in average CO_2 intensity of new cars.

3 - System Frequency Regulation In Renewable Dominated Power Systems With A Large Penetration Of Electric Vehicles

Miguel Carrion, Universidad de Castilla-La Mancha, Avda Carlos III s/n, Toledo, Spain, miguel.carrion@uclm.es,
Rafael Zárate-Miñano

Future power systems based on intermittent and asynchronous units may favor frequency fluctuations owing to a) a high presence of generating units with volatile power output, b) a reduction in the number of units participating in the frequency regulation and c) a reduction in the kinetic energy stored in the rotating parts of the system. In this context, we analyze the impact of using plug-in electric vehicles to provide frequency regulation in renewable-dominated power systems. This problem is formulated as a stochastic unit commitment that takes into account the uncertainty of renewable resources and frequency regulation capabilities. The proposed formulation is tested in a realistic case study.

4 - Developing A Decision Support Tool For Expanding Waste-to-Energy Technology Within The Department Of Defense

Adam Haag, Lieutenant, Student, Naval Postgraduate School, Naval Postgraduate School, 1 University Circle, Monterey, CA, 93943, United States, achaag@nps.edu

This study seeks to improve the the DOD's existing decision support tool with an additional module, which may increase the diversity and breadth of Waste-to-Energy technology within the DoD.

5 - Multiple UAV Assisted Power Network Damage Assessment

Jaeyoung Cho, Assistant Professor, Lamar University, 6195 N Major Dr., Beaumont, TX, 77713, United States, jcho@lamar.edu
Gino J Lim, Seonjin Kim

We presents a two-phase mathematical framework for efficient power network damage assessment using unmanned aerial vehicle (UAV). In the first phase, a two-stage stochastic integer programming optimization model is presented for damage assessment in which the first stage determines the optimal UAV locations anticipating an arrival of an extreme event, and the second stage is to adjust the UAV locations, if necessary, when the arrival time of the predicted extreme event becomes closer with updated information. UAV paths to scan the power network are generated in the second phase while minimizing operating costs of the UAVs.

1 - The High Speed Train Timetable Planning Problem For The Chinese Railways

Paolo Toth, University of Bologna, Bologna, Italy, paolo.toth@unibo.it

We consider the Train Timetabling Problem (TTP) for the planning of high-speed trains on the Beijing-Shanghai line. We are given a set of feasible timetables for the trains already planned along the line, and the main goal consists of scheduling as many additional trains as possible. We are allowed to modify the timetables of the trains, even by changing their stopping patterns, i.e. by removing some stops. A second objective is to obtain a regular schedule with respect to stopping patterns. We propose an Integer Linear Programming Model and a heuristic algorithm. Extensive computational experiments on real-world instances of the Chinese Railways are reported.

2 - Optimal Transportation And Shoreline Infrastructure Investment Planning Under Stochastic Climate Future

Ali Asadabadi, George Mason University - Fairfax, Fairfax, VA, 22030, United States, ali.asadabadi@gmail.com,
Elise D Miller-Hooks

The problem of optimal long-term transportation investment to protect from and mitigate against the impacts of climate change is modeled as a multi-stage, stochastic, bi-level, mixed-integer program. A recursive noisy genetic algorithm is presented to address large-scale applications. It is demonstrated on a Washington, D.C. Greater Metropolitan area case study.

3 - Global Optimization Solution Methods For Transportation Network Design Problems

David Z.W. Wang, Nanyang Technological University, 50 Nanyang Avenue, Singapore, 639798, Singapore, wangzhiweiI@ntu.edu.sg

Transportation network design problems (NDP), which determine the optimal road expansion and addition plan with assumption of various user equilibrium principles, are conventionally modelled into a bilevel programming or MPEC. The NDPs are typically nonlinear and nonconvex. We develop global optimization solution methods, applying various linearization and relaxation techniques, to obtain the global optimal solution to the NDPs. Both continuous and discrete NDPs are considered, while typical user equilibrium principles including deterministic user equilibrium and stochastic user equilibrium will be employed.

4 - Optimal Layout Of Transshipment Facilities Under Traffic Equilibrium In A Continuous Space

Zhaodong Wang, University of Illinois, Wright Street, Urbana, IL, 61801, United States, zwang137@illinois.edu
Yanfeng Ouyang

This talk focuses on generalizing the location-routing problem into one that considers traffic congestion and equilibrium in a continuous space. We present a new proof that a regular hexagon shape is optimal for facility service regions under congestion. Numerical experiments are implemented to verify the correctness of our analytical solution and theoretical results are used as a building block to develop approximate solutions to more general heterogeneous cases.

Fleet and Marketplace Optimization for Mobility-on-Demand (MOD) Systems

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Samitha Samaranayake, Cornell University, 317 Hollister Hall, Ithaca, NY, 14853, United States, samitha@alum.mit.edu

1 - Queueing-theoretical Models For Mobility-on-demand Systems: Theory And Algorithms

Frederico Rossi, Stanford University, Stanford, CA, United States, frossi2@stanford.edu, Marco Pavone

In this talk I will present recent advances towards modeling and controlling autonomous mobility-on-demand (AMoD) systems, an emerging mode of personal transportation wherein robotic, self-driving vehicles transport customers on-demand. First, I will present queueing-theoretical models inspired by the theory of Jackson and BCMP queueing networks. Such models provide structural insights about the performance of AMoD systems and guidelines for the design of routing algorithms for the robotic vehicles. Then, I will discuss large-scale coordination algorithms for AMoD systems that are aimed at throughput maximization and can handle congestion and charging constraints.

2 - Fleet Management In Mobility-on-Demand Systems With Shared Rides

Samitha Samaranayake, Cornell University, samitha@alum.mit.edu

We consider a MoD system with ridesharing between passengers. Inherent to the formulation are two important attributes: (i) the need to rebalance empty vehicles and (ii) the ability to identify lucrative ridesharing corridors via trip chaining. We present a mixed-integer linear programming (MILP) formulation of the problem and show how a heuristic (feasible) solution to the problem can be obtained in polynomial-time by independently solving the ride-matching and rebalancing problems. This approximate solution can be used as a initial guess when solving the coupled problem via an MILP solver.

3 - Dynamic Pricing In Ride-share Platforms

Siddhartha Banerjee, Cornell University, sbanerjee@cornell.edu

Much of the success of ride-sharing platforms like Lyft and Uber is ascribed to their ability to do fast-timescale dynamic pricing - where prices can react to instantaneous system state, and across very small geographic areas. We explore the value of such dynamic pricing via a model which combines a queueing model for the dynamics of the platform's operations with strategic models of both passenger and driver behavior. In particular, we suggest that dynamic pricing may not be better than the optimal static price, but rather, allows the platform to realize the optimal price with limited knowledge of system parameters. Joint work with Ramesh Johari, Carlos Riquelme, and the data science team at Lyft.

4 - Marketplace Optimization At Uber

Robert Phillips, Uber, Palo Alto, CA, United States, robert.phillips@uber.com

The rapid acceleration of the sharing economy has introduced a myriad of challenges for two-sided marketplaces. This talk will address how optimization and machine learning are powering the dynamic marketplace at Uber, a platform that has connected over one billion riders and drivers across more than 60 countries. Topics that will be surveyed include dynamic pricing, matching riders in uberPOOL, and real-time on-demand delivery services.

Sponsored Session

Chair: Mike D Prince, BNSF Railway, Fort Worth

1 - Intermodal Empty Railcar Distribution Optimization

Shantih Spanton, CSX Transportation, Jacksonville, FL, Shantih_Spanton@csx.com, Jagadish Jampani

Optimization models to effectively reposition the empty railcars. The forecasting model predicts the future demand for the containers and trailers, which is subsequently translated into railcars. This demand data is converted into equivalent number of railcars which is input into the optimization model. In addition, train profiles, network and terminal attributes are input into the optimization model. The model also predicts when and where the loaded railcars will become available in the selected optimization time horizon. This optimization model is embedded with a real time tool that is used by the intermodal railcar distribution team.

2 - Intermodal Hub Simulation

Mike Prince, BNSF Railway, Contact: mike.prince@bnsf.com

Intermodal hubs are the facilities at which BNSF Railway's intermodal trains interface with customers. This presentation will discuss an AnyLogic simulation model that was developed for the purpose of assisting in the capital expansion planning process for these facilities.

3 - Utilizing Rail Information In Intermodal Operations

Georgi Tasev, Schneider, Contact: TasevG@Schneider.com

Accurate train ETA information is critical to intermodal dray operations and directly influences the ability to serve customers effectively. In this session, we will review how Schneider uses train information provided by our rail partners to optimize key operations, such as appointment setting and dispatch. In addition, we will cover the analysis that was completed to study the accuracy of rail ETA information at key time intervals. Lastly, we will discuss the implementation and results of building a direct feed for train ETA information into Schneider's system.

1 - The Impact Of Predicted Quality On Customer's Quality Assurance Behaviors In The Us Airline Industry

Woohyun Cho, University of New Orleans, New Orleans, LA, United States, wcho@uno.edu
Dong-jun Min, Pamela Kennett-Hensel

We empirically examine the drivers of customers' voluntary quality assurance behaviors (QAB). Using survey data and archival data from the US airline industry, we show that whereas an increase in predicted quality of airlines departure operations (e.g., on-time performance and flight frequencies) leads to a decrease in the level of QAB (i.e., customer wait time for their flight at the airport), an increase in price leads to an increase in QAB. Our finding also indicates that the expense of exercising QAB reduces QAB. We emphasize the importance of properly measuring the impact of predicted quality and price on the customer's role, as it may help share the cost of managing quality with their customers.

2 - Passenger Facility Charge Vs. Airport Improvement Program Funds: A Dynamic Network Dea Analysis For U.S. Airport Financing

Bo Zou, University of Illinois at Chicago, 2073 Engineering Research Facility, 842 West Taylor Street, Chicago, IL,n Univ60607, United States, bzou@uic.edu
Young-Tae Chang, Hyosoo Park, Nabin Kafle

Passenger Facility Charge (PFC) and the Airport Improvement Program (AIP) are two major sources to finance U.S. airports. This paper develops a novel dynamic network DEA framework to investigate the substitutability between PFC and AIP funds. We find that the studied U.S. airports can substitute PFC for 8-35% of the current AIP funds and contribute significantly to the proposed plan of the US congress to cut AIP funding. In addition, the amount of PFC-for-AIP funds substitution negatively correlates with the productive efficiency of airports. The findings send an important message for future policy reforms on U.S. airport financing.

3 - Measuring Competition Intensity And Product Differentiation: Evidence From The Airline Industry

Benny Mantin,University of Waterloo, bmantin@uwaterloo.ca
David Gillen, Tuba Delibasi

Measuring the degree of competition in markets is essential for policy and decision makers. Commonly used structural indices (e.g., HHI) overlook how firms compete with each other and the intensity of the competition. We propose a new competition measure: Schedule (Temporal) Differentiation Metric, STDM, which encapsulates firms' market shares as well as the degree of overlap and substitution between the competing services—critical elements in service industries. We demonstrate the STDM using aviation markets revealing a significant improvement in explaining prices, how the effect varies across fare percentiles, and how the insights change with the business models of the competing firms.

Continuous Space Location Modeling

Sponsored: Location Analysis

Sponsored Session

Chair: John Gunnar Carlsson, University of Southern California, 3715 McClintock Ave, Los Angeles, CA, 90089, United States, spajcarlsso@usc.edu

1 - On The Dual And Rectangular Bounds For Continuous Facility Location Problem
Nadere Mansouri, SMU, nmansouri@mail.smu.edu
Halit Uster

Lagrangian dual and Rectangular bounds (a rectangular distance location problem specifically devised) are two of the lower bounding techniques for a continuous facility location problem. We present results comparing these bounds at any Weiszfeld iteration and upon convergence.

2 - Delivering Packages Jointly With A Truck And A Drone
John Gunnar Carlsson, University of Southern California, jcarlsso@usc.edu

One of the most talked-about developments in transportation and logistics in recent years has been the potential use of drones for transporting packages. We use a continuous approximation analysis to study a hybrid system in which delivery trucks act as a mobile "base" for launching drones.

3 - The Competitive Facility Location Problem Under Disruption Risks
Lawrence V Snyder, Associate Professor, Lehigh University, 200 West Packer Ave., Mohler Lab, Bethlehem, PA, 18015, United States, lvs2@lehigh.edu, Ying Zhang, Ted K Ralphs

Two players sequentially locate facilities, competing to capture market share. Facilities face disruption risks, and each customer seeks the nearest operational facility for service, regardless of who operates it. The problem combines competitive location and location with disruptions, an important combination that has been absent from the literature. We model the problem as a Stackelberg game, and formulate the leader's decision problem as a binary bilevel optimization problem. We propose a branch-and-cut algorithm and a variable neighborhood decomposition search heuristic. Computational results suggest that high quality solutions can be found quickly.

MCDA Methods and Applications

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Roman Slowinski, Poznan University of Technology, Poland, roman.slowinski@cs.put.poznan.pl

1 - Context Matters: Effects Of Product Type And Information Overload On Choice Accuracy
Jyrki Wallenius, Professor, Aalto University School of Business, Helsinki, Finland, jyrki.wallenius@aalto.fi
Pekka J Korhonen, Pekka Malo, Tommi Juhani Pajala, Niklas Ravaja, Outi Somervuori

We report on the results of an experiment, which utilizes a new method for generating many similar choice problems, enabling the objective measurement of choice accuracy.We show that the product type matters for choice accuracy. Moreover, we show that information overload is a relevant phenomenon in MCDM experiments. However, what matters is the quality of information, not just the quantity. When we add information that does not change the dominance relations between products, choice accuracy is not degraded.

2 - Decision Under Risk And Uncertainty As A Multi-quantile Decision Problem
Roman Slowinski, Poznan University of Technology, Poznan, Poland, roman.slowinski@cs.put.poznan.pl
Salvatore Corrente, Salvatorend,&nbGreco, Benedetto Matarazzo

We formulate the problem of decision under risk & uncertainty as a multiple criteria decision problem, where criteria are some quantiles of the outcome distribution, which are meaningful for the decision maker. To solve the multiple criteria decision problem, we apply the robust ordinal regression approach. We validate all the methodology on the classic newsvendor problem where we apply GRIP and ELECTRE^GKMS methods to recommend a solution respecting preferences of the decision maker.

Gamification and User Engagement

Sponsored: Information Systems

Sponsored Session

Chair: Lei Wang, Pennsylvania State University, University Park, PA, 16801, AssigUnited States, luw21@smeal.psu.edu

1 - Measuring The Impact Of Crowdsourcing On Mobile App User Engagement And Retention: A Randomized Field Experiment
Zhuojun Gu, Pennsylvania State University, zqg5077@psu.edu
Ravi Bapna, Jason Chan, AlokcustomGupta

In this paper, we propose a new strategy for enhancing mobile app user engagement and retention by introducing crowdsourcing features that involve users through the design of the app itself. We measure the causal impact of crowdsourcing by conducting a randomized field experiment on a social mobile game platform. We find higher user retention level could be achieved by allowing users to submit content and customize their products. And sustained user engagement and retention are enhanced most when both submission and access options are available.

2 - Cultivate Consumer Engagement With Mobile And Gamification
Lei Wang, Pennsylvania State University, State College, PA, 16802, United States, Lxluw21@smeal.psu.edu, Siyuan Liu

Despite the growing popularity of gamification and its potentials on customer engagement, we still have very little knowledge about gamification and its impact on customer engagement. In this research, we conduct a large-scale randomized field experiment in a shopping mall in Asia to investigate the impact of gamification on cultivating customer engagement. Our results will allow us to effectively measure the causal impact of gamification and provide insights on quantifying and improving the impacts of gamification on customer engagement and mobile advertising. This study also provides important implications on how firms could benefit from gamification.

3 - What Do Mobile Applications Bring a Longer Tail? An Empirical Study Of Sales Concentration In Online Cchannels
Shahryar Doosti, University of Washington, Foster School of Business, Mackenzie Hall, Seattle, WA, 98195, United States, shahryar@uw.edu, Yong Tan, Youwei Wang

This work uses a dataset from a leading e-retailer which offers two online channels, the desktop channel and mobile applications, to study the effect of long tail on product sales in each channel. Our findings show that the long tail effect exists in mobile application channel. In other words, there is more product variation and less sales concentration on mobile app compared to desktop channel.

Model Calibration

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Matthew Plumlee, University of Michigan, Ann Arbor, MI, United States, mplumlee@umich.edu

1 - Bayesian Calibration Of Inexact Computer Models
Matthew Plumlee, University of Michigan, mplumlee@umich.edu

Bayesian calibration is used to study computer models in the presence of both a calibration parameter and model bias. The parameter in the predominant methodology is left undefined. Among other problems, this results in an issue where the posterior of the parameter is sub-optimally broad. To date, there has been no generally accepted alternatives. This paper proposes using Bayesian calibration where the prior distribution on the bias is orthogonal to the gradient of the computer model. Problems associated with Bayesian calibration are shown to be mitigated through analytic results in addition to numerical and real examples.

2 - Stabilizing Gradient Enhanced Kriging With Sparsity Constraints
Peter Qian, University of Wisconsin,re thepeter.qian@wisc.edu

Gaussian processes are widely used for emulating computer simulations. It is known that the use of partial derivative information can dramatically improve function estimation. However, the use of partial derivative information comes at the cost of high numerical instability. We investigate an approach to mitigate this instability by exploiting the possibility that some partial derivatives may introduce enough error due to numerical instability to significantly degrade predictive accuracy. Experimental results indicate this procedure can dramatically reduce numerical error in interpolation. Applications to model calibration will also be discussed.

3 - Model Calibration With Censored Data
Fang Cao, Georgia Institute of Technology, Atlanta, SGA, United States, fcao6@gatech.edu, Shan Ba, William A Brenneman, Roshan Joseph

The purpose of model calibration is to make inference about the unknown parameters of a computer model. The Kennedy-O'Hagan approach is widely used for calibration which accounts for the inadequacy of the computer model while simultaneously estimating the calibration parameters. In many applications censorship occurs when exact outcome of the physical experiment is not observed but is known to fall within a certain region. In such cases KO approach cannot be used directly and we propose a method to incorporate the censoring information when performing calibration. The method is applied to study the stability of liquid and the results show significant improvements over traditional methods.

1 - Optimal Design Of Hybrid Sequential Testing For A System With Mixtures Of One-shot Units
Yao Cheng, Rutgers University, Department of Industrial & Systems Engineering, Piscataway, NJ, 08809, United States, yao.cheng.ise@gmail.com, Elsayed Elsayed

Non Destructive Testing is conducted to determine the functionality of the units without permanent damage in order to estimate the units' reliability. In this presentation, we investigate a system composed of non-identical units with different characteristics and subjected to hybrid reliability testing (Destructive and NDT). It is of interest to optimally design the hybrid sequential reliability testing. After conducting a number of hybrid testing, we decrease the sample size of the destructive testing as the accuracy of reliability metrics estimation improves. Eventually, we only need to conduct NDT only. The efficiency and accuracy of the proposed methods are validated.

2 - Wind Farm Replacement In A Markov Modulated Environment
David Abdul-Malak, University of Pittsburgh, dta10@pitt.edu, Jeffrey P. Kharoufeh

In this talk we will present a model for jointly replacing wind turbine components in a wind farm setting. Components are assumed to degrade in a shared, exogenous, Markov modulated environment. Continuous state variables and a high dimensional state space cause the problem to be computationally intractable. To overcome these complications, structural results are proven and a reinforcement learning (RL) approach is employed.

3 - An Enhanced Copula-based Prognosis For Proactive Maintenance Of Lithium-ion Batteries
Zhimin Xi, University of Michigan-Dearborn, zxi@umich.edu

Data-driven prognostics typically requires sufficient offline training data sets for accurate remaining useful life (RUL) prediction for the purpose of proactive maintenance of engineering products. We investigate performances of typical data-driven methodologies when the amount of training data sets is insufficient to better understand the methodology limitation. An enhanced copula-based approach is specifically developed for the scenarios with insufficient run-to-failure training data sets. RUL prediction of lithium-ion batteries in terms of the capacity degradation is employed for the demonstration.

4 - Optimizing Periodic Inspection Frequencies For a Class Of Stochastically Degrading Systems
David Kaufman, University of Michigan-Dearborn, Dearborn, MI, United States, davidlk@umich.edu, Mahboubeh Madadi, Murat Kurt

We consider existing models that optimize repair-replacement decisions for systems the degradation status of which follow a discrete time Markov chain over a set of finite states and can be revealed only by costly inspections. Given worse conditions imply higher operation costs, we utilize first-order stochastic dominance relationship among the powers of IFR-structured degradation matrices to propose approximately-optimal periodic inspection decisions that minimize the total expected discounted cost due to operation, repair and inspection. We illustrate our approach through numerical examples.

Game Theory and Competitive Applications

Sponsored: Military Applications

Sponsored Session

Chair: Brian J Lunday, Assistant Professor, Air Force Institute of Technology, 2950 Hobson Way, WPAFB, OH, 45433, United States, brian.lunday@afit.edu

1 - 1 Vs. (n-1) Modeling For Project Scheduling Interdiction
Zachary Little, The Perduco Group, 3610 Pentagon Boulevard #110, Beavercreek, OH, 45431, United States, zach.little@theperducogroup.com

A bilevel programming problem is developed for a one-to-many game involving project scheduling interdiction. As a coalition, the many (n-1) adversaries aim to minimize the total cost of a set of project schedules given a time/cost trade-off. The single interdictor aims to maximize this same total cost for the coalition's project schedules. The modeling framework and use of duality are discussed, with emphasis placed on coalition interaction for this study. Initial results examine the impact of player perceptions on interdictor and coalition decisions.

2 - Approximate Dynamic Programming For Missile Defense Interceptor Fire Control
Matthew J Robbins, Air Force Institute of Technology, Wright-Patterson AFB, OH, United States, matthew.robbins@afit.edu, Michael T Davis, Brian J Lunday

A missile defense system must protect assets against multiple offensive missile salvos over time. The defender must determine how many interceptors to fire at each incoming missile. We develop a Markov decision process (MDP) model to determine optimal fire control policies. Approximate dynamic programming (ADP) is utilized to explore the efficacy of applying approximate methods to the problem. We obtain policy insights by analyzing subsets of the state space that reflect a range of possible defender interceptor inventories. The ADP policy provides high-quality decisions for a substantial proportion of the state space, achieving a 7.7 percent mean optimality gap in the baseline scenario.

3 - Containing The Mess Of Optional Meals Via Approximate Dynamic Programming

Sandra Jackson, Instructor, United States Military Academy, West Point, NY, United States, sandra.jackson@usma.edu, Keith DeGregory, Matthew Fletcher

On any given day, the United States Military Academy Mess Hall provides three meals to the Corps of Cadets, approximately 4,400 people. These meals are simultaneously served meaning the entire Corps arrives, eats, and departs at the same time. In recent years, the Academy has allowed cadets to option out of formally mandatory meals thus moving what was a consistent demand to a stochastic one. As a result, the Academy Mess Hall experiences a stochastic demand similar to dining facilities in the active Army. Variable demand opens the door to food waste and the question of how to make sequential resourcing decisions under uncertainty, a problem for which approximate dynamic programming is suited to solve.

4 - Heterogeneous Surface-to-air Defense Battery Location: A Game Theoretic Approach

Brian Lunday, Air Force Institute of Technology, brian.lunday@afit.edu Nicholas Boardman, Matthew Jd Robbins

We examine a game theoretic model for the location of air defense batteries having different interceptor capabilities, and we find high quality solutions using the game tree search technique Double Oracle, within which we embed either of two alternative heuristics to solve an important subproblem for the attacker. We test and compare these solution methods to solve a designed set of 52 instances having parametric variations. Enhancing the solution methods with alternative initialization strategies, our superlative methodology attains the optimal solution for 75% of the instances tested and solutions within 2.12% of optimal, on average, for the remaining 25% of the instances.

1 - Understanding Vehicle Movement Patterns With Artificial Neural Networks

Burak Cankaya, Lamar University, 13960 Hillcroft St. Apt 724, Houston, TX, 77085, United States, mbcankaya@gmail.com

Geographical Identification System (GIS) is utilized by most of the vehicles and cellphones in recent years. This research proposes an alternative type of methodology to understand vehicle movement patterns with historic geospatial data. This research investigates the vehicle movement patterns with artificial neural networks and compares the results with other machine learning methodologies including decision trees and random forest algorithm. The methodology will be applied on a case study, which is strategic Gulf of Mexico Ports' vessel traffic data. The result of the study will explain the question “Can we understand vessel movement patterns and optimize the vessel traffic?

2 - A Discrete Simulation Of A New Container Terminal – The Case Of Hamad Port Of Qatar

Ghaith Rabadi, Professor, Old Dominion University, Engineering Management Systems Engineering, Engineering Systems Building, Room 2102, Norfolk, VA, 23529, United States, grabadi@odu.edu Mariam Kotachi, Moahmed K Msakni, Mohammad Al-Salem, Ali Diabat

A discrete even simulation is developed for a future container terminal of Hamad’s new port of Qatar. The simulation models vessel arrivals, ship to shore crane operation, container movement from vessels to yard via yard trucks and the operations in the opposite direction from the yard to the vessels. Furthermore, external trucks dropping off and picking up containers from the yard are also modeled. Berth allocation and crane assignment methods are embedded in the simulation. Preliminary analysis and scenarios are presented.

3 - Modeling The Service Network In Container Terminals Considering Process Integration And Decomposition

Qingcheng Zeng, Professor, Dalian Maritime University, School of Transportation Management, Dalian, 116026, China, qzeng@dlmu.edu.cn

Process integration/decomposition and process variation are pair of critical decision variables in service network design. In this paper, the variation of each service process of container terminals is analyzed. A cyclic queue network model is developed. Principles of integration or decomposition, methods of stabilizing the processes are proposed.

4 - A Vessel Scheduling Transportation-inventory Problem With Stochastic Demands

Hossein M Soroush, Kuwait University, Department of Statistics & Operations Research, P.O. Box 5969, Safat, 13060, Kuwait, h.soroush@ku.edu.kw Salem Al-Yakoob

We study a vessel scheduling transportation-inventory problem to transport a product from a source to a destination where demands are stochastic and penalties are imposed on the shortages/excesses in storage levels. The goal is to schedule a set of heterogeneous fleet to meet the demands with acceptable level of reliabilities while minimizing the expected total cost.

Chair: Tao Lu, Erasmus University, Rotterdam, Netherlands, lutao0927@hotmail.com

1 - Shipping Peak Demand For Online Sellers

Ju Myung (J.M.) Song, Rutgers Business School, PhD Program, Washington Park, Room 430C, Newark, NJ, 07102, United States, jumyungsong@gmail.com, Yao Zhao

Online retailing is changing the landscape of retail industry in countries as Amazon’s market cap has recently doubled that of Wal-Mart in the US. Different from brick and mortar, online sellers rely on 3rd party logistics for the delivery of the goods but the hugely spiked demand during holiday seasons (Christmas in the US, Singles’ day in China) poses a substantial challenge for the 3PLs to deliver on time. To better manage demand, 3PLs such as UPS, require the sellers to make reservation and to pay a surcharge for extra work. In this paper, we discuss how these shipping arrangements may affect the online sellers’ inventory decisions, how to coordinate the channel for the sellers and shippers to win-win.

2 - Explosive Storage Location Assignment Problem For Amazon Class Internet Fulfillment Warehouses

Sanchoy Das, New Jersey Institute of Technology, University Heights, Newark, NJ, 07102, United States, das@njit.edu, Jingran Zhang

We establish a storage assignment heuristic for Internet Fulfillment Warehouses. xSLAP is based on an explosive policy, whereby the same item is stored simultaneously in small lots in a large number of locations. Compared with classical storage policies used in traditional warehouses, an explosive policy leverages demand correlated storage assignment by commingling SKUs in the same bin, bins in close proximity, or bins in the same zone. The xSLAP heuristic optimizes the downstream picking processes by finding the optimal assignment of items in order to meet quick customer orders fulfillment.

3 - Analysis Of Hub Ports In Southeast Asia And Northeast Asia

Richard W Monroe, Longwood University, 7413 Nicklaus Cir, Farmville, VA, 23909, United States, monroerw@longwood.edu

Major seaports in Southeast Asia and Northeast Asia have experienced significant growth in the last two decades. Several ports are known as “hub” ports due to the dominant volume of transshipments. This paper will present descriptive statistics for the major ports in Asia among the Top 50 Container Ports in the world. A secondary analysis will focus on a smaller sample of the top hub ports to compare the growth of container volume for those ports with higher transshipment volumes. The differences between hub ports and other ports will also be discussed.

4 - Approximate Dynamic Programming For An Empty Container Repositioning Problem In A Cyclic Route

Shaorui Zhou, Assistant Professor, Sun Yat-sen University, Guangzhou, China, zshaorui@gmail.com, Fan Wang

In this work, we study an empty container repositioning problem in a cyclic route with uncertain demands. We formulate it as a stochastic dynamic programming problem. We study two special cases: in case 1, the route covers only 2 ports and we propose a optimal t ld policy due to the separability of the value function; In case 2, the route covers 3 ports, and the optimal policy can be characterized by state-dependent threshold points. For general case, in order to overcome curse of dimensionality, we propose an approximate dynamic programming algorithm. We compare the performance with heuristics. Numerical results demonstrate the efficiency of the algorithm.

5 - Shipping To Time-sensitive Customers With Competing Carriers

Tao Lu, Erasmus University,o applRotterdam, Netherlands, lutao0927@hotmail.com, Ying-Ju Chen, Jan C Fransoo, Chung-Yee Lee

We consider a shipper selling a kind of products to a destination market where customers obtain higher utility if they receive the product earlier but their time-sensitivity is heterogeneous. Two carriers provide transportation services with different speeds, and compete by quoting freight rates. By splitting shipments between carriers, the shipper may enjoy the benefit of product differentiation through selling early-arrived products at a premium price. However, driven by the underlying trade-off between product differentiation and competition, we show that product differentiation via dual-mode shipping may be inferior to simply restricting to a single shipping mode.

Chair: Youran Fu, University of Pennsylvania, 3730 Walnut Street, Room 532, Philadelphia, PA, 19104, United States, youranfu@wharton.upenn.edu

1 - Coordinating A Textile Supply Chain In Post Multi Fibre Agreement Era: A Developing Economy Perspective

Arnablass="Bisi, Johns Hopkins University Carey Business School, 100 International Drive, Baltimore, MD, 21202, United States, abisi1@jhu.edu, Arnab Adhikari, Badrifrom mNarayanan

The abolishment of the Multi Fibre Agreement (MFA) in 2005 opened up a plethora of export opportunities of textile and cotton for the textile supply chain of many developing economy countries such as India and China. On the other hand, it leads to a shortage of low-cost raw material in these countries and affects the apparel production. In this context, we adopt a realistic three-level structure to represent the textile supply chain of a developing economy country and focus on designing appropriate coordination mechanisms using cost sharing and revenue sharing contracts.

2 - Coordination And Competition In A Supply Chain: Franchise Contract And Facility Sharing Contract

Tulika Mukherjee, Postdoctoral Fellow, Concordia University, 1455 Boulevard de Maisonneuve, Montreal, QC, H3G 1M8, Canada, jum.tulika@gmail.com

A two-suppliers-one-retailer supply chain model is developed for a marketing channel where all the partners either compete or collaborate to enhance their profit. Competitive and collaborative strategies under franchise contract and facility sharing contract are analysed with a game theoretic lens. Finally, a comprehensive computational analysis is carried out to validate our model.

3 - How Prominence Effect & Repeated Channel Interactions Can Lead To Slotting Allowances

Yourann Fu, University of Pennsylvania, 3730 Walnut Street, Room 532, Philadelphia, PA, 19104, United States, youranfu@wharton.upenn.edu, JiaqiconfliXu, Gerard P Cachon

We develop a supply chain model in which the retailer owns two types of shelf space - a prominent and an inconspicuous shelf space. We show that under this setting, slotting allowances can arise even in the absence of retailer competition as the result of collusion between manufacturers when there is repeated channel interaction. We discuss implications of the retailer's sales effort and shelf space values on channel coordination.

Health Care, Modeling V

Contributed Session

Chair: Erin Garcia, Graduate Student, Georgia Institute of Technology, 755 Ferst Drive, Atlanta, GA, 30332, United States, egarcia3@gatech.edu

1 - Analysis Of Blood Banking System Operations At The Time Of Low Demand

Amir H. Masoumi, Assistant Professor of Management, Manhattan College, 4513 Manhattan College Parkway, Bronx, NY, 10471, United States, amir.masoumi@manhattan.edu, Min Yu

We investigate a new trend of demand for human blood which has significantly affected the operations of blood banks in the US over the past few years. Using a supply chain network optimization model, we analyze the effectiveness of the changes made to such systems including downsizing of operations, closure of facilities, as well as mergers and acquisitions.

2 - Reducing Operating Room Time In Robotic Surgery Using Simulation

Yueran Zhuo, University of Massachusetts Amherst, 121 Presidents Drive, Amherst, MA, 01003, United States, yzhuo@som.umass.edu, Senay Solak

Robotic surgery procedures differ from classical surgeries due to the reduced role that the surgeon plays during the operation. In order to study potential performance improvement options in this increasingly common type of surgery, we build a simulation model based on data collected from several urogynecology robotic surgery cases. The model is then used to assess the value of several alternative process improvement ideas aimed at reducing operating room time.

3 - Scheduling Multidisciplinary Cancer Clinics

Anne G. Leeftink, University of Twente, Enschede, Netherlands, a.g.leeftink@utwente.nl, Ingrid M. Vliegen, Erwin Hans

Many hospitals start multidisciplinary clinics to assure timely care. Their planning requires an open access approach. The number and timing of regular appointments influences the performance for the open access patients. Furthermore, since the appointment schedule of the first physician determines the referral rate to the other clinicians, the timing of the open access slots influences the waiting time as well.
This study's objective is to jointly develop a blueprint appointment schedule for all clinicians. Since this can only be analytically solved for small problem instances, we developed a novel local search heuristic to handle real-life instances, which we applied to a real life case study.

4 - Seasonal Variations In Spatial Access To Pediatric Asthma Treatment Across The US

Erin Garcia, Graduate Student, Georgia Institute of Technology, 755 Ferst Drive, Atlanta, GA, 30332, United States, egarcia3@gatech.edu

Asthma is a chronic condition that affects over 7 million children in the US, many of whom will have a preventable severe health outcome due to their asthma. Disease control is as important as underlying severity for a child's health, and is directly related to the quality of the medical care received. Geographic access to care varies by state, provider type, and patient insurance status. This work uses Medicaid Claims data to analyze the seasonal variations in both available provider capacity and patient demand for asthma visits to understand their impact on the health outcomes of asthmatic children. We also propose interventions to decrease seasonal variations and improve access to care year round.

1 - Mindfulness Effect On Technology Acceptance Process In The Context Of Bounded Rationality

Emine Erdogan, PhD Candidate, Rutgers The State University of New Jersey, Newark, NJ, 07102, United States, ee134@scarletmail.rutgers.edu

This study investigates how decision making processes in accepting a new technology have been influenced by consumers' mindfulness. Based on the theory of bounded rationality and TAM, the study will propose the concept of "bounded mindfulness"and will measure it by testing the effects of ambiguity, and time pressure related to the consumers acceptance of high tech vehicles. Previous research suggests that mindfulness can be described by alertness, awareness, and openness to novelty and negatively correlated with heuristic processing. Moving from this, the paper aims to investigate the impact of consumer mindfulness on information processing and its consequences in high tech vehicles adoption .

2 - Considering Customer Representatives' Risk Preference: Acquisition And Retention Delegation Strategies Under The Spoiling Effect

Yi Liao, Professor, Southwestern University of Finance and Economics, 425 Mount Prospect Avenue, 404, Newark, NJ, 07104, United States, yiliaoswufe@gmail.com

In this study, we focus on the spoiling effect and use the discrepancies between customer acquisition and retention efforts to capture how the spoiling effect influences customer demand. We compare firms' performance using the following three strategies: the delegation of acquisition model, in which customer acquisition is delegated to customer representatives; the delegation of retention model, in which customer retention is delegated to customer representatives; and the total delegation model, in which both tasks are delegated to customer representatives. Our main finding is that the spoiling effect significantly affects acquisition and retention efforts and firm profitability.

3 - Price Competition And Direct-to-consumer Advertising In Prescription Drug Markets

Abhik Roy, Professor, Quinnipiac University, Department of Marketing, School of Business (SB-DNF), Hamden, CT, 06518-1949, United States, abhik.roy@quinnipiac.edu
Mary Schramm

We examine the relationship between direct-to-consumer advertising (DTCA), and interdependent pricing among firms marketing competing drugs to patients within the same therapeutic area. We propose that DTCA is a coordinating mechanism, where a firm signals its willingness to be a Stackelberg price leader by spending heavily on advertising promoting the drug formulation, not just its own brand within the category. Propositions are developed about the impact of ad effectiveness, ad spending and substitutability on the occurrence of a Stackelberg system. Evidence to support these propositions is provided through empirical analysis of data from a number of prescription drug categories.

4 - A Dominant Retailer's Strategic Response To More Efficient Weak Retailer

Ehsan Bolandifar, Assistant Professor, Chinese University of Hong Kong, 9/F, Cheng Yu Tung Buliding, No., 12, Chak Cheung Street, Shatin, N.T., Hong Kong, 999077, Hong Kong, ehsan@baf.cuhk.edu.hk, Zhong Chen, Fuqiang Zhang

We construct a multi-stage model to study the strategic interaction between national brand manufacturer, a dominant and weak retailers. We show that more efficiency on the weak retailer's end makes the dominant retailer reduce its joint advertisement level for the national brand and offers lower market prices, while it also receives a discount form the national brand manufacturer. We also show that manufacturer does not always benefit from improvement in its operational efficiency of its retailers. Similarly, dominant retailer does not always benefit from cheaper store brand procurement costs.

5 - Direct Sales, Agent Selling or Reselling? Firms' Channel Structure With Consumers' Channel Preference

Libo Sun, PhD Student, University of Science and Technology of China, 96# Jinzhai Road, Hefei, Anhui, PR China, Hefei, 230026, China, libosun@mail.ustc.edu.cn, Yugang Yu

Numerous firms exert themselves to adopt multiple channels to sell products. However, even when facing identical products, consumers' choices among these channels could be diverse due to channel preference. We use a stylized theoretical model to answer two key questions faced by a monopoly manufacturer: (1) how does consumers channel preference (CCP) affect its channel structure, namely, when should the manufacturer choose a sin-gle-channel and when should it adopt a dual-channel instead? Furthermore, should the manufacturer choose an independent reseller or an agent platform when it intends to leverage external force? We respectively derive the manufacturer's optimal channel deci-sions when consumers show positive and negative CCP to the manufacturer's direct channel. We find that: (1) compared with centralized case, the manufacturer prefers to adopt dual-channel in a larger area in decentralized case; (2) the manufacturer will choose a dual-channel either when consumers' CCP to direct channel is positive or negative enough; (3) the exact forms of dual channel depends on the thresholds of the agent fee charged by the platform.

Technology Tutorial: MathWorks/Artelys

Technology Tutorial

1 - MathWorks: Data Analytics With MATLAB

Mary Fenelon, MathWorks, Natick, MA, United States, mary.fenelon@mathworks.com

MATLAB has evolved to become a platform for predictive and prescriptive analytics. Engineering, Finance, Data Science, and IT teams are using MATLAB to build today's advanced analytics systems ranging from risk analysis to predictive maintenance and telematics to advanced driver assistance systems and sensor analytics. Join us to see how MATLAB can help you: • Access, explore, and analyze data stored in files, on the web, and from data warehouses • Clean, explore, visualize, and combine complex multivariate data sets • Prototype, test, and refine predictive models using machine learning methods • Build and solve prescriptive models and analyze results • Share your results with others We'll highlight our newest features for Big Data, machine learning, deep learning, and optimization through examples such as load forecasting, Monte Carlo simulation, predictive maintenance, and embedded sensor analytics.

2 - Artelys: Solving Large Least-Squares Models With The Artelys Knitro Nonlinear Optimization Solver

Richard Waltz, Artelys, 150 N Michigan Avenue, Suite 800, Chicago, IL, 60601, United States, Richard.waltz@artelys.com

Artelys Knitro is the premier solver for nonlinear optimization problems. This software demonstration will highlight the latest Knitro developments, including a new specialized API, as well as enhanced algorithms, for large-scale nonlinear least-squares models. We will demonstrate how to solve least-squares models using Knitro through a variety of interfaces such as R, MATLAB and C/C++, and also provide some benchmarking results. In addition, we will summarize some of the other recent developments in Knitro.

1 - Public Health Preparedness: Answering (Largely Unanswerable) Questions With Operations Research

Margaret Brandeau, Stanford University, Stanford, CA, United States, brandeau@stanford.edu

Public health security - achieved by effectively preventing, detecting, and responding to events that affect public health such as bioterrorism, disasters, and naturally occurring disease outbreaks - is a key aspect of national security. However, effective public health preparedness depends on answering largely unanswerable questions. For example: What is the chance of a bioterror attack in the United States in the next five years? What is the chance of an anthrax attack? What might be the location and magnitude of such an attack? This talk describes how OR-based analyses can provide insight into complex public health preparedness planning problems - and thus support good decisions.

Data Mining Under Uncertainty

Sponsored: Data Mining

Sponsored Session

Chair: Erhun Kundakcioglu, Ozyegin University, Nisantepe District Orman Street / Cekmekoy, Istanbul, 34794, Turkey, erhun.kundakcioglu@ozyegin.edu.tr

1 - Approximation Algorithms For Solving Large-scale Classification Problems

Neng Fan, University of Arizona, nfan@email.arizona.edu

To deal the classification of data with uncertainties, the distributionally robust optimization models are proposed for the support vector machines. First the problems are reformulated as semidefinite programs or second order cone programs. To solve these problems on large-scale data sets, we design a stochastic subgradient algorithm. The numerical experiments will be presented to show the efficiency of our algorithms.

2 - Margin Maximization Via Benders Decomposition To Solve Multiple Instance Learning Problems

Emel Seyma Kucukasci, Istanbul Commerce University, Istanbul, 34840, Turkey, eskucukasci@ticaret.edu.tr
Emel Seyma Kucukasci, Bogazici University, Istanbul, 34342, Turkey, eskucukasci@ticaret.edu.tr, Mustafa Gokce Baydogan

Multiple instance learning (MIL) aims to solve classification problem where bags of instances form the input data. Margin maximization model of MIL classification is a MINLP problem. We develop a Benders decomposition algorithm for MINLP solution to deal with large datasets. A hybrid approach combining Benders decomposition and bagging procedure is proposed to test the generalizability of the results. Computational results on publicly-available molecular activity prediction, image annotation and text classification datasets are also provided.

3 - Response Modeling With Semi-supervised Support Vector Regression

Dongil Kim, Korea Institute of Industrial Technology, 89 Yangdaegiro-gil, Ipjang-myeon, Seobuk-gu, Cheonan, Korea, Republic of, dikim01@kitech.re.kr, Sungzoon Cho

Two-stage response model has been proposed to maximize a profit of a marketing campaign by estimating the purchase amount of customers. In this paper, we propose a response modeling with Semi-Supervised Support Vector Regression (SS-SVR). In SS-SVR, label distributions of unlabeled data are estimated to consider label uncertainty. Then, training data are generated by oversampling from the unlabeled data and their estimated label distributions. Finally, a data selection algorithm is employed to reduce the training complexity. The experimental results conducted on a real-world marketing dataset showed that the proposed method improved the model accuracy and expected profit, efficiently.

4 - Support Vector Linear Regression With Multiple Instance Data

Ihsan Yanikoglu, Ozyegin University, Istanbul, Turkey, ihsan.yanikoglu@ozyegin.edu.tr, Erhun Kundakcioglu

We present a Support Vector Regression (SVR) framework for multiple instance (MI) data, which consists of bags of pattern vectors instead of individual instances. This setting has interesting applications such as image annotation, drug activity prediction, and causal inference over time. We provide formulations for MI regression, prove the problem is NP-hard, propose and compare efficient heuristics for the problem.

Data Mining in Healthcare

Sponsored: Data Mining

Sponsored Session

Chair: Ramin Moghaddass, University of Miami, 1251 Memorial Drive, MEB 308, Coral Gables, FL, 33146-0630, United States, ramin@miami.edu

1 - A Simple And Direct Projection Approach To Handling Covariate Shift

Fulton Wang, MIT, fultonw@mit.edu

Covariate shift is commonplace in the healthcare setting - the training population, for which labelled data is available, often differs in covariate distribution from the test population, for which predictions must be made. Covariate shift can lower test prediction accuracy even if the relation of covariates to outcomes is the same in both populations. While past methods have searched for a subspace in which the covariates of the two populations are similar, we instead propose a method that directly finds a subspace with which high test prediction accuracy can be achieved.

2 - Optimized Risk Scores In Healthcare Applications

Berk Ustun, MIT, ustunb@mit.edu, Cynthia Rudin

Risk scores are simple models that let users quickly assess risk by adding, subtracting, and multiplying a few small numbers. These models are widely used in healthcare, but difficult to create because they need to be risk-calibrated, use small integer coefficients, and obey operational constraints. We present a new approach to fit risk scores by solving a discrete optimization problem. We formulate the risk score problem as a MINLP, and present a cutting-plane algorithm to recover its optimal solution by solving a MIP. We use our approach to build optimized risk scores for two healthcare applications: (i) seizure prediction in the ICU; (ii) ADHD screening.

3 - Making Impact Through Identifying Impactable Members

Margrét Bjarnadóttir, University of Maryland, margret@rhsmith.umd.edu

A large body of research focuses on identifying patients at risk, for example for hospital readmission, appointment no-shows and declining health. However in many cases interventions to avoid adverse outcomes prove unsuccessful as patients may not be impactable, due to health status and/or the social environment. We introduce the concept of jumpers: patients at risk of adverse outcomes but who go undetected by traditional case management. We discuss the application of data mining methods to identify these members in two different settings: Diabetes management and Medicaid ED use management.

1 - Data-driven Optimization For Multi-disciplinary Staffing In Mayo Clinic Improves Patient Experience

Mutafa Y. Sir, Mayo Clinic, 200 First Street SW, Rochester, MN, 55905, United States, sir.mustafa@mayo.edu, David M Nestler, Thomas R. Hellmich, Devashish Das, Micheal J Laughlin, Michon Dohlman, Kalyan Pasupathy

Emergency Department (ED) patient volumes fluctuate throughout the day leading to delays. Therefore, it is critical to match the staff capacity to the patient demand. A data-driven approach applied regression trees to system-generated data to produce an ideal patient volume representing ED load under optimal staffing conditions. The ideal patient volume was then used to optimize multi-disciplinary staffing levels. The new shift design significantly improved several patient-centered metrics.

2 - Optimizing New Vehicle Inventory At General Motors

Robert Inman, General Motors, 30500 Mound Road, Warren, MI, 48092, United States, robert.inman@gm.com, Michael Frick, Thomas Hitchman, Robert Muiter, Jonathan Owen, Gerald Takasaki

Getting inventory right enables GM to meet customer demand more efficiently. Optimizing new vehicle inventory has two dimensions: determining how many vehicles, and determining which vehicle configurations. Knowing the best aggregate number of vehicles helps manage production and pricing. Knowing the best mix of vehicles helps dealer ordering. Instead of finding “how many” to provide a given fill rate, we find the inventory that maximizes aggregate variable profit. Instead of determining “which vehicles” by simply ranking vehicle configurations by sales, we apply a practical set-covering approach to span customer demand.

Topics in Power Generation Scheduling

Sponsored: Energy, Natural Res & the Environment, Energy I Electricity

Sponsored Session

Chair: Yongpei Guan, University of Florida, 303 Weil Hall, Gainesville, FL, 32611, United States, guan@ise.ufl.edu

1 - Stochastic Scheduling For Large Scale Wind Integrated Power Systems

Lixin Tang, The Institute of Industrial Engineering and Logistics Optimization, Northeastern University, Insititue of Industrial Engineering and, Logistics Optimization, Northeastern, Shenyang, 110004, China, lixintang@mail.neu.edu.cn, Jin Lang

We propose a stochastic optimization problem which takes into account the volatility of large scale wind power integrated power systems. A scenario generation method which contains the information of forecast error distribution and fluctuation distribution for short-term wind power is proposed. The problem is formulated as a MINLP model. A Lagrangian relaxation algorithm is developed to solve the model.

2 - A Decomposition Approach For Hydropower Operation And Maintenance Scheduling

Miguel F. Anjos, Professor and Canada Research Chair, GERAD & Polytechnique Montreal, Montreal, QC, Canada, miguel-f.anjos@polymtl.ca, Jesus A. Rodriguez, Pascal Côté, Charles Audet

The generator maintenance scheduling problem is of great importance for power generation companies not only to prevent costly generator breakdowns, but also because of the impact of planned outages on the system operation. In hydroelectricity generation, the solution of this scheduling problem is complicated by uncertain water inflows, non-linear relationships between physical variables, and multiple interdependencies in space and time. Since the simultaneous solution of the hydro maintenance and operation problem is hard to achieve, we propose a linearized formulation and a decomposition approach for this problem. This work is based on the real case of Rio Tinto Aluminium in Canada.

3 - A Polyhedral Study Of The Integrated Minimum-up/-down Time And Ramping Polytope

Yongpei Guan, University of Florida, Gainesville, FL, United States, guan@ise.ufl.edu, Kai Pan

We study the polyhedral structure of an integrated minimum-up/-down time and ramping polytope, which has broad applications in variant industries. By exploring its structures, we derive strong valid inequalities and explore a new proof technique to prove these inequalities are sufficient to describe variant two-period and three-period convex hulls. For multi-period cases, we derive generalized facet-defining strong valid inequalities with efficient polynomial time separation algorithms to improve the computational efficiency. Extensive computational experiments are conducted to verify the effectiveness of our strong valid inequalities.

4 - Integrated Expansion Planning Framework For Interconnected Power Systems; Heat Supply; And Gas Infrastructure

Yasaman Mozafari, University of Calgary, Calgary, AB, Canada, y.mozafari@ucalgary.ca, William Rosehart

Increasing gas-fired generation capacity and interest in highly efficient combined heat and power generation units (CHPs) in power systems imply interdependencies between electricity, heat, and gas infrastructure. More efficient expansion planning results can be obtained by effectively modeling these couplings in the planning optimization problem. In this work, a comprehensive integrated framework for expansion planning of power systems, heat supply, and gas infrastructure is proposed. Modeling the independencies substantially reduces the cost and GHG emissions incurred in energy sector, which is illustrated through the simulation results for Alberta energy system.

2016 INFORMS BOM Section Best Working Paper Awards

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Stephen Leider, University of Michigan, Ann Arbor, MI, leider@umich.edu

1 - A Behavioral Study On Abandonment Decisions In Multi-Stage Projects

Javad Nasiry, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong, nasiry@ust.hk, Xiaoyang Long, Yaozhong Wu, Yaozhong Wu

We experimentally investigate continuation/abandonment decisions in a multi-stage project under two conditions: when the project is reviewed at every stage and when review opportunities are limited. We find systematic deviations from the optimal solution: subjects may wrongly continue or abandon the project, and their decisions are path dependent. We propose a behavioral model which explains the behavioral regularities.

2 - Ideation-Execution Transition In Product Development

Evgeny Kagan, University of Michigan, Ann Arbor, MI, kagan@umich.edu, Stephen Leider, William Lovejoy

We show experimentally that design performance is significantly worse when designers decide for themselves how to schedule the development process. We demonstrate several remedies for situations when external allocation of time to development phases is not possible. Managers can improve performance by “nudging” individuals towards early physical build, or by requiring them to commit to a transition time beforehand. However, the most effective way to improve performance is contingent transition - a requirement to present a prototype that exceeds a minimum performance hurdle.

3 - Impact of Queue Configuration On Service Time: Evidence From A Supermarket

Yong-Pin Zhou, University of Washington, Seattle, WA, yongpin@uw.edu, Jingqi Wang

We study how queue configuration affects server’s service time using data from a supermarket. We find that servers in dedicated queues are about 10.7% faster than those in pooled queues, after controlling for the queue length, mainly due to a direct social loafing effect. We also demonstrate that pooling has an indirect negative effect on the service time through its impact on the queue length. In aggregation, the social loafing effect dominates and servers slow down (a 6.86% increase in service time) in pooled queues.

Data Mining in Text Analytics

Sponsored: Data Mining

Sponsored Session

Chair: Onur Seref, Virginia Tech, Pamplin 1007, Blacksburg, VA, 24061, United States, seref@vt.edu

1 - Tracking The Evolution Of User Interests In Online Communities

Theodoros Lappas, Stevens University of Technology, tlappas@stevens.edu

Online communities are the hubs of our virtual world. A community is typically focused on a broad area, such as sports or politics. Interested users participate in the community by joining discussion threads on relevant topics within the scope of the general theme. In this work, we hypothesize that a user’s level of interest in each topic is correlated with her maturity within the community. We evaluate our hypothesis on datasets from different domains and present a temporal user-interest model. Our study provides insight on the nature of user generated content and has strong implications for any application based on user interests.

2 - A Network-based Model For Conversation Decomposition In Text Mining

Sukhwa Hong, Virginia Tech, Blacksburg VA, United States, sukhwa@vt.edu, Onur Seref, Michelle Seref, Alan Abrahams

We present a network-based framework to identify and cluster conversational phrases in classes of text data using prevalence scores of n-gram structures and their connections. Our framework extends the “bag-of-words” models by network-based clustering methods to create sub-graphs of connected n-grams. The paths in these sub-graphs represent sequences of words, which form conversational phrases with richer contextual meaning. We use sequence alignment methods to identify variations of these phrases and apply the proposed framework to study a collection of discussion posts from the automotive industry. We compare effectiveness of our method to standard “bag-of-words” models such as LDA.

3 - Two Are Better Than One? An Empirical Study On Crowd Performance For Stock Prediction

Hong Hong, Xiamen University, Xiamen, China, hongh@vt.edu Qianzhou Du, Alan G. Wang, Weiguo Fan, Di Xu

Online investment communities have been a popular venue for individual investors to share and interact with each other. Prior research confirms the importance of crowd wisdom in the stock markets context, but fails to investigate the impact of crowd characteristics on crowd performance. Guided by the Crowd Wisdom theory, we conduct an empirical study using data collected from Stocktwits to fill this research gap. Our findings show that diversity, independence, and decentralization are positively related to crowd performance. In addition, crowd size significantly moderates the influence of crowd characteristics on crowd performance. This study has both theoretical and practical implications.

4 - An Intelligent Multilayer Hotel Recommender System

Ashkan Ebadi, University of Florida, Gainesville, FL, United States, ashkan.ebadi@ufl.edu, Adam Krzyzak

Techniques behind the recommender systems have been improved over the time. Recommenders help users to find their required products or services through analysing and aggregating other users’ activities and behaviour. In this paper, we propose an accurate multi-layer hybrid hotel recommender system that uses multi-aspect rating. We used large-scale data of different types and designed a system that is able to suggest hotels which are tailored to the given user. The system employs natural language processing and topic modelling techniques to assess sentiment of users’ reviews. The recommender engine contains several sub-systems where each sub-system contributes to the final recommendations.

New Product Development

Invited: New Product Development

Invited Session

Chair: Jeremy Kovach, TCU, Fort Worth, TX, 76109, United States, j.j.kovach@tcu.edu

1 - An Economic Model Of Knowledge Outsourcing

Jaeseok Lee, Georgia Institute of Technology, 710 Peachtree St. NE, Apt. 312, Atlanta, GA, 30308, United States, jaeseok.lee@scheller.gatech.edu, Cheryl Gaimon, Karthik Ramachandran

We introduce a game-theoretic model of knowledge outsourcing. We study how the interaction between a knowledge buyer and supplier is affected by two distinctive aspects of knowledge outsourcing: absorptive capacity and the ability to leverage prior knowledge. We also investigate how uncertainty and information asymmetry influence the equilibrium outcomes.

2 - Effect Of Incentive Design On Location Decision Of Collaborative Product Development Teams

Sara Rezaee Vessal, HEC Paris, sara.rezaee-vessal@hec.edu Svenja C Sommer

To successfully compete on an international scale, multinationals increasingly turn towards globally dispersed product development teams, both to draw on a diverse set of expertise and to access moreaccurate local market knowledge. However, dispersion also creates additional challenges for collaboration, which can have negative effects on project performance. In this study, we compare dispersed and co-located teams and address the question how to incentivise them. We show that despite the current trend among firms, geographically dispersed teams are not always the optimal structure, especially when collaboration is in the form of information sharing.

3 - Optimal Price And Customization Of A Conspicuous Product

Cheryl Druehl, George Mason University, cdruehl@gmu.edu, Jesse Bockstedt

Technology has reduced the cost of mass customization, while the availability of design tools has allowed users to easily customize products. The mass customization of conspicuous goods, where utility rises from displaying the product to others, allows consumers to create uniqueness and exclusivity. The firm trades-off the cost vs the demand-enhancing impact of customization. Customers trade-off the cost to customize vs a good that better fits their preferences and their desire for exclusivity. The firm considers: How much customization to have at a given additional marginal cost? What should prices be for the standard and custom goods? Is a monopolist better off with both product offerings?

4 - Modeling Product Demand Using Customer Review Data

Hallie Cho, INSEAD, hallie.cho@insead.edu, Sameer Hasija, Manuel Sosa

Review sites have become a popular destination for consumers seeking product information such as general consensus about a product’s quality or tales of other’s first hand experience with a product. These online reviews suffer from personal bias, which makes them unreliable for potential buyers. However, this collection of personal biases can be of interest to manufacturers since reviews often highlight consumers’ preferences and perceptions of product quality. We explore in what ways these customer reviews are useful for manufacturers using data from the U.S. automobile industry.

Empirical Research in Operations and Service Innovation

Invited: Business Model Innovation

Invited Session

Chair: Jose A Guajardo, University of California - Berkeley, Berkeley, CA, United States, jguajardo@berkeley.edu

1 - Corporate Responsibility Or Greenwashing? An Empirical Analysis Of The Social Impact Of Corporate Social Responsibility Activities

Jun Li, Ross School of Business, University of Michigan, junwli@umich.edu, Andrew Wu

Corporate Social Responsibility (CSR) activities have been increasingly criticized by the public as greenwashing as they fail to deliver the intended social impacts. While most existing research on CSR focus on its link to profitability, little research studies the social impact of CSR. In this paper, we leverage a large-scale dataset collected during the last 9 years to examine the social impact of CSR efforts worldwide, and how voluntary vs. mandatary CSR reporting impacts the effectiveness of CSR.

2 - Surfacing The Submerged State: Operational Transparency Increases Trust In And Engagement With Government Services

Ryan Buell, Harvard Business School, rbuell@hbs.edu Ethan Porter, Michael Norton

As Americans’ trust in government nears historic lows, frustration with government performance approaches record highs. We propose that Americans’ views of government can be reshaped by increasing government’s operational transparency - that is, the extent to which citizens can see the often-hidden work that government performs. Across three studies using laboratory and field data, we provide converging evidence that increasing operational transparency can improve citizens’ views of and increase and sustain their engagement with government.

3 - Mobile Technology In Retail

Jose A Guajardo, University of California-Berkeley, jguajardo@berkeley.edu

We empirically analyze central aspects of the impact of mobile technology in retail in the context of the overall customer shopping experience.

4 - Ration Gaming And The Bullwhip Effect: A Structural Econometric Study

Rob Bray, Kellogg, robertlbray@gmail.com

We develop a dynamic discrete choice estimator of (s, S) inventory models. We apply this estimator to a 5,320-SKU, 1,371-day sample from a Chinese supermarket to quantify the effect of ration gaming.

Development of Electricity Systems

Invited: Energy Systems Management

Invited Session

Chair: Todd Levin, Argonne National Laboratory, 970 S. Cass Avenue, Lemont, IL, 60439, United States, tlevin@anl.gov

1 - Capacity Expansion Planning With Intermittent Energy Resources

Dong Gu Choi, Pohang University of Science and Technology (POSTECH), Pohang, Korea, Republic of, dgchoi@postech.ac.kr, Daiki Min, Jonghyun Ryu

Recently, renewable energy resources have been rapidly integrated into the electricity sector around the world and some recent studies about the capacity expansion planning for electric power system integrating renewable energies have been published. However, the most of these studies did not explicitly interpret the impact of the intermittency and non-dispatchability of some renewable energies on the system reliability. In this study, we propose a stochastic programming model to establish the long-term electricity capacity expansion planning for an electric power system integrating large size intermittent renewable energies with the consideration of the system reliability.

2 - Optimal Capacity Planning In Non-Interconnected Regions: Case Of Saudi Arabia

Bandar Alqahtani, Duke University, 9 Circuit drive, Box 90328, Durham, NC, 27514, United States, dalia.patino@duke.edu, Dalia Patino Echeverri

We conduct a techno-economic and environmental evaluation of the electricity generation options available to supply residential and commercial loads in remote areas in Saudi Arabia, over the next 25 years. A capacity planning model considers and compares the alternatives of developing distributed electricity generation versus the option of building a transmission interconnection to the national grid, operated by the Saudi Electricity Company.

3 - Examining Life Cycle Environmental Impacts Of Energy Storage For Power System Reserves

Jeremiah Johnson, University of Michigan, Ann Arbor, MI, United States, jxjohns@umich.edu, Yashen Lin, Noah Mitchell-Ward, Johanna Mathieu

Due to their speed of response and accuracy, energy storage systems may be a preferable alternative to conventional generation in providing power system reserves. We calculate the environmental impacts using lithium ion batteries for this ancillary service application using a life cycle assessment (LCA) framework, while solving an optimal power flow (OPF) problem under a series of grid configurations. Through this OPF-LCA integration, we demonstrate that (1) the impacts of materials and manufacturing are typically far smaller than use phase impacts and (2) there are many system configurations that yield a net increase in life cycle emissions when using energy storage for power system reserves.

4 - Demand Response Resource Quantification With Detailed Building Energy Models

Elaine Thompson Hale, Senior Engineer, National Renewable Energy Laboratory, Golden, CO, United States, elaine.hale@nrel.gov, Henry Horsey, Noel Merket, Brady Stoll, Ambarish Nag

Demand response is a broad suite of technologies that enables operational changes in electrical load in support of power system reliability and efficiency. Although demand response is not a new concept, there is new appetite for comprehensively evaluating its technical potential in the context of renewable energy integration. The complexity of demand response makes this task difficult—we present new methods for capturing the heterogeneity of potential responses from buildings, their time-varying nature, and metrics such as thermal comfort that help quantify likely acceptability of specific demand response actions. Computed with an automated software framework, the methods are scalable.

Energy Models: Diversity and Complementarity

Sponsored: Energy, Natural Res & the Environment, Energy II Other Sponsored Session

Chair: Denis Lavigne, Royal Military College St-Jean, St-Jean-sur-Richelie, QC, Canada, denis.lavigne@cmrsj-rmcsj.ca

1 - OSeMOSYS And LEAP Energy Modeling Using an Extended UTOPIA Model

Denis Lavigne, Professor, Royal Military College St-Jean, C.P. 100, succ. Bureau-chef, Richelain, QC, J0J 1R0, Canada, denis.lavigne@cmrsj-rmcsj.ca

Energy Models have been used extensively for decades. Leaders and decision makers need to have a basic understanding of such tools to gain insight on the existing (and future) energy systems and their different components. OSeMOSYS (optimization) and LEAP (simulation) offer a package with a smooth learning curve, allowing non-experts and low-budget organizations the possibility to use powerful yet simple software to make coherent analyses. An extended version of OSeMOSYS' UTOPIA model will be presented as a study example that can easily be performed and a link with LEAP will be proposed.

2 - Complementarity Modeling Of Electricity And Renewable Energy Credit Markets To Inform Effective Renewable Energy Policy Formation

Kristen R. Schell, Postdoctoral Fellow, University of Michigan, Ann Arbor, MI, United States, krschell@umich.edu
Joao Claro, Manuel Loureiro

To date, 84% of the world's countries have instituted a renewable energy target, or Renewable Portfolio Standard (RPS). Despite this global prevalence, policy design and target implementation varies widely. This study combines complementarity modeling of the electricity and renewable energy credit markets with generation expansion planning to meet an RPS, to assess the impacts different RPS policy designs have on social welfare, renewable energy investment, electricity prices and greenhouse gas emissions. The policy recommendations move toward optimal policy design to minimize externalities.

3 - The Application Of Promethee With Prospect Theory - opportunities And Challenges The Application Of Promethee With Prospect Theory In The Context Of Energy Sector Management

Jutta Geldermann, Prof. Dr., Georg-August-University Goettingen, Platz der Goettinger Sieben 2, Goettingen, 37073, Germany, jgelder@gwdg.de, Katharina Stahlecker, Nils Lerche

The incorporation of elements from Prospect Theory into PROMETHEE enables the decision maker to integrate reference dependency as well as to express loss aversion. To illustrate occurring opportunities and challenges of the developed approach, the results of an application concerning the identification of a sustainable bioenergy concept as well as the feedback from decision makers are presented. Additionally, potential approaches concerning a corresponding sensitivity analysis and the consideration of risk or uncertainty are discussed. Furthermore, the applicability of the developed approach for long-term decision support in energy systems analysis will be discussed.

4 - Multi-stage Investment Decisions In Renewable Generating Capacity: Comparison Of Different Approaches

Maria Ruth Dominguez Martin, PhD, University of Castilla - La Mancha, Avenida Carlos III, s/n, Toledo, 45071, Spain, Ruth.Dominguez@uclm.es, Miguel Carrion, Antonio J. Conejo

Renewable generating capacity needs to be significantly increased in power systems if the effects of global warming are to be mitigated. Moreover, due to the high uncertainty involved in long-term planning exercises, investment decisions are usually made in several stages as uncertainty unfolds over time. In this work we propose a multi-stage stochastic-programming investment model in renewable generating capacity, and apply different approaches to solve it. Specifically, we solve the proposed problem using stochastic programming under both multi-stage and rolling window frameworks, and linear decision rules, and compare the results with the deterministic approach.

Network Optimization Models and Applications II

Sponsored: Optimization, Network Optimization Sponsored Session

Chair: Jose Luis Walteros, University at Buffalo, SUNY, 413 Bell Hall, Buffalo, NY, 14213, United States, josewalt@buffalo.edu

1 - Integer Programming Models For Bipartitioning A Graph Enforcing Structure Constraints

Chrysafis Vogiatzis, North Dakota State University, chrysafis.vogiatzis@ndsu.edu

In this talk, we consider the problem of partitioning a graph into two distinct subgraphs, where one of the subgraphs satisfies a structural property. In literature, it is common to bipartition a graph using a normalized cut criterion; this well-studied problem leads to the creation of two similarly weighted subgraphs. There exist cases though, when one of the partitions needs to possess a certain structure or "motif". We investigate some structures, and propose ways to formulate and solve the problem. Computational results are also presented.

2 - Computing The Maximum Lifetime Flow Of A Network With Short Node Lifetimes

Hugh Medal, Mississippi State University, hugh.medal@msstate.edu

We study an extension of the maximum flow problem in which nodes have a limited amount of energy available and energy is consumed when the node sends or receives flow. The objective is to maximize the total s-t flow over the lifetime of the network, i.e., until node energy depletions result in a cutset. We present a polynomial-time algorithm as well as computational results.

3 - A Stochastic Programming Approach For Selecting Inland Waterway Maintenance Projects

Khatereh Ahadi, University of Arkansas, Fayetteville, AR, United States, kahadi@uark.edu, Kelly Sullivan

We consider the problem of selecting a budget-limited subset of maintenance actions to maximize the expected tonnage of commodities that can be transported through the system. Our model incorporates uncertainty due to shoaling and unpredictable water conditions. Due to the maritime transportation network's size, along with the variety of commodities transported via waterway, the maintenance project selection problem is large and complex, and small gains in efficiency can have a significant economic impact. We model this problem as a stochastic programming model, develop solution approaches, and analyze computational results.

4 - Convoy Formation Process

Azar Sadeghnejad Barkousaraie, University at Buffalo (SUNY), Buffalo, NY, United States, azarsade@buffalo.edu, Rajan Batta, Moises Sudit

A motor convoy may consist of hundreds of vehicles organized together for the purpose of control and secure movement. Besides specific constraints of convoy routing, length of a convoy, as a single transportation unit, shall not be neglected, which differentiates it from other transportation problems. Convoy formation process addresses an essential decision on how to constitute convoys and plan their movements on limited number of routes. The purpose of this research is to show the effect of convoy length on its movement and how it can be manipulated to better satisfy specific constraints of convoy movement problem.

Co-Chair: Jose R. Zubizarreta, Columbia University, New York, NY, United States, zubizarreta@columbia.edu

1 - Multivariate Matching Methods For Causal Inference That Are Balance-variance Pareto Optimal And Optimal Kernel Matching

Nathan Kallus, Assistant Professor, Cornell University and Cornell Tech, 111 8th Avenue #302, New York, NY, 10011, United States, kallus@cornell.edu

We present minimax and Bayesian optimality criteria for non-parametric matching for causal inference. These lead to extensions of existing methods, including nearest-neighbor (Cochran 1953) and coarsened exact matching (Iacus et al. 2011), that optimally and automatically adjust balance vis-à-vis matched sample variance. We develop a new optimal matching method we call optimal kernel matching (OKM), whose superiority we demonstrate theoretically (optimal rates) and empirically (with real data). We connect our theory to equal percent bias reduction (Rubin 1976), which we generalize to non-linear response functions, showing OKM can achieve uniform error reduction in non-linear settings.

2 - Large-scale Optimal Matching For Design-based Inference Using Integer Programming

Jose R. Zubizarreta, Columbia, New York, NY, United States, zubizarreta@columbia.edu, Juan Pablo Vielma

In observational studies in business research and empirical operations management, matching methods are often used to approximate the ideal study that would be conducted if it were possible to do it by controlled experimentation. In this paper, we present an alternative approach to matching using integer programming, discuss its theoretical properties, and illustrate its performance in real-world data sets.

3 - Leveraging Multiple Outcomes In Matched Observational Studies

Colin Fogarty, Massachusetts Institute of Technology, Cambridge, MA, United States, colin.b.fogarty@gmail.com

We demonstrate that when performing multiple comparisons in an observational study, the loss in power from controlling the familywise error rate can, through the solution of a quadratically constrained linear program, be attenuated when assessing the robustness of the study's findings to unmeasured confounding. We show that this allows for uniform improvements in the power of a sensitivity analysis both for the overall null across outcomes and for outcome-specific null hypotheses when compared to combining individual sensitivity analyses. We illustrate our method through an example examining the impact of smoking on naphthalene levels in the body.

Uncertain Linear Optimization

Sponsored: Optimization, Global Optimization

Sponsored Session

Chair: Jiming Peng, associate professor, University of Houston, 4800 Calhoun Road, Houston, TX, 77204, United States, jopeng@uh.edu

1 - Assessing Systemic Risk In Financial Market Under Uncertain Liabilities

Jiming Peng, University of Houston, jopeng@uh.edu

We consider the linear optimization model for assessing the systemic risk in a financial network where only partial information on the coefficient data matrix in available. We develop iterative procedures to identify the worst-case and the best-case. Our theoretical analysis and numerical experiments illustrate that the potential risk caused by the failure of a single bank in the network is much more severe than what's have been estimated in the literature.

2 - Vulnerability Analysis Of Financial Networks

Aein Khabazian, University of Houston, aeinkhabazian@gmail.com Jiming Peng

In this paper, we analyze the vulnerability of a financial network based on the linear optimization model introduced by Eisenberg and Noe (2001), where the right hand side of the constraints is subject to market shock and only partial information regarding the liability matrix is revealed. We conduct a new sensitivity analysis to characterize the conditions under which a single bank is solvent, default or bankrupted, and estimate the probability that some financial institute in the network will be bankrupted under mild assumptions on the market shock and the network structure. We also present some numerical experiments to verify the theoretical conclusions in the paper.

3 - A Copositive Perspective On Two-stage Adjustable Robust Linear Programming

Guanglin Xu, University of IOWA, guanglin-xu@uiowa.edu

We consider a two-stage adjustable robust linear optimization problem in which the right-hand side is uncertain and belongs to a convex and compact uncertainty set. We propose a copositive representation for the two-stage problem. We then provide a tractable inner approximation for the copositive program, which leads to a better performance compared to the well-known affine-rule policy. We show the effectiveness of our approach on several numerical examples.

1 - Robust Non Parametric Tests To Identify Treatment Effects

Noor E. Alam. M.D., Northeastern University, md.alam@neu.edu

We proposed a number of non-parametric robust testing tools to handle uncertainty in detecting treatment effect from observational studies data. In this work, we present an alternative to the standard non-parametric hypothesis tests by leveraging the power of discrete optimization technique. Its been found that our tests are robust to the choice of experimenter.

2 - Linear Probability Models And Big Data: Prediction, Inference, And Selection Bias

Galit Shmueli, National Tsing Hua University, Hsinchu, Taiwan, galit.shmueli@iss.nthu.edu.tw, Suneel Babu Chatla

Linear probability models (LPM) - linear regression models applied to a binary outcome - are used in various fields. We perform a simulation study to evaluate the pros and cons of LPMs compared to logit and probit, especially with Big Data. We consider common uses of binary outcome models: inference and estimation, prediction and classification, and selection bias. We find that coefficient directions, statistical significance and marginal effects yield results similar to logit and probit. LPM coefficients are consistent up to a multiplicative scalar. For classification and selection bias, LPM is on par with logit/probit in terms of class separation and ranking, but lacking for propensities

3 - Managing Brokers For The Sales Of A Complex New Product

Vahideh Abedi, California State University Fullerton, Fullerton, CA, United States, vabedi@fullerton.edu, Rahul Bhaskar

Firms introducing a new product typically rely on sales efforts of brokers to enhance sales. Customers make their purchase decision not only based on the word of mouth they have received from other customers about the product, but also based on the collective information received from the brokers. Therefore, brokers act synergistically to generate sales while competing. We develop an analytical framework for this sales process and show how it can facilitate important managerial decision making.

Stochastic and First-order Methods for Data Analysis

Invited: Modeling and Methodologies in Big Data

Invited Session

Chair: Guanghui Lan, Gatech, Atlanta, GA, United States, george.lan@isye.gatech.edu

1 - An Optimal Randomized Incremental Gradient Method

Yi Zhou, Georgia Institute of Technology, yizhou@gatech.edu

We introduce a deterministic primal-dual gradient (PDG) method that can achieve the optimal black-box iteration complexity for solving finite-sum convex optimization problems using a primal-dual termination criterion. We also develop a randomized version (RPDG) method, which needs to compute the gradient of only one randomly selected smooth component at each iteration, but can possibly achieve better complexity than PDG in terms of the total number of gradient evaluations. We also show that the complexity of the RPDG method is not improvable by developing a new lower complexity bound for a general class of randomized methods for solving large-scale finite-sum convex optimization problems.

2 - Decentralized Primal-dual Gradient Method

Soomin Lee, Georgia Institute of Technology, Atlanta, GA, United States, soomin.lee@isye.gatech.edu

We present a decentralized primal-dual gradient method for optimizing a class of finite-sum convex optimization problem whose objective function is given by the summation of m smooth components together with other relatively simple terms. The smooth components are distributed over a network of m agents with time-varying topology, but all agents share common components whose structure is suitable for efficiently computing the proximal operator. In our method, each agent alternatively updates its primal and dual estimates by computing the primal and dual proximal operator, and by communicating these estimates with other agents in the network. We provide convergence results of this method.

3 - Decomposing Linearly Constrained Nonconvex Problems By A Proximal Primal Dual Approach

Mangyi Hong, Iowa State University, mingyi@iastate.edu

We propose a new decomposition approach named the proximal primal dual algorithm (Prox-PDA) for smooth nonconvex linearly constrained optimization problems. We show that whenever the penalty parameter in the augmented Lagrangian is larger than a given threshold, the Prox-PDA converges to the set of stationary solutions, globally and in a sublinear manner. Interestingly, when applying a variant of the Prox-PDA to the problem of distributed nonconvex optimization (over a connected undirected graph), the resulting algorithm coincides with the popular EXTRA algorithm, which is only known to work in convex cases.

Data-driven and Robust Optimization

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Linwei Xin, U of Illinois at Urbana-Champaign, Urbana, IL, 61801, United States, lxin@illinois.edu

1 - Distributionally Robust Stochastic Optimization With Wasserstein Distance

Rui Gao, Georgia Institute of Technology, rgao32@gatech.edu, Anton J Kleywegt

We consider a distributionally robust stochastic optimization (DRSO) problem, in which the ambiguity set contains all the distributions that are close to the nominal distribution in terms of Wasserstein distance and satisfies certain correlation structure. Comparing to the widely-used -divergence and moment method, Wasserstein distance yields a more reasonable worst-case distribution. We derive a tractable dual reformulation of the DRSO by constructing the worst-case distribution explicitly via the first-order optimality condition.

2 - Robust Extreme Event Analysis

Clementine Mottet, Boston University, cmottet@bu.edu, Henry Lam

We propose a robust optimization approach to estimate extreme event performance measures. This approach aims to alleviate the issue of model misspecification encountered by conventional statistical methods that is amplified by a lack of data typically occurring in the tail region. We demonstrate the use of shape constraints to mitigate this issue and develop a solution scheme for the resulting optimizations. We show some numerical results and compare our approach to extreme value theory.

3 - Data-driven Optimization Of Reward-risk Ratio Measures

Ran Ji, George Mason University, Fairfax, VA, 22030, United States, jiran@gwu.edu, Miguel Lejeune

We study a class of distributionally robust optimization problems with ambiguous expectation constraints on reward-risk ratios. We develop a reformulation and algorithmic framework based on the Wasserstein metric to model ambiguity and to derive probabilistic guarantees that the ambiguity set contains the true probability distribution. The reformulation phase involves the derivation of the support function of the ambiguity set and the concave conjugate of the ratio function. We design bisection algorithms to efficiently solve the reformulation. We specify new ambiguous portfolio optimization models for various ratios. Computational results will be presented.

4 - Two-stage Distributionally Robust Unit Commitment Using Moment Information

Yuanyuan Guo, University of Michigan, yuanyg@umich.edu Ruiwei Jiang

As the renewable energy takes a growing share of the electricity markets, a considerable number of new renewable generators (e.g., wind and solar farms) are incorporated into daily power system operations. Because of fluctuating weather conditions or a lack of complete historical data, it can be challenging to accurately estimate the joint probability distribution of the renewable energy. In this paper, based on a small amount of historical data, we propose a two-stage distributionally robust unit commitment model that considers a set of plausible probability distributions. This model is less conservative than classical robust unit commitment models.

1 - A Computational Study Of Recent Approaches To Risk-averse Stochastic Optimization

Alexander Vinel, Auburn University, 3301 Shelby Center, Auburn, AL, 36849, United States, alexander.vinel@auburn.edu

We present a computational study evaluating some recent approaches to risk-averse stochastic optimization. We focus on the classes of coherent and convex measures of risk, including higher-moment coherent measures and certainty-equivalent convex measures. While the bigger part of the study is devoted to portfolio optimization model, other problems with real-life data are considered. Our main goal is to evaluate the performance of various recently proposed techniques and determine the properties that can be used in guiding the specific choices of decision criteria in practice.

2 - Risk Parity In The Context Of Risk-averse Stochastic Optimization

Nasrin Mohabbati Kalejahi, PhD Student, Auburn University, Auburn, AL, United States, nasrin@auburn.edu, Alexander Vinel

The concept of risk parity has been recently studied in the area of financial portfolio management. The idea behind it is to promote diversification in the portfolio by ensuring that each asset is equally contributing to the total risk. In this work we propose to consider risk parity in the context of modern risk measure theory, by studying risk parity based on conditional value-at-risk and other coherent measures. We are interested in evaluating the quality of the decisions that arise from this stochastic optimization framework in both financial and engineering applications.

3 - Computational Study For Two-stage Stochastic 0-1 Integer Programs With Absolute Semi Deviation Risk Measure

Saravanan Venkatachalam, Wayne State University, Saravanan.v@wayne.edu, Lewis Ntaimo

We present a methodology for absolute semi-deviation (ASD) risk-measure for stochastic 0-1 programs. ASD risk-measure models lack the typical block structure amenable for decomposition. The proposed methodology uses information from expected excess, and uses cutting planes based on sub-gradient information. Computational results for a supply chain application will be presented.

4 - Decomposition For Multistage Stochastic Programs With Quantile And Deviation Risk Measures

Prasad Parab, PhD Student, Texas A&M University, College Station, TX, United States, prasaddparab@tamu.edu, Lewis Ntaimo

We present decomposition for multistage stochastic linear programs (MSLPs) with quantile and deviation mean-risk measures. Incorporating certain risk measures makes MSLPs very difficult to decompose and solve. In particular, we study stochastic decomposition based algorithms for MSLPs with quantile deviation and absolute semideviation risk measures. A comparative study of the two mean-risk measures will be presented.

Recent Advances in Theory and Applications of IPCO

Sponsored: Optimization, Integer and Discrete Optimization

Sponsored Session

Chair: Manish Bansal, Northwestern University, C234 Technological Institute, 2145 Sheridan Road, Evanston, IL, 60202, United States, manish.bansal@northwestern.edu

1 - Decomposition For Loosely Coupled Mixed-integer Programs: A Multiobjective Perspective

Merve Bodur, Georgia Institute of Technology, merve.bodur@gatech.edu, Natashia Boland, Shabbir Ahmed, George L Nemhauser

We consider loosely coupled mixed-integer programs (MIPs), that consist of (possibly a large number of) interrelated subsystems and a small number of constraints, which link blocks of variables that correspond to different subsystems. Motivated by recent developments in multi-objective programming (MOP), we develop a MOP-based branch-and-price algorithm to solve loosely coupled MIPs. We discuss the similarities and differences of our algorithm with the traditional branch-and-price algorithm. Also, we present computational results on instances with knapsack structure in the subsystems.

2 - Maximum Demand Rectangular Location Problem

Manish Bansal, Northwestern University, Evanston, IL, United States, manish.bansal@northwestern.edu, Kiavash Kianfar

We introduce a new generalization of the classical planar maximum coverage location problem by positioning a given number of rectangular service zones (SZs) on the 2-D plane to cover a set of existing (possibly overlapping) rectangular demand zones such that the total covered demand is maximized. We refer to this problem as Maximum Demand Rectangular Location Problem (MDRLP) which also has application in camera-frame selection for telerobotics. We present an improved algorithm for the single-SZ MDRLP, which is at least two times faster than the existing exact algorithm. We then provide theoretical properties for multi-SZ MDRLP and an exact algorithm to solve it along with our computational results.

3 - Cutting Planes fromMultiple-term Disjunctions

Egon Balas, Carnegie Mellon University, eb17@andrew.cmu.edu

(Less than 600 characters excluding spaces): Lift-and-project cuts from split disjunctions have their counterpart as intersection cuts from a (feasible or infeasible) LP tableau, and thus can be generated by pivoting in the latter. This correspondence breaks down in the case of general disjunctions: here the bases of the CGLP and associated L&P cuts can be either regular or irregular. Irregular cuts do not correspond to intersection cuts and cannot be obtained by pivoting in the LP tableau; they tend to be more numerous and stronger than regular cuts. Some irregular L&P cuts can be generated without recourse to a higher dimensional CGLP, as generalized intersection cuts from the disjunction underlying the L&P cut.

Models and Methods for Large-Scale Mixed-Integer Optimization

Sponsored: Computing

Sponsored Session

Chair: Simge Kucukyavuz, Ohio State University, Ohio State University, Columbus, OH, United States, kucukyavuz.2@osu.edu

1 - Two-stage Stochastic Programming Models Under Multivariate Risk Constraints

Merve Merakli, Ohio State Universtity, Columbus, OH, United States, merakli.1@osu.edu, Simge Kucukyavuz, Nilay Noyan

In this study, we consider multicriteria risk-averse two-stage stochastic programming problems. The aim is to find the best decision for which the associated random outcome vector of interest is preferable to a specified benchmark with respect to the multivariate polyhedral conditional value-at-risk relation. In this case, classical decomposition methods can not be used due to complicating risk constraints. We propose an exact solution algorithm based on Benders decomposition and show its convergence. Computational experiments are performed on a disaster relief network design problem.

2 - Chance-constrained Stochastic Programming Under Variable Reliability Levels With An Application To Humanitarian Relief Network Design

Özgün Elçi, Sabanci University, Istanbul, 34956, Turkey, nnoyan@sabanciuniv.edu, Nilay Noyan, Kerem Bulbul

A recently introduced class of models treats reliability levels associated with chance constraints as decision variables and trades off the actual cost against the cost of the selected reliability levels. Leveraging recent methodological advances for solving chance-constrained linear programs with fixed reliability levels, we develop strong MIP formulations for this new variant with variable reliability levels. In addition, we introduce an alternate cost function type associated with the reliability levels which requires capturing the value-at-risk associated with a variable reliability level. We apply the proposed modeling approach to a new humanitarian relief network design problem.

3 - Bilevel Risk Averse Formulations Of Stochastic Programming Problems

Deniz Eskandani, Rutgers University, 100 Rockafeller Rd, Piscataway, NJ, 08854, United States, deniz.eskandani@rutgers.edu Jonathan Eckstein

We describe a bilevel programming technique to time-consistently formulate 3-stage stochastic programs without using nested risk measures. For some classes of applications, we empirically demonstrate that its behavior can be dramatically different from standard formulations.

4 - Irreducible Infeasible Subsystem Decomposition For Stochastic Integer Programs With Probabilistic Constraints

Lewis Ntaimo, Associate Professor, Texas A&M University, College Station, TX, United States, ntaimo@tamu.edu Bernardo Pagnoncelli

Probabilistically constrained stochastic integer programs (PC-SIPs) are very challenging to solve and linear programming (LP) provides very weak bounds on the optimal value. This work considers a decomposition approach using irreducible infeasible subsystem (IIS) inequalities for strengthening the LP-relaxation of PC-SIPs. Preliminary computational results will be presented.

Research and Teaching Opportunities in Project Management

Invited: Tutorial

Invited Session

Chair: Nicholas G Hall, Ohio State University, 658 Fisher Hall, 2100 Neil Avenue, Columbus, OH, 43210-1144, United States, hall.33@osu.edu

1 - Research And Teaching Opportunities inProject Management

Nicholas G Hall, Ohio State University, 658 Fisher Hall, 2100 Neil Avenue, Columbus, OH, 43210-1144, United States, hall.33@osu.edu

One-fifth of the world's economic activity, with an annual value of $12 trillion, is organized using the business process of project management. This process has exhibited dramatic growth in business interest in recent years, with a greater than 1000% increase in Project Management Institute membership since 1996. Contributing to this growth are many new applications of project management. These include IT implementations, research and development, software development, corporate change management, and new product and service development. However, the very different characteristics of these modern projects present new challenges. The partial resolution of these challenges within project management practice over the last 20 years defines numerous interesting opportunities for academic researchers. These research opportunities make use of a remarkably broad range of methodologies, including robust optimization, cooperative and noncooperative game theory, nonlinear optimization, predictive analytics, empirical studies, and behavioral modeling. Furthermore, the $4.5 trillion that is annually at risk from a shortage of skilled project managers, and the 15.7 million new jobs in project management expected by 2020, provide great opportunities for contributions to project management education. These educational opportunities include the integration of case studies, analytics challenges, online simulations, in-class games, self-assessment exercises, videos, and guest speaker presentations, which together form an appealing course for both business and engineering schools.

Applications of Stochastic Models in Medical Decision Making Problems

Sponsored: Health Applications

Sponsored Session

Chair: Mohammad Reza Skandari, University of British Columbia, #420 2053 Main Mall, Vancouver, BC, V6T-1Z2, Canada, reza.skandari@sauder.ubc.ca

1 - Patient-centered HIV Viral Load Monitoring Strategies In Resource-limited Settings

Diana Maria Negoescu, University of Minnesota, negoescu@umn.edu, Heiner Bucher, Eran Bendavid

Viral load (VL) testing is the most critical monitoring tool for assessing the effectiveness of treatment in HIV patients. The optimal frequency of VL monitoring remains unknown, despite it being the costliest routine monitoring tool for HIV in Sub-Saharan Africa. We formulate a model parameterized using person-level longitudinal data to simulate adherence behavior and disease dynamics over time, and to develop monitoring schedules that adapt to patient characteristics. We then evaluate the total costs and quality-adjusted life years achieved by monitoring VL at fixed intervals (status quo), as well as at variable intervals based on an individualized risk assessment of virologic failure.

2 - Timing The Use Of Breast Cancer Risk Information In Biopsy Decision Making

Mehmet Ayvaci, University of Texas at Dallas, Jindal School of Management, Dallas, TX, United States, ayvaci@stanford.edu, Mehmet Eren Ahsen, Srinivasan Raghunathan, Zahra Gharibi

Available clinical evidence is inconclusive on whether radiologists should use the patient risk profile information when interpreting mammograms. On the one hand, risk profile information is informative and can improve radiologists' performance, but on the other hand, it may impair their judgment by introducing biases in mammography interpretation. Therefore, it is important to assess whether and when profile information use translates into improved outcomes. We model the use of profile information in mammography using a decision theoretic approach and explore the value of profile information.

3 - Developing Near-optimal Biomarker-based Prostate Cancer Screening Strategies

Christine Barnett, University of Michigan, Ann Arbor, MI, United States, clbarnet@umich.edu
Brian Denton

Recent advances in the development of new biomarker tests, which physicians use for the early detection of cancer, have the potential to improve patient survival by catching cancer at an early stage. We describe a partially observable Markov decision process (POMDP) to compute near-optimal prostate cancer screening strategies. We present results based on Monte Carlo simulation to compare the policies developed using our approximated POMDP methods with those recommended in the medical literature.

4 - Optimizing Breast Cancer Diagnostic Decisions While Minimizing Overdiagnosis

Sait Tunc, University of Wisconsin-Madison, Madison, WI, United States, stunc@wisc.edu, Oguzhan Alagoz, Elizabeth S Burnside

Although the early diagnosis of breast cancer saves millions of lives every year, overdiagnosis of breast cancer may cause harm without benefit. We propose a large-scale MDP that uses multi-dimensional cancer risk vectors to incorporate cytologic grade to the breast cancer diagnostic decision problem and concomitantly reduce the overdiagnosis. We present efficient algorithms to find the exact solution to the given large-scale MDP, and introduce upper bounds to further improve the computational performance.

Policy Evaluation from Operations to Public Health

Invited: ORinformed Healthcare Policies

Invited Session

Chair: Diwakar Gupta, University of Minnesota and National Science Foundation, Minneapolis, MN, United States, guptad@umn.edu

1 - Facilitating Early Diagnosis Of Tuberculosis In India

Sarang Deo, Indian School of Business, sarang_deo@isb.edu

High incidence of TB in India is driven by long diagnostic delay resulting from poor practices of unorganized private providers, who are often patients' first point of contact. We develop an operational model of patients' diagnostic pathways and calibrate it using data collected from household surveys. We use it to estimate the impact of new technology and improved provider behavior on reduction of diagnostic delay. We also develop a stylized economic model of private providers and estimate the monetary incentive required to achieve reduction in diagnostic delay. These models have informed the design of a large pilot program funded by the Gates Foundation in two Indian cities of Mumbai and Patna.

2 - Casualty Distribution To Hospitals In The Aftermath Of Mass-casualty Events

Nilay T Argon, University of North Carolina, Chapel Hill, NC, 27514, United States, nilay@unc.edu, Alex Mills, Serhan Ziya

Following a disaster, emergency responders must transport a large number of casualties to hospitals by limited transportation resources. Based on a Markov decision process formulation, we develop heuristic policies that use limited information on travel times and congestion levels to determine how to allocate ambulances to casualty locations and which hospitals should be the destination for those ambulances. By means of a realistic simulation study, we show that the proposed heuristics provide substantial improvement in the expected number of survivors, even when only limited information about the system state is available.

3 - Hospital-physician Gainsharing Contract Design

Diwakar Gupta, University of Minnesota, Minneapolis, MN, United States, guptad@umn.edu, Mili Mehrotra, Xiaoxu Tang

Participation in the bundled payments for care improvement (BPCI) initiative has provided hospitals the ability to gainshare with physicians. We formulate a model to study the contracts that hospitals could offer physicians based on their historical as well as ongoing performance improvement. Physicians have private information about their costs of achieving different improvement targets. Physicians may choose to either enter the gainsharing agreements with the hospital or continue to operate under the fee-for-service schedule. We characterize the optimal contracts and analyze the distribution of the gains within a game-theoretic setting.

1 - Understanding Emergency Department Jumper Behavior: Actionable Insights From Claims Data Using Machine Learning

Xia (Summer) Hu, University of Maryland - College Park, College Park, MD, 20740, United States, xhu64@umd.edu
Sean Barnes, Margret Bjarnadottir, Bruce L Golden

Emergency Department (ED) "jumpers" refers to patients whose ED consumption levels have changed drastically over consecutive periods (e.g. frequent to non-frequent, or vice versa). Based on yearly insurance claim records, we leverage various learning algorithms to predict ED jumpers, whose behaviour are usually difficult to capture using traditional methods. Further, we analyze the characteristics of jumpers via clustering based on Bayesian Information Criteria. Based on this analysis, we provide actionable insights about preventable ED usage and risk management.

2 - Impact Of State And Federal Policy Changes By Socioeconomic Status On Emergency Medicine Practice In Maryland

David Anderson, CUNY Baruch, davidrybergandersonr@gmail.com, Edward Andrew Wasil, Bruce L Golden, Laura Pimentel, Jon Mark Hirshon, Fermin Barrueto

We study the effect of the implementation of the Affordable Care Act (ACA) and a Global Budgeting Revenue (GBR) structure for hospital reimbursement on the operations of Maryland emergency departments. Using a 24-month longitudinal dataset of monthly ED performance, we find that ACA/GBR implementation leads to a decrease in admission rate, increased revenue capture by hospitals, a decrease in the percent of uninsured patients, and a small increase in volume. Further, we find that all of the changes are more pronounced at hospitals with patient populations coming from lower socioeconomic status zip codes.

3 - Risk-adaptive E-triage In Emergency Medicine: A Prospective Analysis

Scott R Levin, Johns Hopkins School of Medicine, slevin33@jhmi.edu, Matthew Toerper, Diego A. Martinez, Heather Gardener, Eric Hamrock, Sean Barnes

Unprecedented levels of crowding and consequential delays in care have intensified the need for accurate triage in emergency departments (ED). For the majority of ED patients, the projected clinical course at presentation not is obvious. Almost half of adult ED visits nationally are triaged to emergency severity index (ESI) Level 3; the ambiguous midpoint of a 5-Level algorithm standard in the US. The objective of our electronic (e) triage tool is to improve differentiation of ED patients by enabling data-driven prognostication of risk of critical events and illness severity. The tool, prospectively evaluated at multiple sites, demonstrates improved detection of critically ill patients.

4 - An Evolutionary Computation Approach For Optimizing Multi-level Data To Predict Individual Patient Outcomes

Sean Barnes, Univ of Maryland-College Park, sbarnes@rhsmith.umd.edu, Suchi Saria, Scott R Levin

Widespread adoption of electronic health records and objectives for meaningful use have increased opportunities for data-driven applications in medicine and healthcare. Optimally specifying multi-level patient data—which can be defined at varying levels of granularity—for predictive modeling is a challenge that must be addressed. We present a general evolutionary computational framework to optimally specify multi-level data to predict individual patient outcomes. We evaluate its performance in predicting critical events for emergency department patients across five populations.

5 - Control System For Electronic Triage In The Emergency Department: Integrating The User Into Development Loop

Diego A. Martinez, Scott R. Levin, Johns Hopkins University School of Medicine, Baltimore, MD, dmart101@jhmi.edu

The potential for machine learning systems to improve via exchange of information with knowledgeable users has yet to be explored in much detail. In a pilot study in an emergency department of a large hospital, nurses were presented with triage level predictions, and they were able to provide feedback through a real-time communication system. The types of some of this feedback seem promising for assimilation of clinical gestalt by machine learning systems. The results show that to benefit from clinical gestalt; machine learning systems must be able to absorb information in a graceful manner and provide clear explanations of their predictions.

Strategy and Uncertainty

Invited: Strategy Science

Invited Session

Chair: Hart Posen, University of Wisconsin, University, Milwaukee, WI, 4, United States, hposen@bus.wisc.edu

1 - High On Innovation: The Impact Of Liberalization Policies On Creative Outcomes

Laurina Zhang, Ivey Business School, Western University, London, ON, Canada, lzhang@ivey.uwo.ca, Keyvan Vakili

We investigate the impact of two social liberalization policies and one anti-liberalization policy on innovation. We find that liberalization policies increase state-level patenting while the anti-liberalization policy reduces patenting. Liberalization policies increase incumbent inventors' patenting rate and the rate of entrance into inventorship. The policies do not impact average innovation quality but patents filed after liberalization are more likely to be built upon novel technological recombinations and cite more recent prior art. The findings highlight the impact of the social context on the rate and direction of innovation.

2 - Seeding The S-curve? The Role Of Early Adopters In Diffusion

Christian Catalini, Massachusetts Institute of Technology, 77 Massachusetts Avenue, Cambridge, MA, 00, United States, catalini@mit.edu, Catherine Tucker

In October 2014, all 4,494 undergraduates at MIT were given access to Bitcoin. As a unique feature of the experiment, students who would generally adopt only mature and established technologies were placed into an early-adopter condition: suddenly they had to decide to either learn more about Bitcoin and try to use it, to bet on its volatile future by holding it, or to simply cash out and convert it into US dollars. In this paper, we explore the students' response to the digital currency, and in particular how randomly delaying different types of students relative to their peers affected their adoption decision. Our results point to a novel mechanism through which early-adopters may influence diffusion.

3 - The AQ Model Of Probabilistic Judgment And Patterns Of Risk And Return

Ulrik W. Nash, University of Southern Denmark, Odense, Denmark, uwn@sod.dias.sdu.dk

We have long known that uncertainty about the world is crucial for understanding profit. Moreover, there are reasons to suspect that differences in the degree of uncertainty that firms perceive about the same situation may be a fundamental cause of their performance heterogeneity. Here I introduce the AQ model of probabilistic judgment and use it to predict the flow of money between firms in factor markets. Heterogeneous distributions of profit that capture observed patterns of risk and return summarize these flows.

4 - The Impact Of Learning And Overconfidence On Entrepreneurial Entry And Exit

Hart E Posen, University of Wisconsin-Madison, Madison, WI, 53705, United States, hposen@wisc.edu, John Chen, David Croson, Daniel Elfenbein

Research examining entrepreneurial entry and performance highlights the phenomena of excess entry and delayed exit. We develop a computational model wherein agents learn from experience both pre- and post-entry making endogenous entry and exit decisions. The model suggests excess entry and delayed exit result from a common process — entrepreneurs' ongoing efforts to learn about their prospects and act according to their updated information. One interesting result is that a population of unbiased entrants exhibits beliefs that overestimate their true success probabilities, providing a rational explanation for empirical patterns typically explained by individuals' biases.

Project Management Methodologies

Invited: Project Management and Scheduling

Invited Session

Chair: Yael S Grushka-Cockayne, Darden School of Business, Charlottesville, VA, United States, GrushkaY@darden.virginia.edu

1 - Multifarious Project Management Methodologies

Vered Holzmann, Tel Aviv University, veredhz@post.tau.ac.il, Yael S Grushka-Cockayne, Hamutal Weisz, Daniel Zitter

In order for a project manager to deliver an effective and efficient solution to the customer's needs, an adaptable methodology for the planning and execution of the project is to be adopted. Following the paradigm that "one size does not fit all", meaning each project has different characteristics that should be taken into consideration when selecting the appropriate management method for a project, this study suggests the exploitation of several methodologies in a project to effectively and efficiently delivery of a successful product. The conceptual framework is based on an integration of the waterfall, agile, and TOC methods to be applied in complex projects derived from specific attributes.

2 - Limiting Financial Risk From Catastrophic Events In Project Management.

Peter D Simonson, North Dakota State University, Fargo, ND, United States, psimonson@mac.com, Joseph Szmerekovsky

For a project manager, planning for uncertainty is a staple of their jobs and education. But the uncertainty associated with a catastrophic event presents difficulties not easily controlled with traditional methods of risk management. This dissertation proposes to bring and modify the concept of a project schedule as a bounded "Alphorn of Uncertainty" to the problem of how to reduce the risk of a catastrophic event wreaking havoc on a project and, by extension. The dissertation will present new mathematical models underpinning the methods proposed to reduce risk as well as simulations to demonstrate the accuracy of those models.

Assignment and Matching Markets

Invited: Auctions

Invited Session

Chair: Thayer Morrill, North Carolina State University, Raleigh, NC, United States, thayermorrill@gmail.com

1 - Which School Assignments Are Legal?

Thayer Morrill, North Carolina State University, thayermorrill@gmail.com

A plaintiff must demonstrate that actions caused her harm and that this harm is redressable in order to have legal standing. We define a set of assignments to be legal if whenever a student is harmed (has justified envy) there is no legal assignment where she is assigned to that school (her harm is not redressable). We show that for any school assignment problem, there is a unique set of legal assignments; the set of legal assignment is a superset of the assignments that eliminate justified envy; but the Lattice Theorem, Decomposition Lemma, and Rural Hospital Theorem all hold. Moreover, there is a unique, Pareto efficient, legal assignment: the assignment made by Kesten's EADA when all students consent.

2 - School Choice Under Partial Fairness

Umut Dur, North Carolina State University, udur@ncsu.edu

A recent trend in school choice suggests that districts are willing to violate certain types of priorities in order to improve students' welfare. We generalize the school choice problem by allowing such violations. We characterize the set of efficient outcomes for a school choice problem in this setting. We introduce a class of algorithms, denoted Student Exchange under Partial Fairness (SEPF), which guarantees to find a constrained efficient matching for any problem. Any efficient matching which improves upon a stable matching can be obtained via an algorithm within the SEPF class. We offer two applications, each corresponding to a different interpretation of priority violations.

3 - Optimization In Team Formation

Hoda Atef-Yekta, University of Connecticut, Hoda.AtefYekta@business.uconn.edu

In this talk we discuss a binary quadratic programming formulation for team-formation problems. We develop a column generation scheme which provides orders of magnitude speedups over existing algorithms, and compare the solutions obtained with those found by existing mechanisms on measures of efficiency, fairness, stability, and the effect of strategic behavior.

1 - Regulation And Efficiency In Government Procurement: A Regression Discontinuity Approach

Juan Camilo Serpa, McGill University, Montreal, QC, Canada, juan.serpa@mcgill.ca, Ruomeng Cui, Eduard Calvo

We study the effect of public regulation on contracting efficiency in the U.S., where efficiency is measured through delay times and budget overruns. To explore this effect, we use data from 12 million procurement contracts from the federal government, and exploit a natural experiment introduced Federal Acquisition Streamlining Act (FASA).

2 - On The Competitive And Collaborative Implications Of Category Captainship

Yasin Alan, Vanderbilt University, Nashville, TN, United States, yasin.alan@owen.vanderbilt.edu, Jeffrey P Dotson, Mumin Kurtulus

We empirically examine the impact of a category captainship implementation performed by a large U.S. grocer on various parties involved, including the retailer, the captain, and the competing manufacturers. Our findings verify some of the hypotheses developed in the relevant theoretical literature and refute others.

3 - The Effects Of Menu Costs On Operational Efficiency In Retail

Yannis Stamatopoulos, McCombs School of Business, Austin, TX, United States, yannis.stamos@mccombs.utexas.edu, Antonio Moreno-Garcia, Achal Bassamboo

It is well-documented that retail prices exhibit a certain degree of inertia. That is, prices often do not immediately respond to changes in demand and/or cost conditions. To explain this phenomenon, economists have employed the notion of menu costs, which summarize all price adjustment costs faced by firms (e.g., the costs of printing and distributing price tags). We empirically study the effect of menu costs on operational efficiency in retail.

4 - The Value Of Fit Information In Online Retail: Evidence From A Randomized Field Experiment

Santiago Gallino, Dartmouth College, Hanover, NH, santiago.gallino@tuck.dartmouth.edu, Antonio Moreno-Garcia

By implementing a series of randomized field experiments, we study the value of virtual fit information in online retail. Customers are randomly assigned to a treatment condition where virtual fit information is available or to a control condition where virtual fit information is not available. Our results show that offering virtual fit information increases conversion, basket sizes, average price of purchased products, and revisits to the site, while reducing fulfillment costs arising from returns and home try-on behavior.

New Models for Pricing

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Gustavo Vulcano, NYU, 44 West Fourth St, New York, NY, 10012, United States, gvulcano@stern.nyu.edu

1 - The Theory Of Large-scale Bundle Size Pricing

Tarek Abdallah, New York University, New York, NY, United States, tabdalla@stern.nyu.edu, Arash Asadpour, Joshua Reed

Bundle size pricing (BSP) is a non-traditional multi-dimensional selling mechanism where the seller prices the size of the bundle rather than the different possible combinations of bundles. In BSP, the seller offers the customer a menu of different sizes and prices. The customer then chooses the size that maximizes his surplus and customizes his bundle accordingly. We present a theoretical framework to analyze the large scale BSP problem. We show that, in the presence of a homogeneous population of consumers, as the number of items grows large, the optimal BSP is to offer a single size which depends on the consumers' budgets and the marginal costs.

2 - Coordinating Supply And Demand On An On-demand Service Platform: Price, Wage, And Commission Rate

Jiaru Bai, University of California- Irvine, Irvine, CA, 92617, United States, jiarub@uci.edu, Kut C So, Christopher S Tang, Hai Wang, Xiqun Chen

We study an on-demand service platform with heterogeneous customers and independent service providers. Customers are sensitive to both price and waiting time for the service, and service providers decide to participate in the platform based on their own reservation wage rates. The platform needs to select the optimal price and wage rates to maximize its own profit subject to some target service requirement.

3 - Price Competition With Consumer Price Perception

Dana Popescu, INSEAD, dana.popescu@insead.edu

While e-commerce has made price comparisons across retailers easier, consumers still have limited ability to search for the best deal on every product all the time. Most often, consumers form perceptions about the price competitiveness of a retailer by comparing the distribution of prices for only a subset of items across different retailers. If they perceive that a retailer has the lowest prices, then consumers can be inclined to purchase products from that retailer without a search, depending on the search costs and the expected savings from finding a better deal. In a market with heterogeneous products and multiple sellers we analyze the best pricing strategy for a retailer and its implications.

Sponsored Session

Chair: Xi Chen, University of Michigan-Dearborn, 2290 HPEC, 4901 Evergreen Rd, Dearborn, MI, 48128, United States, xichenxi@umich.edu

1 - Distribution Strategies For Supporting Poor Retailers In Developing Countries

Luyi Gui, The Paul Merage School of Business, UC Irvine, luyig@uci.edu

We analyze cooperative distribution strategies for supporting poor retailers in in the rural areas of developing countries that lack efficient infrastructure and distribution channels. We examine the effectiveness of two distribution strategies that are widely observed in practice: (1) purchasing cooperatives, (2) non-profit wholesaler. In particular, we consider how these mechanisms can promote the number of poor retailers and consumer welfare.

2 - The Impact Of Product Design On Closed Loop Supply Chain Coordination: Incentives For Input Material Reduction Vs. Enhanced Recycling

Tolga Aydinliyim, Baruch College, Tolga.Aydinliyim@baruch.cuny.edu, Eren Basar Cil, Nagesh N Murthy

We consider a setting wherein a buyer procures standard-size forgings from a supplier, and performs machining, which yields final components and significant scrap. Adopting a principal-agent framework, we investigate coordination implications while accounting for information asymmetry issues, and find that improved recycling across the supply chain can significantly mitigate decentralization cost.

3 - The Effectiveness Of Consumption- Versus Production-based Emission Tax Under Demand Uncertainty

Xi Chen, University of Michigan-Dearborn, xichenxi@umich.edu

In recent years, there has been a debate on whether emission taxes should be imposed at the points of production or directly at points of consumption. We investigate this important issue through a system that integrates tax mechanism design decision of the policy maker, with the production, pricing, and emission reduction decisions of a manufacturer, as well as the price sensitivity and demand uncertainty of consumers.

4 - Incentives And Emission Responsibility Allocation In Supply Chains

Sanjith Gopalakrishnan, University of British Columbia, Vancouver, BC, Canada, sanjith.gopalakrishnan@sauder.ubc.ca, Daniel Granot, Frieda Granot, Greys Sosic, Hailong Cui

Given an assignment, by a dominant supply chain leader, for direct and indirect responsibilities of GHG emissions to the various firms in a supply chain, we adopt cooperative game theory to derive a responsibility allocation, which is the Shapley value of an associated cooperative game. It satisfies several desirable properties - (i) it is easy to compute, (ii) it is uniquely characterized by some compelling axioms, and (iii) among all footprint balanced allocations, it incentivizes firms to exert abatement efforts that minimize the maximum deviation from the socially optimal pollution level.

1 - An Analysis Of Recycled Content Claims Under Demand Benefit And Supply Uncertainty

Aditya Vedantam, State University of New York at Buffalo, Buffalo, NY, United States, adityave@buffalo.edu, Ananth V Iyer, Paul Lacourbe

We investigate the drivers of a manufacturer's recycled content claim decision under demand benefit for recycled content and uncertainty in municipal supply. Two types of claims are identified - batch specific and batch average. We compare both types of claims and impact on manufacturer profit, recycled input and raw material usage. We parameterize our model to the fiberglass insulation industry and suggest insights.

2 - How Does Precision Affect The Adoption Of Energy Efficiency Practices? - Evidence From The Field And Laboratory Data

Suresh Muthulingam, The Pennsylvania State University, State College, PA, United States, suresh@psu.edu, Saurabh Bansal

This study aims to provide a comprehensive picture of how precision can affect the adoption of energy efficiency initiatives. We utilize three studies that start by establishing the impact of precision on the adoption of energy efficiency initiatives and then examine the mechanisms that govern how precision affects the adoption decisions. We find that precision has a positive impact on the adoption of energy efficiency practices. Additionally, the impact of precision is more pronounced in the presence of budgetary constraints. Finally, we identify trust as an important moderator of the precision effect.

3 - Government Subsidies For Green Technology Development Under Technology Uncertainty

Seung Hwan Jung, Washington University in St. Louis, St Louis, MO, United States, seunghwan.jung@wustl.edu, Tianjun Feng, Fuqiang Zhang

This paper investigates the subsidy design problem for green technology development by firms in an evolving market. We find that the subsidy plays a key role in improving social welfare under different industry environments. We also derive insights into how the subsidy policy affects firms' operational strategy.

4 - Price Vs. Revenue Protection: An Analysis Of Government Subsidies In The Agriculture Industry

Foad Iravani, University of Washington, Seattle, WA, United States, firavani@uw.edu, Saed Alizamir, Hamed Mamani

The agriculture industry plays a critical role in the U.S. economy and various industry sectors depend on the output of farms. To protect farmers' income, the U.S. government offers two subsidy programs to farmers: the PLC program which pays farmers a subsidy when the market price of a crop falls below a reference price, and the ARC program which pays a subsidy when a farmer's revenue is below a guaranteed level. We develop models to analyze the effects of these programs on consumers, farmers, and the government. We calibrate our model with USDA data and provide insights about the effects of crop characteristics and market characteristics on the relative performance of PLC and ARC.

Sponsored Session

Chair: Fehmi Tanrisever, Bilkent University, 6800 Bilkent, Ankara, Turkey, tanrisever@bilkent.edu.tr

1 - Mitigating Disruption Risks In Delivery Supply Chains To Serve Contracted Customers

Mert Hakan Hekimoglu, Rensselaer Polytechnic Institute, Troy, NY, United States, hekimm@rpi.edu, John H Park, Burak Kazaz

Motivated by an implementation in a Fortune 150 company, this paper helps a firm determine its capacity expansion decisions as a mitigation strategy against disruptions in a delivery supply chain. We formulate the firm's capacity planning problem using a two-stage stochastic model. While risk aversion generally leads to an increase in capacity investment, we find a surprising result that capacity may decrease with risk aversion. Our capacity expansion model is projected to make a 48% savings in the total expected operating costs stemming from disruptions under risk aversion.

2 - Competitiveness Of Supply Chains: A Financial Market Perspective

Gerd J. Hahn, German Graduate School of Management and Law, Heilbronn, Germany, gerd.hahn@ggs.de, Jochen Becker

In this paper, we analyze supply chain performance across various industries using financial statement and stock market data. By this means, we identify relevant value drivers from a supply chain perspective and show their impact on market valuation.

3 - Managing Price And Demand Risk In Flour Milling

Fehmi Tanrisever, Bilkent University, Bilkent University, Merkez Kampus Lojmanlari 80/5, Ankara, 06800, Turkey, tanrisever@bilkent.edu.tr, Junchi Tan, Zumbul Atan

We explore the value of downward substitution under stochastically evolving exogenous prices. In particular, we consider a multi-period inventory problem, in which a firm procures two kinds of substitutable inputs to be blended at a certain ratio to produce and sell a final output whose demand and price are uncertain. In this setup, we establish the conditions for the optimality of a base-stock policy and derive the optimal myopic policy for a firm's procurement and substitution decisions.

Structural Estimation in Operations

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Gabriel Weintraub, Columbia University, New York, NY, United States, gweintraub@columbia.edu

1 - The Efficacy Of Incentives In Scaling Up Marketplaces

Ashish Kabra, INSEAD, Boulevard de constance, Fontainebleau, 77305, France, ashish.kabra@insead.edu, Elena Belavina, Karan Girotra

Marketplaces spend billions in incentives to achieve scale, which is key to the efficacy and survival of marketplaces. Using detailed transaction data from a leading transportation marketplace, we estimate and compare the effects of incentives given to the "buyer" side and "seller" side of the marketplace as well as the effect of threshold and linear incentives.

2 - Spatial Competition And Preemptive Entry In The Discount Retail Industry

Fanyin Zheng, Columbia Business School, fz2225@gsb.columbia.edu

This paper studies how discount retailers make store location decisions by estimating a dynamic game model. It extends the empirical models of dynamic oligopoly entry by allowing for spatially interdependent entry and introducing machine learning tools to infer market divisions from data. The results suggest that preemptive incentives are important in chain stores' location decisions and that they lead to loss of production efficiency.

3 - Ergodicity And The Estimation Of Markov Decision Processes

Robert Bray, Kellogg, r-bray@kellogg.northwestern.edu

I create a class of dynamic discrete choice estimators that exploit Markov chain ergodicity. The empirical likelihood of a Markov decision process depends only on the differences in the value function. And whereas the value function converges with Bellman contractions at the rate of cash flow discounting, the value function differences converge at the rate of cash flow discounting times the rate of Markov chain mixing (the subdominant eigenvalue of the state transition matrix). With this strong convergence result, I make Rust's (1987) nested fixed point (NFXP) estimator 200 times faster in problems with more than 2,000 states.

4 - When Demand Projections Are Too Optimistic: A Structural Model Of Product Line Decisions

Andres I Musalem, U. de Chile / Complex Engineering Systems Institute, Beauchef 851, Santiago, 8370456, Chile, amusalem@duke.edu

A methodology is proposed to estimate structural models of product line competition. Not accounting for this endogeneity leads to overoptimistic estimates of demand due to a sample selection bias, which may generate misleading managerial recommendations. The methodology is illustrated using simulated and real data.

1 - Operationalizing Industry Cluster Strategies

Tayo Fabusuyi, Numeritics & Carnegie Mellon University, 5520 Baywood Street, Floor #3, Pittsburgh, PA, 15206, United States, tfabusuyi@cmu.edu, Juergen Pfeffer

Local economic development organizations are often tasked with promoting the health of the regional economy. However, the unique composition of each geographical area calls for a distinct approach that reflects the peculiarities of the local economy. We present an approach by which the information in input-output is modeled and enriched using network analysis. Using a simulated policy intervention, we show how the approach can provide insight on regional economies and provide an application to industry cluster analysis.

2 - A Comparison Of Gaussian Process Modeling Software

Collin Erickson, Northwestern University, 2145 Sheridan Road, Room C210, Evanston, IL, 60208, United States, collinerickson@u.northwestern.edu, Bruce Ankenman, Susan M Sanchez

We have found that different software packages can give different results when fitting the same Gaussian process model, often called kriging. We compare various packages on a variety of test problems, finding that the accuracy of predictions can differ significantly. An attractive feature of Gaussian process fitting is that the model includes an estimate of predictive variance. We focus on evaluating the reliability of this predictive error from these various packages. When fitting the same data and model, the run times of certain packages can also differ by orders of magnitude. The study takes a practitioners point of view, using each package with minimal tuning.

3 - Time Management Policies In A Queueing System

Ji-Eun Kim, PhD Student, The Pennsylvania State University, Imperial Towers, University Park, PA, 16801, United States, jxk594@psu.edu, David A. Nembhard, Hyeong Suk Na

Many job assignment problems are organized from a company's perspective to meet the demands of a schedule or to maximize workers' productivity, often ignoring the heterogeneity of pacing styles among workers. We show that if one considers the diversity in pacing styles, system productivity can be increased using one or more approaches. The purpose of this study is to test job assignment policies to be used in a queueing system considering servers' diversity in deadline reactivity. Empirical course website data was used to test a range of job assignment policies.

4 - Coordinating Station And Network Capacity In Urban Rail Transit System

Li Li, Southwest Jiaotong University, No.111, North Section 1, Second Ring Road, Chengdu, China, speciallili@home.swjtu.edu.cn, Haifeng Yan, Gongyuan Lu, Wu You

The performance of urban rail transportation is impacted by fluctuated passenger demand due to both the capacity constraint of station and line. The feature of high accessibility and volume makes a well coordinated train line plan in urban rail network very hard to be achieved. This research will present a stochastic integer programming model to demonstrate the mutual influence between passenger demand and train line plan. This model is solved by a simulation based approach which is applied in a real-world case in Chongqing Rail Transit Company.

1 - Multimodularity In The Stochastic Appointment Scheduling Problem With Discrete Arrival Epochs

Christos Zacharias, Assistant Professor, University of Miami, Coral Gables, FL, United States, czacharias@miami.edu, Tallys Yunes

We address the problem of designing appointment scheduling strategies that account for patients' no-show behavior, non-punctuality, emergency walk-ins and random service times. We maintain the discrete nature of the appointment scheduling problem by considering arrival epochs with discrete supports. We demonstrate that the optimal scheduling strategy minimizes a multimodular function, and a local search algorithm terminates with a globally optimal solution.

2 - Appointment Scheduling With Multiple Providers And Stochastic Service Times

Michele Samorani, Santa Clara University, Santa Clara, CA, United States, samorani@ualberta.ca, S Abolfazl Soltani, Bora Kolfal

We consider a multi-server appointment scheduling problem in which patients may not show up, and those who show up require stochastic service times. We model this problem as a Markov Chain and solve it through complete enumeration. Then, we employ statistical learning techniques to detect patterns among optimal solutions. We develop an effective heuristic method which uses these patterns to build near-optimal solutions. Our numerical experiments show that our methods result in higher-quality schedules than those obtained by existing models. We also test our heuristic with a field experiment made in collaboration with a local legal counseling clinic afflicted by high service time variability.

3 - Coordinated Appointment Scheduling Of An Integrated Practice Unit

Douglas Morrice, The University of Texas, Austin, douglas.morrice@mccombs.utexas.edu, Dongyang Ester Wang, Kumar Muthuraman, Jonathan F Bard, Luci Leykum, Susan Noorily

In this research, we develop a coordinated approach to patient appointment scheduling that enables a patient to receive multiple services on a single visit. The approach is compared to heuristics used in practice. A case study in pre-operative care involving the integration of Anesthesiology and Internal Medicine is used to motivate and illustrate the results.

Empirical Research in Healthcare Operations

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Mor Armony, New York University, Stern School of Business, New York, NY, 10012, United States, marmony@stern.nyu.edu

1 - Refining Workload Measure In Hospital Units: From Census To Acuity-adjusted Census In Intensive Care Units

Song-Hee Kim, Marshall School of Business, University of Southern California, Los Angeles, CA, United States, songheek@marshall.usc.edu, Edieal Pinker, Joan Rimar, Elizabeth Bradley

We aim to better understand the impact of ICU workload on patient outcomes, so that practitioners and researchers can use such understanding to provide high quality care despite increased hospital crowding. Using data from two ICUs and a dynamic measure of patient acuity, we show when acuity-adjusted workload is high sicker patients are discharged and longer-term outcomes are affected. Our findings suggest 1) ICUs need to track changes in patient acuity and 2) future studies of ICU workload should take patient acuity into account in workload measures. Using a simulation study, we show how high acuity-adjusted workload can be prevented by reducing seasonality in patient arrivals.

2 - Data-driven Appointment Scheduling Under Uncertainty: The Case Of An Infusion Unit In An Oncology Center

Nikolaos Trichakis, MIT, Cambridge, MA, United States, ntrichakis@mit.edu, Avishai Mandelbaum, Petar Momcilovic

We develop a novel, data-driven approach to deal with appointment sequencing and scheduling in a multi-server system, where both customer punctuality and service times are stochastic. Our approach relies on an infinite-server queuing model approximation. We calibrate our model using a data set of unprecedented resolution, gathered at a large-scale outpatient oncology practice, and illustrate how our approach can be utilized to improve infusion scheduling. We also demonstrate the performance of our approach by comparing it with existing state-of-the-art sequencing and scheduling algorithms.

3 - The Effect Of Online Reviews On Physician Demand: A Structural Model Of Patient Choice

Yuqian Xu, NYU, yxu@stern.nyu.edu, Mor Armony, Anindya Ghose

Social media platforms for healthcare services are changing how patients choose doctors. In this paper, we wish to derive the impact of online information on patient choice of outpatient care doctors. We are especially interested in how operational factors influence demand. We propose a random coefficient logit model to characterize consumer heterogeneity in doctor choices, taking into account both numeric and textual user-generated content with text mining techniques. Our interdisciplinary approach provides a framework that combines machine learning and structural modeling techniques with empirical operations management.

1 - Assessing Uncertainty From Point Forecasts

Zhi Chen, INSEAD, Singapore, Singapore, Zhi.Chen@insead.edu, Anil Gaba, Dana Popescu

This paper develops a parsimonious model for combining correlated point forecasts into a probability distribution for the quantity of interest. The model is compared with other commonly used methods that either ignore the lack of dependence between the point forecasts and/or use a certainty equivalent approach in estimating the distribution parameters, hence ignoring the parameter uncertainty. We further illustrate the implications for a decision maker in a newsvendor setting, where our model leads to profits that are higher on average when compared to the other widely used methods.

2 - Analytical And Empirical Study Of Complementarities In An Online Advertising Supply Chain And Their Impact On Optimal Operating Policies And Profits

Changseung Yoo, PhD Student, The University of Texas at Austin, Austin, TX, United States, changseung.yoo@phd.mccombs.utexas.edu, Anitesh Barua, Genaro Gutierrez

We examine channel structures and pricing models in an online advertising supply chain using a proprietary dataset. We develop analytic as well as structural econometric models that enable us to and quantify synergy effects between them. While the extant literature emphasizes choosing between pricing models, we show that using multiple models in concert yields higher overall profitability due to strategic complementarities among the pricing schemes. We then explore the operating implications of the complementarities and their impact on profits and supply chain efficiency, and devise information/profit sharing contracts that boost the supply chain profit towards the benchmark scenario.

3 - Supplier Centrality And Auditing Priority In Socially Responsible Supply Chains

Jiayu Chen, The University of Texas at Dallas, Richardson, TX, United States, jxc144030@utdallas.edu, Anyan Qi, Milind Dawande

We consider a supply network where buying firms' brand may be damaged by sourcing from suppliers who fail to comply with socially responsible standards. To mitigate the risk, firms may audit their suppliers. We derive firms' equilibrium auditing strategy and propose approaches to mitigate the inefficiency.

4 - Dynamic Coordination In A Supply Chain With Production Capacity Uncertainty

Zhongjie Ma, Purdue University, 403 W State Street, West Lafayette, IN, 47906, United States, ma220@purdue.edu, Qi Feng, J. George Shanthikumar

We study the effect of upstream supply capacity uncertainty on the inventory decisions in a two-stage supply chain from both centralized and decentralized perspectives. Extending the notion of stochastic linearity and directional concave order, we show that the centralized problem is concave via transformation. This observation allows us to extend the well-known Clark-Scarf decomposition results to the multi-echelon inventory system with random capacity. Furthermore, we discuss the mechanism to dynamically coordinate the supplier's and retailer's decisions when they each possess private information.

1 - Optimal Feed-in Tariff Policies: The Role Of Technology Manufacturers

Shadi Goodarzi, HEC, Paris, France, shadi.goodarzi@hec.edu Sam Aflaki, Andrea Masini

We assess the effectiveness of feed-in tariff policies in promoting renewable energy technologies taking into account technology manufacturers' decisions. Modeling a three-tier supply chain that includes potential adopters, technology manufacturers and a grid operator, we show that the ability of feed-in tariffs to induce renewable energy adoption is strongly affected by the technology manufacturers' market characteristics.

2 - Product Allocation Under The Risk Of Recall

Long He, National University of Singapore, longhe@nus.edu.sg, Ying Rong, Zuo-Jun Max Shen

When product recalls happen, companies not only have to deal with additional logistics costs but also a damaged reputation. To alleviate the severe consequences of product recall, we develop a model to compare dedicated and uniform product allocation strategies with associated sourcing plans. We also discuss the impacts of key factors in the performance comparison.

3 - Reducing Carbon Emissions In Grocery Retail

Ekaterina Astashkina, INSEAD, Boulevard de Constance, Fontainebleau, 77305, France, ekaterina.astashkina@insead.edu, Elena Belavina

We build a stylized model for traditional and online grocery retail chains to understand the drivers of the consumer and retailer carbon footprint, including emissions that come from food waste and transportation. In our model, consumers make endogenous choices between different channels and the associated food-buying policies, while retailers optimally manage their inventory replenishment. We find that, in most cases, the availability of an online retailer reduces the emissions associated with the grocery sector in a city. We also consider the effectiveness of alternate policy instruments including sales and carbon taxes, and identify actions that improve the behavior of the worst offenders.

4 - Optimizing Water Pollution Monitoring System: Regulation Policy Guideline For Curbing Nutrient Pollution

Michael Lim, U of Illinois at Urbana-Champaign, Champaign, IL, 61820, United States, mlim@illinois.edu

We examine regulatory guidelines of surface water quality to curb nutrient pollution resulting from various farming activities. Specifically, we formulate an optimization model that captures the government's regulation decision taking into account farmers' moral hazard issues: determining the optimal location of monitor stations along with optimal penalty schemes for each watershed district. We explore the model using the Illinois State water network to ensure practical relevance and to obtain further insights on regulation policy.

Behavioral Modeling with Social Data

Invited: Social Media Analytics

Invited Session

Chair: Tauhid Zaman, MIT, 77 Mass Ave, Boston, MA, 02139, United States, zlisto@mit.edu

1 - Optimal Policies For Finding Users Hiding In Social Networks

Christopher Marks, MIT, cemarks@mit.edu

During 2015 we collected data from approximately 5000 Twitter accounts belonging to ISIS users, ISIS supporters, and other users that appeared to be closely connected to the ISIS network. We observe that many of these users are frequently suspended, only to immediately open new accounts from which they continue their online activities. We present a dynamic search method for finding new accounts belonging to previously suspended users that relies on machine learning methods to generate model inputs. We analyze this search method in the context of dynamic programming and provide some insights into characteristics of an optimal search policy.

2 - Optimal Following Policies In Social Networks Using Integer Programming And Network Centrality

Tauhid Zaman, Massachusetts Institute of Technology, zlisto@mit.edu, Krishnan Rajagopalan

We consider the problem of interacting with users in a social network in order to maximize the number of followers obtained. We formulate the problem as an integer program (IP). We then show how to dramatically speed the time needed to solve the IP by modifying the objective using network centrality functions. Through simulations on real social networks, we find that our modified IP can increase the number of followers obtained versus random and pure network centrality based policies.

3 - Bayesian Inference Of User Geolocation Using Social Media Activity Time Series

Matthew Robert Webb, MIT, Cambridge, MA, United States, mrwebb@mit.edu

We propose a novel Bayesian classification algorithm to determine the global location of Muslim extremists from their social media activity based on their unique pattern of life. The tenants of Islam require five daily prayers; but rather than being set, prayer times are determined by the location of the Sun in relation to the Earth's horizon. By assuming Muslim users will not utilize social media during prayers, we attempt to infer their longitude and latitude based on their pattern of inactivity.

4 - The Value Of Social Media To Online Content

Michael Zhao, MIT, Cambridge, MA, United States, mfzhao@mit.edu, Sinan Aral

Many believe social media drives online content consumption and vice versa. The potential of this positive feedback loop is critical to marketers, publishers, politicians, and beyond. However, this type of relationship induces endogeneity problems that make casual identification difficult. We overcome this challenge by constructing a unique article-location panel dataset using proprietary data from a large online and print media company. We employ a novel IV estimation strategy by using location-specific weather patterns as instruments for social media sharing thereby allowing us to identify the degree to which social media effects the demand for online content.

Sponsored Session

Chair: Rafael Mendoza, McCombs School of Business, University of Texas, Austin, TX, 78712, United States, rafael.mendoza-arriaga@mccombs.utexas.edu

1 - On Latency And Volatility

Richard Sowers, University of Illinois, r-sowers@illinois.edu

We present a simple model of the effects of latency on the properties of observed asset prices. In our model, latency is a delay between the observed asset price and its true, but latent fundamental price. Because of latency, the observed asset price shadows the true but latent asset price at some deformed time away. Deformation in a clock gives rise to fluctuations in volatility. We provide an asymptotic result that links latency to the volatility of volatility.

2 - Energy Production & Games With Stochastic Demand

Ronnie Sircar, Princeton, sircar@princeton.edu

The dramatic decline in oil prices, from around $110 per barrel in June 2014 to around $30 in January 2016 highlights the importance of competition between different energy sources. Indeed, the price drop has been primarily attributed to OPEC's strategic decision not to curb its oil production in the face of increased supply of shale gas and oil in the US, coupled with reduced demand from China. We model these phenomena as dynamic Cournot games in a stochastic demand environment, and illustrate how traditional oil producers may react in counter-intuitive ways in face of competition from alternative energy sources.

3 - Welfare Analysis Of Dark Pools

Krishnamurthy Iyer, Cornell University, Ithaca, NY, United States, kriyer@cornell.edu, Ramesh Johari, Ciamac Cyrus Moallemi

We investigate the welfare implications of operating alternative market structures known as "dark pools" alongside a "lit" dealer market. Our setting consists of intrinsic traders and speculators, with heterogeneous private information as to an asset's value, who endogenously choose between the two venues. We establish that while the dark pool attracts relatively uninformed traders, the orders therein experience adverse selection. Moreover, the informational segmentation created by a dark pool leads to greater transaction costs in the lit market. From this, we conclude that there exist reasonable parameter regimes where the introduction of a dark pool decreases the overall welfare.

Chair: Rene A Caldentey, University of Chicago, Chicago, IL, United States, rene.caldentey@chicagobooth.edu

Co-Chair: Yifan Feng, The University of Chicago, 5807 S Woodlawn Ave, Chicago, IL, 60637, United States, yfeng4@chicagobooth.edu

1 - Learning Customer Preferences Through Crowdvoting

Yifan Feng, University of Chicago, Chicago, IL, 60637, United States, yfeng4@chicagobooth.edu, Rene A Caldentey, Christopher Ryan

We study a seller introducing a new product with multiple potential product designs into the marketplace. In order to pick the design that is most likely to be preferred by customers, the seller uses an online system that allows potential buyers to vote for their preferred designs. We study how to dynamically customize each individual voter's choice set, in order to most efficiently learn overall customer preferences. We propose an algorithm that balances breadth of choice and accuracy in determining the best product. We show this algorithm is asymptotically optimal in speed of learning.

2 - Simultaneous Vs. Sequential Crowdsourcing Contests

Lu Wang, University of Toronto, Rotman School of Management, 105 St George Street, Toronto, ON, M5S 3E6, Canada, lu.wang12@rotman.utoronto.ca, Ming Hu

In a crowdsourcing contest, innovation is outsourced to an open crowd. We consider two alternative crowdsourcing mechanisms for an innovative product involving multiple attributes. One is to run a simultaneous contest, where the best is selected from the single solution simultaneously submitted by each contestant. The other is to run multiple sequential sub-contests, with each dedicated to one attribute and a later sub-contest built on the best outcome from earlier sub-contests. While both mechanisms have their own advantages, either could win over depending on situations.

3 - Contests And Inequality

Mohamed Mostagir, University of Michigan, Ann Arbor, MI, United States, mosta@umich.edu, Yesim Orhun, Hamidreza Tavafoghi

Contests are one of the standard mechanisms that firms employ to extract the most effort from participants, whether these participants are crowd workers or the firm's own personnel. We study contests that are repeatedly played by the same agents, with a focus on how information revelation about past play impacts future efforts. We show that such revelation can be detrimental to aggregate effort, and discuss how regulations (e.g. the SEC Dodd-Frank act) that require employers to reveal wages in an attempt to curb inequality can lead to unexpected effects that ultimately result in higher inequality amongst workers in environments that resemble contests, i.e. where wages follow a rank-based structure.

1 - Analyzing Both The Cost And Strategic Value Of Sustainable Supply Chains

Jason Merrick, Virginia Commonwealth University, jrmerric@vcu.edu, Paul Brooks, Lance Saunders

The Brazilian government will require the use of additives in all gasoline fuel starting in 2017. We use optimization modeling to help our industry partner design their new supply chain network and study the cost of reducing carbon emissions. However, we then use decision analysis to study the strategic value of sustainable supply chain designs in obtaining market share. In our case study, the strategic value outweighs the cost of reducing emissions.

2 - Eliciting Newsvendor Quantile: Direct Or Decomposed Assessments?

Saurabh Bansal, Penn State, sub32@psu.edu

We consider the newsvendor problem that is commonly used in practice. We report the results of a laboratory study in which participants provide (i) direct solution to the problem, (ii) decomposed solution to the problem. Our results help identify the optimal discretion levels that should be provided to managers.

3 - Supporting The Prioritization Of Emerging Animal Health Threats For The UK Department Of Agriculture With Decision Analysis

Gilberto Montibeller, Loughborough University, Loughborough, United Kingdom, g.montibeller@lboro.ac.uk

Gilberto Montibeller, Decision Consulting Ltd., Leicester, United Kingdom, g.montibeller@lboro.ac.uk, L. Alberto Franco

Emerging animal health threats pose serious risk to humans and countries, and represent a serious challenge for both analysts and policy makers. We employed a decision analytic framework to develop a risk management support system to help the UK Department of Agriculture (DEFRA) with the prioritisation of such threats, providing an effective mechanism for ranking them and supporting the design of policy recommendations. The system is supporting the recommendations of DEFRA's Veterinary Risk Management group since 2009. Benefits for the client include increased rigour in evidence gathering, transparent assessments, and a traceable and more streamlined decision process.

4 - How Did We Integrate Optimization And Machine Learning In our Solution Tool at Mckinsey

Halil I Cobuloglu, Sr. Research Analyst, McKinsey & Company, 404 Wyman Street, Waltham, MA, 02451, United States, halil.cobuloglu@gmail.com, Dimitris Bertsimas, Nathan Uhlenbrock, Prodipto Ghosh

In this project, we have developed a territory optimization tool for our clients. In order to reach solution fast, we have integrated various algorithms including machine learning and optimization techniques in our model. This tool helps companies efficiently use their limited sources and optimize their territories with more balanced workload.

1 - Generalized Likelihood Ratio Method For Stochastic Derivative Estimation

Yijie Peng, Fudan University, pengy10@fudan.edu.cn, Michael Fu, Jianqiang Hu

We propose a generalized likelihood ratio method for stochastic derivative estimation in a general framework that can handle discontinuities in both the sample performance and sample path. The classical likelihood ratio method is a special case where the parameter does not appear in the sample performance. In addition, the new method generalizes the push-out likelihood ratio method. The framework also includes most settings where infinitesimal perturbation analysis applies, although the actual estimator differs in general. Examples demonstrate the proposed method works for a broad set of applications, many of which cannot be handled by existing methods.

2 - Advanced Simulation Optimization Approach

Loo Hay Lee, National University of Singapore, iseleelh@nus.edu.sg, Chun-Hung Chen

In this talk, we will present some potential research topics in simulation optimization and discuss some of the preliminary work.

3 - Challenges In Applying Ranking And Selection After Search

David Eckman, Cornell University, Ithaca, NY, United States, dje88@cornell.edu, Shane Henderson

It is often appealing to reuse simulation replications taken during a simulation optimization search as input into a ranking-and-selection procedure. However, even when replications are i.i.d. and independent across systems, we show that when the search uses the observed performance of explored systems to identify new systems, conducting ranking-and-selection procedures that reuse the search replications can result in probabilities of correct (and good) selection below the prespecified level. We also show a similar deterioration in the guarantees of subset-selection procedures.

4 - A Partition-based Random Search For Stochastic Constrained Optimization Via Simulation

Weiwei Chen, Rutgers Business School, wchen@business.rutgers.edu, Siyang Gao

This research focuses on the global optimization over finite solution space with deterministic objective function and stochastic constraints. Due to the random noise observed in the constraints, the feasibility of a solution is unknown and can be best evaluated by simulation. We propose a partitioning scheme to explore the solution space and develop a feasibility detection procedure for the sampled solutions. A partition-based random search approach with multi-constraint feasibility detection (PRS-MFD) is then proposed to search for the optimal solution. The efficiency of PRS-MFD is shown by numerical experiments, and it is proved to converge to the set of global optima with probability one.

Revenue Management and Assortment Optimization

Sponsored: Revenue Management & Pricing"

Sponsored Session

Chair: Hamid Nazerzadeh, University of Southern California, Marshall School of Business, Los Angeles, CA, 90089, United States, nazerzad@marshall.usc.edu

1 - Real-time Optimization Of Personalized Assortments

Negin Golrezaei, University of Southern California, golrezae@usc.edu

Motivated by the availability of real-time data on customer characteristics, we consider the problem of personalizing the assortment of products for each arriving customer. Using actual sales data from an online retailer, we demonstrate that personalization based on each customer's location can lead to over 10% improvements in revenue compared to a policy that treats all customers the same. We propose a family of index-based policies that effectively coordinate the real-time assortment decisions with the back-end supply chain constraints. We allow the demand process to be arbitrary and prove that our algorithms achieve an optimal competitive ratio.

2 - Online Personalized Resource Allocation With Customer Choice

Van-Anh Truong, Columbia University, New York, NY, United States, vt2196@columbia.edu, Guillermo Gallego, Anran Li, Xinshang Wang

We introduce a general model of resource allocation with customer choice. This problem has a number of applications, including personalized assortment optimization, revenue management of parallel flights, and web- and mobile-based appointment scheduling. We derive online algorithms that are asymptotically optimal and achieve the best constant relative performance guarantees for this class of problems.

3 - Assortment Personalization In High Dimension

Madeleine Udell, Cornell University, Ithaca, NY, United States, udell@cornell.edu, Nathan Kallus

We show how to perform assortment personalization in sublinear time by imposing a natural low rank structure on the problem. In the static setting, we show that this model can be efficiently learned from surprisingly few interactions. In the dynamic setting, we show that structure-aware dynamic assortment personalization can have regret that is an order of magnitude smaller than structure-ignorant approaches.

4 - Position Auctions With Search Cost

Heng Zhang, University of Southern California, Heng.Zhang.2019@marshall.usc.edu, Leon Yang Chu, Hamid Nazerzadeh

Companies such as eBay, Amazon, and Google have created e-commerce platforms that connect online sellers and online users. In this work, we study how these platforms should rank the products displayed to their users. We present a general model that captures several important aspects of these environments including consumer's search cost. Our analysis highlights the inefficiencies that can be created due to the asymmetry of information among the sellers and the platform. We present an optimal mechanism as well as a simple near-optimal heuristic.

Multi-product Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: David Simchi-Levi, Massachusetts Institute of Technology, Cambridge, MA, United States, dslevi@mit.edu

Co-Chair: He Wang, MIT, 77 Massachusetts Ave, Cambrdige, MA, 02139, United States, wanghe@mit.edu

1 - Reaping The Benefits Of Bundling Under High Production Costs

Will Ma, MIT, willma353@gmail.com, David Simchi-Levi

It has long been known that selling different goods in a single bundle can significantly increase revenue, but that this is no longer the case if the goods have high production costs. We introduce a simple pricing scheme, called Pure Bundling with Disposal for Cost (PBDC), that captures the benefits of bundling under high costs, extracting all of the surplus in settings where previous simple mechanisms could not. We also prove a theoretical guarantee on the performance of PBDC that holds for arbitrary independent valuation distributions, by adopting and improving techniques from mechanism design literature. Finally, we perform extensive numerical experiments which support the efficacy of PBDC.

2 - New Algorithms And Guarantees For Assortment Optimization Under General Choice

Clark Pixton, MIT, Cambridge, MA, United States, cpixton@mit.edu, David Simchi-Levi

We present new algorithms for static assortment optimization which apply to general choice models. We show theoretical guarantees, and demonstrate performance via computational experiments. These algorithms sit between the work of Jagabathula (2016) and the choice model assortment optimization literature.

3 - Using Early Click Information In Online Flash Sales Campaigns

Stefano Nasini, Assistant Professor, IESEG School of Management, Lille/Paris, France, s.nasini@ieseg.fr, Victor Martínez de Albéniz, Arnau Planas

In online flash sales, products are heavily discounted during very short sales periods. There is significant uncertainty over product sales, that can be reduced using the chain of sequential decisions that customers take in the website. We build a statistical model based on four layers of conditional probabilities: from (1) clicks to the main webpage to (2) clicks to a particular campaign to (3) request for information of a specific product to (4) final purchase decision. We use information from clicks occurring in the first hours of a campaign to reoptimize prices. We finally test our model with real data.

4 - Offline Assortment Optimization In The Presence Of An Online Channel

Srikanth Jagabathula, NYU Stern School of Business, New York, NY, United States, sjagabat@stern.nyu.edu, Daria Dzyabura

Firms are increasingly selling through both offline and online channels. The offline offerings allow the customers to physically evaluate the products and, as a result, impact the demand in both channels. Given this, we address how firms should select an offline assortment to maximize profits across both channels; we call this the showcase decision problem. We introduce a new model to incorporate the impact of physical evaluation on consumer preferences. We validate this model using a conjoint study; propose algorithms, with approximation guarantees, to determine the profit/sales maximizing assortments; and demonstrate up to 40% improvement in profits on real-world data.

Marketing Insights from Social Media

Invited: Social Media Analytics

Invited Session

Chair: David A. Schweidel, Emory University, 1300 Clifton Road NE, Atlanta, GA, 30322, United States, dschweidel@emory.edu

1 - Is All That Twitters Gold? Effects Of Online Chatter On Stock Market Returns And Stock Market Volatility

Abhishek Borah, University of Washington, abhi7@uw.edu

This study uses natural language processing to extract various dimensions across different sources of Tweets and ascertain their importance. The authors evaluate the effect of Twitter on both 1) Stock Market Returns using a Multivariate Dynamic Descriptive Panel Data Model, and 2) Stock Market Volatility using a Multivariate GARCH model. The authors find that 1) Tweets predict stock market returns and volatility in stock returns 2) Sentiment is the most important dimension and spillover effects between volatility in tweets and stock returns differ in sign depending on the sentiment of tweets, and 3) Firms' new product announcements affect tweets.

2 - Social TV, Advertising, And Sales

Beth L. Fossen, Kelley School of Business, Indiana University, Bloomington, IN, United States, bfossen@indiana.edu
David A Schweidel

The rapid growth of social TV - defined as the integration of social media with television programming - has outpaced the field's understanding of how marketers can extract value out of such activities. In this research, we explore the relationship between social TV, television advertising, and sales by investigating how viewer engagement with television programs and advertisements impacts online shopping behavior. This work aims to address (1) if online chatter about television advertisements spurs sales for the advertised brand and (2) whether television programs with high online social activity are more beneficial to advertisers.

3 - Modeling Latent Homophily In Large-scale Social Networks: A Markov Random Field Approach

Liye Ma, University of Maryland, liyema@rhsmith.umd.edu

The rapid growth of social media platforms makes large scale social network data commonplace. Inferring consumer preference and developing targeting strategies using such data, however, remain challenging. In this study, we introduce a modeling technique, Gaussian Markov Random Fields (GMRF), to model the latent homophily of connected consumers. We show that GMRF can be applied to networks of arbitrary topology, that its conditional independence property is conceptually appealing, and that model parameters have intuitive interpretations. We analyze different model configurations incorporating one or more GMRFs, and demonstrate its application using a mobile network dataset.

4 - Deriving Brand Insights With Social Media Analytics

David A Schweidel, Emory University, dschweidel@emory.edu

Interest in social media continues to grow. While much research has focused on the use of social media as a communication platform, limited work has probed the viability of social media data as a source of marketing insights. In this research, we examine ways in which brands may benefit from the analysis of social media data. We consider two specific applications: assessing brand health and identifying shifts in online word of mouth.

Predicting Business Outcomes Using Social Media

Invited: Social Media Analytics

Invited Session

Chair: Youran Fu, University of Pennsylvania, Philadelphia, PA, United States, youranfu@wharton.upenn.edu

1 - The Operational Value Of Social Media Information

Ruomeng Cui, Kelley School of Business, Indiana University, cuir@indiana.edu, Santiago Gallino, Antonio Moreno-Garcia, Dennis Zhang

We empirically explore how social media information helps sales forecasting. Using daily sales data from an online apparel company and publicly available Facebook posts (users' comments and likes data), we apply various machine learning methods and find a statistically significant improvement in sales forecasts.

2 - Stock Market Movement Prediction Using Disparate Data Sources: A Probabilistic Prediction Model

Bin Weng, Auburn Univeristy, Auburn, AL, 36849, United States, bzw0018@auburn.edu, Hamidreza Dolatsara, Fadel Mounir Megahed

The stock market prediction has attracted much attention from academia as well as business. In recent years, social media and Internet search behavior are considered as new sources that affect human's behavior and decision-making. The purpose of this study is to develop a probabilistic model to predict short-term stock movement by comparing machine learning methods using disparate data sources. This study not only uses traditional historic market data but also the data from technical analysis, social media, and the internet. Finally, a stock prediction tool with machine learning methods incorporated has been developed for predicting the stock's short-term movement with high accuracy.

3 - The Value Of Social Media Data In Color Trends Forecasting

Youran Fu, The Wharton School, University of Pennsylvania, Philadelphia, PA, 19104, United States, youranfu@wharton.upenn.edu, Marshall L Fisher

We partnered with a leading apparel retailer to investigate how to use social media data to improve fashion color trend forecasting. We find that using fine-grained Twitter data and a Google search volume index to predict product-color sales three months out can significantly reduce forecast error compared to conventional methods.

4 - Understanding The Role And Impact Of Discussions On The Quality Of User Generated Content – The Case Of Wikipedia.

Srikar Velichety, University of Arizona, srikarv@email.arizona.edu

We investigate the impact of discussions on the quality of peer-produced content. Using a data science approach on the complete population of English language articles in Wikipedia, we demonstrate the predictive and explanatory power of discussions in article quality. We also compare and contrast the value of discussion characteristics with the article characteristics.
Our results show that discussions add value to the predictive model by increasing both the precision and recall. On the explanatory side, we find that discussions drive both edits and diverse edits leading to better quality. Implications for theory building and policy setting in peer-production environments are discussed.

Community-Based Operations Research I

Sponsored: Public Sector OR

Sponsored Session

Chair: Michael P Johnson, Associate Professor, University of Massachusett - Boston, McCormack Hall, 3rd Floor, Room 428A, 100 Morrissey Blvd., Boston, MA, 02125, United States, Michael.Johnson@umb.edu

1 - Pro Bono Analytics - What Nonprofits Can Learn From Operations Researchers, And Vice Versa

David Hunt, Oliver Wyman, david.hunt@oliverwyman.com
Michael P Johnson

Pro Bono Analytics is an INFORMS program that matches volunteers with nonprofit organizations working in underserved areas and for underserved populations. The nonprofits tend to be small and without the resources to utilize traditional operations research and advanced analytical methods. This talk will focus on how to communicate the value of OR/analytics to nonprofits, and perhaps more importantly, what we have learned about applying OR/analytical methods to problems that truly matter to our nonprofit clients.

2 - Is Crime A Real Estate Problem? A Case Study Of The Neighborhood Of East Liberty, Pittsburgh

Tayo Fabusuyi, Numeritics & Carnegie Mellon University, Pittsburgh, PA, United States, tfabusuyi@cmu.edu

This study documents the innovative efforts of a community development organization (CDO) in the City of Pittsburgh's East End towards combating crime in the neighborhood of East Liberty. Through a community driven process, the CDO was able to establish the nature of the problem and create a strategic intervention to address it. The intervention, which focuses on the identification of crime hot spots coupled with place-based management, along with initiatives designed to increase collective efficacy, resulted in a 49% decrease in crime within the neighborhood's residential area over a span of five years.

3 - Can Improving Youth Decision-making Skills Make Them Less Vulnerable For Sex Traffickers?

Kendra Taylor, KEYfficiencies, Inc, Atlanta, GA, United States, Kendra@KEYfficiencies.com

The old adage "an ounce of prevention is worth a pound of cure" summarizes the motivation for addressing an alarming market for sex trafficking of children in Atlanta, Georgia. Several groups have begun passing legislation, raising awareness, rescuing those previously labeled child prostitutes. With approximately 5,000 students between the ages of 12 and 14 at risk for being victims in the sex trade, much still remains to be done in the area of prevention. The purpose of this study is to assess the potential of a pilot program to reduce the supply of vulnerable children by addressing the role of poor decision-making skills, by engaging adult advisors, and by creating positive peer groups.

4 - Measuring Success: Community Analytics For Local Economic Development

Michael P Johnson, University of Massachusetts Boston, michael.johnson@umb.edu

Main Street organizations develop local development initiatives that support economic and social goals. We describe an application of value-focused thinking and community-based operations research to identify economic development performance metrics and decision alternatives for local development interventions. Using interviews with stakeholders in three Boston communities, we show how values structures vary across communities and stakeholder groups and how attributes can be quantified using a variety of data sources. We conclude by presenting a composite values structure to support improved operations management and strategy design for all Boston Main Street districts.

Resilience Management Concepts for Infrastructure and Service Systems

Sponsored: Public Sector OR

Sponsored Session

Chair: Joost Santos, George Washington University, 800 22nd St NW, Suite 2830, GWU Science and Engineering Hall, Washington, DC, 20052, United States, joost@gwu.edu

1 - Evaluation Of Resilient Point-of-use Water Treatment Technologies Using Multi-attribute Decision-making Analysis

Sheree Ann Pagsuyoin, University of Massachussetts Lowell, sheree_pagsuyoin@uml.edu, Joost Reyes Santos, Jana S Latayan

Many point-of-use (POU) water treatment technologies are now available in the market as a result of efforts to address the persistent poor access to safe water and high incidences of waterborne diseases in low-income regions of the world. While the availability of options is ideal, this has also created a challenge in selecting technologies that are suitable in local settings. In this work, we present an application of Multi-Attribute Decision-Making analysis to rank and select options for POU water treatment in a poor rural community. Six technologies were considered: SODIS, boiling, chlorination, biosand filtration, ceramic pot filtration, and flocculation-disinfection.

2 - Decision Analytics Using Plural Resilience Metrics For Adaptive Supply Chain Management

Shital Thekdi, University of Richmond, sthekdi@richmond.edu, Joost Reyes Santos

Recent events have highlighted the need for supply chain systems to effectively recover, adapt, and reorganize after disruptions. Common modeling methods use single measures of performance in decisions for investing in resilience. However, complex systems such as those involving movement of goods and services require competing units of measurement, such as workforce availability, health, capacity, and safety. This presentation provides a framework for: 1) Data-analytic modeling of resilience with competing measures of performance, and 2) Multi-criteria and multi-stakeholder investment analytics. The proposed framework will be demonstrated on a distributed supply chain network.

3 - Integrating Community Capitals With Resilient Insurance Strategies For Flood Risk Mitigation

Leyla Sadigh, Research Assistant, George Washington University, Washington, DC, 20052, United States, leyla.sadigh@arup.com
Ajita Atreya, Ekundayo Shittu

In this paper, we explore the role of insurance decision making in influencing community resilience along the five dimensions of capital - physical, financial, human, social, and natural. We integrate these five capitals in a dynamic computable general equilibrium model with the demand and supply side of community resilience (measured across robustness, redundancy, resourcefulness, and rapidity) through insurance. Our focus on flood insurance is to achieve a better understanding of how risk perceptions in capital influence insurance-purchasing decisions and identify strategies that encourage investments in flood mitigation measures.

4 - Development Of Multi-attribute Decision Framework For Selecting Flow Control Structures In Irrigation Canals

Sheree Pagsuyoin, University of Massachussetts Lowell, MA, sheree_pagsuyoin@uml.edu

The stiff competition for water between agriculture and non-agricultural users makes it necessary to have effective management of irrigation networks in farms. However, the process of selecting flow control structures in irrigation networks is highly complex and involves multi-level decision makers. In this work, we apply multi-attribute decision making methodology to select and prioritize among check and intake structures for irrigation canals. The relevant attributes for selecting structures were also identified, and a robust scoring system was developed. The model was then applied to analyze the Qazvin irrigation network, one of the oldest and most complex irrigation networks in Iran.

Emerging Scholars in Technology Management

Sponsored: Technology, Innovation Management & Entrepreneurship

Sponsored Session

Chair: Gulru Ozkan-Seely, University of Washington Bothell, School of Business, 18115 Campus Way NE, Box 358584, Bothell, WA, 98011, United States, gulru@uw.edu

1 - What Is The Role Of The State In Entrepreneurship And Venture Performance?

Daniel Armanios, Carnegie Mellon University, darmanios@cmu.edu

What is the role of the state in entrepreneurship and venture performance? I find three roles that the state plays during the venturing process. Public-private institutions play an intermediary role that connects private entrepreneurs to public resources. Public research organizations play an integrator role that develops and transfers public knowledge for private commercial use. Local governments play an implementer role that tailors national policies to local markets. In these three roles, I provide more nuance regarding the state's role in entrepreneurship and advance institutional theory, especially its nexus to entrepreneurship and emerging markets.

2 - The Digital Commons: Tragedy Or Opportunity? The Effect Of Crowdsourced Digital Goods On Innovation And Economic Growth

Frank Nagle, University of Southern California, naglef@marshall.usc.edu

This dissertation is comprised of four studies that explore the transformative nature of the digital commons with a focus on crowdsourced digital goods (CDGs) and open source software. The first chapter explores how lower information costs are leading firms to increasingly engage with external digital communities. The second chapter examines the impact of CDGs at a macro-level and shows that GDP calculations do not properly account for "digital dark matter". The third chapter empirically measures the productivity impact of using CDGs at the firm level. The final chapter investigates how firms that contribute to the development of CDGs enhance their ability to extract value from using them.

3 - Optimal Award Scheme In Innovation Tournaments

Ersin Korpeoglu, UCL School of Management, e.korpeoglu@ucl.ac.uk, Laurence Ales, Soo-Haeng Cho

In an innovation tournament, an organizer solicits innovative ideas from a number of independent agents. Agents exert efforts to develop their solutions, but their outcomes are unknown due to technical uncertainty and/or subjective evaluation criteria. We derive necessary and sufficient conditions under which the winner-take-all scheme that awards only the best solution is optimal. Under these conditions, the organizer should offer a larger winner prize when he seeks a higher number of good solutions, but interestingly the organizer need not raise the winner prize when anticipating more participants to a tournament. Finally, we compare rank-based compensation with other compensation rules.

4 - Demand Heterogeneity And The Adoption Of Platform Complements

Joost Rietveld, Rotterdam School of Management, rietveld@rsm.nl, J P Eggers

We offer a demand-based view on how platform evolution affects the sales of complements. Differences between early and late adopters of the platform create heterogeneous demand conditions that affect both average complement performance and variance in the types of complements that are more or less successful. Using a dataset of 2,921 console video games, we find that platform evolution has a negative effect on games' sales. Furthermore, as the platform evolves, the sales disparity between new intellectual property (IP) games and games based on existing game properties grows to the detriment of new IP games. The sales disparity between superstar games and flops also widens as the platform evolves.

5 - Extreme Performance In Creative Settings: Where Do Stars Come From?

Haibo Liu, University of California Riverside, Riverside, CA, United States, Haibo.Liu@ucr.edu, Jurgen Mihm, Manuel Emilio Sosa

Despite being rare, stars make disproportionately influential contributions to their fields. This paper studies the role of inter-personal collaboration in the emergence of star designers. We examine how the quality of a collaborator (star vs. non-star) moderates the influence of two important contextual factors of collaboration: social network cohesion and expertise similarity. By distinguishing collaborators based on their quality, we reconcile contrasting results regarding those two contextual factors in prior literature. We test our predictions on a large longitudinal data set consisting of all designers who were granted a design patent in the United States from 1975 through 2010.

Optimal Services and Coordination Strategies of O2O Channel in Fast Fashion Supply Chain

Sponsored: Service Science

Sponsored Session

Chair: Qi Xu, Donghua University, Glorious Sun School of Business and Management, Donghua University, Shanghai, 200051, China, xuqi@dhu.edu.cn

1 - Coordination In Apparel Dual-channel Supply Chain With Asymmetric Cost Information

Qi Xu, Donghua University, Shanghai, China, xuqi@dhu.edu.cn, Wenjie Wang

This paper discusses the coordination in apparel dual-channel supply chain with asymmetric cost information. We propose the dual-channel supply chain models under asymmetric cost information and symmetric information scenario respectively. Considering the seasonal characteristics of apparel product, the flexible price contract is applied to adapt the apparel supply chain coordination with asymmetric cost information. The impact of asymmetric demand information on the profits of partners in the supply chain is analyzed.

2 - Optimal Service Decision Consideration Demand Shift Between Online And Offline In Supply Chain System

Dandan Fan, Donghua University, sunshinemarcle@163.com

The paper discusses the optimal service decision under two kinds of situations, the one is demand shift between online and offline when the demand is influenced by service level, the other is demand no shift. The centralized and decentralized service decision models are established. The centralized decision mode means the brands suppliers provide products to themselves stores, and the decentralized decision mode means the brands suppliers provide products to tradition stores. Then, the paper investigates the optimal service strategy of O2O centralized system. For the O2O decentralized system, the conditions of the service level to realize Nash equilibrium is analyzed.

3 - Impact Of Experience Service On Fast Fashion Retail O2O Channel

Lixia Xu, Donghua University, Shanghai, China, 37857909@qq.com

O2O channel is a brand new retailing mode which integrates both characteristics of online and offline channels. Experience service has been become main factor in the operation of fast fashion retail O2O channel. This new channel can help the retailer tap new customer segments and generate additional demand. To study the impact of channel service competition and customer acceptance of O2O channel, a competition model based on price and service sensitivity was established. The comparison of experience service level and O2O chain profit between online and offline was presented. Numerical analysis was conducted on profit allocation of supply chain under different customer acceptance of O2O channel.

4 - Fast Fashion O2o Channel Optimal Service Under Different Revenue Model

Qi Xu, Donghua University, xuqi@dhu.edu.cn, Fan Dandan

Considering two kinds of revenue modes, one is offline stores' revenue sharing and the other is revenue no-sharing, this paper built the optimal O2O services decision models in fast fashion O2O supply chain, according to the offline stores is brand owner themselves or alliance business. Further,the collaboration of this O2O supply chain is discussed. Finally, the numerical simulation are done by analyzing the impact of variables to profits , such as, the rate of service substitution between online and offline, price, the optimal service level, rate of revenue sharing and subsidized price, etc.

Inventory Management I

Contributed Session

Chair: Jagtej S Bewli, Director, Product Management, WalmartLabs, 850 Cherry Avenue, San Bruno, CA, 94066, United States, jbewli@walmartlabs.com

1 - Inventory And Transportation Decisions For Two-echelon Closed-loop Supply Chain Under Emission Constraint

Jian Li, PhD Candidate, Xi'an Jiaotong University, No.28 Westing Xianning Road, Xi'an, +86-029-710049, China, ljlcxwxz@stu.xjtu.edu.cn, Qin Su

Closed-loop supply chain (CLSC) may cause more direct carbon emissions of used product due to the reverse logistics and remanufacturing. In this paper, we address the inventory and transportation management issue on CLSC system consisting of supplier, manufacturer and retailer under cap-and-trade mechanism, and develop a two-echelon system. Extra carbon permits can be taken as a kind of environment resource as well as product to be traded and circulate. Further, we consider decentralized decision-making with supplier, manufacturer and retailer being Stackelberg leader, respectively, and have a comparative analysis with centralized decision-making of CLSC through two numerical studies.

2 - An Inventory Problem With Substitution And Bayesian Estimation

Ulku Gurler, Professor, Bilkent University, Department of Industrial Engineering, Ankara, 06800, Turkey, ulku@bilkent.edu.tr

In this study we consider an inventory problem with two substitutable products. We use a bayesian approach to estimated the demand and substitution rates and investigate the impact of the estimation method on inventory replenishment.

3 - Managing Perishable Inventory Systems With Multiple Demand Classes

Rui Chen, University of Toronto, 105 St George St, Toronto, ON, M5S 3E6, Canada, rui.chen@rotman.utoronto.ca
Hossein Abouee Mehrizi, Opher Baron, Oded Berman

We study a multi-period stochastic perishable inventory system with multiple demand classes that have different requirements on the age of acceptable products. At the end of each period, the firm can savage inventory of any age. An example is a food supplier selling products to retailers that have different market size or have different geographical locations. We characterize the structure of optimal ordering, allocation, and disposal policies. We examine the effectiveness of the optimal control and how to best try and improve the control of perishables. We also propose an effective and computationally-efficient heuristic,which is 5% away from the optimal.

4 - The Design Of A Responsive Vaccine Supply Chain By The Incorporation Of Production Capacity Into The Guaranteed Service Approach

Stef Lemmens, KU Leuven, Naamsestraat 69 Box 3555, VAT BE 0419.052.173, Leuven, 3000, Belgium, stef.lemmens@kuleuven.be, Catherine Jenny Decouttere, Nico Vandaele, Mauro Bernuzzi, Amir Reichman

Both literature and industrial evidence emphasize the importance of the design of a responsive vaccine supply chain as the manufacturing lead times are long and highly variable. We model the buffer exchange between supply chain responsiveness, multi-echelon inventory and production capacity by the incorporation of queuing networks into the guaranteed service approach. Furthermore, we apply our methodology to a real-life rotavirus vaccine supply chain.

5 - Portfolio Management Approach To Inventory Optimization

Jagtej S Bewli, Director, Product Management, WalmartLabs, 850 Cherry Avenue, San Bruno, CA, 94066, United States, jbewli@walmartlabs.com

Choosing the right inventory 'investment' for each SKU in the assortment can improve service levels while reducing overall inventory. However, in spite of significant advancement and research in inventory optimization techniques, inventory policies in industry still managed based on ABC classification of SKUs.Inventory recommendations from mathematically optimal inventory policies may not always line up with human intuition therefore educating the business user is key to driving adoption.

Firm Competitive Strategies

Sponsored: EBusiness

Sponsored Session

Chair: Chao Ding, University of Hong Kong, KKL 807, Pok Fu Lam, Hong Kong, chao.ding@hku.hk

1 - Promotion Design In Free To Play Mobile Games

Sean Raphael Marston, Western Kentucky University, sean.marston@wku.edu, Ismail Civelek, Yipeng Liu

In-game purchases, virtual goods/promotion design for heterogeneous consumers and strong competition are key challenges for game providers. This paper addresses determination of optimal promotion offerings for a game provider in the presence of heterogeneous players and a competitor.

2 - Advertising Role Of Recommender Systems In Electronic Marketplaces: Is It A Boon Or A Bane For Competing Sellers?

Lusi Li, University of Texas at Dallas, Lusi.Li@utdallas.edu

This paper examines the intricate interaction between competing sellers' advertising and pricing strategies in the presence of a recommender system in an electronic marketplace.

3 - Competition And Efficiency In Express Service Industry

Yihong Hu, Assistant Professor, Tongji University, 1293, Siping Road, Tongji University, Shanghai, 200092, China, yhhu@tongji.edu.cn, Ruixia Shi

We consider service firms competing for customers sensitive to price and congestion and operating through a platform which charges a transaction fee. We establish upper and lower bounds of efficiency loss. With linear inverse demand and homogeneous firms, the platform's charge make the worst case increase from 1/4 to 9/16, additionally losing more than one half of social welfare compared to free competition. When heterogeneous, it raise the bound to over 9/16, depending on the largest gap between cost coefficients of firms and the maximum ratio of volume-to-investment. For concave inverse demand and homogeneous firms, the bound increases from 1/3 without the charge to 2/3 with the charge.

4 - The Centrality Of Ict In Network Structures Of Innovation And Impact On R&D

Rajib L Saha, Assistant Professor, Indian School of Business, Room 6123, AC6, Level 1, Hyderabad, 500032, India, Rajib_Saha@isb.edu, Aditya Karanam, Deepa Mani

We document the centrality of Information and Communication Technology (ICT) industries in network structures of innovation and its subsequent impact on R&D processes and outcomes across diverse industries. We find strong evidence for the impact of technology centricity of an industry's innovations, as measured by the industry's position in the network relative to the ICT industries, on its R&D productivity, new product creations, and recombinant intensity. Performance volatility, spread and market returns of an industry also increase with the technology centricity of its innovations.

Queues and Customer Behavior

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Mirko Kremer, Frankfurt School of Finance and Management gGmbh, Sonnemannstrasse 9-11, Frankfurt, 60314, Germany, m.kremer@fs.de

1 - Last Place Aversion In Queues

Ryan Buell, Assistant Professor, Harvard Business School, Morgan Hall 429, Boston, MA, 02163, United States, rbuell@hbs.edu
Michael Norton, Jay Chakraborty

Since customers dislike waiting, much of the existing queuing research concentrates on what's taking place ahead of the customer in line (service rates, queue length, etc.). We examine whether what's taking place behind the customer - specifically, whether they are last in line - influences their perceptions and behaviors. Through a combination of lab and field studies, we document how being in "last place" diminishes wait time satisfaction, and increases the probability of leaving the queue. We also test several interventions aimed at reducing last place aversion and improving queue performance.

2 - Behavioral Drivers Of Routing Decisions: Evidence From Restaurant Table Assignment

Bradley R Staats, University of North Carolina at Chapel Hill, Campus Box 3490, McColl 4721, Chapel Hill, NC, 27599-3490, United States, bstaats@unc.edu, Fangyun Tan

In many settings, humans make routing decisions dynamically, either because algorithms don't exist, decision support tools have not been implemented, or existing rules are not enforced. Understanding how individuals make decisions creates the opportunity to identify both positive deviances, as well as suboptimal decision making that can be improved. In this paper we theoretically identify the factors that may impact decision making before empirically examining a large operational data set in a casual restaurant setting to research whether and how hosts deviate from their predefined round-robin rule to seat customers to servers.

3 - The Impact Of Delay Announcements: An Experimental Approach

Gad Allon, Northwestern University, Evanston, IN, United States, g-allon@kellogg.northwestern.edu, Achal Bassamboo, Mirko Kremer

We explore the impact of delay announcements by studying the data from a lab experiment, where customers are provided with anticipated delay.

4 - Diagnostic Accuracy In Congested Environment

Mirko Kremer, Frankfurt School of Finance and Management gGmbh, m.kremer@fs.de, Francis E DeVericourt

The trade-off between diagnostic accuracy and congestion characterizes many manufacturing and service settings, where the gathering of additional information is likely to improve the diagnosis but may also increase congestion in the system. For example, medical staff often needs to weigh the benefit of running additional tests against the cost of delaying the provision of services to other patients. We present the results from a set of controlled laboratory experiments designed to test the predictions of a formal sequential testing model that captures this trade-off.

Energy VI

Contributed Session

Chair: Luis Baringo, Universidad de Castilla-La Mancha, Av. Camilo José Cela s/n, E.T.S.I.Industriales, Ciudad Real, 13071, Spain, Luis.Baringo@uclm.es

1 - Resilient Based Power System Restoration On Sectionalized Grid

Saeedeh Abbasi, Research and Teaching Assistant, University of Houston, 9000 Braesmont Dr, Apt #4, Houston, TX, 77096, United States, sabbasi5@uh.edu, Masoud Barati, Gino J Lim

Several catastrophic experiences of extreme events increased the criticality of the power grid restoration. This paper discusses a novel resilience-based restoration and sectionalizing model. This restoration approach aims to restore the de-energized power grids to the normal state after cascading outages that may occur during severe conditions. The problem is formulated as a bi-level programming model and solved by the pre-emptive programming method. The proposed approach is illustrated using an IEEE six-bus and 118 bus test systems, with focus on assessing and improving its resilience during the restoration process to severe disasters.

2 - A Generation Capacity Expansion Planning Model Considering Capacity Markets With High Wind Power Penetrations

Jonghwan Kwon, Arizona State University, 10410 N Cave Creek Rd, Tempe, AZ, 85020, United States, Jonghwan.Kwon@asu.edu, Zhi Zhou, Todd Levin, Fernando de Sisternes, Kory W Hedman, Audun Botterud

This work aims to develop a modeling framework for simulating generation capacity expansion planning, considering long-term capacity markets and short-term energy and operating reserve markets with increasing levels of wind power. The framework will provide the ability to analyze the impact of high wind penetrations on the economics and reliability of the grid in a more realistic market environment. System operators and regulators can obtain new and important insights into how wind resources can be efficiently and effectively integrated into electricity markets under various rules and policies.

3 - Electricity Pooling Markets With Inelastic Demand

Mohammad Rasouli, PhD Candidate, University of Michigan, 430 S Fourth Ave, Ann Arbor, MI, 48104, United States, rasouli@umich.edu, Demosthenis Teneketzis

In the restructured electricity industry, electricity pooling markets are an oligopoly with strategic producers possessing private information. We focus on pooling markets where aggregate demand is represented by a non-strategic agent and is inelastic.
Inelasticity of demand is a main difficulty in electricity markets. It can potentially result in market failure and high prices.
We propose a market mechanism that has the following features. (F1)It is individually rational.(F2)It is budget balanced.(F3)It is price efficient(F4)The energy production profile corresponding to every non-zero Nash equilibrium of the game induced by the mechanism is a solution maximizes the social welfare.

4 - Offering Strategy Of A Virtual Power Plant: A Stochastic Adaptive Robust Optimization Approach

Luis Baringo, Universidad de Castilla-La Mancha, Av. Camilo José Cela s/n, E.T.S.I. Industriales, Ciudad Real, 13071, Spain, Luis.Baringo@uclm.es, Ana Baringo

We propose a stochastic adaptive robust optimization model for the offering strategy of a virtual power plant (VPP) that participates in the day-ahead and the real-time energy markets. The VPP comprises a conventional power plant, a wind-power unit, a storage facility, and flexible demands, which participate in the markets as a single entity in order to optimize their energy resources. Uncertainties in the wind-power production and in the market prices are modeled using confidence bounds and scenarios, respectively.

Connected and Automated Vehicles

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Michael Levin, University of Texas, Austin, TX, United States, michaellevin@utexas.edu

1 - Modeling Spatiotemporal Propagation Of Information In a Connected Vehicle System With The Consideration Of Communication Capacity

Jian Wang, Purdue University, Lyles School of Civil Engineering, West Lafayette, IN, United States, wang2084@purdue.edu Xiaozheng He, Yong Hoon kim, Srinivas Peeta

This study proposes integro-differential equations to model the spatiotemporal propagation of information under vehicle-to-vehicle communications while factoring communication capacity and traffic dynamics. We also derive closed form solutions for the asymptotic speeds of information propagation wave under different densities of equipped vehicles. Numerical experiments demonstrate the effectiveness of the proposed model in various traffic conditions.

2 - Road In Transition: Autonomous Vehicle Manufacturer Strategies And Transportation Systems Performance

Mohamadhossein Noruzoliaee, University of Illinois at Chicago, Chicago, IL, United States, h.noruzoliaee@gmail.com, Bo Zou, Yang Liu

This study explores the impacts of autonomous vehicles (AVs) on transportation system equilibrium and AV manufacturer pricing strategies. A mathematical program with equilibrium constraints (MPEC) is formulated, where the upper level determines pricing strategy of an AV manufacturer and the lower-level computes system equilibrium as a variational inequality (VI). Besides, the competition among multiple AV manufacturers is formulated as an equilibrium problem with equilibrium constraints (EPEC). Solving the MPEC and EPEC helps gauge the impact of market-driven AV pricing on system performance.

3 - A Cell Transmission Model For Dynamic Lane Reversal With AutonomousVehicles

Michael Levin, University of Texas, Austin, TX, United States, michaellevin@utexas.edu

Autonomous vehicles admit consideration of novel traffic behaviors such as reservation-based intersection controls and dynamic lane reversal. We present a cell transmission model formulation for dynamic lane reversal. For deterministic demand, we formulate the dynamic lane reversal control problem for a single link as an integer program and derive theoretical results. In reality, demand is not known perfectly at arbitrary times in the future. To address stochastic demand, we present a Markov decision process formulation. Due to the large state size, the Markov decision process is intractable. However, based on theoretical results from the integer program, we derive an effective heuristic. We demonstrate significant improvements over a fixed lane configuration both on a single bottleneck link with varying demands, and on the downtown Austin network.

4 - Integrated Mode Choice And Assignment-simulation Framework With Automated Transit Vehicles

Omer Verbas, Northwestern University, Transportation Center, Evanston, IL, 60208, United States, omer@northwestern.edu
Hani S Mahmassani, Michael F. Hyland

With the advent of automated and connected transportation systems, car and bike sharing, ride sourcing, and on-demand transit services, as well as the increasing availability of real-time traffic and transit information; travelers have the opportunity to evaluate their multiple routing options and make better-informed decisions. This study proposes an integrated mode-choice and a path finding-assignment-simulation framework that evaluates the system performance and traveler behavior under the existence of automated transit vehicles.

Latest Advances in Last Mile Distribution

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Mathias A Klapp, PhD Candidate, Georgia Institute of Technology, 765 Ferst Dr NW, Atlanta, GA, 30318, United States, maklapp@gatech.edu

1 - Complexity Of Dynamic Delivery Problems With Release Dates And Deadlines

Damian Reyes, Georgia Institute Of Technology, Atlanta, GA, United States, ldrr3@gatech.edu, Alan Erera, Martin W P Savelsbergh

Motivated by a case-study in food delivery operations, we investigate the complexity of dynamic delivery problems with release times and service guarantees. At the heart of these problems, there is a trade-off between waiting to consolidate more orders - enabling cost-effective delivery routes - and dispatching a vehicle earlier - in order to complete some orders while preserving capacity for others released later in the operating period. We introduce polynomial-time algorithms for some deterministic variants on a 1-dimensional geometry.

2 - Consolidating Last-mile Delivery Flows

Niels Agatz, Erasmus University, Rotterdam, Netherlands, nagatz@rsm.nl, Joydeep Paul, Remy Spliet

Most multi-channel retailers offer in-store pickup to their online customers. Pickup orders are typically shipped from a dedicated e-fulfilment warehouse while store replenishment takes place from another warehouse. In this contribution, we study the opportunity to use the excess capacity in the replenishment routes to accommodate some of the in-store pickup demand. We develop a heuristic to support the consolidation decisions and present numerical experiments based on artificial and real-world data.

3 - Branch-and-Price For Probabilistic VRP

Felipe Lagos, Georgia Institute Of Technology, falg3@gatech.edu

We study a probabilistic VRP in which a customer’s appearance is uncertain. Customers are divided into routes within which the vehicle may skip customers that do not appear, and the objective is minimizing expected routing cost. We propose a column generation algorithm that uses successively tighter cost approximations to solve the problem within any given numerical tolerance. We also provide an a priori guarantee on the number of iterations needed to satisfy any tolerance, which can be calculated from problem parameters. We embed the column generation framework into an exact branch-and-price algorithm, and test our methods on instances adapted from the literature.

4 - Cost Efficiency Versus Customer Service In The Dynamic Dispatch Waves Problem

Mathias A Klapp, PhD Candidate, Georgia Institute of Technology, 755 Ferst Drive NW, Atlanta, GA, 30332, United States, maklapp@gatech.edu, Mathias A Klapp, PhD Candidate, Pontificia Universidad Católica de Chile, Vicuña Mackenna 4860, Macul, Santiago, Chile, maklapp@gatech.edu, Alan Erera, Alejandro Toriello

We study the Dynamic Dispatch Waves Problem that models the trade-offs between vehicle dispatch, route sequencing, and request selection in same-day delivery systems with dynamic disclosure of orders. The objective is to minimize vehicle travel time (efficiency) and penalties for unserved requests (service). We provide an optimal solution to the deterministic and a priori problems, and design two heuristic dynamic policies. Our computational experiments indicate that in the efficient frontier there is a decreasing marginal rate of substitution between efficiency and service, and that frequency and structure of vehicle dispatches significantly change between these two objectives.

Practical Steps Towards Shipment & Network Capacity Management

Sponsored: Railway Applications

Sponsored Session

Chair: Carl D Van Dyke, TransNetOpt, 6 Snowbird Ct, West Windsor, NJ, 08550, United States, carl@cvdzone.com

1 - Managing Train Scheduling To Optimize Network Capacity

Dharma Acharya, Transport Consultant, acharya.dharma@gmail.com

To move North American rail freight efficiently and reliably, an option for the railroads is to lock down on running of all scheduled and unscheduled trains over their rail network at least a few days in advance. This way railways will be able to line up resources at the right place at right time and avoid/minimize any resource waste and train delays. Railroads will also be able to better plan when trains could meet and pass on their predominantly single track corridors and be able to better predict train/shipment ETAs. We will also discuss what kind of changes in railroad’s operational practice will be needed from their traditional philosophy of running trains whenever there is enough tonnage/shipments.

2 - Managing Intermodal Capacity Through Differentiated Service Products And Load Acceptance

Carl Van Dyke, TransNetOpt, carl@cvdzone.com

As intermodal grows in sophistication and volume, it becomes important to employ effective means to manage capacity to ensure customer service expectations are met, and total revenue & profits are maximized. Currently this is being done by providing differentiated service, and adjusting the underlying terminal and train operations to both match the promised service and better balance variations of traffic volumes between services. An attitude of unlimited capacity is giving way to adopting specific constraints on capacity & the introduction of load acceptance processes. These capacity management strategies, plus some potential new ones that could be adopted in the near future, will be explored.

3 - Unit Train Management System

Bob Golbasi, CSX Transportation, Jacksonville, FL, United States, Hakan_Golbasi@csx.com, Robert Gutman

Unit Train Management System (UTMS) is a comprehensive system that was developed at CSX Transportation to bring all the relevant unit trains information together into one planning tool. A unit train is a special order train of only one commodity type that is not on a fixed scheduled. Shippers, Receivers and CSXT Unit Train Managers all work together in UTMS to ensure full visibility and alignment of upcoming trains. UTMS includes an optimization model to accept, modify or reject reservations in the selected time period based present business conditions and current and predicted availability of right cars at the right place at the right time.

4 - Connected Driver Advisory System: Cost Efficient Way For Improving Rail Traffic Management

Per Leander, Transrail Sweden AB, per.leander@transrail.se

Trains and Traffic Management in co-operation. The presentation will explain the concepts of C-DAS (Connected Driver Advisory System) and C-Cruise (Connected Cruise) for punctual and eco-efficient operation of trains and improved Traffic Management at low cost. These are concepts currently developed and deployed in Europe in order to improve punctuality, capacity and sustainability and to reduce costs. The algorithm developed by Transrail Sweden AB may be used in all types rail operations and the cost function be tuned to the specific needs of the operation. The algorithm may also be used as a powerful engine for future eco-efficient and interoperable ATO.

Data Mining in Air Transportation

Sponsored: Aviation Applications

Sponsored Session

Chair: Yi Liu, University of California, 107 McLaughlin Hall, Berkeley, CA, 94720, United States, liuyi.feier@gmail.com

1 - Using Historical Data To Support Traffic Management Initiative Decisions

Alexander Estes, University of Maryland-College Park, 3117 A.V. Williams, University of Maryland-College Park, College Park, MD, United States, aestes@math.umd.edu, David J Lovell, Michael O Ball

There is a large amount of data collected about traffic management initiatives that have been taken in the past by the Federal Aviation Administration. While this information could be helpful to decision-makers that are attempting to plan traffic management initiatives, this data is currently not very accessible. We propose unsupervised learning methods that identify relevant data and present it to the decision-makers.

2 - Identifying Similar Days To Guide Traffic Management Decision Making

Sreeta Gorripaty, UC Berkeley, Berkeley, CA, 94703, United States, gorripaty@berkeley.edu, Mark M Hansen

The experience of traffic flow management specialists is crucial in managing airport operations efficiently. Historical airport operations data can assist decision-making by augmenting controller experience with a systematic record of past traffic management actions under similar conditions and their consequences. A decision-support tool that finds historical days similar to a query day can guide day-of-operation decisions and assess past performance. Using machine-learning algorithms, we learn a similarity measure between two days based on weather and demand data. This measure is assessed for accuracy using airport operational outcomes and traffic management initiatives (TMI) data.

3 - Impacts Of Airline Mergers On Consumer Welfare

Vikrant Vaze, Assistant Professor, Dartmouth College, 14 Engineering Drive, Hanover, NH, 03755, United States, Vikrant.S.Vaze@dartmouth.edu, Tian Luo

We used publicly available passenger flows data and a discrete choice modeling framework to examine welfare changes due to the five major airline mergers in the past decade in the United States. We found that consolidations of legacy airlines with significantly overlapping markets generally increased the passenger welfare. However, overall passenger welfare in small communities declined after the two mergers whose small community markets data sets are sufficiently large for our analyses. We also found that welfare of passengers, traveling to or from hub airports of the primary merging airline, increased significantly.

4 - Hourly Ground Delay Program Prediction With Local And Convective Weather Variables

Mark M Hansen, University of California - Berkeley, 114 McLaughlin Hall, Berkeley, CA, 94720, United States, mhansen@ce.berkeley.edu, Yi Liu, Danqing Zhang, Alexey Pozdnukhov

We propose a method to predict ground delay program status for each hour using data mining techniques. We use local and convective weather variables as our predictors. We apply the method to 5 top-traffic US airports. The results include prediction performance, variable importance analysis and convective weather weight map.

HUB Location

Sponsored: Location Analysis

Sponsored Session

Chair: Sibel Alumur Alev, University of Waterloo, 200 University Avenue West, Waterloo, ON, N2L 3G1, Canada, sibel.alumur@uwaterloo.ca

1 - Modeling Congestion And Service Time In Hub Location Problems

Stefan Nickel, Karlsruhe Institute of Technology, stefan.nickel@kit.edu, Sibel Alumur Alev, Brita Rohrbeck, Francisco Saldanha-da-Gama

In this paper, we present a modeling framework for hub location problems with a service time limit considering congestion at hubs. Service time is modeled taking the traveling time on the hub network as well as the handling time and the delay caused by congestion at hubs into account. We develop mixed-integer linear programming formulations for the single and multiple allocation versions of this problem. We further extend the multiple allocation model with a possibility of direct shipments. We test our models on the well-known AP data set and analyze the effects of congestion and service time on costs and hub network design.

2 - An Enhanced Milp Model For Stochastic Multi-period Multiple Allocation Hub Location

Francisco Saldanha-da-Gama, University of Lisbon, Lisbon, Portugal, fsgama@ciencias.ulisboa.pt Isabel Correia, Stefan Nickel

A two-stage stochastic programming modeling framework is proposed for a pure phase-in multi-period multiple allocation hub location problem. Stochasticity is associated with the demands. Assuming a finite support for the underlying random vector, a compact formulation can be derived for the extensive form of the deterministic equivalent, which leads to a large-scale mixed-integer linear optimization problem. By considering 4 sets of valid inequalities, the model is enhanced, which makes it possible to solve to optimality by means of a general solver, instances that could not be tackled when the original formulation was considered. Results obtained using the CAB data set are reported.

3 - Modeling Hub Location Problems

James F Campbell, University of Missouri-St Louis, campbell@umsl.edu, Sibel Alumur Alev

In this talk, we focus on some of the key features of hub location models such as demands, costs, economies of scale, capacity and service level constraints, and network topologies including single and multiple allocation and complete and incomplete inter-hub networks. We discuss some of the possible implications of how these features are modeled on the hub locations, network design and performance measures, and emphasize the characteristics within the context of different applications. Additionally, we identify some distinguishing properties of the CAB, AP, and TR data sets commonly used in hub location studies. We aim to provide a road map for future hub location research.

MCDM for System Design: No Camels Allowed

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Stephen Henry, Sandia National Laboratories, P.O. Box 5800, Albuquerque, NM, 87185, United States, smhenry@sandia.gov

1 - Multiple Criteria Decision Making For The United States Army's Robotic Pack Mule Design

Lucas Waddell, Sandia National Laboratories, lawadde@sandia.gov Stephen Henry

The U.S. Army has a strong interest in the development and deployment of unmanned ground systems (UGSs) to provide soldiers with many unique battlefield advantages. As with any new, complex system, UGSs present a vast array of design tradeoffs, interdependencies, and competing stakeholder goals. There is an extremely fine line between design solutions that represent fair compromises, and solutions that nobody is willing to accept. We present lessons learned from an in-depth trade study performed for the U.S. Army on the Squad Multipurpose Equipment Transport (SMET) UGS.

2 - Infrastructure Equipment Optimization For United States Military Contingency Base Designs

Alexander Dessanti, Sandia National Laboratories, Albuquerque, NM, United States, adessan@sandia.gov

Contingency bases provide temporary facilities from which deployed forces can operate overseas. These bases are large-scale complex systems with many interrelated functions, making it difficult to identify the best equipment to utilize when designing a new one without an optimization approach. The Whole System Trades Analysis Tool (WSTAT), a multi-objective optimization capability, is being applied to this problem for the U.S. Army to enable more efficient and affordable future contingency base designs. Focus will be on the unique technical challenges presented by a problem of this magnitude.

3 - Ultra-high Dimensional Optimization For Military Systems Requirements Negotiation

Stephen Henry, Sandia National Laboratories, smhenry@sandia.gov

Complex military system design begins long before the welding of metal. A key early step is the development of a set of requirements - performance levels in various categories that must be achieved by the new system. These requirements are typically drafted by separate communities of experts and lack an analytic mechanism to address incompatibilities between the individual requirements - often leading to program cancellation due to unmet requirements. In this talk, we present a new tool for ensuring holistically feasible requirements. We discuss the mathematical challenges of high-dimensional optimization (>30 objectives) as well as the human challenges of real-time requirements negotiation.

4 - A Preference-Based Evolutionary Algorithm For Bi-Objective UAV Route Planning In Continuous Space

Erdi Da demir, Hacettepe University, Ankara, Turkey, dasdemir.erdi@metu.edu.tr, Murat Köksalan, Diclehan Tezcaner Öztürk

We address the bi-objective route planning problem for unmanned air vehicles that move in a continuous terrain. We develop a preference-based evolutionary algorithm that converge the desired regions of the Pareto front using the route planner's preferences. The algorithm determines both the visiting order of the targets and the specific trajectory between targets. Experiments show that the algorithm works well.

Field Experiment Research on Mobile and Social Applications

Sponsored: Information Systems

Sponsored Session

Chair: Tianshu Sun, University of Southern California, 3670 Trousdale Pkwy, Los Angeles, CA, 90089, United States, tianshu.sun@gmail.com

1 - Evaluating Consumer m-Health Services For User Engagement And Health Promotion

Vibhanshu Abhishek, Carnegie Mellon University, vibs@andrew.cmu.edu, Rema Padman, Yi-Chin Lin

Mobile apps have great potential to deliver promising health-related interventions to engage consumers and change their behaviors such as healthy eating. This study proposes and evaluates three mobile-enabled interventions to address these challenges: a mobile-based visual diary, image-based dietitian support, and peer engagement. We examined their effects on user engagement and food choices via a 4-month randomized field experiment and show a positive impact of the mobile diary and dietitian support on improving customer engagement. Specifically, the mobile-based visual diary and dietitian support each increases the log-odds ratio of user engagement by 43.8% and 50.7%, respectively.

2 - The Effect Of Product Placement On Shopping Behavior At The Point Of Purchase: Evidence From A Randomized Experiment Using Video Tracking In A Physical Bookstore

Pedro Ferreira, Carnegie Mellon University, pedrof@cmu.edu, Qiwei Han, João Paulo Costeira

Physical retailers are increasingly trying to understand in-store shopping behavior in order to increase sales. However, measuring and analyzing shopper behavior at the point of purchase in physical retailing remains challenging. In this paper, we implement an in-vivo randomized field experiment in a physical bookstore. We leverage video tracking technologies to monitor how shoppers respond to random book placement, which induces random search costs. More specifically, we randomize the position of newly released books on the top of a large table with several rows and columns such that each book's search cost becomes independent of the book's characteristics. We use advanced 3D cameras and vision-understanding algorithms that can track human motions in real-time to overcome the large costs associated to large-scale video data. This way we are able to significantly reduce the cost of encoding shopper activities by more than 80%. Our experimental results show that on an average day books placed at the edge of the table are both picked and taken more often by consumers than books placed in the center of the table. However, the likelihood of taking a book that was picked is on average similar for books placed at the edge and at the center of the table, that is, books at the edge of the table sell more only because they are, on average, picked more often. Armed with this knowledge, the bookstore manager may maximize profit by placing books with higher margins at the edge of the table.

3 - Stimulating UGC Contribution Via Performance Feedback: A Randomized Mobile Field Experiment

Yili Hong, Arizona State University, 832 W Wagner Dr, Gilbert, AZ, 85233, United States, hong@asu.edu, Bin Gu, Chen Liang, Gordon Burtch, Nina Huang

This study analyzes the effect of performance feedback on user content generation through a randomized mobile experiment. We find heterogeneous treatment effects that depend upon a subject's gender and the framing of the feedback supplied (altruistic vs. competitive). Specifically, we found that female users are more responsive to altruism-framed performance feedback, whereas male users are more responsive to competitively-framed performance feedback.

4 - Motivating Mobile App Adoption: Evidence From A Large-scale Field Experiment

Tianshu Sun, University of Southern California, Los Angeles, CA, United States, tianshu.sun@gmail.com, Lanfei Shi, Siva Viswanathan, Elena Zheleva

Using a randomized field experiment involving 250,000 customers, we investigate 1) whether and how a platform can motivate customers' app adoption and 2) the causal effect of induced mobile app adoptions on customer engagement. We find that 1) providing information or incentives can both significantly increase customers' app adoption; 2) the effect of app adoption varies greatly depending on how customers are motivated. Providing incentives increases adoption but not engagement. In contrast, providing information leads to effective mobile app adoptions that sustainably increase customers' engagement. We further look into multi-channel browsing data to understand the effect of app adoption.

Data Visualization

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Fadel Mounir Megahed, Auburn University, 3301 L Shelby Center Auburn University, Auburn, AL, 36849, United States, fmegahed@auburn.edu

1 - Stock Market Exploration And Prediction Through Visualization

Xing Wang, Auburn University, Auburn, AL, 36849, United States, xzw0005@auburn.edu, Bin Weng, Fadel Mounir Megahed

Stock Market prediction has attracted much attention from both business and academia. To explore the insight from the stock market history data could help investors to make their decision more efficiently. The purpose of this study is to develop a tool for visualizing and predicting the stock market through data mining methods. In this study, the tool is developed using Shiny R, which gives users useful information via visualizing related data from disparate data sources to assist investors to make decisions. By introducing our application, we focus on two things, one is the data visualization system design, and the other is reactive programming, both are emphasized in our development process.

2 - What We Learned From Visualizing 25 Years Of Statistics Research?

Fadel Megahed, Miami University, fmegahed@miamioh.edu Theyab Alhwiti, Mohammad Alamdar Yazdi, Maria Weese, L. Allison Jones-Farmer

The size and scope of the literature on statistics can be overwhelming, which makes it difficult to identify emerging trends and see the relationships between different developments. Visualization techniques, coupled with statistical and data mining methods, have been found effective in achieving these goals in a number of application domains including healthcare and manufacturing research. In this paper, we apply these concepts to the field of statistical sciences. Our dataset is based on bibliographic information, including: authors, keywords, abstracts, citations, and funding information, extracted from 10,030 papers published in the 17 ASA journals in the period of 1991-2015.

Advances in Degradation Modeling and Operations Management

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Xiao Liu, IBM T.J. Watson Research Center, 1101 Kitchwan Road, Yorktown Heights, NY, 10598, United States, liuxiao@us.ibm.com

1 - Kalman Filter Based Logistic Regression For Degradation Analysis

Erotokritos Skordilis, University of Miami, Miami, FL, United States, sge12@miami.edu, Ramin Moghaddass

We propose a new stochastic approach for degradation analysis using a combination of Bayesian Filtering and Binary Classification that can transform real-time condition monitoring signals to actionable insights. Analytical results for important reliability measures (e.g. RUL) will be given and a closed-form solution for the marginal log-likelihood function will be developed. Finally, a dynamic cost-effective predictive maintenance policy based on the proposed degradation structure will be introduced and its benefit over time-based preventive maintenance and corrective maintenance policies will be presented with a set of numerical experiments.

2 - Degradation Prediction Of Printed Images

Ziyi Wang, Rutgers University, Piscataway, NJ, 08854, United States, ziyiwangcumtb@gmail.com, Elsayed A. Elsayed

Today, a great number of images are produced by digital color printers, especially inkjet printers. Many factors lead to the degradation of such images and accurate prediction modeling of the degradation is of interest. Previous research that addresses image degradation usually measures the density loss or color change of the prints. In this presentation, the area coverage of the Neugebauer primaries for the basic four-colors (CMYK) ink-set is estimated from the spectral information of the print. A degradation model is developed to predict the area coverage loss over time. A numerical example is used to illustrate the proposed approach.

3 - Modeling Spatio-temporal Degradation Data

Xiao Liu, IBM T.J. Watson Research Center, liuxiaodnn_1@hotmail.com

This talk presents a modeling approach for an important type of degradation data, i.e., the degradation data collected over time and from a spatial domain. The connection between the proposed model and traditional pure time-dependent univariate stochastic degradation models is discussed, and an application example is provided.

Sponsored: Quality, Statistics and Reliability/Data Mining

Sponsored Session

Chair: Kaibo Liu, University of Wisconsin-Madison, WI, kliu8@wisc.edu

Co-chair: Haitao Liao, University of Arkansas, Fayetteville, AR, liao@uark.edu

1 - Kernel Fisher Discriminant Analysis For Uncertain Data Objects

Behnam Tavakkol, Rutgers University, Piscataway, NJ, btavakkol66@gmail.com, Myong K Jeong, Susan Albin

Uncertain data problems have features represented by multiple observations or their fitted PDFs. We propose measures of scatter for uncertain data objects which include covariance matrix along with within and between scatter matrices. We also propose Fisher linear discriminant and kernel Fisher discriminant for classifying uncertain data objects.

2 - An Efficient Statistical Quality Control Scheme For High-dimensional Process

Sangahn Kim1, Rutgers University, Piscatawy, Piscataway, NJ, sk1389@scarletmail.rutgers.edu, Myong K Jeong, Elsayed A. Elsayed

As the number of quality characteristics to be monitored increases in those complex processes, the simultaneous monitoring becomes less sensitive to the out-of-control signals especially when only a few variables are responsible for abnormal situation. We introduce a new process control chart for monitoring high-dimensional processes based on the ridge penalizing likelihood. The accurate probability distributions under null and alternative hypotheses are obtained. In addition, we find out several theoretical properties of the proposed method, and finally demonstrate the proposed chart performs well in monitoring high dimensional processes.

3 - A Nonparametric Adaptive Sampling Strategy For Online Monitoring Of Big Data Streams

Xiaochen Xian, UW-Madison, Madison, WI, xxian@wisc.edu, Andi Wang, Kaibo Liu

Modern and rapid advancement in sensor technology generates huge amount of data, posing unique challenges for Statistical Process Control. We propose a Nonparametric Adaptive Sampling (NAS) strategy to online monitor non-normal big data streams in the context of limited resources, such that only partial observations are available. In particular, this proposed method integrates a rank-based CUSUM scheme that corrects with the anti-rank statistics due to partial observations, which can effectively detect a wide range of possible mean shifts in all directions when each data stream follows arbitrary distribution. Two theoretical properties of the NAS algorithm are investigated.

Military Operations Research II

Sponsored: Military Applications

Sponsored Session

Chair: Natalie M Scala, Towson University, 8000 York Road, Towson, MD, 21252, United States, nscala@towson.edu

1 - A Value Model For Cybersecurity Metrics

Natalie M Scala, Assistant Professor, Towson University, 8000 York Road, Towson, MD, 21252, United States, nscala@towson.edu, Paul L Goethals

This research applies decision analysis perspectives to cybersecurity and creates a value model for performance metrics and best practices that is supported by industry data and interviews with subject matter experts. The utility-theory based value model will include attributes and values, score metrics on their contribution to value, and provide a rank ordered list of important metrics and best practices for implementation. We illustrate the value model but contribute an overall framework that can be customized for any organization. Results will enable organizations to assess the performance of cyber systems.

2 - Efficient Benchmarking Tool Regarding Optimal Detection Of Critical Components In A Network

Gokhan Karakose, University of Missouri, gkz7c@mail.missouri.edu, Ronald McGarvey

Many mathematical and heuristic approaches have been provided to assess critical components of the network based on the network connectivity metric. Since examined objectives through this metric (e.g. minimum connectivity) have important values in many areas (e.g. immunization), proposing an effective solution framework to determine optimal values of such objectives is crucial. In this regard, we provide efficient mathematical models along with new valid inequality constraints to further decrease computational complexity compare to the most recent best models. With this improvement, we broaden the application scope of the exact solution method for the determination of critical component.

3 - OMEGA: Evaluating Effectiveness Of Proposed Systems Using Bayesian Networks

Freeman Marvin, Innovative Decisions, 5848 Hunton Wood Drive, Broad Run, VA, 20137, United States, ffmarvin@innovativedecisions.com, Amanda Hepler

OMEGA is a new approach for designing affordable systems architectures that meet user needs. OMEGA uses a Bayesian network of probability distributions that describes functional needs, system capabilities and customer satisfaction. Measures of Effectiveness (MOE) are combined to estimate the probability that a proposed system will meet mission needs. Additionally, OMEGA can "back cast" the system requirements necessary to achieve alternative levels of mission effectiveness. This innovative approach was developed by a collaborative team of requirements engineers and decision analysts. OMEGA is a flexible, low cost approach for conducting architecture trades and developing requirements for any kind of system.

4 - Designing An Objective Metric For Evaluating Army Unit Readiness

Paul Goethals, United States Military Academy, West Point, NY, United States, paul.goethals@usma.edu, Natalie M Scala

Perhaps one of the most difficult assessments to make with some level of accuracy is military readiness - it is a frequent topic of interest in defense news both in times of combat and peace. This research proposes a readiness index tailored to objectively evaluate units based upon their current status and future mission, using quality engineering tools as a foundation for measurement. A simulated comparison of the current and proposed readiness indices is provided to illustrate their differences in assessing Army units.

1 - Container Vessel Capacity Allocation In Liner Shipping

Michele Acciaro, Kuehne Logistics University, Grosser Grassbrook 17, Hamburg, 20457, Germany, michele.acciaro@the-klu.org, Jan Frahnert

The paper deals with the problem of vessel capacity allocation, taking into consideration priority, cargo type and time of the booking. The approach used is based on a a single leg slot allocation model based on the capacity allocation problem solved by Littlewood s Rule and the enhanced version of the EMSRa-heuristic. Protection classes for cargo types are calculated taking into account cancellations and no-shows and allowing for overbooking. The paper shows that the allocation criteria used by major container carriers are sub-optimal. An application on an existing liner shipping service illustrates the practical and economic benefits of the proposed approach in contrast to current practices.

2 - Optimization System At ENAP For Distributing Refined Petroleum Products By Tanker

Martin Quinteros, Head of Operations Research, Empresa Nacional del Petroleo, San Jose de la Sierra 50 depto 1202, Lo Barnechea, Santiago, 7710088, Chile, martinq46@gmail.com
Andres P Weintraub, Monique Guignard-Spielberg, Marc Llambias

ENAP is a petroleum state-owned company in Chile and plays a key role on the national energy matrix. A critical function on its complex supply chain is the maritime distribution to clients. We present a practical approach for determining an optimal schedule for the fleet of tankers delivering petroleum products. This process takes care of satisfying the demand for multiple end-products by multiple clients with different storage capacities and locations. The optimization model is a large scale MIP problem that was unsolvable on CPLEX but through a generation scheme in routes we were able to solve it to optimality. Our approach is currently saving 10 to 12 percent of the total operational cost

3 - Determinant Of Shippers' Port Choice In Rural Areas In Japan

Kazuhiko Ishiguro, Kobe University, 5-1-1, Fukae-minami, Higashi-nada, Kobe, 658-0022, Japan, ishiguro@maritime.kobe-u.ac.jp

This study discusses factors of shipper's port choice in rural areas in Japan by using a logit model considering "average waiting time at port" and four type of "seaborne transportation time." Average waiting time at port is derived by the calling schedule at each port. Results show that, a shippers care the average transit time in export and the longest transit time in import. It turned out that shippers consider transshipment time in case of export and it doesn't consider transshipment time in case of import. Shippers considers a sum of average waiting time at port and seaborne transportation time as a total transit time.

1 - Benders Decomposition For Inventory Routing Problem With Perishable Product In Cold Supply Chain

Faisal M Alkaabneh, PhD Student, Cornell University, Ithaca, NY, 14850, United States, fma34@cornell.edu, Huaizhu Gao

We consider Inventory Routing Problem of perishable products. The developed mathematical model takes into account cost of CO2 emissions during the distribution process. The problem is modeled as a nonlinear mixed integer mathematical model that is difficult to solve directly. To this end, we propose a set of linearization schemes to simplify nonlinearity terms and developed Benders decomposition to solve the model. Furthermore, we provide extensive numerical analysis for Vendor Managed Inventory system taking into consideration different classes of perishable products.

2 - A Bi-level Programming Approach For Optimizing Resilience Of Port-hinterland Container Transportation Networks

Nan Liu, Professor, Zhejiang University, School of Management, Zijingang Campus, Yuhangtang Road, Hangzhou, 310058, China, nliu@zju.edu.cn, Song Gao

In this paper, we employ a bi-level programming model to optimize the resilience of the port-hinterland container transportation network when suffered from natural or human-caused disasters. At the upper level problem, the transportation network planner, i.e. the government, make recovery decision to optimize the resilience of the transportation network when facing the disasters within given budgets constraint such as money and time. At the lower level problem, the transportation network users, i.e. third party logistics companies, make decisions about the transport modes, routes and freight volume to maximize its own profit according to the recovered transportation network.

3 - Effects Of Time Incentives On Container Port Operations

Yuen Ying Lam, Research Assistant, Hang Seng Management College, Hang Shin Link, Siu Lek Yuen, Shatin, N.T., Hong Kong, Hong Kong, avislam@hsmc.edu.hk, Karolina J. Glowacka, Yin Cheung, Eugene Wong

This paper presents a simulation model of Hong Kong container port ship-to-shore operations with inclusion of time incentives and penalties for early/late work completion. The presented method allows for detailed container-level modelling. Assuming continuous berth assignment and variable-in-time crane allocation, we measure the impact of the incentives and penalties on the ship lines and port operators. We present the results for various levels of incentives and penalties, as well as contract incentive adoption rate.

Supply Chain Mgt VI

Contributed Session

Chair: Jie Tan, Huazhong University of Science and Technology, Wuhan, China, jietan@hust.edu.cn

1 - Supply Chain Configuration And Financial Performance: An Empirical Investigation

Marouen Ben Jebara, University of South Carolina Aiken, 471 University Parkway, School of Business, Aiken, SC, 29801, United States, marouenB@usca.edu, Sachin Modi

Disintermediation is gaining attention in pharmaceutical industry: drug companies have the opportunity to sell their products directly to the end consumers as well as to intermediaries. We conceptualize the influence of supply chain disintermediation and product portfolio on financial performance. Using secondary data collected from pharmaceutical industry, we empirically investigate the proposed hypotheses and present results.

2 - Configurations Of Distribution Strategies: An Integrated Analysis Of Quantitative And Qualitative Data In Retailing Industry

Dongtao Xu, Huazhong University of Science and Technology, 1037 Luoyu Road, Wuhan, 430074, China, xudongtao@hust.edu.cn

This paper develops a theoretical framework of distribution strategy and provides empirical evidence onthe configurations of distribution strategies and their strategic fit. To achieve this goal, we identified the configurations of distribution strategies and operational competencies with conducting an integrated analysis of quantitative and qualitative data in retailing industry.

4 - Applications Of Open Innovation To Improve Supply Chain

Tianqin Shi, San Jose State University, One Washington Square, Business Tower 465, San Jose, CA, 95192-0164, United States, tianqin.shi@sjsu.edu, Taeho Park

The concept of open innovation has changed the paradigm of R&D practices by advocating firms' efforts to use external ideas beyond their internal R&D resources. Previous studies have mainly focused on the application of open innovation on the development of new technology and products. However, the concepts and practices of open innovation are not limited to R&D management. Thus, this research provides insights into the current and potential applications of open innovation in a supply chain system. It also identifies the current practices of open innovation in supply chain management, and presents further potentials of applications of open innovation in the supply chain system.

5 - Procurement Strategy In Decentralized Supply Chains Under Supply Disruptions And Uncertain Demand

Jie Tan, Huazhong University of Science and Technology, Wuhan, China, jietan@hust.edu.cn, Haijun Wang

This paper considers a decentralized supply chain consisting of one retailer and one unreliable supplier under single-period setting. The retailer (buyer) has a chance of complete supply disruption and faces uncertain demand simultaneously. She (buyer) offers a contract (q, w), and upon it the supplier then chooses the optimal reliability level and pays for the corresponding cost of technology investment, to maximize his expected profit. Also the interaction between supplier's reliability and production cost has been considered. We finally conduct a numerical analysis with the purpose of providing several managerial suggestions for order size and purchase price as well as reliability level.

Chair: David J Robb, Professor of Operations and Supply Chain Managemen, University of Auckland, Graduate School of Management, The University of Auckland Business School, Auckland, 1142, New Zealand, d.robb@auckland.ac.nz

1 - A Model For Diabetes Clinical Pathway Scheduling

Hossein Badri, PhD Student, Wayne State University, 4185 4th Street, Manufacturing Building, Detroit, MI, 48202, United States, fq2529@wayne.edu, Kai Yang

Clinical Pathway is a very efficient method to improve patient care, to manage clinical risks, and to improve resource efficiency. In this research we develop a model for the scheduling of the diabetes clinical pathway. The proposed model is tested using a real data set and the performance of the proposed model is analyzed.

2 - Modeling The Screening Of Post-traumatic Stress Disorder: A Criticism Of The Current Dichotomous Categorization Of Patients

Navid Ghaffarzadegan, Virginia Tech, 1145 Perry Street, 231 Durham Hall, Blacksburg, VA, 24061, United States, navidg@vt.edu, Mohammad S. Jalali, Alireza Ebrahimvandi, Richard C Larson

Post-traumatic stress disorder (PTSD) stands out as a major mental illness and screening policies have played a critical role in mitigating the effects of PTSD; however, little agreement exists on the optimal cutoff value—a threshold above which screening scores should be considered as PTSD positive. We develop a simulation model of PTSD screening which includes social forces that inhibit accurate screening. Our analysis shows that the results of long-term optimal policies are different than their myopic short-term results. With the presence of public stigma, current dichotomous screening policies are not much effective to minimize the number of false positive and false negative.

3 - Robust Multi Product Network Design For Blood Chain A Priority Queuing System

Mohammad Abdollahi, PhD Candidate, Wayne State University, 4815 Fourth Street, Room 1067, Detroit, MI, 48202, United States, fq6861@wayne.edu, Kai Yang

This study tries to investigate best network configuration in constructing a smooth and cost effective network considering all the modification corresponding to blood supply. Some highly important blood specific considerations such as blood type priority and lateral transshipment and perishability is considered in the proposed model. To cope with the existent uncertainty related to the blood processing and traveling times, a prioritized M/M/C and M/M/C models are considered for laboratories and blood banks, respectively. Moreover, an interval robust counterpart is proposed to deal with the uncertainty in the model corresponding to demand and cost and etc.

5 - Association Between Accident Rates And Daylight Saving Time Transitions

David J Robb, Professor of Operations and Supply Chain Managemen, University of Auckland, Graduate School of Management, The University of Auckland Business School, Auckland, 1142, New Zealand, d.robb@auckland.ac.nz, Thomas P Barnes

A third of nations have adopted Daylight Saving Time, presumably hoping that benefits exceed costs. Studies have found changes in accident rates associated with DST. Using data from 21 million New Zealand accidents during 2003-2015, we model accident rates as a function of various date-based predictors including days before/after the start and end of DST, day of week, and month of year. This is the first study to consider multiple accident categories (work, home, falls, sport, & road), and the first in the southern hemisphere. We find evidence of accident rates impacted in the week prior to the start and end of DST, i.e.,anticipation effects. Our results have implications for implementation and policy.

1 - Why Do Web Retailers And P&G Use "Postage Stamp" Pricing?

Phillip J Lederer, Professor, University of Rochester, Simon School of Bus. Admin., Rochester, NY, 14627, United States, Lederer@simon.rochester.edu

First, this talk explains why some web retailers/mail order firms use zero or postage stamp type delivery charges but others set distance charges. A game theoretic model demonstrates the equilibrium decisions of a web retailer competing against reactive local retailers. I can show why Lands' End and web furniture stores set flat prices but other specialty retailers charge by distance. Second, unrecognized in the literature is that P&G and other consumer products firms set location independent delivery charges to retailers. I present an economic model explaining this pattern.

2 - Marketing Strategies And Empirical Comparisons Between Agricultural Producer Community Structures

Brian A. Bourquard, Purdue University, 403 W State Street, West Lafayette, IN, 47907, United States, bbourqua@purdue.edu, Allan W. Gray

We study agricultural community structures and how influencers relate to information channel preferences. We use 1,300 agricultural producers' ratings of information-source preferences and outside influencers from a nationally delivered survey to determine community structures with sociodemographic characteristics. We develop an empirical comparison of the producer communities' purchasing and management behaviors. We also develop a methodology to predict the most effective marketing channels for input suppliers that accounts for the changing characteristics of agricultural producers.

3 - Modeling The Exposure Effect Of Customized Promotions On Shopping Frequency: A Quasi-experimental Analysis

Russell Zaretzki, Associate Professor, University of Tennessee, 246 Stokely Management Center, Knoxville, TN, 37996, United States, rzaretzk@utk.edu, Amil Williamson, Mary Leitnaker

Modern customer relationship management frequently involves the use of customized direct-to-consumer promotions. How well do such promotions work? We focus on the impact promotions have on the frequency of visits and analyze an unbalanced quasi-experimental crossover design that provides several varieties of customized and non-customized coupons to shoppers. Differences in trip frequency among consumers during periods with and without coupons are modeled. Carryover effects of promotion, decay rates of these effects, and positive feedback in the coupon allocation mechanism are also analyzed.

Mature Oil Fields And Real Options Valuation: Simulation In The Brazilian Oil Industry

Carlos Abreu, Adjunct Professor, Federal University of Rio Grande do Norte State (UFRN), Avenida das Brancas Dunas, Natal, 59064720, Brazil, calexandreabreu@ect.ufrn.br

Real Option Valuation in the Oil industry is an important tool for decision-making valuating a potential flexibility caused by the uncertainties in oil projects. Mature fields are a considerable portion of producing oil fields around the world. These oil fields production projects need positive future expectations regarding oil prices to get a positive investing decision. The Real Options models valuates the decision to wait for better expectation in prices. In this paper we have a Real Options analysis in two simulations for mature oil field in the northeastern of Brazil applying a decision-making rule using Real Options Valuation, net present value and return on investment indicator.

Class-based Warehouse Location Allocation For Textile Products

Esra Agca Aktunc, Kadir Has University, Faculty of Engineering and Natural Sciences, Kadir Has Caddesi Cibali, Istanbul, 34083, Turkey, esra.agca@khas.edu.tr, Halil Argun, Erkin Gokce

This study focuses on building a layout plan by allocating storage space to products in a warehouse of a textile company (English Home) which allows for the minimum total travel distance of operators for order picking or placing. The study is carried out by (1) performing regression analysis for sales forecasting for each product class, (2) applying Analytical Hierarchy Process for determining product class weights, and (3) formulating and solving a linear program to minimize the weighted total distance between storage locations, collecting area, and loading dock using GAMS. Optimal solution results in 26.8% less distance required for order picking than the previous layout.

Application Of Advanced Analytics In Banking Big Data

Mou Dutta, Genpact Analytics & Reserach, Danbury, CT, mou.dutta@genpact.com

Data is meaningful when it delivers insights. Data analysis is smart when insights are actionable. In today's world big data and analytics is transforming the business end to end with smart intelligent insights challenging the conventional thought process and enabling the marketers to optimize strategies to build a genuine customer connect and cultivate a positive relationship. This presentation aims to highlight how marketers are shifting their attention to the application of cutting edge advanced analytics solutions to gain in-depth knowledge of consumer buying preferences and product affinity and hence optimize existing cross selling and up selling marketing strategies.

Efficient Algorithm To Improve Scheduling Problem Solutions

Golshan Madraki, Ohio University, Athens, OH, g.madraki@gmail.com

Any choice-free manufacturing system can be represented by a directed acyclic graph (DAG) where the nodes and edges represent the operations, the sequence of the operations, and with the scheduling of the jobs respectively. Graphical wise, perturbation may occur over structure of the graph denoting scheduling or sequencing of operations. The goal of current research is to find the efficient algorithms to calculate changes to the makespan in a system under multiple structural perturbations. The paper will show that there will be savings in the complexity of the calculations if the perturbations are not extensive. As an example, a buffered job shop system is considered.

Comparing Two Goods-to-person Order Picking Systems For Online Retailing

Francisco Jose Aldarondo, University of Michigan, Ann Arbor, MI, faldaron@umich.edu

Using simulation modeling and an on-line retail setting, we compare the performance of two types of goods-to-person order picking (OP) systems, namely, the Kiva system and the Miniload-AS/RS with a conveyor loop (to connect the pick stations). The two systems are compared on the basis of quantitative factors such as expected throughput (line items picked per hour), expected picker and material handling equipment utilizations, and order completion times. We also compare the two systems in terms of qualitative factors that are relevant for OP systems.

Two-dimensional Cutting Problem And Pallet Loading Problem Using Industrial Robots

David Alvarez Martinez, Los Andes University, Colombia, Bogotá, Colombia; d.alvarezm@uniandes.edu.co, Guillermo A. Camacho Muñoz

We developed an automatic cutting and palletizing system, solving the two-dimensional single knapsack problem and the distributor's pallet loading problem. The system is composed by: optimization stage, code-generator, manipulator and plasma cutter (vacuum gripper). At the optimization we use a GRASP algorithm; at the code generation we use the forward kinematic model (FKM) of the manipulator. The GRASP was validated by using the classical benchmarks. The FKM was validated using the simulator and the controller provided by the Robot vendor. Finally, we enhanced the cutting procedure through a post-processing. It reduces the time and keeps the accuracy, but increases particulate generation.

Meaningful Use Of Health Information Technology And Process Quality Of Care At Hospitals: A Patient Safety Culture Perspective

Ajit Appari, University of Texas Health Science Center at Houston, 1200 Pressler Street, RAS W-310, School of Public Health, Houston, TX, 77030, United States, ajit.appari@uth.tmc.edu
Xin (David) Ding, Rajendar R Aparasu

Based on the Resource Based View and Sociotechnical System Theory, we examined the synergetic effect of meaningful use of health information technology (IT) and patient safety culture on hospital quality of care performance. Hospital safety culture was measured using composite score derived from confirmatory factor analysis. Health IT meaningful use was measured as composite index of nine meaningful use criteria with patient days as weights. We analyzed data from 305 nonfederal acute care hospitals using two-step Heckman estimation approach and adjusting for autocorrelation in performance outcomes. Our results show empirical support for the hypothesized relationship.

Gait Assessment: Correlation Of Gait Parameters With Falls Among Patients With Cognitive Impairment

Idil Arsik, Georgia Institute of Technology, 765 Ferst Drive, Atlanta, GA, 30332, United States, idilarsik@gatech.edu
Pinar Keskinocak, Joe Nocera, Gregory J Esper

In aging, alteration in the customarily stable gait pattern is one of the most consistent predictors of falls. Adults with cognitive impairment fall 5x more than their cognitive intact peers. In this study, we assess the correlation between gait characteristics captured by gait mat technology and history of falls among patients with Mild Cognitive Impairment and Alzheimer's Disease diagnoses.

On Optimization Of Carbon Capture, Utilization, And Storage Supply Chains Under Uncertainty

Mahnaz Asghari Khankandi, Virginia Tech, Blacksburg, VA, 24060, United States, mahnaz@vt.edu

Carbon capture, utilization, and storage (CCUS) is a crucial technology to mitigate climate change. Due to the high costs of the technology, a great deal of attention has been focused on how the captured Co2 can be optimally utilized or stored. We study optimizing CCUS supply chains under an uncertain environment. In this poster, we present an algorithm to generate a candidate network for Co2 transportation and a model for optimizing the utilization and storage of the captured Co2 in CCUS systems.

Ethanol Risk Management Modeling

Iddrisu Awudu, Quinnipiac University, 12 Kaye Plaza, Apt E-22, Hamden, CT, 06514, United States, iddrisu.awudu@quinnipiac.edu

A theoretical model is developed including margins and risk is measured using value at risk (VaR). An empirical model is developed and extended to VaR using copulas to analyze the marginal distribution and dependence structure for input and output prices on margins. Efficient frontier curves analyzing VaR with and without copula are discussed. The results compare varying risk-strategy measures for long corn, short corn, and combining short and long corn. Sensitivity analyses are conducted for functional changes in the margin as a result of ethanol price changes.

A Location Allocation Model For Facility Planning To Minimize The Operational Cost

Damitha Bandara, Dr., Albany State University, 2805, Albany, GA, 31721, United States, damithb@g.clemson.edu

Locating and allocating distribution centers optimally is a crucial and systematic task for decision-makers. Optimally located distribution centers can significantly improve the logistics system's efficiency and reduce its operational costs. In this research, we develop a mathematical model to determine the optimal locations and allocations for distribution centers that minimizes the operational cost. The model is used to find the optimal location and allocation of distributions centers for a leading company in the USA. Computational results show that the company can reduce their operational cost significantly by implementing new optimal distribution locations.

Inference For The Progressively Type-I Censored Step-stress ALT Under Interval Monitoring

David Han, University of Texas at San Antonio, Management Science & Statistics, College of Business, San Antonio, TX, 78249-0632, United States, david.han@utsa.edu
Tianyu Bai

A step-stress ALT under progressive Type-I censoring was considered when a continuous monitoring of failures is infeasible but inspections at certain time points is possible. In addition to the accelerated failure time model, a general scale family of distributions was considered for flexible modeling. The MLE of scale parameters and their conditional densities could be derived explicitly. Using the exact distributions of the estimators, confidence intervals for the parameters were obtained and numerically assessed.

A Probabilistic Unit Commitment Model

Kenneth Bruninx, KU Leuven, Celestijnenlaan 300, Post Box 2421, Leuven, B3001, Belgium, kenneth.bruninx@mech.kuleuven.be, Erik Delarue

Stochastic unit commitment models allow calculating an optimal trade-off between the cost of scheduling and activating reserves, load shedding and curtailment, but may become computationally intractable for real-life power systems. Therefore, we develop a probabilistic unit commitment (PUC) formulation, which allows internalizing the reserve sizing and allocation in a deterministic unit commitment problem, considering the full cost of reserve allocation and activation. This PUC formulation yields UC schedules that are nearly as cost-effective as the theoretical optimal solution of the stochastic model in calculation times similar to that of a deterministic equivalent.

Understanding Vehicle Movement Patterns With Artificial Neural Networks

Burak Cankaya, Lamar University, 13960 Hillcroft St, Apt 724, Houston, TX, 77085, United States, mbcankaya@gmail.com

This research evaluates the question if we can understand the vehicle movement patterns depending o their (Geographic Identification Systems)GIS data. The research propose to classify the vehicle movements as the work they are doing with machine learning algorithms. The results label the vehicle movement states and make it possible to evaluate the performance of the vehicles which is an essential need for work vehicles, personal devices and vehicles, and vessels. The poster also explains the data preparation and the algorithms such as decision tree, random forest, and neural networks to classify the geospatial data.

Algorithms For Identifying Optimal Inspection Paths In Pipe Networks

Thomas Ying-Jeh Chen, University of Michigan, 1780 Broadway Street, Apt S128, Ann Arbor, MI, 48105, United States, tyjchen@umich.edu, Seth Guikema

The inspection of aging water distribution pipes is an important process for utilities. Due to limitations on inspection capabilities (~2% length of system is typically inspected annually), an optimization process is needed to suggest inspection paths. This paper examines the use of 3 algorithms (Genetic Algorithm, Simulated Annealing, Greedy Search) in finding paths that maximizes high risk pipes being inspected while reducing the number of pipe feature changes (material, diameter etc.). The algorithms were applied to a grid network and a virtual water distribution network. Both cases demonstrated genetic algorithms were the most effective in identifying strong candidates for inspection.

Properties Of Location Based Social Networks And Travelers Destination Choice

Ying Chen, Research Assistant Professor, Northwestern University, 600 Foster St, Evanston, IL, 60208, United States, y-chen@northwestern.edu, Hani S. Mahmassani, Fei Zhao

The aim of this study is to investigate the relationship between friendship and distance, the possible influence of friendship in travelers' destination choices, and the importance of this factor in choosing a destination. By analyzing social network properties of two Location based Social Networks (LBSNs), the characteristics of LBSNs are identified. Results show that in general, the distance has the strongest influence on travelers' destination choices, followed by personal preference and social influence from their friends on-line. For users whose friends are in geographical proximity to each other, a possible synchronization characteristic amongst individuals is investigated.

Stadiums And Contraband: A Study On Metal Detectors In The Field

Nelson Christie, Rutgers University, Princeton, NJ, United States, christie.l.nelson.phd@gmail.com

Sports stadiums are increasingly using walk-through metal detectors for patron screening. We utilized experimental design to understand detection rates of real contraband items. These items were identified through interviews of various subject matter experts. Experiments were carried out on machines borrowed from stadium venues. We also created a testing scheme for the metal detectors to ensure functionality prior to events.

Assessing Uncertainty: A Model-output Oriented Approach

Achim Czerny, Dr, Hong Kong Polytechnic University, Hong Kong, Hong Kong, achim.czerny@polyu.edu.hk
Erik T. Verhoef, Anming Zhang

The present paper develops the concept of continuous uncertainty types, which are defined by the extent to which uncertainty affects the firm's optimized price markups and quantities (i.e., "model outputs"). We show that this model-output orientation can cover scenarios where additive, multiplicative and many more stochastic structures all occur with positive probabilities. This approach allows a compact assessment of the impacts of uncertainty. We further show that the optimal inventory level, and the composition of inventory in terms of the number and size of production units, depend strongly on the type of uncertainty and its distribution as defined according to our theory.

Explaining Energy Bonds' Option-adjusted Spread (OAS) Using Multiple Exponential Regression Models

Yan Deng, PhD Student, Cornell University, Cornell University, 2406 Hasbrouck Apartment, Ithaca, NY, 14850, United States, yd256@cornell.edu

In order to explain the OAS of corporate energy bond, we developed exponential regression models for prediction. We found that as the oil prices drop, the OAS of energy bonds widen significantly. The sensitivity of OAS to oil price varied among energy subsectors in line with leverage. In addition, adding treasuries yield predictor could significantly increase the predicting accuracy. In particular, these two variables can explain 87.4%, 75.6%, 86.5%, 64% and 84.4% of credit spread changes for independent, integrated, midstream, oil field, and refining energy bonds respectively. Our predictive model provided a tool to monitor risk and signal rich or cheap bonds as potential buy/sell candidates.

Deep Learning For Sleep Assessment

Skyler C Devine, University of Tennessee - Knoxville, Knoxville, TN, 37916, United States, sdevine2@vols.utk.edu

Based on the physiological and neurological features, sleep is divided into two main types: Rapid Eye Movement, and non-rapid eye movement. NREM sleep consists of three stages, stages 1-3. Brain activity during sleep stochastically alternates between stages. In order to judge sleep, clinicians record the electrical activity of the brain through an electroencephalogram, and visually inspect the results to classify them into the three stages. This process is referred to as "sleep scoring". We apply a deep learning algorithm to automatically score sleep and provide monitoring of sleep quality.

Inventory Placement Supply Chain With Two Competing Retailers

Yi Ding, Southeast University, Sipailou 2, Jiangsu Province, Nanjing, 210096, China, emdy@seu.edu.cn

This study examines service time competition in the context of inventory and environmental constraints. We first discuss the case of a downstream duopoly market without regulator, and then we extend the model by including a regulator that is dedicated to carbon emission abatement. We analyse how service time can be affected internally through inventory placement and externally through market competition as well as government regulation of carbon emissions. The results suggest that although expedited service requires higher safety stock, increasing unit inventory holding cost does not seem to slow down service, nor does imposing higher carbon tax.

Decision Support Model To Planning A Mobility Scheme For Critical System Services In Urban Networks With Natural Interruptions

Andrea Margarita Ditta, Universidad del Norte, km 5 Antigua vía Puerto Colombia, Barranquilla, Colombia, dittaa@uninorte.edu.co, Ruben Yie, Gina Galindo

This work aims to design a Decision Support Model (DSM) to planning a mobility scheme in emergency scenarios in urban networks. The DSM seeks to evaluate the transportation between points of incidents and points of care. The research is focused in the area of humanitarian logistics considering natural interruptions like streams, storms, downpours, among others. We undertake emergency response systems with critical services. Fire brigade, police force requirements or urgent medical attention, are examples of critical services.We hope to increase the efficiency in dealing with emergencies, by decreasing attention times and risk of accidents.

Supermarket Optimization: Simulation Modeling And Analysis Of A Grocery Store Layout

Jessica Peggy Dorismond, University at Buffalo, 3028 Elmwood Avenue, Buffalo, NY, 14217, United States, jpdorism@buffalo.edu

This is a study on how to optimize the layout of a supermarket in order to increase its gross profit via the maximization of impulse sales. In most supermarkets many items often get unnoticed because on average customers only walk one-third of the store. Recent advances in marketing research reveal that encouraging customers to walk longer paths can often increase spending because they are exposed to more products. Retailers can then increase their sales by using the store layout—i.e., the design of the aisles and the product location—to extend the customers' shopping paths and thus indirectly motivate them to purchase items that are not originally on their shopping list.

Allocation Of Organization's Resource Using Data Envelopment Analysis & Topsis Method: A Case Of Capital Medical University

Tao Du, Beijing Institute of Technology, Beijing, China, dutao0608@163.com

We proposes a DEA-TOPSIS combined method for the problem of organization's resource allocation. This method, firstly, measures the DMUs'relative efficiency using DEA model, and determines the organization's efficiency objectives and alternatives. In the second stage, we ranks the alternatives using TOPSIS method for organization making decision. DEA measures the DMUs' relative efficiency about multiple-input and multiple-output index, so it is theoretically possible to the decision matrix for the TOPSIS method. Taking the 10 affiliation hospitals of capital medical university for example, results show DEA-TOPSIS combined method can sequence alternatives effectively.

Spent Microbial Biomass As An Alternative Fertilizer: A Spatial Cost And Optimal Product Mix Analysis

Rachel Eatherly, Graduate Research Assistant, University of Tennessee, 2621 Morgan Circle, 307 G-Agricultural Economics, Knoxville, TN, 37996, United States, reather1@vols.utk.edu

High commercial fertilizer costs have necessitated further investigation into alternative sources of N, P, and K to meet the fertility requirements of crops grown in East Tennessee. The objective of this analysis is to determine the optimal fertilizer mix strategy and minimum cost threshold for utilizing spent microbial biomass as an alternative to commercial fertilizer in Loudon County, Tennessee using a linear programming model. Additionally, the analysis will examine the optimal spatial distribution of the spent microbial biomass across typical crops and crop rotations.

A Cyber-physical Vulnerabilities Framework For Manufacturing Systems: A Quality Control Perspective

Ahmed Elhabashy, PhD Student, Virginia Tech, 1145 Perry Street, 114 Durham Hall, Blacksburg, VA, 24061, United States, habashy@vt.edu, Lee J Wells, Jaime Camelio, William Woodall

With recent technological advancements, manufacturing systems have become more susceptible to cyber-attacks that can maliciously affect the physical world. Moreover, such cyber-physical attacks can be designed to avoid detection by traditional Quality Control (QC) tools. Hence, this work proposes a framework that allows for understanding the relationships between QC systems, manufacturing systems, and cyber-physical attacks; in order to develop better QC tools minimizing the chances of such attacks being effective in manufacturing systems. The proposed framework analyzes the different levels involved in cyber-physical attacks and explores potential QC tools exploitation mechanisms.

Analysis Of Competition And Cooperation Strategy Of Railway Inland Port And Seaport

Mi Gan, Associate Professor, Southwest Jiaotong University, Jinniu District, 111 N 1st Erhuan Road, Chengdu, 610031, China, migan@swjtu.cn, Shuai Yang, chen si, Juan Yu

China government has constructed a number of inland ports to narrow the economic development gap between coastal developed areas and inland area. The function of inland port is similar to seaport; especially to those inland ports possess an international express railway could transport cargoes by freight train directly from inland region to abroad. Given that, there is a new decision problem urgent to solving for urban policy maker and related enterprises: what is the optimal strategy (competition /cooperation) for the inland port and seaport? In this sense, we aim to construct a competition-cooperation model to support the port operators and local government to make decisions on strategy level.

Optimal Number Of Choices In Rating Contexts

Sam Ganzfried, Assistant Professor, Florida International University, 11200 SW 8th St, Miami, FL, 33199, United States, sam.ganzfried@gmail.com

In many settings people give numerical scores to entities from a small discrete set, e.g., attractiveness from 1-5 on dating sites and papers from 1-10 for conferences. We study the problem of understanding when using a different number of options is optimal. We study several natural processes for score generation. One may expect that using more options always improves performance, but we show that this is not the case, and that using fewer choices—even just two—can surprisingly be optimal. Our results suggest that using fewer options than typical could be optimal in certain situations. This would have many potential applications, as settings requiring entities to be ranked by humans are ubiquitous.

Information Technology Investment And Logistics Outsourcing Contract

Fengmei Gong, Assistant Professor of Information Technology, University of La Verne, 1950 Third Street, La Verne, CA, 91750, United States, fgong@laverne.edu, David Kung

Third party logistics (3PL) providers have invested a lot in information technologies (IT) to improve its logistics service quality. We compare four different contracts for logistics outsourcing and consider a 3PL's investment in IT. We find that the performance of contracts is related to the 3PL's IT investment.

Comparing The Impact Of Park And Ride, Non-park And Ride, And Terminals On Schedule Time For The Hudson-Bergen Light Rail

Erika Gonzalez, New Jersey City University, 1809 Bergenline Ave, Apt 2B, Union City, NJ, 07087, United States, erikaygonz482@gmail.com

The Hudson-Bergen Light Rail transportation service provides commuters accessible ways to travel throughout Hudson and Bergen Counties in New Jersey. In addition, commuters have the option to use a "Park and Ride" service adjacent to several light rail stations. Hence, this study investigates the service quality with respect to the efficiency and reliability of train arrival and departure time.

The Effect Of High Socioeconomic Inequalities On The Educational Efficiency

Maria Cristina Gramani, Professor, INSPER, rua Indiana, 463 ap. 82, Brooklin, Sao Paulo-SP, 04562000, Brazil, mcgramani@gmail.com

This study constructs a two-stage model that takes into account the link between educational efficiency and socioeconomic indicators, using DEA methodology followed by the tobit regression. These aims are achieved using data from 5,020 municipalities in Brazil. The results suggest that for less wealthy municipalities other factors than expenditure per capita have much more influence on IDEB, but for the richest municipalities the expenditure per capita is considered an efficient determinant of education. The tobit regression results strongly confirm that municipalities with high inequality are inclined to have lower educational efficiency.

Obtaining Lower Bounds For Conditional Value-at-risk Optimization In Stochastic Mixed-integer Programs

Ge Guo, PhD Candidate, Iowa State University, 3004 Black Engineering Building, Iowa State University, Ames, IA, 50011-2164, United States, geguo@iastate.edu

Recently, optimization of risk measures has attracted attention in stochastic mixed-integer programs. Computational issues regarding lower bound for Conditional Value-at-Risk (CVaR) models, however, are largely unexplored. We present a method to obtain convergent and tight lower bounds from the Progressive Hedging Algorithm (PHA) for CVaR-based stochastic mixed-integer programs. This method can assess solution quality for PHA and also integrate with exact algorithms that rely on lower bounds. We report computational results on stochastic server location and manufacturing instances.

Evaluation Of Traffic Management Strategies At The Swedish Emeregency Call Center

Klas Gustavsson, PhD Student, Mid Sweden University, Sundsvall, 85170, Sweden, klas.gustavsson@miun.se

The Swedish emergency call center fail in achieving government agreement regarding availability. In this project we evaluate different traffic management strategies using our designed discrete event simulation model, also supposed to apply as a traffic planning tool assisting daily issues. Outputs from the study has so far contributed to the managerial decision of implementing a new strategy, currently being evaluated. The result from this evaluation is statistical significant. As a result of our evaluation we have pinpointed some challenges of great value for the management team. For instance, if they measure sociological parameters, the model performance will be significantly improved.

The Growing Role Of Analytics In Management Education

Owen P Hall, Professor, Pepperdine University, 6100 Center Drive, Suite 400, Los Angeles, CA, 90045, United States, ohall@pepperdine.edu, Ken Ko

Business schools are under growing pressure to engage in significant programmatic reforms in light of the business community's call for web-savvy, problem solving graduates. The increase use of Analytics represents one approach for helping addressing these challenges. The purpose of this presentation is to highlight best practices in the use of Analytics throughout the management

VHA Supply Chain Enterprise System Benchmarking Analysis

Julie Lynn Hammett, Texas A&M University, 301 Holleman Dr E, Apt 728, College Station, TX, 77840, United States, jhammett@tamu.edu

We present the final outcome of a benchmarking analysis of supply chain enterprise systems conducted by Texas A&M University for the Veterans Health Administration and the Veterans Affairs Center for Applied Systems Engineering. This project entailed market research, stakeholder analysis, functionality requirements definition and prioritization, and benchmarking analysis using SWOT and Data Envelopment Analysis. The use of dual benchmarking methodologies was beneficial for representing the alternatives to the varied perspectives of the decision making units.

Non-convex Problems For Long-term Hydropower Scheduling

Martin N. Hjelmeland, PhD Candidate, Norwegian University of Science and Technology, O.S. Bragstads plass 2E, Trondheim, 7491, Norway, martin.hjelmeland@ntnu.no

With its large operational flexibility, hydropower may provide spinning reserves at a low cost. With the introduction of a market for providing capacity in the scheduling, the unit commitment problem in the stochastic multistage hydropower scheduling problem becomes essential. This is mainly due to the minimum generation restriction for a hydropower station that should be enforced to ensure a practicable dispatch. This work will focus on methods to solve these kinds of problems, and evaluate its importance for the hydropower scheduling problem. Methods that will be applied are Stochastic Dynamic Programming (SDP) and Stochastic Dual Dynamic Programming (SDDP) with possible extensions.

A Two-echelon Decomposition Method On Fresh Product Distribution Problem

hongtao HU, Associate Professor, Shanghai Maritime University, Room101, No 96, 555 Guzong Road, Shanghai, 201306, China, hu.hongtao@foxmail.com

Refrigerator cars are widely used for fresh product distribution. The energy consumption of these vehicles is sensitive to the environment temperature. To reduce operation costs of third-party transportation providers (TPTP), the refrigerator car scheduling problem is addressed in this research. A time-dependent mixed-integer programming model is established to reduce total operation costs. An adaptive heuristic method is proposed by combining the variable neighborhood search and particle swarm optimization.Numerical experiments are conducted to demonstrate the effectiveness of the proposed time-dependent decision model.

Modeling Capacity Planning Projects In The Automotive Industry Using A Markov Decision Process

Paul Jana, Technische Universität München (TUM), Arcisstr 21, Munich, 80333, Germany, paul.jana@tum.de, Martin Grunow

To support automotive OEMs in time-phased decision making during capacity planning projects connected to new vehicle introductions, we present a dynamic programming approach based on a Markov Decision Process. We employ Bayesian updating to anticipate forecast updates and adapt standard risk measures. Our methodology is superior over alternative stochastic approaches.

Assessment Of Clustering Algorithms Based On A Data Mining Technique

Youngseon Jeong, Assistant Professor, Chonnam National University, 77 Yongbong-ro, Buk-gu, Gwangju, 61186, Korea, Republic of, youngseonjeong@gmail.com

This research presents a novel performance assessment of clustering compactness based on one-class classification algorithms. The proposed method evaluates the compactness of each cluster by using support vector data description (SVDD) and Bayesian support vector data description (BSVDD), which is robust to arbitrary shapes of a clustering. In addition, the proposed approach can accurately evaluate a clustering compactness in kernel space. The experimental results show that the proposed method can evaluate the accurate compactness for arbitrary shapes of a clustering.

The Status, Development Potential Prediction And Policy Recommendations Of New Energy In China

HongDian Jiang, Master Degree Candidate, China University of Petroleum, No.18, Fuxue Road, Changping District,, Beijing, 102249, China, cupjhd@163.com, KangYin Dong, RenJin Sun

By combining the GM (1, 1) grey model with BP neural network model and establishing a combined Grey-BP modelling tool, future the development potential of China's new energy is forecasted. In addition, the ranking of the development potential for the different new energy fuel types is performed, from both the development scale and growth rate perspective. According to our estimation, China's total new energy consumption will increase to 690.5 Mtoe in 2020, accounting for 19.7% of the domestic energy need. Besides, according to the rank results, nuclear and solar energy will be considered as future oriented composition of the new energy, as well as hydropower considered as the key element in China.

Predictive Maintenance From Analysis Of Airplane Sensor Data

Ruiwei Jiang, Data Scientist, Boeing Vancouver, 1146 Homer Street, Vancouver, BC, V6B 2X6, Canada, ruiwei.jiang@aeroinfo.com, Phillip Mah, Dawen Nozdryn-Plotnicki, Benji Shieh, Hubert Duan

Unscheduled maintenance drives 10% of the annual operational cost to airlines worldwide. Predictive Maintenance could reduce those costs, particularly when synchronized with airline's operations. By using engineering expertise, statistics and machine learning on aircraft sensor and fault data, as well as analysis of an airline's flight and maintenance schedule, we detect impending issues on the aircraft and suggest maintenance tasks in accordance with the prediction and an airline's working rhythm. These predictive maintenance tasks will increase reliability and reduce unscheduled maintenance.

Eliminating Preventable Motor Vehicle Accidents Through Simulation Scenarios Of Vehicle Modifications

Sahar Khamsehi, Prospective Phd Student/Practical trainer, Binghamton University, 4400 Vestal Pkwy E,, Binghamton, NY, 13902, United States, skhamse1@binghamton.edu, Constance Dwyer

Facilitator for express work out initiative to determine ways to improve driving performance in enterprise divisions. Developed SharePoint team site. Supported effort with Jack 7.1 simulation tool model to evaluate statistical significance of vehicle improvements with extended graduate student team resulted in optimized scenarios where the certain vehicle modification resulted in an improved visibility measured by simulation software. Consequently, the study led to proved solutions in order to eliminate preventable accidents.

Building A Luxury Products Evaluation Model

Youn Sung Kim, Professor, Inha University, 253 Yonghyun-Dong, Nam-Gu, Incheon, 402-751, Korea, Republic of, keziah@inha.ac.kr

Considering the market size and history of luxury product, it is very surprising that there is no holistic model to evaluate luxury product market. In this study we try to propose comprehensive perspectives and policy considerations on existing research about the evaluation of luxury products in terms of both product characteristics and value. It has been focused on the brand value. Even though it needs the verification process of proposed evaluation model, this research indicates that it considers the new viewpoint of the evaluation of luxury products. Therefore, the following study will be substantiated based on case study and focused expert group interview.

Strengthening Keystroke Dynamics Based User Authentication Based On User Adaptive Feature Construction For One Class Classification

Junhong Kim, Korea University, Seoul, Korea, Republic of, junhongkim@korea.ac.kr, Haedong Kim, Boseop Kim

This study present a new KDA method based on one-class classification(OCC) with user-adaptive feature construction scheme. Since users have their own typing patterns, the average typing speeds of digraphs are also different between users. Hence, we construct eight features by considering the rank of the typing speed of digraph for four typing speed measures for each user. A total of five OCC is then trained for a valid user is applied to classify a new keystroke data. We collected more than 10,000 keystrokes from 150 participant. Based on the experiment with 25 combinations of training and test keystroke size, the proposed model yielded lower EER than the conventional feature construction method.

Evaluating Information Quality For News Articles Based On Topic Modeling

Hyungseok Kim, Korea University, Anam-dong Seongbuk-gu, Korea University, School of Industrial Management Engineering, Seoul, 163-713, Korea, Republic of, hskim0263@korea.ac.kr, Kim Boseop

We propose two topic model-based information quality evaluation measures for news articles: Relevance and Uniqueness. Relevance of an article is assessed by the weighted sum of the average per-topic posterior probabilities of user-provided keywords and the per-document topic distributions. Uniqueness of an article is assessed by the score of a novelty detection algorithm based on per-document topic distributions. The proposed model is applied to Korean economic news articles and qualitatively verified by domain experts.

Why Firms Disappear: Bankruptcy In The Thoroughbred Horse Industry's Social Network

Angela King, Chapman University CMB: 1406, 1 University Drive, Orange, CA, 92866, United States, amxk96@gmail.com Darcy Fudge Kamal, Cristina Nistor

I look at how social influence in the Thoroughbred Horse Industry network can influence the value for goods at auction. Firms going through a bankruptcy are forced to sell off their goods while the network of social connections is affected by the news of their impending bankruptcy. I analyze whether the network takes into account that these firms will not exist in the future. I use clustering analysis to find network patterns in which account for the differences in network structures related to the node deletion from 2010-2014.

Nondestructive Quality Inspection Using Piezoelectric Transducers Affixed To A Fixture

Tomilayo Komolafe, PhD Candidate, Virginia Polytechnic Institute and State University, 1145 Perry Street, Blacksburg, VA, 24061, United States, tomilayo@vt.edu

Product change detection is of utmost importance in any manufacturing environment and it is one of the major goals in quality control practices. Some changes could be due to a malicious cyber-physical attack which is inherently very difficult to detect by traditional inspection schemes. This study proposes to use piezoelectric transducers (PZT) affixed to a fixture to perform nondestructive quality inspection. Mechanical impedance information is obtained through exciting the PZT bonded to the fixture-part combination and signal processing is used to identify presence of an alteration.

Demand-driven Movie Scheduling In A Multiplex

Julia Charlotte Krake, Research Associate, University of Hamburg - Institute for Operations Research, Von-Melle-Park 5, Hamburg, 20146, Germany, julia.krake@uni-hamburg.de

A cinema chain is confronted with the weekly problem of creating a movie schedule. Decisions need to be taken about the set of movies, the assignment to screens and the start times. The proposed model improves this decision-making process with possible objectives like the increase of total attendance or revenue.

Unittracker: Enhancing Conventional Generation Modeling Resolution In The Regional Energy Deployment System (ReEDS) Model

Venkat Krishnan, Engineer, National Renewable Energy Laboratory, 15013 Denver West Parkway, Golden, CO, 80401, United States, Venkat.Krishnan@nrel.gov, Jonathan Ho, Kelly Eurek

The Regional Energy Deployment System (ReEDS) model is the National Renewable Energy Laboratory's flagship planning model for projecting the long-term build-out and operation of the U.S. electric power generation and transmission system. In this poster, we explore the effects of model resolution on solution quality and tractability. Specifically, for each of 134 load balancing areas in ReEDS, we increase the resolution of conventional plant thermal efficiencies and examine the consequent impacts on the planning results from ReEDS.

Network Simplex Based Algorithm For The Minimum Cost Flow Problem With Linear Interdependencies

Adam Rumpf, Illinois Institute of Technology, 10 West 32nd Street, Room 208, Chicago, IL, 60616, United States, arumpf@hawk.iit.edu

We consider a generalization of the minimum cost network flow problem in which the flows through certain arcs are bounded by linear functions of the flows through other arcs. This formulation can be used to model interdependent infrastructure systems, for example a subway system whose components require delivery of electrical power from a separate system. We characterize the basis of this problem as a spanning forest plus some supplementary structures, and use these to develop an efficient solution algorithm based on the well-known network simplex algorithm. This is joint work with H. Kaul.

Modelling Competitive Equilibrium Prices For Energy And Balancing Capacity In Electricity Markets Involving Non-convexities

Andre Ortner, Researcher, Technical University of Vienna, Gusshausstraße 25-29, Vienna, 1040, Austria, ortner@eeg.tuwien.ac.at, Daniel Huppmann

In economic analyses of markets often the dual variables of market clearing equations derived from the optimal solution of cost-benefit optimization models are interpreted as efficient market prices. Whereas in convex (linear) problems the validity of this approach is undisputed it cannot be generalized to problem formulations containing non-convexities. The withholding of spinning reserves in electricity markets are a good example of such cases as costs in these markets are essentially driven by indivisibilities. In this paper we present a novel modelling approach designed to find equilibria in binary games to derive equilibrium prices of self-committed electricity market models.

Multi-period Matching Under Relaxed Stability

Zihao Li, Georgia Institute of Technology, 765 Ferst Drive, School of ISyE, Atlanta, GA, 30332-0225, United States, zli66@gatech.edu, Özlem Ergun, Julie L Swann

Organizations sometimes face challenges in producing assignments of staff to jobs that are good (in the sense that preferences are met), and stable (which promotes high morale and less turnover in staff). In some situations, assignments have to be made more than once, allowing organizations to be more flexible in making assignments and negotiate with workers more efficiently. We extend the stable matching problem to a multi-period setting and consider stability as measured over all periods. We consider notions of relaxed stability to improve the quality of matching by analyzing stability over the entire horizon of the assignment.

Stochastic Optimal Power Flow With Forecast Errors And Failures In Communication

Basel Alnajjab, Lehigh University, 19 Memorial Drive, West, Bethlehem, PA, 18015, United States, bra212@lehigh.edu, Alberto J Lamadrid, Rick S Blum, Shalinee Kishore, Lawrence V Snyder

The role of communication networks in supporting the operation of power grids will become increasingly more critical as we continue to integrate renewable energy sources into power grids, We present a stochastic optimal power flow formulation in which we account for errors in forecasting future load and renewable generation while also considering random failures in the communication network employed to communicate the realized values of the quantities for which we have forecasts. The communication network is also assumed to be employed for the control of loads and generators in the power system. We present results comparing different topologies for the communication network.

Reducing Response Categories In Multinomial Regression

Brad Price, West Virginia University, College of Business and Economics, PO Box 6025, Morgantown, WV, 26506, United States, brad.price@mail.wvu.edu, Adam Rothman, Charles Geyer

In this work we propose penalized likelihood estimators to reduce the number of response categories in multinomial regression. Typically the multinomial model is made simpler by trying to reduce the number of covariates in the model. We instead approach it by combining response categories in situations where a set of covariates does a poor job of differentiating between these categories. An ADMM algorithm is proposed, and convergence properties presented. Tuning parameter selection is also addressed.

Reliability And Economic Criteria To Determine Management Policies Of Wind Energy Systems With Storage

Cristina M Azcarate, Universidad Publica de Navarra, Dep of Statistics & OR, Campus Arrosadia, Pamplona, Navarra, 31006, Spain, cazcarate@unavarra.es, Fermin Mallor, Pedro Mateo

Electrical energy storage systems integrated into a renewable generation system reduce the effects of forecasting errors and enable the determination of management policies. In this work, we propose a management strategy for a wind energy system with storage capacity that integrates tactical and operational decisions in a single stochastic mathematical model. The mathematical model includes economical and reliability criteria, and an updated probabilistic wind speed forecast. A simulation model inspired on a real wind-hydrogen energy system is built to assess the performance of this strategy.

Electric Transmission Expansion Considering Property Value Reduction On Routing

Juan Andrade, University of Texas at Austin, 4405 Avenue A, Apt 11, Austin, TX, 78751, United States, jandraderam@utexas.edu, Ross Baldick

The development of utility scale renewable generation requires new transmission infrastructure, whose proximity to urban areas produces social opposition. This opposition can be quantified as a social cost produced in property value reduction by transmission proximity to population. It is presented a MILP formulation that minimizes costs for generation, and investment and social impact for transmission considering an electrical and a routing networks. An implementation that uses geographical information was developed, and tested with typical IEEE test systems.

Detection Of Copyrightable Images From Social Media Feeds

Manoj Pooleery, Scopio LLC, 175 Varick St, New York, NY, United States, manoj@scopio.io, Binu Josephi, Jinjin Qin

Finding ``original" images-those that can be potentially protected by copyright laws-from social media channels is a challenging problem. The images may contain objectionable/unusable content (spam) and are often modified by users by addition of text, change of texture and color. This paper presents a framework for detection of original images by first filtering out spam, then identifying presence of user generated text and finally augmenting the decision making process by manual curation & verification. Empirical results obtained from Twitter & Instagram feeds suggest that an automated technique for identification of original images with minimal manual intervention can be developed.

Application Of Data-driven Analytics To Optimal Decisions

Meng-Chen Hsieh, Assistant Professor I, Rider University, 2083 Lawrenceville Rd, SWG 313, Lawrence Township, NJ, 08648, United States, mehsieh@rider.edu, Jeffrey Simonoff, Clifford Hurvich, Avi H Giloni

In operation research and management science problems, a traditional approach in deriving optimal decision rules under uncertainty has been to optimize an univariate target quantity while ignoring the presence of auxiliary variables. These auxiliary variables, if used wisely, can provide valuable information on their association with the target variable and thus substantially reduce the target variable's prediction uncertainty. This work provides guidelines on applying statistical learning to leverage the association between target and auxiliary variables thereby enhancing the efficiency of optimal decisions.

Modeling In-Process Machining Data as Spatial Point Clouds vs. Time Series: Research Challenges and Opportunities

Mohammed Shafae, PhD Candidate, Virginia Tech, Blacksburg, VA, United States, shafae1@vt.edu, Lee Wells, Jaime Camelio

Traditional approaches for analyzing machining process data revolve around representing them as time-series. What tends to be missing is the relationship between the time-series and the part physical dimensions. This research discusses the concept of a novel representation of machining data as spatial point clouds and the corresponding practical advantages.

Using Anom Slicing For Multiway Models With Binomial Or Poisson Data

peter wludyka, CEO, Wludykaandassociates, 4285 Baltic Street, Jacksonville, FL, 32210, United States, pwludyka@unf.edu, John Noguera

Results from "Using ANOM Slicing for Multi-Way Models with Significant Interaction" (Wludyka, JQT 2015) are extended to binomial and Poisson data. Analysis of Means (ANOM) slice charts using an overall estimate for the proportion/rate (which will often have more power than by analysis charts) are presented.

Data-driven Decision Making In The Sharing Economy

Qiaochu He, Assistant Professor, University of North Carolina, Charlotte, 9201 University City Blvd., Univ. North Carolina, Charlotte, NC, 28223, United States, qhe4@uncc.edu
Yun Yang

In this presentation, we propose several new models related to the sharing economy. We investigate this industry from a data-driven perspective, and focus on the following issues: (1) Delayed matching mechanism in a two-sided market; (2) The value of forecasting in matching with uncertainty; (3) Emerging service mechanism in the sharing economy.

Optimization Problems In The Design And Control Of Internet Fulfillment Warehouses

Sevilay Onal, PhD Candidate, New Jersey Institute of Technology, 323 Dr Martin Luther King Jr Blvd, Newark, NJ, 07102, United States, so59@njit.edu, Jingran Zhang, Sanchoy Das

Internet Fulfillment Warehouses (IFWs) are facilities that have been designed and built exclusively to process online retail orders. The nature of e-commerce is described with a high number of transactions in small quantities. Therefore, human controlled systems are being replaced with total digital control. Thus, a revision is required for existing methodology such as adoption of pick and storage policies, resource allocation strategies, warehouse design and control. We aim to introduce the operational and design environment of IFWs and summarize associated emerging optimization problems

Container Port Selection In West Africa A Multicriteria Decision Analysis

Rivelino De Icaza, PhD Candidate, University of Arkansas, 1301 N Prairie Dunes Trail, Apt 305, Fayetteville, AR, 72704, United States, rdeicaza@uark.edu

West Africa gross domestic product is expected to grow to 6.2 percent in 2016 and port capacity will increase by over 12 million TEUs by 2020. Despite the region economic potential and the steady grow of container traffic over the years, port selection decision by shipping lines is complex because the region still has poor shipping infrastructure and political instability that impact transportation security, and consequently the logistics and supply chain services. This research applies a multiattribute value theory (MAVT) with valued-focused thinking (VFT) and an alternative-focused thinking (AFT) methodologies to develop a shipping lines' container port selection decision models.

Dynamic Data-driven Physician Rostering Under Variable Availability

Monique Bakker, City University of Hong Kong, Hong Kong SAR, Hong Kong. mbakker2-c@my.cityu.edu.hk, Kwok L. Tsui

Efficient staff rostering and patient scheduling to meet outpatient demand is a very complex and dynamic task. Medical specialists are typically restricted in sub-specialization, serve several patient groups and are the key resource in a chain of patient appointments at the outpatient clinic, endoscopy unit, and surgical unit. We present a new, data-driven algorithmic approach to automatic allocation of specialists to activities and patient groups. This approach minimizes variability in specialist activity rosters. It outperforms traditional cyclic scheduling with increased patient service level (% patients served in time) and capacity utilization, and decreased patient wait time (days).

How Can Mathematical Modelling Quantify Future Fishing Risks Under Climate Change Scenarios?

Sara Rezaee, Dalhousie University, Halifax, NS, Canada, BC, Canada. sara.rezaee@dal.ca, Ronald P. Pelot, Christian Seiler, Alireza Ghasemi

Studies have shown that extreme weather factors can affect fishing safety significantly. Changes in weather patterns due to climate change effects will add uncertainty to fishing safety systems. This study proposes a framework to quantify fishing incident risks in the future due to changes in weather conditions. The framework builds relationships between fishing incidents and weather conditions based on historical data using mathematical modelling and data mining techniques and then predicts future risks according to these relationships with respect to potential changes in weather patterns.

Evaluation Of Low Carbon Level Of Enterprise Logistics Based On Improved Entropy Law And Cloud Model

Mi Gan, Southwest Jiaotong University, Chengdu, China. migan@swjtu.cn, Xiaofan Guo, Shuai Yang, Lei Wang

To evaluate the low-carbon level of logistics enterprise, we construct corresponding evaluation index system and introduce the concept of centrality in DEMATEL method to improve the entropy method, use data variability to do objective weighting of evaluation index. Then combine with cloud model theory, use reverse cloud generator to convert evaluation data into cloud parameters, and use index approximation method to construct evaluation cloud, reflect and obtain the evaluation results in the form of normal cloud chart, to solve fuzziness and randomness quantification in the evaluation process.

A Simple Classification Framework For Discrimination Of Antipsychotic Treatment Resistant And Treatment Responsive Schizophrenia Patients

Farnaz Zamani Esfahlani, PHD Candidate, SUNY Binghamton, 4400 Vestal Parkway East, Binghamton, NY, 13902-6000, United States, fzamani1@binghamton.edu, Katherine Frost, Gregory Strauss, Hiroki Sayama

Predicting the outcome of different treatment options for patients is essential for effective treatment planning. However, this is a challenging task especially in mental disorders such as schizophrenia where the treatment outcome of patients depends on the complex interaction of various symptoms. In this study, we used analytical tools of network science to study the interaction of the symptoms in schizophrenia and identify symptoms that best discriminate antipsychotic treatment resistant and treatment responsive schizophrenia patients. The features selected based on network analysis provided better classification accuracy when compared to traditional feature selection methods.

Anticipatory Dynamic Traffic Sensor Location Problems with Connected Vehicle Technologies

John (Hyoshin) Park, Research Associate, University of Massachusetts Amherst, 370 Northampton Rd. Apt B, Amherst, MA, 01002, United States, hyoshin0724@gmail.com, Song Gao, Ali Haghani

Despite the potential benefits of sensor technologies, the challenges associated with identifying optimal sensor locations for multiple time stages throughout a day with uncertain demand patterns has received little attention. In this paper, we focus on proactively reducing the network delay by controlling traffic signals through an optimized sensor deployment. The framework is based upon portable sensors that may be repositioned within the day to new locations such that delay savings over multiple time stages will be maximized. To tackle this multi-period stochastic problem, dynamic models are proposed, considering the future sensor locations given budget constraints on the sensor costs and relocation costs. A subproblem decomposed by Lagrangian relaxation enhanced with valid cuts has a better bound and a variable neighborhood search algorithm quickly finds solutions. Two dynamic models that constrain a flexible or restricted relocation present higher savings compared to the stationary model without sensor relocation. The flexible relocation model guarantees higher savings than restricted model by achieving the same maximum savings with fewer number of sensors.

Resilient Offgrid Microgrids – Capacity Planning And N-1 Security

Sreenath Chalil Madathil, Clemson University, 324 Village Walk Ln, Clemson, SC, 29631, United States, schalil@g.clemson.edu
Scott J. Mason, Russell Bent, Harsha Nagarajan, Emre Yamangil, Scott Backhaus, Arthur Barnes, Salman Mashayekh, Michael Stadler

Despite the long distance power transmission capabilities, there are some remote communities in Alaska and Hawaii that are not connected to these systems. These communities rely on small, disconnected microgrids to deliver power. These microgrids are not held to same reliability standards as transmission grids and can place many communities at risk for extended black-outs. To address this issue, we develop an optimization model and algorithm for capacity planning and operations of microgrids that includes N-1 security and other modeling features. The effectiveness of the approach is demonstrated using the IEEE 13 node test feeder and a model of the Nome, Alaska distribution system.

Two-stage Game Theoretic Modeling Of Airline Frequency And Fare Competition

Reed Harder, Dartmouth College, 14 Engineering Drive, Hanover, NH, 03755, United States, reed.haseltine.harder.TH@dartmouth.edu, Vikrant Vaze

We develop a 2-stage game-theoretic model of airline competition, with flight frequency decisions followed by fare decisions. For a simple 2-player model, we show that this game has properties that ensure a tractable and credible equilibrium solution. We then use quadratic approximations of payoffs to extend these results to more realistic scenarios. Finally, we calibrate model parameters on a real-world network and validate out-of-sample predicted frequencies against observed airline behavior.

Identification And Allocation Of Increased-risk Encephalitis Organs

Pinar Keskinocak, Georgia Institute of Technology, School of Indust/System Eng, 765 Ferst Drive, Atlanta, GA, 30332, United States, pinar@isye.gatech.edu, Hannah Smalley, Nishi Anand, Dylan Buczek, Nicholas Buczek, Tim Lin, Tanay Rajore, Muriel Wacker, Brian Gurbaxani, Matthew Kuehnert, Sridhar Basavaraju, Teresa Hammett

We developed decision-support tools to aid organ transplant physicians (and patients) in the identification and allocation of organs that carry the risk of infectious encephalitis. The Infectious Encephalitis Risk Calculator assesses whether a donor (and his/her organs) may have infectious versus non-infectious encephalitis. The Liver Transplant Decision Aid helps patients and physicians evaluate the trade-offs between accepting and rejecting an increased-risk encephalitis liver, thus potentially enabling a better allocation of high-risk organs and reducing deaths on the waitlist. The tool provides wait time estimates for liver transplants based on patient characteristics.

Evaluation Of Google's Voice Recognition And Sentence Classification For Health Care Applications

M. Majbah Uddin, University of South Carolina, 300 Main Street, Civil and Environmental Engineering, Columbia, SC, 29208, United States, muddin@cec.sc.edu, Nathan Huynh, Jose M Vidal, Kevin M Taaffe, Lawrence Fredendall, Joel S Greenstein

This study examined the use of voice recognition (VR) technology in perioperative services (Periop) to enable Periop staff to record workflow milestones using mobile technology. The use of mobile technology to improve patient flow and quality of care could be facilitated if such VR technology could be made robust. The goal of this experiment was to allow the Periop staff to provide care without being interrupted with data entry and querying tasks. This study enhanced Google's VR capability by using post-processing classifiers (i.e., bag-of-sentences, support vector machine, and maximum entropy), which would facilitate its use in health care and other applications.

A Heuristic Algorithm Assigning Optimal Tolls

Vyacheslav V. Kalashnikov, Tecnologico de Monterrey, ITESM, Campus Monterrey, Ave. Eugenio Garza Sada 2501 Sur, Monterrey, 64849, Mexico, kalash@itesm.mx, Nataliya I. Kalashnykova, Arturo García-Martínez

The problem of assigning optimal tolls to the arcs of a multi-commodity transportation network is formulated as a bilevel mathematical program. We describe an algorithm based on the allowable ranges to stay optimal (ARSO) resulting from sensitivity analysis applied to the lower level problem. In this way, one can analyze possible changes in the coefficients of some variables in the objective function within these allowed ranges without affecting the optimal solution. In addition, when stuck to a local maximum solution, the "filled function" technique helps one "jump" to another local maximum (if such does exist) or stop the search. Numerical experiments confirm the robustness of our heuristics.

Developing A Novel Inventory Classification Approach For Large Scale Multi Echelon Inventory Systems

Alireza Sheikhzadeh, University of Arkansas, 4207 Bell Engineering Center, Fayetteville, AR, 72701, United States, asheikhz@uark.edu, Manuel D Rossetti

The purpose of this research is to create a new inventory classification approach for large-scale multi-echelon repairable item provisioning systems. In this research, we develop a new concept for defining the classification criteria which is the artificial stocking policy (ASP). We also propose a new partitioning approach which takes into the account the characteristics of the (aggregated) pseudo-items. The proposed technique is evaluated and compared with complete enumeration and eight alternative clustering and classification methods via 36 different problem instances. The results indicate that the proposed methods significantly outperform the alternative techniques.

The Value Of Aggregation Under Minimax Pricing Scheme In The Electricity Retail Market

Alberto J Lamadrid, Associate Professor, Lehigh University, 621 Taylor Street, R451, Bethlehem, PA, 18015-3120, United States, ajl259@cornell.edu, Kwami Senam Sedzro, Mooi Choo Chuah

We explore both economic and technical benefits of demand responsive load aggregation under a specific retail pricing scheme we call Minimax. It is a 3-rate scheme with a threshold level. Each region is applied a differentiated rate. To assess how adopting Minimax would impact both end-users and distribution system operators (DSO), we model consumers' optimal response to Minimax as an MILP and evaluated the DSO's operating conditions and costs. A case study with different aggregation scenarios implemented on the IEEE 33-bus system reveals that larger aggregate groups achieve lower energy bills and help the DSO lower generation cost and aggregate peak demand, and achieve better voltage profiles.

Designing A Space-efficient Warehouse Layout

Shahab Derhami, PhD Candidate, Auburn University, 3301 Shelby Center, Auburn, AL, 36849, United States, shahab.derhami@hotmail.comJeffrey Smith, Kevin Gue

In this research, we analyze the factors that impact the space utilization in a warehouse. We develop mathematical models to maximize space utilization in the warehouse and depict the trade-off exist between space utilization and transportation cost in the warehouse layout.

Optimizing Decisions In Prenatal Integrated Screening For Down Syndrome

Jia Yan, Georgia Institute of Technology, 710 Peachtree Street NE, Apt 1612, Atlanta, GA, 30308, United States, jyan40@gatech.edu, Turgay Ayer, Pinar Keskinocak, Aaron Caughey

Down syndrome (DS) is a common type of chromosomal abnormality. Currently a one-size-fits-all type of risk-cutoff value of 1/270 is commonly used in DS screening to identify high-risk women and recommend an invasive confirmatory test, such as amniocentesis. In this study, we construct modeling frameworks to determine the optimal cutoffs from two practical perspectives of DS screening: one is the fairness across ages, and the other is the heterogeneity in women's preferences about adverse pregnancy outcomes. We have shown the potential to improve health outcomes and patient satisfaction.

Identification Of Optimal Partition For Semidefinite Optimization

Ali Mohammad Nezhad, PhD Candidate, Lehigh University, 200 West Packer Ave, Bethlehem, PA, 18015, United States, alm413@lehigh.edu, Tamas Terlaky

The concept of optimal partition was originally introduced for linear optimization and linear complementary problems and subsequently extended to semidefinite optimization. In this paper, under no assumption on strict complementarity, we formalize the optimal partition concept for semidefinite optimization. The magnitude of the eigenvalues belonging to each partition is quantified using a condition number and the degree of singularity of the problem.

Wasserstein Distance And The Distributionally Robust Tsp

Mehdi Behroozi, Assistant Professor, Northeastern University, 334 Snell Engineering Center, 360 Huntington Avenue, Boston, MA, 02115, United States, m.behroozi@neu.edu

Recent research on the robust and stochastic Euclidean travelling salesman problem has seen many different approaches for describing the region of uncertainty, such as taking convex combinations of observed demand vectors or imposing constraints on the moments of the spatial demand distribution. In this paper, we consider a distributionally robust version of the Euclidean travelling salesman problem in which we compute the worst-case spatial distribution of demand against all distributions whose Wasserstein distance to an observed demand distribution is bounded from above. This constraint allows us to circumvent common overestimation that arises when other procedures are used.

Reformulating The Disjunctive Cut Generating Linear Program

Thiago Serra, Carnegie Mellon University, 5000 Forbes Ave, Pittsburgh, PA, 15213, United States, tserra@cmu.edu, Egon Balas, Francois Margot

In lift-and-project, CGLP optima may yield dominated cuts due to distortions caused by normalization. This work proposes the Reverse Polar CGLP, a reformulation where normalization defines separability and the resulting cut minimizes the slack for a point in the disjunctive hull. Cuts derived from RP-CGLP optima define supporting hyperplanes of the disjunctive hull, hence never being strongly dominated. For a point in the interior of the disjunctive hull, the cutting plane is a combination of facets separating the fractional solution. We show equivalent CGLP formulations, explain the benefits of RP-CGLP, and present computational experiments where a larger gap can be closed after two rounds.

Acceleration Of A Communication Efficient Distributed Dual Block Descent Algorithm

Chenxin Ma, Lehigh University, 200 West Packer Avenue, Bethlehem, PA, 08801, United States, chm514@lehigh.edu

Distributed optimization algorithms for very large-scale machine learning suffer from communication bottlenecks. Confronting this issue, a communication-efficient primal-dual coordinate ascent framework (CoCoA) and its improved variant CoCoA+ have been proposed, achieving a convergence rate of O(1/t) for solving empirical risk minimization problems with Lipschitz losses. In this paper, we propose an accelerated variant of CoCoA+ and show that it has a rate of O(1/t2) in terms of reducing dual suboptimality. Our analysis is also notable in that our convergence rate bounds involve constants that, except in extreme cases, are significantly reduced.

Primal-dual Interior-point Methods With Domain-driven Barriers

Mehdi Karimi, PhD Student, University of Waterloo, 200 University Avenue West, Department of Combinatorics and Optimization, University of Waterloo, Waterloo, ON, N2L 3G1, Canada, m7karimi@uwaterloo.ca, Levent Tuncel

While primal-dual algorithms have yielded efficient solvers for convex optimization problems in conic form over symmetric cones, many other highly demanded convex optimization problems lack comparable solvers. To close this gap, we develop infeasible-start primal-dual interior-point algorithms for convex optimization problems in “domain-driven” formulation, which we show covers many interesting optimization problems including the conic ones. After presenting our techniques, we introduce our Matlab-based code that solves a large class of problems including LP, SOCP, SDP, QCQP, Geometric programming, and Entropy programming among others, and mention some numerical challenges.

Upward Reward Perturbation For Reinforcement Learning

LATE CANCELLATION

Zhengyuan Zhou, Stanford University, 160 Comstock Circle, Unit 306D2, Stanford, CA, 94305, United States, zyzhou@stanford.edu, Ling Zhu, Benjamin Van Roy, Nicholas Bambos

Applying Case Queries To Network Clusters: Identifying The Intussusception Signal In Rotashield Adverse Event Reports

Matthew Foster, ORISE Fellow, FDA, 10903 New Hampshire Ave, Silver Spring, MD, 20993, United States, matthew.foster@fda.hhs.gov

We constructed a network of Medical Dictionary for Regulatory Activities (MedDRA) Preferred Terms (PTs) from RotaShield adverse event reports and calculated the eigenvector, betweenness, and closeness centrality metrics. We used these metrics to cluster PTs and assessed the sensitivity of clusters using an intussusception (IS) case definition and a variety of Standardized MedDRA Queries. Clustering using eigenvector vs closeness centrality was superior to other combinations, although all identified the IS signal before the July 1999 CDC recommendation for discontinuation. The early detection of this safety signal supports the potential use of our methodology for safety surveillance.

Neighborhood-based Reductions And Cuts For Signed Graphs

Christopher Muir, University of Tennessee - Knoxville, 2044 Wilkerson Road, Knoxville, TN, 37922, United States, cmuir1@vols.utk.edu

This research is concerned with improving solve times for instances of the Balanced Subgraph problem. We discuss various data reduction techniques based on the neighborhoods of vertices and on cut vertices. Additionally, we show that certain structures often present in signed graphs can be exploited to allow for faster solve times. Computational test results are also presented for previously explored problems, including the toll-like problem from the MIPLIB 2010 instance library.

Monday, 1:30PM - 3:00PM

1 - State Space Model For Time-varying Density Estimation

Yanjun Qian, Texas A&M University, College Station, TX, 77840, United States, qianyanjun09@gmail.com, Yu Ding, Jianhua Huang

In both scientific and industrial fields, estimating the time-varying density can provide an important tool for the monitoring or research purpose. In our work, we propose a new method for the time-varying density estimation based on the state space model. Our method can learn the system parameters off-line, and provides an on-line density curve updating from the observed histogram data. By adding a spatial penalty term, we can guarantee the smoothness of the estimated curves and prevent the over-fitting. At last, we show the application of our method on the study of the nanocrystal growth process.

2 - Dynamic Network Modeling Of In-situ Image Profiles For Statistical Process Control – Applications In Ultraprecision Machining And Biomanufacturing Process

Chen Kan, Pennsylvania State University, PSU, University Park, PA, 16802, United States, CJK5654@psu.edu, Hui Yang

Modern industries are investing in advanced imaging technology to increase information visibility, cope with system complexity, and improve the quality and integrity of system operations. Realizing the full potential of advanced imaging technology for process monitoring and control hinges on the development of new SPC methodologies. This paper presents a novel dynamic network methodology for monitoring and control of high-dimensional imaging streams.

3 - Structured Point Cloud Data Modeling Via Regularized Tensor Decomposition And Regression

Hao Yan, Georgia Institute of Technology, yanhao@gatech.edu, Massimo Pacella, Kamran Paynabar

Due to the easy accessibility of the 3D metrology tools such as Coordinate Measuring Machine or scanning tools, structured point cloud data is becoming more and more popular. Therefore, modeling the structured point cloud is an important task in many application domains. We model the structure point cloud as tensor and propose regularized tucker decomposition and regularized tensor regression to detect the variation patterns in the data and link these patterns to the process variables. Furthermore, the performance of the proposed method is evaluated through simulation and a real case study in the point cloud data in the turning process.

4 - Statistical Analysis Of Preferential Orientations Of Two Shapes In Their Aggregate

Ali Esmaieeli, Florida State University, Tallahassee, FL, 32304, United States, ae13e@my.fsu.edu, Chiwoo Park, David Welch, Roland Faller, Taylor Woehl, James Evans, Nigel Browning

Nanoscientists believe that adjacent nanoparticles aggregate with each other in specific preferential directions. This phenomenon is known as oriented attachment and can be studied by direct observations using dynamic electron microscopy. These studies relied on manual and qualitative analysis up to now; therefore, in this research we are proposing a statistical approach to study the oriented attachment believing that certain geometries have specific preferential orientation when they aggregate. We use multiple aggregation examples collected from dynamic microscope data in order to examine the performance of our approach.

Sponsored Session

Chair: Michael Lash, University of Iowa, S210 John Pappajohn Business Building, Iowa City, IA, 52242-1000, United States, michael-lash@uiowa.edu

1 - Multi-site Evidence-based Best Practice Discovery – Finding Factors That Influence Treatment Outcome

Eva Lee, Georgia Tech, evakylee@isye.gatech.edu
Cody Wang

This work is joint with Care Coordination Institute. The work focuses on establishing inter-operability among electronic-medical-records(EMRs) from 737 providers for large-scale data mining to identify discriminatory characteristics that can predict the quality of treatment outcome. We demonstrate the system usability by analyzing Type II diabetic patients. DAMIP establishes a classification rule on a training set that results in greater than 80% predictive accuracy on a blind set of patients. This facilitates evidence-based treatment and optimization of site performance through best practice dissemination and knowledge transfer.

2 - Scalable Support Vector Machines For Massive Healthcare Datasets

Talayeh Razzaghi, Clemson University, trazzag@g.clemson.edu

Solving the optimization model of support vector machines is often an expensive computational task for massive healthcare training sets. We propose an efficient, effective, multilevel algorithmic framework that scales to very large data sets. Our multilevel framework substantially improves the computational time without loosing the quality of classifiers for balanced and imbalanced datasets.

3 - Exploring Feasibility To Early Detect Alzheimer's Disease (AD) And Dementia Progression Using Big Data + Machine Learning Approach

Chih-Lin Chi, University of Minnesota, Minneapolis, MN, United States, cchi@umn.edu, Wenjun Zeng, Wonsuk Oh, Soo Borson

We aim to develop a 3-step data strategy to develop a model to predict long-term cognitive changes for AD. We show results from the first step: exploring feasibility of long-term prediction by optimizing time-varying risk factors. The developed model predicts cognitive scores and annual changes in up to 8 years when most subjects were cognitive normal or mild cognitive impairment. This model demonstrates accurate prediction of how dementia progress for cognitive stable, mild deterioration, moderate deterioration, and sharp deterioration subgroups. The presentation will also discuss the next steps that aim at converting the data-research results into informatics tools.

Health Care, Modeling I

Contributed Session

Chair: Sina Faridimehr, PhD Student, Wayne State University, 4815 Fourth Street, Detroit, MI, 48202, United States, sina.faridimehr@wayne.edu

1 - Measure And Predict Medication Adherence Behavior Using Administrative Data

Shan Xie, Purdue University, 315 N Grant Street, W Lafayette, IN, 47907, United States, xie34@purdue.edu, Yuehwern Yih

For patients with diabetes, poor adherence to medication has been associated with suboptimal glycemic control, increased health care costs and adverse health outcomes. Thus, improving medication adherence is important to realize the full benefit of medication therapies. The existing measures of medication adherence based on administrative data only provide an aggregate number, which lack the ability to distinguish between different adherence behaviors. This study will develop an analytic framework to quantify and predict medication adherence patterns, and provide useful information to efficiently target patients at high risk and customize adherence improvement interventions.

2 - Improving Access To Healthcare By Minimizing Appointment Delays

Ashley N. Anhalt, PhD Student, University of Pittsburgh, 525 S. Aiken Avenue, APT #3, Pittsburgh, PA, 15232, United States, ana88@pitt.edu, Jeffrey P. Kharoufeh

Providing patients with timely access to healthcare is an important issue for major healthcare providers. One major problem is that patients are often unable to schedule appointments with specialists in a reasonable time. We present queueing models and decision tools to find effective appointment scheduling strategies with the objective of maximizing the likelihood that a majority of patients can be seen within a time threshold.

3 - Managing Access To Primary Care Through Advanced Scheduling

Sina Faridimehr, PhD Student, Wayne State University, 4815 Fourth Street, Detroit, MI, 48202, United States, sina.faridimehr@wayne.edu, Ratna Babu Chinnam, Saravanan Venkatachalam

In this research, we develop a scheduling framework that employs stochastic programming to improve access to care within primary care clinics. The model leverages correlations between scheduling practice, continuity of care, appointment utilization and access performance. Results from testing the models at VA facilities are promising.

Optimal Procurement, Tariff, and Cybersecurity in Smart Grid

Sponsored: Energy, Natural Res & the Environment, Energy I Electricity

Sponsored Session

Chair: Lawrence V Snyder, Lehigh University, 200 West Packer Avenue, Bethlehem, PA, 18015, United States, lvs2@lehigh.edu

1 - Optimal Day-ahead Power Procurement With Renewable Energy, Storage, And Demand Response

Soongeol Kwon, Texas A&M University, College Station, TX, United States, soongeol@tamu.edu, Natarajan Gautam, Lewis Ntaimo

Motivation of this research stems from pressing issues related to reducing energy cost, specifically focused on demand-side. From energy consumers perspective, there exist opportunities to reduce energy cost by adjusting purchase and consumption of energy in responding to time-varying electricity prices while utilizing renewable energy with energy storage. Considering this scenario, the main research objective is to develop a decision model to determine optimal day-ahead purchase commitment while considering real-time adjustments in response to variability and uncertainty in actual power demand, renewable supply, and electricity price.

2 - A Game Theoretic Analysis Of Electricity Time-of-use (TOU) Tariff For Residential Customers

Dong Gu Choi, Pohang University of Science and Technology, Pohang, Korea, Republic of, dgchoi@postech.ac.kr, Valerie Thomas

We properly formulate a game-theoretic model for analyzing not only the optimal behaviors of both an electric utility and residential customers but also their monetary gains or losses under a TOU tariff. With two heterogeneous customer types in terms of consumption pattern, we identify that a win-win situation is not possible. Also, we emphasize our analytic results by describing a numerical example, and we discuss the implications of our results for electric utilities and regulatory agencies.

3 - Risk Assessment And Network Optimization For Smart Grid Cybersecurity

Lawrence V Snyder, Lehigh University, lvs2@lehigh.edu, Jiyun Yao, Parv Venkitasubramaniam, Shalinee Kishore, Rick Blum

Mesh communication networks are widely used to facilitate communication to and between smart grid sensors such as advanced meters and demand response devices. Despite this wide use, a comprehensive risk assessment of cyber attacks on distributed networks has not been fully explored. In this work, we propose a framework for connectivity analysis of smart grid sensor networks to ensure robust communication when a given number of communication nodes are compromised. We also propose an efficient algorithm to construct a graph to meet given connectivity criteria by augmentation of communication links or strong authentication on certain nodes.

4 - Electricity Market Clearing With Enhanced Dispatch Of Wind Producers: Market Design And Environmental Implications

Ali Daraeepour, Duke University, Durham, NC, 27708, United States, a.daraeepour@duke.edu, Dalia Patino-Echeverri

This study explores the market design, operational, and environmental effects of the stochastic electricity market clearing. We propose a framework that allows a robust assessment of the relative advantages of the stochastic market clearing with respect to the conventional deterministic mechanism under wind production uncertainty. Using a stylized version of PJM, the two mechanisms are compared in terms of air emissions, wind integration, prices and supply-side revenue adequacy, and out-of-market adjustments.

Text Analytics for Quality Management

Sponsored: Data Mining

Sponsored Session

Chair: Alan Abrahams, Virginia Tech, Pamplin 1007, Blacksburg, VA, 24061, United States, abra@vt.edu

1 - Human Intelligence In Keyword Query Formulation: Comparing The Recall Performance Of Computer- And Human-generated Smoke Word Lists

Richard Gruss, Pamplin College of Business, Virginia Tech, Blacksburg, VA, United States, rgruss@vt.edu
Alan Abrahams, Siriporn Srisawas

Are humans better at producing safety concern keyword searches than computers? 72 subjects annotated 263 reviews of over-the-counter medicines, half of which contained known safety concerns. Subjects then compiled a list of words and phrases that might be effective filter terms in finding reviews with safety concerns. Subjects then collaborated in groups of 2, 3 or 4 to assemble a group list. Lists were scored on how many of the known safety concerns they were able to recall in a separate test set. Preliminary results indicate that human-generated lists frequently outperform computer-generated lists.

2 - Let'S Not Get Too Sentimental: A Critical Analysis Of Sentiment Analysis For Quality Surveillance

Nohel Zaman, Virginia Tech, Blacksburg, VA, 24060, United States, znohel@vt.edu, Alan Abrahams, Richard James Gruss, Siriporn Srisawas

Our study will be beneficial for quality management (QM) professionals analyzing unstructured user-generated-content in social media. The goal is to determine whether and to what extent negative sentiment and defect existence are associated, in different products across multiple industries. With product defects being expensive, this paper could help manufacturers more rapidly discover defects. This paper aims to assess which sentiment and non-sentiment scoring methods are most effective at finding product defects in each industry, and which methods generalize well across industries.

3 - Online Reviews To Revenue: Contributory Factors And Moderating Effects In The Airline Industry

Zachary Davis, Virginia Tech, zached1@vt.edu
Alan S. Abrahams, Lara Z Khansa

In this study, online reviews of airlines are examined with respect to company revenue. Though previous studies have examined online reviews' effect on product sales, the relationship has not been elicited in service industries, including the airline industry. Using passengers' reviews of the 7 airline groups with the highest revenue we consider the impact of these reviews on the quarterly revenue of each of these companies. Compared with other major industries, the airline industry has the highest defect rate in their online reviews. Our findings suggest that online reviews do have an impact on company revenue, however this impact is dampened by offline maneuvers.

4 - Identifying Product Defects From User Complaints: A Probabilistic Defect Model

Alan Wang, Associate Professor, Virginia Tech, 2070 Pamplin Hall, Virginia Tech, Blacksburg, VA, 24060, United States, alanwang@vt.edu, Xuan Zhang, Zhilei Qiao, Weiguo Fan, Edward A Fox

Discovering potential product defects from large amounts of user complaints is a challenging task. In this research, we develop a probabilistic defect model (PDM) that identifies the most critical product issues and corresponding product attributes (e.g., product model-year, defective components, symptoms, etc.), simultaneously. We conduct comprehensive evaluations to ensure the quality of discovered information. Our research has significant managerial implications for managers, manufacturers, and policy makers.

Data Analytics in Renewable Energy

Sponsored: Data Mining

Sponsored Session

Chair: Zijun Zhang, City University of Hong Kong, 83 Tat Chee Avenue, Kowloon Tong, Hong Kong, zijzhang@cityu.edu.hk

1 - Exploratory Data Analytics For Temporal Lighting Energy Usage In Commercial Buildings

Mingyang Li, University of South Florida, Tampa, FL, United States, mingyangli@usf.edu, Kara C Heuer, Dina Villalba-Sanchez, Zhe Song

Lighting energy usage accounts for a major proportion of building energy consumption. A better understanding of lighting energy data will facilitate building energy management. Conventional studies mainly focused on aggregate-level energy usage, ignoring the temporal usage patterns featured in stochasticity, nonlinearity and intermittency. In this study, an exploratory data analytics approach is proposed to extract, cluster and visualize temporal patterns of lighting energy usage in commercial buildings. A real data study is further provided to illustrate the proposed work and demonstrate its validity.

2 - Characterization Of Air Traffic Network Using Ads-b Data

Lishuai Li, City University of Hong Kong, P6606, AC1, Tat Chee Avenue, Kowloon, Hong Kong, lishuai.li@cityu.edu.hk
Pan Ren

Airspace capacity has been credited as a major factor for air traffic congestion and flight delays. However, few studies provided measures of airspace capacity and efficiency for a large air traffic network. This research aims at evaluating whether airspace capacity is a significant factor in relation to recent air traffic delays in China. We developed a novel method to characterize flow patterns in the airspace and construct an air traffic network using cluster analysis on historical flight trajectories. Findings will be useful in evaluating the efficiency and robustness of an air traffic network in relation to its actual operation and management.

3 - Image-based Wind Turbine Blade Surface Crack Detection And Analysis

Zijun Zhang, City University of Hong Kong, zijzhang@cityu.edu.hk
Long Wang

A data-driven framework for automatically detecting wind turbine (WT) blade surface cracks based on images taken by unmanned aerial vehicles (UAVs) is proposed in this paper. Haar-like features are applied to depict crack regions and train a cascading classifier. The computational results demonstrate that the proposed framework can successfully provide the number of cracks and locate them in original images.

Innovation in Product and Service Development

Invited: Business Model Innovation

Invited Session

Chair: Morvarid Rahmani, Georgia Institute of Technology, Atlanta, GA, United States, morvarid.rahmani@scheller.gatech.edu

1 - An Economic Analysis Of Customer Codesign

Sreekumar R Bhaskaran, Southern Methodist University, sbhaskar@mail.cox.smu.edu, Amit Basu

A key barrier to companies successfully engaging customers in the design of new products is customers fearing that they will be forced to pay much more for the custom products they help design. We show how a firm can motivate its customers to engage in co-design through its product line choices. The effect of market and firm characteristics on the value of engaging customers in the co-design process is also examined. In addition, we analyze the effects of (a) information asymmetry about the firm's co-design capability, and (b) competition, on the firm's decisions regarding co-design.

2 - Allocating Customer Control In Service Processes

Ioannis Bellos, George Mason University, ibellos@gmu.edu, Stylianos Kavadias

In most services customers actively participate in the service deliver process. In practice we observe services that require varying degrees of customer involvement. Motivated by this, we develop an analytical model to determine which parts of a service process should be performed by the service provider and which parts should be delegated to the customers.

3 - Sourcing Innovation: Private And Public Feedback In Contests

Jurgen Mihm, Insead, Fontainebleau, France, jurgen.mihm@insead.edu, Jochen Schlapp

Contests, in which contestants compete for a prize offered by a contest holder, have become a popular way to source innovation. Despite great interest from the academic community, many important managerial aspects of contests have received very little formal inquiry. The most important of these is feedback from the contest holder to the contestants while the contest unfolds. This paper sets out to establish a comprehensive understanding of how to give feedback in a contest by answering the questions of when to give feedback and when not to give feedback and which type of feedback to give, public (which all solvers can observe) or private (which only the concerned party can observe).

4 - Balancing Diagnostic And Resolution Efforts In A Nonprofit Service Delivery Organization

Priyank Arora, Georgia Institute of Technology, 800 W Peachtree St NW, Atlanta, GA, 30308, United States, Priyank.Arora@scheller.gatech.edu, Morvarid Rahmani, Karthik Ramachandran

This paper studies service design of a nonprofit organization (NPO) that aims to maximize overall utility delivered to its clients. We examine how the NPO should balance levels of effort between diagnostic and resolution stages of its service delivery, in the presence of client heterogeneity and resource constraint. Our analytical model is based on secondary data collected from an NPO working towards empowerment of victims of domestic violence.

Nonlinear Optimization Problems for Power Systems

Invited: Energy Systems Management

Invited Session

Chair: Javad Lavaei, University of California, Berkeley, 4121 Etcheverry, Berkeley, CA, 94720, United States, lavaei@berkeley.edu

1 - Power System State Estimation With A Limited Number Of Measurements

Ramtin Madani, University of California, Berkeley, Berkeley, CA, United States, ramtin.madani@berkeley.edu, Javad Lavaei, Ross Baldick

This work is concerned with the power system state estimation (PSSE) problem, which aims to find the unknown operating point of a power network based on a given set of measurements. We develop a set of convex programs with the property that they all solve the non-convex PSSE problem in the case of noiseless measurements if the voltage angles are relatively small. This result is then extended to a general PSSE problem with noisy measurements, and an upper bound on the estimation error is derived. The objective function of each convex program has two terms to account for the non-convexity of the power flow equations and estimate the noise levels. The proposed technique is demonstrated on a 9000-bus network.

2 - Stochastic Unit Commitment With Topology Control Recourse For Renewables Integration

Jiaying Shi, University of California, Berkeley, Berkeley, CA, 94720, United States, shijy07@berkeley.edu, Shmuel S Oren

We propose a two-stage stochastic unit commitment formulation with topology control recourse decisions for power systems with renewables integration. We investigate applying progressive hedging algorithm to solve this problem. Preliminary test results on both IEEE 118 system and central European system show that such capability of controlling the system configuration actively through switching transmission lines can help improve the efficiency of unit commitment.

3 - A Strong Semidefinite Programming Relaxation Of The Unit Commitment Problem

Javad Lavaei, University of California-Berkeley, Berkeley, CA, United States, lavaei@berkeley.edu, Morteza Ashraphijuo, Salar Fattahi, Alper Atamturk

The unit commitment (UC) problem aims to find an optimal schedule of generating units subject to the demand and operating constraints for an electricity grid. We develop a strengthened semidefinite program (SDP) based on first deriving certain valid quadratic constraints and then relaxing them to linear matrix inequalities. These valid inequalities are obtained by the multiplication of the linear constraints of the UC problem. The performance of the proposed convex relaxation is evaluated on several hard instances of the UC problem. By solving a single convex problem, globally optimal integer solutions are obtained in most of the experiments that we have conducted.

4 - Optimal Distributed Control Of Power Systems

Salar Fattahi, University of California, Berkeley, Berkeley, CA, United States, fattahi@berkeley.edu, Abdulrahman Kalbat, Javad Lavaei

This talk is concerned with the optimal distributed control of power systems under input disturbance and measurement noise. This optimal control problem is highly nonlinear and NP-hard. In this work, we design an efficient computational method that transforms the optimal centralized controller to a near-optimal distributed controller. We also study how the connectivity of its underlying communication network affects the optimal performance of the stochastic power system under control. As a case study, the proposed technique is used to design a distributed primary frequency controller for the IEEE 39-Bus New England test System.

Food, Energy, Water and Extreme Events

Sponsored: Energy, Natural Res & the Environment, Energy II Other

Sponsored Session

Chair: Sauleh Ahmad Siddiqui, Johns Hopkins University, 3400 N. Charles St., Latrobe Hall 205, Baltimore, MD, 21218, United States, siddiqui@jhu.edu

Co-Chair: Craig Bakkar, Johns Hopkins University, 3400 N. Charles St., Baltimore, MD, 21218, United States, cbakker2@jhu.edu

1 - Mixed Complementarity Modelling In Food Systems

Sauleh Ahmad Siddiqui, Johns Hopkins University, 3400 N. Charles St., Latrobe Hall 205, Baltimore, MD, 21218, United States, siddiqui@jhu.edu, Craig Bakkar

We are developing a new food systems model investigate the impacts of climate change. This model is designed to build upon past climate-food research by modelling the entire food supply chain, connecting more fully with energy and water sector models, and capturing shock propagation. Our model uses a microeconomic Mixed Complementarity Problem (MCP) formulation and a new MCP decomposition method that both reduces wall clock time to solution and increases the size of solvable problems.

2 - Post-disaster Distribution Systems Restoration

Yushi Tan, University of Washington, 185 Stevens Way, Seattle, WA, 98195, United States, ystan@uw.edu, Feng Qiu

We investigate the problem of repairing a distribution network after a natural disaster. Such a post-disaster restoration is identified as an NP-hard variant of a job scheduling problem, in which crew are dispatched to repair the damaged lines in a way that minimizes the total harm caused by the outages. We implement a time-indexed ILP formulation with valid inequalities as a benchmark. Two practical methods are also proposed to solve the problem: a conversion algorithm and a linear-relaxation-based list scheduling algorithm. Worst case bounds are analyzed for both algorithms. Numerical results validate the effectiveness of the proposed methods.

3 - Nonlinear Optimization Of Water Supply Network Pumping Plans In A Deregulated Electricity Market

Maxime Fender, Optimization Consultant, Artelys, 2001 Boulevard Robert-Bourassa, Suite 1700, Montreal, QC, H3A 2A6, Canada, maxime.fender@artelys.com

Within the context of deregulated electricity markets, electro-intensive companies are encouraged to optimize their electricity consumption patterns. This talk presents a study led by Artelys showing how a water distribution network operator, facing varying electricity wholesale market prices, can minimize its water pumping costs. This MINLP (nonlinear pressure loss constraints in pipes / OnOff pumps binary variables) has been solved using an iterative process composed of a linear relaxation and a continuous nonlinear optimization solved respectively by FICO Xpress-Optimizer and Artelys Knitro.

1 - Critical Arcs Detection In Influence Networks

Colin P. Gillen, University of Pittsburgh, Pittsburgh, PA, 15261, United States, cpg12@pitt.edu, Alexander Veremyev, Oleg A Prokopyev, Eduardo Pasiliao

The influence maximization (MAXINF) problem chooses an optimal set of seed nodes to maximize the propagation of influence (cascading behavior) in a network. Given a set of seed nodes and the linear threshold model, our work proposes to determine which edges - e.g. relationships in a social network - are most critical to the influence propagation process. NP-completeness of the problem is proved. Naïve time-dependent and time-independent mixed-integer programming (MIP) models are stated. An improved MIP-based exact algorithm and a heuristic are proposed, and computational results presented.

2 - Randomized Network Inspection For Security Against Link Disruption Attacks

Mathieu Dahan, Massachusetts Institute of Technology, Cambridge, MA, United States, mdahan@mit.edu, Polina Sela Perelman, Saurabh Amin

We consider a network inspection game, in which a defender collects state measurements at few nodes of the network to detect simultaneous link disruptions by an attacker. The defender's objective is to maximize the detection score and the attacker's objective is to maximize the missed detection rate. Both players face budget constraints. We study the mixed Nash equilibria of this game in terms of the defender's inspection capabilities and the network structure. We characterize the player strategies using a generalization of the minimum vertex cover and the maximum matching of the network.

3 - A Stochastic Programming Unified Framework For Travel Demand Estimation Problems With Multiple Observation Sets

Yudi Yang, University of California, Davis, Davis, CA, United States, ydyang@ucdavis.edu, Yueyue Fan, Roger J-B Wets

This paper proposes a unied framework of modeling Origin-Destination (O-D) demand estimation problems in transportation networks using multiple observation sets. Unlike traditional approaches that aim at either parameter estimation or reconstruction, our approach employs a hierarchical structure to integrate both problems. This proposed framework has a great flexibility to incorporate various data input and domain knowledge.

1 - New Certificates For Nonnegativity Via Circuit Polynomials And Geometric Programming

Timo de Wolff, Texas A&M University, dewolff@math.tamu.edu

Deciding nonnegativity of real polynomials is a fundamental problem in polynomial optimization. In practice, one uses semidefinite programming (SDP), which is based on sums of squares (SOS) certificates, the standard certificates since the 19th century.

We introduce an entirely new class of nonnegativity certificate based on circuit polynomials, which are independent of SOS. Similar as SOS correspond to SDP our certificates correspond to geometric programming (GP). Our certificates yield GPs which compute lower bounds both for unconstrained and constrained polynomial optimization problems efficiently. Our approach is significantly faster and often provides better bounds than SDPs.

2 - Analysis Of Strength Of Convex Relaxations Of Monomials

Akshay Gupte, Clemson University, Clemson, SC, 29634, United States, agupte@clemson.edu, Warren P Adams, Yibo Xu

Convexifying each monomial in a polynomial optimization problem yields a lower bound on the global optimum. The quality of this lower bound and the additive error on the global optimum can be quantified by analyzing the approximation error produced by the closure convex hull of each monomial. For any monomial whose domain is a subset of [0,1]^n, we give degree-dependent upper bounds on this approximation error. Special structures of the domain for which our bounds are tight are also analyzed. For a multilinear monomial, we refine this bound for the [1,r]^n case and also give a formula for the [-1,1]^n case.

3 - Optimal Power Flow Problem

Santanu Dey, Georgia Institute of Technology, santanu.dey@isye.gatech.edu

The AC optimal power flow (OPF) problem is a key polynomial optimization problem in the area of electrical power systems operations. We present a few families of cutting-planes to strengthen the standard SOCP relaxation of this problem. Extensive computational experiments show that these relaxations have numerous advantages over existing convex relaxations.

1 - Coordination Between Constraint Filtering Techniques And Reduced RLT Representations In RLT-POS

Evrim Dalkiran, Wayne State University, evrimd@wayne.edu Hanif D. Sherali

RLT-POS is a Reformulation-Linearization Technique (RLT)-based open-source optimization software for solving polynomial optimization problems. RLT-POS theoretically filters standard bound-factor constraints to obtain tractable relaxations. Using linear equality subsystem, RLT-POS generates reduced sized LP relaxations. In this talk, we discuss the coordination between constraint filtering techniques and reduced RLT representations for sparse polynomial programming problems.

2 - A Global Optimization Algorithm For Routing Heterogeneous Jobs To Heterogeneous Servers

Vahid Nourbakhsh, PhD Candidate, University of California - Irvine, Irvine, CA, 92617, United States, vahidn@uci.edu, John G Turner

The problem of routing heterogeneous jobs to heterogeneous servers with job-server dependent service rates arises in different applications. We formulate the problem as a math problem which allows us to use the general framework of math programming to embed the problem into planning problems. For the objective functions of maximizing service level and minimizing average waiting time, the problem is non-convex. We develop an optimization algorithm called fixed-ratio shifting envelopes (FSE) to find the global optimal solution and compare its performance against the global solver BARON.

3 - Tuning Baron Using Derivative-free Optimization Algorithms

Nikolaos Ploskas, Carnegie Mellon University, Pittsburgh, PA, United States, nploskas@andrew.cmu.edu, Jianfeng Liu, Nikolaos Sahinidis

Optimization solvers include many options that allow users to control different aspects of them. All previous proposed methods for tuning optimization solvers options have focused on MILP and local NLP solvers. A total of 27 derivative-free optimization algorithms are used on a set of 126 benchmark problems to find the optimal values for the options of the global optimization solver BARON. Detailed computational results will be presented.

4 - Recent Advances In Baron

Mustafa Kilinc, Carnegie Mellon University, Pittsburgh, PA, United States, mkilinc@cmu.edu, Nikolaos Sahinidis

In this talk, we provide a brief account of key software engineering and algorithmic developments in BARON and discuss recent advances that result in dynamic solution strategies aimed to provide tight relaxations for solving difficult problems, and present extensive computational results on a collection of benchmarks.

Emerging Applications of Optimization in Industry

Sponsored: Analytics

Sponsored Session

Chair: Juan Ma, Turner Broadcasting Systems, 1050 Techwood Drive NW, Atlanta, GA, 30318, United States, juan.ma@turner.com

1 - Scheduling Television Programs Optimally

Juan Ma, Turner Broadcasting System, Inc., Atlanta, GA, 30318, United States, juan.ma@turner.com, Jose Antonio Carbajal Orozco, Peter Williams, Wassim (Wes) Chaar

Deciding a television program schedule that generates the highest viewer ratings is critical and challenging for professionals in the media industry. In this study, we developed a novel analytical model for optimal television program scheduling. Our model combines program rating predictions during different time slots of a scheduling window with a shortest path problem under resource constraints. Solution techniques and preliminary experiment results will also be discussed.

2 - Scheduling Commercial Spots Using Mixed Integer Programming

Vivek Vasudeva, Turner Broadcasting System, Inc., Atlanta, GA, United States, vivek.vasudeva@turner.com, Jose Antonio Carbajal Orozco, Wassim (Wes) Chaar

A broadcasting company sells airtime to advertisers to air their commercial spots in accordance with certain agreed-upon rules. We examine a mixed integer programming-based formulation that can be used to schedule spots such that a desired measure can be optimized while honoring the deal rules. We also analyze how the measure changes as we relax different sets of constraints, to gain insights into the relative impact of these constraints on the optimization measure.

Disaster and Emergency Management I

Contributed Session

1 - Apropos Resilient System Design

Henry Lester, University of South Alabama, P.O. Box 8172, Mobile, AL, 36689, United States, hlester@southalabama.edu

System resiliency signifies the ability to resist and recover from an extreme event. Critical measures of this resiliency are extreme event damages and disaster recovery time. This paper presents an analytical approach to capturing extreme event system behaviors with respect to system resiliency in order to predict disaster recovery time. The approach isolates significant system factors to estimate recovery function parameters to enhance a resilient system design. The resultant resilient system design can provide situational awareness for future decision analysis pertaining system deployment and operations while subject to extreme events.

2 - A Follow-Up Sharing Method For Post-Event Response Resource Distribution With Group Information Updates

Yong Ye, Wenzhou Medical University, Chashan Street, Ouhai District, Wenzhou, 325035, China, yong_ye@foxmail.com, Guiling Liu, Lingle Pan

This paper addresses a Follow-up Sharing Character (FSC), which coordinates resources between different phases. Based on FSC, this paper proposes a general model by minimizing the RAEL (the losses caused by the mismatch between supply and demand in impacted areas) of all phases, the RAEL of all affected areas in the present phase, and the ELTL of the distribution plan in the present phase. We also apply the Bayesian information updates approach to deal with uncertainties of demand and traffic condition, by using historical and sample information. Then, a solution algorithm is proposed to solve the model; and a simulation study is presented. Insights derived from the model are provided in the conclusion.

1 - Machine Learning & Portfolio Optimization

Gah-Yi Ban, London Business School, gban@london.edu, Noureddine El Karoui, Andrew Lim

We adapt two machine learning methods, regularization and cross-validation, for portfolio optimization. First, we introduce performance-based regularization (PBR), where the idea is to constrain the sample variances of the estimated portfolio risk and return. We consider PBR for both mean-variance and mean-CVaR problems. We show that the PBR models can be cast as robust optimization problems with novel uncertainty sets and establish asymptotic optimality of both Sample Average Approximation (SAA) and PBR solutions and the corresponding efficient frontiers. We also develop new, performance-based k-fold cross-validation algorithms.

2 - Smart Predict Then Optimize

Paul Grigas, UC Berkeley, 4177 Etcheverry Hall, University of California, Berkeley, CA, 94720-1777, United States, pgrigas@berkeley.edu, Adam Elmachtoub

We consider a class of optimization problems where the objective function is not explicitly provided, but contextual information can be used to predict the objective based on historical data. A traditional approach would be to simply predict the objective based on minimizing prediction error, and then solve the corresponding optimization problem. Instead, we propose a prediction framework that leverages the structure of the optimization problem that will be solved given the prediction. We provide theoretical, algorithmic, and computational results to show the validity and practicality of our framework.

3 - Distribution Sensitivities For Quantile, Distortion Risk Measure, And Inference

Yijie Peng, Fudan University, pengy10@fudan.edu.cn Michael Fu

We treat quantile sensitivity, sensitivity of distortion risk measure, and statistical inference under a single umbrella of distribution sensitivities. A new stochastic derivative estimation technique called generalized likelihood ratio method is proposed to address three applications in a uniform manner. We illustrate advantages of the proposed method over existing stochastic derivative estimation techniques for distribution sensitivities estimation, and provide supporting numerical evidences.

4 - Small Data Optimization

Vishal Gupta, University of Southern California, guptavis@usc.edu, Paat Rusmevichientong

Notwithstanding press about “Big Data,” many real-world problems exhibit both a large number of uncertain parameters and a small amount of data per parameter. We propose a novel approach to linear optimization in this “small-data regime” inspired by empirical Bayes methods. Our approach uses the large-scale structure to circumvent the insufficient data; as the size of the optimization tends to infinity while the amount of data remains fixed, our approach performs comparably to an oracle best-in-class policy. Other popular methods do NOT enjoy this property. Empirical evidence confirms that our approach significantly outperforms state-of-the-art data-driven methods in this small-data regime.

Sponsored Session

Chair: Anirudh Subramanyam, Carnegie Mellon University, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, asubramanyam@cmu.edu

1 - Exploiting The Structure Of Two-stage Robust Optimization Models With Integer Adversarial Variables

Seyed Hossein Hashemi Doulabi, Polytechnique Montréal, Montreal, QC, Canada, hashemi.doulabi@polymtl.ca Patrick Jaillet, Gilles Pesant, Louis-Martin Rousseau

This paper addresses a class of two-stage robust optimization models with integer variables in the adversary’s problem. We apply Dantzig-Wolfe decomposition to exploit the structure of these models and show that the original problem reduces to a single-stage robust problem. We propose a Benders algorithm for the reformulated problem. Since the master problem and subproblem in the Benders algorithm are mixed integer programs it is computationally burdensome to optimally solve them in each iteration of the algorithm. Therefore, we develop novel stopping conditions for these mixed integer. Some computational experiments are performed on a two-stage nurse planning problem.

2 - A New Algorithmic Framework For Two-stage K-adaptable Robust Optimization Problems With Mixed-integer Recourse

Anirudh Subramanyam, Carnegie Mellon University, Pittsburgh, PA, 15213, United States, asubramanyam@cmu.edu Wolfram Wiesemann, Chrysanthos Gounaris

We present a new algorithm for solving K-adaptability versions of two-stage robust mixed-integer linear programs (MILPs), in which we commit to K recourse policies here-and-now and implement the best policy once the uncertain parameters are observed. Viewing such problems as semi-infinite disjunctive MILPs, our framework is able to address mixed-integer and random recourse in K-adaptability problems for the first time. It is also able to incorporate tailored solution approaches for the corresponding deterministic problems and decomposition techniques widely used in stochastic programming. We conduct extensive numerical experiments on benchmark data from a number of popular applications.

3 - Weekly Two Stage Robust Generation Scheduling For Hydrothermal Power Systems

Hossein Dashti, University of Arizona, hdashti@email.arizona.edu, Antonio J. Conejo, Ruiwei Jiang, Jianhui Wang

As compared to short-term forecasting, it is challenging to accurately forecast the volume of precipitation in a medium-term horizon. As a result, fluctuations in water inflow can trigger generation shortage and electricity price spikes in a power system with major hydro resources. In this work, we study a two-stage robust scheduling approach for a hydrothermal power system. We consider water inflow uncertainty and employ a vector autoregressive (VAR) model to represent its seasonality and construct an uncertainty set in the robust optimization approach. We design a Benders’ decomposition algorithm to solve the problem. Results are presented for the proposed approach on a real-world case study.

1 - An Algorithm To Exploit Diversification And Exploration For Solving Mixed-integer Linear Programs

Rodolfo Carvajal, Universidad Adolfo Ibáñez, Viña del Mar, Chile, rodolfo.carvajal@uai.cl, Shabbir Ahmed, George L Nemhauser

Mixed-Integer Linear Programming solvers are known to exhibit performance variability. We present an algorithm that takes advantage of this variability by using diversification together with exploration during the tree search. Preliminary computational results are presented.

2 - On Multi-row Chvatal- Gomory Cuts

Babak Badri Koohi, PhD Candidate, Virginia Tech, Blacksburg, VA, United States, babakbk@vt.edu, Diego A Moran

In recent years, cutting planes obtained from multi-row relaxations of polyhedra have been widely studied in the integer programming community, both from a theoretical and computational point of view. In this talk, we study k-row Chvatal-Gomory (k-CG) cuts, that are obtained by computing integer hulls of k-row relaxations of a polyhedron. This is a generalization of Chvatal-Gomory (CG) cuts (k=1), a very important class of cuts that is well-understood. Here, we present some basic properties of k-CG cuts for the case $k \geq 2$.

3 - Extended Formulations For Vertex Cover

Austin Buchanan, Oklahoma State University, buchanan@okstate.edu

The vertex cover polytopes of graphs do not admit polynomial-size extended formulations. This motivates the search for polyhedral analogues to approximation algorithms and fixed-parameter tractable (FPT) algorithms. In this paper, we take the FPT approach and study the k-vertex cover polytope (the convex hull of vertex covers of size k). Our main result is that there are extended formulations of size O(kn+1.47^k). We also provide FPT extended formulations for solutions of size k to instances of d-hitting set.

4 - Complete Efficient Frontier Of Multidimensional Nonlinear Knapsack Problems With Multiple Objectives

Yuji Nakagawa, Kansai University, nakagawa@res.kutc.kansai-u.ac.jp, Yoshiko Hanada, Chanaka Edirisinghe

We propose a technique for finding all efficient solutions of multi-objective nonlinear separable discrete optimization problems using a unique enumeration approach, termed the Target Method, based on the surrogate constraint technique. The Target Method is superior to the existing algorithms, in both speed and accuracy, on 0-1 separable discrete problems with a single constraint. Comparative results of the proposed method and metaheuristic are presented.

1 - A Backward Sampling Framework For Interdiction Problems With Fortification

Cole Smith, Clemson University, 110 Freeman Hall, Clemson, SC, 29634, United States, jcsmith@clemson.edu, Leonardo Lozano

We examine three-stage sequential defender-attacker-defender problems that are notoriously difficult to optimize, and almost always require the third-stage (recourse) problem to be convex. We propose an approach in which we allow the recourse problem to take any form. The proposed framework restricts the defender to select a recourse decision from a sample of feasible vectors and iteratively refines the sample to force finite convergence to an optimal solution. We provide computational experiments on different interdiction problems with fortification to demonstrate that our algorithm solves problems involving NP-hard recourse problems within reasonable computational limits.

2 - Interdicting Layered Information And Physical Flow Networks

Orkun Baycik, Rensselaer Polytechnic Institute, Troy, NY, United States, baycin@rpi.edu, Thomas Sharkey, Chase Rainwater

We study the interdiction of layered networks that involve a physical flow network and an information flow network. The objective of the defender is to maximize the physical flow and the objective of the attacker is to minimize this maximum amount. There exist interdependencies between the networks which lead to a network interdiction problem with a discrete inner problem. We reformulate the problem by using duality and obtain a single-level model. We apply this technique to the applications of combating illegal drug trafficking and protecting cyber infrastructures, and present computational results.

3 - Integer Programming Formulations For Minimum Spanning Tree Interdiction

Ningji Wei, University at Buffalo, Buffalo, NY, United States, ningjiwe@buffalo.edu, Jose Luis Walteros, Foad Mahdavi Pajouh

We solve the problem of removing a set of edges with minimized removal cost in a weighted graph so that the weight of any spanning tree in the remaining graph is bounded below by a value r. We developed several formulations and compare their strength analytically. We also study the convex hull of feasible solutions and identify several facets, as well as other polyhedral properties. Finally we present the computational results for three algorithms.

4 - Assortment Optimization Under Worst-case In-store Consumer Shopping Behavior

Saharnaz Mehrani, Arizona State University, Tempe, AZ, United States, smehrani@asu.edu, Jorge A. Sefair

We study an assortment problem that incorporates in-store customer response to product unavailability. In this approach, each customer has a list of products to be purchased in a given sequence. If at some point of the sequence a product is not available, the customer either chooses a substitute product or leaves the store. We propose a multi-level optimization approach to find a robust assortment under a worst-case customer's shopping list and purchasing sequence. Our approach includes a probabilistic model of the customer in-store behavior embedded into an integer program.

Systemic Risk, Policies, and Data Needs

Invited: Tutorial

Invited Session

Chair: Agostino Capponi, Columbia University, 500 West 120th street, New York, NY, 10027, United States, ac3827@columbia.edu

1 - Systemic Risk, Policies, And Data Needs

Agostino Capponi, Columbia University, 500 West 120th Street, New York, NY, 10027, United States, ac3827@columbia.edu

The study of financial system stability is of fundamental importance in modern economies. The failure or distress experienced by systemically important financial institutions can have contagious effects on the rest of the financial system. This may in turn result in deteriorating macroeconomic conditions and price instability, with negative consequences and spillover effects to other sectors of the real economy. This tutorial surveys the different approaches put forward by academic and practitioner literature to systemic risk modeling and measurement. We analyze the relevant economic forces in play, the mechanisms leading systemic instabilities, and discuss the methodologies used in the analysis. We discuss macroprudential, monetary and resolution policies targeting financial stability. We highlight the supervisory authorities of the different financial institutions, as well as barriers to data sharing.

Applications Supporting Clinical and Public Health Decision Making

Sponsored: Health Applications

Sponsored Session

Chair: Hussein Ezzeldin, ORISE, 10903 New Hampshire Ave, Bldg 71 Rm 1009C, Silver Spring, MD, 20993, United States, hussein.ezzeldin@fda.hhs.gov

1 - On The Application Of Big Data To Microbial Risk Assessment

Mark Walderhaug, FDA/CBER/OBE, mark.walderhaug@fda.hhs.gov, Steven Anderson

"Big Data" is a term that seems to be currently inescapable. New hardware, software, and data sources are transforming the nature and size of risk assessment models. Each component of microbial risk assessment is impacted by big data. Hazard Identification is becoming knowledge discovery. Dose-Response is being refined by both microbial and human variability on the genetic level. Exposure assessment is gaining depth through data made available by the evolving Internet of Things. The use of big data and sophisticated software models creates a highly complex risk characterization that is a challenge to manage, to process, and to meaningfully communicate results to risk managers and to stakeholders.

2 - Supporting The Decision Making Process In Safety Review

Taxiarchis Botsis, FDA/CBER/OBE, Taxiarchis.Botsis@fda.hhs.gov

Medical experts at the US Food and Drug Administration (FDA) conduct surveillance of licensed medical products to assure continued safety. The review process requires the thorough evaluation of multiple parameters and can be time-consuming for the end users. To assist them in this process, the FDA has developed a Decision Support Environment that extracts key clinical (and time) information from the texts, normalizes it to medical codes, and visualizes it in meaningful manners. It also allows for other analysis, case management and report generation.

3 - The Impact Of Transfusing Newer Blood Versus Current Practice On The US Blood Supply

Hussein Ezzeldin, FDA/CBER/OBE, Silver Spring, MD, United States, hussein.ezzeldin@fda.hhs.gov, Richard Forshee, Arianna Simonetti

The prolonged storage of red blood cells (RBCs) may be associated with transfusion adverse events. Mixed findings between observational and clinical studies demand larger and better-designed studies. We enhanced the US blood supply model by implementing an adaptive feedback-control mechanism, where blood collection is dynamically adjusted, to maintain inventory collector's levels and overcome potential shocks. If any benefits in transfusion outcomes of younger RBCs are proven, an increase in their demand may be expected. We evaluate the impact of such changes on the US blood system with respect to current blood transfusion practice.

4 - Optimal Resource Allocation For Adaptive Clinical Trials

Alba Rojas-Cordova, Virginia Tech, Blacksburg, VA, 24060, United States, albarc@vt.edu, Ebru Korular Bish

Certain adaptive designs allow decision-makers to alter the course of a clinical trial based on revised estimates of a drug's probability of technical success. We develop a stochastic dynamic programming model to analyze the resource allocation decision, of continuing or stopping a trial, based on frequent data updates. We determine the structure of the optimal resource allocation strategy and support our findings with a numerical analysis.

1 - Data-driven Approaches To Improve The U.S. Kidney Allocation System

Nikolaos Trichakis, MIT, Cambridge, MA, United States, ntrichakis@mit.edu, Chaithanya Bandi, Phebe Vayanos

We present a data-driven optimization approach to estimate wait times for individual patients in the U.S. Kidney Allocation System, based on the very limited system information that they possess in practice. To deal with this information incompleteness, we develop a novel robust optimization analytical framework for wait time estimation in multiclass, multiserver queuing systems. We calibrate our model with highly detailed historical data and illustrate how it can be used to inform medical decision making and improve patient welfare.

2 - Optimization-driven Framework To Understand Healthcare Networks Cost And Resource Allocation

Fernanda Bravo, UCLA Anderson School of Management, Los Angeles, CA, United States, fernanda.bravo@anderson.ucla.edu Marcus Braun, Vivek Farias, Retsef Levi

Consolidation in the US healthcare industry has resulted in the formation of large delivery networks. However, integration remains uncertain. In order for large care providers to best utilize their growing networks, it will be critical to understand not only system-wide demand and capacity, but also how the deployment of limited resources can be improved. We develop an optimization-driven framework, inspired by revenue management, to understand network costs and provide solutions to strategic problems, such as access, resource deployment, and case-mix in multi-site networks. In collaboration with a network of hospitals, we demonstrate our framework applicability.

3 - New Data-driven Approach To Safety And Risk Management In Health Systems

Retsef Levi, Professor of Operations Management, MIT, 100 Main Street, BDG E62-562, Cambridge, MA, 02142, United States, retsef@mit.edu, Patricia Folcarelli, Yiqun Hu, Daniel Talmor, Jeffrey Adam Traina

We present an innovative system approach to safety in Health Systems. The approach is based on the innovative concept of risk drivers, which are states of the System, its environment and its staff that affect the likelihood of harms, as well as an innovative aggregated measure of the 'burden of harm'. Using large scale data we develop statistical models that identify predictive risky states.

Healthcare Delivery Modeling

Sponsored: Health Applications

Sponsored Session

Chair: Bryan A Norman, University of Pittsburgh, 1006 Benedum Hall, Pittsburgh, PA, 15261, United States, banorman@pitt.edu

1 - Modeling To Enhance The Nurse Handoff Process

Anna Svirsko, University of Pittsburgh, ACS167@pitt.edu Bryan A Norman, David Rausch, Emily Shawley

Nurses in emergency departments often rotate between different zones during their 12 hour shift to balance nurse workload. However, this rotation significantly increases the number of nurse handoffs which reduces the amount of available nurse-patient time and can result in errors in patient care. This model reduces the number of nurse handoffs while still allowing nurses to rotate during their shift and balancing workload among nurses. Furthermore, we look to reduce long chains and cycles that can occur that hinder the rotation and handoff processes. The effectiveness of the model is demonstrated by applying the model to the nursing schedule from a local hospital.

2 - Closed-Form Solutions For Periodic Review Inventory Systemsin Healthcare

Nazanin Esmaili, University of Pittsburgh, Pittsburgh, PA, United States, nae22@pitt.edu, Bryan A Norman, Jayant Rajgopal

Most inventory management systems at points of use in hospitals are characterized by stochastic demand, periodic reviews, fractional lead time, expedited delivery, limited storage capacity, and service level requirements. We develop discrete time Markov chain models for such systems to minimize the total expected replenishment effort. We derive closed form expressions and propose an exact algorithm to calculate the limiting probability distribution by locally decomposing the state space. We investigate the structural results and the tradeoffs of performance measures of interest for different policies and show that the computational effort is less than other algorithms from the literature.

3 - Considering No-shows And Procedure Time Variability When Scheduling Endoscopy Patients

Karmel Shehadeh, University of Michigan, Ann Arbor, MI, United States, ksheha@umich.edu, Amy Cohn, Sameer Saini, Jacob Kurlander

We consider the problem of how to schedule patients for colonoscopy appointments, recognizing both the high frequency of no-shows and the significant variability in procedure time. We review the clinic process flow, identify metrics for evaluating schedule quality, and simulate different scheduling approaches.

4 - Improving Healthcare Resource Management Through Demand Prediction And Staff Scheduling

Nazanin Zinouri, Clemson University, 269 Freeman Hall, Clemson, SC, 29634, United States, nzinour@g.clemson.edu, Kevin Taffe

Staff scheduling in healthcare is very challenging. Hospitals typically operate 24 hours a day, 7 days a week, and are faced with high fluctuations in demand. We developed an ARIMA model to forecast daily patient volumes a month in advance. This information was used to compute workload and solve staff scheduling problems. We used a risk adverse approach to find a feasible nurse assignment that minimizes labor costs and to avoid risky cases, i.e., highly overstaffed or understaffed. The liabilities of overstaffing and understaffing are many. Overstaffing increases payrolls and results in excessive idle times, while understaffing will negatively impact patient outcomes and results in loss of revenue.

Personalizing Healthcare Decision-Making

Sponsored: Health Applications

Sponsored Session

Chair: Anil Aswani, UC Berkeley, 1, San Francisco, CA, United States, aaswani@berkeley.edu

1 - Incentive Design In The Medicare Shared Savings Program

Auyon Siddiq, UC Berkeley, Berkeley, CA, United States, auyon@berkeley.edu, Anil Aswani, Zuo-Jun (Max) Shen

The Medicare Shared Savings Program (MSSP) was created to control rising healthcare costs by offering Medicare providers financial incentives to reduce spending on healthcare delivery. We place the MSSP within a principal-agent framework and investigate the impact of directly subsidizing investments made by a provider to improve operational efficiency. We then estimate parameters of the principal-agent model using financial performance data of Medicare providers participating in the MSSP. Our analytical and empirical results both suggest that a direct subsidy can yield net reductions in total Medicare spending, despite the additional payments made to providers.

2 - Approximation Algorithms For Population-scale Personal Dietary Management

Pedro Hespanhol, UC Berkeley, pedrohespanhol@berkeley.edu Anil Aswani

Diet is an important component of wellness and health; however, various fiscal, geographic, and time constraints can make it difficult for families to healthfully manage dietary decisions and purchases. This talk describes a novel mixed-integer formulation for personal management of dietary decisions, and this formulation can be generalized to a new class of knapsack-like problems. We design an approximation algorithm to solve these problems, and such an approximation algorithm enables scaling the use of our personal dietary management formulation to the broader population.

3 - A Decision Analytics Approach For Clinical Intervention Design

Yonatan Mintz, UC Berkeley, ymintz@berkeley.edu, Anil Aswani, Philip Kaminsky, Yoshimi Fukuoka, Elena Flowers

When designing behavioral interventions it is crucial to take into account the inherent tradeoff between quality of care and intervention cost. In this paper, we develop an algorithm which uses patient data to resolve this tradeoff effectively in the context of weight loss interventions. We expand on a previously developed utility maximization model for patient behavior by utilizing integer programming and Bayesian prediction to evaluate the efficacy of various weight loss interventions and combine them into a weight loss program. We then present simulation results which show that our method maintains efficacy while potentially reducing the associated person hours and cost of the intervention.

4 - A Correlation-preserving Method To Estimate Risk Factor Trajectories From Cross-sectional Data

Sze-chuan Suen, USC, Los Angeles, CA, United States, suensze@gmail.com, Jeremy D. Goldhaber-Fiebert, Sanjay Basu

How should we approximate individual risk factors (i.e., cholesterol levels, BMI, etc.) over time when we only have information about the distributions over the whole population at each time period? We use a shortest-distance algorithm which preserves correlation to approximate risk factor trajectories for use in microsimulation models of disease when only cross-sectional data is available. We compare the treatment implications of using this algorithm with other commonly used methods.

Project Related SCM I

Invited: Project Management and Scheduling

Invited Session

Chair: Xiaoqiang Cai, The Chinese University of Hong Kong, Shatin, Hong Kong, Hong Kong, xqcai@se.cuhk.edu.hk

1 - Capacity Control Policies For Leasing Industry Based On Customers' Behavior

Lifeng Zhang, University of Electronic Science and Technology of China, Chengdu, China, anny78@163.com, Yinping Mu, Shiming Li

The paper studies the capacity control strategy for multiperiod and multiproduct leasing based on customers' behavior pricing strategy. Considering that the customers' behavior will affect the value of the products in the process of using rental products, and then affect the benefit of the industry. We regard product prices as a function of customers' behavior, and build a model to analyze how to solve the mismatching problem between capacity and demand with upgrades. We present the stochastic dynamic programming formulation for customers' behavior, and propose a new product upgrade mechanism.Finally, we perform computational expeiments to testify the qualities of the model.

2 - Downstream Firm's Investment With Equity Holding In Decentralized Assembly Systems

Hong Fu, University of Electronic Science and Technology of China, Chengdu, China, hongfu@uestc.edu.cn Yongkai Ma, Xiaoqiang Cai

We consider a decentralized assembly system in which n upstream firms sell complementary components to a downstream firm facing a stochastic and price-sensitive demand. The downstream firm may make an investment to hold equity in an upstream firm. This not only enables the downstream firm to share the profit of the upstream firm as determined by the equity held, but also provides the needed resources for the upstream firm to improve its production efficiency and consequently benefits the entire system. We consider two distinct decision settings: upstream Stackelberg and downstream Stackelberg. We characterize the optimal decisions of the chain members, and obtain some useful insights.

3 - Ex-ante Transfer Pricing Decision In a Multinational Firm

Lianmin Zhang, Nanjing University, Nanjing, China, zhanglm@nju.edu.cn, Xiaopeng Zhang

This paper focus on the practice observed recently that MNFs do not only produce for themselves but also for the local competitors. TP decision has ex-ante feature in the analytical model and the arm's length principle is applied also.

4 - Optimal Policies For Two-products Supply Chain With Free Gift Cards Promotion

Yuefeng Li, University of Electronic Science and Technology of China, Chengdu, China, yuefengliuestc@yahoo.com Jingming Pan, Xiaowo Tang

Many retailers offer free gift cards for attracting more consumers. These gift cards are rewarded to consumers and can be redeemed on the purchase of other products at the retailer. In this paper, we consider a supply chain system with two independent manufacturers (M1 and M2) and one retailer. The retailer sells two products, product 1 from the manufacturer 1 and product 2 from the manufacturer 2. And she offers a specific "free" gift cards promotion, i.e., the consumer who buy the product 1 can get a gift card then redeem gift card only to buy product 2. Based on the above assumptions, we develop a decision model and get the optimal strategies for the retailer.

Optimal Auctions

Invited: Auctions

Invited Session

Chair: Ian Kash, Microsoft, Cambridge, United Kingdom, iankash@microsoft.com

1 - A Continuous Approximation Method For Optimal Auction Design

Eiichiro Kazumori, SUNY, Buffalo, NY, United States, eiichiro.kazumori@gmail.com

This paper propose a new method to analyze the optimal auction design problem. The starting point is an observation that seller's profit function is Baire class 1 that can be derived as a pointwise limit of a sequence of continuous functions. Thus the optimal auction mechanism is a limit of the nonlinear pricing problems. This continuous approximation method can be regarded as an application of the path-following method to the optimal auction design problem. Using this novel method, we characterize the optimal auction mechanism with heterogeneous objects and multidimensional types with continuous distributions by unifying Myerson(1981), Mussa and Rosen(1978), and Rochet and Choné (1998).

2 - Strong Duality For A Multiple Good Monopolist

Christos Tzamos, MIT, tzamos@csail.mit.edu

We provide a duality-based framework for revenue maximization in a multiple-good monopoly. Our framework shows that every optimal mechanism has a certificate of optimality, taking the form of an optimal transportation map between measures. Using our framework, we characterize optimal mechanisms showing that a mechanism is optimal if and only if stochastic dominance conditions hold between specific measures induced by the buyer's type distribution. As a corollary, we consider the case of n independent uniform items each supported on [c,c+1] and show that grand bundling is optimal if and only if c is sufficiently large compared to n. This extends Pavlov's result for 2 items [Pavlov11].

3 - Optimal Auctions With Restricted Allocations

Ian Kash, Microsoft, iankash@microsoft.com

We study the design of optimal auctions under restrictions on the set of allocations. In addition to allowing us to restrict to deterministic mechanisms, we can also indirectly model non-additive valuations. We prove a strong duality result, extending a result due to Daskalakis et al. [2015], that guarantees the existence of a certificate of optimality for optimal restricted mechanisms. As a corollary, we provide a new characterization of the allocations that the optimal mechanism may use. We find and certify optimal mechanisms for four settings where previous frameworks do not apply and provide new economic intuition about some of the tools that have previously been used to find optimal mechanisms.

4 - Sample Complexity Of Revenue Maximization In The Hierarchy Of Deterministic Combinatorial Auctions

Tuomas Sandholm, Carnegie Mellon University, sandholm@cs.cmu.edu, Nina Balcan, Ellen Vitercik

Designing revenue-maximizing combinatorial auctions (CAs) is elusive. It is typically assumed that the designer knows the prior distribution over valuations, which is unrealistic because the prior is doubly exponential. Sandholm and Likhodedov introduced automated mechanism design that takes as input samples from the prior, and searches for a high-revenue CA within rich auction classes. There was no formal characterization of the number of samples required to guarantee that the CA revenue on the samples is close to its revenue on the underlying prior. We fill that gap, providing tight sample complexity bounds over the hierarchy of deterministic CA classes, and uncover structural properties.

Organizational Learning and Problem Solving Strategies in Service Organizations

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Anita L Tucker, Brandeis, 415 South Street, MS 032, Waltham, MA, 02453-2728, United States, altucker@bu.edu

1 - Checklists In Aviation And Healthcare

Roger E Bohn, University of California-San Diego, rbohn@ucsd.edu

Checklists in health care are often motivated by citing their use in aviation. But aviation struggled with checklists and standardization for decades. Craft-based pilots were often better than pilots who used standard procedures. Combining the benefits of both centralized explicit knowledge and individual tacit knowledge is still not fully solved. Medicine will have similar tradeoffs, and needs a flexible and learning-centered approach to checklists and other procedural knowledge.

2 - The Moderating Role Of Organizational Context On Learning-by-doing

Bradley R Staats, University of North Carolina at Chapel Hill, bstaats@unc.edu

In this paper, we examine relatedness from a strategic perspective. We consider one aspect of strategic relatedness that is particularly salient at all levels of analysis: goals. In doing so, we argue that even where otherwise diverse activities are knowledge-related, if they are not goal-related, learning-by-doing is likely to suffer. Using data from the hospital industry our findings suggest that goal-relatedness is an important consideration when it comes to learning. Although goal-related teaching aids learning-by-doing in clinical care, we find that strong academic affiliations (and the research-oriented tasks and goals they bring with them) may detract from it.

3 - Impact Of Tightly-coupled Team Familiarity And Learning-curve Heterogeneity On Orthopedic Procedure Times

Michael A Lapre, Vanderbilt University, michael.lapre@owen.vanderbilt.edu, David W Moore

We study team familiarity and learning-curve heterogeneity in the context of orthopedic surgery times. We find that learning from team experience depends on familiarity between team members who have to closely coordinate their tasks. When we allow for learning-curve heterogeneity for individual and tightly-coupled team experience, organizational experience is no longer significant. This finding suggests that organizational experience could be a proxy for individuals and teams learning at different rates.

4 - Integration And Quality Performance In Hospitals

Eitan Naveh, Technion – Israel Institute of Technology, Haifa, Israel, naveh@ie.technion.ac.il, Wiljeana Glover, Qing Li, Michael Gross

While many studies suggest that integration is positively associated with improved quality of care, others assert that integration may not necessarily result in better quality of care. The inconsistent success of integration to improve performance is not limited to healthcare operations, but in operations and engineering management in general. We suggest that this inconsistency exists due to the predominant view that does not consider that systems integration requires consideration of both technical and human components. We use the theory of Human Systems Integration (HSI) to explain how the technical component and the human component of a system interact to influence quality performance.

New Supply Chain Inventory Problems Motivated by Practice

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Jeannette Song, Duke University, NC, United States, jingsheng.song@duke.edu

Co-Chair: Yue Zhang, Duke University, Durham, NC, United States, yueyue.zhang@duke.edu

1 - Online-retail Inventory Replenishment: A Dynamic Programming Approach

Stephen C Graves, Massachusetts Institute of Technology, Cambridge, MA, United States, sgraves@mit.edu
Annie I-An Chen

An online-retail inventory system consists of fulfillment centers where items are stored and shipped. Demand can be satisfied by any fulfillment center carrying the item, but a system-wide stockout results in lost sales. Assuming myopic fulfillment and joint periodic review, we formulate the online-retail inventory replenishment problem as a dynamic program. We study the optimal solution structure and propose near-optimal heuristic policies of tractable complexity, including base-stock and constant-basestock hybrid policies, which can be found by simulation optimization methods. Numerical examples demonstrate that our approach outperforms the status-quo base-stock policy.

2 - Robust Inventory Allocation Under Process Flexibility

He Wang, Massachusetts Institute of Technology, 77 Massachusetts Avenue, E40-130, Cambridge, MA, 02139, United States, hewang150@gmail.com, David Simchi-Levi, Yehua Wei

We consider a hybrid strategy that combines process flexibility and inventory to help firms meet uncertain supply with uncertain demand. We propose a robust optimization framework to model this hybrid strategy, and show that the problem can be efficiently solved using a cutting-plane algorithm. We then demonstrate the benefit of this method in practical applications such as supply chain risk mitigation and production postponement.

3 - Stock Or Print? Impact Of 3D Printing On Critical Spare Parts Logistics

Yue Zhang, Duke University, Durham, NC, United States, yueyue.zhang@duke.edu, Jing-Sheng Jeannette Song

In this paper, we construct a general framework to analyze the impact of 3D printing in spare part sourcing. Our results provide guidance in how to partition the spare part service among an oversea supplier and a local 3D printer.

Issues in Energy Efficiency and Renewable Energy

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Mili Mehrotra, University Of Minnesota, 321 19th Ave South, Minneapolis, MN, 55455, United States, milim@umn.edu

1 - Operational Response To Climate Change: Do Profitable Carbon Abatement Opportunities Decrease Over Time?

Christian Blanco, UCLA Anderson School of Management, Los Angeles, CA, United States, cblanco@anderson.ucla.edu
Felipe Caro, Charles J Corbett

We explore data collected by CDP (formerly the Carbon Disclosure Project) on over 11,000 projects implemented by 956 firms. We find that the average payback period is increasing by about one month for each reporting period, but less so for firms that pursue opportunities that are directly related to core company operations.

2 - Closing A Supplier's Energy Efficiency Gap: The Role Of Assessment Assistance And Procurement Commitment

Quang Dang Nguyen, University of Minnesota, Minneapolis, MN, 55455, United States, nguy1762@umn.edu
Karen Donohue, Mili Mehrotra

This paper analyzes the Energy Efficiency (EE) investment decisions of a capital-constrained manufacturer that competes with an alternate supplier for the business of a large industrial buyer. Through a series of game theoretic models, we analyze the impact of EE assessment assistance and procurement commitment on the supplier's EE investment.

3 - Mind The Gap: Coordinating Energy Efficiency And Demand Response

Eric Webb, Kelley School of Business, Indiana University, Bloomington, IN, 47405, United States, ermwebb@indiana.edu
Owen Wu, Kyle D Cattani

Traditionally, energy demand-side management techniques, such as energy efficiency (EE) and demand response (DR), are evaluated in isolation. We examine the interactions between long-term EE upgrades and daily DR participation at an industrial firm. We find that EE and DR act as substitutes in terms of reduction of peak electricity demand, and the long-studied energy efficiency gap between firm-optimal and societal-optimal levels of EE is smaller when DR is considered. We suggest three approaches to reducing the energy efficiency gap, including an original suggestion that relies upon the interactions between EE and DR.

New Business Models In Transportation

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Karan Girotra, INSEAD, Fontainebleau, France, karan.girotra@insead.edu

1 - Service Region Design For Urban Electric Vehicle Systems

Long He, National University of Singapore, longhe@nus.edu.sg,
Ho-Yin Mak, Ying Rong, Zuo-Jun Max Shen

We consider the service region design problem for electric vehicle sharing systems. We then develop a model that incorporates both customer adoption behavior and fleet operations under spatially-imbalanced and time-varying travel patterns. To address the uncertainty in adoption patterns, we employ a distributionally-robust optimization framework. Applying this approach to the case of Car2Go's service, with real operations data, we address a number of planning questions.

2 - Dynamic Type Matching

Ming Hu, University of Toronto, Toronto, ON, Canada, ming.hu@rotman.utoronto.ca, Yun Zhou

We study a dynamic multi-period assignment/transportation problem, in which an intermediary dynamically matches demand and supply of heterogeneous types and the unmatched will incur waiting or holding costs, and be carried over to the next period with abandonments. This problem also applies to many emerging settings in the sharing economy. The Monge sequence discovered by Gaspard Monge in 1781 was introduced to solve a deterministic, balanced transportation problem in a greedy fashion. We propose modified Monge conditions that are sufficient and robustly necessary for structural priority properties for the dynamic, stochastic and unbalanced transportation problem.

3 - Algorithmic Support For Bike-sharing System Operations At Motivate

David B Shmoys, Cornell University, david.shmoys@cornell.edu
Daniel Freund, Shane Henderson, Nanjing Jian

Bike-sharing systems (BSSs) have become increasinglly prevalent as part of the urban landscape, and are common even in smaller towns. For larger cities, these systems give rise to a number of interesting logistical problems to support their operations. A group at Cornell has been embedded within the support structure for Motivate, which operates BSSs in several major US cities. We will give an update on a number of the models and algorithmic advances that have been implemented to support operations at Motivate, and in particular, for Citibike in NYC.

4 - Maximizing Ridership In Bike Sharing Systems Using Empirical Data And Stochastic Models

Vinayak Deshpande, University of North Carolina, Chapel Hill, NC, 27599, United States, Vinayak_Deshpande@kenan-flagler.unc.edu
Pradeep Kumar Pendem

We analyze the optimal allocation of bikes in a network of stations to improve ridership under non-stationarity demand and station substitution. We utilize large datasets on trips, real time inventory information at stations, and distances between stations. Our demand model captures both bike pickups and dropffs, as well as demand non-stationarity and substitution under stockouts. The optimal allocation of bikes across stations to maximize ridership is determined using a dynamic program. Our study provides insights on the relationship between the allocation of bikes and ridership, and the value of incorporating non-stationarity, real-time inventory information, and station substitution.

Operational Issues in Agriculture

Sponsored: Manufacturing & Service Oper Mgmt, iFORM

Sponsored Session

Chair: Onur Boyabatli, Singapore Management University, 50 Stamford Road 04-01, Singapore, 178899, Singapore, oboyabatli@smu.edu.sg

1 - Designing Contracts And Sourcing Channels To Create Shared Value

Joann de Zegher, Stanford University, jfdezegher@stanford.edu,
Hau Leung Lee, Dan Andrei Iancu

We study contract and channel design to create mutual benefit in decentralized agricultural value chains, where suppliers bear costs of new technologies while benefits accrue primarily to buyers. We provide insights to companies seeking to incorporate responsible sourcing strategies while also creating economic value - a concept called creating shared value. We identify that the technology's cost elasticity drives whether switching sourcing channel, changing contract structure, or adopting an integrated change is necessary. Using a dataset of farms in Argentina we estimate that the our mechanism could increase average supply chain profit by 6.9% while realizing environmental benefits.

2 - Third-wave Coffee: Sourcing And Pricing A Specialty Product Under Uncertainty

Shahryar Gheibi, Siena College, Loudonville, NY, United States, sgheibi@siena.edu, Burak Kazaz, Scott Webster

Motivated by an emerging phenomenon in the coffee industry—third-wave coffee—we study an agricultural supply chain where a firm sells a finished product which requires processing an agricultural product as input. In order to target the quality-sensitive segment of consumers, the firm (processor) offers specialty coffee by engaging in Direct Trade which in turn leads to exposure to supply risk. Our study provides insights into the main driving forces that influence the sourcing and pricing decisions of the processor in a specialty-coffee supply chain.

3 - New Results For Bounds In Newsvendor Problems

Saurabh Bansal, Penn State University, sub32@psu.edu

We discuss new results for the bounds on the newsvendor problem in the agribusiness context and quantify the value of decisions based on these bounds over some commonly used approaches.

Scheduling VI

Contributed Session

Chair: Matthew J Liberatore, Villanova University, 800 Lancaster Avenue, Villanova, PA, 19085, United States, matthew.liberatore@villanova.edu

1 - Job Shop Scheduling With Convex Costs

Reinhard Burgy, GERAD and Polytechnique Montreal, GERAD – HEC Montréal, 3000, ch. de la Côte-Sainte-Catherine, Montreal, QC, H3T 2A7, Canada, reinhard.burgy@gerad.ca

We address an extension of the classical job shop scheduling problem with a generic convex cost objective. This objective makes it possible to model, for example, convex tardiness costs and convex (intermediate) holding costs. It is, to the best of our knowledge, the first time such a generic nonlinear and nonregular objective is considered in job shop scheduling. We give a disjunctive graph formulation and develop a local search heuristic. Numerical results support the validity of our approach.

2 - Heuristics For Lot Streaming In Flow Shop Scheduling

Anurag Agarwal, Professor, University of South Florida, Information Systems and Decision Sciences, Coll of Business, Sarasota, FL, 34243, United States, agarwala@usf.edu,
Ramakrishna Govindu

We develop heuristic solutions to generate efficient schedules for a lot streaming scheduling problem within the flowshop environment. We formulate this problem as a multiobjective problem that attempts to strike a balance between makespan and cost of handling the sublots. We consider transfer times, sequence dependent lot setup times, as well as sublot setup times.

3 - A Multistart Algorithm For The Parallel Machine Scheduling Problem With Dependent Setup Times And Preventive Maintenance

Oliver Avalos-Rosales, Profesor Investigador de Tiempo Completo, Universidad Autónoma de Coahuila, orion 338, Satelite Norte, Saltillo, 25115, Mexico, aoliver84@gmail.com, Ada M. Álvarez, Francisco Angel-Bello

We address an unrelated parallel machine scheduling problem minimizing the makespan. We consider dependent setup times and periodic preventive maintenance. These aspects have not been jointly studied in parallel machine environment. The problem is NP-hard. We consider the structure of feasible solutions and the structure of the objective function to design each component of the multistart proposed algorithm. We present computational experiments to compare the algorithm with exact solutions in small an medium size instances, and validate the contribution of each part of the algorithm in large instances.

4 - Operating Room Scheduling Under Hybrid Demand

Hamed Yarmand, University of Massachusetts Boston, 2 Fatima Rd, Stoneham, MA, 02180, United States, hamed.yarmand@umb.edu, Amirreza Shojaeifard, Babak Rezaee

We present a novel model for the elective surgery scheduling problem for multiple operating rooms to improve the efficiency of ORs with the intent of maximizing the profit (considering revenue of surgeries, fixed cost, and overtime cost). We develop an integer linear programming model for this scheduling problem. The developed model is a four dimensional assignment problem that determines the weekly schedule (day, surgeon, operating room, and type of surgery) considering three types of surgery demands simultaneously (pre-scheduled, pre-assigned, and other). It also considers surgeons' availabilities for performing surgeries. Two heuristic algorithms are proposed and investigated.

5 - Project Planning And Scheduling To Maximize Expected Quality In The Presence Of Stochastic Time Delays

Matthew J Liberatore, Villanova University, 800 Lancaster Avenue, Villanova, PA, 19085, United States, matthew.liberatore@villanova.edu, Bruce Pollack-Johnson

We present research designed to help deal with probabilistic time delays and cost overruns which endanger project quality. We present strategies to find the planned durations for tasks and the scheduling protocol that maximize the expected overall project quality by applying our previously developed notion of a continuous quality function for a task (and the project overall) in terms of the time and investment put into it.

Simulation I

Contributed Session

Chair: Barret Pengyuan Shao, Crabel Capital Management, 414 East Market Street Second Floor, Charlottesville, VA, 22903, United States, barretshao@gmail.com

1 - Simulation-based Optimization For Layout-based Grafting Resource Allocation

Sara Masoud, University of Arizona, 1300 E Fort Lowell Road, # A214, Tucson, AZ, 85719, United States, saramasoud@email.arizona.edu, Young-Jun Son, Chieri Kubota, Russell Tronstad

Optimal resource planning in vegetable seedling propagation facilities is complicated due to the dynamicity of workers' performance. In addition, the negative impact of an inefficient layout on workers' performance reduces the productivity in grafting facilities substantially. In this work, a simulation-based optimization model is devised to achieve the optimal layout-based resource allocation. The proposed model is customized based on workers' individual performance and managerial design preferences. The optimal solution is expected to reduce the production cost of grafting systems. systems.

2 - Interfirm Imitation Under Relational And Institutional Influences

Kyun Kim, Doctoral Student, University of Texas at Dallas, 800 West Campbell Road, SM43, Richardson, TX, 75080, United States, kyun.kim@utdallas.edu, Zhiang (John) Lin

In the interfirm imitation research, the role of imitation targets is often underexplored since imitators have received the most attention. Also, the connection between macro and micro constructs related to imitation has not been clearly discussed. We endeavor to shed light on imitation targets and to connect macro and micro factors. We develop a status based approach and introduce how status (macro and micro) of a firm lets imitators reduce uncertainty and gain legitimacy. We also examine performance (micro) and institutional environment (macro) of an imitation target. We conduct empirical tests and computational analyses regarding firms' resource acquisition activities: M&As and Alliances.

3 - Climate Prediction Markets And Investor Beliefs: An Agent-based Simulation

Jonathan Gilligan, Associate Professor, Vanderbilt University, 2301 Vanderbilt Place, PMB 351805, Nashville, TN, 37235-1805, United States, jonathan.gilligan@vanderbilt.edu, John J. Nay, Martin Van der Linden

A large fraction of the American public doubts the scientific consensus that human activity is causing global warming. Climate prediction markets might influence beliefs in people who distrust scientists but trust free markets. We present an agent-based computational test-bed to examine prediction market dynamics. Traders with different beliefs about climate bet on future temperatures and adapt their beliefs based on the profits of other traders. Traders believe that global climate is primarily controlled by carbon dioxide or by solar irradiance. Market participation causes traders' beliefs to converge rapidly, suggesting that a climate market could be useful for building public consensus.

4 - Agent-Based Simulation Of Production And Seeding Strategies For Innovations

Ashkan Negahban, Assistant Professor, Pennsylvania State University, 30 E Swedesford Rd, Malvern, PA, 19355, United States, anegahban@psu.edu, Jeffrey Smith

We develop an agent-based simulation model of new technology diffusion to evaluate different viral marketing and inventory build-up policies under various social network structures. We show that determining seeding and build-up policies sequentially may lead to suboptimal decisions. We show how the optimal joint policy varies for different product categories and that the seeding strategy that maximizes demand rate is not necessarily optimal under supply constraints. We also investigate the role of high-degree nodes and long-range connections in scale-free and small-world networks.

5 - Approximation Of Long Memory Process With Short Memory Process And Some Numerical Experiments

Barret Pengyuan Shao, Crabel Capital Management, 414 East Market Street Second Floor, Charlottesville, VA, 22903, United States, barretshao@gmail.com

Taking FARIMA(p,d,q) process with $d > 0$ as an example for long memory process, we use information distance to prove that stationary ARMA processes are dense in all FARIMA processes in the total variation distance. As a consequence, statistical tests with finite sample size fail to distinguish a FARIMA process from ARMA processes. We provide Monte Carlo experiments that confirm that long memory processes are not easily distinguished from our approximate ARMA processes with finite sample sizes using a variety of well known statistical tests.

1 - Nursing Shift Assignment And Its Influence On Medical Outcomes: First Insights Of A Multicenter Study

Ludwig Kuntz, University of Cologne, Cologne, Germany, kuntz@wiso.uni-koeln.de, Felix Miedaner, Stefan Scholtes

Low staffing levels are known to be a risk factor for medical outcomes. However, it is important not only to consider the right staffing levels but also to assign the available staff in the most sensible manner. Based on data from a multicenter study of 66 neonatal intensive care units, we analyze variation in staffing allocation decisions and present the first insights into their association with outcomes.

2 - The Impact Of Internal Service Quality On Nurse Inefficiency And Medical Errors

Xin(Sarah) Zheng, Boston University, Boston, MA, United States, xinzheng@bu.edu, Anita L Tucker, Z Justin Ren, Janelle Heineke, Amy McLaughlin, Aubrey Podell

Drawing on the theories of swift, even flow and conservation of resources, we propose a new avenue for addressing medical errors—improving internal service quality (ISQ), which is the quality of service provided by support departments such as housekeeping, and materials management. Using 13 months of panel data from five nursing units that gather weekly data on ISQ delivered by 11 support departments, we find that a one standard deviation increase in ISQ is associated with near elimination of hospital-acquired pressure ulcer and patient fall. The one standard deviation increase in ISQ is further associated with a 5% reduction in nurse inefficiency and a financial benefit as high as $7 million.

3 - Using Patient-centric Quality Information To Unlock Hidden Health Care Capabilities

Guihua Wang, Ross School of Business, University of Michigan, Ann Arbor, MI, 48105, United States, guihuaw@umich.edu
Jun Li, Wallace J Hopp

We document a wide variation in quality among 188 surgeons at 35 hospitals in New York state that perform mitral valve surgery. Our analysis shows that patients of different demographics and levels of acuity benefit differently from elite surgeons. In this paper, we develop an approach for computing patient-centric information from outcome data and evaluate the potential health benefits from using such information to guide patients to surgeons. We estimate that the total societal benefits from using patient-centric information are comparable to those achievable by enabling the best surgeons to treat 40% more patients under population-average information.

4 - Evidence Of Upcoding In Pay-for-Performance Programs

Hamsa Sridhar Bastani, Stanford University, Stanford, CA, United States, hsridhar@stanford.edu, Joel Goh, Mohsen Bayati

Medicare has sought to improve patient care by penalizing providers for hospital-acquired infections (HAIs). However, these efforts may be undermined if providers upcode, i.e. mis-report HAIs (possibly unintentionally) to increase reimbursement. Identifying upcoding is challenging due to unobservable confounders. We exploit state-level variations in adverse event regulation and instrumental variables to estimate that over 10,000 infections (nearly 15%) are upcoded each year, resulting in an added cost of $200 million. Our findings suggest that increasing financial penalties alone may not reduce HAI incidence. We make several policy recommendations accordingly.

Empirical Research in Services

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Qiuping Yu, Indiana University, Kelley School of Business, Bloomington, IN, 47405, United States, qiupyu@indiana.edu

Co-Chair: Gad Allon, Professor, Kellogg School of Management, 2001 Sheridan Rd, Evanston, IL, 60208, United States, g-allon@kellogg.northwestern.edu

1 - Understanding Customers Retrial In Call Centers: Preference Of Service Quality And Service Speed

Kejia Hu, Kellogg School of Management, Northwestern University, k-hu@kellogg.northwestern.edu
Gad Allon, Achal Bassamboo

In this paper we want to understand retrial by connecting customers decisions with their preferences on service aspects: the speed in service access and the quality in service delivered. We use a dynamic random-coefficient structural model along with observations in a call center to capture customers behavior. Our results suggest different preferences for service speed and service quality exist across different customer segments. Using counterfactual analysis, we suggest two cost-effective strategies to reduce retrial. Our new service system design increases private customer welfare by 8.91% and business customer welfare by 37.6%.

2 - The Reference Effect Of Delay Announcements: A Field Experiment

Qiuping Yu, Assistant Professor, Kelley School of Business, Indiana University, Bloomington, IN, 47405, United States, qiupyu@indiana.edu, Gad Allon, Achal Bassamboo

We empirically explore whether delay announcements induce the reference effect and customers' loss aversion in a field experiment approach. We find that customers exhibit loss aversion, whether they are provided with announcements or not. Moreover, providing delay announcements appears to impact customers' reference points and may reduce customers' per unit waiting cost compared to the case when announcements are not provided.

3 - When You Work With A Super Man, Will You Also Fly? An Empirical Study Of The Impact Of The Coworkers On Workers' Performance

Tom Tan, Cox School of Business, Southern Methodist University, ttan@smu.edu, Serguei Netessine

We examine a large operational data set in a casual restaurant setting to study how coworkers' sales ability (measured as servers' sales premium) affects workers' performance in terms of service speed and service quality. We find that servers react non-linearly to their coworkers' ability. Our empirical findings imply that managers should mix servers having heterogeneous ability levels during the same shift. Through a counterfactual analysis, we find that considering the inverted-U-shaped peer effects to optimize current servers' schedules without changing their capacity may increase total sales by 2.7%.

4 - Responsiveness And Learning In The Medical Device Product Recall Process

George Ball, Kelley School of Business, Indiana University, gpball@indiana.edu, Rachna Shah

Product recalls move through multiple steps in a firm. Deciphering the impact of moving fast or slow can help unravel the complexities associated with product recalls and reveal the impact of learning on future recalls. We investigate recall responsiveness with unique data obtained from the Food and Drug Administration consisting of over 4,000 medical device recalls from 2003 to 2013. We find that moving too quickly to identify root cause and corrective action may hamper learning, and lead to additional future recalls. We also find that the speed at which the firm opens a recall is not associated with future recalls, supporting the view that firms should move quickly to recall risky products.

Incentive Design in Marketing and Operations

Sponsored: Manufacturing & Service Oper Mgmt, Supply Chain

Sponsored Session

Chair: Tinglong Dai, Johns Hopkins University, Baltimore, MD, United States, dai@jhu.edu

Co-Chair: Kinshuk Jerath, Columbia University, 3022 Broadway, New York, NY, 10027, United States, jerath@columbia.edu

1 - Salesforce Compensation With Network Effects

Hemant Bhargava, University of California, Davis, hemantb@ucdavis.edu, Olivier J Rubel

This paper examines the management problem of "selling" platforms, i.e., designing appropriate salesforce management and incentives schemes to obtain participation by paying customers. The paper shows that network effects increase not only the mean, but also the variance of the performance metrics used to compensate sales agents.

2 - Salesforce Contracting Under Yield Uncertainty

Tinglong Dai, Assistant Professor, Johns Hopkins University, 100 International Drive, Baltimore, MD, 21202, United States, dai@jhu.edu, Kinshuk Jerath

We consider a scenario in which a firm hires a salesperson to market a product with uncertainty in both demand and supply. We build a principal-agent model of the above situation and study the optimal structure and timing of the contracts, and obtain a number of interesting results. We find that bonus contracts are optimal in both cases, and the bonus may be higher if the yield is lower. Our paper also provides interesting insights into optimal timing of salesforce contracting. For example, we find that when it is difficult to infer marketing effort from observing the sales outcome, it may be in the best interests of the firm to contract with the salesperson before the inventory information becomes available.

3 - Long-term Versus Short-term Contracting With Effort Shifting

Fei Long, Columbia University, New York, NY, United States, FLong18@gsb.columbia.edu, Kinshuk Jerath, Fangruo Chen

We investigate multi-period contracts to understand agents' gaming in terms of effort shifting, and what is a firm's best response. We model a risk-neutral principal employs a risk-neutral agent with limited liability to exert unobservable effort to increase demand over two periods. We find that the principal may find it optimal to use either a short-term plan paying at each period, or a long-term plan paying at the end that concentrates rewards at a single output level. Under limited liability, the latter one provides larger incentives compared to the former, but it suffers from agents' effort shifting. We extend to a case when the inventory is limited and find it makes the short-term plan more preferred.

4 - Who Compensates The Sales Agent?

Duo Shi, PhD Student, Washington University in St. Louis, KH 401, Olin Business School, 1 Brookings Drive, Saint Louis, MO, 63130, United States, dshi@wustl.edu, Panos Kouvelis

We analytically study a value chain consisting of three segments: a manufacturer, a retailer, and a sales agent. Five distinct value-chain structures are considered: an integrated value chain, an integrated distribution channel (the manufacturer and the retailer) compensating the sales agent, non-integrated channels with the manufacturer compensating the sales agent, with the retailer compensating the sales agent, and with joint compensation. We compare the strategic implications across all these value-chain structures.

Socially Responsible Business Models

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Serguei Netessine, INSEAD, Singapore, Singapore, serguei.netessine@insead.edu

1 - To Sell And To Provide? The Economic And Environmental Implications Of The Auto Manufacturer's Involvement In The Car Sharing Business

Ioannis Bellos, George Mason University, ibellos@gmu.edu Mark Ferguson, Beril L Toktay

Motivated by the involvement of Daimler and BMW in the car sharing business we consider an OEM who contemplates introducing a car sharing program. The OEM designs its product line by accounting for the trade-off between driving performance and fuel efficiency. We determine the efficiency of the vehicles offered and we characterize the effect on the OEM's Corporate Average Fuel Economy (CAFE) along with the economic and environmental implications.

2 - Optimal Allocation Rules With Waste Considerations

Sara Rezaee Vessal, HEC Paris, Jouy en josas, France, sara.rezaee-vessal@hec.edu, Sam Aflaki, Dimitrios Andritsos

We study capacity allocation of a scarce and perishable product among stockout-averse retailers that face stochastic demand. We focus on two commonly practiced allocation mechanisms and using a dynamic model characterize the conditions under which each allocation mechanism performs superior from a waste and profit point of view.

3 - Child Labor In Supply Chains: An Empirical Investigation

Sameer Hasija, INSEAD, sameer.hasija@insead.edu, Hsiao-Hui Lee, Niyazi Taneri

Due to increasing globalization, labor malpractices at upstream positions in supply chains directly or indirectly impact many organizations. Moreover, from a social/moral perspective poor labor conditions may have long term adverse effects on society. Lack of visibility in long supply chains hinders our capability in overcoming such issues. In this paper, we generate empirical insights on the drivers of labor malpractices, and child labor in particular.

4 - Philanthropic Campaigns And Customer Behavior: Field Experiments In An Online Taxi Booking Company

Serguei Netessine, INSEAD, 1 Ayer Rajah Avenue, Singapore, 138676, Singapore, serguei.netessine@insead.edu Jasjit Singh, Nina Teng

Companies commonly use philanthropic campaigns to attract and retain customers in the form of charity-linked promotions, where a company donates money to a cause when a customer makes a purchase. Customer-related effects of such promotions remain under-studied, an issue this study investigates using field experiments in an online taxi booking company. Take-up rates for charity-linked promotions were smaller than for discount-based promotions, and also less sensitive to the monetary amount. Although promotion take-up did represent new bookings rather than substitution of non-promotional bookings, there is little evidence of an increase in subsequent purchase frequency.

1 - App Developers' Product Offering Strategies In Multi-platform Markets

Degan Yu, PhD Candidate, University of Rhode Island, Ballentine Hall, 7 Lippitt Road, Kingston, RI, 02881, United States, yudegan@gmail.com

Mobile application (app) developers usually face challenges in deciding product offering choices. In this research we construct an analytical model for product offering problem that app and software developers face in a two-platform environment and the developers offer paid or free app (free app offers advertisement) in each platform. Our findings shed light on some insights into the business practices in industries including mobile apps, computer software, and social media games.

2 - Positive Impact Of Graphical Visualization Of Discussion Forums On Collaborative Learning

Jacqueline Ng, Northwestern University, 2145 Sheridan Road, C-230, Evanston, IL, 60208, United States, jacqueline.ng@u.northwestern.edu, Seyed Iravani

Widespread internet connectivity has increased the popularity of online delivery of course content. With the rise of online courses, e.g., MOOCs, there is an increasing need to create opportunities for learners to interact and exchange ideas. Dynamic online discussion forums can accomplish these goals. We use visualization techniques to design a novel graphical interface for discussion forums that presents posts as nodes and replies as edges connecting nodes. By comparing the effectiveness of graphical and text-based discussion forums, we find that the graphical interface promotes higher levels of both activity and interactivity, creating increased engagement in online discussions.

3 - Public Reactions To Supply Chain Events: A Twitter Sentimental Analysis Event Study

David Wuttke, EBS University, Burgstr. 5, Oestrich-Winkel, 65375, Germany, david.wuttke@ebs.edu, Christoph Schmidt, H. Sebastian Heese

We conduct sentiment analysis on Twitter data to evaluate public reactions to supply chain events.

4 - Effectiveness Of Network-Based Evacuation Warning Dissemination: An Experimental Investigation

Sulian Wang, Tsinghua University, 30 Shuangqing Road, Haidian, Beijing, 100084, China, wangsulian13@mails.tsinghua.edu.cn, Chen Wang

Effective risk communication with the general public plays a vital role in emergency preparedness and response. Spontaneous dissemination of warning messages in the decentralized channel (e.g., through online social network) is shown to be an efficient way of complementing the traditional channels such as television and radio. We model the individual willingness to spread warning messages as a function of their past experiences and trust of the information source, which is determined by both the false positive and false negative rates of historical warnings. We validate our model by lab experiments and simulation.

Applied Probability and Optimization II

Sponsored: Applied Probability

Sponsored Session

Chair: Jiaming Xu, The Wharton School of the University of Pennsylvania, jiamingx@wharton.upenn.edu

1 - Low-rank Estimation: Why Non-convex Gradient Descent Works

Yudong Chen, Cornell University, Ithaca, NY, United States, yudong.chen@cornell.edu

Many problems in statistics involve fitting a low-rank matrix to noisy data. A popular approach to the resulting rank-constrained optimization is SDP relaxation, which does not scale to large problems. We instead consider gradient descent over the low-rank space. This approach is scalable, but convergence was unclear due to non-convexity. We develop a unified framework characterizing its convergence and statistical properties. Our results provide insights to why we expect non-convex methods to work in general, and yield global guarantees for linear convergence in various concrete problems. Our framework handles arbitrary ranks, noise and constraints, and does not require sample splitting.

2 - Scaled Least Squares Estimator For Glms

Murat A. Erdogdu, Stanford University, erdogdu@stanford.edu

We study the problem of efficiently estimating the coefficients of generalized linear models (GLMs) in the large-scale setting where the number of observations n is much larger than the number of predictors p, i.e. n>>p>>1. We show that in GLMs with random design, the GLM coefficients are approximately proportional to the corresponding ordinary least squares (OLS) coefficients.Using this relation, we design an algorithm that achieves the same accuracy as the maximum likelihood estimator through iterations that attain up to a cubic convergence rate, and that are cheaper than any batch optimization algorithm by at least a factor of O(p).

3 - Reinforcement With Fading Memories

Se-Young Yun, Los Alamos National Lab, Los Alamos, NM, United States, yunseyoung@gmail.com, Kuang Xu

Can one make good decisions despite having a faulty memory? We study a continuous-time action-rewards process, where an agent is to select a sequence of actions from a finite set of alternative, and during the period when action k is selected, she accrues discrete rewards according to a Poisson process of rate λ_k. However, each unit of reward randomly "fades" from the agent's memory at rate n^{-1}. We analyse a simple reward matching rule: the new action is sampled from a distribution proportional to the recallable rewards associated with actions chosen in the past.

4 - Social Learning In The Presence Of Adversaries

Lili Su, University of Illinois at Urbana-Champaign, lilisu3@illinois.edu

We focus on the impact of the adversarial agents on the performance of consensus-based non-Bayesian learning. We propose an update rule wherein each agent updates its local beliefs as (up to normalization) the product of (1) the likelihood of the cumulative private signals and (2) the weighted geometric average of the beliefs of its incoming neighbors and itself (using Byzantine consensus). Under mild assumptions on the underlying network structure and the global identifiability of the network, we show that all the non-faulty agents asymptotically agree on the true state almost surely.

Target Setting in Efficiency Analysis

Invited: Data Envelopment Analysis

Invited Session

Chair: Dong Joon Lim, Portland State University, Engineering & Technology Management - Engineering & Computer Science, Maseeh College of (ETM), Portland, OR, 97207, United States, dongjoon@pdx.edu

1 - Study Of Capital Requirement And Bank Operating Efficiency

Yang Li, National University of Kaohsiung, Kaohsiung, Taiwan, yangli@nuk.edu.tw

Following the 2008 financial tsunami, the Bank of International Settlements proposed Basel III in 2010, in which banks need to raise their capital adequacy ratio in order to make them sound and safe. This study employs the two-stage bootstrapped truncated regression model, proposed by Simar and Wilson (2007), and takes into account undesirable outputs to investigate how the increases in core, tier I, and total capital adequacy ratios influence the efficiency of Chinese commercial banks. The data set is obtained from Bankscope for the period 2012-2014. Empirical results are consistent with the schedule and intention set by Basel III.

2 - Inverse DEA With Frontier Changes For New Product Target Setting

Timothy Anderson, Portland State University, Portland, OR, 97201, United States, tim.anderson@pdx.edu, Dong-Joon Lim

Inverse DEA can serve as a useful planning tool by providing information such as how much resources should be invested to achieve a desired level of efficiency. Inverse DEA studies however are based on an assumption that the PPS will not change within the period of interest, which in fact confines the use of inverse DEA to a sensitivity analysis by simply addressing what alternative levels of input/output would have been possible to result in the same efficiency score obtained. In this study, we discuss an inverse DEA problem considering expected changes of the production frontier in the future so that it can be an ex-ante decision support tool for the new product target setting practices.

3 - Evaluating Banker Et Al (2007) Allocative Efficiency Method

Paul Rouse, University of Auckland, p.rouse@auckland.ac.nz

When price information is unavailable, Banker, Chang, & Natarajan (2007) proposed a method to estimate technical and allocative inefficiency using aggregate cost or revenue data. This research replicates their analysis using the same data but supplemented by simulated data. The results show that when using individual firm prices, the Banker et al. (2007) method produces upwardly biased inefficiency measures and appears to misclassify some allocative inefficiency as technical inefficiency. The method does work, however, if uniform prices are known but in that situation, the quantities can then be derived and allocative efficiency calculated in the usual fashion.

4 - Measuring The Efficiency Of Suffolk County School Districts

Diana Hagedorn, Stony Brook University, 14 Orleans Court, Commack, NY, 11725, United States, diana.hagedorn@stonybrook.edu, Herbert F. Lewis, Thomas R Sexton

In this paper, we use an input oriented DEA model to evaluate the performance of 69 school districts in Suffolk County, New York. We then consider merging adjacent school districts to potentially improve efficiency due to economies of scale.

1 - Optimal Portfolio Deleveraging With Cross Asset Price Pressure

Jingnan Chen, Singapore University of Technology and Design, jingnan_chen@sutd.edu.sg, Yufei Yang, Jie Zhang

We study an optimal portfolio deleveraging problem, where the objective is to meet specified debt/equity requirements at the minimal execution cost. During the course of trading, permanent and temporary price impact is taken into account. In particular, we include the cross-asset price pressure which measures the impact on an asset caused by the trading of other assets. Mathematically, the optimal deleveraging problem is formulated as a non-convex quadratic program with quadratic and box constraints. We develop a successive convex optimization algorithm to obtain the optimal deleveraging strategy.

2 - A New Smooth Perturbation Analysis Approach To Sensitivity Analysis For Options With Discontinuous Payoffs

Yanchu Liu, Sun Yat-sen University, liuych26@mail.sysu.edu.cn, Zhijian He, Guangwu Liu

Greeks estimation is one of the most important procedures in financial risk management. Pathwise and likelihood ratio (LR) methods are two classical ways generating unbiased estimates to Greeks. The pathwise method usually has a smaller variance than the LR method. But it typically requires the payoff functions to be (Lipschitz) continuous. This paper proposes a new smooth perturbation analysis (SPA) method that can liberate the Lipschitz continuity requirement on the payoff functions. Our estimator is unbiased and can be easily implemented. Extensive numerical experiments illustrate the advantage of our method.

3 - Catastrophe Option Pricing With Auto-correlated And Catastrophe-dependent Intensity

Guanying Wang, Tianjin University, Tianjin, 300072, China, wangguanyingnk@163.com

A discrete-time pricing model is proposed to investigate catastrophe equity put options with auto-correlated and catastrophe-dependent intensity. Catastrophic events are assumed to occur according to a Poisson process and the intensity is affected by the numbers of catastrophic events that occurred in the past. Stochastic volatility of
the underlying asset is captured by a GARCH process. We derive a pricing formula for catastrophe equity put options and then illustrate effects of the catastrophe intensity on catastrophe equity put option prices.

4 - Option Pricing Under The Price Limits Mechanism: Evidence From China

Xuewei Yang, Nanjing University, xwyang@nju.edu.cn
Ning Cai

We study the effects of the so-called price limits mechnism (PLM) on option pricing. Our setting considers options written on 50-ETF (510050.SH) traded in Shanghai Stock Exchange of China, which is subject to the PLM. Numerical results reveal the implications of PLM on option pricing and hedging.

Revenue Management in the Social Environment

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Ming Hu, University of Toronto, Toronto, ON, Canada, ming.hu@rotman.utoronto.ca

1 - Optimal Pricing In Networks With Latent Agents

Ozan Candogan, Chicago Booth, Ozan.Candogan@chicagobooth.edu, Baris Ata, Alexandre Belloni

We analyze the question of targeted pricing/advertising in social networks, in settings where the platform does not have full information about the underlying network. In particular, we assume that certain agents are latent, and characterize the optimal pricing rule of the platform. We establish that unlike the case with full information, in the presence of latent agents even with symmetric influence structure, using network information can significantly improve the profits of the platform. We then explore how the platform can efficiently learn the optimal prices when the latent component is small when compared to the observable part.

2 - When Do Bidders Anticipate Regret During Auctions? Empirical Evidence From Ebay

A. Serdar Simsek, The University of Texas at Dallas, Richardson, TX, United States, Serdar.Simsek@utdallas.edu, Ozalp Ozer, Meisam Hejazi Nia

We developed a structural model that accounts for bidders' learning and their anticipation of winner and loser regrets in auctions. Using a large data set from eBay, we quantify in which product categories bidders anticipate regret and show how our results can be used to increase eBay's revenue significantly

3 - Optimal Pricing In Social Networks Under Asymmetric Information

Yang Zhang, Tsinghua University, yangzhanguser@mail.tsinghua.edu.cn, Ying-ju Chen

We study the optimal pricing of products / services in social networks, where customers are strategic and their consumptions exhibit local externality. Our model concerns the information asymmetry — Consumers know about their local network characteristics while the selling firm has only knowledge of global network. The network model we employ embeds random network and scale free network as special cases. We characterize the optimal menu for the firm, the induced sales, and their properties with regard to the network structure.

Decision Analysis Arcade I

Sponsored: Decision Analysis

Sponsored Session

Chair: Joshua Woodruff, University of Texas, Austin, TX, United States, joshua.woodruff@utexas.edu

1 - Assessment Of Drug Development Options: If, When And How Much?

Ozgur Ozkan, Decision Science Director, Astrazeneca Pharmaceuticals, Gaithersburg, MD, United States, Ozgur.Ozkan@astrazeneca.com

New approaches in clinical trial design and changing regulatory and payer environment make it a challenging task to compare different drug development paths. We will describe a modeling approach to assess different options in time, risk and value dimensions. This will cover uncertainties around success measures, clinical trial timelines and market share expectations. Ideas of eliciting information from subject matter experts as well as combining expert opinion with statistical estimates will be shared. The talk will also reflect on our experience of utilizing different metrics and visualizations to communicate with stakeholders.

2 - Optimal Discretization For Decision Analysis

Joshua Woodruff, University of Texas, joshua.woodruff@utexas.edu

Optimal discretization is a new method to discretize uncertainties. By using optimization techniques to discretize uncertainties, it is possible to create robust discretizations that are more accurate. Our method produces more accurate project certain equivalents which will improve decision quality. We use non-linear optimization to select and assign probabilities to candidate percentiles for each model uncertainty. With optimal discretization we found we can use the model information and potential distributions of the uncertainties to find discretizations that yield certain equivalent errors that can be orders of magnitude better than other discretization methods we tested.

3 - Network Interdiction In Competitive Market Entry And Product Design

Benjamin Harris, Northeastern University, 360 Huntington Avenue, Boston, MA, 02115, United States, harris.be@husky.neu.edu, Sagar S Kamarthi

Optimal strategy for product design in the Internet of Things (IoT) must consider input beyond that of stakeholders and customers and include the highly connected infrastructure on which the product will be released. Firms involved in the IoT need to develop strategy and risk mitigation techniques and remain competitive. This research will enable firms to identify optimal strategies under current requirement and market conditions, as well as analyze changes in strategy if a requirements space is changed. As a result, product designers and firm leadership can anticipate and respond to market and industrial changes with increased fidelity and predictive power through network model insights.

Optimization via Simulation under Input Uncertainty

Sponsored: Simulation

Sponsored Session

Chair: Eunhye Song, Northwestern University, 2145 Sheridan Road, Evanston, IL, 60208, United States, eunhyesong2016@u.northwestern.edu

1 - Data-driven Construction Of Uncertainty Sets For Joint Chance-constrained Programs

Jeff Hong, City University of Hong Kong, jeffhong@cityu.edu.hk Henry Lam, Zhiyuan Huang

We study the use of robust optimization (RO) in approximating joint chance-constrained programs (CCP), in situations where only limited data, or Monte Carlo samples, are available in inferring the underlying probability distributions. We introduce a procedure to construct uncertainty set in the RO problem that translates into provable statistical guarantees for the joint CCP. This procedure relies on learning the high probability region of the data and controlling the region's size via a reformulation as quantile estimation. We show some encouraging numerical results.

2 - Asymptotics Of Risk Formulations For Simulation Optimization Under Input Uncertainty

Di Wu, Georgia Institute of Technology, Atlanta, GA, United States, dwu80@gatech.edu, Enlu Zhou

Input distributions are the distributions (of stochastic uncertainty) that drive a simulation process. Since input distributions are usually estimated from finite data, optimizing the model may yield solutions that perform poorly under the true input distributions. To hedge against the risk of input uncertainty, we minimize the risk measures of mean output with respect to the unknown parameters' posterior distribution. We establish the consistency and the asymptotic normality of risk formulations, and show that when the input data has a small size, the risk formulations are essentially seeking a tradeoff between average performance and the risk of actual performance.

3 - An Optimization-based Approach To Input Uncertainty Via The Empirical Likelihood

Henry Lam, University of Michigan, khlam@umich.edu Huajie Qian

We study a simulation-optimization-based approach in constructing statistically accurate confidence bounds for stochastic simulation under nonparametric input uncertainty. This approach utilizes the empirical likelihood method that converts the computation of confidence bounds into a pair of optimizations over the uncertain input distributions, with a suitable weighted-average divergence constraint calibrated with a chi-square quantile. We present the theory giving rise to the constraint and the calibration, and compare the performance of our optimization algorithm with existing standard methods such as the bootstrap.

4 - Leveraging The Common Input Data In Comparisons Of Systems Under Input Uncertainty

Eunhye Song, Northwestern University, Evanston, IL, United States, eunhyesong2016@u.northwestern.edu, Barry L Nelson

This talk focuses on a discrete optimization via simulation problem when all systems share the same input models estimated from common input data. Standard methods that are conditional on the estimated input models may not provide the target correct-selection inference, exposing the user to unmeasured model risk. We define the common-input-data (CID) effect as the joint impact of input uncertainty due to the common distribution on each system's outputs. The proposed procedure incorporates input uncertainty by leveraging the CID effect and is proven to provide the desired inference asymptotically under mild conditions.

Chair: Joline Uichanco, University of Michigan, Ross School of Business, Ann Arbor, MI, United States, jolineu@umich.edu

1 - Minimum Advertised Pricing Policy: An Economic Analysis

Ozge Sahin, Johns Hopkins University, ozge.sahin@jhu.edu
Liang Ding, Roman Kapuscinski

During last twenty years, many brick-and-mortar retailers face competition from online retailers and local discounters. Customers are able to experience products in a brick-and-mortar store but purchase online for lower prices. As a result, brick-and-mortar retailers' sales decrease and they stop promoting or carrying such products. For manufacturers, however, brick-and-mortar retailers play a crucial role by showcasing and advertising products to customers. In this paper, we build a stylized model to study and compare the performance of common price restraining policies.

2 - Omni-channel Revenue Management Through Pricing And Fulfillment Planning

Joline Uichanco, University of Michigan, Ann Arbor, MI, United States, jolineu@umich.edu
Pavithra Harsha, Shivaram Subramanian

In an omni-channel environment, inventory is shared across channels through multiple fulfillment options. We present a tractable optimization model to determine optimal lifecycle channel prices, inventory allocations and partitions across channels that maximizes the total chain level profit. This solution was tested in a production pilot setting and demonstrated a 6% increase in markdown revenue over current practices across the categories analyzed.

3 - Cash-on-delivery In Emerging Markets: An Empirical Study

Richard Zhiji Xu, Kellogg School of Management, Northwestern University, Evanston, IL, United States, zhiji-xu@kellogg.northwestern.edu, Antonio Moreno-Garcia, Chaithanya Bandi

Cash-on-delivery (COD), the payment method where customers pay for the products in cash at the time of delivery, is widely used in online retailing in developing countries. Using a unique data set from a leading online fashion retailer in India, we study the impacts of COD on pricing strategies, firm revenue, and other operational consequences.

4 - Inventory Optimization For Fulfillment Integration In Omnichannel Retailing

Aravind Govindarajan, University of Michigan, 701 Tappan Street, Ann Arbor, MI, 48109, United States, arav@umich.edu, Amitabh Sinha, Joline Uichanco

Omnichannel refers to the seamless integration of a retailer's channels such as brick-and-mortar and e-commerce. Using analytical models, we study three basic omnichannel fulfillment models varying in the level of integration between in-store and online demands. We obtain optimal order-up-to quantities for the single period, two-store problem, and extend our analyses to the multi-store setting, developing an asymptotically optimal heuristic which provides significant cost savings over current practice. We then numerically study the effects of cost and demand parameters on the choice of fulfillment structures. Finally, we discuss extensions to the multi-period setting under lost sales.

New Revenue Management Practices in Airline and Hotel Industries

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Ovunc Yilmaz, University of South Carolina, Columbia, SC, United States, oyilmaz@email.sc.edu

Co-Chair: Mark Ferguson, University of South Carolina, Columbia, SC, United States, mark.ferguson@moore.sc.edu

1 - Dynamic Pricing With A Fare-lock Option

Zhi-Long Chen, University of Maryland, Robert H Smith School of Business, Dept of Decision, Operations & Info Tech, College Park, MD, 20742-1815, United States, zchen@rhsmith.umd.edu
Ming Chen

We study a relatively new revenue management practice frequently seen in the airlines industry where customers have the option to lock a fare at a small fee for a certain period of time. The free 24 hour cancellation policy enforced by DOT can be viewed as a special case of this problem. This provides a valuable option for those undecided travelers when finalizing their travel plans. We investigate the implications of such practice on both the airlines and the passengers, as well as the resulting pricing policies.

2 - You Are Eligible For An Upgrade: A Critical Look At Hotel Standby Upgrades

Ovunc Yilmaz, PhD Student, University of South Carolina, Columbia, SC, United States, oyilmaz@email.sc.edu
Mark Ferguson, Pelin Pekgun

Standby upgrades, where the guest is only charged if the upgrade is available at the time of arrival, is one technique that has become increasingly popular in the hotel industry. Working on a data set from a major hotel chain, we analyze the guest decision-making process for these upgrades.

3 - The Rise Of The Sharing Economy: Estimating The Impact Of Air BnB On The Hotel Industry

Davide Proserpio, Boston University, dproserp@cs.bu.edu

In this paper we study Air BnB and its entry into the short-term accommodation market in Texas. We first explore Air BnB's impact on hotel room revenue, and show that in Austin, where Air BnB supply is highest, the impact on hotel revenue is in the 8-10% range; moreover, the impact is non-uniformly distributed, with lower-priced hotels and those hotels not catering to business travelers being the most affected. We then examine seasonal effects and provide evidence that the flexibility of Airbnb supply impacts hotels disproportionately during high season, limiting their pricing power.

4 - Price Volatility And Market Performance Measure: The Case Of Revenue Managed Goods

Benny Mantin, University of Waterloo, benny.mantin@uwaterloo.ca, Eran Rubin

The airline industry has embraced revenue management practices which are manifested through frequent updates to posted airfares. When shopping for the lowest available fare, consumers are exposed to volatile prices. Different routes exhibit substantially different volatility levels of the lowest available fare. We quantify the relation between these volatility levels and performance metrics such as sales and revenue at the route level using US domestic aviation markets.

New Insights from Social Media: Empirical Study, Field Experiment, and Algorithm Development

Invited: Social Media Analytics

Invited Session

Chair: Yen-Yao Wang, Michigan State University, 632 Bogue Street, Room N204, Okemos, MI, 48824, United States, wangyen@broad.msu.edu

1 - Social Media Engagement, Product Evaluations, And Demand Spillover In The Automobile Industry

Yen-Yao Wang, Michigan State University, wangyen@broad.msu.edu, Anjana Susarla, Roger Calantone, Yingda Lu

Online Word of Mouth (WOM) is an important aspect of consumer-firm relationship and a leading indicator of product performance. However, prior research focuses considerably on the static view of it. This paper examines the dynamics of the spillover effects in online WOM in the US automobile industry. To measure online WOM, we focus specifically on customers' test drive experience. We collected data from around 1000 different social media platforms for 32 car brands from 2009 to 2015. We used a Bayesian modeling framework and estimated the model using Markov Chain Monte Carlo (MCMC) methods.

2 - The Dark Side Of Positive Social Influence

Che-Wei Liu, University of Maryland, College Park, MD, Un ited States, cwliu@rhsmith.umd.edu, Ritu Agarwal, Guodong (Gordon) Gao

Social influence has been widely used to transform behaviors. However, when individuals are pressured to conform to behavior of the majority, would it lead to an unexpected backfire effect? We conducted a randomized field experiment of more than 10,000 individuals for a two-month period on an online physical activity community to examine the dark side of social influence. We studied the effect of social norms on users' goal setting and goal achievement behavior. While social influence increased the rate of goal setting, strikingly, we also observe the dark side of social influence. Our findings have important implications for the design of interventions in the context of mHealth technologies.

3 - Influencers In Social Media – An Assessment Of Algorithmic Approaches In Big Data Environments

Shih-Hui Hsiao, Lawrence Technological University, Southfield, MI, United States, suade0904@msn.com, Ram Pakath

Growing social media usage, accompanied by explosive growth in related Big Data, has resulted in increasing interest in finding automated ways of discovering influencers (i.e., opinion leaders) in online social interactions. Beginning 2008, about two dozen variants of six basic approaches have been proposed. Yet, there is no comprehensive study investigating the relative efficacy of these methods in specific settings. We investigate and report on the relative performances of 15 methods on 9 twitter data sets ranging in size from tens of thousands to hundreds of thousands of tweets.

4 - Natural Language Processing: From Text Mining To Social Media Analysis

Chih-Hao Ku, Assistant Professor, Lawrence Technological University, 21000 W 10 Mile Rd, M309A, Southfield, MI, 48331, United States, cku@ltu.edu, Yung-Chun Chang

Today, the number of digital reports, e.g., crime reports and social media data derived from Twitter, LinkedIn, and Facebook are growing rapidly. However, this immerse amount of digital data post challenges and opportunities for data analysis. The rise of social media has drawn interest on text mining and social media analysis, e.g., sentiment analysis. Natural language processing (NLP) is an important component for those analyses. We report here on research work on text mining, sentiment analysis, and future trend using NLP techniques.

Estimating Sentiments Using Social Media

Invited: Social Media Analytics

Invited Session

Chair: Subodha Kumar, Mays Business School, Texas A&M University, 301-F, Wehner, 4217 TAMU, Mays Business School, College Station, TX, 77843, United States, skumar@mays.tamu.edu

1 - The Effects Of Social Media Sentiment On Engagement

Rakesh Reddy Mallipeddi, Mays Business School, Texas A&M University, College Station, TX, United States, rmallipeddi@mays.tamu.edu, Ramkumar Janakiraman, Subodha Kumar, Seema Gupta

In this study, we propose an econometric model to examine the drivers of social media engagement. Set in the context of national elections, we examine the impacts of tweeting behavior of the candidates contesting in an election on the social media engagement with their constituents. To meet our objectives, we assemble a novel candidate-level data of social media engagement.

2 - The Effect Of "online following" On Contributions To Open Source Communities

Xiaowei Mei, University of Florida, xiaowei.mei@warrington.ufl.edu, Mahdi Moqri, Liangfei Qiu, Subhajyoti Bandyopadhyay

We estimate the effect of "online following," a basic form of online social interaction, on members' contributions in open source software (OSS) communities. We employ a panel vector autoregression model using individual level data across time in GitHub to achieve identification of causal effects, while controlling for individual heterogeneity and time effects. We find that the following behavior of others has a significant positive effect on users' contribution level to the platform even after controlling for the aforementioned factors. On the other hand, users' contribution level also has a significant positive effect on their following behavior.

3 - Manipulation For Competition: An Empirical Investigation Of Click Farming

Jingchuan Pu, University of Florida, jingchuan@ufl.edu Liangfei Qiu, Hsing K Cheng

Anytime there's a monetary value added to clicks, there's going to be people going to the dark side. This research focuses on the economic incentive of the click farming, a popular form of click fraud which is widely conducted by sellers or content generators. We cooperate with a website that uses an algorithm to detect the robot or unreal viewing activity, a black list is built for the suspicious user account which may be used as click farming. Using the detection results as a proxy of the content generators' click farming activity, we test the impact of potential incentive, like the status of this content, content generator and the competition environment on the content generators' click farming activity.

Pricing and Revenue Management Applications

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: N. Bora Keskin, Duke University, Durham, NC, United States, bora.keskin@duke.edu

1 - Pricing Reservations: Dealing With No-shows

Jaelynn Oh, University of Utah, jaelynn.oh@business.utah.edu

We study two remedies to deal with reservation no-shows: charging no-show fees and price discrimination. We also study how to allocate capacity between reservations and walk-ins.

2 - Trade Credit And Lifetime Value Of A Newsvendor Buyer

Meisam Soltani-koopa, Queen's University, Kingston, ON, Canada, 15msk3@queensu.ca, Yuri Levin, Mikhail Nediak, Anton Ovchinnikov

Trade credit typically appears as a grace period for invoice payment. It helps retailers overcome temporary cash shortages as an alternative to seeking financing from banks. We consider a supply chain with one supplier and one repeated newsvendor retailer where the supplier maximizes its long-term profit by offering the retailer a financing and wholesale price contract. In each period, the retailer decides about the quantity to order and the amount of money to borrow from the supplier or a bank. We study the lifetime value of the retailer using a dynamic Stackelberg game, from the perspective of the supplier who, as a leader, takes into account the long-term view of its relationship with the retailer.

3 - Asymptotically Optimal Markdown Policies For Demand Learning

Hongfan Chen, University of Chicago, hongfan.chen@chicagobooth.edu, N. Bora Keskin

Consider a firm selling a product to a population of customers with heterogeneous valuations. In this setting, we develop guidelines for designing markdown policies and derive asymptotically optimal performance guarantees. (Joint work with Bora Keskin)

Service Innovation in the Cognitive Era

Invited: Service Science

Invited Session

Chair: Changrui Ren, IBM Research - China, IBM Research - China, Beijing, 100193, China, rencr@cn.ibm.com

1 - Enterprise Cloud Garbage Collector

Sai Zeng, IBM T.J. Watson Research Center, Yorktown Heights, NY, United States, saizeng@us.ibm.com, Christopher Young, Karin Murthy

Infrastructure as a Service (IaaS) clouds empowers the agility to provision servers. Recent findings indicate that this agility led to a situation where 1 in 3 data center servers is a zombie server, aka server is running but does not do any useful work. In this paper, we present Enterprise Cloud Garbage Collector, a tool that detects zombie severs. It establishes dependency between users/clients and servers by constructing a weighted reference model based on application knowledge. In the situation of insufficient application knowledge, it supplements its dependency results with a machine learning model trained on resource utilization data.

2 - Big Data Fueled Supply Risk Management: Sensing, Prediction, Evaluation And Mitigation

Changrui Ren, IBM Research - China, Beijing, China, rencr@cn.ibm.com, Miao He, Qinhua Wang

Supplier risks jeopardize on-time or complete delivery of supply in a supply chain. This talk will introduce a big data fueled approach to monitor and manage supply risks, which includes a big data analytics component, a simulation component and an optimization component. The big data analytics component senses and predicts supply disruptions with internally (operational) and external (environmental) data. The simulation component supports risk evaluation to convert predicted risk severity to key performance indices (KPIs) such as cost and stockout percentage. The optimization component assists the risk-hedging decision-making.

Inventory Management II

Contributed Session

Chair: Heinrich Kuhn, Catholic University of Eichstaett-Ingolstadt, Auf der Schanz 49, Ingolstadt, 85049, Germany, heinrich.kuhn@ku.de

1 - Base-stock Models For Lost Sales - A Markovian Approach

Sang-Phil Kim, Assistant Professor, Winona State University, 175 W. Mark st., Somsen 406, Winona, MN, 55987, United States, Ksphil@me.com, Yanyi Xu, Maqbool Dada, Arnab Bisi, Suresh Chand

We consider the lost sales model with discrete demand. The inventory is reviewed every T periods and an order is placed to bring the inventory position back to the target base-stock level R, and is received after a lead time of L periods. Based on the outstanding orders in the pipeline, we represent the state of the system as a Markov chain. We show that the structure of the transition probability matrix is recursive in R and L. This special structure is used to facilitate computation of the stationary distribution. Analytical results complemented by numerical examples reveal that neither the optimal base-stock nor the expected cost is monotone in L for a given T.

2 - Capacity Usage Estimation Methodology For Inventory Management

Ahmet Nuroglu, Yildiz Technical University, Barbaros Bulvari, Yildiz-Istanbul, 34349, Turkey, envernuroglu@gmail.com, Fahrettin Eldemir

New analytical capacity usage estimation methodology for economic order quantity (EOQ) model is proposed. In multiple item warehouse-space capacity constrained EOQ model, by applying the randomized storage concept, capacity usage is estimated from expected inventory occurrences instead of order quantities. In joint replenishment problem under power of two (PoT) policy, the capacity usage is estimated from average inventory occurrences which are the function of PoT parameter of each item. The feasible optimal solutions are simulated and validated.

3 - An Inventory Model With Fuzzy Demand In a Two-echelon Supply Chain Management: Drug Distribution In Hospital Pharmacy

Parisa Jannatifard, graduate Student and teacher assistant, Southern Illinoise University Edwardsville, Edwardsville, IL, 62026, United States, pjannat@siue.edu, Javad Sadeghi

This paper develops an inventory model with fuzzy demand regarding the vendor managed inventory (VMI) policy. In recent past few decades, VMI policies have been used in modeling inventory problems. The vendor's warehouse has a capacity constraint while a vendor supplies several products to retailers. This policy reduces total costs in healthcare system like drug distribution in hospital pharmacy. The aim of this paper is to find a near optimal solution including order quantities for vendor and retailer and replenishment frequencies to minimize the total cost with a metaheuristic algorithm.

4 - Inventory Pooling And Transshipment Under Correlated Fat-Tail Demands

Zhen Liu, Numerix LLC, 1237 Bristol Ln, Buffalo Grove, IL, 60089, United States, zhenliu@alum.northwestern.edu

We study the classic inventory pooling problem by Eppen (1979) under a special class of multivariate fat-tail distribution: Normal Inverse Gaussian (NIG) demands to better fit real-world demand data. We obtain the optimal inventory level in a closed form by employing standardized NIG density function, and express the optimal expected costs in terms of unit NIG loss function. Rather than independent and identically distributed demands, our results complement Bimpikis and Markakis (2015) by considering correlated demands. We further discuss the transshipment problem of Dong and Rudi (2004) under NIG demands.

5 - Cyclic Vs. Static Inventory Policy Assumptions When Optimizing Case-pack Sizes In Grocery Retailing

Heinrich Kuhn, Catholic University of Eichstaett-Ingolstadt, Auf der Schanz 49, Ingolstadt, 85049, Germany, heinrich.kuhn@ku.de, Thomas Wensing, Michael Sternbeck

We analyze two possible approaches quantifying the optimal case-pack (CP) size in retail distribution systems. One approach assumes a cyclic inventory policy taking into account the weekly seasonality of product demands. The other approach assumes an equal demand distribution on each day of the week, i.e., assuming a stationary inventory policy. The general assumptions of a periodic review reorder inventory policy, i.e., (r, s, nq) policy, are assumed. We conduct several experiments analyzing the question under what circumstances both approaches achieve equal results.

1 - Data-driven Optimization: Revenue Analytics For A Supply-side Network Via Traffic-stream Mixing

Zhen Sun, University of Texas-Dallas, 800 west campbell rd, Richardson, TX, United States, zhen.sun@utdallas.edu, Milind Dawande, Ganesh Janakiraman, Vijay S Mookerjee

This study develops a data-driven approach to solve constrained optimization problems in which the decision maker does not have an analytic form for the objective function, but knows what decision variables affect the function. Our approach comes with a worst-case performance guarantee that improves with the characteristics (size, pervasiveness) of the available data. We apply our technique to a traffic-stream mixing problem encountered by a supply-side internet advertising network that wishes to optimize the click revenue earned from ads.

2 - Cardinality Bundles With Complex Costs

Jianqing Wu, Foster School of Business, University of Washington, Seattle, WA, United States, fisherwu@uw.edu, Mohit Tawarmalani, Karthik Kannan

This paper studies pricing of cardinality bundles (CB) when bundling involves complex costs. When implementing CB, a firm set prices on the sizes of bundle and lets consumers choose specific products based on bundle sizes. The basic model of CB is analyzed in Wu et al. (2016). In this paper, we first extend the existing CB model to allow fixed costs in adding additional bundles. We show that CB problem with fixed costs can be solved as a shortest-path problem. We then extend the CB model in another way to solve CB problem with submodular cost structure. Such analysis is especially useful when there exists economies of scale in production.

4 - An Economic Analysis Of The Impact Of Recommender Systems On Product Search

Abhijeet Ghoshal, University of Louisville, abhijeet.ghoshal@louisville.edu, Vijay M. Mookerjee, Sumit Sarkar

We perform an economic analysis of firms providing recommendation services considering the influence of recommendations on the search process of customers. We determine the price and recommendation system effectiveness equilibrium and analyze how the equilibrium shifts when costs of recommendations change.

Experiments in Supply Chain Management

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Andrew M. Davis, Cornell University, Ithaca, NY, United States, adavis@cornell.edu

1 - Experimental Evidence On Post-choice Forecasting Bias: Do Optimizers Know They're Cursed?

Jordan Tong, University of Wisconsin, jtong@bus.wisc.edu

Choose the best alternative and predict its outcome. We find that people tend to be too optimistic in such post-choice forecasting tasks. This tendency has important implications. For example, it suggests that managers who pick products to include in assortments tend to forecast higher demand and order more inventory than managers who don't pick. We develop a behavioral model to help explain the phenomenon and provide supporting experimental evidence in three settings: guessing the number of pennies in jars, forecasting and making inventory decisions for products, and estimating sales prices of houses. Finally, we study factors that exacerbate the bias and possible ways to mitigate it.

2 - Firm Objectives And Managers' Pricing Decisions: Theory And Experiments

Rashmi Sharma, Penn State University, rashmi.sharma@psu.edu, Saurabh Bansal, Elena Katok

In this paper we develop a model to determine what compensation plan a firm should offer to managers who make pricing decisions under price-responsive, uncertain demand. We show that the structure of the compensation plan depends on the firm's objective function. We then report the results of a behavioral experiment to test the model's predictions.

3 - Multidimensional Bargaining In Supply Chains: An Experimental Study

Kyle Hyndman, University of Texas at Dallas, kyleb.hyndman@utdallas.edu, Andrew M. Davis

We experimentally investigate the impact of bargaining and the allocation of inventory risk on the performance of a two-stage supply chain. We show that when allowing the parties to bargain over all contract terms simultaneously, observed supply chain efficiencies are at least 90%, which are considerably higher than those seen in past studies. Second, contrary to the theoretical prediction, the party incurring the inventory risk always earns a substantially lower profit than the other party. Third, a win-win situation is created when all contract terms are simultaneously negotiated.

4 - Group Identity To Manipulate Social Preferences In Sales And Operations Planning

Felix Papier, Associate Professor, ESSEC Business School, 3 Av Bernhard Hirsch BP 50105, Cergy Pontoise Cedex, France, papier@essec.edu, Ulrich Thonemann, Torsten Gully

We analyze a supply chain in which a demand planner provides demand forecasts to a production planner. The production planner needs information about the forecast accuracy. If the actual effort of the demand planner and the belief of the production planner are not aligned, the supply chain performance suffers. We develop a game theoretic model to show how social preferences affect the alignment between the two supply chain actors. Using lab experiments we find that some demand planners invest effort, and that production planners anticipate this effort. We further show that group identity can increase social preferences, which ultimately leads to higher supply chain profit.

1 - Electricity Resource Capacity Expansion With Distributed Energy Resources: A New MILP Formulation

Jesse D Jenkins, PhD Candidate, Massachusetts Institute of Technology, Cambridge, MA, 02139, United States, jessedj@mit.edu

Conventional electricity capacity expansion models do not properly consider distributed energy resources (DERs), including distributed generation, storage and demand response. DERs provide locational benefits—e.g. loss mitigation, congestion relief, network capacity deferral—which must be considered along with the costs of different unit scales. In this new MILP formulation, conventional generation and DER investments are made across several transmission zones and distribution voltage levels subject to power flow constraints, network reinforcement costs, losses, and operational constraints capturing reserves, ramp rates, and unit commitment constraints for thermal generators.

2 - Price Projections For Ancillary Services Markets Under Hypothetical Future Scenarios

Todd Levin, Energy Systems Engineer, Argonne National Laboratory, 9700 S. Cass Ave, Bldg 362, Lemont, IL, 60439, United States, tlevin@anl.gov, Zhi Zhou

We forecast broad future ancillary service price trends in U.S. power markets by first identifying a set of key parameters that influence prices. Baseline models are then developed and calibrated based on historical data and current regional characteristics. We then utilize AURORAxmp to model hourly dispatch in each region and forecast the impact of changes in these inputs, such as electricity demand, fuel prices, renewable penetration levels, and availability of AS supply. Finally, we identify correlations to broadly project price trends under hypothetical future scenarios, e.g. increased wind penetration, decreased natural gas prices, and increased supply of flexible generation resources.

3 - An Efficient Integer L-shaped Method For A Two-stage Self-healing Power Grid Problem

Amir Golshani, PhD Candidate, University of Central Florida, Orlando, FL, United States, amir.golshani@knights.ucf.edu, Wei Sun, Qipeng Zheng

When a power system enters an emergency state, the self-healing process is initiated by system operators to bring the system back to its normal condition. This presentation proposes a two-stage self-healing optimization problem with a set of practical constraints containing integer variables in both stages. To solve the proposed problem, the integer L-shaped algorithm together with an efficient optimality cut based on the physical characteristics of power system will be presented. Standard IEEE test system is used to demonstrate the effectiveness of the proposed algorithm and optimality cut.

4 - Toward Cost-efficient And Reliable Unit Commitment Under Uncertainty

Hrvoje Pandzic, Faculty of Electrical Engineering and Computing University of Zagreb, Unska 3, Zagreb, 10000, Croatia, hrvoje.pandzic@fer.hr, Yury Dvorkin, Ting Qiu, Yishen Wang, Daniel Kirschen

This presentation will describe a new improved interval unit commitment formulation that combines some aspects of stochastic and interval formulations. A systematic and rigorous assessment of the cost and reliability performance of the improved interval, interval, stochastic and robust unit commitment will be demonstrated as well.

5 - Price Instability In Multi-unit Auctions

Par Holmberg, Associate Professor, Research Insitute of Industrial Economics (IFN), Grevgatan 34, Stockholm, SE10215, Sweden, par.holmberg@ifn.se, Edward James Anderson

We consider a uniform-price procurement auction with indivisible units and private costs. We solve for a Bayesian Nash equilibrium and show that the equilibrium has a price instability in the sense that a minor change in a supplier's realized cost can result in a drastic change in the market price. The price instability is reduced as the size of indivisible units decreases for a given total production capacity. In the limit, where the size of units approaches zero and costs are almost surely common knowledge, the Bayesian equilibrium converges to a pure-strategy NE without price instability, the Supply Function Equilibrium (SFE).

Freight Network Design

General Session

Chair: James F Campbell, University of Missouri-St Louis, Saint Louis, MO, TBD, United States, campbell@umsl.edu

1 - Strategic Design For Delivery With Drones And Trucks

James F Campbell, University of Missouri-St Louis, St. Louis, MO, United States, campbell@umsl.edu, Donald C. Sweeney II, Juan Zhang

Our research develops continuous approximation models for the strategic design of drone and hybrid truck-drone delivery systems. We consider aerial and ground-based drones that can be launched from fixed or relocatable facilities, or from trucks. In contrast to discrete VRP-based optimization models, we treat the demand for deliveries as a continuous spatial density over a region. Analytical results and illustrations assess the economic and service performance from using the best mix of drones and trucks, and provide strategic managerial insights. Results show how using drones in conjunction with trucks alters the optimal delivery strategy and can facilitate lower cost and faster deliveries.

2 - A Quantitative Model For Truck Parking And Hours Of Service Regulations

Sarah G Nurre, University of Arkansas, 425 W. Louise Street, Fayetteville, AR, 72701, United States, snurre@uark.edu

Truck parking and hours-of-service (HOS) regulations are consistently reported as two of the top concerns in the trucking industry. Parking shortages are a function of inadequate capacity and changes to HOS regulations requiring drivers to stop frequently and for longer periods. We develop a network-based optimization model which determines the best times and locations for stopping along a set of truck routes while adhering to system-wide HOS regulations, network, and scheduling constraints. We present the results and insights deduced from experiments run using historical truck route data.

Methodological Advances and Empirical Discoveries in Travel and Activity Choice Modeling

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Sayeeda B. Ayaz, UMass Amherst, UMass Amherst, Amherst, MA, 01003, United States, sbayaz@engin.umass.edu

1 - Bike Route Choice Modeling Without Choice Sets Of Paths: Estimation, Prediction And Accessibility Measure

Maelle Zimmermann, Université de Montreal, maelle.zimmermann@gmail.com

We estimate a link-based bike route choice model in a real network which does not require to sample any choice set of paths, similar to the recursive logit (RL) model formulated by Fosgerau (2013). We provide numerical estimation results, and we show the advantages of this approach in the context of prediction by focusing on two applications of the model: i) simulation of bike traffic flows; ii) measuring bike accessibility. Compared to the path-based approach which requires to generate choice sets, the RL model proves to make significant gains in computational time and to avoid paradoxical results discussed in previous works, e.g. in Nassir (2014).

2 - A Random Utility Based Estimation Framework For The Household Activity Pattern Problem

Zhiheng Xu, University at Buffalo, Buffalo, NY, United States, zhihengx@buffalo.edu, Jee Eun Kang, Roger Chen

We develop an estimation framework for the Household Activity Pattern Problem (HAPP) based on random utility theory. The estimation procedure is based on the realization that travelers' complex activity-travel pattern decisions form a continuous path in space-time. The proposed framework is comprised of choice set generation, choice set individualization, and multinomial logit estimation procedures.

3 - Looking-ahead Route Choice Behavior Based On Driving Simulator And Pc-based Experiments

Sayeeda B. Ayaz, University of Massachusetts Amherst, Marston 139, 130 Natural Resources Rd, Amherst, MA, 01003, United States, sbayaz@engin.umass.edu, Hengliang Tian, Song Gao, Donald Fisher

We study drivers' route choice behavior with real-time traffic information based on driving simulator and PC-based experiments. A looking-ahead route choice refers to a decision taking into account future diversion possibilities at downstream nodes based on real-time information not yet available at the time of decision-making. A mixed Logit model with two latent classes, myopic and looking-ahead route choice, is specified and estimated. Factors influencing looking-ahead behaviors such as information bias, experience, network complexity, and cognitive load are studied.

4 - The Initial Condition Problem With Complete History Dependency In Learning Models For Travel Choice

Yue Tang, UMass Amherst, yuet@umass.edu

Missing initial observations in longitudinal data can lead to inconsistent parameter estimates in learning models for travel choice due to the complete history dependency of choices of such models. This study proposes the maximum simulated likelihood (MSL) and multiple imputation (MI) methods to address this problem, and examines their efficacy and efficiency using an instance-based learning (IBL) model. Monte Carlo simulations with synthetic data are carried out to verify that the true parameter values are retrieved. An experimental dataset of repeated binary route choice is used to illustrate the empirical applicability of the methods.

Rail Safety and Risk

Sponsored: Railway Applications

Sponsored Session

Chair: Xiang Liu, Rutgers, The State University of New Jersey, Piscataway, NJ, United States, xiang.liu@rutgers.edu

1 - Analysis Of Railroad Accident Investigation Reports Using Probabilistic Topic Models And K-means Clustering

Trefor Williams, Rutgers University, New Brunswick, NJ, United States, tpw@rci.rutgers.edu, John Betak

Railroad accident investigation reports from the National Transportation Safety Board in the United States and the Transportation Safety Board of Canada were analyzed using Latent Dirichlet Allocation (LDA) and k-means clustering. The analysis suggests that recurring accident themes are track defects, wheel defects, grade crossing accidents, signaling issues, train crew fatigue and switching accidents. The Canadian analysis additionally highlighted accidents related to bridges and track drainage. The LDA analysis of the accident reports will also be contrasted with the results from an LDA analysis of the text fields of the FRA Railroad Equipment Accident database.

2 - Statistical Modeling Of Freight Train Accident Estimation

Zhao Wang, University of Illinois at Urbana - Champaign, Urbana, IL, United States, zwang144@illinois.edu

Accurate train accident rate estimation is critical in railway safety and risk management. In current methodology, the accident rate estimation methodology is based on a single exposure variable and could be improved. Utilizing statistical distribution modeling methods, a new train rate predictive model is build that accounts for more complex factors.

3 - Simulation-based Risk Analysis Model For Optimizing Rail Flaw Inspection Frequency

Xiang Liu, Rutgers University, xiang.liu@rutgers.edu

A simulation based risk analysis model is developed to quantify broken rail caused derailment risk on U.S. freight railroads. The model can be used to determine optimal inspection and maintenance scheduling.

Market Structure, Competition and Constraints in the Airline Industry

Sponsored: Aviation Applications

Sponsored Session

Chair: Martin E Dresner, University of Maryland-College Park, R H Smith School of Business, College Park, MD, 20742, United States, mdresner@rhsmith.umd.edu

1 - Excess Inventory As A Market Entry Deterrence Mechanism: Evidence From The Us Airline Markets

Chen Zhou, University of South Carolina, chen.zhou@moore.sc.edu

Inventory may have strategic value because it is necessary for production and consumer satisfaction that are crucial for firms to achieve competitive advantage. In service industries, inventory is often a result of extra capacity, which play a critical role in customer service. In this research, we examine the strategic role of inventory beyond cost efficiency and customer service, using data on the domestic airline industry in the United States. We find that extra inventory discourage market entry on major routes and the intensity of market competition strengthens the relationship between inventory and market entry.

2 - Modeling Multimodal Network Equilibrium For Unregulated Intercity Travel: An Equilibrium Problem With Equilibrium Constraints Approach

Bo Zou, University of Illinois at Chicago, Chicago, IL, United States, bzou@uic.edu, Mohamadhossein Noruzoliaee, Lili Du

This paper proposes a new approach to modeling network competition for multimodal intercity transportation. We view the interactions of transportation operators and travelers as a Multi-Leader-Multi-Follower game, which is modeled as an Equilibrium Problem with Equilibrium Constraints characterized by a series of transportation operators' profit maximization problems. To solve the EPEC, we propose an algorithm that combines the Gauss-Seidel diagonalization method and the relaxation method. The validity of the EPEC model and the algorithm is demonstrated by applying them to a small network as well as a large network representing the US Midwest.

3 - Costs And Benefits Of 'Open Skies' In The East African Community (EAC)

Megersa Abate, Swedish National Road and Transport Research Institute, megersa.abate@vti.se

This paper investigates the economic effects of open skies in the East African Community (EAC) member countries. We find two important results. Firstly, fare levels are lower and departure frequencies are higher for countries with the most liberal air services agreements (ASA). Secondly, our welfare estimate shows that liberal ASAs have had significant economic impact in the order of $400 gain per passenger. The paper also makes normative analysis of the role of liberal policies on the long-term supply side responses in the EAC's air transport market with respect to airline output, market structure, fares and the position of national airlines.

4 - The Impacts Of Merging And Acquisition On Route Entry Behavior: An Empirical Test Of The Contingency Framework In The US Domestic Airline Industry

Li Zou, Embry-Riddle Aeronautical University, zoul@erau.edu, Janani Thiagarajan

This paper examines the impacts on route structure development of the merger and acquisition (M&A) within the airline industry. Several contingent factors considered include the timing of the M&A in the economic cycle, the financial strength of the merging airlines, and their inclination toward merger activities, and similarity in terms of cost structure, operation scale, market strategy, and network structure. The estimation of the model is based on data drawn from the US domestic airline industry over the 1993-2011 period. A total of 14 airline mergers are covered in the analysis using data collected from Form 41, DB1B Market Data, T100 Domestic Segment Data, and other supplemental sources.

Robust Planning in Air Transportation Systems

Sponsored: Aviation Applications

Sponsored Session

Chair: Adan Vela, Technical Staff, MIT Lincoln Laboratory, 244 Wood Street, Lexington, MA, 02420-9108, United States, adan.vela@ll.mit.edu

Co-Chair: James Jones, Technical Staff, MIT Lincoln Laboratory, 244 Wood St., Arlington, MA, 02420, United States, James.Jones@ll.mit.edu

1 - Inferring The State Of The Air Transportation System Using Mobile Phone Data

Eric Feron, Georgia Institute of Technology, Atlanta, GA, United States, feron@gatech.edu, Aude Marzuoli, Emmanuel Boidot, Helene Piquet

The Air Transportation system is becoming increasingly congested, leading to perturbations that propagate through the entire airspace, disproportionately impacting passengers. Most performance metrics in aviation are flight-centric, simply because passenger data belongs to airlines. Yet, using anonymized mobile phone location data, we can analyze passenger flow movements between airports, under nominal and degraded conditions. Once passengers are identified amongst mobile phone users, a matrix representing passenger flow movements between airports is extracted. We study the impact of a bad weather event on passenger flow movements, connections and wait times at airports.

2 - An Integrated Framework For Military Airlift Planning

James Jones, MIT Lincoln Laboratory, James.Jones@ll.mit.edu

As the sole manager of the United States' global defense resources USTRANSCOM is charged with the mission of routing military cargo and passengers across the world. In this presentation we propose a simulation that integrates multiple interacting airlift algorithms to enhance their scheduling and routing process at the strategic and tactical levels.

This material is based upon work supported by USTRANSCOM under Air Force Contract No. FA8721-05-C-0002 and/or FA8702-15-D-0001. Any opinions, findings, conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of USTRANSCOM.

MCDM in Infrastructure Network Resilience Planning

Sponsored: Multiple Criteria Decision Making

Sponsored Session

Chair: Kash Barker, Associate Professor, University of Oklahoma, 202 W Boyd St, Rm. 124, Norman, OK, 73019, United States, kashbarker@ou.edu

1 - Multiple Criteria Multidimensional Resilience Framework For Disaster Evaluation

Dante Gama Dessavre, Stevens Institute of Technology, Castle Point on Hudson, Hoboken, NJ, 07030, United States, dgamades@stevens.edu, Jose Emmanuel Ramirez-Marquez, Andrea Garcia Tapia

System resilience refers to the ability to cope with adversities and be restored back to a pre-disruption state. Resilience is a global concept that encompasses reliability, vulnerability and restorability. This works presents a multiple criteria system resilience formulation regarding this components, using a multi-event resilience model. Showing preliminary results for a group of Mexican hydro-meteorological disaster events, we show how this approach can enhance the understanding of disaster consequences, therefore improving future decision making in similar situations.

2 - Multi-criteria Formulation For Defending Multi-commodity Networks

Matthew McCarter, University of Oklahoma, Norman, OK, United States, mattm@ou.edu, Kash Barker

The vulnerability of a multi-commodity network to disruption is defined by the extent to which commodities can no longer flow through the network to satisfy demand. A multiobjective formulation and heuristic-driven decision support environment is developed to find defense strategies that balance minimal cost with an ability to maintain a high level of demand satisfaction across all commodities. The solution approach is applied to a Swedish railway dataset.

3 - Component Criticality Analysis Of A Multi-commodity Network

Mackenzie G Whitman, University of Oklahoma, Norman, OK, United States, mgwhitman@ou.edu, Kash Barker

Preparedness planning for critical infrastructure networks requires evaluating the impact to the network when its components are disrupted. We extend the well-studied problem of component importance measures in single-commodity networks to multi-commodity networks by integrating a multi-commodity optimization model with a multi-criteria decision analysis tool to evaluate the impact of one-at-a-time component disruptions. We analyze commodity-specific impacts on network performance of a Swedish railway system application to rank critical links.

4 - Multi-criteria Formulation For Network Recovery Decision Making

Nazanin Morshedlou, University of Oklahoma, nazanin.morshedlou@ou.edu

Recent work has offered optimization formulations for optimal recovery of infrastructure networks after a disruption. Building upon this literature, we introduce a dynamic network component recovery rate, recognizing that recovery speed may change (i) over time after recovery commences, and (ii) with the assignment of different spatial work crews. Enhancing resilience, as well as other objectives, is considered.

Sponsored Session

Chair: Hilal Atasoy, Temple University, Fox School of Business, Philadelphia, PA, 19122, United States, hilal.atasoy@temple.edu

1 - Antecedents And Consequences Of Electronic Medical Record System Changes

Kartik Krishna Ganju, Temple University, tuc67632@temple.edu

The adoption of EMR systems has been found to have a number of organization wide changes and is often met with resistance from users. Additionally, EMR systems often do not meet all the requirements over time. Due to these reasons, EMR systems are occasionally switched or abandoned. In this paper, we examine the phenomenon of switching and abandoning EMR systems and identify the impact of policy and hospital characteristics on EMR system switching and abandonment. We first examine the role of the HITECH Act on changes of EMR systems. We also examine the choices that hospitals make and if they choose to adopt the market leader and the impact of these changes both during and outside the purview of the HITEH Act.

2 - Impact Of Organizational Usage Experience On Service Operation Efficiency: A Study Of Online Care Delivery

Changmi Jung, Johns Hopkins University, changmi@jhu.edu

Advanced online medical services are regarded as visiting physicians virtually in an asynchronous way. If patients' wait time in online is longer than what patients experience in office visits, the service's merit becomes undermined, and thus, the organizations need to consider redesigning the service processes or the way they integrate the service into their current operation. Also, if the newly introduced service acquires high efficiency at the cost of the existing operation, the efficiency gain might be offset. We examine the operational aspect of the online service, specifically patients' waiting time and work coordination among the members in practices.

3 - Is Technology Eating Nurses? Staffing Decisions In Nursing Homes

Abraham Seidmann, University of Rochester, Simon Business School, Dir of OR Dept, Rochester, NY, 14627, United States, avi.seidmann@simon.rochester.edu, Lu Feng, Huaxia Rui

We study the effect of IT-enabled automation on staffing decisions in healthcare facilities. Our findings suggest that the impact of automation technology on staffing decisions depends crucially on a facility's strategic position in the local marketplace.

Sponsored Session

Chair: Jingshan Li, University of Wisconsin-Madison, 1513 University Ave, Madison, WI, 53706, United States, Jingshan.li@wisc.edu

1 - A Decentralized Stay-time Based Occupant Distribution Estimation Method For Buildings

Qing-Shan Jia, Tsinghua University, jiaqs@mail.tsinghua.edu.cn

Zonal occupant level is of great practical interest for building energy saving and fast evacuation. The problem is challenging due to the privacy concerns, the random human movement, and the accumulative error. We consider this important problem and focus on infrared beam systems that monitor the zonal arrival and departure events. We make three contributions. First, a rule based on the stay time is developed to reduce the accumulated estimation error in each zone. Second, another rule is designed to coordinate the estimation among neighboring zones. A decentralized estimation method is then developed. Third, the advantage of this method is demonstrated through simulation results and field tests.

2 - Collaborative Energy And Thermal Comfort Management Through Distributed Consensus Algorithms

John Wen, RPI, wenj@rpi.edu

Buildings with shared spaces are occupied by multiple occupants typically with have different temperature preferences. Using occupant-differentiated dynamically-adjusted penalty factor as feedback signals, we propose a distributed solution which ensures that a consensus is attained among all occupants upon convergence, irrespective of their ideal temperature preferences being in coherence or conflicting. We establish the convergence of the proposed algorithm to the optimal temperature set-point that minimizes the sum of the energy cost and the aggregate discomfort of all occupants in a multizone building.

3 - Analysis on Energy Efficient Switching Of Machine Tool With Stochastic Arrivals And Buffer Information

Andrea Matta, Shanghai Jiaotong University, matta@sjtu.edu.cn

Energy saving in production plants is becoming more and more relevant due to the pressure from governments to contain the environmental impact of manufacturing, and from companies to reduce costs. One of the measures for saving energy is the implementation of control strategies that reduce energy consumption during the machine idle periods. This talk will deal with switching policies that turn the machine off when production is not critical, and on when the part flow has to be resumed. A general policy is formalized by modelling explicitly the energy consumed at each machine state.

1 - A Space-time Autoregressive Model For Radar Images Under A Lagrangian Integration Scheme

Xiao Liu, IBM T.J. Watson Research Center, Yorktown Heights, NY, United States, liuxiaodnn_1@hotmail.com

This paper is concerned with the spatio-temporal modeling of two dimensional radar echo fields from a sequence of radar images. The method is useful for many environment- and energy-related problems. For example, the precipitation forecast, and the prediction of solar power production.

2 - Reliability Modeling For Continuous-state Systems

Xinying Wu, Ohio University, wuxinying2009@gmail.com, Tao Yuan

This talk presents a Bayesian hierarchical modeling framework for modeling the reliability and degradation of continuous-state systems composed of continuous-state components. Degradation modeling, degradation data analysis, system reliability prediction, and component important measures will be discussed.

3 - On The Probabilistic Site Selection Problem

Yiwen Xu, North Dakota State University, Fargo, ND, 58102, United States, yiwen.xu6@gmail.com, Haitao Liao

In this research, we study a site-selection problem in probabilistic networks where both nodes and edges are prone to be failed. To enhance the probability of connectivity from one node to another, options for adding multiple edges (i.e., edge-level redundancy) are considered. We formulate the mathematical programming problem and develop a method to solve the problem. Numerical examples are provided to demonstrate the problem and the use of the proposed solution methodology.

4 - A Physical-statistical Hybrid Model For Li-ion Battery Prognosis

Nan Chen, National University of Singapore, isecn@nus.edu.sg

The traditional PHM approaches for Li-Ion batteries relied on the experimental data, like battery capacity or impedance. We proposed a physical-statistical model to take full use of operational data, which are readily available, to model and predict the performance and reliability of Li-Ion batteries. Both numerical and case studies are constructed to demonstrate the effectiveness and promising futures of this physical-statistical model in the real applications.

1 - Discrete Event Simulation-based Analysis Of Personnel Evaluation Policy

Lee A. Evans, University of Louisville, Louisville, KY, United States, laevan04@louisville.edu, Prajwal Khadgi

The United States Army uses a forced ranking appraisal system, a practice largely abandoned in the private sector, in evaluating its officer corps. The psychological aspects of forced ranking evaluation systems have been well documented, but this study examines the mathematical aspects of how these systems can lead to misidentification of high-performing individuals. We show how the binomial distribution can explain many of the challenges, analyze human behavior in such a system, and create a discrete event simulation to analyze the effects of policy-driven constraints.

2 - Modeling And Forecasting Army Enlistments With Geographic Data Weighting, Principal Components Analysis, And Linear Regression

Joshua McDonald, U.S. Army, Aberdeen Proving Ground, MD, United States, joshua.l.mcdonald10.mil@mail.mil

Using ordinary least squares regression applied to geographically weighted panel data we forecast the production of Regular U.S. Army enlistments in 38 recruiting markets. We find that a set of five continuous independent variables obtained through principal components analysis plus categorical variables for markets and quarters of the fiscal year achieves effective 15-month forecasts; when forecasting independent variables, the models explain between 63% and 73% of the variation between actual and predicted data at the highest level of aggregation, depending on enlistment contract type.

3 - Optimal Design Of Piezoelectric Materials For Maximal Energy Harvesting

Russell Nelson, United States Military Academy, West Point, NY, 10996, United States, russell.nelson@usma.edu, Hong Zhou, Susan Sanchez

The DoD seeks alternative methods to produce electricity, thus decreasing dependence on fossil fuels and increasing combat power. Piezoelectric generators can produce alternative electrical power in isolated and austere conditions. We use three and six variable mathematical models to analyze piezoelectric generator power capabilities. Using mk factorial sampling, nearly orthogonal and balanced Latin hypercube (NOBLH) design, and NOBLH iterative methods, we find solutions to maximize piezoelectric generator power output. We further analyze our optimal results using robustness analysis techniques. Our results provide optimal material parameter and environmental designs.

4 - Risk Assessment In Robust Goal Programming

Robert Hanks, Air Force Institute of Technology, robert.hanks@afit.edu

We investigate interval-based and norm-based uncertainty sets using cardinality-constrained robustness in the Robust Goal Programming (RGP) construct in addition to strict robustness using ellipsoidal uncertainty sets. Then, using utility theory, a decision maker's (DM) view of risk is quantified via a utility function, which will be mapped back to relevant parameters of the varying uncertainty sets to model the DM's risk attitude toward a robust solution. The findings offer theoretical contributions to the RGP framework and will be applied in a future endeavor to setting shipping rates for the United States Transportation Command's customers as it pertains to revenue management.

Chair: Liliana Delgado Hidalgo, Doctoral Candidate, University of Arkansas and Universidad del Valle, 4207 Bell Engineering Center, Fayetteville, AR, 72701, United States, ld002@uark.edu

1 - A Constraint Programming Approach For A Parallel Machine Scheduling Problem With Time Intervals And Sequence Dependent Setup Times

Ridvan Gedik, University of New Haven, 300 Boston Post Rd, Buckman Hall 223 F, West Haven, CT, 06516, United States, rgedik@newhaven.edu, Chase Rainwater

In this study, we introduce a scheduling problem that aims to minimize the makespan of jobs on unrelated machines subject to time availability intervals and sequence dependent setup times in a fixed planning horizon. Computational tests on a real-life case study prepared in collaboration with the U.S. Army Corps of Engineers (USACE) show that the constraint programming model outperforms the mixed integer programming model in terms of solution time and quality. In addition, sensitivity analysis conducted on time interval restrictions provide decision makers with quantitative insights into how much savings might be obtained if these were relaxed.

2 - A Rolling Horizon Approach For Integrated Yard Crane Scheduling And Container Handling In A Stochastic Environment

Filip Covic, PhD Student, Institute for Operations Research, University of Hamburg, Von-Melle-Park 5, Hamburg, 20146, Germany, filip.covic@uni-hamburg.de, Mehdi Karimi-Nasab

A container terminal with multiple blocks, each operated by a yard crane is considered. A mixed-integer model is developed for integrating following operational sub-problems: crane scheduling, container storage allocation, relocation and re-marshaling. The objective function is to minimize the total weighted number of shuffle and re-marshaling moves. A rolling horizon framework is used to deal with uncertainty of container arrival and retrieval times. Within this framework, these data are periodically updated according to available berthing and truck arrival times. In each period the time capacity of the crane is limited. A solution approach to exploit the decompsoable sturcture is applied.

3 - Simulation Approach For A Container Terminal, A Case Study

Nabil Nehme, Assistant Professor, Lebanese American University, Ramlet El- Baida, Thomas Edison Street, Beirut, Lebanon, nehme_nabil@hotmail.com, Faten Abou Shakra, Clovis Francis

This research investigates the tactical operations inside a container terminal. The case of Beirut Container Terminal (BCT) is considered. A simulation model is developed to reflect the current state of BCT and existing berthing problems. Both qualitative and quantitative data are collected. Several scenarios are tested to minimize the queue for berthing vessels. A strategic work policy is suggested to leverage competition taking into consideration financial and operational constraints.

4 - Barge Assignment And Scheduling During Inland Waterway Disruption Response

Liliana Delgado Hidalgo, Doctoral Candidate, University of Arkansas and Universidad del Valle, 4207 Bell Engineering Center, Fayetteville, AR, 72701, United States, ld002@uark.edu, Heather Nachtmann

We study the problem of assigning and scheduling barges to terminals during inland waterway disruption response. The problem is formulated as a heterogeneous vehicle routing problem with time windows that minimizes total value loss. We present an improvement to the initial formulation by adding valid inequalities. Several disruption instances are solved, comparing our approach with prior work in this area and resulting in improved results.

1 - Application Of Service Industry In Port Management

Maryam Hamidi, University of Arizona, 3121 E Bellevue Street, Unit 2, Tucson, AZ, 85716, United States, mhamidi@email.arizona.edu

In this presentation, we will study the port management and supply chain in maritime.

2 - Centralized And Decentralized Warehouse Logistics With Stochastic Demand Collaboration

Shiman Ding, University of California Berkeley, Berkeley, CA, 94706, United States, shiman@berkeley.edu, Philip Kaminsky

An emerging paradigm for horizontal logistics collaboration in the grocery industry involves the use of large third-party warehouses used by suppliers as outbound warehouses, and by retailers as distribution centers. We model a setting where safety stock is maintained at both the warehouse and retailers, and build on our previous work for a deterministic version of this problem to develop a heuristic for this model with a worst-case bound of 1.19. We also develop effective heuristics for decentralized versions of this model, and finally, we characterize the "cost of anarchy" in this system - the loss due to decentralized operation.

3 - A Change Of Gear: Managing Modal Split Transport (mst)

Chuanwen Dong, Kuehne Logistics University, Grosser Grasbrook 17, Hamburg, 20457, Germany, chuanwen.dong@the-klu.org, Sandra Transchel, Stefan Minner

The truck driver shortage rises freight cost and erodes firms' SC margins. We study a MST policy to shift volume to trains. We model the two modes differently based on their nature: a train has a fixed schedule over a long period and requires stable deliveries. The economics of scale in rail freight cost and inventory mismatch cost is also incorporated. The model is solved via Stochastic DP optimally for: the fixed load and delivery frequency of the train, and the delivery policy of the truck. Real data application shows considerably modal shift into trains, and suggests the firm the favorable products for MST.

4 - Multiproduct Batch Production And Truck Shipment Scheduling Under Different Shipping Policies

Umit Saglam, Assistant Professor, East Tennessee State University, East Tennessee State University Department of Management and Marketing, PO Box 70625, Johnson City, TN, 37614, United States, saglam@etsu.edu

In this paper, we formulate mathematical models that attempt to integrate the production lot scheduling problem with outbound shipment decisions. The optimization objective is to minimize the total relevant costs of a manufacturer, which distributes a set of products to multiple retailers. In making the production/distribution decisions, the common cycle approach is employed to solve the ELSP, for simplicity. The resulting mixed-integer, non-linear programming models (MINLPs) are solved by the BONMIN solver. Finally, a set of numerical examples illustrate and evaluate the relative efficacies of these policies.

1 - Robust Supply Chain System Under Yield Uncertainty

Samir A Alsobhi, Assistant Professor, Yanbu University College, Yanbu Alsinaiyah, 51000, Saudi Arabia, Alsobhis@rcyci.edu.sa, Krishna Krishnan

Products are often damaged in transit.These damages are stochastic in nature.To minimize the impact of damage,the selection of routes should consider not only the expected damage but also the variability of damage.In this research,the first model is of the supply chain network in order to minimize total cost,which consists of product cost and transportation cost while considering multiple routes and products.In the second model,the concept of robust design has been applied to minimize damage.

2 - A Location Allocation Model For Facility Planning To Minimize The Operational Cost

Damitha Bandara, Assistant Professor, Albany State University, 504 College Dr, Albany, GA, 31705, United States, damitha.bandara@asurams.edu

Locating and allocating distribution centers optimally is a crucial and systematic task for decision-makers. Optimally located distribution centers can significantly improve the logistics system's efficiency and reduce its operational costs. In this research, we develop a mathematical model to determine the optimal locations and allocations for distribution centers that minimizes the operational cost. The model is used to find the optimal location and allocation of distributions centers for a leading company in the USA. Computational results show that the company can reduce their operational cost significantly by implementing new optimal distribution locations.

3 - Project Management Inventory And Due Date Study In Push And Pull Contracts

Xingxing Chen, Washington University- St. Louis, Campus Box 1156, One Brookings Drive, Saint Louis, MO, 63130, United States, xingxing.chen@wustl.edu, Panos Kouvelis, Yu Xia

This research studies the inventory management and project cycle in project management. We investigate a supply chain with one manufacturer and one supplier. The manufacturer replenishes a critical part from the supplier to meet the stochastic demand during the project cycle time. Both the manufacturer and the supplier target at optimizing their profits respectively. The games between the manufacturer and the supplier are studied under different contract formats: push, pull and push-pull contracts. Optimal inventory policy and project cycle time are found indifferent cases.

4 - Product Recalls In The Consumer Products Industry: Evidence Of A Silver Lining

Carolyn Queenan, Assistant Professor, University of South Carolina, Darla Moore School of Business, 1014 Greene St, Columbia, SC, 29208, United States, carrie.queenan@moore.sc.edu, Adams Steven, Yan Dong, Manus Rungtusanatham

Research shows us that recalls generally harm firm performance and intuition confirms this. We, however, investigate if recalls universally harm firm performance. After analyzing seven years of consumer products recall data and corresponding firm performance, we find certain circumstances mitigate some of the potential negative impacts of recalls on firm performance. Results suggest new ways to consider recalls and ways to mitigate their effects.

5 - Demand And Supply Planning In Configure-to-order Supply Chains

Turgut Aykin, Managing Member, Aykin Associates, 136 Buckmanville Rd., New Hope, PA, 18938, United States, taykin@aykinassociates.com

Configure-to-order (CTO) products involve variable bills of materials (BOM), which may vary from one order to another in SKU's and quantities required, and customers who are sensitive to the promised delivery times. In this presentation, we review the approaches available for CTO supply chains and present a new approach to model variable BOM's, as well as link supply levels to the targeted delivery performance, forecasts, forecast accuracy and lead times.

1 - Optimizing Chemoradiotherapy To Target Multi-Site Metastatic Disease And Tumor Growth

Hamidreza Badri, PhD Student, University of Minnesota, IsyE University of Minnesota, 111 Church Street S.E., Minneapolis, MN, 55455, United States, badri019@umn.edu, Kevin Leder, Ehsan Salari

We introduce a model to obtain optimal drug and radiation protocols in a chemoradiotherapy scheduling problem with the objective of minimizing metastatic cancer cell populations at multiple sites while maintaining a minimum level of damage to the primary tumor site. We derive closed-form expressions for an optimal chemotherapy fractionation regimen. A dynamic programming framework is used to determine the optimal radiotherapy fractionation regimen. We quantify the trade-off between the new and traditional objectives of minimizing the metastatic population size and maximizing the tumor control probability, respectively, for a cervical cancer case.

2 - Integrated Physician And Clinic Scheduling Problem In an Ambulatory Cancer Treatment Polyclinic

Mohammad Tohidi, PhD Candidate, Concordia University, 7400 Sherbrooke West, Apt 218, Montreal, QC, H4B 1R8, Canada, m_tohidi@encs.concordia.ca, Masoumeh Kazemi Zanjani, Ivan Contreras

In this presentation, we present an extension of physician scheduling problems which arises in hospitals with polyclinic centers. In these centers, a patient can be assessed by multiple clinics in a single visit. The clinics share available resources, and interdisciplinary clinics have to be scheduled together on simultaneous shifts. This work is inspired by a case study in a hospital in Montreal. We integrate clinic session scheduling with physician scheduling and formulate the problem as a multi-objective mathematical program. For some problem instances that the exact method is not able to find the optimal solution, we present an iterated variable neighborhood search mathheuristic.

3 - Does Specialization Of Hospitals Increase Operational Efficiency?

Saied Samiedaluie, Postdoctoral Fellow, The University of British Columbia, Vancouver, BC, Canada, saied.samiedaluie@gmail.com, Vedat Verter

We study a health care network configuration problem considering two scenarios: specialization versus generalization. We characterize the situations in which each scenario is preferred in terms of accessibility to care. Our results show that the decision of system configuration for a multi-hospital network requires careful consideration of patient mix among arrivals, relative length of stay of patients, and distribution of patient load between hospitals.

5 - Multi Attribute Balanced Scheduling In An Integrated Outpatient Clinic

Jacqueline Griffin, Northeastern University, 360 Huntington Ave., 334 Snell Engineering Center, Boston, MA, 02115, United States, ja.griffin@neu.edu, Vahab Vahdatzad, Sarah Burns

Using a discrete event simulation modelling approach, we examine new policies for the design and operation of a new integrated orthopedic, rheumatology, and radiology healthcare facility. With interdependent flows and shared resources between these units, the importance of balancing workload across the facility, and strategies for accomplishing this are examined. Specifically, we quantify the impact of various patient and provider scheduling policies, both independently and simultaneously, to identify the cost effectiveness of implementation.

1 - Nonlinear Customer Satisfaction Index Model

Nobuhiko Terui, Professor, Tohoku University, Faculty of Economics, Kawauchi Aoba-Ku, Sendai, 980-8576, Japan, terui@econ.tohoku.ac.jp, Xing Aijing, PK Kannan

We extend the relationship proposed by the customer satisfaction index (CSI) model to include a nonlinear functional form between satisfaction and loyalty. We examine different functional forms on how satisfaction affects loyalty and propose a model that reflects intrinsic characteristics of nonlinear effects, such as saturation-attainable limit of effectiveness, non-constant marginal return, and asymmetric response between satisfied and dissatisfied customers, in a parsimonious way. The model is estimated via a hierarchical Bayes model to accommodate structural heterogeneity of companies surveyed in the analysis by proposing an efficient multi-move sampler.

2 - When Better Product Quality Imply More Advertising

Regis Chenavaz, KEDGE Business School, Marseille Cedex 9, France. r.chenavaz@gmail.com, Sajjad Jasimuddin

This article examines when does better quality lead to more advertising. It models the advertising-quality relationship in an optimal control setting. This article proposes a rule for the advertising-quality relationship generating both positive and negative relationships: Advertising increases with quality if the demand effects (quality and advertising effects on demand) outweigh the supply effect (quality effect on cost); alternatively, advertising decreases with quality if the demand effects are lower than the supply effect. Consequently, despite consumer awareness of quality, to maximize profit the firm may advertise a product of lower quality more.

3 - Intimacy And Loyalty In Parasocial Relationships

Lenita Davis, Professor, University of Arkansas-Little Rock, 1200 Brookwood Drive, Apt 463, Little Rock, AR, 72202, United States, lmdavis@ualr.edu, Elizabeth Micahel

This research seeks to identify how negative information affects the loyalty and commitment of fans engaged in a parasocial relationship that is established or strengthened through social media. This research will use multiple methods including social media ethnography, qualitative comparative analysis of celebrity and fan social media and empirical analysis. This research will be conducted in the context of the presidential election, social media data will be collected on the front runners' social media in the Presidential campaign during the primaries up to a week post their respective national conventions.

4 - Managerial Overconfidence And Brand Capital

Nithya Shankar, Assistant Professor of Marketing, State University of New York at Plattsburgh, Plattsburgh, NY, United States, nithya.shankar21@gmail.com, Staceyann Sharpe, Bill Francis

A growing area of research in marketing focuses on the impact of firm-level factors on brand capital. Largely lacking in the marketing literature is the impact of managerial behavioral traits on firms' brand capital. Our research investigates this relationship by examining the impact of managerial overconfidence on brand capital. Preliminary results indicate a negative relationship between managerial overconfidence and brand capital. Further analysis will evaluate the impact of managerial overconfidence on change in brand capital, as well as the impact of industry factors on this relationship.

Data Mining for State Transition Modeling

Sponsored: Data Mining

Sponsored Session

Chair: Victoria C. P. Chen, The University of Texas at Arlington, Dept. of Ind., Manuf., & Sys. Engr., Campus Box 19017, Arlington, TX, 76019, United States, vchen@uta.edu

1 - A High-dimensional State Transition Development Framework For Deicing Activities At Dallas-fort Worth International Airport

Zirun Zhang, FedEx, zhang.zirun@gmail.com

For high-dimensional and complex systems, state transitions can be empirically represented from data to enable system simulation or optimization. This paper presents a data-driven framework for state transition development in the context of deicing/anti-icing activities at Dallas-Fort Worth (D/FW) International Airport. From study of the framework, the D/FW deicing system is stochastic, finite horizon and discrete-time, non-stationary, and non-convex with mostly continuous state variables.

2 - State Transition Modeling For An Interdisciplinary Pain Management Program

Nilabh Ohol, The University of Texas at Arlington, nilabh.ohol@mavs.uta.edu

We discuss state transition modeling for an adaptive interdisciplinary pain management program at the University of Texas Southwestern Medical Center at Dallas. Challenges include data collection and preparation, endogeneity, and statistical modeling for optimization. Different modeling approaches will be presented, including linear and piecewise linear regression, piecewise linear networks, and regression splines models.

3 - Challenges In State Transition Modeling For A System Of Electric Vehicle Charging Stations

Ying Chen, The University of Texas at Arlington, ying.chen@mavs.uta.edu

In order to supervise the running of plug-in hybrid electric vehicle (PHEV) charging station intelligently, approximated dynamic programming (ADP) algorithm is proposed to control this system, which is equipped with a distributed energy storage system charged by solar power, wind power and electricity from the power grid. The sampling of state space and state transition model are the critical parts to build a converged future value function (FVF) in ADP considering the dimension of state space and multicollinearity issue between state variables. In PHEV charging station control problem, the objective is to minimize the operational cost.

4 - Multicollinearity In State Transition Modeling

Victoria C. P. Chen, University of Texas, 701 S. Nedderman Drive, Arlington, TX, 76019, United States, vchen@uta.edu, Bancha Ariyajunya, Ying Chen, Seoung Bum Kim

Multicollinearity is known to have a negative impact on statistical modeling, specifically with respect to variance inflation. A state transition modeling approach based on orthogonalization of the state space is presented. Results are shown for a ground-level ozone pollution stochastic dynamic program.

1 - IBM Cognitive Technology Helps Aqualia Reduce Costs And Save Resources In Wastewater Treatment

Alexander Zadorojniy, IBM Research, IBM Haifa Research Lab, Haifa, Israel, Zalex@il.ibm.com, Segev Wasserkrug, Sergey Zeltyn, Vladimir Lipets

This work takes a deep dive into operational management optimization problems in wastewater treatment plants. We used a constrained Markov Decision Process as the key optimization framework. Our technology was tested in a one-year pilot at a plant in Lleida, Spain, operated by Aqualia, the world's 3rd-largest water company. The results showed a dramatic 13.5 percent general reduction in the plant's electricity consumption, a 14 percent reduction in the amount of chemicals needed to remove phosphorus from the water, and a 17 percent reduction in sludge production.

2 - Implementationof The Genetic Gain Performance Metric Accelerates Agricultural Productivity

Joseph Byrum, Syngenta, West Des Moines, IA, 50265, United States, joseph.byrum@syngenta.com, Craig Davis, Greg Doonan, Tracy Doubler, Bill Beavis, Von Kaster, Sam Parry, Ronald Mowers

Yield is the most important metric for a farmer, as crop output directly impacts profitability. We now refer to the rate of increase in the genetic potential for yield in cultivars as “genetic gain,” and it is measured in bushels per acre (bu/ac). The challenge was to develop models and methods that provide unbiased estimates of the genetic components of yield for unbalanced field trials conducted across years. An algorithm was implemented that minimizes the confounding influence of unpredictable environmental contributions to estimated yields of varieties enabling real-time unbiased estimation of performance metrics that are used in operational decision making and optimization.

Optimization for Enhancing Critical Infrastructure Resilience

Sponsored: Energy, Natural Res & the Environment, Energy I Electricity

Sponsored Session

Chair: Feng Qiu, Argonne National Laboratory, 9700 S. Cass Avenue, Lemont, IL, 60439, United States, fqiu@anl.gov

Co-Chair: Matteo Spada, Paul Scherrer Institut, OHSA/D19, 5232 Villigen PSI, Villigen PSI, Switzerland, matteo.spada@psi.ch

1 - A Framework For Measuring Infrastructure Resilience Of Energy Systems Taking Natural Hazards And Technical Failures As Disruption Triggers

Peter Lustenberger, Paul Scherrer Institut/ETH Zurich, Singapore, Singapore, lustenberger@frs.ethz.ch, Tianyin Sun, Patrick Gasser, Wansub Kim, Peter Burgherr, Matteo Spada, Stefan Hirschberg

This work first provides a quantifiable and feasible technical resilience definition and measure specifically for energy systems. Following this definition, we propose a framework for measuring the technical resilience of both the components (power plants, substations, refineries, compressor stations etc.) and the network topology of power grid and oil/gas supply systems by considering probabilistic disruption triggers of both natural hazards and technical failures as well as recovery dynamics.

2 - Prioritization Of Infrastructure Resilience Investments

Julia Phillips, Argonne National Laboratory, phillipsj@anl.gov

Recent events emphasize the importance of the protection and resilience of systems of critical infrastructure. This talk explores initial research on prioritization of infrastructure investments for resilience through optimization considering owner risk profiles. It is hypothesized that owners of different types of critical infrastructure systems may let their risk tendencies influence how to allocate funds as opposed to what investments are “optimal” considering monetary value only. The research community has struggled with the measurement of resilience. We use a technique of perceived value to assist in measurement of resilience and prioritization of investment funds.

3 - Wind-participated Power System Restoration

Feng Qiu, Argonne National Laboratory, fqiu@anl.gov

Black-start resources, electric generators that can start on their own without power supply from the grid, are critical initial power sources for power system restoration. Wind generation, with black-start capability, however, has not been considered as black-start resources due to its unreliability (variable and uncertain). As the wind integration continues to grow, wind-participated system restoration becomes not only a viable but also a valuable solution. In this talk, we will present an optimization model to incorporate wind in the system restoration. Wind uncertainty and variability will be addressed to ensure the success of system restoration.

4 - Repair, Rebuild, Or Replace? Protecting Aging Infrastructure From Hazards And Threats

David L. Alderson, Naval Postgraduate School, dlalders@nps.edu, Jan Brendecke, Kyle Y Lin

We consider an infrastructure system whose function depends on a number of components that fail randomly according to known rates. Components that are “new” have a small failure rate and components that are “old” have a larger failure rate. When a component fails it can be replaced to “new” status or repaired to “old” status. An “old” component can also be proactively replaced to “new” status. We formulate and solve a Markov decision process to identify the optimal replace/repair policies for given system operating costs and discuss implications for real infrastructure systems.

Power System Generation and Transmission Expansion

Sponsored: Energy, Natural Res & the Environment, Energy I Electricity

Sponsored Session

Chair: Enzo E Sauma, Pontificia Universidad Catolica de Chile, Vicuña Mackenna 4860, Macul., Santiago, 7820436, Chile, esauma@ing.puc.cl

1 - Risk-averse Transmission And Generation Planning: Wecc Case Study

Francisco Munoz, Universidad Adolfo Ibáñez, elpanchomunoz@gmail.com, Harry van der Weijde, Benjamin Field Hobbs, Jean-Paul Watson

We investigate the effects of risk aversion on optimal transmission and generation expansion planning in a competitive market. To do so, we formulate a stochastic model which minimizes a weighted average of expected transmission and generation costs and their conditional value at risk (CVaR), and which can be shown to have an equivalent solution to a perfectly competitive risk-averse Stackelberg equilibrium in which a risk-averse transmission planner maximizes welfare after which risk-averse generators maximize profits.

2 - How Technical Operational Details Affect Generation Expansion In Oligopolist Markets

Efraim Centeno, Universidad Pontificia Comillas - IIT, Efraim.Centeno@iit.comillas.edu, Sonja Wogrin, Adelaida Nogales

We propose a generation expansion model including an oligopolistic market representation based on an equilibrium approach. We incorporate the system states methodology into this generation expansion model allowing us to recover some chronological information in a LDC framework, thereby more accurately accounting for start-up and shut-down costs without making use of an hourly representation of demand. We find that when operational details are considered, flexible technologies are preferred by the companies in the optimal mix. We also observe that under perfect competition in comparison with oligopolistic markets, more base-load plants are built as well as more peaking plants.

3 - Sustainable Transmission Planning In Imperfectly Competitive Electricity Industries: Balancing Economic Efficiency And Environmental Outcomes

Afzal S. Siddiqui, Stockholm University, Stockholm, Sweden, Afzal S. Siddiqui, HEC Montréal, Montréal, QC, H3T 2A7, Canada, afzal.siddiqui@ucl.ac.uk, Makoto Tanaka, Yihsu Chen

We address the problem of a TSO that builds a transmission line in order to maximise social welfare inclusive of the cost of emissions. A TSO in a deregulated industry can only indirectly influence outcomes via its choice of the transmission line capacity. Via a bi-level model, we show that this results in less transmission capacity with limited emissions control if industry is perfectly competitive. A carbon tax on industry leads to perfect alignment of incentives and maximised social welfare only under perfect competition. By contrast, a carbon tax actually lowers social welfare under a Cournot oligopoly as the resulting reduction in consumption facilitates the further exercise of market power.

4 - Power Capacity Expansion Planning And The Influence Of Network Payment Schemes

Enzo Sauma, Pontificia Universidad Católica de Chile, esauma@ing.puc.cl, Diego Bravo, Javier Contreras, Sebastián de la Torre, José Aguado, David Pozo

We propose a multi-annual transmission expansion planning model seeking to reduce the total system costs and considering different network payment schemes. The proposed models are reformulated as Mixed Integer Linear Programming (MILP) problems. A realistic case study based on the main power system in Chile is analyzed to illustrate the proposed models. It is shown that integrating line cost-recovering equations into the Transmission Expansion Planning model may result into a more realistic and less congested power network. Also, total system cost is highly related with transmission tariff discrimination.

Business Analytics and Text Mining

Sponsored: Data Mining

Sponsored Session

Chair: Xiao Liu, University of Arizona, 1130 E. Helen St., Tucson, AZ, 85721, United States, xiaoliu@email.arizona.edu

1 - A Network-based Inference Model For Estimating Missing Attributes

Da Xu, University of Utah, da.xu@eccles.utah.edu

The attribute information, which is critical for recommendations, search engines, and advertising targeting, is valuable for business intelligence. While, all the aforementioned machine learning based applications are only capable of optimal performance when the data utilized are of high quality. And in many cases, the attribute information is incomplete, which makes a big obstacle in targeting products, businesses, or promotions effectively. In this paper, we utilized both networks and content information to infer missing business attributes, which could benefit business recommendations, help validate online business information, and provide better personalized offerings.

2 - Extracting Signals From Social Media Text With Natural Language Processing, Machine Learning And Domain Adaptation

Wenli Zhang, University of Arizona, Tucson, AZ, United States, wenlizhang@email.arizona.edu, Sudha Ram

There has been increasing interest in using social media data for predictive analytics in different domains. Although significant promise has been shown, mounting evidence suggests many of the results can be misrepresented because of the loosely structured text and noise caused by media spikes and use of misleading phases. We introduce efficient techniques combining Natural Language Processing and Machine Learning to extract signal from social media text. Sophisticated domain adaptation method is introduced to address multi-domain adaptation problem. The methodology can be used for extracting signals in health care and other domains with a view to enabling improved predictions.

3 - The Effect Of Rating System Design On Emotion Sharing

Ying Liu, Arizona State University, yingliu_is@asu.edu

How do ratings and reviews reflect consumers' overall evaluations toward the product? Does the overall evaluation reflect average experience or is it biased? In this study, we focus on evaluating the integration bias in consumers' rating behavior through rating system design. Analysis of data from two leading restaurant review websites with different rating systems suggests that the overall ratings tend to reflect consumers' extreme experiences in a single-dimensional rating system, however, their average experience by taking all dimensions into consideration in multi-dimensional rating systems. The results are confirmed by information from text reviews through text mining skills.

4 - Webcasting Game Or Sharing Experience? Exploring The Role Of Team-created Word-of-mouth In Football Game Attendance

Yang Wang, University of Utah, yang.wang@eccles.utah.edu, Nick Sullivan, Shyam Gopinath

A 2015 NCAA report shows that college football attendance drops to the lowest in 15 years. To help generate demand, the 128 FBS teams develop different strategies and use social media as a tool to attract fans. Among them, those schools with top game attendance usually tweet a lot about game ambiance which shows the unique game experience at the stadium, while the others only webcast the team performance on the pitch. This study aims to examine the differential impacts of the two types of team-created word-of-mouth on the future game attendance versus the TV viewership. We find the unique role of each type of the content and provide relevant business implications.

Chair: Xun Zhou, University of Iowa, S210 PBB 21 East Market Street, Iowa City, IA, 52242, United States, xun-zhou@uiowa.edu

1 - A Traffic Flow Approach To Early Detection Of Gathering Events

Amin Vahedian, University of Iowa, Iowa City, IA, United States, amin-vahediankhezerlou@uiowa.edu, Xun Zhou

Given traffic flows in a spatial field, early detection of gathering events problem aims to discover the most likely gathering events. It is important for city planners to identify emerging gathering events which might cause public safety or sustainability issues. Here, we model the footprint of a gathering event as a directed acyclic Graph, which captures routes of the flows to an event and their most likely destination. We also propose an efficient algorithm to discover the most likely events. Our analysis shows that the proposed model and algorithm efficiently and effectively capture important gathering events from real-world mobility data while saving 50% time over the baseline algorithm.

2 - Mapping The Structure Of China'S Cities Network

Xiaolong Xue, Harbin Institute of Technology, xlxue@hit.edu.cn

The structure of China's cities network is dramatical changing with the rapid urbanization process. This paper analyzes the research status of cities network theory, and constructs China's cities network model using China's transportation infrastructure data. The structure of China's cities network is described through network characteristics, and China's cities network is divided into different network communities by clustering analysis. We find the center city, traffic hub and regional centers by calculating cities nodes' effectiveness. The calculating of network effectiveness provides a reference for improving the efficiency of China's cities network.

3 - A Markov Decision Process Approach To Optimizing Taxi Driver Business Efficiency

Xun Zhou, University of Iowa, xun-zhou@uiowa.edu

Improving taxi business efficiency is an important societal problem. This work investigates how to increase the revenue efficiency (revenue per unit time) of taxi drivers. To solve this problem we model the passenger seeking process as a Markov Decision Process(MDP) and learn necessary parameters from historical taxi data. A case study and several experimental evaluation on a real dataset from a major city in China show that our proposed approach improve the revenue efficiency of inexperienced drivers by up to 15%.

4 - Operation Strategies And Algorithms For Minibus Systems In Hong Kong

Jacky Pak Ki Li, PhD Student, VU University Amsterdam, De Boelelaan 1081a, Amsterdam, 1081 HV, Netherlands, jacky.li@kpu.ca

In Hong Kong, the spatial distribution of Minibuses within the public transportation system is self-organized, lacking a clearly defined operation strategy. There is no optimization based on current demand. Within this paper several operation strategies are introduced. A new integrated algorithm for optimal strategy is described in detail, including two approaches: a user-based approach, outlining a strategy to capture and optimize consumer demand, and an operation-based approach, outlining a strategy to balance revenue and consumer satisfaction.

Tutorial: Data-Driven Research in Revenue Management

Invited: Business Model Innovation

Invited Session

Chair: David Simchi-Levi, Massachusetts Institute of Technology, Masachusetts Avenue, Cambridge, MA, 0, United States, dslevi@mit.edu

1 - Data-Driven Research In Revenue Management

David Simchi-Levi, Massachusetts Institute of Technology, 77 Massachusetts Avenue, Cambridge, MA, United States, dslevi@mit.edu

We present a pricing optimization problem for the data plans of a big satellite firm. First we address the problem of missing data (as reservation prices are not directly observed especially for those who are not current customers). We formulate the price optimization problem as a MIP and develop properties and heuristics in order to solve realistic instances providing analytical lower bounds of their performance. We conclude that with our method the company can increase its profits by more than 10% and outperform the current plans' prices even under misspecifications of the assumptions.

103B-MCC

Management of Stochastic Resources, Demand, and Energy Efficiency

Invited: Energy Systems Management

Invited Session

Chair: Lindsay Anderson, Cornell University, 316 Riley Robb Hall, Ithaca, NY, 14853, United States, landerson@cornell.edu

1 - The Value Of Transmission Lines And Its Implications For Electricity Systems With Stochastic Resources

Alberto J Lamadrid, Lehigh University, ajlamadrid@Lehigh.EDU

We demonstrate an analytical method for determining the economic value of individual transmission lines in a meshed network by calculating the total welfare effects for the system. We show that the uncertainty in system conditions breaks down the congestion rents paradigm. The results show that a substantial portion of the economic benefits for an individual line may come from maintaining system reliability when equipment failures occur.

2 - Optimal Offering Of Wind Power In Energy And Primary Reserve Markets

Tue Vissing Jensen, Technical University of Denmark, Kgs Lyngby, Denmark, tvjens@elektro.dtu.dk, Pierre Pinson, Tiago Soares, Hugo Morais, Hugo Morais

As wind power generation comes to dominate electricity systems, wind turbines may be needed to provide reserves. To allow for this, the reserve market must accept and price that the wind turbine can fail to deliver reserves when called on. For such a market, we give analytical results on the optimal energy and reserve bids for a wind generator under its day-ahead forecast.

3 - Integrating Roof-top Solar PV And Residential Energy Efficiency In The Carolinas: Feasibility And Impacts On Costs, Reliability And Emissions

Dalia Patino Echeverri, Duke University, dp52@duke.edu, Bandar Alqahtani

We estimate the reliability, environmental, and economic effects of large levels of roof-top Photovoltaic (PV), and residential energy efficiency penetration within the services areas of the Duke Energy Carolinas (DEC) and Duke Energy Progress (DEP). A PV production model based on household density and a gridded hourly global horizontal irradiance dataset simulates hourly PV power output from roof-top installations; a demand adjustment model simulates the effects of residential energy efficiency investments, and a unit commitment and real time economic dispatch (UC/ED) model simulates hourly system operations.

4 - Energy Efficiency Of Data Center Operating Practices: Server Clustering, Powering On/off And Bang-bang Control

Young Myoung Ko, Pohang University of Science and Technology, Pohang, 37673, Korea, Republic of, youngko@postech.ac.kr, Yongkyu Cho

We examine common data center operating practices such as server clustering, powering on/off, and the bang-bang control in terms of energy efficiency. We add new constraints reflecting the operating practices to the existing MIP model and propose an algorithm for constructing energy efficient clusters of servers from the two upper bounds of the maximum cluster size. Numerical experiments show that server clustering and the bang-bang control can be used in an energy-efficient way, but powering on/off alone may not be sufficient.

1 - A Hybrid Top-down, Bottom-up Approach For Saudi Arabia

Hossa Al-Mutairi, King Abdullah Petroleum Studies and Research Center, P.O. Box 88550, Riyadh, Saudi Arabia, hossa.mutairi@kapsarc.org

We show how to combine a CGE-like top-down model with a technology-rich bottom-up energy model in a single Mixed Complementarity Problem (MCP). Calibrated on Saudi Arabia's data, this hybrid model will be used to study the interaction between energy and non-energy sectors and to get insights on the effects of energy policies on the whole Saudi economy.

2 - North America Natural Gas Model: Impacts Of Market Deregulation In Mexico

Felipe Feijoo, Pacific Northwest National Laboratory, College Park, MD, 2, United States, felipe.feijoo@pnnl.gov

Mexico has recently launched a new energy regulation, with its focus on increasing Natural Gas consumption form the electricity sector. It is expected that the U.S. will serve as the main exporter to Mexico to satisfy their demand. We use both, the North American Natural Gas Model (NANGAM) and the Global Assessment Model (GCAM) to assess the short term impacts of the Mexican energy regulation.

3 - US Biofuel Market And Policy Model – A GAMS/EMP Approach

Adam Christensen, University of Wisconsin - Madison, Madison, WI, 4, United States, adam.christensen@wisc.edu

In this work we discuss the landscape of US biofuel policies (both federal and state level) and highlight market challenges and opportunities. A policy modeling tool was developed using the Extended Mathematical Programming (EMP) framework within GAMS to analyze the complicated network of overlapping policies, in particular the Renewable Fuel Standard as well as the California Low Carbon Fuel Standard. The EMP framework is utilized in order to speed the development of different market models which can help identify effects of market power for policymakers.

4 - How do Price Caps In China's Electricity Sector Impact The Economics Of Coal, Power And Wind? Potential Gains From Reforms

Bertrand Williams-Rioux, King Abdullah Petroleum Studies And Research Center, P.O. Box 88550, Riyadh, Saudi Arabia, Bertrand.rioux@kapsarc.org

China imposes maximum prices by plant type and region on the electricity that generators sell to utilities. We examine the impact of the price caps on the electricity sector and on the economics of wind power. We model this sector as a Stackelberg game formulated as a mixed complementarity problem, calibrated to 2012 data.

Network Vulnerability Analysis and its Applications

Sponsored: Optimization, Network Optimization

Sponsored Session

Chair: Neng Fan, University of Arizona, Tucson, AZ, United States, nfan@email.arizona.edu

1 - Subgraph Identification With Connectivity Requirements

Ou Sun, University of Arizona, suno@email.arizona.edu

Many combinatorial optimization problems, such as the maximum leaf spanning tree problem and the connected dominating set problem, involve finding a connected subgraph embedded in a larger graph while satisfying other problem-specific constraints. These structures appear in many applications, such as wildlife conservation, forest planning, and power grid islanding. In this talk, we review some existed approaches by mixed integer constraints for subgraph connectivity, and also propose some mixed integer constraints and valid inequalities. Some numerical experiments are performed to compare these approaches.

2 - Reliable Power Grid Expansion With Renewable Integration And Storage System

Bader Alsuhaim, University of Arizona, alsuhaib@email.arizona.edu

A reliable power grid system is important to ensure the delivery of power to consumers while minimizing the cost of new technologies. A plan of a power grid expansion is going to be proposed with different type of renewable energies to meet the demand and minimize the cost of installation; as well as, different type of storage systems that would be compared to come up with an optimal solution of a reliable power grid. The NERC contingency criteria are also considered in the optimization model, such as line failures, generator failures, loss-of-load, and etc. Also, numerical experiments and results will be presented.

3 - Multilevel Optimization For Resilient Planning Of Interdependent Water And Energy System

Shanshan Hou, University of Arizona, shanshanh@email.arizona.edu

Water is used for energy generation, and the energy network supply power for water distribution and extraction. They two could be modeled as an interdependent network. In this talk, we not only consider their operations and management, but also the planning stage, which contains analysis of the possible failures to ensure the system resiliency. We build the optimization model to simulate the water and energy relevant flow network. This model consists of the facilities that could be built in water network and different generation stations in energy network.

4 - Diameter-constrained Lambda-edge-connected K-subgraph Problem

Yongying Zhou, University of Arizona, yongyingz@email.arizona.edu

In this talk, we study the diameter-constrained lambda-edge-connected k-subgraph problem, or the DC (k, lambda)-subgraph problem. Besides the requirements on the number of the vertices and edge connectivity, the subgraph has a diameter limit. This problem is a generalization of (k, lambda)-subgraph problem and diameter constrained minimum spanning tree. Commodity flow-based and hop constrained formulations are established, which are both integer programming (IP) formulation. Additionally, numerical experiments are performed to compare all proposed IP formulation.

1 - Small Independent Branching Formulations For Unions Of V-polyhedra

Joey Huchette, Massachusetts Institute of Technology, Cambridge, MA, United States, huchette@mit.edu, Juan Pablo Vielma

We present a framework for constructing small, strong mixed-integer formulations for disjunctive constraints. Our approach is a generalization of the logarithmically-sized formulations of Vielma and Nemhauser for SOS2 constraints, and we offer a complete characterization of its expressive power. We apply the framework to a variety of disjunctive constraints, producing novel, small, and strong formulations for outer approximations of multilinear terms, generalizations of special ordered sets, piecewise linear functions over a variety of domains, and collision avoidance constraints.

2 - Embedding Formulations For Unions Of Convex Bodies

Juan Pablo Vielma, MIT, jvielma@mit.edu

In this talk we extend to the non-polyhedral setting a systematic procedure to construct non-extended ideal formulations for unions of polyhedral introduced in Vielma (2015). Using geometric tools from the study of Minkoswki sums we show that the procedure can be used to recover and extend several special purpose non-extended ideal formulations. We also illustrate how the tools can be used to prove that no polynomially constrained non-extended ideal formulation can be obtained for some simple convex quadratic sets.

3 - Winning Daily Fantasy Sports Hockey Contests Using Integer Programming

Scott Hunter, MIT, dshunter@mit.edu, Juan Pablo Vielma, Tauhid Zaman

We present an integer programming (IP) approach to winning daily fantasy sports hockey contests which have top heavy payoff structures. Our approach incorporates publicly available predictions into a series of IPs that compute optimal lineups. We find that the produced lineups perform well in practice and are able to come in first place in contests with thousands of entries. We also show through simulations how the profit margin varies with various parameters. Our approach can easily be extended to other sports, such as American football and baseball.

4 - Smart Grids Observability Using Bilevel Programming

Claudia D'Ambrosio, Ecole Polytechnique, LIX CNRS (UMR7161), Palaiseau, France, dambrosio@lix.polytechnique.fr

Monitoring an electrical network is an important and challenging task. Phasor measurement units (PMU) are devices that can be used for a state estimation of this network. We consider a PMU placement problem and propose two new approaches to model this problem, which take into account a propagation rule based on Ohm's and Kirchoff's laws. First, we describe the natural binary linear programming model based on an iterative observability process. Then, we remove the iteration by reformulating its fixed point conditions to a bilevel program, which we solve with a tailored cutting plane algorithm. Finally, we show computational evidence of the effectiveness of our method.

1 - An Optimization Approach To Workforce Planning In Professional Service Firms

Vincent Hargaden, Assistant Professor, University College Dublin, 209 Engineering & Materials Science Centre, Belfield, Dublin 4, Ireland, vincent.hargaden@ucd.ie, Jennifer K. Ryan, Amir Azaron

We develop a comprehensive mixed integer programming model for the workforce planning process in professional service firms. We will present results from the model which show the impact of skill mix, skill capability levels and cross training on key performance metrics such as project completion rates, staff utilization and profit. We show how extensions to our base model can incorporate issues such as a rolling planning horizon approach and variable project start dates.

2 - Simulation -Optimization For Strategic Workforce Planning

Manuel Laguna, University of Colorado Boulder, laguna@colorado.edu

OptForce is a data analytics tool for workforce planning. We describe how company data is used to build a simulation model of a workforce. This model is then used for what-if analysis and optimization. The techniques associated with this application of simulation-optimization are also discussed.

3 - Talent Optimization For The Knowledge Economy

Cipriano A. Santos, HP Enterprise, cipriano.santos@hpe.com

Allocating the right talent for the right job at the right time, location, and cost is critical for the operational efficiency of Professional Services Organizations. In this talk we present a hierarchical planning approach for labor resources allocations

1 - Co-clustering Of Non-smooth Graphons

David Sungjun Choi, Carnegie Mellon University, davidch@andrew.cmu.edu

Theory is becoming known for community detection and network clustering; however, the results assume an idealized model that is unlikely to hold in many settings. Here we consider exploratory co-clustering of a bipartite network whose nodes are sampled from an arbitrary population. This is equivalent to assuming a nonparametric generative model known as a graphon. We show that clusters found in the data by any method will extend to the population, or equivalently that the estimated blockmodel approximates a blocked version of the generative graphon, with error bounded by n^{-1/2}. Analogous results are also shown for degree-corrected and random dot product graph models.

2 - Aggregate Variation Under Network Perturbation

Azarakhsh Malekian, Rotman School of management, azarakhsh.malekian@rotman.utoronto.ca

We consider a game among agents represented by nodes of a graph in which the utility of each agent depends on the externalities from his neighbors. We study the sensitivity of equilibrium actions of agents with respect to the strengths of the network structure and its connections in both random and deterministic settings.

3 - Diffusion Disparities In Competitive Settings

Yotam Shmargad, School of Information, University of Arizona, yotam@email.arizona.edu

In many settings, competing groups have different resources at their disposal, resulting in imbalances in their abilities to seed messages. We conduct an experimental study to investigate the effect of network structure on diffusion in a setting with asymmetric seeding. We manipulate network structure by randomly assigning participants to social networks that vary in clustering (i.e. the extent to which individuals' ties are connected to each other). We then seed competing messages in these networks and model their diffusion over the course of eight days. We find that clustering perpetuates the disparities in exposure to asymmetrically-seeded messages.

Distributionally Robust Optimization

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Angelos Georghiou, Swiss Federal Institute of Technology, Zurich, Zurich, 00000, Switzerland, angelosg@control.ee.ethz.ch

Co-Chair: Grani Adiwena Hanasusanto, University of Texas at Austin, Austin, TX, 1015, United States, grani.hanasusanto@utexas.edu

1 - Robust Control With Adjustable Uncertainty Sets: Providing Frequency Reserves To The Power Grid Via Demand Response

Angelos Georghiou, Dr, Swiss Federal Institute of Technology, Zurich, Switzerland, angelosg@control.ee.ethz.ch, Xiaojing Zhang, Maryam Kamgarpour, John Lygeros

Given a fixed uncertainty set, robust control finds a policy that minimizes a given cost while satisfying the system's constraints for all uncertainty realizations. In this work, we extend the robust control setup by allowing both the policies and the uncertainty sets to be decision-dependent, which we refer to as adjustable uncertainty sets. By restricting the set of admissible policies, we can cast the problem as a tractable convex optimization problem. We showcase the effectiveness of our approach on a demand response problem, providing frequency reserves to the power grid.

2 - Two-stage Distributionally Robust Linear Programming Over Wasserstein Balls

Grani Adiwena Hanasusanto, Assistant Professor, The University of Texas at Austin, Austin, TX, United States, grani.hanasusanto@utexas.edu, Daniel Kuhn

We study two-stage stochastic linear programming problems where the distribution of the uncertain parameters is ambiguous and is only known to belong to a family of all distributions that are close to the empirical distribution with respect to the Wasserstein metric. We derive an exact copositive program for the generic problems and formulate a tractable linear program for instances with only right-hand side uncertainty. We illustrate the effectiveness of our reformulations in numerical experiments and demonstrate their superiority over the classical sample average approximation scheme and the state-of-the-art moment-based model.

3 - Bounds On Random Binary Quadratic Programs

Karthik Natarajan, Singapore University of Technology and Design, karthik_natarajan@sutd.edu.sg

In this paper, we consider a binary quadratic program (BQP) with random objective coefficients. Given information on the marginal distributions of the objective coefficients, we propose new bounds on the expected optimal value of the random BQP. Preliminary computational results on random quadratic unconstrained binary optimization problems and random quadratic knapsack problems provides evidence of the quality of the bounds.

4 - Multi-objective Robust Optimization

Aurelie Thiele, Associate Professor, Southern Methodist University, Dallas, TX, United States, aurelie@alum.mit.edu

We investigate robust optimization frameworks for decision-making under high uncertainty when the decision maker has multiple, possibly conflicting objectives. Of particular interest is a situation with competitors seeking to either maintain or gain the lead in some of the markets the decision maker operates in. The decision maker must decide whether to use his budget defending his current positions or trying to take the lead in others. We investigate distributionally robust paradigms in those cases.

1 - Piecewise Affine Policies For Two-stage Optimization Under Demand Uncertainty

Vineet Goyal, Columbia University, vgoyal@ieor.columbia.edu, Aharon Ben-Tal, Omar El Housni

We consider the problem of designing piecewise affine policies for two-stage robust linear optimization under right hand side uncertainty. Such problems arise in many settings with demand uncertainty. One of the main challenges for piecewise affine policy is designing the pieces of the uncertainty set. We introduce a new framework where we approximate the set by a simplex and construct a piecewise affine policy from a map between the uncertainty set and simplex. Our policy can be computed efficiently and performs significantly better than affine policy for many interesting uncertainty sets.

2 - Distributional Robust Analysis For Log-concave And IFR Distributions

Simai He, Shanghai University of Finance and Economics, simaihe@mail.shufe.edu.cn

Distributional free robust optimization have raised attention for a long time, however it has been criticized as too over-conservative. Especially, the bounds yield from the so-called moment problems corresponds to few points discrete distributions, which are usually considered too extreme in practice. Increasing failure rate (IFR) and log-concave distribution assumptions are too widely accepted and applied distribution assumptions in many area. We develop general distributional free robust optimization theory with such distribution assumptions, based on optimum solution structure of a particular class of non-convex optimization problems.

3 - Recovering Statistical Guarantees Via The Empirical Robust Optimization

Henry Lam, University of Michigan, khlam@umich.edu

We investigate the use of distributionally robust optimization (DRO) in recovering the statistical guarantees provided by the best benchmark that is in line with the central limit theorem, for the feasibility of expected value constraints. We show that the divergence ball, suitably empirically defined, and with its size calibrated by the quantile of a chi-square process excursion, amounts to such guarantees. The construction of this ball deviates from the standard mechanism of DRO in that the ball can have low, or even zero probability of covering the true distribution. Rather its performance is explained by connecting the dual of the DRO with a generalization of the empirical likelihood method.

4 - Optimal Regret In Multi Armed Bandits Under Heavy Tailed And Correlated Reward Processes

Alexej Proskynitopoulos, Northwestern University, Evanston, IL, United States, alexej.proskynitopoulos@kellogg.northwestern.edu, Chaithanya Bandi

It is well known that Thomson Sampling and UCB based algorithms achieve the optimal regret for Bandits with light tailed reward processes. In this talk, we present a new framework for deriving these optimal algorithms which achieves optimal regret for heavy tailed reward processes as well as a bound for correlated arms. We also derive the order of the optimal regret as a function of the heavy tail coefficient and correlation.

1 - Missing Data Imputation Via A Modern Optimization Lens

Colin Pawlowski, Massachusetts Institute of Technology, Cambridge, MA, United States, cpawlows@mit.edu, Dimitris Bertsimas, Ying Zhuo

We propose an optimization framework for missing data imputation. The formulation imputes missing values to minimize the total distance to the K-nearest neighbors of each data point. Because the problem is non-convex, we derive a fast first-order method opt.impute to find high-quality solutions. On a sample of 64 data sets with 25% hidden values, opt.impute produces the best overall imputation in 40 data sets benchmarked against state-of-the-art methods. Further, the relative performance of opt.impute improves as the percentage of missing data increases, and for problems with the highest percentage of missing data, the mean absolute deviation from true values is lowered by 2.4%.

2 - Multi-target Tracking Via Mixed Integer Optimization

Shimrit Shtern, Operations Research Center, MIT, sshtern@mit.edu, Zachary C. Saunders

The Multi-target tracking problem combines the problems of assigning sensor detections to targets and estimating the target trajectory. Inaccuracies in the detection process make this a difficult problem. The literature is abundant with probability based models, but few optimization based models have been suggested, which mostly focus on model accuracy rather than interoperability or solvability. In our work we develop a simple and interpretable mixed integer optimization model, which is warm started by an appropriate heuristic, and yields high quality solutions in a reasonable time.

3 - Optimal Sparse Inverse Covariance Estimation

Jourdain Bernard Lamperski, Operations Research Center, MIT, jourdain@mit.edu

We consider the maximum likelihood estimation of sparse inverse covariance matrices. We formulate the estimation problem as a nonlinear MIP and develop a novel decomposition approach that solves the formulation to optimality. Using a variety of datasets, we demonstrate that the approach scales to problem sizes of interest and yields sparser solutions than existing methods, while maintaining desirable statistical properties.

4 - Optimal Low Rank Factor Analysis

Martin S. Copenhaver, Operations Research Center, MIT, Cambridge, MA, United States, mcopen@mit.edu, Dimitris Bertsimas, Rahul Mazumder

Factor Analysis (FA) is a technique that is widely used to obtain a parsimonious representation of correlation structure among a set of variables in terms of a smaller number of common hidden factors. In this talk we revisit the classical rank-constrained FA problem and propose a flexible family of exact, smooth reformulations for this task. By coupling state-of-the-art techniques from nonlinear optimization with methods from discrete and global optimization, we show that our approach often finds certifiably optimal solutions and significantly outperforms existing publicly available methods across a variety of real and synthetic examples.

1 - A Decomposition Heuristic For The One-warehouse Multi-retailer Problem With Batch Costs

Alejandro Toriello, Georgia Institute of Technology, Atlanta, GA, United States, atoriello@isye.gatech.edu, Weihong Hu

We consider a one-warehouse, multi-retailer system with deterministic dynamic demand over a discrete finite horizon, where orders placed by any facility incur batched fixed costs. We propose a decomposition heuristic that solves the warehouse's and retailers' problems separately and then judiciously converts the separate solutions into a globally feasible solution with worst-case approximation guarantee of 2; this improves the previously best-known ratio of 3.6. Time permitting, we will discuss the extension to concave batch costs.

2 - Bounds For The Euclidean Generalized Travelling Salesman Problem

John Gunnar Carlsson, University of Southern California, jcarlsso@usc.edu

We study the Euclidean generalized travelling salesman problem (GTSP), in which the goal is to find a tour that visits one element from each of a collection of point sets. Our results characterize the long-term, asymptotic behavior of the tour length when a large number of points are sampled, and give rise to a number of counterintuitive managerial insights.

3 - Distributionally Robust Travelling Salesman Problem With Wasserstein Distance

Mehdi Behroozi, Visiting Scholar, University of Southern California, Los Angeles, CA, United States, mehdi.behroozi@usc.edu, John Gunnar Carlsson

Recent research on the robust and stochastic Euclidean travelling salesman problem has seen many different approaches for describing the region of uncertainty, such as taking convex combinations of observed demand vectors or imposing constraints on the moments of the spatial demand distribution. In this paper, we consider a distributionally robust version of the Euclidean travelling salesman problem in which we compute the worst-case spatial distribution of demand against all distributions whose Wasserstein distance to an observed demand distribution is bounded from above. This constraint allows us to circumvent common overestimation that arises when other procedures are used.

1 - Physician Quality And Online Reviews

Danish Saifee, PhD Student, Naveen Jindal School of Management/The University of Texas at Dallas, 800 West Campbell Road, Richardson, TX, 75080, United States, dxs121230@utdallas.edu, Indranil Bardhan, Eric Zheng

We investigate how online reviews and physician competence differ in terms of their impact on clinical outcomes. Using a panel of COPD patients, we find that physicians with higher competence exhibit better patient outcomes.

2 - Patient Experience And The Adoption And Use Of Hospital Health Information Technology

Yunfeng Shi, Assistant Professor, The Pennsylvania State University, 504E Ford Building, University Park, PA, 16802, United States, yus16@psu.edu, Verónica Fuentes Cáceres

This study evaluates the impact of EHR capability on Patient Experience. Using information from the Hospital Compare and HIMSS, we constructed a longitudinal sample (2007 -2013) of 2808 hospitals and estimated the impact with a linear fixed effects model. In particular, we examined how the 5 different levels of EHR capabilities, as defined in previous research, were related to the 10 HCAHPS outcomes reported in Hospital Compare, including patient satisfaction, patient-provider communication, and discharge information. Our findings suggest that having the highest level of EHR capability may have a positive impact on patient experience, although the magnitude of the impact is generally small.

3 - The Evidence On Chronic Kidney Disease Patient Education: A Review Of The Literature And A Case Study

Hilary Wolfendale, Doctoral Student, Carnegie Mellon University, Hamburg Hall, 4800 Forbes Avenue, Pittsburgh, PA, 15213, United States, hwolfend@andrew.cmu.edu, Rema Padman, Amelia M Haviland

The prevalence of chronic kidney disease (CKD) is rising in the United States. While CKD cannot be reversed, CKD health education may delay the progression of the disease. Consequently, Medicare began offering a series of education sessions promoting behaviors that can postpone the need for dialysis or transplant in CKD patients. This study 1) evaluates the current state of evidence supporting education-based interventions for CKD patients and 2) examines electronic health record data from a community nephrology practice for preliminary evidence of any impact of Medicare's education sessions.

4 - Designing M-health Services For User Engagement And Health Promotion: An App For Healthy Eating

Yi-Chin Kato-Lin, Hofstra University, Hempstead, NY, United States, yichin.lin@hofstra.edu

Mobile technologies have the potential to engage patients in managing their healthy behaviors, such as healthy eating. However, few advanced functionalities have been employed in practice for promoting healthy eating. This study proposes novel mobile-enabled interventions by upgrading three interventions commonly used in practice: self-monitoring, professional support, and peer support. Surveys reveal user satisfaction and heterogeneous preferences among subpopulations. This study provides strategic insights that are generalizable to other healthy behaviors.

1 - Evaluating Diversion Programs For Drug Offenders

Margaret Brandeau, Stanford University, Stanford, CA, United States, brandeau@stanford.edu, Cora Bernard, Konner Robison

Jails in the US process more than 11 million people each year, and the prevalence of communicable diseases such as HIV, hepatitis C and tuberculosis is much higher in jails than in the general population. We investigate the costs and health impact of a jail-diversion program for low-level drug offenders which is currently being pioneered in Seattle. We simulate the flow of at-risk people through the criminal justice system and drug treatment programs, comparing outcomes for those who get into the diversion program with those who do not. The goal is to estimate the costs and health benefits of the diversion program, and its impact on public health as well as on the criminal justice system.

2 - Carrot Or Stick? The Role Of Incentives In Achieving Meaningful Health It Security

M Eric Johnson, Professor, Vanderbilt Universtity, Nashville, TN, 37205, United States, eric.johnson@owen.vanderbilt.edu, Juhee Kwon

The U.S. HITECH Act provided healthcare providers with both financial incentives and penalties linked to an EHR certification process, referred to as "meaningful-use" attestation. We consider the impact of these incentive on information security. We find that both carrot and stick strategies are required for mitigating different information security risks.

3 - Prioritizing Hepatitis C Treatment In US Prisons

Turgay Ayer, Georgia Tech, ayer@isye.gatech.edu, Can Zhang, Anthony Bonifonte, Anne Spaulding, Jagpreet Chhatwal

Prisons, which represent approximately 30% of the national HCV prevalence, offer a great opportunity to control the epidemic of HCV. However, state prison systems typically have very tight budgets and cannot bear the cost burden of HCV treatment. Therefore, in current practice, only a small portion of HCV-infected inmates are treated based on some prioritization rules. In this study, we propose a restless bandit model framework to support HCV treatment decisions in prisons. We propose a capacity-adjusted closed-form index-based prioritization policy and show that our policy performs much better than the myopic policy and the well-known Whittle's index.

Sponsored Session

Chair: Mabel Chou, National University of Singapore, Mochtar Riady Building, 15 Kent Ridge Drive, BIZ1 #8-66, Singapore, Singapore, mabelchou@nus.edu.sg

1 - Optimal Mobile Health Clinic Delivery Aimed At Minimizing Long-run Average Healthcare Costs

Fang Liu, Nanyang Technological University, liu_fang@ntu.edu.sg, Pengfei Guo, Song Jiu, Yulan Wang

People in remote area have poor access to health care services. Mobile health clinics (MHC) provides a solution to this problem by delivering health care services to them. We first develop a discrete-time Markov model to capture the progression of a chronic disease and then characterise the optimal delivery policy that minimizes the long-run average healthcare cost. we find that when the disease is fast progressive, MHC should be delivered in every period or two periods.

2 - Appointment Scheduling With Time-dependent Patient No-show

Qingxia Kong, Assistant Professor, Erasmus University, Rotterdam, Netherlands, qingxia.kong@gmail.com, Shan Li, Nan Liu, Chung-Piaw Teo, Zhenzhen Yan

We study independent data sets from countries on two continents which identify a significant time-of-day effect on patient arrival probabilities. We deploy a distributionally robust model to find the optimal scheduled arrival times for patients.

3 - Hospital Portering Service Delivery Analysis And Design

Mabel Chou, National University of Singapore, Singapore, Singapore, mabelchou@nus.edu.sg

This paper aims to improve the overall performance of the porter system at a hospital in Singapore. We focus on reducing the response times of porters and therefore reducing the patient waiting times. Our analysis reveals that the performance of porter stations is in general better than the performance of central pool station with respect to response and completion times for jobs. We discover three main reasons for the performance differences, which are an understaffed central pool, an overstaffed emergency department and possibly other stations, and differences in distances travelled between central pool and stations. We then discuss how to redesign the system to improve the overall performance.

Decision Models in Healthcare/Clinical Settings.

Sponsored: Health Applications

Sponsored Session

Chair: Vishal Ahuja, Southern Methodist University, 12, Dallas, TX, United States, vahuja@smu.edu

1 - Issuing Policies For Hospital Blood Inventory

Alireza Sabouri, Haskayne School of Business, University of Calgary, alireza.sabouri@haskayne.ucalgary.ca, Steven Shechter, Woonghee Tim Huh

We propose a model for allocating red blood cells for transfusion to patients, which is motivated by recent evidence suggesting that transfusing older blood is associated with increased mortality rate. We study the properties of blood issuance policies that balance the trade-off between "quality" measured in average age of blood transfused and "efficiency" measured in the amount of shortage. Based on our analysis, we design efficient issuance policies and evaluate their performance.

2 - Quantitative Approaches For Measuring And Relieving Congestion In A Dialysis Unit At A Hospital: The Case Of Compassionate Dialysis

Olga Bountali, Southern Methodist University, 3145 Dyer street, Dallas, TX, United States, obountali@smu.edu, Sila Çetinkaya, Vishal Ahuja

We examine a congested healthcare delivery setting due to emergency treatment of a chronic disease. A prominent example of the problem of interest is congestion in the emergency room due to arrival of unfunded ESRD patients needing dialysis (a.k.a., compassionate dialysis). Unfortunately, this is the only treatment option for undocumented immigrants with ESRD., i.e., when their clinical condition is deemed as life-threatening. We model the problem as a queueing network with recurrent arrivals and service and examine various performance metrics impacting patient welfare and social cost.

3 - Efficient Sampling From Large Databases For Controlled Trials

Sanjay Mehrotra, Professor, Northwestern University, Evanston, IL, 60208, United States, mehrotra@northwestern.edu, Daniel Apley, Liwen Ouyang

Controlled trials are ubiquitously used to investigate the effect of a medical treatment. The trial outcome can be dependent on a set of patient covariates. Traditional approaches have relied primarily on randomized patient sampling and allocation to treatment and control groups. We will present an approach that uses optimal design of experiments (DOE) concepts to select the patients for the treatment and control groups, based on their covariate values, in a manner that optimizes the information content in the data.

4 - Optimal Stopping For Response-guided Dosing

Jakob Kotas, PhD, University of Portland, Portland, OR, 37221, United States, kotas@up.edu

One important decision in response-guided dosing is when to stop treatment. In practice, stopping often occurs for patients in remission, or due to a finding of futility or a desire to switch to a different drug. We have previously developed a stochastic dynamic programming framework for response-guided dosing which tailors dose to a patient's stochastic evolution of disease state. In this talk we present an extension of that model that allows for stopping before the scheduled end time. Our numerical simulations show optimality of stopping below a threshold state. We also outline structural properties of the stopping formulation, including monotonicity of the threshold state with respect to time.

Chair: Xiaoqiang Cai, The Chinese University of Hong Kong, Shatin NT, xqcai@se.cuhk.edu.hk

1 - Procurement Strategies With Asymmetric Yield Information

Houcai Shen, Nanjing University, hcshen@nju.edu.cn

In this paper, we study firm purchase behavior when her supplier has private information about his yield rate.

2 - Optimal Design Of Omnichannel

Xiaolin Xu, Nanjing University, xuxl@nju.edu.cn

Nowadays omnichannel has received much attention in retail industry. However, how to design an appropriate omnichannel strategy is a challenge facing the retailers. For example, retailer can provide BOPS (buy online and pickup at store) or STOP (shipment to store for consumers to pickup at store), in addtion to the traditional O2O (online vs. offline) channels. The channel BOPS shares the store inventory with the offline channel, while the channel STOP shares the DC (distribution center) inventory with the online channel. We investigate how these two omnichannel strateties affect the market segmentation, fill rates at store and the retailer's profit.

3 - Pricing And Ordering Strategies Of Supply Chain With Selling Gift Cards

Wenqing Shi, University of Electronic Science and Technology of China, Chengdu, China, shiwenqing1218@163.com, Jingming Pan, Xiaowo Tang

Gift cards is one popular promotion way in market, which is widely used to replace traditional gift cash and gift products, especially when gift givers do not know gift receivers' performances. Basing on this phenomenon, we develop a Stackelberg model to analyze the supplier's and retailer's optimal strategies with selling gift cards. We also exam the influences of different parameters on the optimal decisions and the supply chain performance.

4 - Product Quality Choice In Two-echelon Supply Chains Under Post-sale Liability: Insights From Wholesale Price Contracts

Jianchang Fan, Doctor, University of Electronic Science and Technology of China, Qingshuihe Campus: No.2006, Xiyuan Ave, West Hi-Tech Zone, Chengdu, 611731, China, love.andyfan@163.com, Debing Ni

A two-stage game model in a supply chain consisting of a manufacturer (M) and a Retailer (R) is built via a wholesale price contract. M is liable for the harm caused by its low-quality products. In the equilibrium, we find that (1) in spite that product liability positively affects the wholesale price, M's quality level, the contracted quantity and the supply chain members' profitability are independent of it; (2) in response to changes in liability-related factors, the product quality is in conflict with the profits for both M and R, but the quality and the profit increase in quality improvement efficiency; (3) the wholesale price serves as a medium for M to share its ex ante expected liability cost with R.

Auctions, Markets, and Mechanism Design

Invited: Auctions

Invited Session

Chair: Brian Baisa, Amherst College, Amherst, MA, United States, bbaisa@amherst.edu

1 - Mechanism Design For Team Formation

Greg Leo, Vanderbilt University, Nashville, TN, United States, g.leo@vanderbilt.edu, Martin van der Linden, Jian Lou, Yevgeniy Vorobeychik, Myrna Wonders

Team, or coalition, formation is a fundamental problem in AI and game theory. While there has been extensive research on coalitional stability, especially in hedonic games, the problem of designing mechanisms for coalition formation has received relatively little attention. Theoretically, most of what is known about such design problems is negative; for example, no mechanism that always matches soulmates (individuals who prefer to be matched together) is strategyproof in general. We describe some of our recent positive results about achieving efficiency, incentive compatibility, individual rationality, and coalitional stability in important restricted classes of hedonic preferences.

2 - Equilibrium In a Uniform-Price Auction withPrivate Values

Justin Burkett, Wake Forest University, burketje@wfu.edu

In a model incorporating bidders with private information bidding for multiple units of a homogeneous good, I show that the equilibrium bid functions can be completely characterized, sometimes in closed form. The equilibrium bid functions can be considered aggregated bid functions from first-price single unit bidders. This property allows one to extend results from the single-unit auction literature to this multi-unit setting.

3 - Strategic Ironing In Pay-as-bid Auctions: Equilibrium Existence With Private Information

Kyle Woodward, University of North Carolina at Chapel Hill, Gardner Hall, CB 3305, Chapel Hill, NC, 27599-3305, United States, kyle.woodward@unc.edu

I establish the existence of pure-strategy Bayesian-Nash equilibria in divisible-good pay-as-bid auctions with private information, and show that such equilibria can approximate equilibria in nearby multi-unit auctions. I show that equilibrium strategies exhibit strategic ironing, a reduction of bids below what might be expected. Strategic ironing has implications for the tractability of equilibrium strategies.

4 - Efficient Multi-unit Auction Design Without Quasilinear Preferences

Brian Baisa, Amherst College, bbaisa@amherst.edu

I study efficient multi-unit auction design when bidders have private values, multi-unit demands, and non-quasilinear preferences. Without quasilinearity, the Vickrey auction loses it desired incentive and efficiency properties. I construct a novel mechanism that retains the desirable properties of Vickrey auction, even in cases when bidders have non-quasilinear preferences. When bidders have single dimensional types, the mechanism (1) is dominant strategy incentive compatible, (2) is Pareto efficient, and (3) provides no subsidies. If bidders types are multi-dimensional, I show that there is no mechanism that satisfies these three properties.

New Frontiers in Operations Management

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Retsef Levi, Sloan School of Management, 100 Main Street, Building E62-562, Cambridge, MA, 02142, United States, retsef@mit.edu

1 - Exploration Vs. Exploitation: Reducing Uncertainty In Operational Problems

Yaron Shaposhnik, MIT, Cambridge, MA, 02139, United States, shap@mit.edu, Chen Attias, Robert Krauthgamer, Retsef Levi

We study a broad class of multistage stochastic combinatorial optimization models that capture a fundamental tradeoff between performing work and making decisions under uncertainty (exploitation) and investing capacity to reduce the uncertainty in the decision making (exploration). Unlike existing models that take a Bayesian approach to learning (through sampling), we study a learning mechanism called testing (also known as probing or querying), in which exact realizations from known distributions are observed. We derive insightful structural results on the optimal policies that include the optimality of local decision rules.

2 - Competitive Analysis Of Online Scheduling Algorithms For Infusion Center Appointments

Michael Hu, MIT, Cambridge, MA, United States, hum@mit.edu, Kimia Ghobadi, Retsef Levi

We study the problem of minimizing resource requirements of infusion centers through the use of optimized appointment scheduling. We do this by developing a modeling framework that generalizes online bin packing. We then describe 3 different online scheduling algorithms for the problem and analyze their performance via competitive analysis. Our main result in this work is an online algorithm that is 2-competitive under certain assumptions on the appointment requests. We also establish lower bounds on the competitive ratios for all 3 online algorithms in both the most general setting and when assumptions are made on the appointment data.

3 - Incentivized Actions In Freemium Games

Lifei Sheng, PhD Candidate, UBC, 2053 Main Mall, Vancouver, BC, Canada, fay.sheng@sauder.ubc.ca, Christopher Ryan, Mahesh Nagarajan

We study the common phenomena of mobile game companies offering users “virtual” benefits to take actions in-game that earn the game company revenue from third parties. Examples of “incentivized actions” include paying users in “gold coins” to watch video advertising or to fill out a survey. We explore the costs and benefits of offering incentivized actions as users progress in their engagement with the game. We find sufficient conditions for when it is optimal to follow a threshold strategy of offering incentivized actions to low-engaged users and then remove them once a user is sufficiently engaged. We also provide insights into what types of games benefit most from offering incentivized actions.

4 - Process Capacity: Exact Analysis And The Bottleneck Formula

Yang Bo, Naveen Jindal School of Management, The University of Texas at Dallas, 2200 Waterview Pkwy, Apt. 27304, Richardson, TX, 75080, United States, yxb120630@utdallas.edu, Milind Dawande, Tim Huh, Ganesh Janakiraman, Mahesh Nagarajan

We offer a rigorous understanding of process capacity for a single-product process, culminating in a precise expression for this quantity. We also contrast this with the widely used formula based on bottle-neck capacity.

Operations Management for Fashion Goods

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Robert Swinney, Duke University, Durham, NC, United States, robert.swinney@duke.edu

1 - Attribute-based Modeling Of Product Recommendations

Sajad Modaresi, Duke University, Durham, NC, United States, sajad.modaresi@duke.edu, Fernando Bernstein

We study product recommendations through data analytics in the context of fashion retailing. Using a Bayesian semi-parametric approach, we identify customers with similar preferences for products, which is the basis for the product recommendation system. We test our results using a dataset from a large European clothing manufacturer.

2 - Managing Online Content To Build A Follower Base

Felipe Caro, UCLA Anderson School of Management, felipe.caro@anderson.ucla.edu, Victor Martínez-de-Albéniz

Content providers typically manage a dual objective of generating interest for current followers and at the same time reaching out to new audiences that may become repeat visitors. The pace at which content is created must thus take into account how much it contributes to maintain the follower base. We formulate a simple model to study follower base build-up dynamics under the assumption that the attractiveness of past content decays over time. Using stochastic dynamic programming we develop heuristics for content release and an upper bound to assess performance. We then apply our model to the case of blogs.

3 - Inventory And Channel Integration In The Presence Of Strategic Consumers

Arian Aflaki, Duke University, Durham, NC, United States, aa251@duke.edu, Robert Swinney

We study the impact of inventory and channel integration on a firm that sells a product to consumers that are strategic in two dimensions: they decide “whether” and “when” to visit the firm based on the availability risk, cost to visit, and price of the product. The firm decides whether to operate in a multichannel setting and dedicate separate inventory to multiple markets, or to integrate the system and combine the inventory between the markets. We show that integration can be much less valuable in the presence of strategic consumers and may even possess a negative value.

4 - Fast And Furious? The Impact Of Delivery Lead-times In Online Buyer Behavior

Eduard Calvo, Assistant Professor, IESE, Barcelona, Spain, ecalvo@iese.edu, Víctor Martínez-de-Albéniz, Alex Thiele

Many e-commerce firms implement efforts to reduce their lead-times believing that faster deliveries make online buyers “happier” and thus more likely to buy more. However, the specific mechanisms through which lead-time reductions connect with sales growth are still not well understood. In this work, we leverage user and click-level activity data from an e-commerce player to find evidence of this connection. The data spans a period of time during which the firm undertook several lead-time cutting initiatives, and we build a structural model that allows us to study the impact of those on online buyer behaviour as described by traffic, conversion rates, and average ticket values.

Innovative Models in CLSC: Returns, Remanufacturing, Recycling, and Servicization

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Gal Raz, Ivey Business School, 1255 Western Rd., London, ON, N6G 0N1, Canada, graz@ivey.ca

1 - Recycling As A Strategic Supply Source

Gal Raz, Ivey Business School, Western Unversity, graz@ivey.ca

We investigate how recycling can be used as a strategic source of supply in the presence of competition and a powerful material supplier. We examine the economic and environmental impact of a manufacturer’s decision to recycle its products and the implications for its customers, supplier, and society. We show that the result depends on the type of recycling the manufacturer does as well as on the market dynamics and price of recycling.

2 - Servicizing Business Models: A Supply Chain Perspective

Jeremy John Kovach, Assistant Professor, Texas Christian University, TCU Box 298530, Fort Worth, TX, 76129, United States, j.j.kovach@tcu.edu, Ioannis Bellos

In recent years we have observed several auto manufacturers introducing car sharing programs. In this paper we study the different types of supply chain structures that manufacturers can use to sell cars and provide car sharing services.

3 - The Effect Of Regulation on DfE Innovation

Cheryl Druehl, George Mason University, cdruehl@gmu.edu, Gal Raz, Vered Blass

We examine the DfE innovations, use stage and refurbishing, of a firm selling new primary market products and refurbished products in a secondary market. The firm determines innovations, prices, and fraction collected. Using LCA data from cell phones, we compare EPR and Use stage regulations on profits and environmental impact.

4 - Drivers And Benefits Of Return Policies For Online Retailers

Guangzhi Shang, Florida State University, gshang@business.fsu.edu

The common retail practice of full refunds is inconsistent with the recommendations of many analyticalmodels of returns, which almost always show that a partial refund is optimal. We use data collected from eBay to analyze both the return policy drivers from the seller's perspective and the return policy value from the consumer's perspective, providing insights to two potential explanations for the gap between theory and practice.

Retail Operations II

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Santiago Gallino, Dartmouth College, Hanover, NH, United States, santiago.gallino@tuck.dartmouth.edu

1 - Optimizing Customer Pick-up Locations Using An Empirical Model

Chloe Kim, The Whaton School, chloekim@wharton.upenn.edu, Marshall L Fisher, Xuanming Su

We empirically study the determinants of pick-up location success for an online grocery retailer. We consider various aspects of individual locations, including local competition, local consumer attributes, and the potential for cannibalizing sales from other locations. We suggest an algorithm for optimizing pick-up locations and measure its impact on revenue.

2 - Prioritizing Outbound Calls In A Sales Contact Center

Marcelo Olivares, Universidad de Chile, molivares@u.uchile.cl

We study an outbound call center that provides sales support to an online platform selling auto insurance. When setting priorities among which customers to contact, it is necessary to identify which calls are more likely to convert into sales. We develop an econometric approach to conduct this segmentation using detailed customer-level transaction data. A key factor in our analysis is the customer elapsed time since receiving the quote, which has a significant negative effect in sales conversion. This approach can be used to implement an automated priority system to manage outbound calls and can be adapted to other types of contact centers.

3 - Management And Effects Of In-store Promotional Displays

Oguz Cetin, UNC Kenan-Flagler Business School, Oguz_Cetin@kenan-flagler.unc.edu, Adam J Mersereau, Ali Kemal Parlakturk

Promoting a product via an in-store display can increase demand for it by making it more visible to customers, but it may also impact demand for other products by changing customer traffic patterns in the store. We characterize the optimal choice of product to promote in a nested multinomial logit formulation, and we examine the impact on product, category, and store profits.

4 - Spatial Competition And Preemptive Entry In The Discount Retail Industry

Fanyin Zheng, Columbia Business School, fz2225@gsb.columbia.edu

This paper studies how discount retailers make store location decisions by estimating a dynamic game model. It extends the empirical models of dynamic oligopoly entry by allowing for spatially interdependent entry and introducing machine learning tools to infer market divisions from data. The results suggest that preemptive incentives are important in chain stores' location decisions and that they lead to loss of production efficiency.

Co-Chair: Qi Wu, Case Western Reserve University, Cleveland, OH, 44106, United States, qxw132@case.edu

1 - Capital Structure With Asset Flexibility

Qi Wu, CWRU, Cleveland, OH, United States, qxw132@case.edu, Peter Ritchken

We study the impact of asset flexibility on the design of an optimal capital structure in a dynamic model in which the firm has multiple debt issues and equityholders choose the timing and financing of future growth options as well as the operating policy for assets in place. We show that, all things being equal, profitable firms with flexible assets exercise their growth options earlier, use less debt, and will typically be less leveraged than otherwise identical firms with no asset flexibility. When asset flexibility allows risk-shifting possibilities, firms exercise growth options even earlier.

2 - Operational And Financial Interactions In Supply Chain Network Structure

John R Birge, University of Chicago, John.Birge@ChicagoBooth.edu

3 - Competitive Risk Management

Danko Turcic, Washington Univ. in St. Louis, turcic@wustl.edu, Guang Xiao, Panos Kouvelis

This paper provides a new rationale for hedging that is based, in part, on non-competitive behavior in product markets. We identify a set of conditions, which imply that a firm may want to hedge. Both operational and financial hedging strategies are considered.

4 - Inventory Operations Under The Shadow Of Company Stock Price

Guoming Lai, UT-Austin, laiguoming@gmail.com

Inventory management is one central problem of operations. The classical inventory theories typically focus on the operational tradeoffs to optimize the inventory decisions. In practice, however, many firms are public that often have short-term interests in their market value. Our analysis reveals that public firms may install more inventory in equilibrium to influence their earnings. We discuss the determinants of such an effect as well as the empirical evidence.

Chair: Med Labidi, Assistant professor, King Saud University, IED, Riyadh, 11421, Saudi Arabia, mlabidi@ksu.edu.sa

1 - A Mathematical Model And A Heuristic For The Capacitated Lot Sizing Problem In Process Industries

Chandrasekharan Rajendran, Professor, IIT Madras, DoMS, IIT Madras, Chennai, 600036, India, crajiitm@gmail.com, Ramya Ravi, Hans Ziegler

In this work, we consider the capacitated lot sizing problem (CLSP) with production carryover and setup carryover across multiple periods in process industries. This CLSP is characterized by the commencement of production immediately after the setup of the product, and without any interruption in production. Mathematical and heuristic models are specifically developed for this class of CLSP. Also, the proposed heuristic exploits the Fixed-and-Relaxed principle. The computational effectiveness of both the models are evaluated using problem instances of various sizes, and are also reported. It is possibly the first time that such a CLSP is presented.

2 - Scheduling When You Don't Know The Number Of Machines

Mingxian Zhong, Columbia University, 528 Riverside Drive, Apt 4A, New York, NY, 10027, United States, mz2325@columbia.edu, Clifford Stein

We study scheduling environments in which you have to make some decisions before learning the number of machines. Specifically, we introduce a model in which you first need to group jobs into some sets, next you learn the number of machines and then you need to schedule sets of jobs on machines without separating them. We give a 9/5(1+epsilon)-approximation algorithm for minimizing makespan in this environment and show some hardness results.

3 - Facility Recovery Plan Under Resource Constraints

Gang Li, Bentley University, Management Department, 175 Forest Street, Waltham, MA, 02452-4705, United States, gli@bentley.edu, Xiangtong Qi

We address a facility recovery plan problem after disruption. The disruption has damaged some of the existing facilities while the resources used to repair these facilities are limited. This plan entails supply adjustment among customers and resource allocation among damaged facilities in order to minimize the total supply and shortage cost during the recovery period. In this talk, we present the problem formulation and discuss efficient algorithms to solve.

4 - Energy Conscious Robot Scheduling In Robotic Cell Manufacturing

Vahid Eghbal Akhlaghi, Research Assistant, Middle East Technical University, Cankaya, METU, Yurt. 2, room 112-1, Ankara, 06800, Turkey, vahid.akhlaghi@metu.edu.tr, Hakan Gultekin, Sinan Gurel

Robotic cells usually operate under time pressure to minimize time related objectives such as cycle time. Besides, robots consume significant amount of energy determined by the speeds and distances of their moves. We study the tradeoff between cycle time and energy consumption of a robot in a two machine flexible robotic cell. There are alternative cyclic schedules for such a cell and each cycle involves a number of different robot moves. Energy consumption of a robot is formulated as a convex function of its speed. Given a cycle time, we find optimal speeds for different robot moves in robotic cell cycles. We determine the best cyclic schedule and optimal robot speeds that minimize energy consumption.

Chair: Geonsik Yu, Yonsei University, Seoul, Korea, Republic of, geonsik.yu@gmail.com

1 - Siting A Geological Disposal Facility – A Discrete Event Simulation Approach.

Matthew Gilbert, Mr, University of Warwick, Statistics, University of Warwick, Coventry, CV4 7ES, United Kingdom, m.g.gilbert@warwick.ac.uk, Simon French, Jim Q Smith

Disposal of nuclear waste has become an increasing concern for the UK government over the past few decades. We present a discrete event simulation modelling changes in public opinion for their previous failed geological disposal siting attempt in Cumbria between 2009 and 2013. Using this we explore potential bias that could have been introduced at the end of the process.

2 - Estimating Cumulative Mean Behavior Using Standardized Time Series

Dashi Singham, Naval Postgraduate School, 1411 Cunningham Road, Operations Research Department, Monterey, CA, 93943, United States, dsingham@nps.edu, Michael Atkinson

We present an alternative to confidence intervals that evaluates the probability a sequentially updated sample mean stays within a given distance from the true mean of a process after a given initial sample size. This measure of reliability relies on properties of standardized time series, which we explore in relation to Brownian bridges.

3 - Managing The Delays Caused By Slow Groups In Golf

MoonSoo Choi, Columbia University, 500 West 120th Street, S.W. Mudd Building, New York, NY, 10027, United States, moonsoo.choi@columbia.edu, Qi Fu, Ward Whitt

We use simulation to study various models of slow groups and their significant impact on the pace of play in golf. We also compare different remedies to reduce the delays caused by slow groups. The golf course model is a series of eighteen queues in which multiple groups can play simultaneously with random stage playing times and precedence constraints.

4 - Simulation Metamodeling In The Presence Of Model Inadequacy

Xiaowei Zhang, Hong Kong University of Science and Technology-HKUST, Room 5559B, Academic Building, HKUST, Clear Water Bay, Hong Kong, NA, China, xiaoweiz@ust.hk, Lu Zou

A simulation model is often used as a proxy for the real system of interest in a decision-making process. However, no simulation model is totally representative of the reality. The impact of the model inadequacy on the prediction of system performance should be carefully assessed. We propose a new metamodeling approach to simultaneously characterize both the simulation model and its model inadequacy. Our approach utilizes both simulation outputs and real data to predict system performance, and accounts for four types of uncertainty that arise from unknown performance measure of the simulation model, simulation errors, unknown model inadequacy, and observation errors of the real system.

5 - When The Diversified Organization Prevails: A Simulation Approach

Geonsik Yu, Yonsei University, Seoul, Korea, Republic of, geonsik.yu@gmail.com

This research investigates through simulation the mechanism under which diversity improves the performance of a company. In experiments, we focus on the settings where the organization consisting of dissimilar members and try to explain the reported reality-instances where diversity is ineffective. Analyzing the characteristics of those settings, we identify that under what conditions the organizational diversity is more or less effective. The simulation model newly formulated in this study extends the existing methods that use discrete vectors and genetic algorithm and is able to include market needs and product paradigm shifts.

Joint Session HAS/MSOM: Healthcare Operations

Sponsored: Manufacturing & Service Oper Mgmt, Healthcare Operations

Sponsored Session

Chair: Mahboubeh Madadi, Louisiana Tech University, 123, Ruston, LA, 71272, United States, madadi@latech.edu

1 - Team Primary Care Practice Scheduling Problem

Ekin Koker, University of Massachusetts-Amherst, Amherst, MA, United States, ekoker@umass.edu, Hyun Jung Oh, Hari Balasubramanian, Ana Muriel

We consider the team primary care practice scheduling problem where each patient is seen by one of many available nurses before seeing her provider. In other words, the nurse step is flexible while the provider step is dedicated. Both steps have uncertain durations and these durations further depend on the type of patient — some patients require a longer service duration than others. The patients can also crossover in schedule, so the order of patients seen by the nurse might not be the same as the order in which the provider sees patients. We develop a two-stage stochastic integer programming model to solve this challenging scheduling problem and present computational results.

2 - Optimal Decision Making In The Processing Of Human Breast Milk

Ruichen Sun, University of Pittsburgh, Pittsburgh, PA, United States, rus19@pitt.edu, Lisa M Maillart, Andrew J Schaefer

Donated breast milk - collected, processed and dispensed via milk banks - is the standard of care for premature and unhealthy infants whose mothers cannot provide adequate supply. We formulate a multi-criteria mixed-integer program to optimize the daily decisions involved in the pooling of milk from different donors to meet macronutrient requirements across different product types, and the batching of pooled milk for efficient pasteurization. Our numerical results demonstrate significant improvements compared to historical decisions at our partner milk bank.

3 - A Stochastic Programming Approach For Surgery Scheduling Under Limited Availability Of Turnover Teams

Serhat Gul, TED University, serhat.gul@tedu.edu.tr

The number and availability of turnover teams may significantly affect the performance of a surgery schedule. We propose a two-stage stochastic integer programming formulation for setting the patient appointment times under limited availability of turnover teams. We consider the duration of surgical operation and turnover to be random variables. The objective is to minimize the competing criteria of patient waiting time and operating room idle time. We present a heuristic to solve the problem. We conduct numerical experiments using data from a large hospital.

Empirical Service Operations

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Robert Louis Bray, Kellogg School of Management, 830 Hinman Ave, Apt 2S, Evanston, IL, 60202, United States, robertlbray@gmail.com

1 - Modeling Growth In Service Operations: Evidence From The App Economy

Ken Moon, The Wharton School, Philadelphia, PA, United States, kenmoon@wharton.upenn.edu, Haim Mendelson

The best service firms expand and sustain their customer bases and profits organically through word of mouth and customer retention. We propose a customer-flow model fashioned after classical service operations models that focuses on the effects of customer retention, usage frequency, and growth (RFG). Using daily, weekly, and monthly usership data for services in the app economy, our results empirically demonstrate the importance of RFG, including that new apps score increasingly higher in growth by improving in service quality. Finally, we present evidence of an experience curve, analogous to that in manufacturing, whereby service events drive advances in service quality and RFG.

2 - Managing Product Quality In The Face Of Field Failures

Ahmet Colak, Northwestern University, Evanston, IL, United States, a-colak@kellogg.northwestern.edu

We model a manufacturer's and regulator's joint recall decisions as a dynamic discrete choice game. We estimate our model with 14,124 U.S. auto recalls and 976,062 defect reports over the period 1994—2015. We find that (i) automakers initiate recalls mainly to avoid field failure costs, and (ii) automakers don't preempt the regulator's interventions in 86% of our sample.

3 - Impact Of Callers' History On Abandonment: Model And Implications

Seyed Emadi, UNC - Kenan Flagler Business School, Chapel Hill, NC, 27599, United States, Seyed_Emadi@kenan-flagler.unc.edu, Jayashankar M Swaminathan

Caller abandonment could depend on their past waiting experiences. To tease out the impact of callers' waiting experiences on their abandonment behavior from the impact of their heterogeneity, we use a structural estimation approach in a Bayesian learning setting. Our framework has managerial implications at both tactical and operational levels such as managing customer expectation about their delays in the system, and implementation of patience-based priority policies such as Least-Patience-First and Most-Patience-First scheduling.

4 - Multitasking, Multi-armed Bandits, And The Italian Judiciary

Robert Louis Bray, Kellogg School of Management, robertlbray@gmail.com

We model how a judge schedules cases as a multi-armed bandit problem. The model indicates that a first-in-first-out (FIFO) scheduling policy is optimal when the case completion hazard rate function is monotonic. But there are two ways to implement FIFO in this context: at the hearing level or at the case level. Our model indicates the latter policy, prioritizing the oldest case, is optimal when the case completion hazard rate function increases. This result convinced six judges of the Roman Labor Court of Appeals—-a court that exhibits increasing hazard rates—-to switch from hearing-level FIFO to case-level FIFO. We estimate that our intervention decreased the average case duration by 12%.

Control, Learning, and Strategic Behavior in Queueing Models

Sponsored: Manufacturing & Service Oper Mgmt, Service Operations

Sponsored Session

Chair: Philipp Afeche, University of Toronto, 105 St. George Street, Toronto, ON, M5S 3E6, Canada, afeche@rotman.utoronto.ca

1 - Dynamic Control Of A Call Center With The Callback Option

Xiaoshan Peng, University of Chicago Booth School of Business, x-peng@chicagobooth.edu, Baris Ata

We investigate a call center with the callback option. An incoming customer is routed to an online queue or to an offline queue where she needs to hang up the phone and waits for the system to call her back. We characterize the optimal routing policy and service policy when the forecast of the arrival rate is available.

2 - Learning And Impatience In Queues

Senthil Veeraraghavan, Wharton School of the University of Pennsylvania, senthilv@upenn.edu, Li Xiao, Hanqin Zhang

We study the abandonment behavior of customers in M/M/1+G by the Bayesian learning approach. An arriving impatient customer knows the average arrival rate but does not know the average service rate. To have a rational abandonment, the arriving impatient customer has to learn the service rate. Two Bayesian learning ways are discussed in accordance with what kind information of the queueing system is available to the arriving impatient customer. Based on the learned service rate, the abandonment behavior is quantitatively characterized by the utility of the arriving impatient customer.

3 - Jumping The Line, Charitably: Analysis And Remedy Of The Donor Priority Rule

Tinglong Dai, Assistant Professor, Johns Hopkins University, 100 International Drive, Baltimore, MD, 21202, United States, dai@jhu.edu, Ronghuo Zheng, Katia P. Sycara

In the United States, the growth of the organ transplantation waiting list significantly outpaces the supply of donated cadaveric organs. Among a myriad of initiatives aiming to boost the supply, the donor priority rule, under which a registered organ donor, in case of needing a transplant, is given priority to receive a donated organ, has been weighed by U.S. policy makers. In this paper, we model the U.S. organ donation and allocation system using the strategic queueing theoretic framework. We propose a simple freeze-period mechanism, and prove that in conjunction with the donor priority rule, it can increase the supply of donated organs without compromising the average quality of the donor pool.

4 - Learning And Earning For Congestion-prone Service Systems

N. Bora Keskin, Duke University, Durham, NC, United States, bora.keskin@duke.edu, Philipp Afeche

Consider a firm selling a service in a congestion-prone system to price- and delay-sensitive customers. The firm faces Bayesian uncertainty about the consumer demand for its service and can dynamically make noisy observations on the demand. We characterize the structure and performance of the myopic Bayesian policy and well-performing variants.

1 - Optimal Stopping Of Subsidies To Products With Network Externality

Ningyuan Chen, HKUST, Hong Kong, Hong Kong, nychen@ust.hk, Saed Alizamir, Vahideh Manshadi

Many products exhibit network externality: a customer who has purchased the product makes his/her neighbors or friends more likely to buy the same product. This includes eco-friendly products such as electronic cars and solar panels. The government subsidizes customers to promote such products. We find that it is optimal for the government to stop the subsidy when the total externality of the owners reaches a threshold, which depends on the spectrum of the externality matrix. The optimal stopping time is not monotone in the strength of the externality between customers. We investigate how the structure of the network affects the stopping time and the optimal reward of the government.

2 - A Unifying Framework For Consumer Surplus Under Demand Uncertainty

Charles Thraves, MIT, cthraves@mit.edu, Maxime Cohen, Georgia Perakis

We present a general framework for consumer surplus when demand is stochastic and there are multiple items. We take a utility maximization approach in order to study the impact of demand uncertainty on consumers in several interesting settings. We show how the impact of uncertainty on consumers depends on the demand shape (convexity) and the allocation rule. In many settings we show that it can in fact hurt consumers.

3 - Price Competition Based On Relative Prices Or Subsidies

Awi Federgruen, Columbia University, New York, NY, United States, af7@gsb.columbia.edu, Lijian Lu

We consider price competition models for oligopolistic markets in which the consumer reacts to relative rather than absolute prices. The relative price is defined as the difference between the absolute price and a reference value., either a third party subsidy or a prospect theoretical reference price. Application areas We review five different application areas. We then characterize the equilibrium behavior under general reference value scheme , assuming the consumer choice model is of the general MultiNomial Logit type. We also derive comparison results for the price equilibria that arise under alternative Subsidy schemes. These have important applications for the design of subsidy schemes.

4 - Risk-aware Demand Management Of Aggregators Participating In Energy Programs With Utilities

Ana Radovanovic, Google, anaradovanovic@google.com

We present a methodology for modeling and optimally managing the demand of an aggregator with deferrable (flexible) loads (e.g., electric vehicles and HVACs) under uncertainty. We propose a unified framework for treating different types of flexible loads, that captures uncertainties in their parameters, and environmental conditions they are exposed to. Our optimization formulation minimizes the total expected cost, whose goal is to optimally balance two terms: user discomfort cost (regret), and cost paid to the utility. We propose a cost-efficient procedure for risk estimation, and provide guidelines for its consideration in cost-effective program selection.

Reliability

Contributed Session

Chair: Zhimin Xi, University of Michigan-Dearborn, 4901 Evergreen Road, 2240 HPEC, Dearborn, MI, 48128, United States, zxi@umich.edu

1 - Estimation Of Field Reliability Based On Aggregate Lifetime Data

Piao Chen, National University of Singapore, Singapore, Singapore, cp@u.nus.edu

Because of the exponential distribution assumption, many reliability databases recorded data in an aggregate way. The data format is different from traditional lifetime data and the statistical inference is challenging. In this study, we model the aggregate data by gamma distribution and inverse Gaussian (IG) distribution. Statistical inference methods are proposed.

2 - ALT With Exponentially Changing Stress Durations Under Cost Constraint

David Han, University of Texas at San Antonio, Management Science & Statistics, College of Business, San Antonio, TX, 78249-0632, United States, david.han@utsa.edu

When designing ALT, several variables such as the allocation proportions and stress durations must be determined carefully because of constrained resources. This talk discusses the optimal decision variables based on the popular optimality criteria under the constraint that the total cost does not exceed a pre-specified budget. A general scale family of distributions is considered to accommodate different lifetime models for flexible modeling with exponentially decreasing stress durations.

3 - Fault Localization Of A Series System When Tests Are Imperfect

Tonguc Unluyurt, Sabanci University, Orhanli Tuzla, Istanbul, 34956, Turkey, tonguc@sabanciuniv.edu, Zahed Shahmoradi

We consider a failed series system. The goal is to find the component that caused the failure with the minimum expected cost. In order to do this, we conduct costly tests and we know the probability that a certain component is the reason of the failure. The complicating factor is the fact that tests are imperfect and this is described by type I and type II error probabilities. In addition to the testing costs, we also consider misclassification costs. In order to decrease the total cost we develop a model that allows repetition of the tests in a certain way. We compute the expected cost of such a solution and we demonstrate the potential savings resulting from repetition of tests.

4 - Model Uncertainty Approximation Using A Copula-based Approach For Reliability Based Design Optimization

Zhimin Xi, University of Michigan-Dearborn, 4901 Evergreen Road, 2240 HPEC, Dearborn, MI, 48128, United States, zxi@umich.edu

Reliability-based design optimization (RBDO) has been widely used to design engineering products with minimum cost function while meeting reliability constraints. Model uncertainty, i.e., the uncertainty of model bias indicating the inherent model inadequacy for representing the real physical system, is typically overlooked in RBDO. This paper addresses model uncertainty approximation in a product design space and further integrates the model uncertainty into RBDO. In particular, a copula-based bias modeling approach is proposed and results are demonstrated by two vehicle design problems.

1 - Piecewise Deterministic Markov Processes For Monte Carlo

Gareth Roberts, University of Warwick, Coventry, United Kingdom, Gareth.O.Roberts@warwick.ac.uk

Traditional MCMC approaches for sampling complex distributions are almost all based on the Metropolis-Hastings framework, which, although versatile, restrict algorithms to be reversible, discrete time, and to require target density evaluation at each iteration. All of these features can sometimes be significant disadvantages. To overcome these difficulties, new algorithms are being developed which are non-reversible and continuous in time, for example the Zigzag, Bouncy Particle sampler, and the SCALE and CIS algorithms. The first two of these are pure MCMC algorithms whereas the latter two involve combination with sequential Monte Carlo methods. They all share the property that they can be couched in terms of Piecewise Deterministic Markov processes. The presentation will also touch on the impressive theoretical and empirical properties of these methods, including the super-efficiency properties of the zigzag algorithm, the unbiased subsampling properties of the SCALE approach and the stability of the CIS importance sampling approach, and is based on joint work with Joris Bierkens, Paul Fearnhead, Adam Johansen, and Krys Latuszynski.

2 - Adaptive MCMC For Everyone

Jeffrey Rosenthal, University of Toronto, Toronto, ON, Canada, rosenthal, jeff@math.toronto.edu

In this discussion, we shall briefly discuss the theory behind “adaptive” Markov chain Monte Carlo (MCMC), which automatically modify the algorithm while it runs in an effort to improve its performance “on the fly”. Adaptation can greatly improve convergence, but it can also destroy the ergodicity properties necessary for the algorithm to be valid. We shall present some examples and theorems concerning the ergodicity and efficiency of adaptive MCMC, with an aim towards making it more widely applicable in broader contexts

3 - Optimal Scaling Of MCMC Algorithms

Natesh Pillai, Harvard University, Cambridge, MA, United States, nateshspillai@gmail.com

In this discussion, we will give a brief overview of optimal scaling of MCMC algorithms. Optimal scaling offers a new perspective for studying the efficiency of MCMC algorithms in high dimensions. The key idea is to study the properties of the proposal distribution as a function of the dimension. This point of view gives us new insights on the behavior of the algorithm, such as precise estimates of the number of steps required to explore the target measure as a function of the dimension of the state space. After reviewing the original results, we will mention some recent progress as well.

Theoretical Development in Estimation

Invited: Data Envelopment Analysis

Invited Session

Chair: Ole Olesen, Southern Denmark University, Campusvej 55, Odense, 5230, Denmark, ole@sam.sdu.dk

1 - An Improved Afriat-Diewert-Parkan Nonparametric Production Function Estimator

Ole Olesen, Southern Denmark University, ole@sam.sdu.dk, John Ruggiero

Nonparametric regression estimators with shape constraints have recently been extended based on the Afriat inequalities. Overfitting of the ADP estimator suggests that estimators based on a weighted average of restricted estimators may provide an equally unbiased estimator but an estimator with lower variance. Both an Average Random k-Hinge estimator, a Jackknife Model Average (JMA) or a slightly modified JMA are considered. Small sample properties of the estimators are presented

2 - Production Of Schooling

John Ruggiero, University of Dayton, jruggiero1@udayton.edu

In this paper we analyze the production of schooling using stochastic DEA. Using Banker's stochastic DEA model, we estimate frontier production allowing for measurement error while controlling for the socioeconomic environment. We derive useful policy measures related to costs to help guide school funding.

3 - Insights From Machine Learning For Evaluating Production Function Estimators On Manufacturing Survey Data

Andrew Johnson, Texas A & M University-College Station, ajohnson@tamu.edu, José Luis Preciado Arreola

Organizations like census bureaus rely on non-exhaustive surveys to estimate industry population-level production functions. In this paper we propose selecting an estimator based on a weighting of its in-sample and predictive performance on actual application datasets. We compare Cobb-Douglas functional assumptions to nonparametric shape constrained estimators. For simulated data, we find that our proposed estimator has the lowest weighted errors. For actual data, specifically the 2010 Chilean Annual National Industrial Survey, a Cobb-Douglas specification describes at least 90% as much variance as the best alternative estimators in practically all cases considered.

4 - Endogenous Environmental Variables In Stochastic Frontier Models

Artem Prokhorov, University of Sydney Business School, Sydney, Australia, artem.b.prokhorov@gmail.com, Christine Amsler, Peter Schmidt

We consider an SFA model with errors e=v+uoexp(q'd), where v is normally distributed noise, uo generates technical inefficiency and q are the environmental variables that influence the level of technical inefficiency. In a previous paper we looked at the case that the input variables are correlated with v and u but q are exogenous. Here we allow q to be endogenous in the sense that they are not independent of v and/or uo. We consider estimation by IV and by MLE. MLE requires specification of reduced form equations. The case that q and uo are dependent is difficult because we need to assume a copula and so there are computational issues.

Chair: Mendoza Rafael, rafamendoza1977@gmail.com

1 - Modeling Dependent Outages Of Electricity Generators

Vishwakant Malladi, McCombs School of Business, vishwakant@gmail.com

We present a framework where the electricity plants in a region are modeled as subordinated Markov Chains. We also develop a factor model for Markov chain generators to separate both the idiosyncratic and correlated behavior of the plants. Calibration shows that supply curves are bent resulting in lower generation capacity available at higher reliability levels.

2 - Dynamic Mean-variance Under Predictable Criteria

Xiao Han, University of Texas-Austin, xhan581@gmail.com

While mean-variance analysis has been widely adopted by investment professional as a basic asset allocation tool, its dynamic counterpart was rarely studied in academic literature. We aim to fill this gap by proposing a type of mean-variance criteria that is predictable, self-generating and consistent over time. The framework partially resolves the dilemma when searching for dynamic optimal portfolio strategies while facing uncertainties about model parameters and investment horizons. As an example, we solve the forward mean-variance problem when the investor only has partial information regarding the dynamics of asset returns.

3 - Static Hedging And Pricing Under The JDCEV Model Via Integral Equations

Dong-Young Lim, Korea Advanced Institute of Science & Technology, DaeJeon, Korea, Republic of, ldy1848@kaist.ac.kr, Kyoung-Kuk Kim

We provide a systematic approach to construct an exact static hedge for exotic options under the JDCEV model, using the theory of integral equations. We show the existence and uniqueness of an exact static hedging portfolio which consists of continuum of vanilla or binary options. Under suitable conditions, such a hedging portfolio can be explicitly found in terms of generalized hypergeometric functions. Also, we work on constructing a robust static hedge with finitely many hedging instruments, together with an efficient method of evaluating hedge errors. The effectiveness of the proposed method is demonstrated by several examples, including double barrier options and step up(down) options.

Pricing and Information Provision of Services

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Gad Allon, Northwestern University, Evanston, IL, United States, g-allon@kellogg.northwestern.edu

1 - Managing Customer Expectations And Priorities With Delay Announcements

Gad Allon, Northwestern University, g-allon@kellogg.northwestern.edu, Achal Bassamboo, Qiuping Yu

We study in a service environment, how to manage customers' expectations and to prioritize customers appropriately to maximize the firm's profits. Specifically, we focus on a setting where the firm uses only delay announcements and study the opportunities and limitations of this mechanism. We are particularly interested in when and how the customers can be influenced by delay announcements.

2 - Trading Time In A Congested Environment

Luyi Yang, The University of Chicago, Chicago, IL, United States, luyi.yang@chicagobooth.edu, Laurens Debo, Varun Gupta

We propose time trading mechanisms, in which customers who are privately informed about their waiting costs mutually agree on the ordering in the queue by trading positions. We design optimal mechanisms for the social planner, the service provider, and an intermediary who might mediate the trading platform. Both the social planner's and the service provider's optimal mechanisms involve a flat admission fee and an auction that implements strict priority. If a revenue-maximizing intermediary operates the trading platform, it should charge a trade participation fee and implement an auction with some restrictions on customer trade.

3 - Learning To Bid In Sequential Auctions With Budgets Without Market Information

Yonatan Gur, Stanford University, ygur@stanford.edu, Santiago Balseiro

We consider the of bidding in sequential auctions with budget constraints under incomplete information, where bidders do not know the valuation distributions and the budgets of their competitors. We present a general adaptive strategy consisting of an approximation scheme in the dual space, in which bidders adjust their multipliers (and accordingly, their bid functions) through the campaign according to their expenditures. When adopted by all bidders, we show that the long-run average payoffs of the strategy asymptotically converge to those under a fluid mean-field equilibrium. We also analyze off-equilibrium performance under arbitrary and utility maximizing deviations.

4 - Impact Of Uncertainty About Co-workers Capability On Server Behavior In Queueing Systems

Masha Shunko, University of Washington, mshunko@gmail.com, Yaroslav Rosokha, Saurabh Bansal

We study business environment in which multiple servers process individual orders, but receive payment based on the team performance. Specifically, we are interested in the case when there is uncertainty about each other's capability, such as when teams are newly formed or when new members join the group. What impact does this uncertainty have on the productivity of workers? Do workers perform better or worse if they know what the co-workers are capable of? Can the productivity be manipulated (impacted) by provision of relevant information regarding others' capability? We answer these questions using a behavioral lab experiment.

Chair: Abdullah A Alabdulkarim, Dean, College of Engineering, Majmaah University, university campus, Majmaah, Majmaah, 1176, Saudi Arabia, aalabdulkarim2010@gmail.com

1 - Statistical Selection Of The Best Path In A Supply Chain

David Goldsman, Georgia Institute of Technology, sman@gatech.edu

We study statistical formulations of problems involving the selection of the best path from an origin to a destination through a network such as a supply chain. The term "best" can take a variety of meanings, e.g., the path having the (i) smallest expected travel time, (ii) highest probability of meeting a deadline, and

(iii) highest probability of yielding the shortest travel time. In each case, the goal is to determine the number of experiments that one has to perform in order to satisfy a certain indifference-zone requirement on the probability of correctly selecting the best path. The experiments can involve actual observed travel times or simulated realizations of travel times.

2 - Production Scheduling Of Jobs Limited By The Number Of Machines And Workers With Setup Times And Route Flexibility

Alejandro Garcia del Valle, University of A Coruna, Head Modeling & Simulation UMI Navantia, Ferrol, Spain, alejandro.garcia.delvalle@udc.es, Javier Faulin, Jose Antonio Muina Dono

Planning in dual resource constrained job shops like shipyards, is a very difficult task, due to the large number of tasks and limited resources and the setup times. In this paper, we develop a methodology using discrete event simulation models, together with efficient and robust dispatching rules. This models are going to be applied in the Navantia shipyard (Ferrol, Spain) in the context of a virtual shipyard following the concept of Industry 4.0. Results will be presented explaining the influence of jobs priority, assignation of workers to machines, and the reduction of setup times.

3 - Stress Testing For Supply Chain Risk Management Using Simulation Modeling

Harrison Luvai, University of Missouri - St. Louis, Saint Louis, MO, 63005, United States, hl6d9@umsl.edu, L. Douglas Smith”

We employ a discrete-event simulation model with embedded MILP and heuristics to test the resilience of a three-tier supply network when a blend of strategies is used for mitigating risk. Production and material flows are adjusted in response to daily simulated events. We investigate supply-network vulnerability to system contagion by adjusting correlations in demands downstream and in material deliveries upstream.

4 - MetaSimLab: A Laboratory For Validating And Calibrating Agent-based Simulation For Business Analytics

Janina Knepper, Research Group Advanced Analytics, Janina.knepper@ada.rwth-aachen.de

Agent-based simulations are frequently used to develop and evaluate new and improved approaches for business analytics and decision support. To be reliable, they have to be empirically calibrated and validated. Existing calibration approaches are rarely automated; however, manual calibration is costly in terms of time and effort. Therefore, this contribution introduces the laboratory environment MetaSimLab, which is designed to evaluate the efficiency and effectiveness of alternative calibration approaches. We present numerical examples to illustrate MetaSimLab’s functionality, novel calibration methods, and an outlook on further research.

DAS Awards Session

Sponsored: Decision Analysis

Sponsored Session

Chair: Eric Bickel, Associate Professor & Director, The University of Texas at Austin, 204 E Dean Keeton St, Stop C2200, Austin, TX, 78712, United States, ebickel@utexas.edu

1 - DAS Student Paper Award

Emanuele Borgonovo, Bocconi University, Milano, Italy, emanuele.borgonovo@unibocconi.it, Robert Hammond

The Student Paper Award is given annually to the best decision analysis paper by a student author, as judged by a panel of the Decision Analysis Society of INFORMS. Students who did not complete their Ph.D. prior to May 1, 2015 are eligible for this year’s competition.

2 - DAS Publication Award

Kenneth Charles Lichtendahl, University of Virginia, lichtendahlc@darden.virginia.edu

This award is given annually to the best decision analysis article or book published in the second preceding calendar year (i.e. calendar year 2014 for consideration in 2016). The intent of the award is to recognize the best publication in “decision analysis, broadly defined.” This includes, but is not limited to, theoretical work on decision analysis methodology (including behavioral decision making and non-expected utility theory), descriptions of applications, and experimental studies.

3 - DAS Practice Award

Franklyn Koch, Koch Decision Consulting, kochfg@gmail.com

The Decision Analysis Practice Award is awarded to the best example of decision analysis practice as judged by the Decision Analysis Practice Award Committee. The purpose of the award is to publicize and encourage outstanding applications of decision analysis practice. We will present the finalists and this year’s winner.

4 - DAS Ramsey Medal

Jeffrey M Keisler, University of Massachusetts - Boston, jeff.keisler@umb.edu

The Ramsey Medal of the Decision Analysis Society is awarded for distinguished contributions in decision analysis. Distinguished contributions can be internal, such as theoretical and procedural advances in decision analysis, or external, such as developing or spreading decision analysis in new fields. We will introduce the 2016 Ramsey Medal winner, followed by a presentation by the winner.

Simulation-based Optimization

Sponsored: Simulation

Sponsored Session

Chair: Tahir Ekin, Texas State University, San Marcos, TX, United States, tahirekin@gmail.com

1 - Nested Augmented Simulation For Stochastic Optimization

Tahir Ekin, Texas State University, t_e18@txstate.edu, Refik Soyer, Nick Polson

This talk presents nested augmented probability simulation to solve for decision making problems with uncertainty. The focus will be on stochastic programs with recourse under decision dependent (endogenous) uncertainty. Augmented probability simulation is based on the idea of treating the decision variable as random and investigating the optimal decision in the joint space of decision and random variables. We present the use of Nested Sampling for simulation from this joint distribution. An illustration is provided on a two stage news-vendor problem. We provide performance comparisons with traditional Monte Carlo simulation and present computational insights.

2 - Bayesian Inference And Augmented Probability Simulation In Call Center Staffing

Tevfik Aktekin, University of New Hampshire, Tevfik.Aktekin@unh.edu

We consider the issue of short term staffing in a queuing system such as a call center where the system rates are dependent random variables. We consider their estimation using Bayesian inference and the well-known Erlang A queueing model. We formulate the optimization model such that both the objective function and the constraints are random due to the uncertainty in the system rates and propose the use of an augmented probability simulation approach. In our numerical illustration, we consider both real and simulated data examples. In each case, we divide the day into discrete time intervals to determine staffing levels and discuss further implications of our approach.

3 - A Simulation Optimization Framework For Scheduling Preventive Maintenance In Wind Energy Systems

Eduardo Perez, Texas State University, eduardopr@txstate.edu

Because of the continuously escalating costs of wind farms O&M in the United States, determining methods for using available data in conditioning-monitoring systems is critical to decreasing wind farms operational costs. To accomplish this objective, we have developed a data-driven integrated stochastic online optimization and discrete event simulation methodology that takes into account data uncertainties in turbines status, weather conditions, and resources availability in scheduling maintenance and resources. Discrete event simulation coupled with optimization provides a powerful instrument for assessing and revising schedules prior to actual implementation.

4 - On The Sample Average Approximation Of The Two Stage Chance Constrained Staffing Problem In Call Centers With Arrival Rate Uncertainty

Anh Thuy Ta, PhD Student, University of Montreal, CP 6128 Succursale Centre-Ville, Montreal, QC, H3W1C5, Canada, tathuyanh1989@gmail.com, Wyean Chan, Pierre L’ecuyer, Fabian Bastin

We consider a chance constrained two stage stochastic staffing problem for multi-skill call centers with arrival rate uncertainty. The aim is to minimize the total cost of agents under some chance constraints, defined over the randomness of the service level in a given time period. We use the Monte Carlo method to generate M scenarios of arrival rates and we perform N simulation runs to get the estimates of probabilities that the service level is satisfied. We then obtain a sample average approximation (SAA) of the problem. We investigate the convergence of the optimal solution of the SAA to that of the original one when the sample size increases and present numerical illustrations on the sample sizes M and N.

Customer Choice Estimation and Assortment Optimization

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Vineet Goyal, Columbia University, New York, NY, United States, vgoyal@ieor.columbia.edu

1 - Rationalizing Empirical Choice Counts

Srikanth Jagabathula, NYU Stern School of Business, sjagabat@stern.nyu.edu, Paat Rusmevichientong

We consider the rank-aggregation problem where the objective is to find the ranking over n items that minimizes the number of conflicts with the given choice observations. A ranking has a conflict with a choice observation (i, S) if i is not the most preferred item in the subset S according to the ranking. This problem appears in many practical applications. This a known NP-hard problem with almost no algorithms that provide theoretical guarantees. We propose a graphical model approach and show that the complexity scales in the tree-width of the graph, defined on the choice sets. Numerically, our algorithm out-performs existing heuristics for important sub-classes of problems of interest in operations.

2 - The Impact Of Consumer Search Cost On Assortment Planning And Pricing

Ozge Sahin, Johns Hopkins University, ozge.sahin@jhu.edu, Ruxian Wang

Consumers search for product information to resolve valuation uncertainties before purchase. Under the consider-then-choose policy: a consumer forms her consideration set by balancing utility uncertainty and search cost, then she evaluates all products in her consideration set and chooses the one with the highest net utility. The choice behavior within consideration sets is governed by the multinomial logit model. The assortment problems are NP-hard. For the joint assortment planning and pricing problem, we show that the intrinsic-utility-ordered assortment and the quasi-same-price policy, which charges a same price for all products except at most one, are optimal for the joint problem.

3 - Waste Reduction Of Perishable Products Using Dynamic Pricing

Arnoud V. den Boer, University of amsterdam, KdVI, science park 904, room F3.33, amsterdam, Netherlands, A.V.denBoer@uva.nl, Jieying Jiao

According to the 2013 UN Food Wastage Footprint study, “approximately one-third of all food produced for human consumption in the world is lost or wasted”. The impact of this waste can hardly be overstated. Some Dutch supermarkets try to mitigate food loss by discounting products sold on their expiry date. This measure reduces the expected waste, but its effect on profit is an open question. In this talk we show how to optimize the discount percentage in a Markovian framework, and we discuss the effect on profit and waste in a diffusion limit of the inventory process.

Pricing, Promotion Planning, and Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: N. Bora Keskin, Duke University, Durham, NC, United States, bora.keskin@duke.edu

1 - Multiple Equilibria In Pricing Problems With Network Effects

William L Cooper, University of Minnesota, 111 Church Street S.E., University of Minnesota, Minneapolis, MN, 55455, United States, billcoop@umn.edu, Chenhao Du, Zizhuo Wang

We consider multi-product price-optimization problems with network effects wherein the expected utility each individual customer obtains from a product is increasing in the number of other customers who buy that product. Such network effects give rise to equilibrium constraints that describe how sales depend upon prices. In some cases there may be multiple different vectors of sales quantities that satisfy the equilibrium constraint for a given vector of prices. Moreover, the seller’s revenue may be quite different at those different equilibria. In this talk, we compare the seller’s revenue-maximizing prices under differing assumptions about which of the multiple equilibria will prevail.

2 - Value Of Targeted Promotions: Evidence From A Large Department Store

Bharadwaj Kadiyala, PhD Candidate, The University of Texas at Dallas, Richardson, TX, 75080, United States, bharadwaj.kadiyala@utdallas.edu, Ozalp Ozer, A Serdar Simsek

Gift cards have become a popular vehicle for promotional campaigns run by many departmental, consumer electronic, and online retail stores. Using a proprietary data set from a large department store, we investigate the value of targeted marketing efforts via emails in the context of gift-card promotional campaigns. We estimate the effects of online gift card promotions on customer purchase behavior and then discuss how to use these estimates to plan for targeted promotional events, a step towards one-to-one marketing.

3 - Pricing From Observational Data

Nathan Kallus, Assistant Professor, Cornell University and Cornell Tech, 111 8th Avenue #302, New York, NY, 10011, United States, kallus@cornell.edu, Dimitris Bertsimas

Given price-demand data, pricing is often addressed by a predictive approach: fit a model to predict demand given price observation, substitute into profit, and optimize price. Predictive approaches fail to find the optimal price, which is not generally identifiable from observational data. We bound suboptimality. We provide identifiability conditions and corresponding methods for pricing and prove consistency, asymptotic normality, and convergence rates. We develop a hypothesis test for optimality of pricing from observational data and demonstrate predictive approaches lose significant profit while our parametric method is indistinguishable from optimal and recovers 36-70% of losses.

4 - Using Contingent Markdown With Reservation To Deter Strategic Consumer Behavior

Gustavo Vulcano, NYU/UTDT, New York, NY, United States, gvulcano@stern.nyu.edu, Navaporn Surasvadi, Christopher S Tang

We examine a contingent price markdown (CM) mechanism with guaranteed reservations under which a retailer sells multiple units to forward-looking consumers who arrive over time according to a Poisson process. We study the consumer purchasing behavior in equilibrium, and numercially compare the performance of our mechanism against two benchmarks: Fixed Price (FP) and Pre-announced Discount (PD). Using extensive numerics, we identify market conditions under which CM dominates both FP and PD in terms of the retailer’s revenue and consumer’s surplus. Finally, through a fluid approximation to the stochastic model, we analytically show that CM weakly dominates the other two mechanisms.

Peeling Back the Onion in Social Media Analysis

Invited: Social Media Analytics

Invited Session

Chair: Chris Smith, Air Force Institute of Technology, 2950 Hobson Way, Wright-Patterson AFB, OH, 45433, United States, cms3am@virginia.edu

1 - Assessing Bias Correction For Social Media Samples

Christopher Wienberg, USC Institute for Creative Technologies, cwienberg@ict.usc.edu

While social media has made it possible to quickly and cheaply gather the opinions and experiences of large numbers of people, it is unclear how well social media users represent broader real-world populations, introducing the possibility of serious estimation bias. We investigate the applicability of traditional sample reweighting techniques for estimating real world population characteristics from a sample of social media users, with an eye towards using automatic attribute inference from social media profiles to make predictions about real-world populations.

2 - Who’s In Charge: Looking At Hierarchy And Heterarchy On Social Media

Robert Schroeder, Naval Postgraduate School, rcschroe@nps.edu, Sean Everton

Depending on the context of the information being passed on social media, conversations can seem to be fairly flat with no-one in charge, or highly centralized with a few main accounts key to the flow of information. With networks of different size, this paper compares various network measures of hierarchy in order to better classify social media conversations.

3 - Communication And Conflict: Analyzing Homophily On Social Media During Conflict

Sean Everton, Associate Professor, Naval Postgraduate School, Monterey, CA, 93943, United States, sfeverto@nps.edu, Robert Schroeder

Social media is used as a way to spread news-related messages. Research suggests that such messages tend to be transmitted between like-minded individuals. This paper examines whether during the conflict in Ukraine Twitter users shared messages primarily with similar users, thereby (possibly) contributing to the fragmentation of Ukrainian society, or with a heterophilous cross-section of users, thereby (possibly) contributing to societal cohesion.

4 - Determinants Of Social Media Privacy Protection Behaviors

Shalini Wunnava, Assistant Professor, State University of New York at Potsdam, 44 Pierrepont Avenue, Potsdam, NY, 13676, United States, wunnavss@potsdam.edu

Despite the growing availability of tools and options to ensure greater privacy on social media, not many people seem to actually utilize and benefit from them. Why? This research question will be examined under the lens of the Protection Motivation Theory (PMT). The goal of this project is to draw upon previous research on information privacy and PMT in order to develop a research model that could potentially identify and explain the determinants/motivators of privacy protection behaviors on social media.

Social Media User Behavior

Invited: Social Media Analytics

Invited Session

Chair: Donghyun Kim, Delta State University, Cleveland, MS, 11111, United States, dkim@deltastate.edu

1 - Social Relativeness

Eyad Youssef, Delta State University, eyoussef@deltastate.edu

This research seeks to gain a better understanding of how the social connectedness of a community can influence and affect health outcomes. Social connectedness can be defined as the structure for which social support is provided. The goal is to understand how individuals interact within their communities and how that interaction can play a role, either directly or indirectly, affecting their health outcomes.

2 - Social Media Analytics Using IBM SPSS Modeler's Text Analytics

Lakisha Simmons, Belmont University, lakisha.simmons@belmont.edu, Sumali Conlon, Chris Simmons

IBM SPSS Modeler empowers marketers to import data from multiple sources for fast decision making. For example, merge data from a sales database and text from a social media account to make predictions about future customer behavior. This session will demonstrate the ease of use and usefulness of IBM SPSS Modeler to analyze text from social media accounts to improve traditional quantitative based decision making.

3 - Analyzing User-it Artifact Interaction And Technology Implementation Using Mobile Social Capital

Donghyun Kim, Delta State University, dkim@deltastate.edu

This paper has two objectives. First, it introduces and tests a richer theoretical model than has been examined previously in order to explain the drivers of mobile social networking (MSN) and outcomes derived from MSN. To do so, the study develops a research model utilizing social network theories to examine the impact of "mobile social capital" on IT usage and social cognitive theory to investigate the outcomes from IT usage.

Humanitarian & Disaster Relief Logistics

Sponsored: Public Sector OR

Sponsored Session

Chair: Christopher W Zobel, Virginia Tech, Pamplin Hall, Room 1007, 880 West Campus Drive, Blacksburg, VA, 24061, United States, czobel@vt.edu

Co-Chair: Andrew N Arnette, University of Wyoming, 1000 E. University Avenue, Laramie, WY, 82071, United States, aarnette@uwyo.edu

1 - An Optimization Model For Disaster Relief Asset Pre-positioning

Andrew Arnette, University of Wyoming, aarnette@uwyo.edu, Christopher Zobel

This research extends previous work on improving the pre-positioning of assets used for disaster relief. It is founded on an evidence-based analytical model that utilizes multiple factors for analytically characterizing risk. This, in turn, is used to determine the potential need for the sheltering of impacted populations in the face of multiple possible natural disasters. By explicitly considering risk, the model is able to consider overall effectiveness at the same time that it ensures equity in the resource allocations.

2 - Empirical Analysis Of Volunteer Convergence At A Disaster Relief Center

Lauren Davis, North Carolina A&T University, lbdavis@ncat.edu, Emmett J Lodree

Volunteer convergence refers to the mass movement of volunteers toward affected areas following disaster events. This study explores volunteer convergence following the April 2011 tornado disaster in Tuscaloosa, Alabama. Specifically, we characterize selected stochastic variables that are relevant to volunteer task assignment within the context of a disaster relief warehouse environment using data collected during tornado relief efforts. We also discuss the implications of our findings with respect to modeling relief center convergence as a queuing system.

3 - Collaborative Emergency Supply-chains For Essential Goods And Services

Marcus Wiens, Dr., Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany, marcus.wiens@kit.edu, Frank Schätter, Christopher Zobel, Frank Schultmann

We outline the scope of a Public-Private-Emergency Collaboration (PPEC) with a focus on the provision of essential goods and services which are urgently needed in a disaster situation. We evaluate the potential for such cooperation for each phase of a disaster from an economic perspective. The best chance for synergies and improvements for crisis management depend - among others - on two critical requirements: Public and private actors need to coordinate on critical stages of a relief supply chain and private actors need sufficient incentives to engage in a PPEC on a sustainable basis instead of launching a fast-paced PR-campaign.

4 - Models For The Needs Assessment Routing Problem

Burcu Balcik, Ozyegin University, Istanbul, Turkey, burcu.balcik@ozyegin.edu.tr, Duygu Pamukcu

We focus on site selection and routing decisions of rapid needs assessment teams, which aim to collect adequate information about the post-disaster conditions of affected communities in a short period of time. We develop alternative mathematical models, which facilitate completing assessments quickly while meeting coverage targets. We present a heuristic, which decomposes the problem into site selection and routing components. We present computational results to show the efficiency of our heuristic.

1 - Drone Routing Models With Applications To Disaster Relief

Stefan Poikonen, University of Maryland - College Park, MD, spoikone@math.umd.edu, Xingyin Wang, Bruce L Golden

The Vehicle Routing Problem with Drones (VRPD) is a model that allows the range and carrying capacity of trucks to be complemented by the ability of drones to operate on the as-the-crow-flies metric. Trucks act as mobile recharging stations for the drones. Applications include efficient delivery of medical supplies and communications equipment to remote regions (potentially after a disaster) where traversal of road networks may be slow or non-direct. VRPD will be compared to other models of vehicle routing. Bounds and computational results will be presented, as times allows.

2 - Online Patrol Routing Problem

Ibrahim Capar, Bowling Green State University, icapar@bgsu.edu, Burcu B Keskin

In this research, we consider online patrol routing problem (OPRP). The objective of OPRP is to maximize the visibility of state troopers at pre-determined hot spots while responding to accidents. We develop several scenarios to explore different reoptimization strategies after responding to an accident. In addition, we evaluate diversification strategies to improve coverage while responding to accidents.

1 - Processes In Entrepreneurship

Moren Levesque, York University, mlevesque@schulich.yorku.ca

Phenomena in the scholarly field of entrepreneurship must often be studied as processes that involve assumptions of dynamism, nonlinearity, complexity, ambiguity, with multi-theoretical and multi-level analyses. While acknowledging these properties in the conceptual, formal or empirical framing of my research, I go over some findings from investigating the business investment process and entrepreneurial market process. I also offer some thoughts on research opportunities to further our understanding of such processes and their practical implications. I conclude with real-life examples where the knowledge of these practical implications has resulted in entrepreneurial achievements.

Service Optimization, Design and Measure in Emerging Market

Sponsored: Service Science

Sponsored Session

Chair: Yihong Hu, Tongji University, 1239, Siping Road, Shanghai, 200092, China, yhhu@tongji.edu.cn

1 - Benefiting From Seasonal Overloading Problem Of Delivery Service: A Strategic Analysis Of Dual Channel Business

Xiang Ji, School of Management, University of Science and Technology of China, Hefei, China, xxj150630@utdallas.edu, Jie Wu, Jiasen Sun

The tension between limited delivery service capacity and concentrated enormous orders in online hot selling seasons is one of the most serious problems that troubles nowadays e-commerce. To tackle this issue, we present a strategic analysis for the retailer who is involved in both online sales channel and bricks-and-mortar retail channel. A series optimal decisions on pricing, inventory and service level in different scenarios of consumer segments are derived. We also propose several contractual methods for the retailer to coordinate with its upstream manufacturer and its delivery supplier.

2 - Risk Measure Of Automobile Supply Chain Based On Conditional Value At Risk Approximation To Value At Risk Constrained Program

Shiting Zhang, Tongji University, Shanghai, China, 1531159@tongji.edu.cn, Jiantong Zhang, Xiaodong Chen

VaR and CVaR are time-honored risk measures in the field of finance. We apply them to construct a three-hierarchical quantitative risk measure model for automobile supply chain. VaR does not necessarily preserve the convexity and thus leads to difficulties of accurate computation. We first construct a tight binding with the CVaR approximation, which is known as the best CCA of VaR, then remedy the gap between VaR and CVaR by deriving the formulation of Hong et al., and finally obtain the accurate solution of VaR. We select fifteen public automobile companies, input their stock prices into the model, and finally explain its feasibility and practicality for risk assessment and risk orientation hunting.

3 - Path-Based Model And Algorithm For Emergency Evacuation

Tianhu Deng, Tsinghua University, Beijing, China, deng13@mail.tsinghua.edu.cn., Jianghua Zhang

Natural disasters such as earthquake or tsunami can easily take the lives of thousands of people and millions worth of property in a fleeting moment. A successful emergency evacuation plan is critical in response to disasters. In this paper, we seek to investigate the multi-source, multi-destination evacuation problem. First, we build a mixed integer linear programming model. Second, based on K shortest paths and User Equilibrium, we propose a novel algorithm (hereafter KPUE), whose complexity is polynomial in the numbers of nodes and evacuees. We prove that the algorithm is exact when there is only one source node. Finally, we demonstrate the effectiveness of Algorithm KPUE by a real evacuation network in Shanghai, China. The numerical examples show that the average computation time of the proposed algorithm is 93% less than that of IBM ILOG CPLEX solver and the optimality gap is no more than 5%.

1 - Internet Of Things Business Innovations And Opportunities

Michael Chuang, State University of New York at New Paltz, New Paltz, NY, 1, United States, huangm@newpaltz.edu

: Internet of Things (IoT), a global infrastructure enabling services by interconnecting physical and virtual things based on interoperable information and communication technologies, has emerged in business applications in various industrial areas. However, there is lack of holistic research that explores business opportunities enabled by IoT and related analytics. In this preliminary study, to build a needed foundation for IoT research, we review literature focusing on IoT-enabled business scenarios, and delineate related issues such as innovation for future research. .

2 - Network Analysis Of Supply Chain Adaptation For Disruption Recovery: An Empirically Grounded Complex Adaptive Systems Approach

Kang Zhao, University of Iowa, kang-zhao@uiowa.edu

This study investigates adaptive decisions and strategies in a real-world large-scale supply chain network in the face of a disruption in the network through the development and usage of an agent-based model. With real-world data, we show the supply chain network has structures similar to scale-free networks, and how the model of adaptive behaviors can leverage competition relationships within a supply chain network. We also illustrate how disruptions propagate in the supply chain network through cascading failures and develop metrics to predict such propagation. Finally, we test strategies an individual firm can trigger to reduce the negative effects of a supply chain network disruption.

3 - A Spatial Adaptive Sampling Procedure For Monitoring High-dimensional Data Streams

Xiaochen Xian, University of Wisconsin, 500 Lincoln Drive, Madison, WI, 53706, United States, xxian@wisc.edu

High dimensional (HD) data streams frequently appear in modern engineering applications and provide challenges for process monitoring. A spatial adaptive sampling and monitoring (SASAM) procedure is proposed under the limited resource constraint for detecting clustered out-of-control variables. Numerical studies show that the proposed method significantly outperforms the adaptive sampling strategy taking no consideration of the variables' spatial distribution.

3 - Consumer's Preferences Modeling For Rail Transportation In Qatar

Rana Sobh, Qatar University, Doha, Qatar; r.sobh@qu.edu.qa, Belaid Aouni

The increase in traffic congestion, road safety and pollution have led Qatar to improve the existing public transportation system and introduce Doha Metro. This shift in public transportation requires changes in consumers' perceptions about rail transportation. The aim of our paper is to predict the factors that may impact consumers' behavior and their preferences in choosing transportation systems. Moreover, our study aims to develop a better understanding of the rail transportation mode adoption in Qatar and provides some recommendations to the policy makers in Qatar Rail.

4 - Optimal Process Adaptation For Robust Iot Collaboration

Zhe Shan, University of Cincinnati, Cincinnati, OH, Contact: zhe.shan@uc.edu

The purpose of process adaptation is to mediate the communication between several independent IoT processes to overcome their mismatches and incompatibilities. In this work, we propose a new framework and efficient algorithms for creating optimal adapters for IoT process collaboration. This solution integrates message adaptation patterns with control flow adapters to create a complete adapter for multiple processes. The comparisons against existing methods show that our approach produces remarkable improvements.

Influencing Behavior in Aircraft Operations

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Kenneth Schultz, Air Force Institute of Technology, 2950 Hobson Way, WPAFB, OH, 45433, United States, kschultz@afit.edu

1 - Antecedents Of Fuel Efficiency

James Cotton, AFIT, James.cotton@afit.edu

The United States Air Force (USAF) uses $15B of fuel each year, more than all other Department of Defense agencies combined (USAF 2014, 30). USAF data show that certain pilots fly more efficiently than their peers; however, current literature has little research on discretionary pro-environmental professional behaviors. We use the Theory of Planned Behavior as a starting point (Ajzen, 1985, 2011), and incorporate theory as proposed by Lülfs and Hahn (2013, 2014) and McDonald (2014), including additional factors to more accurately capture the behavior and context of USAF cargo pilots. The results should help us understand pilot motivation and help us encourage more efficient vehicle operation.

2 - The Effects Of Public Versus Private Feedback On Autonomous Motivation

Kenneth Schultz, Air Force Institute of Technology, WPAFB, OH, Kenneth.Schultz@afit.edu, Cory Sanders

Research has shown public feedback increases work performance compared to private feedback (Song, Tucker, Murrell, and Vinson, 2015). What motivates employees to perform differently in the two conditions is an open question. To answer this, we can investigate the motivation type differential between the two (Ryan and Deci, 2000). Motivation type is important because controlled motivation can result in unethical behavior (Welsh and Ordonez, 2014), lower quality of life (Gagne, 2014), and lower task persistence (Ryan and Deci, 2000) compared to autonomous motivation. We will investigate this question in a longitudinal field experiment using Boeing C-17 pilots' fuel efficiency performance.

Energy VIII

Contributed Session

Chair: Carlos Abreu, Adjunct Professor, Federal University of Rio Grande do Norte State (UFRN), Natal, Brazil, calexandreabreu@ect.ufrn.br

1 - Optimal Multi-Period Energy Procurement Policies With The Integration Of Wind Energy

Tian Wang, Huazhong University of Science and Technology, School of Management, Hongshan Distrct, Wuhan, 430074, China, wangtian3261@gmail.com

The changes of electricity market are envisioned to be revolutionary in power generation and consumption. How to manage the increasing potential of adjustable demand with the increasing penetration of renewable sources is one of the most significant problems. We investigate a multi-period energy procurement model for a smart grid community. Multiple periods of harvesting (renewable energy) and purchasing (traditional energy) are required for satisfying demand. Demand can be delayed if any energy shortfall. At the end, all demand must be fulfilled. We obtain dynamic solutions and provide numerical studies.

2 - Energy Flow Network Stochastic Optimization Through Predictive Analytics Of Energy Demand

Ebisa Wollega, Assistant Professor, Colorado State University-Pueblo, 2200 Bonforte Blvd, Pueblo, CO, 81001, United States, ebisa.wollega@csupueblo.edu, Hiba Baroud, Vitor Winckler

Modeling energy flow depends on a number of uncertain factors that are related to economic development, extreme weather, and renewable energy sources availability, among many others. In order to improve decision making under uncertainty in the energy sector, we present a stochastic non-linear mixed integer energy flow network model under supply uncertainty where the energy demand is determined through data-driven statistical models. Computational results that compare the performance of different predictive models for energy demand and the efficiency of the solution approach will be presented.

3 - Real Time Pricing Strategies And Dynamic Load Scheduling In Smart Communities

Vignesh Subramanian, University of South Florida, 5006, Bordeaux Village pl, Apt #201, Tampa, FL, 33617, United States, vigneshs@mail.usf.edu, Tapas K. Das

Real Time pricing will actively engage the electricity consumers, having an advanced metering infrastructure (AMI), in a centralized demand side management (CDSM), a key to price stability and network reliability. We propose a Quadratic Binary Programming model for a centralized controller to schedule the consumer load. The numerical result demonstrates how CDSM can lower the price peaks, reduce the reserve capacity of the generator and minimize the consumer's hourly tariff.

4 - The Effects Of Low Prices And Higher Uncertainty On Enhanced Oil Recovery Projects: A Real Options Valuation Perspective

Carlos Abreu, Adjunct Professor, Federal University of Rio Grande do Norte State (UFRN), Natal, Brazil, calexandreabreu@ect.ufrn.br, Lielson Santos, Juli Sergine, Nayara Nagly

Real Option Valuation main objective is the financial analysis of projects under uncertainty conditions. The Oil and Gas industry is full of uncertainties starting with its main economic variable, oil prices. Using a Real Options model to evaluate the potential return of an oil project captures the flexibility of a decision-maker to capture possible prices oscillations. Enhanced oil recovery projects are developed to try to elevate mature oil field production using injection technology. We focus on the injection of natural gas to boost the oil production analyzing uncertainty scenarios involving oil and gas markets to estimate a decision - making rule for investment in a Real Option perspective.

Modeling and Analysis of Innovative Mobility Services I

Sponsored: TSL, Urban Transportation

Sponsored Session

Chair: Yafeng Yin, University of Florida, University of Florida, Gainesville, FL, 32611, United States, yafeng@ce.ufl.edu

1 - A Stable Matching Paradigm For Transport Service Allocation, User Assignment, And Pricing

Joseph Y J Chow, New York University, joseph.chow@nyu.edu

Assignment in a generic transportation system (including shared mobility options) is modeled as a many-to-one stable matching problem of passengers to tour sets. The result allows joint assignment of flows and mechanism design for allocation of costs, with implications for designing fare pricing and incentives for shared mobility, and designing for partnerships between operators in this setting.

2 - Modeling Surge Pricing In Ride Sourcing Markets

Yafeng Yin, University of Florida, Civil and Coastal Engineering, 365 Weil Hall Box 116580, Gainesville, FL, 32611, United States, yafeng@ce.ufl.edu, Liteng Zha

This study proposes an equilibrium model to quantitatively investigate the effects of surge pricing on the ride-sourcing market (e.g., Uber and Lyft). The proposed model explicitly captures the behaviors of agents at both demand and supply sides. Equilibrium outcomes under surging strategies with different control objectives are compared and discussed.

3 - Is Ride-sourcing Services Worsening Traffic Congestion?

Hongyu Chen, Northwestern University, chyy1989@gmail.com, Yu Nie

Ride-sourcing services which allow private car owners to provide taxi-like services for profit, have offered passengers a convenient choice of transportation but also created controversies. It has been argued that they might have worsened traffic congestion by both attracting more demand for mobility services and inducing more empty-loaded vehicles on the road network. This research aims to analyze the personal mobility services market with both traditional taxi and ride-sourcing services using an aggregate economic model. Various impacts of the emerging services on the market, especially on traffic congestion, will be the focus of this research.

4 - Design And Modeling Of A Crowdsource-enabled System For Urban Parcel Delivery

Bo Zou, University of Illinois at Chicago, Chicago, IL, United States, bzou@uic.edu, Nabin Kafle, Jane Lin

We consider cyclists and pedestrians close to customers as crowdsources to relay parcels with a truck carrier and undertake last-leg parcel delivery. The crowdsources express their interests in doing so by submitting bids to the truck carrier. The truck carrier then selects bids and coordinate crowdsources' last-leg delivery with its truck operations. A Tabu Search based algorithm is proposed to solve the truck carrier problem. Results show that truck VMT and total cost can be considerably reduced compared to pure-truck delivery.

Advances in Blocking and Trip Planning

Sponsored: Railway Applications

Sponsored Session

Chair: Shrikant Jarugumilli, BNSF Railway, Fort Worth, TX, United States, shrikant.jarugumilli@bnsf.com

1 - Arc Costing Approaches For Railroad Algorithmic Blocking

Erick D Wikum, TCS, erick.wikum@tcs.com

Algorithmic blocking provides a way to generate travel routes for freight rail car movements by computing shortest paths in a network of blocks. Traditionally, the cost of a block (arc) has been a function of two components—the distance between the block's origin and destination yards in the railroad's physical track network and the relative cost of classifying a rail car at the block's origin yard. We explore alternative cost structures which take into account time as well as incremental operating cost. We compare and contrast the various approaches and draw analogies to airline passenger itineraries to arrive at a promising approach.

2 - Next Generation Blocking And Trip Planning Systems

Carl D Van Dyke, TransNetOpt, carl@cvdzone.com

Algorithmic blocking has now been in production for close to 20 years, and is slowly spreading to more railroads. The basic trip planning logic used by railways is even older, having been in wide use for about 35 years. As railroads think about the future, the obvious question is how blocking and trip planning should evolve to meet current and future needs, due to both changes in technology and changes in the fundamental business mix. Are the current technologies still relevant given the rise of intermodal and unit trains? How should these technologies be adapted to support these lines of business? What changes should be considered in how traditional carload traffic is blocked and trip planned?

3 - Modernizing Blocking And Trip Planning

Pooja Dewan, BNSF Railway, pooja.dewan@bnsf.com

In this talk, we present the various challenges and opportunities that need to be considered and carefully evaluated as railroads modernize various information

1 - Deliver Or Not?: Revenue Management For Future Delivery Service Operations Using Unmanned Aerial Vehicles

Heng Chen, Assistant Professor, University of Nebraska–Lincoln, Lincoln, NE, 68588, United States, heng@unl.edu, Senay Solak

Unmanned Aerial Vehicles (UAVs) are expected to fulfill commercial delivery services for retailers and courier companies in the near future. We study certain capacity and revenue management decisions that these companies will face in UAV based delivery operations, and use currently available data to develop models for guiding such decisions.

2 - On Routing Unmanned Aerial Vehicles For Surveillance And Reconnaissance Activities

Cai Gao, University at Buffalo, Buffalo, NY, 14260, United States, caigao@buffalo.edu, Jose Luis Walteros

We tackle a variation of the close-enough traveling salesman problem in which the salesman is accounted of visiting a node if he traverses a predefined distance through a circular area surrounding the node. This variation arises in the context of unmanned aerial vehicle routing, where a vehicle must cross an area collecting information form a set of targets, while minimizing the detection risks. We consider two approaches for modeling the tradeoff between the amount of collected information and the observed risk and test them by solving a collection of instances adapted from the literature.

3 - Mission Planning For Unmanned Aerial Vehicles And Human Operators

Chase Murray, University at Buffalo, Dept of Industrial & Systems Engineering, 309 Bell Hall, Amherst, NY, 14260-2050, United States, cmurray3@buffalo.edu

Advances in autonomy promise to enable human operators to manage multiple UAVs simultaneously. This talk presents a new algorithm to optimally allocate complex tasks to operators and machines. This algorithm mitigates the impacts of increased operator multitasking, and considers the degree to which each operator "trusts" the automated system. Operator stress caused by multitasking overload or lack of trust can compromise task performance and increase the likelihood of a mishap or mission failure.

4 - Routing Problems For Unmanned Surface Vehicles With Limited Battery Life

Joshua Margolis, Clemson University, Clemson, SC, 29634, United States, jtmargo@clemson.edu, Lawrence V Snyder

Given a set of locations that must be inspected and a set of waypoints, we design and implement a model to construct the optimal set of routes for at most K unmanned surface vehicles that minimizes the fleet's total distance, subject to distance, battery life, and site number constraints, while ensuring that a set of sites are covered during the tours. The model also determines the velocity of each vehicle along each arc of the tour, where the velocity is dependent upon the importance of the sites that are covered along that arc. Lastly, we modify, design, and implement heuristics to construct feasible solutions.

Sponsored Session

Chair: Richard Forrester, Associate Professor, Dickinson College, P.O. Box 1773, Carlisle, PA, 17013, United States, forrestr@dickinson.edu

1 - The Protest Casino; A Procurement Policy Simulation

Steven D Roemerman, Lone Star Analysis, 4555 Excel Pkwy, Ste 500, Addison, TX, 75001-5691, United States, sroemerman@lone-star.com, Randal Allen

Protests are a controversial component of public procurement. Governments and agencies use a range of approaches to contested awards of funds from the public treasury. This paper examines policy questions facing the House Armed Services Committee of the U. S. Congress. A policy simulation examined economic rationality of three agents; government setting protest rules, and two CEOs, one who always protests and one never does. The model helped inform lawmakers who drafted the National Defense Authorization Act. The approach to modeling and supporting research is presented, along with results and progress toward improved protest policy. A survey of prior work is provided.

2 - Assigning Students To Schools To Minimize Socioeconomic Variation Between Schools

Richard Forrester, Associate Professor of Mathematics, Dickinson College, College and Louther Streets, Carlisle, PA, 17013, United States, forrestr@dickinson.edu, Kevin Hutson, Elizabeth Bouzarth

Numerous studies have found that a student's academic achievement is as much determined by the socioeconomic composition of their school as their own socioeconomic status. In this talk we provide a methodology for assigning students to schools so as to balance the socioeconomic compositions of the schools while taking into consideration the total travel distance. Our technique utilizes a bi-objective general 0-1 fractional program that is linearized into a mixed 0-1 linear program which can be submitted directly to a standard optimization package. As a test case for our approach we analyze data from the Greenville County School District in Greenville, South Carolina.

3 - Consumer's Preferences Modeling For Rail Transportation In Qatar

Rana Sobh, Qatar University, Doha, Qatar; r.sobh@qu.edu.qa, Belaid Aouni

The increase in traffic congestion, road safety and pollution have led Qatar to improve the existing public transportation system and introduce Doha Metro. This shift in public transportation requires changes in consumers' perceptions about rail transportation. The aim of our paper is to predict the factors that may impact consumers' behavior and their preferences in choosing transportation systems. Moreover, our study aims to develop a better understanding of the rail transportation mode adoption in Qatar and provides some recommendations to the policy makers in Qatar Rail.

1 - Analytical And Empirical Modeling Of Complementarities In An Online Advertising Supply Chain

Changseung Yoo, The University of Texas at Austin, Austin, TX, United States, csyoo@utexas.edu, Anitesh Barua, Genaro Gutierrez

We examine channel structures and pricing models in an online advertising supply chain using a proprietary dataset. We develop analytic as well as structural econometric models that enable us to model interactions between the channel structures/pricing models, and quantify synergy effects between them. To the best of our knowledge, our study takes the first step of analyzing details of an online advertising supply chain. Moreover, while the extant literature emphasizes choosing between pricing models, we demonstrate that using multiple models in concert yields higher overall profitability due to spillover effects and strategic complementarities among the pricing schemes.

2 - Predicting Hotel Revenue Using Hotel Latent Quality

Uttara Madurai Ananthakrishnan, Carnegie Mellon University, umadurai@andrew.cmu.edu

Online reviews have become a major source of information for consumers in the past decade and influence various aspects of e-commerce such as purchase decisions and product sales in a variety of settings. Most of the work in this field has focused on numerical ratings to understand the impact of online reviews on sales. In our paper, we use a novel topic-modeling technique on a large dataset of online reviews of hotels and study if topics obtained from this technique provide a better representation of a hotel's quality. We then analyze how each hotel's quality evolves over time and predict the changes in hotel revenue using such topics.

3 - SkillR: Personalized Skill Recommendations Using Joint Bayesian Member-job Clustering

Abhinav Maurya, Carnegie Mellon University, Pittsburgh, PA, United States, ahmaurya@cmu.edu, Rahul Telang, Sai Sundar

Skill gaps in various sectors of the economy are considered to be major problems facing economies today. Increasing the productivity of a member of the workforce depends on recommending skills whose acquisition will yield the highest utility gains for the member. We present SkillR - a skill recommendation algorithm that employs a joint Bayesian clustering model to match members to other similar members as well as relevant jobs, and to identify the top skills that provide the maximum utility gains to a member. Our evaluation suggests that SkillR leads to orders of magnitude improvement in the job propensity of recommended skills compared to a traditional collaborative filtering system.

4 - Does Government Surveillance Give Twitter The Chills?

Sriram Somanchi, University of Notre Dame, somanchi.1@nd.edu, Laura Brandimarte, Edward McFowland, Uttara Madurai Ananthakrishnan

Since Snowden's revelations regarding mass surveillance programs implemented by the NSA, Government surveillance has garnered huge attention. The research community has attempted to estimate the "chilling effects" of surveillance, the tendency to self-censor. Until now, such effects have been estimated using either the search terms, Wikipedia articles, or survey data. In this work, we propose a new method in order to test for chilling effects in online social media. We use large Twitter dataset and propose the use of new statistical machine learning method in order to detect anomalous trends in user behavior after Snowden's revelations made users aware of existing surveillance programs.

Computer Experiments and Uncertainty Quantification

Sponsored: Quality, Statistics and Reliability

Sponsored Session

Chair: Ying Hung, Rutgers State University of New Jersey, Piscataway, NJ, United States, yhung@stat.rutgers.edu

1 - Robust Parameter Design Using Computer Experiments

Roshan Vengazhiyil, Georgia Institute of Technology, roshan@gatech.edu

Space-filling designs, commonly used in computer experiments, try to spread out points uniformly in the experimental region. However, when the objective is to achieve robustness against noise factors, uniformity is no longer needed in the space of noise factors. This is because noise factors usually follow nonuniform distributions such as normal distribution. It makes more sense to place points in the high probability regions where more "actions" take place. Unfortunately, nonuniform points in the experimental region can lead to problems in model fitting. In this article we propose novel design and modeling strategies to deal with these issues.

2 - Invariance-preserving Emulation For Computer Models, With Application To Structural Energy Prediction

Peter Qian, University of Wisconsin - Madison, peter.qian@wisc.edu

Simulation models with invariance properties appear in material science, physics, biology and other fields. Standard emulation methods such as Gaussian process regression cannot accommodate input invariance and thus do not work for this new problem. We will propose a kernel-based emulation method to preserve invariance in inputs. The method employs a direct graph representation and equivalence relations to characterize relabeling invariance. The effectiveness of the proposed method is illustrated by using several examples from material science.

3 - A Sequential Maximum Projection Design Framework For Computer Experiments With Inert Factors

Shan Ba, The Procter & Gamble Company, Cincinnati, OH, United States, ba.s@pg.com

Many computer experiments involve a large number of input factors, but many of them are inert and only a subset are important. In this talk we present a new sequential design framework which can accommodate multiple responses and quickly screen out inert factors so that the final space-filling design is close to optimal with respect to the active factors. The new approach does not require prescribing the total sample size, and under the presence of inert factors, it can lead to substantial savings in simulation resources. Even if all the factors are important, the proposed sequential design can still achieve similar overall space-filling property compared to a maximin LHD optimized in a single stage.

IEEE T-ASE Invited Session II

General Session

Chair: Jingshan Li, University of Wisconsin - Madison, jli252@wisc.edu

1 - Sparse Modeling And Recursive Prediction Of Space-time Dynamics In Stochastic Sensor Networks

Hui Yang, Penn State University, huy25@engr.psu.edu

Wireless sensor network has emerged as a key technology for monitoring space-time dynamics of complex systems, e.g., and body area sensor network. However, sensor failures are not uncommon in traditional sensing systems. As such, we propose the design of stochastic sensor networks to allow a subset of sensors at varying locations within the network to transmit dynamic information intermittently. Experimental results on real-world data and different scenarios of stochastic sensor networks demonstrated the effectiveness of sparse particle filtering to support the stochastic design and harness the uncertain information for modeling space-time dynamics of complex systems.

2 - Integration Of Data Fusion Methodology And Degradation Modeling Process To Improve Prognostics

Kaibo Liu, UW-Madison, 1513 University Avenue, Madison, WI, 53706, United States, kliu8@wisc.edu, Shuai Huang

The rapid development of sensing and computing technologies has enabled multiple sensors embedded in a system to simultaneously monitor the degradation status of an operation unit. Unlike other existing data fusion methodologies that treat the fusion procedure and the degradation modeling as two separate tasks, this paper aims at solving these two challenging problems in a unified manner. A case study that involves a degradation dataset of an aircraft gas turbine engine is implemented to numerically evaluate and compare the prognostic performance of the developed health index with existing literature.

3 - Bottleneck Analysis To Reduce Surgical Flow Disruptions: Theory And Application

Xiang Zhong, UW-Madison, xzhong4@wisc.edu, Jingshan Li

The work flow of surgical operations in emergency department and operating rooms can be interrupted due to various disruptions. Reducing such disruptions is of significant importance to ensure successful operations. In this paper, we introduce a continuous-time Markov chain model to analyze the disruptions and their impacts. A continuous improvement method is developed to identify the bottleneck disruption, so that reducing the interruption time and frequency of the bottleneck can lead to the largest improvement. An application of the method at an emergency department of a large academic medical center is presented to illustrate the effectiveness of the model and the improvement approach.

4 - Integrating Optimal Simulation Budget Allocation And Genetic Algorithm To Find The Approximate Pareto Patient Flow Distribution

Zekun Liu, Washington University, liu.zekun@wustl.edu

The imbalanced development among different levels of hospitals caused by the irrational patient flow distribution has become a major social issue in China's urban healthcare system. In this work, we propose a methodology framework integrating discrete-event simulation, multi-objective optimization and multi-objective optimal computing budget allocation to find the optimal macro-level patient flow distribution. A case study validating the optimization framework shows the Pareto optimal patient flow distribution can improve overall system performances.

1 - Metamodel Based Method For Optimization Of Multilayer Thin Film Architecture

Srikant Nekkanty, Intel Corporation, nekkanty2001@gmail.com, Danel Draguljic, Thomas Santner, Angela Dean, Rajiv Shivpuri

The application of thin, hard coatings is one of the most effective ways to protect engineering components operating under heavy contact. We describe a metamodel based approach for improving the performance of a multilayer coating architecture using finite element models. From finite element models, the stresses in the coating material were evaluated and used to build the metamodel for optimizing the multilayer system. The complexity of this engineering application involved (1) a nonrectangular input region of coating designs and (2) opposing objectives to be minimized simultaneously.

2 - Measurement Error Of Binary Quality Inspections In Industry

Thomas Akkerhuis, University of Amsterdam, T.S.Akkerhuis@uva.nl

The evaluation of the reliability of binary measurements, such as quality inspections in industry, is challenging. This especially holds in gold standard unavailable situations, where the true conditions of the inspected items are unobservable. Our studies show that methods in literature for such evaluation perform poorly. We found that binary measurement error can be decomposed in a random and a systematic part. Although this is a well-known decomposition for numerical measurement, it is a new insight for binary measurement. It turns out that, in a gold standard unavailable situation, generally only the random component is identifiable. We have developed a robust and efficient method to do so.

3 - Qfd Customer-requirement Prioritization Based On The Law Of Comparative Judgments

Domenico Augusto Maisano, Associate Professor, Politecnico di Torino, Corso Duca degli Abruzzi 24, Turin, 10129, Italy, domenico.maisano@polito.it, Fiorenzo Franceschini

Quality Function Deployment (QFD) is a structured process to design and develop products/services that better fulfill customers' requirements (CRs). The initial collection and analysis of the CRs is particularly critical, as any distortion can propagate to the whole process results. The focus of this article is on the prioritization of CRs, which can be improved by introducing a new prioritization technique based on the Thurstone's Law of Comparative Judgment. The greatest strength of this technique is combining a refined theoretical model with a simple and user-friendly data collection process. The description is supported by a realistic application example.

Routing and Allocation in Military Operations

Sponsored: Military Applications

Sponsored Session

Chair: Alexandra M Newman, Colorado School of Mines, 1104 Maple Street, Golden, CO, 80401, United States, anewman@mines.edu

1 - Minimum Risk Routing Through A Mapped Mine Field

Chris Richards, Colorado School of Mines, chrichar@mymail.mines.edu

A typical risk-additive routing model in a network or network representation of continuous space may be unrealistic. We present an alternative ``threat-additive model" formulated as an integer program. We then develop a specialized, shortest-path approximation to this model. In a realistic model of a ship seeking to traverse a mapped minefield with minimum risk, we show that the approximation provides ``true risk" while constraining computation time via implicit enumeration.

2 - Building An Optimization-based, Decision Support System For Routing Vehicles For Randomized Inspections

Doug Altner, MITRE Corporation, daltner@mitre.org, Justin Nave, Abby Ng

Suppose we want to maximize the number of 500,000+ sites that 60+ vehicles can visit subject to constraints on time, area covered, overnight travel, and the mix of sites selected, while also ensuring selections are "sufficiently random" and vehicle territories are "well defined". This talk discusses how we heuristically solved this problem, and how we turned our methods into an optimization-based, decision support system for our customer.

3 - Daily Aircraft Routing For Amphibious Ready Groups

Robert Dell, Professor of Operations Research, Naval Postgraduate School, Monterey, CA, United States, dell@nps.edu, Travis Hartman, Connor McLemore, Ertan Yakici

An Amphibious Ready Group (ARG) consists of ships capable of conducting flight operations that routinely require the transport of personnel and cargo (PMC) to remain operationally viable. Planning PMC transport for an ARG and nearby airfields is a unique vehicle routing problem (VRP) characterized by a heterogeneous capacitated fleet, two cargo types, multiple depots, disjoint time windows, and synchronized routing of two aircraft required between some but not all node pairs. We solve most realistic instances optimally but solution time can become excessive so we also solve instances using a metaheuristic. This talk describes this unique VRP, our metaheuristic and our computational experience.

4 - Robust Allocation Of Testing Resources In Reliability Growth
MohammadHossein Heydari, University of Arkansas, Fayetteville, AR, United States, mhheydar@uark.edu, Kelly Sullivan

Reliability growth testing seeks to improve system reliability by identifying and removing failure modes. Recent models maximize system reliability by allocating limited testing resources across the system's components, each of which exhibits reliability growth according to the AMSAA model (Crow, 1974) with known parameters. We extend this research to solve a robust version of this problem in which AMSAA parameters are uncertain but assumed to lie within a budget-restricted uncertainty set.

Transportation, Rail I

Contributed Session

Chair: Ginger Yi Ke, Memorial University of Newfoundland, Faculty of Business Administration, Memorial University of Newfoundland, St. John's, NL, A1B 3X5, Canada, gke@mun.ca

1 - Passenger Centric Railway Planning
Yousef Maknoon, EPFL, Lausanne, Switzerland, Yousef.maknoon@epfl.ch, Tomas Robenek, Stefan Binder, Michel Bierlaire

Traditional railway systems use operations research techniques to optimize their system. Most of the time such mathematical models take only operators' cost and benefit into account. However, passengers' decision as the main users of such systems play an important role in the performance of such networks. We introduce a state of the art methodology that takes both sides (demand and supply) into account in timetable design as well as recovery plans for trains.

2 - The Locomotive Planning Problem With Alternative Train Speeds An Integrative Environmental Perspective
Ginger Yi Ke, Memorial University of Newfoundland, Faculty of Business Administration, Memorial University of Newfoundland, St. John's, NL, A1B 3X5, Canada, gke@mun.ca, Kan Fang, Manish Verma

We develop multi-objective models for the locomotive planning problem to minimize the GHG emissions and the operational costs. The amount of GHG emitted by a locomotive depends on the train speed, train load, and the locomotive type, etc. We determine the assignment of locomotives to each train, so that sufficient power can be provided to pull the trains; we generate train schedules that meet customer demands within different time windows, and determine the number of active, deadheading, light traveling locomotives, and the train-to-train connections (e.g. consist busting) for each train. Real-life railway systems are used for numerical experiments to provide additional managerial insights.

Vehicle Routing I

Contributed Session

Chair: Michael F Gorman, Professor, University of Dayton, 300 College Park, Dayton, OH, 45469, United States, michael.gorman@udayton.edu

1 - An Optimization Method Of Petrol Distribution Considering Drivers' Workload Balance
Lijun Sun, Associate Professor, Dalian University of Technology, 2 Linggong Road, Ganjingzi District, Dalian City, 116023, China, slj@dlut.edu.cn, Haiyang Shi

We present a multi-objective optimization model of petrol distribution considering drivers' workload balance based on Adams's equity theory. A heuristic algorithm is designed based on the NSGA-II algorithm. Computational results show that the proposed algorithm can generate a non-dominated solution set corresponding to distribution plans that perform well both in the total distribution cost and drivers' workload balance.

2 - Two Level Logic-based Benders Decomposition For Optimal Service NetworkDesign
Amin Hosseininasab, Carnegie Mellon University, Pittsburgh, PA, United States, aminhosseininasab@gmail.com, Fatma Gzara

We present a new continuous time network and model for the service network design problem (SNDP). SNDP addresses the planning of operations for freight transportation carriers. Given a set of requests to transport commodities from specific origins to specific destinations with given availability and delivery times, SNDP determines a continuous movement of vehicles. We propose a two-stage Logic-based Benders decomposition and develop several valid cuts for SNDP. Numerical results show the benefits of the continuous time approach and the effectiveness of the solution methodology.

3 - A Multi Stage Heuristic Solution For A Consultant Assignment And Routing Problem
Andrew Junfang Yu, Associate Professor, The University of Tennessee - Knoxville, 411 B. H. Goethert Pkwy., MS 19, Tullahoma, TN, 37388-9700, United States, ajyu@utk.edu, Brett Shields

In this study, a heuristic algorithm is developed for a novel Vehicle Routing Problem (VRP), namely the Heterogeneous Fleet Vehicle Routing Problem with Multiple Depots, Fixed Visits, and Priority Matching. The heuristic is four stage, in which the first stage is a conversion of skills and priorities to one set, second a listing of consultants is constructed based on the items in step one, third a fixed visit based assignment is given considering the availability of consultants and clustered demand, and lastly an optimal routing for each consultant is determined.

4 - Two Echelon Location Routing Problem In The Presence Of Third Party Logistics
Khosro Pichka, PhD Student, S. B. Lubar School of Business, 3202 N. Maryland Ave., Milwaukee, WI, 53211, United States, kpichka@uwm.edu, Amirsaman Hamzeh Bajgiran, Xiaohang Yue, Jaejin Jang, Matthew Petering

This paper addresses a two echelon location routing problem (2E-LRP) considering third party logistics. A 2E-LRP is a variant of the classical LRP; however, it seeks to find a set of vehicle routs in two echelons. First, from a single depot to a set of possible satelites and second, from the opened satelites to customers. In spite of the large amount of research on LRPs, the 2E-LRP has received very little attention from researchers. A mixed integer program (MIP) formulation is proposed, and a hybrid heuristic algorithm is developed to solve its medium and large size problems.

5 - Inventory-based Delivery Scheduling And Routing
Michael F Gorman, Professor, University of Dayton, 300 College Park, Dayton, OH, 45469, United States, michael.gorman@udayton.edu

Milk-run deliveries of product to customers depend on both inventory levels and customer proximity to one another. We describe a system designed to improve delivery economies through careful assessment of the trade-offs between stopping costs and mileage costs. We use k-means clustering to great groups of "like" customer in both geography and inventory depletion dates. We use a novel "furtherst neighbor" heuristic to then sequence deliveries. We discuss the application of this approach at a US manufacturer.

Supply Chain Mgt VIII

Contributed Session

Chair: Nathalia Hernandez, Universidad del Norte, Km 5 Vía Puerto Colombia, Barranquilla, AA1569, Colombia, inhernandez@uninorte.edu.co

1 - An Econometric Analysis Of Omnichannel Retailing Using Data Analytics
Serkan M. Akturk, Texas A&M University, 4217 TAMU, Wehner 320 M, College Station, TX, 77843-4217, United States, makturk@mays.tamu.edu, Michael Ketzenberg

The advent of omnichannel technologies, like ship-to-store capability, enable integration of both physical and electronic marketplaces and thereby offer consumers shopping flexibility and enhanced services. For a retailer, these capabilities require significant investment in order to deliver a seemless shopping experience, yet hold the promise of greater customer loyalty, higher marketshare, and increased competitiveness. We assess this promise by analyzing the impact of ship-to-store capability on a retailer's performance using transactional data from a national retailer.

2 - Determining The Optimal Level Of Supply Chain Forecast Coordination With Bidirectional Option Contracts
Seong-Hyun Nam, Professor, University of North Dakota, 2517 Sand Hills Avenue, Grand Forks, ND, 58201, United States, snam@business.und.edu

We have studied bidirectional option contracts associated to demand uncertainty. By analyzing how the buyer's procurement and supplier's production decisions are affected by the level of the coordination/collaboration of demand forecast under bidirectional option contracts, we have found that the optimal procurement for buyer and optimal production strategy for supplier to maximize supply chain surplus is associated with the level of forecast collaboration under bidirectional option contracts.

3 - The Impact Of Manufactures Comptition To Pay Incentive Funds On Supply Chain

Neda Khanjari, Assistant Professor, Rutgers University, 227 Penn St, BSB 260, Camden, PA, 08102, United States, neda.khanjari@rutgers.edu

In many industries manufacturers pay incentive funds to retailer hired sales agents to boost the demand for the manufacturers' products. In this paper, we study a supply chain in which two manufactures are competing to get the attention of the retailer hired sales agent to boost their own product.

4 - Partial Outsourcing And Linked Learning Processes

Burcu Tan, Tulane University, A. B. Freeman School Of Business, 7 Mcalister Dr., New Orleans, LA, 70118, United States, btan@tulane.edu, Edward Anderson, Geoffrey Parker, Xiaoyue Jiang

Firms are increasingly outsourcing software and technology development as well as other knowledge work. Standard economic models predict that firms should outsource either all or none of a particular activity; however, recent evidence contradicts that. We develop a dynamic optimization model to provide a rational explanation for partial outsourcing. Our explanation hinges upon the linked learning processes at the subsystem development level and the systems integration level.

5 - A Hybrid Stochastic Fuzzy Approach For Inventory Control In Multi Item Job Shop Processes With Unsteady Lead Time

Alcides Santander, Universidad del Norte, Barranquilla, Colombia, asantand@uninorte.edu.co, Kevin Melendez, Nathalia Hernandez, Diego Guillen, Marco E. Sanjuan

Uncertainties inherent in customer demands and variable lead times make difficult for supply chains to achieve either just-in-time inventory replenishment or economic optimal process. This results in a low service level among the different echelons of the supply chain. A hybrid stochastic-fuzzy approach for inventory control is proposed in order to guarantee production rate despite fluctuations in demand and process lead time to minimize the work in process. Demand forecast and probabilistic depiction of lead times, along with the process variables, are the inputs of a fuzzy inference system designed to determine whether it is profitable to generate a purchase order in a given period of time.

Health Care, Modeling VIII

Contributed Session

1 - Multi-period Appointment Scheduling In Outpatient Procedure Centers

Utku Tarik Bilgic, Middle East Technical University, Department of Industrial Engineering, Middle East Technical University, Ankara, 06800, Turkey, utbilgic@metu.edu.tr, Sakine Batun

Single-period appointment scheduling for a given sequence of outpatient procedures is a well-studied problem. We consider the problem determining the sequence of and the appointment times for a given set of surgeries to be operated over a multi-period planning horizon in the presence of patient no-shows and uncertainty in surgery durations. We formulate and solve the problem as a two-stage stochastic program to estimate the value of capturing uncertainty.

2 - Robust Design Of A Stroke Hospital Network

Amir Ardestani Jaafari, McGill University, 1001 Rue Sherbrooke West, Montreal, QC, H3A 1G5, Canada, amir.ardestani-jaafari@hec.ca, Beste Kucukyazici

With advances in the diagnosis and treatment of acute stroke, timely medical intention is increasingly critical; however, simply transporting the patients to the closest stroke hospital may cause congestions in some hospitals, while the stroke beds are underutilized in other hospitals. In this research, we study the trade-off between minimizing transportation time to the hospital and minimizing the congestion experiences by the patient at the hospital using robust optimization.

3 - Method To Assign Specialties To Timetable Slots In Surgery Units To Smooth Postoperative Inward Bed Demand

Flavio S Fogliatto, Prof., Federal Univ of Rio Grande do Sul, Av. Osvaldo Aranha, 99/5o andar, Porto Alegre, RS, 90040020, Brazil, ffogliatto@producao.ufrgs.br, Marcos Gerchman, Jeruza Neyeloff, Michel J Anzanello, Beatriz D Schaan

Peaks in patients' demand for inward hospitalization usually lead to disruptions in the provision of healthcare, having negative effects on patient and staff satisfaction. A main source of inward bed demand is the surgical theater. This paper proposes a method to determine the best assignment of specialties to timetable slots in surgical theaters, such that the variance of inward bed demand is minimized. For that, we use integer programming heuristics. Our propositions are tested in the surgical unit of a large public University hospital located in the south of Brazil. We were able to reduce the inward bed demand variability by 90%, smoothing the flow of post-surgical patients to hospital wards.

Technology Tutorial: Gurobi/AMPL

Technology Tutorial

1 - Gurobi Optimization

Dr. Greg Glockner, Vice President of Engineering, Bellevue, WA, glockner@gurobi.com

Advanced Python Modeling with Gurobi Are you looking for an environment that combines the expressiveness of a modeling language with the power and flexibility of a programming language? The Gurobi Python interface allows you to build concise and efficient optimization a model using high-level modeling constructs. This tutorial will provide an overview of these capabilities, including an introduction to new modeling features that significantly enhance the expressiveness of our environment.

2 - AMPL In The Cloud: Using Online Services To Develop And Deploy Optimization Applications Through Algebraic Modeling

Robert Fourer, AMPL Optimization Inc., 2521 Asbury Ave, Evanston, IL, 60201, United States, 4er@ampl.com

Optimization modeling systems first appeared online almost 20 years ago, not long after web browsers came into widespread use. This presentation describes the evolution of optimization alternatives in what has come to be known as cloud computing, with emphasis on the role of the AMPL modeling language in making models easy to develop and deploy. We start with the pioneering free NEOS Server, and then compare more recent commercial offerings such as Gurobi Instant Cloud; the benefits of these solver services are readily leveraged through their use with the AMPL modeling tools. We conclude by introducing QuanDec, which creates web-based collaborative applications from an AMPL models. Robert Fourer, an authority on the design and implementation of computer software to support large-scale optimization, studied at M.I.T. and Stanford and was a professor of Industrial Engineering and Management Sciences for over 30 years. He is a founder and is currently President of AMPL Optimization Inc. and is co-author of a popular book on modeling in the AMPL language.

1 - Expectation Maximization For Finite Mixture Of Linear Regression Models With Group Structure Data

Haidar Almohri, PhD Candidate, Wayne State University, 2833 Catalpa Circle, Ann Arbor, MI, 48108, United States, almohrih@yahoo.com, Ratna Babu Chinnam, Arash Ali Amini

One of the limitations with the available methods for fitting Finite Mixture of Linear Regression (FMR) models is that they do not explicitly account for group structure within the datasets during modeling. It is sometimes desirable to force the algorithm to allocate groups/blocks of observations to individual models, instead of individual observations. We propose an Expectation Maximization (EM) approach to fit FMR to data with group structure.

2 - A Comparison Method For Association Rule Mining Algorithms

Gulser Koksal, Prof. Dr., Middle East Technical University, Industrial Engineering Department, Ankara, 06800, Turkey, koksal@metu.edu.tr, Sanam Azadiamin

Association rule mining algorithms are helpful in extracting useful information from large amount of data. In literature, these algorithms are compared using data sets for which interesting association rules are unknown. A novel comparison method is developed to perform the comparison using designed data sets containing interesting rules generated by logistic regression. Several comparison measures are defined. Statistical analyses and multi-criteria decision making approaches are applied to find the best algorithm considering the selected measures.

3 - Productivity Assessment Through Knowledge Generation In Automotive Manufacturing Sector, Utilizing Statistical Methods

Amir Abolhassani, West Virginia University, 1233 Pineview Drive, Apt 14, Morgantown, WV, 26505, United States, Amirabolhassani@gmail.com, Bhaskaran Gopalakrishnan

The research investigates current strategies that help automobile manufacturers to enhance their productivity. The study utilizes statistical methods to define the most important effective factors on the most well-known productivity measurement, Hours per Vehicle (HPV), in the automotive industry in North American manufacturing plants.

4 - A Machine Learning Approach For Developing Intersection Safety Performance Function

Hamidreza Ahady Dolatsara, Auburn University, Suite 3301, 345 West Magnolia Ave., Auburn, AL, 36849, United States, hamid@auburn.edu, Fadel Mounir Megahed

This study introduces a non-subjective method for identifying intersection related crashes based on their distance to the center of intersection. Then utilizes data of those crashes for developing Safety Performance Functions (SPFs). This study utilizes machine learning algorithm to investigate histogram of crashes' distance to the center of intersections. The histogram classified to intersection and non-intersection related parts. After classifying the crashes, intersection SPFs are developed.

Predictive Modeling for Wind Power

Sponsored: Data Mining

Sponsored Session

Chair: Seth Guikema, University of Michigan, 1205 Beal Ave., Ann Arbor, MI, 48109-2117, United States, sguikema@umich.edu

1 - Adverse Event Prediction: Forecasting Wind Power Ramps

Andrea Staid, Sandia National Labs, Albuquerque, NM, United States, astaid@sandia.gov

Wind power ramp events (large changes in output over a short period of time) are of particular concern in power systems with high wind penetration. They are also often difficult to predict. We present statistical methods for combining multi-source data to better predict the adverse ramp events that are typically not captured in a standard weather forecast. We present a case study using data from the Bonneville Power Administration and focus on farm-specific ramps.

2 - Predicting Low-wind Events To Inform Planning And Policy Incentives

Kristen R. Schell, University of Michigan, Ann Arbor, MI, United States, krschell@umich.edu, Seth Guikema

Wind power is currently the most cost-effective source of renewable energy, from the perspective of life-cycle cost estimates. Given major government backing to support the general expansion of renewable energy, wind power continues to be the investment of choice for developers, largely due to its generally higher resource potential and capacity factors. Hence, as wind power becomes increasingly integrated into the electric grid, the power system in turn becomes increasingly vulnerable to "wind droughts", or periods of low-to-no wind power. This study uses large-scale wind data to predict low-wind events, to better inform system planning and renewable policy incentives.

3 - Learning Of Imbalanced Data For Predicting The Power Outage

Elnaz Kabir, PhD Student, University of Michigan, 1205 Beal Avenue, Ann Arbor, MI, 48109-2117, United States, ekabir@umich.edu, Seth Guikema

In this article we want to model the number of power outages during the hurricanes. Making accurate prediction of power outage can be really valuable for the utility companies as well as customers and public agencies to make better response planning. Our data-set is highly zero inflated and imbalanced because power outages occur rarely. Since no techniques for dealing with imbalanced data sets are consistently better for all conditions, we investigate several methods to find the most appropriate strategy for our data set.

1 - Freemium Pricing: A Stylized Framework And Evidence From A Large-scale Field Experiment

Jörg Claussen, LMU Munich, Munich, Germany, j.claussen@lmu.de, Jörg Claussen, Copenhagen Business School, Frederiksberg, Denmark, j.claussen@lmu.de, Julian Runge, Julian Runge, Stefan Wagner

Marketers struggle to find optimal designs for their freemium offerings. We present a stylized framework of freemium pricing that systematizes key choice variables and identifies their interaction with relevant outcome variables. Firms set the share of free product features and the price of premium content and implement viral mechanisms. These choices affect monetization not only via their effect on users' conversion to paying customers, but also via their effects on usage behavior and viral activities. We apply our framework to a large-scale field experiment and show that a reduction of free product features increases conversion rates and viral activities, and has ambivalent effects on usage.

2 - Building An Online Reputation With Free Content: Evidence From The E-book Market

Dainis Zegners, LMU Munich, d.zegners@lmu.de

An important strategy to build a reputation is to offer products for free to induce buyers to provide feedback. I argue that giving away free products to build a reputation can be a double-edged strategy. It does not only attract buyers with a high preference, but also buyers with a low preference, who give worse feedback. I test the strength of this negative effect on reputation using data from an online platform where I observe self-published authors either selling their e-books at a positive price or giving them away as free content. Consistent with a negative selection effect on reputation, I observe that buyers who receive an e-book as free content rate it worse than buyers who buy it at a positive price.

Chair: David Pozo, Pontificia Universidad Catolica, Avendia Vicuna Mackenna #4860, Puebla del Principe, 7820436, Chile, davidpozocamara@gmail.com

1 - Non-cooperative Multi-regional Transmission Planning

Saamrat Kasina, Johns Hopkins University, Ames 214, Baltimore, MD, 21218, United States, bkasina1@jhu.edu, Benjamin Field Hobbs

Traditional transmission planning methods overlook the political boundaries within which planning entities operate. However, in reality, there are multiple regional transmission planning agencies with limited coordination with each other during planning. We develop a bi-level model that defines the relationship between multiple non-cooperating transmission planners, generation investors, and the energy market equilibrium. We ask how the transmission plans from such a process differ from those from a cooperative planning process and what the value of cooperation is, if any.

2 - Bi-level Network Planning Model Considering Generation-market Equilibria Subject To Inefficient Network Pricing

Pengcheng Ding, Johns Hopkins University, Baltimore, MD, United States, pangchingting@gmail.com, Benjamin Hobbs

We consider proactive planning of transmission subject to the response of a generation market with imperfect long-run transmission pricing based on a MW-km charging system, similar to that of the UK and elsewhere. MW-km-based charging distorts siting decisions of both thermal and renewable plants relative to the social optimum because (1) congestion and locations of needed reinforcements are ignored and (2) all generation types at a location pay the same charge, no matter how they use the grid.

3 - Reliable Renewable Generation And Transmission Expansion Planning: Co-optimizing System's Resources For Meeting Renewable Targets

David Pozo, Pontificia Universidad Católica de Chile, Santiago, Chile, davidpozocamara@gmail.com, Alexandre Moreira, Alexandre Street, Enzo E Sauma

We propose a two-stage renewable generation and transmission expansion planning model that jointly finds the best subset of new transmission assets and renewable sites to be developed. The main goal of this co-optimization planning model is to address renewable targets while accounting for the least-cost reserve scheduling to ensure reserve deliverability under generation and transmission outages and renewable variability. A case study with realistic data from the Chilean system is presented and solutions obtained with different level of security are tested against a set of 10,000 simulated scenarios of renewable injections and system component outages.

1 - Topics On Optimal Power Flow

Richard O'Neill, FERC, Richard.O'Neill@ferc.gov

2 - Load-dependent Sensor-driven Maintenance And Operations In Power Systems

Murat Yildirim, Georgia Institute of Technology, Atlanta, GA, 30332, United States, murat@gatech.edu, Andy Sun, Nagi Gebraeel

The operational loads on the generating units have a significant impact on how fast they degrade. For instance, the frequency of start-up and shut-down cycles can change the lifetime of combined-cycle power plants by an order of magnitude. In this talk, we use in-situ sensor based signals to provide i) an accurate load-dependent degradation model for generating units, and ii) a flexible framework whereby the scheduler gains some control on how fast the generating units are degrading. The proposed framework achieves significant improvements in cost and reliability.

3 - Impact Of Short-term Variability And Uncertainty On Long-term Planning Problems

Henrik Bylling, University of Copenhagen, Universitetsparken 5, Copenhagen, DK-2100, Denmark, bylling@math.ku.dk, Salvador Pineda, Trine Krogh Boomsma

Considering a detailed representation of short-term system operations turns long-term planning problems, such as generation expansion, computationally intractable. Simplified models reduce the computational burden by focusing on a particular aspect of the short-term operation. We compare existing simplified models in terms of i) their ability to capture the impact of both short-term variability and short-term uncertainty on long-term planning decisions and ii) their computational complexity. We also propose a new procedure that outperforms existing ones in these two aspects.

Chair: Petros Xanthopoulos, University of Central Florida, 4000 Central Florida Blvd., P.O. BOX 162993, Orlando, FL, United States, petrosx@ucf.edu

1 - Relaxing Support Vector Machines

Orestis P. Panagopoulos, California State University, Stanislaus, Turlock, CA, United States, orepana@gmail.com, Talayeh Razzaghi, Petros Xanthopoulos, Onur Seref

In this paper, we extend Relaxed Support Vector Machines (RSVM) to perform regression as well as one-class classification tasks. Our models, Relaxed Support Vector Regression (RSVR) and One-Class Relaxed Support Vector Machines (ORSVM) are formulated using both linear and quadratic loss functions and are solved with sequential minimal optimization. Their performance is measured on several publicly available datasets and are compared to other state-of-the-art regression and classification methods.

2 - Online Feature Importance Ranking Based On Sensitivity Analysis

Alaleh Razmjoo, University of Central Florida, Orlando, FL, 32765, United States, alaleh.razmjoo@Knights.ucf.edu, Petros Xanthopoulos

In this paper, we present a fast and efficient incremental online feature ranking and feature selection. We employ the concept of global sensitivity and rank features based on their impact on the outcome of classification model. In the feature selection part, we use a two stage filtering method to first eliminate highly correlated and redundant features and then eliminating irrelevant features in the second stage. It can be implemented along with any online classification method. The proposed method is primarily developed for online tasks, however, significant experimental results in comparison with popular feature selection methods suggest that it can be also used in batch learning tasks.

3 - A Novel Weighting Policy For Unsupervised Ensemble Learning Based On Mean-variance Portfolio Optimization Method.

Ramazan Unlu, UCF, ramazanunlu@gmail.com

Unsupervised ensemble learning is an optimal combination strategy of individual clustering methods to create a model that fits to data better. Determining proper weights for clustering methods is a crucial step to build a well-combined partition. Recently, an approach was proposed based on concept of internal validity measures that has profound advantages over traditional ensemble learning. Despite its robust properties this approach consider only index values itself, but not variation of them. In this paper, we propose a better weighting policy for this problem that is based on mean-variance portfolio optimization method and compare against other popular approaches.

4 - Nonlinear Dimensionality Reduction For Analysis Ofelectroencephalography Records

Anton Kocheturov, University of Florida, Gainesville, FL, United States, antrubler@gmail.com

We suggest using nonlinear dimensionality reduction technique called the Local Linear Embedding for analysis of EEG records. This approach enabled us to distinguish between different states of the brain in a more efficient way comparing to the existing machine learning techniques since it is faster and doesn't require training of the algorithm. We also detected evidence for local linearity of the brain in the resting state and introduced a new model of the brain based on it.

Chair: Matthew Lanham, Virginia Tech, Pamplin 1007, Blacksburg, VA, 24061, United States, lanham@vt.edu

1 - Analytics on The Edge Of Retail

Aaron Burciaga, Accenture, adburciaga@gmail.com

The fervor of big data and business analytics have led to a bumper crop of education, training, tools, and methods. It's has become increasingly difficult to detect the signal from the noise of those same people, processes, and tools that purportedly exist to distinguish signals from noise. This presentation will review several case studies of how commercial and national government programs are developing (or stumbling) in their analytics programs. Emergent technologies and methods, including the application of Machine Learning and Artificial Intelligence on edge devices will be presented, showing how the last mile and last dollar can be closed in both new and traditional challenges.

2 - An Investigation Of Cluster Analysis Of Retail Stores To Improve Predictive Modeling Of Sales

Linda Schumacher, Merchandise Scientist, Raleigh, NC, 27604, United States, schumachers@bellsouth.net

Data mining clustering algorithms are used to identify similar groups of retail stores for segmenting data to improve predictive modeling results. Clustering methods including centroid-based, hierarchical, two-step and probabilistic clustering are considered. The performance of these clustering methods is evaluated and compared with calculated metrics. Using data from a national retailer, the impact of segmenting the data to improve overall predictive performance is reported.

3 - Investigating Sparse Demand Models To Support The Assortment Planning Decision

Matthew Lanham, Clinical Assistant Professor, Purdue University, West Lafayette, IN, United States, malanham@gmail.com

We present research examining the performance of substitution-based multi-classification models currently being researched and employed in practice by major retailers, versus more naïve binary classification models to understand purchase propensity. We discuss how these models would yield different assortments for sparse demand products.

Collaborative Innovation and Project Supply Chain Management Interfaces

Invited: Business Model Innovation

Invited Session

Chair: Yao Zhao, Rutgers University, Newark, NJ, United States, yaozhao@andromeda.rutgers.edu

Co-Chair: Onesun Steve Yoo, University College London, School of Management, Gower Street, London, WC1E 6BT, United Kingdom, onesun.yoo@ucl.ac.uk

1 - Investment In Shared Suppliers

Youngsoo Kim, University of Illinois, Champaign, IL, WC1E 6BT, United States, mailto:ykim180@illinois.edu, Anupam Agrawal, Dharma Kwon, Suresh Muthulingam

Motivated by an auto maker's supplier quality management, we study the investment time game of firms in a shared supplier when investment can spillover to the other. In our model, each firm decides when to invest by observing continuous flow of supplier performance with incomplete information on the type of supplier. We first characterize equilibria by a region of preemption and war of attrition. Then, we examine the interactive effects of spillover, competition, and learning on investment strategies and time to invest. We identify the simple conditions under which competition delays or hastens the first investment in a shared supplier.

2 - Project Management Contracts Under Information Asymmetry

Ju Myung Song, Rutgers University, jumyung.song@rutgers.edu

Collaboration and partnership are essential for development projects many industries. We develop game theoretical models to show how firms behave on behalf of their best interest in collaboration and how it affects the project performance under information asymmetry.

3 - On-demand Delivery Via On-demand Drivers

Michael Wagner, University of Washington, mrwagner@uw.edu, Soraya Fatehi

Controlling shipping costs has always been a challenge for most retailers. With the consumer trend towards more on-demand orders and the expectation of fast shipping times, some retailers have decided to crowdsource their deliveries (e.g., Amazon Flex, Uber Rush). This delivery method uses an on-demand work force to deliver orders. Retailers typically pay drivers hourly wages whereas couriers such as UPS charge retailers per package. The use of an on-demand crowd for logistics creates new challenges such as crowd availability, service level constraints, and liability. In this presentation, we evaluate the crowdsourcing delivery method and derive optimal strategies for firms.

4 - Managing Risks In Major Defense Acquisition Programs From The Supply Chain Perspective.

Olena Rudna, Rutgers University, omr20@scarletmail.rutgers.edu

The Major Defense Acquisition Programs (MDAP) cost overrun problem was on the high-profile issues list of the U.S. Government Accountability Office since 1990s. Drawing on organizational theory, this work develops a series of proposals explaining MDAP cost overrun from a supply chain management perspective. Using data mining techniques, we combined two independent publicly available data sources related to the MDAP performance and contracting activities over the past twenty years. Then we conducted a three-tier analysis—strategic, operational and tactical—to detect data patterns related to risks related to the MDAP project performance from the supply chain point of view.

Renewable Energy Systems and Grid Integration

Sponsored: Energy, Natural Res & the Environment, Energy II Other

Sponsored Session

Chair: Alexandra M Newman, Colorado School of Mines, newman@mines.edu

1 - Optimization Of Stored Energy Dispatch For Concentrating Solar Power Systems

Michael J Wagner, National Renewable Energy Laboratory, mike.wagner@nrel.gov

2 - Optimal Design Of Concentrating Solar Power Systems

Will Hamilton, Colorado School of Mines, whamilton@mines.edu

In 2011, the United States Department of Energy launched the SunShot Initiative, the mission of which is to make solar energy technologies more affordable and accessible to citizens by 2020. With the use of thermal storage devices, concentrated solar power (CSP) technologies store solar energy in the form of thermal energy which can be used to supply electrical power during hours of little to no solar resource. In order to make CSP systems competitive with current technologies, we optimize design to minimize system, operation, and maintenance costs for the lifetime of the plant, providing preliminary numerical results.

3 - ROC-ing The Grid: The Unintended Consequences Of Northern Ireland's Renewable Obligation Credit

Destenie Supreece Nock, University of Massachusetts - Amherst, Amherst, MA, 01002, United States, dnock@umass.edu, Erin Baker

In 2005 Northern Ireland introduced the renewable obligation certificate (ROC) policy, which was designed to increase the levels of renewable generation in the country. While the ROC was successful in encouraging the uptake of renewable generation technology, the amount of small- and micro-generation incorporated into the power system was much larger than anticipated. We use this case study as an illustration of specific opportunities for IEOR research in power system reliability and cost optimization. We discuss reliability metrics useful for evaluating potential responses to Northern Ireland's challenges.

4 - Siting And Sizing Of Merchant Energy Storage

Yury Dvorkin, University of Washington, Seattle, WA, United States, dvorkin@uw.edu, Yury Dvorkin, New York University, New York, NY, United States, dvorkin@uw.edu, Ricardo Fernandez-Blanco, Jean-Paul Watson, Cesar A Silva-Monroy, Cesar A Silva-Monroy, Hrvoje Pandzic, Daniel Kirschen

A high capital cost of battery energy storage systems (BESSs) raises concerns over whether merchant BESSs are economically viable within a market environment. This presentation will describe two multi-level optimization models that explicitly guarantee the profitability of merchant investment decisions on BESSs siting and sizing. The presentation will also demonstrate how these decisions are affected by a co-optimization with transmission expansion plans. Numerical simulations carried out on test-beds of the ISO New England and WECC systems demonstrate that considering the profitability of merchant BESSs also leads to improvements in market efficiency.

Novel Applications of Network Optimization

Sponsored: Optimization, Network Optimization

Sponsored Session

Chair: Anna Nagurney, John F. Smith Memorial Professor, Isenberg School of Management, University of Massachuseets, Amherst, MA, 01003, United States, nagurney@isenberg.umass.edu

1 - A General Multitiered Supply Chain Network Model Of Quality Competition With Suppliers

Dong Li, Arkansas State University, dli@astate.edu, Anna B Nagurney

In this paper, we develop a general multitiered supply chain network equilibrium model consisting of competing suppliers and competing firms who purchase components from suppliers. The competitive behavior of each tier of decision-makers is described along with their strategic variables, which include quality of the components and, in the case of the firms, the quality of the assembly process itself. The governing equilibrium conditions of the supply chain network are formulated as a variational inequality and qualitative properties are presented. The algorithm, accompanied with convergence results, is then applied to numerical supply chain network examples along with sensitivity analysis.

2 - Supply Chain Network Equilibrium With Strategic Financial Hedging Using Futures Contracts

Zugang Liu, Pennsylvania State University - Hazleton, Hazleton, PA, United States, zxl23@psu.edu, Jia Wang

We develop a modeling and computational framework for supply chain networks with strategic financial hedging. We consider multiple competing firms that purchase multiple materials to manufacture their products. The supply chain firms' procurement activities are exposed to several risk factors such as commodity price uncertainty and exchange rate volatility. The firms can use futures contracts to hedge the risks. Our research studies the equilibrium of the entire network where each firm optimizes its own operation and hedging decisions.

3 - A Time-space Network Model For Medical Resources Allocation In An Epidemic Outbreak

Ding Zhang, SUNY Oswego, New York, NY, United States, ding.zhang@oswego.edu

This paper presents a dynamic logistics model for medical resources allocation that can be used in the control of an epidemic diffusion. It couples a forecasting mechanism, constructed for the demand of a medicine in the course of such epidemic diffusion, and a logistic planning system to satisfy the forecasted demand and minimize the total cost. The model is built as a closed-loop cycle, comprises of forecast phase, planning phase, execution phase, and adjustment phase. The parameters of the forecast mechanism are adjusted in reflection of the real data collected in the execution phase by solving a quadratic programming problem. A numerical example is presented to illustrate the model.

4 - A Generalized Nash Equilibrium Network Model For Post-disaster Humanitarian Relief

Anna Nagurney, John F. Smith Memorial Professor, University of Massachusetts Amherst, Amherst, MA, 01003, United States, nagurney@isenberg.umass.edu, Emilio Alvarez Flores, Ceren Soylu

We develop a Generalized Nash Equilibrium network model for post-disaster humanitarian relief by nongovernmental organizations (NGOs). NGOs derive utility from providing relief supplies to the victims of the disasters at multiple demand points in a supply chain context while competing with each other for financial funds provided by donations. The shared constraints consist of the lower and upper bounds for demand for relief items at the demand points and can be imposed by the regulatory body or higher level coordinating NGO to reduce materiel convergence and congestion. We provide an effective computational scheme and numerical examples plus solutions under the Nash Equilibrium counterpart.

1 - Coordinated Capacitated Lot-sizing For Multiple Product Families With Setup Times

Tiffany Bayley, University of Waterloo, Waterloo, ON, Canada, tiffany.bayley@uwaterloo.ca, Haldun Sural, James H Bookbinder

We examine a coordinated capacitated lot-sizing problem for multiple product families, where demand is deterministic and time-varying. The problem considers only holding costs, where capacity constraints limit the number of item and family setups and the amount of production in each period. Using a strong reformulation and relaxing the demand constraint, we improve both the upper and lower bounds using Benders decomposition and a cutting plane procedure. Through computational experiments, we show that our method consistently achieves better bounds, reducing the duality gap compared to other single-family methods studied in the literature.

2 - A Polyhedral Study On Lot-sizing Problem With Capacity Acquisition

Jia Guo, The University of Alabama, Tuscaloosa, AL, 35487, United States, jguo23@crimson.ua.edu, Minjiao Zhang

Determining the optimal capacity level to invest is one of the fundamental problems for an enterprise's operation. In this study, we consider a single-echelon lot-sizing problem with capacity acquisition (CALS). Two families of the so-called capacity definition and demand satisfying inequalities are proposed to describe the convex hull of CALS. Our computational results show that the proposed inequalities are very effective in solving CALS.

3 - The Slim Branch And Price Method With An Application To The Hamiltonian P-median Problem

Ahmed Marzouk, Texas A&M University, College Station, TX, 77840, United States, ambadr@email.tamu.edu, Erick Moreno-Centeno, Halit Uster

We present the Slim Branch and Price (SBP) method which is an improvement over traditional Branch and Price in the case of binary master problems. The main advantage in SBP is that the branching tree has only one main branch with several leaves. We illustrate the computational advantage of SBP over Branch and Price on the Hamiltonian p-median problem. In particular, under one hour limit, SBP can solve to optimality instances with up to 200 nodes; whereas Branch and Price can solve to optimality instances with up to 127 nodes.

4 - Multiechelon Lot Sizing With Intermediate Demands

Ming Zhao, Assistant Professor, University of Houston, Houston, TX, 77204, United States, mzhao@bauer.uh.edu, Minjiao Zhang

We prove that multiechelon lot sizing with intermediate demands is NP-hard. However, in the case of fixed number of echelons, we are able to derive polynomial time algorithms for both capacitated and uncapacitated models.

Computational Linear Optimization

General Session

Chair: Nikolaos Ploskas, Carnegie Mellon University, 5000 Forbes Avenue, Pittsburgh, PA, 15213, United States, ploskasn@gmail.com

1 - Vector Space Decomposition For Solving Linear Programs

Marco Lübbecke, RWTH Aachen University, marco.luebbecke@rwth-aachen.de, Jean Bertrand Gauthier, Jacques Desrosiers

We propose a general algorithmic framework for solving linear programs. An iteration moves from one solution to the next in a direction with a certain step size. Part of the direction is determined by a pricing problem that is interesting in its primal and dual form: the dual fixes part of the dual variables and optimizes the rest; the primal selects a convex combinations of variables. Several known algorithms are unified by our view, in particular the primal simplex method, the minimum mean cycle canceling algorithm, and the improved primal simplex method. The framework allows us to precisely characterize when degenerate iterations can occur, and how to avoid them (of course, at a computational cost).

2 - Some Thoughts On Implementing Linear Optimization Algorithms

Tamás Terlaky, Lehigh University, terlaky@lehigh.edu

We discuss some aspects of implementing simplex and interior point algorithms for LO. Among others, we discuss the role of duality in algorithms design, in preprocessing, in choosing the most promising algorithm, in choosing if the given problem should be considered as primal or dual. The provocative question naturally arises: Do we indeed have both primal and dual simplex algorithms? Another question is if an optimal basis is always needed? Then, the algorithmic and practical consequences of choosing either crossover or optimal basis identification procedure are discussed.

3 - An Advanced Starting Basis For The Simplex Algorithm

Nikolaos Ploskas, Carnegie Mellon University, Pittsburgh, PA, United States, nploskas@andrew.cmu.edu, Nikolaos Samaras, Nikolaos Sahinidis

The computation of a starting basis for the simplex algorithm is of great importance. We propose six algorithms for constructing an initial basis using various ordering methods in order to generate a nearly-triangular and sparse initial basis. We give the initial bases as input to the CPLEX solver and compare the performance of the primal and dual simplex algorithm using the proposed algorithms against CPLEX advanced starting basis and crash procedures. The best algorithm results in 95% and 87% reduction of the execution time of the primal and the dual simplex algorithm, respectively.

4 - A Planning Approach And a Decision Support System For Wine Bottling Operations

Alfredo R. Squadritto, Pontificia Universidad Católica de Valparaíso, School of Industrial Engineering, Valparaíso, Chile, squadritto@ucv.cl, Ernesto Vásquez, Ricardo A. Gatica, Sergio G. Flores, Ricardo Gatica

We will describe a MIP-heuristic based decision support system (DSS) for production planning and scheduling at wine bottling plants. The production system involves several complicating features such as the coexistence of items made-to-order with items made-to-inventory, a complex structure, several constraints on wine supply, and a variety of company's policies. The DSS offers tools for easily modifying and analyzing the production schedule using a friendly graphic user interface. It's been implemented in 3 plants. The largest plant handles about 2400 SKUs, 400 intermediate products, and 3500 types of raw material, and it processes, on average, 250 production orders per week on 2 parallel production lines.

Data Mining in Genetics and Genomics

Sponsored: Data Mining

Sponsored Session

Chair: Michael M Hoffman, Princess Margaret Cancer Centre/University of Toronto, Toronto Medical Discovery Tower 11-311, 101 College Street, Toronto, ON, M5G 1L7, Canada, michael.hoffman@utoronto.ca

1 - Modeling Methyl-sensitive Transcription Factor Motifs With An Expanded Epigenetic Alphabet

Michael M Hoffman, Scientist, Princess Margaret Cancer Centre, Toronto Medical Discovery Tower 11-311, 101 College St, Toronto, ON, M5G 1L7, Canada, michael.hoffman@utoronto.ca
Michael M Hoffman, Scientist, University of Toronto, Toronto Medical Discovery Tower 15-701, 101 College St, Toronto, ON, M5G 1L7, Canada, michael.hoffman@utoronto.ca

To understand the effect of DNA methylation on gene regulation, we developed methods to discover motifs and identify TF binding sites (TFBS) in DNA with covalent modifications. Our models expand the standard A/C/G/T alphabet, adding m for 5-methylcytosine. We adapted the position weight matrix model of TFBS affinity to an expanded alphabet. Using ChIP-seq data from Mouse ENCODE and others, we identified modification-sensitive cis-regulatory modules. We elucidated various known methylation binding preferences, including the methylation preferences of ZFP57, C/EBP , and c-Myc.

2 - Data, Informatics, And Analytical Challenges In Genomic Medicine

Elizabeth A. Worthey, Faculty Investigator & Director, HudsonAlpha Institute for Biotechnology, 601 Genome Way, Huntsville, AL, United States, lworthey@hudsonalpha.org

Application of Next Generation Sequencing has transformed genomic research. It is also transforming medicine through use as a molecular diagnostic test in both rare disease and oncology. It can also identify much (though not all) of the variation associated with more common and polygenic disease. To support such clinical and translational advances investment in computational applications, hardware, and methodologies has been necessary. Informatics environments, tools, and processes supporting medical genomics have been developed or refined and validated for clinical use. This talk will highlight various successes and will discuss potential solutions to some of the challenges that remain.

3 - Machine Learning For Predicting Vaccine Immunity

Eva K. Lee, Georgia Institute of Technology, eva.lee@isye.gatech.edu

This work is joint with Emory Vaccine Center and CDC. The ability to better predict how different individuals will respond to vaccination and to understand what best protects individuals from infection greatly facilitates developing next-generation vaccines. It facilitates both the rapid design and evaluation of new and emerging vaccines as well as identifies individuals unlikely to be protected by vaccine. We describe a general-purpose machine learning framework, DAMIP, for discovering gene signatures that can predict vaccine immunity and efficacy.

Chair: Bruno Fanzeres, Visiting PhD Student, Georgia Institute of Technology, 755 Ferst Drive, NW, Atlanta, GA, 30332, United States, santosbruno85@gmail.com

1 - The Information-collecting Vehicle Routing Problem For Emergency Storm Response

Lina Al-Kanj, Postdoctoral Research Associate, Princeton University, Olden Street, Sherrerd Hall, room 119, Princeton, NJ, 08544, United States, lalkanj@princeton.edu, Warren B Powell"

This talk presents a new policy that routes a utility truck to restore outages in the power grid using trouble calls and the truck's route as a mechanism for collecting information to create beliefs about outages. This means that routing decisions change our belief about the network, creating the first stochastic vehicle routing problem that explicitly models information collection. The problem is formulated as a sequential stochastic optimization program. Then, a stochastic lookahead policy is presented that uses Monte Carlo tree search (MCTS) to produce a practical policy that is asymptotically optimal. Simulation results show that the developed policy has a close-to-optimal performance.

2 - Sampling Based Optimization Algorithms For Power Systems Application

Harsha Gangammanavar, Clemson University, harsha@clemson.edu

We present sampling-based approaches for addressing a class of stochastic optimization problems arising in power systems with significant renewable penetration, including economic dispatch and distributed storage control. These approaches provide a distribution-free alternative to methods based on Benders decomposition. This allows them to directly operate with external state-of-the-art simulators accessible to power systems operators. We will demonstrate their advantages in two-stage and multistage setups through computational experiments on real-scale power systems.

3 - Robust Strategic Bidding In Day Ahead Electricity Markets

Bruno Fanzeres, Georgia Institute of Technology, 765 Ferst Drive NW, Atlanta, GA, United States, santosbruno85@gmail.com, Shabbir Ahmed, Alexandre Street

The standard approach to devise bidding strategies in day-ahead electricity markets assumes available a joint probability distribution that drives the probabilistic nature of rival players' behavior. Nevertheless, construct such probabilistic description is a challenging task due to its complex nature. In this talk, robust optimization techniques are adapted to the bidding strategy problem to characterize the uncertainty on rival players' bids. A Column-and-Constraint Generation algorithm is constructed to solve the bidding problem. An illustrative example is presented to highlight the applicability of the proposed model as well as to provide intuition behind the algorithm.

4 - Modeling Power Markets With Multi-stage Stochastic Nash Equilibrium

Joaquim Dias Garcia, PSR-Inc., Praia de Botafogo, 228, Botafogo, Rio de Janiero, Brazil, joaquimgarcia@psr-inc.com

The modeling of modern power markets requires the representation of the following main features: (i) a stochastic dynamic decision process, with uncertainties related to renewable production and fuel costs, and (ii) a game-theoretic framework that represents the strategic behaviour of multiple agents., These features can be in theory represented as a stochastic dynamic programming recursion, where we have a Nash equilibrium for multiple agents. This work presents an iterative process to solve the above problem for realistic power systems. The proposed algorithm consists of a fixed point algorithm, in which, each step is solved via stochastic dual dynamic programming method.

Stochastic Programming for Long Term Planning

Sponsored: Optimization, Optimization Under Uncertainty

Sponsored Session

Chair: Anderson Rodrigo de Queiroz, NCSU, n, 1, NC, 12, United States, arqueiroz@ncsu.edu

Co-Chair: Joseph F DeCarolis, North Carolina State University, Raleigh, NC, United States, jdecarolis@ncsu.edu

1 - The Value Of Stochastic Programming For Energy Systems Planning

Anderson Rodrigo de Queiroz, North Carolina State University, Raleigh, NC, United States, arqueiroz@ncsu.edu, Joseph F DeCarolis

Energy system models should reflect the reality that planners must make decisions prior to the realization of future uncertainties. Multi-stage stochastic programs, which embed uncertainty in the decision process, optimize over future possibilities to yield a near-term decision strategy. We use the expected value of perfect information and the value of the stochastic solution as metrics to quantify the value of such strategies for long-term capacity expansion of energy systems.

2 - Stochastic Optimization Of Design Under Heuristic Operation In Mixed Integer Programs

Alexander Zolan, The University of Texas at Austin, alex.zolan@utexas.edu, David Morton, Alexandra M Newman

We present a framework for optimizing system design in the face of a restricted class of policies governing system operation, which aim to model realistic operation for stochastic integer programs with a long operating time horizon. This leads to a natural decomposition of the problem yielding upper and lower bounds, which we can compute quickly. We illustrate application of these ideas using a model that seeks to design and operate a microgrid to support a forward-operating base under load and photovoltaic (PV) uncertainty, as well as other examples from the literature.

4 - Power System Planning In Fragile States: A Case Study Of South Sudan

Evangelia Spyrou, Johns Hopkins University, Baltimore, MD, United States, elina.spirou@gmail.com, Morgan Bazilian, Debabrata Chattopadhyay, Benjamin Field Hobbs

In countries suffering from fragility, conflict and violence, power system planning and investment is essential for development and economic growth. However, the sector has to contend with deep uncertainty that may impact on an already vulnerable power system. We propose the application of a multi-stage stochastic program that explicitly considers probability of conflict and its consequences on power system infrastructure. Results for the power system in South Sudan are provided and discussed.

Finance, Portfolio I

Contributed Session

Chair: Markku Kallio, Professor, Aalto Univertsity, Runeberginkatu 22-24, Helsinki, FIN-00200, Finland, markku.kallio@aalto.fi

1 - Trade Space Exploration Tools And Methods With Applications To Capital Investments And Portfolio Management Decisions For Optimality

Simon Miller, Applied Research Laboratory, The Pennsylvania State University, 411 Waupelani Drive, D-221, State College, PA, 16801, United States, swm154@psu.edu, Christopher M. Farrell, Michael A. Yukish, Gary M Stump

Faced with constrained portfolio conditions, senior leaders must often make strategic choices and fiscal trades with implications on capabilities, capacities, and system attributes to maximize value, manage risk, and satisfy stakeholder requirements. Researchers have developed robust tools and methods to explore large scale, complex, multi-objective problems for portfolio analyses, where data visualization techniques and optimization algorithms are simultaneously applied to support decision processes in a binary combinatorial space. The tools and methods may be applied to a wide range of financial management and resource allocation problems to provide flexibility and options.

2 - Forth Order Stochastic Dominance Efficiency Test And An Empirical Evaluation

Nasim Dehghan Hardoroudi, PhD Candidate, Aalto University School of Business, Runeberginkatu 22-24, Chydenia (4th floor), Helsinki, 00100, Finland, nasim.dehghan.hardoroudi@aalto.fi

Stochastic dominance is an important tool in aiding decisions under uncertainty when the decision maker's utility function is unknown. In this study, we propose a novel forth order stochastic dominance (FOSD) efficiency test. We derive the necessary and sufficient conditions for such test, which is based on nonlinear convex optimization problem. For comparison, we provide numerical illustrations for second and third order stochastic dominance (SSD, TSD) as well as decreasing absolute risk aversion stochastic dominance (DSD) besides the FOSD test, using stock market data of the US. The market index as benchmark is found inefficient and dominated under the all types of stochastic dominance.

3 - Some Tests For Stochastic Dominance Efficiency

Markku Kallio, Professor, Aalto Univertsity, Runeberginkatu 22-24, Helsinki, FIN-00200, Finland, markku.kallio@aalto.fi

We consider third order stochastic dominance (TSD), decreasing absolute risk aversion (DARA) stochastic dominance (DSD) as well as stochastic dominance (ESD) based on the family negative exponential utility functions. These concepts are of interest because the respective classes of utility functions convey observed properties of individual preferences. Using the efficiency concept introduced by Post, we derive necessary and sufficient tests for efficiency under the three types of stochastic dominance. Our DSD efficiency test is new, it relies on our argument for the TSD test, and it circumvents shortcomings in recent literature.

Chair: Leo Lopes, SAS, SAS Campus Drive, Cary, NC, 27513, United States, Leo.Lopes@sas.com

1 - Optimization Modeling With Python Using Pandas

Irv Lustig, Princeton Consulting, irv@princeton.com

The Python library pandas (http://pandas.pydata.org/) is a popular library used by data scientists to carry out an entire data analysis workflow in Python. When building optimization models, we often work with data in tables that are sourced from databases, CSV files, and spreadsheets. pandas provides a uniform environment for working with data tables with a large number of methods for manipulating tabular data, many of which are directly applicable for building large scale optimization models. In this talk, we will illustrate some of these powerful features that can accelerate optimization model development and deployment.

2 - SAS/OR Value Beyond the Model

Leo Lopes, SAS Institute, Leo.Lopes@sas.com

We focus on uses of SAS/OR that go beyond modeling and solving, but are are just as essential to deliver production quality prescriptive analytics models quickly. The tasks we describe support testing, instance generation, access to alternative solvers, data manipulation, algorithmic control, and visualization.

3 - Building Optimization-enabled Applications Using AMPL Api

Robert Fourer, AMPL Optimization Inc., 2521 Asbury Ave, Evanston, IL, 60201, United States, 4er@ampl.com

We describe how to combine the power of the AMPL modeling system and a general-purpose programming language to build rich optimization-enabled client applications. Having an optimization model expressed in a high-level declarative form with model and data separation facilitates its evolution and maintenance, and makes switching between different solvers and data sources easy. At the same time it is possible to use a familiar development environment and have access to a wide variety of programming libraries for data management and interface development.

4 - Decision Optimizer 7.0: Combinatorial Optimization For Business Analysts

Susanne Heipcke, FICO, San Jose, CA, United States, SusanneHeipcke@fico.com, Livio Bertacco, Sebastien Lannez

With Decision Optimizer a strategy analyst can define and optimize complex decision problems using an intuitive graphical workflow. By designing the interactions between decisions and constrained metrics, it is possible to create models for optimizing the assignment of actions, such as investment options or transaction authorization, for large-scale datasets of input elements leveraging analytic techniques for sampling and segmentation. In the new version 7.0, DO has been integrated with FICO Optimization Modeler to provide a more collaborative, web and cloud based experience, improved scenario management, distributed execution and Tableau based reporting.

1 - Mathematical Finance, Models, Simulation And Today's Pressing Problem

Joseph M. Pimbley, Maxwell Consulting, LLC, a, Croton-on-Hudson, NY, 10520, United States, pimbley@maxwell-consulting.com

Financial markets are awash in information ranging in form from numerical data to unstructured news reports to nebulous narratives of executives and regulators. Investors, fiduciaries, intermediaries and other "market actors" apply an exceedingly broad spectrum of human skill and ingenuity to the interpretation of this streaming information. Mathematical techniques and analysis, in particular, are notable tools in which mathematical advances and discoveries may improve markets' liquidity, efficiency and pace. This article outlines the origin and techniques of mathematical finance and associated models and simulations. We note strengths and shortcomings of these mathematical tools. The greatest challenge today is to learn and teach to the financial world the necessary judgment to avoid and rescind destructive deployment of financial models.

1 - Data-driven Specification Of Cyclical Arrival Processes

Donald Lee, Yale University, 165 Whitney Ave, Box 208200, New Haven, CT, 06520, United States, donald.lee@yale.edu, Ningyuan Chen, Sahand Negahban

The arrival processes of real-world systems usually exhibit cyclical behaviour. For example, patient arrivals to emergency departments often peak around midday and drops off at night. In this talk we show how this periodic structure can be exploited to obtain a compact and analytic description of the underlying arrival process from data. Such a model is clearly useful for both simulation and modeling purposes. We demonstrate the method on arrivals data from an Emergency Department in southern Connecticut.

2 - Incorporating Dose-prediction Within A Personalized Treatment Paradigm

Eva Lee, Georgia Institute of Technology, eva.lee@gatech.edu, Xin Wei

This work is joint with Grady Health Systems and Atlanta VA Medical Center. We design an outcome-based decision support tool that couples a predictive treatment-effect model with a planning optimization model. The predictive model uncovers treatment effect analysis of anti-diabetic drug dosage and the blood glucose level recorded in the titration period of each patient. This evidence is then incorporated within a personalized planning model for optimal treatment design. The decision support tool allows continuous learning of evidence for each patient as new treatment outcomes are recorded.

3 - Optimal Selection Of Health Care Providers

Jerry Kung, MIT, jkung@mit.edu

Given electronic health claims data for employees of a company, we propose a mixed integer optimization approach to select a collection of providers that optimizes over total cost, while maintaining quality and respecting travel distance for employees. We demonstrate that our formulation is tractable for large datasets and present the computational results on a real claims dataset. By following the prescriptions generated by our optimization model, we estimate that cost reductions of up to 10% can be achieved by reassigning patients for a small number of different types of procedures. We demonstrate that these cost reductions are robust to changes in a variety of parameters.

Joint Session MSOM-HC/HAS: Modeling and Optimization for Chronic and End-Stage Renal Disease Patients

Sponsored: Health Applications

Sponsored Session

Chair: Murat Kurt, Merck, Merck, Philadelphia, PA, 07033, United States, murat.kurt7@gmail.com

Co-Chair: David Kaufman, University of Michigan-Dearborn, 19000 Hubbard Dr, Dearborn, MI, 48126, United States, davidlk@umich.edu

1 - Optimal Decision Making In A Markov Model With Parameter Uncertainty: The Case Of Chronic Kidney Disease

Reza Skandari, University of British Columbia, Reza.Skandari@sauder.ubc.ca, Steven Shechter

We investigate a Markov decision process whose unknown transition parameters are revealed partially through state observation. Decisions are made as the state evolves. We use the model to study the optimal time to start preparing a type of vascular access for chronic kidney disease patients who will need dialysis.

2 - Optimal Integration Of Kidney Exchange Programs With Antibody Reduction Therapy To Increase Successful Transplant In Difficult To Match Recipients

Naoru Koizumi, George Mason University, nkoizumi@gmu.edu, Monica Gentili

Kidney paired donation (KPD) allows incompatible pairs to exchange kidneys with other incompatible pairs. However, evidence suggests there stills exist barriers to KPD utilization, especially among difficult-to-match transplant candidates and positive actual or virtual crossmatches. We use optimization and simulation analyses to optimally integrate antibody reduction therapy in KPD matching runs to increase the overall number of transplants. The proposed mathematical model matches incompatible pairs taking into consideration the possibility that some of the recipients could undergo a desensitization protocol to improve compatibility with the matched donor.

3 - Position-indexed Formulations For Kidney Exchange

Tuomas Sandholm, Carnegie Mellon University, sandholm@cs.cmu.edu, John Dickerson, David Manlove, Benjamin Plaut, James Trimble

We address the tractable clearing of kidney exchanges with short cycles and practical (long, but not unbounded) chains. We introduce three compact integer programming formulations with linear programming relaxations that are at least as tight as the previous tightest formulation (which was not compact) for instances in which each donor has a paired patient. Then, on real data from the UNOS US-wide exchange and the NHS UK-wide exchange, as well as on generated data, we show that our models dramatically outperform all prior solvers. We also present models that are more scalable than the state-of-the-art models for failure-aware kidney exchange.

Chair: Michael W Carter, University of Toronto, 5 King's College Rd., Toronto, ON, M5S 3G8, Canada, carter@mie.utoronto.ca

1 - Chronic Care Disease Management Through Operations Research & Analytics – Lessons From Ontario

Ali Vahit Esensoy, Manager, Strategic Analytics, CCO, Toronto, ON, Canada, AliVahit.Esensoy@cancercare.on.ca, Kiren Handa

CCO acts as a key Ontario government advisor on cancer care, renal, palliative and access to care. Part of CCO's mandate is to drive improvement through developing multi-year system plans, setting standards and guidelines, developing and deploying information systems, and measuring performance. Since 2010, CCO has actively tested and deployed numerous operational research methodologies as part of their advanced analytics work. This session will review the evolution of CCO's OR practice within the advanced analytics group and discuss successes and challenges of applying OR for system planning and policy decisions within Ontario's healthcare system.

2 - An Analytics Approach To Dementia Capacity Planning

Tannaz Mahootchi, Cancer Care Ontario, Tannaz.Mahootchi@cancercare.on.ca, Azadeh Mostaghel, Ali Vahit Esensoy

We use a data-driven approach to identify and project capacity issues in Ontario for the persons living with dementia (PLwD). Evidence suggests that while PLwD prefer to stay at home for as long as possible. Lack of appropriate community-care could lead to hospitalization and residential long-term care (LTC) placements. Using the person-level care trajectory data and evidence from literature, we develop a simulation model to predict the effect of augmented home and community care options on the patient flow and LTC placements for the future dementia incidence cases.

3 - Nurse Scheduling And Risk Analysis Of Hemodialysis Patients

Michael W Carter, University of Toronto, carter@mie.utoronto.ca, Mahsa Shateri

Kidney failure patients require dialysis treatment three times a week until a suitable donor is found. During dialysis, nurses monitor several patients at once, but when complications occur, a nurse must be available quickly to attend to the problem and restart dialysis. This paper provides a model to determine the minimum staffing levels required in order to deliver safe, effective care.

4 - Two-stage Stochastic Programming For Adaptive Interdisciplinary Pain Management With PIN Transition Models

Gazi Md Daud Iqbal, The University of Texas at Arlington, gazimddaud.iqbal@mavs.uta.edu, Jay Michael Rosenberger, Victoria C. P. Chen, Robert Gatchel

This research uses a two-stage stochastic programming approach to optimize personal adaptive treatment strategies for pain management. Transition models are represented by Piecewise Linear Networks. A multi-objective mixed integer linear program is developed to optimize treatment strategies for patients based upon on these transition models.

Sponsored Session

Chair: Jónas Oddur Jónasson, London School of Business, Regent's Park, NW1 4SA, London, TX, 00000, United Kingdom, jjonasson@london.edu

1 - Staff Planning For Anesthesiologists

Sandeep Rath, University of California-Los Angeles, sandeep.rath.1@anderson.ucla.edu, Kumar Rajaram

Staff planning for human resources like anesthesiologists at hospitals takes place sequentially, where planning is done for regular staffing as well as reserve capacity. The staff planners balance the expected overtime, under-utilization costs as well as the cost of keeping staff on reserve. Some of these costs are not explicitly known. We employ a structural estimation model to infer these implicit costs and subsequently find heuristic solution for the medium term staff planning. We apply this approach to staff planning for anesthesiologists.

2 - Separate & Concentrate: Accounting For Patient Complexity In General Hospitals

Sandra Sülz, Assistant Professor, Erasmus University Rotterdam, Rotterdam, Netherlands, sulz@bmg.eur.nl, Ludwig M Kuntz, Stefan Scholtes

We show that the positive association between patient volume, focus and service quality is worse for complex patients, and that hospitals that route the majority patients in a disease segment to the same department have fewer department allocation errors and better outcomes, particularly for complex patients. These findings suggest a redesign of general hospitals: Separate out routine patients and route them away from general hospitals into high-volume and focused value-adding process clinics and concentrate disease segments in the clinical departments of solution shop hospitals rather than scattering patients across several departments.

3 - Towards An Equitable Allocation Of Organs Among End-stage Liver Disease Patients

Mustafa Akan, Associate Professor of Operations Management, Carnegie Mellon University, Tepper School of Business, Posner Hall 381C, Pittsburgh, PA, 15213, United States, akan@andrew.cmu.edu, Ngai-Hang Z Leung, James F. Markmann, Sridhar R Tayur, Heidi Yeh

Patients on the waiting list for liver transplants receive priority based on their MELD scores, which reflect the severity of liver disease. Recent studies have shown that Hepatocellular Carcinoma (HCC) patients have significantly higher liver transplant rates than non-HCC patients due to non-individualized MELD calculation of the former. By using clinical data from SRTR we calibrate Markov Models and build a new simulator (MYATLAS). We then compute alternative MELD scores for the HCC patients that are a function of the candidate's tumor biology and its progression.

4 - Ambulance Emergency Response Optimization In Developing Urban Centers

Justin J. Boutilier, University of Toronto, Toronto, ON, Canada, j.boutilier@mail.utoronto.ca, Timothy Chan

Time sensitive medical emergencies are a major health concern comprising over 33% of all deaths in low and middle income countries (LMICs). Despite evidence that ambulance services can save lives, poor access and availability of emergency medical care in LMICs continues to be a widespread problem. In this work, we develop a novel ambulance location-routing model, tailored to address the challenges faced by urban areas in LMICs. We use extensive field data from Dhaka, the capital of Bangladesh and one of the most densely populated cities on earth, to develop and validate our modelling framework.

Invited: Project Management and Scheduling

Invited Session

Chair: Xiaoqiang Cai, The Chinese University of Hong Kong, Shatin, Hong Kong, 000, Hong Kong, xqcai@se.cuhk.edu.hk

1 - An Iterative Capacity Sharing Mechanism For Freight Forwarders

Minghui Lai, Southeast University, Nanjing, China, laimh@seu.edu.cn, Weili Xue

We consider the collaboration problem of forwarders in transportation capacity sharing over a general logistics network. As competition for capacity is intensive and usually carriers reserve more capacity for big customers, small forwarders can form an alliance to jointly book allotment capacity before the freight season. During the season, forwarders observe their private demand realization and then share the capacity to deliver their services. Capacity sharing also reduces cost, due to economies of scale from fixed cost. We propose a strategy-proof iterative mechanism, and prove that the mechanism is finitely convergent and individually rational.

2 - Value Of Category Captainship With Shelf-space Dependent Demand

Weili Xue, Southeast University, wlxue1981@gmail.com, Minghui Xu

We consider a supply chain with one retailer and two manufacturers, who sell his product through the retailer to the consumer market. We consider two category management scenarios. In the retailer category management scenario, the retailer makes decisions on how to allocate the total shelfspace to all his products, and what is the selling price for each product. In the captain category management scenario, the retailer delegates the pricing and allocation decisions to one of the supplier (the captain). In both scenarios, the retailer will decide the total shelf-space allocated to this category. We analyze these two scenarios when the selling prices for both products are exogenously given.

3 - A Noncooperative Game Model And Algorithm For a Utility Computing System

Pengyu Yan, Associate professor, University of Electronic Science and Technology of China, Chengdu, China, yanpy@uestc.edu.cn, Hongru Miao, Nicholas G Hall, Guanhua Wang

Selfish behaviors of resource users and providers can damage the performance of utility computing systems. Existing market-based approaches effectively allocate resources and schedule tasks to minimize the costs for users. Using a noncooperative sequencing game model, we study the providers' decisions about the computing resources they allocate to the system to complete tasks. To find a Nash equilibrium strategy, the model is transformed into a directed bi-valued cyclic graph, and a polynomial time algorithm is proposed. The price of anarchy and incentive contract design are also discussed.

4 - Principal-agent vs Revenue Sharing Contracts In The Optimal Supplier Switching Model With Learning Effect

Qian Wei, Tianjin University, qwei@tju.edu.cn, Jianxiong Zhang

This paper examines two contracts (Principal-agent and Revenue sharing) in a supplier switching model with considering learning effect. Our analysis reveals that both contracts can be optimal under different parameter settings. Furthermore, we compare the two contracts from an ex-post perspective. We find the switching strategy on the basis of the principal-agent theory dominates that based on the revenue sharing contract when the learning rate lies in an intermediate region, while the result is reversed with a relatively large or small learning rate.

Auctions and Econometrics

Invited: Auctions

Invited Session

Chair: Robert Day, University of Connecticut, Storrs, CT, United States, Bob.Day@business.uconn.edu

1 - Dynamic Demand Estimation In Auction Markets

Greg Lewis, Microsoft Research New England, glewis@microsoft.com, Matthew Backus

Auction mechanisms play an important part in allocating goods, yet existing empirical auction techniques treat each auction in isolation, obscuring market interactions. We provide a framework for estimating demand in a large auction market with a dynamic population of buyers with unit demand and heterogeneous preferences over a finite set of differentiated products. We offer an empirically tractable equilibrium concept, characterize bidding and prove existence of equilibrium. Having developed a demand system, we show that it is non-parametrically identified from panel data. We apply the model to measure consumer surplus in the market for compact cameras on eBay.

2 - Identification And Estimation Of Affiliated Private Values Auctions With Unobserved Heterogeneity

Jorge Balat, Johns Hopkins, jorge.balat@jhu.edu

I consider a first-price auction model with affiliated private values and unobserved heterogeneity. Both affiliation and unobserved heterogeneity manifest in bids that are correlated and it is hard to disentangle these two sources apart from bid data alone. I show that the model is nonparametrically identified once we allow for endogenous participation and leverage entry data combining ideas from the control function and measurement error literatures. I propose a nonparametric estimator and show how one can test for different information structures. I then take the model to data from highway procurement auctions from California. I find evidence of both unobserved heterogeneity and affiliation.

3 - Simultaneous First-price Auctions With Preferences Over Combinations

Matthew Gentry, LSE, United Kingdom, M.L.Gentry@lse.ac.uk, Tatiana Komarova, Pasquale Schiraldi

We develop a structural model of strategic bidding in simultaneous first-price auctions when objects are heterogeneous and bidders have preferences over combinations. We then apply this model using data on Michigan Department of Transportation (MDOT) highway procurement auctions. Our results suggest that the simultaneous first-price mechanism performs very well relative to theoretically attractive but practically costly alternatives such as combinatorial proxy auctions, helping to rationalize the widespread use of simultaneous auctions in practice.

4 - Robust Data-driven Welfare Guarantees In Auctions

Vasilis Syrgkanis, Microsoft Research, vasy@microsoft.com, Darrell Hoy, Denis Nekipelov

Analysis of welfare in auctions comes traditionally via one of two approaches: precise but fragile inference of the exact details of a setting from data or robust but coarse theoretical price of anarchy bounds that hold in any setting. As markets get more and more dynamic and bidders become more and more sophisticated, the weaknesses of each approach are magnified.In this paper, we provide tools for analyzing and estimating the empirical price of anarchy of an auction. The empirical price of anarchy is the worst case efficiency loss of any auction that could have produced the observed data.

New Developments in Sourcing and Selling Strategies

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Basak Kalkanci, Georgia Institute of Technology, Atlanta, GA, United States, basak.kalkanci@scheller.gatech.edu

Co-Chair: Necati Tereyagoglu, Scheller College of Business, Georgia Institute of Technology, Atlanta, GA, United States, necati.tereyagoglu@scheller.gatech.edu

1 - Strategic Sourcing Under Competition And Asymmetric Cost Information

Lusheng Shao, The University of Melbourne, Level 10, 198 Berkeley Street, Melbourne, 3010, Australia, lusheng.shao@unimelb.edu.au, Xiaole Wu, Fuqiang Zhang

We study a sourcing game where competing firms choose between a supplier with certain cost (C-supplier) and a supplier with potentially lower, but uncertain cost (U-supplier). We find that with a larger market potential, the firms would more likely choose a C-supplier despite its higher average cost. The higher cost uncertainty of a U-supplier may either improve or reduce its attractiveness to the sourcing firms, depending on its current uncertainty level. The increasing cost of C-supplier may lead to a new sourcing equilibrium and thus make both sourcing firms better off.

2 - Money-back Guarantees In A Distribution Channel: Bargaining Power & Downstream Competition

Yufei Huang, Assistant Professor, University of Bath, Bath, United Kingdom, y.huang@bath.ac.uk, Tingliang Huang, Ying-Ju Chen

Although existing literature emphasizes the usefulness of Money-back Guarantees (MBG), little is known about why retailers may adopt different MBG choices in practice. To understand this, we examine two competing retailers' MBG decisions, who also simultaneously bargain for wholesale prices with a wholesaler in a distribution channel. We show that, retailers' asymmetric bargaining power may lead to asymmetric MBG choices. We provide economic rationales for all possible MBG outcomes.

3 - Selling To Socially Connected Customers

Ruslan Momot, INSEAD, Fontainebleau, France, ruslan.momot@insead.edu, Elena Belavina, Karan Girotra

We study the value of different kinds of social network information and illustrate its use. We build a model of a social network of strategically interacting customers who value exclusive ownership of the product and are heterogeneous in the number of friends (degree) and proclivity for social comparisons (conspicuity). We find that high-conspicuity customers within intermediate-degree segments are the firm's best targets. Our analysis reveals how they should be selectively targeted by the firms with information on either (or both) of the customer traits. We find that information about degree is more valuable than information about conspicuity and that the two are substitutes.

4 - Subscription Box Business Models: Pricing And Quality Decisions

Basak Kalkanci, Georgia Institute of Technology, basak.kalkanci@scheller.gatech.edu, Necati Tereyagoglu

We model the value of online subscription box business model for a consumer who chooses the replenishment frequency (or timing) of a frequently used durable good. We explore the seller's pricing and quality decisions under the online subscription box business model, and evaluate the performance of such a model in comparison to selling through an offline retail channel.

Sequential Sampling and Optimization

Sponsored: Applied Probability

Sponsored Session

Chair: Raghu Pasupathy, Purdue University, West Lafayette, IN, United States, pasupath@purdue.edu

1 - Sequential Stopping Rules For Simulation Problems Where Variance Estimation Is Difficult

Jing Dong, Northwestern University, jing.dong@northwestern.edu, Peter W Glynn

We solve the sequential stopping problem for a class of simulation problems in which variance estimation is difficult. In particular, we establish the asymptotic validity of sequential stopping procedures for estimators constructed using various cancellation methods. We characterize the limiting distribution of the estimators at stopping times as the error size (the absolute error or the relative error) goes to 0, which is different from the limiting distribution of the estimator constructed based on a fixed size of samples as the sample size goes to infinity.

2 - Probabilistic Bisection Converges Almost As Quickly As Stochastic Approximation

Shane Henderson, Professor, Cornell University, 230 Rhodes Hall, Ithaca, NY, 14853, United States, sgh9@cornell.edu, Peter Frazier, Rolf Waeber

The probabilistic bisection algorithm (PBA) can be applied to stochastic root finding problems in one dimension. The PBA successively updates a Bayesian prior on the location of the root after using a power-one test at the median of the posterior to estimate the direction of the root from the median. The power-one test has a variable sample size. The PBA has features that we believe make it attractive relative to stochastic approximation for such problems. I will discuss the algorithm and sketch a proof that it converges at a rate arbitrarily close to the canonical "square root" rate of stochastic approximation.

3 - Fixed-Step, Line Search, And Trust-Region Adaptive Sampling Recursions for Simulation Optimization

Raghu Pasupathy, Purdue University, pasupath@purdue.edu

We present a sequential sampling framework for recursively solving stochastic optimization problems. The framework consists of embedding a globally convergent numerical optimization search routine, e.g., line search, trust region, with Monte Carlo sampled estimators of the objective function and gradient. Global convergence to a stationary point depends crucially on a result characterizing the sample size at each iteration. We will outline the conditions that guarantee the attainment of the Monte Carlo canonical rate.

Managing Capacity in Energy Markets Through Demand and Supply-side Interventions

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Charles J Corbett, University of California - Los Angeles, Los Angeles, CA, United States, charles.corbett@anderson.ucla.edu

1 - Energy Efficiency Contracting In Supply Chains Under Asymmetric Bargaining Power

Ali Shantia, HEC Paris, 1 rue de la Liberation, Jouy-en-Josas, 78350, France, ali.shantia@hec.edu, Sam Aflaki, Andrea Masini

Evidence shows that suppliers refrain from investing in energy efficiency (EE) measures because they fear that a buyer with greater bargaining power will use the EE-related cost reductions to push prices down, in the purchase bargaining process, and thereby further reduce the supplier's profit margin. In a supply chain consisting of a buyer and a supplier, this study analyses the effect of relative bargaining power and technology uncertainty on the supplier's decision to invest in energy efficiency measures. We analyse price commitment and shared investment contracts as potential coordination mechanisms and compare them in their ability to boost EE investment by the supplier.

2 - An Analysis Of Time-based Pricing In Electricity Supply Chains

Asligul Serasu Duran, Kellogg School of Management, 2001 Sheridan Road, 5th floor, Evanston, IL, 60208, United States, a-duran@kellogg.northwestern.edu, Baris Ata, Ozge Islegen

This study builds a framework for the retail electricity market to empirically evaluate the impact of time-based tariffs on the electricity supply chain. We find that optimal time-based tariffs reduce peak demand, but do not change consumers' electricity bills significantly. Time-of-use tariffs with predetermined rates can capture most of the benefits of real-time prices. The environmental impact of time-based tariffs depends on the characteristics of the electricity market under study.

3 - Investments In Renewable And Conventional Energy: The Role Of Operational Flexibility

Kevin Shang, Duke University, Durham, NC, United States, khshang@duke.edu, Gurhan Kok, Safak Yucel

We study capacity investments of a utility firm in renewable and conventional energy sources with different levels of operational flexibility, i.e., the ability to quickly ramp up or down the output of a generator. We consider supply characteristics of conventional and renewable sources and derive the optimal capacity investment portfolio. We find that inflexible sources (e.g., nuclear energy) and renewables are substitutes; flexible sources (e.g., natural gas) and renewables are complements.

4 - Explaining The Variation In Progress In The Us Nuclear Industry

Christian Blanco, University of California - Los Angeles, Los Angeles, CA, United States, cblanco@anderson.ucla.edu, Felipe Caro, Charles J Corbett

We examine the factors that influenced the US nuclear power production efficiency and safety over time.

Studies in Service Operations

Sponsored: Manufacturing & Service Oper Mgmt

Sponsored Session

Chair: Robert Batt, Wisconsin School of Business, UW - Madison, Madison, WI, United States, rbatt@bus.wisc.edu

1 - Heart Failure transitions: Staffing Follow-up Clinics To Reduce Readmissions

Itai Gurvich, Kellogg School of Management, i-gurvich@kellogg.northwestern.edu, Benjamin Grant, Jan A Van Mieghem, Kannan Mutharasan

Heart failure (HF) readmissions are a major driver of cost and health care utilization. Timely follow-up of patients post-discharge represents an evidence-based intervention proven to reduce readmission rates. Patients discharged after HF hospitalization are scheduled to meet a cardiologist in the outpatient clinic. Meeting targets for timely follow-up requires appropriate capacity planning for these clinics that takes into account the inpatient-discharge variability. An intervention based on simple safety capacity rules and more aggressive utilization of existing capacity resulted in more than doubling the fraction of patients seen within one week of discharge.

2 - Question-and-answer Forums For Product Support: Crowdsourcing Service To Customers

Konstantinos Stouras, INSEAD, konstantinos.stouras@insead.edu

Online product support forums where customers can post complaints and questions, or report issues about a product or service of a firm abound. A large number of companies choose to crowdsource their product and service support back to their customers, employing a few dedicated service operators. We characterize the equilibrium behavior of such a novel business model for service and compare it with a call center model.

3 - Scale, Scope And Hospital Productivity: An Empirical Study Of Volume Spillovers Across Hospital Services

Michael Freeman, Judge Business School, University of Cambridge, Cambridge, United Kingdom, mef35@cam.ac.uk, Nicos Savva, Stefan Scholtes

Demand pressures mean that hospitals are increasingly getting bigger (i.e. treat more patients per year) and also more complex (i.e. see patients with more diverse care needs). Although prior work has shown that increased volume is positively associated with patient outcomes, the relationship between volume, complexity, and costs is less-well understood. This paper uses a detailed panel of 130 hospitals in England over a period of nine years to examine the relationship between scale and costs in hospitals by investigating spillovers between treating together related (e.g. same service line, same degree of urgency) and unrelated (e.g. different service lines, different urgency) activity.

4 - Finding A Needle In A Haystack: The Effects Of Searching And Learning On Pick-worker Performance

Robert Batt, Assistant Professor, Wisconsin School of Business, UW-Madison, Madison, WI, United States, bob.batt@wisc.edu, Santiago Gallino

We use a unique dataset from an online apparel retailer to estimate the magnitude of intra-bin search time and what operational and behavioral factors affect it. We find that intra-bin search time increases with both the number of items in the bin and the density of items in the bin (i.e., items per foot). Further, we find that the deleterious effects of bin load and density are attenuated by worker experience. More experienced workers are less impacted by bin load and density than are less experienced workers. We use simulation to show that incorporating these bin load and experience effects into pick assignments and routing can lead to meaningful improvements in pick times.

Supply Chain Finance and Risk Management

Sponsored: Manufacturing & Service Oper Mgmt, iFORM

Sponsored Session

Chair: Wei Luo, IESE Business School, Av. Pearson 21, Barcelona, n/a, Spain, wluo@iese.edu

1 - The Effectiveness Of Supplier Buy Back Finance: Evidence From Chinese Automobile Industry

Weiming Zhu, University of Maryland, weimingzhu@rhsmith.umd.edu

Facing a budget-constrained buyer, a novel approach for large suppliers is adopting buy-back financing schemes to relieve their downstream partners and reduce channel costs. Through counterfactual analysis, we analyze the efficiency of these financing schemes. We find that such contract agreements can improve channel efficiency over traditional financing methods.

2 - Suppliers As Liquidity Providers

Panos Markou, IE Business School, pmarkou.phd2016@Student.ie.edu, Daniel S Corsten, Reint Gropp

Using a data set of private and public French firms and their suppliers, we examine how supplier financial constraint affects buyer cash holdings. When external financing is costly or unavailable, firms rely on their suppliers for backup liquidity, freeing up cash. Using matching estimators, we show that constrained buyers with unconstrained suppliers hold less cash than buyers with constrained suppliers. This effect persists during the financial crisis, highlighting that suppliers may be viable liquidity sources when banks are not. Finally, not only do buyers with unconstrained suppliers hold less cash, but they adjust cash holdings downwards following a supplier IPO.

3 - Financial Fluctuations Through Dynamic Networks

Stefano Nasini, IESEG School of Management, Paris/Lille, France, s.nasini@ieseg.fr, Mireia Giné, Miguel Antón

Decisions and outcomes of listed enterprises are strongly related by different types of associations, such as supply-chain, competition and partnership. In the context of financial stock markets, we introduce a network-based econometric framework to explain cross-section dependencies of stock prices. After a detailed analysis of the proposed methodology, estimation and forecast are carried out, based on the COMPUSTAT data set (with information about supply-chain, competition and partnership between U.S. listed companies). The inclusion of these pairwise dependencies results in a substantial improvement of the predictive power, in comparison with the standard auto-regressive approach.

4 - Financing Sellers Via E-commerce Platform In The Presence Of Seller Competition

Long Ren, Tsinghua University, renl.12@sem.tsinghua.edu.cn, Lingxiu Dong

Small-business sellers selling products via e-retailing platforms (e.g., Amazon.com, eBay, Taobao) operate under consignment-revenue-sharing (commission) contracts, under which the seller decides his product portfolio, inventory, and selling price. Many of those sellers face capital constraints that limit their ability to build inventory, expand product offerings. We investigate the effect of e-commerce platform backed financing on sellers' operational decisions and the competition landscape.

Revenue Mgt, Pricing I

Contributed Session

Chair: Syed Asif Raza, Qatar University, College of Business and Economics, Doha, 2713, Qatar, syedar@qu.edu.qa

1 - Reputation-based Pricing In E-commerce Retailing

Renato E de Matta, Associate Professor, University of Iowa, 2360 Mulberry Street, Coralville, IA, 52241, United States, renato-dematta@uiowa.edu, Timothy Joe Lowe, Dengfeng Zhang

We examine a revenue management problem involving an online seller of a seasonal product in an e-commerce setting where consumers are sensitive to both price and seller service rating. This rating is the aggregated consumer perception of service quality and is used as a reputation indicator in setting prices. Using a Markov decision process to model the problem over a finite horizon, we examine the impact of changes in seller service rating and consumer heterogeneity on the seller's optimal pricing policy and expected revenues. Using simulated market settings, we validate our model and compare our pricing policy with two other competing policies.

2 - Research On Pricing Decision Of Remanufacturing Considering Product Disassemblability And Recycling Quality Uncertainty

Juhong Gao, Dr., College of Management and Economics, Tianjin University, Building 25-A No.92 Weijin Road, Nankai, Tianjin, 300072, China, gaojuhong@tju.edu.cn, Mengmeng Li

In this paper, the target of CLSC is to realize the members' profit maximization considering product disassemblability and recycling quality uncertainty. The four different remanufacturing models have been analyzed and the coordination mechanism has been introduced, in which the separation and cooperation model of OEM and IO. Research shows the members obtain less profit when both of OEM and IO are involved into remanufacturing. And OEM's profit is higher in centralized decision; IO still prefers to give up part of the profit and to participate in the cooperation model considering that IO is more easily to be driven out of remanufacturing market by OEM in decentralized decision.

3 - Dynamic Pricing In China's Largest E-retailer JD.com

Dongdong Ge, Professor, Shanghai University of Finance and Economics, School of Information management and eng, 777 Guoding Road, Shanghai, 200433, China, dongdong@gmail.com

In China's largest E-Retailer JingDong(JD.com), there are 20 millions SKUs on sale and 3 million orders made every day. Dynamic pricing in this gigantic system has been recognized a vital issue in company's revenue management operations. In this talk, we briefly introduce our data-driven optimization models and findings with JD.com. We also report our A/B test result, which shows a great improvement in GMV/GP.

4 - Economic Order Quantity Models For Joint Pricing And Greening Effort Decisions With Discounts

Syed Asif Raza, Qatar University, College of Business and Economics, Doha, 2713, Qatar, syedar@qu.edu.qa

Environmental protection and greening concerns have gained greatly emphasis both at the procedures and consumers alike. Nowadays, customers are often willing to pay a premium for environmentally friendly products, however, the investment in greening effort by a firm must yield profitability to a firm. This required the use of contemporary tools from Revenue Management (RM) and pricing. Economic order quantity (EOQ) models are among the most studied in inventory management context. This paper develops EOQ models with joint pricing, greening effort (investment) decision in an RM context. Efficient solution procedure is also proposed to consider the quantity discount in the EOQ models analysis.

Queueing Models

Contributed Session

Chair: Pedro Cesar Lopes Gerum, PhD Student, Rutgers University, 96 Frelinghuysen Road, CoRE Building, Room 201, piscataway, NJ, 8854, United States, pedro.gerum@rutgers.edu

1 - Mean Value Analysis Of Mixed Queuing Networks

Ivo Adan, Eindhoven University of Technology, Den Dolech 2, Eindhoven, 5600 MB, Netherlands, I.Adan@tue.nl, Vidyadhar Kulkarni

We study a mixed queuing network with multi-server stations. The mixed network has both closed and open network components: it has a fixed number of customers (called permanent customers) that circulate among the service stations indefinitely, and it also serves customers (called transient customers) who enter from outside, visit the stations in a random order and leave. We develop novel mean-value equations for recursively computing the mean queue lengths and mean waiting waiting times, and we study the asymptotic behavior of these quantities in the presence of multiple bottle-neck stations as the number of permanent customers tends to infinity.

2 - Simple And Efficient Ways For Discrete GI/G/1 Queues

Winfried K Grassmann, Professor emeritus, University of Saskatchewan, 110 Science Place, 176 Thorvaldson Building, Saskatoon, SK, S7N 5C9, Canada, grassman@cs.usask.ca

We present a number of simple and not so simple methods to find the distribution of the number of elements in a GI/G/1 queue and related problems. As it turns out, many methods described in literature are mathematically challenging, but this does not imply that they are numerically efficient numerically. In fact, it is our experience that the simpler methods tend to be the most efficient ones, while also easy to understand. This leads to the suspicion that criteria for publication typically favor mathematical elegance over practical usefulness.

3 - A Queueing System With On-demand Servers: Local Stability Of Fluid Limits

Lam M Nguyen, PhD Student, Lehigh University, 200 West Packer Avenue, Room 362, Bethlehem, PA, 18015, United States, lmn214@lehigh.edu, Alexander Stolyar

We consider a system, where a random flow of customers is served by agents invited on-demand. Each invited agent arrives into the system after a random time, and leaves it with some probability after each service completion. Customers and/or agents may be impatient. The objective is to design a real-time adaptive invitation scheme that minimizes customer and agent waiting times. We consider a queue-length-based feedback scheme; study it in the asymptotic regime where the customer arrival rate goes to infinity; and derive a variety of sufficient conditions for the system local stability at the desired equilibrium point. Under these conditions, simulations show good overall performance of the scheme.

4 - Traffic Density Analytical Model Validation And Applications

Pedro Cesar Lopes Gerum, PhD Student, Rutgers University, 96 Frelinghuysen Road, CoRE Building, Room 201, piscataway, NJ, 08854, United States, pedro.gerum@rutgers.edu, Melike Baykal-Gursoy, Marcelo Ricardo Figueroa

This paper compares a general equation for the probability generating function of density for a general road system, discovered by W. Xiao and Baykal-Gursoy, with real data from Milwaukee, Wisconsin. Furthermore, once shown the analytical model is valid, this paper presents some insights in possible applications taken from these formulations. These insights include improving efficiency of evacuation in extreme scenarios, such as flooding or other weather conditions; providing useful information to decision-makers on how to better invest their money in infrastructure; allowing the end-user of a routing system to choose between routes according to the risk of delay he is willing to take.

Provider Staffing and its Impact on Patient Flow

Sponsored: Manufacturing & Service Oper Mgmt, Healthcare Operations

Sponsored Session

Chair: Retsef Levi, MIT, 100 Main Street, Building E62-562, Cambridge, MA, 02142, United States, retsef@mit.edu

Co-Chair: Cecilia Zenteno, Massachusetts General Hospital, 55 Fruit Street, White 400, Boston, MA, 02114, United States, azentenolangle@mgh.harvard.edu

1 - Ed Physician Staffing Via Multi-stage Multi-class Network

Caglar Caglayan, Georgia Institute of Technology, Atlanta, GA, 30318, United States, ccaglayan6@gatech.edu, Mustafa Y Sir, Kalyan Pasupathy, Turgay Ayer, Yunan Liu

We propose an “intuitive”, “realistic” and “tractable” model of the emergency department (ED) by a multi-class multi-stage queuing network with multiple targeted service levels. Based on infinite-server approximation and offered load analysis, we employ a modified version of square-root safety principle to determine the right number of physicians in the ED. Our model is detailed enough to capture the key dynamics of the ED but simple enough to understand, infer results and implement in a clinical setting.

2 - Discrete Event Simulation Of Outpatient Flow In A Phlebotomy Clinic

Elizabeth Olin, University of Michigan, 1205 Beal, Ann Arbor, MI, 48109, United States, genehkim@umich.edu, Amy Cohn, Ajaay Chandrasekaran

The University of Michigan Comprehensive Cancer Center handles approximately 97,000 outpatient visits annually, with most including a blood draw, clinic appointment, preparation of infusion drugs, and an infusion appointment. The goal of our project is to reduce patient waiting times at the phlebotomy (blood draw) clinic, which appears to be a primary bottleneck in the patient experience. In order to accomplish this goal, we developed a discrete-event simulation of the clinic’s patient and work flow. By adjusting the various simulation parameters, we can evaluate alternative methods to improve turnaround time, patient wait time, and phlebotomist utilization.

3 - Quantifying Provider’s Schedule Effects On Patient’s Length-of-Stay

Kimia Ghobadi, MIT, Cambridge, MA, United States, kimiag@mit.edu, Andrew Johnston, Retsef Levi, Walter O’Donnell

We identify a natural randomized control setting between providers’ schedule and patients arrival in a congested Department of Medicine in a large academic hospital. We use this setting to build a predictive model and quantify the impact of care team handoff on patients’ length-of-stay.

1 - Efficiency And Performance Guarantees For Network Revenue Management Problems With Customer Choice

David Simchi-Levi, Massachusetts Institute of Technology, Dept of Civil and Environmental Engineering, 77 Massachusetts Avenue Rm 1-171, Cambridge, MA, 02139, United States, dslevi@mit.edu, Wang Chi Cheung

We consider the network revenue management problem with customer choice. While the solution to the Choice-based Deterministic Linear Program (CDLP) can be used to design a near-optimal policy, CDLP has an exponential size. We propose algorithms that solves CDLP with polynomially many elementary operations and invocations to an oracle that solves the underlying single period problems. Next, we design an efficient online algorithm for the problem with MNL choice models, where the parameters are unknown. The algorithm achieves a regret of O(T2/3), where T is the length of the time horizon.

2 - Optimal Version Updates

Gad Allon, Northwestern University, g-allon@kellogg.northwestern.edu

Mobile apps have become an economy with a market size of $25 Billion in 2013 and with a projected market size of $77 Billion by 2017. One of the key features that distinguishes mobile apps from other types of digital goods (such as movies, songs or books) is the they have versions. A developer can release an app into a mobile app store, and can then keep adding, removing or editing features of the app with subsequent version updates. We study empirically and theoretically the optimal strategy for such updates.

3 - Service Systems With Coarse Priorities: The Social Cost Of Revenue Maximization

Martin Lariviere, Northwestern University,
2001 Sheridan Rd, Evanston, IL, 60208, United States,
m-lariviere@kellogg.northwestern.edu, Itai Gurvich, Can Ozkan

We consider how social maximization differs from revenue maximization in a queuing system in which a continuum of customer types is mapped to a finite number of priority classes. The decision maker controls coverage (how many customers to serve), coarseness (how many priority levels to offer), and classification (how types are assigned to classes). We show that both types of decision makers provide similar coverage and coarseness. They differ in how they split customers between classes. Relative to the social planner, the revenue maximizer may have the highest priority class over- or undersubscribed depending on the behavior of the distribution of customer values.

4 - Learning In Online Matching Platforms: Multi-armed Bandits With Capacity Constraints

Vijay Kamble, Stanford University, Stanford, CA, 9, United States,
vijaykamble.iitkgp@gmail.com

We consider the interaction between two central operational challenges for almost any matching platform: on the one hand, new users are continuously arriving, and the platform's goal is to learn the attributes of these users quickly enough to ensure satisfactory matches. On the other hand, learning these attributes typically requires experimenting with matches and observing the outcomes, which is difficult since the supply of entities to be matched to is limited. In this paper we address the correct balance between these activities in such two-sided matching platforms, in the presence of supply constraints.

Operations and Supply Chains for Innovative Goods

Sponsored: Manufacturing & Service Oper Mgmt, Supply Chain

Sponsored Session

Chair: Robert Swinney, Duke University, Durham, NC, United States,
robert.swinney@duke.edu

1 - Promoting Innovative Technology In Developing Countries Through Solution-based Contracts

Guangrui Ma, Tianjin University, Tianjin, China,
magr@connect.ust.hk, Ying-Ju Chen, Hau Leung Lee

Limited knowledge and lack of proper skills make potential users reluctant to purchase innovative technology, e.g., drip irrigation systems, even though it can improve yields incredibly. We show that through solution-based service, firms can help farmers, especially in developing countries, overcome the above knowledge barrier of using the technology, thus leading to higher market adoption and profitability. Besides, a yield-based payment structure can facilitate efficient financial cost saving when farmers face financial constraint, and hence incentivises farmers' adoption further more.

2 - Designing Supply Chains For Substitutable Digital And Physical Goods

Zhenhuan Lei, Duke University, zhenhuan.lei@duke.edu,
Robert Swinney

We consider a firm selling two partially substitutable goods, one digital and one physical, e.g., a downloadable and DVD version of the same movie. The physical good is characterized by non-zero marginal production cost, positive production leadtime, and, potentially, a mismatch between supply and demand. The digital good is characterized by zero marginal cost and no inventory constraints. We consider how market and product characteristics drive the firm to price each product, determine inventory, choose a selling strategy involving one or both goods, and design its supply chain.

3 - Dynamic Stimulus In Crowdfunding

Longyuan Du, University of Toronto, Toronto, ON, Canada,
Longyuan.Du14@rotman.utoronto.ca, Ming Hu, Jiahua Wu

We study the dynamics of online crowdfunding in which a campaign would fail unless a predetermined funding goal is achieved within a given duration. We demonstrate empirically using KickStarter data the significant benefit of dynamically offering stimulus. Motivated by the empirical results, we build a theoretical model to analyze several policies, such as seeding, feature upgrade and promotional discount, and provide the optimal timing of stimulus offerings depending on time- and pledge-to-go. We then illustrate the stimulus policies' benefits using failed projects from Kickstarter.

4 - Food Wastage In Commercial Kitchens

Varun Karamshetty, INSEAD, Fontainebleau, 77300, France,
varun.karamshetty@insead.edu, Elena Belavina, Karan Girotra

Kitchens are wasting as much on food waste as they make in profits. With an estimated $1 trillion in food being wasted every year, food waste is not only a huge economic loss, but also has a major impact on our environment accounting for nearly 15% of global GHG emissions. We analyze proprietary data to understand key drivers of food wastage in commercial kitchens. We identify the controllable factors, and quantify the impact of each of them. We then propose changes in their operations that minimize wastage while maintaining their service quality and bottom-line.

Sustainability Issues in Supply Chains I

Sponsored: Manufacturing & Service Oper Mgmt, Sustainable Operations

Sponsored Session

Chair: Saed Alizamir, Yale University, 165 Whitney Ave,
New Haven, CT, 06511, United States, saed.alizamir@yale.edu

1 - Should Brands Tighten Certification Standards

Li Chen, Cornell University, Ithaca, NY, United States,
li.chen@cornell.edu, Shiqing Yao, Kaijie Zhu

Global brands are increasingly relying on third-party certification to screen out low-quality suppliers. However, an unethical certifier may collude with a low-quality supplier to produce a false certification. In this study, we investigate the buyer's equilibrium strategy in setting certification standard under the risk of supplier-certifier collusion.

2 - Can Brands Claim Ignorance? Unauthorized Subcontracting In Apparel Supply Chains

Anna Saez de Tejada Cuenca, PhD Student, UCLA Anderson School of Management, Los Angeles, CA, United States,
anna.sdtc.1@anderson.ucla.edu, Felipe Caro

The collapse of the Rana Plaza building in Bangladesh brought into focus the poor safety conditions faced by many workers in the apparel industry. A common way in which safety and environmental standards are violated is through unauthorized subcontracting. We analyze empirically some factors that can lead suppliers to outsource their production to third parties without their retailers' knowledge. We use data provided by a supply chain manager that consists of over 30,000 orders, including 36% of subcontracted ones. Our results provide managerial insights to retailers on what factory and order characteristics increase the probability of unauthorized subcontracting, and how it can be prevented.

3 - Optimal Production Planing In Agricultural Supply Chains

Utku Serhatli, PhD Student, INSEAD, Constance de le Boulevard,
Fontainebleau, 77590, France, utku.serhatli@insead.edu,
Enver Yucesan, Andre Du Pin Calmon

We model the production decisions of a corn seed manufacturer who faces supply and demand uncertainties, product returns, and quality problems over a finite horizon. More specifically, we build an N-period model to capture the inherent complexities and solve the two-period scenario where we prove the optimality of a base stock policy and show the impact of operational agility on profit. We also investigate the impact of yield variability and return rates on the optimal production quantities. We complement our theory using numerical results with data from a major European agro-chemical company.

4 - Managing A Responsible Supply Chain Under Threat Of Public Disclosure

Saed Alizamir, Yale University, saed.alizamir@yale.edu, Sang Kim

We analyze a game-theoretic model in which a downstream supply chain member ("buyer") is penalized disproportionately due to a compliance violation by an upstream member ("supplier"). Buyer's ability to audit the supplier is limited, and she faces a risk of being publicly blamed after the supplier's violation is caught by a third party. Supplier exerts effort to enhance compliance in each period, but risks having his relationship terminated due to a stochastic compliance outcome.

Reliability II

Contributed Session

Chair: Mengmeng Zhu, Rutgers University, Piscataway, NJ, 8854, United States, mengmeng.zhu@rutgers.edu

1 - Optimal Design Of Hybrid Sequential Testing For A System With Mixture Of One-shot Units

Elsayed A Elsayed, Distinguished Professor, Rutgers University, 96 Frelinghuysen Rd, Piscataway, NJ, 08854-8018, United States, elsayed@rci.rutgers.edu

Non Destructive Testing is conducted to determine the functionality of the units without permanent damage in order to estimate the units' reliability. In this presentation, we investigate a system composed of non-identical units with different characteristics and subjected to hybrid reliability testing (Destructive and NDT). It is of interest to optimally design the hybrid sequential reliability testing. After conducting a number of hybrid testing, we decrease the sample size of the destructive testing as the accuracy of reliability metrics estimation improves. Eventually, we only need to conduct NDT only. The efficiency and accuracy of the proposed methods are validated.

2 - Transportation Network Fragility And Economic Losses

Narges Kaveshgar, University of South Carolina, 300 Main Street, Department of Civil and Environmental Engineering, Columbia, SC, 29208, United States, kaveshga@email.sc.edu, Nathan Huynh, Joseph Von Nessen

Interdependencies between the transportation system and other critical infrastructures necessitate the need to protect it to achieve system resiliency. Current study develops a methodology to quantify the robustness and investigate the reliability of transport network under extreme events. To this end, perishable field data is collected to determine the impact of the recent road and bridge closures caused by historic rainfall event in South Carolina to the traveling public and businesses.

3 - Analyzing Coastal Highway Network Reliability In Hurricane Flooding Surge Through Geographic Information System

Lei Bu, Institute for Multimodal Transportation, Jackson, MS, United States, leibu04168@gmail.com, Feng Wang

Reliability is related to the ability of a network to carry out desire traffic flow which includes node to node blocking or delay. Based on the history data of hurricane flooding surge in Gulf coastal region, coastal highway network reliability is analyzed using a geographic information system. Spatial statistics and analyst methods based on density, geographic distribution and bilinear interpolation are used to calculate point density, Z score and hot spots for the hurricane flooding surge data. Based on the spatial statistics and analyst results, the blocking or delay links, namely, nodes to nodes, on highway network are found to determine the network reliability.

4 - Two Phase Imperfect Debugging And Imperfect Fault Removal Software Reliability Modeling

Mengmeng Zhu, Rutgers University, Piscataway, NJ, 08854, United States, mengmeng.zhu@rutgers.edu, Hoang Pham

A software reliability modeling considering software fault type and multi-phase debugging process is proposed in this paper. Type I fault and Type II fault represent independent and dependent software fault during debugging, respectively. Two-Phase debugging process are discussed in the model development. Additionally, a small portion of software faults that software testers are not able to remove is included in this study due to the limitation of resource and knowledge.

Artificial Intelligence in Big Data

General Session

Chair: Xiao Liu, University of Arizona, 1300 E. Fort Lowell Road G109, Tucson, AZ, 85719, United States, xiaoliu@email.arizona.edu

1 - Does Interim Winner's Performance Information Playa Role? An Empirical Investigation Of The Rank-order Newsvendor Contests

Abraham Seidmann, Simon Business School, University of Rochester, Simon Business School, Dir of OR Dept, Rochester, NY, 14627, United States, avi.seidmann@simon.rochester.edu, Tong Wu

Many firms award bonuses to their employees based on their relative performance. When facing newsvendor-type decisions under this type of inter-worker competition, firms need to consider what type of information to disclose to the employees from period to period in order to achieve better outcomes in the long run. Using a laboratory experiment, we find that publicly displaying the winner's performance information every period can significantly improve individuals' overall newsvendor decision making compared to the control group, although the pull-to-center effect is observed. Using another experiment, we find that impulsivity can explain the observed pull-to-center bias.

2 - Big Data In The Healthcare And Wellness Industry

Stephen J Stoyan, Director, Business Analytics and Strategy, Abbott Laboratories, 100 Abbort Park Road, Chicago, IL, 60064, United States, stephen.stoyan@abbott.com

Today's healthcare and wellness industry is dynamic, competitive, and global demands require extremely high volume. Keeping your supply chain lean and efficient is imperative to driving cost savings. Staying competitive requires a sales campaign that is connected to customers at new levels. Big data and advanced analytics are integral parts of the business that provide supply chain efficiencies and top line growth through strategic and operational initiatives. Analytically tuned tools are discovering new opportunities, making connections, and creating business value streams in areas not well understood. We present big data initiatives at Abbott Laboratories and their impact on the business.

3 - Sales Assistance Search And Purchase Decisions An Analysis Using Retail Video Data

Aditya Jain, Baruch College, Zicklin School of Business, 55 Lexington Ave, Suite 9-240, New York, NY, 10010, United States, aditya.jain@baruch.cuny.edu, Sanjog Misra, Nils Rudi

We investigate the roles of sales assistance and search in driving customer's purchase decision using unique observational video data from retail stores. Our analysis reveals that both sales assistance and search play substantial roles which differ based on the context of specific decisions—search has a more dominant role in purchase incidence, whereas the latter in conditional expenditure.

4 - Mining E-cigarette Adverse Events Using The LSTM-based RNN Model With Word Embeddings Features

Jiaheng Xie, University of Arizona, Department of Management Information Systems, Tucson, AZ, 6, United States, xiej@email.arizona.edu

The past years have witnessed increased popularity of e-cigarette use across the world. However, the risk of cartridge fluids and emissions is relatively under-examined due to limited user sample size. Social media provide a large corpus that contains e-cigarette related information. In order to study the e-cigarette adverse effects in a more comprehensive manner, we propose to study the adverse events of e-cigarette with a large volume of health social media data. The challenges in e-cigarette safety social media monitoring lie in identifying relevant adverse events reported by consumers in noisy social media content with high accuracy. The current automatic entity recognition methods have unsatisfying performance due to consumer vocabulary used in social media. To address this issue, we developed a Long Short Term Memory (LSTM) based Recurrent Neural Network (RNN) model to extract the medical entities. Based on our results, our proposed LSTM-based RNN model with word embeddings achieved better entity extraction performance, with a precision of 90.58%, recall of 82.43% and f-score of 86.31%. We identified 1,212 adverse event entities, 397 e-cigarette component entities (chemicals, flavors, and brands) and the corresponding component-event relationships. Since certain e-liquid chemicals, flavors and e-cigarette brands are significantly associated with adverse events, regulatory actions are in need. Certain flavors and brands should also be controlled due to their adverse events.

1 - Optimal Policies For Risk-averse Electric Vehicle Charging With Spot Purchases

Daniel Jiang, University of Pittsburgh, Pittsburgh, PA, 15261, United States, drjiang@pitt.edu, Warren B Powell

We consider the sequential decision problem faced by the manager of an electric vehicle (EV) charging station, who aims to satisfy the charging demand of the customer while minimizing cost. We formulate the problem as a finite horizon Markov decision process (MDP) and provide an analysis of the effect that risk parameters, e.g., the risk-level used in CVaR, have on the structure of the optimal policy. We show that becoming more risk-averse in the dynamic risk measure sense corresponds to the intuitively appealing notion of becoming more risk-averse in the order thresholds of the optimal policy.

2 - On The Optimal Timing Of Meld Score Updates In The Liver Transplantation System

Sepehr Nemati, Ivey School of Business, 1255 Western Road, Ivey Business School, London, ON, N6G 0N1, Canada, sproon@ivey.uwo.ca, Zeynep Icten, Lisa N Maillart, Andrew J Schaefer, Mark Roberts

Patients on the waiting list for liver transplants have opportunities to game the system by concealing changes in their health status. We formulate a model that determines, as a function of the last reported health status, current health status, days until the next required update and the quality of the current liver offer, whether the patient should do nothing, report her current health status, or accept the current liver offer (if any) to maximize expected lifetime. We analyze the degree to which a patient can benefit from the flexibility inherent to the current reporting requirements.

3 - Operational And Financial Decisions Within Proportional Investment Cooperatives

Xiaoyan Qian, PhD Student, University of Auckland, 12 Grafton Road, Auckland, 1010, New Zealand, x.qian@auckland.ac.nz, Tava Olsen

In a proportional investment co-op, operational and financial decisions are inseparable because members' capital investment is required to be in proportion to their economic transactions with the co-op. In agriculture where yield and market are uncertain, we propose a Markov decision process wherein the decisions of processing quantity interact with the financial decisions of retained earnings and short term loans. The results include: (1) characterization of the value function and the optimal policy; (2) explicit expressions for the deterministic-yield dynamic program; and (3) identification of financial risks. Keywords: cooperative; finance and operations; coordination.

4 - Easy Affine Markov Decision Processes: Applications And Algorithms

Jie Ning, Case Western Reserve University, jie.ning@case.edu, Matthew J Sobel

Affine Markov decision processes (MDPs) with continuous state and action vectors and decomposable constraints on actions have unique features that free them from the curse of dimensionality. Exploiting the properties of affine MDPs (a companion paper presented in another session), we present algorithms that efficiently compute an optimal policy and the value function. We show that affine MDPs are applicable in a variety of decision-making contexts such as fishery management and advertising, and that the optimal policies generate qualitative insights.

Quantitative Methods in Finance VI

Sponsored: Financial Services

Sponsored Session

Chair: Xuefeng Gao, The Chinese University of Hong Kong, William MWM Engineering Building, Shatin, NA, Hong Kong, xfgao@se.cuhk.edu.hk

1 - A Primal-dual Iterative Method For Stochastic Dynamic Programming And Its Applications

Nan Chen, Chinese University of Hong Kong, nchen@se.cuhk.edu.hk

Due to the curse of dimensionality, people often rely on computationally tractable, but suboptimal, heustric policies to solve stochastic dynamic programs (SDP). Our work develops a recursive approach from the technique of information relaxation to obtain a sequence of confidence intervals for SDP optimal value. The width of the confidence interval can be used to measure the quality of currently used heuristics. We also show the resulting intervals converge in a finite number of iterations to the true value. Thereby our approach presents a systematic way to improve the quality of control polices. Two applications in optimal trading execution and network revenue management are discussed.

2 - Operational Risk Management: Coordinating Capital Investment And Firm Growth

Lingjiong Zhu, Florida State University, zhu@math.fsu.edu

We consider a jump-diffusion model to analyze the impact on a firm's value of small shocks caused by market risk events and large shocks caused by operational risk events. We consider the investments in the infrastructure of a firm that aims at mitigating the impact of operational risk events through changes in the stochastic nature of the large shocks. We study the investment strategies in two settings: the maximization the firm's value over a fixed investment horizon and the minimization of the ruin probability over an infinite horizon. This is based on the joint work with Yuqian Xu and Mike Pinedo.

3 - Limit Theorems For Hawkes Processes With A Large Initial Intensity

Xuefeng Gao, The Chinese University of Hong Kong, xfgao@se.cuhk.edu.hk

Hawkes process is a class of simple point processes that is self-exciting and has clustering effect. The intensity of this point process depends on its entire past history. It has wide applications in finance, neuroscience, social networks, criminology, seismology, and many other fields. In this paper, we study the linear Hawkes process with an exponential kernel in the asymptotic regime where the initial intensity of the Hawkes process is large. We derive limit theorems for this asymptotic regime as well as the regime when both the initial intensity and the time are large. The limit theorems could be useful for approximating the transient behavior of Hawkes processes.

4 - Testing The Capital Asset Pricing Model Under Economic Regime Shifts

Yonggan Zhao, Professor, Dalhousie University, 6100 University Avenue, Suite 2010, Halifax, NS, B3H 4R2, Canada, yonggan.zhao@dal.ca

We present a dynamic version of the Capital Asset Pricing Model (CAPM) with economic regime shifts. Assuming the equilibrium security returns are characterized by economic indicators, we test the hypotheses that risk premiums on financial securities are asymmetric across economic regimes with positive risk premium in the expansion regimes and negative risk premium in the contraction regimes. Using a sector rotation investment strategy, the superiority of the dynamic CAPM to the traditional CAPM in predicting stock returns is shown.

Choice Models and Assortment Optimization

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Sumit Kunnumkal, Indian School of Business, Hyderabad, India, sumit_kunnumkal@isb.edu

1 - Assortment, Pricing And Market Expansion

Ruxian Wang, Johns Hopkins Carey Business School, Baltimore, MD, 21202, United States, ruxian.wang@jhu.edu

We incorporate market expansion into consumer choice models and investigate the revenue management problems. We characterize the structure of the optimal policies for the problems under the consumer choice models with various market expansion effects, and develop efficient algorithms.

2 - Assortment Planning Decision In Two-sided Market

Ying Cao, University of Texas at Dallas, Ying.Cao@utdallas.edu, Dorothee Honhon, Sridhar Seshadri

We consider a firm which makes product assortment decisions when facing a two-sided market, which means it receives revenues from two distinct groups. We obtain structural properties of the optimal assortment and theoretical bounds on the performance of heuristic policies, showing the value of considering both sides of the market.

3 - A Near-optimal Exploration-exploitation Approach For Assortment Selection

Vashist Avadhanula, Columbia University, New York, NY, 10027, United States, va2297@columbia.edu, Shipra Agrawal, Vineet Goyal, Assaf Zeevi

We consider a dynamic assortment optimization problem where customers choose according to an unknown MNL choice model. In each period, we offer an assortment of at most K products out of N and observe the customer's choice to learn the model parameters. We present an exploration-exploitation policy that achieves a near-optimal worst case regret of $\tilde {O}(\sqrt{NT})$. Our policy is based on the principle of optimism under uncertainty and does not require any separability assumption on the parameters. We also present a nearly matching lower bound of $\Omega(\sqrt{NT/K})$ for this problem.

4 - New Bounds For Assortment Optimization Under The Nested Logit Model

Sumit Kunnumkal, Indian School of Business, sumit_kunnumkal@isb.edu

We consider the assortment optimization problem under the nested logit choice model. We establish new bounds on the quality of revenue ordered assortments.

Chair: Hiba Baroud, Assistant Professor, Vanderbilt University, 2301 Vanderbilt Place, PMB# 351831, Nashville, TN, 37212, United States, hiba.baroud@vanderbilt.edu

1 - Combining Data And Weakly Informative Priors To Make Better Decisions Faster

Adam Jason Fleischhacker, University of Delaware, ajf@udel.edu

In tackling decision problems, a decision maker must choose how to represent uncertainty using techniques that may be classified on a spectrum; on one end you have fully specified distributions which make strong assumptions, and on the other end, completely non-parametric and robust approaches which minimize assumptions. In this work, we develop and use an analytically tractable model of uncertainty that can model mild assumptions and which can more rapidly extract value from data than non-parametric approaches.

2 - Projection Of Drought Risk For Thermoelectric Power Plants Using Downscaled Climate Scenarios

Royce Francis, Assistant Professor, George Washington University, Washington, DC, 20052, United States, seed@email.gwu.edu

Many climate researchers have studied a number of climate forcing scenarios to determine how the coupled oceanic-atmospheric systems will respond. At the same time, these responses will be part of a complex feedback loop with infrastructure systems. Thus, it is important to help infrastructure decision makers incorporate climate scenarios into risk and reliability assessments. This presentation demonstrates a Copula Bayesian Network for projecting thermoelectric power plant drought risk over CMIP5 downscaled climate scenarios.

3 - Data-driven Decision Analysis Model For Planning And Management Of Multiple Purpose Reservoir Cascade Systems

Thushara De Silva, Vanderbilt University, 400 24th Avenue South, 267 Jacobs Hall, Nashville, TN, 37212, United States, thushara.k.de.silva@vanderbilt.edu, George Hornberger, Hiba Baroud

The objective of this study is to develop a decision analysis model for the planning and management of water resources that maximizes multiple objectives such as economic viability, environmental sustainability, and social development. The model is deployed to the Mahaweli water resources development which is the largest multipurpose project of Sri Lanka. A multicriteria decision analysis model is considered and several data sources are used to assess the multiple attributes in the model. The utility function incorporates the preferences of multiple decision makers to assess the weights on the attributes.

4 - Using Data In Decision Making: Big Data, Little Data, No Data

Hiba Baroud, Vanderbilt University, hiba.baroud@vanderbilt.edu

The role of data analytics in decision making has evolved as the volume of data changed and the tools and technologies to handle such data improved. Are decision makers overwhelmed with data or do they still lack the amount of data they need to improve their decision models? This work is a review of the current state of the art of the use of data-driven tools in decision analysis techniques in practice and theory. The objective is to identify gaps between data and decisions while highlighting opportunities and challenges in research.

Investment Analysis and Financial Applications

Sponsored: Decision Analysis

Sponsored Session

Chair: Manel Baucells, University of Virginia Darden School of Business, 100 Darden Blvd, Charlottesville, VA, 22903, United States, baucellsm@darden.virginia.edu

1 - Net Present Value Analysis And Individual Utility

Manel Baucells, University of Virginia Darden School of Business, baucellsm@darden.virginia.edu, Sam Bodily

Standard investment analysis employs expected Net Present Value discounting at a risk-adjusted market return. Such prescription takes the viewpoint of the capital market, but neglects the risk aversion of the project owner or the individual investor. We develop an approach that is consistent with expected utility, and requires the integration of project and market returns. The approach recommends the use of the certainty equivalent discount rate, which depends on both the market and the risk aversion of the individual. We explore conditions in which market returns can be omitted from the analysis; or in which our approach particularizes into the standard analysis.

2 - An Expected Utility Approach For The Mean-variance Portfolio Problem

Felipe Macedo de Morais Pinto, Universidade Federal de Pernambuco, Caixa Postal 7471, Recife, 50630971, Brazil, felipe_mmp94@hotmail.com, Adiel T de Almeida Filho

This paper presents an expected utility approach for decision makers with exponential utility behavior as an alternative to the mean-variance approach when considering a financial portfolio. The DA framework is used for modeling the classical Markowitz's portfolio decision problem incorporating a Bayesian perspective, which allows to include aspects such as the evaluation of macroeconomic environment and minimizing the Bayes Risk. A numerical application is presented based on financial data for an investment decision evaluating a portfolio of DOW 30, FTSE 100 and NASDAQ 100.

3 - A Bayesian Approach For Consumer Credit Debt Collections Process

Adiel T de Almeida Filho, Assistant Professor, Universidade Federal de Pernambuco, Caixa Postal 7471, Recife, 50630971, Brazil, adieltaf@cdsid.org.br, Mee Chi So, Christophe Mues, Lyn C Thomas

After a borrower defaults on their repayment obligations, collectors of unsecured consumer credit debt have a number of actions they can take to secure some repayment of the debt. The operations management challenge in this setting is to decide which of these actions to take, how long to take them, and in what sequence to take them. In this paper, a Bayesian Markov Decision Process (MDP) model is used to find an optimal policy of what action to undertake in the next period given the current information on the individual debtor's repayment performance thus far.

4 - An Analytic Method For Investment Analysis In Mulichannel Retailing

Somayeh Yasamin Salmani, Drexel University, 2007 Chestnut Street, Apt D2, Philadelphia, PA, 19103, United States, ss3858@drexel.edu, Fariborz Partovi

We propose a two-stage stylized model to help firms in making a major strategic decision in distribution channels investment. Our study is motivated by firms that provide multiple channels for customers. We develop an analytic model using customer input and operating costs for specific channel structures to find optimal investing allocation across different distribution channels.

Efficient Learning in Stochastic Optimization

Sponsored: Simulation

Sponsored Session

Chair: Ilya O. Ryzhov, University of Maryland, 4322 Van Munching Hall, College Park, MD, 20742-1815, United States, iryzhov@rhsmith.umd.edu

1 - Continuous Learning For Contextual Bandits With Nonstationary Rewards

John G Turner, University of California Irvine, Irvine, CA, United States, john.turner@uci.edu, Amelia C Regan, Tianbing Xu, Yaming Yu

We study how best to match ads to viewers using high-dimensional contextual features (demographic, browsing behavior) to predict click-through probability. Using Thompson Sampling in a Bayesian framework, our model learns the importance of contextual features while adapting/forgetting over time, capturing changing individuals' tastes and shifts in the viewing population's composition.

2 - Bayesian Bandits For Sequential Clinical Trials Of Multiple Technologies

Ozge Yapar, University of Pennsylvania, Philadelphia, PA, United States, yapar@wharton.upenn.edu, Stephen E Chick, Noah Gans

We extend recent work on fully sequential trials for health technologies that explore the potential benefits of linking Phase III trials with health technology assessments for market access. We take a bandit perspective that uses Bayesian learning about multiple health technologies.

3 - Vssa – A Variable Sample-size Stochastic Approximation Schemes For Stochastic Convex Optimization

Uday V. Shanbhag, Pennsylvania State University, udaybag@engr.psu.edu, Afrooz Jalilzadeh, Jose Blanchet, Peter W Glynn

Traditional stochastic approximation (SA) schemes employ a single gradient or a fixed batch of noisy gradients in computing a new iterate. We consider SA schemes in which Nk samples are utilized at step k and the total simulation budget is M. This paper derives error bounds in this budget-constrained regime in both strongly convex and convex regimes with constant and increasing sample-sizes. Notably, trade-offs between sample-complexity and computational complexity are examined. Preliminary numerics suggest that such avenues provide approximate solutions in less than a hundredth of the time taken by standard SA schemes with modest drops in accuracy.

4 - A New Consistency Theory For Approximate Bayesian Inference

Ye Chen, University of Maryland, yechen@math.umd.edu, Ilya O Ryzhov

Approximate Bayesian inference is a powerful methodology for constructing statistical learning mechanisms in problems where incomplete information is collected sequentially. Approximate Bayesian models have been widely applied, but the convergence or consistency results for approximate Bayesian estimators are largely unavailable. We develop a new consistency theory for these learning schemes by interpreting them as stochastic approximation (SA) algorithms with additional "bias" terms. We prove the convergence of a general SA algorithm of this type, and through this, for the first time, show the consistency of several approximate Bayesian methods from the recent literature.

Dynamic Games and Applications to Revenue Management

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Konstantinos Bimpikis, Stanford, Stanford, Palo Alto, CA, 94305, United States, kostasb@stanford.edu

1 - Dynamic Selling Mechanisms For Product Differentiation And Learning

N. Bora Keskin, Duke University, Durham, NC, United States, bora.keskin@duke.edu, John R Birge

We consider a firm that designs a menu of vertically differentiated products for a population of customers with heterogeneous quality sensitivities. The firm faces an uncertainty about production costs. We characterize the structure of the firm's optimal dynamic learning policy and construct simple and practically implementable policies that are near-optimal.

2 - When Fixed Price Meets Priority Auctions: Service Systems With Dual Modes

Krishnamurthy Iyer, Cornell University, kriyer@cornell.edu, Jiayang Gao, Huseyin Topaloglu

We consider a service system where service is offered via two modes. The first mode charges a fixed price, and the service discipline is FIFO. In the second mode, called the bid-based priority mode, customers submit a bid, obtain service in the descending order of their bids, and make payments equal to their bids. We assume the customers have heterogeneous waiting costs, and choose the service mode strategically on arrival. We establish the existence and uniqueness of a symmetric equilibrium, which has a simple threshold structure: customers with either high or low waiting cost obtain service from the bid-based priority mode, whereas those with moderate waiting cost obtain service from the FIFO mode.

3 - Customizing Marketing Decisions Using Field Experiments

Spyros Zoumpoulis, INSEAD, spyros.zoumpoulis@insead.edu, Theodoros Evgeniou, Duncan I Simester, Artem Timoshenko

We investigate how firms can use the results of field experiments to optimize marketing decisions, and in particular allocating different promotional offers to different customer segments for the customer acquisition problem of a large retailer. In the first stand of the work, we solve the problem of finding the optimal one-shot promotion policy: what promotional offer should be sent to what customer segment? In the second strand of the work, we solve the problem of optimally retargeting nonrespondents through promotions in multiple waves: what customer segment should we stop mailing to, and for what segment would we benefit from repeated promotions?

Personalized E-commerce

Sponsored: Revenue Management & Pricing

Sponsored Session

Chair: Van Anh Truong, Cornell University, Ithaca, NY, United States, vat3@cornell.edu

1 - Distribution-free Pricing

Ming Hu, University of Toronto, Toronto, ON, Canada, Ming.Hu@rotman.utoronto.ca, Hongqiao Chen

We study a monopoly robust pricing problem in which the seller does not know the customers' valuation distribution but knows its mean and variance. Such minimum requirement of information is nothing but asking two questions: How much your targeted customers are going to pay on average? And how sure are you? We obtain the best robust price heuristic in closed form and provide its distribution-free, worst-case performance bound. We then provide easily verifiable distribution-free sufficient conditions to guarantee the pure bundle to be more profitable than separately sales. We illustrate the benefit of bundling by a couple of practical examples such as subscription services of digital music.

2 - Revenue Management With Consumer Search Cost

Zizhuo Wang, University of Minnesota, Minneapolis, MN, United States, zwang@umn.edu, Yan Liu, William L Cooper

We consider a pricing problem in which the product valuations are uncertain to the consumers. The consumers can find the valuation of the product by incurring a search cost. We study the seller's problems of whether it should lower the search costs of the products, and what prices it should charge. We find that when there are two products, lowering the search cost of one product while maintaining a high search cost for the other product may be optimal. We also show how our results vary depending on the correlation between the uncertainty of the products.

3 - Approximation Algorithms For Product Framing And Pricing

Anran Li, Columbia University, al2942@columbia.edu

We propose one of the first models of "product framing" and pricing. Product framing refers to the way consumer choice is influenced by how the products are displayed. We present a model where consumers consider only products in a random number of top web pages. Consumers select a product from these pages following a general choice model. We show that the product framing problem is NP-hard. We derive algorithms with guaranteed performance relative to an optimal algorithm under reasonable assumptions. We also present structural results for pricing under framing effects. At optimality, products are sorted in descending order of quality, and prices are shown to be page dependent.

Social Media Analysis II

Invited: Social Media Analytics

Invited Session

Chair: Yen-Yao Wang, Michigan State University, 5211 Madison Avenue, Apartment A5, Okemos, MI, 48864, United States, wangyen@broad.msu.edu

1 - A Unified Framework For Credit Evaluation For Internet Finance Companies

Meheli Basu, Graduate Research Assistant, University of Pittsburgh, 5820 Elwood Street, APT 33, Pittsburgh, PA, 15232, United States, meb209@pitt.edu

We developed and detailed a multi-criteria decision-making framework based on interface of the subjective approach of analytical hierarchical process (AHP) and validated by comparative analysis using the objective approach of data envelopment analysis (DEA) to evaluate credit index. Our framework identifies and weighs the most important characteristics of SMEs and start-ups which contribute to overall credit rating. Although our target implementation group is the internet finance industry, our framework for credit evaluation will also give start-ups and SMEs an insight into favorable criteria for a good credit standing.

3 - Advances In Social Media Analytics For Ultra-low Latency Fintech Applications

Martin M Spollen, Queen's University, Belfast, BT9 5JX, United Kingdom, m.spollen@qub.ac.uk

This presentation will discuss some recent advances in adaptive machine learning designed to extract more reliable capital markets foresight from streaming social media firehose data. Such techniques must keep pace with the rapidly evolving human language used on social media and deliver outputs with a minimum of latency for real time applications for Hedge Funds and High Frequency Algorithmic Traders.

4 - Momentum In Social Media And Sale Performance After Automobile Recalls

Yen-Yao Wang, Michigan State University, N204 Business College Complex, East Lansing, MI, United States, wangyen@broad.msu.edu, Tawei Wang, Roger Calantone

Due to the unique nature of social media, many firms have turned their attentions to social media to manage their recall campaigns. However, the role of social media before and after recalls has not received a more detailed examination. The purpose of this paper is to (1) assess the impact of social media on customers' attentions to US mid-size vehicle recalls, and (2) examine the role of momentum in social media before and after the recall process. We obtained all mid-size automobile recall events and supplemented with social media data on customers' discussions on defected vehicles and firms' recall process from around 1,000 different social media platforms from 2010 to 2015.

Classroom Activities

Sponsored: Education (INFORMED)

Sponsored Session

Chair: Vincent Hargaden, Assistant Professor, University College Dublin, 209 Engineering & Materials Science Centre,, Belfield, 00000, Ireland, vincent.hargaden@ucd.ie

1 - An Interactive Spreadsheet Based Game For Teaching Design Of Experiments And Response Surface Methodology

Anthony Bonifonte, Georgia Institute of Technology, ABonifon@gatech.edu

Experimentation is a key feature of many scientific and engineering disciplines. This presentation describes an interactive spreadsheet based game implemented in a quality control course. The game is designed to simulate an industrial or laboratory experimentation process and develops skills in design of experiments, response surface methodology, optimization, and statistical analysis. The game is appropriate for the undergraduate or masters level and relevant for any course that teaches experimentation.

2 - Using Jupyter Notebook In The Operations Research Classroom

Nelson A Uhan, United States Naval Academy, uhan@usna.edu

Jupyter Notebook is an interactive computational environment that allows you to create documents that contain live code, text, equations, and visualizations. As a result, Jupyter Notebook can be a very useful teaching and learning tool for classes with a considerable emphasis on programming and computation. In this talk, I will share my experience with using Jupyter Notebook in undergraduate operations research classes, and discuss some of my plans for using it in the future.

3 - Analysis And Design Of Discrete Material Flow Systems: A Virtual Industrial Engineering Systems Pilot Laboratory

United States, dima.nazzal@isye.gatech.edu, Leon McGinnis, Timothy Sprock, George Thiers

In this project we redesigned a core undergraduate course that focuses on the analysis and design of discrete material flow systems. We partnered with MathWorks to use Matlab and created a virtual Industrial Engineering systems lab; a suite of computational components that enable students to "experiment" not just with the kinds of analytic models we routinely teach, but also with computational models of versions of the systems they represent where the simplifying assumptions are relaxed. This talk will illustrate samples of the computational tools we developed and how they were integrated into the course and utilized to enhance students' understanding of the key concepts covered in this course.

4 - Teaching Earned Value Analysis Using A Classroom-based Dice Game

Vincent Hargaden, Assistant Professor, University College Dublin, 209 Engineering & Materials Science Centre, Belfield, Ireland, vincent.hargaden@ucd.ie, Virpi Turkulainen

We describe the use and evaluation of a classroom based dice game to teach the concept of Earned Value Analysis. A summary of the game and teaching materials will be outlined. We describe how the perceived effectiveness of the game as a teaching tool was measured among different cohorts of students.

Sponsored Session

Chair: Keith A Willoughby, University of Saskatchewan, 25 Campus Drive, Saskatoon, SK, S7N 5A7, Canada, willoughby@edwards.usask.ca

1 - Bracketology: How Business Analytics Can Help You Fill Out Your Bracket

Michael Magazine, University of Cincinnati, mike.magazine@uc.edu

This course is open to advanced undergraduates/graduate students with at least one course in probability and statistics. It meets over three Saturdays -one each in February, March and April. The course covers research papers that both determine the probability that one team beats another and also how brackets should be formed and filled out. One class is devoted to student teams acting as the selection committee and justifying how they form brackets. Students and instructors (I co-teach this with Paul Bessire, an ex-student who is founder of Predictionmachine.com) compete in a bracket challenge and prizes awarded to the best performers. The last class has included visitors, like Joe Lunardi of ESPN.

2 - When Is It Ok Not To Score? Teaching Decision Analysis With The Sport Of Curling

Keith A Willoughby, University of Saskatchewan, Saskatoon, SK, Canada, willoughby@edwards.usask.ca, Kent J. Kostuk

The object of sports is to outscore your opponent. Curling is a winter team sport popular in Canada, Europe, the northern United States and the Pacific Rim. In the sport of curling, teams may encounter a crucial decision in the latter stages of the game; namely, should they score a point (thereby providing last-shot advantage to the opposition in subsequent stages of the game) or deliberately fail to score a point (thus retaining last-shot opportunity in the next part of the match)? We develop a model for this particular scenario that can be used to teach introductory decision analysis.

3 - A Playbook For Teaching Sports Analytics To Undergraduate Business And MBA Students

Scott Nestler, University of Notre Dame, snestler@nd.edu

Last year, the presenter taught a half-semester length course (2 credits for MBA students, 1.5 credits for undergraduates) in Sports Analytics for the first time at the University of Notre Dame. Offensive plays — reaching out to faculty members at other schools who had taught a similar course yielded many great examples; allowing students freedom to use whatever tool or coding language they were comfortable with for the course project. Defensive plays — selecting Excel as a common language for class examples to account for difference in technical preparation (may revisit for next semester with a more pro-style scheme that incorporates R); using a known but somewhat dated text (Winston's "Mathletics"). Please come listen and your experiences in teaching quantitative techniques using a subject matter that students are truly excited about.

1 - Resilience-based Post-disaster Recovery Strategies For Community Road-bridge Networks

Weili Zhang, University of Oklahoma, 202 W. Boyd St., Room 116, Norman, OK, 73019, United States, weili.zhang-1@ou.edu, Naiyu Wang, Charles Nicholson

This paper presents a novel resilience-based framework to optimize the scheduling of the post-disaster recovery actions for community road-bridge transportation networks. Two metrics are proposed for measuring rapidity and efficiency of the network recovery: the TRT is the time required for the network to be restored to its pre-hazard functionality level, while the SRT is a metric defined for the first time in this study to capture the characteristics of the recovery trajectory that relate to the efficiency of those restoration strategies considered. Based on this two-dimensional metric, we propose a restoration scheduling method for optimal post-disaster recovery planning.

2 - A Multi-objective Optimization Model For Mitigating Community Economic Loss And Population Dislocation

Weili Zhang, University of Oklahoma, 202 W. Boyd St., Room 116, Norman, OK, 73019, United States, weili.zhang-1@ou.edu, Charles Nicholson

Decisions regarding allocation of limited resources to improve the infrastructure components are complex and involve various tradeoffs. In this study we develop a mathematical model that incorporates expected building damage from an earthquake, an estimate of the value of monetary loss from damaged buildings, and a likelihood of families to be dislocated based on the damage to the housing stock to determine which types of buildings should be prioritized for code level improvements given a variety of external constraints. The model is applied to the well-developed virtual city, Centerville, designed collaboratively by a team of engineering experts, economists, and social scientists.

3 - A Data-driven Approach On Training Set Optimizaton For Genomic Selection In Plant Breeding

Guiping Hu, Iowa State University, guiping.hu.2011@gmail.com, Shiyang Huang

We propose a data-driven approach for training set optimization in genomic selection for plant breeding. To deal with the enormous scaled genetic data, we extract specific information according to the stages of decision making. The data are processed and analyzed with different tools, including data mining and stochastic process analysis. With the analytic tool, the plant breeding process is expected to accelerate with high throughput.

4 - How To Provide Food Aid In Kenya: In Kind, Cash Or Voucher?

Feyza Guliz Sahinyazan, PhD Candidate, McGill University, 1001 Sherbrooke Street West, Montreal, QC, H3A 1G5, Canada, feyza.sahinyazan@mail.mcgill.ca, Marie-Ève Rancourt, Vedat Verter

As of 2016, there are still more than 800 million people dealing with hunger who are mostly located in Sub-Saharan Africa. Recently, relief efforts of humanitarian organizations are shifting from in-kind food aid to different food assistance programs. There are multiple reports suggesting that providing cash or vouchers can be significantly more effective compared to in-kind food distribution. However, our study is the first attempt to mathematically formulate the aid modality selection problem. We develop a flexible methodology that can adjust to the ever-changing dynamics of the food assistance environment using real data from Kenya.

Transportation Issues in Smart Cities

Sponsored: Public Sector OR

Sponsored Session

Chair: Leila Hajibabai, WSU, 405 Spokane St, Pullman, WA, 99163, United States, leila.hajibabai@wsu.edu

1 - Development Of An Optimal Control Logic For Autonomous Intersection Management

Amir Mirheli, Washington State University, Pullman, WA, 99163, United States, amir.mirheli@wsu.edu, Clayton Cline, Leila Hajibabai, Ali Hajbabaie

Reliable coordination between connected-autonomous vehicles (CAVs) and transportation infrastructure offers the possibility of eliminating existing traffic signals in smart cities. This research develops an intersection control system (ICS) that obtains advance information on CAVs' arrivals, locations, and speeds over time. ICS models an optimal logic to simultaneously maximize intersection throughput and minimize delay while upholding safety constraints on vehicle maneuvers to prevent collisions. Numerical results confirm that the proposed technique can solve the problem efficiently.

2 - Variable Speed Limit Optimization In Urban Street Networks

Mehrdad Tajalli, Graduate Research Assistant, Washington State University, Pullman, WA, United States, mehrdad.tajalli@wsu.edu, Sattar Sattarov, Ali Hajbabaie

Emergence of connected vehicle technology provides the opportunity to facilitate the movement of vehicles in smart transportation networks and reduce their travel time. Dynamic speed limit on different links of the network helps efficiently utilize the roadway capacity and facilitates network-wide vehicular movements. This study develops a novel formulation and an efficient solution technique for variable speed limit optimization based on cell transmission model.

3 - Dynamic Traffic Metering In Urban Street Networks

Rasool Mohebifard, Washington State University, Pullman, WA, United States, rasool.mohebifard@wsu.edu, Andrew Stephenson, Ali Hajbabaie

Traffic metering offers great potential to reduce congestion in oversaturated urban street networks. This research presents a linear program for traffic metering in smart urban street networks. We also present a Mixed-Integer Linear Program (MILP) to address the flow holding-back problem of the linear program. We propose a novel solution algorithm and show that it converts the MILP to a linear program and several simulation runs.

4 - Distributed-coordinated Signal Timing Optimization In Connected Transportation Networks

S.M.A Bin Al Islam, Graduate Research Assistant, Washington State University, 545 NE Morton Street, Apt 202, Pullman, WA, 99163, United States, smabinal.islam@wsu.edu, James Amundsen, Ali Hajbabaie

This research presents a Distributed-Coordinated methodology for signal timing optimization in connected urban street networks. The novelty of the work arises from reformulating the signal timing optimization problem from a central to a distributed architecture, where a mathematical program controls the timing of only a single intersection. The distribution, reduces the complexity of the problem. Furthermore, distributed mathematical programs continuously coordinate with each other to avoid finding locally optimal solutions and to move towards global optimality.

5 - Strategic Design Of Station Location And Patrol Routing For Incident Response Programs

Debashis Saha, Washington State University, Pullman, WA, 1, United States, debashis.saha@wsu.edu, Leila Hajibabai

Transportation and enforcement agencies aim to clear traffic accidents in a timely manner to mitigate congestion and improve traffic safety. This research develops a set of mathematical programs to determine the optimal patrol routing scheme for connected response teams under strategic dispatching station location decisions in smart cities. The proposed models minimize the expected maximum response time to all possible hotspots on transportation networks. A hybrid solution algorithm including Lagrangian relaxation and column generation techniques is developed. Numerical tests are conducted to evaluate the efficiency of the proposed algorithm.

Charles Weber, Portland State University, Portland, OR, United States, webercm@gmail.com, Nitin Mayande

2 - Role Of Firm Knowledge, Quality Conformance And Lean Practices On Product Development

Vashkar Ghosh, University of Florida, Warrington College of Business, Gainesville, FL, United States, vashkar.ghosh@warrington.ufl.edu, Janice E Carrillo

We investigate the implementation of lean principles which constitutes value creation and waste elimination in a product development setting. We view a firm's design knowledge creation and quality development as value creation and study its impact on product development. We also investigate a goal level of quality performance.

3 - The Impact Of Learning On Cumulative Innovation

Leonardo Santiago, Copenhagen Business School, ls.om@cbs.dk, Julia Couto, Nitin Joglekar

The ability to continuously innovate is a key asset to maintain a competitive advantage. A sequence of successful innovations can render a company not only a new product or technique but also a platform which could be used in future. This work investigates how knowledge is accumulated over time as a function of managerial decisions and the dynamics of firm's knowledge. Our results show that an organization can actively select pivoting points to appropriately balance exploration and exploitation initiatives and successfully learn. Moreover, we show how companies improve their performance by reacting to environmental shocks or to turbulent environments.

1 - Guided Particle Swarm Optimizer For Transactive Operation Of Interconnected Micro-grids

Yang Chen, University of Illinois at Chicago, Chicago, IL, 60607, United States, ychen429@uic.edu, Mengqi Hu

Existing research has demonstrated that micro-grid clusters can freely share energy to achieve more cost savings. However, few solution approaches are developed to realize transactive operation for micro-grid clusters, not to mention large scale application. To this end, we develop a scalable distributed decision approach to study the transcative operation of micro-grid clusters where a virtual transaction center is introduced to coordinate all the micro-grids using a particle swarm optimizer (PSO). The dual price of local transactive energy is employed to guide the convergence of PSO. The effectiveness of the proposed dual-price guided PSO is demonstrated using a cluster of 256 micro-grids.

2 - Coordinated Multi-area Dispatch For Wholesale Electricity Markets

Feng Zhao, ISO New England, Holyoke, MA, United States, fzhao@iso-ne.com, Dane Andrew Schiro, Eugene Litvinov

Wholesale regional electricity markets in the U.S. are managed by Independent System Operators (ISOs) through tools such as Security Constrained Economic Dispatch (SCED). The disconnection between the regional markets contradicts the interconnected nature of the corresponding regional power systems. This entails coordination between regional markets. This presentation describes a novel coordination method for the multi-area SCED problem by exchanging critical information of free variables and binding constraints. The method is also extended to solving general large-scale linear programs with demonstrated computational efficiency.

3 - Nuclear Plants Market Competitiveness With Flexible Operational Capability

Zhi Zhou, Argonne National Laboratory, zzhou@anl.gov, Jesse D Jenkins, Audun Botterud

The economic viability of nuclear energy is increasingly challenged in the U.S. deregulated electricity markets due to large availability of cheap natural gas and increased penetration of renewables. It is critical to improve the competitiveness of nuclear energy to maintain energy supply diversity. In this study, we investigate the economic impact of flexible operations of a nuclear plant on its profitability, considering reliability issues on both plant and reactor levels, under the context of a deregulated electricity market. Case study results on a utility scale system show that operational flexibility can not only increase a nuclear plant's profit, but also have benefit to the whole system.

1 - A Queueing Service Problem With MDP In Steel Slab Yard

Yanhe Jia, Student, Northeastern University, Heping Street, Shenyang,Liaoning, 110819, China, yhejia@126.com, Lixin Tang

The paper analyzes a serving storage problem of slab yard in iron and steel enterprises. Slabs from a continuous casting stage are stored in a slab yard (as a buffer) for further processing in a hot rolling stage. The coming slabs well be carried by some servers-cranes, these slabs come randomly. In this paper, we consider the slab serving storage problem to minimize the service cost. We give a queueing model and propose a dynamic programming algorithm to present a staffing policy.

2 - Integrating Inventory Classification And Control Decisions To Maximize Order Fulfillment Measures

Liu Yang, Assistant Professor, Purdue University, 3000 Technology Ave, New Albany, IN, 47150, United States, LYang@purdue.edu, Haitao Li, James F Campbell, Donald C. Sweeney

This study presents a linear optimization model that integrates inventory classification and control decisions to maximize the order fulfillment performance, subject to inventory budget constraint and minimum profit requirement. The focus of the research is the order-based performance measures, rather than the commonly used item fill rate. With the proposed models, companies have the ability to arrange the inventory in a way to meet customer segmentation strategy, to evaluate the tradeoff of two order-based measures and profitability, and to simulate the impact of different levels of inventory investment.

3 - A Partially Observed Inventory Control Problem

Satya Sarvani Malladi, PhD Student, Georgia Institute of Technology, 2209 Briarcliff Rd NE, Apt 17, Atlanta, GA, 30329, United States, mss@gatech.edu, Alan Erera, Chelsea C. White

We consider the inventory control problem with backlogging and partially observed discrete demands. We prove the optimality of a myopic policy under a key assumption. We present upper and lower bounds on the optimal expected cost and a bound on the difference between the bounds.

4 - Dynamic Inventory Management Of Hybrid Manufacturing/Remanufacturing Systems With Different Lead Times

Tong Wang, PhD Student, The Chinese University of Hong Kong, 511D William M Engineering Building, Hong Kong, twang@se.cuhk.edu.hk, Xiting Gong, Xiuli Chao

In this paper, we consider an inventory management problem where a firm replenishes its inventory from both manufacturing and remanufacturing processes in finite periods. Production lead time for manufacturing is different from that for remanufacturing. Besides the complete characterization of the optimal replenishment policy, we provide some managerial insights on results as well.

5 - Inventory Management Under Labor Constraints On Restocking

Naser Nikandish, California State University Fullerton, 800 N State College Blvd, Anaheim, CA, 92806, United States, nnikandish@fullerton.edu, Lawrence W Robinson

we present a linear programming model for determining inventory replenishment policies under limited restocking labor. We use this model to solve the restocking problem facing a specific European supermarket. We discuss three inventory replenishment policies and report impact of limiting labor on retailer's profitability. We also develop a Lagrangian Relaxation based algorithm for finding inventory replenishment policies under one of these policies.

1 - Sponsored Data: Smarter Data Pricing In The Age Of Data Cap

Xiaowei Mei, University of Florida, xmei@ufl.edu

We investigate a recent phenomenon whereby network service providers are encouraging content providers to sponsor data for consumers. We analyze this phenomenon using game theory within a setting of one monopoly mobile network operator (MNO) and two competing content providers (CPs). Consumers are heterogeneous in both data usage and in their preference for the CPs. We find the optimal pricing scheme for MNO is a two-part tariff without any data caps. The CPs are in a Prisoner's Dilemma regarding sponsored data in the sense that they would prefer not to subsidize the consumers' data consumption but doing so unilaterally would put them in a relatively inferior position.

2 - Please Share! Online Word Of Mouth And Charitable Crowdfunding

Mahdi Moqri, University of Florida, Gainesville, FL, United States, mahdi.moqri@warrington.ufl.edu

While online WOM is commonly used to share information about crowdfunding campaigns, there is hitherto limited understanding as to whether or how this information sharing affect individuals' contribution behavior or the outcome of crowdfunding campaigns. In this study, using a unique dataset from 590 crowdfunding campaigns observed over 12 days, we examine to what extent, and how quickly online WOM affect the rate of contributions. In addition, we explore the effect of different phases of fundraising (over time or as they approach their target goals) and of the coverage of the campaigns in major online news websites.

3 - "Hidden Profiles" In Corporate Prediction Markets: The Impact Of Public Information Precision And Social Interactions

Jingchuan Pu, University of Florida, Gainesville, FL, United States, jingchuan@ufl.edu, Liangfei Qiu, Hsing K Cheng

Recently, large companies are experimenting with corporate prediction markets run among their employees. we develop an analytical model to analyze the effects of information precision and social interactions on prediction market performance. But increased precision of public information is not always beneficial to prediction market accuracy because of the "hidden profiles" effect: participants place a larger than efficient weight on existing public information. A socially embedded prediction market with information sharing mechanism may help correct such inefficiency. We also identify conditions under which increased precision of public information is detrimental in both cases.

4 - Credit Card Companies And Is-integrated Marketing Platforms: A Comparison Of Social Network Promotions And Targeted Promotions

Soohyun Cho, University of Florida, Gainesville, FL, United States, soohyun.cho@warrington.ufl.edu, Liangfei Qiu, Subhajyoti Bandyopadhyay

In this paper, we investigate two types of marketing promotions that credit card companies have recently been featuring in collaboration with partnered retailers: public promotions through social networking services and targeted promotions through companies' websites. To analyze the strategic impacts on the promotion's participants (including companies/retailers and consumers), we develop a game theoretical model and then determine the best strategies for different participants. The study is extended by considering the advertising effect of social network services as well as security issues involving targeted promotions.

Insights from Relaxing Traditional Modeling Assumptions about Human Behavior in OM Settings

Sponsored: Behavioral Operations Management

Sponsored Session

Chair: Jordan Tong, Wisconsin School of Business, 4293 Grainger Hall, Madison, WI, 53706, United States, jtong@bus.wisc.edu

1 - Utility Based Queueing: Predicting Delay When Servers Are Strategic

Amy Ward, University of Southern California, amyward@marshall.usc.edu, Sherwin Doroudi, Ragavendran Gopalakrishnan, Adam Wierman, Dongyuan Zhan

Most common queueing models used for service system design assume the servers work at fixed (possibly heterogeneous) rates. However, real-life service systems are staffed by people, and people may change their service speed in response to incentives. To model this, we assume each server selfishly chooses his service speed in order to maximize his expected utility. Under various assumptions on the utility function, we characterize the equilibrium service speed, which can then be used to estimate system performance.

2 - Service Systems With Unknown Quality & Customer Anecdotal Reasoning

Tingliang Huang, Carroll School of Management, Boston College, 140 Commonwealth Avenue, Chestnut Hill, MA, 02467, United States, tingliang.huang@bc.edu, Hang Ren, Kenan Arifoglu

We consider a service system where customers do not know the distribution of uncertain service quality and cannot estimate it fully rationally; instead, they form beliefs by taking sample averages of anecdotes. The number of anecdotes can be used to measure to what extent customers are boundedly rational. We characterize customers' joining behavior and the server's pricing and quality decisions.

3 - The Effect Of Social Information On Demand In Quality Competition

Dayoung Kim, Cornell University, dk668@cornell.edu

We investigate the impact of different types of social information on the demand characteristics of firms competing through service quality. We develop a Hidden Markov model to understand the choice mechanism of a consumer under social information. We then conduct a lab experiment where a consumer chooses to visit one of two firms, each with unknown service quality. In the experiment, a consumer may have access to (1) no information, (2) market "share-based" social information, or (3) "quality-based" social information. Our results show that different types of information have dramatically different effects on firms' market shares and demand uncertainty.

4 - Selling To Experience-sampling Customers: Quality Conformance, Pricing, And Promotions

Gregory A DeCroix, University of Wisconsin - Madison, greg.decroix@wisc.edu, Jordan Tong

We consider a firm that sells a service, the quality of which is stationary but stochastic. Customers cannot directly observe mean quality, but instead base their estimate of quality on their own past purchases. Customers are risk neutral but boundedly rational - their purchase decisions are described by a logit model based on customer surplus (estimated quality minus price). We explore several phenomena that arise in such a setting. For example, poor quality conformance (high service variability) leads to reduced sales revenues, even though customers are risk neutral. In addition, under certain circumstances occasional promotions can help counter this erosion in revenues.

1 - Managing Stored Energy In Microgrids Via Multistage Stochastic Programming

Arnab Bhattacharya, PhD Candidate, University of Pittsburgh, 1031 Benedum Hall, 3700 O'Hara Street, Pittsburgh, PA, 15261, United States, cfcarnabiitkgp@gmail.com, Jeffrey P. Kharoufeh, Bo Zeng

Energy storage systems are used to mitigate adverse effects of renewable sources in a microgrid where procurement and storage decisions are made under uncertain demand, renewable supply and prices. A multistage stochastic programming (SP) model is formulated to minimize the expected total costs in a microgrid. To improve computational tractability of the SP model, a customized stochastic dual-dynamic programming (SDDP) algorithm is employed to obtain high-quality solutions within reasonable time bounds. A numerical study highlights significant cost reductions and computational benefits.

2 - A Crowdfunding Model For Green Energy Investment

Ying Xu, Assistant Professor, Singapore University of Technology and Design, Singapore, Singapore, xu_ying@sutd.edu.sg, Ronghuo Zheng, Nilanjan. Chakraborty, Katia P. Sycara

Motivated by emerging community solar farms, this paper studies a new renewable energy investment model through crowdfunding. We develop a sequential game theory model to capture the interactions among crowdfunders, the solar farm owner, and an electricity company in a multi-period framework. We find that under crowdfunding although the farm owner reduces its investment level, the overall green energy investment level is increased due to the contribution of crowdfunders. We also find that crowdfunding can increase the penetration of green energy in consumption. Finally, the numerical results based on real data indicates crowdfunding is a simple but effective way to boost green generation.

3 - Incentive-based Coordination Mechanism For Backup Renewable Energy Investment

Sadra Babaei, Oklahoma State University, Stillwater, OK, United States, sadra.babaei@okstate.edu, Chaoyue Zhao

Due to the intermittent nature of renewable energy, the renewable energy producers are exposed to high risks in delivering what they have already committed to the energy market. Cooperating with other market participants like conventional energy producers poses a possibility to mitigate this issue. Using stochastic modeling formulation, this paper aims to find optimal bidding strategies that provide incentive for both renewable and conventional power producers to cooperate with each other. Additionally, the trading volume and price between the participants are determined by using Nash game framework. Numerical experiments have been conducted to verify the effectiveness of the model.

4 - Nomination Validation In Gas Grids Under Uncertainty

Ruediger Schultz, University of Duisburg Essen, Thea-Leymann-Str. 9, Essen, D-45127, Germany, ruediger.schultz@uni-due.de

Gas flows in the pipes and pressures at the nodes, both under uncertainty of gas withdrawals from the network (loads) at exit (delivery) nodes are studied. Assuming the uncertainty of withdrawals is stochastic with known distributions, methods for calculating probabilities for the feasibility of load coverage are presented. Emphasis is placed on mildly meshed networks.

Modeling Interdependent Infrastructure Networks

Sponsored: Transportation Science & Logistics

Sponsored Session

Chair: Xiaozhang He, Perdue University, West Lafayette, IN, United States, seanhe@purdue.edu

1 - Algorithm To Identify Intermodal Project Prioritization

Irina Benedyk, Purdue University, West Lafayette, IN, United States, birina@purdue.edu, Srinivas Peeta

We propose intermodal connectivity measures for freight intermodal facilities and develop an algorithm to assist the system-level intermodal facility investment planning process. The intermodal connectivity measures combine spatial data, characteristics of the intermodal facilities and potential demand for intermodal freight transportation. The proposed algorithm helps to identify regions that require intermodal facility development, and can be used for intermodal project prioritization.

2 - Multi-objective Spare Parts Location-inventory Optimization

Hector Vergara, Oregon State University, School of Mechanical, Industrial and, Manufacturing Engineering, Corvallis, OR, 97331, United States, hector.vergara@oregonstate.edu, Prasanna Venkatesh Rajaraman

Facility location-allocation decisions and inventory stocking decisions are very important in spare parts logistics. Both sets of decisions affect service levels by establishing distances between customers and warehouses in facility location-allocation, and by determining the availability of parts in inventory stocking. Integrating location-inventory decisions and considering multiple objectives can help to overcome the sub-optimality of solutions obtained separately. This research formulated this problem as a nonlinear multi-objective model where the objectives are to minimize cost and maximize the service level. An NSGA-II approach is used to obtain Pareto optimal solutions.

3 - Interdiction And Restoration Of Interdependent Infrastructure Systems In Military Operations

Liqun Lu, University of Illinois, Normal, IL, United States, liqunlu2@illinois.edu, Zhaodong Wang, Yanfeng Ouyang

In the modern world with complicated politics and humanitarian concerns, military landpower in the war game is demonstrated by the interdiction on the urban infrastructure systems, which enables the offense .force to take control, as well as the restoration of the systems afterwards. An infrastructure interdependency model is integrated into interdiction-restoration decision-making framework as a two-stage optimization problem.

4 - Critical Component Strengthening Strategies To Enhance The Resilience Of Interdependent Infrastructure Systems

Xiaozheng He, Purdue University, 3000 Kent Ave., West Lafayette, IN, 47906, United States, seanhe@purdue.edu, Chao Zhang, Srinivas Peeta

This study proposes three component strengthening strategies to enhance the resilience of interdependent infrastructure systems, considering the failure propagation within and across the systems. These strategies are developed from structural, functional, and synergistic effect perspectives. Numerical examples are used to investigate the effectiveness of the proposed strategies and provide insights into enhancing the resilience of interdependent infrastructure systems.

5 - Identifying Critical Components Of The Public Transit Network To Mitigate Contagion Episodes

Lauren Gardner, UNSW Australia, Sydney, Australia, l.gardner@unsw.edu.au, András Bota, Alireza Khani

We explore the risk posed by a regional public transit system in the event of an epidemic outbreak. We use metro transit data from Twin Cities, MN, and present a novel network structure to represent the contacts and movement of individuals using the transit system, which can be used to model outbreak behaviour within the region. The model developed is used to identify critical components of the system (e.g., super spreading vehicle-trips), which can be prioritized for monitoring and control during an emerging outbreak.

1 - Green Same Day Package Delivery Service With Real-time Demand

Lin Jane, University of Illinois - Chicago, janelin@uic.edu, Wei Zhou, Lili Du

This study evaluates a green same day delivery (green-SDDS) paradigm for its cost performance by comparing three delivery paradigms: hub-and-spoke, green-SDDS with a commercial fleet, and green-SDDS by crowdsourcing. Hub-and-spoke proves to be cost-effective for traditional distribution service provided by commercial carriers but ill suited for providing same day delivery service. Crowdsourcing provides low cost same day delivery service. Regardless of the delivery paradigm, total cost goes down as the economy of scale increases; and green-SDDS by crowdsourcing would become even more competitive when the demand ratio is very high; however, its fuel consumption and emissions tend to go up.
