PROGRAMME

Basic Clinical Radiobiology

Paris, France

16 - 20 September 2017

Saturday 16 September			
	08:00-09:00	**Registrations**	
	09:00-09:20	Introduction	M. Joiner
	09.20-10.00	1.1 Importance of radiobiology in the clinic	V. Grégoire
	10.00-10.30	1.2 Hallmarks of cancer	M. Koritzinsky
	10.30-11.00	**Coffee break**	
	11.00-11.45	1.3 Molecular basis of cell death	M. Koritzinsky
	11.45-12.30	1.4 Cell survival – in vitro and in vivo	R. Coppes
	12.30-13.00	General discussion	
	13.00-14.00	**Lunch**	
	14.00-14.45	1.5 Models of radiation cell killing	M. Joiner
	14.45-15.45	1.6 Pathogenesis of normal tissue side effects	W. Dörr
	15.45-16.15	**Coffee break**	
	16.15-17.00	1.7 Clinical side effects and their quantification	K. Haustermans

Sunday 17 September			
	09.00-09.45	2.1 The linear-quadratic approach to fractionation	M. Joiner
	09.45-10.30	2.2 Molecular basis of radiation response: DNA repair/checkpoints	M. Koritzinsky
	10.30-11.00	**Coffee break**	
	11.00-11.30	2.3 Normal tissues: radiosensitivity & fractionation	W. Dörr
	11.30-12.30	2.4 Normal tissues: overall treatment time	W. Dörr
	12.30-13.00	General discussion	
	13.00-14.00	**Lunch**	
	14.00-15.00	2.5 Modified fractionation in radiotherapy	V. Grégoire
	15.00-15.45	2.6a The LQ-model in practice – introduction to calculations	M. Joiner
	15:45-16:15	**Coffee break**	
	16.15-17.00	2.6b The LQ-model in practice – examples of calculations	M. Joiner / K. Haustermans
		Social Dinner	

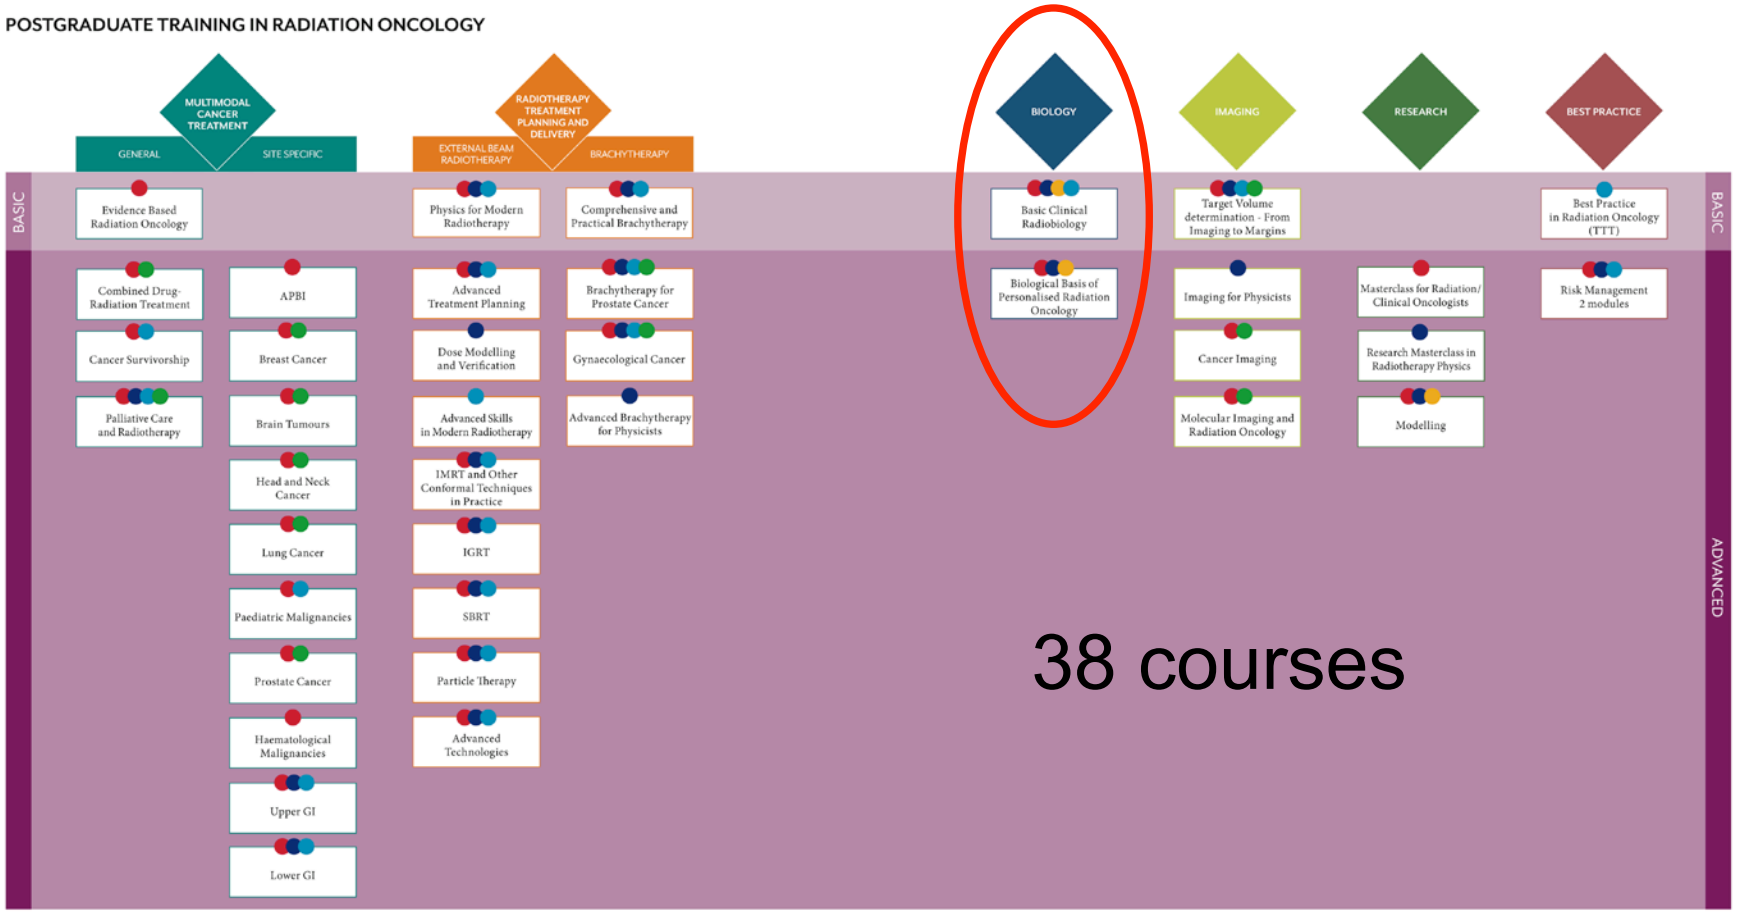
Monday 18 September			
	09.00-09.45	3.1 The volume effect in radiotherapy	W. Dörr
	09.45-10.45	3.2 The oxygen effect, hypoxia and the tumor microenvironment	M. Koritzinsky
	10.45-11.15	**Coffee break**	
	11.15-12.30	3.3 Clinical efforts to modify tumor hypoxia	K. Haustermans
	12.30-13.00	General discussion	
	13.00-14.00	**Lunch**	
	14.00-14.45	3.4 Dose-response relationships in radiotherapy	M. Joiner
	14.45-15.30	3.5 LET and RBE	M. Joiner
	15.30-16.00	**Coffee break**	
	16.00-17.30	3.6 Clinical examples – Lower GU	K. Haustermans / V. Grégoire

Tuesday 19 September			
	09.00-09.45	4.1 Biological response modifiers in tumours – preclinical	M. Koritzinsky
	09.45-10.30	4.2 Biological response modifiers in tumours – clinical	K. Haustermans
	10.30-11.00	**Coffee break**	
	11.00-11.45	4.3 Biological modifiers of normal tissue effects	R. Coppes
	11.45-12.30	4.4 Combined radiotherapy and chemotherapy	V. Grégoire
	12.30-13.00	General discussion	
	13.00-14.00	**Lunch**	
	14.00-14.45	4.5 Retreatment tolerance of normal tissues	R. Coppes
	14.45-15.30	4.6 Biological image guided radiotherapy	V. Grégoire
	15.30-16.00	**Coffee break**	
	16.00-17.30	4.7 Clinical examples – Head & Neck and Lung	V. Grégoire / K. Haustermans

Wednesday 20 September			
	09.00-09.45	5.1 Tumor growth and response to irradiation	K. Haustermans
	09.45-10.30	5.2 The dose-rate effect	R. Coppes
	10.30-11.00	**Coffee break**	
	11.00-11.45	5.3 Particles in radiotherapy	V. Grégoire
	11.45-12.30	5.4 Radiation-induced malignancies	M. Joiner
	12:30-13:00	Course evaluation and certificates	

39th ESTRO teaching course on
Basic Clinical Radiobiology
Paris, France
September 2017

2017 Roadmap to Teaching Courses



38 courses

ESTRO
European Society for
RADIOTHERAPY
& ONCOLOGY

ESTRO School

Biology Courses

- RADIATION ONCOLOGIST
- MEDICAL PHYSICIST
- RADIOBIOLOGIST
- RADIATION THERAPIST

Basic

Advanced

Basic Clinical Radiobiology Locations

1.	Granada, Spain	16 – 20 November	1990
2.	Athens, Greece	5 – 9 October	1991
3.	Aarhus, Denmark	18 – 22 October	1992
4.	Tours, France	26 – 30 September	1993
5.	Prague, Czech Republic	16 – 20 October	1994
6.	Tübingen, Germany	24 – 28 September	1995
7.	Izmir, Turkey	24 – 28 November	1996
8.	Como, Italy	12 – 16 October	1997
9.	Lisboa, Portugal	25 – 29 October	1998
10.	Gdansk, Poland	17 – 21 October	1999
11.	Bratislava, Slovakia	8 – 12 October	2000
12.	Tenerife, Spain	7 – 11 October	2001
13.	St. Petersburg, Russia	25 – 29 August	2002
14.	Uppsala, Sweden	5 – 9 May	2002
15.	Santorini, Greece	12 – 16 October	2003
16.	Lausanne, Switzerland	19 – 23 September	2004
17.	Izmir, Turkey	2 – 6 October	2005
18.	Ljubljana, Slovenia	21 – 25 May	2006
19.	Lisboa, Portugal	17 – 21 September	2006
20.	Beijing, China	3 – 7 June	2007
21.	Sicily, Italy	14 – 18 October	2007

Where, *When* do we teach BCR most?

Where

Three: Spain, Greece, Turkey, Australia, China

Two: Portugal, Italy, Czech Republic, Poland, Russia, France

When

Three: 2009 (Spain, China, Australia)

Two: 2002, 2006, 2007, 2008, 2010, 2011, 2013, 2015, 2016

Here we are again! (after 24 years…)

Two: France

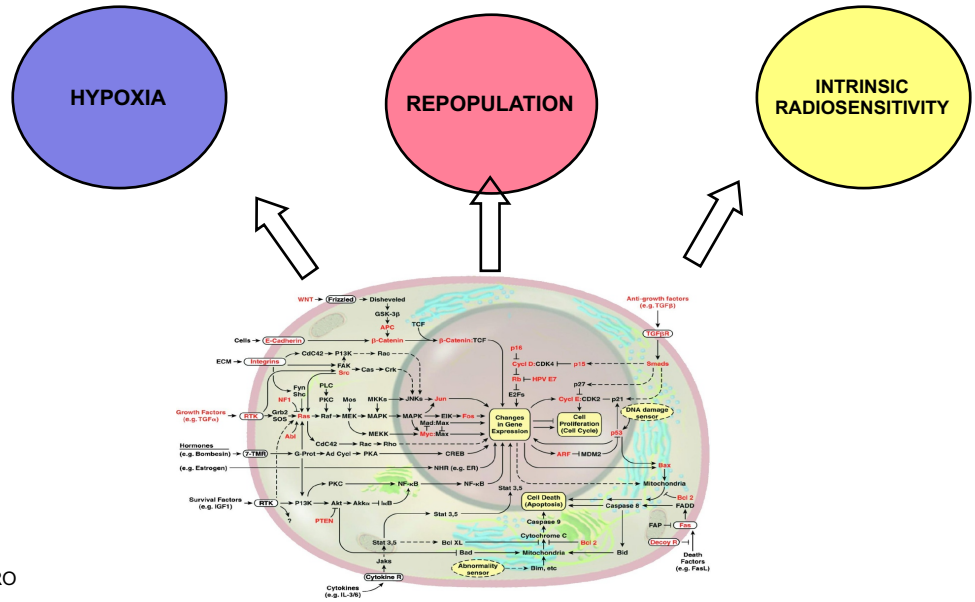
Target pathways that influence radiotherapy



ESTRO 2017

Therapeutic interventions

- Modification of dose fractionation
- Modification of overall treatment time
- Combined modalities (chemo, biological modifiers)
- Non-conventional radiation beams
- Functional Image-guided IMRT
- …

ESTRO 2017

Yes… but in my daily practice…

Mr John Drinker (56 years old) from Hopeless city:

- History of hypopharyngeal SCC 1 year ago
- RxTh (70 Gy) with concomitant cddp (100 mg/m^2)
- Diagnosed with upper esophageal SCC

Treatment with RT? If so, how and which dose?

ESTRO 2017

Yes… but in my daily practice…

Mrs Julia BadGene (35 years old):

- Her son died with AT at the age of 15
- Diagnosed with left breast cancer (pT2-pN0-M0)
- Treatment should include breast radiotherapy

Risk of RT-induced late normal tissue toxicity? Dose reduction? Special RT technique?

ESTRO 2017

Yes… but in my daily practice…

Julia Freud (11 years old girl) from Vienna:

- Diagnosed with pelvic rhabdomyosarcoma
- 3 courses of chemotherapy
- Pelvic radiotherapy is planned

Risk of RT-induced secondary cancer? Benefit of hadrons therapy (protons or carbon ions)?

ESTRO 2017

Yes… but in my daily practice…

Mr David PSA (82 years old) from Paris:

- Diagnosed with prostate adenocarcinoma (Gleason 8) T2-N0-M0
- Prostate radiotherapy is proposed (78 Gy, 2.5 Gy/f)
- After 2 weeks, he has to travel to South Africa for unforeseen reason, thus a week break!

Probability of lower efficacy? RT dose adaptation? How?

ESTRO 2017

The Hallmarks of Cancer

Marianne Koritzinsky

Princess Margaret Cancer Centre
Toronto, Canada
Marianne.Koritzinsky@uhnresearch.ca

Radiobiology

- The response to radiation is different in normal tissues and cancer:
  - at the cellular level
  - at the tissue level

- These differences are due to the underlying biological properties of different tissues and cancers

Tumor Radiobiology

Fact: We deliver a known physical dose with a high degree of accuracy to similar tumors

Observation: The radiocurability of tumors varies widely

Aim: Understand the biological factors that influence the sensitivity of tumors and normal tissues to radiation

What is Cancer?

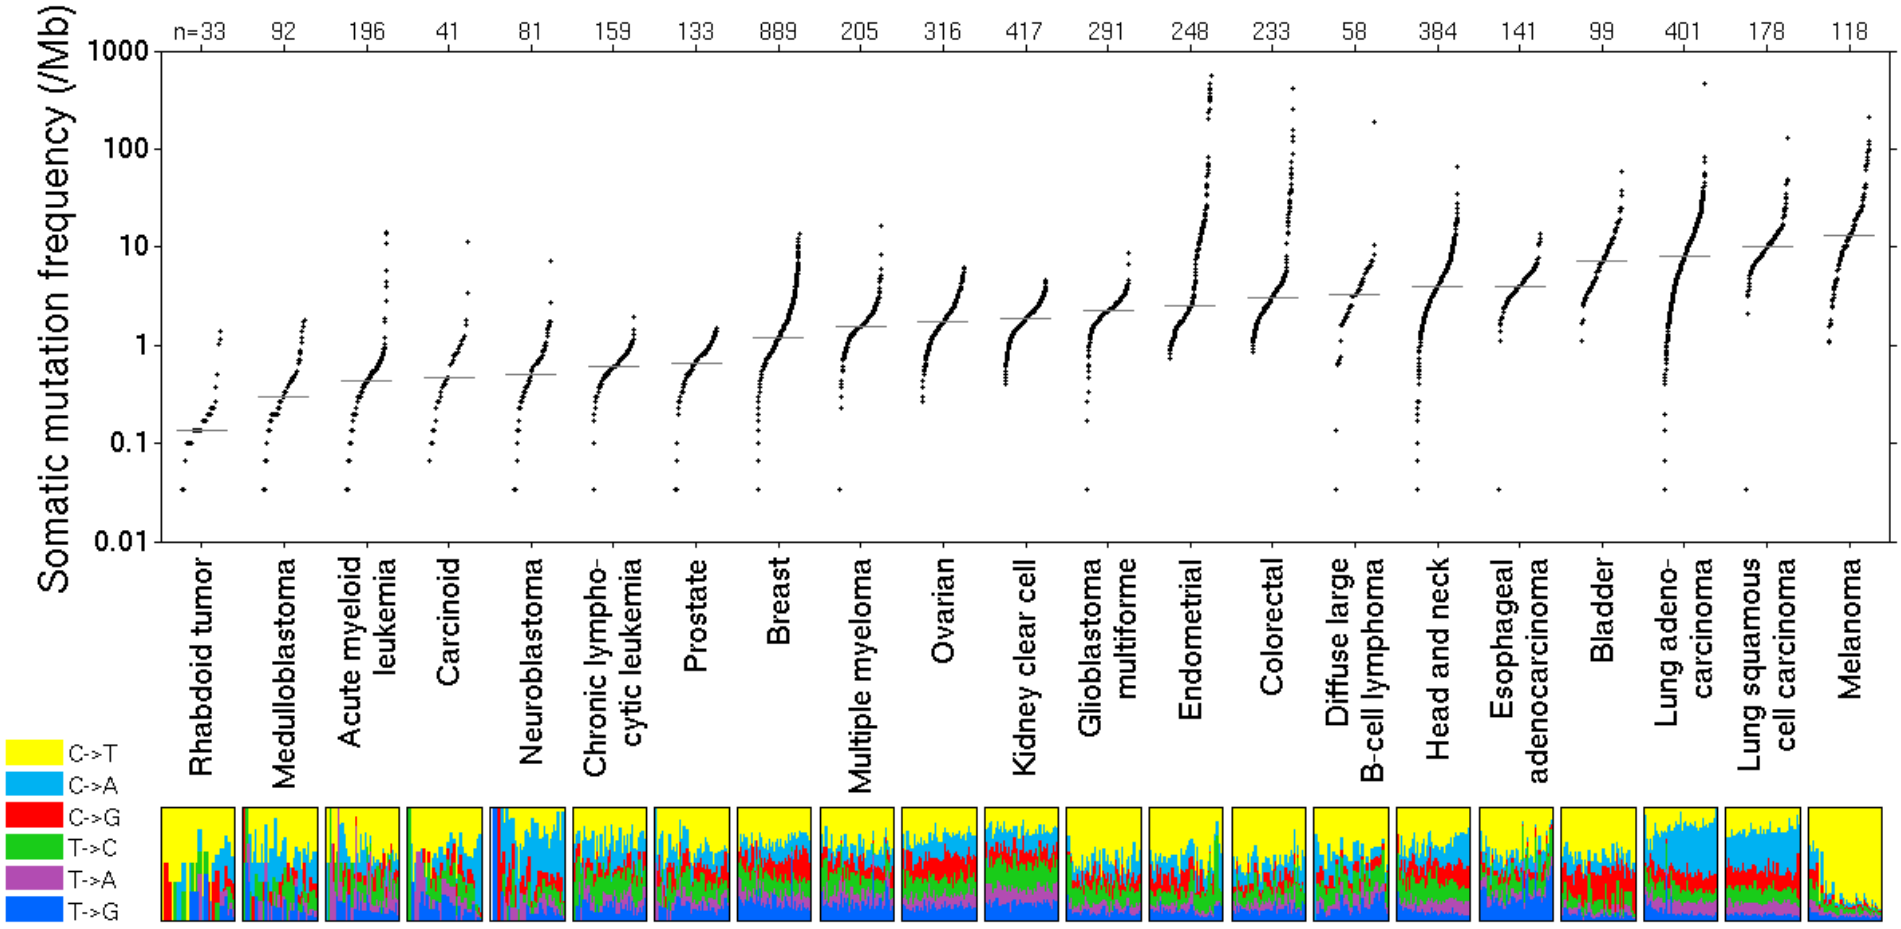
Cancer – Important Concepts

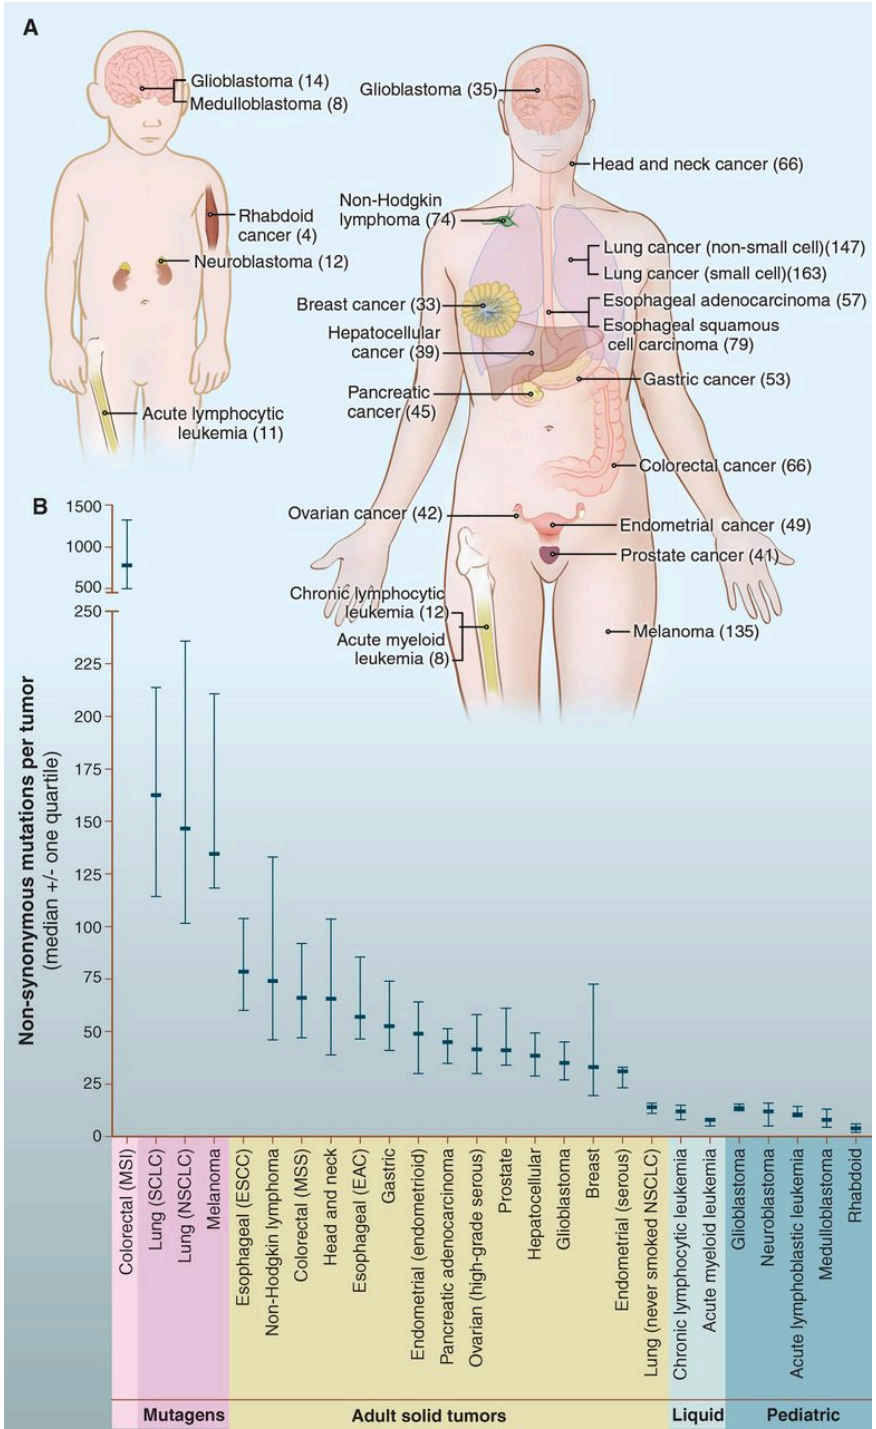
- Cancer cells are derived from normal cells in the body
- Cancer cells have acquired a series of changes which distinguishes them from normal cells.
  - These changes are the basis for much of the difference in the ways tumors respond to radiation compared to normal tissues
- There are multiple ways of creating cancer
  - This can explain why even tumors of the same type can differ dramatically in how they response to radiation

Cancer is a genetic disease

- Disease involving changes in the genome
  - point mutations
  - gene amplification
  - chromosome instability
  - deletions, silencing
- 2 classes of cancer genes:
  - Oncogenes
  - Tumor suppressors
- “Driving” mutation:
  - Confers growth advantage
  - Causative of cancer
- “Passenger” mutation:
  - No growth advantage
  - No causative role in cancer

Cancer Analysis - TCGA

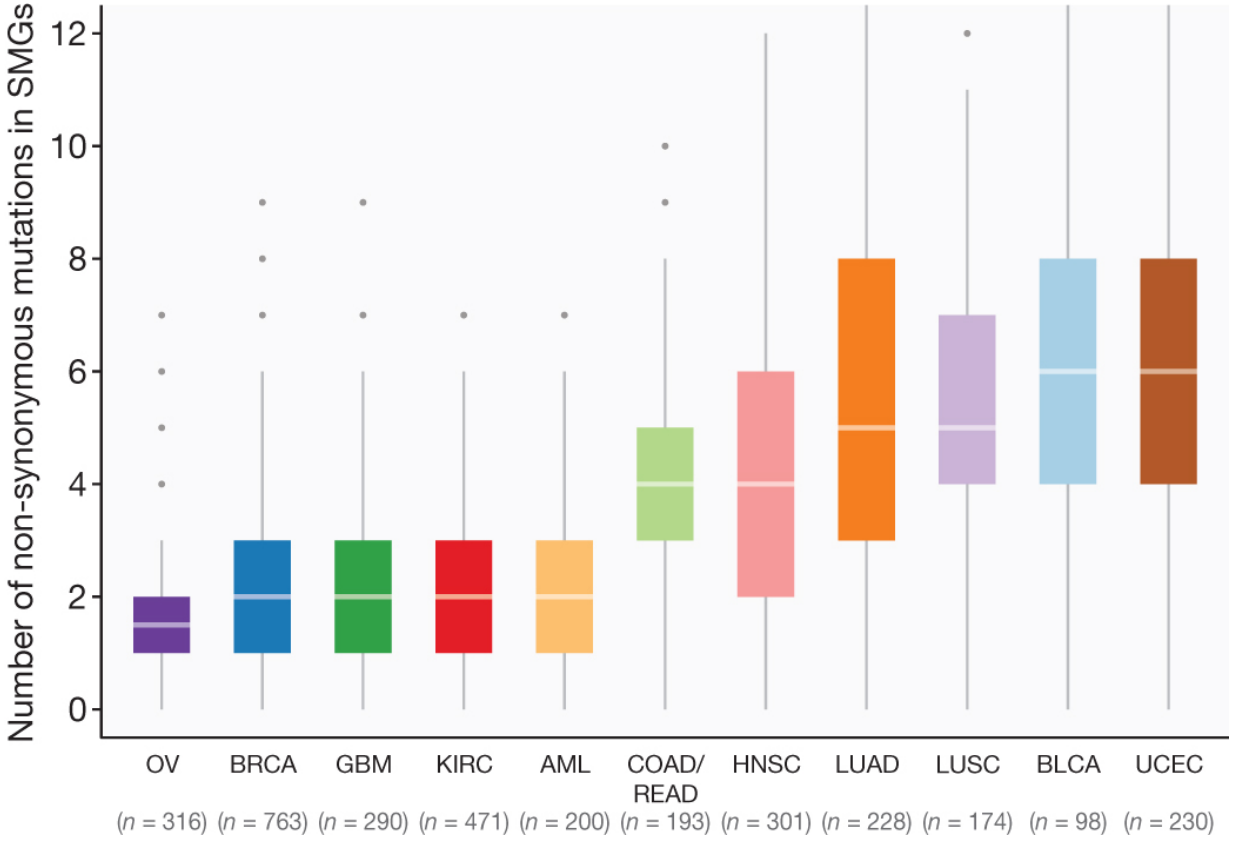




B Vogelstein et al. Science 2013;339:1546-1558

Identifying Drivers

Distribution of mutations in 127 SMGs across Pan-Cancer cohort.



•C Kandoth *et al. Nature* **502**, 333-339 (2013) doi:10.1038/nature12634

nature

Summary

- Most cancers contain mutations in 2-8 commonly mutated cancer genes
- Many cancers have additional but rare cancer genes
- Much larger background of passenger mutations
- Passenger mutations increase with age

Pathways in Human Cancer

This poster summarizes some of the key signaling pathways implicated in tumorigenesis and tumor progression in humans. Within each pathway, gene products known to be mutated in human tumors - oncogenes and tumor suppressor genes - have been color-coded. The most common types of genetic alterations and conferred capabilities to the tumor are also appended for these gene products. Proteins are shown using a structural representative (see structural legend). Since not all known pathways or proteins could be included, we regret not being able to show the work of many, and refer the viewer to the textbook *The Biology of Cancer* by Robert A. Weinberg for an in-depth treatment of this material and references.

Cell PRESS

Conclusions

- Cancer is caused by a series (~2-8) changes in the genome
  - Additional ~10^3 passenger genetic alterations
- The changes which occur can be classified, giving rise to 6 essential acquired properties, 2 emerging properties and 2 enabling properties
- The hallmarks of cancer can be arrived at by many different genetic routes
  - As a result tumors are very heterogeneous. For each ‘type’ of cancer there are several genetic routes
- These hallmarks (and accompanying genetic alterations) affect treatment and radiation sensitivity in complex ways.
  - Understanding the molecular basis of cancer is important to understand radiation responses

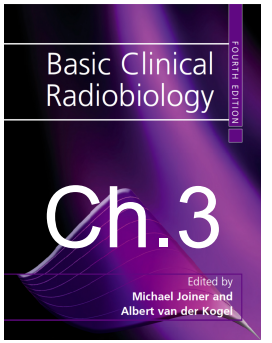
Molecular Basis of Cell Death

Marianne Koritzinsky

Princess Margaret Cancer Centre
Toronto, Canada
Marianne Koritzinsky@uhnresearch.ca



What do we mean by cell death?

- Cell death
  - Loss of reproductive (clonogenic) capacity
  - Cell may or may not appear dead
  - Cells are unable to contribute to tumor growth or metastasis – goal of treatment

- For normal cells, this definition may not be relevant
  - Has no meaning for non-dividing cells
  - Different definitions may be better

How do cells die?

Type of death	Morphology			Biochemistry	Detection
	Nucleus	Membrane	Cytoplasm		
Apoptosis (Programmed I)	Chromatin condensation Nuclear fragmentation DNA laddering	Blebbing	Fragmentation (Apoptotic bodies)	Caspase-dependent	Electron microscopy TUNEL DNA fragmentation Mitochondrial membrane potential Caspase activity
Autophagy (Programmed II)	Partial chromatin condensation	Blebbing	Autophagic vesicles	Lysosomal activity	Electron microscopy Protein degradation Autophagosome membrane markers
Necrosis (Programmed III)	Random DNA fragmentation DNA clumping	Rupture	Swelling Vacuolation Organelle degeneration Mitochondrial swelling		Electron microscopy Nuclear staining (loss) Tissue inflammation
Senescence	Heterochromatic foci		Flattening Granularity	SA-β-gal activity	Electron microscopy SA-β-gal staining Proliferation, P-pRB (loss) p53, INK4A, ARF (increased)

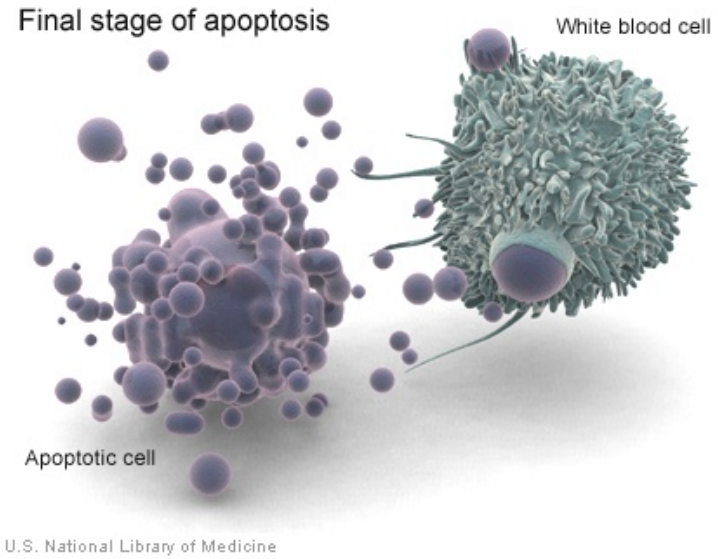
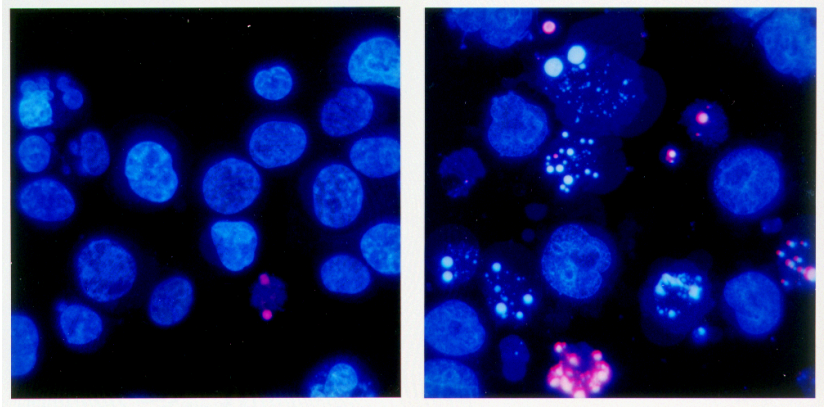
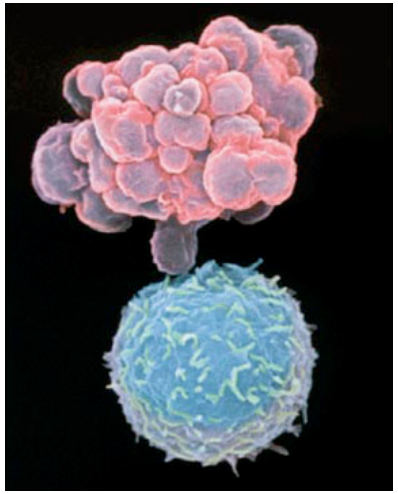
Apoptosis



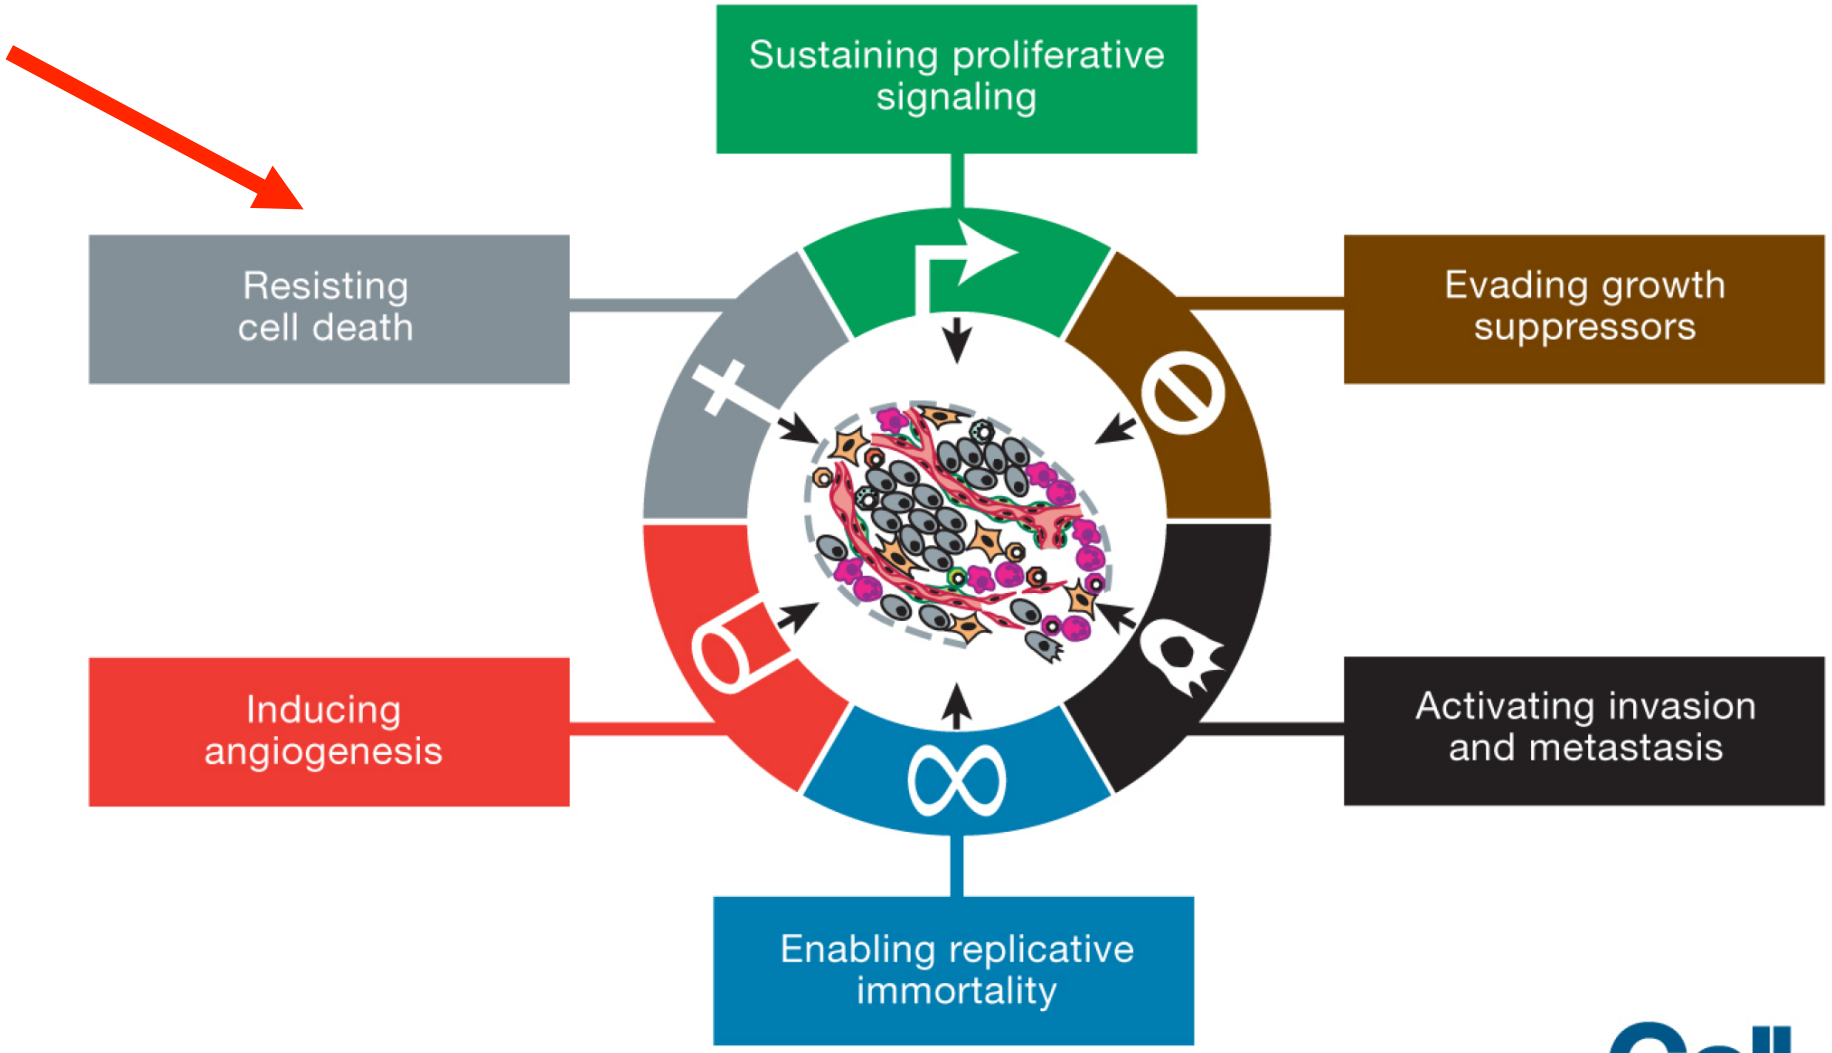
U.S. National Library of Medicine

- Active (programmed) form of cell death
- A decision to die is made





The 6 Hallmarks of Cancer



Hanahan and Weinberg, 2011

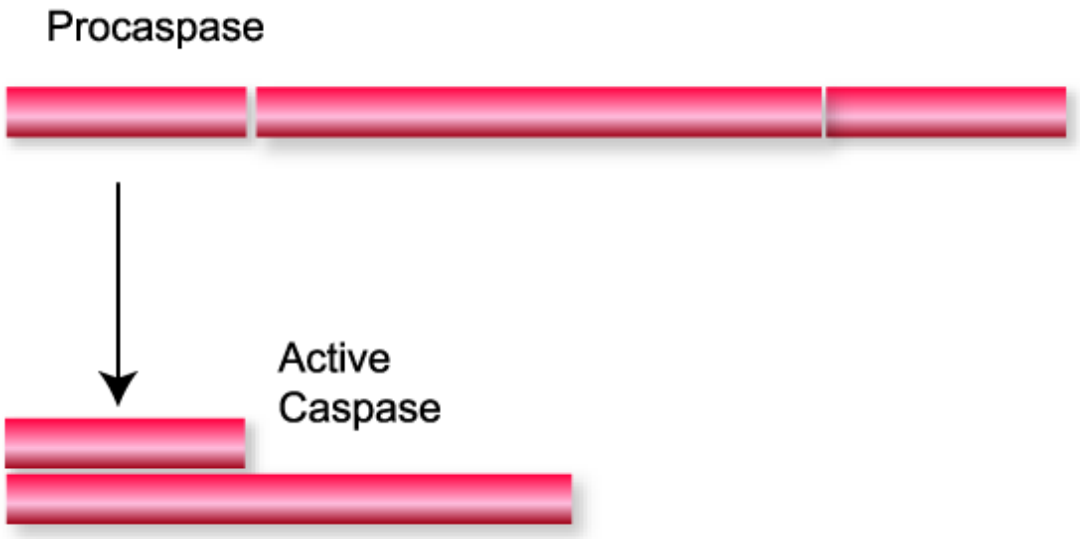
Cell PRESS

Apoptotic Machinery

- Sensors
  - Monitor extracellular (extrinsic pathway) and intracellular (intrinsic pathway) environment for conditions of normality and abnormality e.g. hypoxia, growth factors, damage

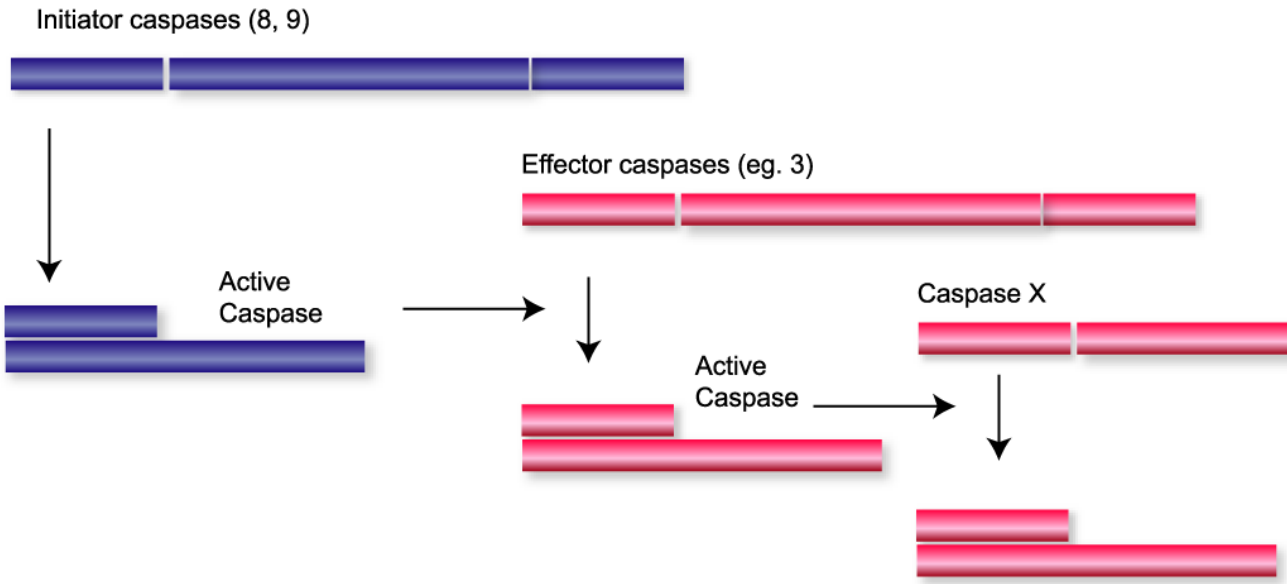
- Effectors
  - Intracellular proteases called caspases

Effectors: Caspases



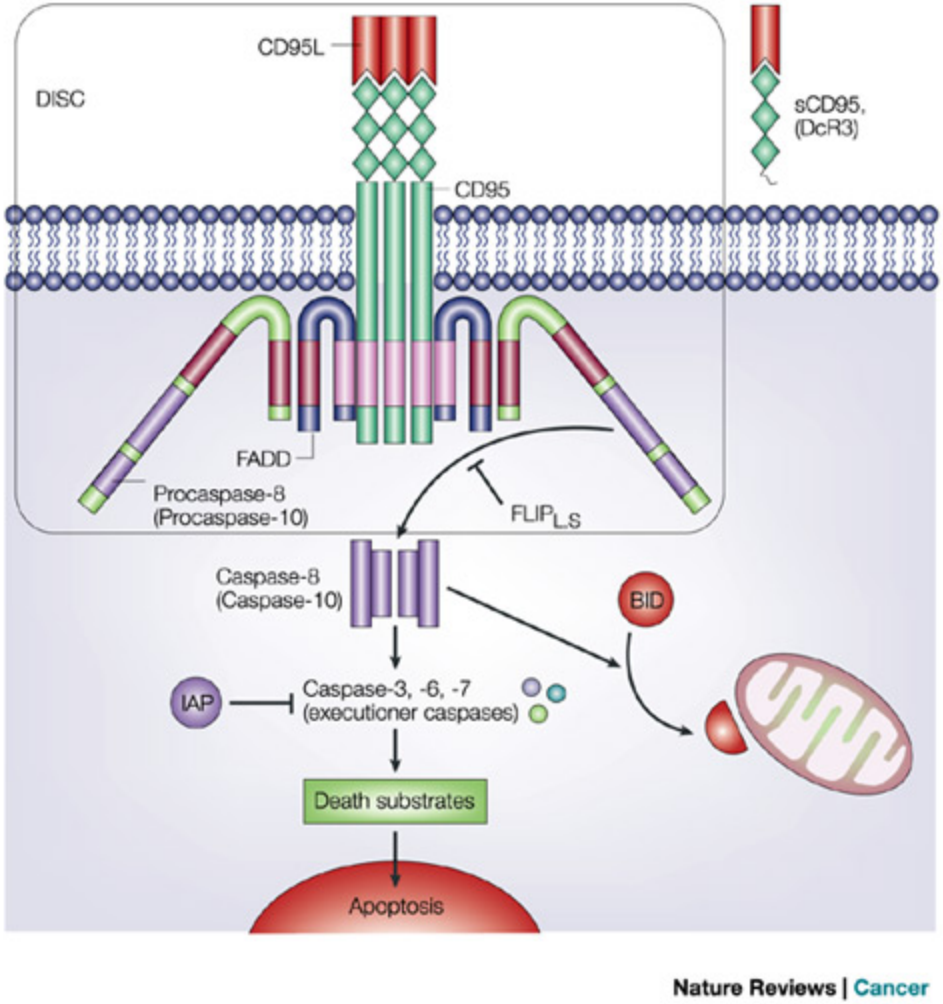
- Executioners of apoptosis
- Cleave proteins at certain sites
- Disassemble the cell
- Present in a pro-form (inactive)

Caspase cascade



Irreversible “switch” for cell death

Extrinsic Pathway – Death Receptors

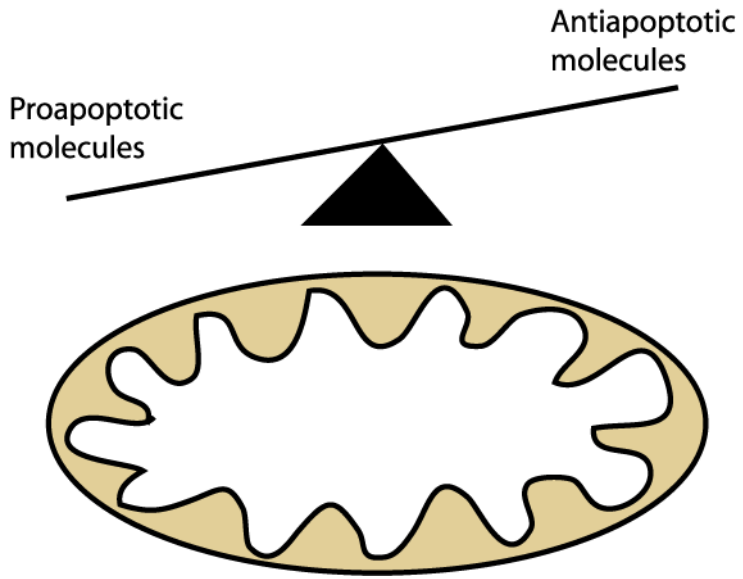


Extrinsic – caspase 8
– signal given to the cell

Receptors	Ligands
TRAILR1, TRAILR2	TRAIL
TNFR1	TNF
FAS	FASL

Intrinsic Pathway – Mitochondria dependent

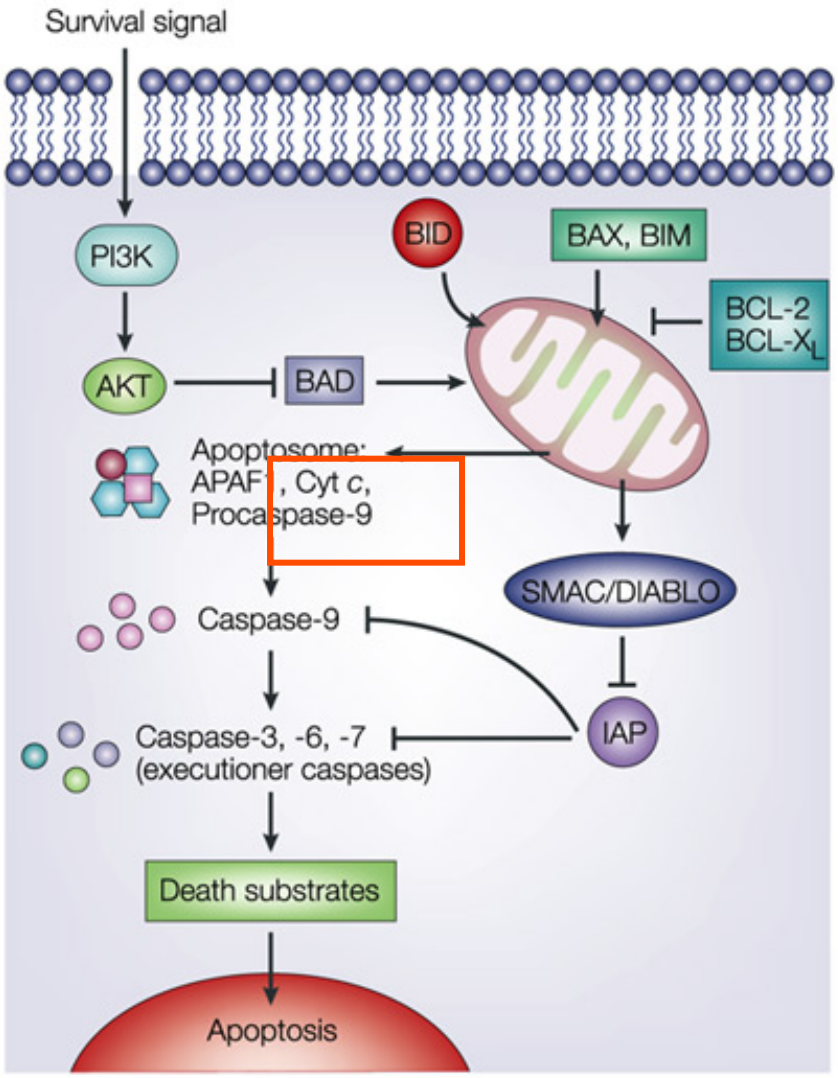
- Mitochondria induce apoptosis when pro-apoptotic factors outnumber anti-apoptotic factors



Step 1)

Increase in the balance of proapoptotic to antiapoptotic factors (Bax/Bcl2)

Intrinsic Pathway



Nature Reviews | Cancer

Mitochondria :

Storage site for apoptosis regulating molecules

Step 2) Release of cytochrome C, formation of apoptosome

Step 3) Activation of caspase 9

How do cells die?

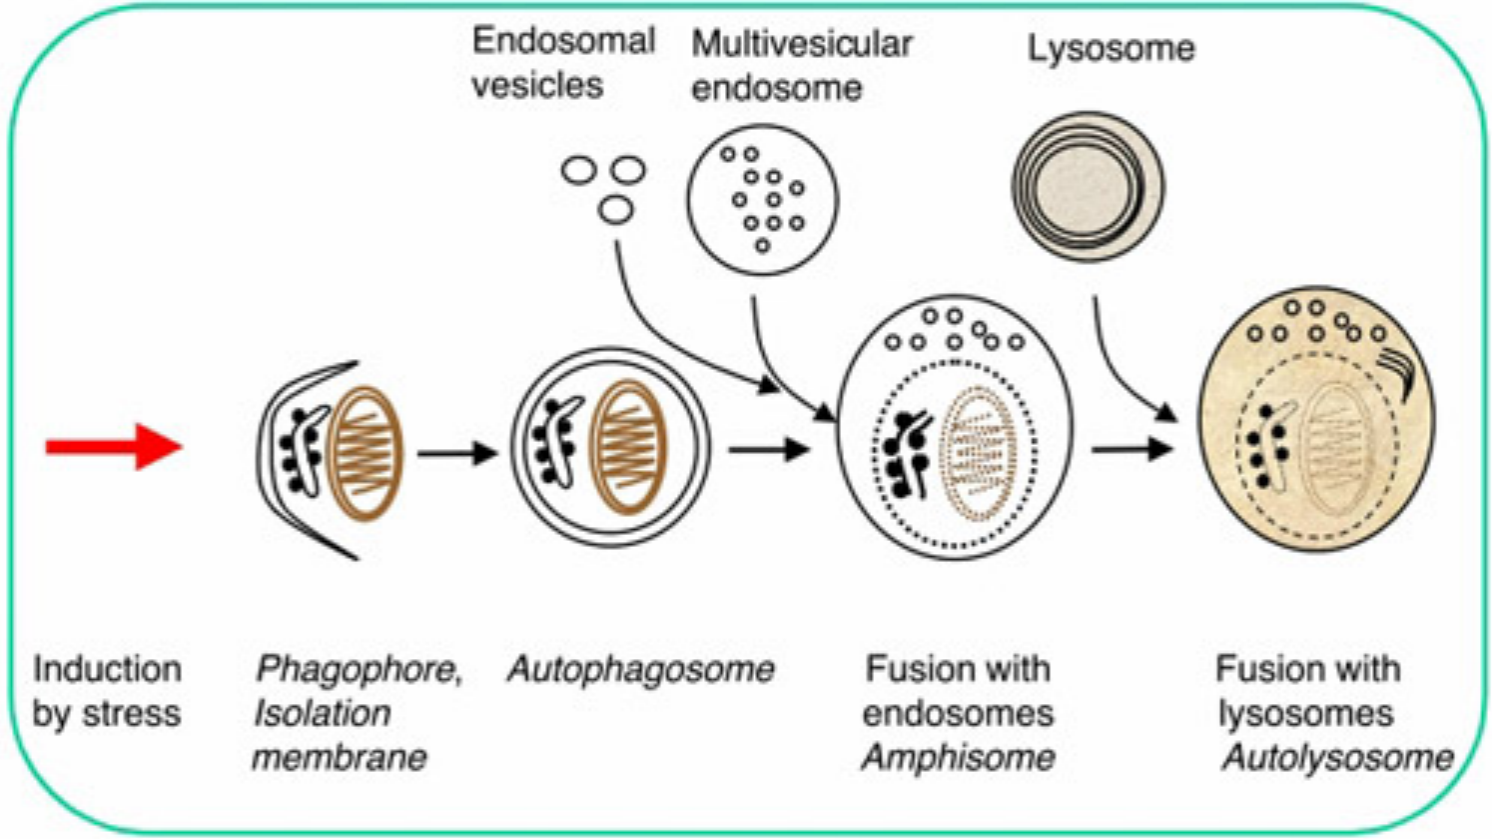
Type of death	Morphology			Biochemistry	Detection
	Nucleus	Membrane	Cytoplasm		
Apoptosis (Programmed I)	Chromatin condensation Nuclear fragmentation DNA laddering	Blebbing	Fragmentation (Apoptotic bodies)	Caspase-dependent	Electron microscopy TUNEL DNA fragmentation Mitochondrial membrane potential Caspase activity
Autophagy (Programmed II)	Partial chromatin condensation	Blebbing	Autophagic vesicles	Lysosomal activity	Electron microscopy Protein degradation Autophagosome membrane markers
Necrosis (Programmed III)	Random DNA fragmentation DNA clumping	Rupture	Swelling Vacuolation Organelle degeneration Mitochondrial swelling		Electron microscopy Nuclear staining (loss) Tissue inflammation
Senescence	Heterochromatic foci		Flattening Granularity	SA-β-gal activity	Electron microscopy SA-β-gal staining Proliferation, P-pRB (loss) p53, INK4A, ARF (increased)
Mitotic catastrophe	Micronuclei Nuclear fragmentation			CDK1/cyclinB activation	Electron microscopy Mitotic markers (MPM2)

Autophagy

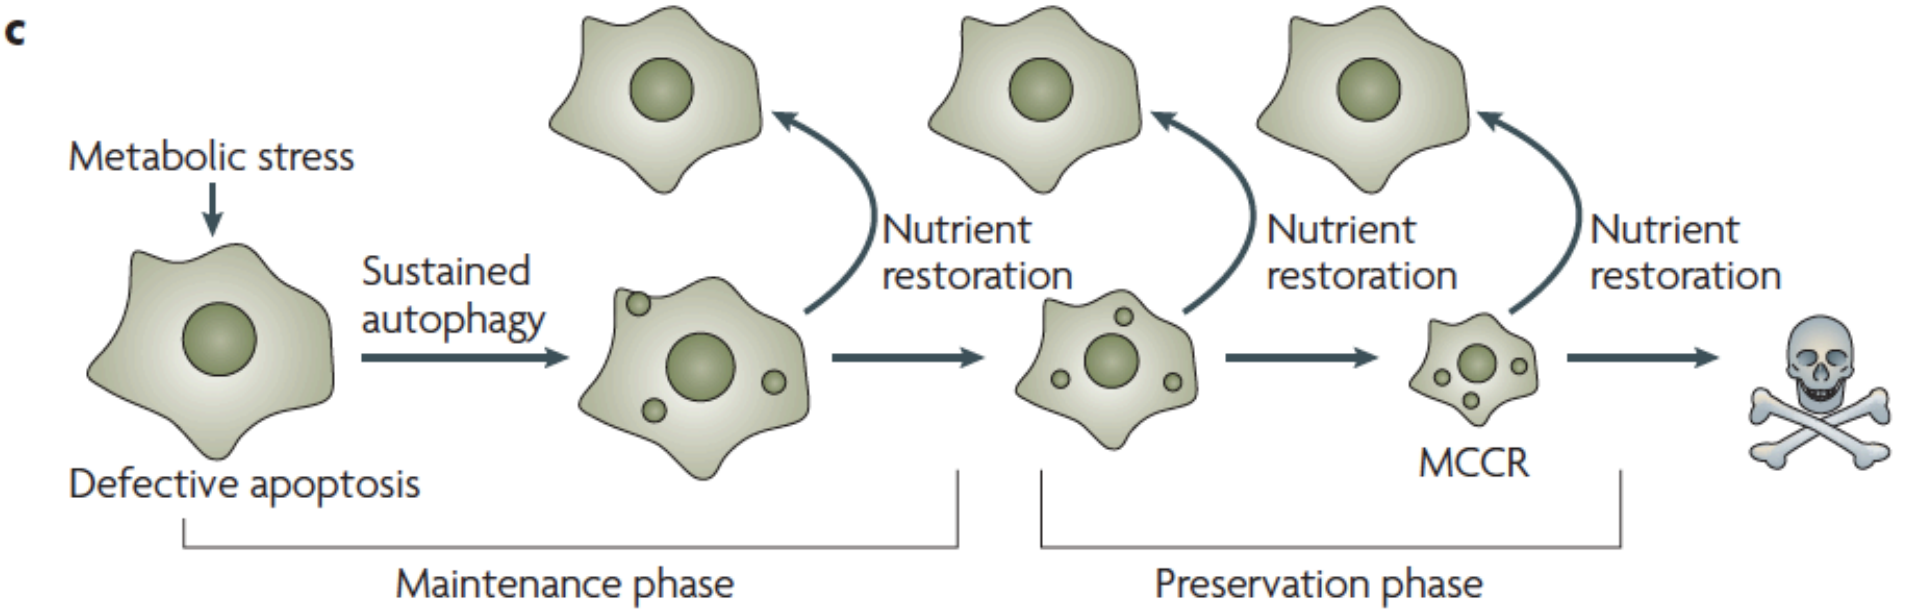
- Important survival mechanism during short-term starvation
  - Degradation of non-essential cell components by lysosomal hydrolases
  - Degradation products are transported back to cytoplasm for reuse in metabolism

- Important mechanism for quality control
  - Removal of defective organelles, proteins

Autophagy –to eat oneself



Autophagy – Survival or Death?

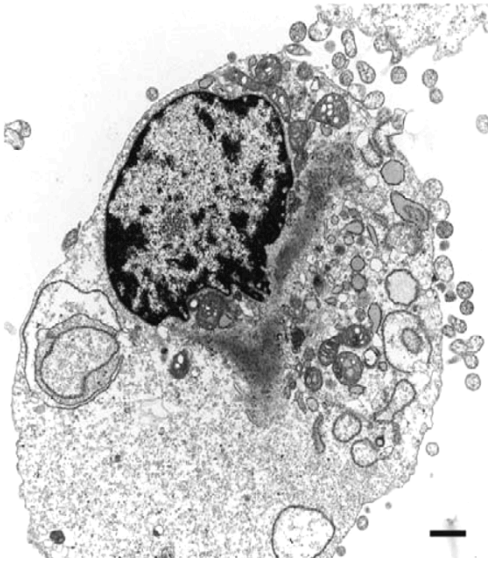


How do cells die?

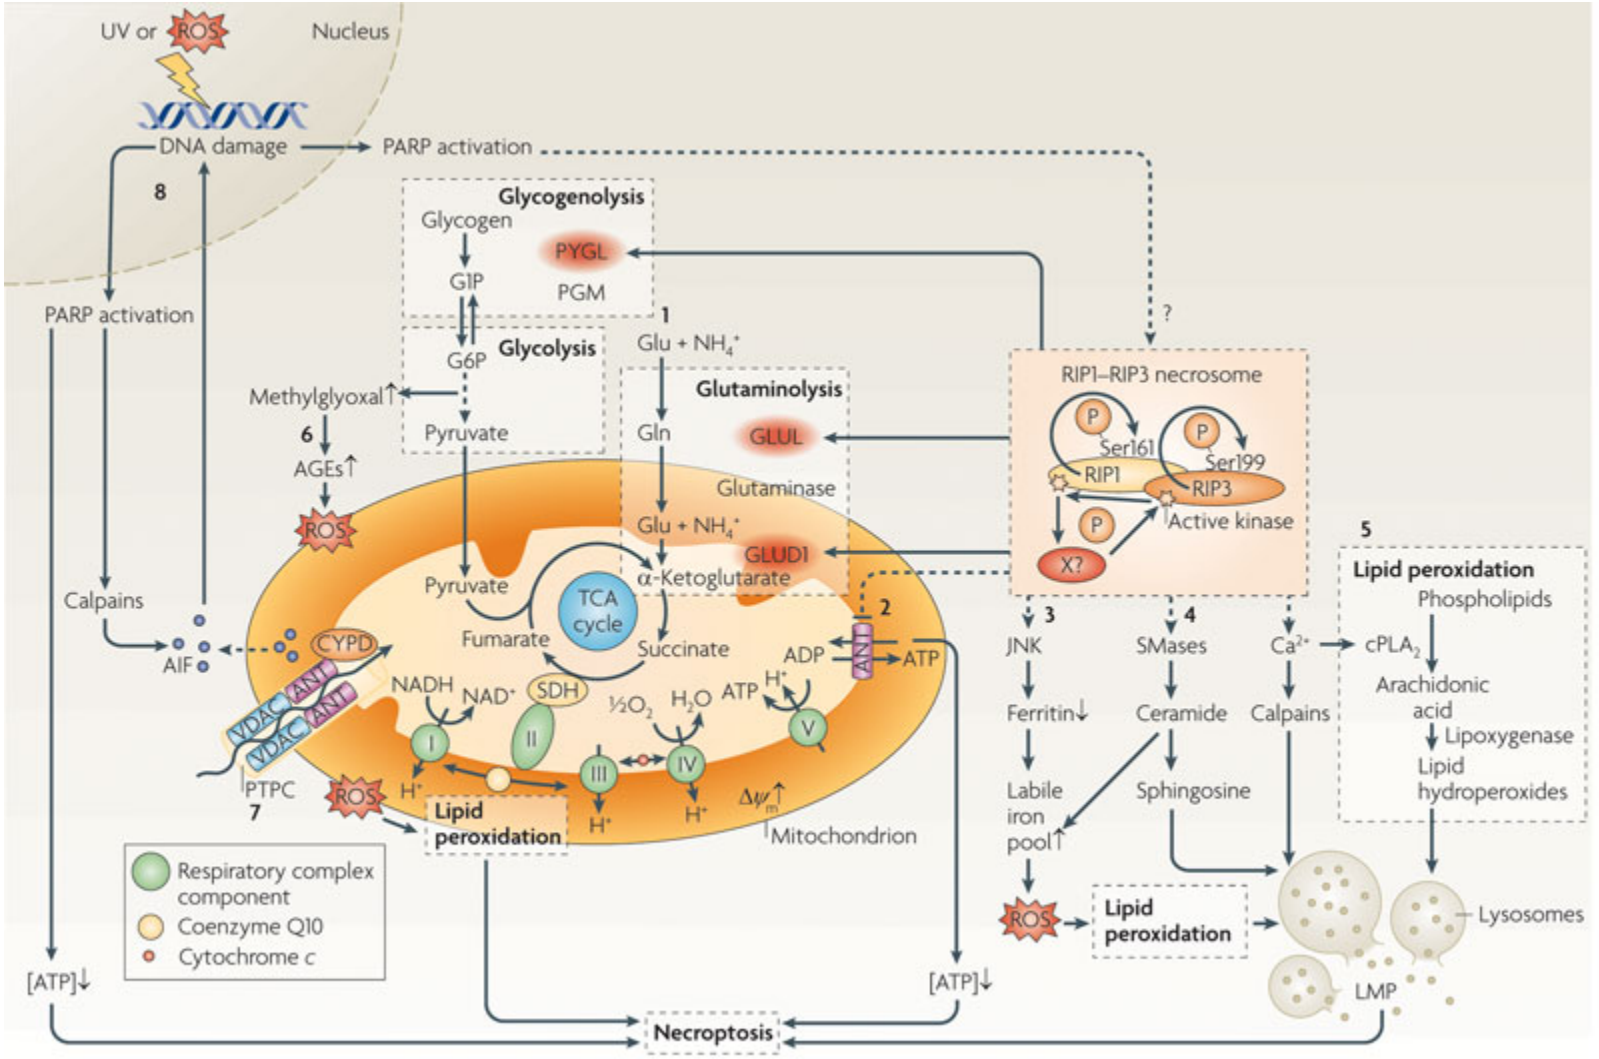
Type of death	Morphology			Biochemistry	Detection
	Nucleus	Membrane	Cytoplasm		
Apoptosis (Programmed I)	Chromatin condensation Nuclear fragmentation DNA laddering	Blebbing	Fragmentation (Apoptotic bodies)	Caspase-dependent	Electron microscopy TUNEL DNA fragmentation Mitochondrial membrane potential Caspase activity
Autophagy (Programmed II)	Partial chromatin condensation	Blebbing	Autophagic vesicles	Lysosomal activity	Electron microscopy Protein degradation Autophagosome membrane markers
Necrosis (Programmed III)	Random DNA fragmentation DNA clumping	Rupture	Swelling Vacuolation Organelle degeneration Mitochondrial swelling		Electron microscopy Nuclear staining (loss) Tissue inflammation
Senescence	Heterochromatic foci		Flattening Granularity	SA-β-gal activity	Electron microscopy SA-β-gal staining Proliferation, P-pRB (loss) p53, INK4A, ARF (increased)
Mitotic catastrophe	Micronuclei Nuclear fragmentation			CDK1/cyclinB activation	Electron microscopy Mitotic markers (MPM2)

Necrosis

- Insults inducing necrosis
  - Defective membrane potential
  - Cellular energy depletion
  - Nutrient starvation
  - Damage to membrane lipids
  - Loss of function of ion channels/pumps



Execution of necroptosis



Nature Reviews | Molecular Cell Biology

How do cells die?

Type of death	Morphology			Biochemistry	Detection
	Nucleus	Membrane	Cytoplasm		
Apoptosis (Programmed I)	Chromatin condensation Nuclear fragmentation DNA laddering	Blebbing	Fragmentation (Apoptotic bodies)	Caspase-dependent	Electron microscopy TUNEL DNA fragmentation Mitochondrial membrane potential Caspase activity

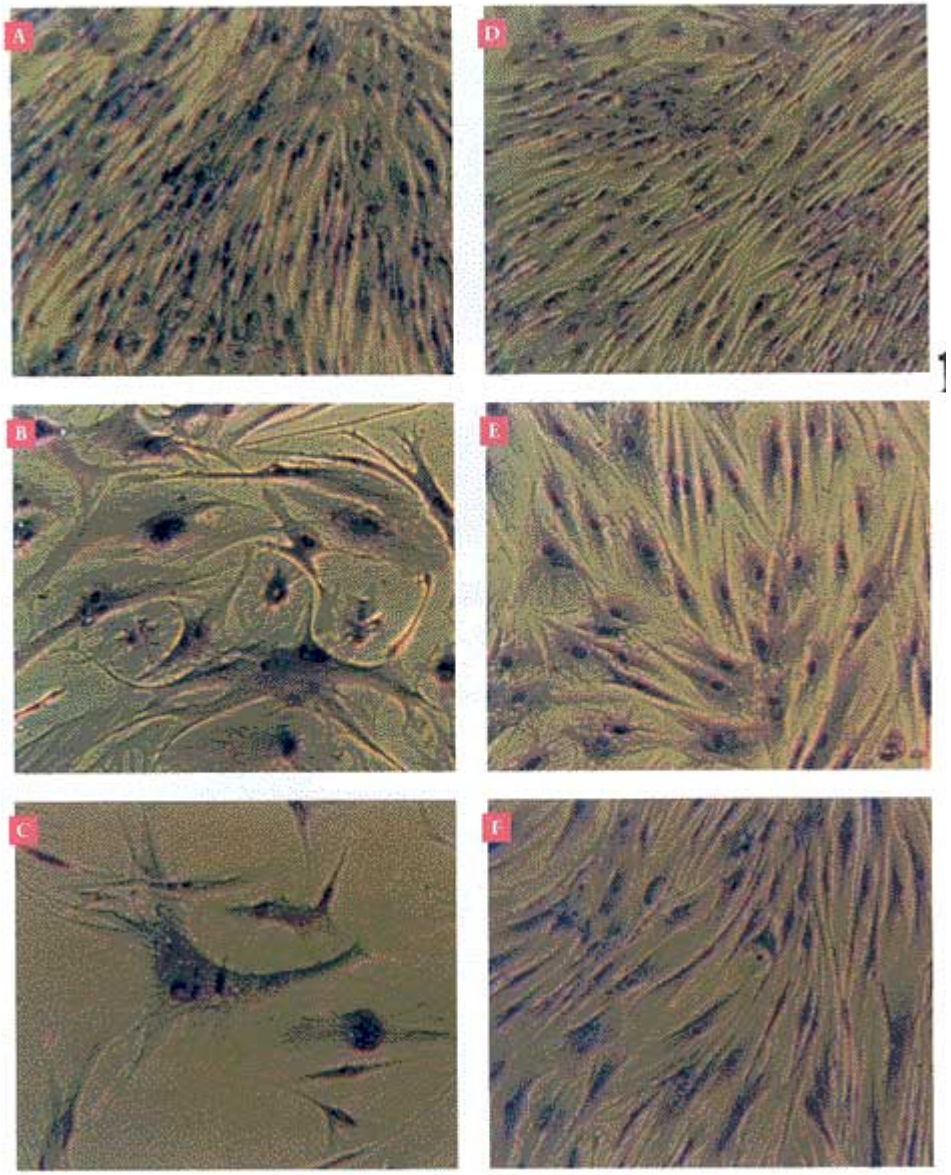
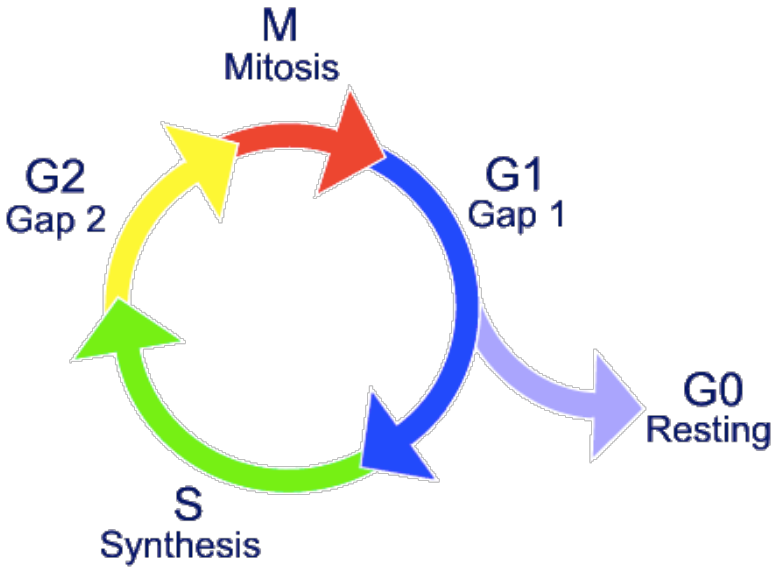
Senescence	Heterochromatic foci		Flattening Granularity	SA-β-gal activity	Electron microscopy SA-β-gal staining Proliferation, P-pRB (loss) p53, INK4A, ARF (increased)
Mitotic catastrophe	Micronuclei Nuclear fragmentation			CDK1/cyclinB activation	Electron microscopy Mitotic markers (MPM2)

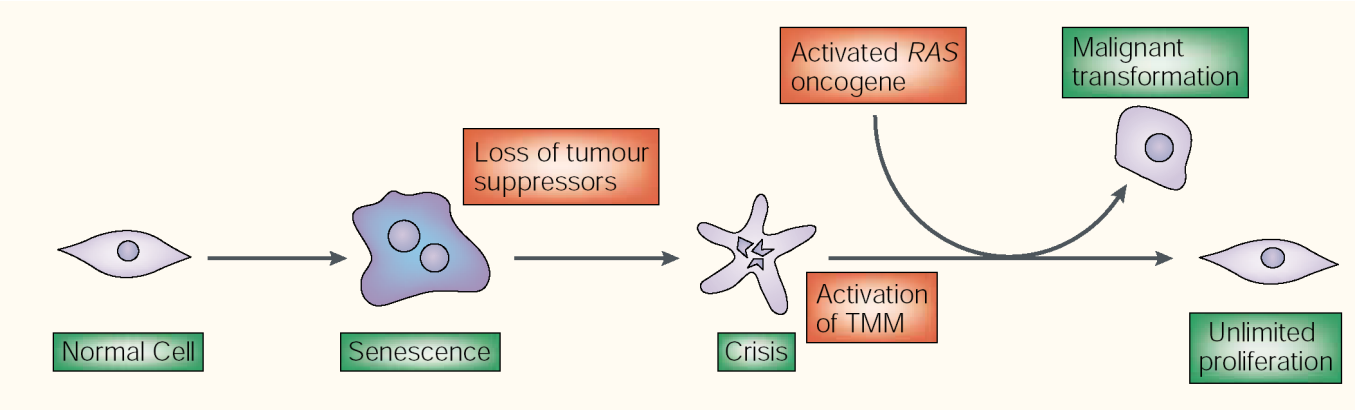
Senescence - Permanent loss of proliferative capacity





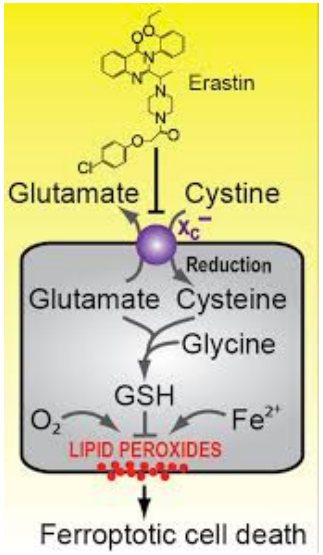
Senescence

- Associated with aging
  - Telomere shortening can induce senescence
  - Limits proliferation in normal cells
- Accelerated senescence
  - Induced by oncogenes, DNA damage
- Genes involved in the G1 checkpoint are important
  -

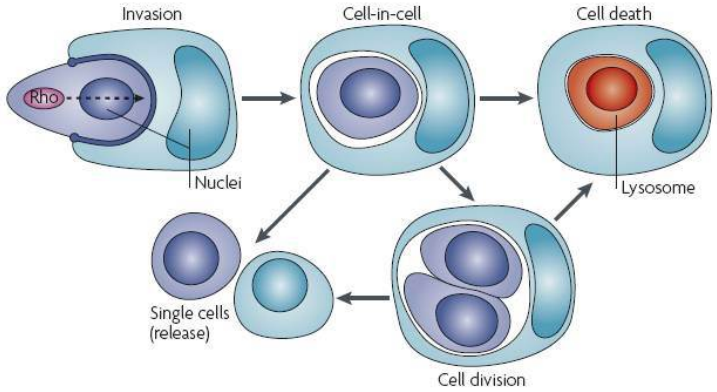


Other forms of cell death (emerging)

- Ferroptosis
  - Iron linked death caused by ROS



- Entosis
  - Cell engulfment



How do cells die?

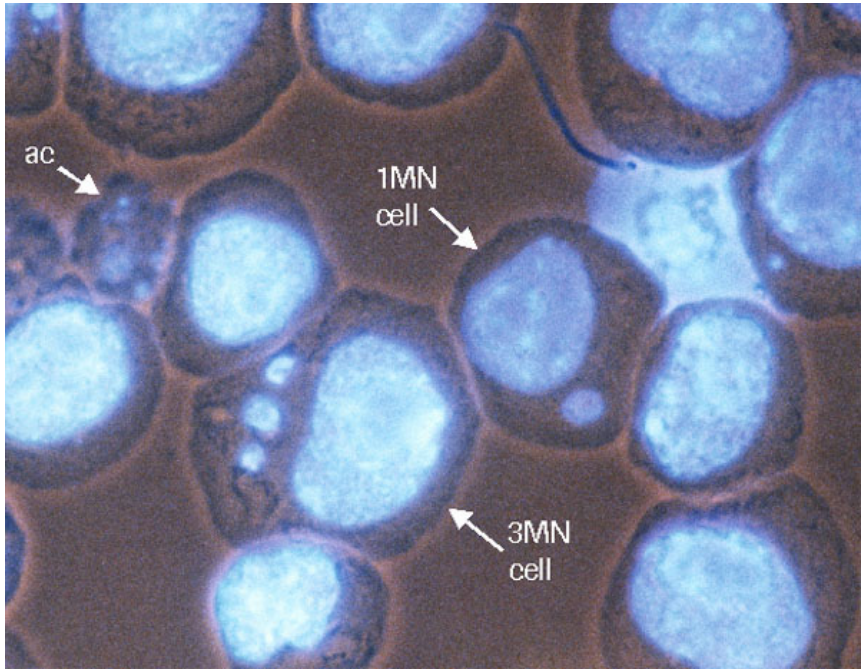
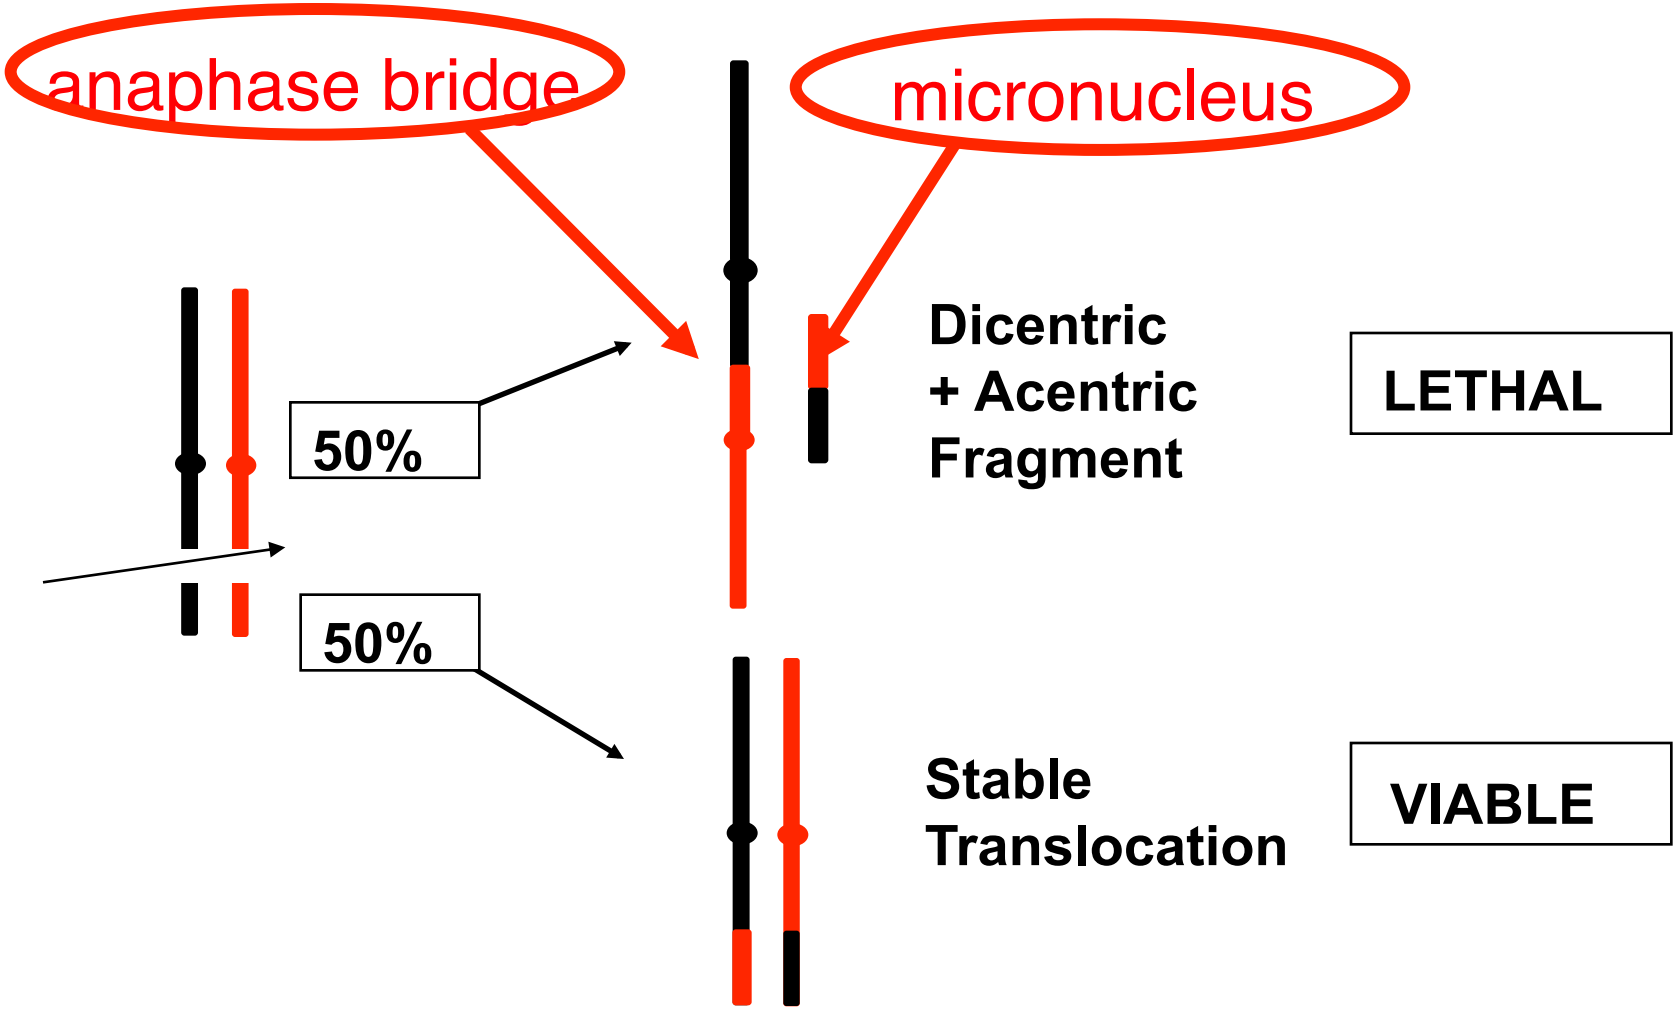
Mitotic Catastrophe

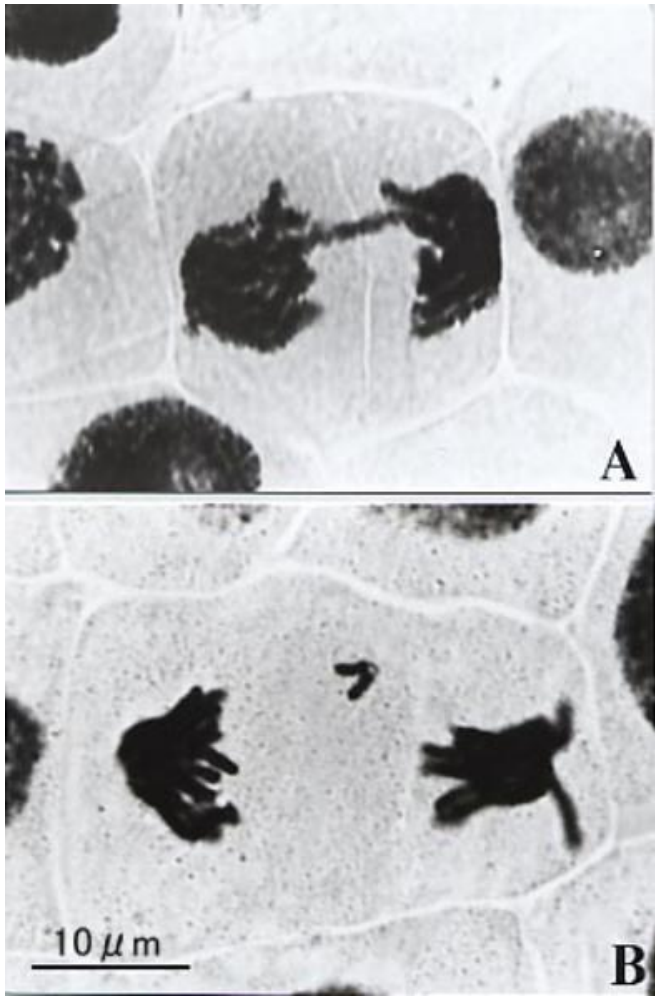


- Mitotic catastrophe
  - Cells attempt to divide without proper repair of DNA damage
- May lead to secondary death by apoptosis, necrosis, autophagy, or senescence

Mitotic catastrophe is caused by chromosome aberrations



Mitotic Catastrophe



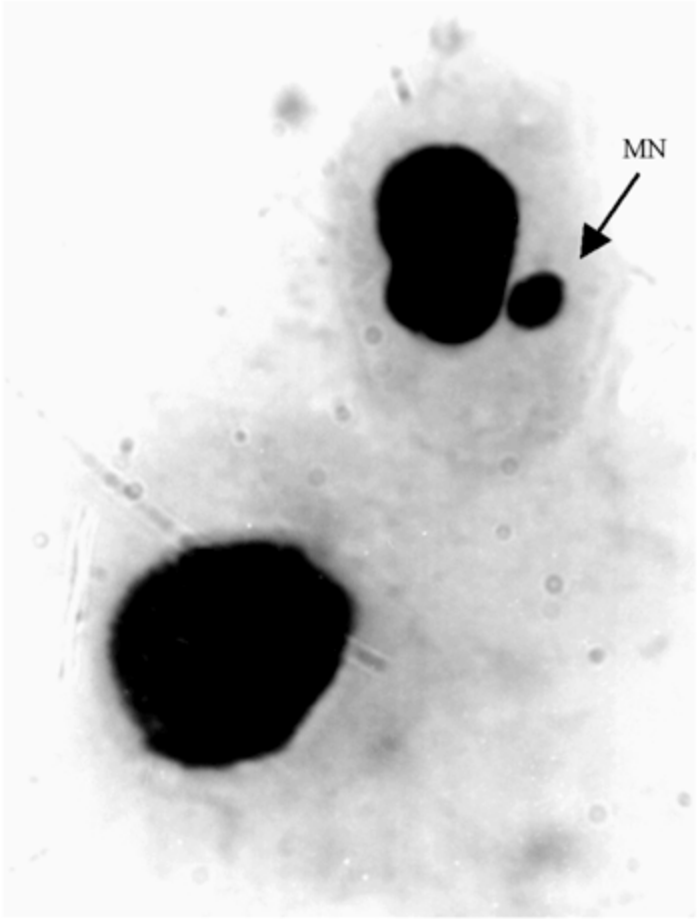


Figure 3 - Micronucleated erythrocyte (arrow) in *R. Catesbeiana* tadpole exposed to lambda-cyhalothrin. Giemsa-stained blood smear 1,000 x.

Mitotic Catastrophe

- Mitotic catastrophe takes place at long times after irradiation
  - Depends on proliferation rate
  - Influenced by DNA repair capacity
- Cell death may occur at different times following mitotic catastrophe
  - Nuclear fragmentation
  - Apoptosis, necrosis, senescence, autophagy
- Cells may attempt several divisions
  - Multiple failed divisions
  - Cell fusions
  - Giant cell formation, multiple micronuclei
- Genome becomes so unstable as to no longer support normal cell function

What about radiation?

- What is the contribution of these death pathways to radiation sensitivity ?
  - The propensity to initiate programmed cell death varies widely
  - The genes controlling these pathways are frequently mutated in cancer

How do cells die?

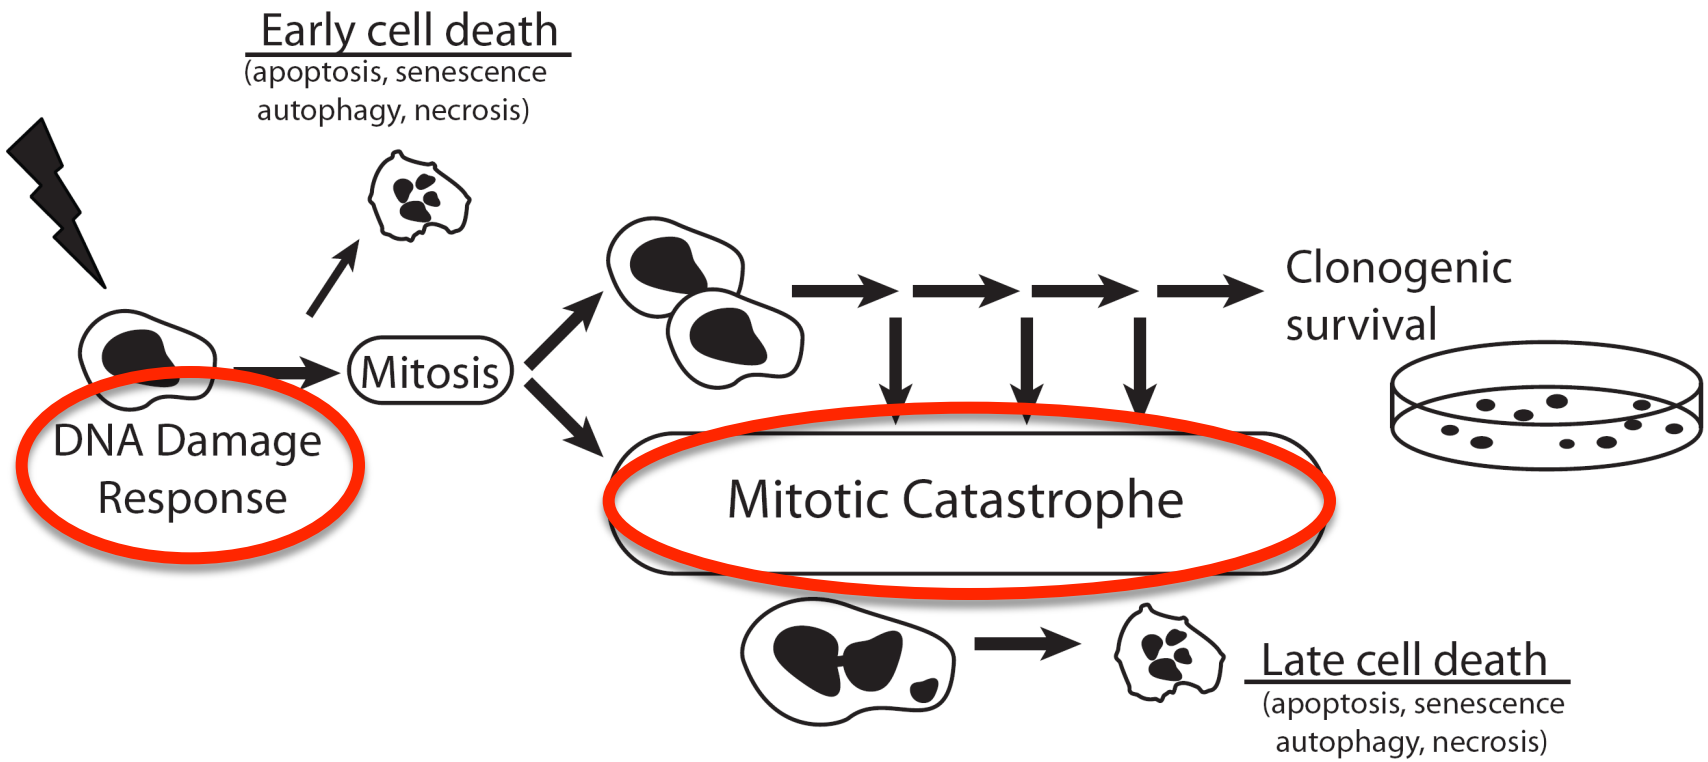
- Necrosis
- Senescence
- Apoptosis
- Autophagy
- …

Why do cells die?

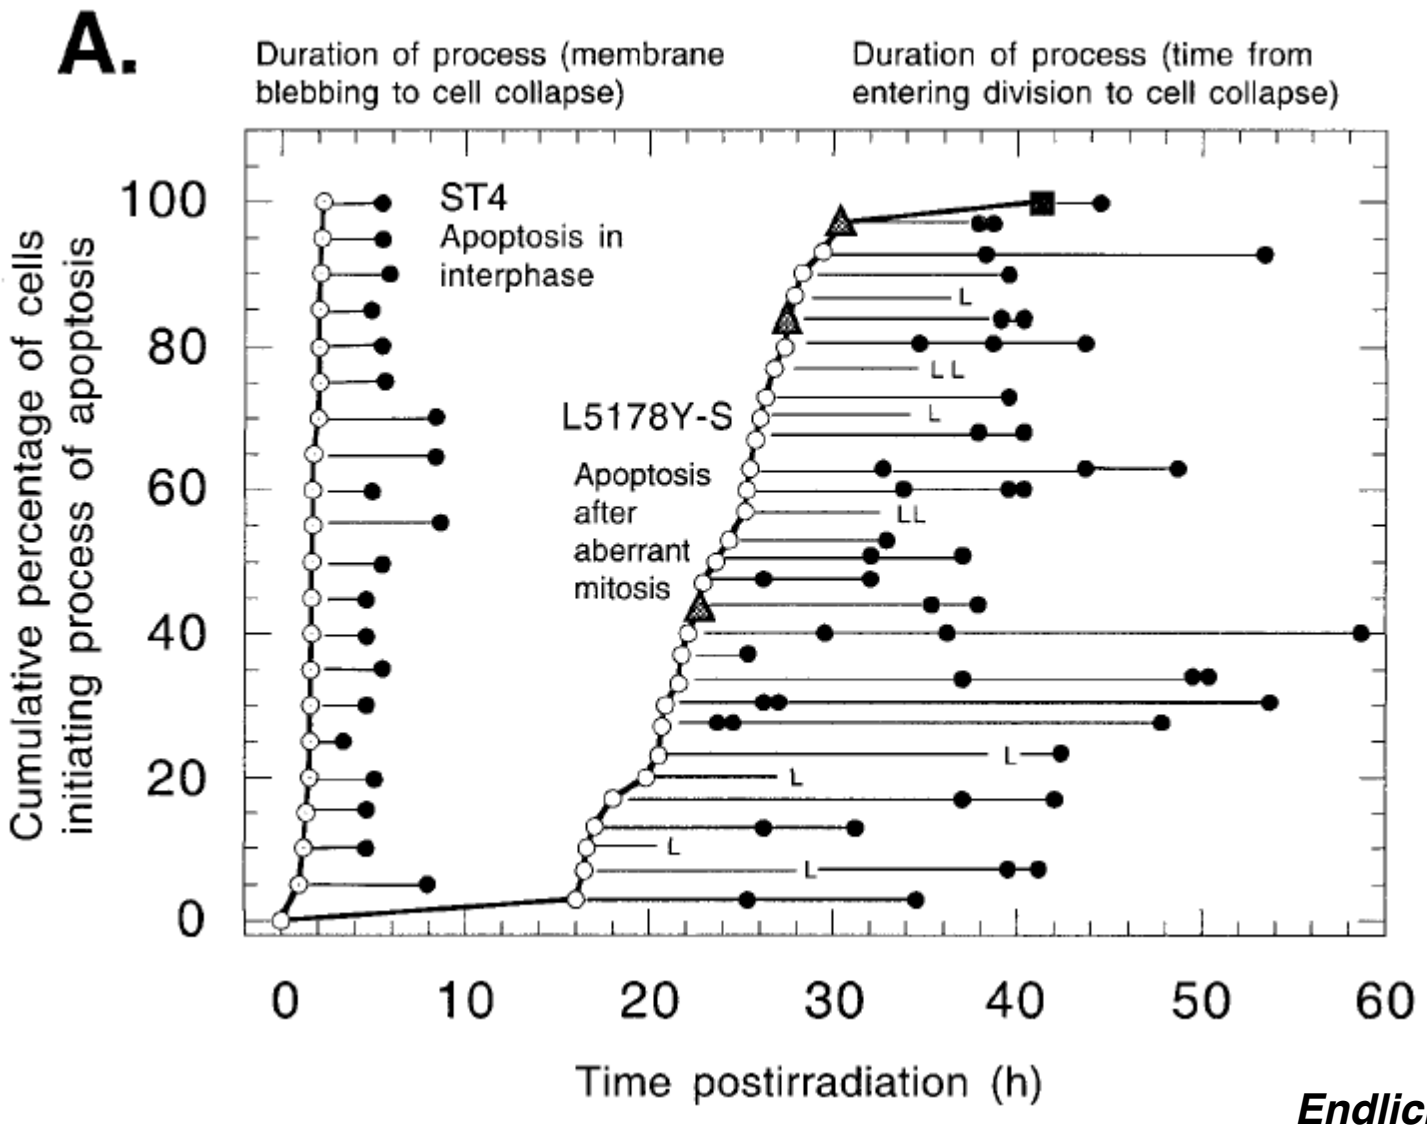
1) Initial damage to DNA (sometimes other molecules)

2) Mitotic catastrophy

What is the *cause* of cell death?



Two Types of Apoptosis - Pre and post mitotic



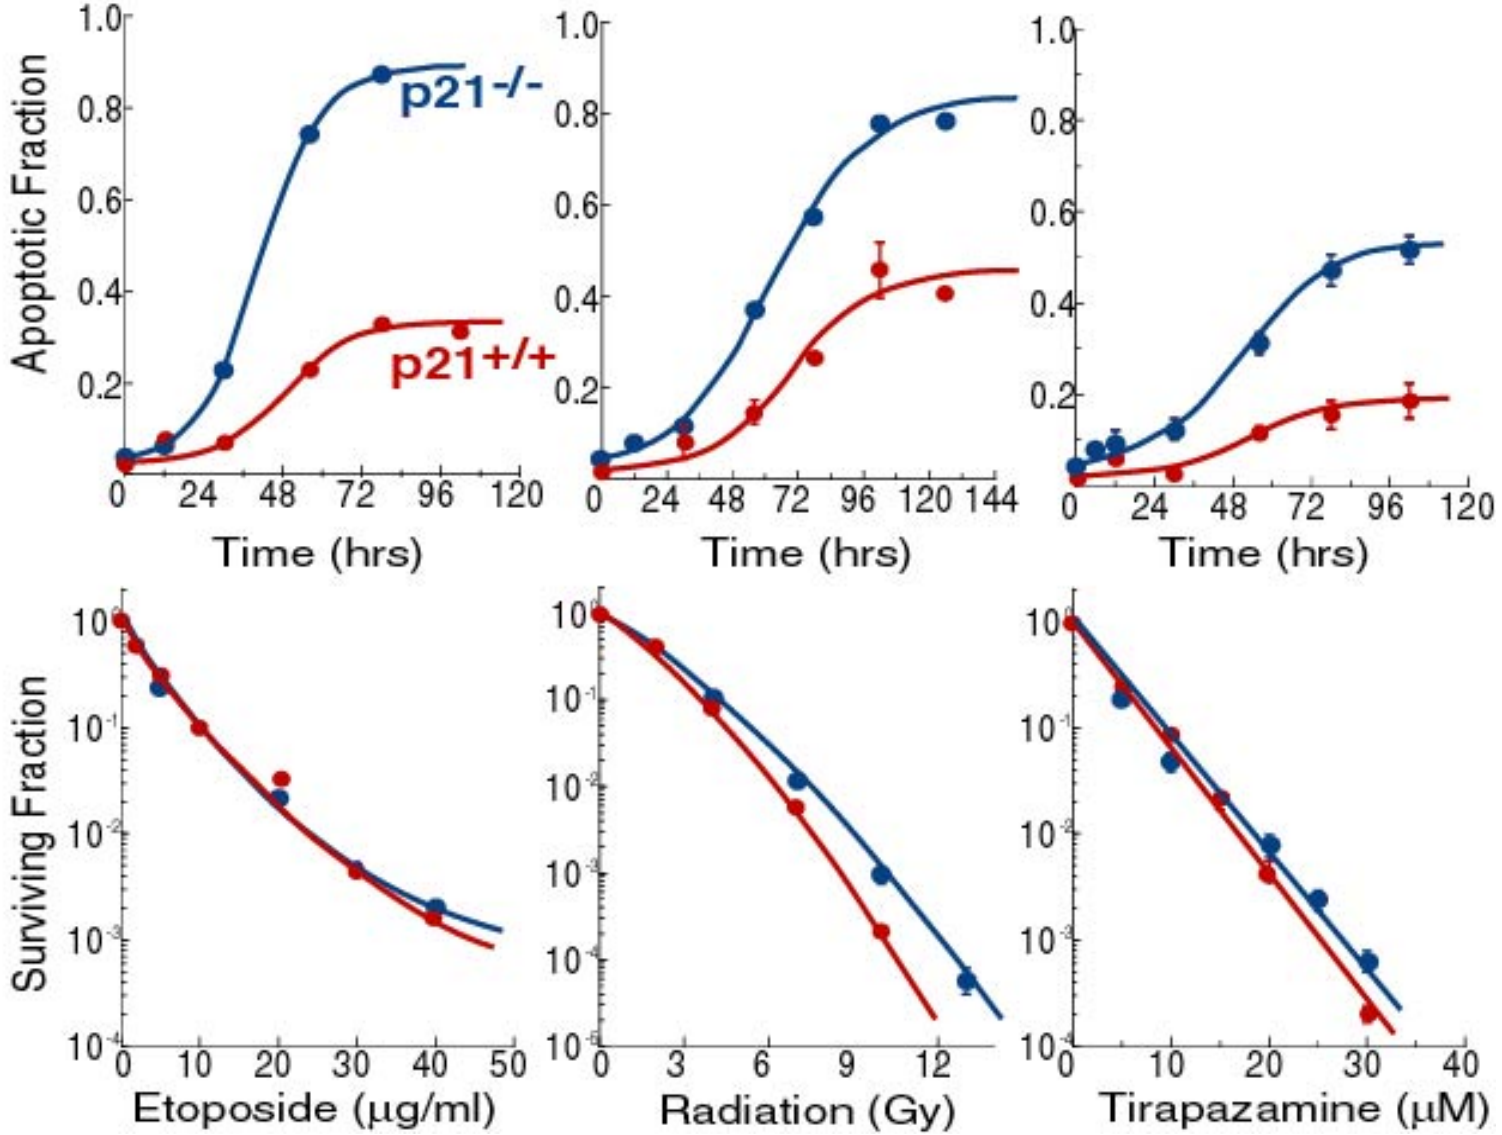
Endlich et al (2000)

Apoptosis is Both a Reason for Cell Death and a Type of Funeral

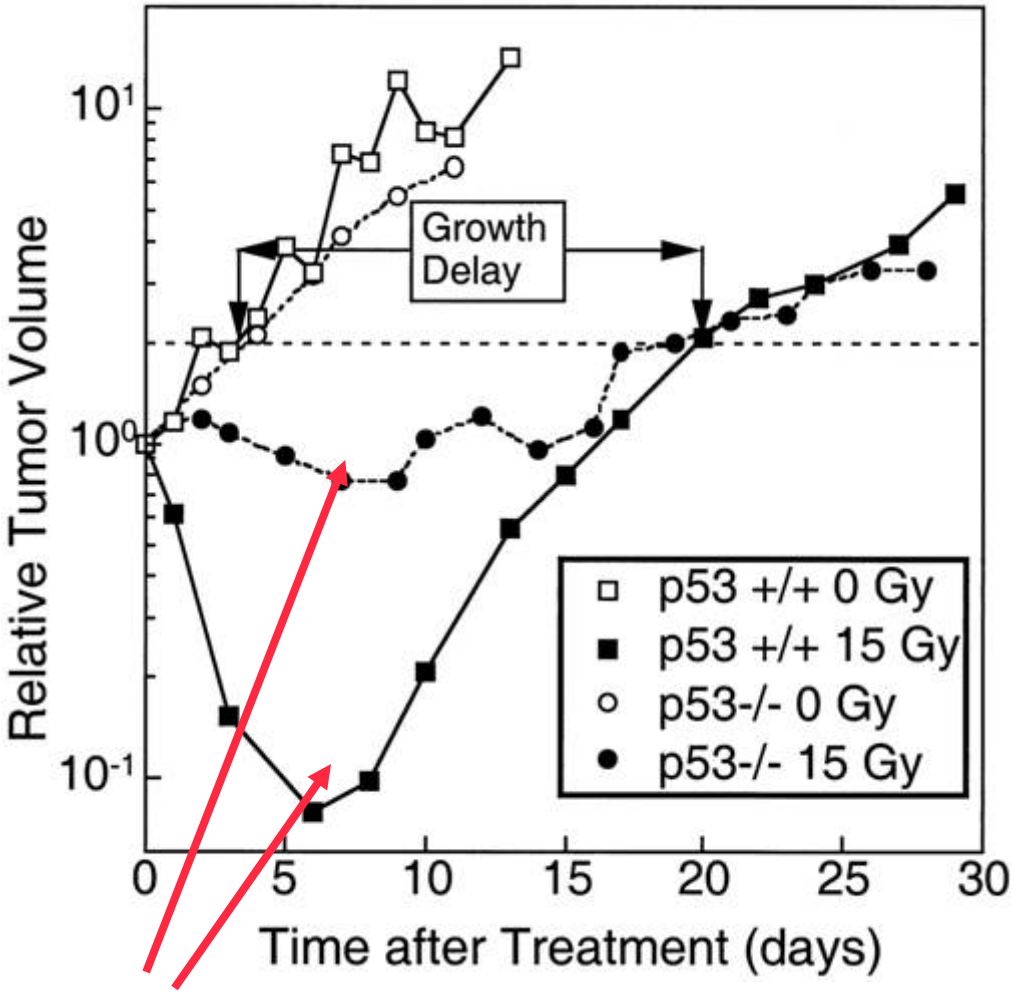
- Early apoptosis: Apoptosis is the reason the cell dies - it is the most sensitive mode of cell death and genes that affect apoptosis also affect cell death - e.g. some lymphomas and leukemias.

- Delayed apoptosis: The reason the cell dies is usually by mitotic catastrophe. However, the cell may, or may not, have an apoptotic "funeral". Changing apoptotic sensitivity does not change overall cell killing - e.g. most epithelial cancers.

Apoptosis can change without affecting clonogenic survival of HCT116 tumor cells



Affecting how cells die can dramatically influence the rate at which cells die



apoptosis difference

Early Apoptosis explains:

- The sensitivity of lymphocytes at low radiation dose.

- The efficacy of low dose radiation dose in non-hodgkin lymphomas: 2x2 Gy results in a high proportion of responses in Low grade non-Hodgkin Lymphoma

Apoptotic index and prognosis in cancer

Results

6 better outcome with high AI

8 worse outcome with high AI

13 not significant

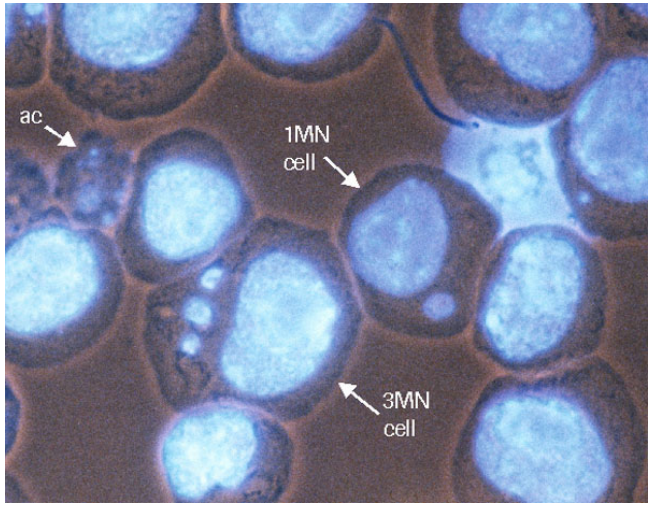
Summary of many clinical-preclinical studies

- The mechanism of killing of the cells of solid tumors is not by early apoptosis.
- Solid tumor cells may die of apoptosis, but it is by post-mitotic (delayed) apoptosis.
- Modification of post-mitotic apoptosis does not usually change overall cell kill.

(Brown and Attardi, Nat Rev Cancer, 5: 232, 2005)

Mitotic Catastrophe

- The major form of cell killing after ionizing radiation and other DNA damaging agents.
- Almost all death occurs after cells attempt division one or more times



Movie

Conclusions

- Most cell death is controlled or programmed in some way.
  - Major pathways include apoptosis, senescence, autophagy and necrosis
- Measuring one form of cell death (eg Apoptosis) will not necessarily correlate with how many cells die
  - Cell may die by other mechanisms
- The form of cell death may influence the rate at which cells die
  - Affect tumor regression
- Genetic changes may dramatically alter how cells die without changing if they will die

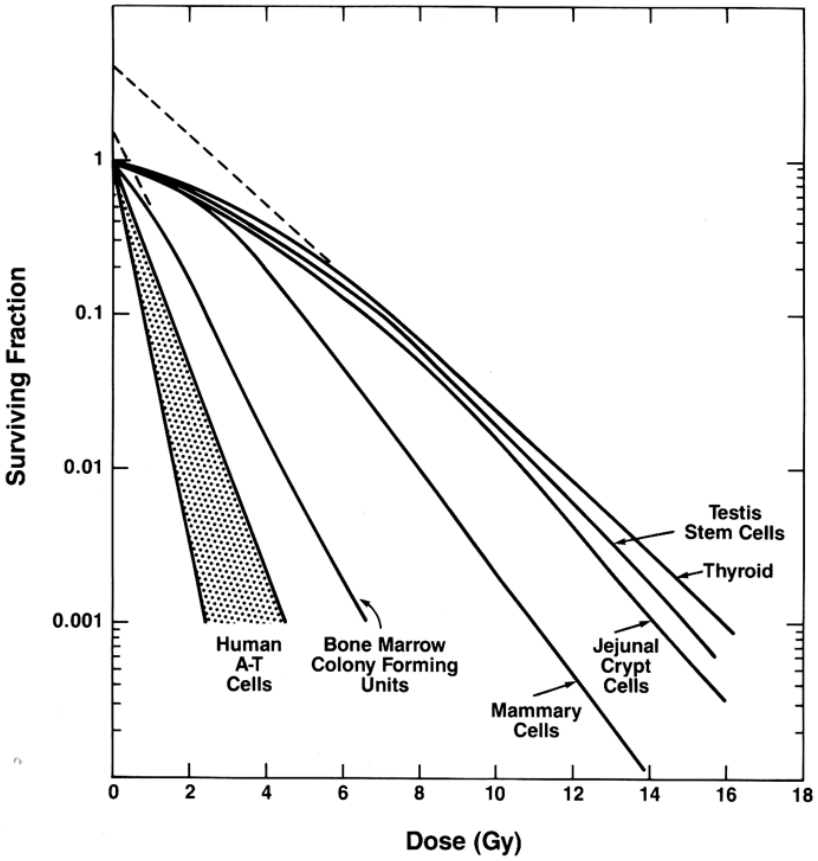
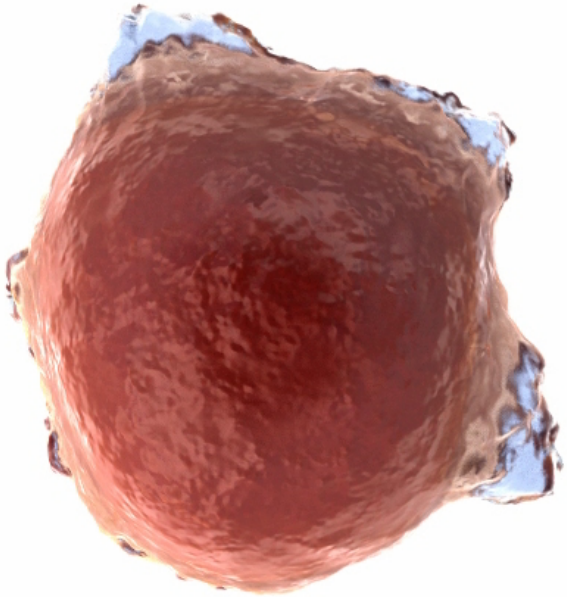
Clonogenic survival in normal tissues summary



Stem cells from different tissues show large differences in radiosensitivity, as determined in assays of clonogenic survival

This only partly reflects the different sensitivities of different organs, as many other factors determine the radiation response and tolerance of different organs, especially late responding organs like CNS, lung, kidney, etc

What are adult/tissue stem cells



What is a stem cell

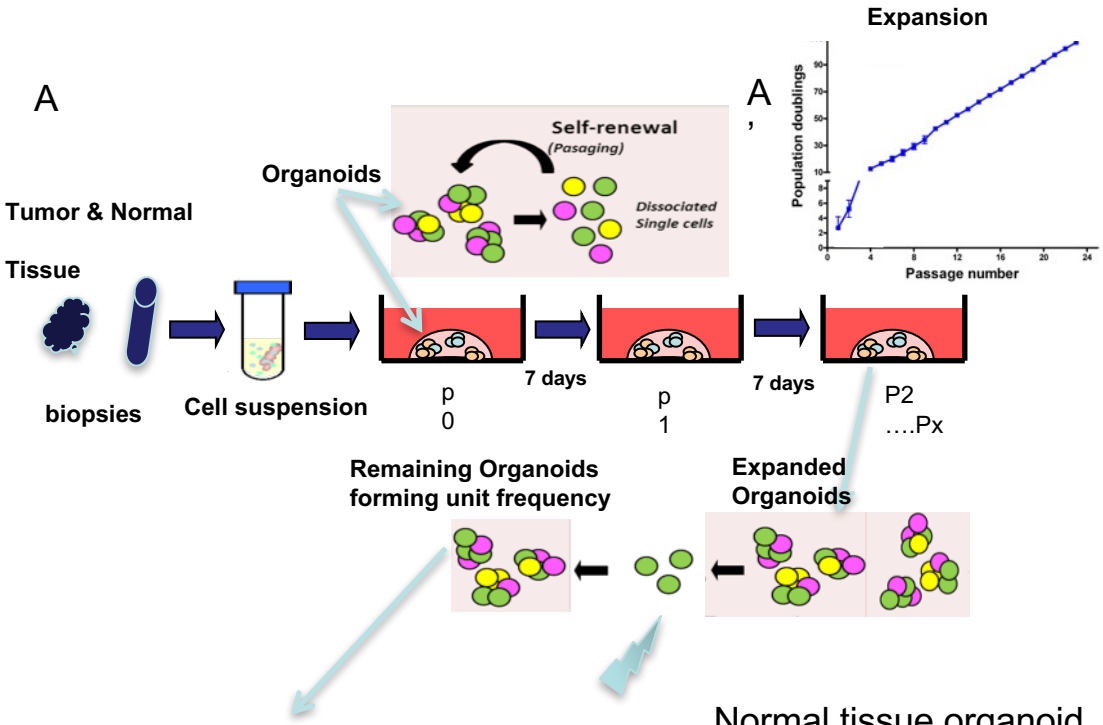
Organoid radiation response assessment



Response to treatment?

Normal tissue organoid
vs
tumor organoid,
therapeutic ratio?

Summary

- Tumor recurrence depends on surviving clones.
- Evaluation of the survival of clonogenic cells following treatment is an important aspect of experimental cancer therapy.
- Hyper-radiosensitivity at very low radiation doses may be of clinical importance for normal tissue.
- Patient specific normal and tissue organoid cultures may provide future assays to personalized medicine.

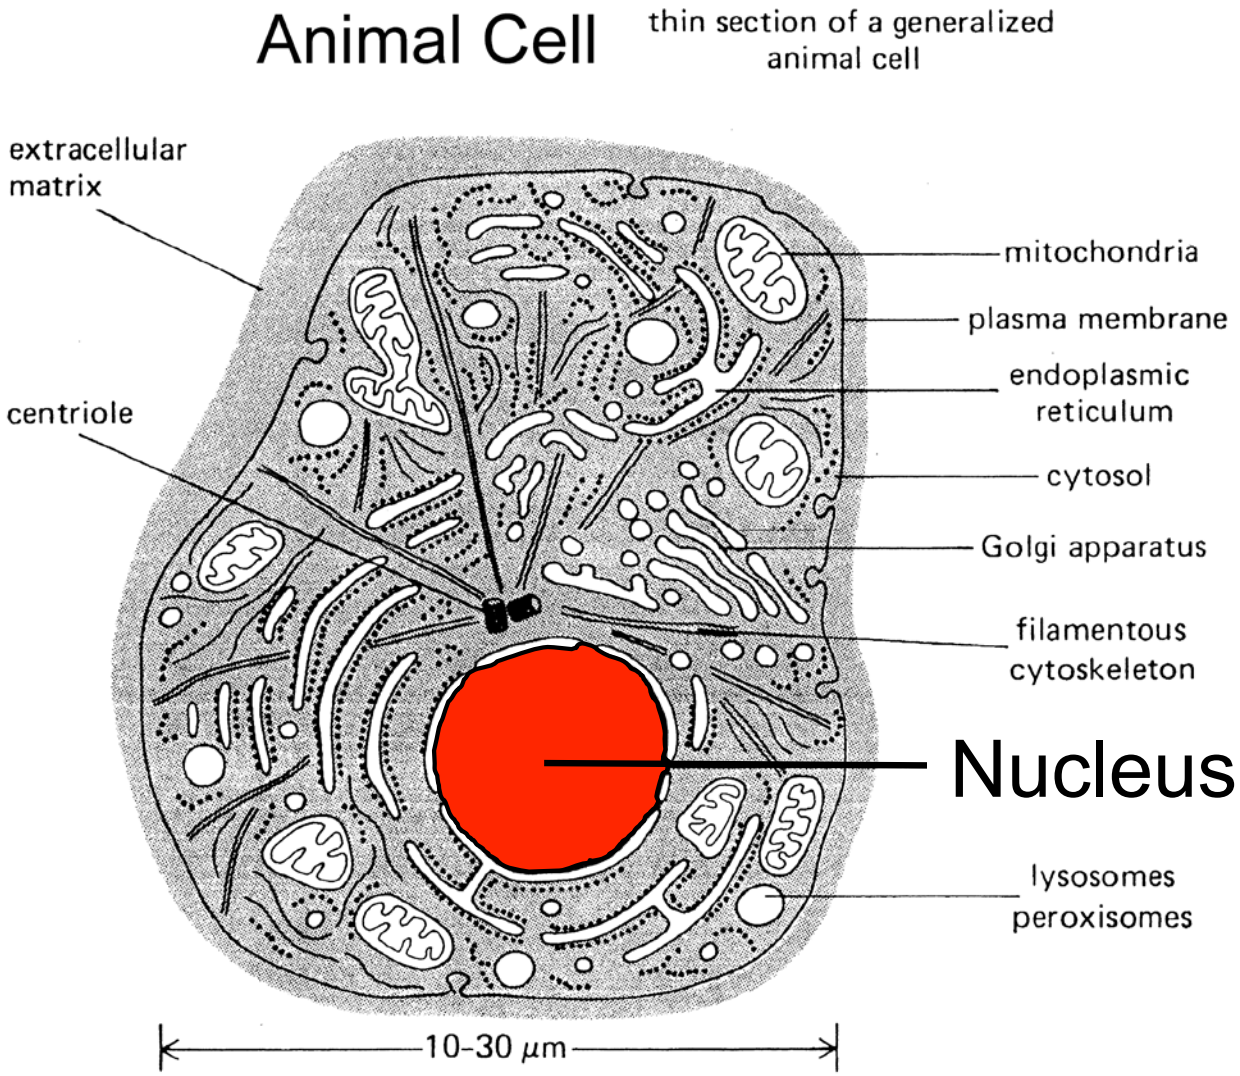
lesion production
versus
lesion repair



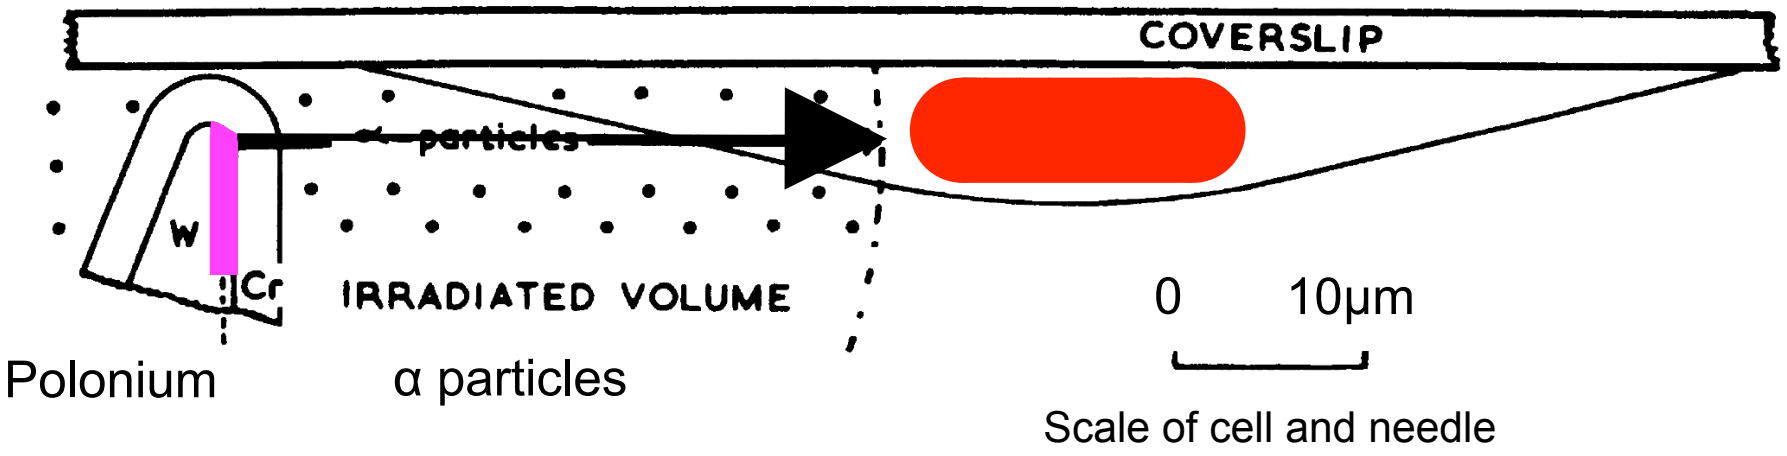
DNA is the principal target

Radiation Source	*Subcellular dose (Gy)*		
	Nucleus	*Cytoplasm*	*Membrane*
X-ray	3.3	3.3	3.3
^{3}H-Tdr	3.8	0.27	0.01
^{125}I-concanavalin	4.1	24.7	516.7

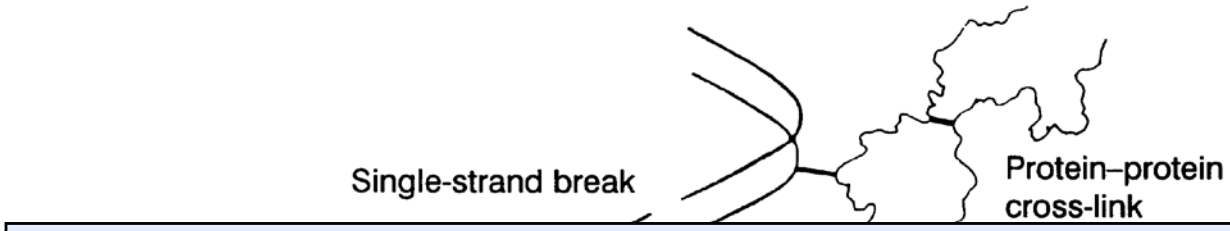
Warters et al. *Curr Top Radiat Res Q* 1977;12:389

DNA is the principal target

Microbeam experiments with α particles from polonium show that the cell nucleus is the sensitive site

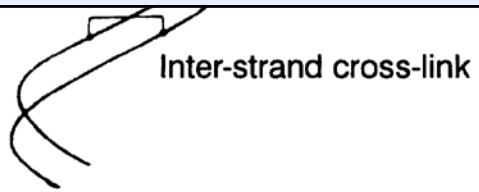


Munro TR. *Radiat Res* 1970;42:451



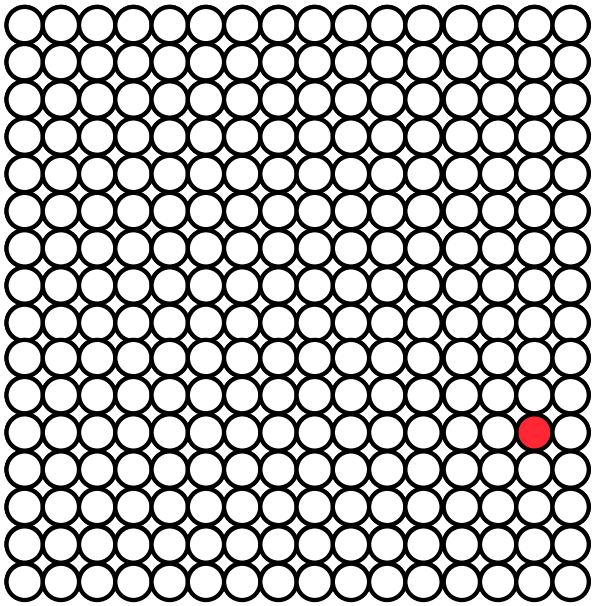
Each 1 Gy produces:

Base damage	>1000
single-strand breaks	~1000
double-strand breaks	~20
equivalent UV dose	10^6 dimers



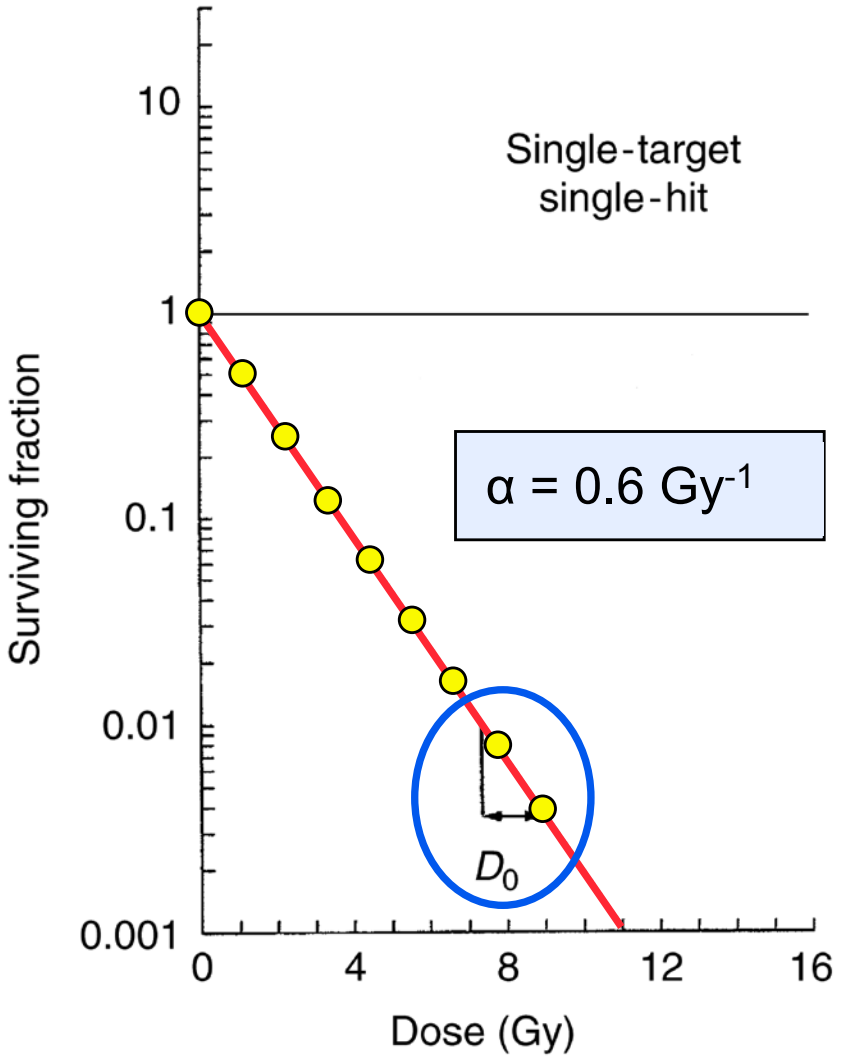
Modifier	Cell kill	**DSB**	SSB	Base damage	DPC
↑ LET	↑	↑	↓	↓	–
↑ hypoxia	↓	↓	↓	0	↑
↑ thiols	↓	↓	↓	0	↓
↑ heat	↑	↑	0	0	0

From Frankenberg-Schwager (1989)



$$\frac{N}{N_0} = S = e^{-\alpha D}$$

$$D_0 = 1/\alpha$$



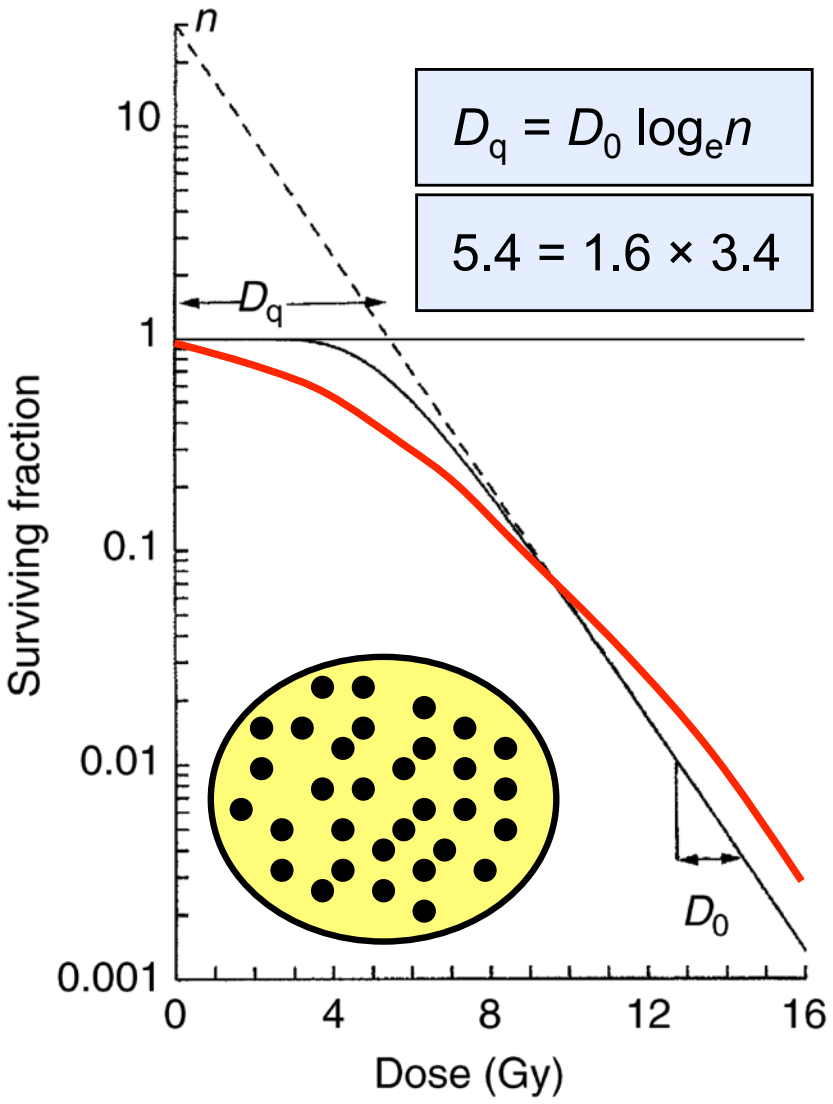
P(0 hits on a target) $= e^{-D/D0}$

P(≥1 hit on a target) $= 1 - e^{-D/D0}$

P(≥1 hit on n targets) $= (1 - e^{-D/D0})^n$

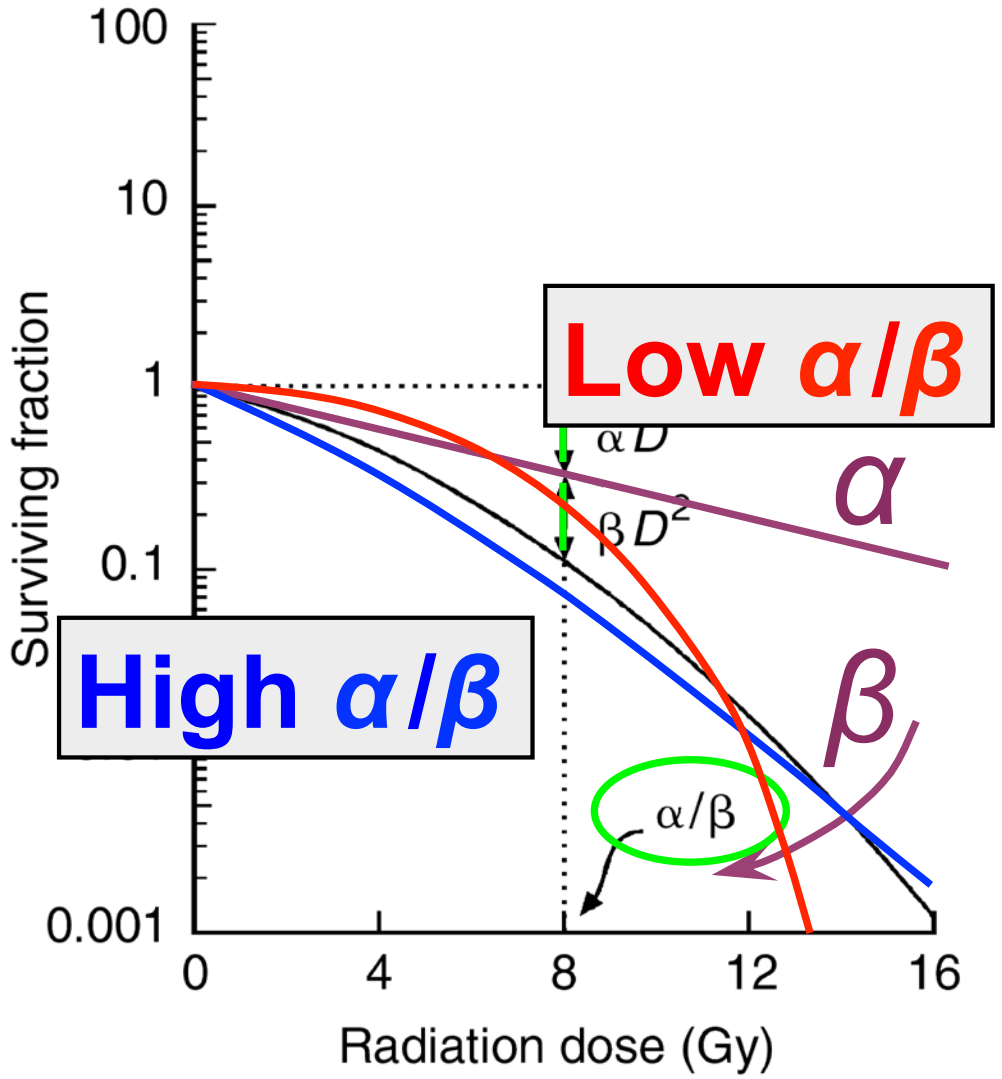
P(not **all** targets hit) $= 1 - (1 - e^{-D/D0})^n$

$$S = 1 - \left(1 - e^{-D/D_0}\right)^n$$



$$S = e^{-\alpha D - \beta D^2}$$

$$-\log_e S = \alpha D + \beta D^2$$



Curtis' LPL model

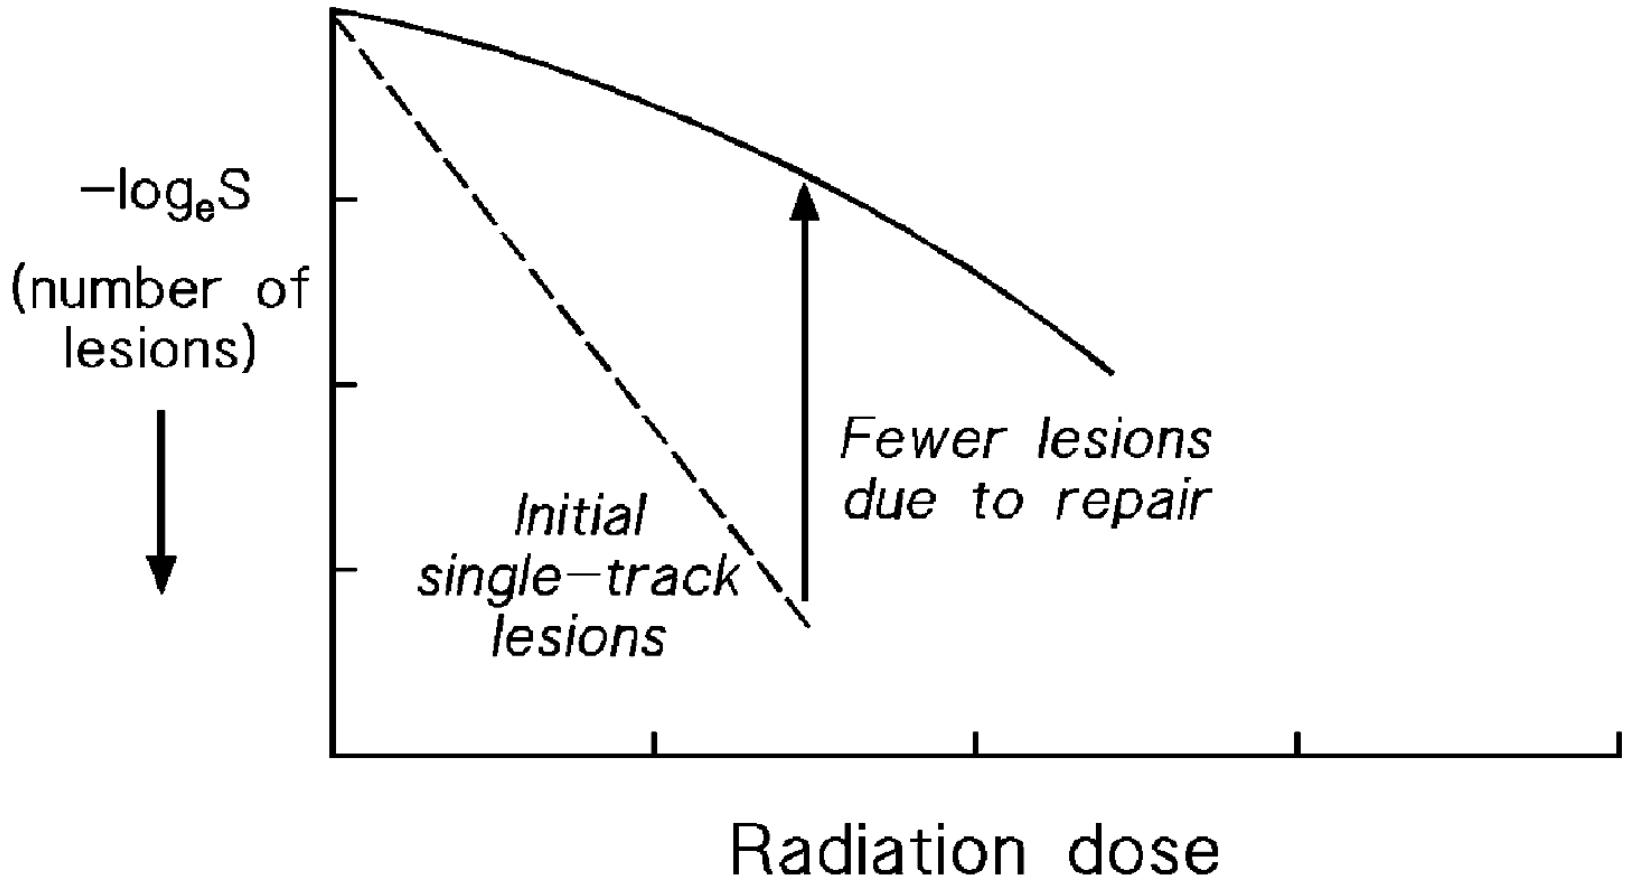
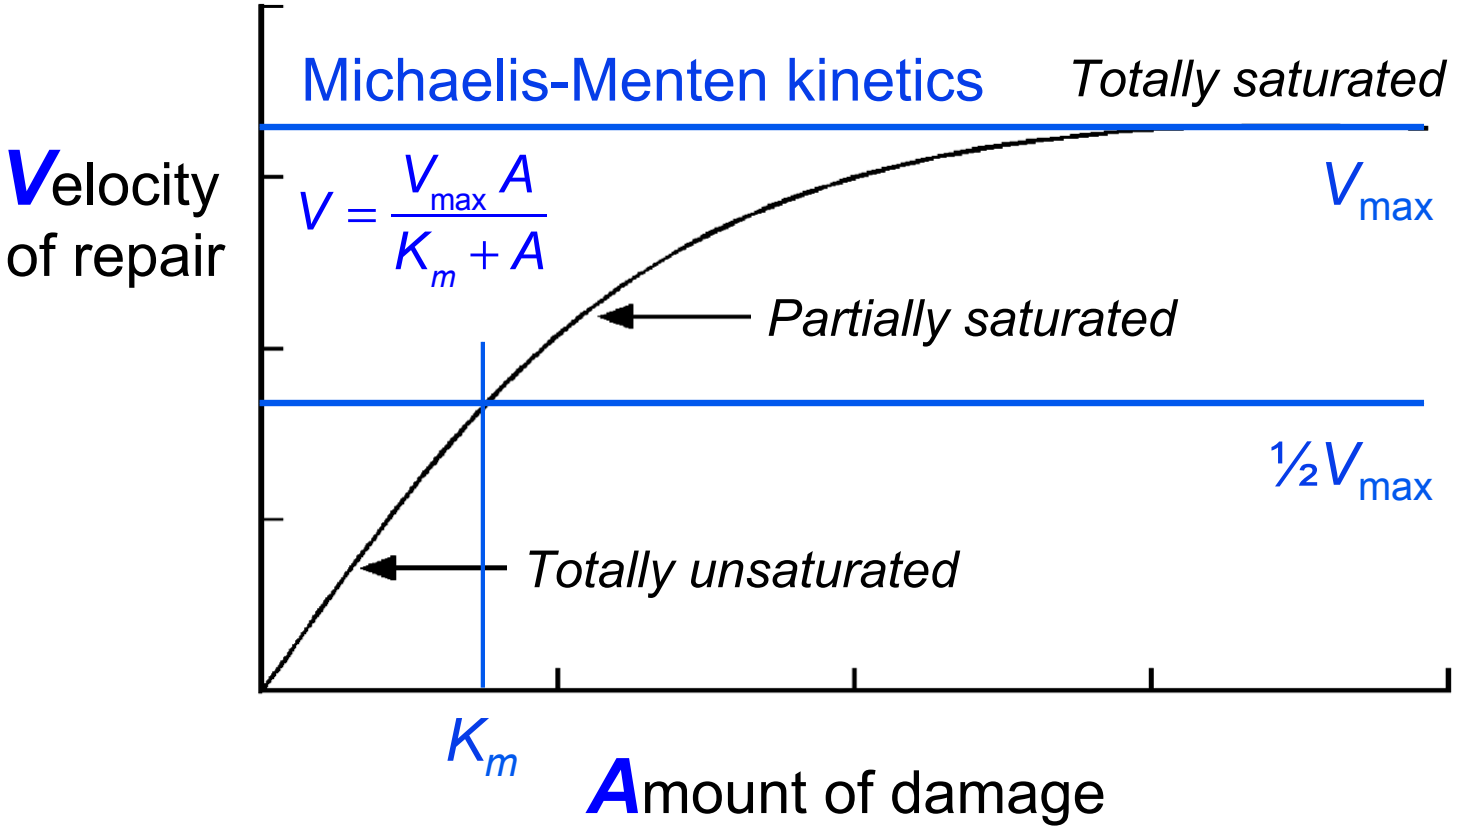
The concept of repair saturation



The concept of repair saturation



Lesion interaction vs repair saturation

Table 4.1 Different interpretations of radiobiological phenomena by lesion-interaction and saturable-repair models

Observation	Explanation Lesion interaction	Repair saturation
Curved dose–effect relationship	Interaction of sublesions	Saturation of capacity to repair sublesions
Split-dose recovery	Repair of sublesions (sublethal damage repair)	Recovery of capacity to repair sublesions
RBE increase with LET	More non-repairable lesions at high LET	High-LET lesions are less repairable
Low dose rate is less effective	Repair of sublesions during irradiation	Repair system not saturating

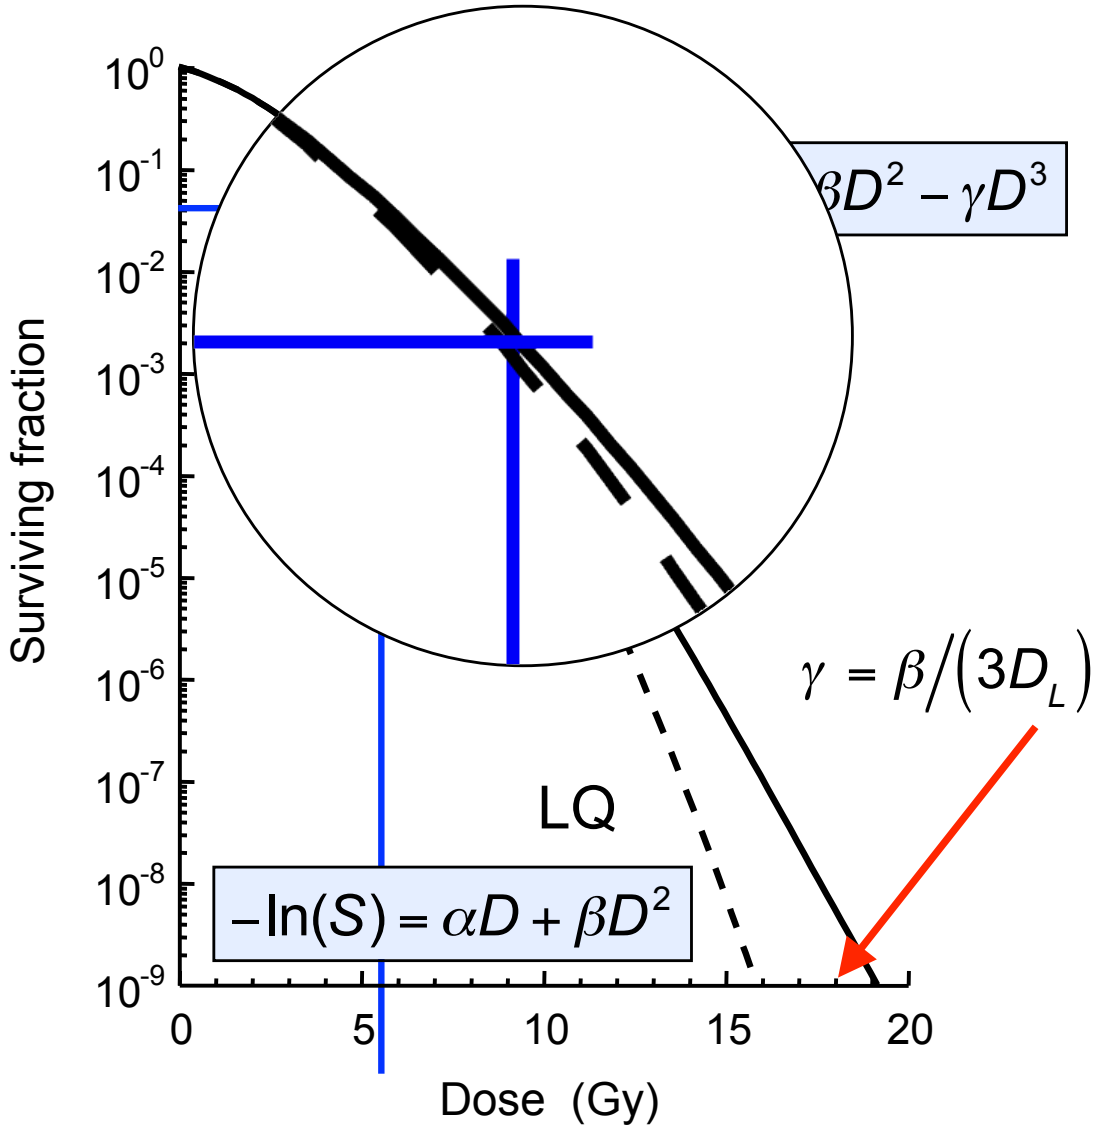
LET, linear energy transfer; RBE, relative biological effectiveneness.

Adapted from Goodhead (1985).

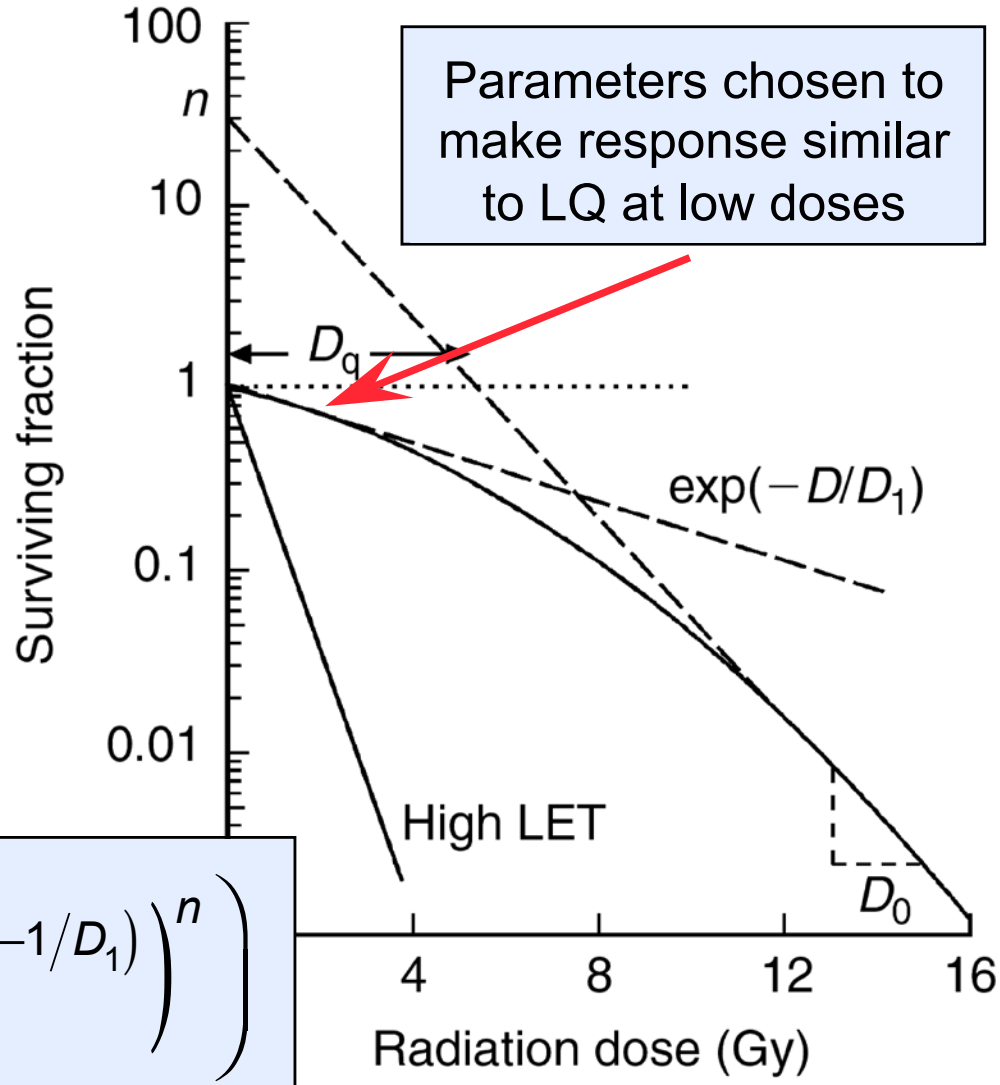
The **L**inear **Q**uadratic **C**ubic model

α/β = 3 Gy

SF2 = 0.5



Two-component model may also better describe response to **high-dose** fractions



$$S = e^{-D/D_1}\left(1-\left(1-e^{-D\left(1/D_0-1/D_1\right)}\right)^n\right)$$

Low-dose hyper-radiosensitivity

Short S, Mayes C, Woodcock M, Johns H, Joiner MC.
Int J Radiat Biol 1999;75:847–55.

$$S = e^{-\alpha D - \beta D^2}$$

$$\alpha = \alpha_r \left(1 + \left(\alpha_s / \alpha_r - 1\right) e^{-D/D_c}\right)$$

First reported in 1986 in mouse epidermis and kidney

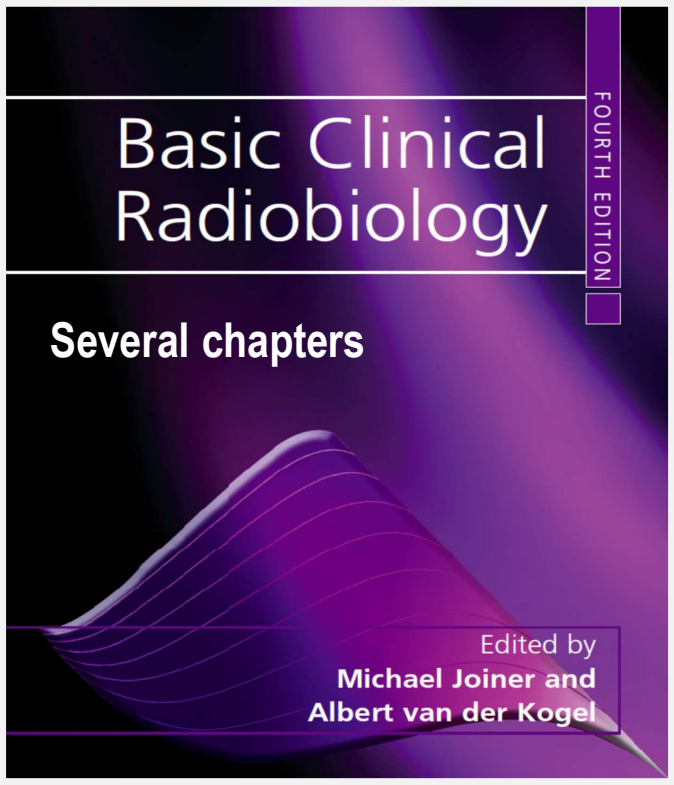
Clinical side effects and their quantification

Karin Haustermans

Department of Radiation Oncology, University Hospitals Leuven, Belgium

Overview

- Why?
- What?
  - Early adverse events
  - Late adverse events
  - Relevant factors
- How?
- Take home messages

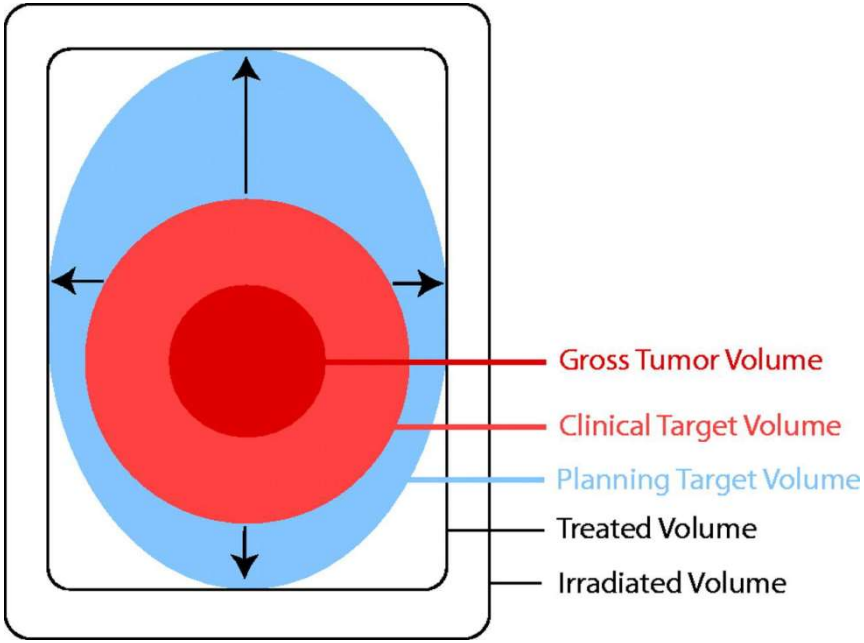


"As soon as we solve one problem, another one appears.
So let's keep this problem going for as long as we can!"

Why?

Target volume includes normal tissue

- Microscopic tumor infiltration in surrounding normal tissue
- Normal tissues within tumor (soft tissue, blood vessels)
- Normal structures in entrance and exit dose of the radiation beam



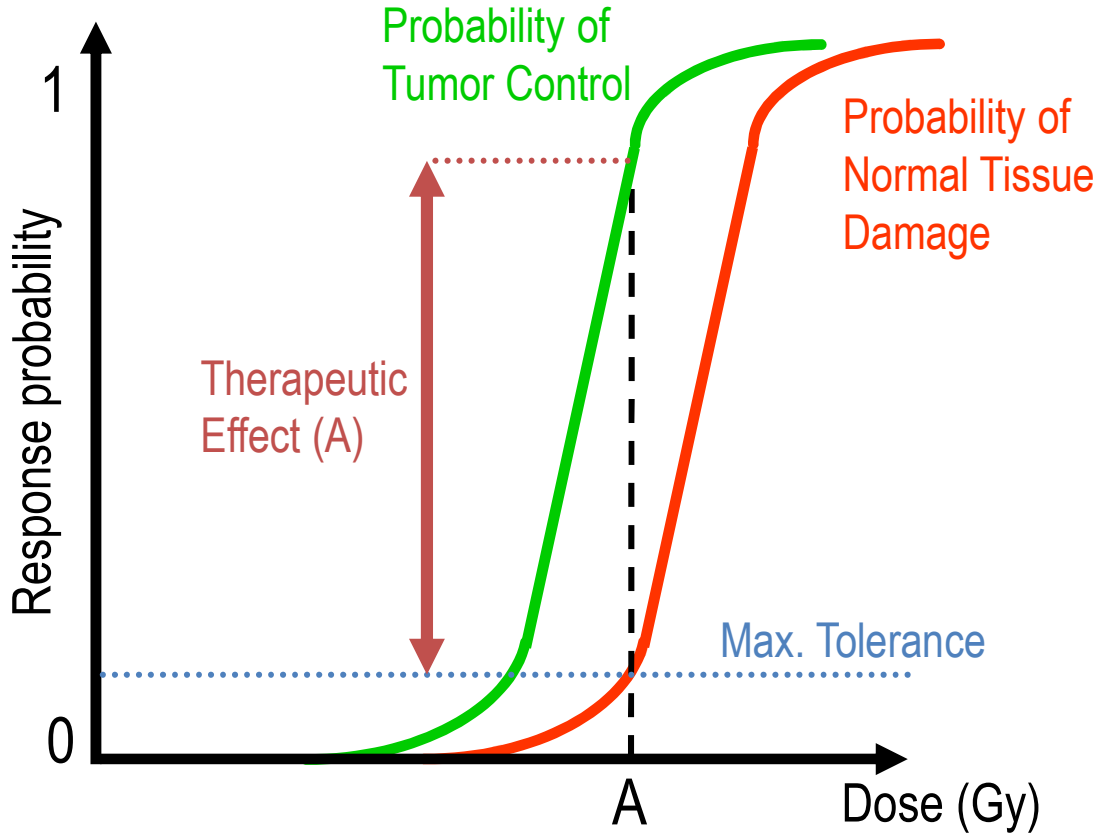
Side-effects cannot, a priori, be considered a consequence of incorrect treatment

Why assess adverse effects?

- To facilitate the evaluation of new cancer therapies, treatment modalities and supportive measures
- To monitor safety data
  - To aid in the recognition of severe toxicity & to ensure regulatory reporting
- Essential to standardize reporting
  - Within and across treatment modalities
  - Between investigators, institutions and studies

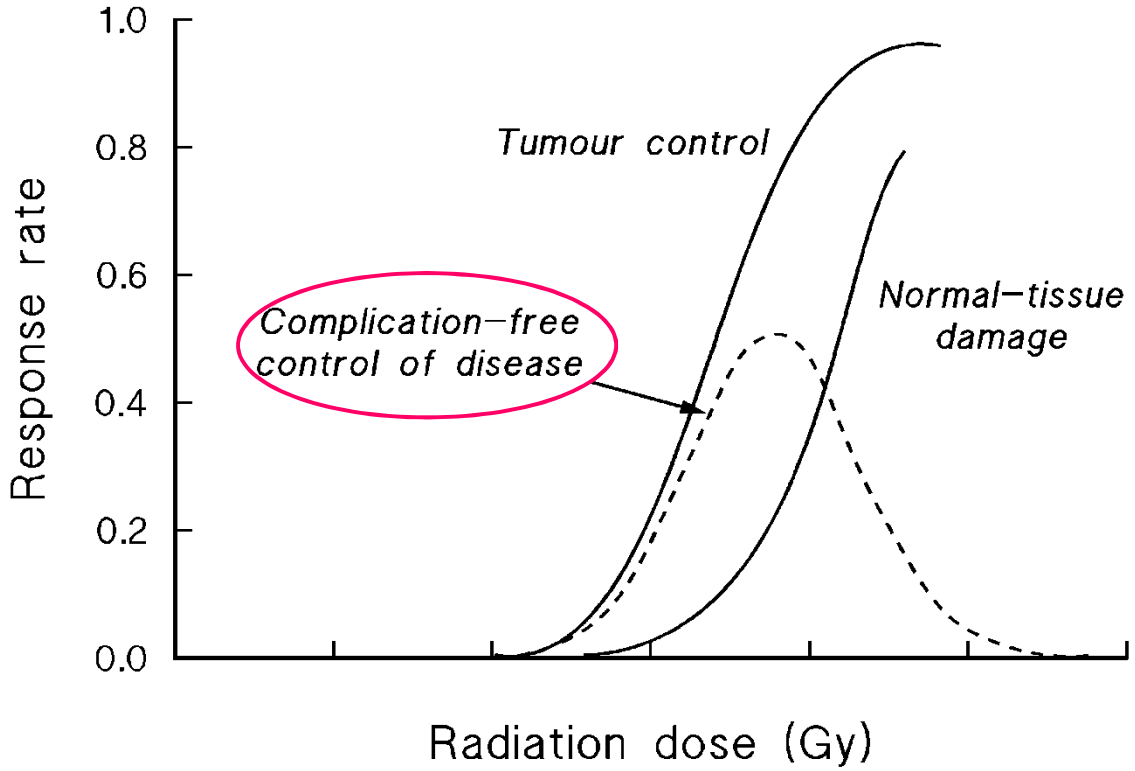
Why assess adverse effects?

- To assess the therapeutic ratio
  - eg change in treatment strategy



Why assess adverse effects?

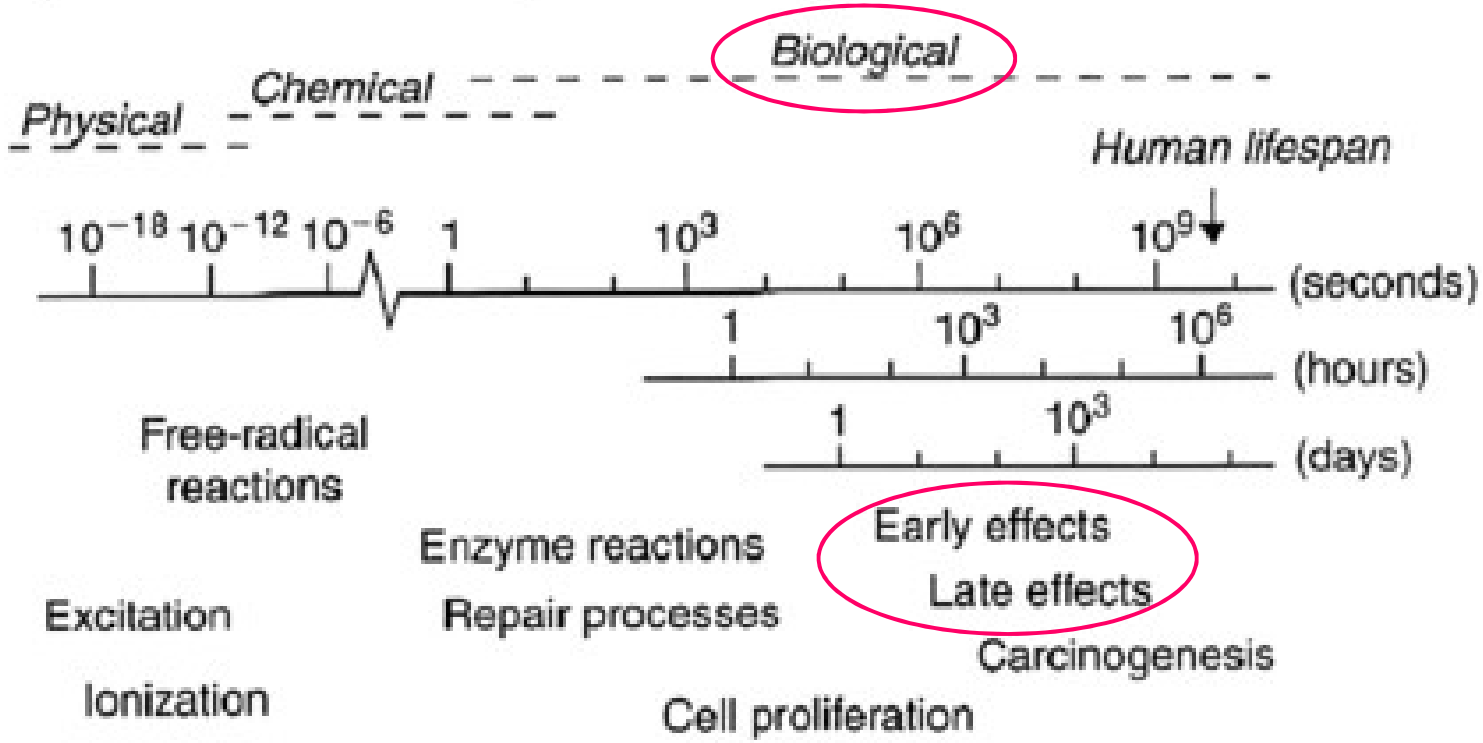
- Manifestation of side-effects = indicator for optimum treatment and maximum TCP



What?

Time-scale of radiation effects

Figure 2 from Issam El Naqa et al 2012 Phys. Med. Biol. 57 R75



Radiation-induced effects may already appear during IR but may also extend up to many years after exposure to IR and are due to killing of stem cells

Typical clinical manifestation of EARLY normal tissue reactions

- Alopecia
- Bone marrow suppression
- Diarrhea
- Mucositis
- Pneumonitis
- Xerostomia
- Skin desquamation

Early skin reactions grade 1-4

ESTRO School

Early versus late reactions

	Early reactions	Late reactions
Latency (Time to onset of clinical manifestion)	<90 days after onset RT; typically 3-9 weeks Not influenced by dose, but severity and duration of damage are dose-dependent	>90 days after onset RT; typically 0,5-5 years Inversely dependent on dose: higher dose leads to shorter latent period
Fractionation sensitivity	Low (high α/β ~ 6-10 Gy)	High (low α/β ~ 1-5 Gy)
Influence of overall treatment time (OTT)	Shorter OTT leads to greater injury	No significant influence
Clinical course	Typically transient, but consequential late reactions may occur	Progressive and irreversible Compensation may occur Rehabilitation or treatment for complications may relieve

Relevant factors

- Organs in the irradiated volume
  - Normal tissue constraints
- Pathogenesis of functional tissue (L1.7)
  - Vascular component
  - Connective tissue
  - Specific functional tissue compartments
- Previous irradations
  - Retreatment tolerance (L4.5)

Relevant factors

- Patient-related factors influencing normal tissue reactions
  - Age
  - Co-morbidity (e.g. cardiovascular diseases, diabetes)
  - Genetic syndromes (e.g. Ataxia Telangiectasia)
  - Infection (e.g. IBD, Crohn's disease)
  - Interaction with other treatments (e.g. chemotherapy)
  - Patient's general condition
  - Smoking

Relevant factors

- Tumor-related factors influencing normal tissue reactions
  - Stage of disease
  - Volume of the tumor
  - Lymphatic spread

  - Radiation dose
  - Volume of normal tissue irradiated
  - Fractionation schedule
  - Use of concomitant chemotherapy

Relevant factors

- Radiobiological-related factors influencing normal tissue reactions
  - Intrinsic radiosensitivity (L2.3)
  - Total radiation dose (L3.5)
  - Technique and irradiated volume (L3.6)
  - Fractionation schedule (late reactions) (L2.3)
  - Overall treatment time (early reactions) (L2.4)
  - Concomitant treatment (L4.4, L5.2)

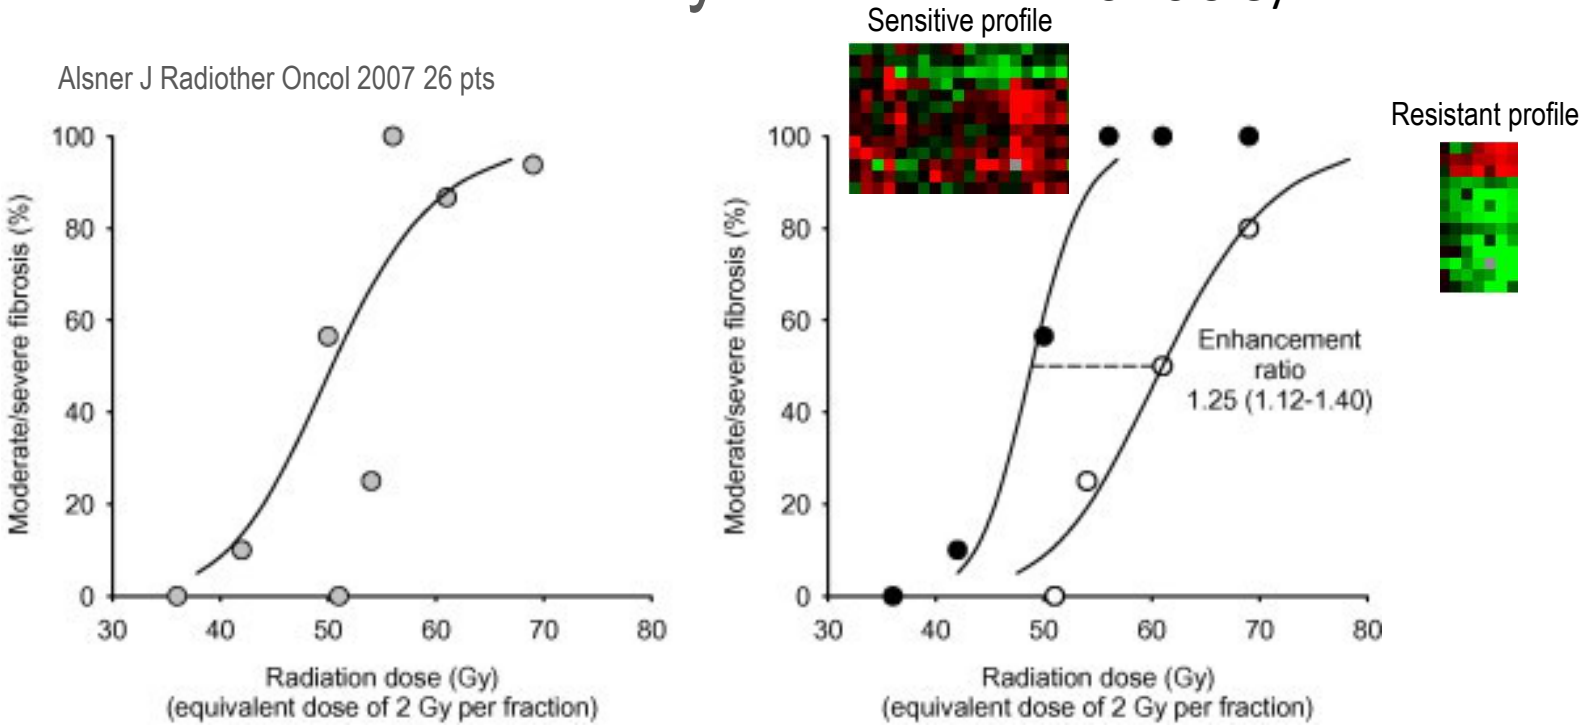
Relevant factors

- Radiobiological-related factors influencing normal tissue reactions
  - Intrinsic radiosensitivity (L2.3)
  - Total radiation dose (L3.5)
  - Technique and irradiated volume (L3.6)
  - Fractionation schedule (late reactions) (L2.3)
  - Overall treatment time (early reactions) (L2.4)
  - Concomitant treatment (L4.4, L5.2)

Relevant radiobiological factors

- Intrinsic radiosensitivity

26 patients derived fibroblasts
Hierarchical clustering
3 x 3.5 Gy



Differential gene expression in irradiated fibroblasts between pts with variable risk of radiation-induced fibrosis

Relevant factors

- Radiobiological-related factors influencing normal tissue reactions
  - Intrinsic radiosensitivity (L2.3)
  - Total radiation dose (L3.5)
  - Technique and irradiated volume (L3.6)
  - Fractionation schedule (late reactions) (L2.3)
  - Overall treatment time (early reactions) (L2.4)
  - Concomitant treatment (L4.4, L5.2)

Relevant radiobiological factors

- Total radiation dose

Average MLD 10.3±5.6Gy
MLD Pts with RP12.5±4.3Gy > MLD pts without RP MLD 9.9±5.8Gy

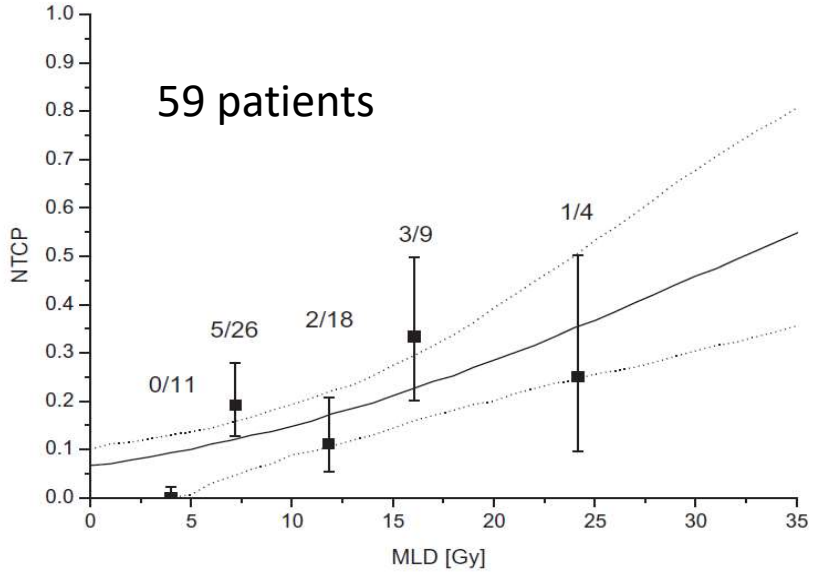


Fig. 1. Patients were grouped in bins of 5 Gy MLD, observed incidences of radiation-induced pneumonitis (RP) for the median dose within each bin are shown and the error bars represent the 68% confidence interval (CI) of the observed incidences. The thick solid line shows the best fit of the NTCP model based on the MLD and the dashed lines represent the 68% CI of the fitted curve.

Dose-response relationship for radiation-induced pneumonitis (RP) after pulmonary stereotactic body radiotherapy

Guckenberger Radiother Oncol 2010 59 pts

Relevant factors

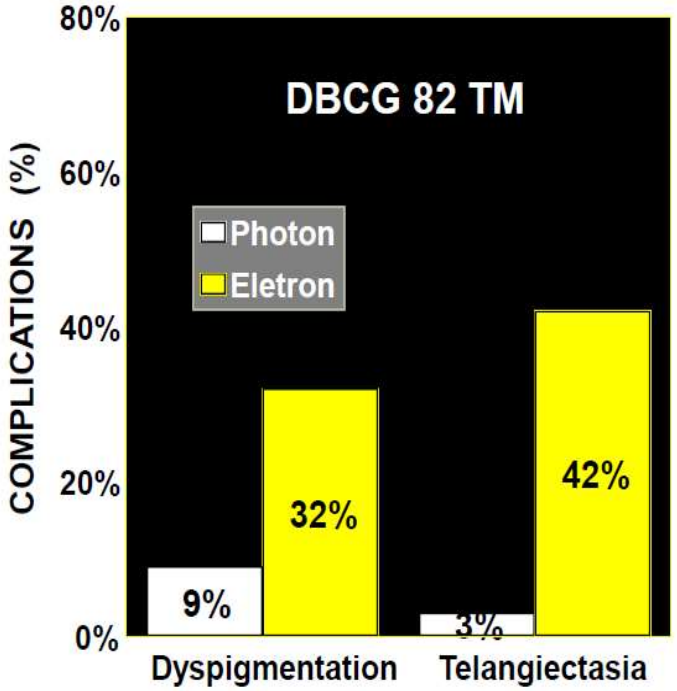
- Radiobiological-related factors influencing normal tissue reactions
  - Intrinsic radiosensitivity (L2.3)
  - Total radiation dose (L3.5)
  - Technique and irradiated volume (L3.6)
  - Fractionation schedule (late reactions) (L2.3)
  - Overall treatment time (early reactions) (L2.4)
  - Concomitant treatment (L4.4, L5.2)

Relevant radiobiological factors

- Technique: electrons vs photons

Electron irraditation

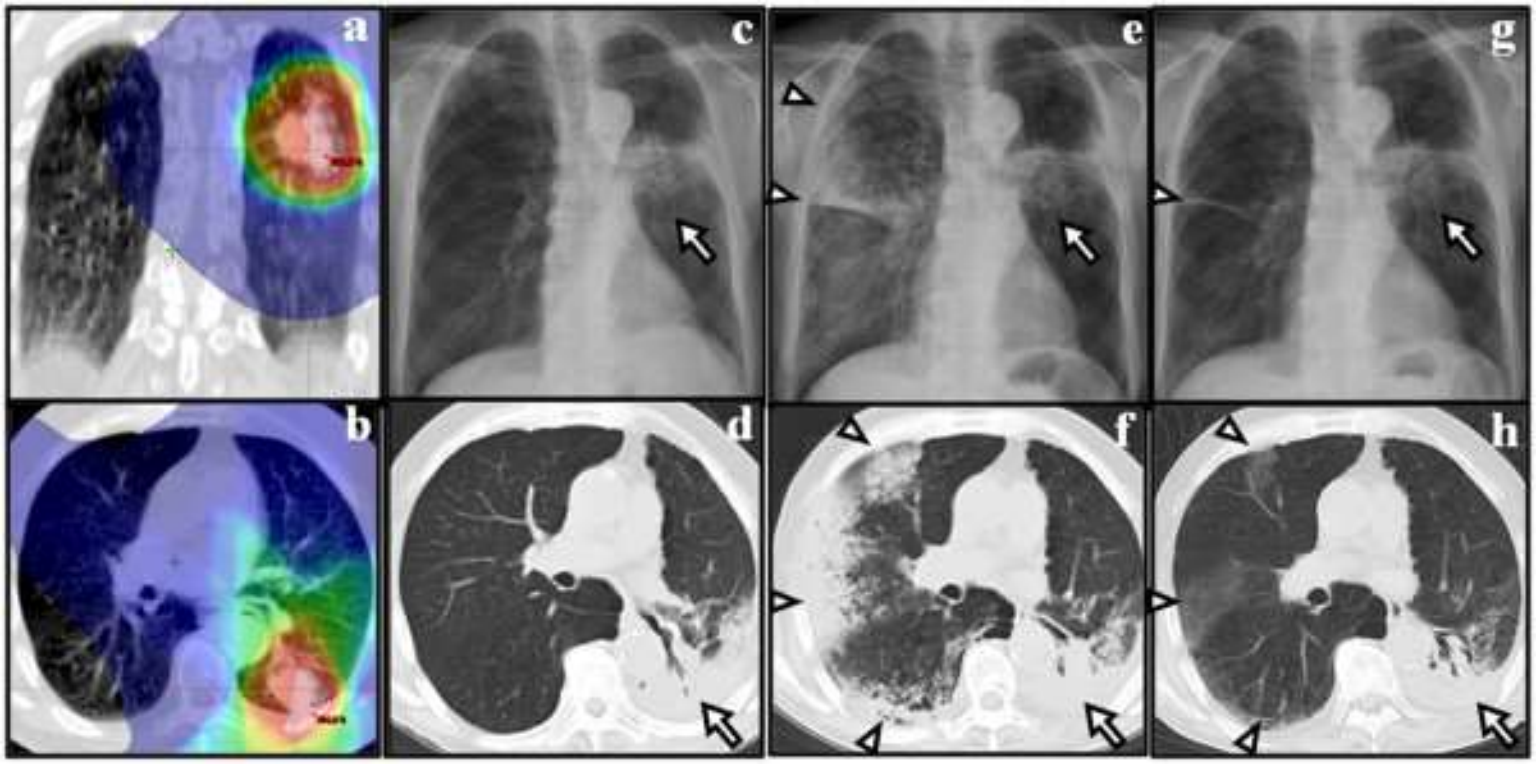
Photon irraditation



Johansen et al. 1998

Relevant radiobiological factors

- Technique: stereotactic ablative radiotherapy



Radiation pneumonitis - 3 months after resolution: organizing pneumonitis – 5 mg prednison

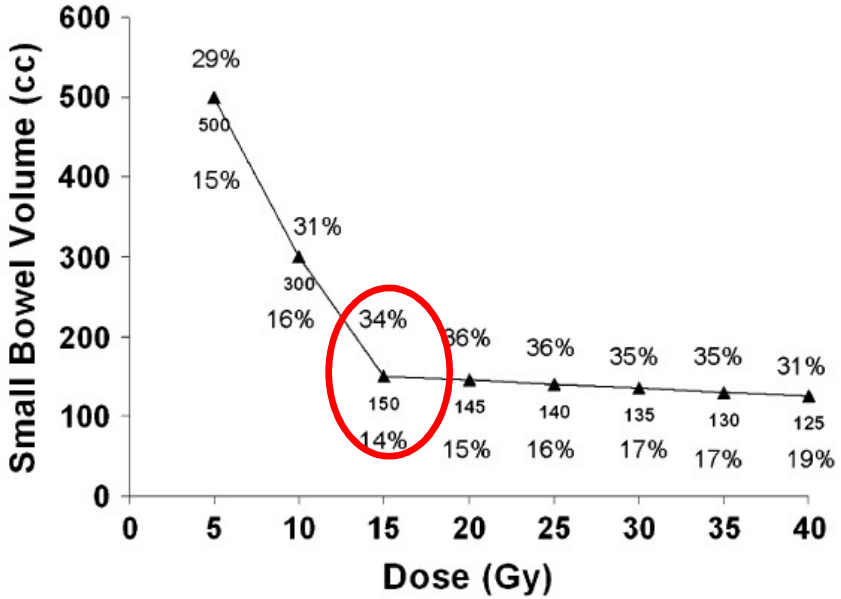
Murai Radiat Oncol 2012 189 pts

Small bowel toxicity

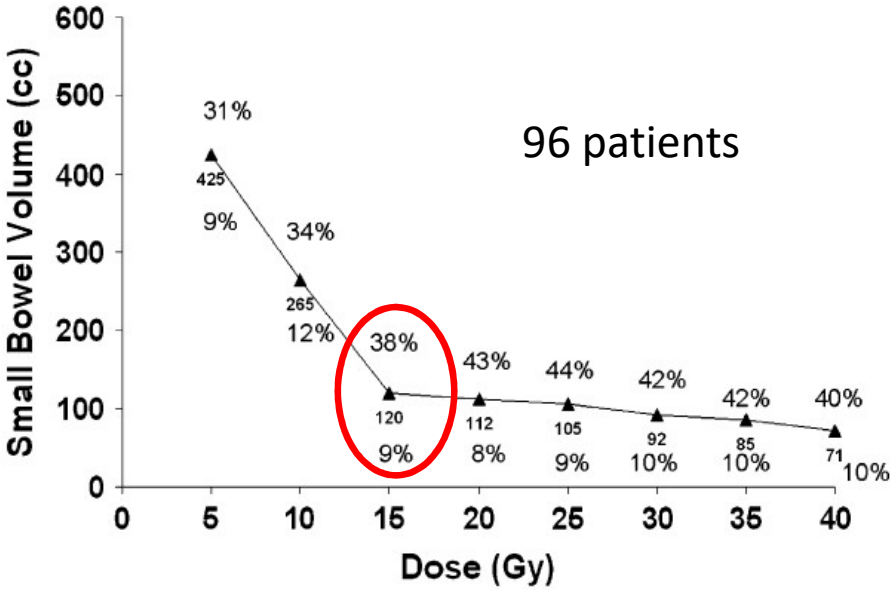
- Acute small bowel toxicity depends on irradiated volume

Better modeling of preoperative patients

Previous parameters



Revised parameters



ESTRO School

Robertson et al., Int J Rad Onc Biol Phys 2008

Relevant radiobiological factors

- Irradiated volume with SBRT

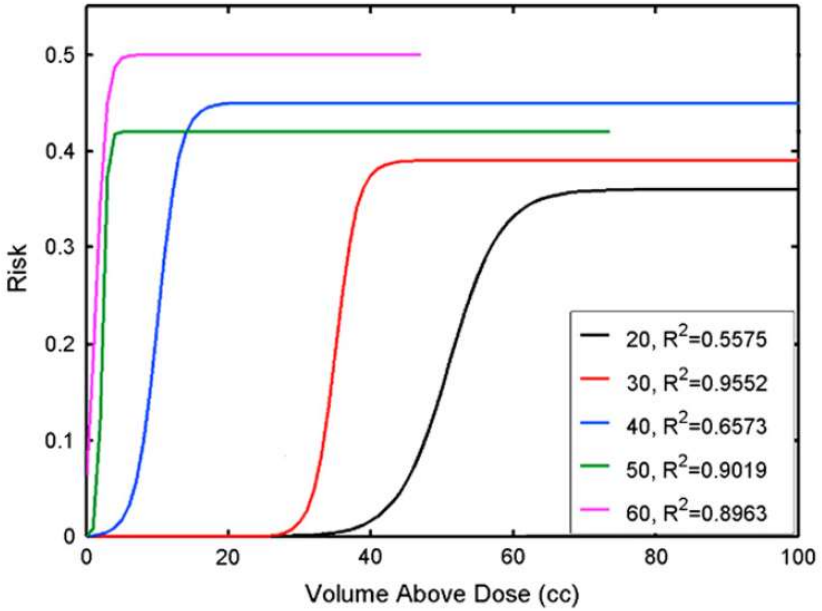


Fig. 1. Volume–risk analysis based on median effective concentration dose–response model for designated dose levels (20, 30, 40, 50, and 60 Gy) for development of severe chest wall toxicity.

Dunlap Int J Radiat Oncol 2010 60 pts

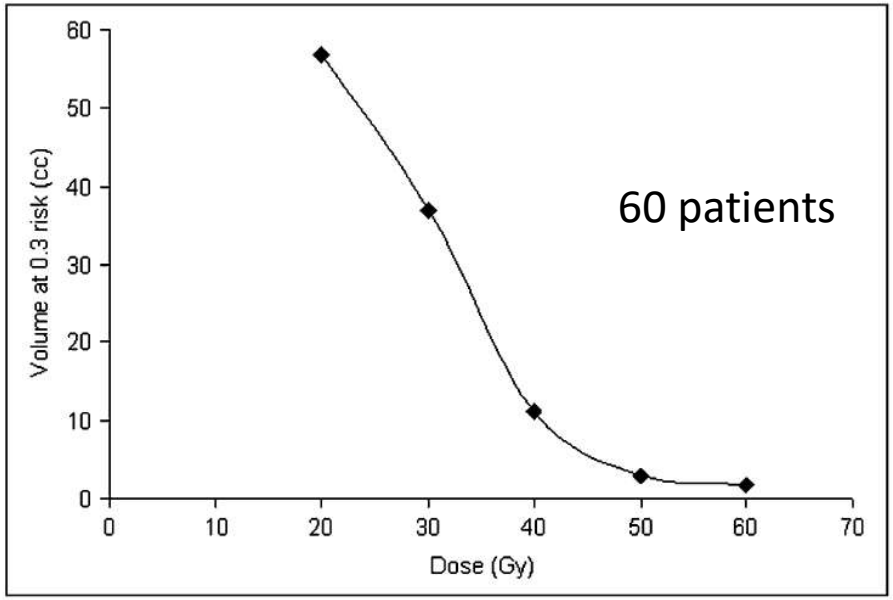

Fig. 2. Dose–volume relationship for 30% risk of severe chest wall toxicity.

Chest wall volume receiving >30Gy predicts risk of severe pain and/or rib fracture after lung SBRT

Relevant factors

- Radiobiological-related factors influencing normal tissue reactions
  - Intrinsic radiosensitivity (L2.3)
  - Total radiation dose (L3.5)
  - Technique and irradiated volume (L3.6)
  - Fractionation schedule (late reactions) (L2.3)
  - Overall treatment time (early reactions) (L2.4)
  - Concomitant treatment (L4.4, L5.2)

Relevant radiobiological factors

- Fractionation schedule START-A

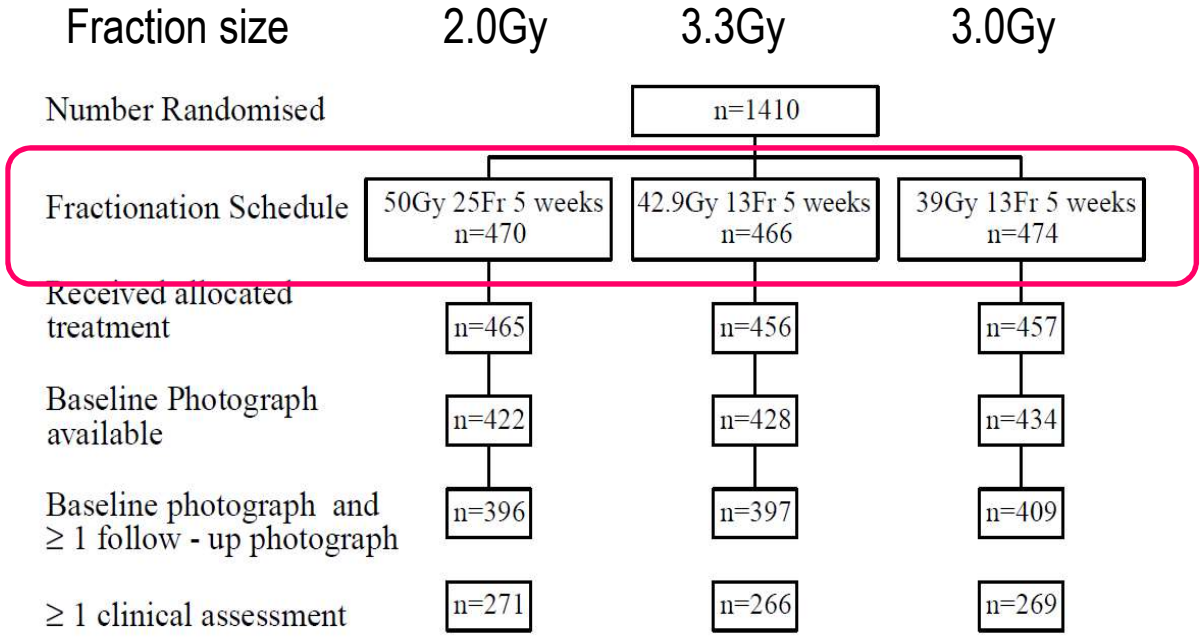

Fig. 1. Number of patients randomised into each fractionation schedule and with available follow-up data.

Yarnold Radiother Oncol 2005

Relevant radiobiological factors

Yarnold Radiother Oncol 2005

- Fractionation schedule: relation to EQD_{2Gy}

α/β = 3	EQD_{2Gy}
39Gy/13fx	46.8Gy
50Gy/25fx	50Gy
42.9Gy/13fx	54Gy

α/β of 3.6 Gy
(95% CI 1.8-5.4 Gy)

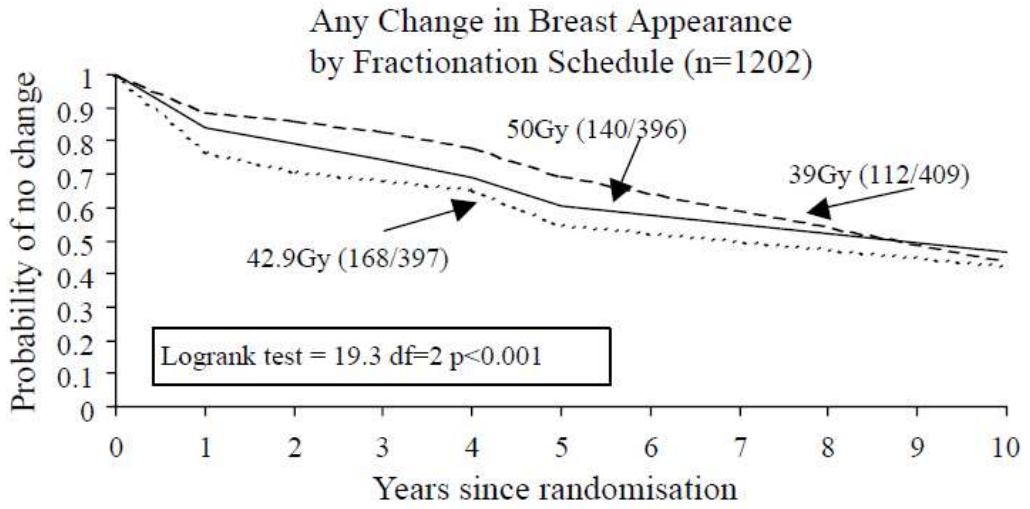

Fig. 2. Probability of any change in breast appearance late radiation effect ten years after radiotherapy by fractionation schedule.

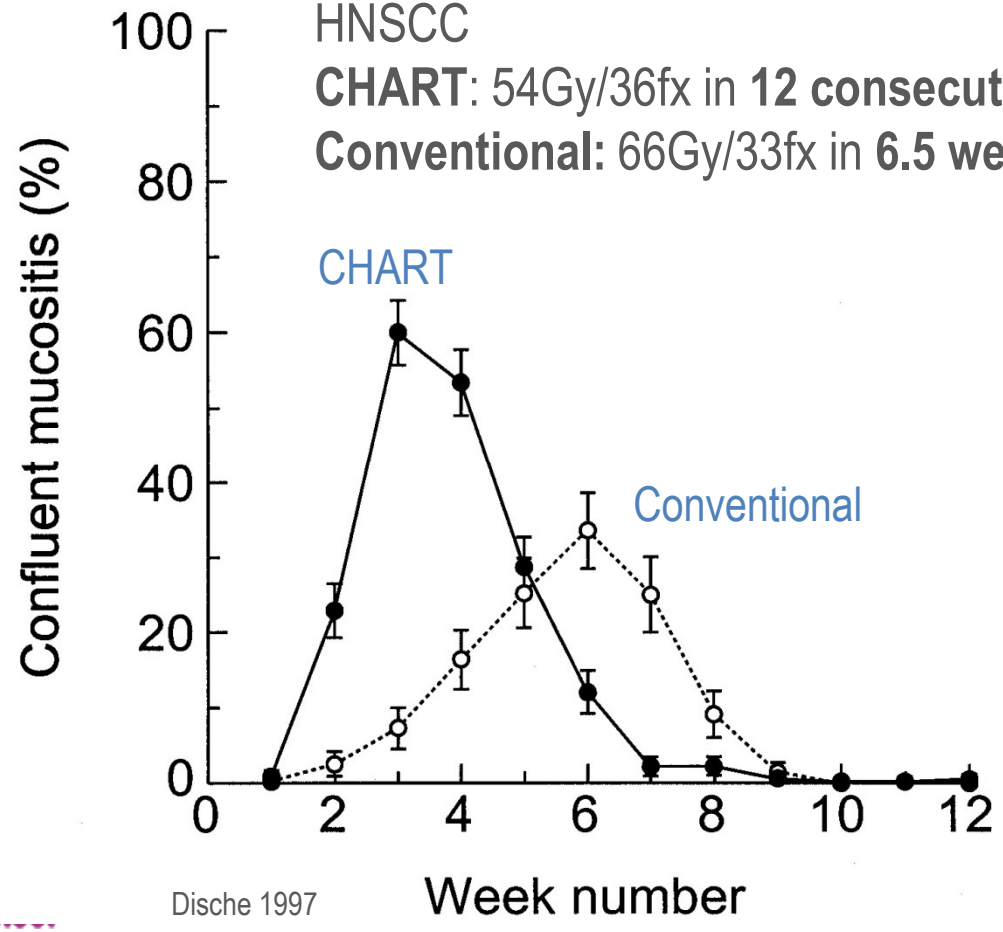
Relevant factors

- Radiobiological-related factors influencing normal tissue reactions
  - Intrinsic radiosensitivity (L2.3)
  - Total radiation dose (L3.5)
  - Technique and irradiated volume (L3.6)
  - Fractionation schedule (late reactions) (L2.3)
  - Overall treatment time (early reactions) (L2.4)
  - Concomitant treatment (L4.4, L5.2)

Relevant radiobiological factors

- Overall treatment time



Shorter OTT resulted in aggravation of early side effects

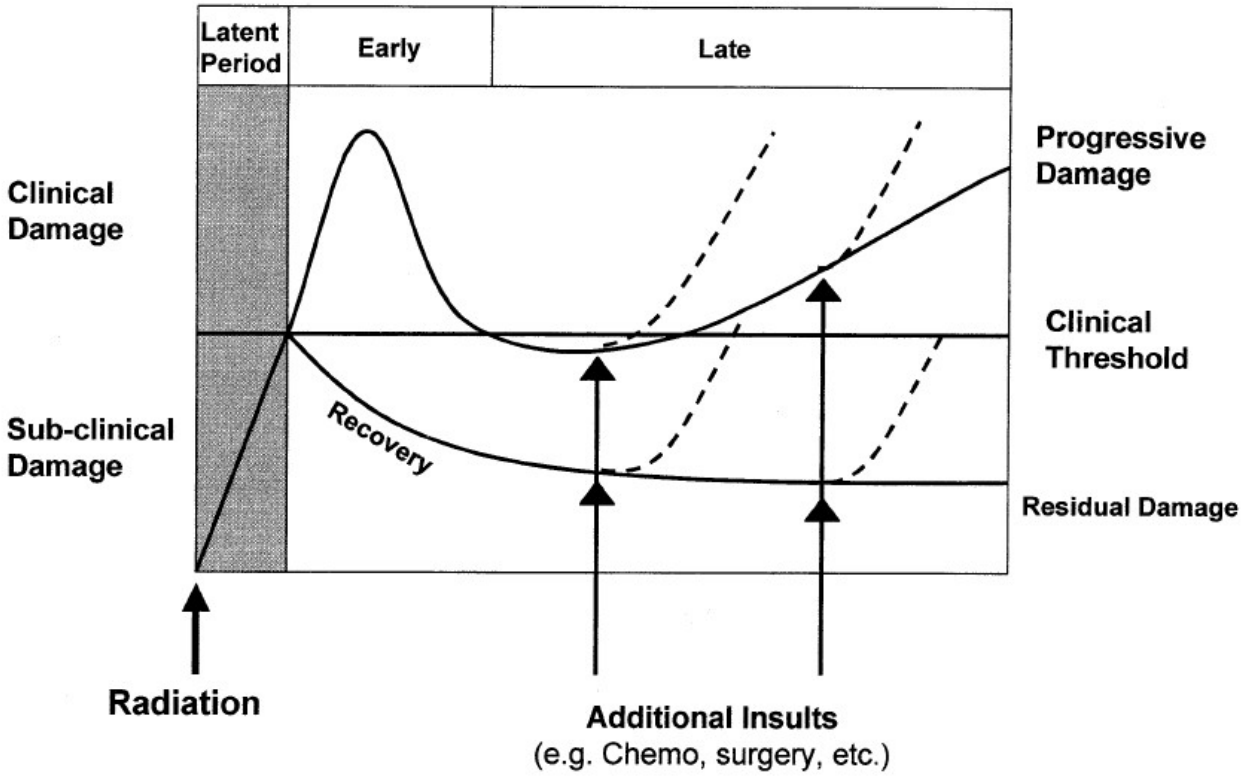
Dische 1997

Relevant factors

- Radiobiological-related factors influencing normal tissue reactions
  - Intrinsic radiosensitivity (L2.3)
  - Total radiation dose (L3.5)
  - Technique and irradiated volume (L3.6)
  - Fractionation schedule (late reactions) (L2.3)
  - Overall treatment time (early reactions) (L2.4)
  - Concomitant treatment (L4.4, L5.2)

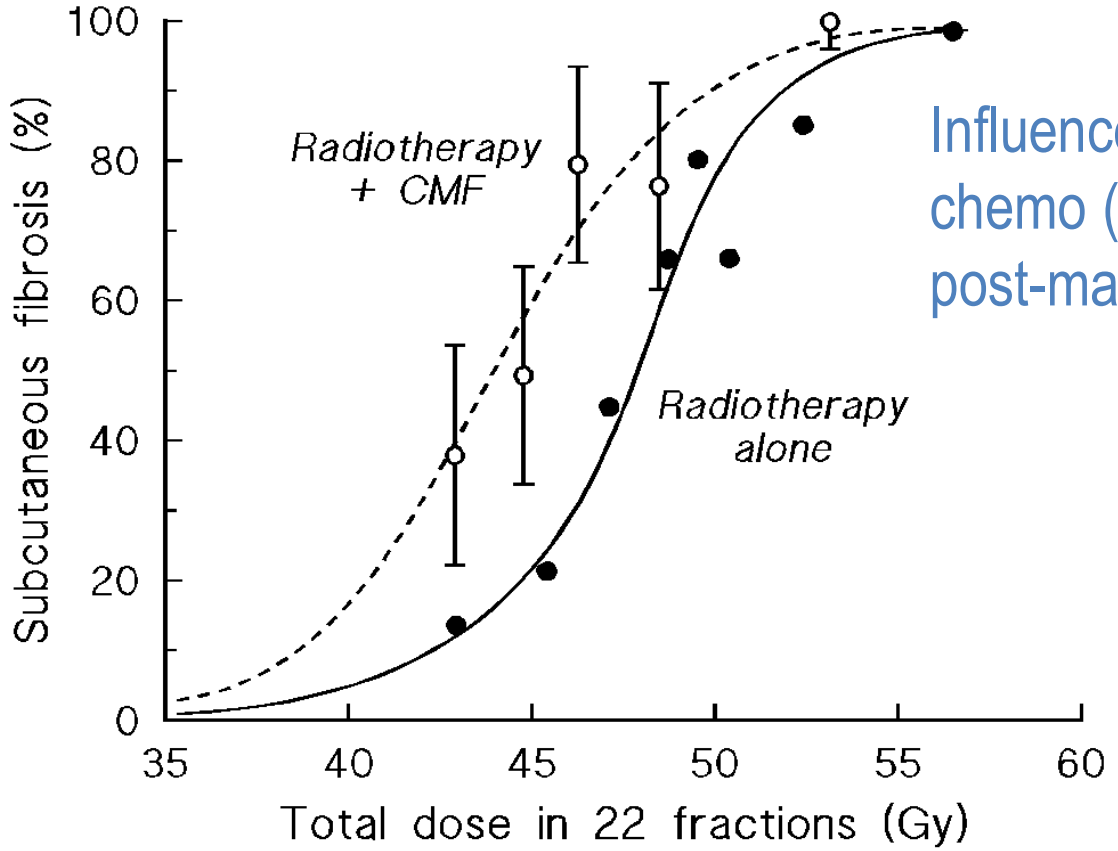
Relevant radiobiological factors

- Combined modality treatment



Relevant radiobiological factors

- Concomitant treatment



Influence of adjuvant chemo (CMF) on post-mastectomy RT

Bentzen 1989

How?

Treatment-related toxicity

- Underreported, vague symptoms … → result in greater morbidity that is costly to patients and the health system
- Different scoring systems used
- Prospective vs retrospective data
- Patient vs physician
- Affects QoL
- Requires appropriate treatment
- Many patients have become long-term survivors

How to measure normal tissue response?

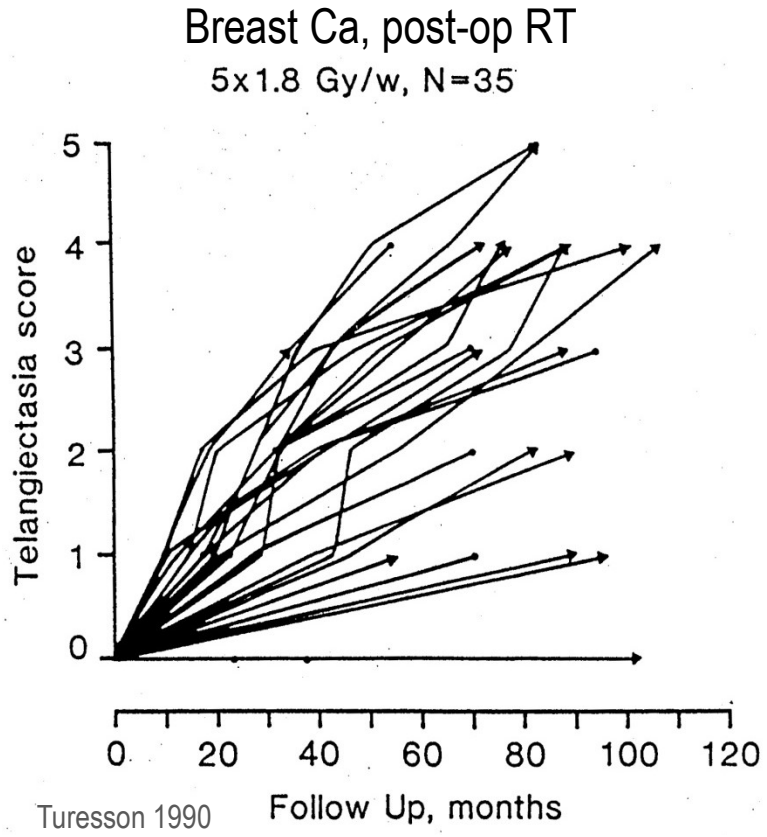
- Scoring of gross tissue effects
  - Scoring systems: grade the severity of tissue damage using an arbitrary scale
- Assays of tissue function
  - Functional assays to measure radiation effects
    - E.g. blood counts as an indicator of bone marrow function
- Clonogenic assays (L1.4)
  - Methods by which colony of cells that derive from a single irradiated cell can be observed

Scoring of side-effects: frequency

- Two aspects must be considered for documentation
  - Frequency
    - Early reactions can undergo considerable changes in clinical manifestation in short periods
      - Scoring at weekly basis: during and for some weeks after RT
    - Late reactions develop slowly and are usually irreversible
      - Scoring at intervals of several months after the end of RT (dynamics)
      - At later time points at annual intervals

Scoring of side-effects: frequency

- Progressive nature of late reactions

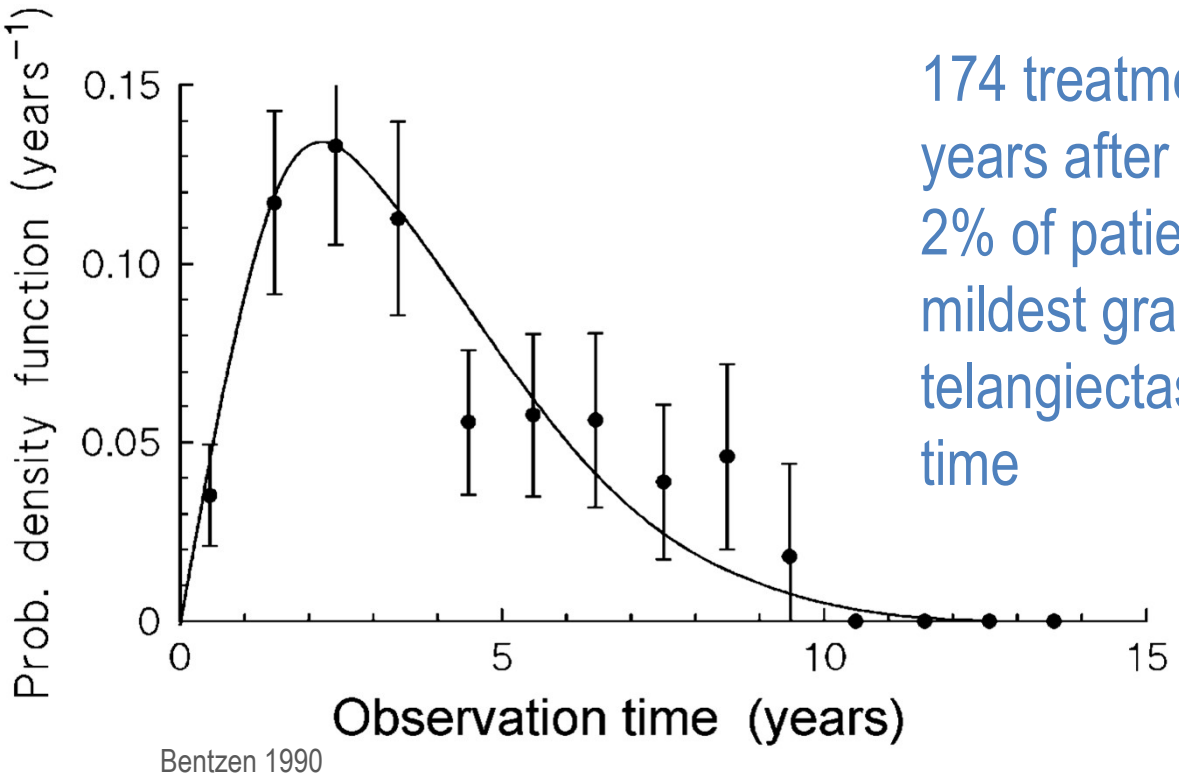


Turesson 1990

Long latent times
Large inter-patient variation

Scoring of side-effects: frequency

- Long latent time of late reactions



Bentzen 1990

174 treatment fields: even 9 years after treatment, about 2% of patients show the mildest grade of telangiectasia for the first time

Scoring of side-effects: scoring sytems

- Two aspects must be considered for documentation
  - Scoring system used
    - WHO (World Health Organisation)
    - RTOG/EORTC (Radiation and Oncology Therapy Group/European Organisation for Research and Treatment of Cancer
    - CTCAE (Common Terminology Criteria for Adverse Events; latest version CTCAE v4.03)
    - LENT-SOMA (Late Effects of Normal Tissues – Subjective, Objective, Managment & Analytical)
    - IPSS (International Prostate System Score)

Scoring of side-effects: scoring sytems

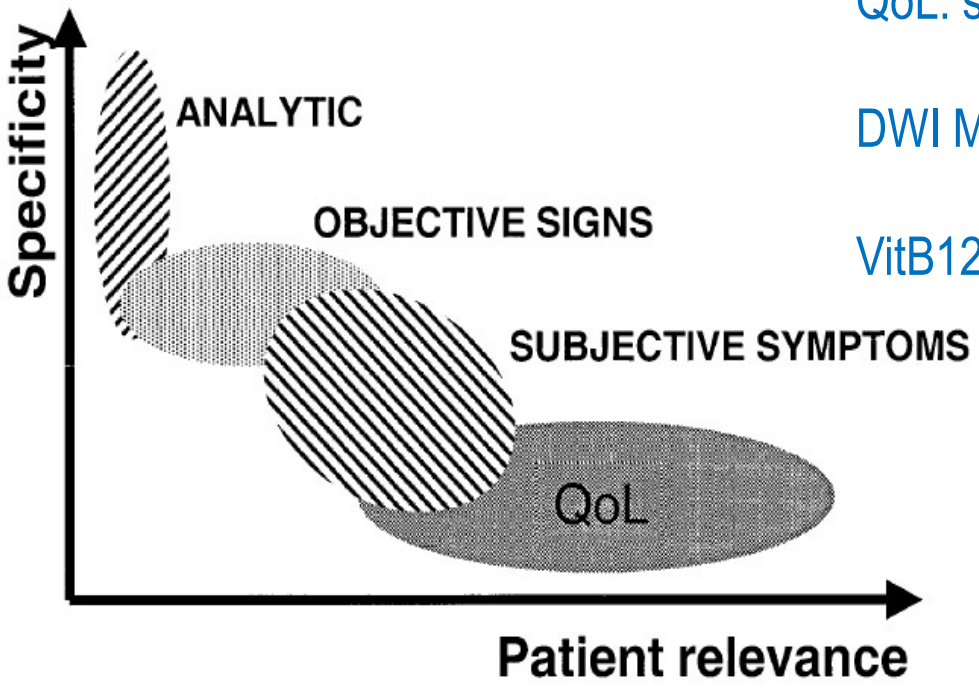
Table 13.1 Systems for documentation of side effects, with examples for oral mucositis.

Grade	General	RTOG/EORTC	CTCAE v3	WHO
0	No change	No change	No change	No change
1	Mild	Erythema, mild soreness, painless erosions	Erythema; normal diet	Soreness, erythema
2	Moderate/ clear	Painful erythema, edema or ulcers; can eat	Patchy ulceration; can eat and swallow modified diet	Erythema, ulcers; can eat solids
3	Severe/ significant	Painful erythema, edema or ulcers; cannot eat	Confluent ulcerations, bleeding with minor trauma; unable to adequately aliment or hydrate orally	Ulcers; requires liquid diet only
4	Life-threatening	Requires parental or enteral support	Tissue necrosis; significant spontaneous bleeding	Alimentation not possible
5	Death due to side effects	Death due to side effects	Death due to side effects	Death due to side effects

Need for therapeutic intervention

Scoring of side-effects: scoring systems

- Trade-off between specificity and patient relevance



QoL: some are health related, others not

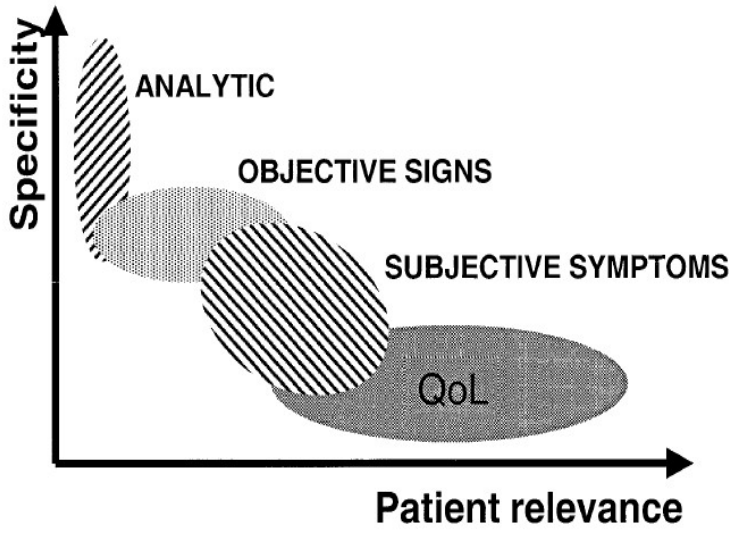
DWI MRI: biological significance

VitB12: malabsorption

Bentzen Sem Rad Oncol 2003

Scoring of side-effects: scoring systems

- Patient's role in toxicity reporting: how well do different scoring systems compare?



Patient-reported late toxicities have a negative impact on QoL

Patient-based questionnaires are an important contributor to capturing late RT effects

Bentzen Sem Rad Oncol 2003

Ho Radiother Oncol 2010

Patient-reported outcome measures

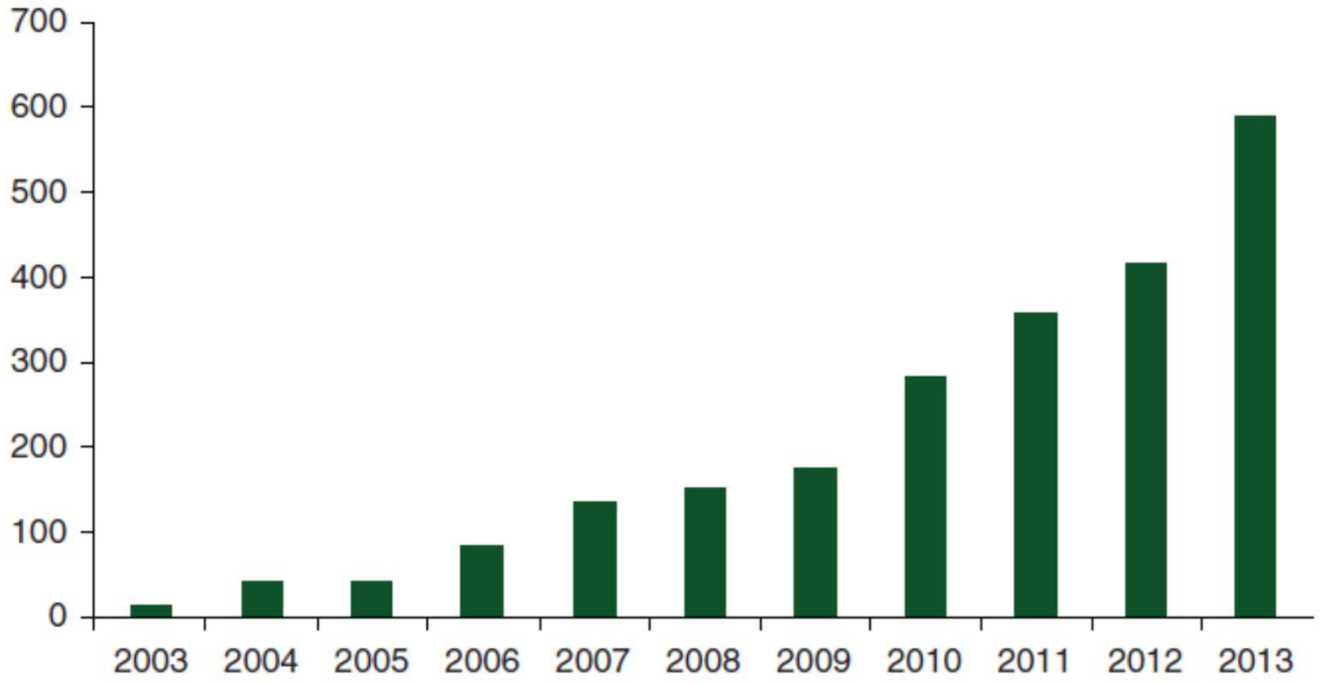
Howell D et al Ann Oncol 2015

- PROM
  - = ‘any report coming directly from the patient about a health condition and its treatment’ using a self-reported measure’
  - focus on physical symptoms, treatment toxicities, psychosocial problems or global health-related QoL impacts of a health condition
  - valued for ensuring that the patients’ experience of cancer and treatment is represented in the measurement of health and for capturing the effectiveness of clinical interventions

Patient-reported outcome measures

Howell D et al Ann Oncol 2015

- Trend of published articles citing PROMs



Implementation of PROMs

Howell D et al Ann Oncol 2015

- Implementation of PROMs in routine cancer care
  - Increased patient satisfaction with clinical consultations
  - Better perceived quality of care
  - Improved overall patient well-being
  - Early detection and monitoring of symptoms / improved symptom management
  - Improved patient-physician communication (emotional, psychosocial, sensitive issues)
  - Support clinical decision making / psychosocial referrals
  - No significant impact on length of clinical encounter (if results available before consultation)

Implementation of PROMs

Howell D et al Ann Oncol 2015

Barriers

- Clinicians
  - Time constraints
  - Lack of training on the use and interpretation of PROMs
  - Value add
  - Liability issues

Enablers

- Clinicians
  - Integration with clinical practice guidelines
  - Automatic ‘flagging’ of clinically important scores
  - Provide longitudinal interpretation of what signifies a clinically important difference in PROMs data

Implementation of PROMs

Howell D et al Ann Oncol 2015

Barriers

- Patients
  - Length and complexity of the scale
  - Availability of translated and culturally meaningful versions
  - Patient comfort level with technology
  - Degree of disability

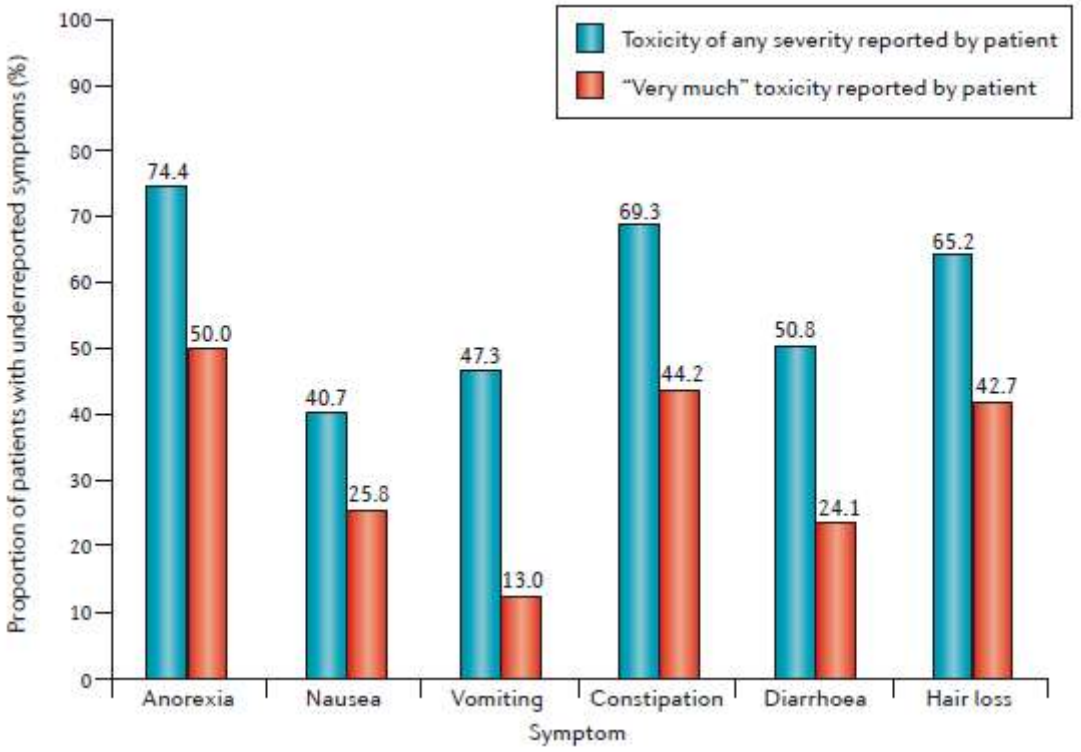
Enablers

- Patients
  - More disease-specific questions
  - Simplifying scales

PROMs in the evaluation of toxicity

Di Maio M, Nature 2016

- Underreporting of anticancer treatment-related toxicity by physicians



Effect of PROMs on QoL and survival

Basch E et al JAMA 2017;318(2):197

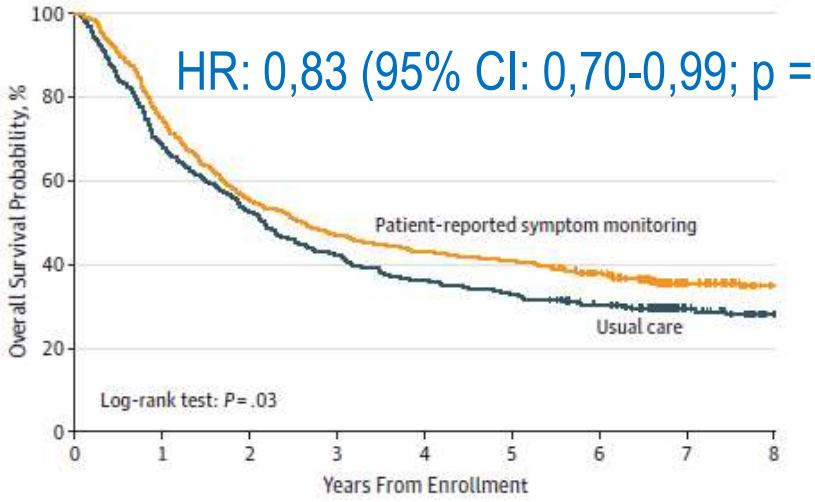
- On-line self-reporting of symptoms improves QoL and extends survival

766 consecutive patients initiating routine chemotherapy for metastatic solid tumor

Randomization: usual care vs electronic PROMs

Median OS was 5 months longer in PROMs group (p = ,03)

Figure. Overall Survival Among Patients With Metastatic Cancer Assigned to Electronic Patient-Reported Symptom Monitoring During Routine Chemotherapy vs Usual Care

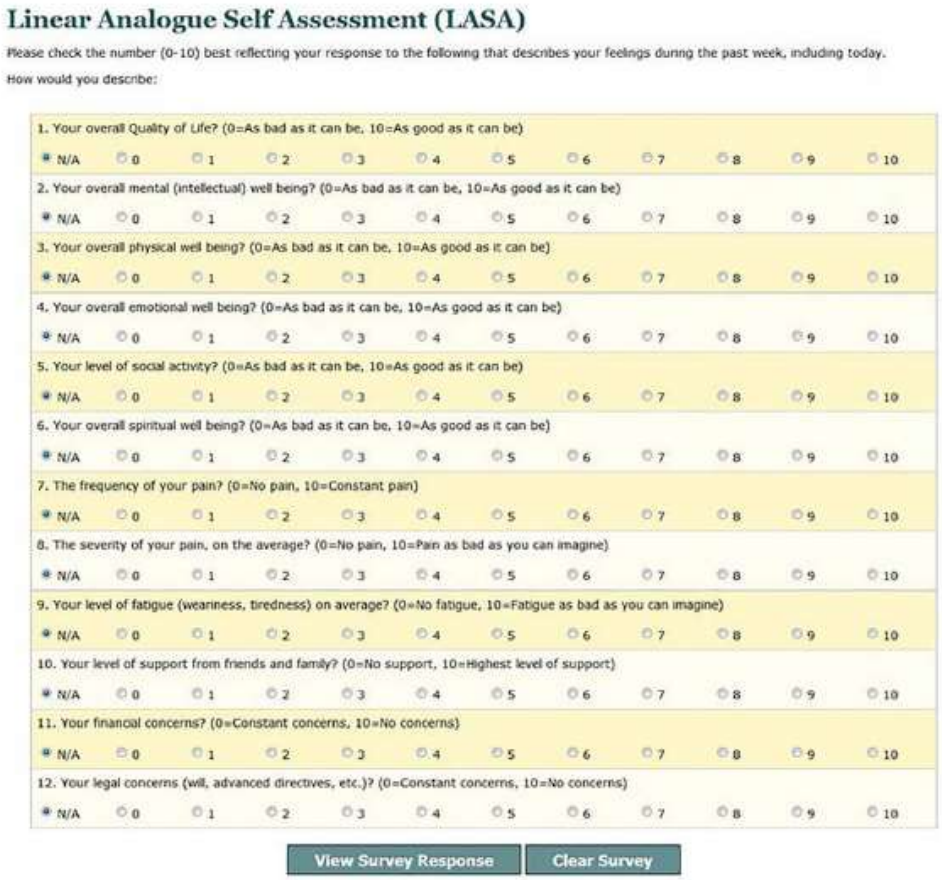


No. at risk									
Patient-reported symptom monitoring	441	331	244	207	190	181	148	65	33
Usual care	325	223	171	137	118	107	89	50	27

PROMs and radiotherapy

Niska JR et al Qual Life Res 2017

- Electronic patient-reported outcomes and toxicities during RT for HNSCC
  - 65 pts
  - Electronic, real-time, 12-item LASA
  - Timepoints: baseline, before biweekly appointments and at last week of RT
  - Changes in QoL domains over time



Linear Analogue Self Assessment (LASA)

Please check the number (0-10) best reflecting your response to the following that describes your feelings during the past week, including today.

How would you describe:

1. Your overall Quality of Life? (0=As bad as it can be, 10=As good as it can be)
2. Your overall mental (intellectual) well being? (0=As bad as it can be, 10=As good as it can be)
3. Your overall physical well being? (0=As bad as it can be, 10=As good as it can be)
4. Your overall emotional well being? (0=As bad as it can be, 10=As good as it can be)
5. Your level of social activity? (0=As bad as it can be, 10=As good as it can be)
6. Your overall spiritual well being? (0=As bad as it can be, 10=As good as it can be)
7. The frequency of your pain? (0=No pain, 10=Constant pain)
8. The severity of your pain, on the average? (0=No pain, 10=Pain as bad as you can imagine)
9. Your level of fatigue (weariness, tiredness) on average? (0=No fatigue, 10=Fatigue as bad as you can imagine)
10. Your level of support from friends and family? (0=No support, 10=Highest level of support)
11. Your financial concerns? (0=Constant concerns, 10=No concerns)
12. Your legal concerns (will, advanced directives, etc.)? (0=Constant concerns, 10=No concerns)

Legal Concerns	1	2	10	0	10	10

Fig. 2 Data display provided to clinicians. *LASA* indicates linear analog self-assessment; *QOL* quality of life; *WB* well-being

Scoring of side-effects: key points

- Use a published system
- Minimize the number of variables
- Use forms easy to read
- Define endpoints
- Test inter-observer variability
- Document observations (e.g. pictures)
- Record
  - Baseline morbidity
  - Invasive procedures
  - Comorbidity
  - Other relevant treatments

Take home messages

- Normal tissue side effects are mandatory to score
  - Therapeutic ratio
  - Quality assurance (QA)
- Both early and late reactions may develop in the same organ
- Use validated scoring systems to record normal tissue effects
- Score before, during and after RT
  - Extend follow-up to several years after RT to get knowledge on late morbidity

*INSER... France;
Departm... cology,
Cedars-... k, MI;
#British... ia, PA;
††D... gy,

Mean = 1.55 [CL 0.46 – 4.52]

Results: Adjusted for other factors, total dose of EBRT and sum of squared doses per fraction were associated with long-term rate of change of PSA level ($p = 0.0017$ and $p = 0.0003$, respectively), an increase of each being associated with a lower rate of rise. The α/β ratio was estimated at 1.55 Gy (95% confidence band, 0.46–4.52 Gy). This estimate was robust to adjustment of the linear mixed model.

Fractionation in breast cancer

Effect of radiotherapy fraction size on tumour control in patients with early-stage breast cancer after local tumour excision: long-term results of a randomised trial

J Roger Owen, Anita Ashton, Judith M Bliss, Janis Homewood, Caroline Harper, Jane Hanson, Joanne Haviland, Soren M Bentzen, John R Yarnold

Lancet Oncol 2006: 7: 467–71

Summary

Background Standard curative schedules of radiotherapy to the breast deliver 25 fractions of 2·0 Gy over 5 weeks. In a randomised trial, we tested whether fewer, larger fractions were at least as safe and as effective as standard regimens. In this analysis, we assessed the long-term results of tumour control in the same population.

Methods In 1986–98, we randomly assigned 1410 women with invasive breast cancer (tumour stage 1–3 with a maximum of one positive node and no metastasis) who had had local tumour excision of early stage breast cancer to receive 50 C
given over 5
elsewhere. He
appearance of

Findings After
ipsilateral tumour relapse after 10 years was 12·1% (95% CI 8·8–15·3) in the 50 Gy group, 14·8% (11·2–18·3) in the 39 Gy group, and 9·6% (6·7–12·6) in the 42·9 Gy group (difference between 39 Gy and 42·9 Gy groups, χ^2 test, p=0·027). The sensitivity of breast cancer to dose per fraction was estimated to be 4·0 Gy (95% CI 1·0–7·8), similar to that estimated for the late adverse effects in healthy tissue from breast radiotherapy.

Interpretation Breast cancer tissue is probably just as sensitive to fraction size as dose-limiting healthy tissues. If this finding is confirmed, radiotherapy schedules can be greatly simplified by the delivery of fewer, larger fractions without compromising effectiveness or safety, and possibly improving both.

Mean = 4.0 [CL 1.0–7.8]

Molecular basis of the DNA damage response

Marianne Koritzinsky

Princess Margaret Cancer Centre
Toronto, Canada
Marianne.Koritzinsky@uhnresearch.ca

DNA - The Main Target of Radiation

DNA **D**amage **R**esponse

DNA

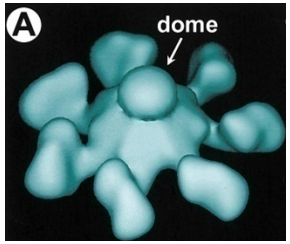
- Only molecule which is repaired

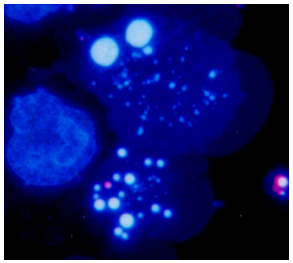
Initial cellular responses to radiation

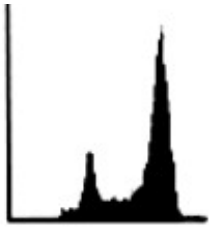
Sensors of damage

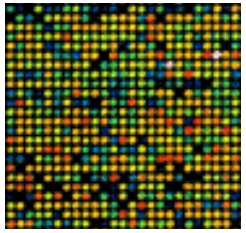
Biological Pathways

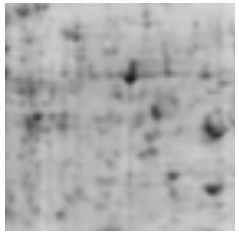
DNA Repair	Early Apoptosis	Cell cycle checkpoints	Gene expression











Endogenous DNA damage

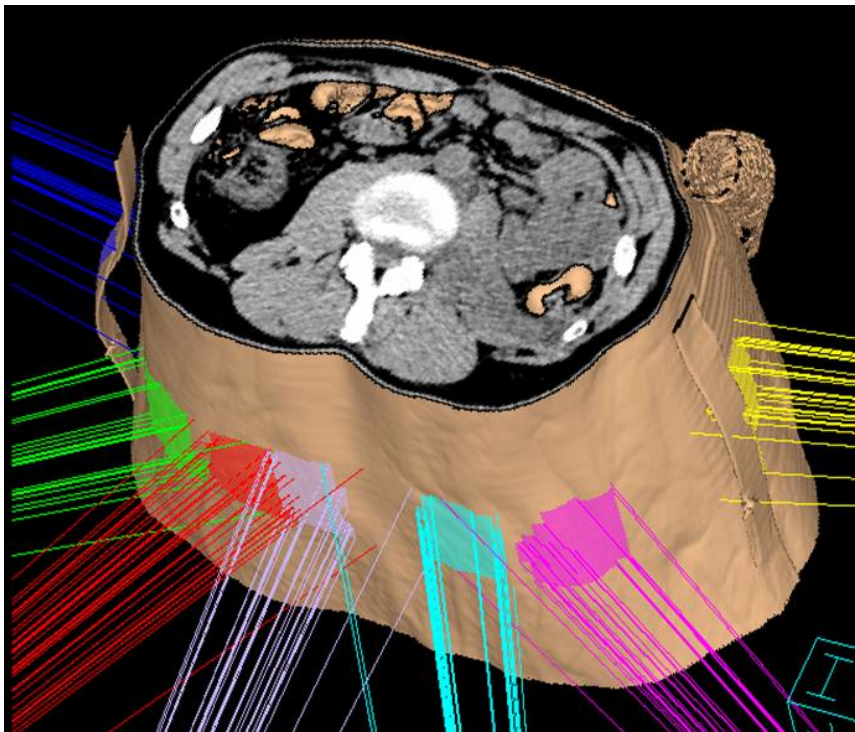
- In every human cell per day:
  - 50,000 SSB
  - 10,000 depurinations
  - 600 deaminations
  - 2000 oxidative base damages
  - 5000 alkylation damage
  - 10 cross links
  - 10 DSB's

Ionizing radiation damage

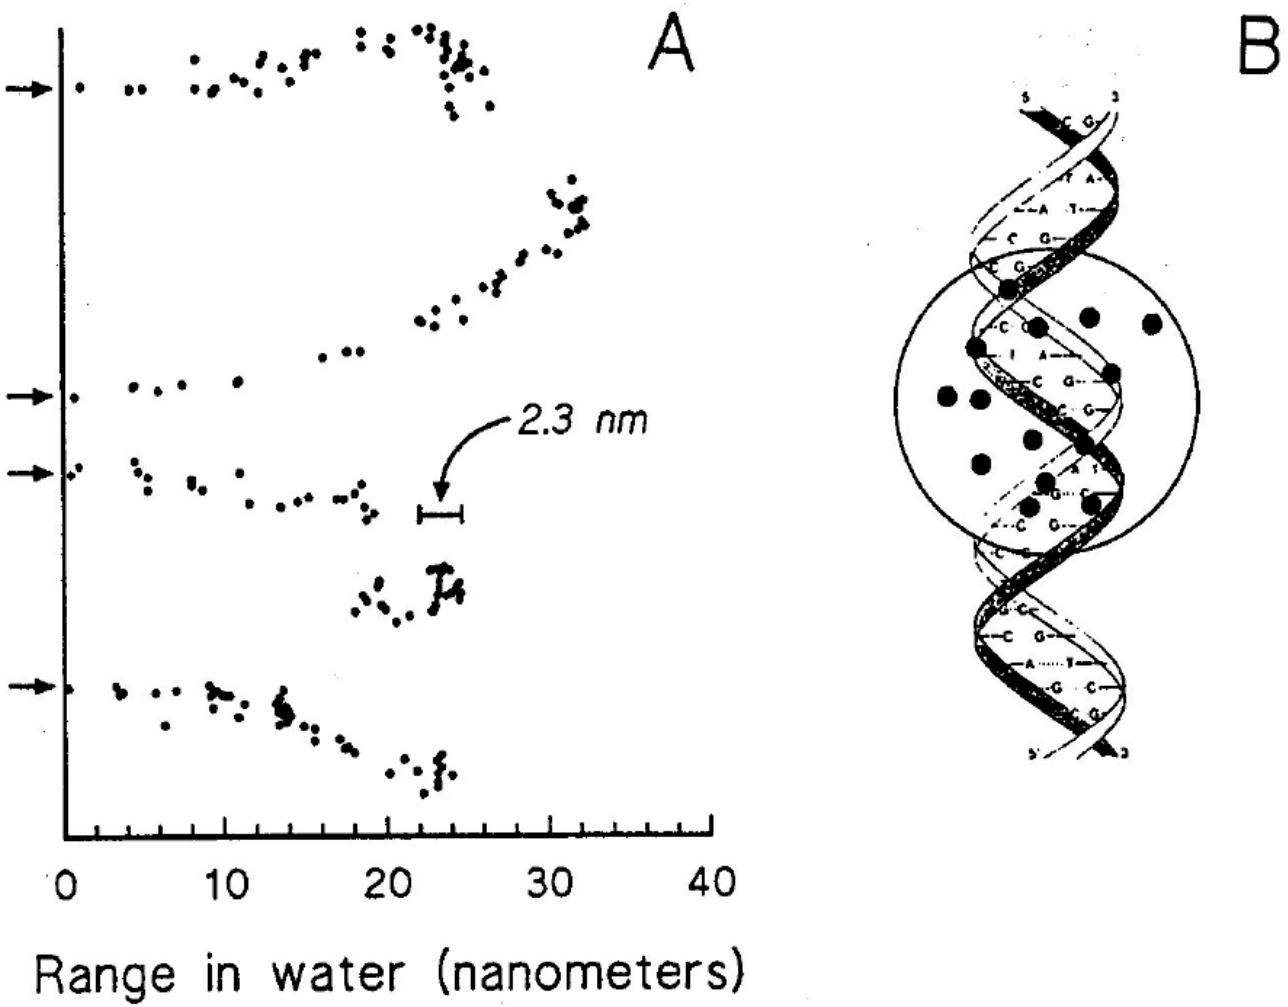
Primary target is the DNA

1Gy of low LET Xrays produces:

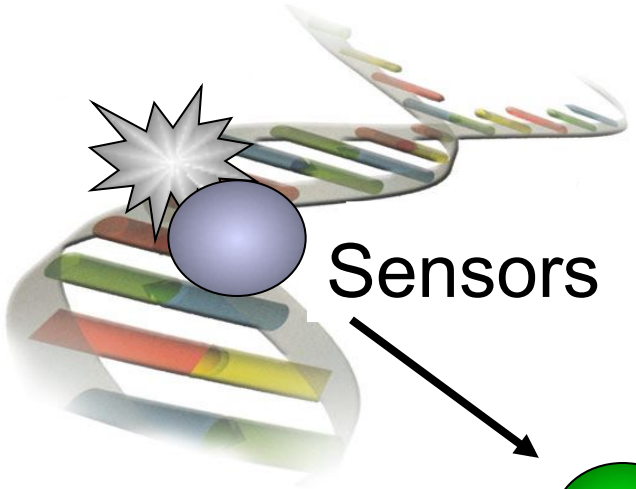
1000	single strand breaks
40	double strand breaks
1000	altered bases



Multiple damaged sites



DNA Damage Response



Sensors

Transducers/Mediators

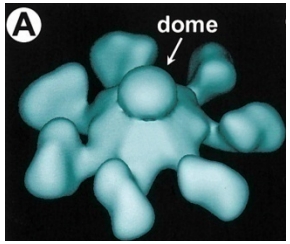
Effectors

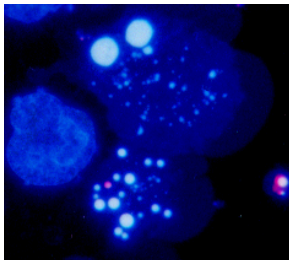
Initial cellular responses to radiation

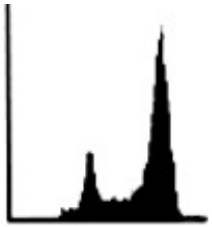
Sensors of damage

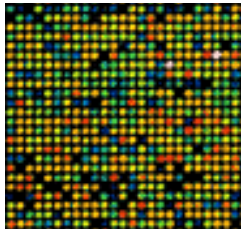
Biological Pathways

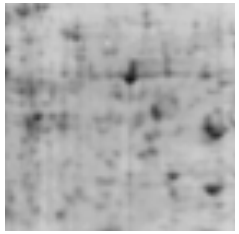
DNA Repair	Early Apoptosis	Cell cycle checkpoints	Gene expression



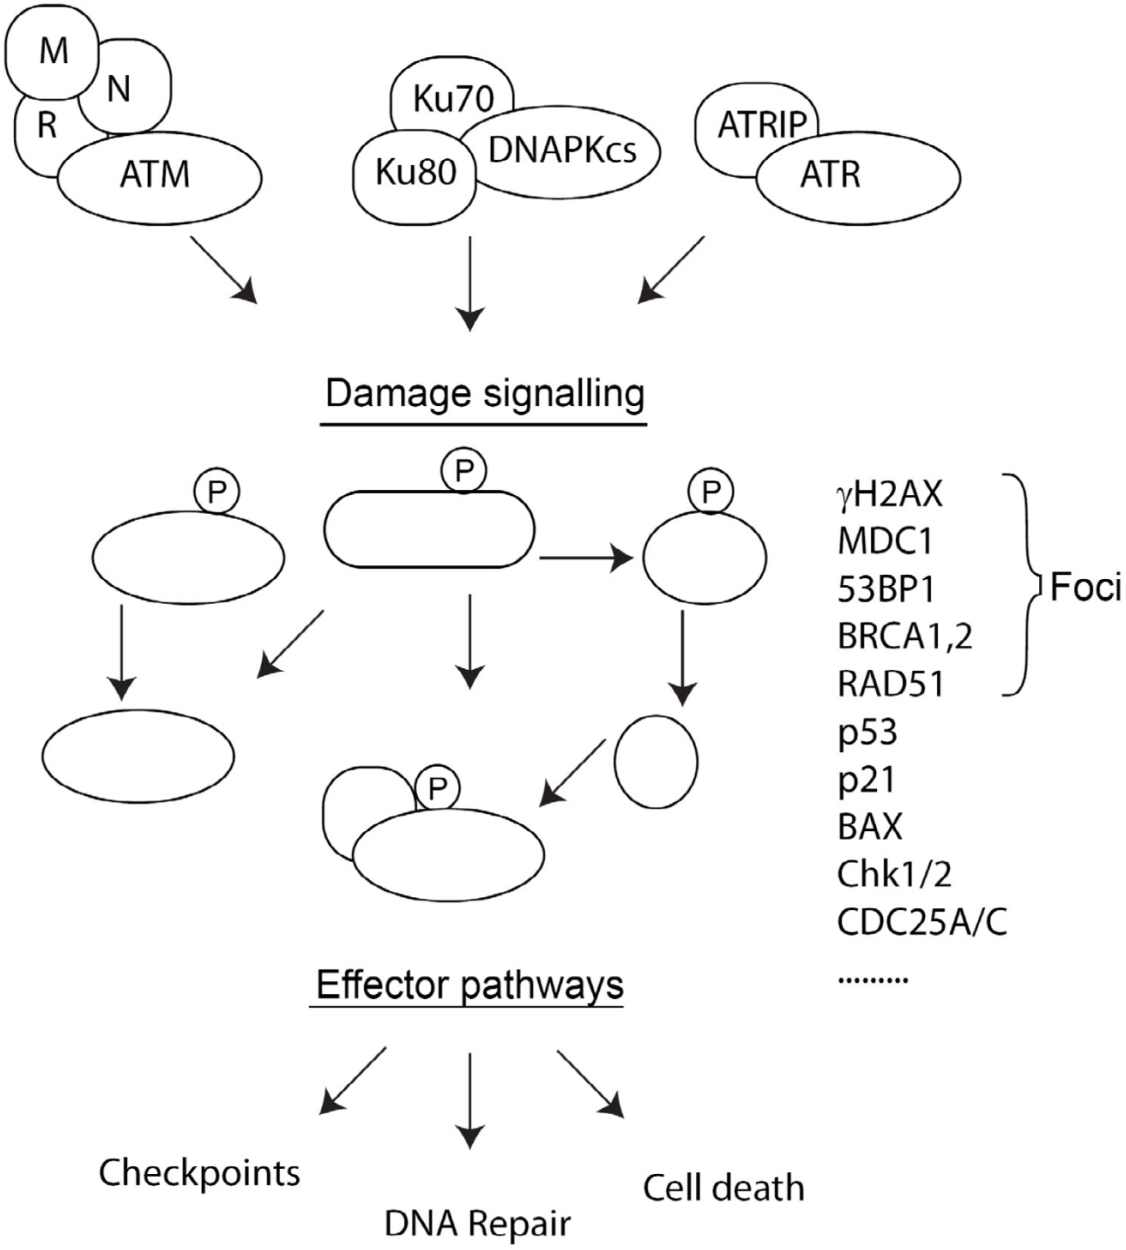




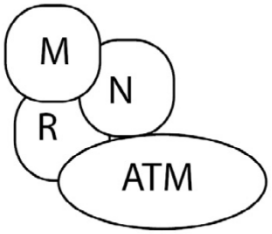




DNA damage signaling

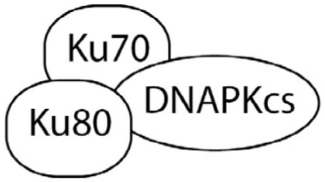


The Sensors



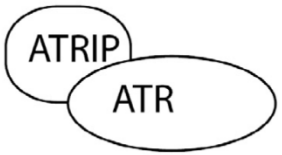
ATM
- PIKK kinase
- mutated in Ataxia Telangiectasia
- patients are radiosensitive
- activated by DNA damage (DSB), phosphorylates many proteins

MRN
- important for ATM activation, recruitment
- involved in processing damage
- nuclease activity



DNAPKcs
- PIKK kinase
- activated by DNA damage (DSB)
- involved directly in repair

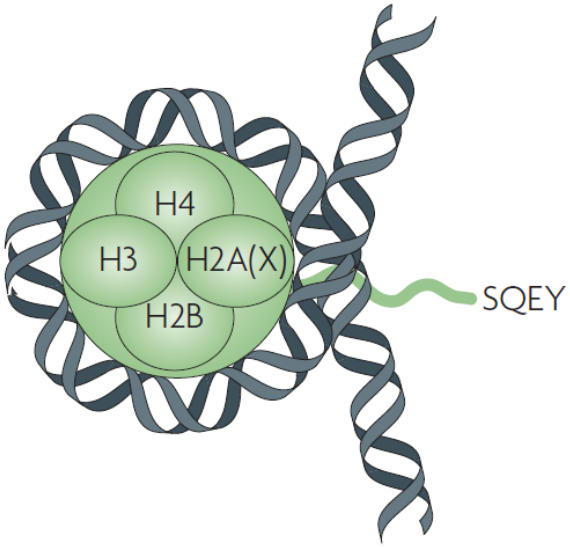
Ku
- DNA end binding proteins
- recognize damage, recruit DNAPKcs

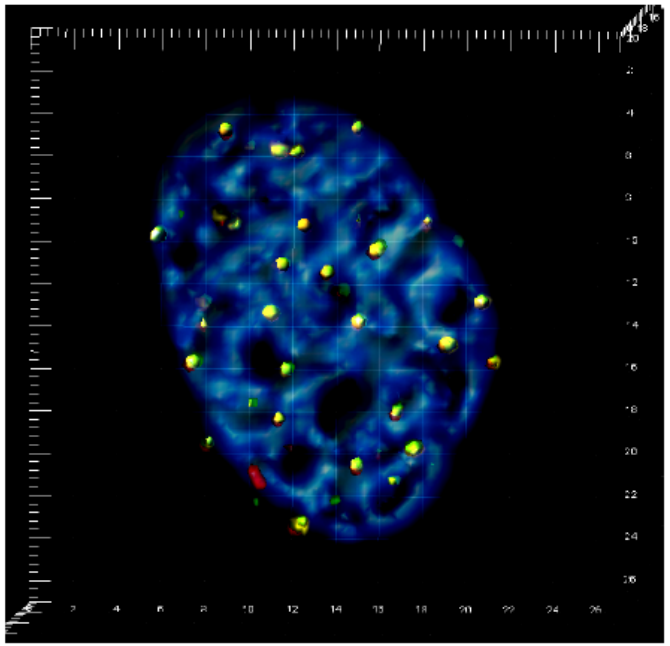


ATR
- PIKK kinase
- ATM and rad3 related kinase
- not involved in recognizing DSB
- important for replication stress, stalled forks
- is often activated during DSB repair

IRIF

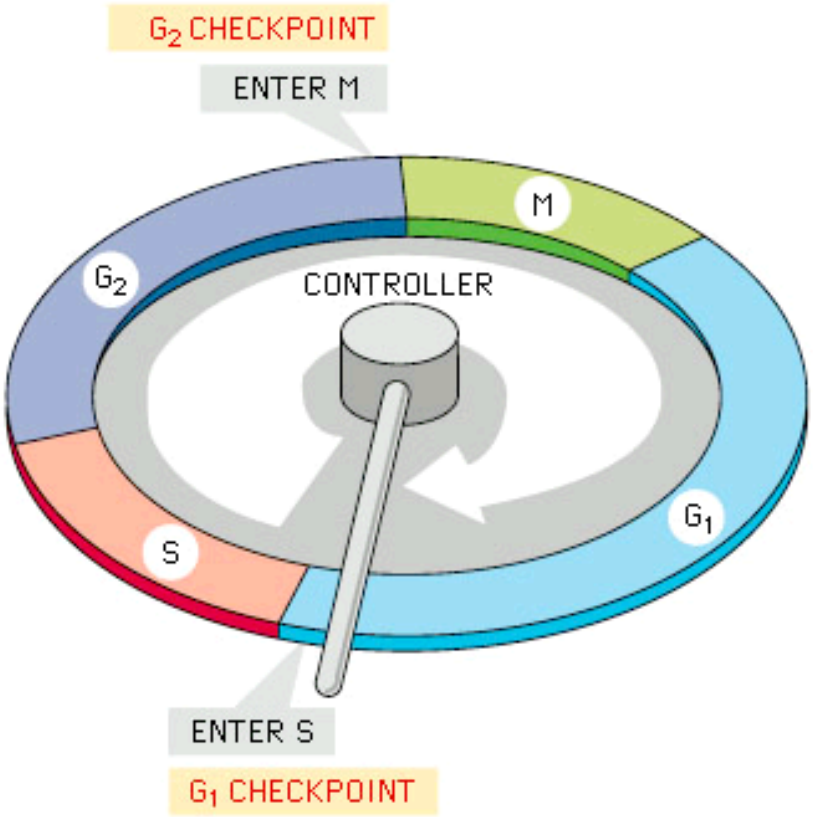
- Form rapidly after irradiation – minutes
- Occur at sites of damage
- Foci extend over larges region around the break





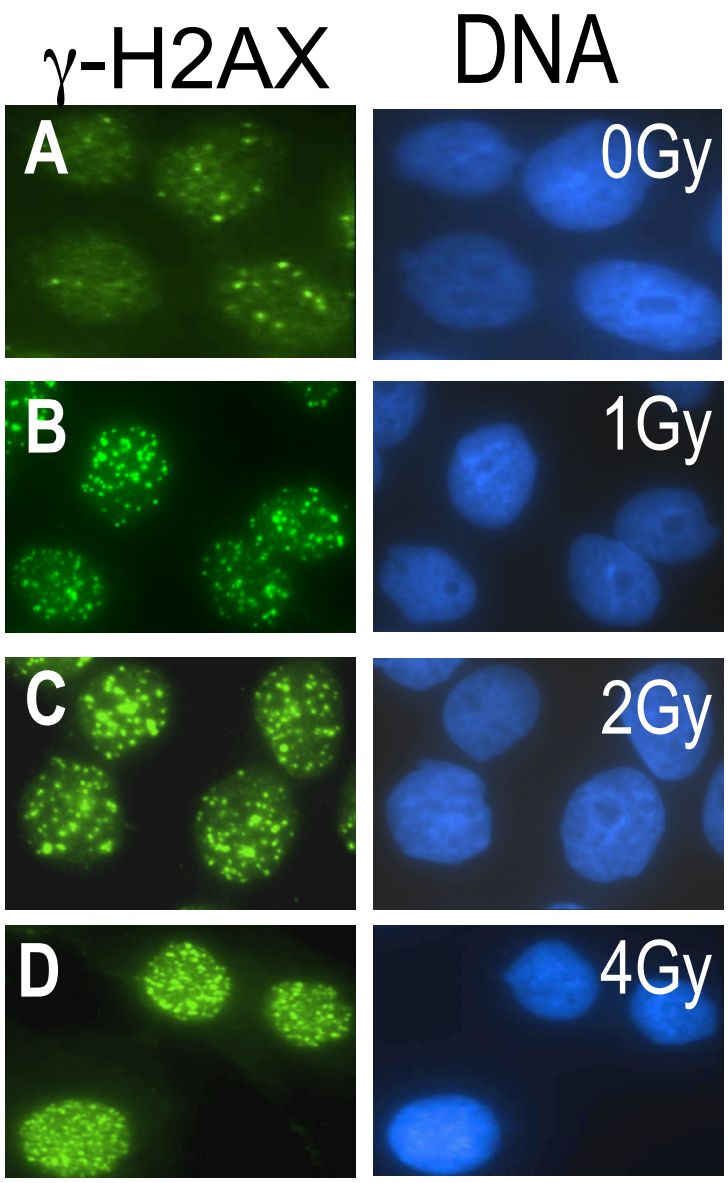
Checkpoints

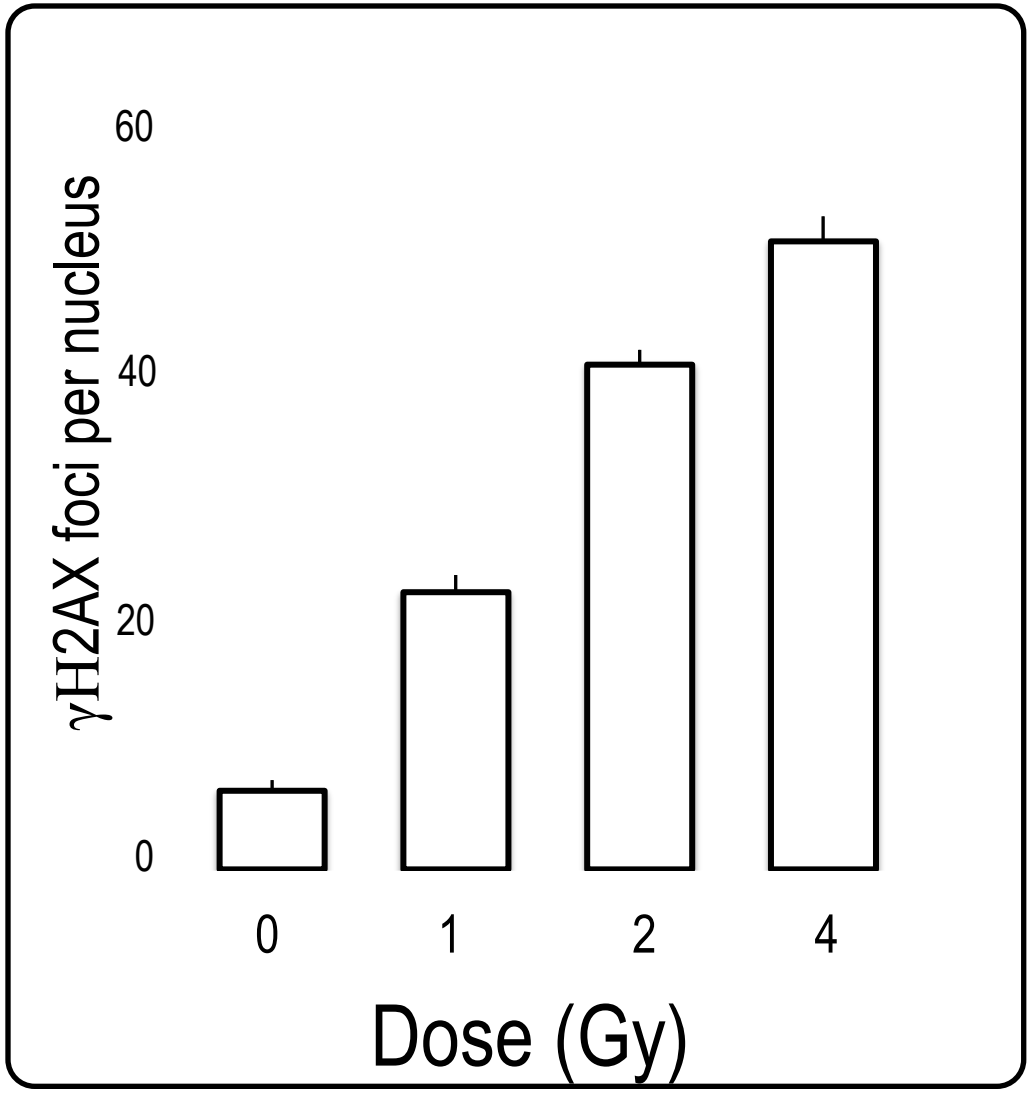
Checkpoints occur at several points in the cell cycle



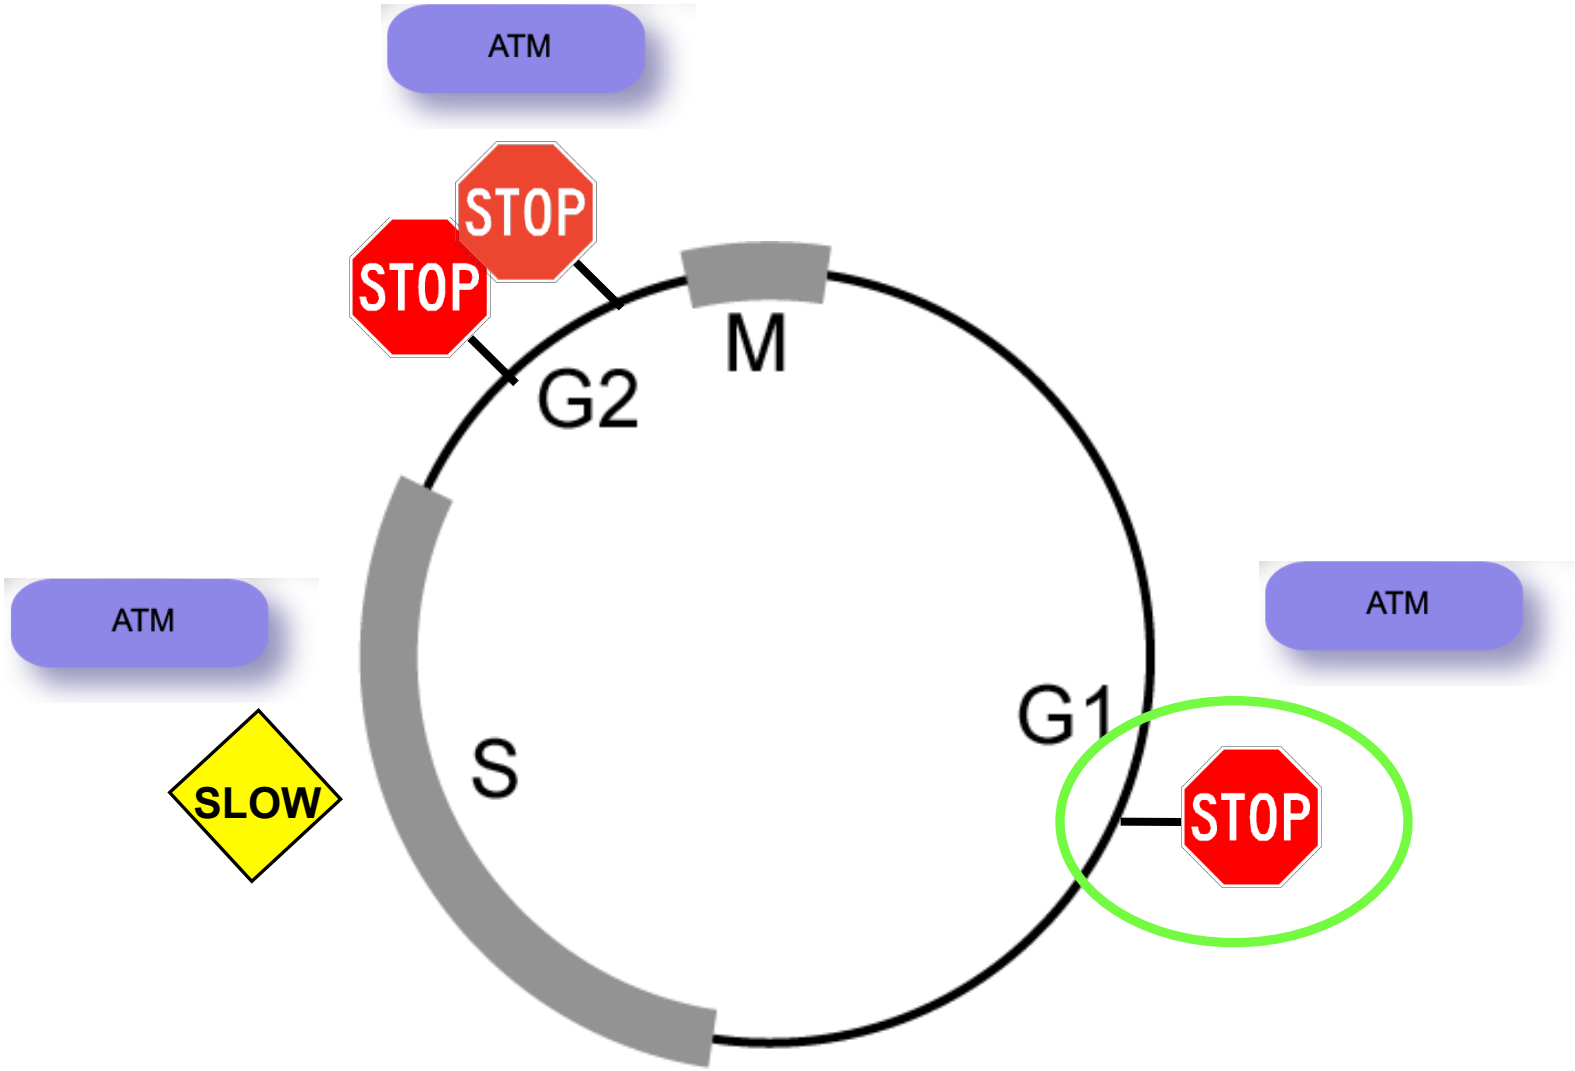
DNA damage?
Nutrients?
Growth factors?

IRIF mark DSBs





IR induces 4 distinct checkpoints



G1, S and Early G2 checkpoints

- Rapidly activated after IR
- Blocks entry into the next cell cycle phase
- Not important for intrinsic radiosensitivity
  - To single doses!
- Often altered in cancer
  - Important for avoiding mutations
  - Tumor cells and normal cells proliferate differently after IR
- Involved in activation of premature senescence

Late G2 checkpoint

- Not part of the initial DDR
  - Becomes evident many hours after irradiation
- Checkpoint is activated in cells irradiated in G1, S and G2 that arrive at mitosis with damage

- *Protects against mitotic catastrophe*

- Important for radiation sensitivity

G1 checkpoint and early apoptosis

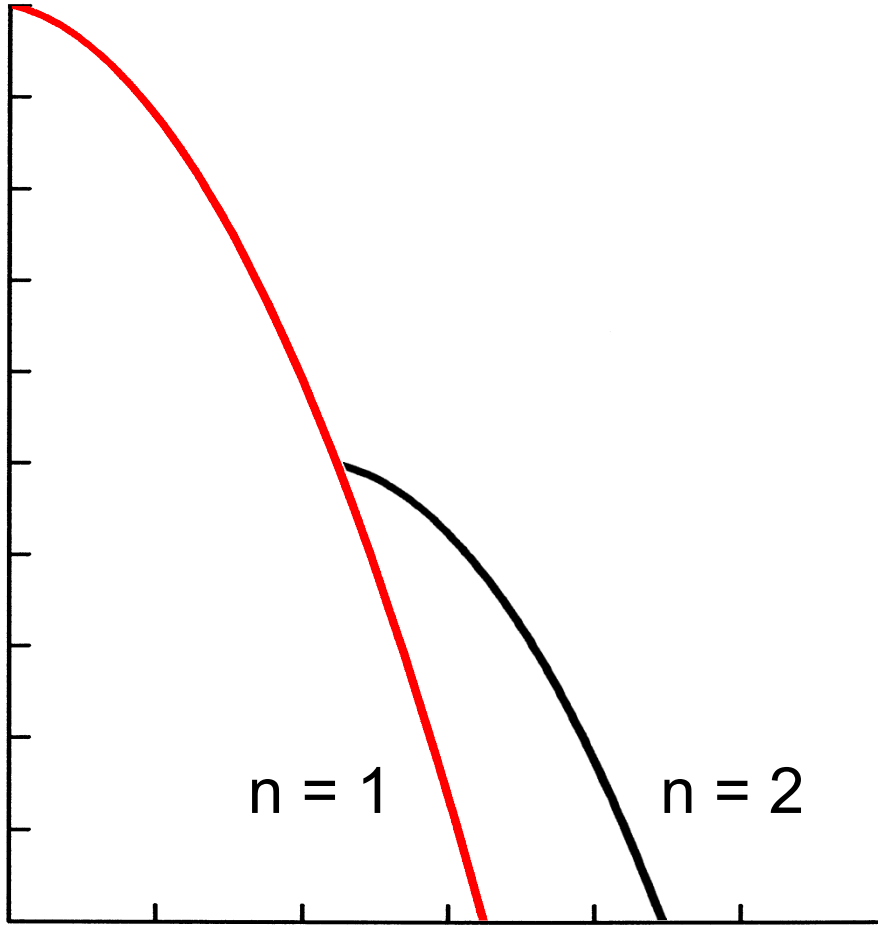
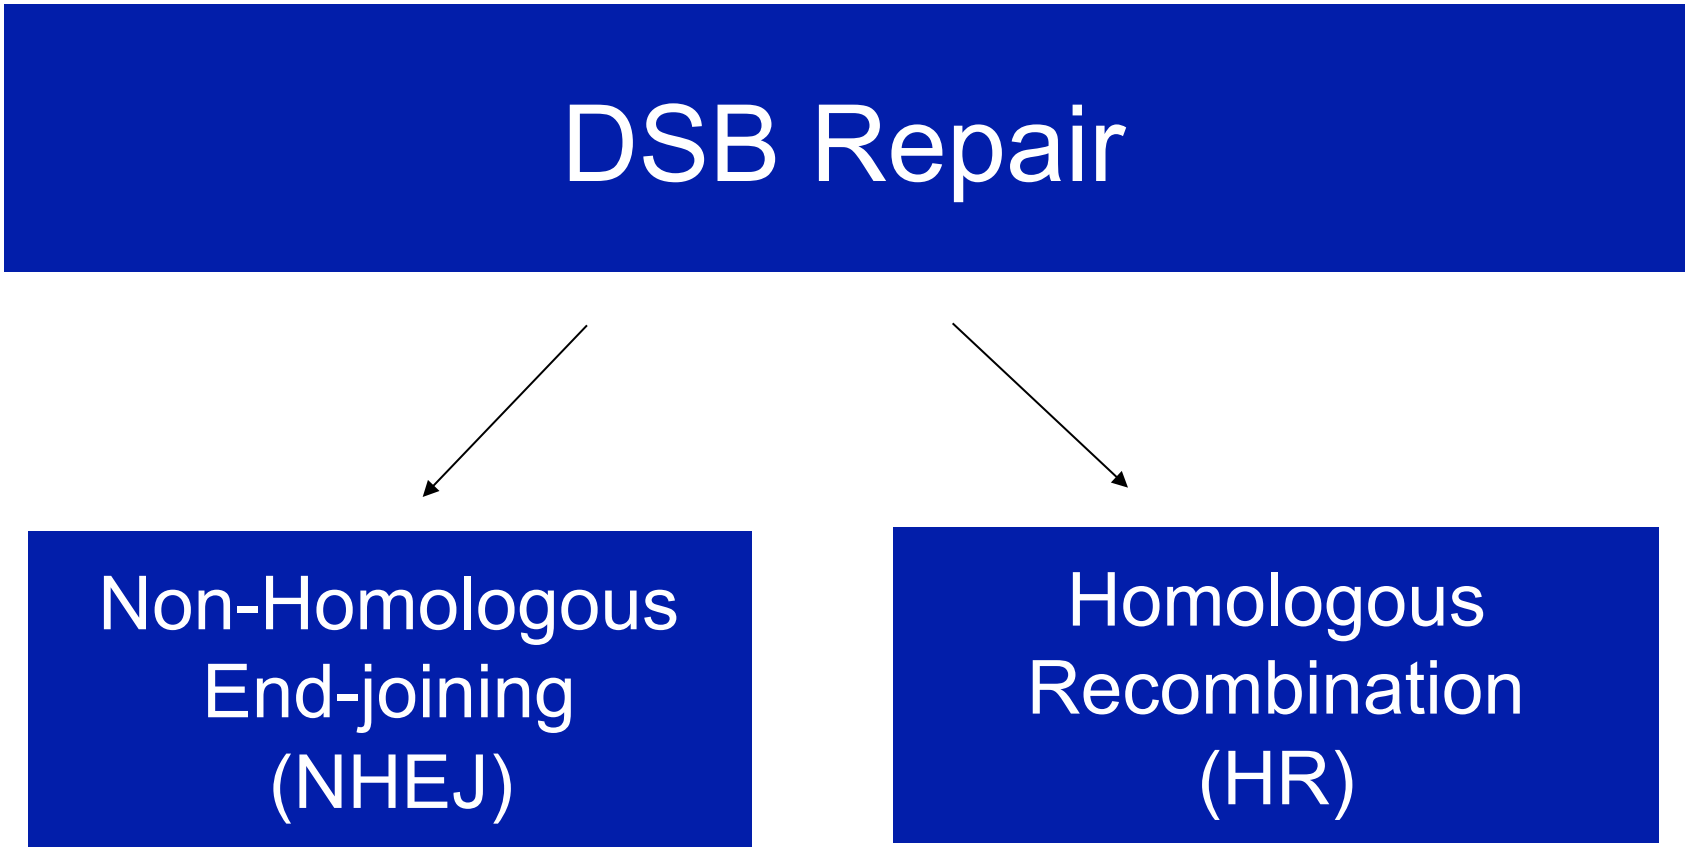
Repair process

DNA Repair and Fractionation

- The fractionation effect is due mainly to DNA repair
- ½ time for recovery is similar to ½ time for repair

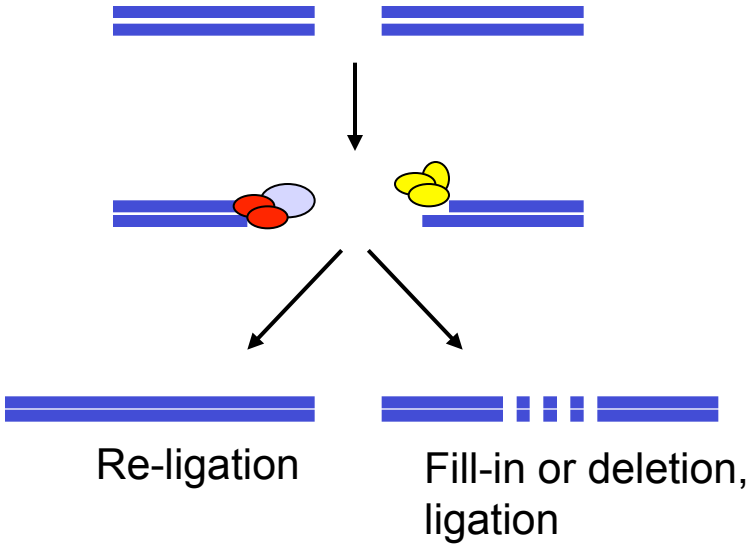




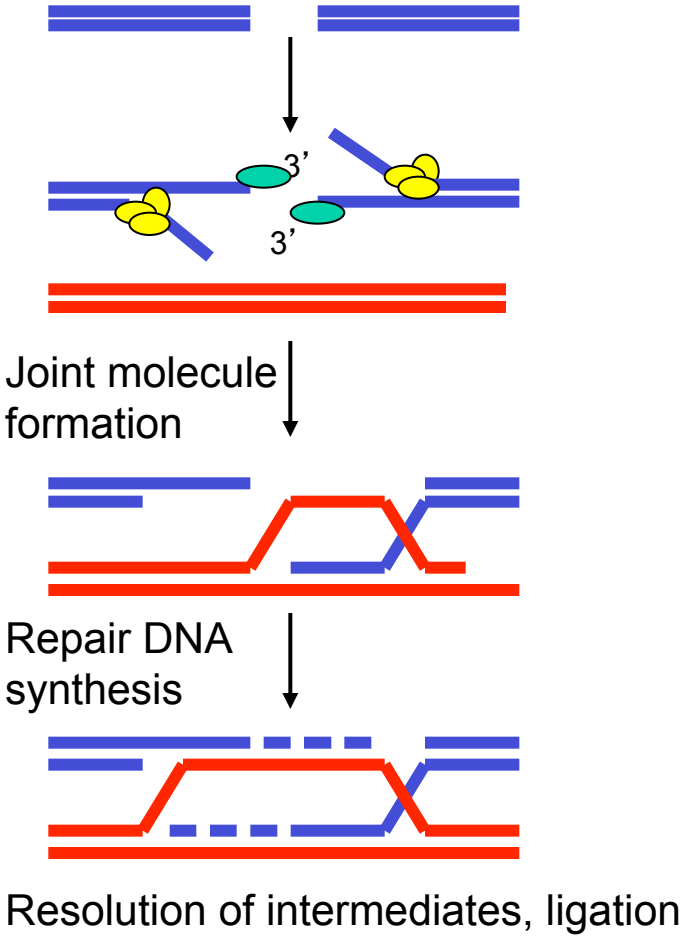
DSB Repair
Non-Homologous End-joining (NHEJ)
Homologous Recombination (HR)

HR and NHEJ

Non-homologous end-joining

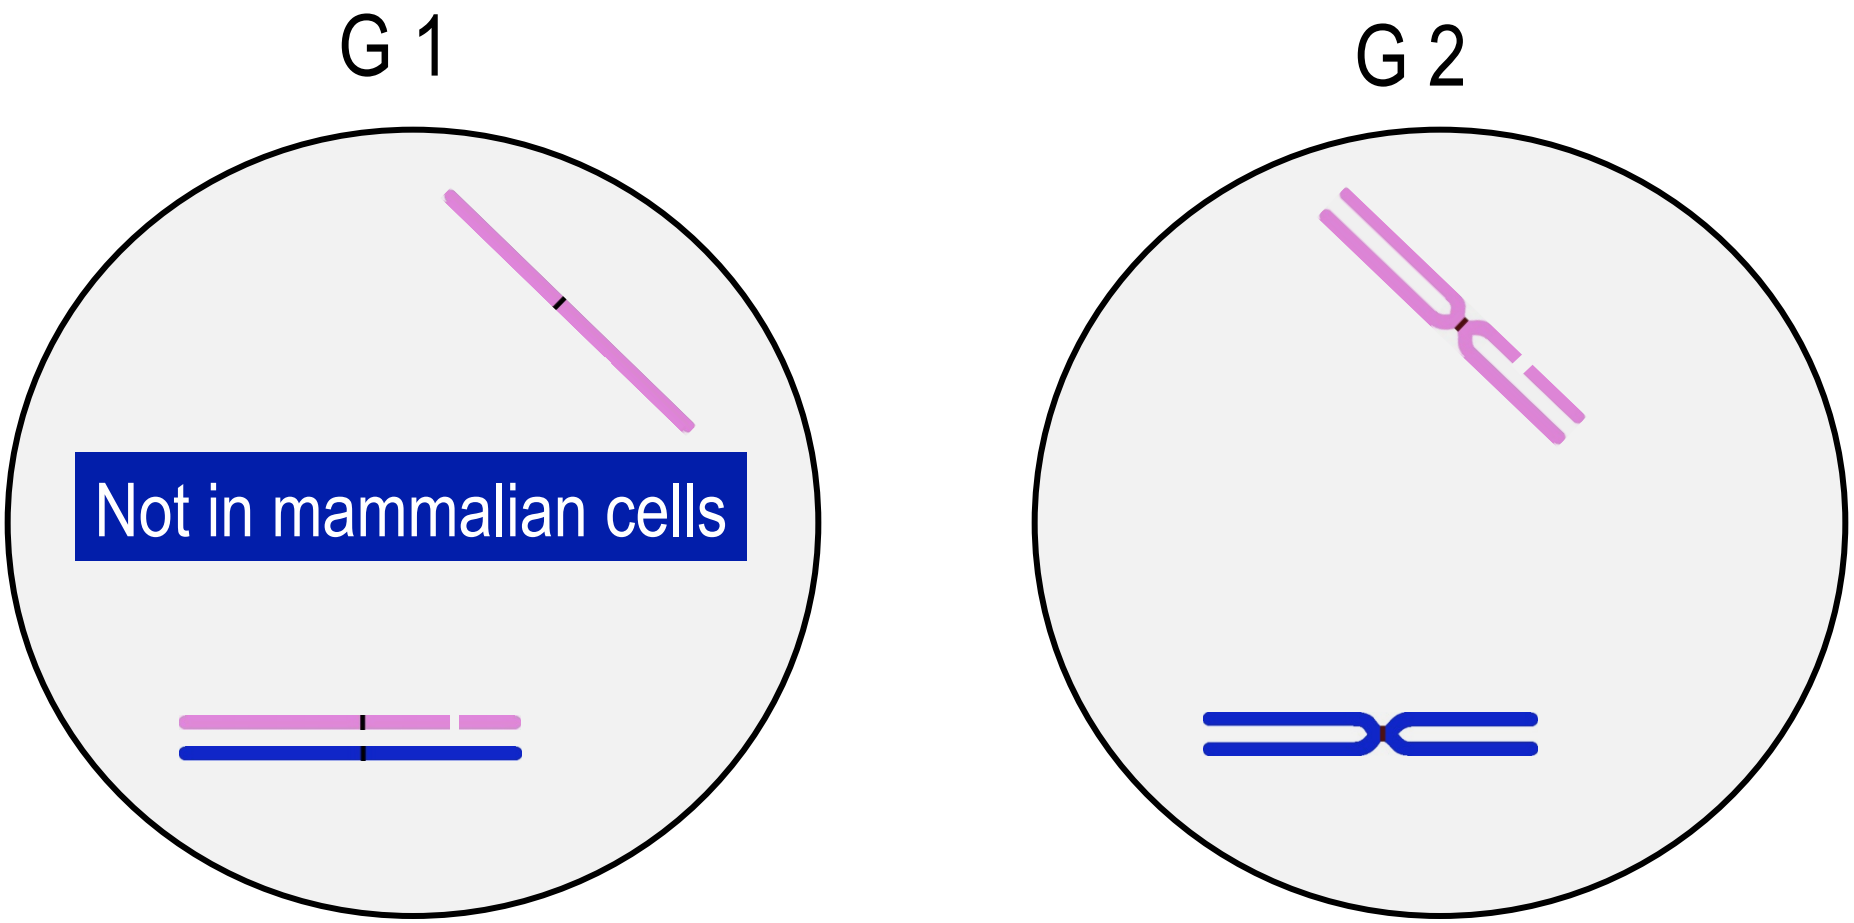


Homologous recombination

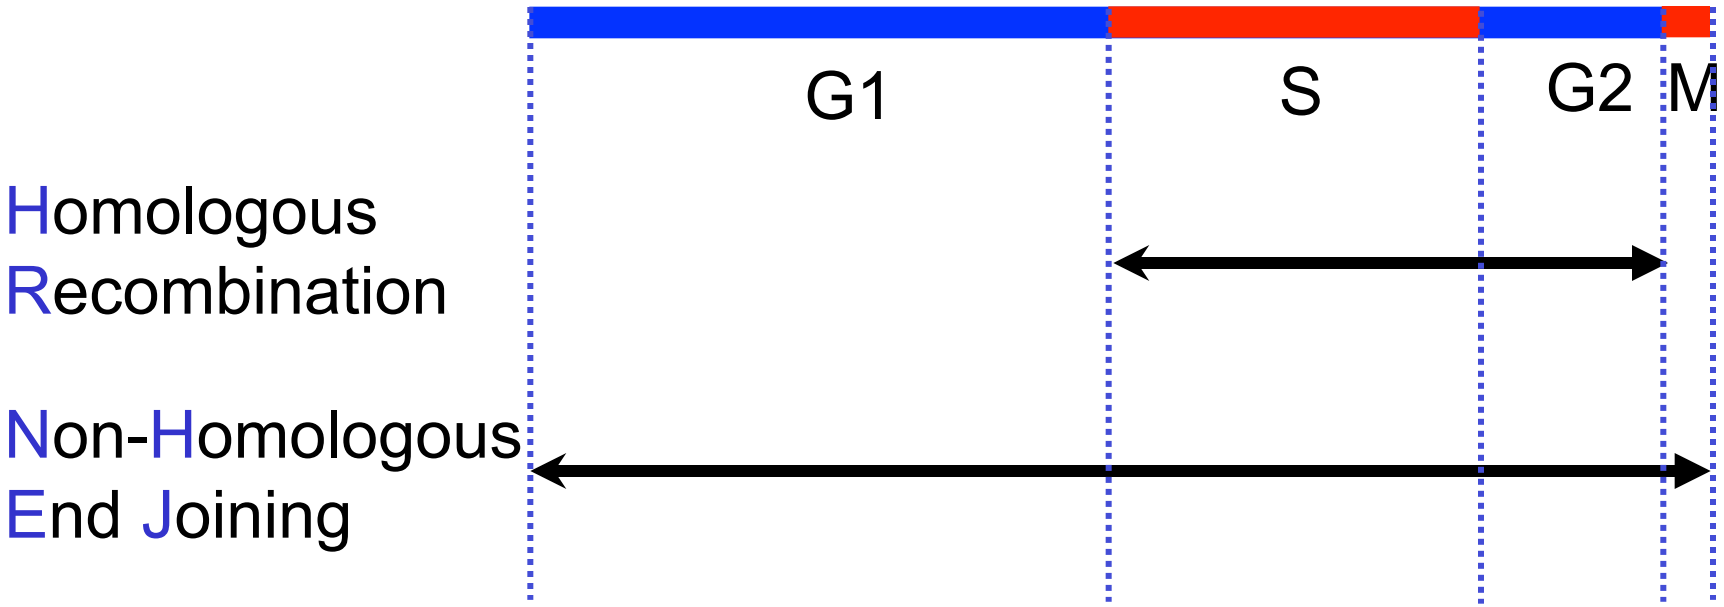


Cell-cycle dependence of HR repair

- HR requires a homologous template



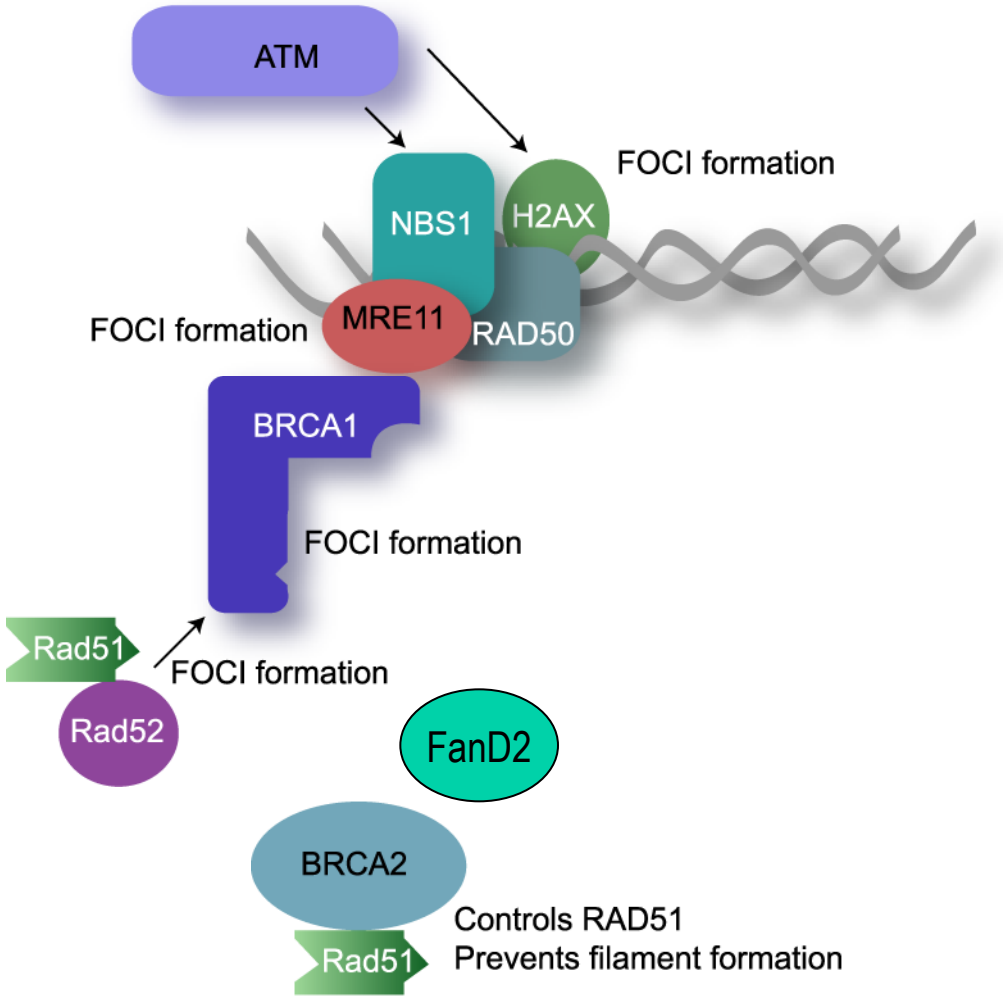
DNA Repair Through the cell cycle



HR versus NHEJ

- NHEJ
  - Repairs most DSB - 80%
  - Very important for radiosensitivity
  - Error prone
  - All parts of the cell cycle
  - Similar in all cell types
- HR
  - Repairs fewer DSB – 20%
  - Important for radiosensitivity
  - Error free
  - S and G2 phase
  - responsible for change in sensitivity in the cell cycle
  - Varies more between cell lines (high in stem cells)
  - Defects common in cancer

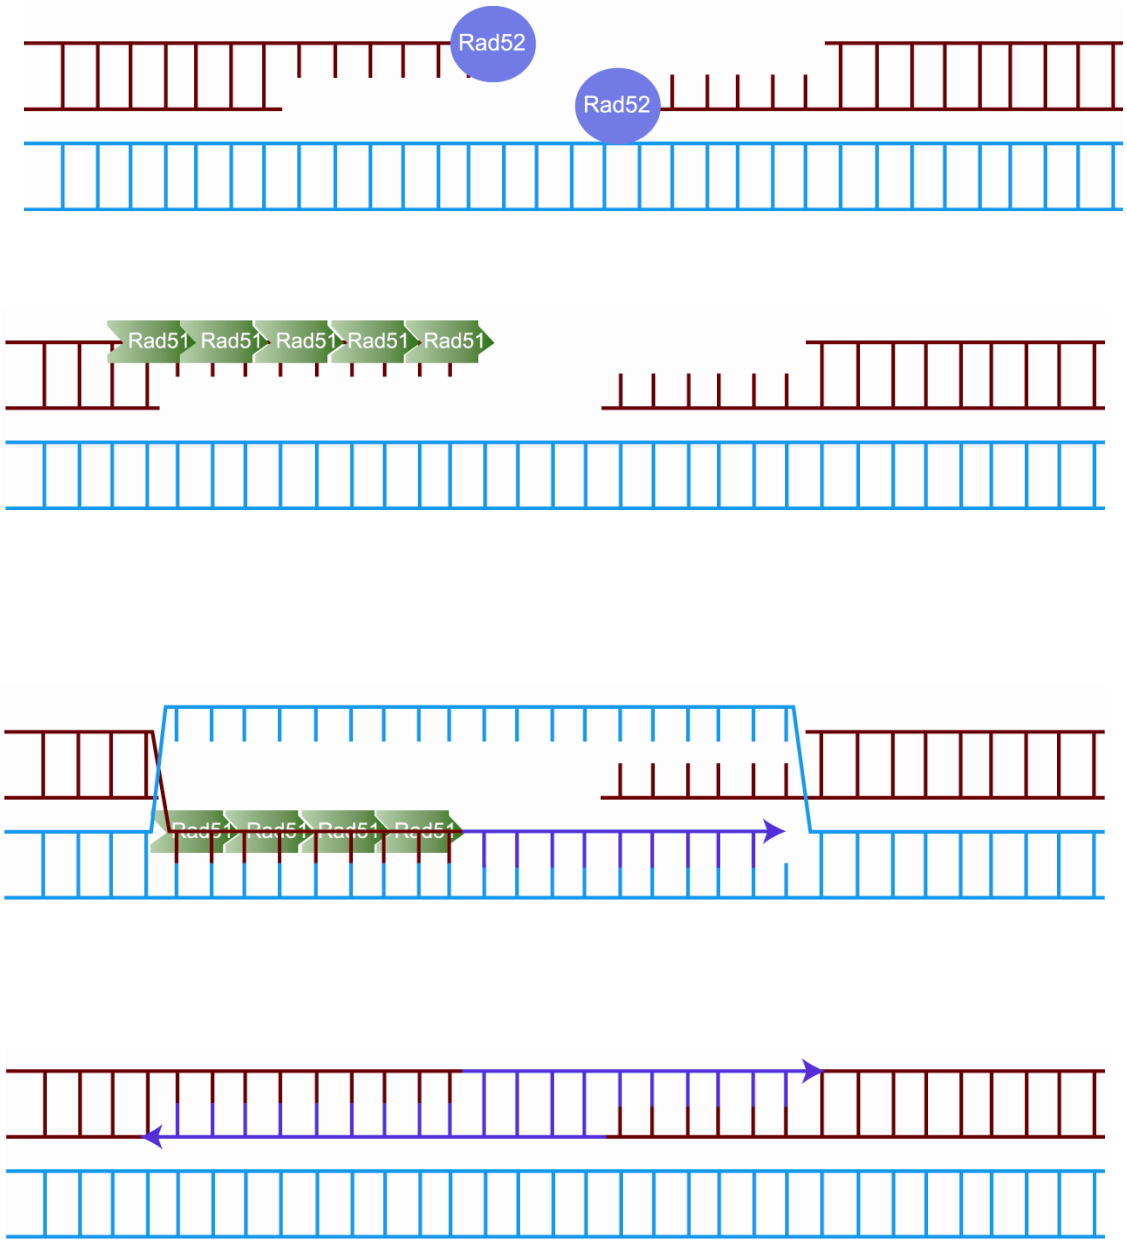
Recruitment of repair machinery - HR



BRCA1 aids recruitment of HR machinery

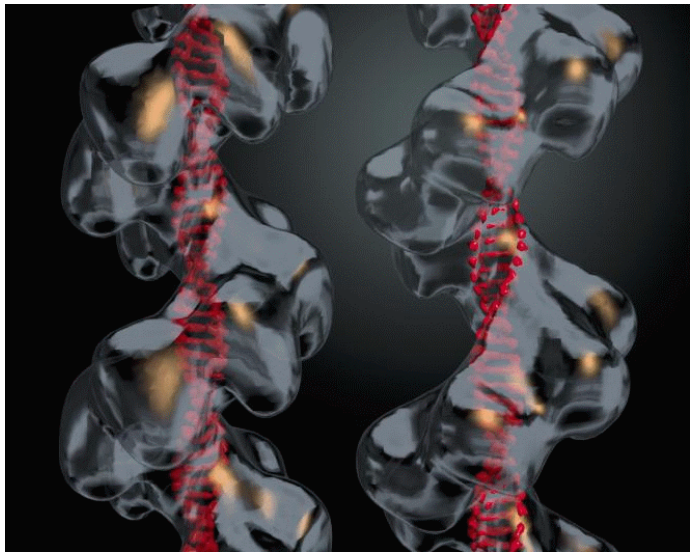
HR machinery influenced by FANCD2 and BRCA2

Homologous Recombination - HR

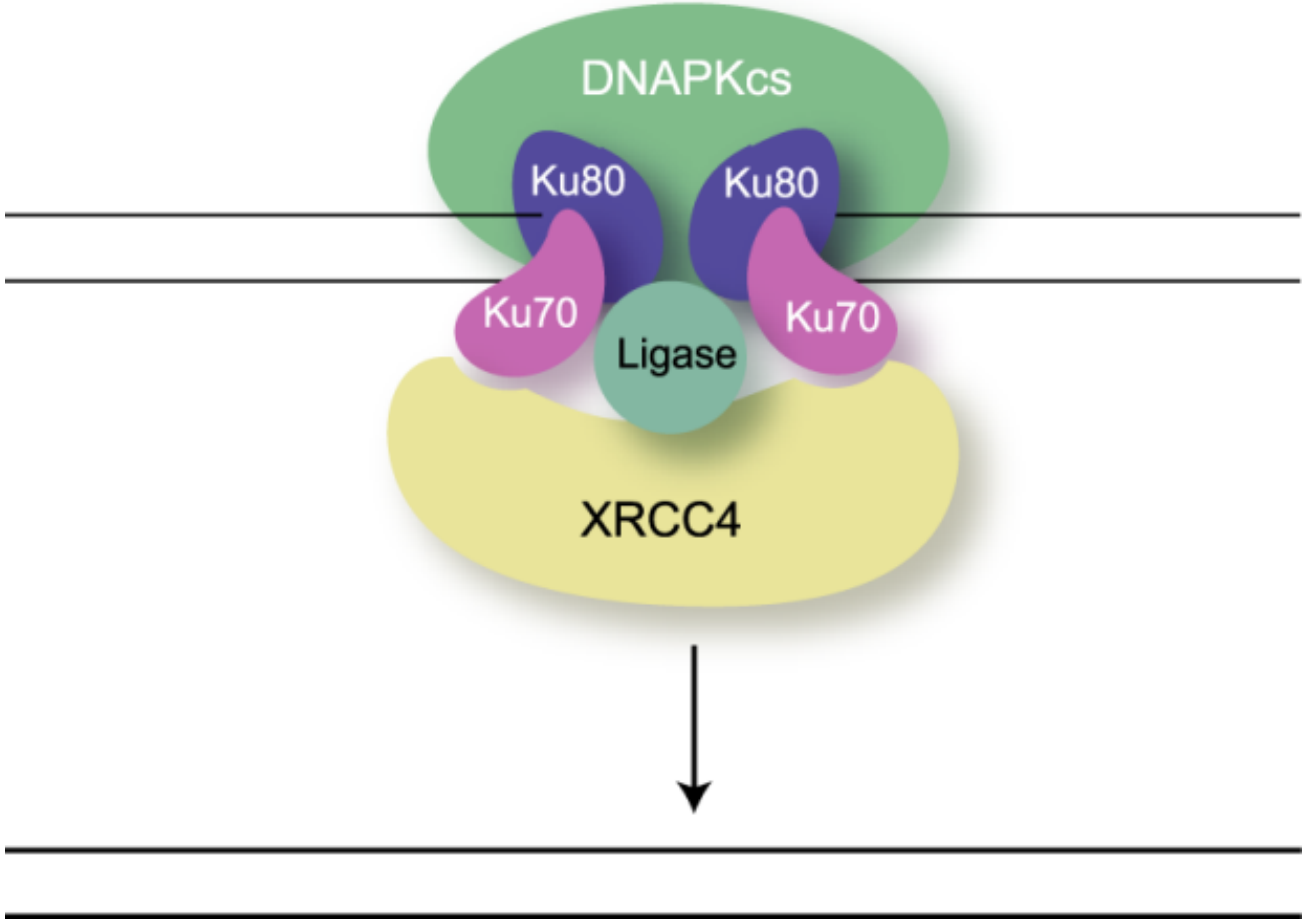


Accurate repair of a double stand break

Requires a sister chromatid as undamaged template

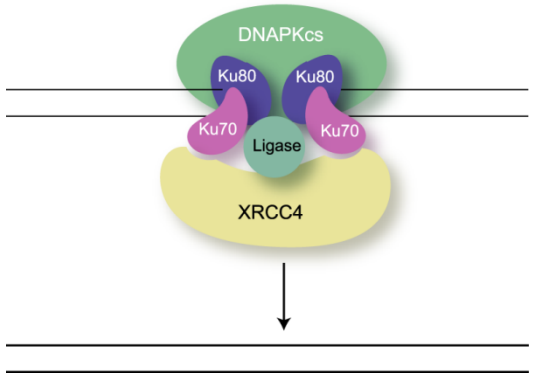


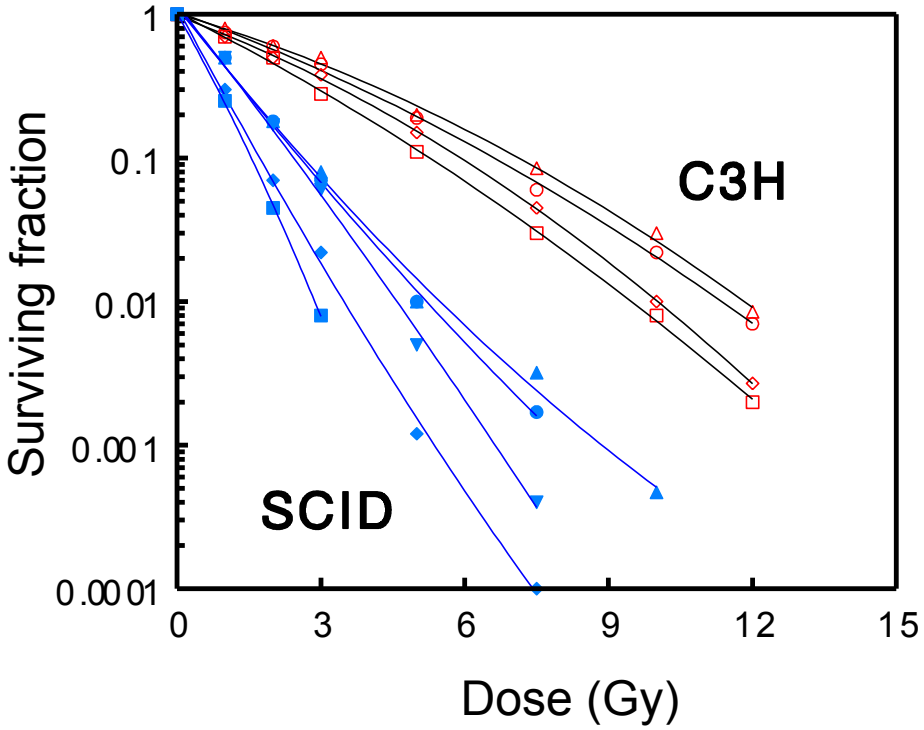
NHEJ



NHEJ

Defects in EJ cause extreme radiosensitivity





All tumors arising in DNA-PK deficient mice are radiosensitive

Clinical: DNA repair inhibitors

- BRCA tumours
  - BRCA proteins are haplosufficient tumor suppressors
  - BRCA biallelic loss causes mild radiosensitivity
- Synergy with PARP inhibition (Base excision repair, Single strand break repair)

Summary of DNA damage repair

- DSBs are the most important damage produced by IR
- DSBs are sensed by ATM and MRN
  - Apoptosis (rarely)
  - Checkpoint activation
  - DNA repair
- Repair requires large repair factories containing many proteins
  - NHEJ (DNAPKcs, Ku70/80, Artemis, XRCC4, Ligase)
  - HR (BRCA1/2, Rad51/52, FANCD2)
- Impaired DNA repair machinery (NHEJ) causes (extreme) radiosensitivity

Dose fractionation:
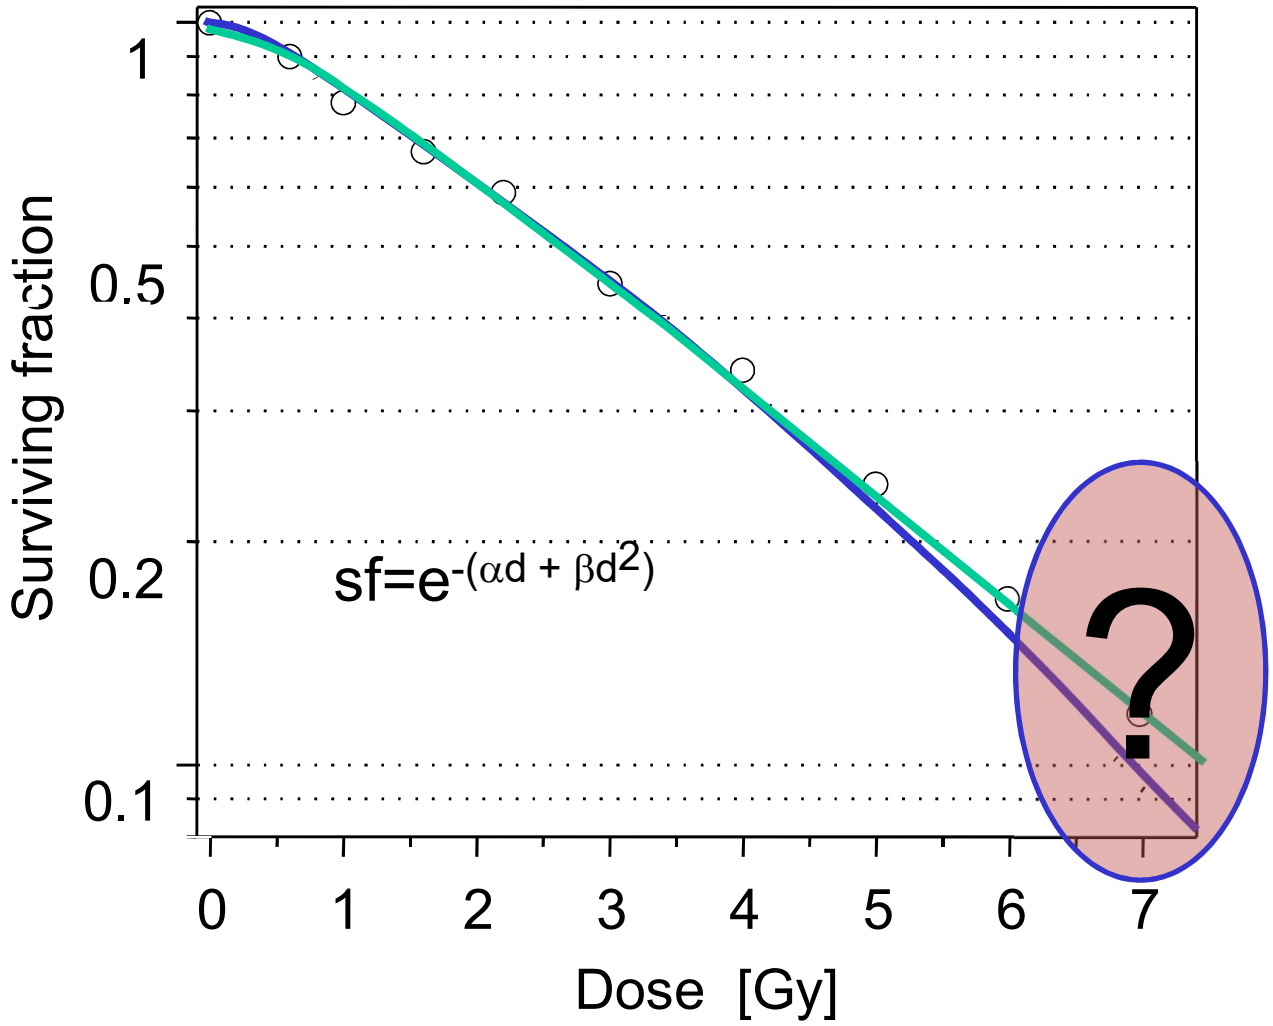
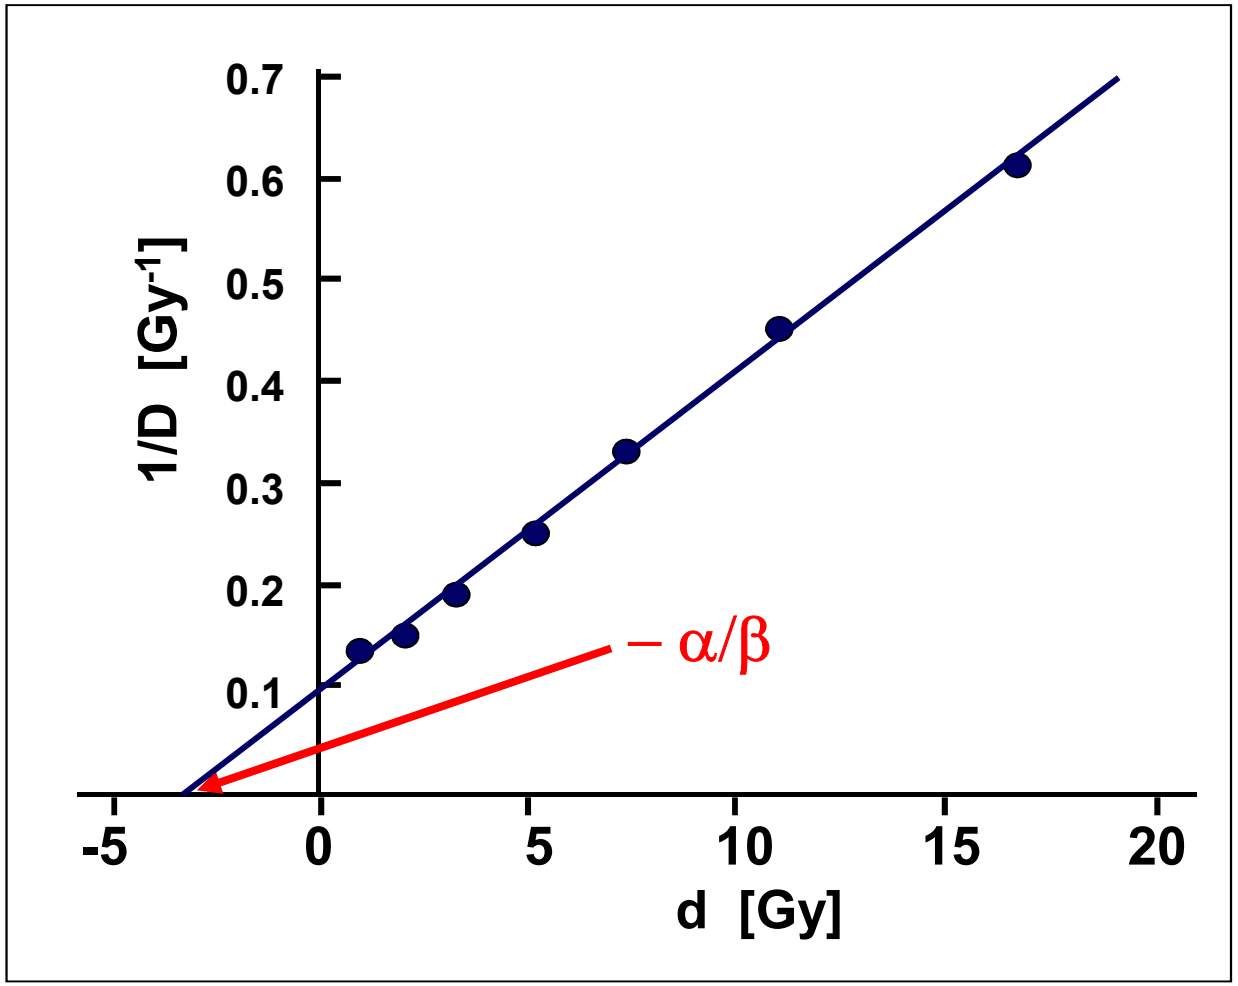
LQ at high doses per fraction (???)



Dose fractionation: LQ at high doses per fraction (???)



Mouse kidney, late response

data from:
Stewart et al.
Radiat. Res. 98,
1984, 407-420

F_e-Plot

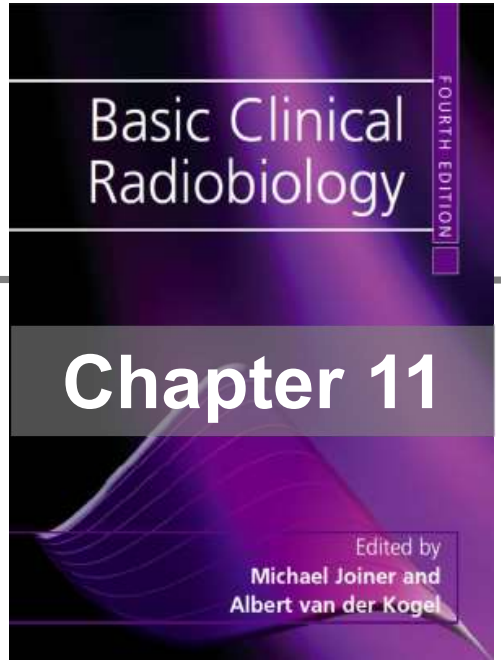
Douglas und Fowler 66, 1976, 401-426

Take home message

Recovery:

- **marked for late effects (low α/β-value)**
- **significant but less pronounced for early effects**
  - and tumours (exceptions!)
  - and consequential late effects
- **time interval between fractions important**

Normal tissues:
Overall treatment time



Wolfgang Dörr

ATRAB – Applied and Translational Radiobiology

Radiation effects - 5 Rs of radiotherapy

Radiation sensitivity
Recovery
Redistribution
Repopulation
Reoxygenation

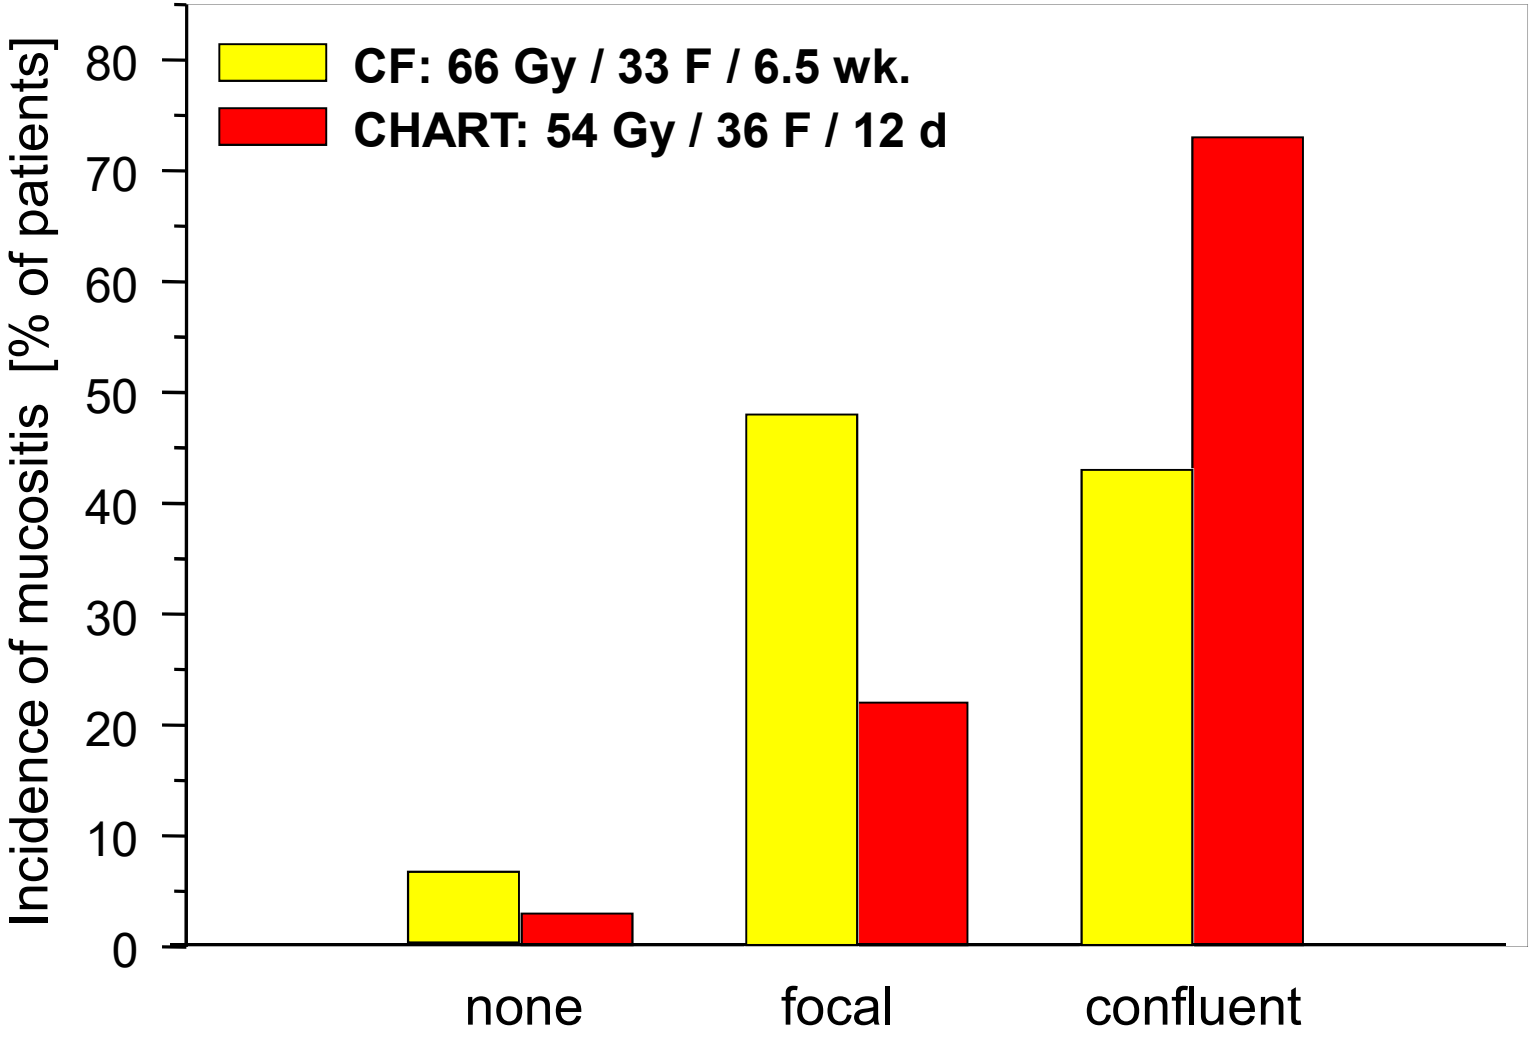
Repopulation

Regeneration response of turnover tissues and tumours to radio-therapy, resulting in increased radiation tolerance with increasing overall treatment time.

==> overall treatment time
==> accelerated radiotherapy

Repopulation – clinical observations

CHART head-and neck-trial



Dische et al., RTO 44, 1997, 123-136

Repopulation – clinical observations

Healing of mucositis during last treatment weeks

	Type 1 continual increase	Type 2 increase–plateau	Type 3 decreasing
CF	9/33 (27%)	13/33 (40%)	11/33 (33%)
AF	8/33 (24%)	16/33 (49%)	9/33 (27%)

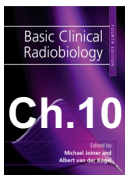
Take home message

Overall treatment time / repopulation:

- early effects (turnover tissues) and tumours
- not in late effects (exception: CLE)
- biology/mechanisms complex

NTCP models:

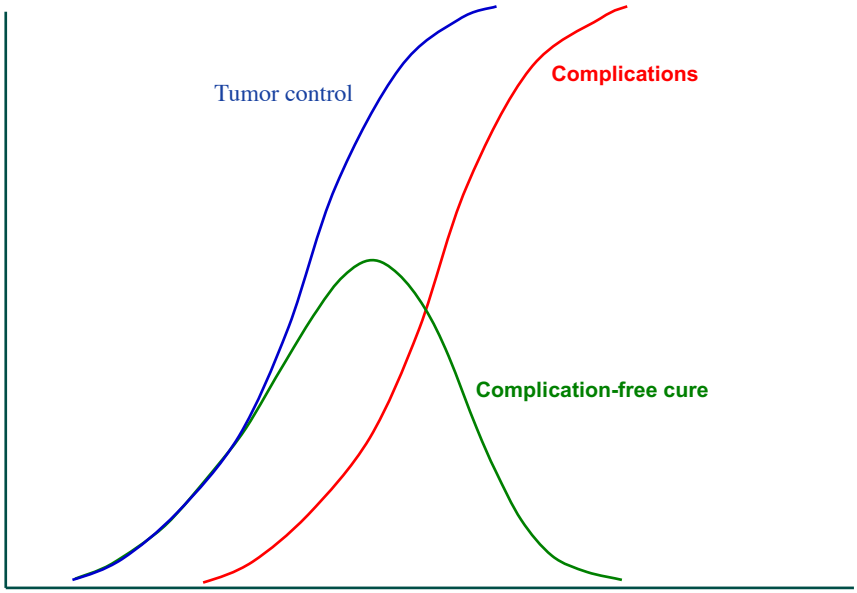
- no time factor !!!



Hyper-, hypofractionation and accelerated radiotherapy

Vincent GREGOIRE, MD, PhD, Hon. FRCR

The paradigm of radiotherapy



Conventional fractionation

1.8 – 2.0 Gy per fraction, 5 fractions per week

IIIII IIIII IIIII IIIII IIIII IIIII IIIII

	Example	Dose (Gy)	Tumor control (%)
Sensitive	Seminoma, Lymphoma	≤ 45	≥ 90
Intermediate	SCC, Adeno-Ca	50	≥ 90 (subclinical)
		60	~ 85 (Ø 1 cm)
		70	~ 70 (Ø 3 cm)
			~ 30 (Ø 5 cm)
Resistant	Glioblastoma	≥ 60	none?
	Melanoma	≥ 60	none?

Prototypes of modified fractionation

- Hyperfractionation (HF)
- Accelerated fractionation (AF)
- (Hybrid schedules)
- Hypofractionation

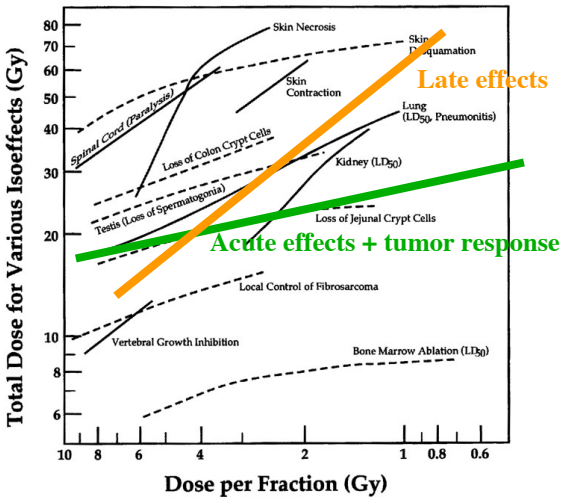
Prototypes of modified fractionation

- Hyperfractionation (HF)
- Accelerated fractionation (AF)
- (Hybrid schedules)
- Hypofractionation

Fractionation sensitivity

"Typical" dose per fraction

- 1.8-2 Gy for standard fractionation
- 1.1-1.3 Gy for hyper-fractionation



Withers et al, 1983

Hyperfractionation (HF)

reduced dose per fraction (< 1.8 Gy)

CF 70Gy/ 2.0 Gy/ 7w

HF 80.5Gy/ 2x1.15 Gy/ ti=6h/ 7w

Expectations (dose-escalated HF):

- Increased tumor control
- More severe early reactions
- Unchanged or less late reactions

ESTRO 2017

EORTC Hyperfractionation trial in oropharynx cancer (N = 356)

Oropharyngeal Ca T2-3, N0-1

Hypofractionation in NSCLC

Selected published series of stereotactic body radiotherapy for primary non-small cell lung cancer

Reference	Type of publication	Number of patients	Accounting for tumour movement	Location	Dose	Follow-up	Local control	Overall survival	Grade ≥3 radiation toxicity
[21]	Multi-centre retrospective series	257	Varied (breath hold; respiratory gating; slow computed tomography scan)	Peripheral or central	30–84 Gy/1–14 fractions	Median 38 months (2–128)	5 year 84% for BED ≥ 100 Gy	5 year 47% (71% for medically operable, and BED ≥ 100 Gy)	5.4% lung 1% oesophagitis 1.2% dermatitis
[23]	Multi-centre retrospective series	138	Abdominal pressure if needed	Peripheral (mainly) or central	30-48 Gy/2–4 fractions	Median 33 months	88% at median 33 months	3 year 55%	10%
[26]	Multi-centre phase II	57	Abdominal pressure if needed	Peripheral	45 Gy/3 fractions	Median 35 months	3 year 92%	3 year 60%	26% grade 3 2% grade 4
[24]	Single centre retrospective series	68	Planning target volume margins guided by computed tomography assessment	Peripheral or central	24–40 Gy/3–5 fractions	Mean 17 months	3 year 88%	3 year 53%	6% pneumonitis 3% rib fracture
[14]	Single centre phase I, dose escalation	47	Abdominal pressure	Peripheral or central	24 Gy/3 fractions escalating to 72 Gy/3 fractions	Median 15 months	79% at median 15 months	–	11% lung 2% pericardial 2% dermatitis
[27]	Single centre phase II	70	Abdominal pressure	Peripheral or central	60–66 Gy/3 fractions	Median 17.5 months	2 year 95%	2 year 54%	20% (includes 6 possible grade 5 cases)
[28]	Single centre retrospective series	27	Four-dimensional computed tomography planning	Central or superior	40–50 Gy/4 fractions	Median 17 months	100% at median 17 months (50 Gy) or 57% (4 Gy)	–	11% grade 2–3 pneumonitis/ chest wall pain
[30]*	Single centre retrospective series	59	Synchrony respiratory tracking system	Peripheral or central	15–67.5 Gy/1–5 fractions	1–33 months	90% free from persistent or recurrent disease	86%	0% grade 4/5 toxicity 7% grade 1–3 pneumonitis
[9]*	Single centre retrospective series	70	Synchrony respiratory tracking system	Peripheral	45 or 60 Gy/3 fractions	Median 15 months	2 year 96% (60 Gy) or 78% (45 Gy)	2 year 62%	10% late toxicity 4% acute toxicity

ESTRO 2017

Martin et al., 2010

Conclusions

- Benefit of hyper- and accelerated fractionation for loco-regional control probability
- Slight increase in acute toxicity but no change in late toxicity
- Moderately hypofractionation for tumors with low α/β
- Extreme hypofractionation for well selected indications, e.g. small peripheral lung tumors (dose distribution effect only!)

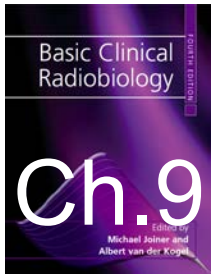
Basic Clinical Radiobiology

Correcting dose errors in radiation treatment delivery

Michael Joiner

Paris 2017



Example:

Standard treatment is 35 × 2 Gy to 70 Gy.

Initially the schedule is given in error as
4 Gy per fraction for the first 6 fractions

i.e. the first 24 Gy is given “hypofractionated”

How do you correct?

Considering late injury, using $\alpha/\beta = 3$ Gy,

$$EQD2_{late} = 24\left(\frac{4+3}{2+3}\right) = 33.6$$

Therefore, giving the rest of the treatment as

70 – 33.6 = **36.4** Gy in 2 Gy fractions

would give equal late injury as 35 × 2 Gy.

In practice, 36.4 ÷ 2 ≈ 18 (maybe 19) fractions.

Considering tumor effect, using α/β = 10 Gy,

$$EQD2_{tumor} = 24\left(\frac{4+10}{2+10}\right) = 28$$

Therefore, giving the rest of the treatment as

70 – 28 = **42** Gy in 2 Gy fractions

would give equal tumor effect as 35 × 2 Gy.

Thus:

To maintain equal late injury,
total tumor *EQD2* is
28 + 36.4 = **64.4** Gy underdosing by 8%
12–20% loss in LTCP?

To maintain equal tumor effect,
total late injury *EQD2* is
33.6 + 42 = **75.6** Gy overdosing by 8%
10–30% increase in complications?

A better solution:

The initial error was *hypo*fractionated.

∴ It should be corrected by *hyper*fractionating to achieve identical tumor effect *and* late injury as expected with 35 × 2 Gy.

Solution numerical:

Propose to give the balance of the treatment as ***d*** Gy per fraction to total dose ***D***.

$$D\left(\frac{d+3}{2+3}\right)=36.4$$ for equal late injury

$$D\left(\frac{d+10}{2+10}\right)=42$$ for equal tumor effect

$$\therefore \quad \frac{d+10}{d+3}=\frac{504}{182} \qquad 10D-3D=504-182$$

Thus d = 0.9565[217] Gy and D = 46 Gy

Observation:

24 Gy (4 Gy/#) + 46 Gy (0.96 Gy/#)
= 70 Gy (2 Gy/#)

i.e. the total doses of "error" plus "correction" sum to the ***original total dose prescribed***

How general is this result?

Definitions:

Planned:	*p* Gy per fraction to *P* Gy
Error:	*e* Gy per fraction to *E* Gy
Correctdion:	*d* Gy per fraction to *D* Gy

Int. J. Radiation Oncology Biol. Phys., Vol. 58, No. 3, pp. 871–875, 2004

A SIMPLE α/β-INDEPENDENT METHOD TO DERIVE FULLY ISOEFFECTIVE SCHEDULES FOLLOWING CHANGES IN DOSE PER FRACTION

MICHAEL C. JOINER, M.A., PH.D.

Department of Radiation Oncology, Karmanos Cancer Institute, Wayne State University, Detroit, MI

Purpose: Dosimetric errors in delivering the prescribed dose per fraction made early in a treatment can be corrected by modifying the dose per fraction and total dose given subsequently to discovery of the error, using the linear-quadratic model to calculate the correcting doses which should be completed within the same overall time as originally prescribed. This study shows how these calculations can be carried out independently of any α/β ratios to bring the treatment back exactly to planned tolerance simultaneously for all tissues and tumor involved.

Methods: Planned treatment is defined as p Gy per fraction to a total dose P Gy; the initial error is e Gy per fraction given to a total of E Gy. The linear-quadratic formula is assumed to describe all isoeffect relationships between total dose and dose per fraction.

Results and Conclusion: An exact solution is found that describes a compensating dose of d Gy per fraction to a total of D Gy. The formulae are:

$$D = P - E$$

$$d = \frac{Pp - Ee}{P - E}$$

Result

$$D = P - E$$

$$d = \frac{Pp - Ee}{P - E}$$

Example revisited:

Standard treatment is 35 × 2 Gy to 70 Gy.
Initially the schedule is given in error as
4 Gy per fraction for the first 6 fractions
i.e. the first 24 Gy is given "hypofractionated"

Compensation:

$$70 - 24 = 46$$

$$\frac{70 \times 2 - 24 \times 4}{70 - 24} = 0.9565...$$

46/0.9565… = **48** fractions; *d* = **0.958 Gy**

Another example:

Standard treatment is 35 × 2 Gy to 70 Gy.
Initially the schedule is given in error as
4 Gy per fraction for the first 3 fractions
i.e. the first 12 Gy is given "hypofractionated"

Compensation:

$$70 - 12 = 58$$

$$\frac{70 \times 2 - 12 \times 4}{70 - 12} = 1.5862...$$

58/1.5862… = **37** fractions; *d* = **1.568 Gy**

Common errors - summary

Planned 35 × 2 Gy to 70 Gy, Error = 4 Gy per fraction

Error	Correction		
	***D* Gy**	***d* Gy**	***n***
1 × 4 Gy to **4** Gy	66	1.886	35
2 × 4 Gy to **8** Gy	62	1.722	36
3 × 4 Gy to **12** Gy	58	1.568	37
4 × 4 Gy to **16** Gy	54	1.421	38
5 × 4 Gy to **20** Gy	50	1.190	42
6 × 4 Gy to **24** Gy	46	0.958	48

Further example:

Standard treatment is 35 × 2 Gy to 70 Gy.
Initially the schedule is given in error as
1 Gy per fraction for the first 4 fractions
i.e. the first 4 Gy is given "*hyper*fractionated"

Compensation:

$$70 - 4 = 66$$

$$\frac{70 \times 2 - 4 \times 1}{70 - 4} = 2.0606...$$

66/20.0606… = **32** fractions; *d* = **2.063 Gy**

Common errors - summary

Planned 35 × 2 Gy to 70 Gy, Error = 1 Gy per fraction

Error	Correction		
	***D* Gy**	***d* Gy**	***n***
1 × 1 Gy to **1** Gy	69	2.029	34
2 × 1 Gy to **2** Gy	68	2.000	34
3 × 1 Gy to **3** Gy	67	2.030	33
4 × 1 Gy to **4** Gy	66	2.063	32
5 × 1 Gy to **5** Gy	65	2.097	31
6 × 1 Gy to **6** Gy	64	2.065	31

Remember…

$$D = P - E$$

$$d = \frac{Pp - Ee}{P - E}$$

Joiner MC.
Int J Radiat Oncol Biol Phys 2004;58:871-5

Generalization

Any plan (*P*, *p*) of dose per fraction *p* to total dose *P*, may be given to identical effect in all tissues and tumors using components (*Q*, *q*), (*R*, *r*), (*S*, *s*), (*T*, *t*) etc., where:

$$P = Q + R + S + T + \ldots$$

$$Pp = Qq + Rr + Ss + Tt + \ldots$$

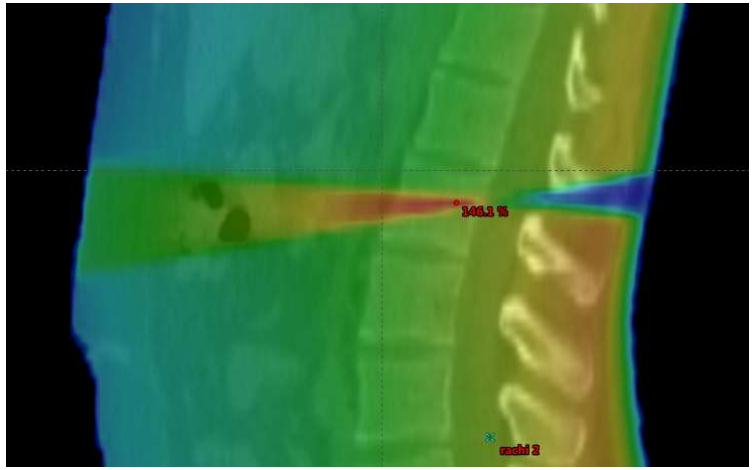
Craniospinal irradiation case

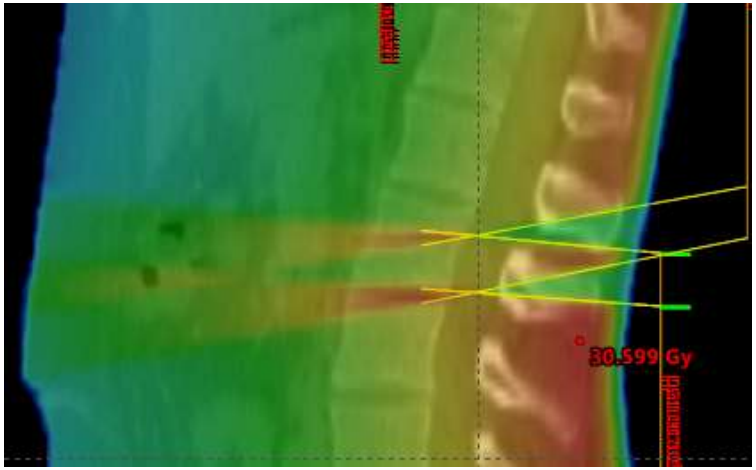
- A patient was treated with 39 Gy in 13 fractions to the craniospinal axis.
- A shift was foreseen after 7 fractions.
- As result of a mistake an overlap of 1 cm was created instead of a gap of 1 cm after 7 fractions. This mistake was applied for 2 fractions.
- In the overlap region of 1 cm, the spinal cord received 7x 3.1 Gy Dmax and 2 x 6.2 Gy.

Planning technique of craniospinal irradiation

Gap-junction method
No Field Edge Matching



Junction shift
Dose feathering



- Not robust for setup errors, i.e. 100% dose difference expected for setup errors larger than 5-7 mm

ESTRO School

Craniospinal irradiation case

- What is the physical dose in the overlap zone?

- Do we exceed the spinal cord tolerance in the overlap zone?

Craniospinal irradiation case

- What is the physical dose in the overlap zone?

- D = 7 x 3,1 Gy + 2 x 6,2 = 33,9 Gy

- Do we exceed the spinal cord tolerance, regarding the biological dose in the overlap zone?
  (α/β is assumed to be 2 Gy for spinal cord late toxicity)

- $EQD_2 = D \frac{d + (\alpha/\beta)}{2 + (\alpha/\beta)}$
- $EQD_2 = 21{,}7 \times \frac{3{,}1 + 2}{2 + 2} = 27{,}67$ Gy (7 fractions)
- $EQD_2 = 12{,}4 \times \frac{6{,}2 + 2}{2 + 2} = 25{,}42$ Gy (2 overlap fractions)

Craniospinal irradiation case

- Do we exceed the spinal cord tolerance dose?
  (α/β is assumed to be 2 Gy for spinal cord late toxicity)

- EQD_2 = 27,67 Gy + 25,42 Gy = 53,09 Gy (Total)

DVH & Double Trouble

		EQD_2	
% Pres dose	Phys dose (cGy)	α/β = 1,0 Gy	α/β = 10,0 Gy
130	260	310	275
120	240	270	250
110	220	235	225
100	200	200	200
90	180	170	175
80	160	140	155
70	140	110	135

Planning technique of craniospinal irradiation

- IMRT: The inferior edges of the lateral brain fields and the superior edge of the lower posterior spine field are manually designed with long, smooth dose gradients by IMRT field-in-field (FIF) techniques.

- More robust for setup errors
- 1%/mm dose gradient in junction
- 1 cm shift will result in 5-10% dose difference

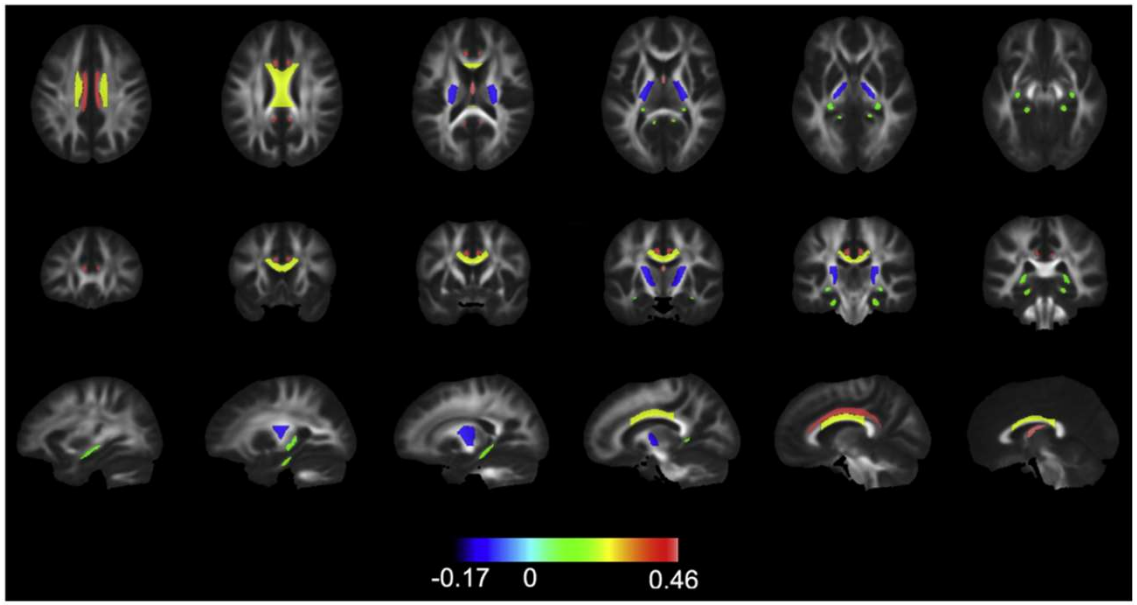

Fig. 4. Regional sensitivity to radiation. Tracts are filled with their corresponding coefficient for percent change in FA (from the model correlating mean dose to changes in the whole atlas ROI) and color coded according to value. Only statistically significant coefficients are shown. The signs for coefficients are flipped, i.e. FA is expected to decrease, so greater decreases in FA are represented by positive numbers and intensifying red color.

Results: The associations of the spatially specific dose measures to urinary dysfunction were dependent on the presence of specific symptoms. The doses received by the anteroinferior and, to lesser extent, posterosuperior surface of the bladder had the strongest relationship with the incidence of dysuria, hematuria, and ΔIPSS10, both with and without adjustment for clinical factors. For the doses to the posteroinferior region corresponding to the area of the trigone, the only symptom with significance was incontinence.

Lessons of QUANTEC

Each with 10 sections

1. **Clinical Significance**- Describes the clinical situations where the organ is irradiated, and the incidence/significance of organ injury.
2. **Endpoints**- Describes the different endpoints often considered when assessing injury, the impact of endpoint-selection on **the reported injury rates, the challenges/utilities of different endpoints, and the time course of organ injury.**
3. **Challenges Defining Volumes**- Describes how the organ is **typically defined (or segmented)** on treatment planning images. Includes a discussion of uncertainties/challenges in organ definition (e.g. changes in organ volume/shape during therapy), and the associated impact on DVH's and dose/volume/outcome analyses.
4. **Review of Dose/Volume Data**- A comprehensive summary of reported 3D dose/volume data for clinically-relevant outcomes.
5. **Factors Affecting Risk**- Other clinical factors affecting the risk of injury are noted (e.g. age, combined modality therapy, dose fractionation).
6. **Mathematical/Biological Models**- Models that have been used to relate 3D dose/volume data to clinical outcomes are summarized, along with associated model parameters, limitations and uncertainties.
7. **Special Situations**- Most of the data discussed relates to conventional fractionation. This section describes situations were the presented data/models may not apply (e.g. hypo-fractionation).
8. **Recommended Dose/Volume Limits**- The available information is condensed into meaningful dose/volume limits, with associated risk rates, to apply clinically.
9. **Future Toxicity Studies**- Describes areas in need of future study.
10. **Toxicity Scoring**- Recommendations on how to score organ injury.

APPENDIX

Normal Tissue Constraint Guidelines

The radiation dose constraints below are meant to serve as a guide only and may not be applicable to all clinical scenarios. Most doses are derived from randomized studies or consensus guidelines and we have attempted to provide the sources for these recommendations. Please refer to the individual pediatric chapters for dose constraints in the pediatric population as these can vary greatly from protocol to protocol and tend to be particularly site- and age-dependent.

What are the recommended dose constraints for the following organs and clinical scenarios?

ORGAN	*CONSTRAINTS*
CNS (1.8-2.0 Gy/fx)	
Spinal cord	max 50 Gy (full cord cross-section); tolerance increases by 25% 6 mos after 1st course (for re-irradiation) (QUANTEC)
Brain	max 72 Gy (partial brain); avoid >2 Gy/fx or hyperfractionation (QUANTEC)
Chiasm/optic nerves	max 55 Gy (QUANTEC)
Brainstem	Entire brainstem <54 Gy, V59 Gy <1-10 cc (QUANTEC)
Eyes (globe)	Mean <35 Gy (RTOG 0225), max 54 Gy (RTOG 0615)
Lens	max 7 Gy (RTOG 0539)
Retina	max 50 Gy (RTOG 0539)
Lacrimal Gland	max 40 Gy (Parsons)
Inner ear/cochlea	mean ≤45 Gy (consider constraining to ≤35 Gy with concurrent cisplatin) (QUANTEC)
Pituitary gland	max 45 Gy (for panhypopituitarism, lower for GH deficiency) (Emami)
Cauda equina	Max 60 Gy (Emami)
CNS (single fraction)	
Spinal cord	max 13 Gy (if 3 fxs, max 20 Gy) (QUANTEC)

Is there a relation between the radiation dose to the different sub-segments of the lower urinary tract and urinary morbidity aft brachytherapy of the prostate with I-125 seeds?

Marcel J. Steggerda*, Thelma Witteveen, Ferrie van den Boom, Luc M.F. Moonen

Department of Radiation Oncology, The Netherlands Cancer Institute -Antoni van Leeuwenhoek Hospital, Amsterdam, The Netherlands

Results: The dose to 0.5 cm^3 of the bladder neck '$D_{0.5cc}$-blne' ($p = 0.002$ and $p = 0.005$), the prostate volume prior to treatment 'V_{pr}-0' ($p = 0.005$ and $p = 0.024$) and the pre-treatment IPSS (both $p < 0.001$) were independently correlated with mean and maximum IPSS, respectively. Of the patients with a $D_{0.5cc}$-blne $\geqslant$ 175 Gy and a V_{pr}-0 $\geqslant$ 42 cm^3, 68% suffered from enhanced LUTS, against just 30% of the other patients ($p < 0.0001$).

Cervical cancer radiotherapy

Variability of clinical target volume delineation for definitive radiotherapy in cervix cancer

Gemma Eminowicz *, Mary McCormack

University College Hospital, London, UK

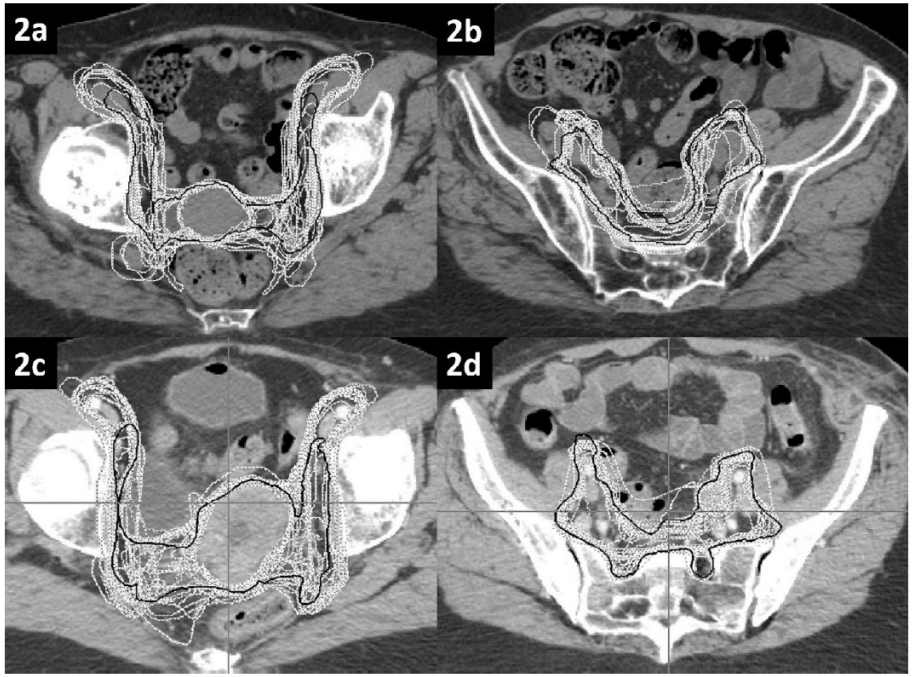

Fig. 2. Transverse CT images of CTVs(white) and GSCTV1 + 2(black) for case 1 (a and b) and 2 (c and d) at sacro-iliac level (a and c) and superior to femoral heads (b and d).

Results: 21 outlines were compared for case 1 and 22 for case 2. Volume ranged from 340 cc to 676 cc (case 1) and from 458 cc to 806 cc (case 2). A maximum 4 cm difference between outlines was observed in one direction. JCI ranged from 0.51 to 0.81 (case 1) and 0.57 to 0.81 (case 2). Variation in anatomical areas included in CTV exists between the two cases and between centres.

Conclusions: Significant inter-observer variation in cervical cancer delineation has been demonstrated. Ongoing efforts are needed to ensure inter-observer consistency through education, guidelines and multi-centre collaboration.

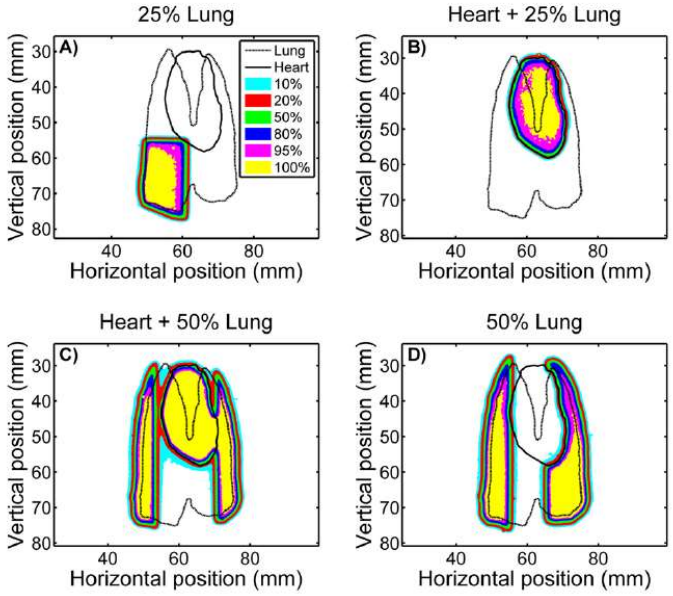

Fig. 1. Isodose contours and anatomy. Colored areas indicate dose, and the solid and dashed contour indicate the outlines of the heart and lung, respectively.

Summary

Coirradiation of the heart enhances risk and severity of radiation-induced lung toxicity through an unknown mechanism. We show that irradiation of heart, lung, or both independently induces specific cardiac dysfunction and pulmonary vascular damage, mutually enhancing each other. These results show that treatment of thoracic cancer with radiation therapy requires optimization for both pulmonary and cardiac function to reduce the risk of toxicity.

Complication Probability Models for Radiation-Induced Heart Valvular Dysfunction: Do Heart-Lung Interactions Play a Role?

Abstract

Purpose: The purpose of this study is to compare different normal tissue complication probability (NTCP) models for predicting heart valve dysfunction (RVD) following thoracic irradiation.

Methods: All patients from our institutional Hodgkin lymphoma survivors database with analyzable datasets were included (n = 90). All patients were treated with three-dimensional conformal radiotherapy with a median total dose of 32 Gy. The cardiac toxicity profile was available for each patient. Heart and lung dose-volume histograms (DVHs) were extracted and both organs were considered for Lyman-Kutcher-Burman (LKB) and Relative Seriality (RS) NTCP model fitting using maximum likelihood estimation. Bootstrap refitting was used to test the robustness of the model fit. Model performance was estimated using the area under the receiver operating characteristic curve (AUC).

Results: Using only heart-DVHs, parameter estimates were, for the LKB model: $D_{50} = 32.8$ Gy, $n = 0.16$ and $m = 0.67$; and for the RS model: $D_{50} = 32.4$ Gy, $s = 0.99$ and $\gamma = 0.42$. AUC values were 0.67 for LKB and 0.66 for RS, respectively. Similar performance was obtained for models using only lung-DVHs (LKB: $D_{50} = 33.2$ Gy, $n = 0.01$, $m = 0.19$, AUC = 0.68; RS: $D_{50} = 24.4$ Gy, $s = 0.99$, $\gamma = 2.12$, AUC = 0.66). Bootstrap result showed that the parameter fits for lung-LKB were extremely robust. A combined heart-lung LKB model was also tested and showed a minor improvement (AUC = 0.70). However, the best performance was obtained using the previously determined multivariate regression model including maximum heart dose with increasing risk for larger heart and smaller lung volumes (AUC = 0.82).

Conclusions: The risk of radiation induced valvular disease cannot be modeled using NTCP models only based on heart dose-volume distribution. A predictive model with an improved performance can be obtained but requires the inclusion of heart and lung volume terms, indicating that heart-lung interactions are apparently important for this endpoint.

Hypoxia and Tumor Microenvironment

Marianne Koritzinsky

Princess Margaret Cancer Centre
Toronto, Canada
mazinsky@gmail.com

Tumor hypoxia

1. How and why hypoxia arises in tumors
2. Heterogeneity in tumor oxygenation
3. Cellular consequences of hypoxia

Tissue hypoxia – poor oxygenation

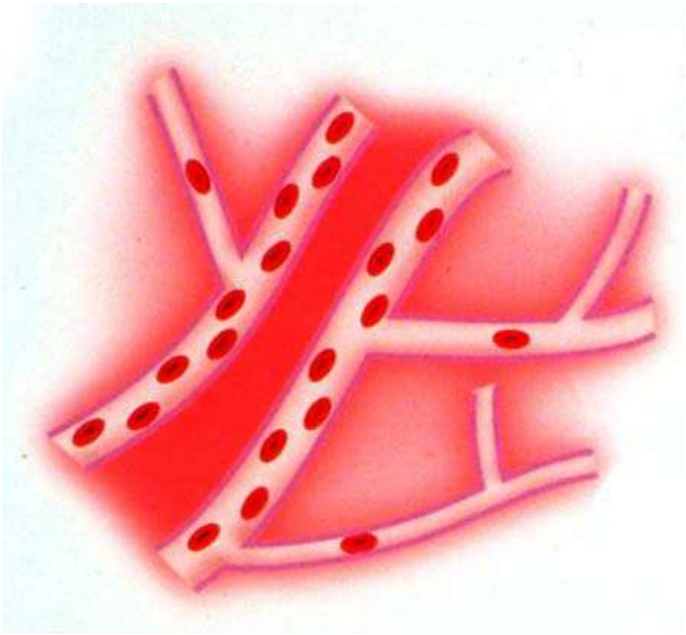
Air: 21% O2
Tissue normoxia: 5-7% O2
Tissue hypoxia: < 3% O2

Physiology

- Development
- Exercise
- Altitude

Pathology

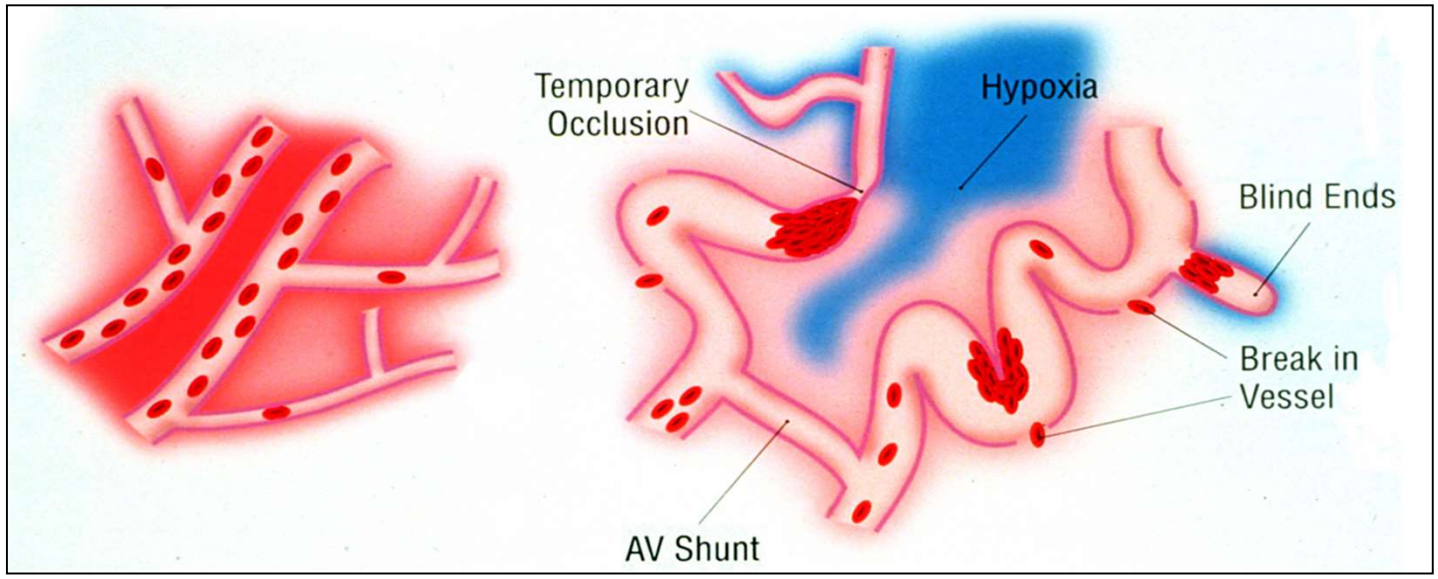
- Wound
- Stroke
- Infarctation
- Solid tumors



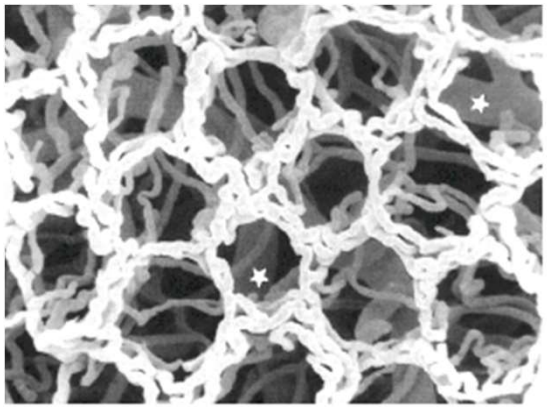
1) How and why hypoxia arises

Tumor hypoxia

Abnormal vasculature is a prime cause of hypoxia in cancer



Corrosion castings

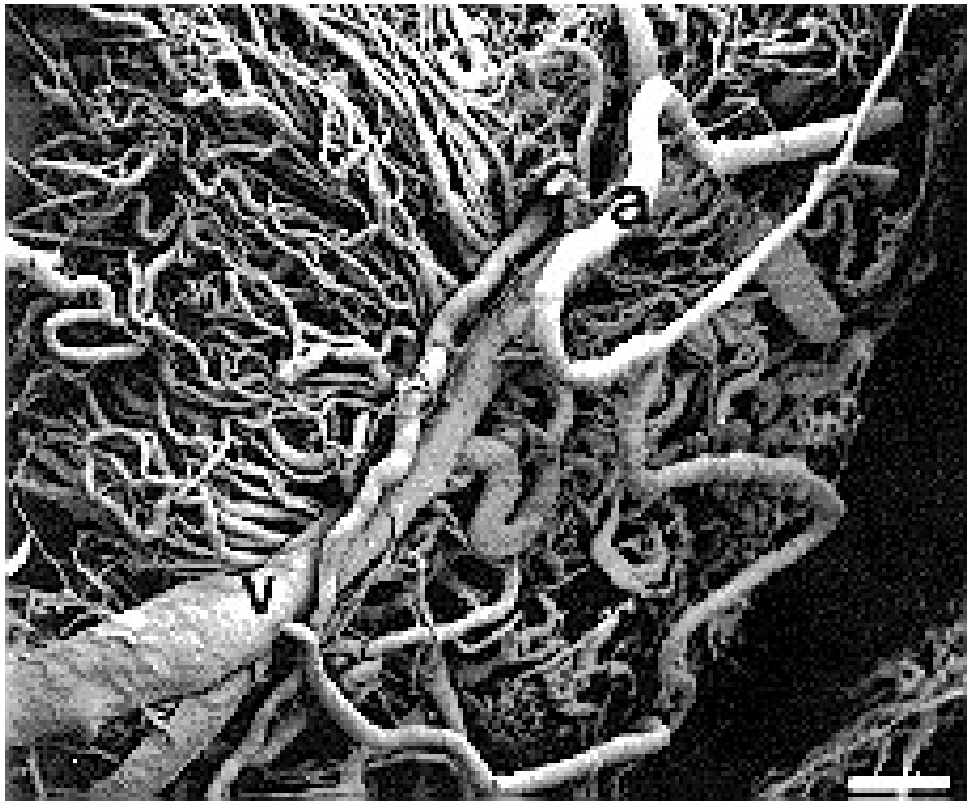


Normal colon

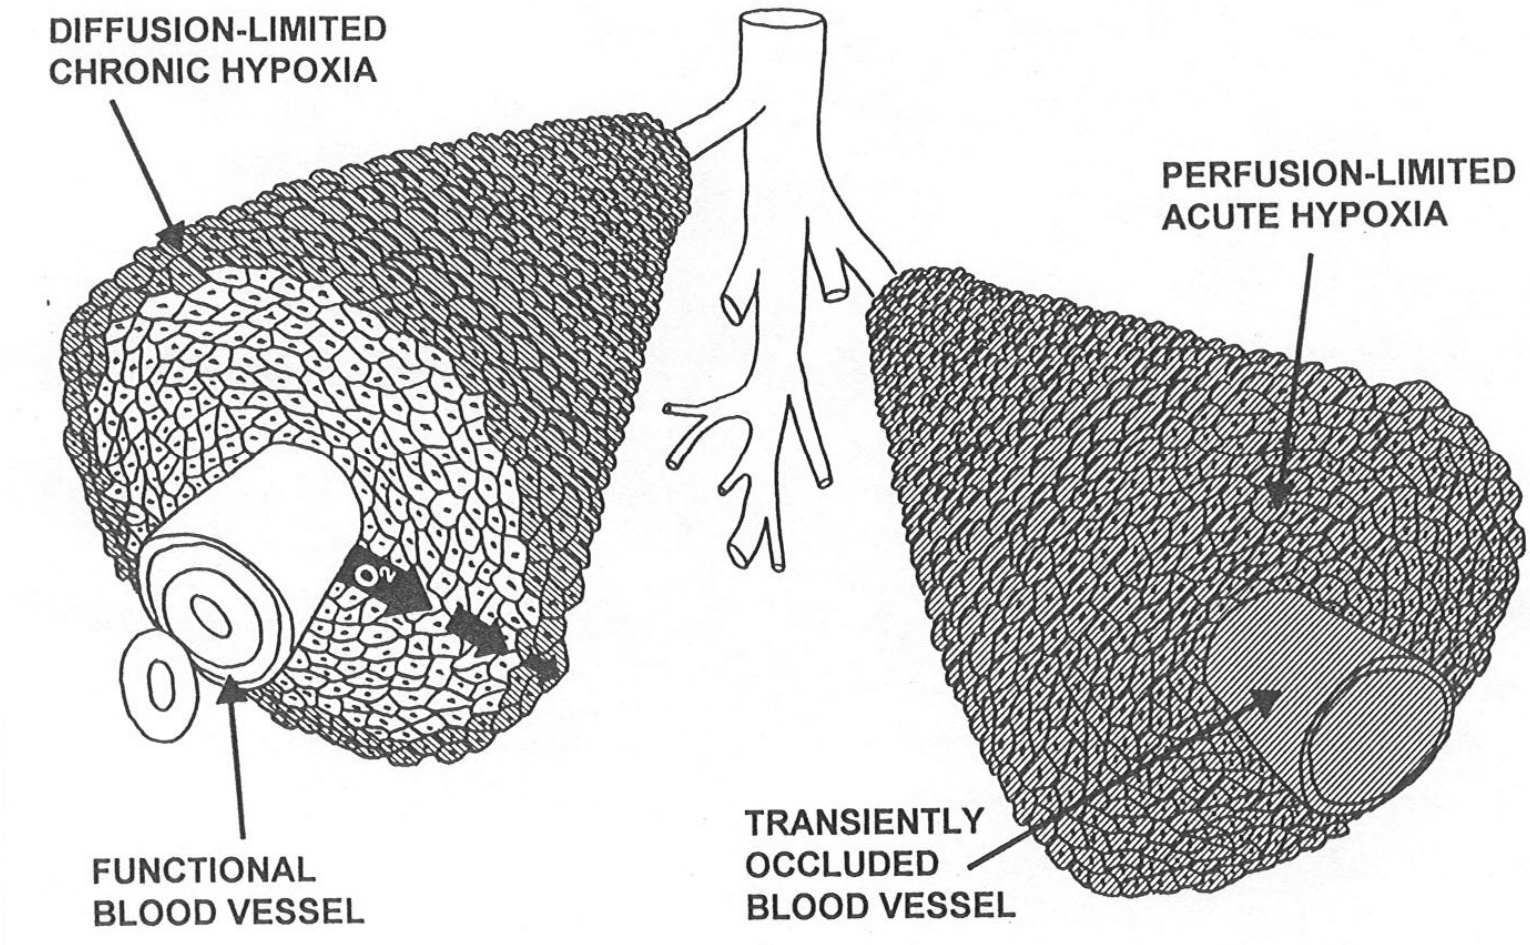
Colon xenograft

The vasculature in tumors is abnormal

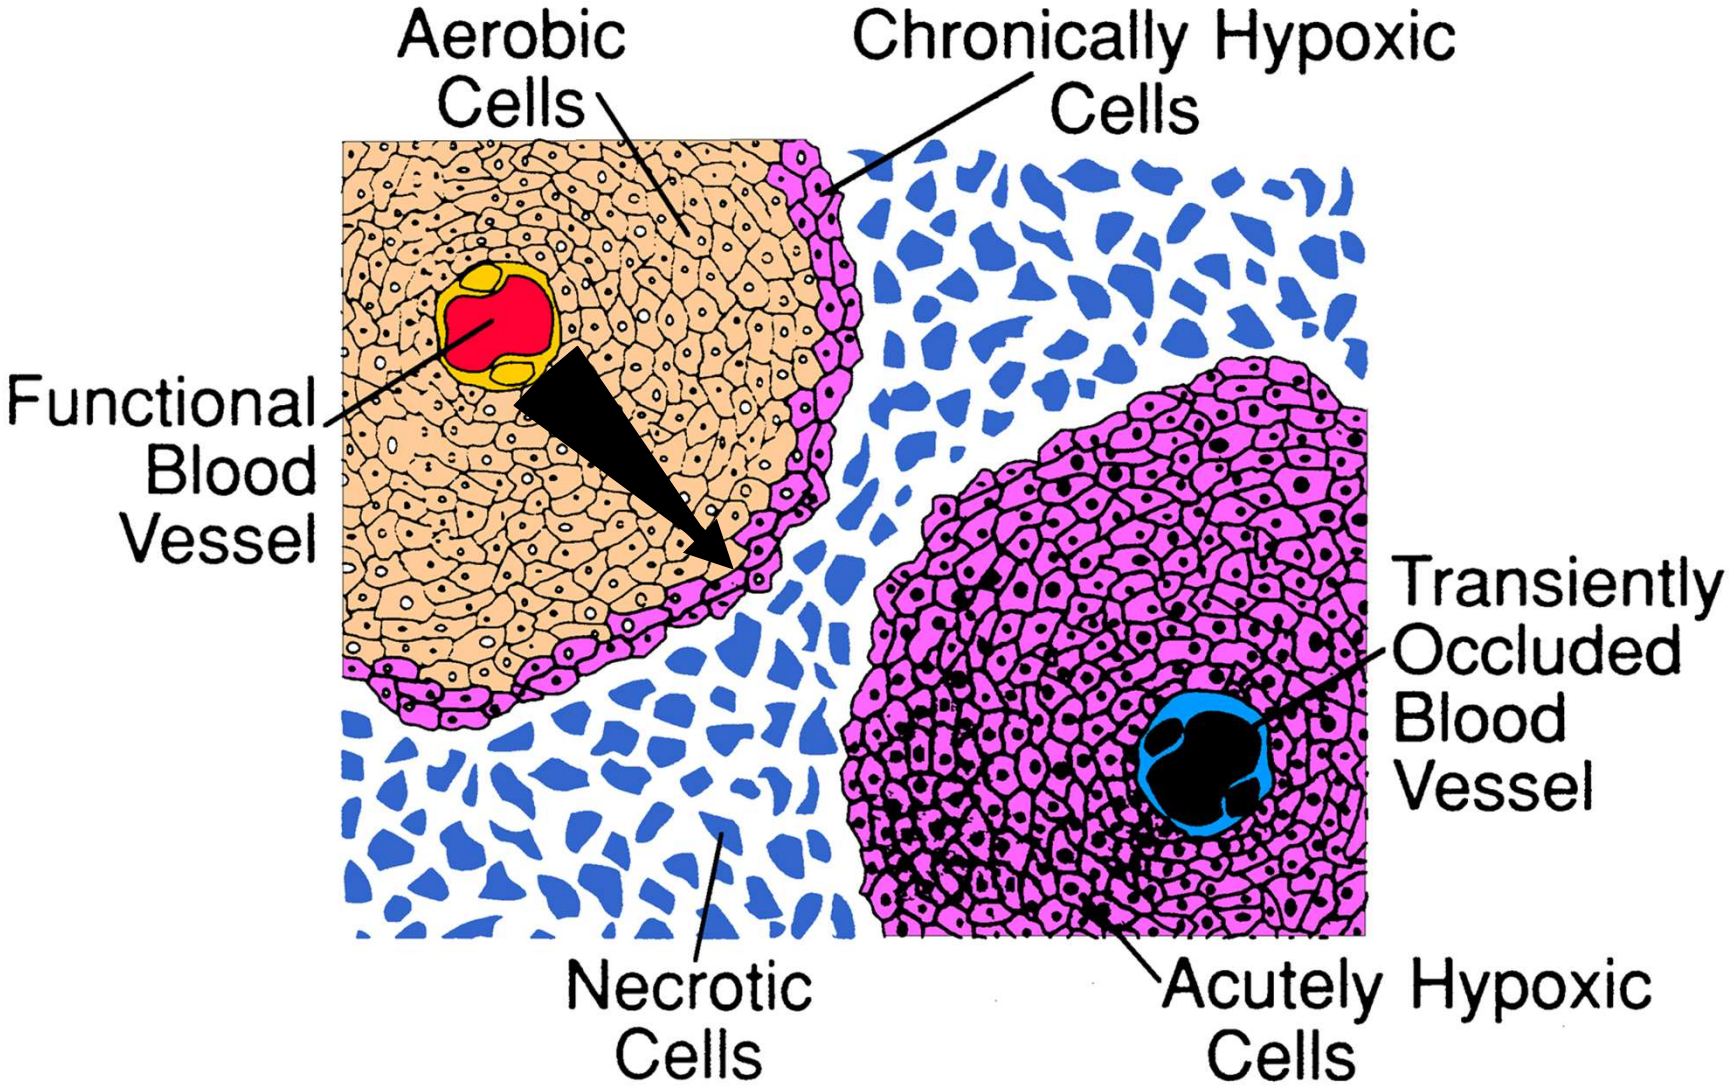
Leads to low overall levels of oxygen in most tumors, with many areas being extremely hypoxic.



Chronic versus acute hypoxia



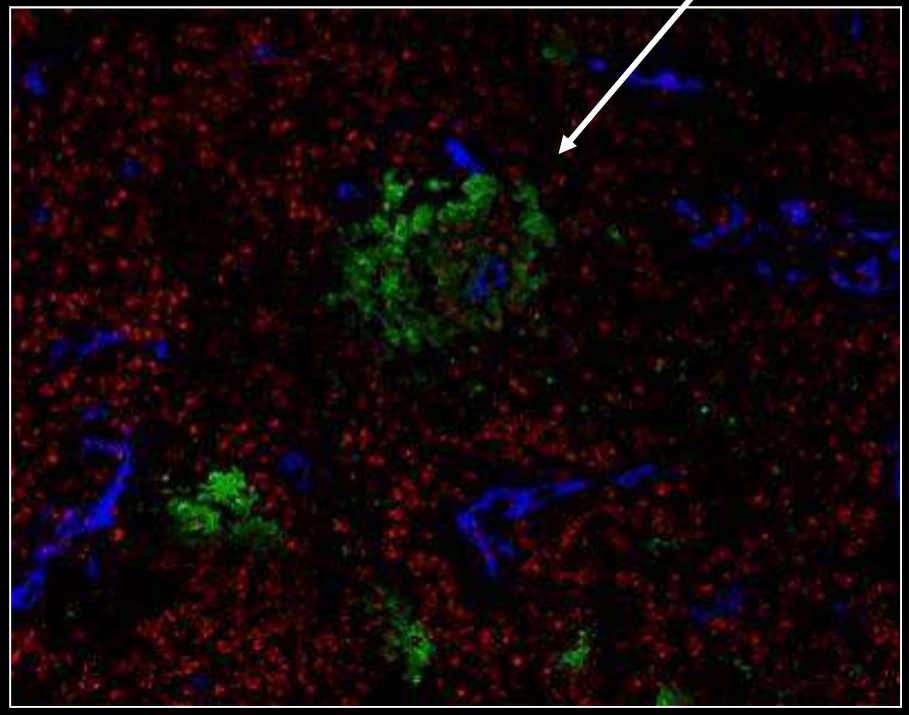
Chronic versus acute hypoxia



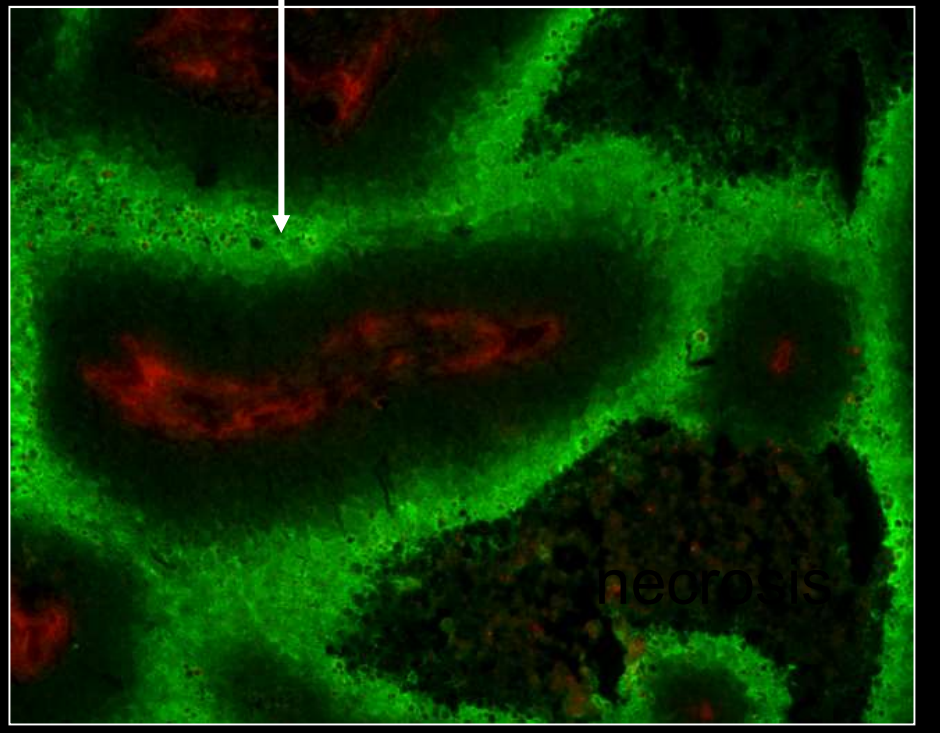
Different types of hypoxia

Perfusion-limited (“acute”)
Diffusion-limited (“chronic”)

Hypoxia: CCl-103F (-2.5h)
Proliferation: BrdU (-0.5h)
Vessels



Hypoxia
Vessels



Hypoxia is a result of:

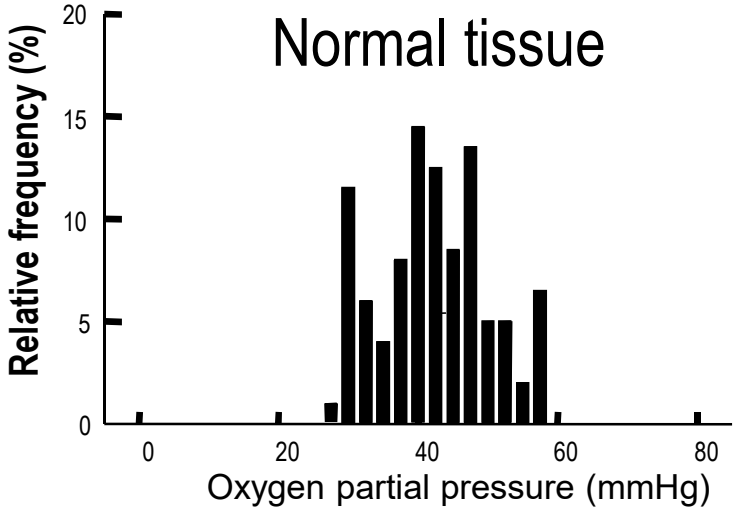
- Oxygen delivery
- Oxygen consumption
- Hypoxia tolerance

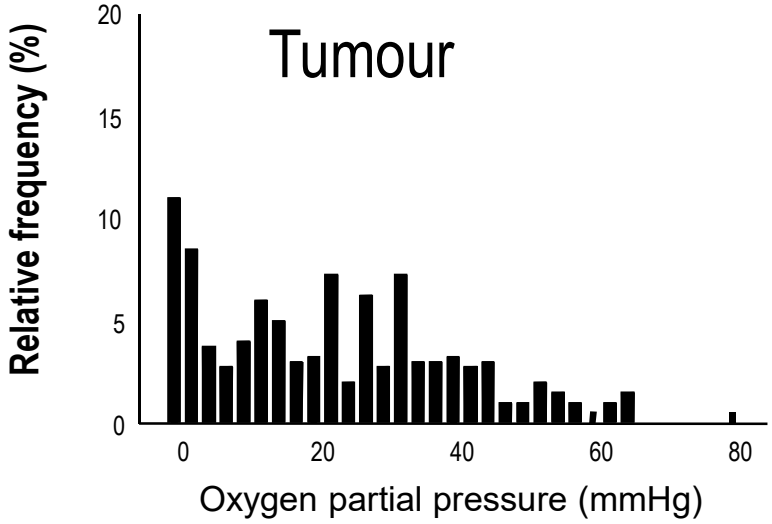
2) Heterogeneity of tumor oxygenation

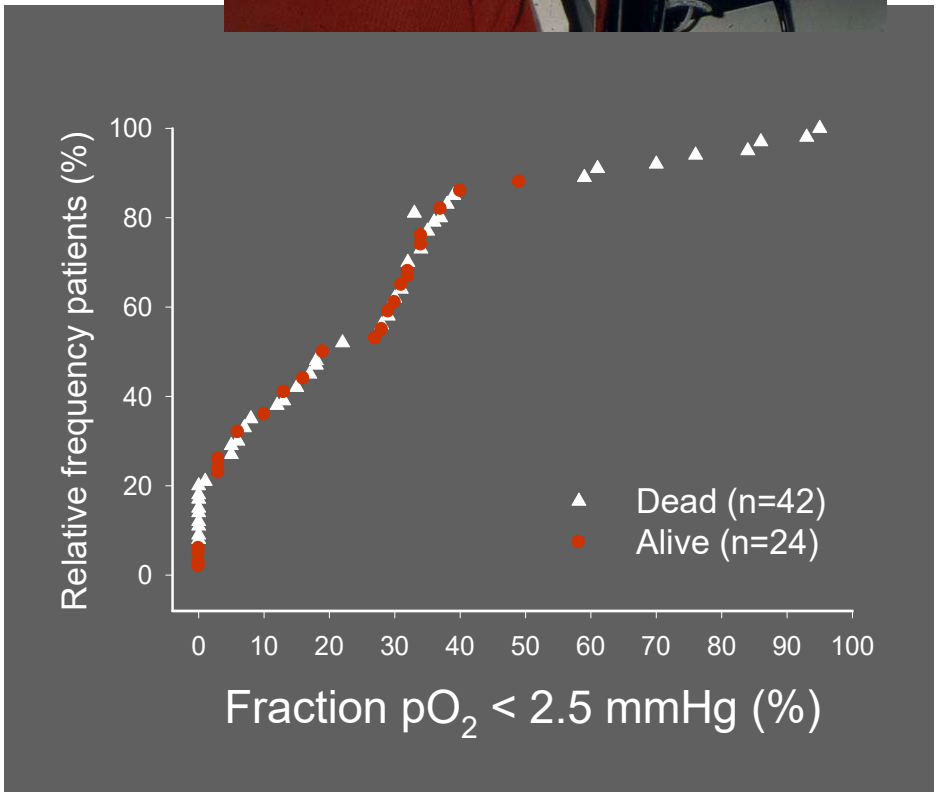
Heterogeneity in Oxygenation

a) Amount (%) amongst patients
b) In severity
c) In space
d) In time

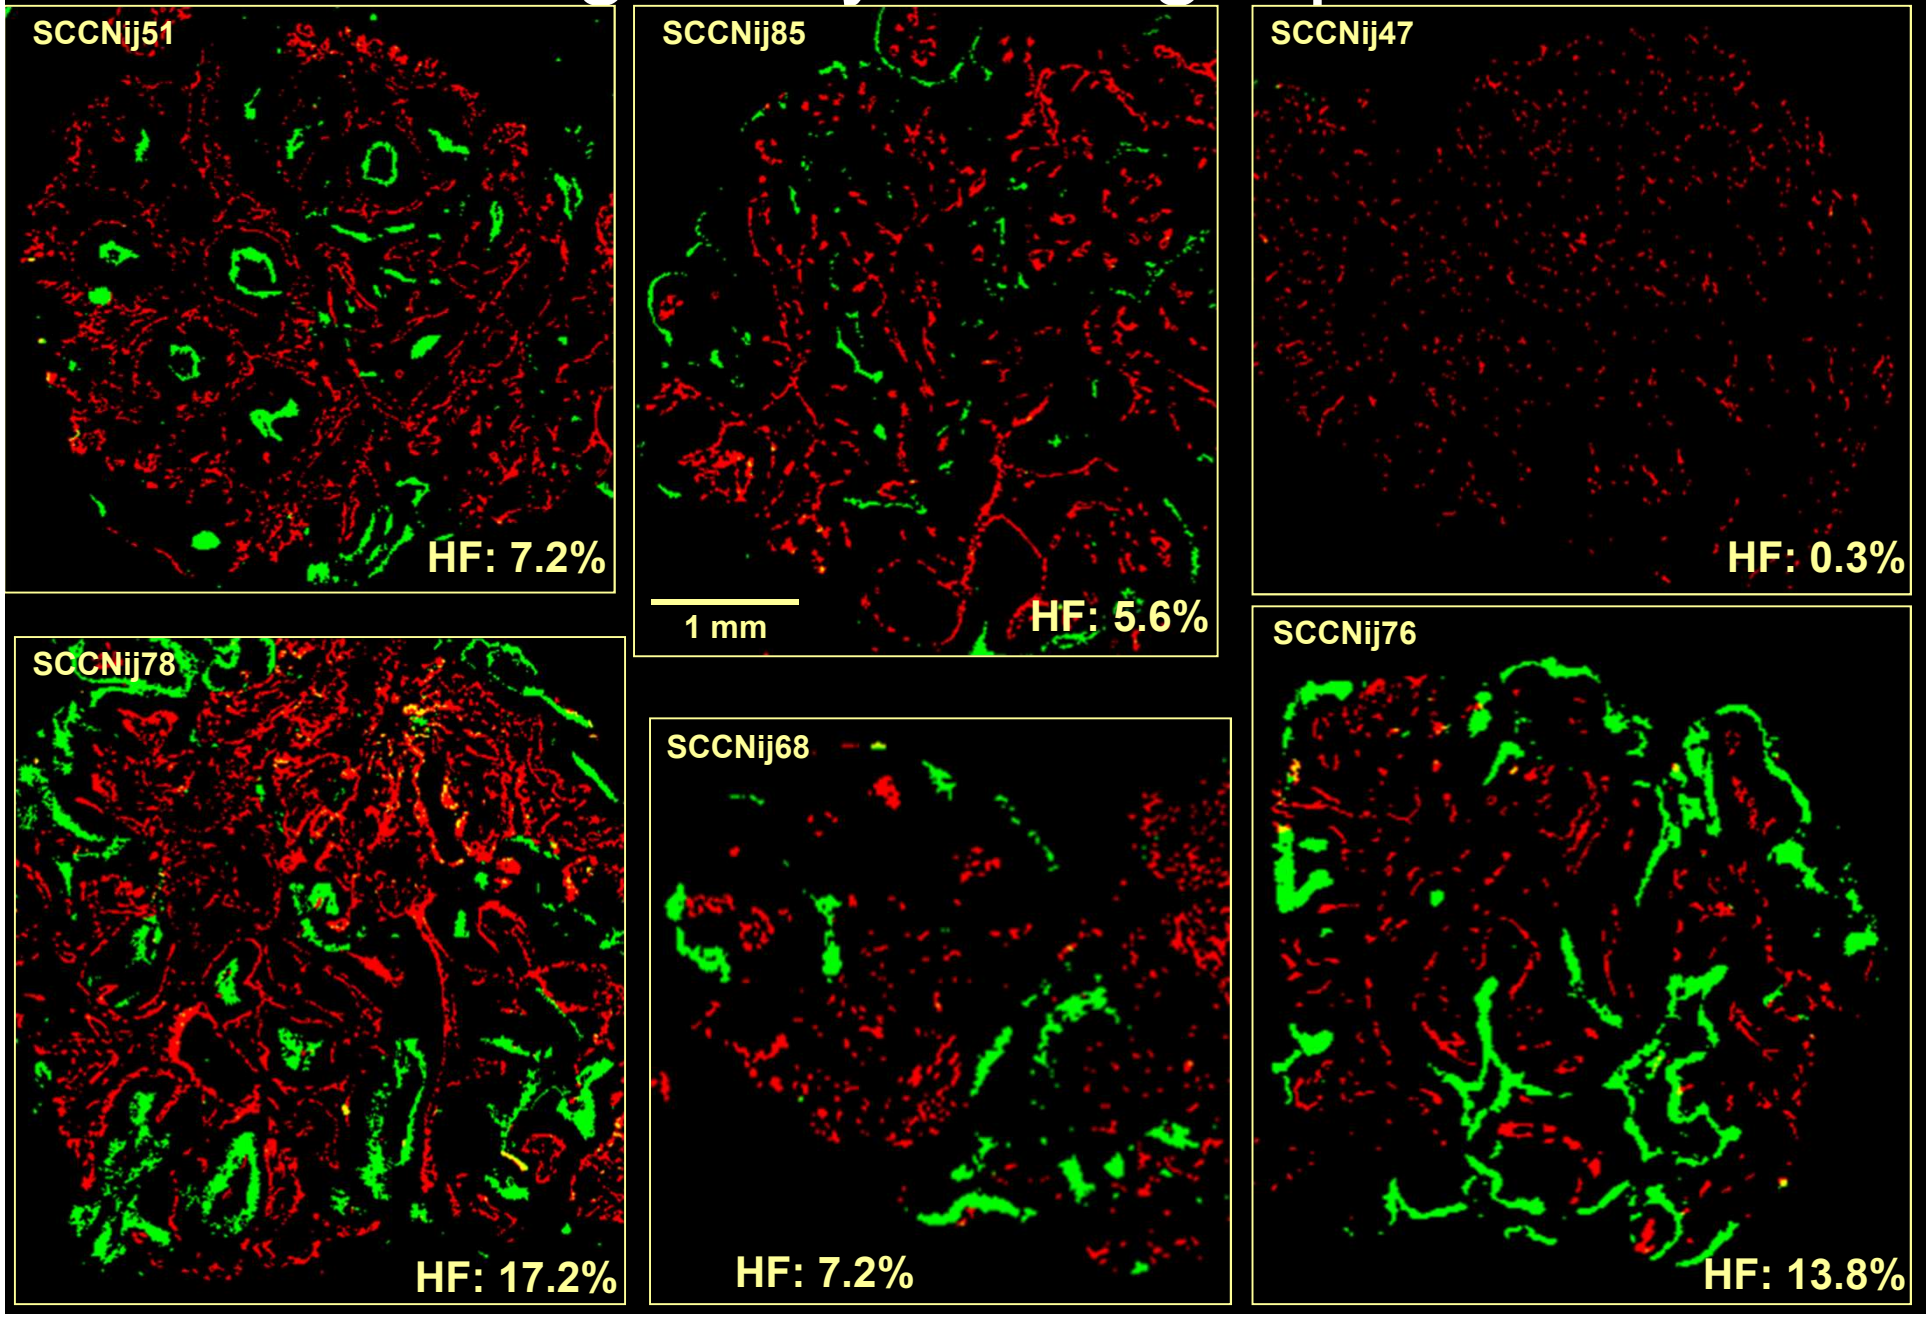
a) Heterogeneity in hypoxia (%) amongst patients







Heterogeneity amongst patients



Hypoxia predicts for poor outcome

397 head and neck patients – 7 centers
Nordsmark M et al, Radiother Oncol. 2005

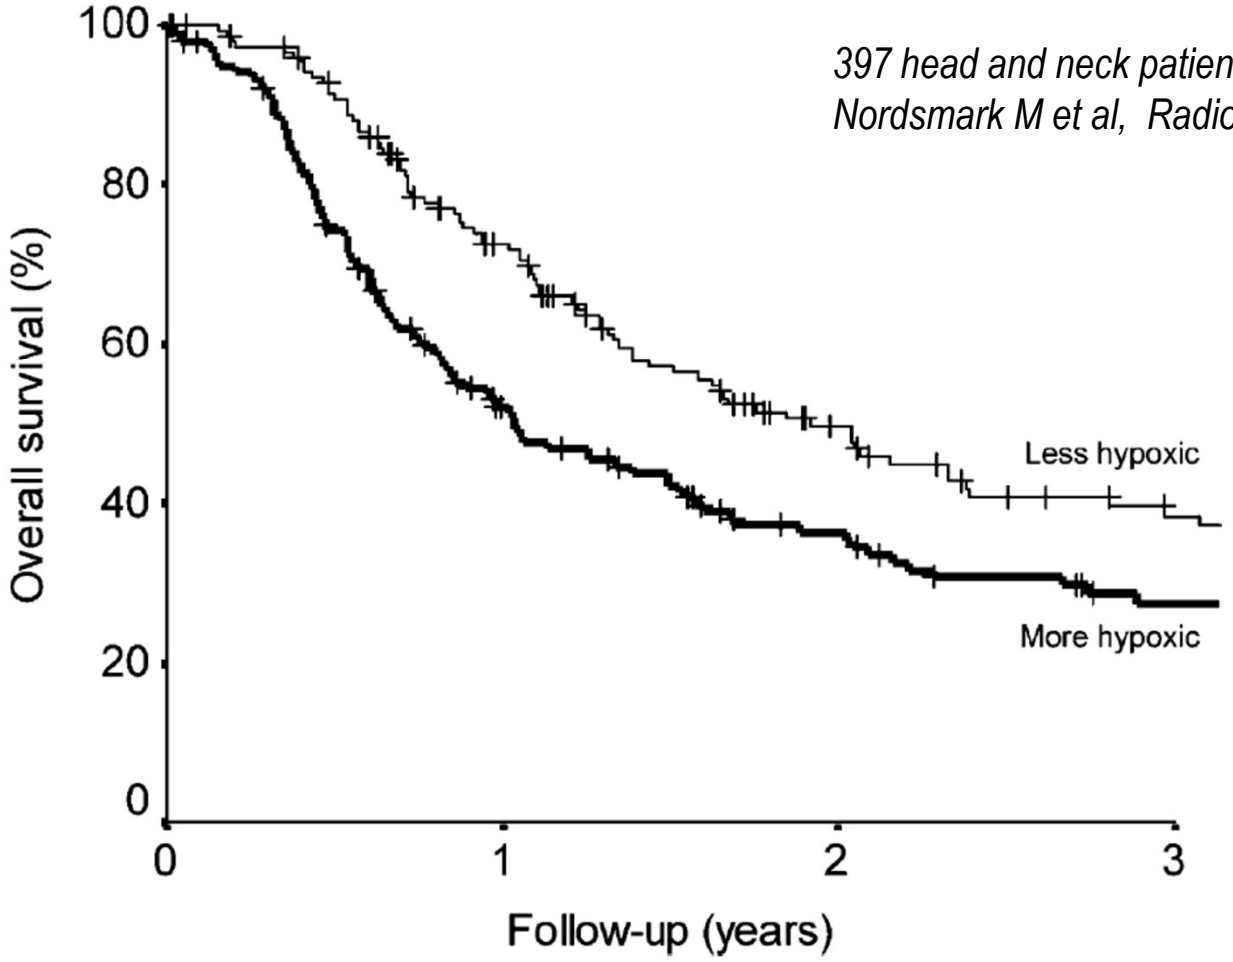


Fig. 2. Actuarial overall survival rate for patients with less hypoxic tumors ($HP_{2.5} \leq 19\%$, thin line) compared with more hypoxic tumors ($HP_{2.5} > 19\%$, bold line), $P = 0.006$.

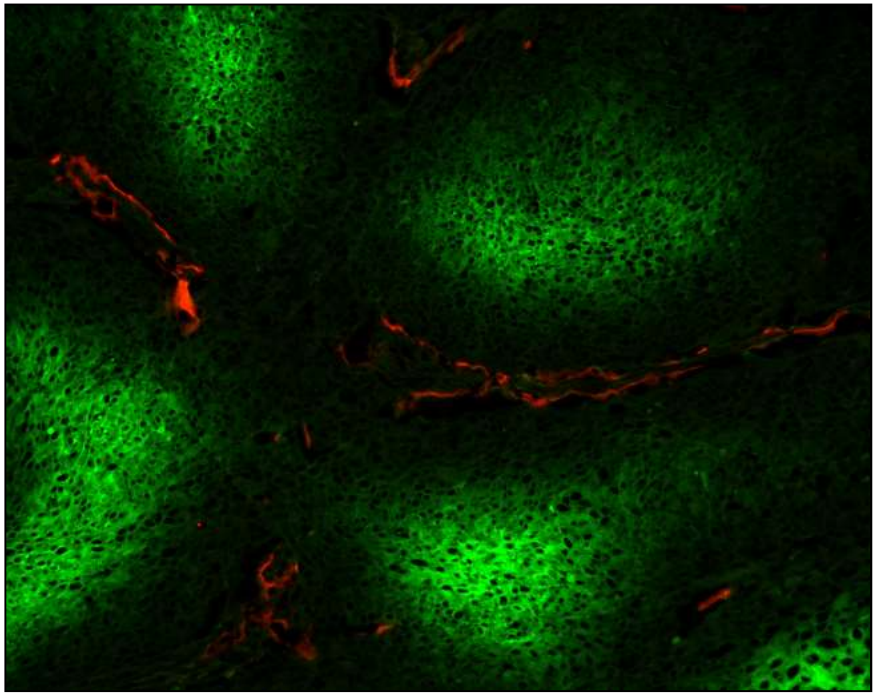
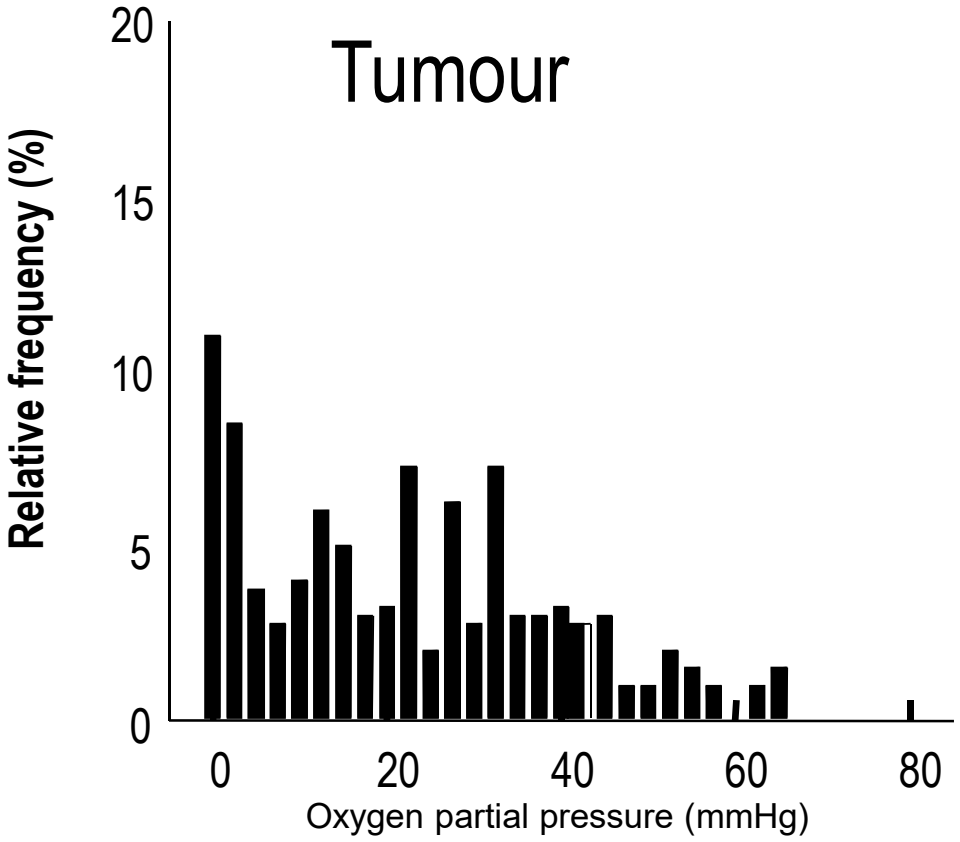
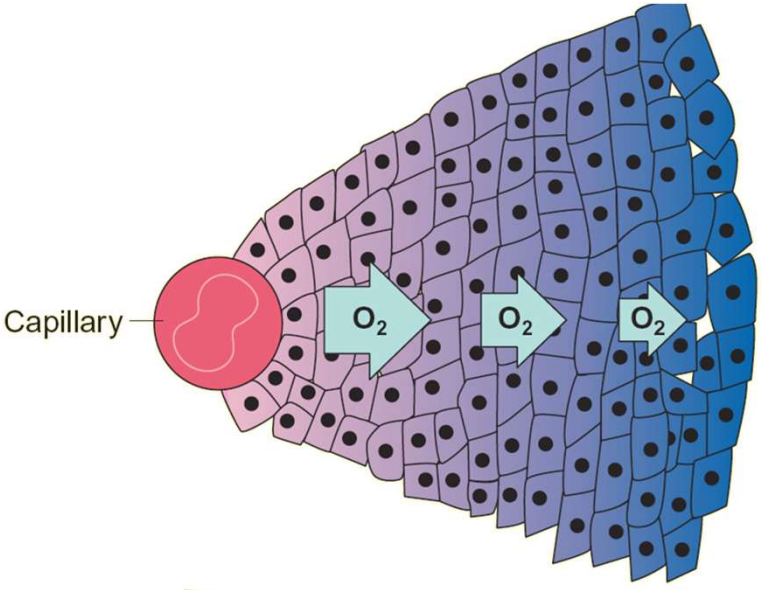
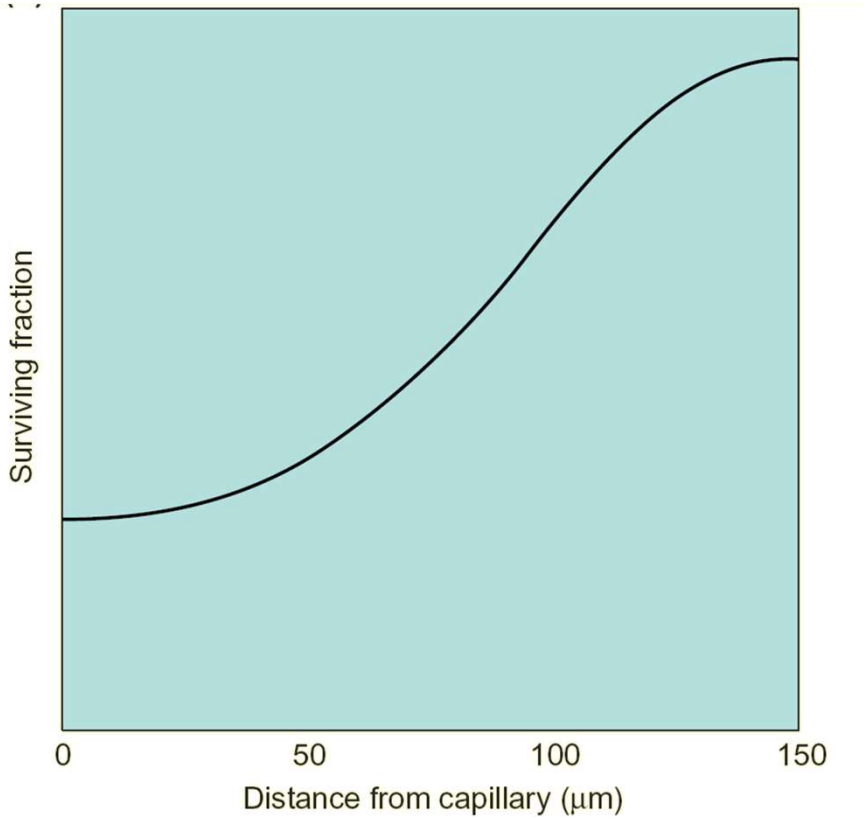
b) Heterogeneity in severity





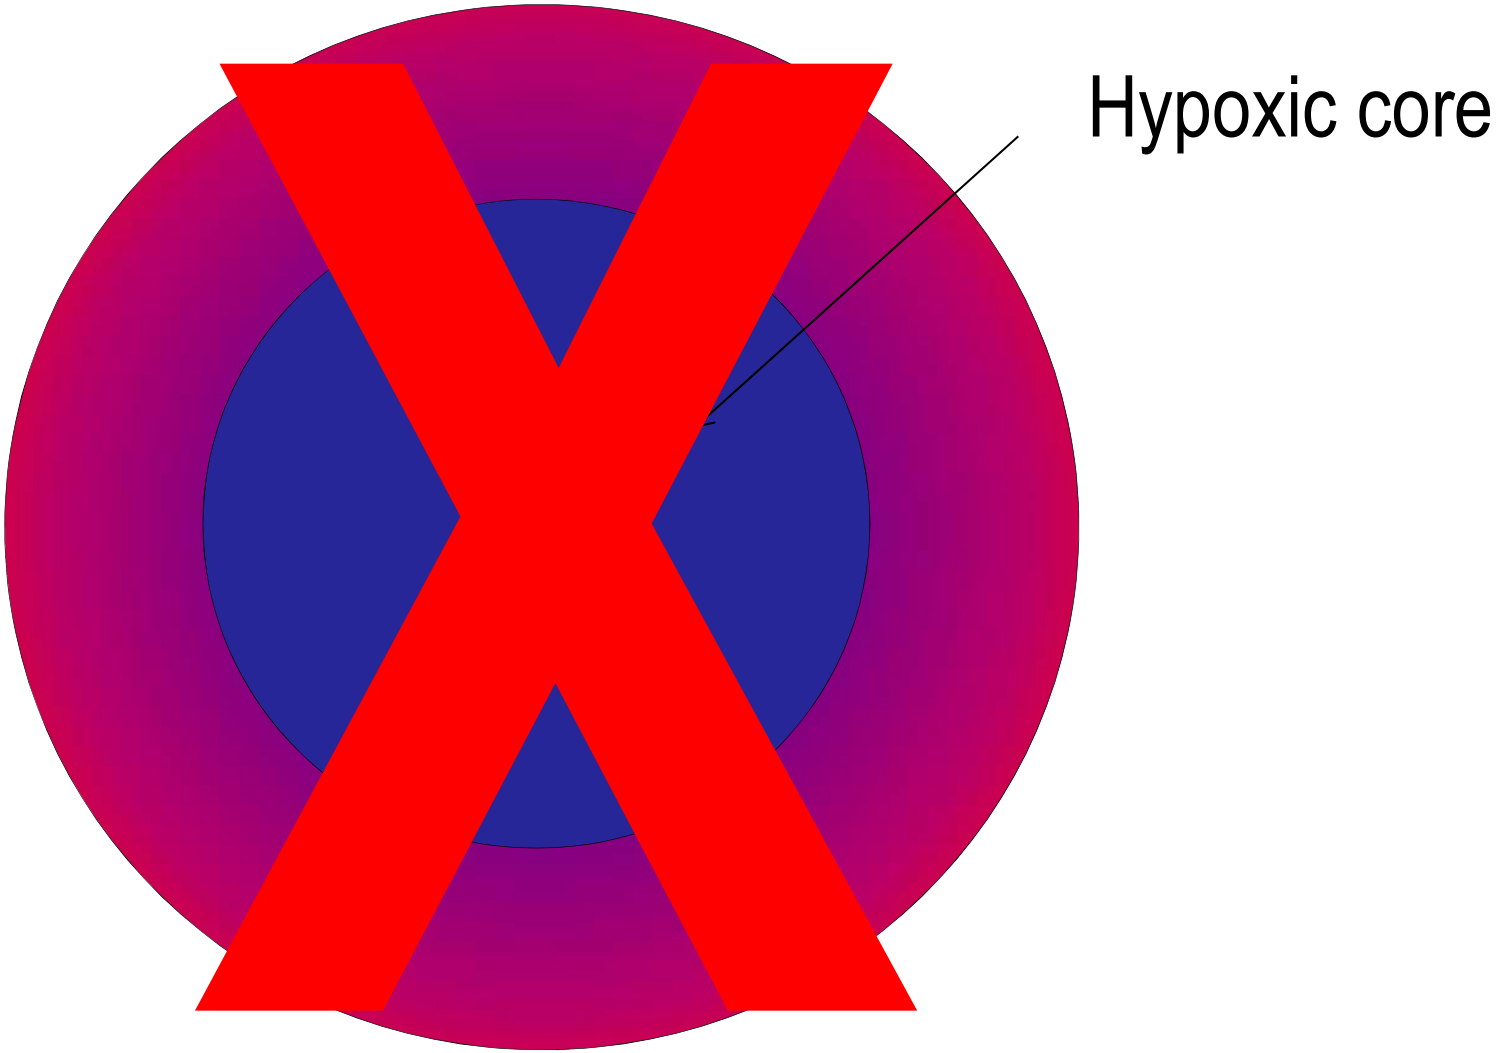
Severity and radiation response



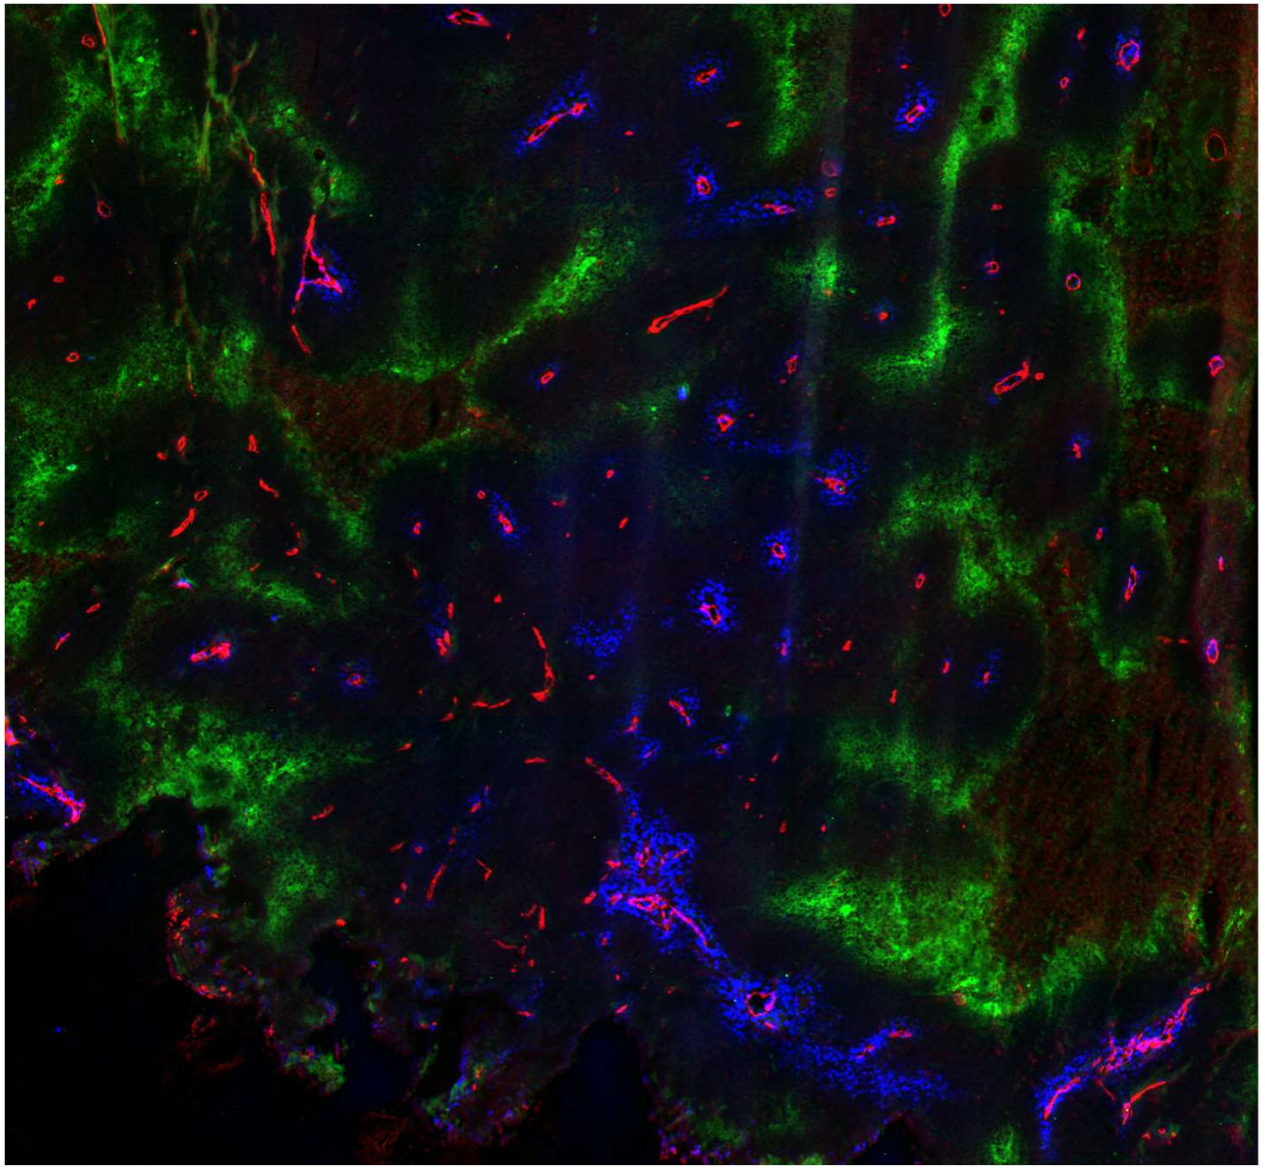


Cell killing by radiation will be reduced as a function of distance from the capillary.

c) Heterogeneity in space



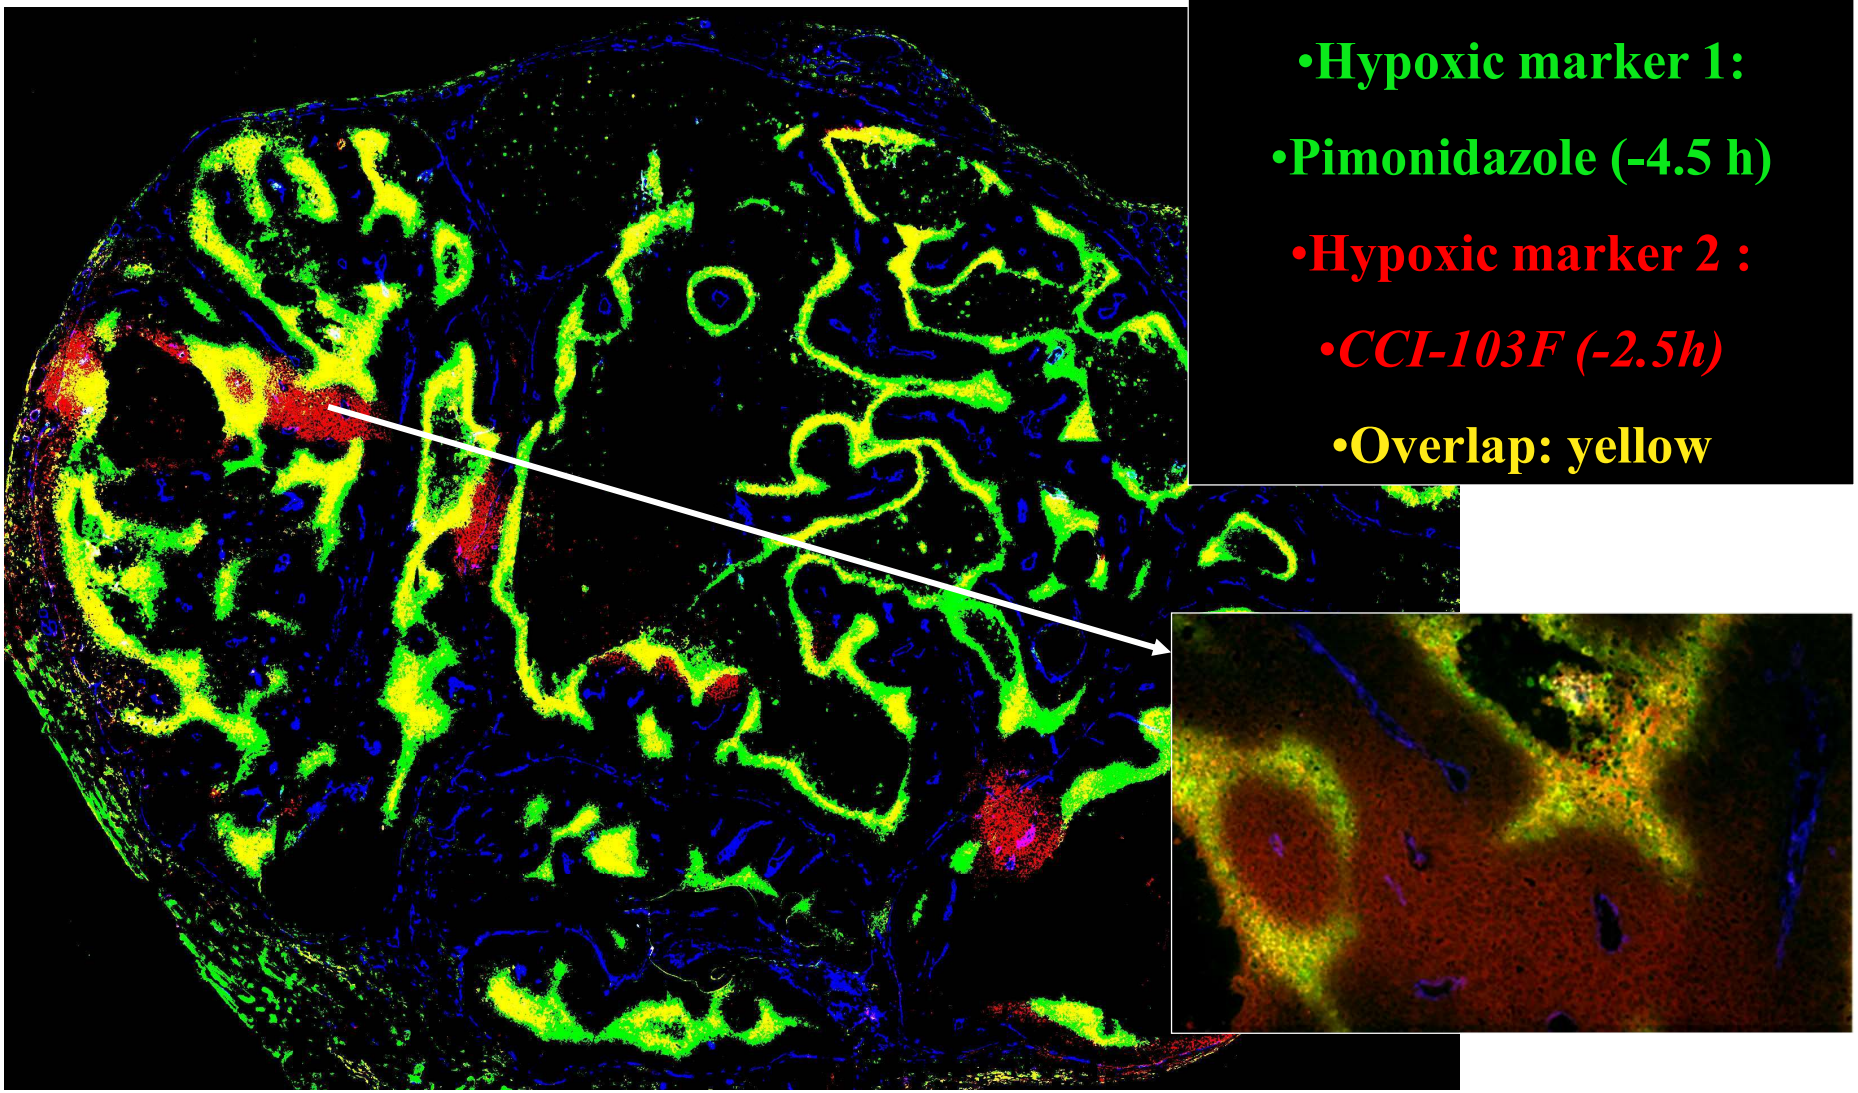
c) Heterogeneity in space



c) Consequences of spatial heterogeneity

- Hypoxia can exist around all vessels in a tumor
  - No relationship between hypoxia and tumor size!
- Oxygenation varies at the cellular (micron) level
- Imaging hypoxia always involves averaging over very large numbers of cells.
  - Hypoxic cells are likely to exist in all imaging voxels
  - It will never be possible to deliver dose specifically to hypoxic cells

d) Heterogeneity in time



- Vessels (blue)
- Hypoxic marker 1:
- Pimonidazole (-4.5 h)
- Hypoxic marker 2 :
- *CCI-103F (-2.5h)*
- Overlap: yellow

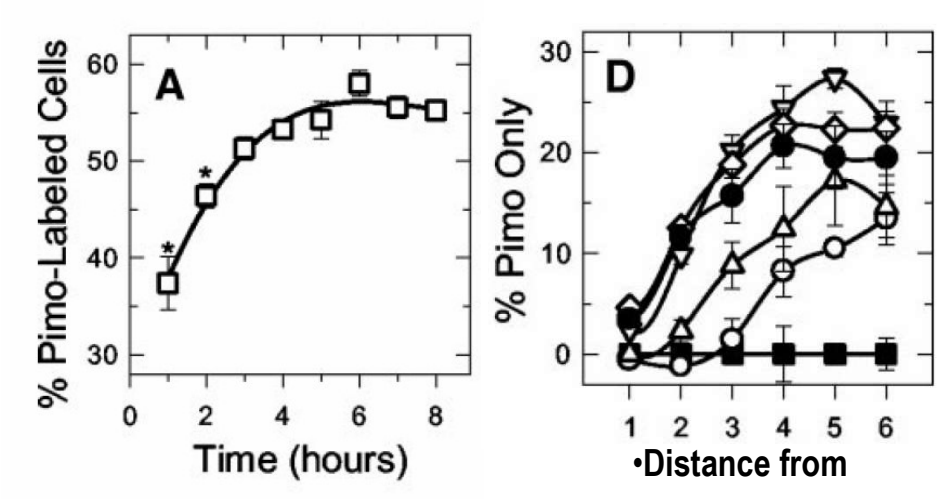
d) Heterogeneity in time

[CANCER RESEARCH 64, 6183–6189, September 1, 2004]

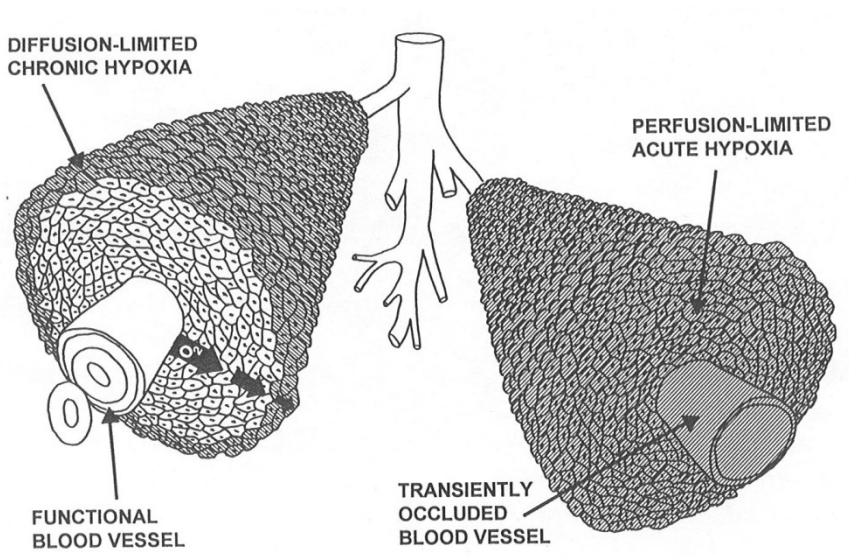
Quantifying Transient Hypoxia in Human Tumor Xenografts by Flow Cytometry

Kevin L. Bennewith and Ralph E. Durand

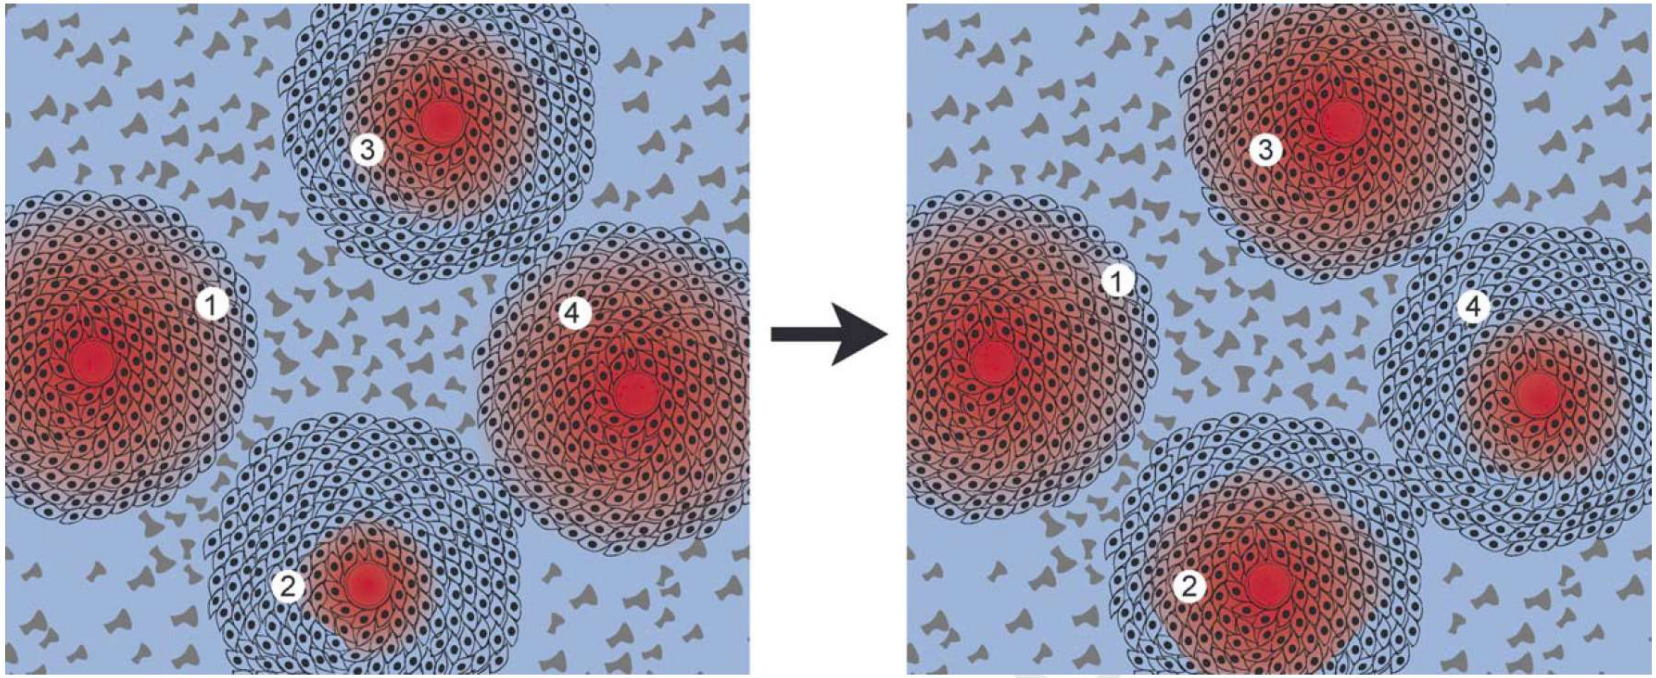
Medical Biophysics Department, British Columbia Cancer Research Centre, Vancouver, British Columbia, Canada



- Distance from
- blood vessel



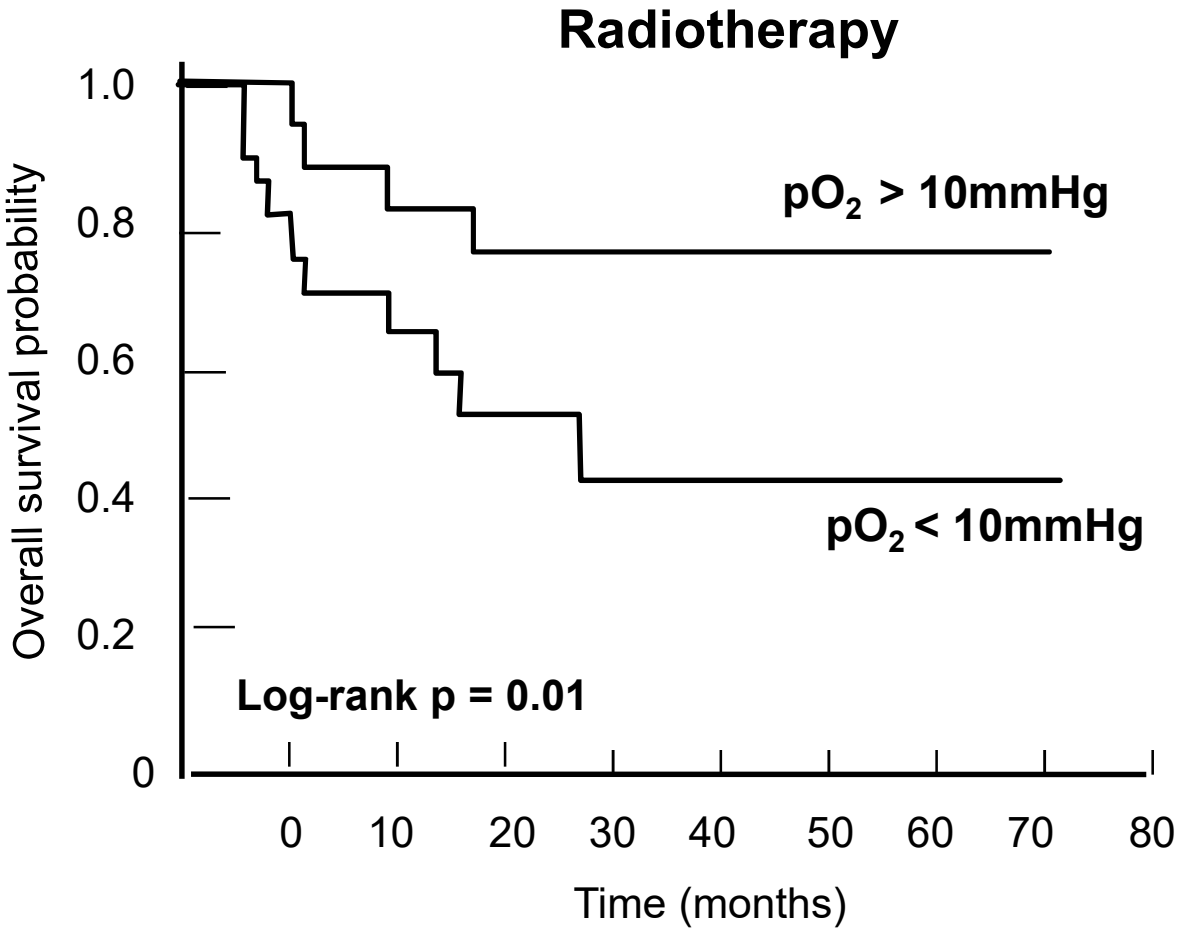
Oxygenation is dynamic



Hypoxic cells vary at every fraction

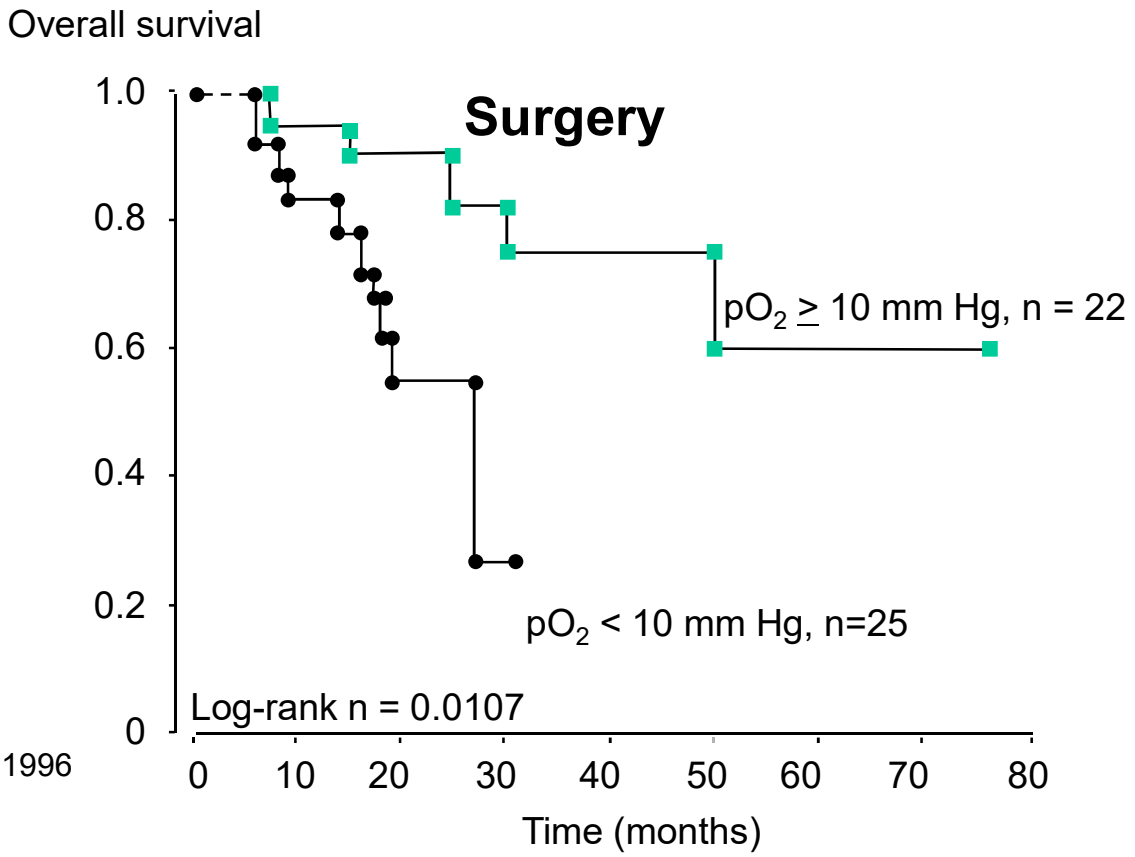
3) Cellular consequences of hypoxia

Treatment resistance - Radiotherapy



Höckel M. et al. Cancer Res 56, 4509-4515 (1996)

Hypoxia and Treatment Outcome - Surgery



Höckel M. et al, 1996

Hypoxia is a prognostic factor

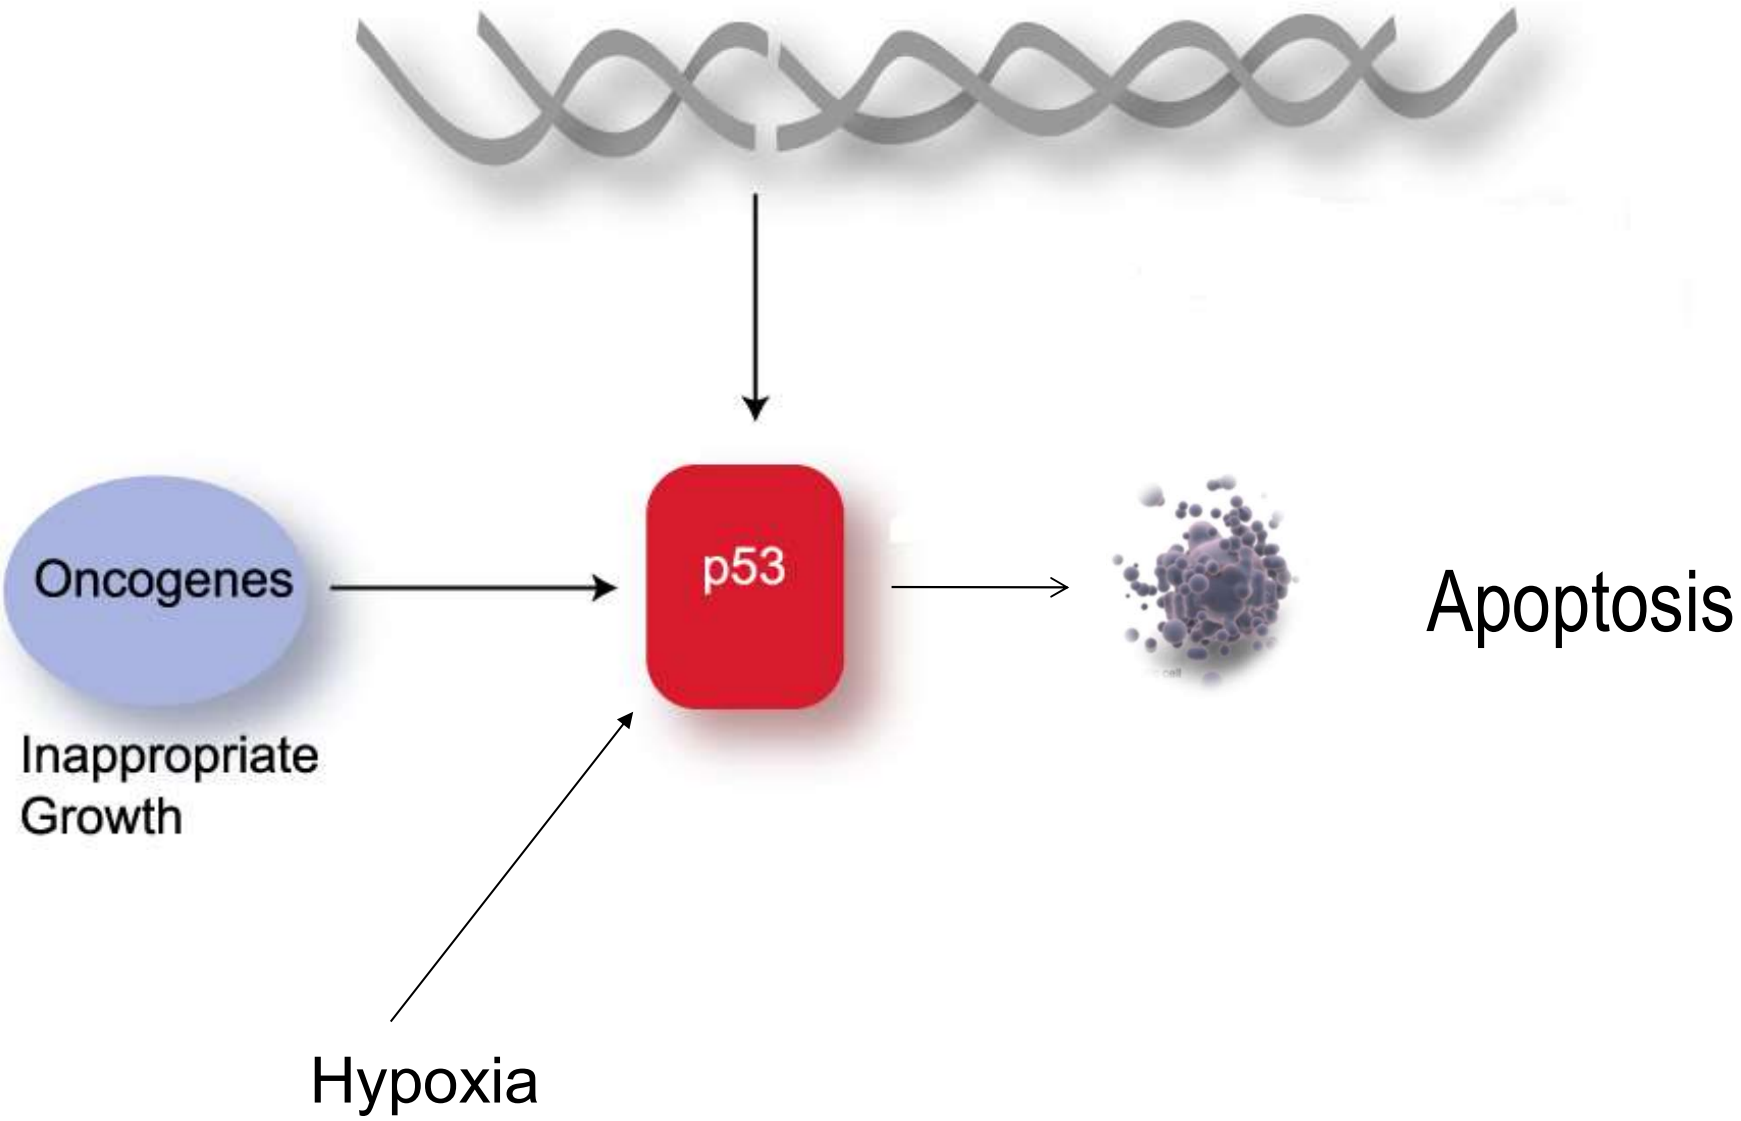
- **Hypoxic tumors are more malignant**
  - Cervix tumors have larger extensions, more frequent parametrial spread, more lymph-vascular space involvement
  - recurrent tumors are more hypoxic than primary tumors
  - predicts for the likelihood of distant metastases in soft tissue sarcomas
  - hypoxia is a strong prognostic factor (*Independent of primary mode of treatment)*

Hypoxia and malignancy – mechanisms

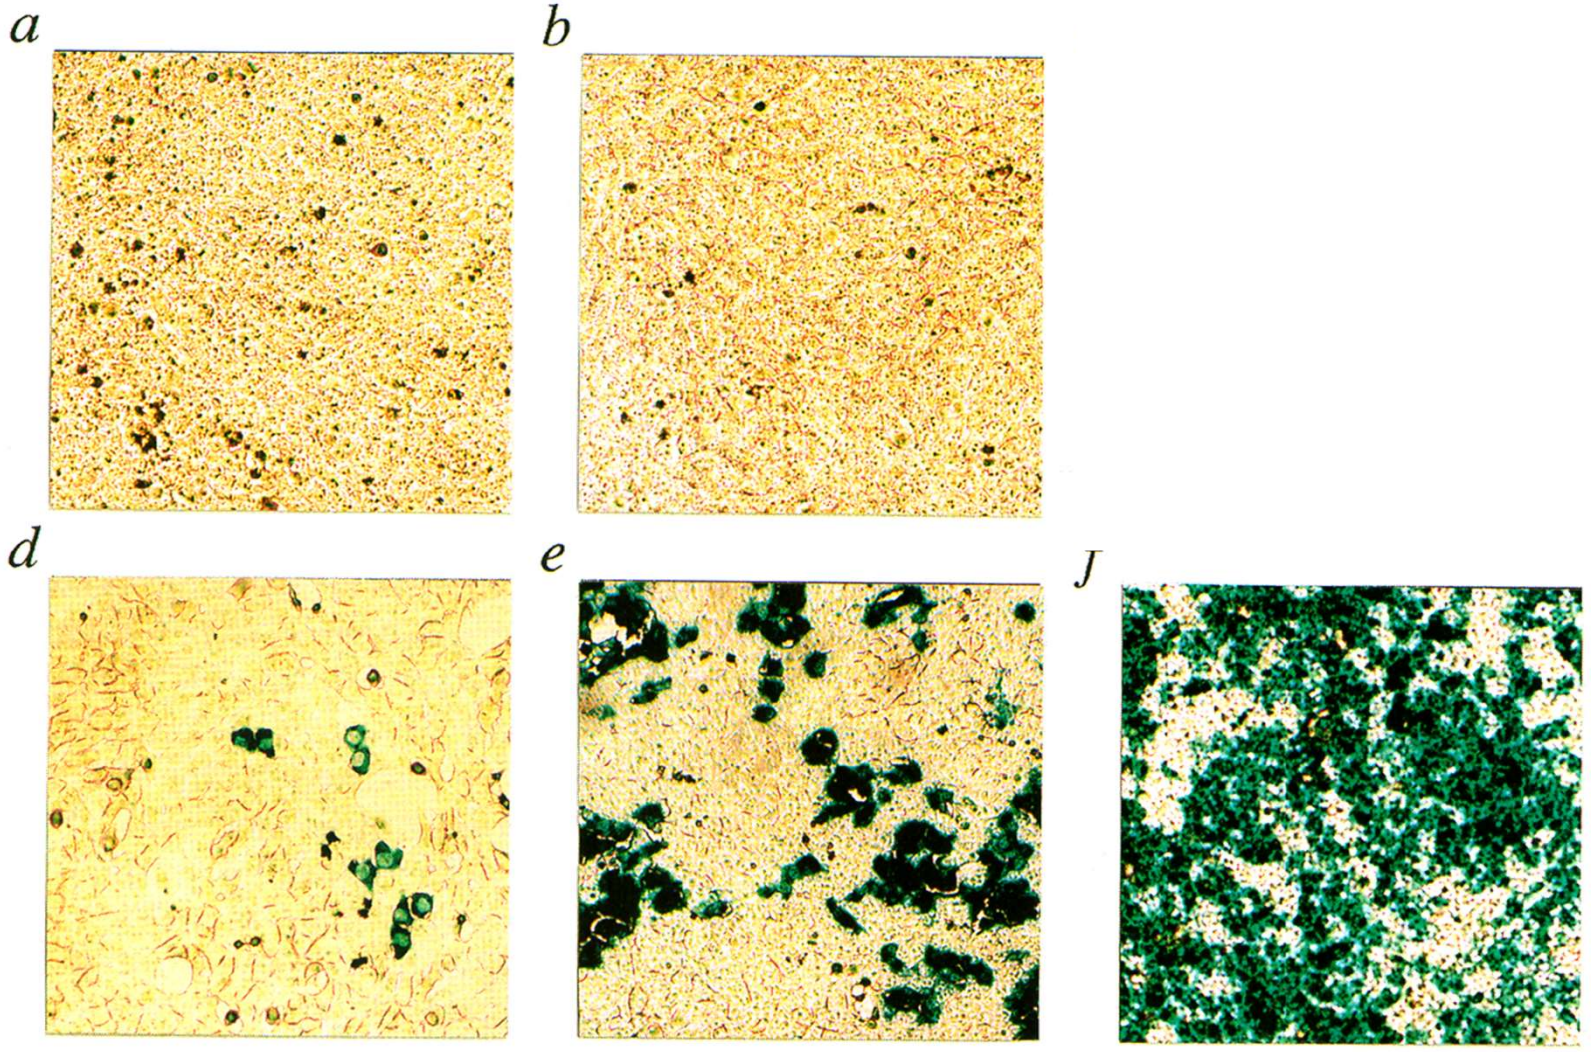
a) Tumor hypoxia can “select” for cells that are more malignant

b) Cellular response to hypoxia affect cell behavior in an adverse way

Hypoxia activates p53



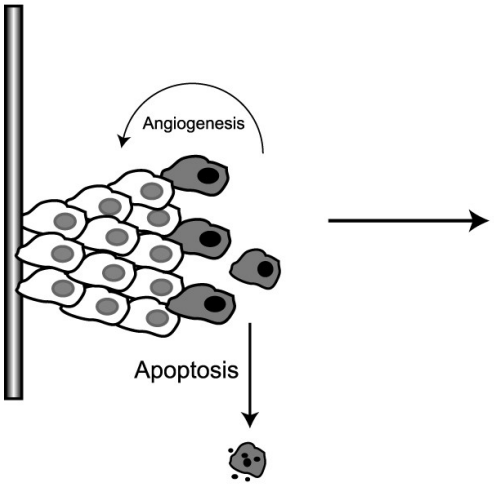
Hypoxia mediated selection of cells



Graeber, Nature 1996

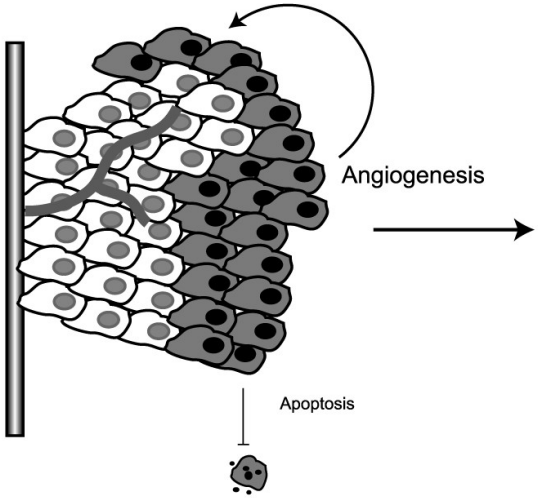
The concept of hypoxia tolerance

Early Cancer - rapid death
transient angiogenic signal



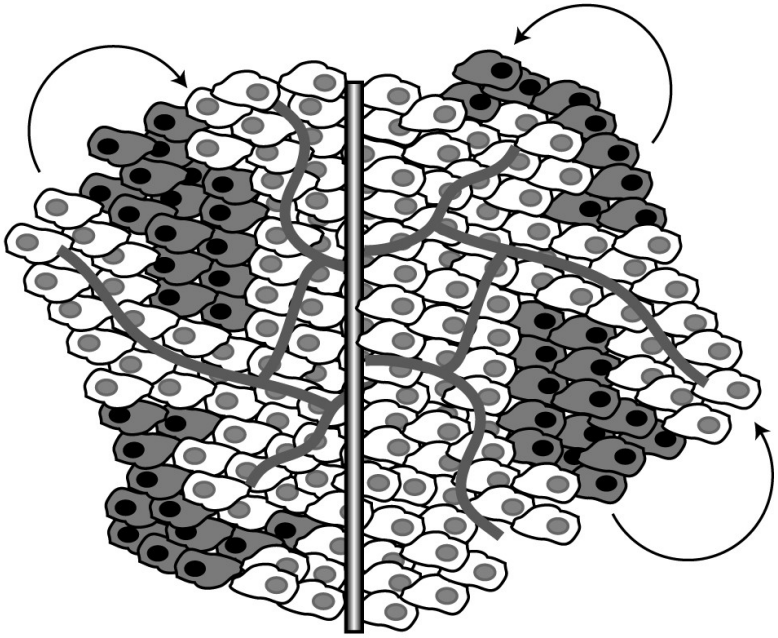
Apoptosis
Loss of energy homeostasis

Hypoxia Tolerance -delayed cell death
sustained angiogenic singal

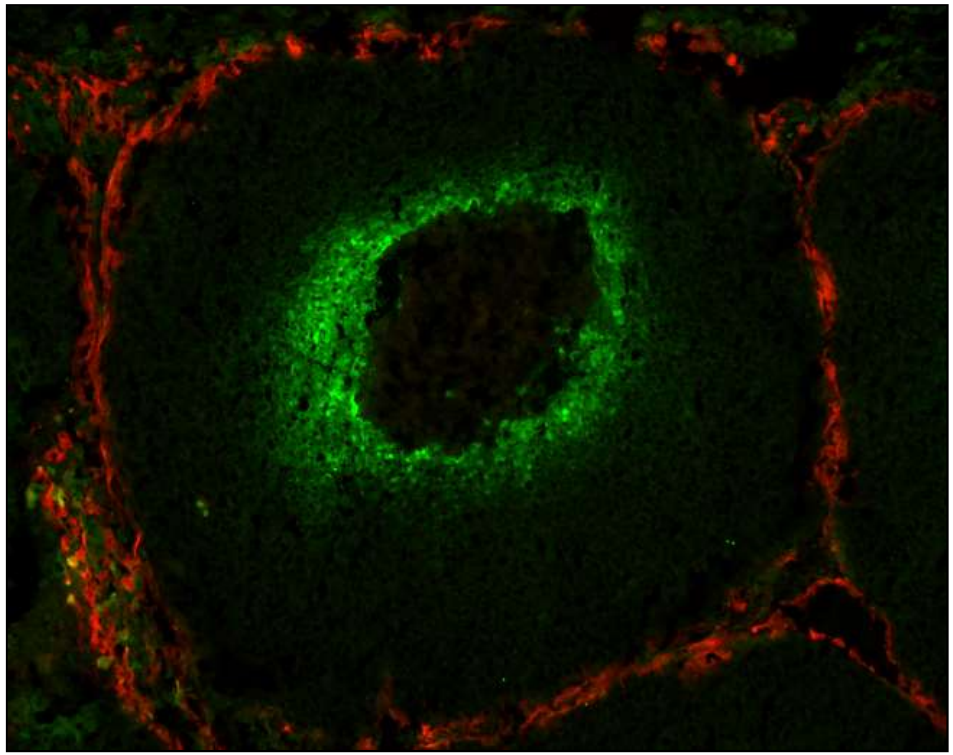


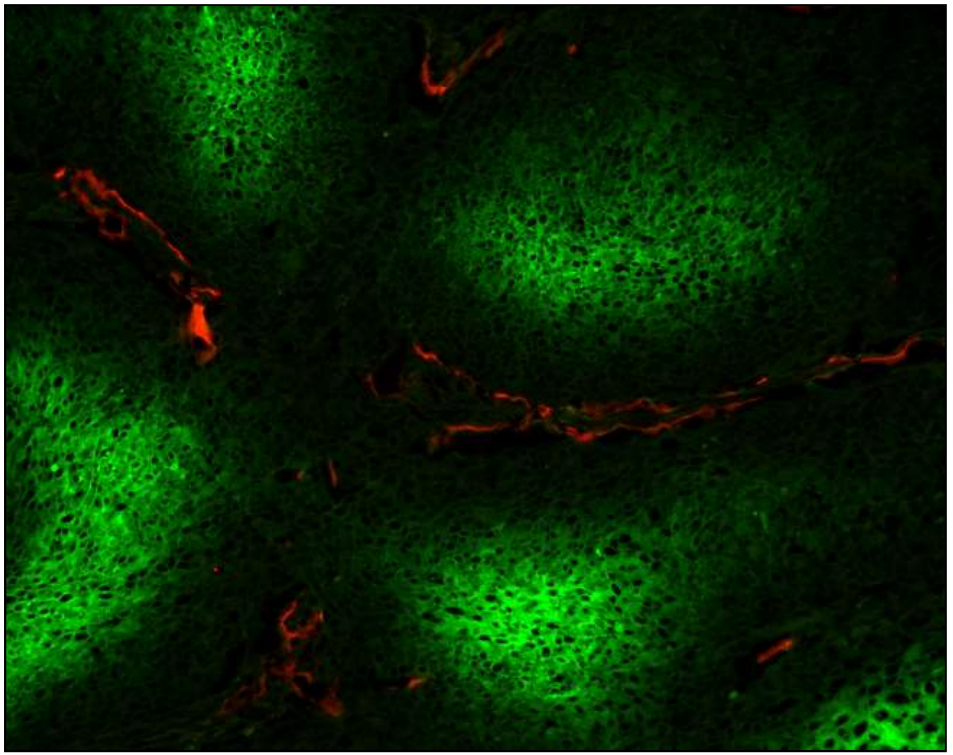
Resistance to apoptosis
Anaerobic glycolysis
Reduced protein synthesis

Mature Tumor - heterogenous hypoxia
sustained angiogenic singals



Hypoxia tolerance varies amongst tumors



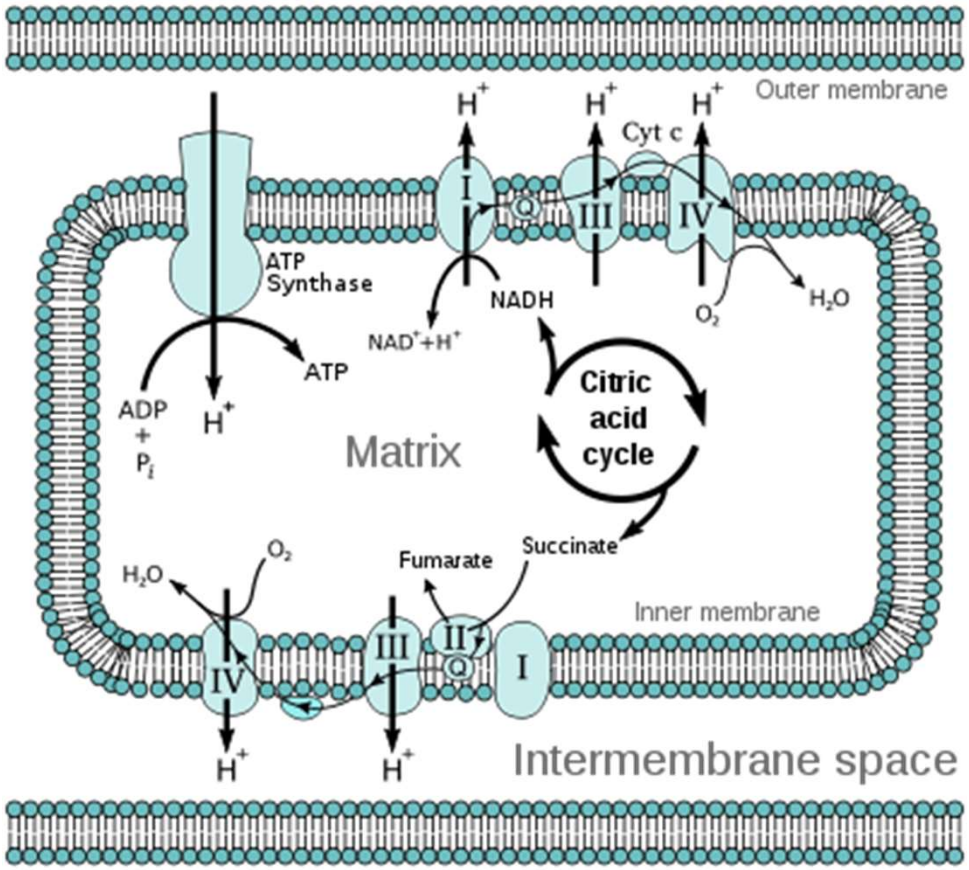


Cellular responses to hypoxia promote malignancy

- Hypoxia causes biological changes that promote
  - Metabolic adaptation
  - Angiogenesis / vasculogenesis
  - Migration, invasion and metastasis (EMT)
  - Genetic instability
  - Cell cycle checkpoints

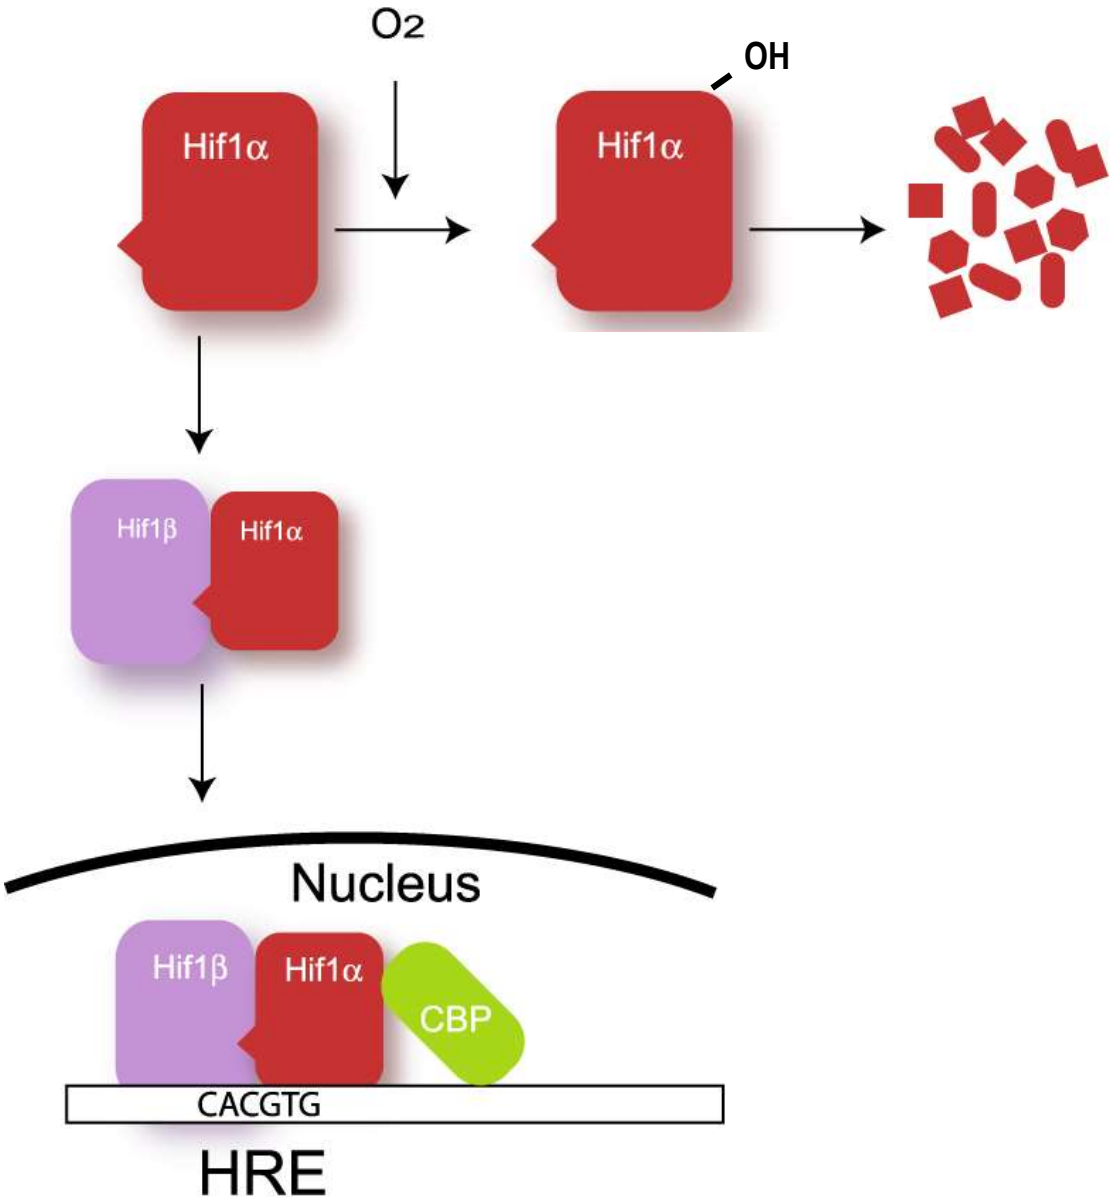
Biological changes are a consequence of altered protein activity and gene expression

Oxygen sensors: cytochrome c oxidase

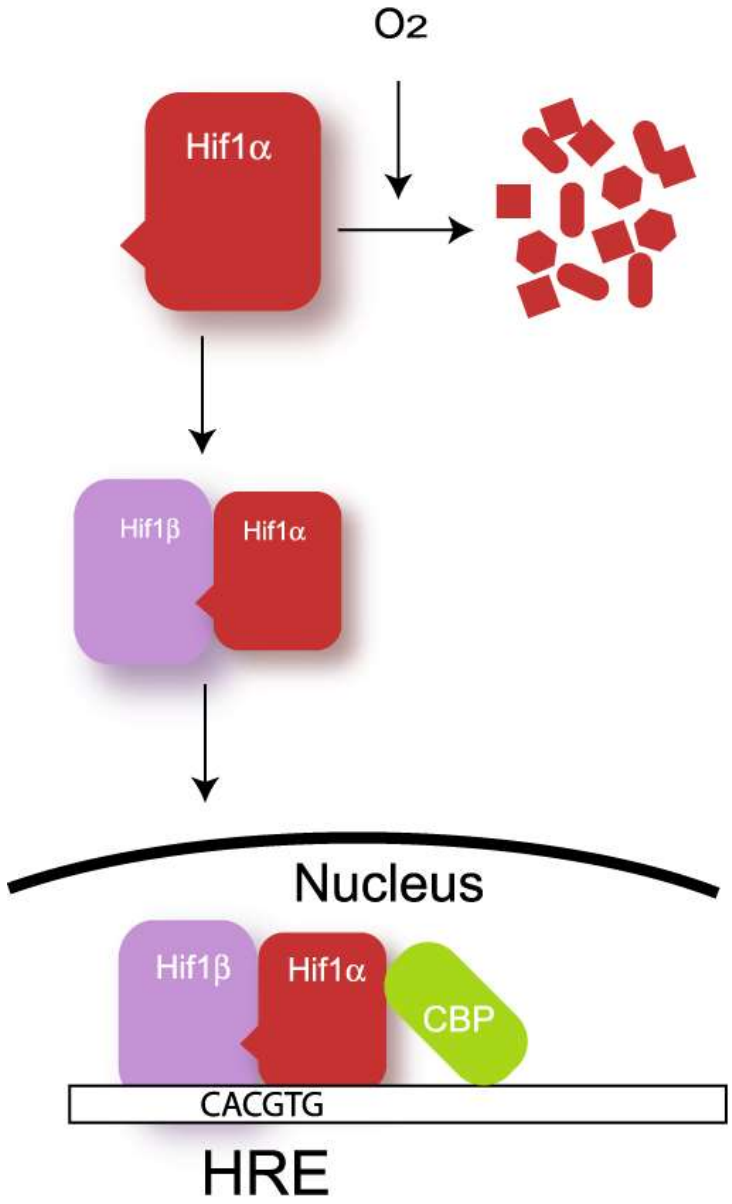


- ~80% oxygen consumption
- Reprogrammed metabolism
- ATP drop
  - Signaling pathways

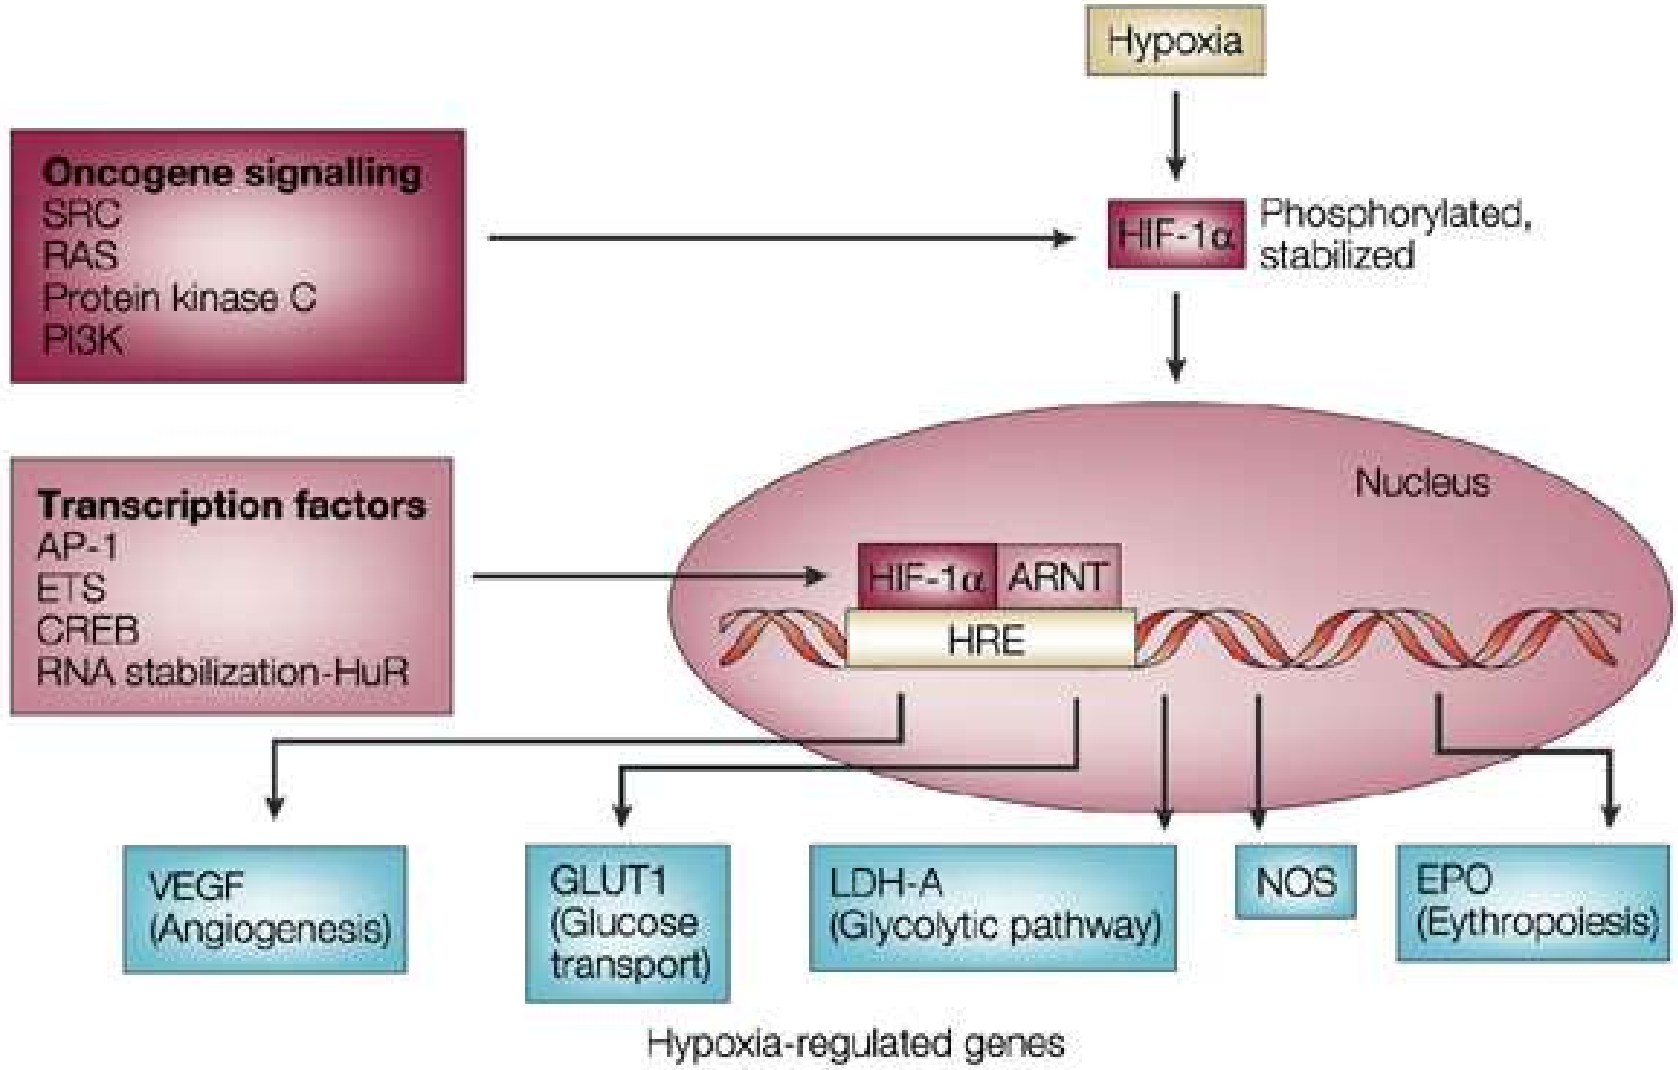
Oxygen sensors: HIF hydroxylases



HIF activation



HIF mediated pathways

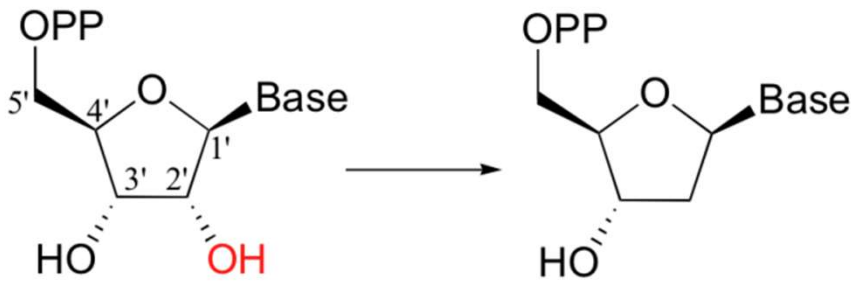


Nature Reviews | Cancer

HIF and cancer

- Loss of VHL causes overexpression of HIF and renal cell carcinoma
- HIF is overexpressed in many cancers
  - Mimics hypoxia biology in normoxia

Oxygen sensors: Ribonucleotide reductase

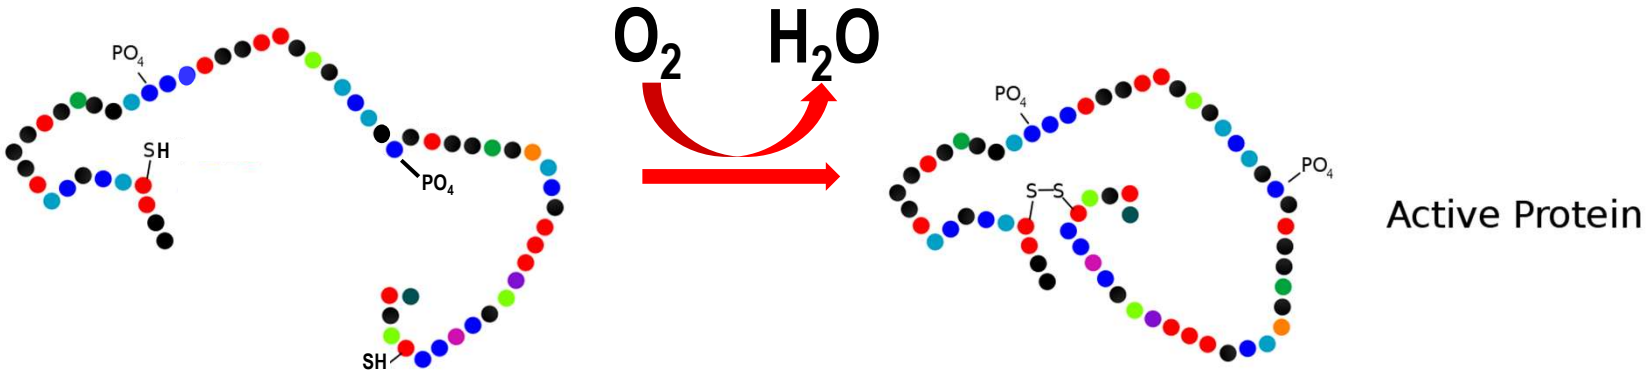


ribonucleotide diphosphate (RNA)

deoxyribonucleotide diphosphate (DNA)

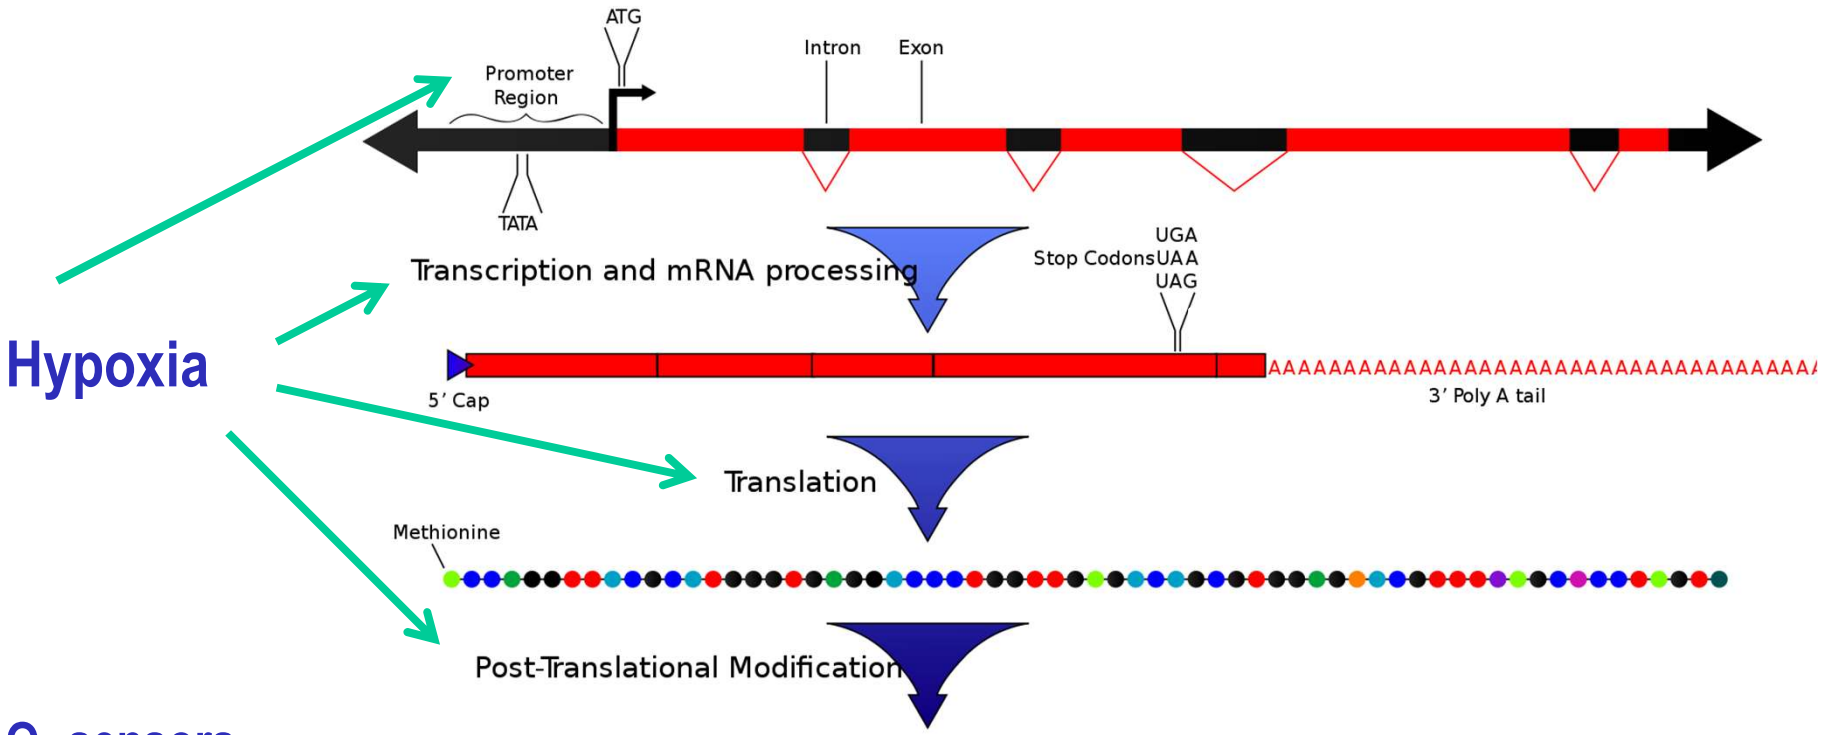
DNA synthesis

Oxygen sensors: disulfide oxidases



"Unfolded protein response"
Transcription
Translation

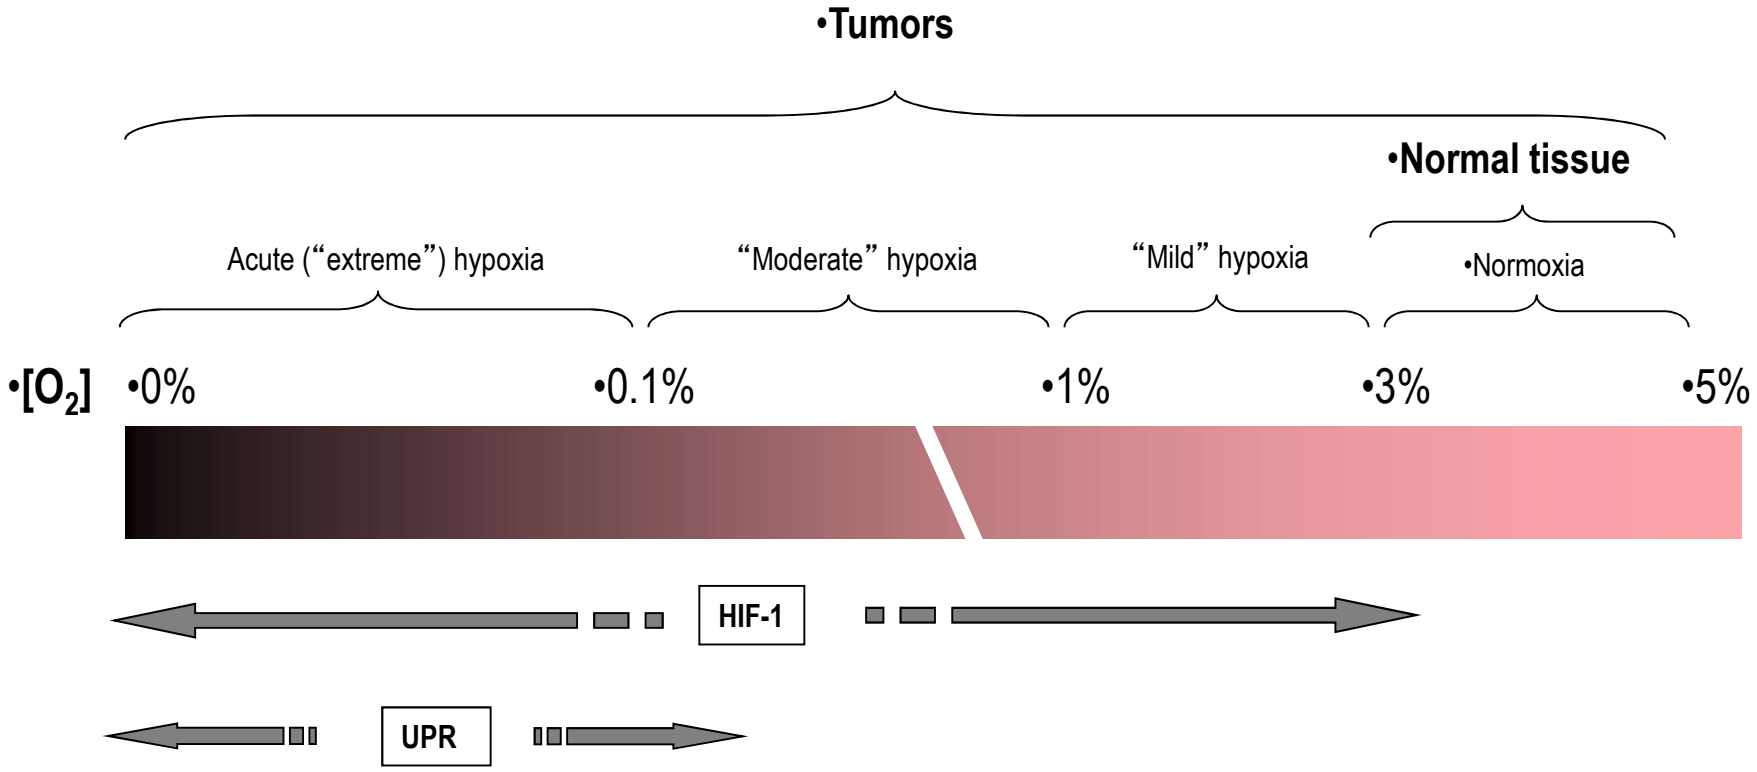
Molecular consequences of hypoxia



Hypoxia

O_2 sensors
Cytochrome c oxidase
Hydroxylases
Ribonucleotide reductase
Disulfide oxidases
Demethylases

Hypoxic severity affects cellular response



Summary of tumor hypoxia

- Mechanisms responsible for tumor hypoxia
  - chronic and acute
  - Supply, demand, tolerance
- Hypoxia is heterogeneous
  - amount, spatial, severity, time
- Hypoxia can promote malignancy
  - Tumors become hypoxia tolerant (selection for p53 mutations)
  - Hypoxia alters cellular function through transcription, translation and protein activity

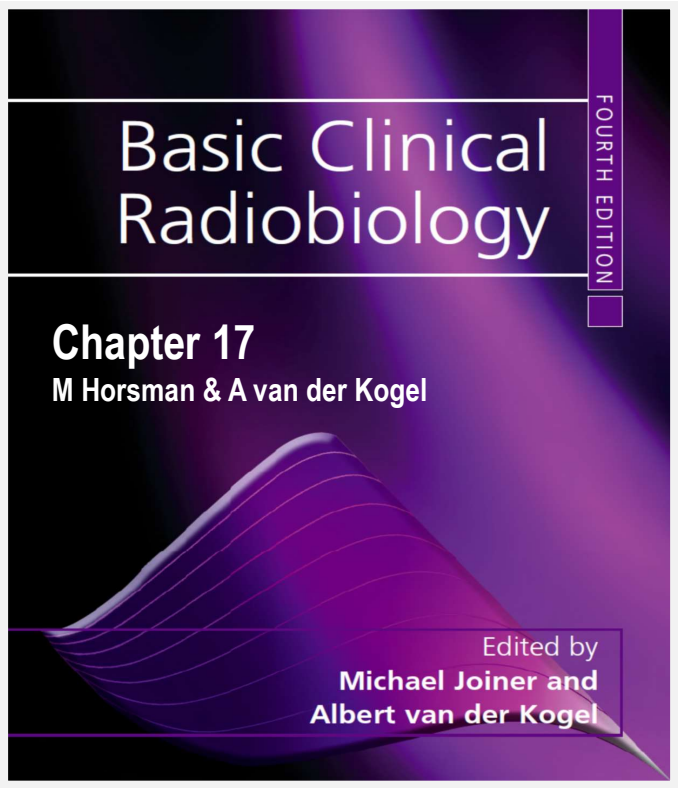
Clinical efforts to modify tumor hypoxia

Karin Haustermans

Department of Radiation Oncology, University Hospitals Leuven, Belgium

Overview

- Raising O_2 content of inspired gas
- Hypoxic cell radiosensitizers
- Increasing haemoglobin
- Overcoming acute hypoxia
- Meta-analysis
- Take home messages



Introduction

- Human tumors are hypoxic

Table 1 | **Oxygenation of tumours and the surrounding normal tissue**

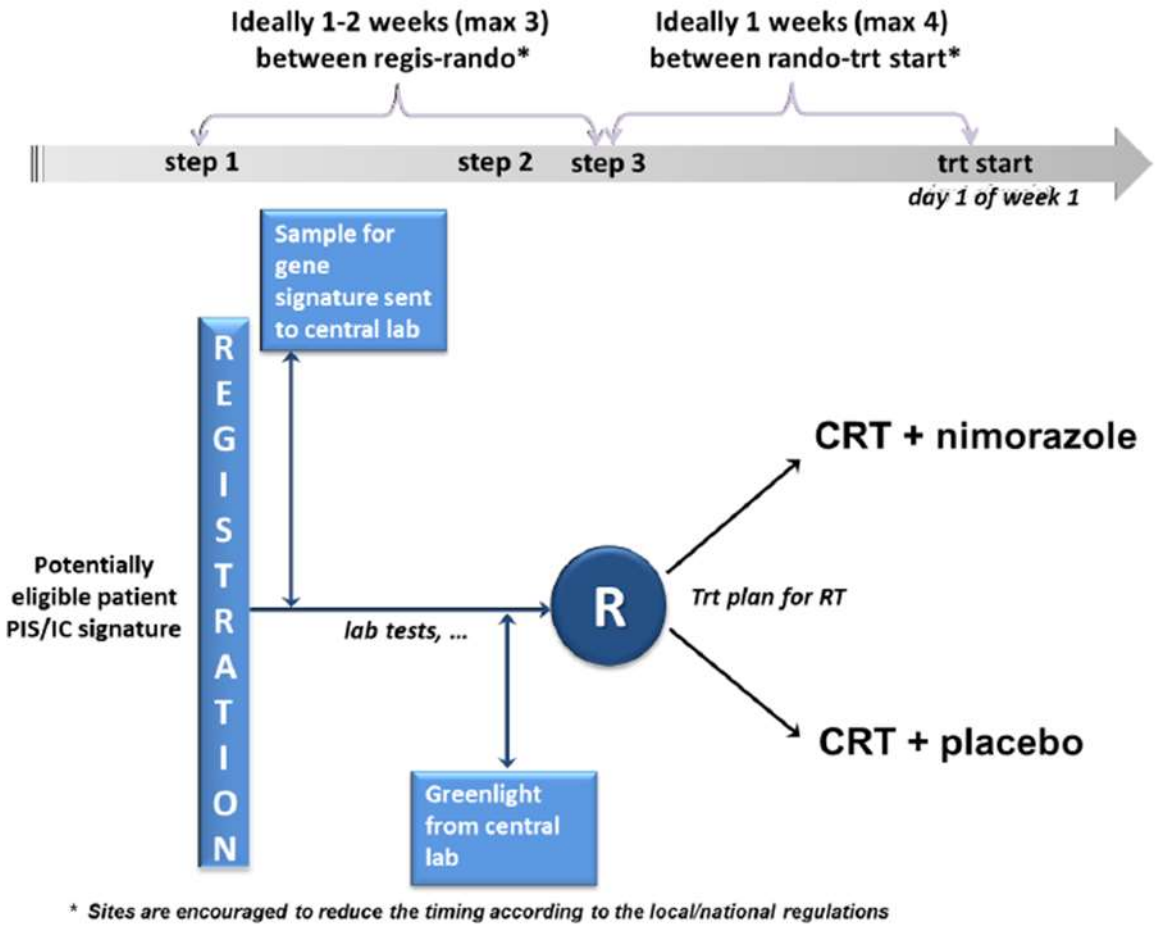
EORTC – 1219-ROG-HNCG
A blind randomized multicenter study of accelerated fractionated chemo-radiotherapy with or without the hypoxic radiosensitizer nimorazole (Nimoral), using a 15 gene signature for hypoxia in the treatment of squamous cell carcinoma of the head and neck

Pr. Vincent Grégoire, Cliniques Universitaires Saint-Luc, Brussels, Belgium

Pr. Jens Overgaard, Aarhus, Denmark

Study design



* *Sites are encouraged to reduce the timing according to the local/national regulations*

ESTRO School

Study design

- Phase III superiority study
- Primary endpoint: loco-regional control rate
- Secondary endpoints: local control, regional control, time to distant metastases, overall survival, disease-free survival, disease-specific survival, acute and late morbidity
- Stratification for:
  - Institution
  - Localization: hypopharynx *vs* oropharynx *vs* larynx
  - T-stage: T1-2 *vs* T3-4
  - N-stage: N0-1 *vs* N2-3
  - WHO - PS: 0-1 *vs* 2
  - Hypoxic gene-profile: positive *vs* negative *vs* undetermined
- Size: 640 patients (320 in each treatment arm)
  (the recruitment will continue until 200 patients are available in the hypoxic signature positive subgroup)

Effect of transfusion

Hoff et al Radiother Oncol 2010

Conclusions from DAHANCA 5

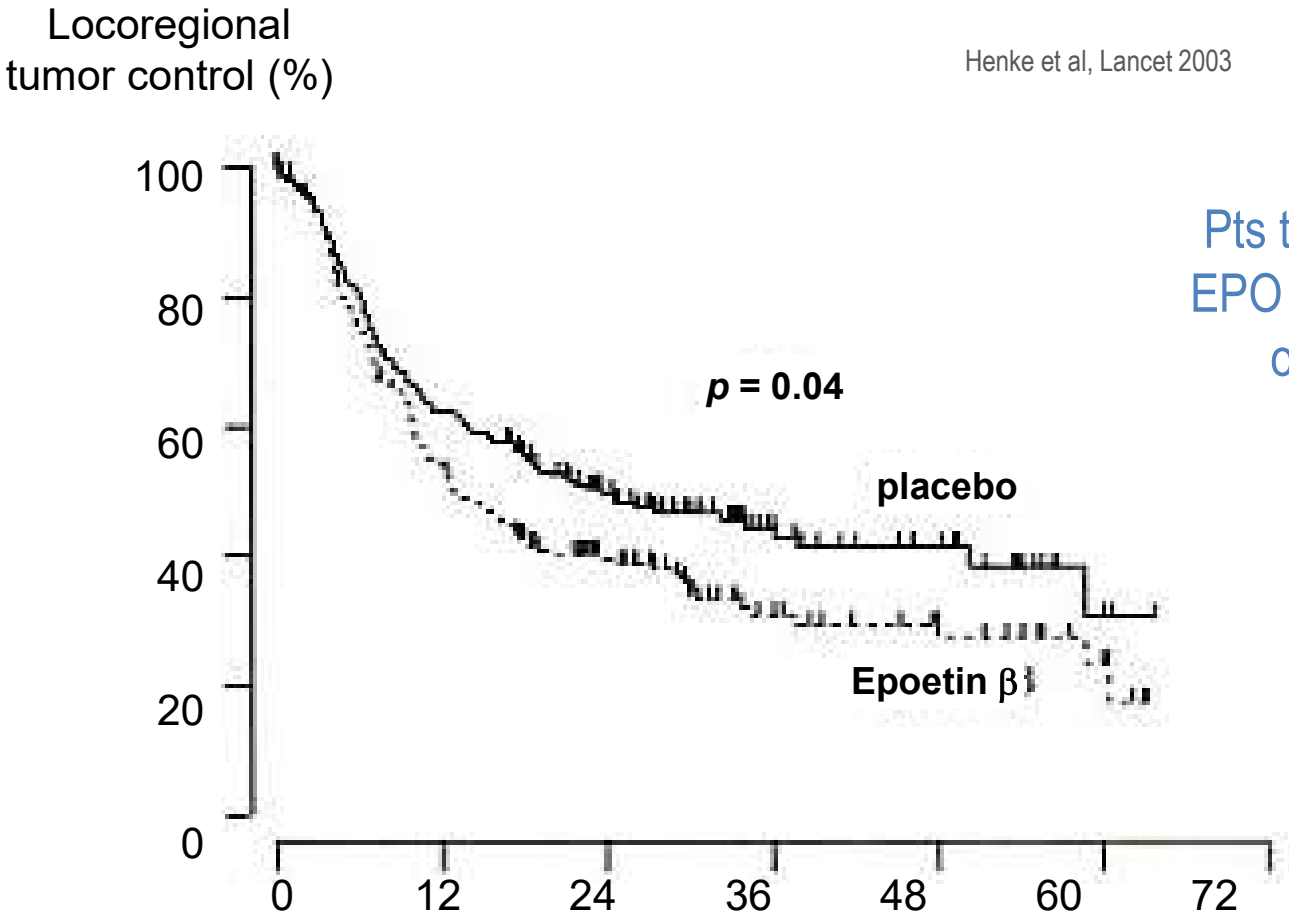
- Low hemoglobin level is associated with poor prognosis
- Hemoglobin level was raised with transfusion during radiotherapy
- Transfusion was unable to improve the effect of radiotherapy in head and neck cancer patients

Erythropoietin

- EPO is another approach to increase the haemoglobin levels
  - Gradual increase of oxygen supply over time

EPO and radiotherapy

Henke et al, Lancet 2003



Pts treated with EPO have worse outcome

EPO and radiotherapy

Lambin P et al Cochrane review 2009

Study or Subgroup	RT + EPO Events	Total	RT Events	Total	Weight	Peto Odds Ratio Peto, Fixed, 95% CI
1.1.1 Overall survival						
Henke 2003	71	180	82	171	27.5%	0.71 [0.46, 1.08]

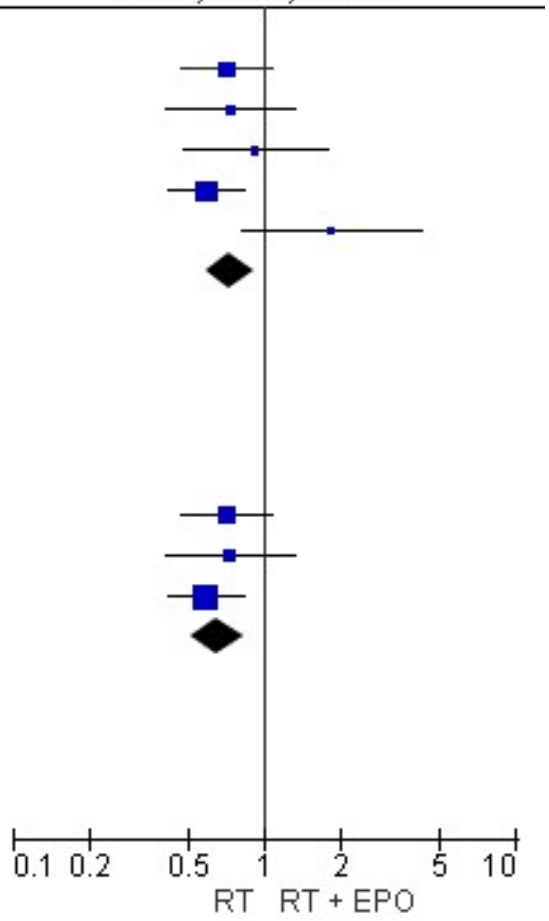
Machtay 2007	37	72	37	69	11.3%	0.91 [0.47, 1.77]
Overgaard 2007	97	255	133	260	40.5%	0.59 [0.42, 0.83]
Rosen 2003	28	47	19	43	7.2%	1.84 [0.81, 4.19]
Subtotal (95% CI)		**705**		**692**	**100.0%**	**0.73 [0.58, 0.91]**
Total events	355		398			
Heterogeneity: Chi² = 6.79, df = 4 (P = 0.15); I² = 41%						
Test for overall effect: Z = 2.82 (P = 0.005)						
1.1.2 Without studies supplementing iron to intervention group only						
Henke 2003	71	180	82	171	33.7%	0.71 [0.46, 1.08]
Hoskin 2004	122	151	127	149	16.6%	0.73 [0.40, 1.33]
Overgaard 2007	97	255	133	260	49.7%	0.59 [0.42, 0.83]
Subtotal (95% CI)		**586**		**580**	**100.0%**	**0.65 [0.51, 0.83]**
Total events	290		342			
Heterogeneity: Chi² = 0.62, df = 2 (P = 0.73); I² = 0%						
Test for overall effect: Z = 3.46 (P = 0.0005)						



Conclusions from EPO trials

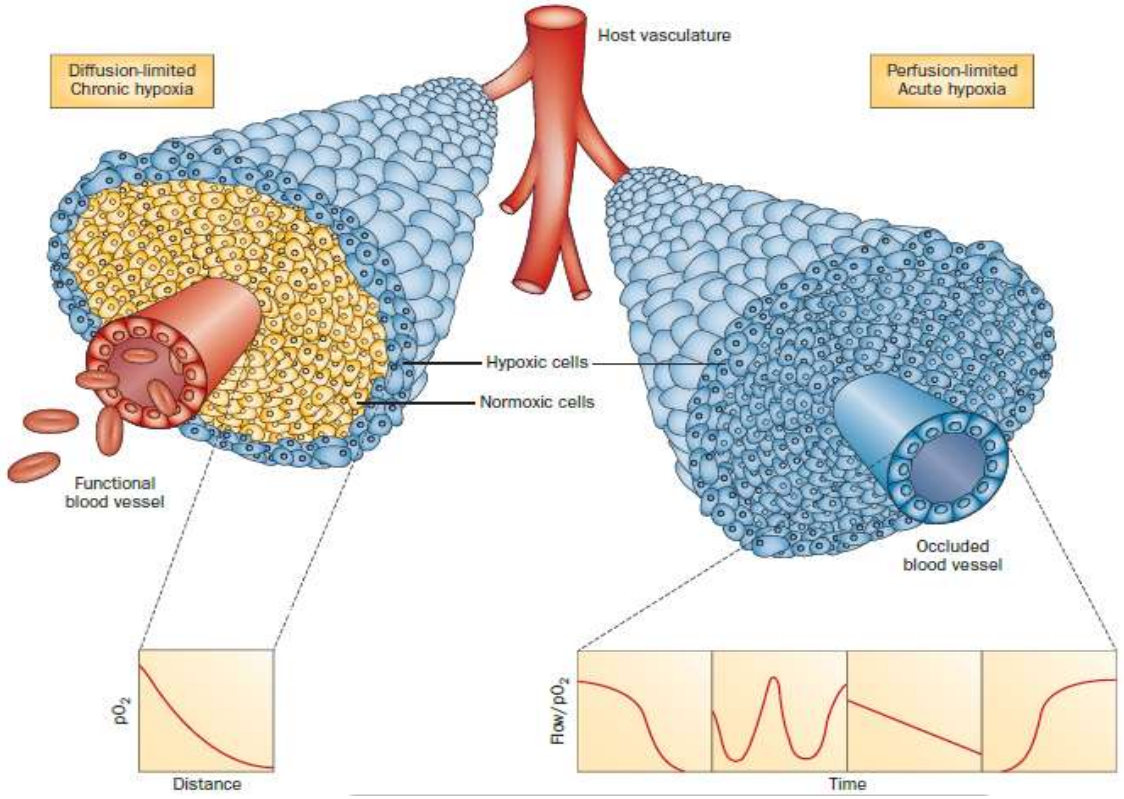
- RT plus EPO has a negative influence on outcome as opposed to RT alone (non-haemopoietic effects of EPO?)

- EPO should not be administered as an addition to RT outside the experimental setting for patients with head and neck cancer.

Overcoming acute hypoxia

Overcoming acute hypoxia

- Most procedures have no or little influence on perfusion-limited acute hypoxia



Horsman et al Nat Rev Clin Oncol 2012

Meta Analysis - Hypoxic modification of radiotherapy in HNSCC

* 95% CI.
** Numbers of patients Needed to Treat to achieve benefit in one patients.

Level 1a evidence in favor of adding hypoxic modification to radiotherapy in HNSCC

Back to the future: SBRT & tumor hypoxia

- With the developments in image-guided radiotherapy (IGRT), the use of high single doses or a few large fractions is rapidly gaining popularity in the clinic
- Stereotactic Body RadioTherapy (SBRT) is now widely used for early stage lung cancer, but also metastases in various sites
- One reason fractionated radiotherapy became standard was the absence of a therapeutic window with large single doses, predominantly because of hypoxia!

Back to the future: SBRT & tumor hypoxia

Table 2
Effect of hypoxic modification of radiotherapy of HNSCC given with different dose per fraction schedules.

Fractionation pattern	Endpoint and Odds Ratio (95% CI)		
	Loco-regional failure	Disease specific death	Late radiation related morbidity
Hypo-fractionation[a]	0.56 (0.40–0.77) $p > 0.001$	0.62 (0.44–0.86) $p > 0.001$	1.83 (1.05–3.18) $p > 0.03$
Conventional fractionation[a]	0.77 (0.67–0.89) $p > 0.001$	0.78 (0.67–0.90 $p > 0.001$	0.90 (0.71–1.14) $p > 0.39$

[a] The same fractionation pattern has been applied in hypoxic modification and control arms.

Overgaard Radiother Oncol 2011

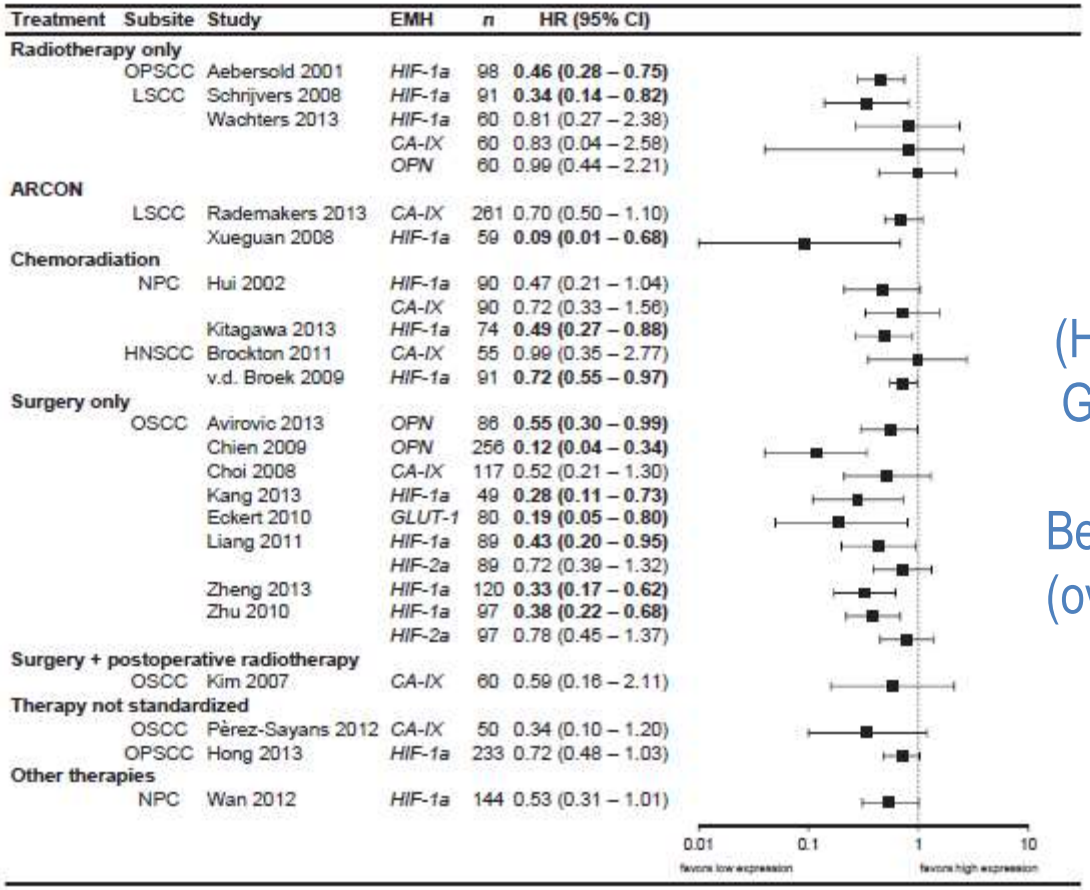
Targeting hypoxia – holy grail of radiotherapy?

- Hypoxia targeting has come a long way, from increasing oxygen supply and enhancing perfusion, to inhibitors of specific signaling or metabolic pathways
- Tumor hypoxia represents a highly dynamic condition, distributed heterogenously in tumors and changing over time
- The concept of acute vs chronic hypoxia is clearly an oversimplification of a complex condition
- The comeback of large doses/fx or even single doses also needs consideration of adding relatively non-toxic hypoxic sensitizers like nimorazole: “back to the future”

Patient selection

- Endogenous biomarkers for hypoxia

Swartz JE et al Cancer Med 2015



Low EMH expression (HIF-1a, CA-IX, GLUT-1, OPN)

-

Better prognosis (overall survival)

Favors low expression Favors high expression

Add

- Reduce oxygen consumption metformine
- Hypoxia tolerance HIF1a inhibitors

Patient selection

Swartz JE et al Cancer Med 2015

Table 2. Clinical outcome: radiotherapy/ARCON.

The outcomes locoregional control (LRC), overall survival (OS), disease-free survival (DFS), and disease-specific survival (DSS) are shown as hazard ratio (95% confidence interval). Hazard ratios <1 indicate beneficial prognosis for nonhypoxic tumors. Significant values are shown in bold Cutoff: EMHs were scored according to nuclear (N), membranous (M), cytoplasmic (C), or diffuse (D) staining patterns. XRT: radiotherapy. ARCON; accelerated radiotherapy, carbogen gas breathing and nicotinamide. Pos: number of patients with staining above the mentioned cutoff. LR: Logrank test. ns: not specified. Multiple subsites, patients were not analyzed per subsite. EMH, endogenous markers of hypoxia; HIF-1, hypoxia-inducible factor 1.

Hypoxia-modified treatment schedules for patients with high expression of endogenous hypoxia markers

Take home messages

- Hypoxic cell radioresistance is a significant cause of faillure in local tumor control in particular in SCC of head and neck and uterine cervix
- Using high oxygen content gas breathing, chemical radiosensitizers or blood transfusion have shown mixed results
- Meta-analysis of randomized trials does however demonstrate a significant benefit and level 1a evidence for head and neck tumors

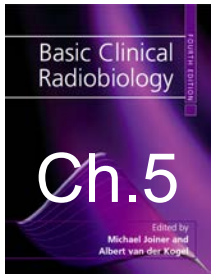
ESTRO School

Basic Clinical Radiobiology

Dose-response relationships in radiotherapy

Michael Joiner

Paris 2017

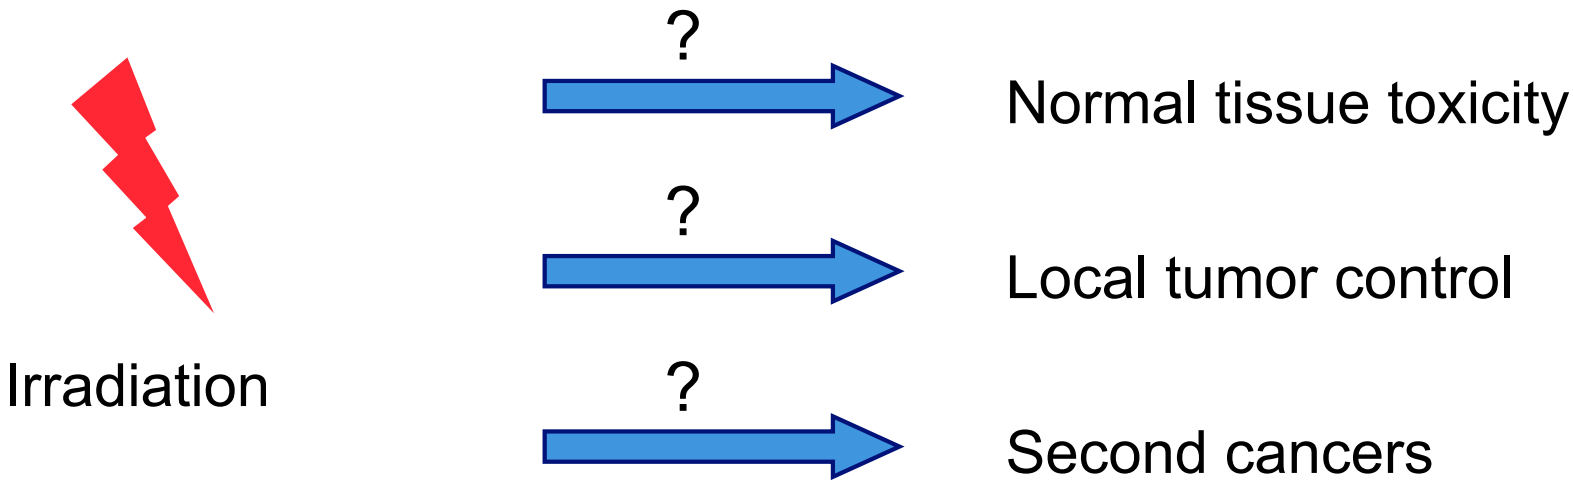


Definitions

Dose Response: Relationship between a given physical absorbed dose and the resulting biological response

Endpoint: A specific event that may or may not have occurred at a given time after irradiation

Dose response

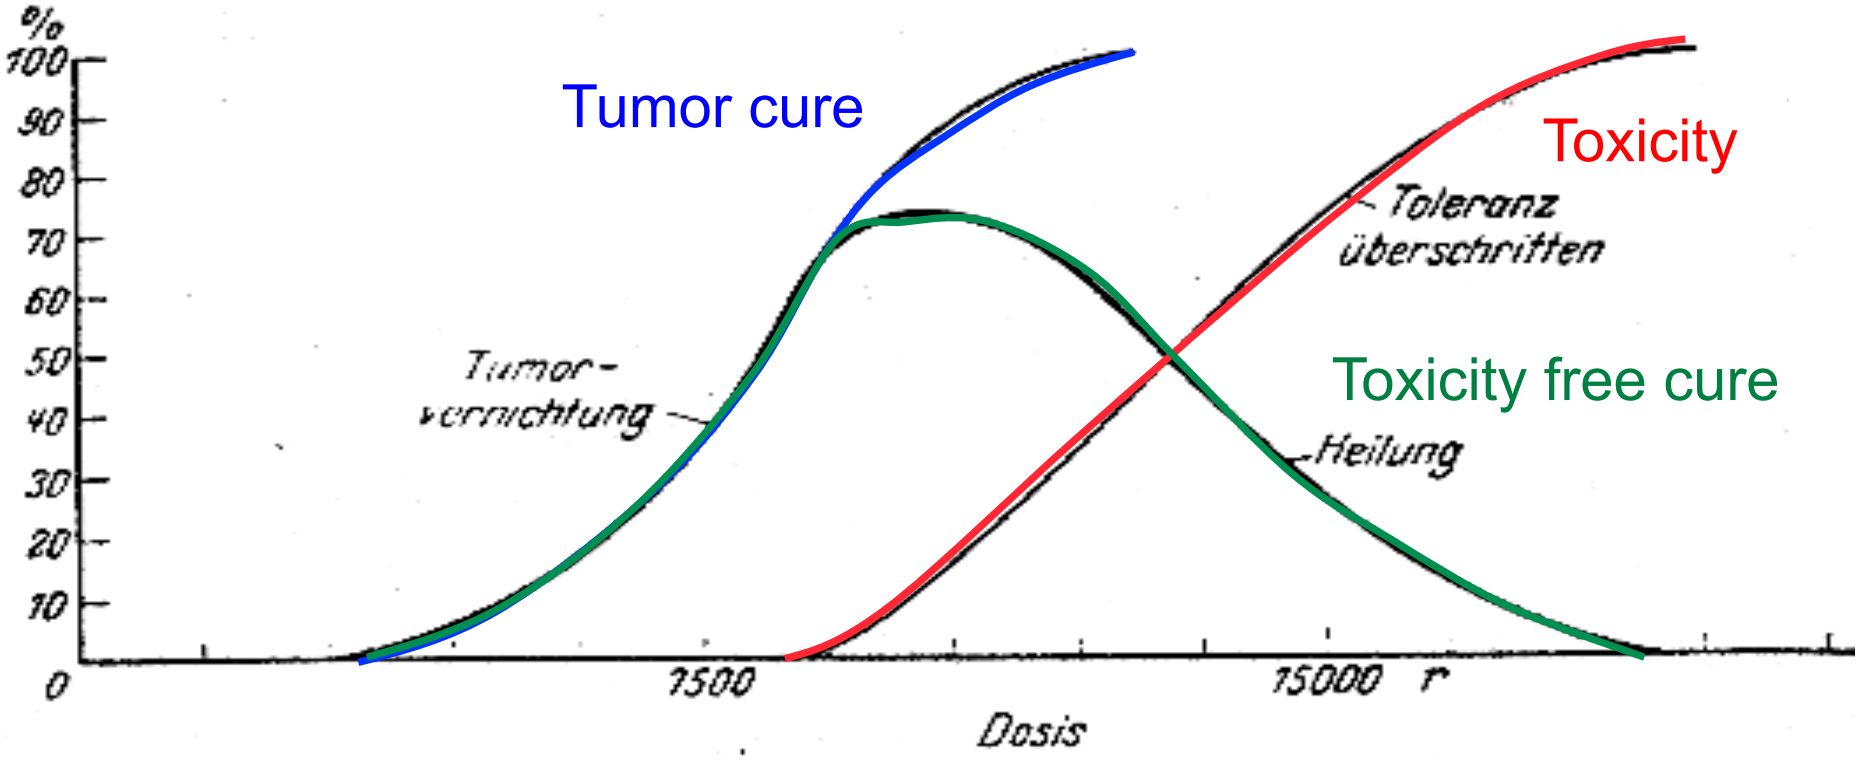


Relationship between given dose and each clinically relevant outcome needs to be defined

i.e. Define the incidence or probability of a certain outcome after a defined dose

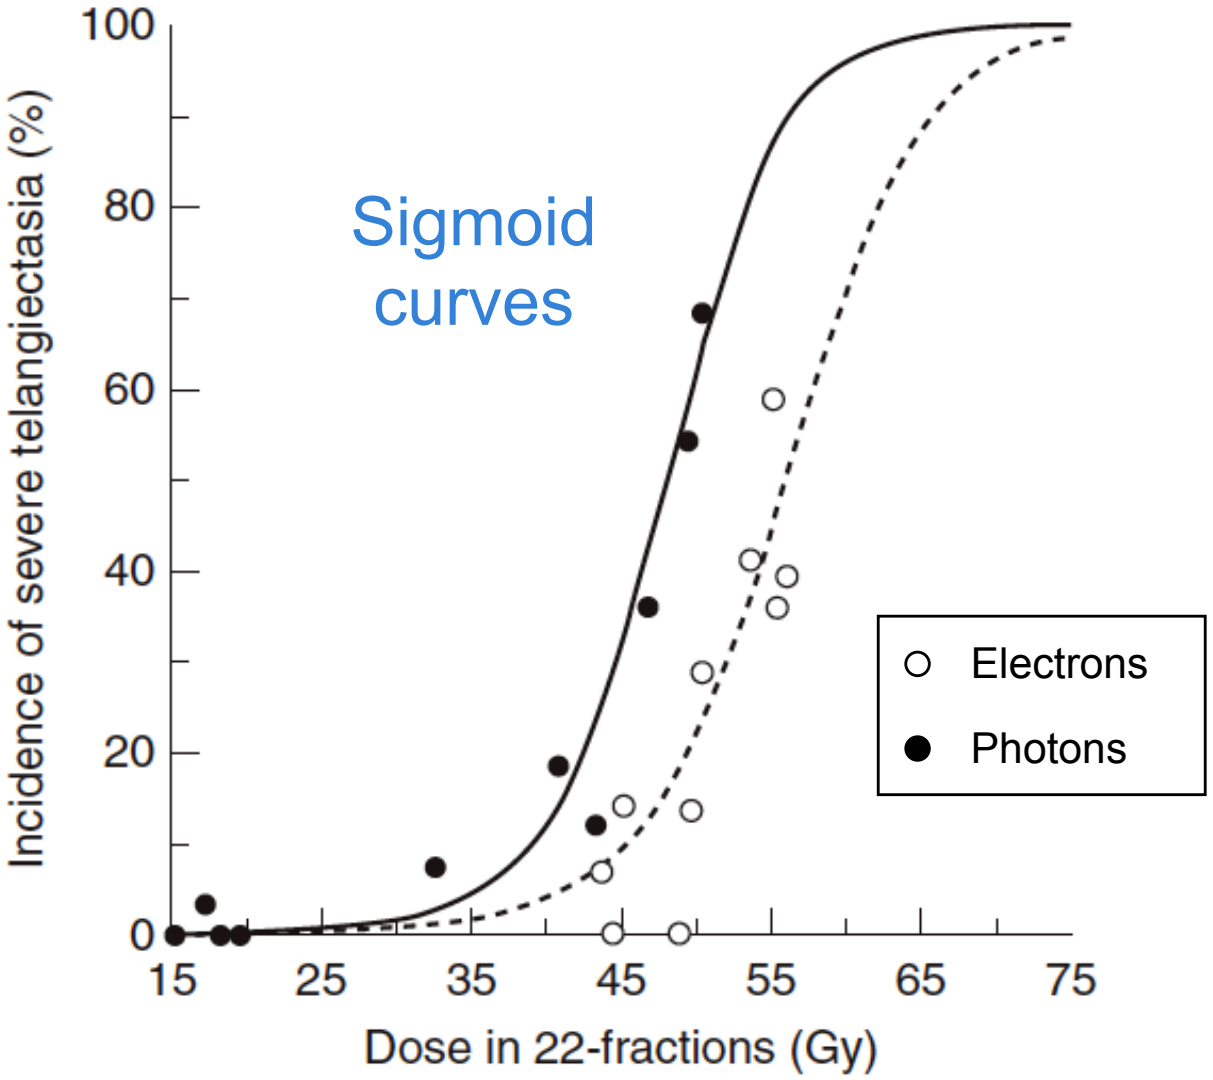
Dose response: Empirical data

Sigmoid curves indicate variability of clinical radioresponse



Holthusen. *Strahlentherapie* 1936;57:254-68

Examples of dose response relationships



Bentzen and Overgaard (1991)

Dose response models

Most frequently used models to fit sigmoid dose-response curves:

- Poisson model …tumor
- Logistic model …normal

Dose response model: Tumor control

The target cell hypothesis: Munro & Gilbert 1961

- Relevant is the number of tumor stem cells (clonogenic cells) left at the end of treatment
- This is reduced with dose in a manner which accounts for randomness in radiation effects, described by Poisson statistics
- The probability of tumor cure depends on the average number of clonogens surviving per tumor

Simulation of a Poisson distribution of surviving cells

0	0	0	2	1	1	1	0	0	0
0	0	0	0	0	0	0	0	1	0
0	0	0	2	1	2	1	2	0	1
1	0	0	0	0	2	1	0	1	2
1	2	0	0	0	0	0	0	0	3
0	0	0	0	0	0	0	1	1	0
1	0	2	0	0	0	0	0	0	1
0	0	0	0	0	3	0	0	1	0
0	3	1	1	1	1	0	0	0	1
0	1	2	1	1	0	0	1	1	0

100 tumors.
Average number of
surviving clonogens per tumor
= 0.5

Each box indicates
the number of surviving clonogens
actually in that tumor

Poisson Statistics – a reminder

In the **Poisson** statistical distribution,
the probability $P(x)$ of obtaining x surviving cells per tumor
when the mean number of surviving cells per tumor is λ, is:

$$P(x) = \frac{e^{-\lambda} \lambda^{x}}{x!}$$

Condition: a very, very **large** number of cells in each tumor, but the probability that *any given cell* survives is very, very **small**

Poisson Statistics: local tumor control ("cure")

Tumor Control Probability, *TCP*, is the probability of **no** surviving cells in the tumor (*i.e.* $x = 0$).

TCP is therefore given by:

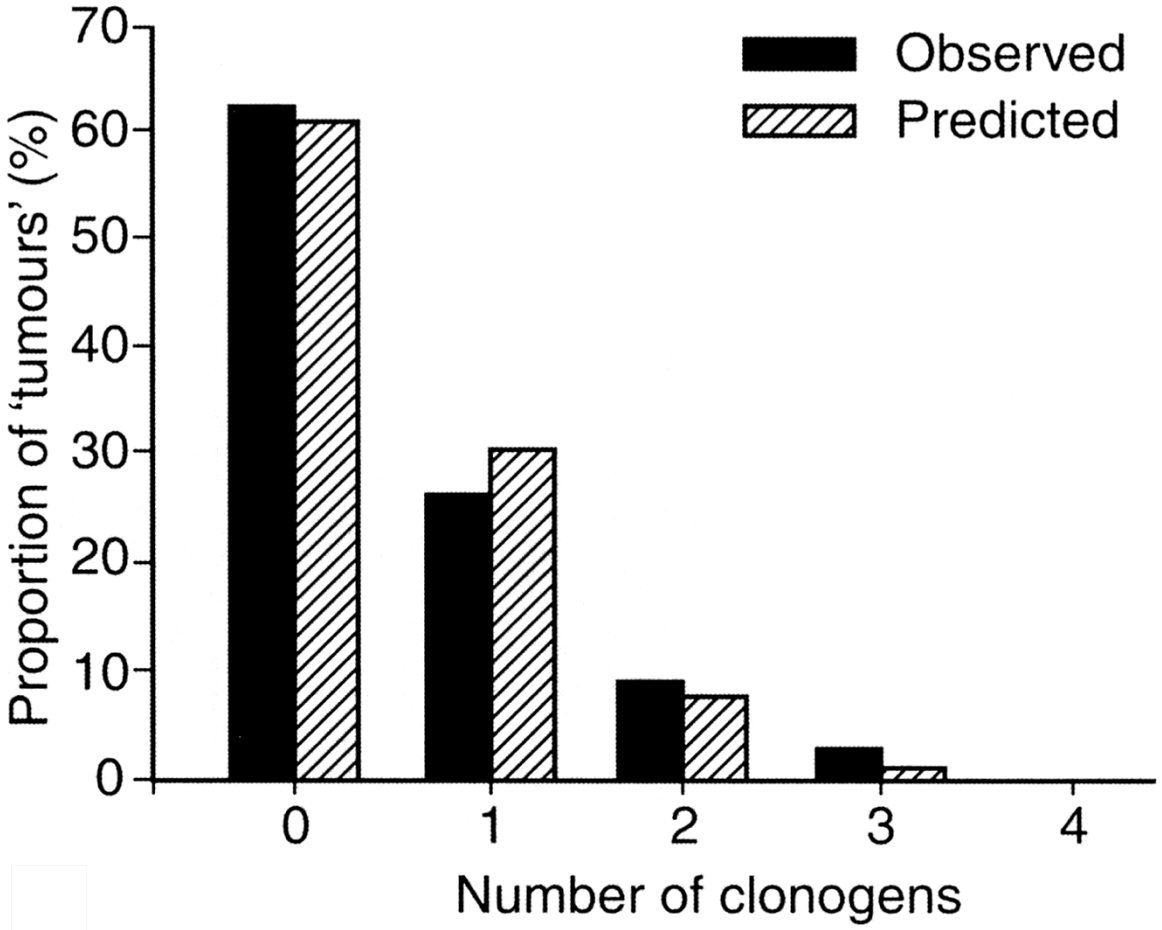
$$TCP = P(0) = \frac{e^{-\lambda}\lambda^{0}}{0!} = e^{-\lambda} = \exp\left(-\lambda\right)$$

λ is the mean number of surviving cells per tumor

Poisson “predicted” versus Monte Carlo “observed”

Average number of surviving clonogens = 0.5

Poisson distribution is confirmed by “observation”



But λ is a function of:
dose per fraction, *d*, and number of fractions, *n*.

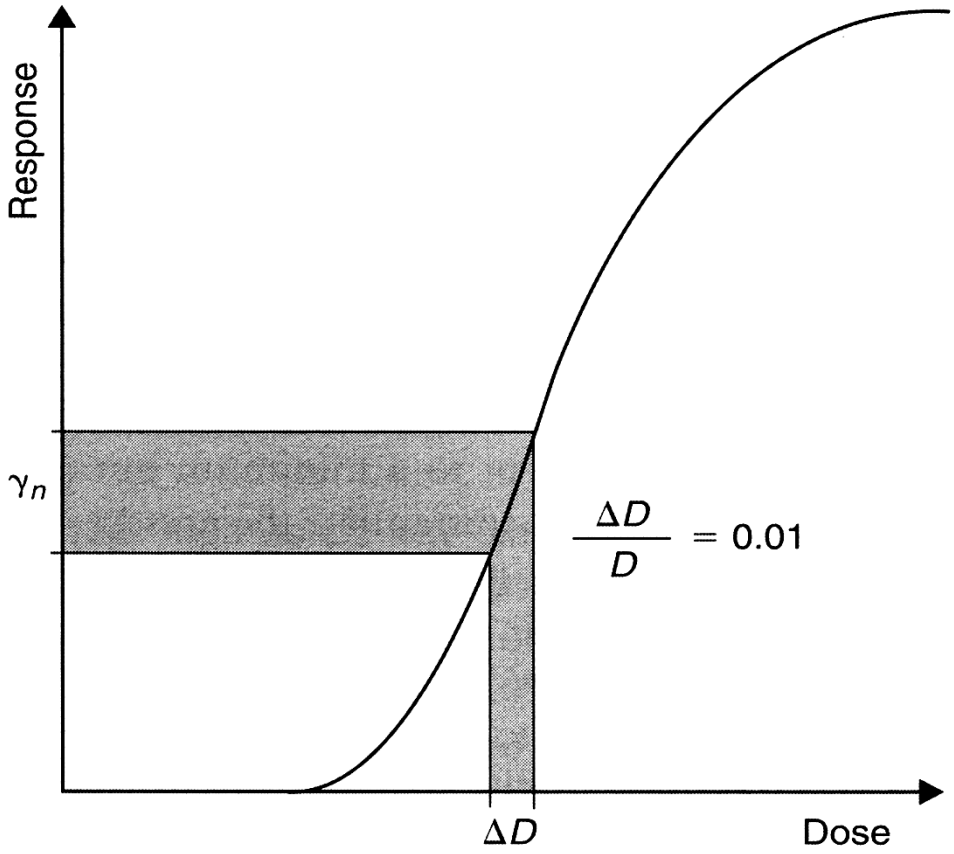
Remember that:

$$S = \lambda / N_0 = e^{-n\left(\alpha d + \beta d^2\right)} = \exp\left(-\alpha D - \beta d D\right)$$

Therefore:

$$TCP = \exp\left[-N_0 \exp\left(-\alpha D - \beta d D\right)\right]$$

Definition of dose-response curve slope



Normalized
dose response gradient, γ :

$$\Delta P \approx \gamma \frac{\Delta D}{D}$$

1% change in dose gives
increase in response = γ %

Usually defined at
the steepest part of curve:
With Poisson model,
at Response = 37% (0.3679…, e^{-1})

Interesting consequence of Poisson

It can be shown that:

$$\gamma_{37} = \frac{\ln N_0}{e}$$

This may be used for deducing the number of “tumor clonogens” but any relevance to normal tissue response is doubtful

Logistic model of response

$$P = \frac{\exp(u)}{1+\exp(u)} \qquad u = \ln\left(\frac{P}{1-P}\right)$$

$$u = a_0 + a_1 D + a_2 D d + \ldots$$

P/(1-*P*) is called the ***odds*** of the response,
u is called the ***logit*** of *P*

With Logistic, the inflection (max slope) occurs at Response = 50% (*P* = 0.5, *u* = 0)

Beware: γ changes with response level

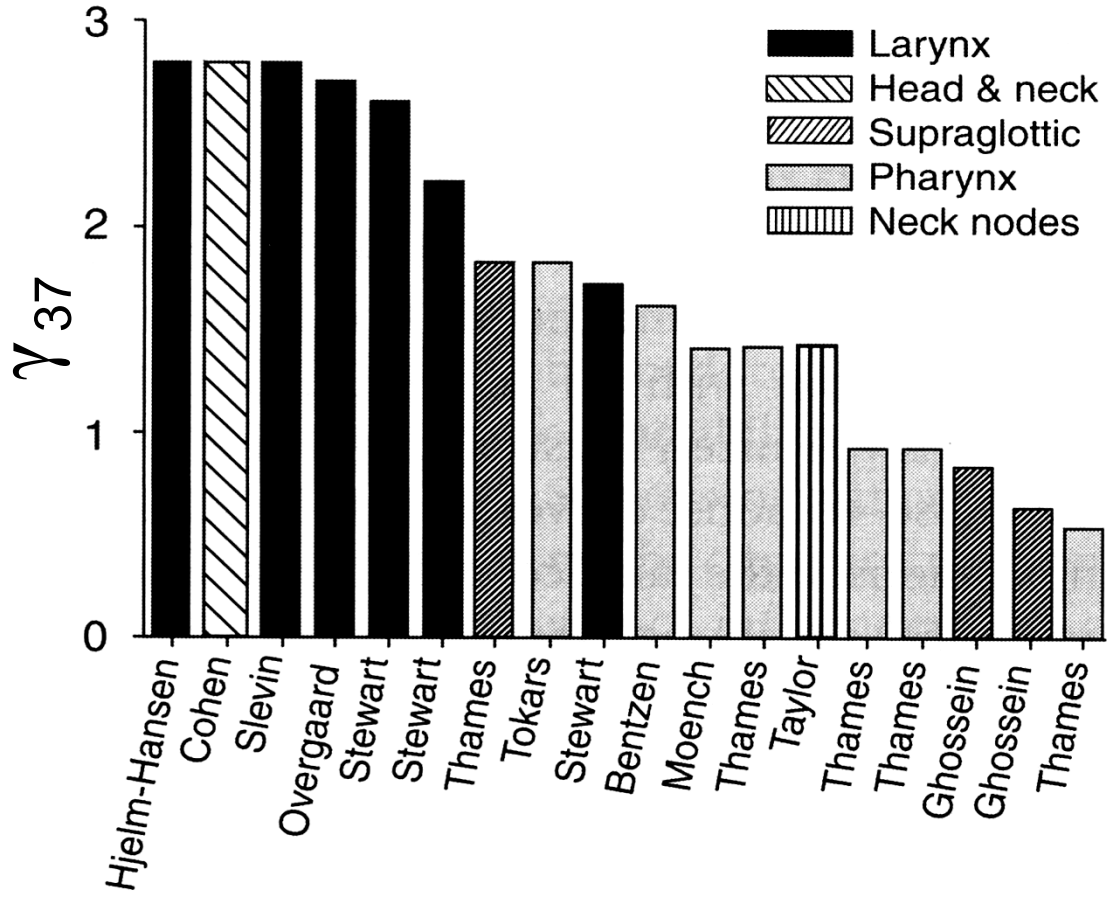
γ_{50}	Response level, %								
	10	20	30	40	50	60	70	80	90
1	0.2	0.4	0.7	0.9	1.0	1.1	1.0	0.9	0.6
2	0.5	1.1	1.5	1.8	2.0	2.0	1.9	1.5	0.9
3	0.9	1.7	2.3	2.8	3.0	3.0	2.7	2.1	1.3
4	1.2	2.3	3.2	3.7	4.0	3.9	3.5	2.8	1.6
5	1.6	3.0	4.0	4.7	5.0	4.9	4.4	3.4	2.0

γ is only useful when you are “on the curve”!

Clinical estimates of γ

Average γ_{37} for H&N ≈ 2%

From studies in which dose per fraction was fixed

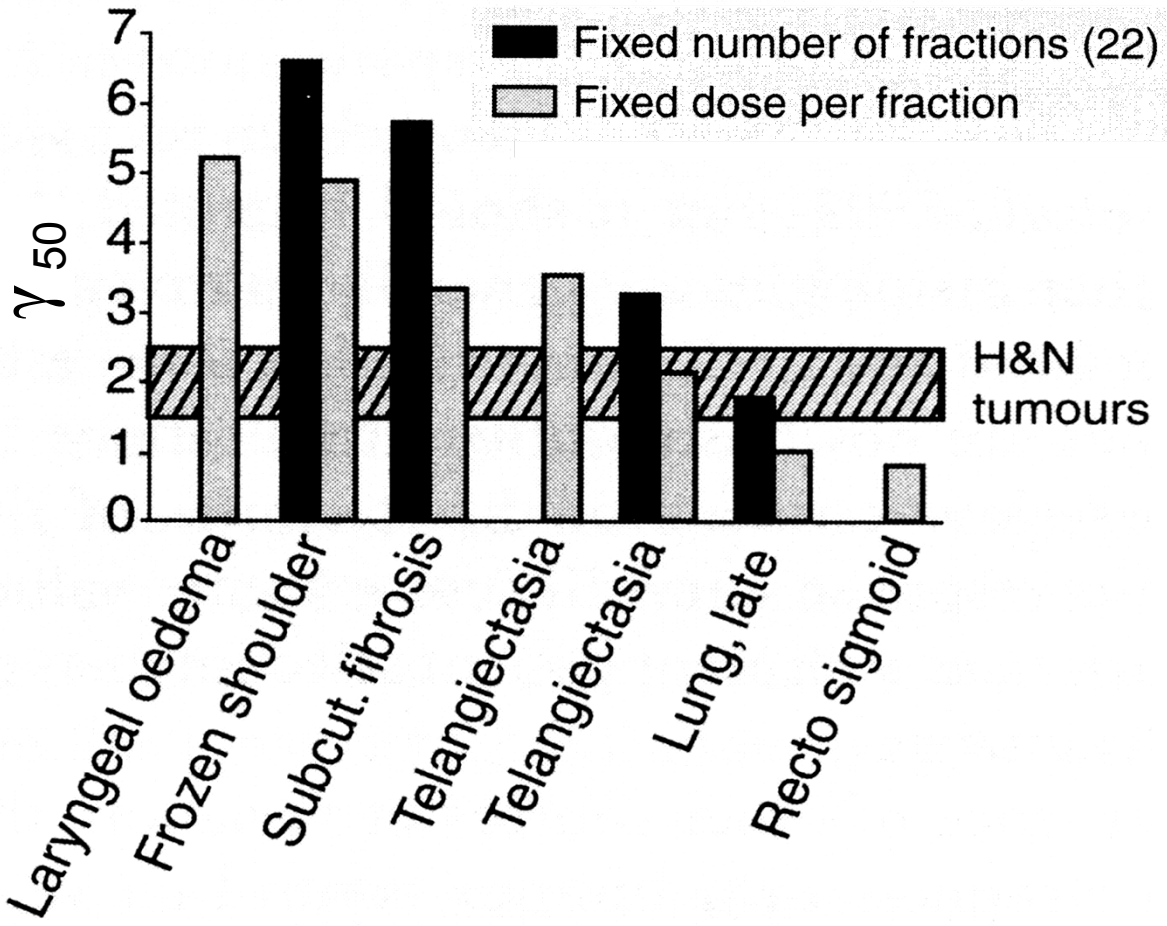


Bentzen (1994)

Value of γ in some late-reacting tissues

Compared with tumors,
γ is larger

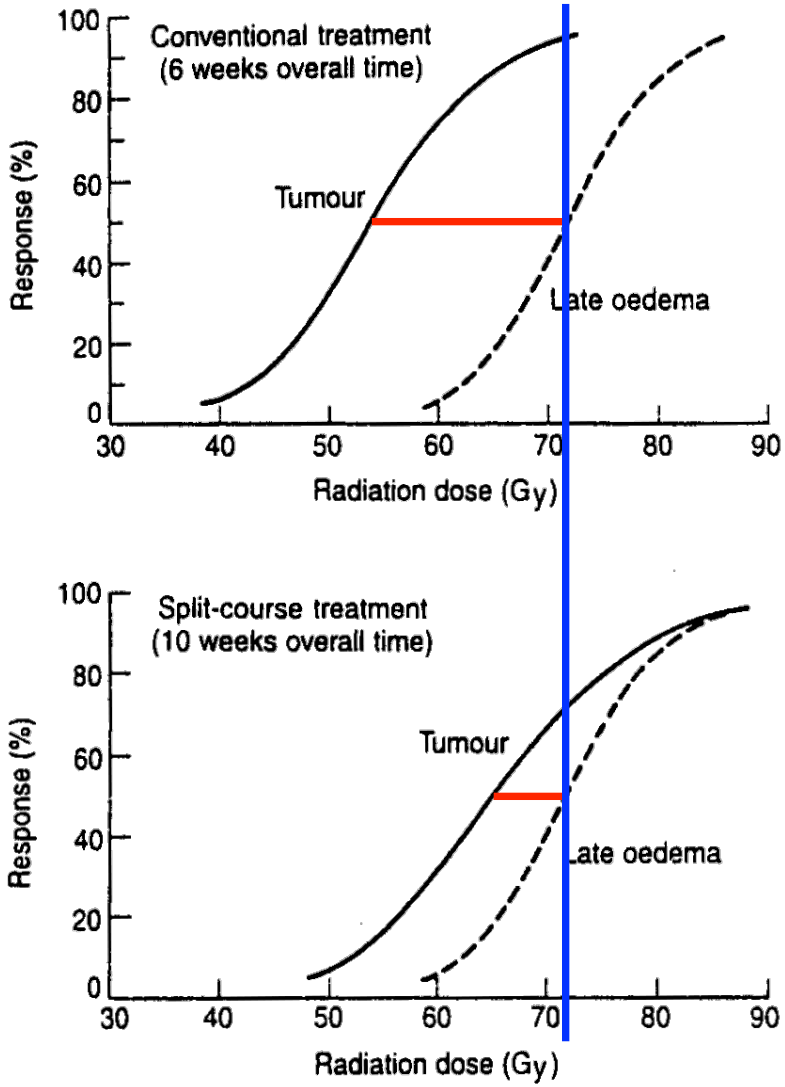
Dose response curves
can be steeper,
more so when
fixed fraction number,
i.e. higher dose per fraction



Bentzen (1994)
Bentzen and Overgaard (1996)

Balancing risks and benefits: The therapeutic window

Example: protraction of overall treatment time is detrimental!

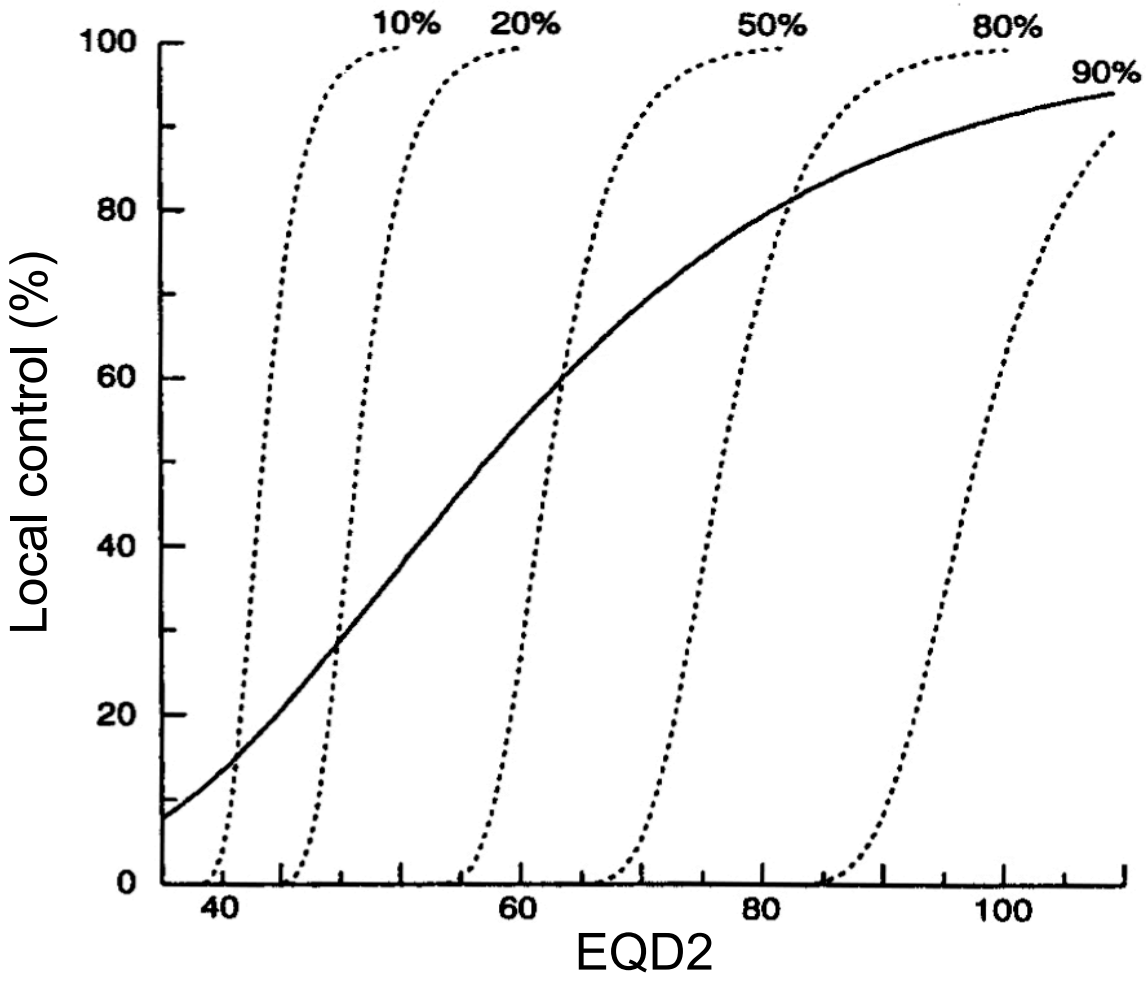


Bentzen and Overgaard (1996)

Modifying the steepness of the dose-response

Oropharyngeal cancer

Homogeneous patient populations with radiosensitivity equal to selected percentiles of radiosensitivity distribution in total population



Bentzen (1994)

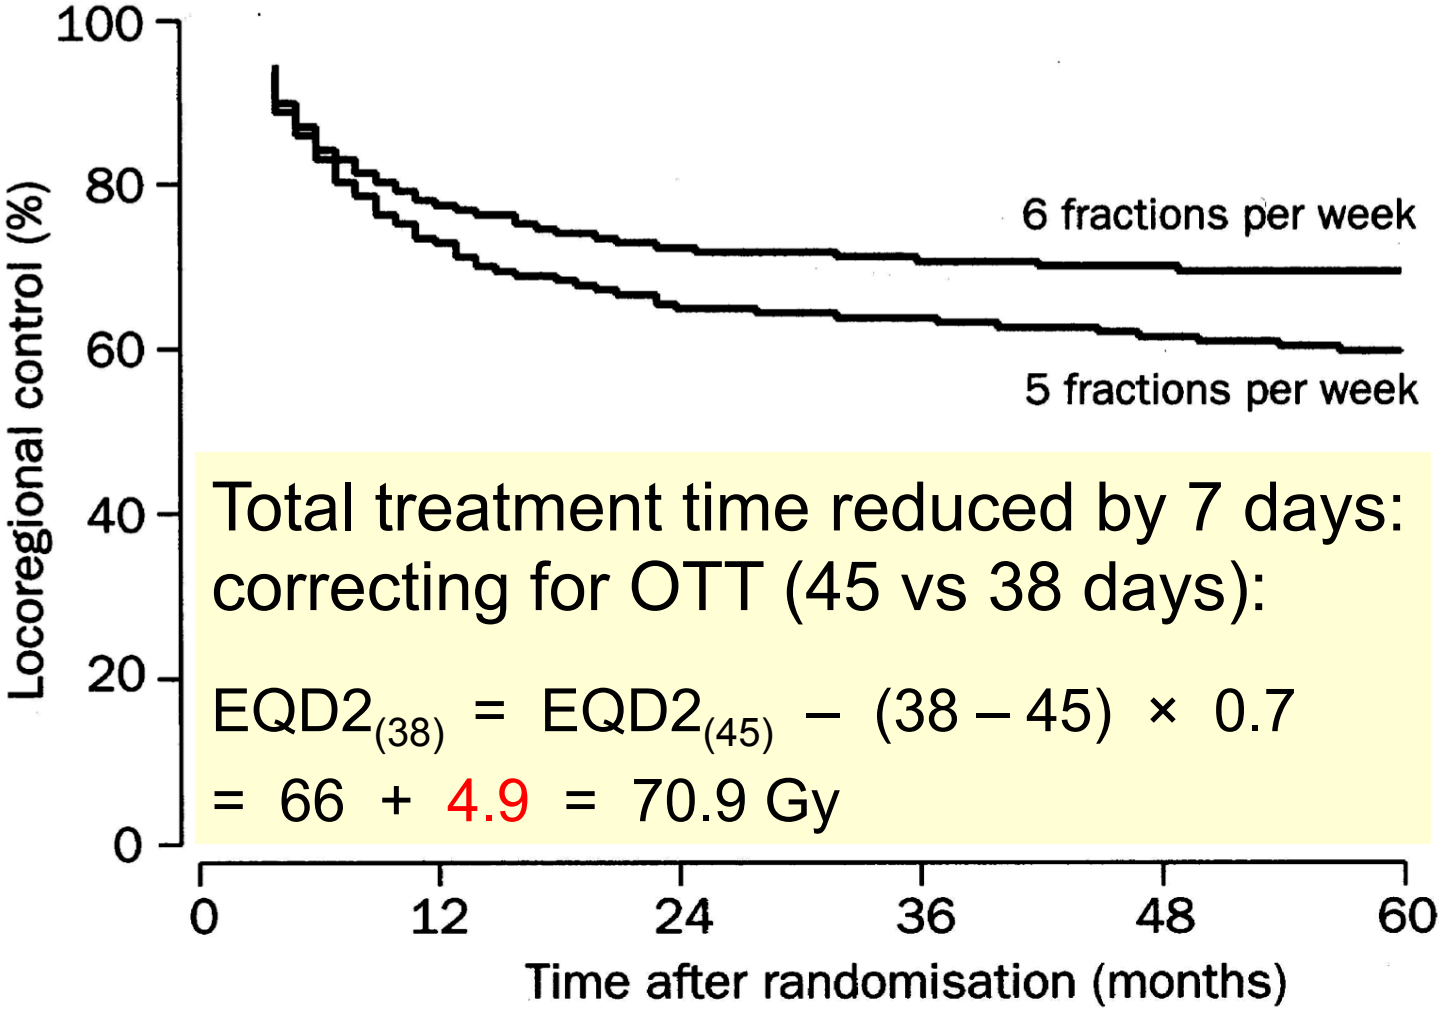
Clinical data to test modeling

Five compared with six fractions per week of conventional radiotherapy of squamous-cell carcinoma of head and neck: DAHANCA 6&7 randomised controlled trial

Jens Overgaard, Hanne Sand Hansen, Lena Specht, Marie Overgaard, Cai Grau, Elo Andersen, Jens Bentzen, Lars Bastholt, Olfred Hansen, Jørgen Johansen, Lisbeth Andersen, Jan F Evensen, on behalf of the Danish Head and Neck Cancer Study Group

Lancet 2003;362:933-40

Convert from a change in dose
to a change in response rate



Total treatment time reduced by 7 days: correcting for OTT (45 vs 38 days):

$EQD2_{(38)} = EQD2_{(45)} - (38 - 45) \times 0.7$

$= 66 + 4.9 = 70.9$ Gy

From change in dose to change in RR

$$\Delta R \approx \gamma \times \frac{\Delta D}{D} \times 100\%$$

$$= 1.6 \times \frac{4.9}{66} \times 100 = 12\%$$

Dose-volume models for normal tissues

- Predicting normal tissue toxicity has become more complicated by the use of IMRT, non-uniform dose distributions and partial organ irradiation
- Mathematical and biophysical models are developed to describe late normal tissue toxicity
- Toxicity is assessed from the complete dose distribution throughout an OAR in an integrative manner

NTCP models

Example:

The Lyman model of dose-volume effects in normal tissue

- Relates NTCP to dose and volume irradiated
- Assumes a normal distribution of complications as a function of dose for each uniformly irradiated fractional organ volume

Lyman model of dose-volume effects in normal tissue

$$NTCP(D,V) = \frac{1}{\sqrt{2\pi}} \cdot \int_{-\infty}^{u(D,V)} \exp(-\tfrac{1}{2} \cdot x^2)\,dx$$

$$u(D,V) = \frac{D - D_{50}(V)}{m \cdot D_{50}(V)}$$

$0 < n < 1$

Larger n, more volume effect

$$D_{50}(V) = \frac{D_{50}(1)}{V^n}$$

(see BCR book, Ch 5.9)

D_{50} = uniform dose producing 50% incidence of specific effect

n = denotes influence of volume effect in organ of interest

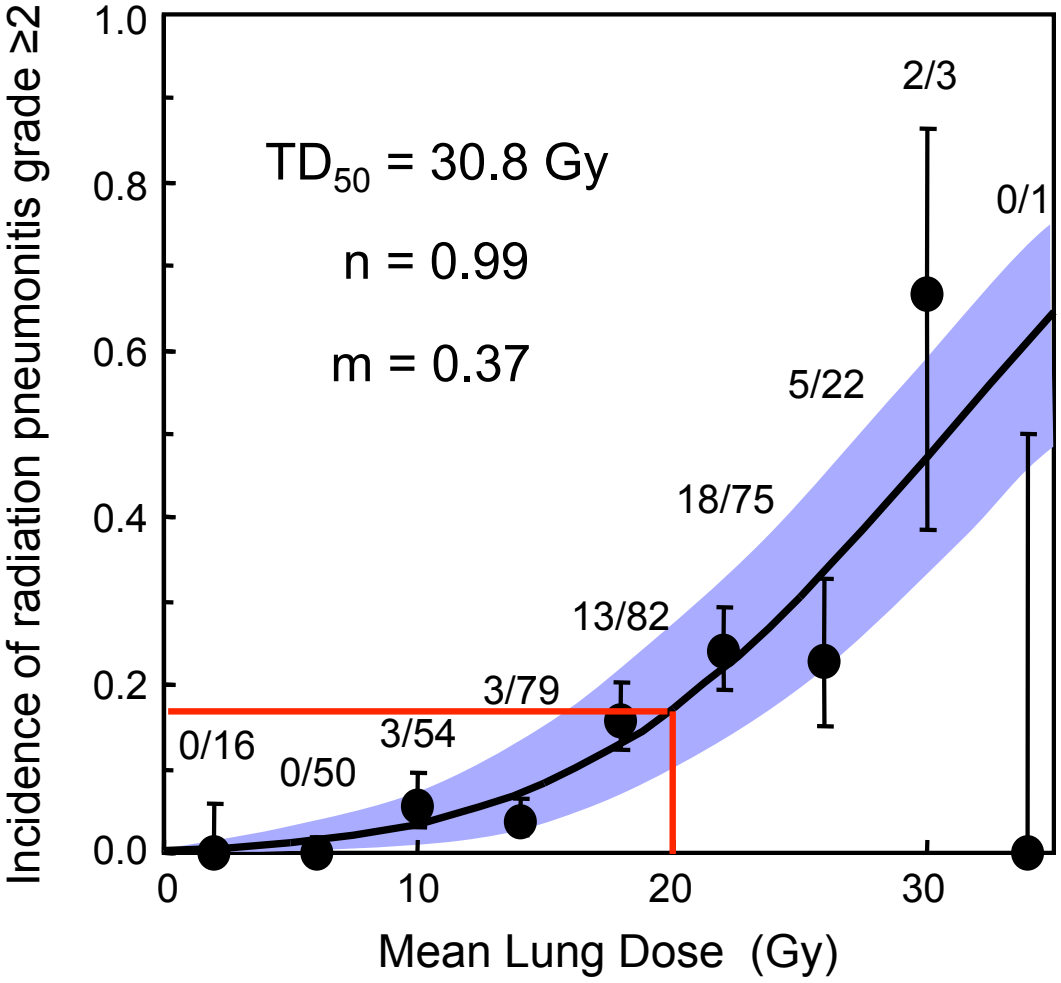
m = inverse of dose response curve gradient

NTCP models

Organ	**Toxicity**	**TD_{50}**	**Volume effect** (n)	**Dosimetric descriptor**
Parotid gland	Xerostomia	28.4 Gy	large (1)	mean dose
Lung	gr ≥ 2 pneumonitis	30.8 Gy	large (0.99)	V20, MLD
Heart	RIHD		intermediate (0.35–0.64)	Vd, MHD
Spinal cord	myelopathy		marginal (except very small volumes)	EQD2
Liver	RILD	40-45 Gy	large (0.69–0.97)	MLD, Vd
Rectum	proctitis, ulceration	80 Gy	small (serial)	V70, V50

Kong et al. *Semin Radiat Oncol* 2007;17:108-20

Complications versus mean lung dose



Seppenwoolde et al.
Int J Radiat Oncol Biol Phys 2003;55:724-35

Summary

- Dose-response data are defined in terms of probability
- Steepness of dose response at defined level can be used to convert change in dose to response
- Dose-response curves for normal tissues are steeper than those for tumors
- Heterogeneity in population data tend to make dose-response curves less steep
- NTCP models are not well validated and require caution when applied to clinical data; simpler dosimetric descriptors may be more useful

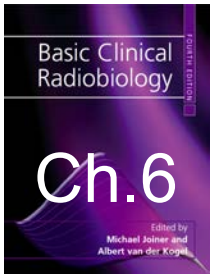
LET and RBE

Michael Joiner

Paris 2017



Wide spectrum of DNA damage

Class	Initial physical damage	Typical energy and target dimensions	Possible target	Frequency of occurrence (cell^{-1} Gy^{-1})†	Comment
1	Sparse	Few tens of eV within ~2 nm	DNA segment	~10^3	Little biological rel
2	Moderate cluster	~100 eV within ~2 nm	DNA segment	~20–100	Charac ~repa
3	Large cluster	~400 eV within 5–10 nm	Nucleosome	~4–100	Characteristic of high-LET; ~u
4	Very large cluster	~800 eV within 5–10 nm	(Nucleosome)	~0–4	Unique to high-LET;

SSB

simple DSB

complex DSB

very complex DSB

†These frequencies assume that the targets are as in the previous column and that all the cell's DNA (~6 pg) is arranged in this way (Goodhead and Nikjoo 1989).

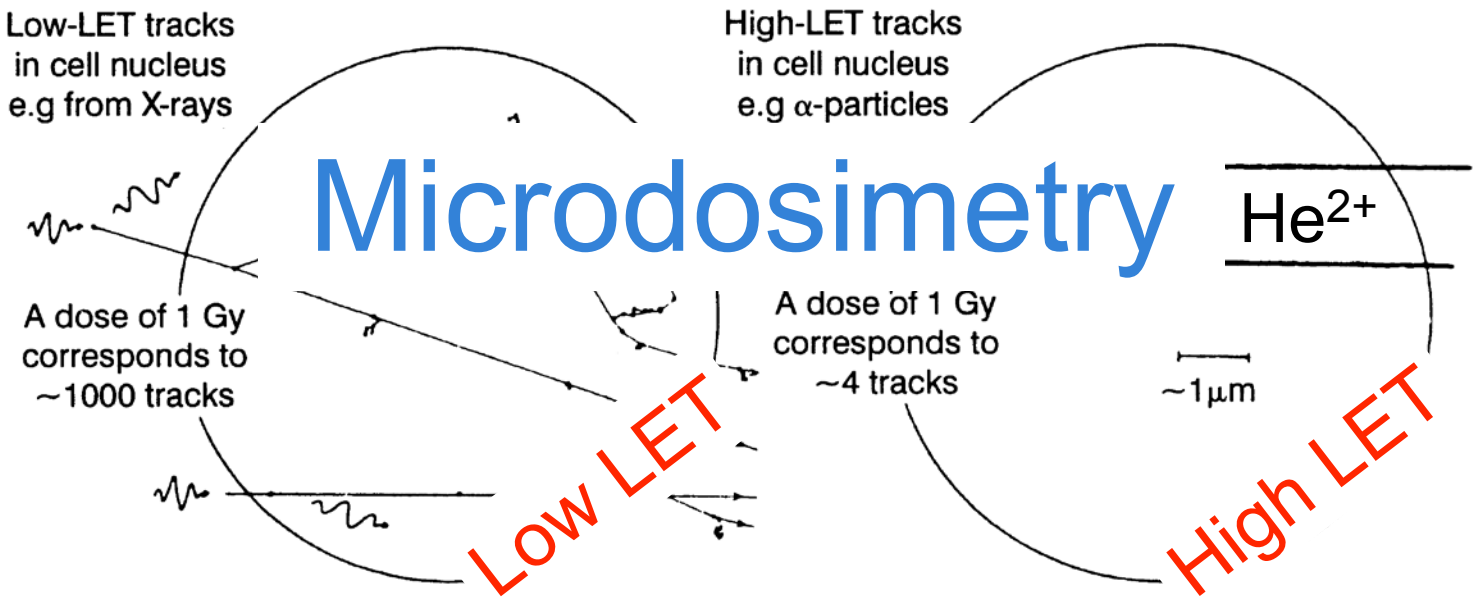
Linear Energy Transfer (LET)

$$\text{LET} = \mathrm{d}E/\mathrm{d}l$$

Where:

$\mathrm{d}E$ is the average energy locally imparted to the medium by a charged particle of a specified energy in traversing a distance of length $\mathrm{d}l$.

Units are typically keV μm^{-1} (keV/μm)



Microdosimetry

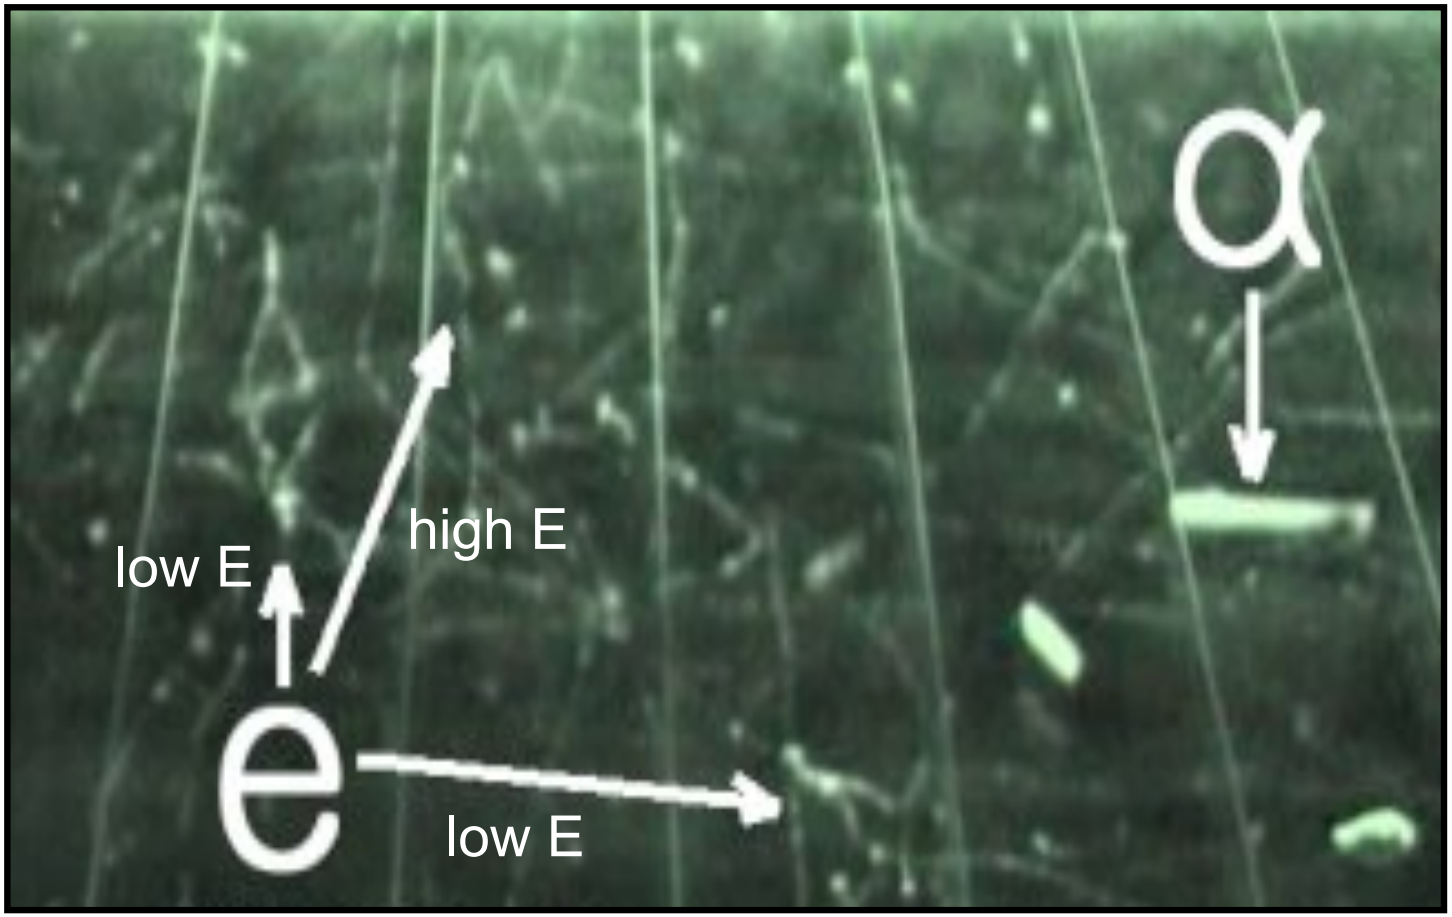
LET: Linear Energy Transfer.

A measure of average ionization density.

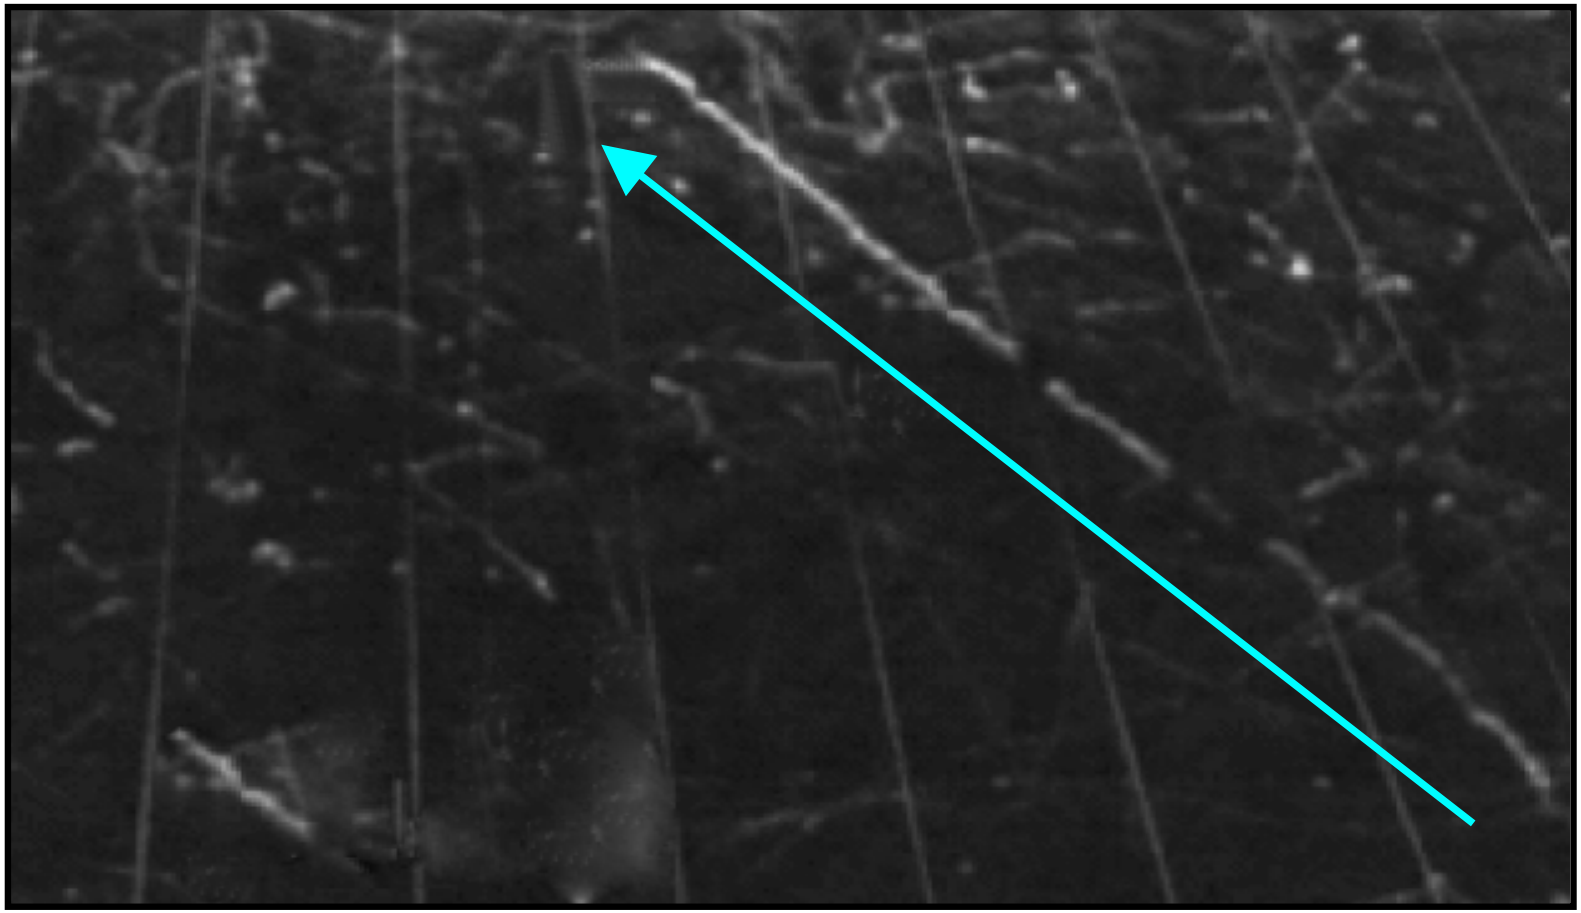
$$LET \propto \frac{charge^2}{velocity^2}$$

Charged particle tracks in a cloud chamber

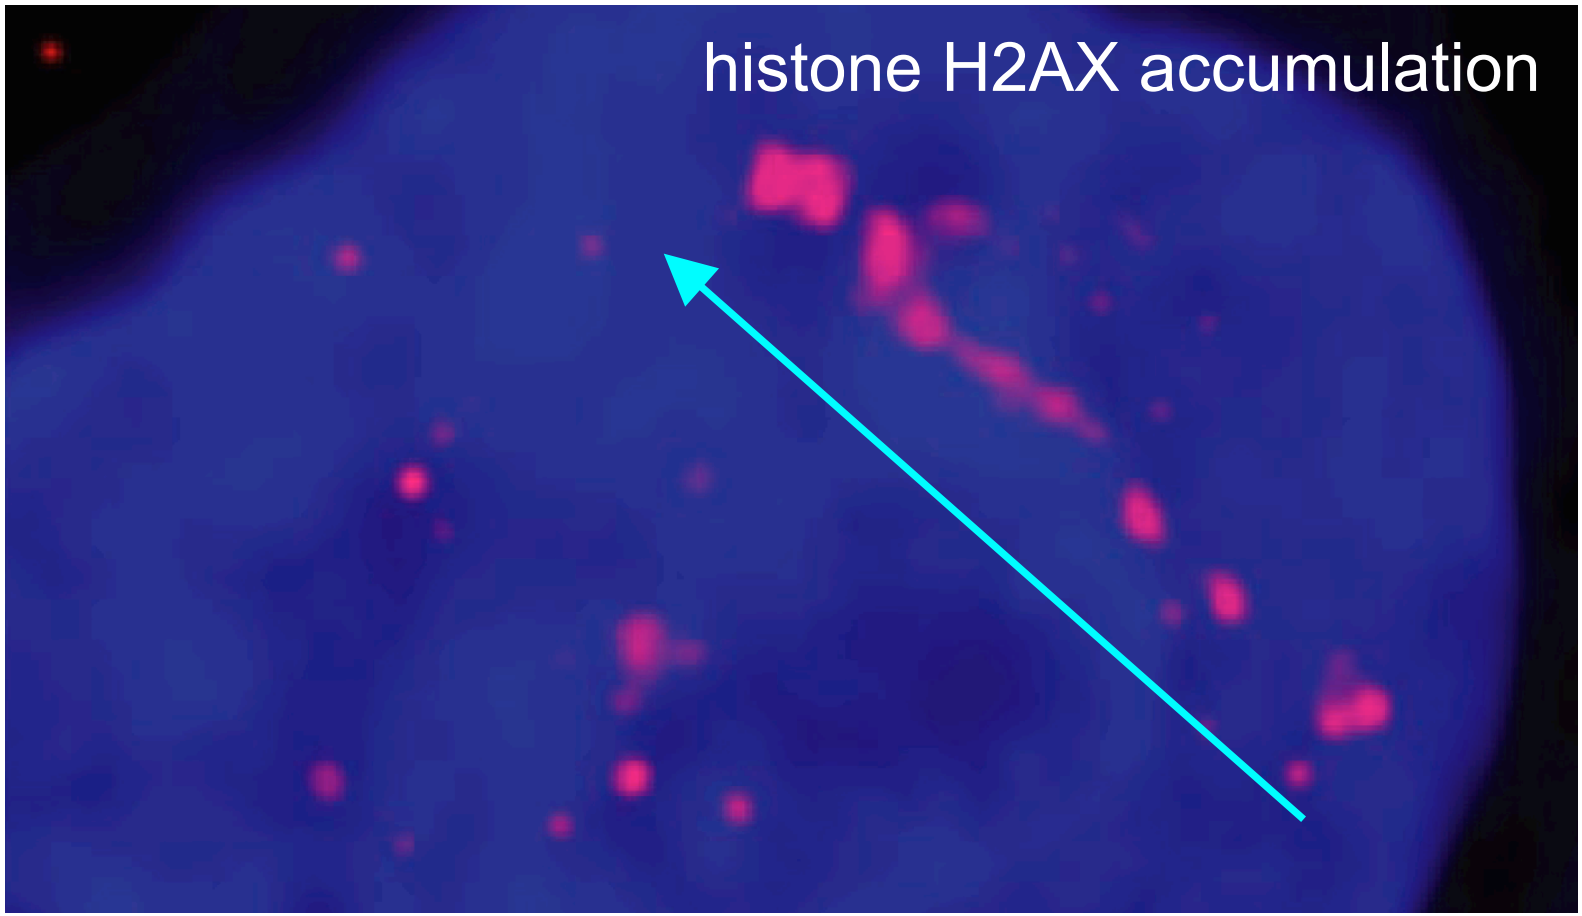
Cloud chamber photograph shows many high-energy electrons (thin tracks), low energy electrons (thicker tracks), and α particles (thickest tracks)



Charged particle slows from lower right to upper left



Initial DNA damage from an α particle



Typical LET values

Radiation	Linear Energy Transfer, KeV/μm	
Cobalt-60 γ-rays	0.2	
250-kV x-rays	2.0	
10-MeV protons	4.7	
150-MeV protons	0.5	
	Track Avg.	Energy Avg.
14-MeV neutrons	12	100
2.5-MeV α-particles	166	
2-GeV Fe ions	1,000	

Relative Biological Effectiveness (RBE)

$$RBE = \frac{\textit{dose of a } \textbf{standard radiation}}{\textit{dose of the } \textbf{test radiation}}$$

to produce the same biological effect,
where the "standard radiation" is usually either
orthovoltage X rays (~250 kVp) or ^{60}Co γ rays

Note: The RBE between 250kVp X and ^{60}Co γ (and MV) is about 1.10–1.15 (depending on dose)

RBE
LET

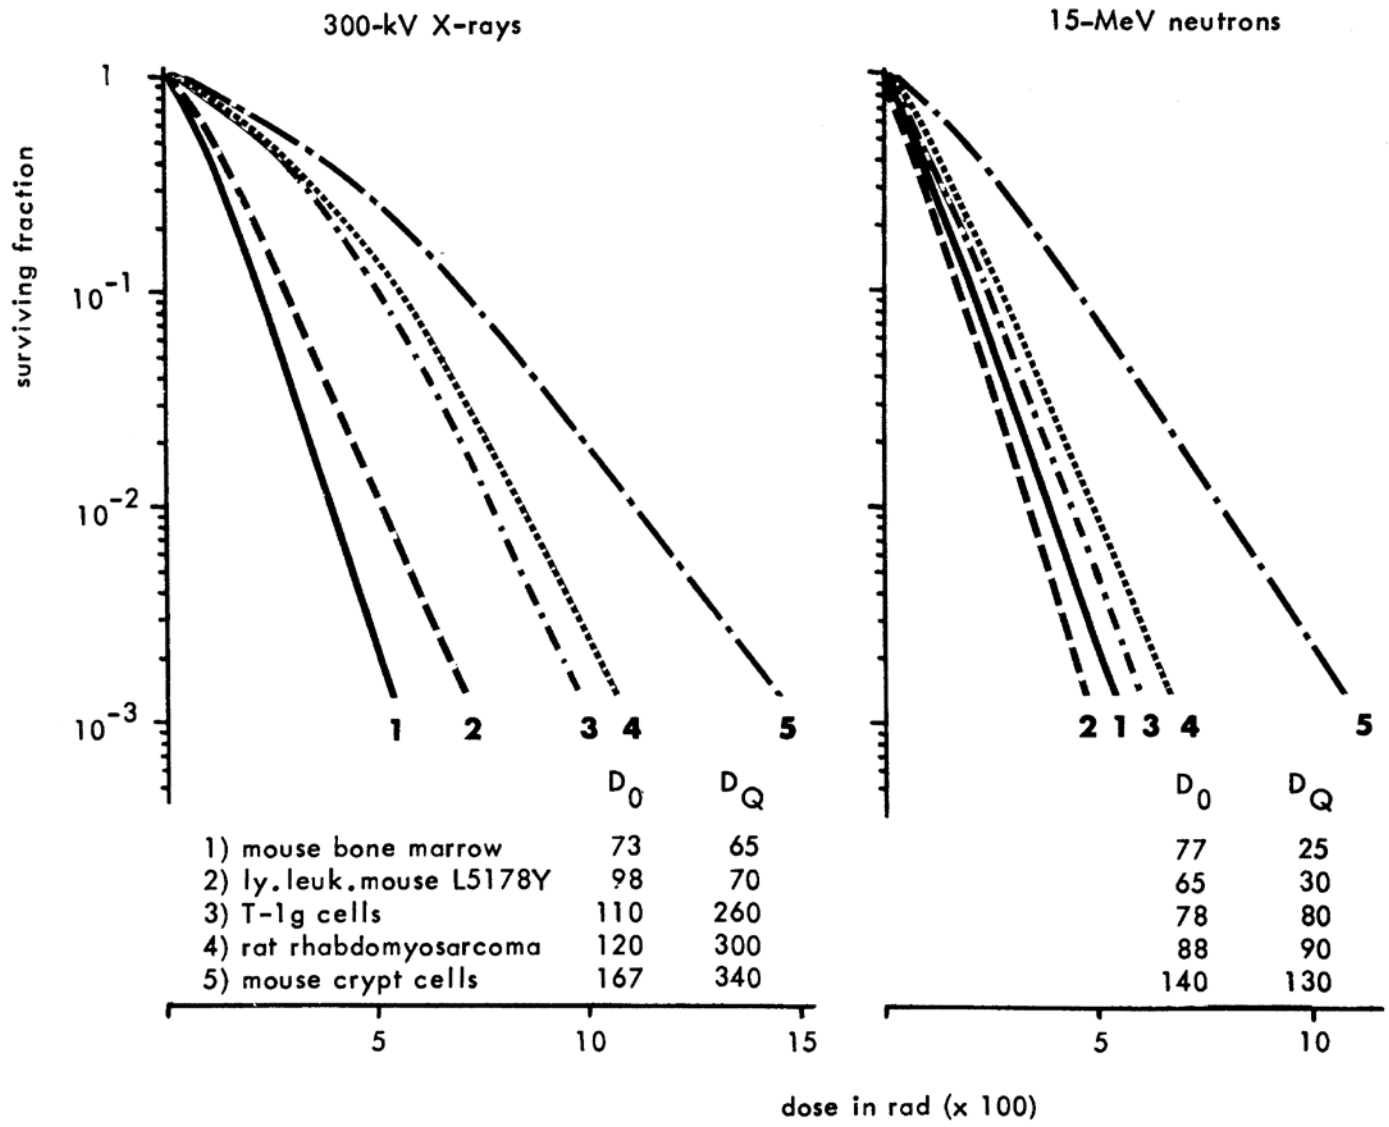
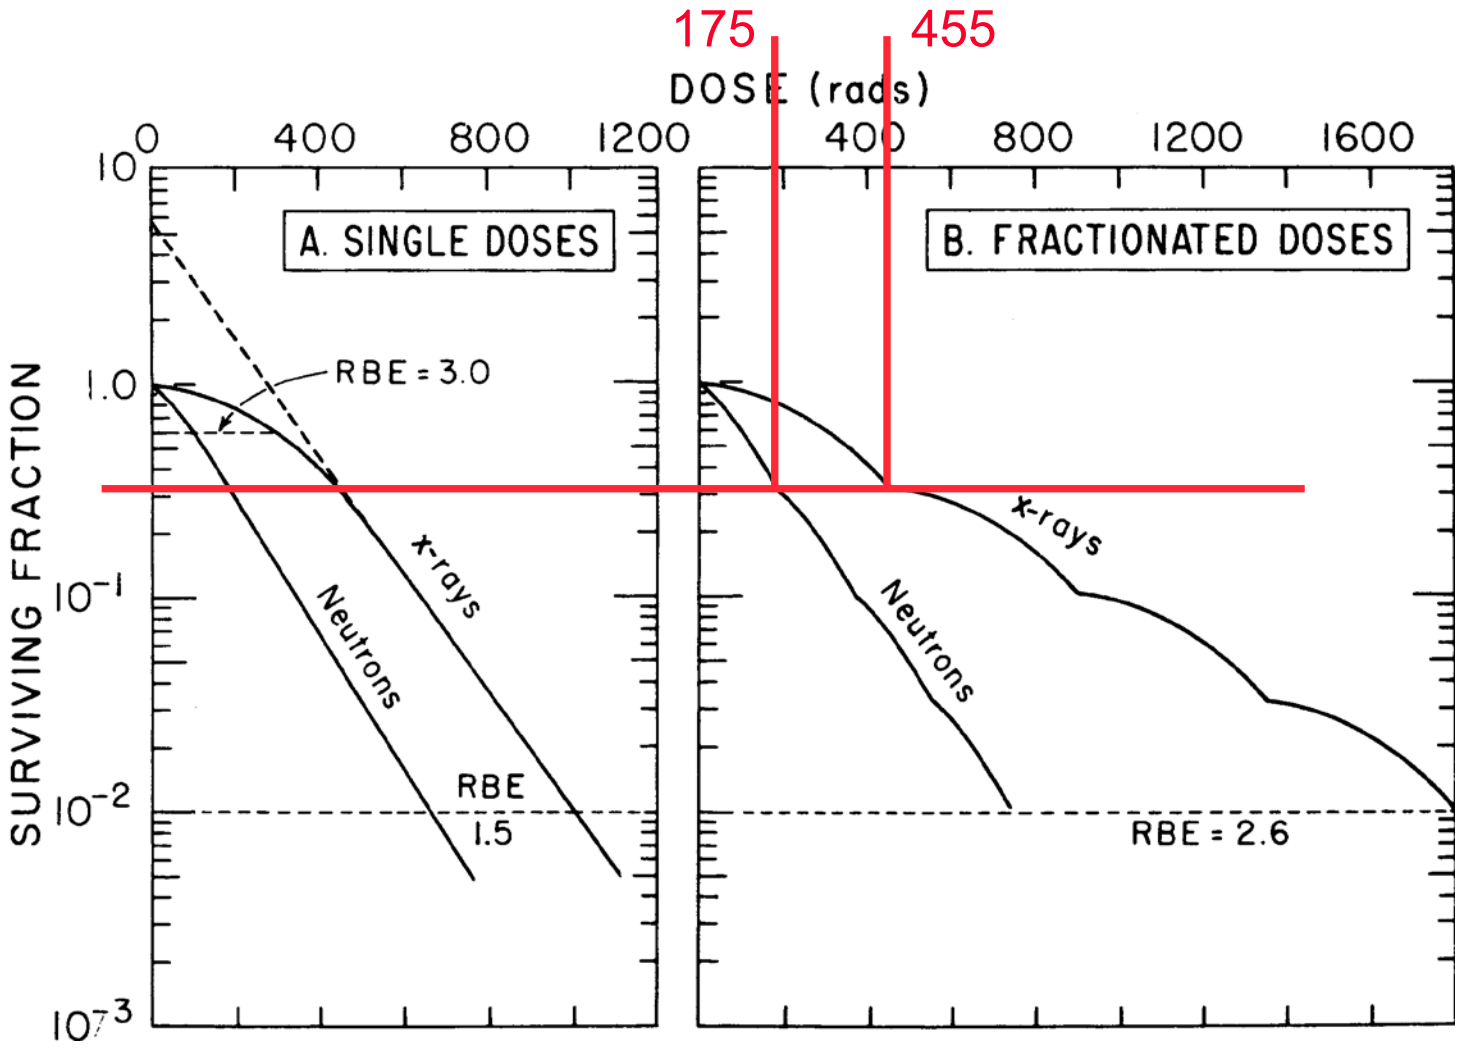
Dependence of RBE on type of cell irradiated



Dependence of RBE on the type of cell irradiated

- Cells which exhibit large shoulders in their X-ray survival curves tend to have high RBEs
- Cells with *little, if any, shoulder* tend to have *low RBEs*
- There are exceptions, due to the different interaction mechanisms between low and high LET radiations *e.g.* cell-cycle effect

Effect of dose and dose per fraction on the RBE



Effect of dose and dose per fraction on the RBE

At low doses (and low doses per fraction), the RBE is higher since the dose in the numerator of the RBE will be relatively higher at low doses than in the denominator because of repair at low doses with the low-LET standard radiation

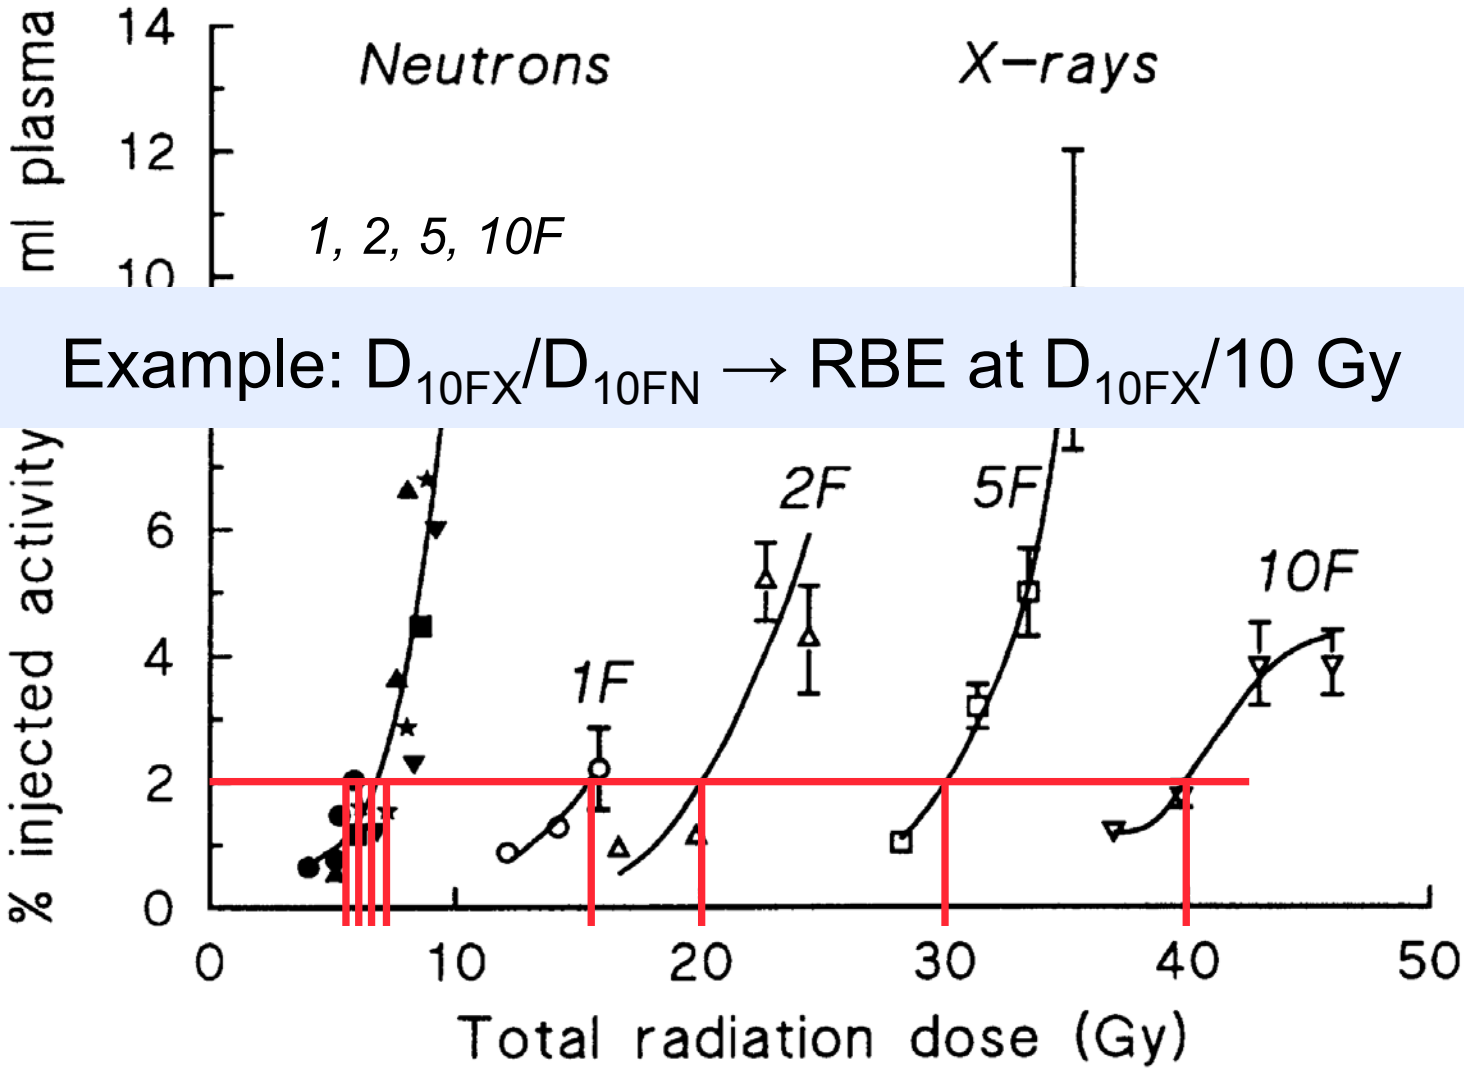
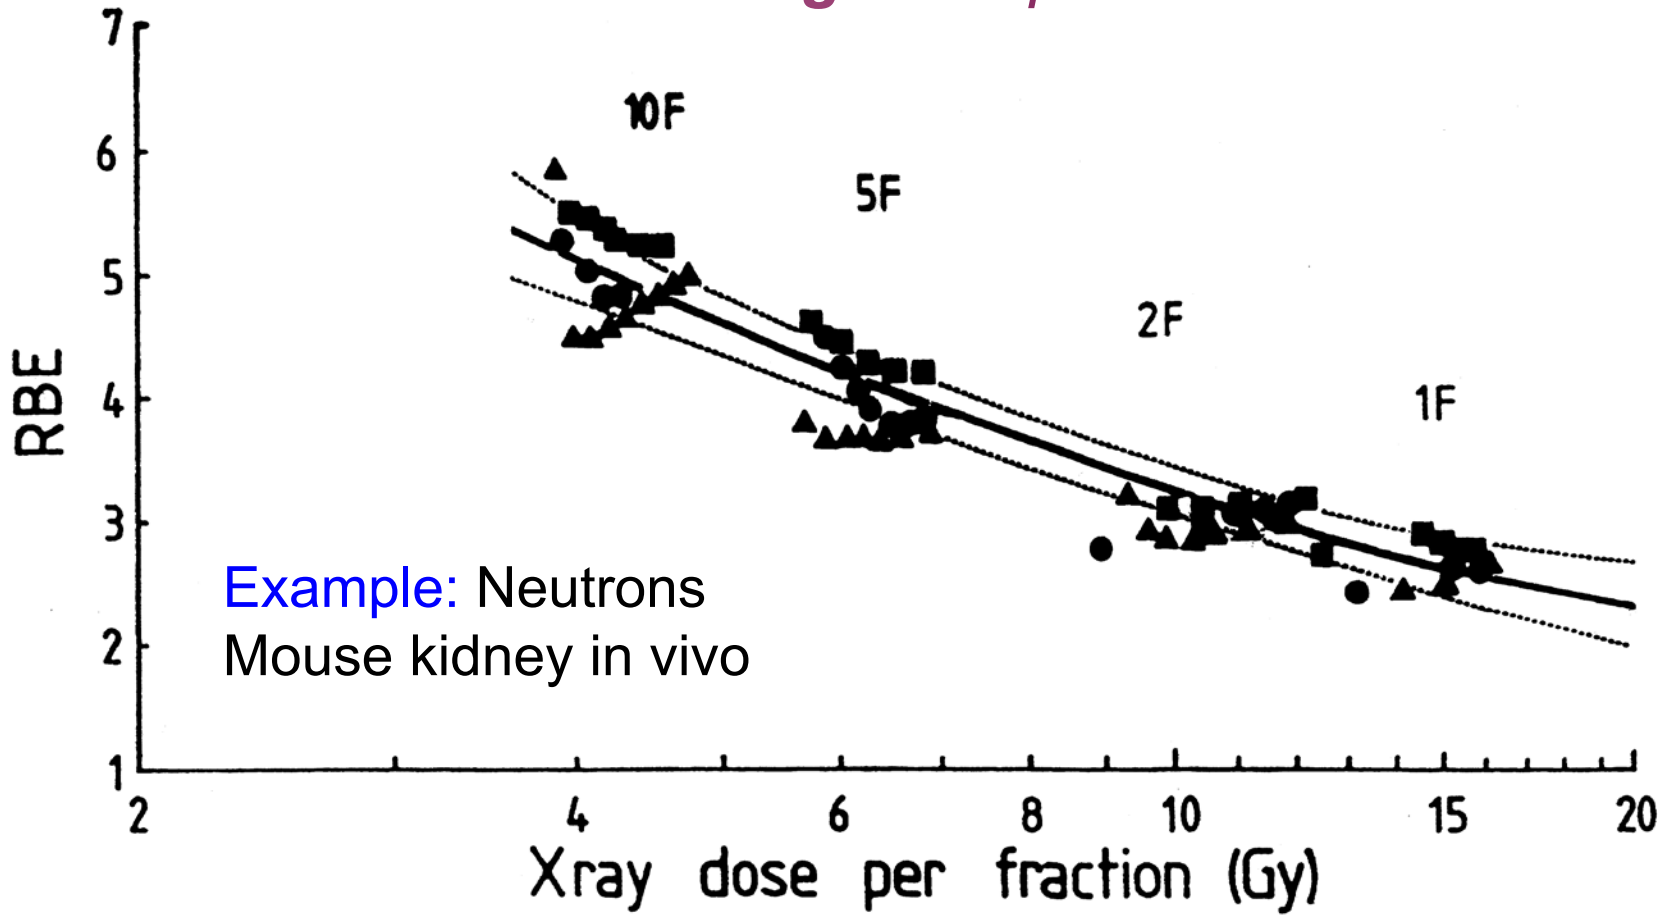
X–ray dose (Gy)



Example: $D_{10FX}/D_{10FN} \rightarrow$ RBE at D_{10FX}/10 Gy

RBE **increases**

with ***decreasing*** *dose per fraction*



Example: Neutrons
Mouse kidney in vivo

Factors which influence the RBE

RBE depends upon:

- radiation quality (LET)
- radiation dose (dose per fraction)
- dose rate
- biological system or endpoint
- conditions, *e.g.* oxygenation

Applications in Radiation Protection

Radiation Weighting Factor (W_R)

Equivalent Dose = dose × W_R

where W_R is a “rounded” value of the RBE.

A “rounded” (approximate) RBE is needed in radiation protection to cover all biological systems, doses, and endpoints.

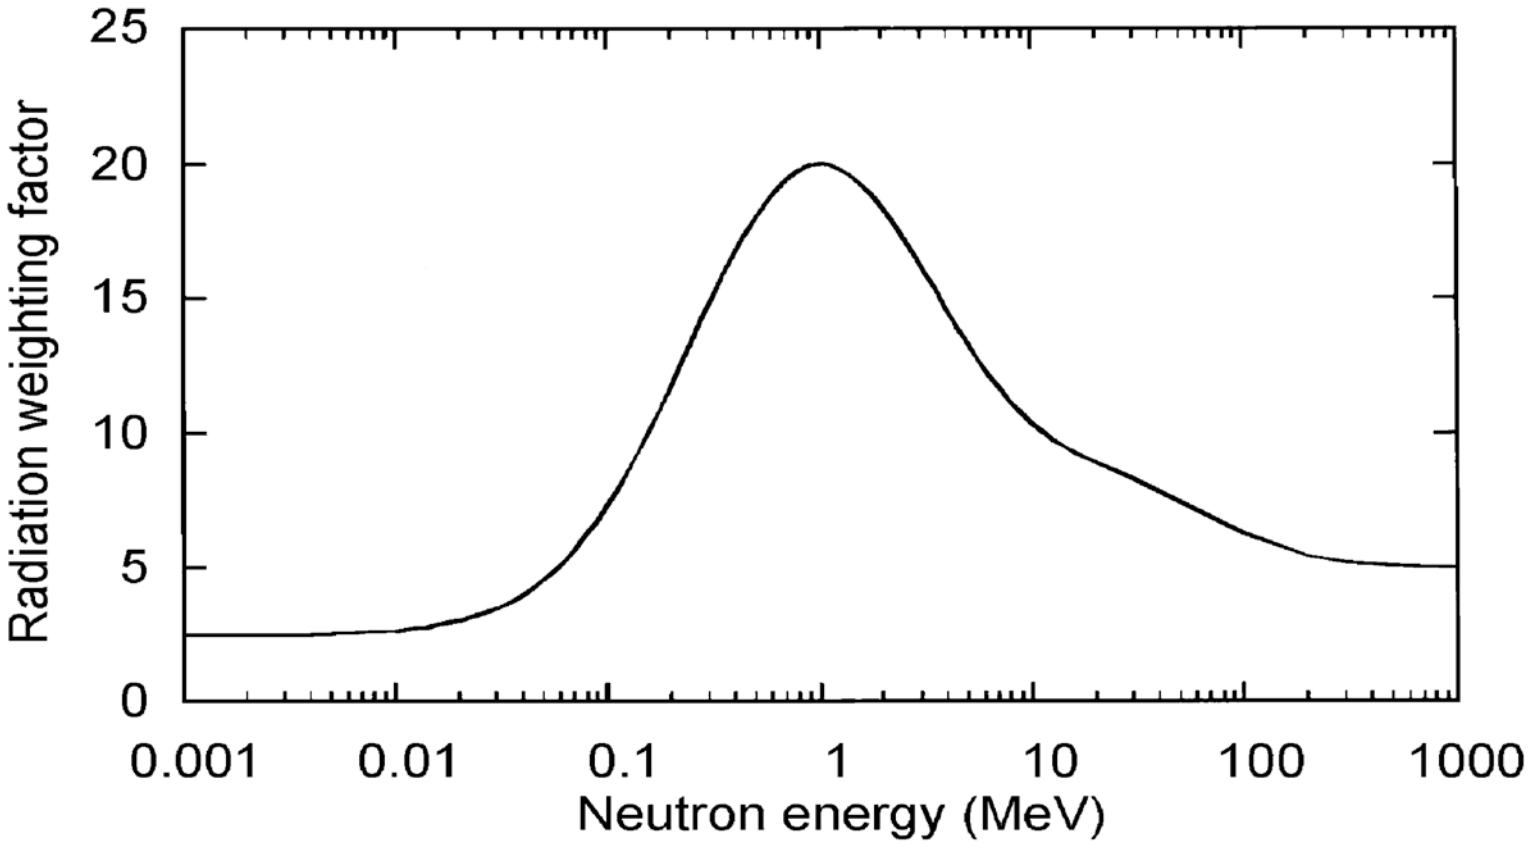
Radiation weighting factors (W_R)

ICRP 92 (2003), ICRP 103 (2007)

Radiation type	W_R
Photons (X-rays and gamma-rays):	1
Electrons and muons:	1
Neutrons:	function of neutron energy
Protons and charged pions:	2
Alpha-particles, fission fragments, heavy ions:	20

W_R for neutrons

ICRP 92 (2003), ICRP 103 (2007)



LET and RBE Conclusions 1

- LET is the average energy transferred per unit path length of the track of a charged particle
- X rays and gamma rays are usually referred to as low LET, although this is actually the LET of the charged particles released when they interact

LET and RBE Conclusions 2

Typical values of LET are:

~0.3 keV μm^{-1} for high-energy X and γ rays

~2 keV μm^{-1} for orthovoltage (~250 kVp) X rays

>100 keV μm^{-1} for heavy charged particles

LET and RBE Conclusions 3

- RBE is the ratio of dose of a “standard” radiation to dose of the radiation of interest producing the same biological effect
- The “standard” radiation is either orthovoltage X rays (~250 kVp) or ^{60}Co gamma rays
- RBE increases with LET up to a maximum at ~100 keV μm^{-1}, and thereafter decreases due to the “overkill” effect

LET and RBE Conclusions 4

- RBE increases as the dose per fraction (or dose rate) decreases or the LET increases
- RBE depends on:
  - *radiation quality (LET)*
  - *radiation dose (dose/fraction)*
  - *dose rate*
  - *biological system or endpoint*
  - *conditions*

LET and RBE Conclusions 5

- The radiation weighting factor (W_R) is used in **radiation protection** (that is, **NOT** in radiation oncology!) as a surrogate for RBE because the RBE depends on so many variable factors
- Equivalent Dose is: Dose × W_R

The LQ model in practice
A prostate cancer case

Karin Haustermans

Department of Radiation Oncology, University Hospitals Leuven, Belgium

Prostate cancer case

- A famous Belgian man 65 years old
- WHO performance status 1
- PSA 9,6 µg/l
- MR guided biopsy in the right lobe: Gleason score 3+4 in two cylinders (60% and 85%)
- Bone scan en CT scan of the pelvis negative
- cT2aN0M0

Prostate cancer case

- We proposed him 35 fractions of 2,2 Gy (TD 77 Gy) with 6 months of ADT
- What would be the chance to achieve biochemical control for this patient?
- α/β is assumed to be 1,5 Gy for prostate cancer

Prostate cancer case

- Calculation:
  - $EQD_2 = D \frac{d + (\alpha/\beta)}{2 + (\alpha/\beta)}$
  - $EQD_2 = 77 \times \frac{2{,}2 + 1{,}5}{2 + 1{,}5}$
  - $EQD_2 = 81{,}4$ Gy

- Difference = 90,4 Gy – 81,4 Gy = 9 Gy

→ 1,8% / 1 Gy = 16,2 %

Prostate cancer case

- He went to the UK for a second opinion …

CHHiP-trial

- 74 Gy / 2 Gy (37#) vs 60 Gy / 3 Gy (20#) vs 57 Gy / 3 Gy (19#)
- 3152 analysable patients
- 73% Intermediate risk; 15% Low risk; 12% High risk (NCCN)
- 97% Androgen deprivation (3-6 months)
- IMRT
- Non-inferior design (bNED or cNED -free survival ± 5% at 5 years)

Dearnaley et al. Lancet Oncol. 2016

EQD2 for prostate cancer in these 3 arms?

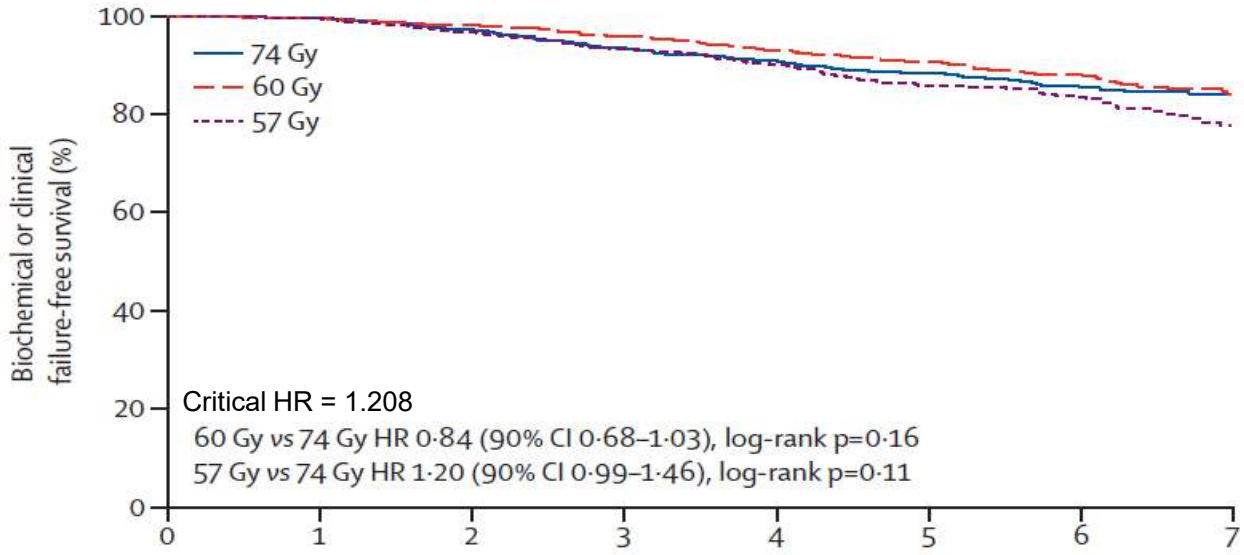
Prostate cancer case

Question 2: Which study-arm is biologically the most iso-effective with the standard-arm (74 Gy), regarding tumour control?

- Calculation: $E/\alpha = BED = D\left(1 + \frac{d}{(\alpha/\beta)}\right)$
- 74 Gy – arm $= 74\left(1 + \frac{2}{1,5}\right) = 172,67$ Gy
- 60 Gy – arm $= 60\left(1 + \frac{3}{1,5}\right) = 180$ Gy
- 57 Gy – arm $= 57\left(1 + \frac{3}{1,5}\right) = 171$ Gy

CHHiP-trial

- 60 Gy / 3 Gy (20#) = non-inferior (5y DFS)
- 57 Gy / 3 Gy (19#) = could not be claimed non-inferior (5y DFS)



Number at risk (events)								
74 Gy	1065 (4)	1037 (24)	991 (39)	926 (24)	795 (20)	495 (11)	284 (3)	167 (11*)

57 Gy	0	28	10	25	115	275	221	98

Dearnaley et al. Lancet Oncol. 2016

EQD2 for OAR in these 3 arms?

Acute?

Late?

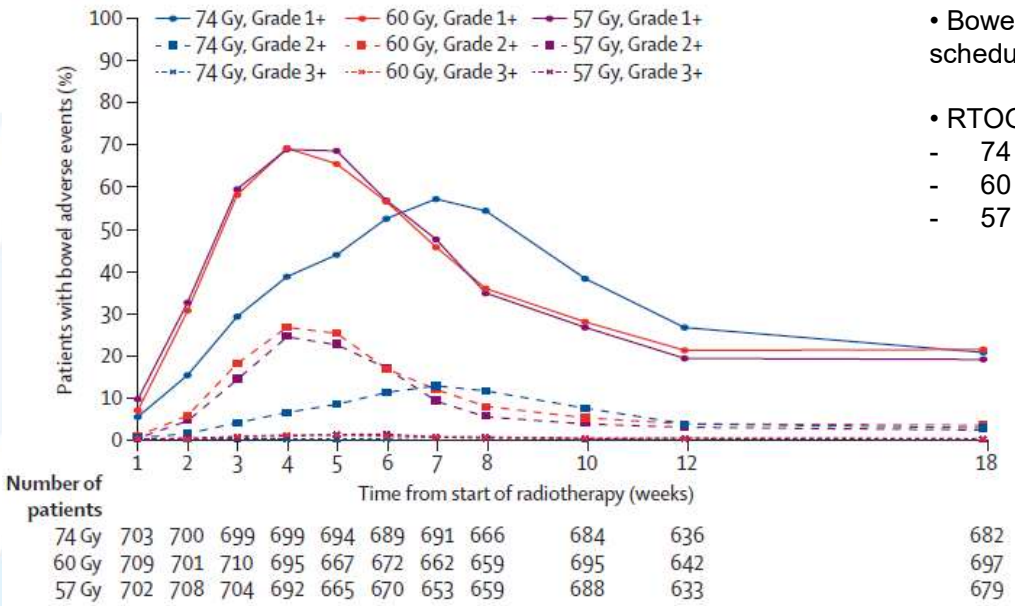
Prostate cancer case

Question 3: Which arm will cause theoretically the most late toxicity?

- Calculation: $E/\alpha = BED = D\left(1 + \frac{d}{(\alpha/\beta)}\right)$
- 74 Gy – arm: $= 74\left(1 + \frac{2}{3}\right) = 123{,}33$ Gy
- 60 Gy – arm: $= 60\left(1 + \frac{3}{3}\right) = 120$ Gy
- 57 Gy – arm: $= 57\left(1 + \frac{3}{3}\right) = 114$ Gy

CHHiP-trial

- Acute toxicity: greater peak for acute bowel toxicity
- Late toxicity: no significant differences between the 74 Gy and the 60 Gy group



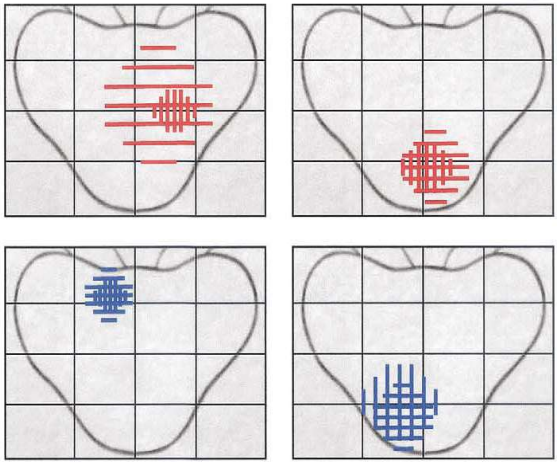
• Bowel symptoms peaked sooner in hypofractionated schedules

• RTOG grade 2 or worse bowel toxicity
- 74 Gy: 25%
- 60 Gy: 38%
- 57 Gy: 38%

Dearnaley et al. Lancet Oncol. 2016

Prostate cancer case

found out that recurrences most frequently occur at the primary tumor site …



ESTRO School

Cellini N et al. 2002

Universitair Medisch Centrum
Utrecht

- FLAME-trial

Randomized phase III trial

  - Standard arm: 77 Gy/2.2 Gy (35 fr) to the prostate
  - Experimental arm: additional integrated boost to macroscopically visible tumor, delineated based on 2 different imaging techniques, to a maximal total dose of 95 Gy (35 fr of 2.7 Gy)

– Primary endpoint

  - To decrease the 5-year biochemical relapse rate with at least 10%

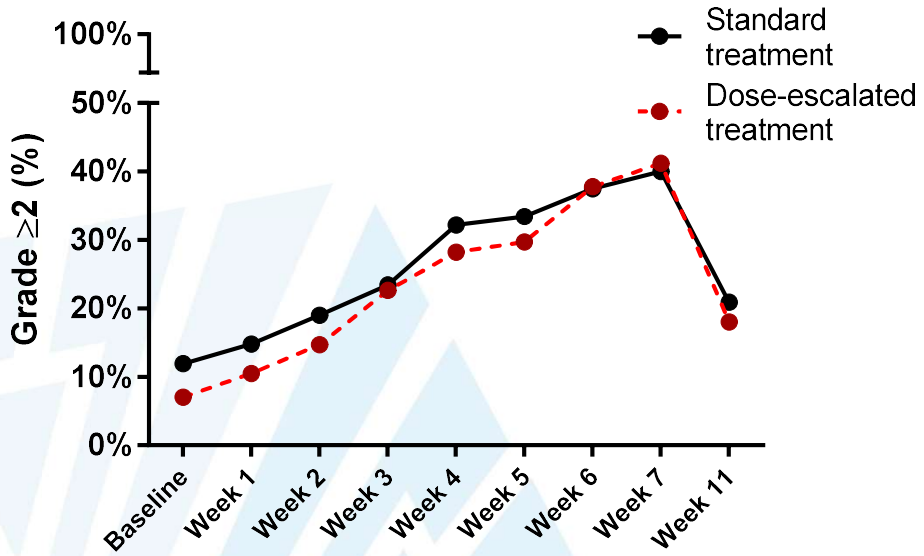
EQD2 for prostate cancer in these 2 arms?

EQD2 for OAR in these 2 arms?

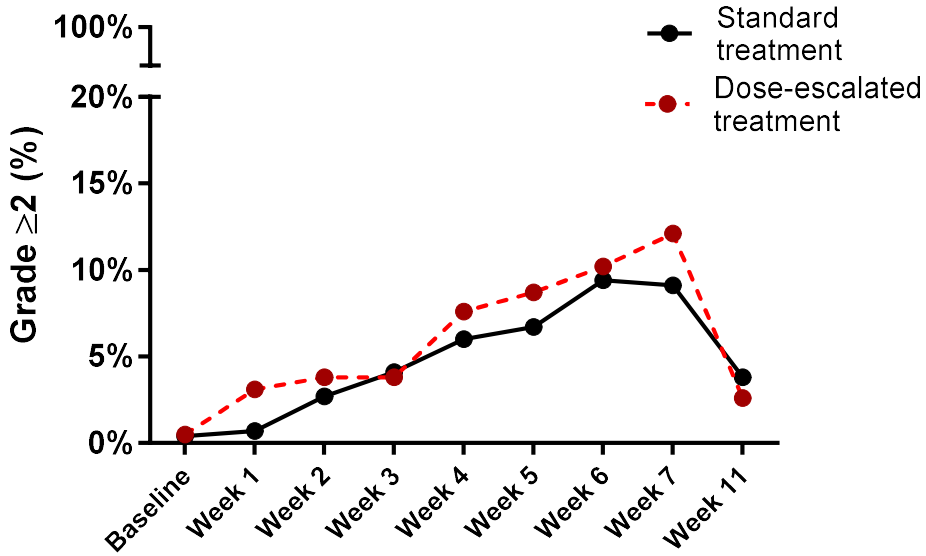
Acute?

Late?

A. Grade 2 or worse GU events over time



B. Grade 2 or worse GI events over time



Prostate cancer case

He wanted a shorter OTT due to his busy professional life …

ESTRO School

Extreme hypofractionation

Hypo – FLAME (phase II – trial)

- Patients are treated by external beam radiotherapy with a SBRT technique with 35 Gy in 5 weekly fractions and an additional simultaneously integrated focal boost to the tumor nodule(s) visible on MRI up to 50 Gy.

- The dose constraints for the bladder and rectum are maintained as in the Canadian SBRT PATRIOT protocol (which were proven safe and were associated with a very low rate of severe toxicity). To achieve equal or less toxicity compared to the current radiotherapy protocols, the organs at risk dose will be prioritised

Prostate cancer case

He decided to join the phase II Hypo-FLAME trial

Prostate cancer case

→ Dose constraints (GTV boost)

$D_{99\%} \geq 40$ Gy
$D_{0,1cc} < 52$ Gy

Prostate cancer case

Additional constraints corresponding to our standard dose constraints (2,2 Gy fractions) to prevent rectal toxicity

Volume	Max dose (35 fractions)
< 50%	42,9 Gy
< 70%	36,2 Gy
< 75%	28,6 Gy

Prostate cancer case

- The first fraction was delivered
- We noticed a change in rectum distension when we compared CBCT before and after
- Rectum D_{max} was 9,5 Gy while Rectum D_{max} = 42 Gy (5 fractions) or 8,4 Gy / fraction

Prostate cancer case

Which dose may be delivered to the rectum in the 4 remaining fractions to not exceed Rectum D_{max}?

Prostate cancer case

- Question 5: Which dose may be delivered to the rectum in the 4 remaining fractions to not exceed Rectum D_{max}? (α/β is assumed to be 3 for late toxicity)

- Given:

	Fraction 1(Rectum)	Tolerance (Rectum)
	- D_{max} = 9,5 Gy	- D_{max} = 42 Gy
	- n = 1	- n = 5
	- d = 9,5 Gy	- d = 8,4 Gy

Prostate cancer case

- Given:

Fraction 1(Rectum)	Tolerance (Rectum)
- D_{max} = 9,5 Gy	- D_{max} = 42 Gy
- n = 1	- n = 5
- d = 9,5 Gy	- d = 8,4 Gy

- Calculation: $E/\alpha = BED = D\left(1 + \frac{d}{(\alpha/\beta)}\right)$

→ $BED_{fraction\ 1} = 9{,}5\left(1 + \frac{9{,}5}{3}\right) = 39{,}58$ Gy

→ $BED_{tolerance} = 42\left(1 + \frac{42/5}{3}\right) = 159{,}6$ Gy

ESTRO School

Prostate cancer case

- Calculation:

→ $BED_{fraction\ 1} = 9{,}5\ (1 + \frac{9{,}5}{3}) = 39{,}58$ Gy

→ $BED_{tolerance} = 42\ (1 + \frac{42/5}{3}) = 159{,}6$ Gy

→ $BED_{rest} = BED_{tolerance} - BED_{fraction1}$

$= 159{,}6$ Gy $- 39{,}58$ Gy

$= 120{,}0$ Gy

→ $BED_{rest/fraction} = 120{,}0$ Gy $/ 4 = 30{,}0$ Gy

Prostate cancer case

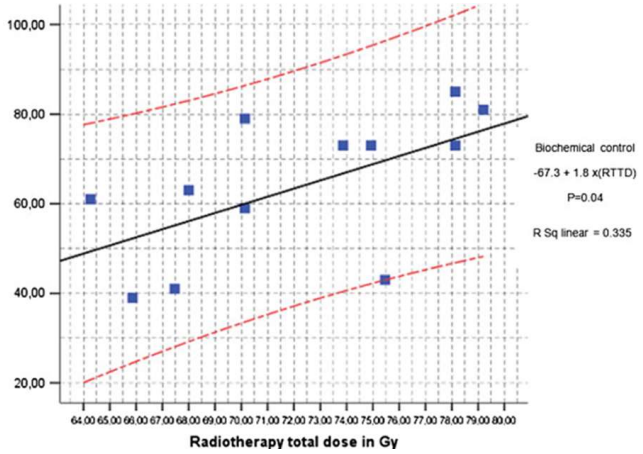
Dose Escalation = Improved Biochemical Outcome

- Reduction in biochemical relapse of 1.8% per 1 Gy
- Predicted radiation doses to achieve a 100% BC rate:

Risk	Dose (EQD2)
Low risk	86,5 Gy
Intermediate risk	90,4 Gy
High Risk	95,5 Gy



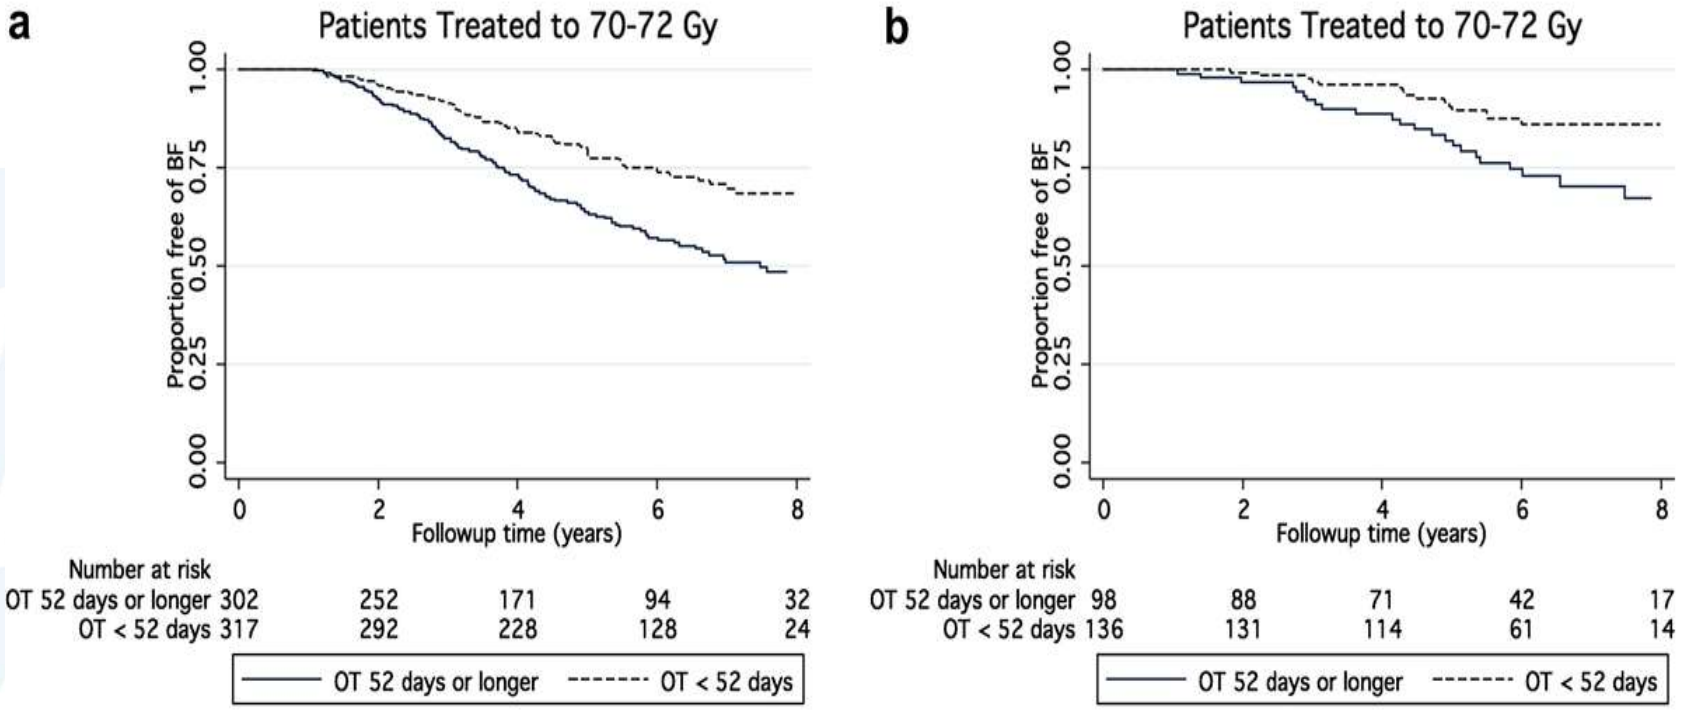
Viani et al. int J Radiat Oncol Biol Phys. 2009

ESTRO School

Dose escalation but …

- There is probably also an overall time factor …

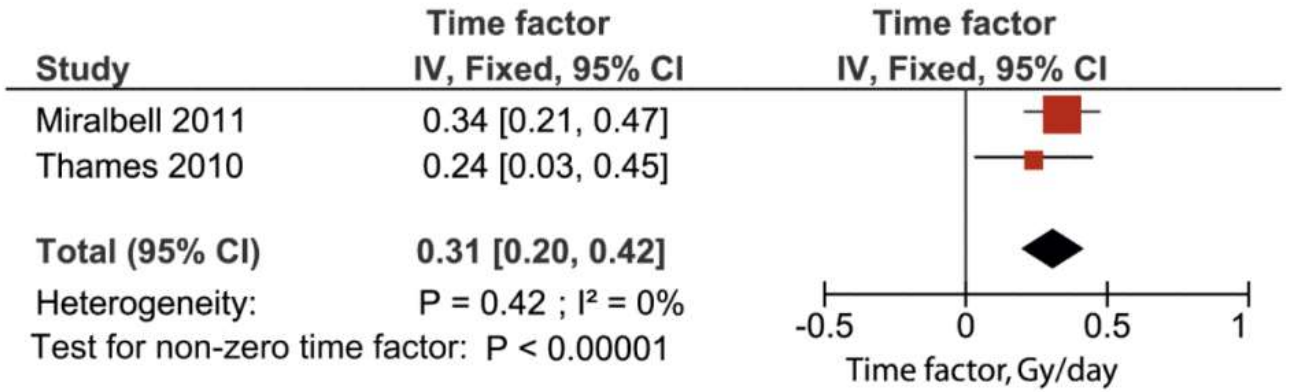
  dose equivalent of proliferation of 0.24 Gy/day



Thames et al, Radiother Oncol 2010

Dose escalation but …

- There is probably also an overall time factor …



- Could reduce the effect of some hypo-fractionated schedules

Vogelius et al. Int J Radiat Oncol Biol Phys. 2013

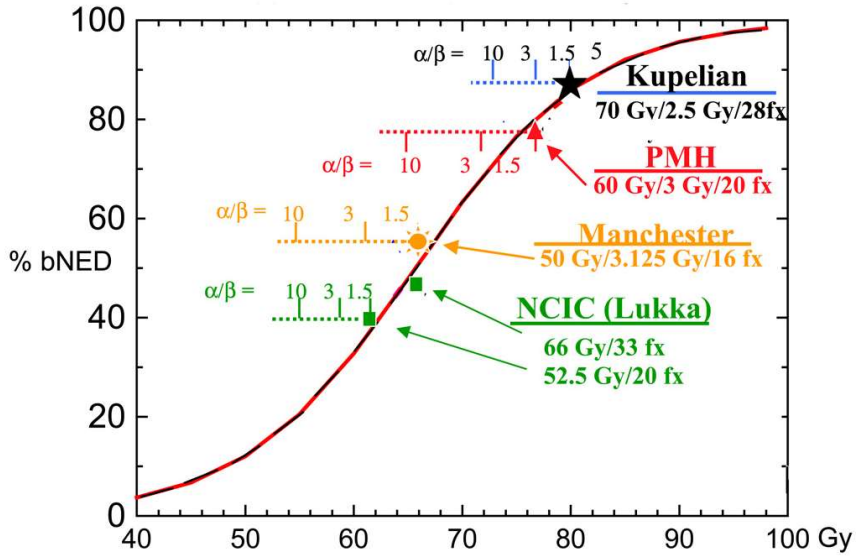
What if …

- The fractionation sensitivity of prostate cancer is uniquely high (α/β 1.5 Gy)?

- The α/β is lower than in normal tissues at risk (α/β 3 to 4 Gy)?

Hypofractionation in prostate cancer

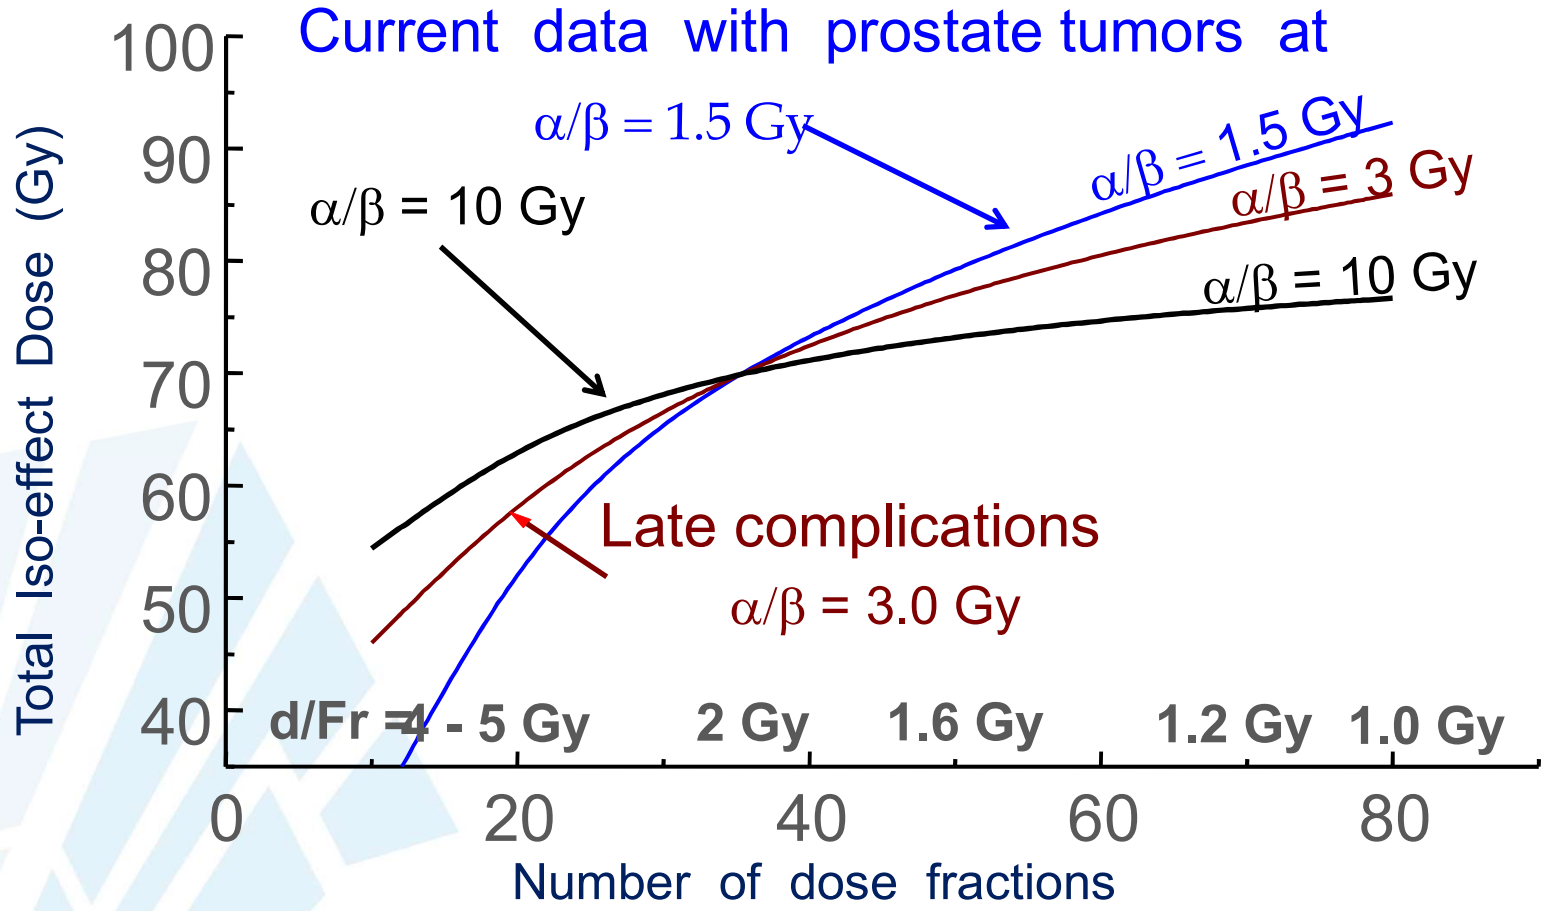
- Fractionation sensitivity of prostate tumors is uniquely high (α/β 1.5 Gy)
- The α/β is lower than normal tissues at risk (α/β 3-4 Gy)



EQD2 in 2 Gy fractions with α/β 1.5 Gy

Ritter et al. Semin. Radiat. Oncol. 2008

HYPOFRACTIONATION I HYPERFRACTIONATION



Hypofractionation in prostate cancer

	Fractionation schedule		
	Conventional	Moderate	Extreme
Total dose (Gy)	76–80	57–70.2	38–50
Total treatment duration (weeks)	8–9	4–6	1–2
Number of fractions (*n*)	38–40	19–30	4–5
Dose per fraction (Gy)	1.8–2	2.4–4	6–10
Interval between fractions (days)	1	1	1–2

Arcangeli et al. Nat Rev Urol. 2016

Hypofractionation in prostate cancer

Non-disease related advantages

- Improvement in patient comfort and convenience

- Decline in workload for radiation oncology departments:

  UK: 2014-2015: Prostate cancer: 455638 attendances

  (27% workload)

  → 20-fraction schedule: - 200 000 attendances

Possible strategies

If α/β is significantly lower for prostate cancer than for rectum

- Equal tumor effect
- Equal late complications

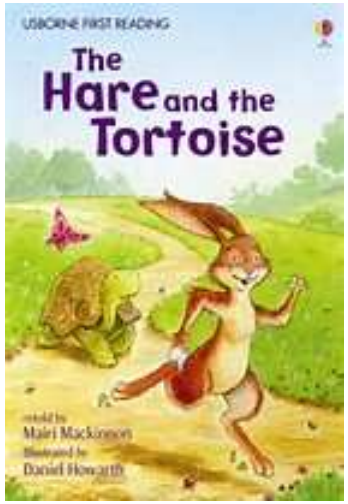
Try to keep the total dose per week below 13 Gy?

Hypofractionation – Conclusion

BUT …

“Here’s where the
alpha/beta ratio is flawed: normal tissue can be seriously injured functionally without necessarily killing the cells involved.”

“To me radiation therapy is all about the tortoise and the hare. You want to get to the destination safely, but the rapidity with which you get there is a secondary and essentially minor issue.”



Glatstein, Int J Rad Onc Biol Phys 2008

Molecular Targeting of Cancer

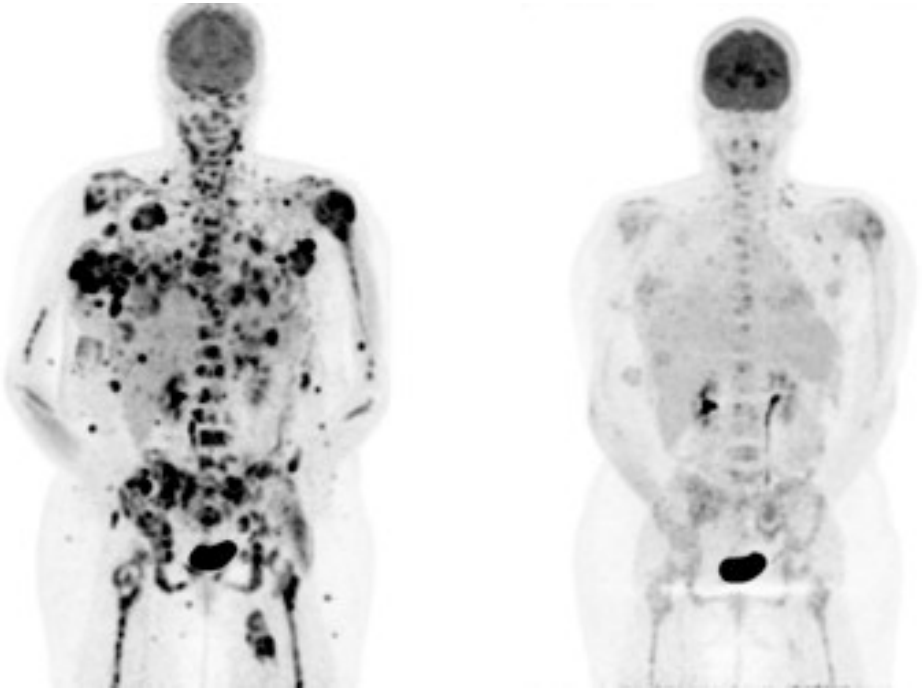
The New York Times

February 2010



Biological response modifiers

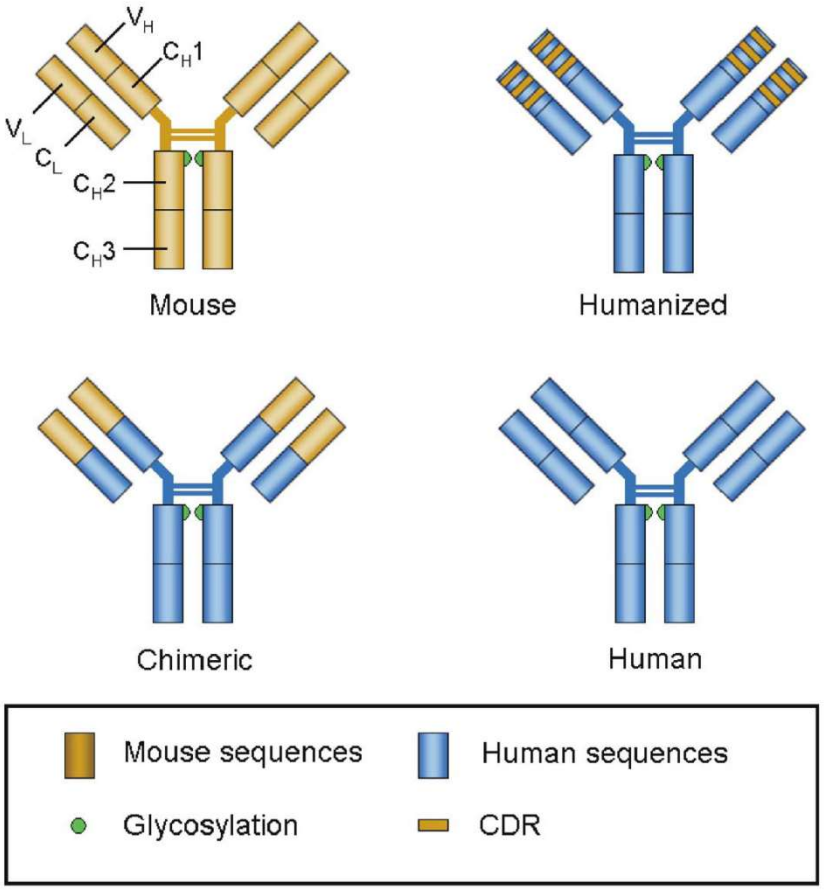
- New drugs designed to target the function of specific molecules
  - Small molecules
  - Antibodies
- Can have low toxicity
- Can have extremely high specificity

Name	Target	Company	Class
Bevacizumab	VEGF	Genentech	Monoclonal antibody
BIBW 2992 (Tovok)	EGFR and Erb2	Boehringer Ingelheim	Small molecule
Cetuximab	EGFR	Imclone/BMS	Monoclonal antibody
Imatinib	Bcr-Abl	Novartis	Small molecule
Trastuzumab	Erb2 (Her2)	Genentech/Roche	Monoclonal antibody
Gefitinib	EGFR	AstraZeneca	Small molecule
Ranibizumab	VEGF	Genentech	Monoclonal antibody
Pegaptanib	VEGF	OSI/Pfizer	Small molecule
Sorafenib	Multiple targets	Onyx/Bayer	Small molecule
Dasatinib	Multiple targets	BMS	Small molecule
Sunitinib	Multiple targets	Pfizer	Small molecule
Erlotinib	EGFR	Genentech/Roche	Small molecule
Nilotinib	Bcl-Abr	Novartis	Small molecule
Lapatinib	EGFR/Erb2	GSK	Small molecule
Panitumumab	EGFR	Amgen	Monoclonal antibody

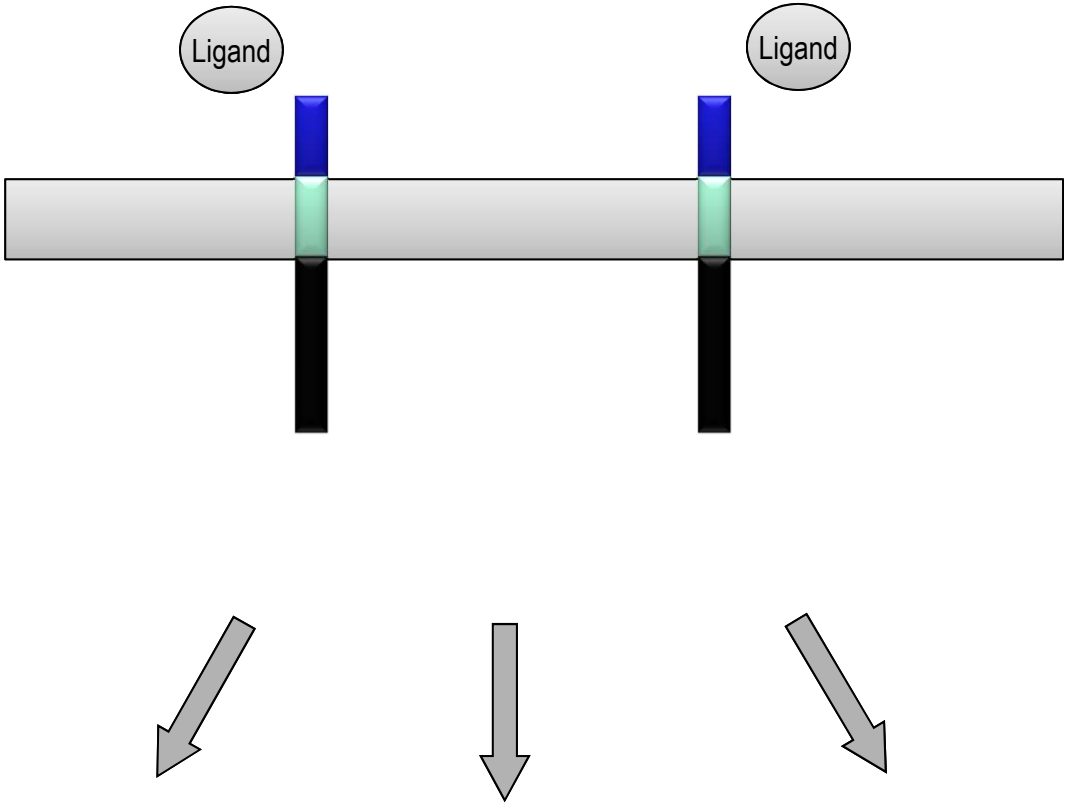
+ many more

Mechanisms of mAB Action

- Signal transduction changes
  - Ligand-receptor interaction
  - Clearance of ligand
- Delivery of cytotoxic payloads
  - Radioisotopes
  - Toxins
- Interaction with immune system
  - Antibody-dependent cellular cytotoxicity
  - Complement-dependent cytotoxicity

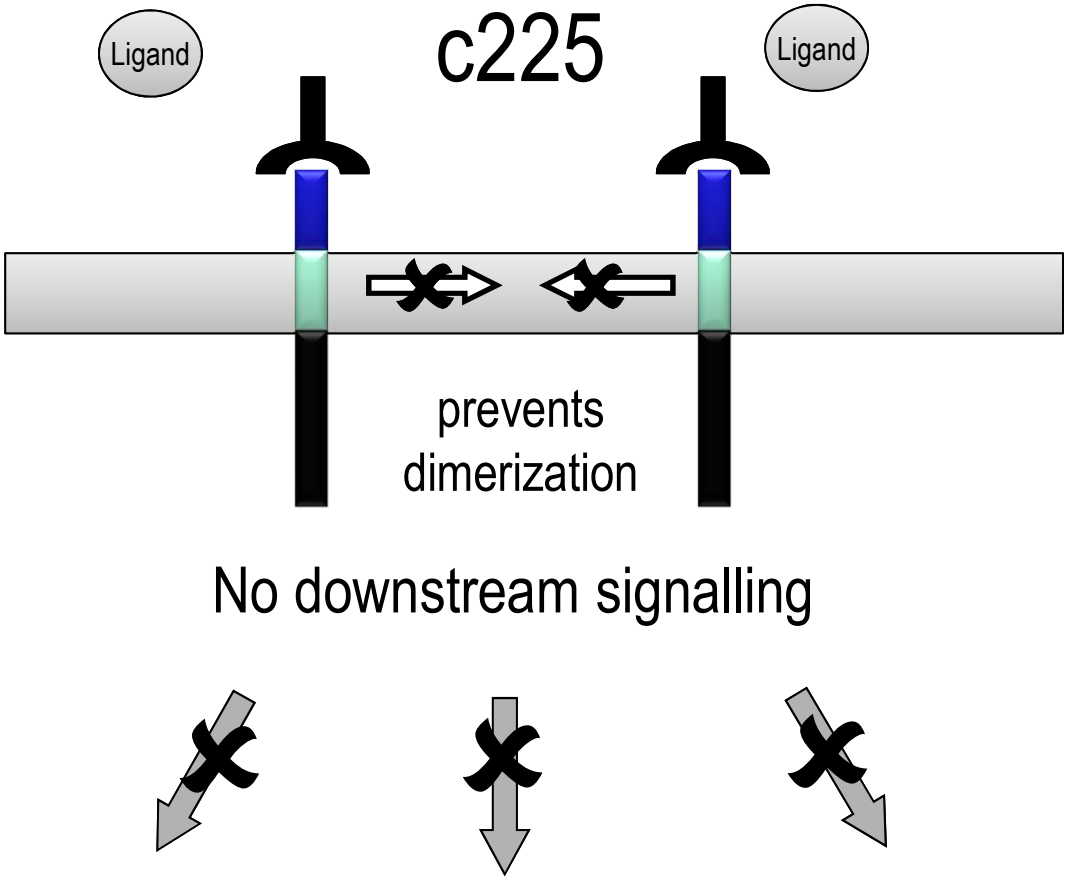


EGFR-signaling



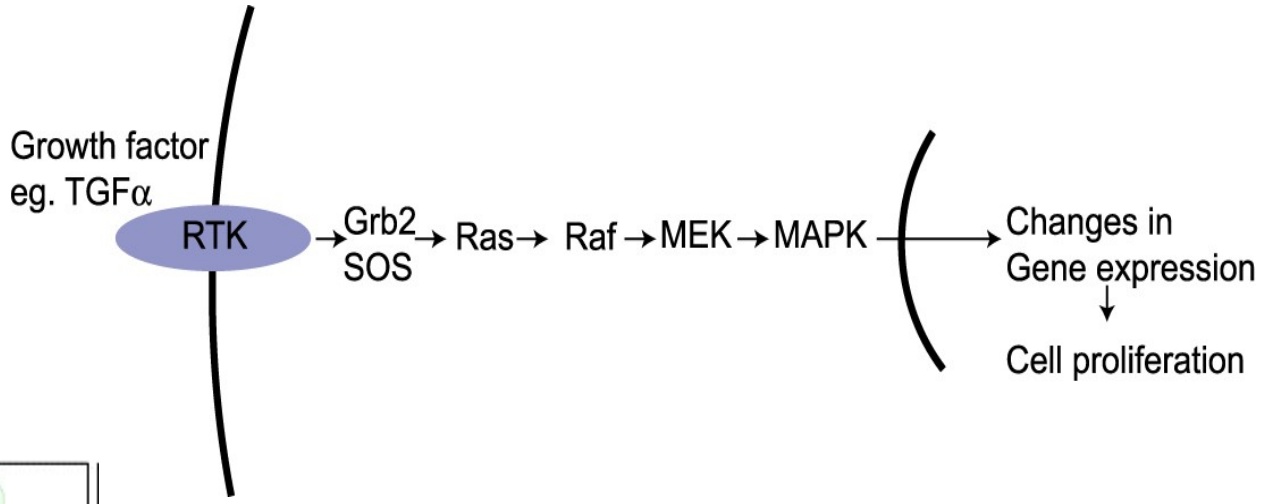
Proliferation, DNA repair, angiogenesis

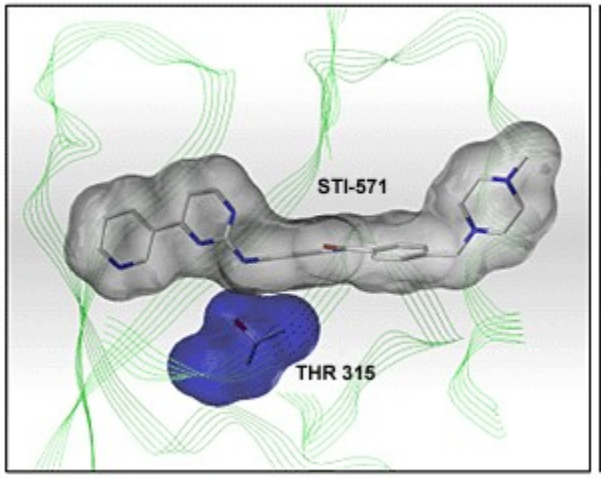
Cetuximab prevents EGFR-signaling



Proliferation, DNA repair, angiogenesis

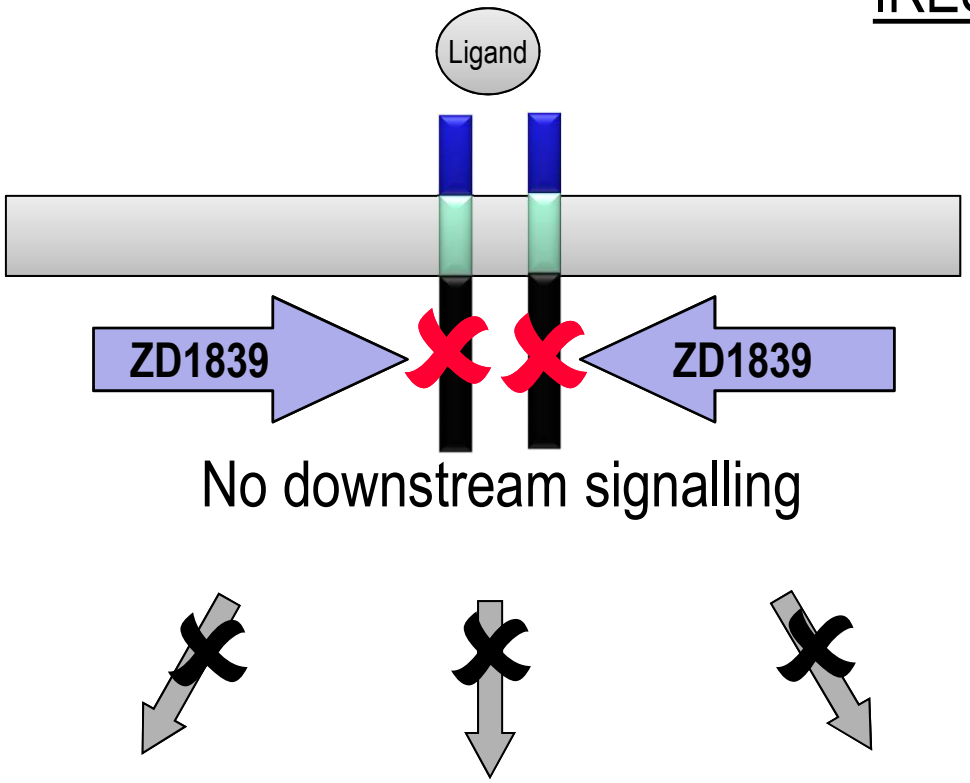
Small molecules





- Tyrosine Kinase Inhibitors
  - Imatinib – gleevec
  - EGFR - Iressa
  - VEGFR
- Farnesyl transferase inhibitors
  - Ras
- Prostaglandin (PGE2) pathway
  - COX-2

Small molecule EGFR inhibitors



IRESSA / ZD1839

- orally bioavailable
- selective inhibitor of EGFR tyrosine kinase
- competitive inhibitor of ATP-binding

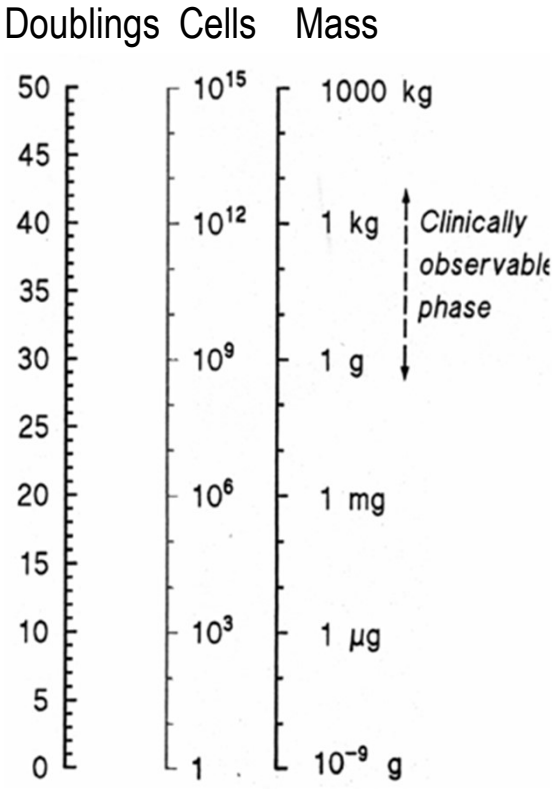
Canadian clinical trials with RT

Phase	Agent	Site	Target
I	Sorafenib	SCCHN	Raf/MEK/ERK
I	Sorafenib	Thorax, abdomen, pelvis	Raf/MEK/ERK
I	Sorafenib	Hepatocellular carcinoma	Raf/MEK/ERK
I	Sunitinib	brain met	PDGFR/VEGFR/KIT
I/II	Sorafenib	bone mets, RCC	Raf/MEK/ERK
I/II	Sorafenib	Unresectable liver mets	Raf/MEK/ERK
I/II	Sorafenib	Cervix	Raf/MEK/ERK
I/II	Nimotuzumab	NSCLC	EGFR
II	Erlotinib	NSCLC	EGFR
II	Nimotuzumab	Brain met NSCLC	EGFR
II	Vandetanib	SCCHN	VEGFR, EGFR
II/III	CDX-110	GBM	EGFRvIII
III	Cetuximab	HN	EGFR
III	Cetuximab	Esophageal	EGFR
III	Panitumumab	SCCHN	EGFR
III	Avastin	glioblastoma	VEGF-A

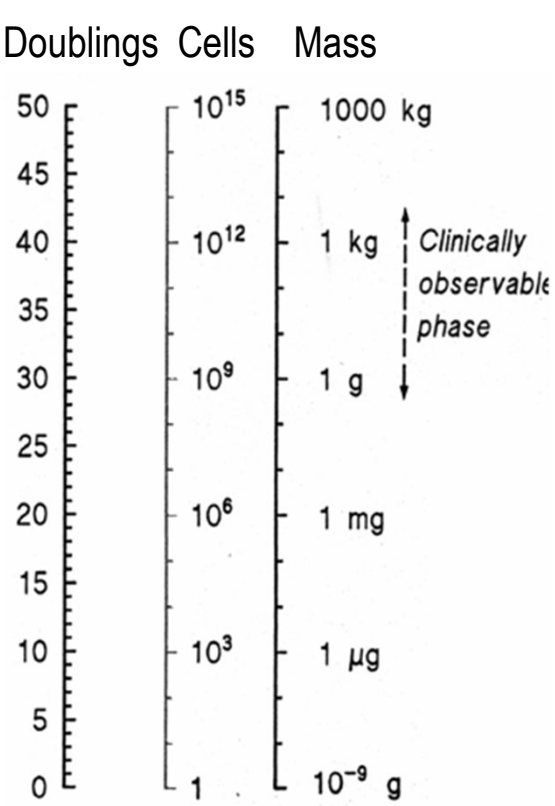
Targeting with RT: achieving cure

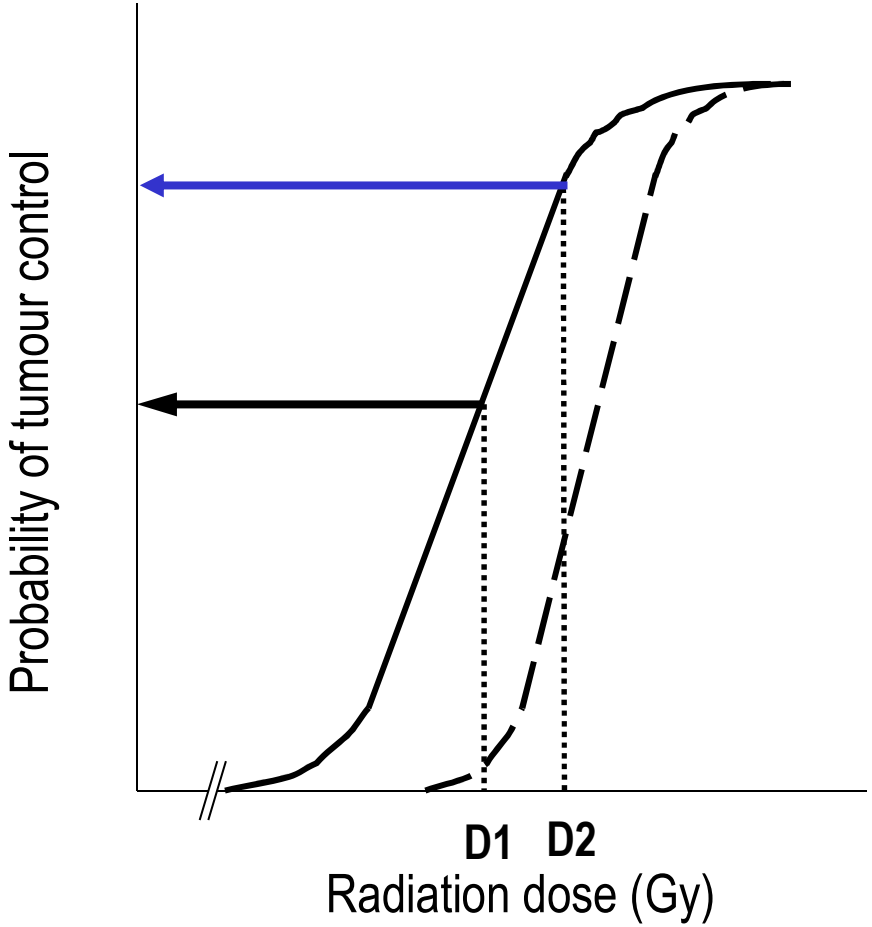
New targeted drugs unlikely to be effective stand-alone therapies

- Number of cells
- Heterogeneity in the target
- Adaptation to the agent

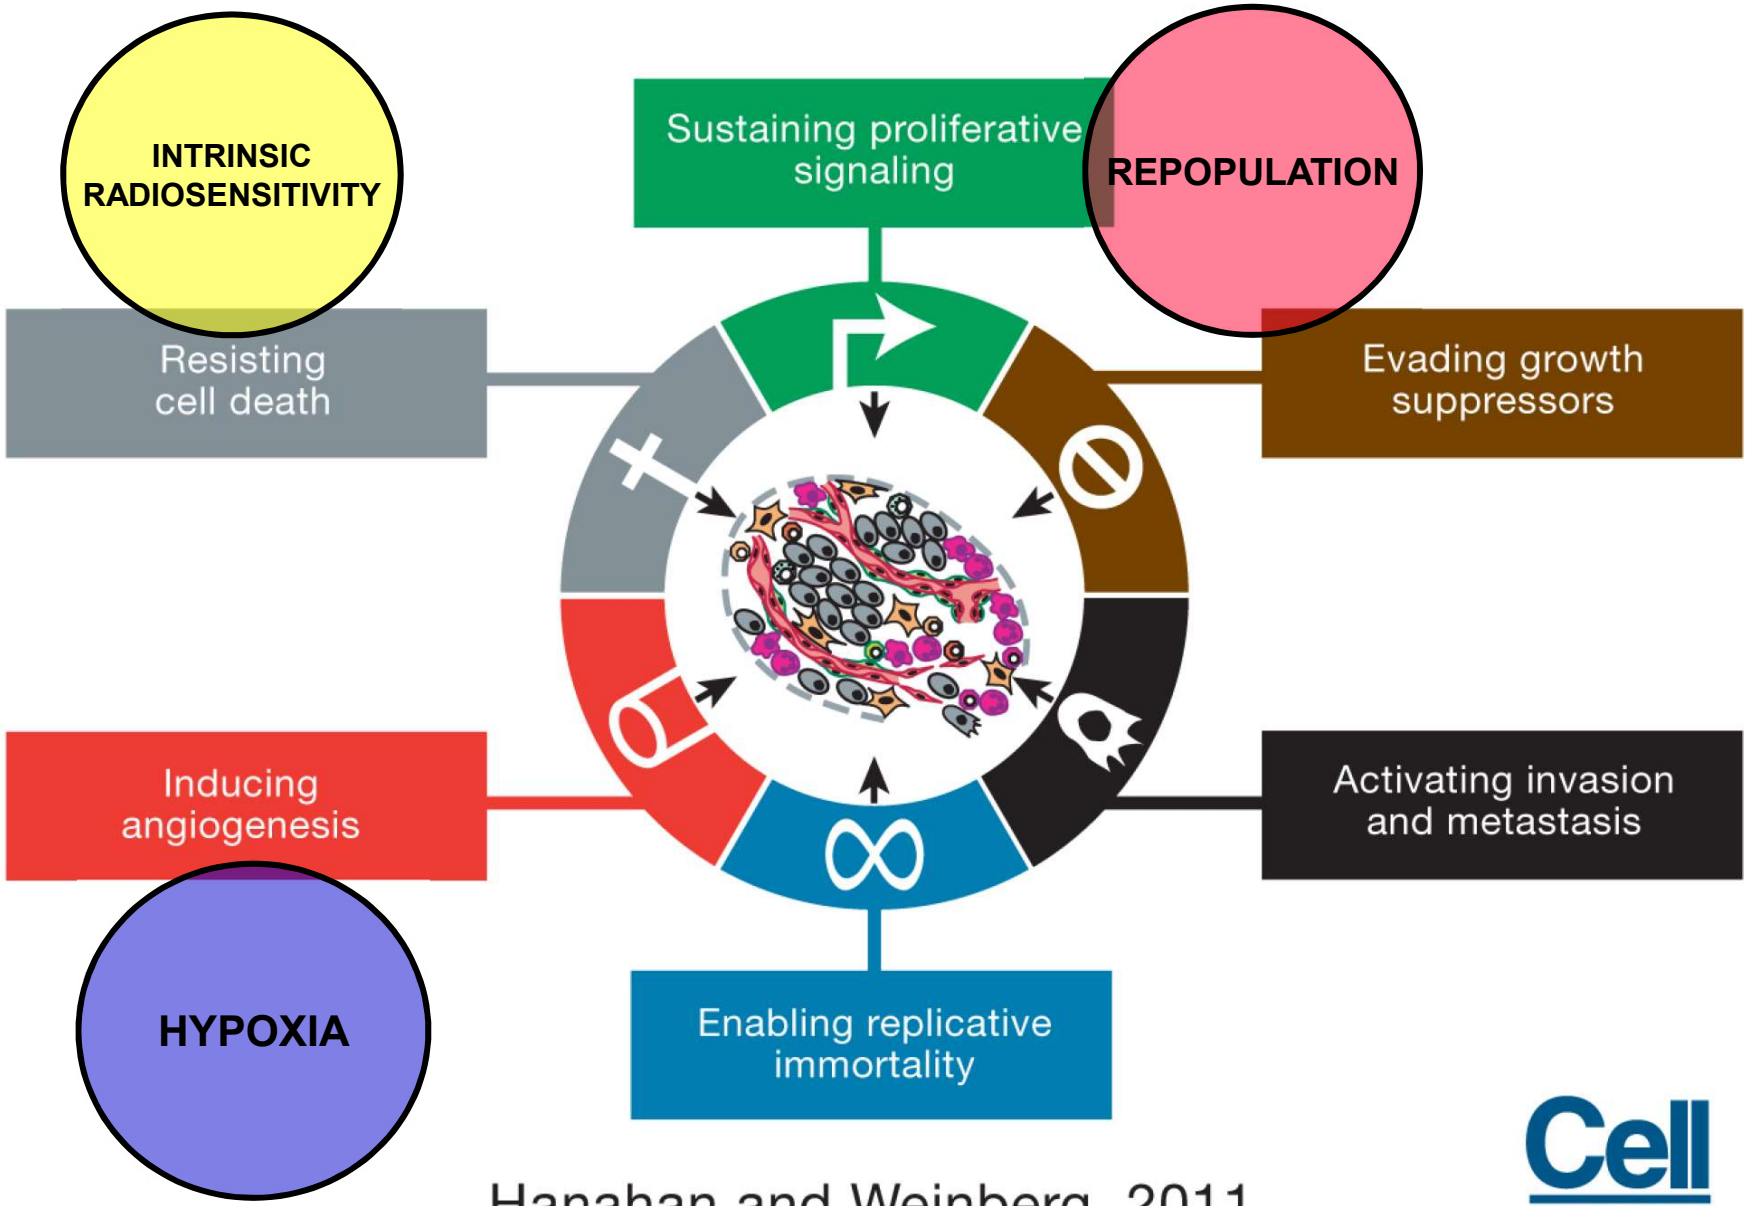


Targeting with RT: the last drop





Targeting with RT: favorable combinations

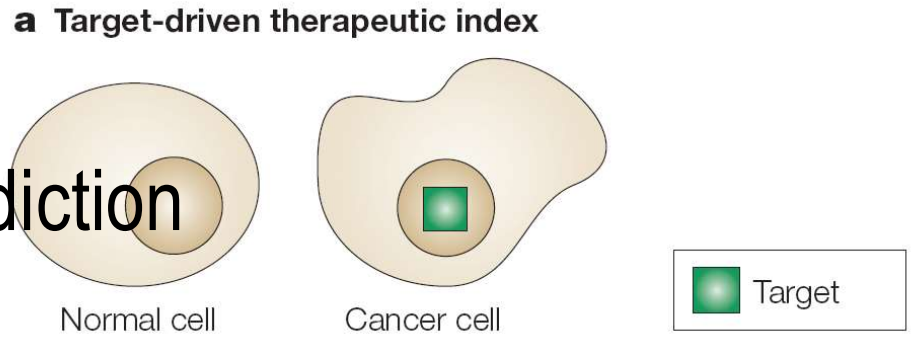


Hanahan and Weinberg, 2011

Cell PRESS

Making choices: Therapeutic index

Oncogene addiction



Bcr-abl (Gleevec)
B-raf (PLX4032)
EGFR (Iressa)

Synthetic lethality

PARP/BRCA2

Contextual synthetic lethality

VEGF (Avastin)
Hypoxia tolerance

Example 1: Target driven lethality - EGFR

Tumors showing high EGFR expression

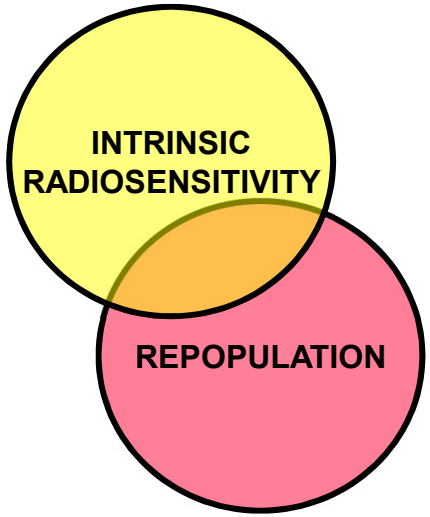
• NSCLC	40-80%
• Prostate	40-80%
• Gastric	33-74%
• Breast	14-91%
• Colorectal	25-77%
• Pancreatic	30-50%
• Ovarian	35-70%
• Bladder	31-48%
• Renal cell	50-90%
• H&N	80-100%
• Glioma	40-63%
• Esophageal	43-89%

High expression generally associated with

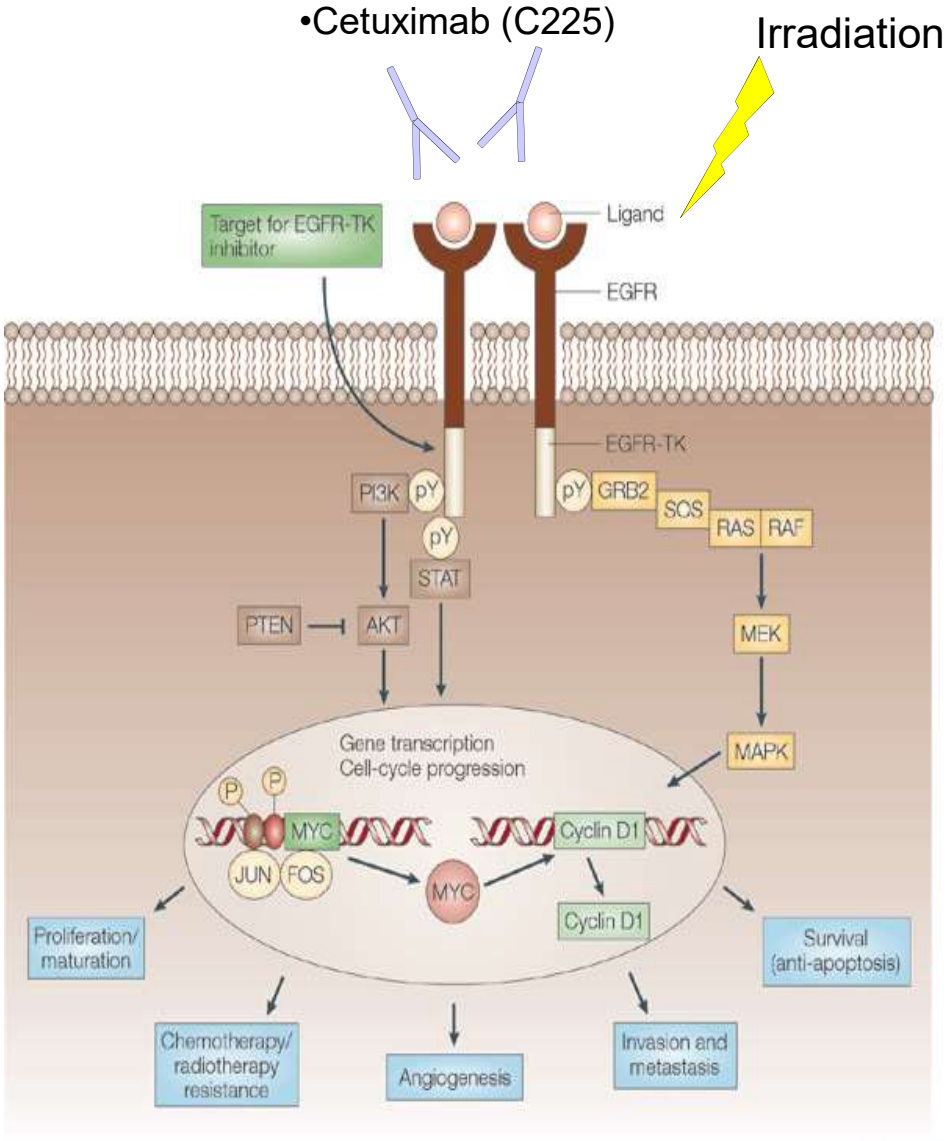
- **Invasion**
- **Metastasis**
- **Late-stage disease**
- **Chemo-/Radiotherapy resistance**
- **Poor outcome**

Example 1: Target driven lethality (EGFR)

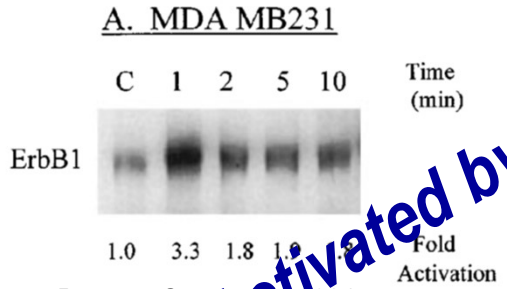
EGFR



- **Proliferation**
  - MAPK signaling
- **Radiosensitivity**
  - PI3K signaling
  - DNA repair

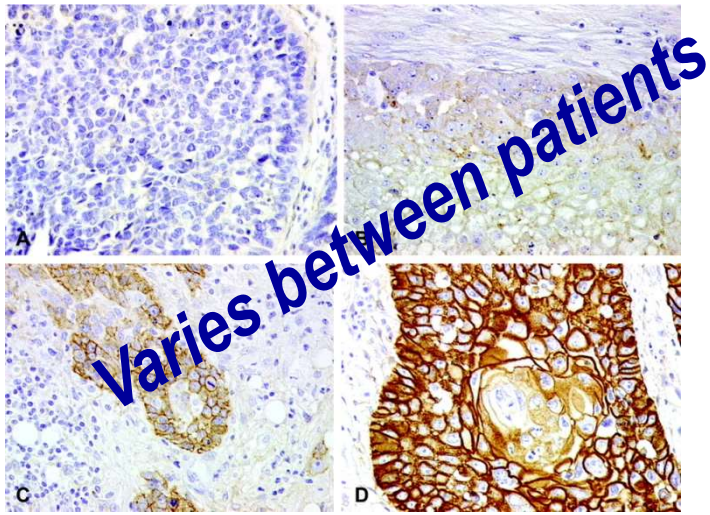


Example 1: Target driven lethality (EGFR)

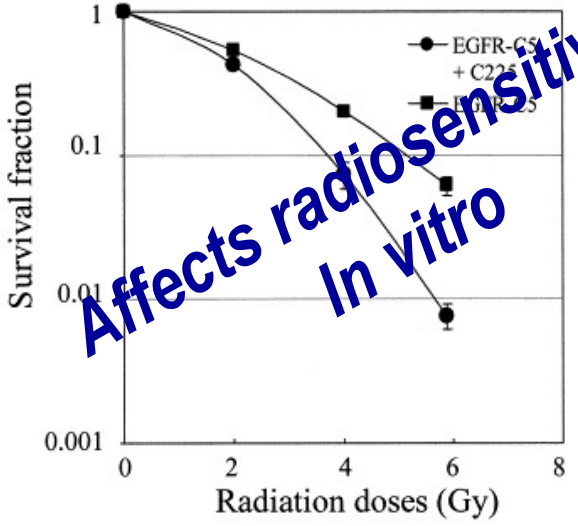


Bowers, Oncogene, 2001

Activated by radiation

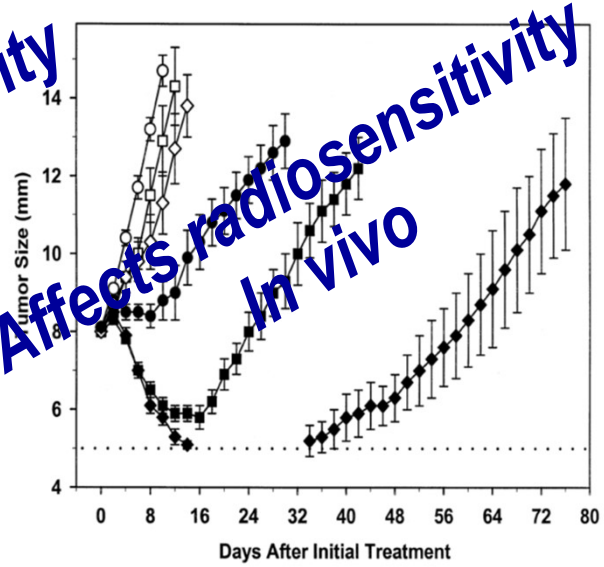


Varies between patients

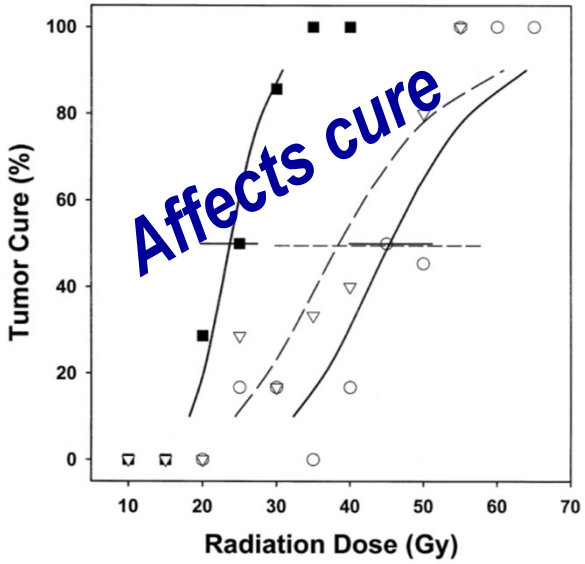


Affects radiosensitivity In vitro

Liang, IJROBP, 2003



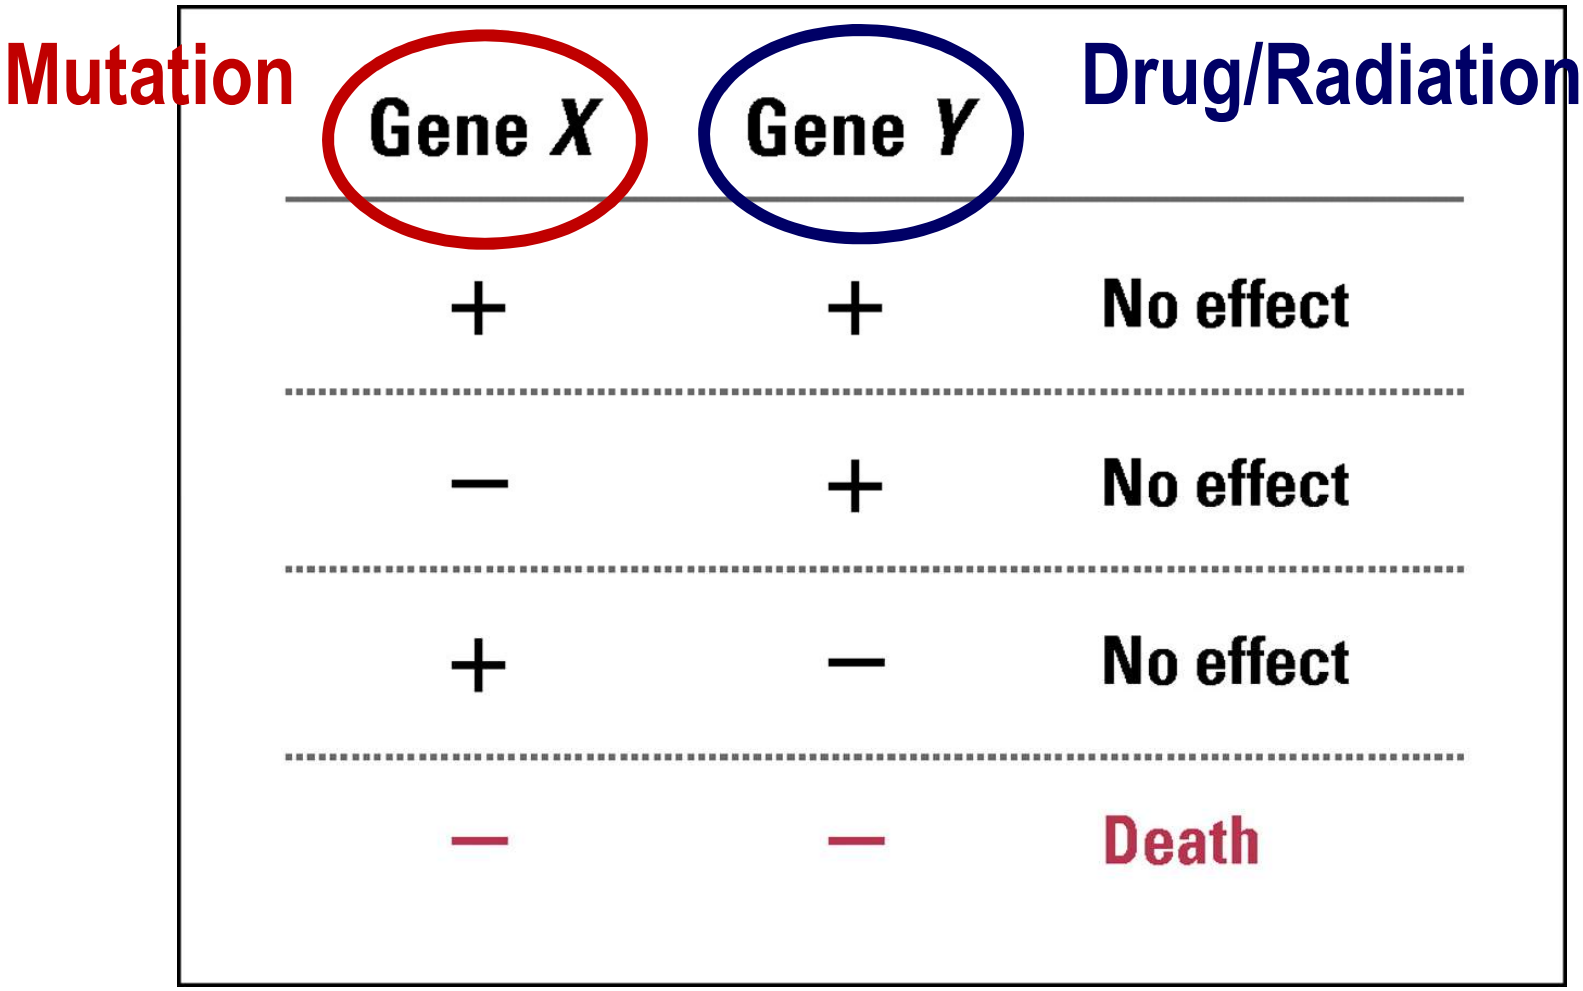
Affects radiosensitivity In vivo



Affects cure

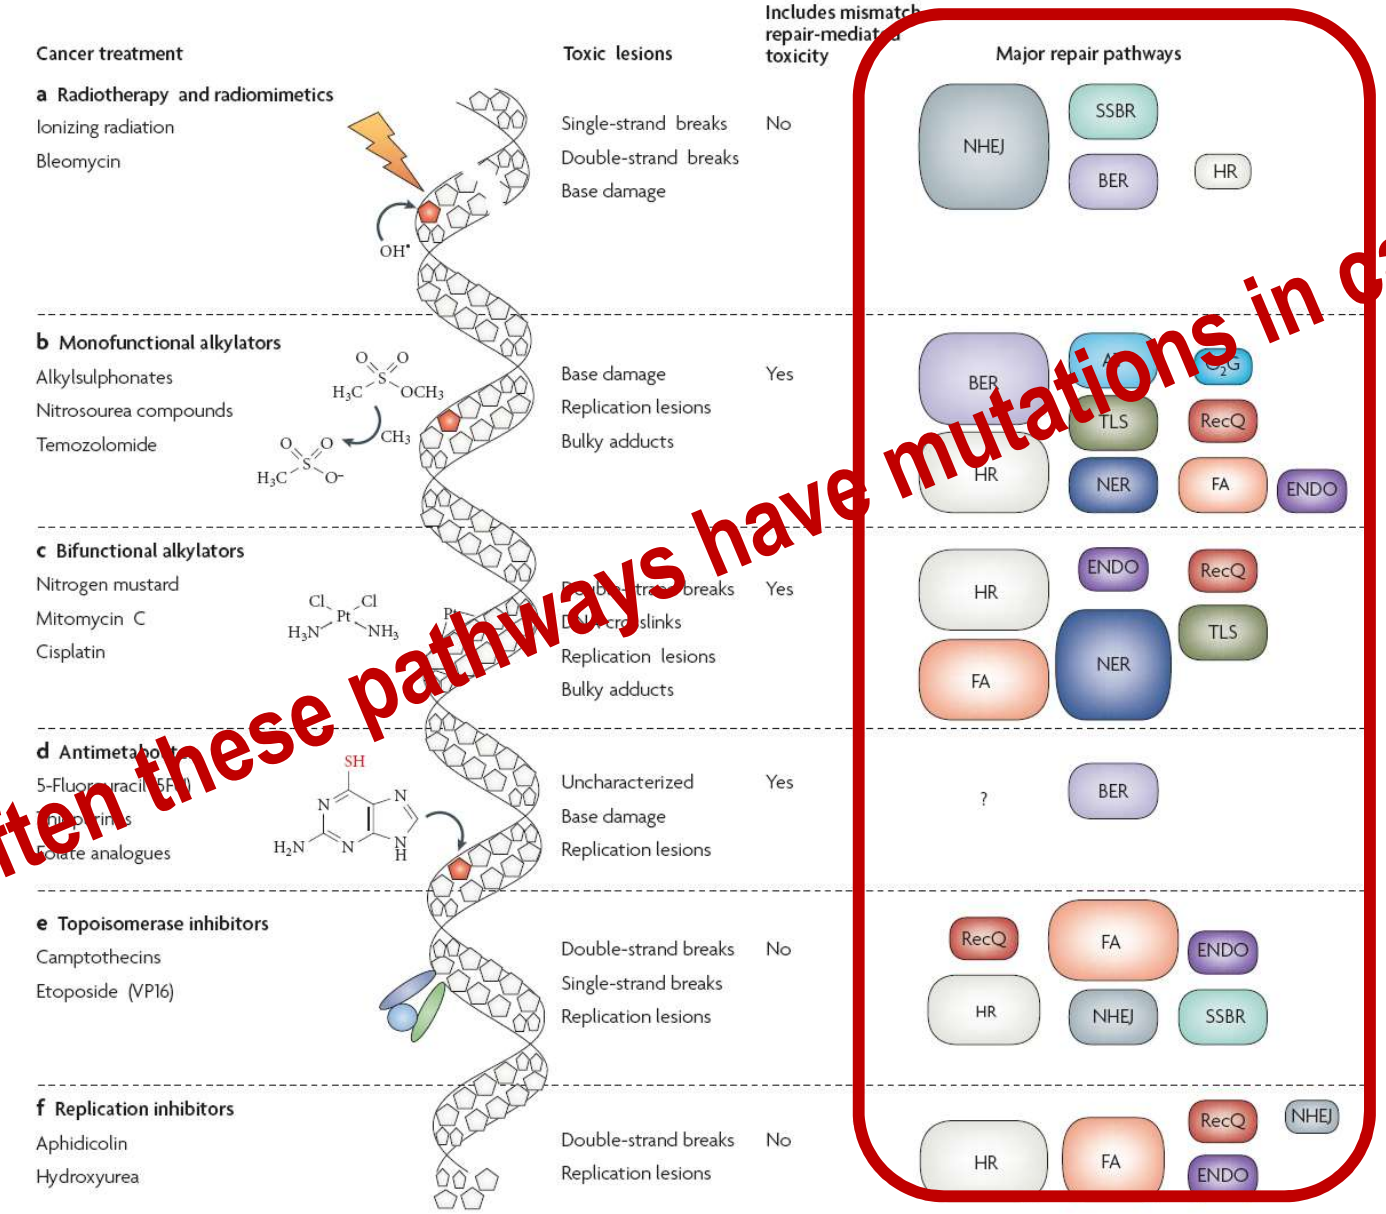
Milas, IJROBP, 2004

The Concept of Synthetic Lethality



Ashworth, A. J Clin Oncol; 26:3785-3790 2008

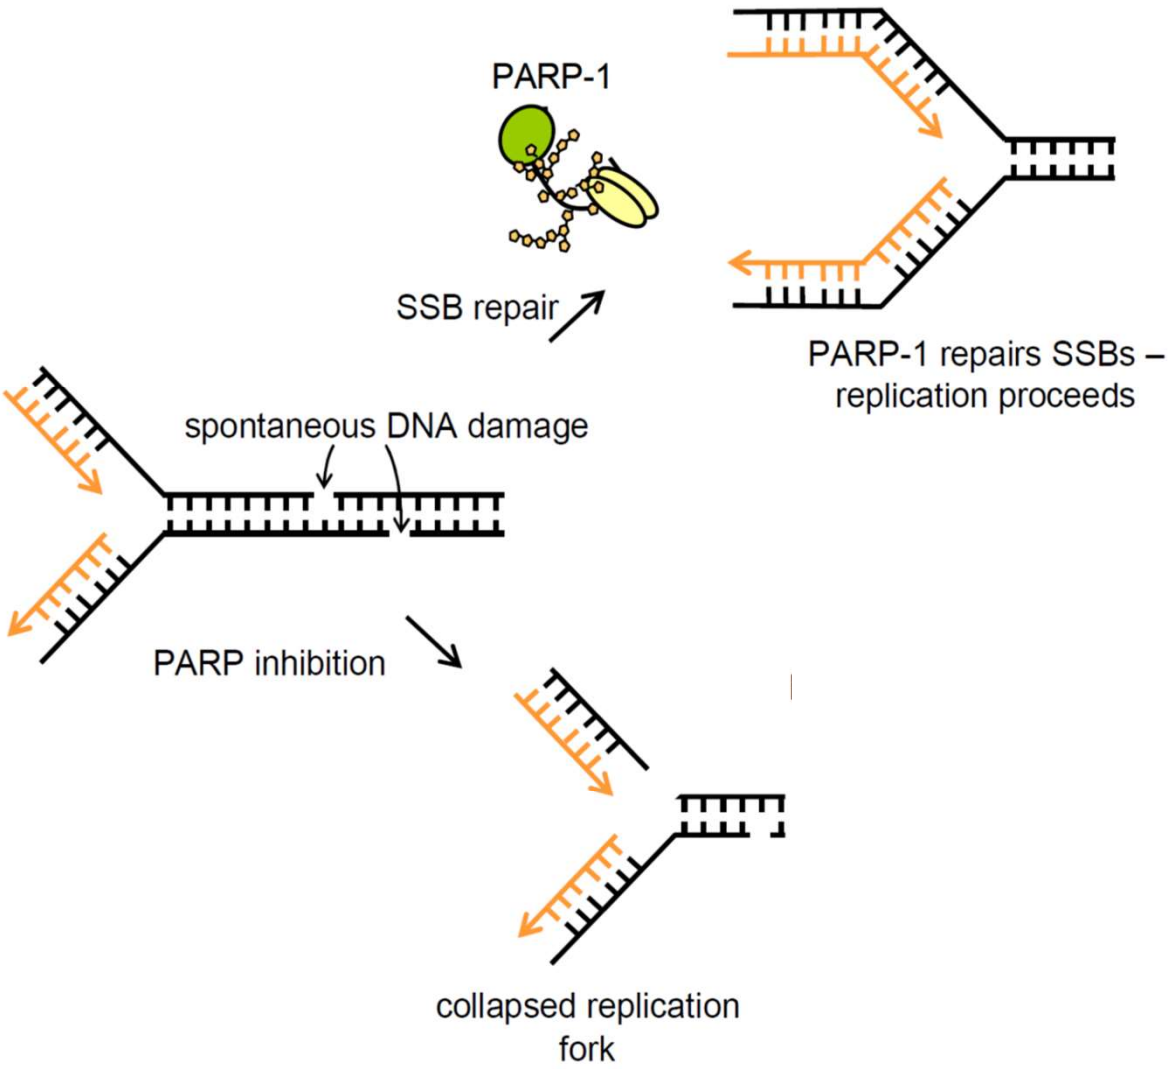
Example 2 – Synthetic lethality



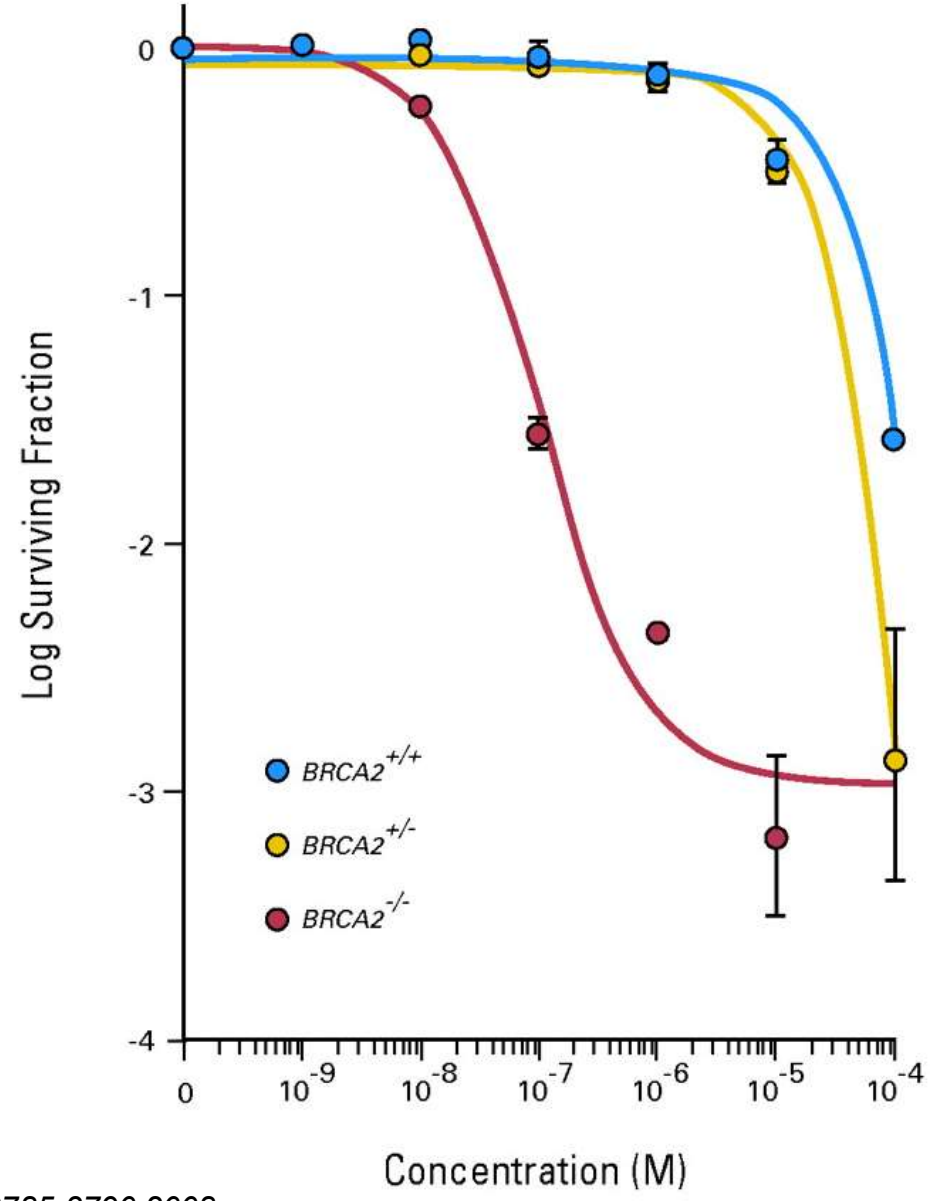
INTRINSIC RADIOSENSITIVITY

Often these pathways have mutations in cancers

2. Synthetic lethality: PARP inhibitors for BRCA2$^{-/-}$



2. Synthetic lethality: PARP inhibitors for BRCA2$^{-/-}$



Ashworth, A. J Clin Oncol; 26:3785-3790 2008

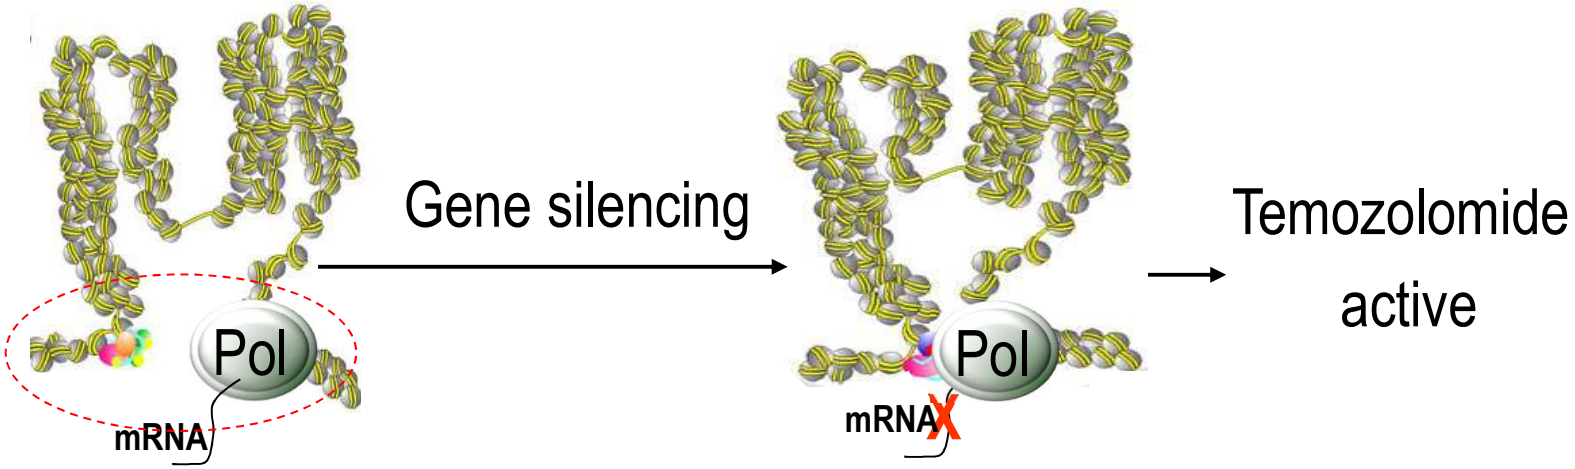
2. Synthetic lethality: Temozolomide for MGMT silencing

The NEW ENGLAND JOURNAL of MEDICINE

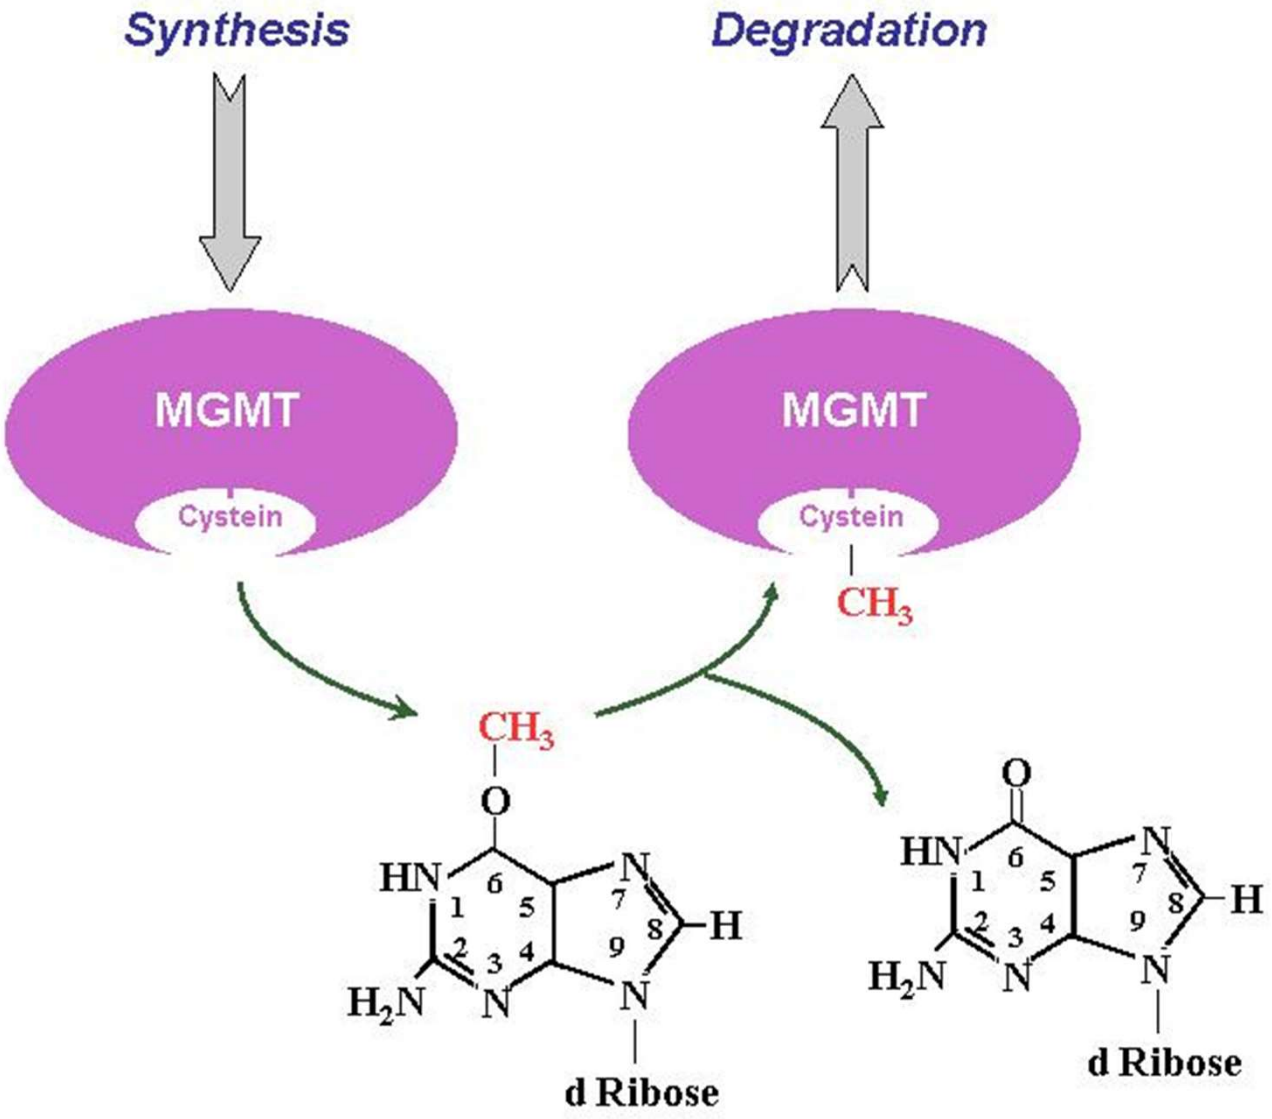
ORIGINAL ARTICLE

MGMT Gene Silencing and Benefit from Temozolomide in Glioblastoma

Monika E. Hegi, Ph.D., Annie-Claire Diserens, M.Sc., Thierry Gorlia, M.Sc., Marie-France Hamou, Nicolas de Tribolet, M.D., Michael Weller, M.D., Johan M. Kros, M.D., Johannes A. Hainfellner, M.D., Warren Mason, M.D., Luigi Mariani, M.D., Jacoline E.C. Bromberg, M.D., Peter Hau, M.D., René O. Mirimanoff, M.D., J. Gregory Cairncross, M.D., Robert C. Janzer, M.D., and Roger Stupp, M.D.



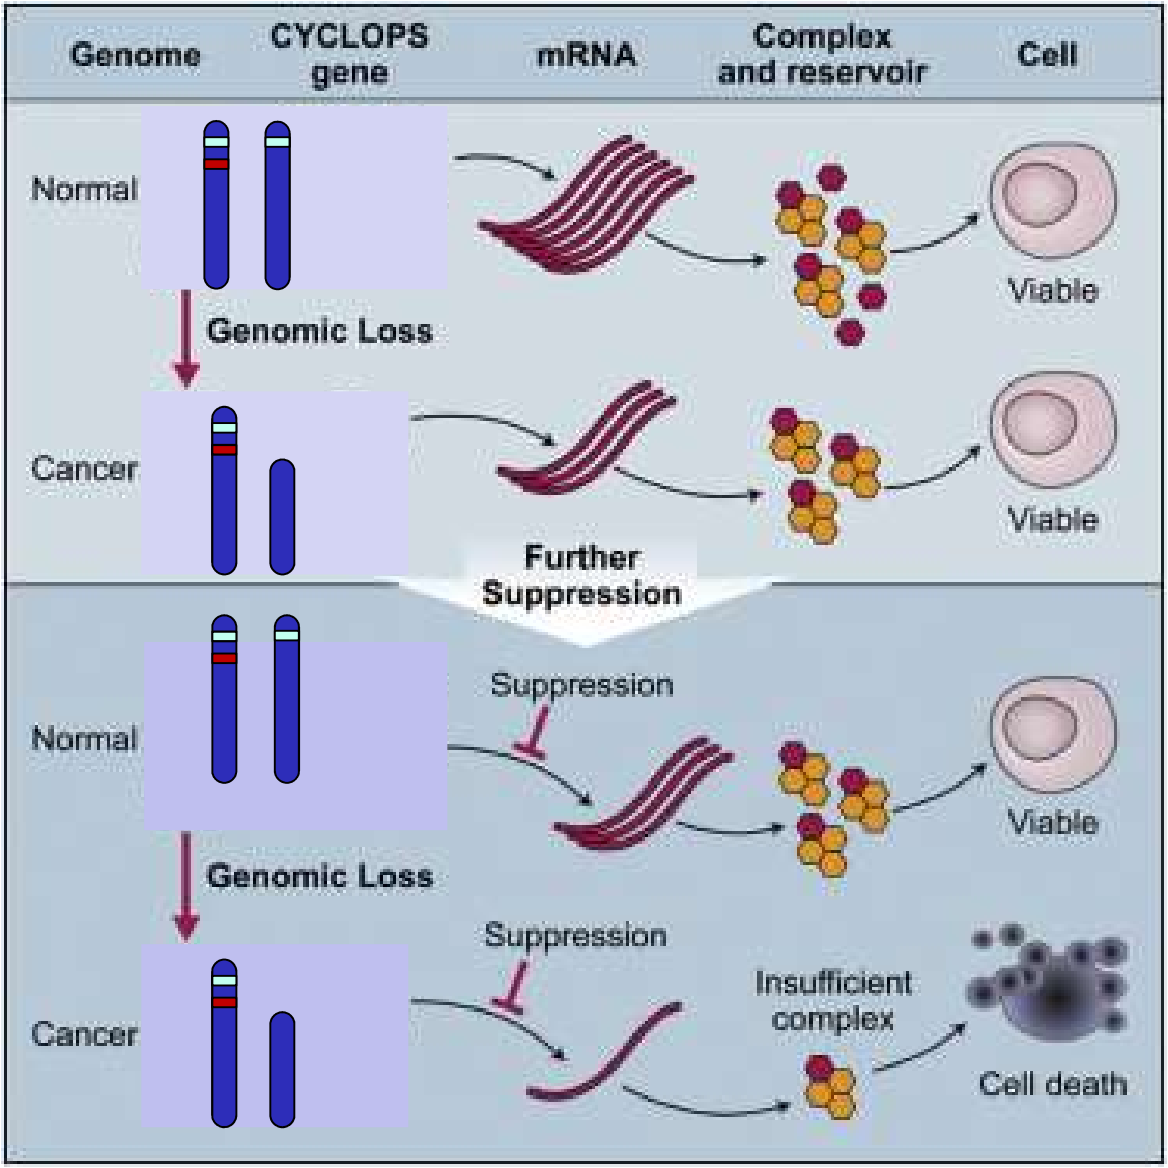
2. Synthetic lethality: Temozolomide for MGMT silencing



2. Synthetic lethality: CYCLOPS

Copy number alterations Yielding Cancer Liabilities Owing to Partial losS

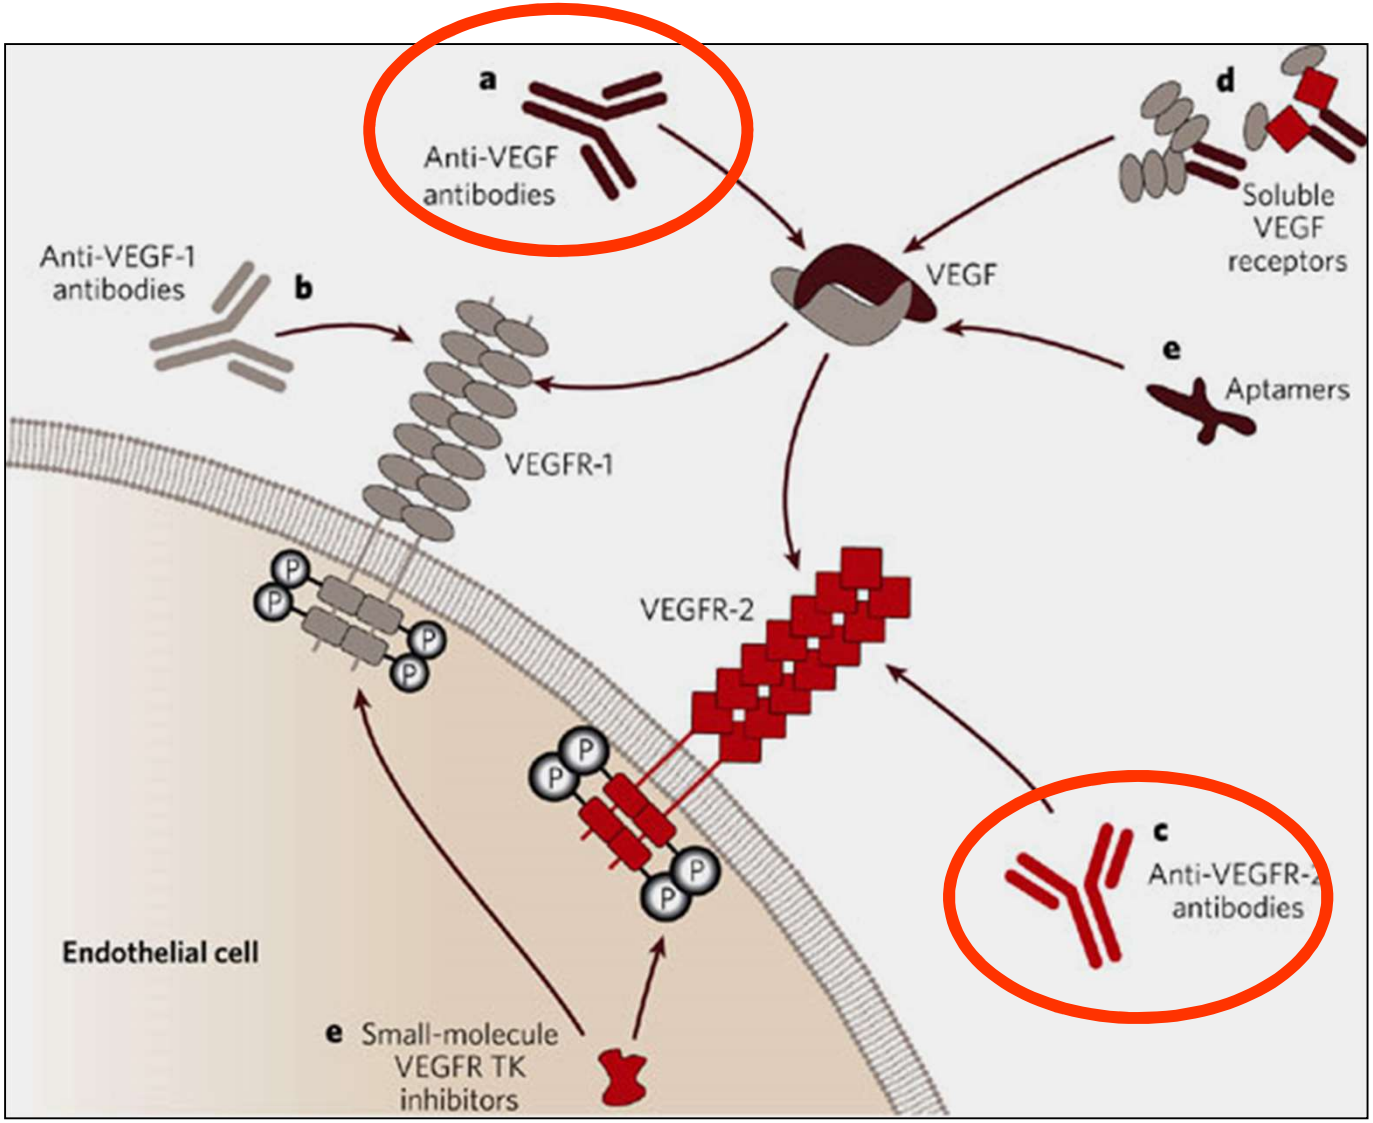
- Tumor suppressor
- CYCLOPS gene



Nijhawan et al., Cell 2012

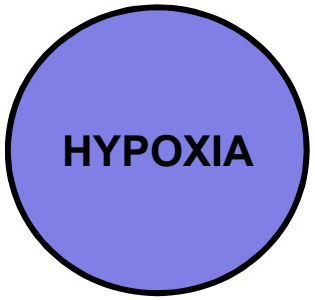
Example 3: Contextual lethality - VEGF

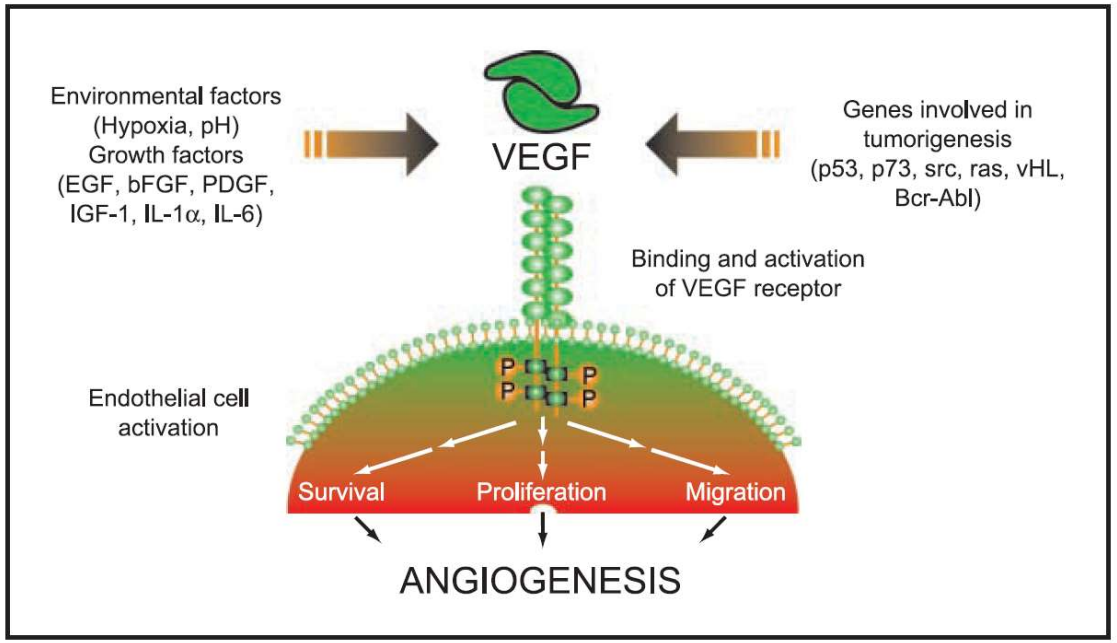
HYPOXIA



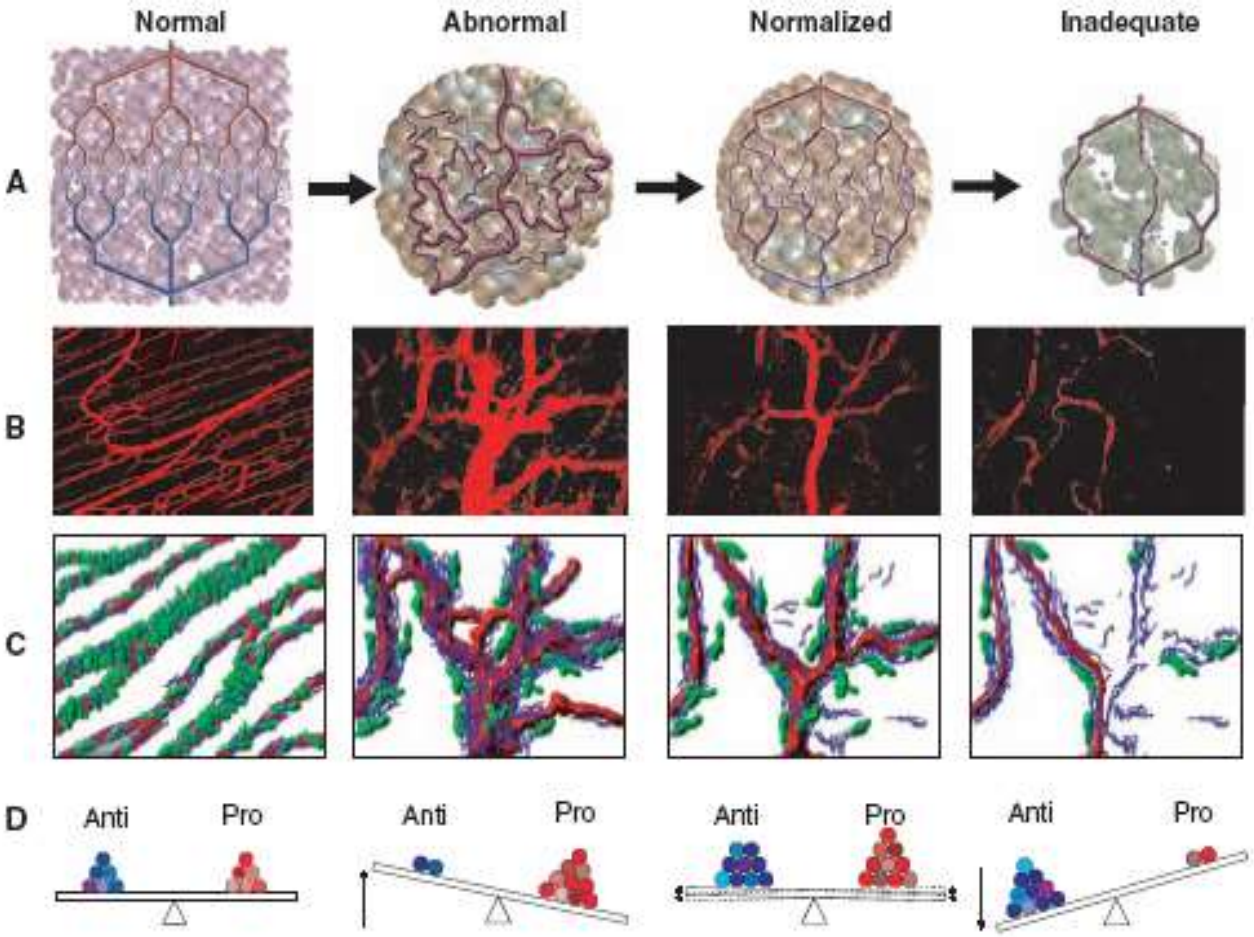
Example 3: Contextual lethality - VEGF

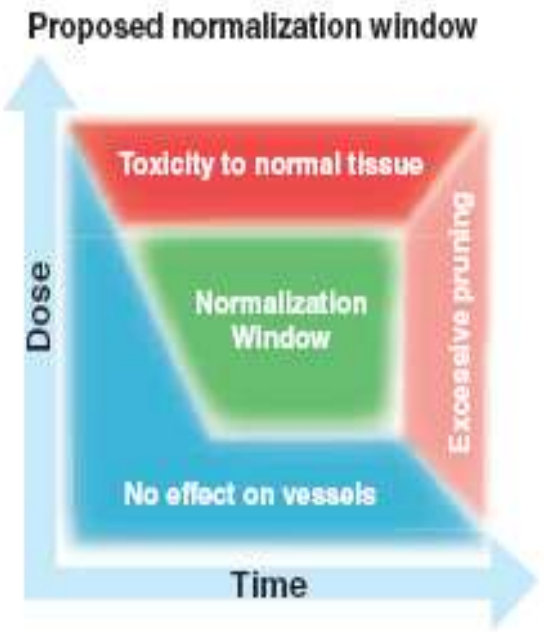
- VEGF plays central role in tumor angiogenesis
- VEGF is induced by hypoxia and expressed by many tumors
- VEGF circulates in the blood, and acts directly on endothelial cells



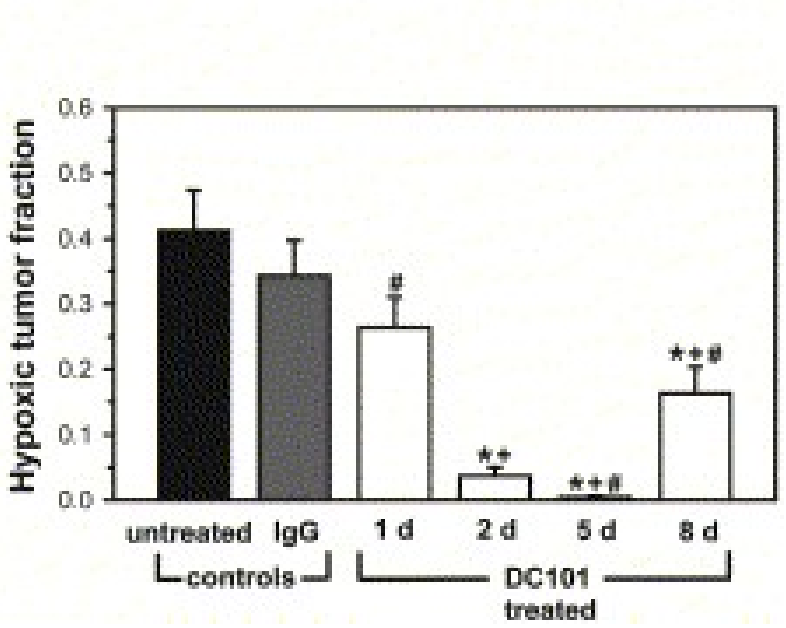


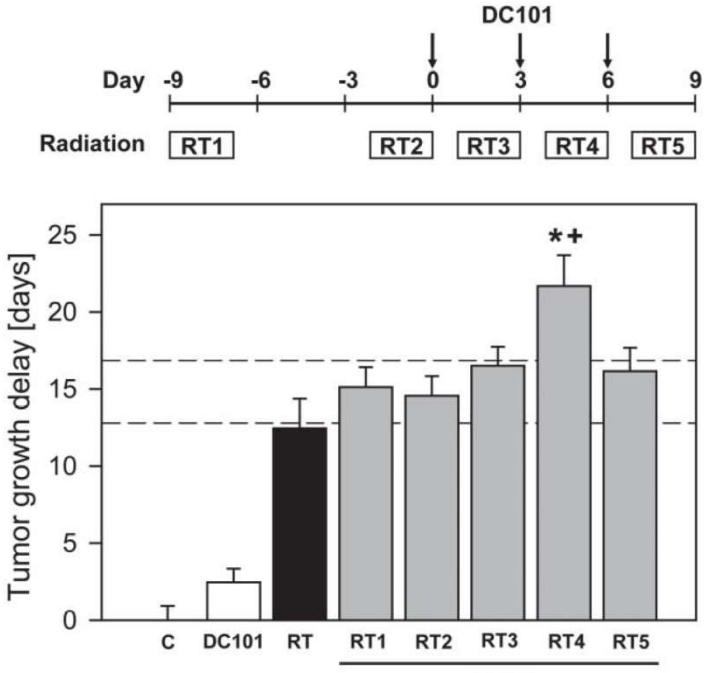
Normalisation of Tumour Vasculature

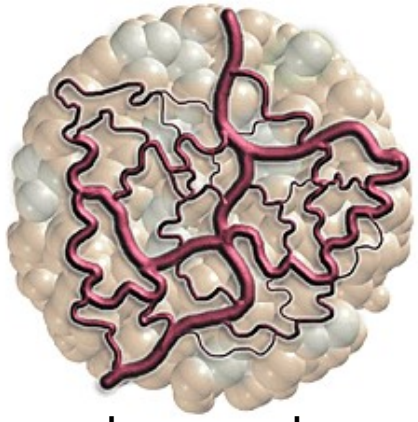




VEGF targeting can improve radiation response



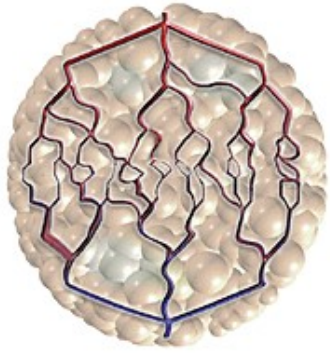




abnormal vasculature

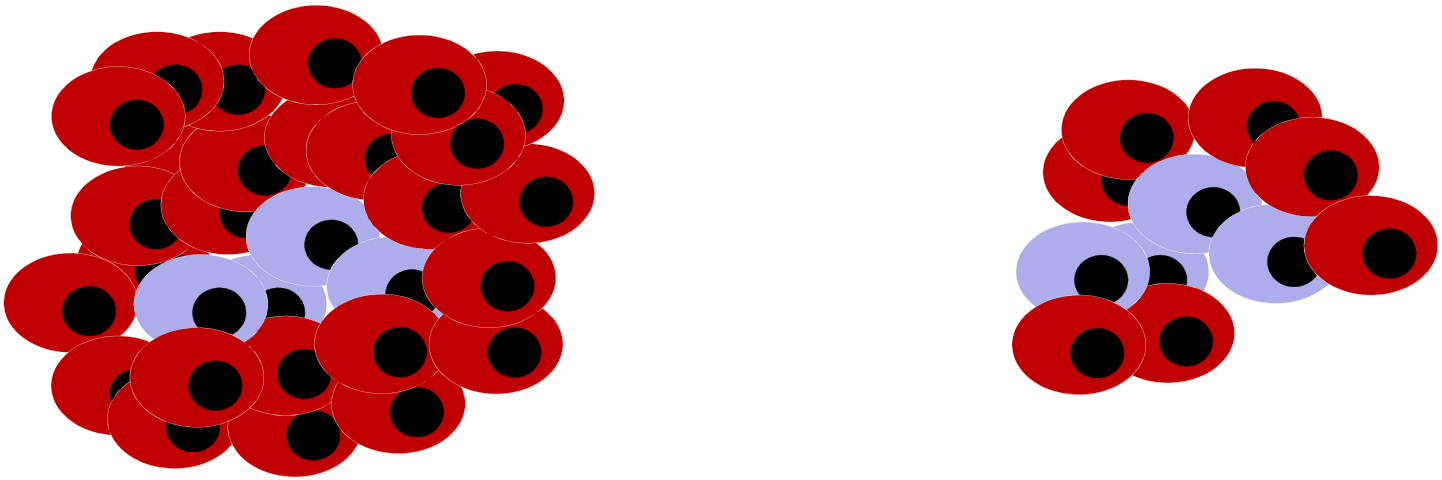
during treatment with DC101

Winkler et al., Cancer Cell,2004, 6, 553ff



normalized vasculature

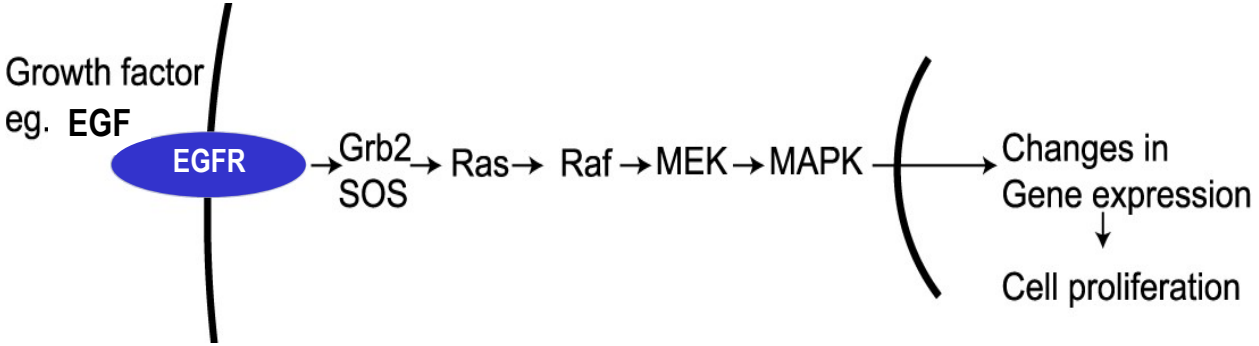
Molecular targeting: Challenges
Tumor subpopulations



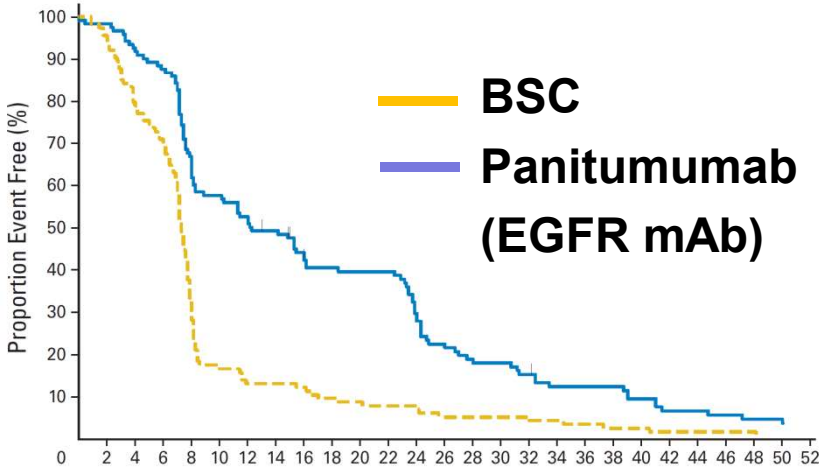
Tumor bulk, determines response

Rare cell, determines cure

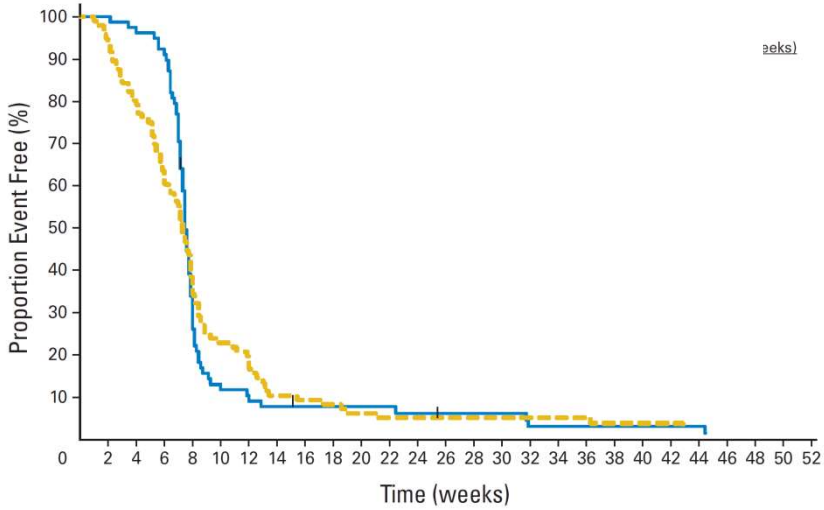
Molecular targeting: Challenges Biomarkers



Ras WT

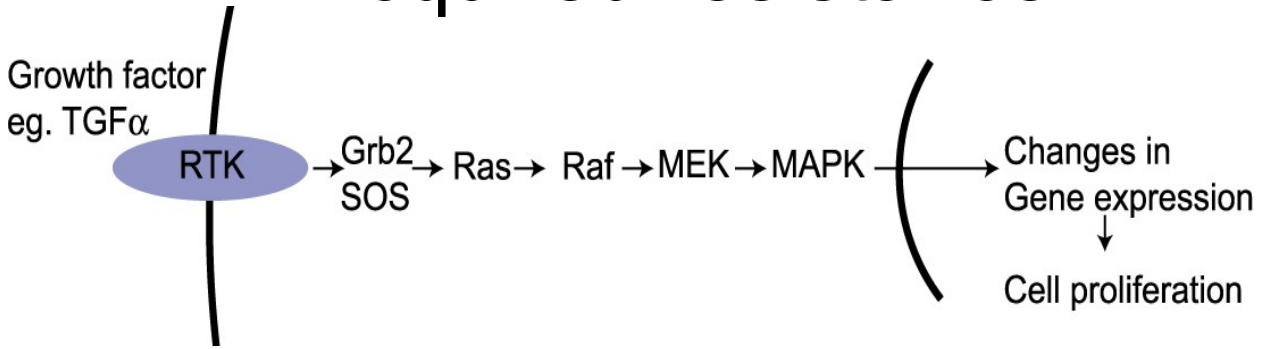


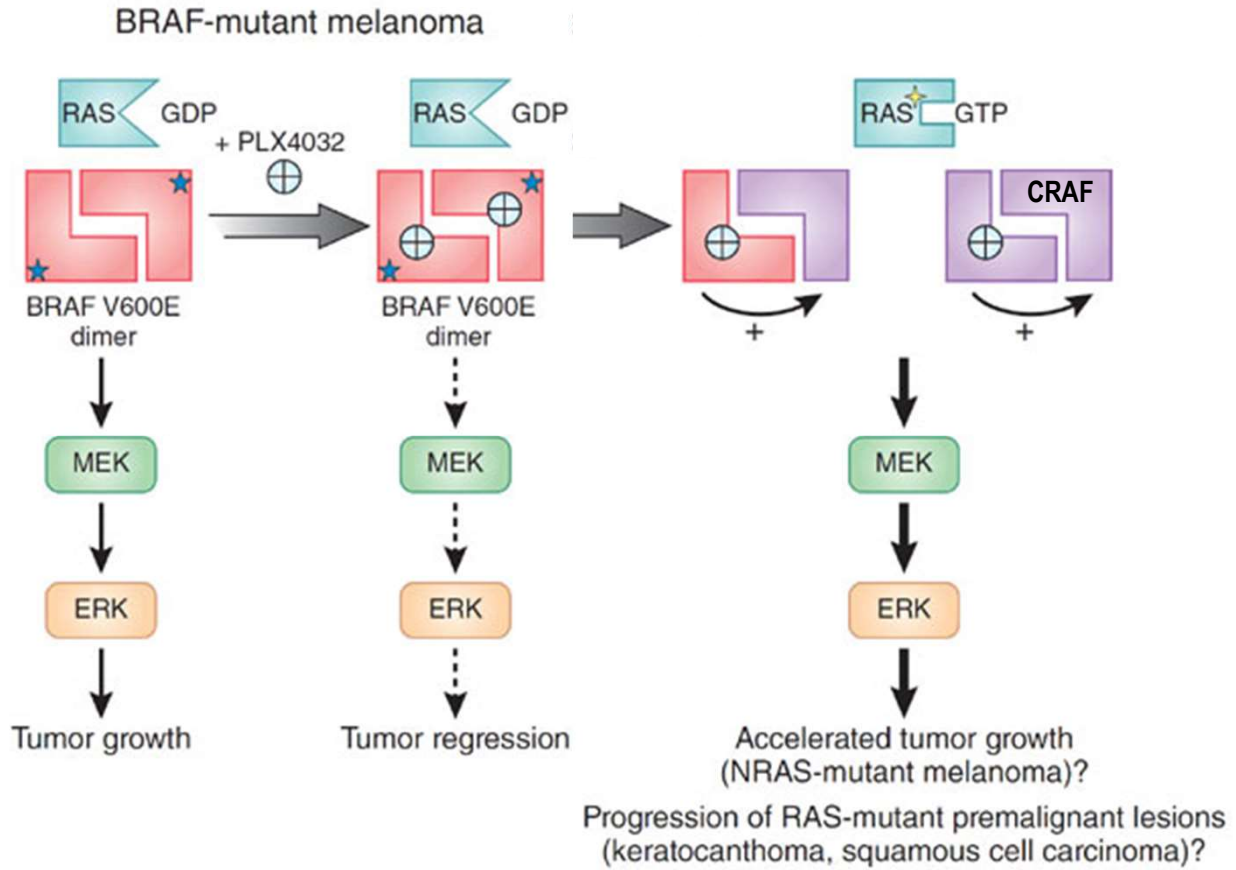
Ras MT



Amado, JCO 2008

Molecular targeting: challenges
Acquired resistance



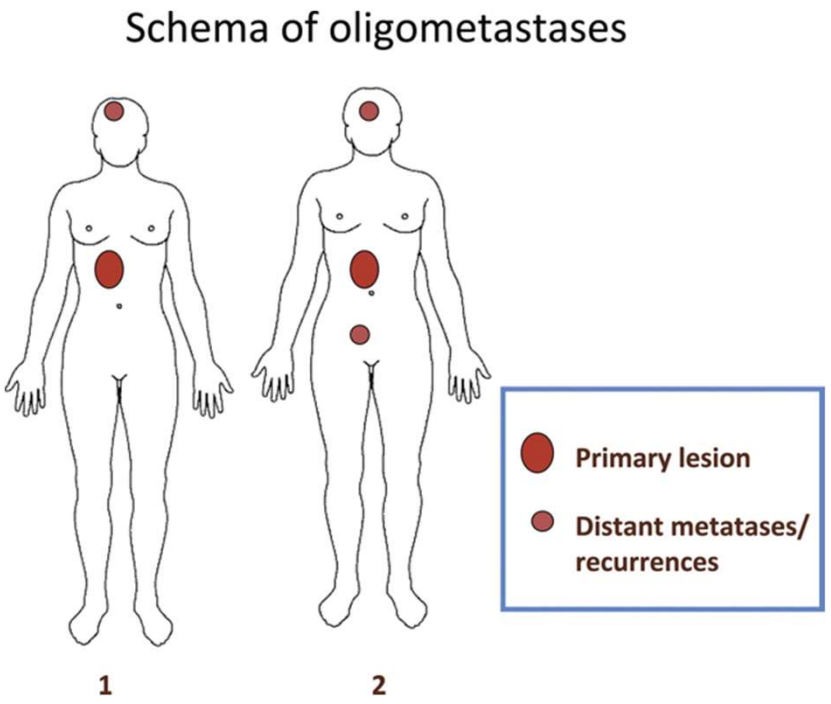


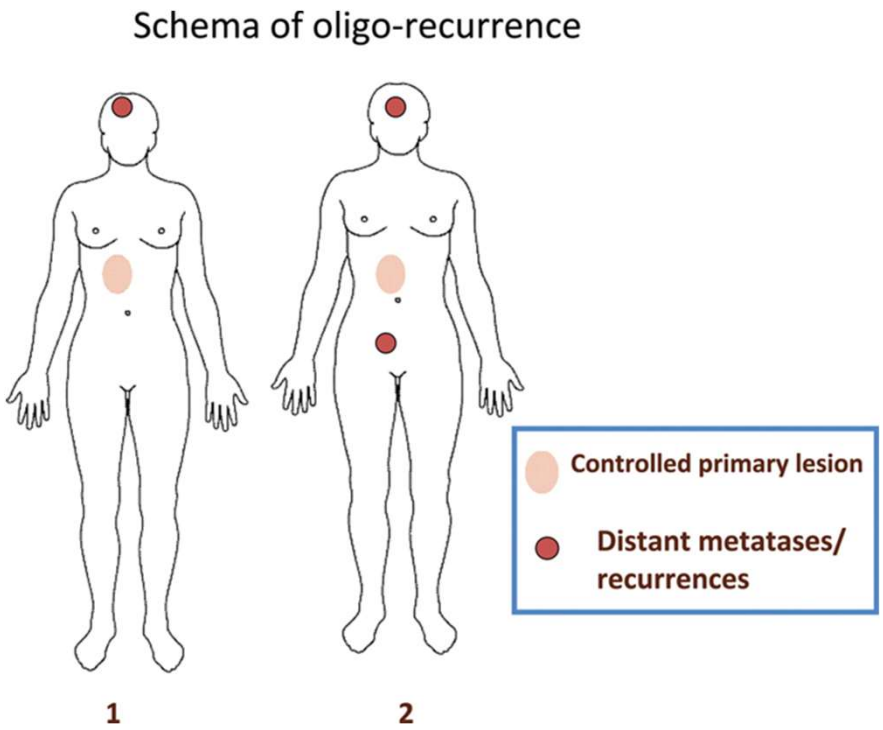
Challenge - High quality translational research

- New targeted therapies require different clinical trials
  - New therapies may be highly TUMOR or PATIENT specific – *need biomarkers*
  - Single attributes (eg hypoxia) or single molecules (EGFR) are targets
  - Benefit limited to specific, perhaps small patient populations

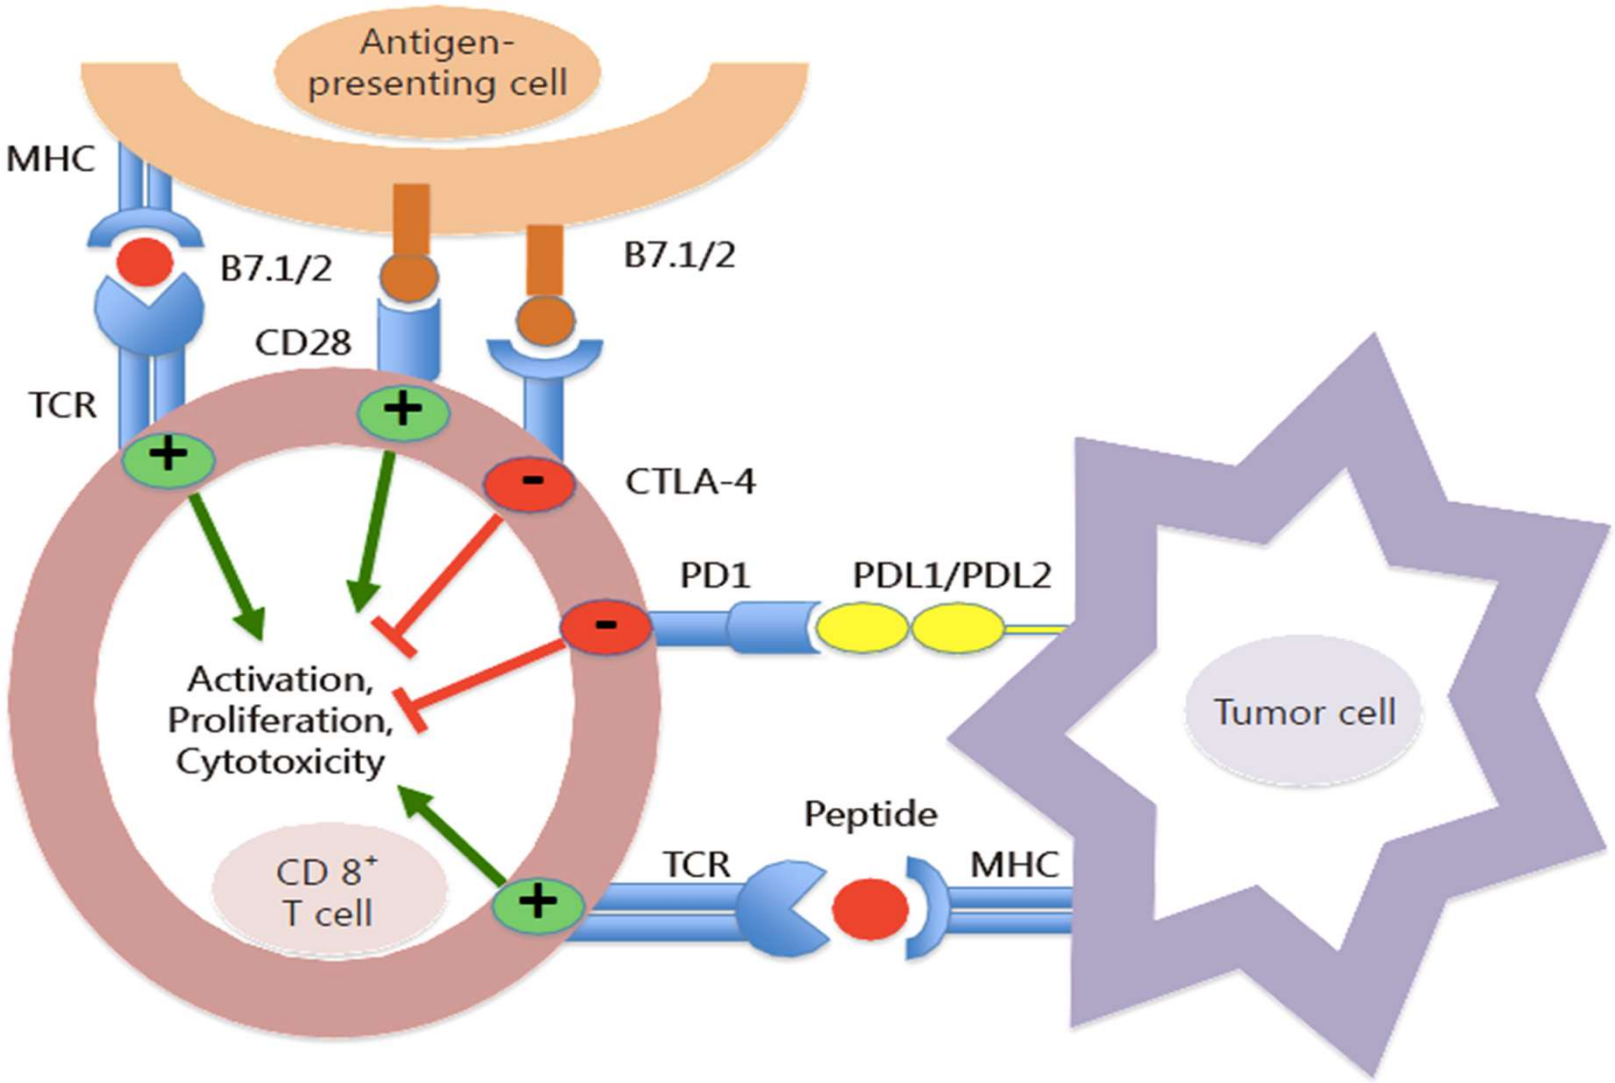
Radiation will become a part of curative systemic therapies

Oligometastases





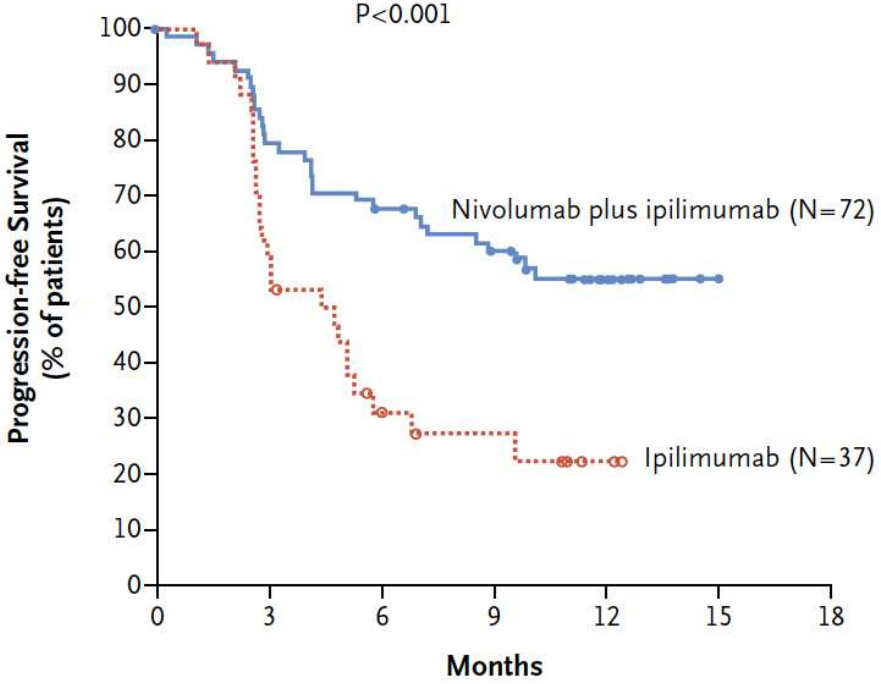
Immune therapies: Blocking CTLA4 and PD1 signaling



Immune therapy

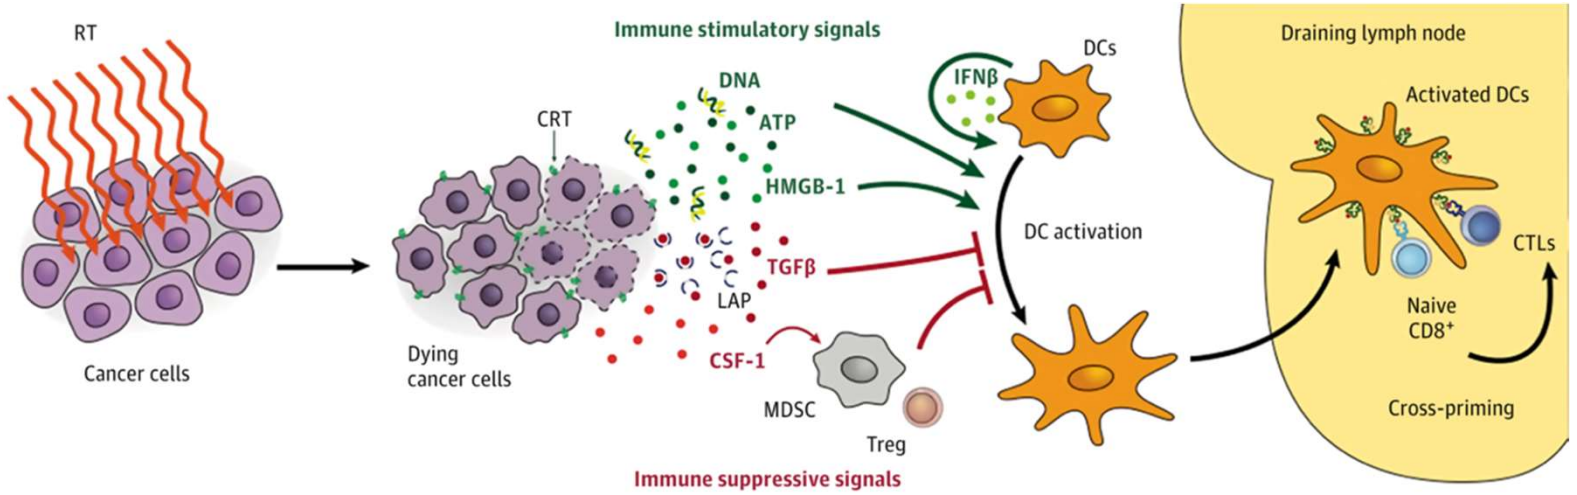
	Death or Disease Progression	Median Progression-free Survival
	no. of patients/total no.	*mo (95% CI)*
Nivolumab plus Ipilimumab	30/72	NR
Ipilimumab	25/37	4.4 (2.8–5.7)

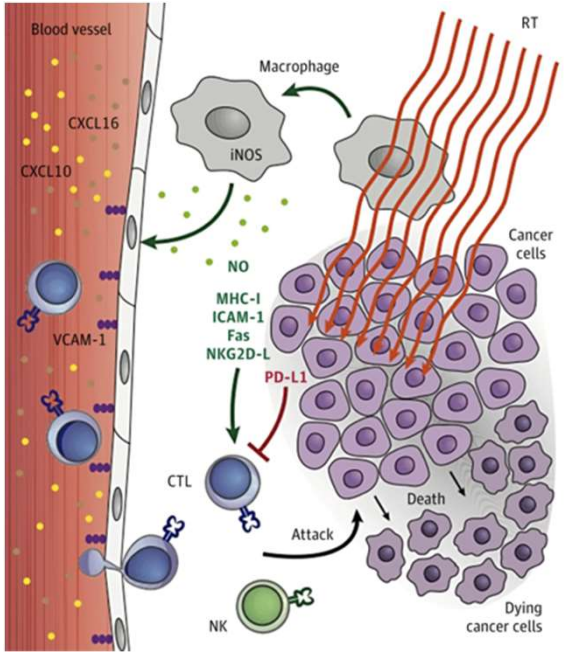
Hazard ratio, 0.40 (95% CI, 0.23–0.68)
P<0.001



No. at Risk							
Nivolumab plus ipilimumab	72	54	45	38	20	1	0
Ipilimumab	37	20	9	6	2	0	0

NEJM - 2015





The total dose and fractionation dose affect these processes in a way that may be distinct from effects on cell survival

•JAMA Oncol. Published online August 13, 2015. doi:10.1001/jamaoncol.2015.2756

Summary

- New biological agents are here and more are coming monthly
- Biological agents can be combined with radiation in a rational way
  - Target something important/different in cancer
  - Target something important for radiotherapy
- Patient selection/individualization will become more important as these agents enter the clinic

Immune modulation

Herrera FG et al CA Cancer J Clin 2017

- Clinical efficacy of RT
  - Traditionally: local effect, through direct tumor cell death (DNA damage)
  - More recently: systemic effects on “out-of-field” tumor deposits = abscopal effect, mediated by immune mechanisms

  - RT induces ‘in situ’ vaccination
  - RT reprograms the tumor micro-environment

Immune mechanisms triggered by RT

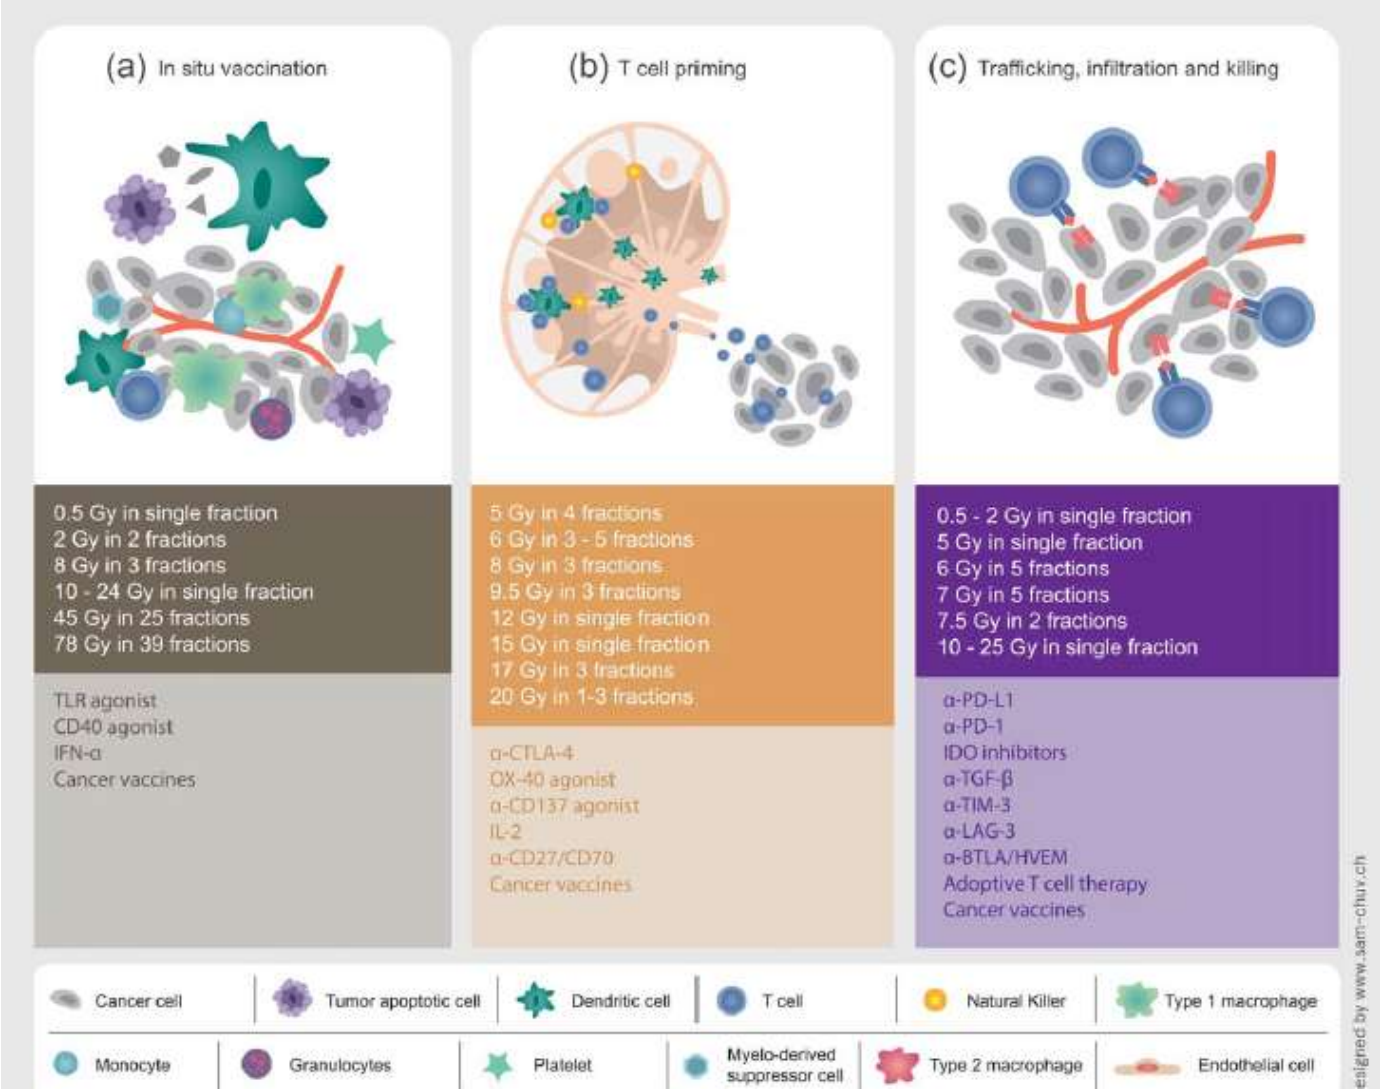
Dörthe Schaue and William H. McBride, Nature 2015

Radioimmunotherapy combinations

- 3 main clinical scenario's
  - IT + hypofractionated RT for oligometastatic disease
    - Clinical goal: reduce distant failures (effect outside radiation field)
    - Mechanism: in situ vaccination effect coupled to local and systemic effects IT
  - IT + chemoRT
    - Clinical goal: enhance efficacy of chemo-RT locally and reduce distant failures
    - Mechanism: local and distant synergies between RT and immunomodulation
  - RT + IT
    - Clinical goal: maximize efficacy of IT against specific tumor deposit (effect within radiation field)
    - Mechanism: RT = biological response modifier

Radioimmunotherapy combinations

Herrera FG et al CA Cancer J Clin 2017

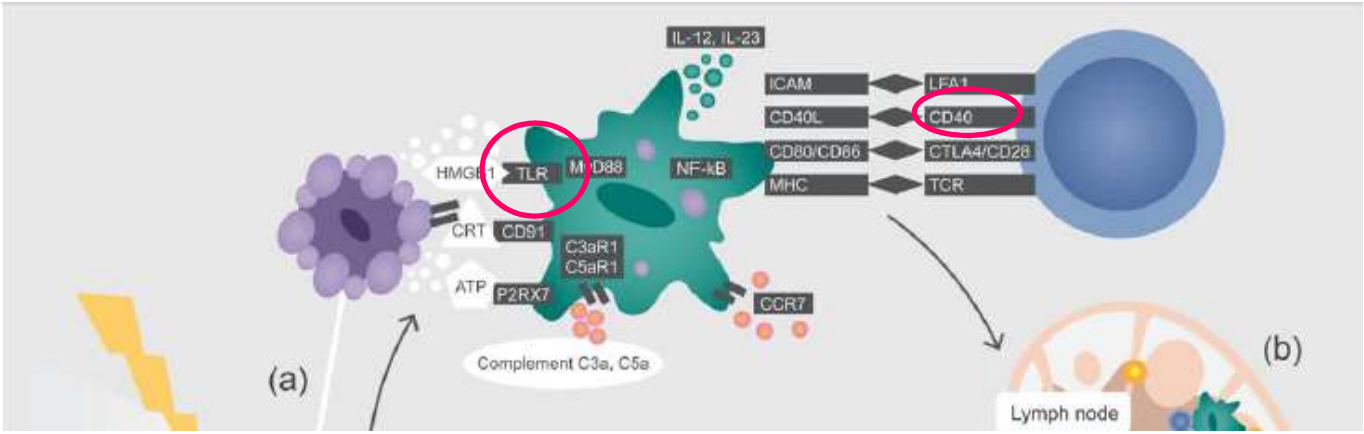


ESTRO School

Boosting in situ vaccination effect of RT

Herrera FG et al CA Cancer J Clin 2017

- Pharmacological activation of APCs → because immunomodulatory effects of RT are often not sufficient to trigger effective antitumor immune response due to potent immune suppression in tumor micro-environment and draining lymph node
- E.g. agonists of stimulator receptor CD40 and to TLR

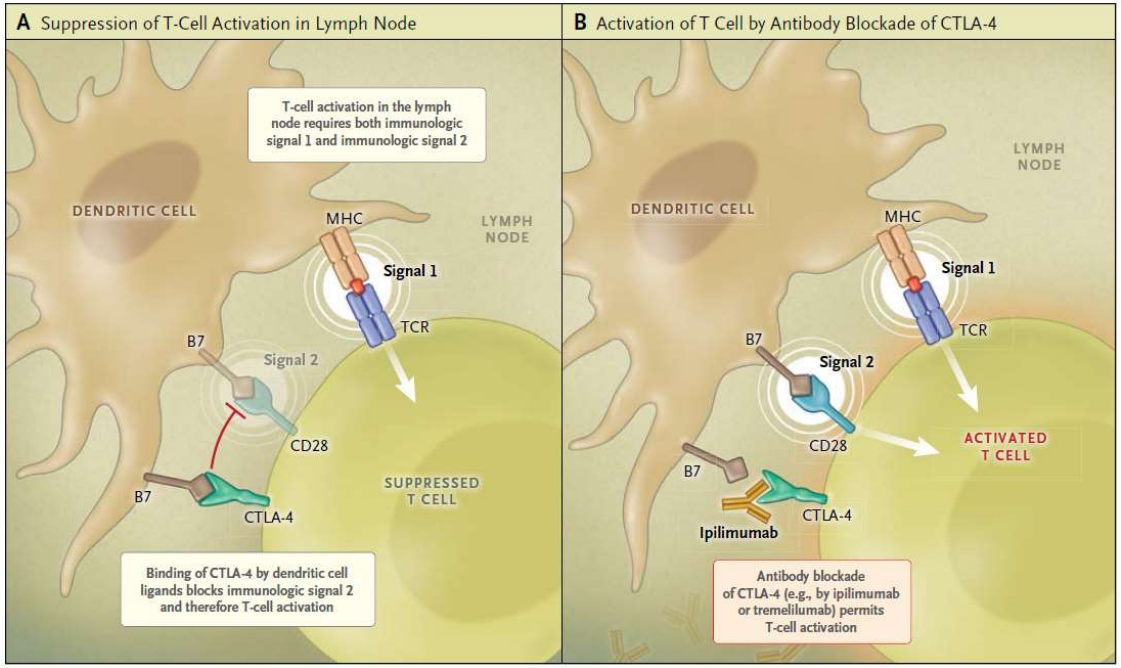


ESTRO School

T-cell priming

Herrera FG et al CA Cancer J Clin 2017

- Agonistic antibodies directed against costimulatory molecules on T-cells and/or blocking antibodies against coinhibitory molecules to increase T-cell function
- E.g. CTLA-4 blockade (ipilimumab)



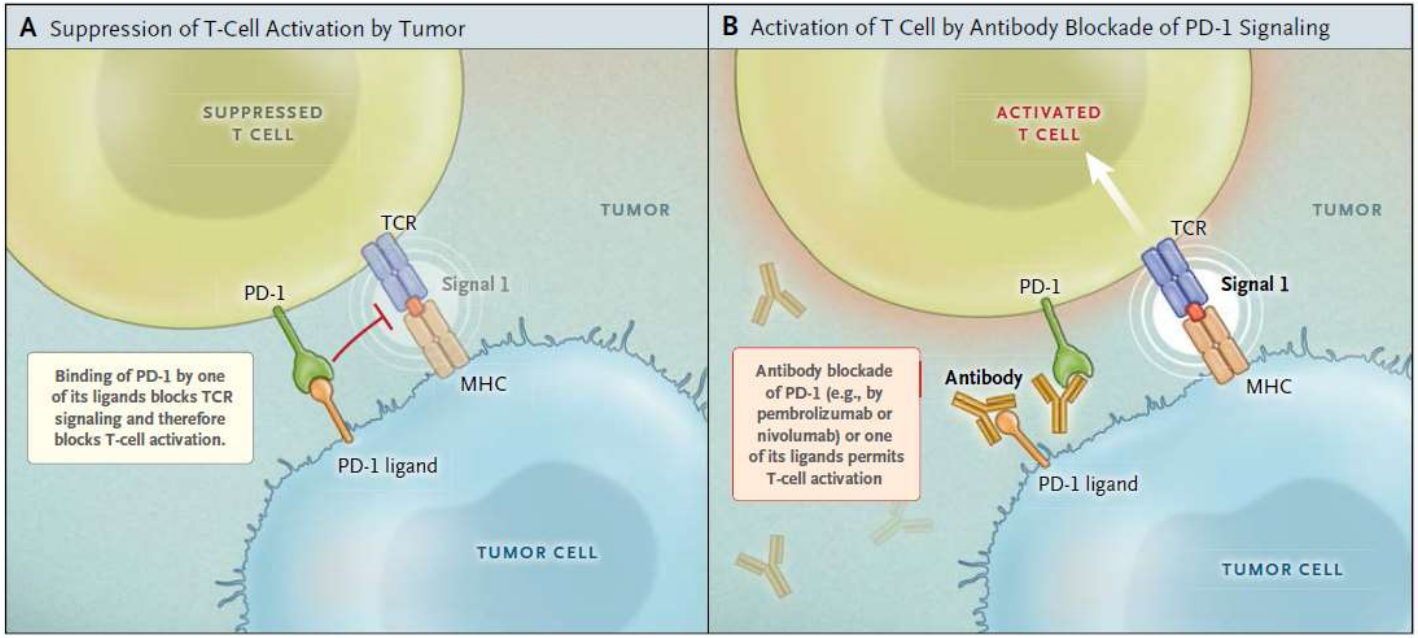
Ribas, NEJM 2015

ESTRO School

T-cell trafficking, infiltration, killing

Herrera FG et al CA Cancer J Clin 2017

- Antibodies directed against coinhibitory T-cell receptors (TCR) or TGF-blocking drugs
- E.g. PD-1 or PD-L1 antibodies (pembrolizumab, nivolumab)



Ribas, NEJM 2015

Rationale for combination with anti-PD-L1 Ab

Golden et al., Lancet Oncology, 2015 and Frey, Gaipl, Lancet Oncology,

Radio(chemo)-immunotherapy: works with various solid tumors

Local radiotherapy and granulocyte-macrophage colony-stimulating factor to generate abscopal responses in patients with metastatic solid tumours: a proof-of-principle trial

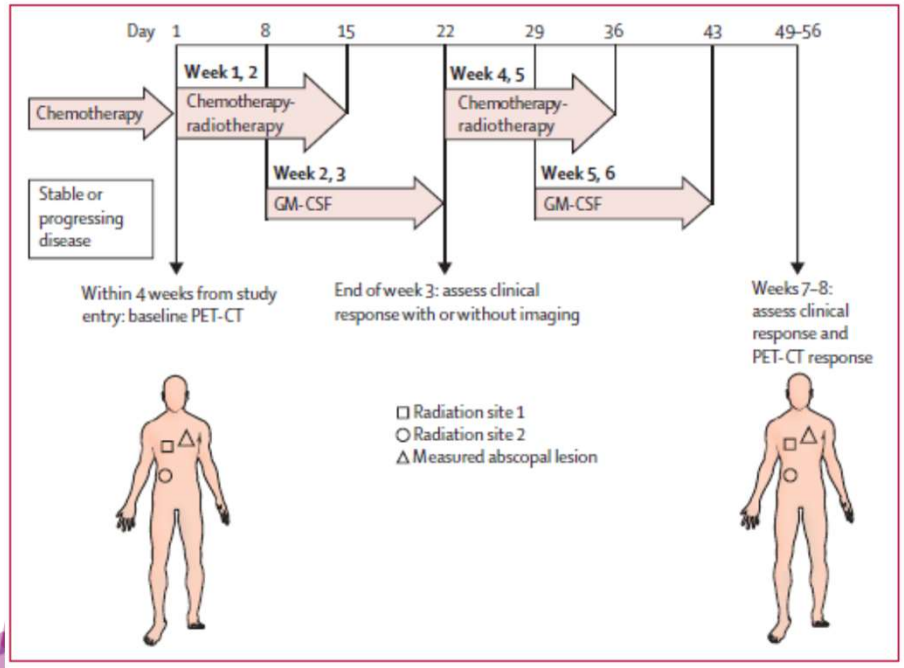


Figure 1: Treatment and assessment schema for induction and determination of abscopal responses

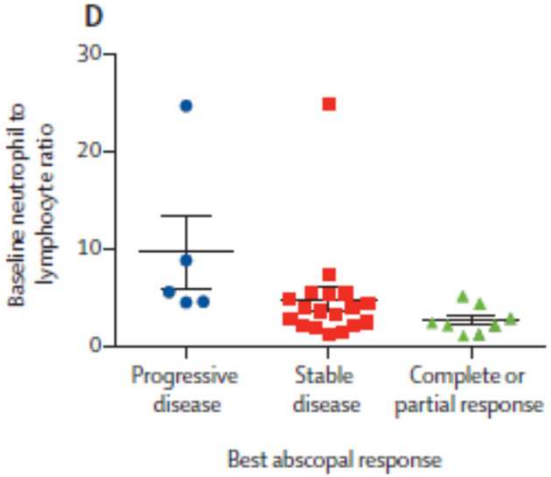


In Golden and colleagues' study,[5] the combination of granulocyte-macrophage colony-stimulating factor (GM-CSF) with radiochemotherapy resulted in abscopal responses in four (22%) of 18 patients with non-small-cell lung cancer and five (36%) of 14 patients with breast cancer. These findings emphasise that systemic anti-tumour immunity can be induced by rendering the tumour cells immunogenic. Radiotherapy alone

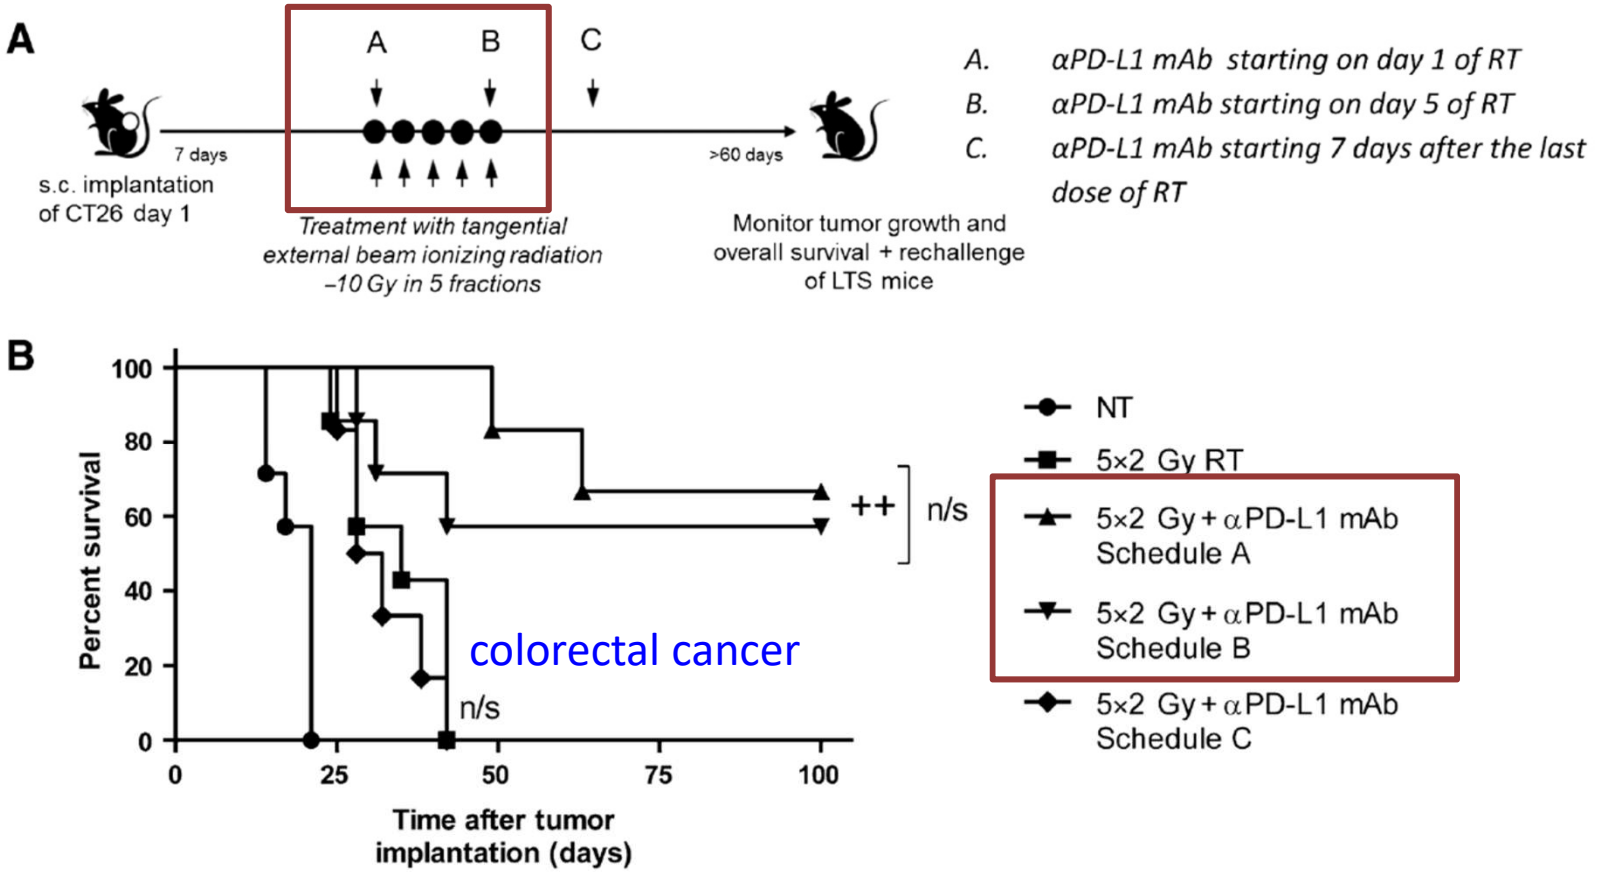
Radioimmunotherapy combinations: challenges

- Define optimal RT dose/fractionation schemes to create maximal interactions with IT
- Identify type, dose and schedule of immunogenic chemotherapy and type and schedule of immunomodulatory drugs for combination with chemo-RT
- Role of particle radiation and radionuclide therapy for their potential immunomodulatory effects

Dose scheduling for RT+IT combinations

Dovedi et al. Cancer Res 2014

- Dosing schedule is critical for outcome of combined radio-immunotherapy – concurrently is beneficial



Take home messages

- Numerous trials in progress combining RT + targeted agents
- Challenges
  - Bridge between preclinical and clinical models (tumor growth delay vs tumor control (TCD_{50}))
  - Translational research
    - Biomarkers
  - Trial design – patient stratification
  - New toxicities – late effects

Change in induration score of fibrosis of 2 grades or more by randomisation at 12 months from baseline ($n=64$)

Induration	All patients	Placebo	Treatment	*P*-value
Site 1	6/37=16.2	4/20=20.0	2/17=11.8	0.45
Site 2	8/28=28.6	4/14=28.6	4/14=28.6	1.00

Table 2 Representative prevention/mitigation studies targeting free radical production

Agent	Study	Patients	Mechanism of action	Radiation therapy details	Intervention	Results (*primary endpoint[s])	Comments
Alpha-tocopherol and β-carotene (7)	Bairati et al, 2005	540 patients with Stage I-II head and neck cancer	Antioxidant	Definitive radiation therapy per treating physician	Alpha-tocopherol (400 IU/d) (vitamin E) and β-carotene (30 mg/d) (discontinued after 154 patients enrolled) during radiation and for 3 y afterwards	*Odds ratio of acute side effects with supplementation 0.72 (95% CI 0.52-1.02) If received both α-tocopherol and β-carotene, odds ratio 0.38 (95% CI 0.20-0.74) Acute grade 3-4 toxicity during radiation therapy 19% vs 25%	Odds of local recurrence higher in supplement arm (hazard ratio 1.37; 95% CI 0.93-2.02) Beta-carotene stopped after another study showed its use was associated with increased lung cancer incidence
Amifostine (8, 9)	RTOG 98-01 (Movsas et al, 2005; Lawrence et al, 2013)	242 patients stage II to IIIB NSCLC	Free radical scavenger	Induction chemotherapy then concurrent chemoradiotherapy 69.6 Gy at 1.2 Gy BID (50.4 Gy to larger volume)	Amifostine 500 mg IV 4 times per week during radiation therapy given before afternoon treatment	Acute: *Grade 3+ esophagitis 30% vs 34% ($P=.9$) Grade 2+ cardiovascular (hypotension) 16% vs 7% ($P=.0001$) Grade 2+ nausea 33% vs 21% ($P=.03$) Grade 2+ vomiting 30% vs 14% ($P=.007$) Chronic: Grade 3+ pneumonitis 8% vs 17% (NS)	During treatment, swallow scores, weight loss, and pain scores favored amifostine arm ($P=.025$, .045, and .015, respectively) No difference in overall survival
Curcumin (10)	Ryan et al, 2013	30 patients with localized breast cancer	Anti-inflammatory Antioxidant	Breast radiation to at least 42 Gy in daily fractions	Curcumin 2 g per os TID during radiation therapy	*Dermatitis at end of treatment: • *Mean grade 2.6 vs 3.4 ($P=.008$) • *Moist desquamation 29% vs 88% ($P=.002$)	No curcumin-related toxicities

Moulder et al., Int. J. Radiat. Biol. 73, 1998, 415-421

Table 3 Representative prevention/mitigation studies targeting inflammatory pathways

Agent	Study	Patients	Mechanism of action	Radiation therapy details
Captopril (88, 89)	Cohen et al, 2008 and 2012	55 patients undergoing stem cell transplant	↓TGF-β levels Free radical scavenger	Total body irradiation 14 Gy in 9 fractions over 3 d with at least 4 h between fractions Shielding to limit kidney dose to 9.8 Gy and lung dose to 5-7 Gy
Statins (90, 91)	Anscher et al, 2016	53 patients with prostate cancer with portion of rectum receiving >60 Gy	↓Inflammatory cytokines and pathways ↓Endothelial dysfunction and fibrosis	78-79 Gy to the prostate in 1.8- to 2-Gy fractions, or 45-46 Gy plus a brachytherapy boost, or brachytherapy monotherapy
Steroid cream (92)	Ulff et al, 2013	102 patients with breast cancer	Numerous anti-inflammatory effects	50 Gy in 2-Gy fractions to breast ± lymph nodes after breast conservation surgery or mastectomy ± lymph node dissection
Probiotic VSL#3 (lactobacilli preparation) (93)	Delia et al, 2002	190 patients with colorectal or cervical cancer	↓Inflammatory pathways Protects intestinal barrier	Postoperative radiation therapy per treating physician

Intervention	Results (*primary endpoint[s])	Comments
Captopril 6.25 mg BID (escalated to 25 mg TID if tolerated) for total of 1 y starting after neutrophil engraftment	1 y: *Serum creatinine 0.95 vs 1.10 mg/dL ($P=.2$) *Glomerular filtration rate 86 vs 77 mL/min ($P=.07$) 4 y: Chronic renal failure 11% vs 17% ($P>.2$) Pulmonary mortality 11% vs 26% ($P=.15$) 8-y survival 37% vs 22% ($P=.26$)	Average time on drug was 1.8 mo At 4 y, survival in the captopril group higher but not statistically significant ($P>.2$)
Lovastatin (20-80 mg/d) starting day 1 of radiation, for 12 mo	*Physician-reported grade 2+ rectal toxicity during first 2 y showed no difference relative to historical series Erectile function and orgasmic function declined immediately after treatment but was preserved at later time points out to 2 y	Late grade 2 rectal injury in 38% of patients
Betametasone-17-valerate cream vs 2 emollient creams, given 7 days per week for 5 wk of radiation starting first week of radiation	*Acute dermatitis better with steroid vs emollient creams: • *4 wk: $P=.003$ • *5 wk: $P=.01$ *Patient-rated itch, burn, irritation improved with steroid ($P=.048$)	Patients at greatest risk benefited more, including those postmastectomy, with lymph node irradiation, and with fair skin
VSL#3 PO TID during radiation therapy	*Any diarrhea 38% vs 55% ($P=.001$) *Grade 3-4 diarrhea 7% vs 29% ($P=.001$) *Grade 1-2 diarrhea 30% vs 21% (NS) *Mean daily BMs 5 vs 12 ($P<.05$)	No patients reported toxicity from VSL#3

Kalman et al
IJROBP 2017

Table 4 Representative prevention/mitigation studies targeting vascular endothelial dysfunction

Agent	Study	Patients	Mechanism of action	Radiation therapy details	Intervention	Results (*primary endpoint[s])	Comments
Pentoxifylline + vitamin E (140)	Jacobson et al, 2012	53 patients with localized breast cancer	↑Microvascular blood flow Anti-inflammatory	46.8-50.4 Gy in 1.8-Gy fractions to breast/chest wall followed by a 10-Gy boost	Pentoxifylline (400 mg per os TID) and vitamin E (400 IU per os daily for 6 mo) after completion of radiation therapy	*Median difference in tissue compliance between treated and untreated breast at 18 mo: 1.0 mm vs 2.4 mm ($P=.0478$) No difference physician-reported late toxicity	Measurements were obtained using tissue compliance meter at mirror sites on treated and untreated breast
Hyperbaric oxygen (141)	Teguh et al, 2009	19 patients with oropharyngeal or nasopharyngeal cancer	↑Oxygenation of hypoxic tissue Reduction of edema Anti-inflammatory	Head and neck radiation therapy to 46-70 Gy with possible brachytherapy or Cyberknife boost	Hyperbaric oxygen 2.5 absolute atmospheres 90 min daily for 30 treatments over 6 wk starting within 2 d of completing radiation	*Improved quality of life scores at 3-18 mo: • *Swallowing ($P=.011$) • *Dry mouth ($P=.009$) • *Sticky saliva ($P=.01$) • *Eating in public ($P=.027$) • *Mouth pain visual analogue scale ($P<.0001$)	Hyperbaric oxygen is mostly used to treat radiation-induced injuries, not mitigate potential toxicity

Intervention with signaling / stem cell therapy

Bone marrow stem cell mobilisation (G-CSF)

Works only when enough surviving stem cells are presence

Table 5 Representative prevention/mitigation studies targeting tissue resilience and function

Agent	Study	Patients	Mechanism of action	Radiation therapy details
Memantine (197)	RTOG 06-14 (Brown et al, 2013)	508 patients with brain metastases	Blocks NMDA receptors to prevent neurotoxic excessive NMDA stimulation	Whole-brain radiation 37.5 Gy in 15 daily fractions of 2.5 Gy
Pilocarpine (198, 199)	RTOG 97-09 (Fisher et al, 2003; Scaratino et al, 2006)	213 patients with head and neck cancer and ≥50% of major salivary glands receiving 50 Gy	Cholinergic receptor agonists promoting salivary secretion	60-70 Gy using standard or BID fractionation without chemotherapy
Palifermin (200)	Le et al, 2011	188 patients stage III-IVB cancer of head and neck	Keratinocyte growth factor ↑cell turnover	70 Gy in 2-Gy fractions with concurrent cisplatin
Tadalafil (202)	RTOG 08-31 (Pisansky et al, 2014)	221 patients stage II prostate cancer and intact erectile function	Phosphodiesterase = 5 inhibitor ↑Nitric acid production	Prostate radiation therapy 75-79.2 Gy in daily fractions of 1.8-2 Gy or prostate brachytherapy with 145 Gy (^{125}I) or 125 Gy (^{103}Pd)
Skin washing (203)	Roy et al, 2000	99 breast cancer patients	↓Inflammatory response and damage to basal cell layers by reducing bacteria and fungi	Radiation to breast or chest wall to 45 Gy in 2.25 Gy fractions or 50 Gy in 2-Gy fractions, with electron boost to 7.5-11.25 Gy in some patients

Intervention	Results (*primary endpoint[s])	Comments
Memantine 5 mg PO daily (escalated to 10 mg BID by week 4 if tolerated) for 24 weeks starting within 3 days of initiation of radiation therapy	*HVLT-R delayed recall median decline 0.0 vs 0.9 (P=.059) at 24 wk HVLT-R delayed recognition median decline 0.0 vs 1.0 (P=.0149) at 24 wk MMSE median decline 0 vs 1 (P=.0093) at 24 wk	33% of patients died before 24 wk
Pilocarpine (5 mg per os QID for 3-6 mo) starting at time of radiation initiation	*Unstimulated salivary flow improved at end of radiation therapy, 3 mo, and 6 mo (P=.002, .047, and .093, respectively) *No difference self-reported quality of life scores in pain, chewing, swallowing, taste, saliva amount at 3 or 6 mo	Numerous previous studies have shown limited preventative effect Though objective increase in saliva, not reflected in patient's self-assessment
Palifermin (180 μg/kg IV weekly × 8 wk) starting Friday before initiation of radiation therapy	*Incidence of grade 3-4 oral mucositis 54% vs 69% (P=.041) Duration of severe oral mucositis 5 d vs 26 d (P=.112) Days to development of severe oral mucositis 47 vs 35 (P=.157) Incidence of supplemental nutrition 67% vs 55% No difference in overall survival	Similar benefit seen in postoperative patients (201)
Tadalafil (5 mg per os daily for 24 wk) starting with radiation therapy	Retained erectile function: • *At 28-30 wk, 79% vs 74% (P=.49) • At 52 wk, 72% vs 71% (P=.93)	Additionally, tadalafil did not improve overall sexual satisfaction
Gentle washing of treatment field with warm water and mild soap	*Acute skin toxicity maximum scores improved with skin washing (P=.04): • *Grade 0 0% vs 2% • *Grade 1 64% vs 41% • *Grade 2 34% vs 57% • *Grade 3 2% vs 0% Mean time to maximal toxicity score not significant: 3.3 wk vs 3.1 wk	Also trend toward decreased pain and burning

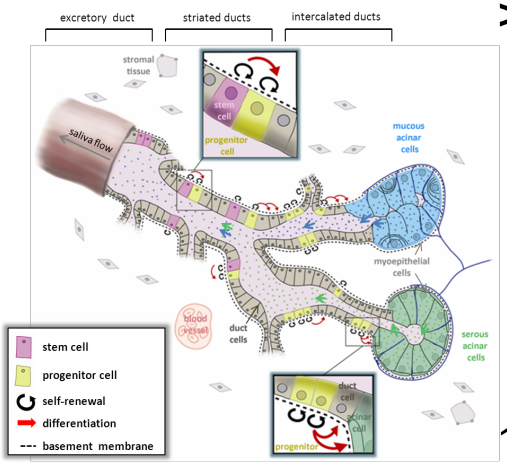
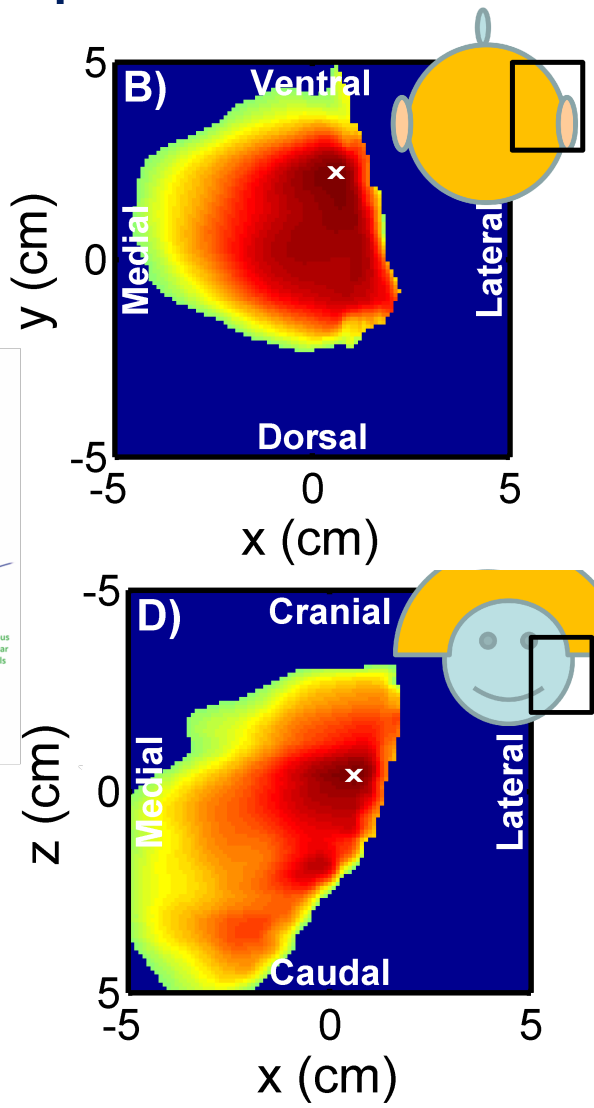
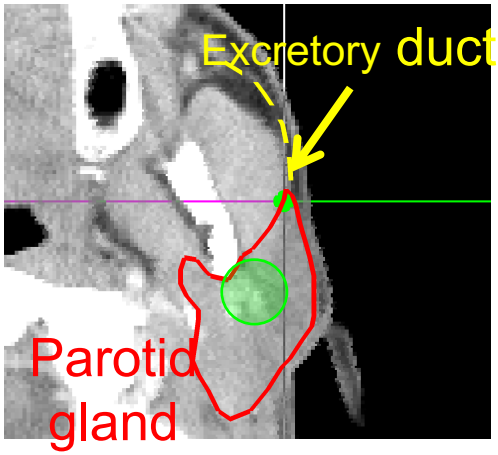
Restoration of tissue + endocrine stimulation

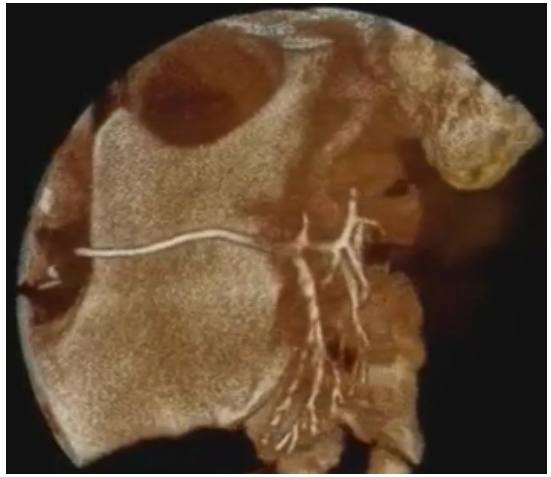
- Re-entrance in cell cycle
- ECM remodelling
- Reduction of fibrosis
- Re-vascularisation

Impact on function: human





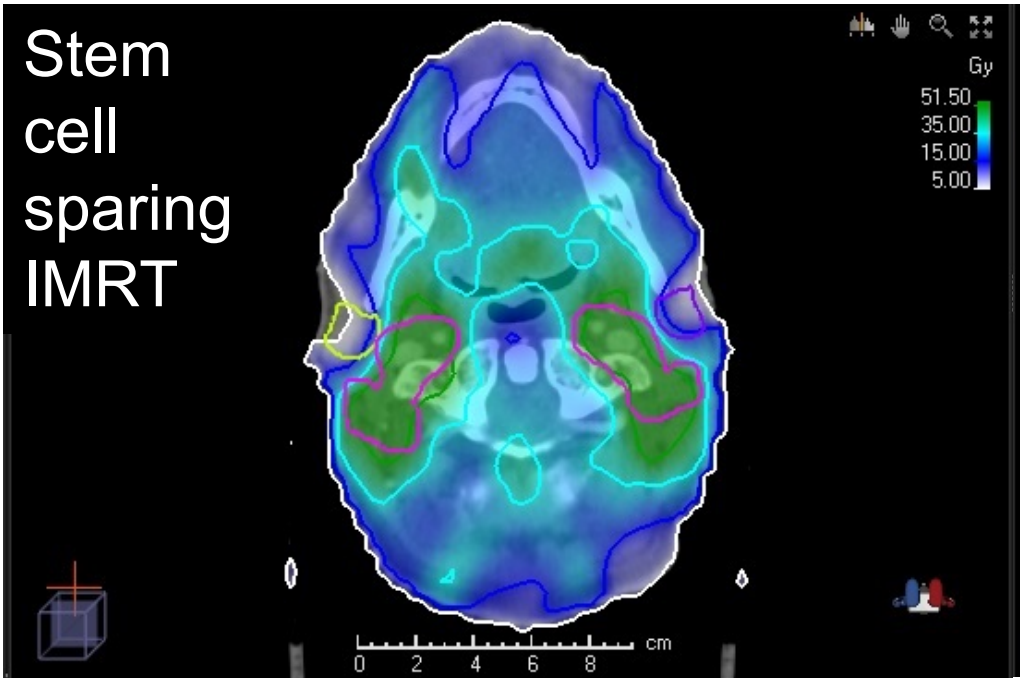


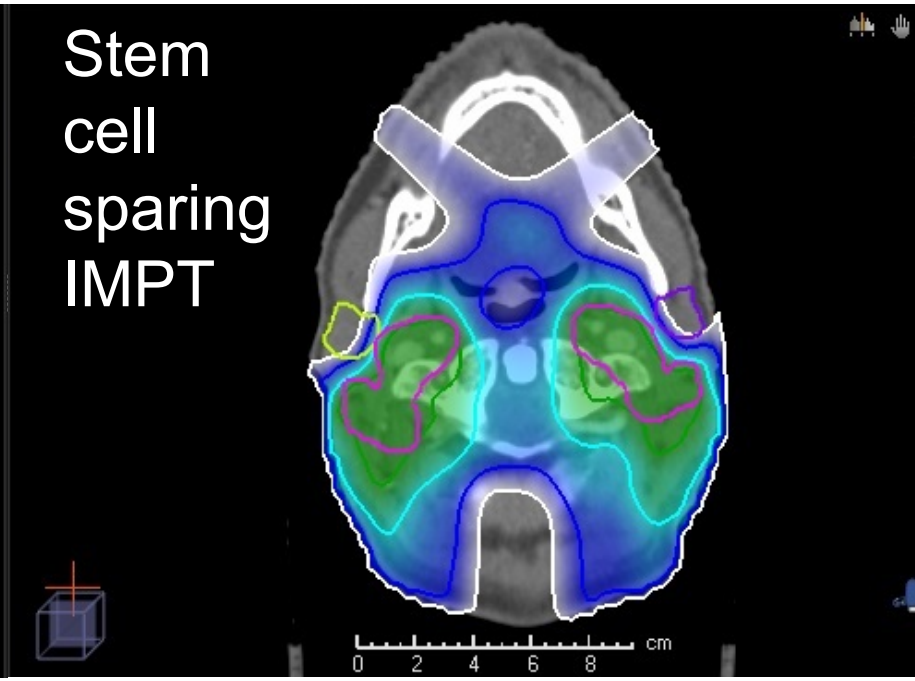


Dose to main ducts strongly determines outcome

Van Luijk et al Science Translational Medicine 2015

Protons vs. Photons





Optimum intervention strategies required

- precise knowledge of the signaling chains
  - cell type/ tissue specific/*tumor*?
- clarification of mechanisms
- validation in suitable animal models
  - with clinically relevant endpoints
  - with relevant treatment protocols
- proof of selectivity
  (tumour studies, same premises)
- Modification cocktails!?
  Localize effect?
  Long-term effects?

ESTRO 2017

Pelvic radiation with concurrent chemotherapy compared with pelvic and para-aortic radiation for high-risk cervical cancer.

M. Morris et al, NEJM, 340:1137-1143, 1999.

	RT (n=193)	RT+Chemo (n=195)
Early toxicity (G3-5)	10 (5%)	88 (45%)
Early toxicity* (G3-5)	4 (2%)	20 (10%)
Late toxicity (G3-5)	22 (11%)	24 (12%)

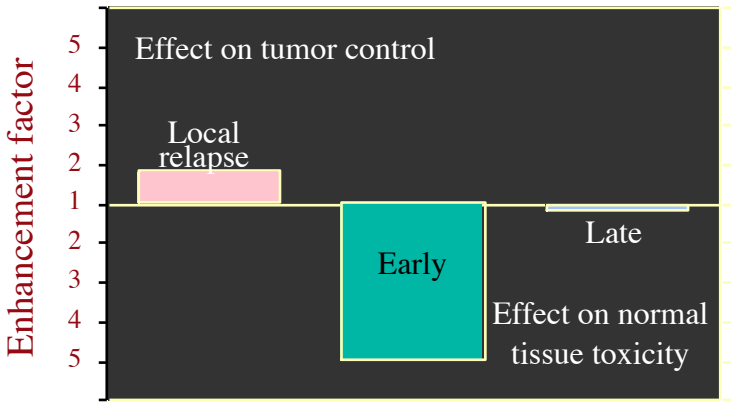
* non hematologic only

RT: 45 Gy + brachytherapy (total dose ≥ 85 Gy)
Chemo: cddp (75mg/m^2, d1), 5Fu (1g/m^2/d, d1-4), x3

ESTRO 2017

Pelvic radiation with concurrent chemotherapy compared with pelvic and para-aortic radiation for high-risk cervical cancer.

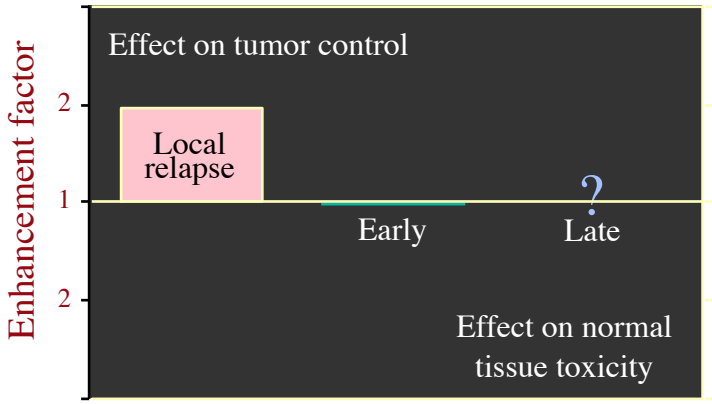
M. Morris et al, NEJM, 340:1137-1143, 1999.



ESTRO 2017

Treatment of advanced squamous-cell carcinoma of the head and neck with alternating chemotherapy and radiotherapy.

M. Merlano et al, NEJM, 327:1115-1121, 1992.



RT: 70 Gy, 7 weeks
RT+CH: 3 x 20 Gy, 9 weeks;
cddp (20mg/m^2/d, d1-5)-5Fu (200 mg/m^2/d, d1-5) x4

ESTRO 2017

Combined chemo- and radiotherapy treatment

- "Objective-oriented" design of clinical trials
- Benefit of RT+Chemo is due to tissular interaction
- Anti-proliferation-based efficacy and toxicity
- More data needed to design combined RT+Chemo trial based on cellular/molecular interaction
- Equal dose trial <> equal toxicity trial

Retreatment tolerance of normal tissues

Rob Coppes

Department of Radiation Oncology

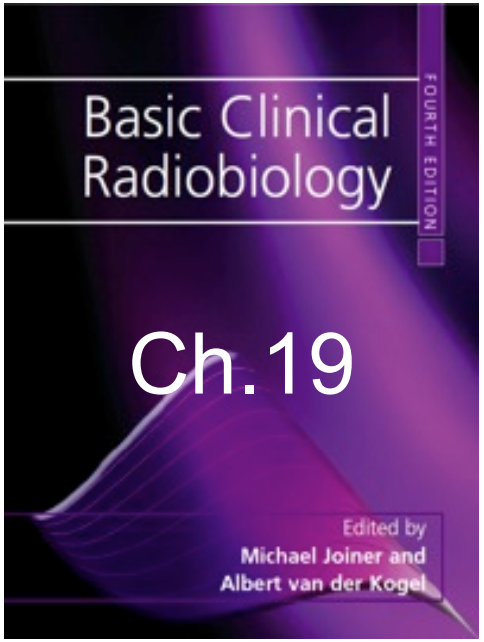
&

Department of Cell Biology

University Medical Center Groningen /
University of Groningen

Groningen

The Netherlands



Introduction

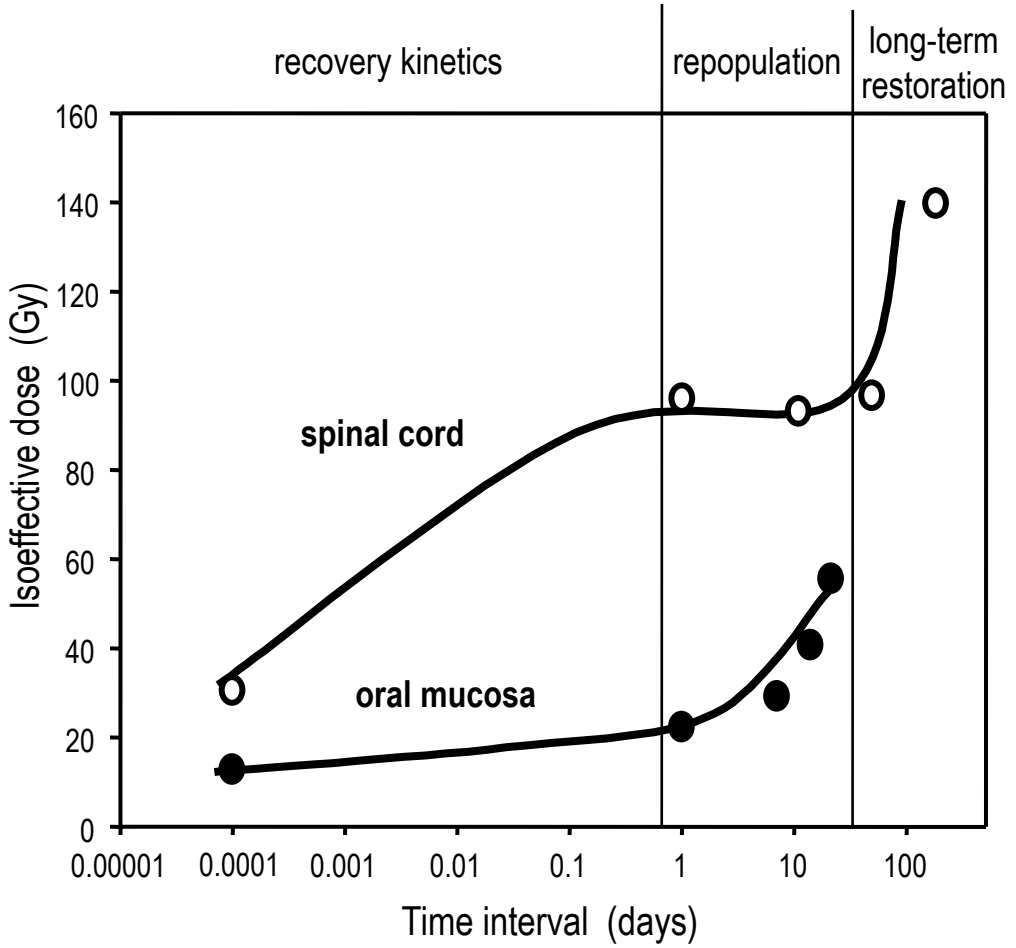
- Reirradiation of previously treated areas: why?
  - New primary tumor
    - Cancer survivors are at an increased risk of developing secondary malignancies
      - Pts still retain more risk (e.g. molecular predisposition)
      - Aetiological factors can continue (e.g. Smoking)
      - Therapy itself
    - Within or close to initial high-dose treatment volume
  - Recurrence
    - Within or close to original gross tumor volume
  - Nodes and metastases

Introduction

- Factors influencing decision on how to retreat
  - Previous dose/fractionation and volume irradiated
  - Organs at risk eg. spinal cord
  - Time from the first treatment
  - Local disease or metastases
  - Curative or palliative intent
  - Alternatives to reirradiation

Introduction

- Changes in normal tissue tolerance with time



Long-term recovery from radiation injury in some tissues (not all!)

Introduction

No further treatment

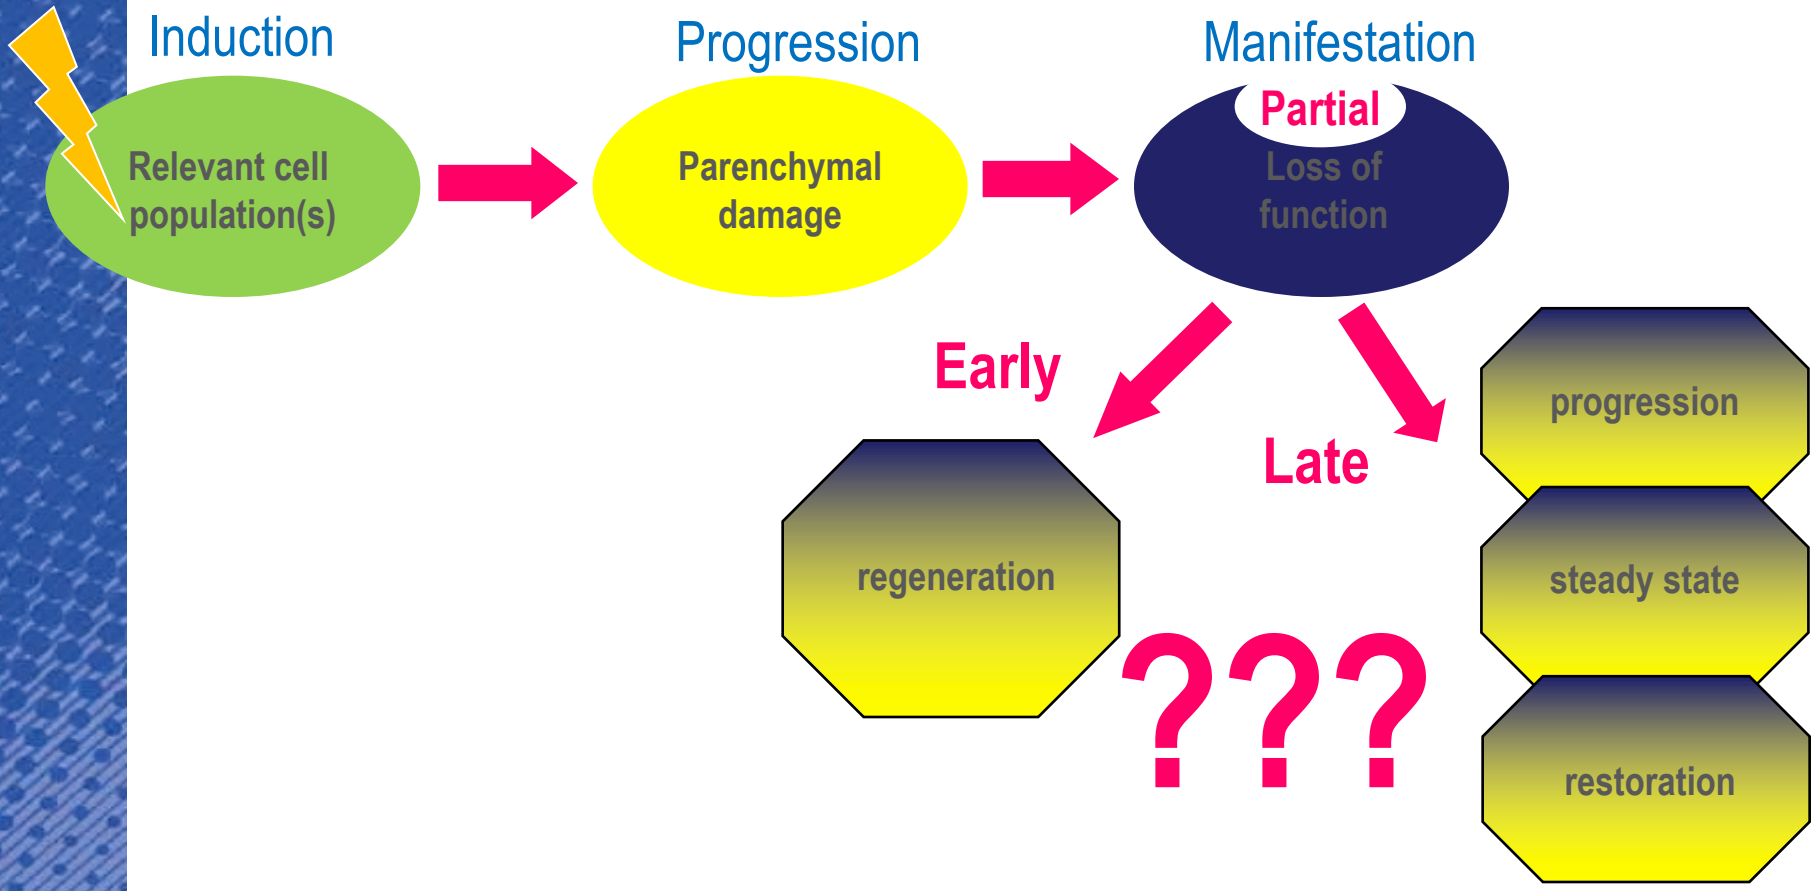
- If the radiation tolerance within a given volume or organ has already been exceeded during the first treatment
- And function is lost (or loss is to be expected)

Retreatment possible

- If initial radiation treatment was in subtolerance dose range
- With the induction of only subclinical or minimal damage
- And with possible long-term recovery or potential residual damage after longer periods

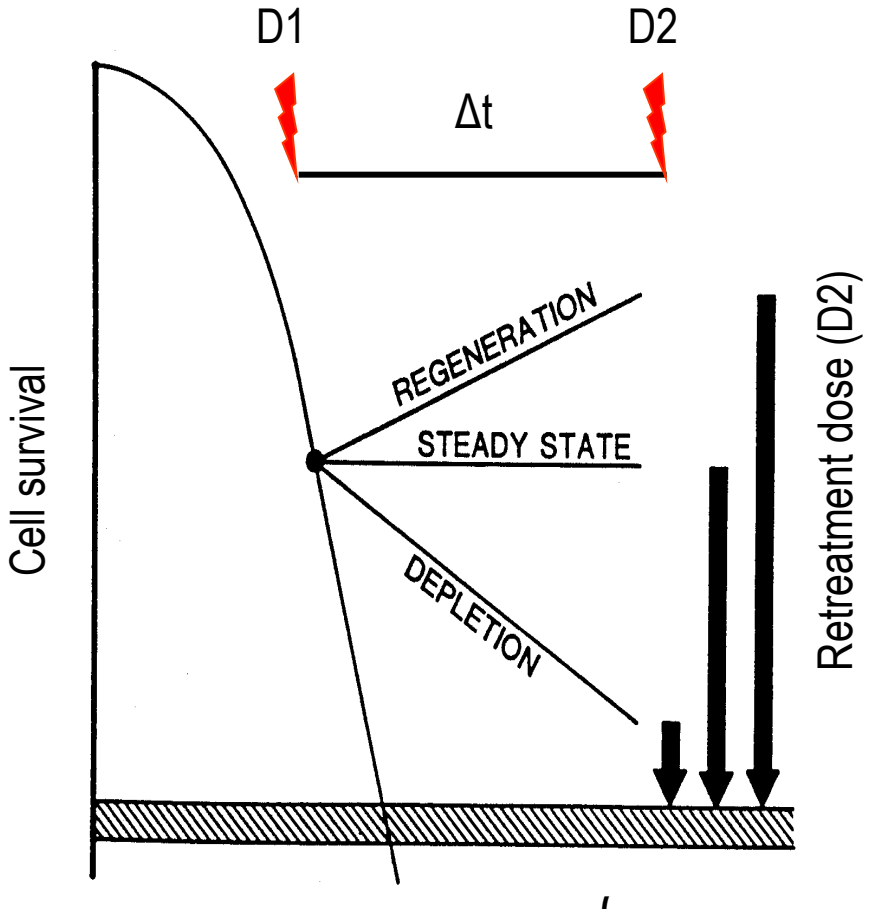
Introduction

- Pathogenesis of normal tissue radiation effects



Introduction

- Retreatment tolerance depends on the level of cell kill and regeneration



"E"

Level of cell kill
for tissue damage

Introduction

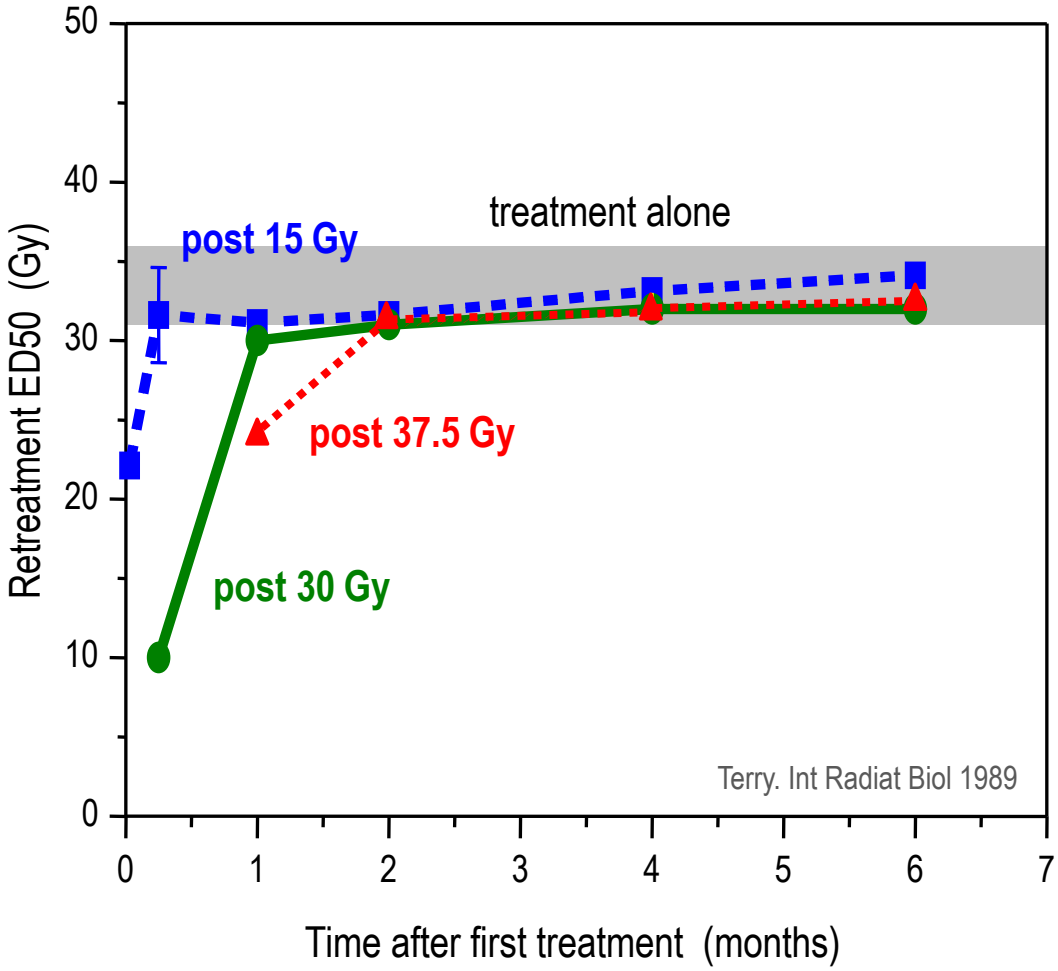
- Some concepts
  - EQD_2: equivalent dose in 2-Gy fractions
    - Calculated using LQ-model with α/β values
      - 10 Gy for early reactions
      - 3 Gy for late reactions
  - EQD_{2tol}: tolerance doses
    - Threshold doses above which defined grades of toxicity are observed
  - % EQD_{2tol}: intensity of the initial treatment or the retreatment

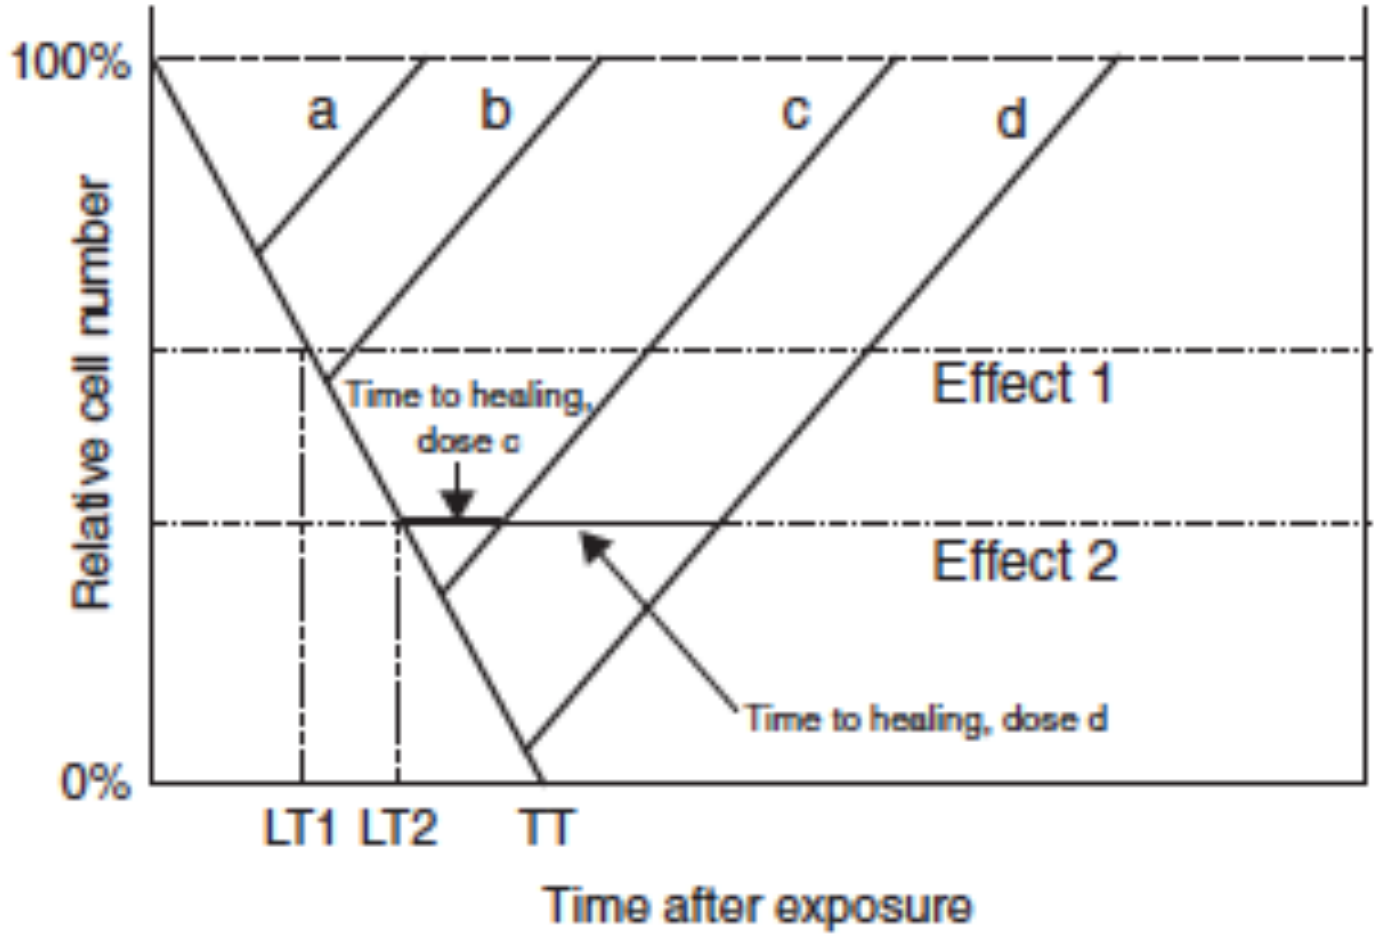
Experimental studies
Early effects

Epidermis

- Retreatment tolerance of mouse epidermis

Recovery to full tolerance within 1-2 months





100%

Relative cell number
Time to healing, dose c
Effect 1
Effect 2
Time to healing, dose d
0%
LT1
LT2
TT
Time after exposure

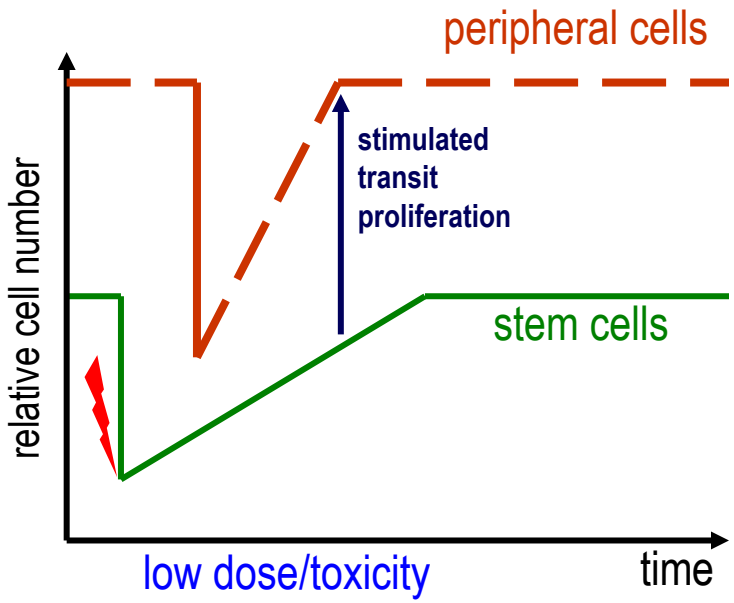
Retreatment skin and oral mucosa

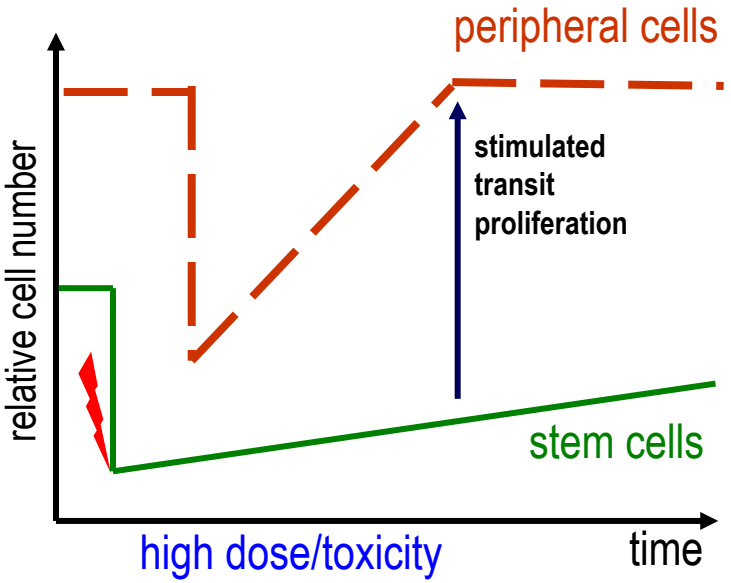
- Rapid proliferative recovery begins within 2 weeks
- Full re-irradiation tolerance for early injury is reached within 2-3 months
- Re-irradiation tolerance for late damage will be less (cfr. slides mouse limb)

Bone marrow

- Toxicity of initial treatment must be considered, independently of blood cell counts that may be misleading!

Earlier recovery of peripheral cell number does not reflect recovery of stem cell population (*i.e.* restoration of radiation tolerance)

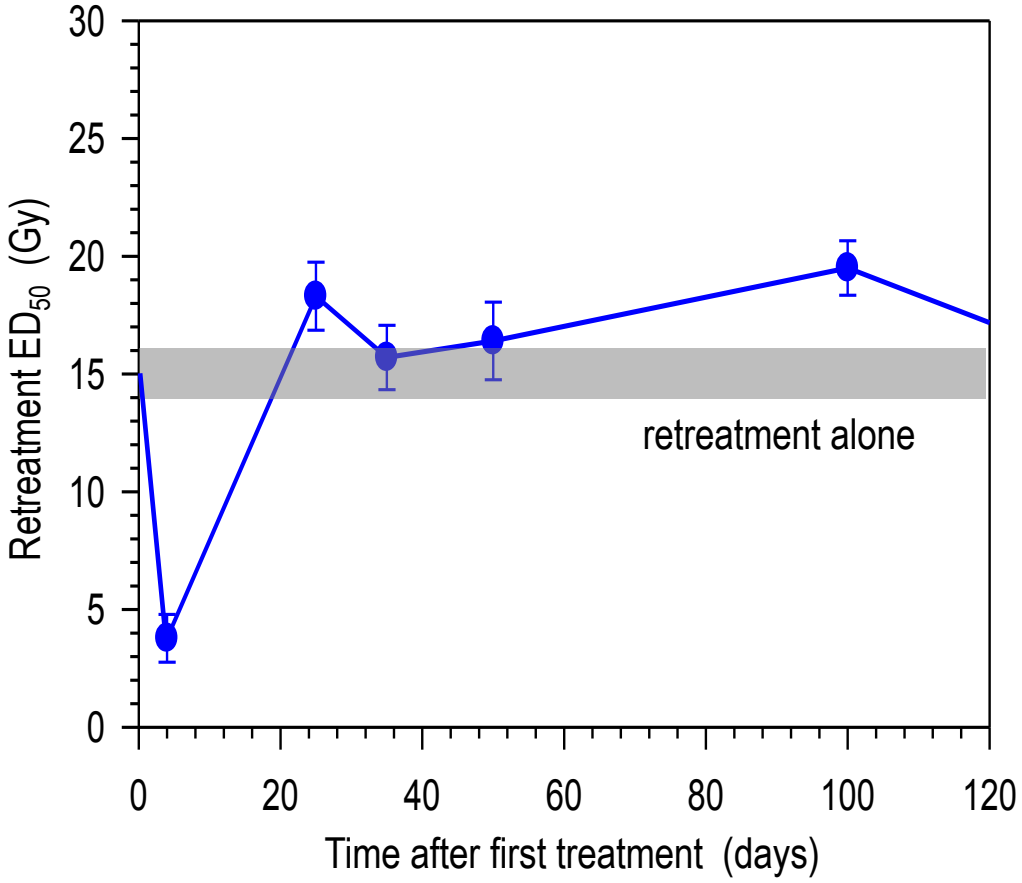




Urinary bladder (mouse)

- Original tolerance restored between 25-50 days

First treatment:
5 × 5.3 Gy over 1 week
Endpoint:
50% reduction in bladder storage capacity at 1–3 weeks
post retreatment



Retreatment principles: early effects

- Can achieve complete restoration of the initial tolerance
  - Epidermis: 2-3 months (rodents)
  - Oral mucosa: 12 days (but long term effects possible)
- Restoration of the stem cell compartment may take longer than “morphological” recovery

Experimental studies
Late effects

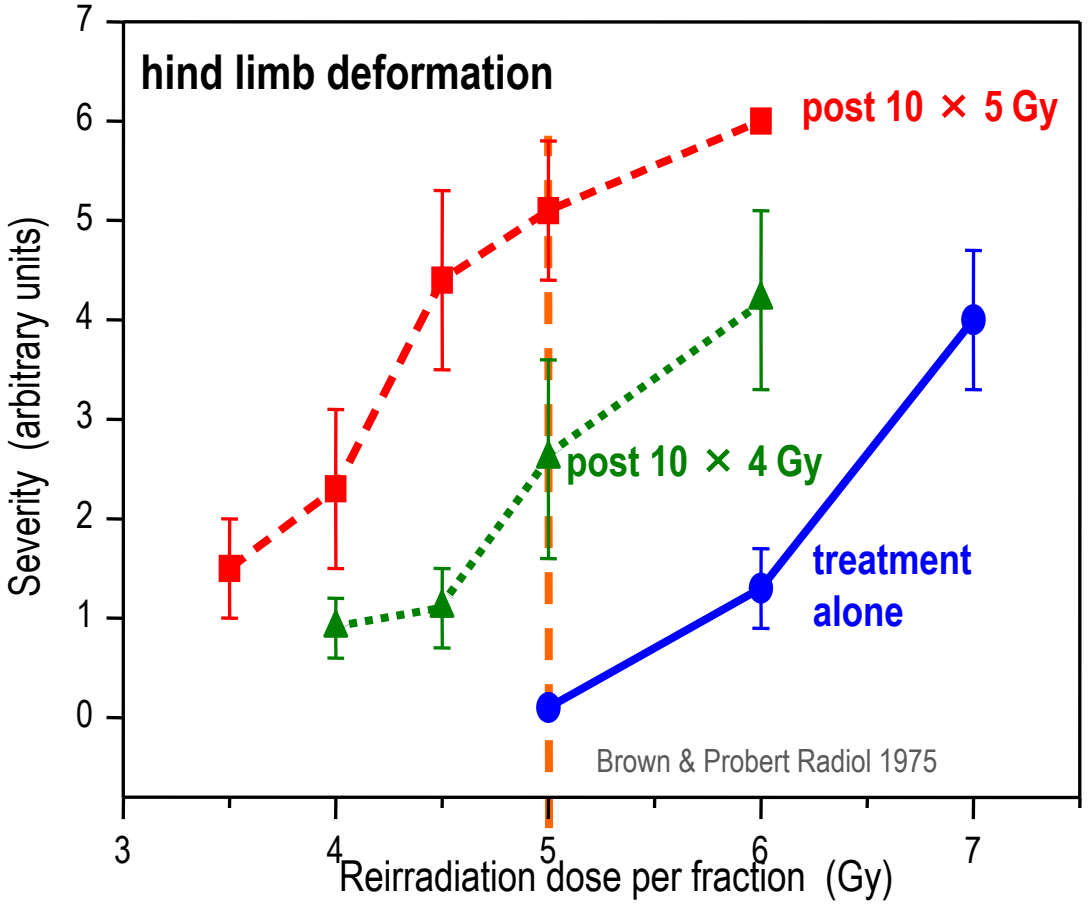
Skin

- Late radiation effects – mouse hind-limb

Two 10-fraction courses separated by 6 months

Effect of re-irradiation more pronounced after more aggressive initial treatment

Poorer retreatment tolerance than for early skin reactions



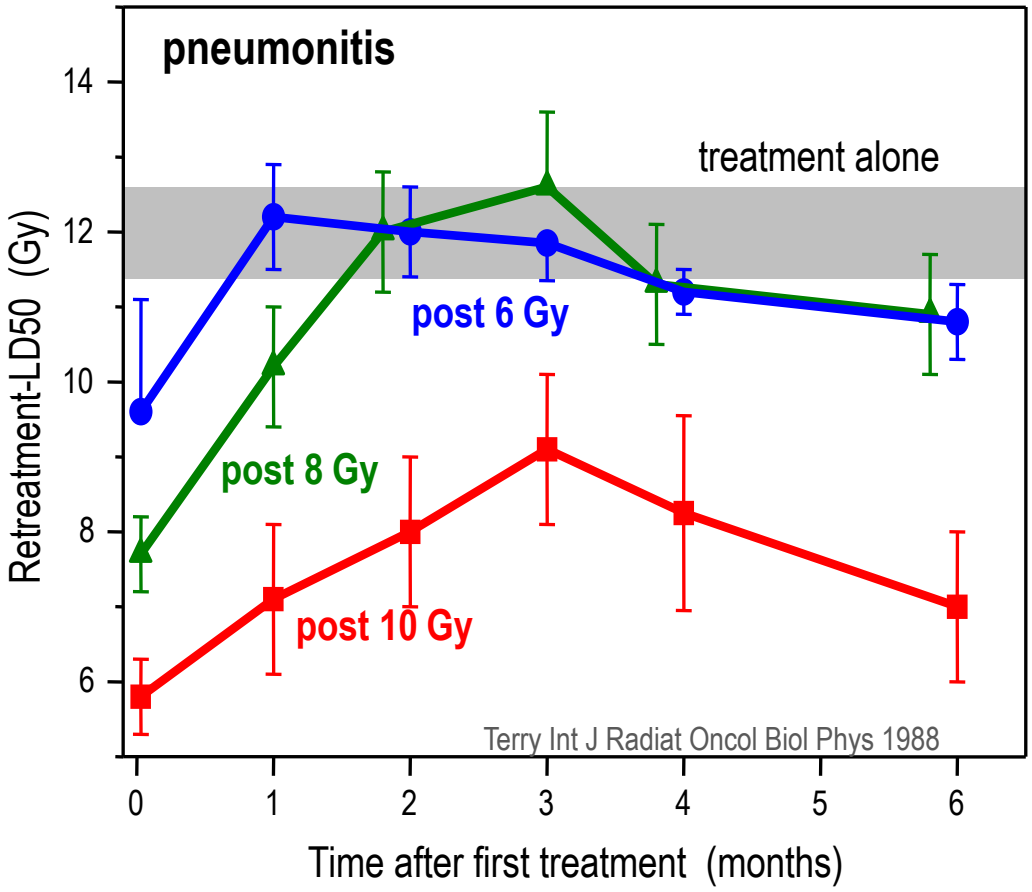
Lung

- Retreatment tolerance of the mouse lung

Initial dose <50% tolerance:
full recovery, 2 months

Higher initial doses:
partial recovery, 3 months

Only applies for pneumonitis phase: retreatment tolerance fibrosis might be poorer



Kidney

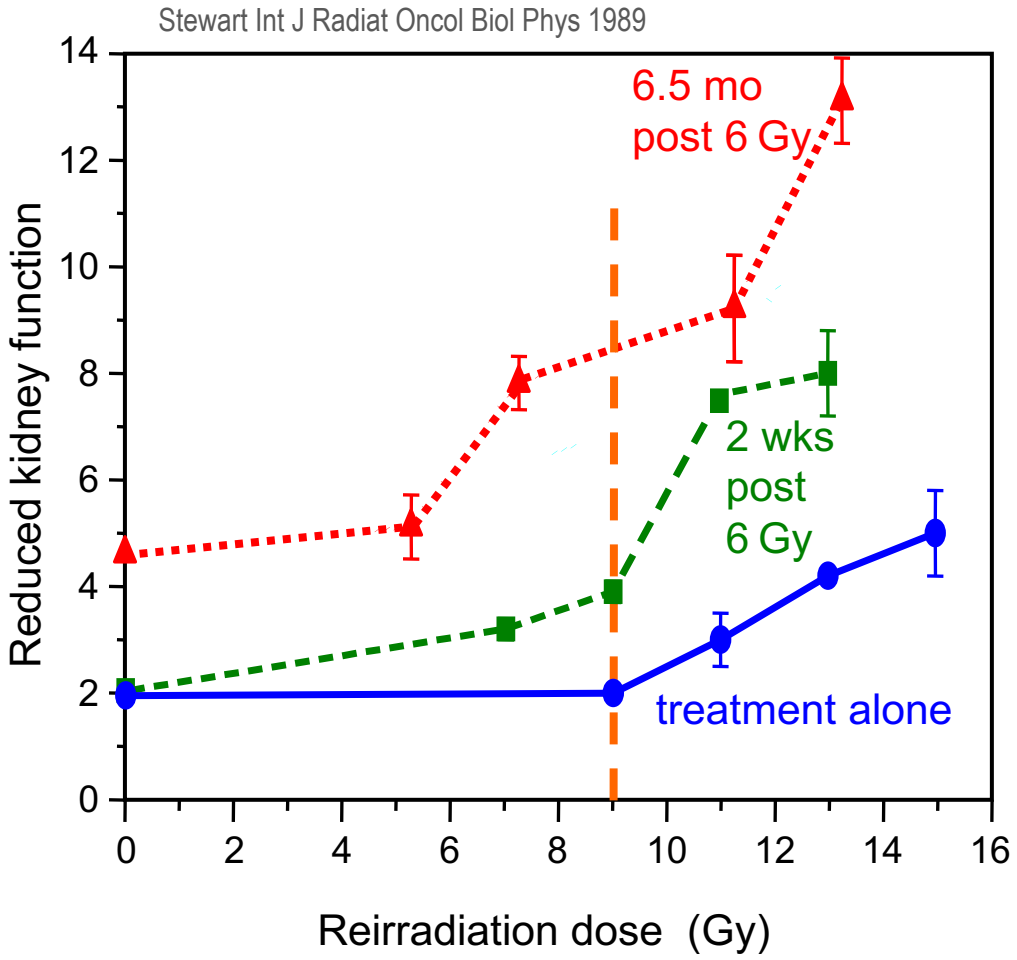
- Retreatment tolerance mouse kidney

No recovery between 1 day and 6 months after initial treatment

Progression of (subclinical) damage

Retreatment tolerance decreases with time

Extreme caution when re-irradiating kidneys!



Urinary bladder

- Retreatment tolerance mouse bladder

No recovery between 1 day and 9 months after initial treatment

Progression of (subclinical) damage results in shortening of latent times after retreatment

Extreme caution when re-irradiating urinary bladder!

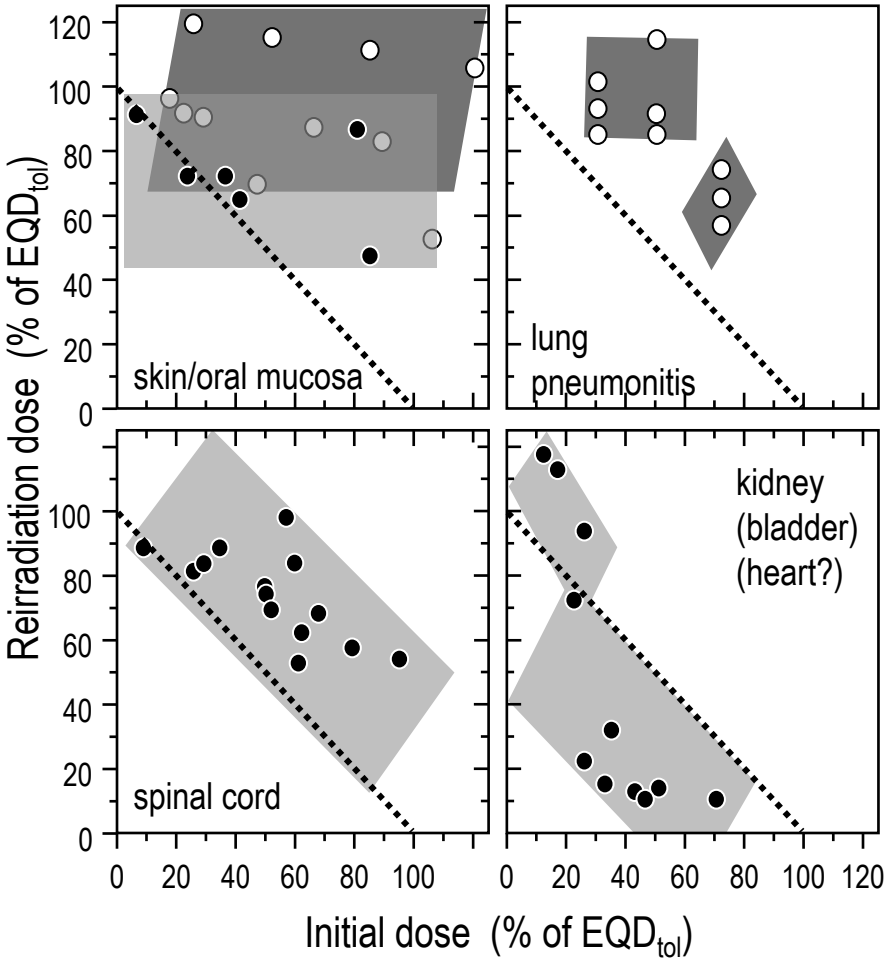
Summary experimental data



Modified from Stewart FA & van der Kogel AJ *Semin Radiat Oncol* 1994

Several, but not all, normal tissues are able to tolerate considerable retreatment with radiation

Clinical studies

Pitfalls

- Problems with clinical data!
  - Extremely heterogeneous populations
  - Curative and palliative intent in the same series
  - Changes in staging and radiotherapy techniques
  - Changes in normal tissue scoring

Experimental animal systems *have been* essential to understand the radiobiology of retreatment tolerance

Head & neck

- Review post-op RT for recurrent HNSCC
  - Major late complications are fibrosis, mucosal ulceration/necrosis and osteoradionecrosis
  - Nevertheless, high-dose re-irradiation recommended

Table 8 Results of studies of postoperative radiotherapy for recurrent head and neck cancer

Author	Clinical response rate	Survival	Acute complications	Late complications	Treatment-related deaths
Emami[31] (1967–1985)	CR at 3 months: 81% PR at 3 months: 4%	2 years OS: 45% 5 years OS: 20%	Not reported	Marked fibrosis: 16/99 (16%)[1] Trismus: 3/99 (3%) Fistula: 3/99 (3%) Esophagal stenosis: 2/99 (2%) Osteoradionecrosis: 1/99 (1%)	None

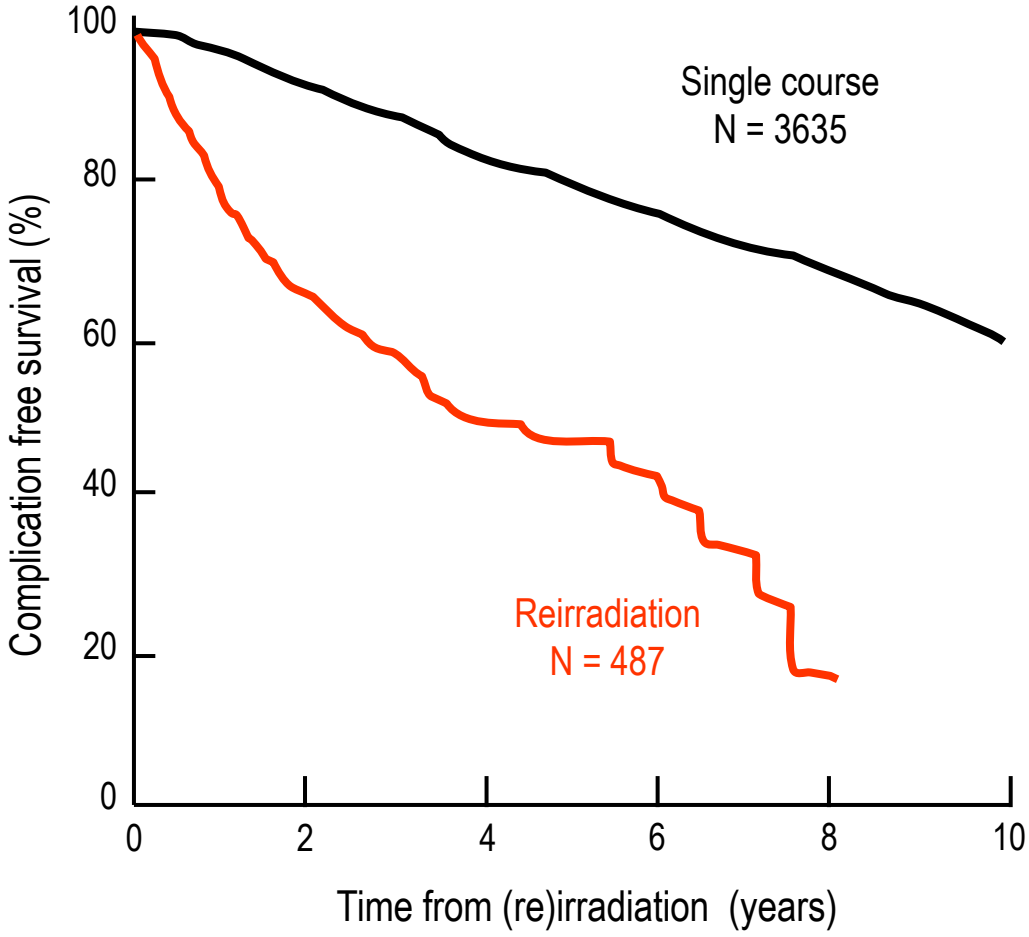
Nag[35] (1992–1997)	6-months LC: 33% 2 years LC: 4% Median time to LR-failure: 4 months	2 years OS: 21% 3 years OS: 8% Median survival: 7 months	Wound dehiscence: 1/38 (3%)	Orocutaneous fistula: 2/38 (5%) Tracheal dehiscence: 1/38 (3%) Carotid occlusion: 1/38 (3%) Tracheovascular fistula (FX): 1/38 (3%)	Tracheovascular fistula: 3% (1/38)

Complications not specified for patients who underwent salvage surgery and postoperative reirradiation Abbreviations: CR = complete response, PR = partial response, NR = no response, C = local control, LRC = local-regional control, LRRFS = local-regional recurrence free survival, OS = overall survival, DFS = disease free survival.

Kasperts Oral Oncol 2005

Head & neck

- Risk of late damage is higher in retreated patients…
- But cumulative total dose for 20% complication rate at 5 y is higher than predicted from single course treatment ($EQD2_3$ = 86 vs 67 Gy) indicating partial recovery!



Lee AWM et al. Int J Radiat Oncol Biol Phys 20000

Head & neck

115 patients
reirradiation + various CT

Initial treatment median 68 Gy
Retreatment median 65 Gy

18% LT
16% fatal

Table 7. Grade 4–5 complications*

Complication	*n*

Osteoradionecrosis	13
Brain necrosis	0
Myelopathy	1
Peripheral neuropathy	1

* Using common terminology criteria for adverse events.

Salama Int J Radiat Oncol Biol Phys 2006

Head & neck

- Head & neck reirradiation: selection criteria
  - Patient related considerations
    - No severe sequelae of previous radiation treatment
    - No significant comorbidities
    - PET-CT is suggested for staging
    - Interval between RT courses: at least 6 months, preferably longer (1y)
    - Better prognosis:
      - Previous surgery
      - Small (<30cm³) tumor size; caution with bulky tumors (>60cm³)
      - True second primary tumors (as compared to recurrences)
      - Tumors in nasopharynx and larynx
      - EGFR expression/HPV status: uncertain (needs to be evaluated in the context of re-irradiation)

Head & neck

- Head & neck reirradiation: selection criteria
  - Treatment related considerations
    - Previous treatment plan: previous dose in area of recurrence ≤50Gy preferred (≥60-70Gy higher risk)
    - CTV = GTV + margin
    - Re-irradiation dose:
      - ≥ 60Gy to achieve more local control
    - Critical structures:
      - Spinal cord: do not exceed 50Gy (total cumulative dose)
      - No cases of myelopathy if cumulative doses ≤60Gy in 2Gy equivalent doses
    - Brachytherapy for small recurrences in oral cavity and oropharynx
    - IMRT or SBRT to reduce treatment-related toxicity

Cacicedo Cancer Treatment Reviews 2014

Head & neck

- Head & neck reirradiation: selection criteria
  - General considerations
    - Treatment decision in multidisciplinary team
    - Consider including patient in clincial trial if possible

Cacicedo Cancer Treatment Reviews 2014

Rectum

- Palliative reirradiation for recurrent rectal cancer (n=52)
  - Median reirradiation dose 30.6 Gy,
  - 2 × 1.2 Gy/f per day or 2 Gy/f per day

- Significantly lower risk of late complications with hyperfractionated treatment delivery (2 × 1.2 Gy/day)

Table 2. Late toxicity

RTOG Grade 3 toxicity	12/52 (23%)
Small bowel obstruction	9/52 (17%)
Cystitis	3/52 (6%)
RTOG Grade 4 toxicity	5/52 (10%)
Fistula	4/52 (8%)
Skin ulceration	1/52 (2%)

Table 4. Logistic regression analysis of factors influencing late toxicity

(< 2 years between courses and Dmax > 95 Gy)

Chen et al. IJROBP 2017

Summary clinical data

- Re-irradiation is an option for patients with recurrent or second tumors
- Risk of normal tissue damage and impact on quality of life must be taken into account

Take home messages

- If tolerance has already been exceeded: no re-irradiation possible without loss of function

- Early effects
  - Low to moderate doses:
    - Restitution of original tolerance may be complete after tissue-specific and dose-dependent time intervals
  - High doses:
    - Residual damage may remain for longer intervals, particular at the stem cell level, which is not necessarily reflected in functional tissue compartments

Take home messages

- Late-responding tissues
  - Partial (CNS, lung) or complete (skin) restoration of tolerance after low to moderate doses (<60% initial tolerance)
  - Progression of damage at subclinical level (kidney, urinary bladder) must be expected thus precluding re-irradiation without exceeding tolerance

Take home messages

- Strategies for retreatment
  - Alternative treatment options must be considered before re-irradiation
  - If (curative) re-irradiation is to be considered
    - Use best available treatment planning
    - Consider hyperfractionation for treatment with curative intent
    - Consider combined EBRT and brachytherapy

Grégoire & Leclerc, 2013

Validation study in locally advanced HNSCC

Use of FDG-PET for target volume delineation in 3D-CRT/IMRT for head and neck tumors

- $GTV\text{-}T_{FDG\text{-}PET} < GTV\text{-}T_{CT}$
- $CTV\text{-}T_{FDG\text{-}PET} < CTV\text{-}T_{CT}$
- $PTV\text{-}T_{FDG\text{-}PET} < PTV\text{-}T_{CT}$ (oropharyngeal SCC)
- More parotid sparing with the use of FDG-PET (oropharyngeal SCC)
- Loco-regional control probability within the expected range

Grégoire & Leclerc, 2013

Validation study in locally advanced HNSCC

- Local relapse: 9/41
  - No marginal recurrence (i.e. in the CTV_{CT} and not CTV_{PET})
- Regional relapse: 2/41
- Metastasis: 6/41
- Second primary: 2/41

Grégoire & Leclerc, 2013

Molecular Imaging across the board

- Lung carcinoma: more accurate delineation of the NSCLC GTV with FDG-PET
- Esophageal tumor: no convincing data for FDG-PET
- Brain tumor: ^{11}C-Met in low grade glioma and meningioma
- Rectal tumor: promising data with FDG-PET, but clinical usefulness still unknown
- Cervix carcinoma: FDG-PET for delineation of mombo-aortic node GTV
- Prostate carcinoma: ^{11}C-choline for recurrent disease; MRI and DW-MRI for GTV delineation

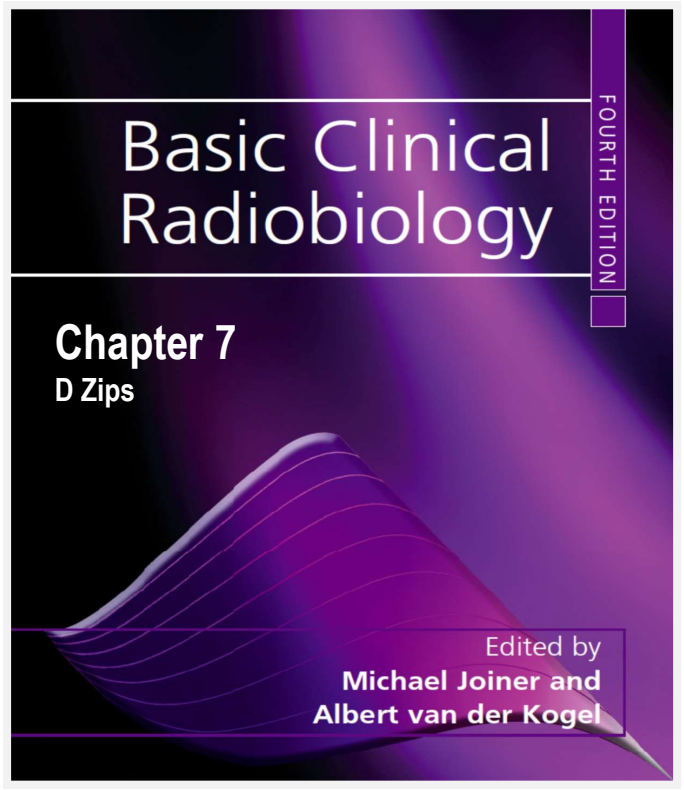
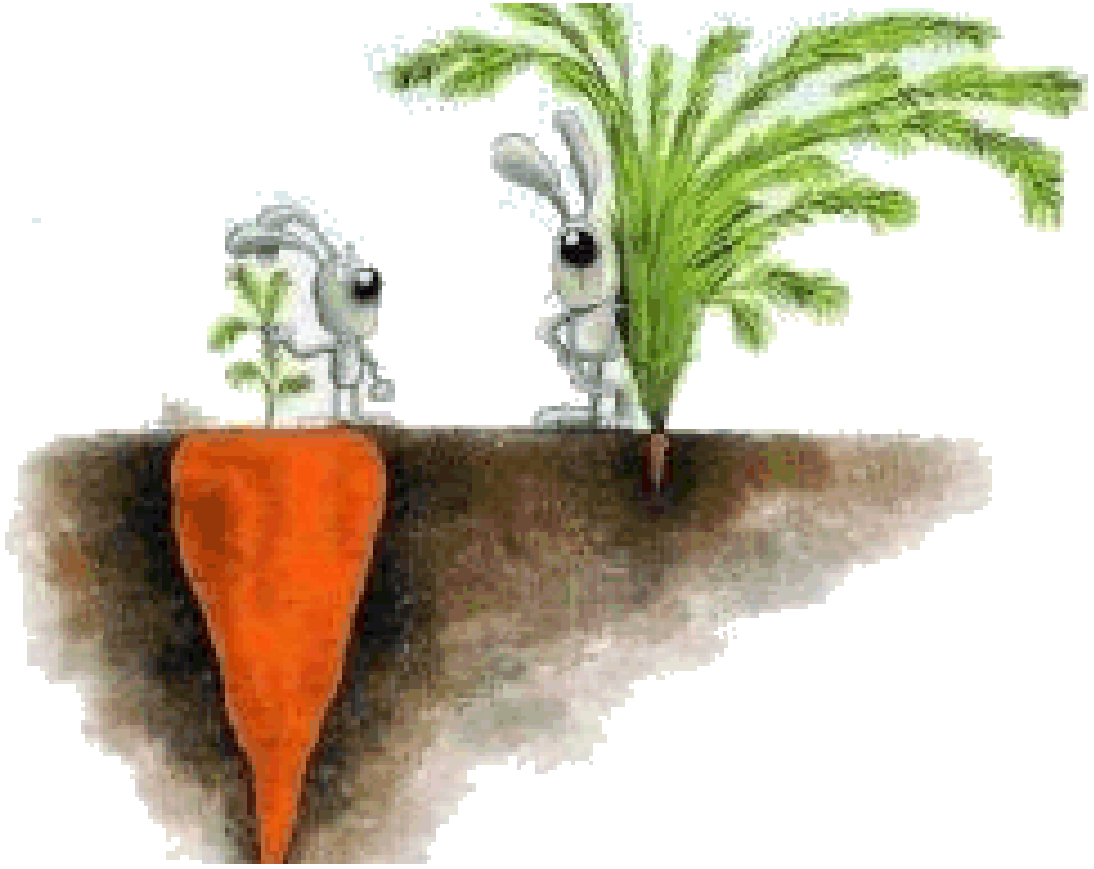
- Take home messages





Tumor growth

Tumor growth

- Disturbed tissue homeostasis, driven by functional capabilities aquired during tumorigenesis

Hanahan and Weinberg, Cell 2011

Exponential and non-exponential growth

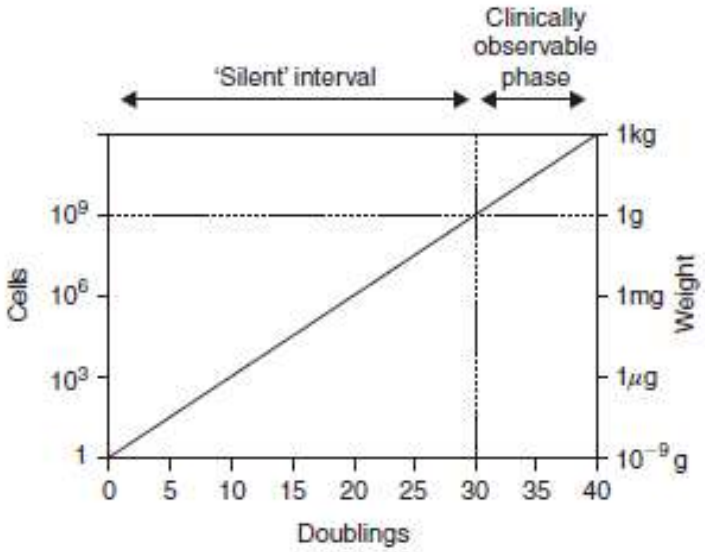


Figure 7.1 Relationship between the number of doublings from a single cell and the number of resulting cells in a tumour. To calculate the tumour weight, a cell number of 10^9 per gram was assumed. The clinically observable phase represents a minor part in the history of the tumour. Tumour weight is plotted on a logarithmic scale. If the doubling time is constant, a straight line indicates exponential tumour growth.

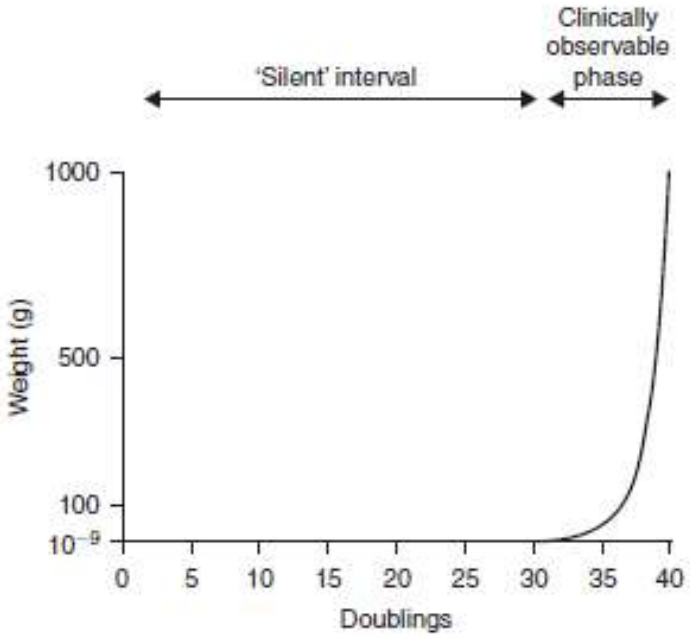

Figure 7.2 The same data as used for Fig. 7.1 but tumour weight is plotted on a linear scale. This may lead to the erroneous impression that tumour growth accelerates during the clinically observable phase.

Definitions

- Tumor volume doubling time (VDT): time required for tumor to double its volume
- Growth fraction (GF): cells in the compartment of actively dividing cells
- Cell-cycle time (Tc): time required to complete the cell cycle
- Ts: duration of S-phase
- Potential doubling time (Tpot): cell doubling time without any cell loss (Tpot = Tc/GF)
- Cell loss factor (CLF): tumor cell loss during growth

  (CLF = 1 – Tpot/VDT)

Volume doubling time

- Tumor growth rate varies considerable between tumors
- Tumors grow fast if growth fraction is high, cell-cycle time short and cell loss low

Basic clinical radiobiology

Table 7.1 Volume doubling times (VDTs) for human tumours taken from a review of early data on the growth rate of human tumours

Site and histology	Number of tumours measured	Mean VDT* (days)	Confidence limits (days)
Lung metastases

Bladder	35	3–55	Hoskin *et al.* (2004)
Oesophagus	33	6–95	Sarbia *et al.* (1996)

LI, labelling index.

Cell cycle kinetics

Table 7.4 Cell kinetic parameters of human tumours derived from *in vivo* labelling with iododeoxyuridine (IdUrd) or bromodeoxyuridine (BrdUrd) and measured by flow cytometry

Site	Number of patients	LI (%)	T_S (hours)	T_{pot} (days)
Head and neck	712	9.6 (6.8–20.0)	11.9 (8.8–16.1)	4.5 (1.8–5.9)
Central nervous system	193	2.6 (2.1–3.0)	10.1 (4.5–16.7)	34.3 (5.4–63.2)
Upper intestinal	183	10.5 (4.9–19.0)	13.5 (9.8–17.2)	5.8 (4.3–9.8)
Colorectal	345	13.1 (9.0–21.0)	15.3 (13.1–20.0)	4.0 (3.3–4.5)
Breast	159	3.7 (3.2–4.2)	10.4 (8.7–12.0)	10.4 (8.2–12.5)
Ovarian	55	6.7	14.7	12.5
Cervix	159	9.8	12.8	4.8 (4.0–5.5)
Melanoma	24	4.2	10.7	7.2
Haematological	106	13.3 (6.1–27.7)	14.6 (12.1–16.2)	9.6 (2.3–18.1)
Bladder	19	2.5	6.2	17.1
Renal cell carcinoma	2	4.3	9.5	11.3
Prostate	5	1.4	11.7	28.0

Fraction of cells in S phase (LI), duration of S phase (T_S) and potential doubling time (T_{pot}) were taken from Haustermans *et al.* (1997) and Rew and Wilson (2000). Ranges (in parenthesis) represent variations in median values between studies; ranges for individual tumours are considerably larger.

Basic clinical radiobiology

Cell loss factor

- Tpot is much shorter than VDT!?

- Vast majority of newly produced cells are lost from the GF (e.g. by differentiation, necrosis, metastasis), explaining the slow growth rate of tumors

Cell loss factor

Table 7.5 Calculation of cell loss factors (CLFs) for human tumours based on labelling with radiolabelled thymidine or thymidine analogues and volume doubling times (VDTs) in separate series

Site	LI (%)	T_{pot} (days)	VDT (days)	CLF (%)
Undifferentiated bronchus carcinoma*,[1]	19.0	2.5	90	97
Sarcoma*,[1]	2.0	23.3	39	40

Tumor response to radiation

Endpoints

- Tumor regression → non-specific endpoint
- Tumor regrowth delay → difficult or impossible to accurately estimate cell kill
- Local tumor control
  - Aim of curative RT → improvements in LC often translate into prolonged survival
  - When all clonogenic cells (i.e. cells with the capacity to proliferate and to cause recurrence after RT) have been inactivated

Clonogenic cell survival after RT

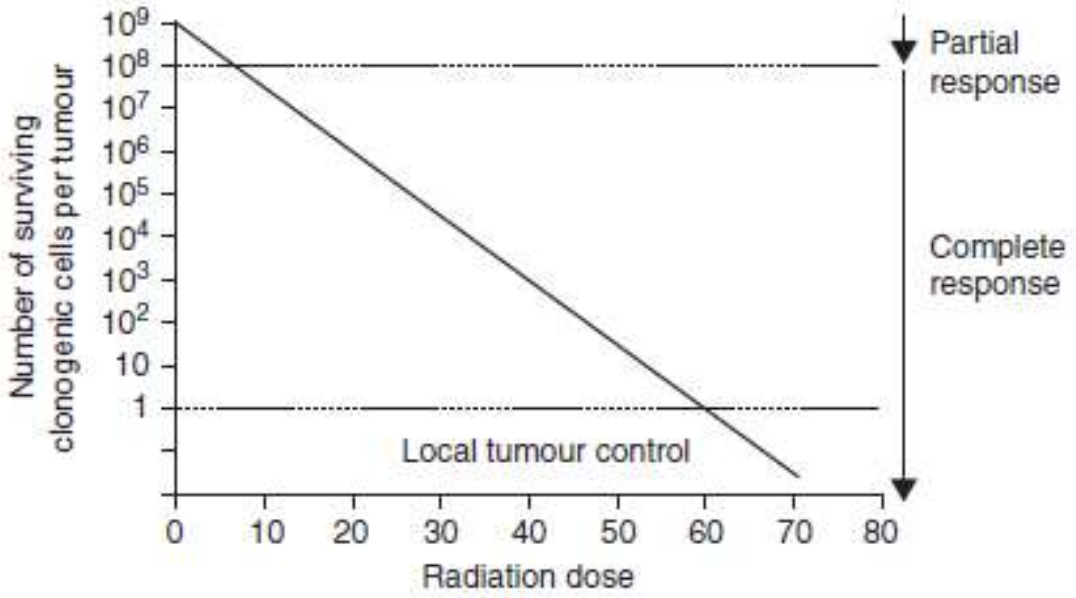

Figure 7.3 Relationship between clonogenic cell survival, radiation dose and different endpoints to assay tumour response, assuming a tumour consisting of 10^9 clonogenic cells and a surviving fraction after 2 Gy of 50 per cent.

Basic clinical radiobiology

Local tumor control

- TCP as a function of radiation dose – Poisson distribution
- Random distribution of radiation-induced cell kill within a population of clonogenic cells

1				1	2
2	3	1	2	1	
	1		2		1
1	1	2		4	1
1		1		3	1
	2	1	1		

Figure 7.4 A model tumour consisting of 36 clonogenic tumour cells (each square represents one clonogenic cell) after irradiation with a dose sufficient to inflict an average of one 'lethal hit' per clonogenic cell. Owing to random distribution of the 'lethal hits' among the tumour, some clonogenic cells received one (1), two (2), three (3) or four (4) lethal hits. These cells subsequently die (grey shadow). According to Poisson statistics (SF = $exp(-m)$, see text) 37 per cent of the clonogenic cells (i.e. a total of 13 cells (received no 'lethal hit' and survived white background). The tumour control probability (TCP) after this 'treatment' can be calculated as TCP = $exp(-13) = 2.3 \times 10^{-7}$. This means that only 1 out of 23 million tumours will be locally controlled in this situation. In Table 7.6 and Fig. 7.5, the dose effects on surviving cell fraction (SF) and TCP are illustrated.

Local tumor control

Table 7.6 Relationship between radiation dose, fraction of surviving clonogenic tumour cells (SF) and local tumour control probability (TCP) according to Poisson statistics for the 'treatment' of a model tumour consisting of 36 clonogenic tumour cells.

Radiation dose (relative units)	Number of 'lethal hits' per clonogenic cell (m)	SF = $\exp^{(-m)}$ (%)	Number of surviving clonogenic tumour cells (N = SF × 36)	TCP = $\exp^{(-N)}$ (%)
1	36/36 = 1	37	13	<0.0001
2	72/36 = 2	14	5	1
3	108/36 = 3	5	2	17
4	144/36 = 4	1.8	0.7	52
5	180/36 = 5	0.7	0.2	78
6	216/36 = 6	0.25	0.09	91
7	252/36 = 7	0.09	0.03	97
8	288/36 = 8	0.03	0.01	99

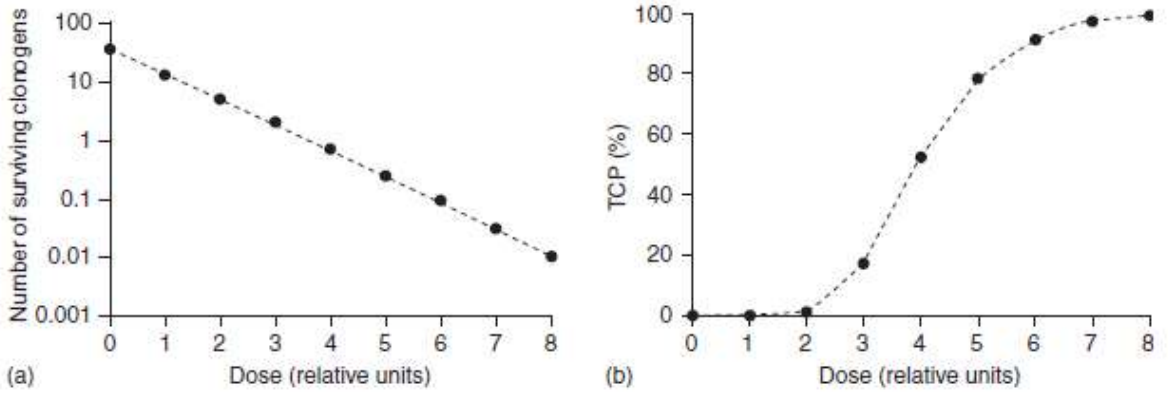

Figure 7.5 Illustration of the 'treatment effects' on the model tumour consisting of 36 clonogenic cells (compare Fig. 7.4 and Table 7.6). Values for the number of surviving clonogens and tumour control probability (TCP) were taken from Table 7.6.

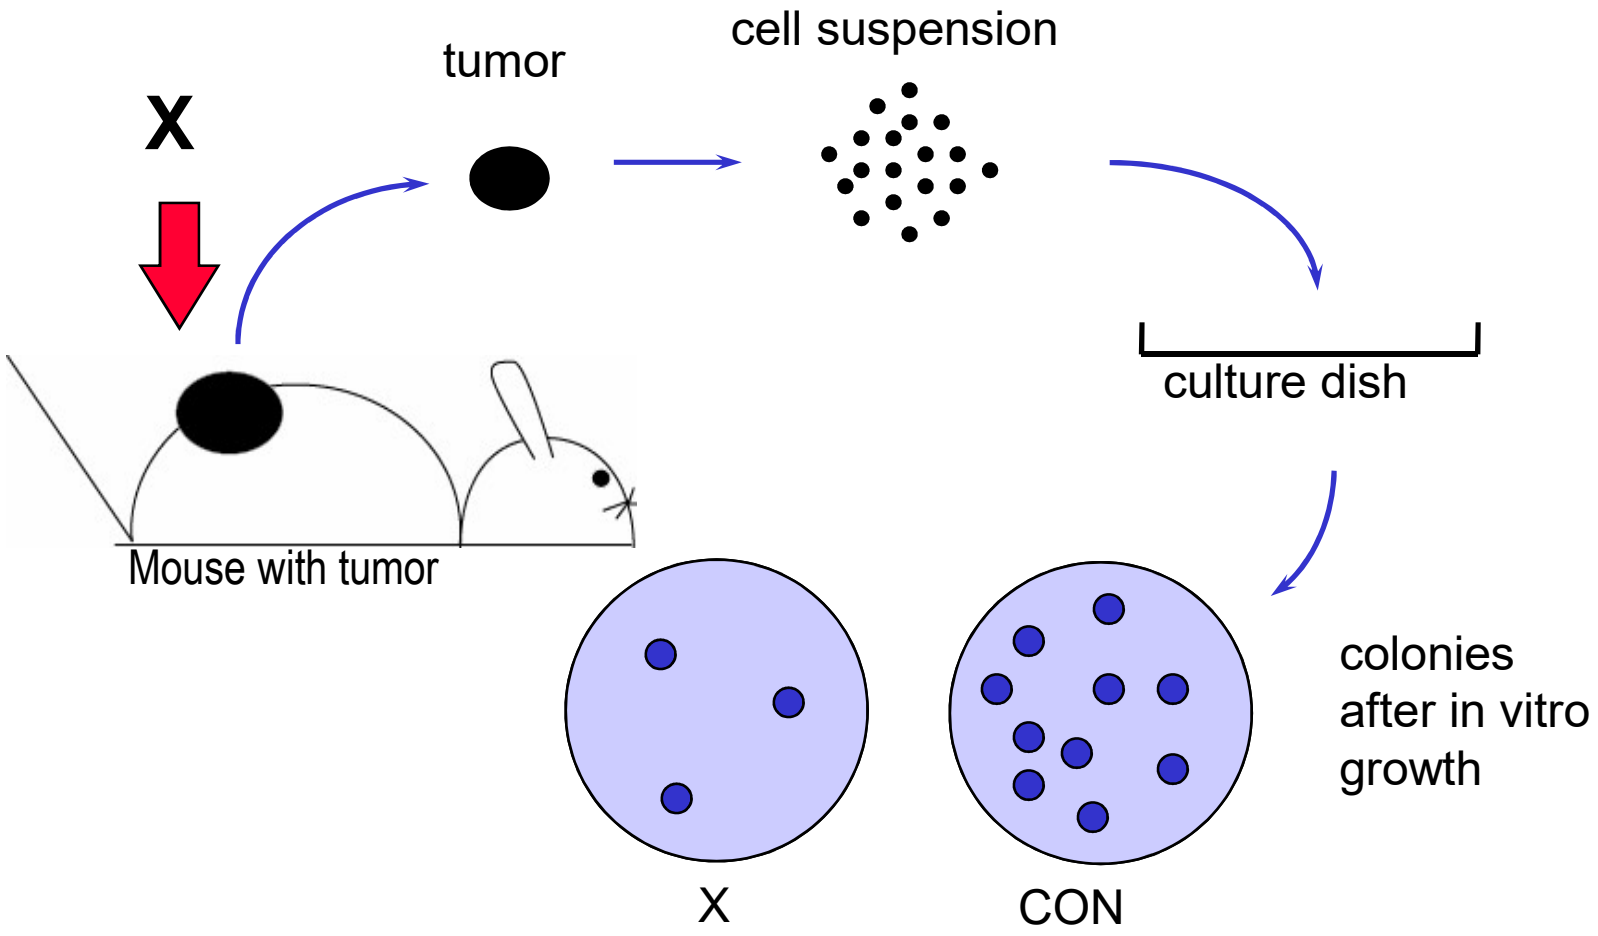
Ex-vivo assays

- Clonogenic assays (plating assays)
  - Tumors are excised, reduced to single cells and grown in a test environment
  - Provide a direct measure of the surviving fraction of clonogenic cells.
  - Limitation: relationship between clonogens (in test environment) and stem cells (in situ) is uncertain.

Clonogenic cell survival: ex vivo



Ex-vivo assays

- Culturing as organoids
  - Tumors are excised, reduced to single cells, and grown in 3D matrix
  - Measurement of tumor stem cells
  - Show potential to differentiate in all tumor subtype cells
  - Lack of environmental factors and vascularisation

Cancer Stem Cells (CSCs)

- Self-renewal
- Capability to develop into multiple lineages
- Chemo- and radiation resistant
- Formation of spheres in suspension culture
- Generation of tumors when transplanted in immunodeficient mice with limited number of cells

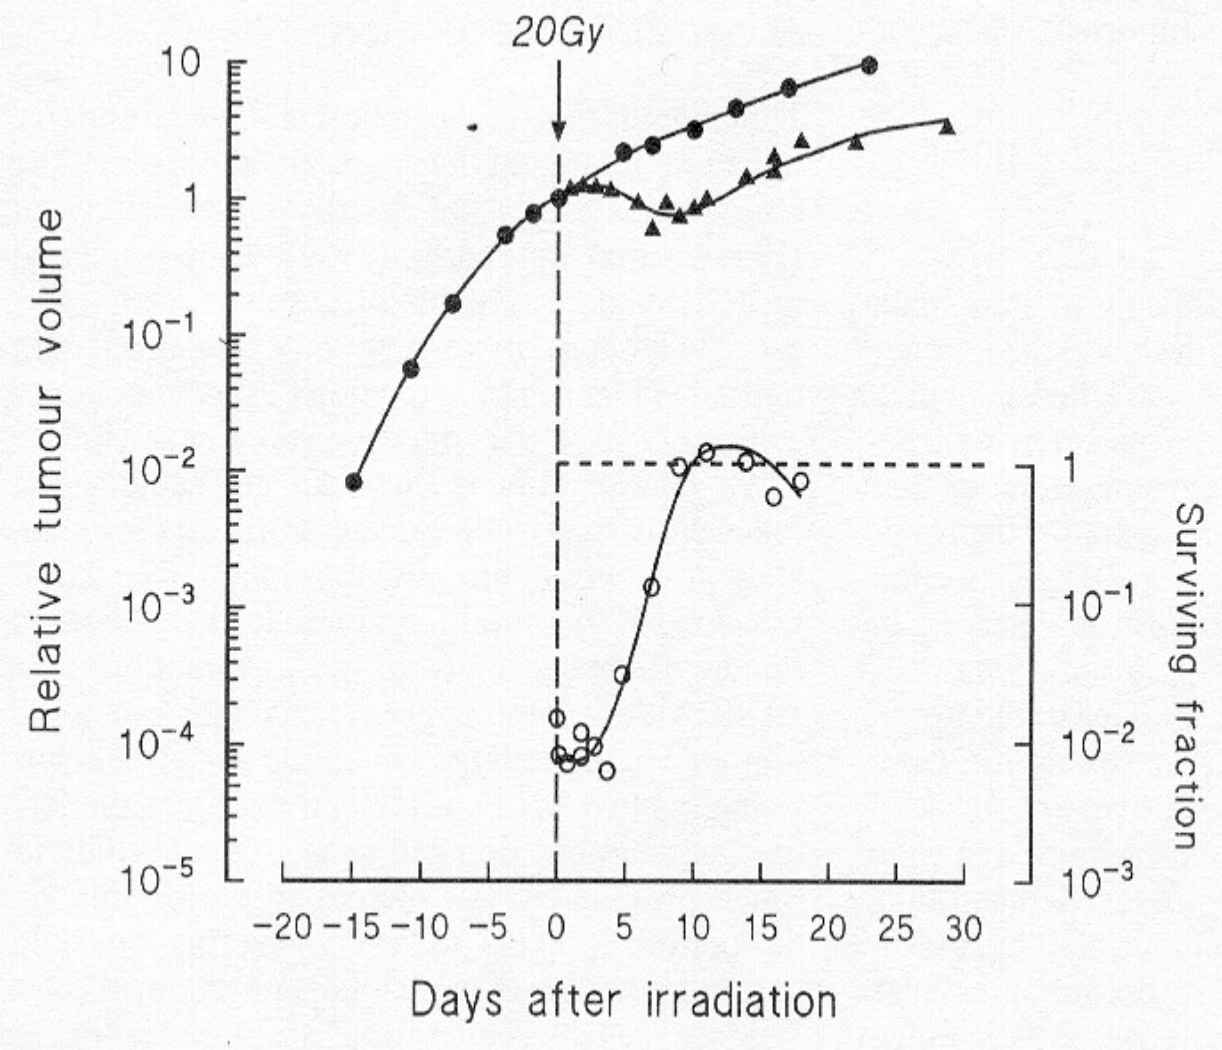
In situ assays

- In Situ assays (growth delay, tumor control):
  - Tumors left in place
  - Measure response of effective and potential stem cells
  - Limitation: no quantification of stem cells; surviving fraction is difficult to assess

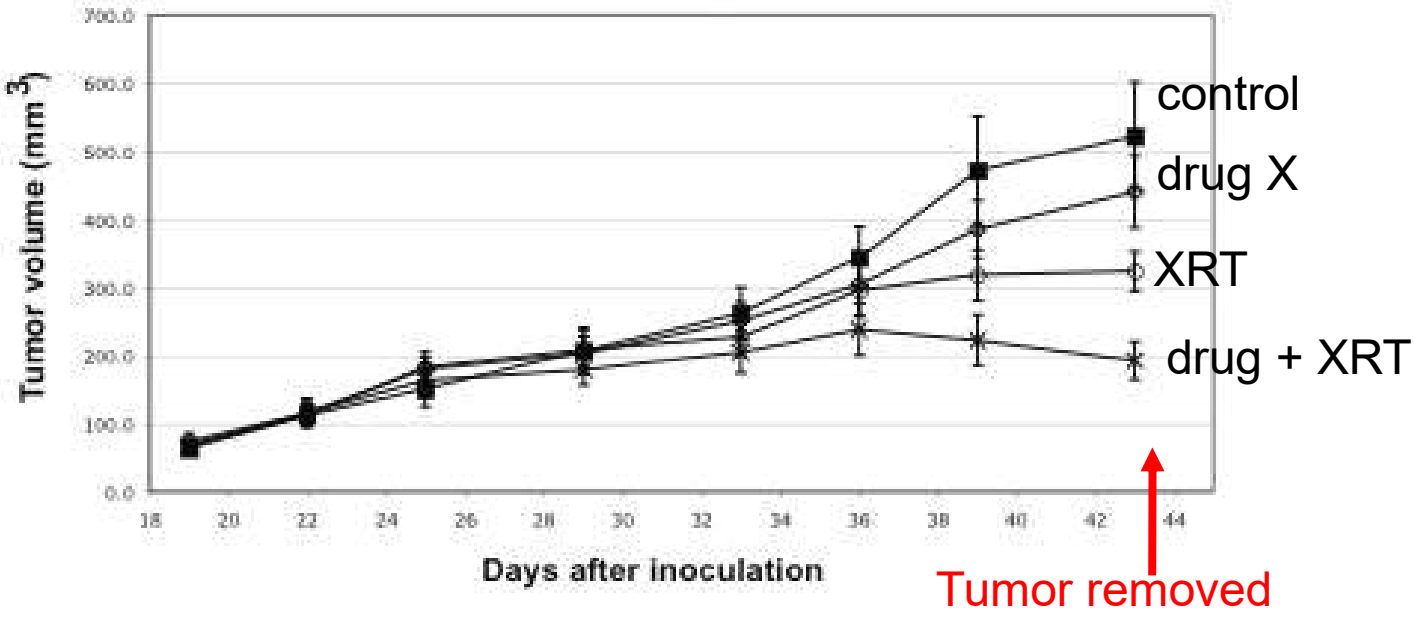
Tumor regression ≠ cell survival



Hermens and Barendsen, *Eur. J. Cancer* 1969

Tumor regression ≠ cell survival

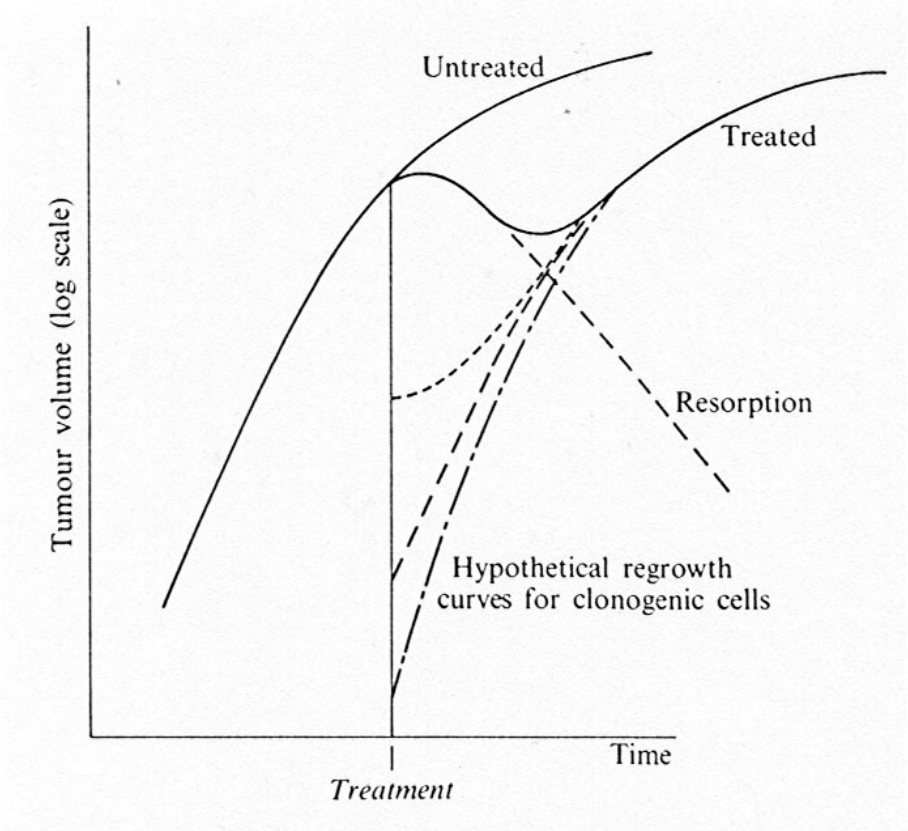
Human s.c.c. xenograft treated with 8 X 3 Gy / 4 wks



drug X = VEGFR2 inhibitor

Regrowth delay assay

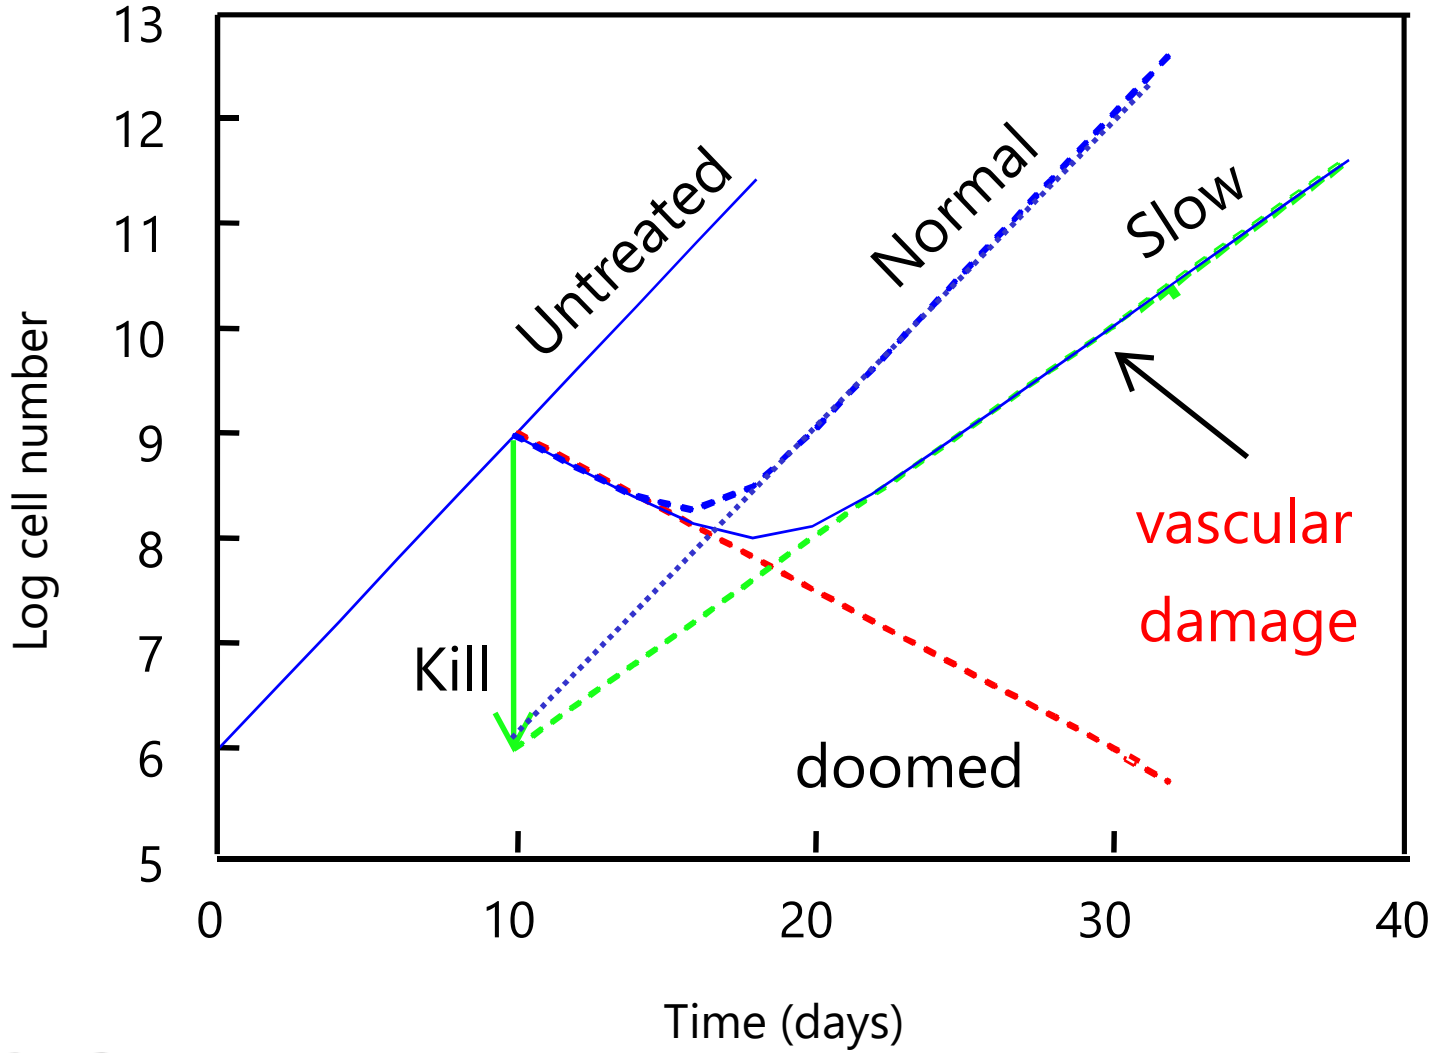
- Comparison of growth curves of treated and untreated tumors gives the delay caused by treatment
- Relationship between growth delay and surviving fraction of stem cells is complex
- Regrowing cells have different environment: surrounded by dead and dying cells; vascular network is already in place
- Tumor bed effect



Growth Kinetics of Tumors, G.G. Steel, 1977

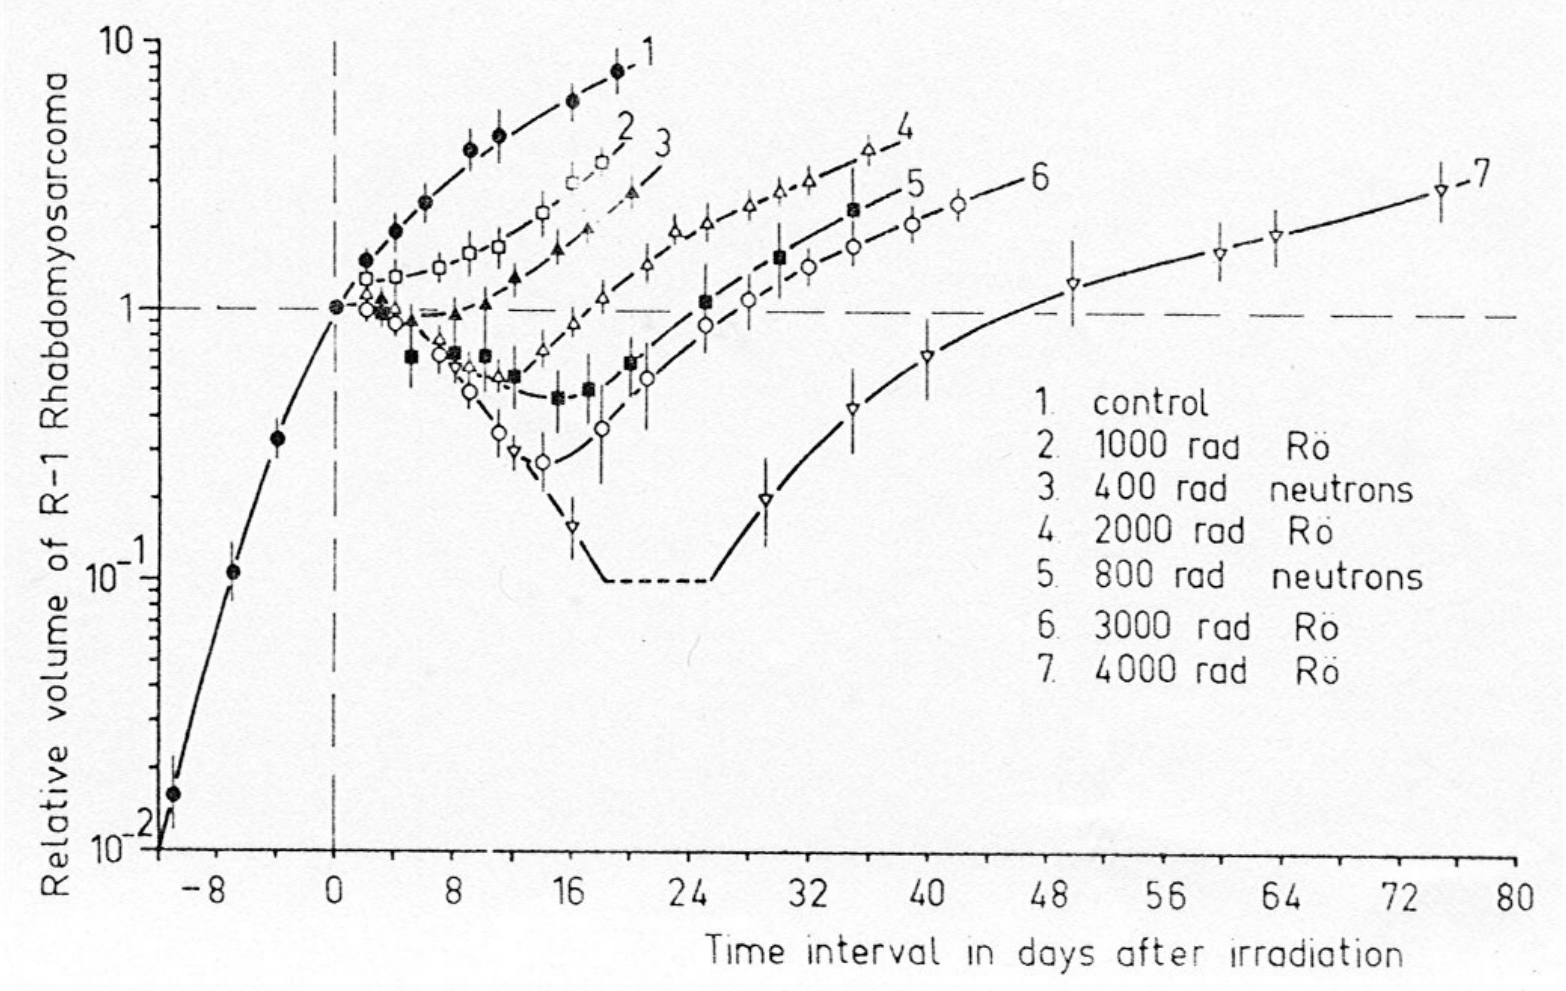
ESTRO School

Vascular damage: tumor bed effect



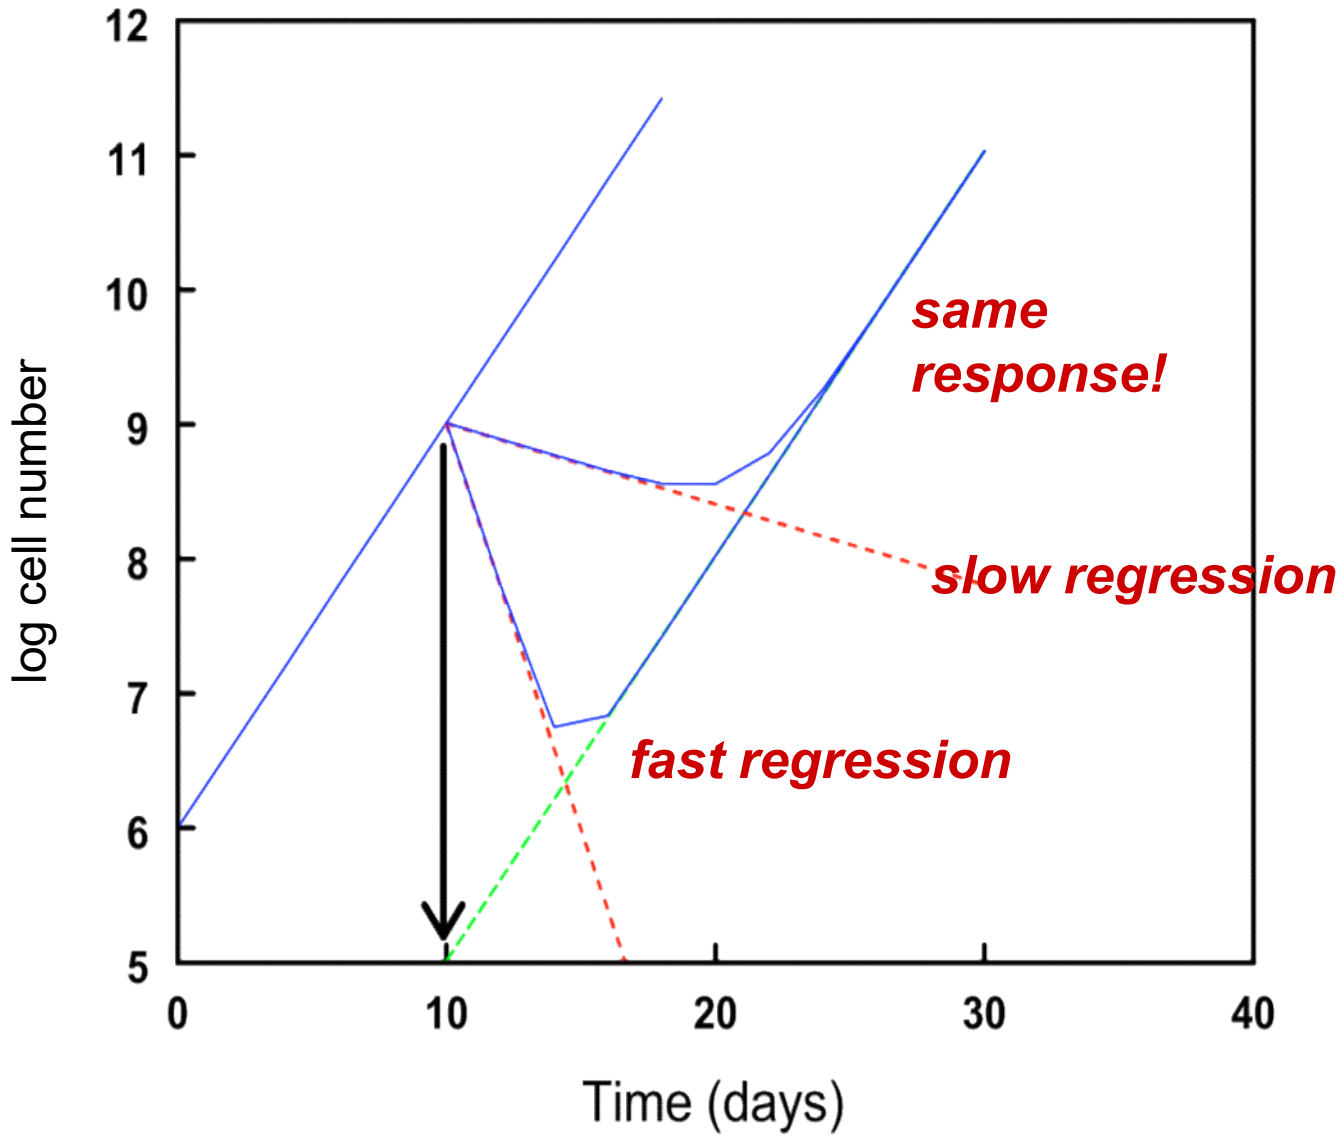
ESTRO School

Application of Regrowth Delay Assay
Comparison of different treatments

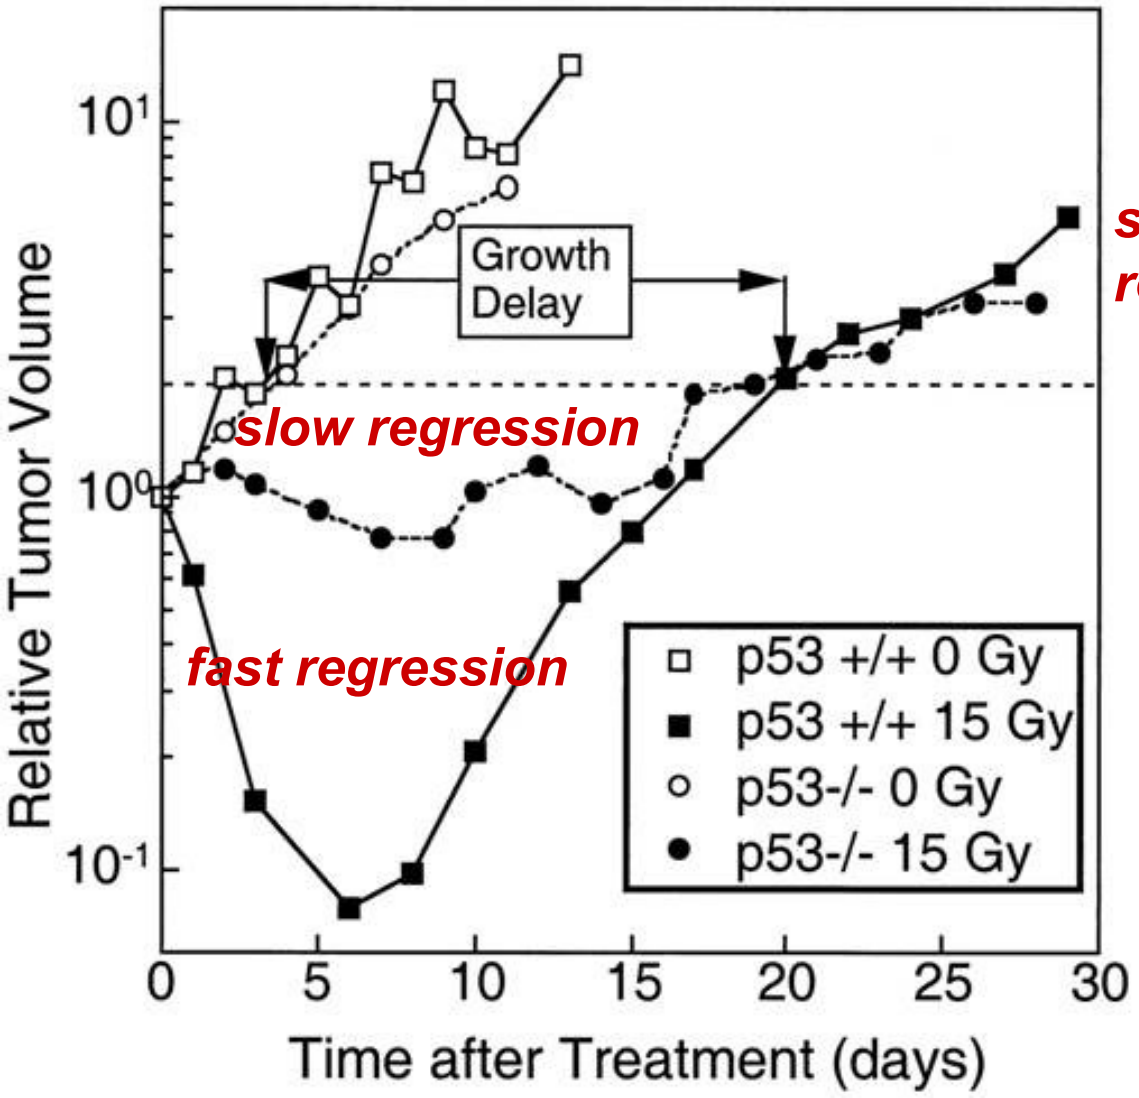


Barendsen and Broerse, Eur. J. Cancer 1969.

Delay independent of regression rate



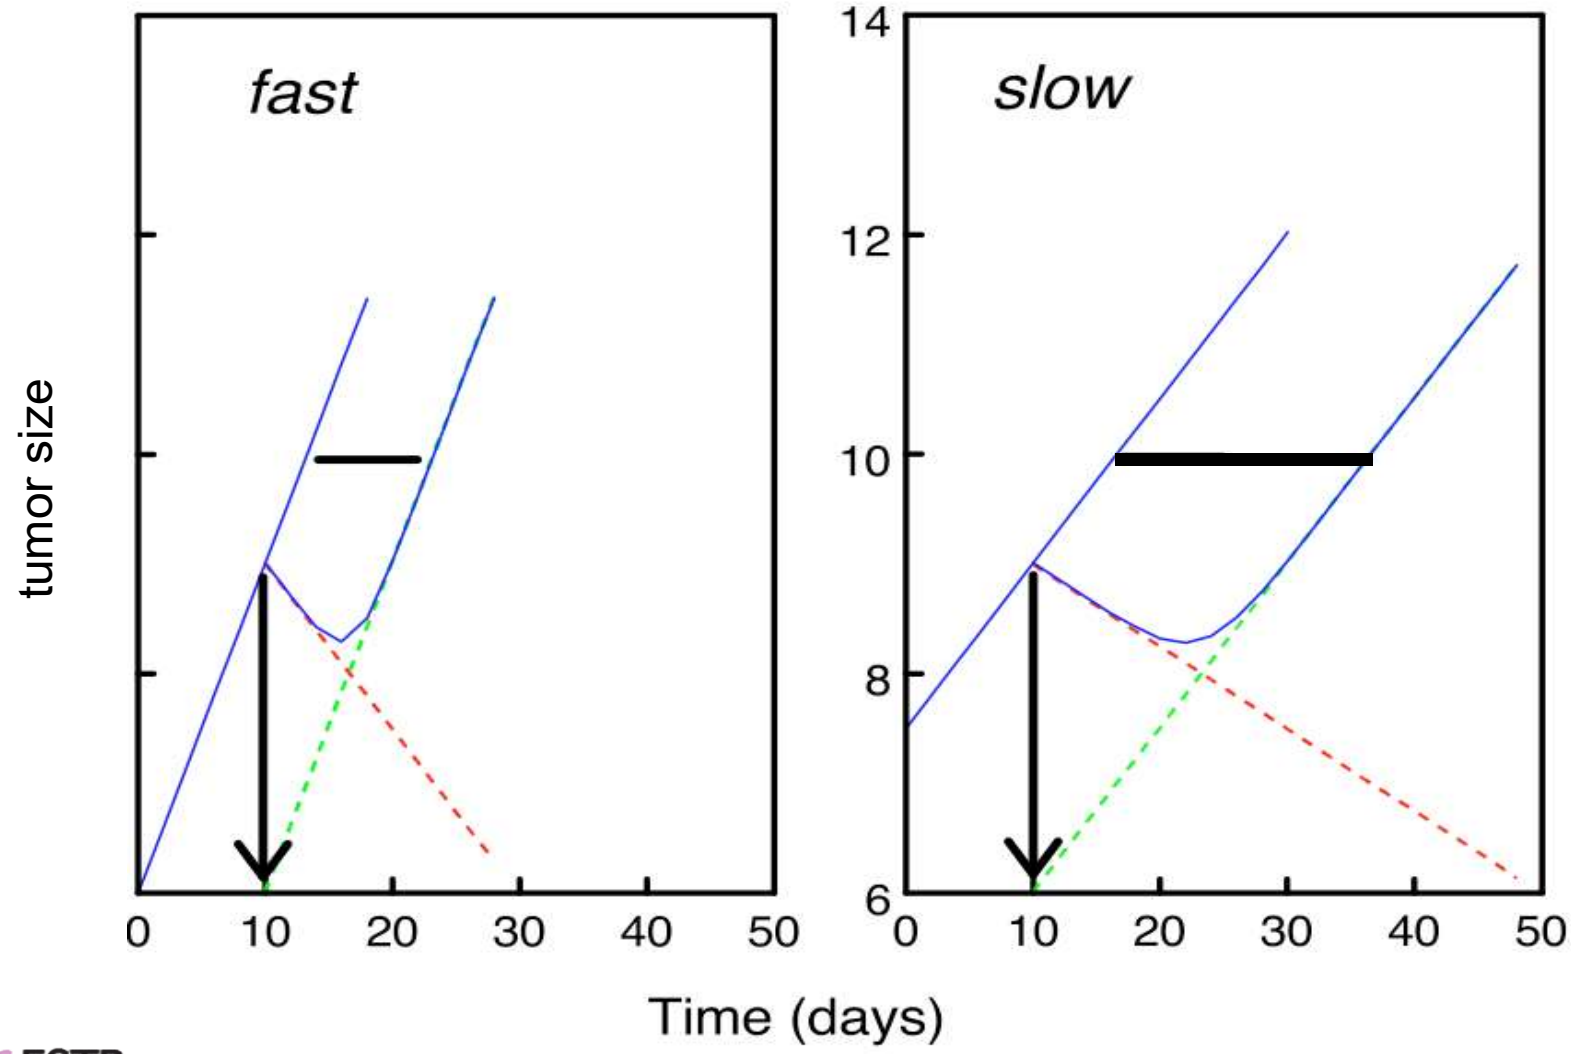
Delay independent of regression rate



same response!

Wouters & Brown, 1999

Growth delay depends on doubling time



Summary growth delay assay

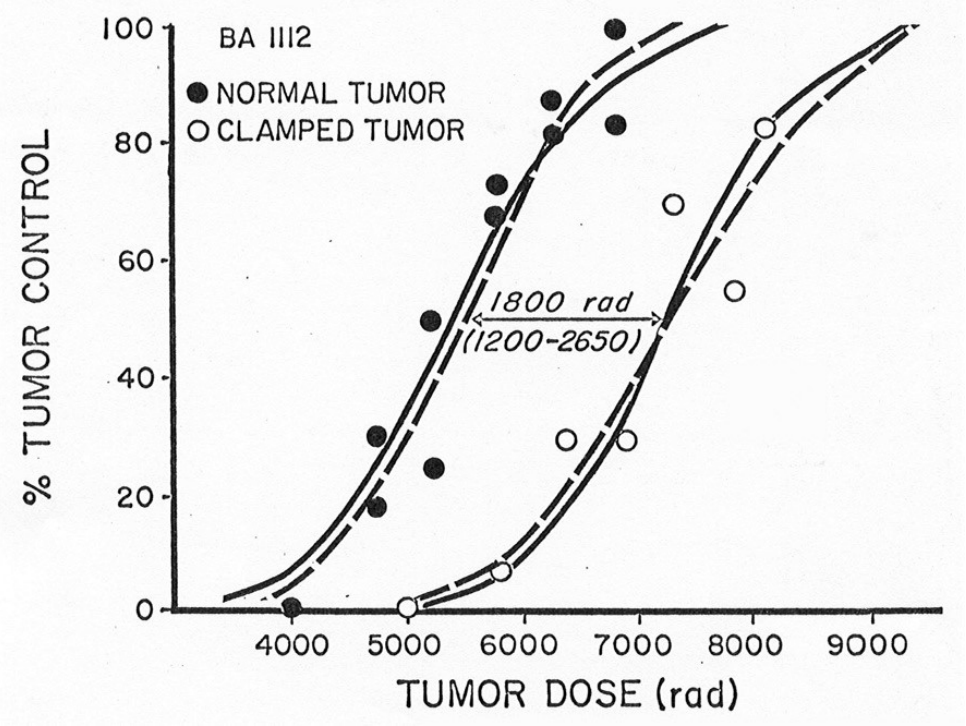
- Dependent on reliable volume measurement (difficult!)
  - with ultrasound imaging or bioluminescence more reliable than manual caliper
- Only suitable for few logs of tumor cells (selection)
- Reflects growth rate of clonogenic and non-clonogenic cells
- Dependent on growth rate of tumor
  - comparison of different tumors difficult
  - drugs may change growth rate (overestimation of efficacy)
  - radiation damage of vessels changes growth rate (tumor bed effect; overestimation of efficacy)

Local tumor control assay

- Irradiation of tumors in vivo
- Groups of tumors, different dose levels (graded doses)
- Follow up: local control or recurrence
- Evaluation of local control rates for each dose level
- Construction of dose response curves

Tumor Control (Cure) – TCD50

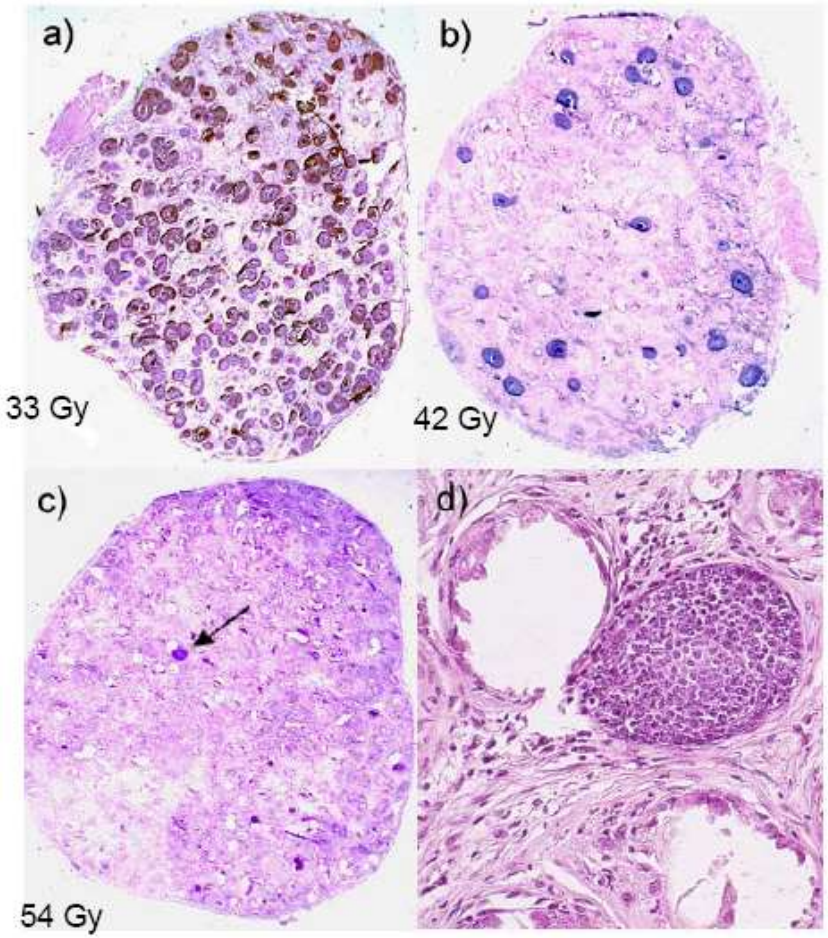
- The radiation dose which cures 50% of a homogeneous population of tumors (TCD50) is estimated.
- This assay most directly assesses the sensitivity of the stem cell population in the tumor.

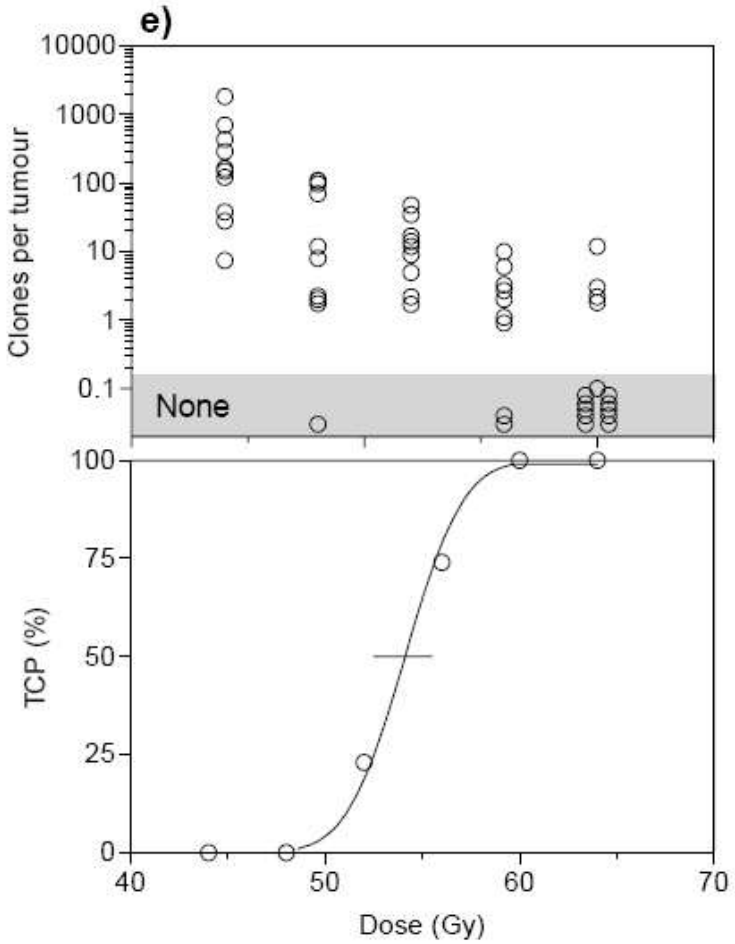


Moulder & Rockwell, IJROBP 1984

ESTRO School

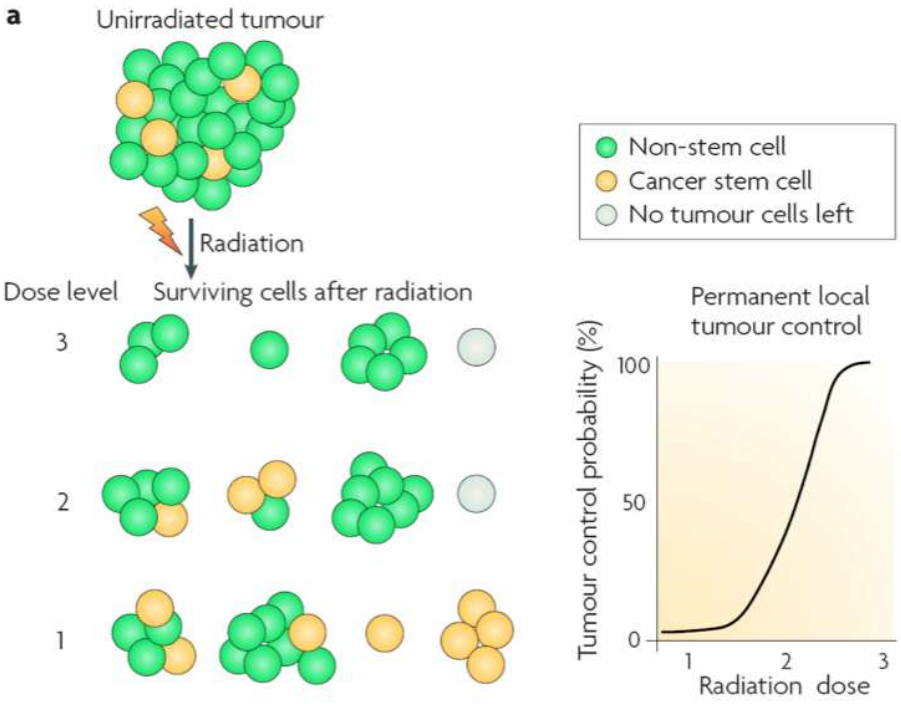
Local tumor control

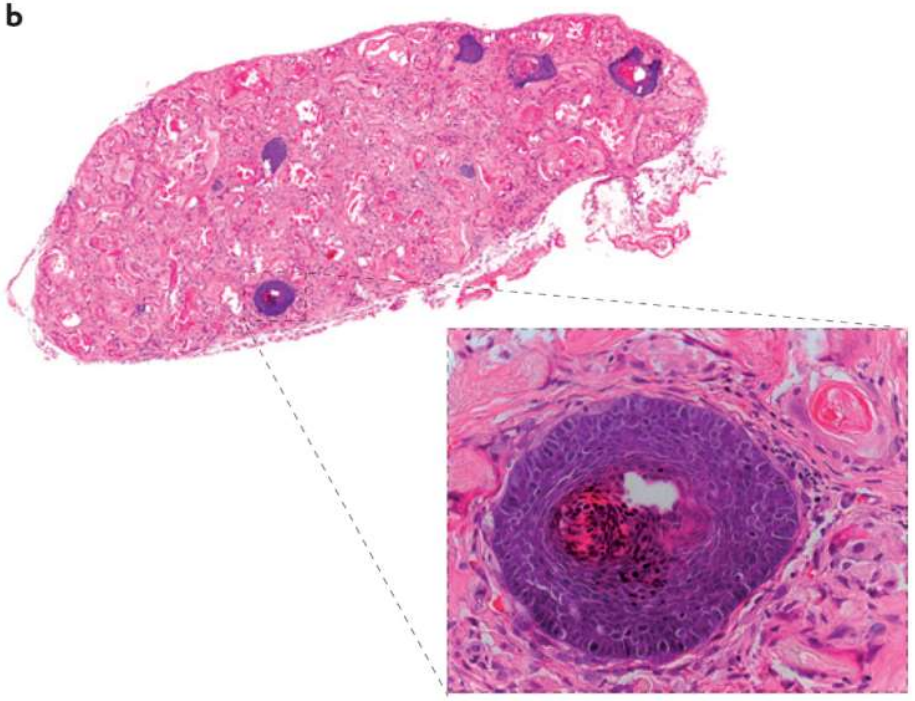




ESTRO School

Killing all cancer stem cells is necessary for local tumour control





Baumann, Krause, Hill, Nature Rev Cancer 545-554, 2008

ESTRO School

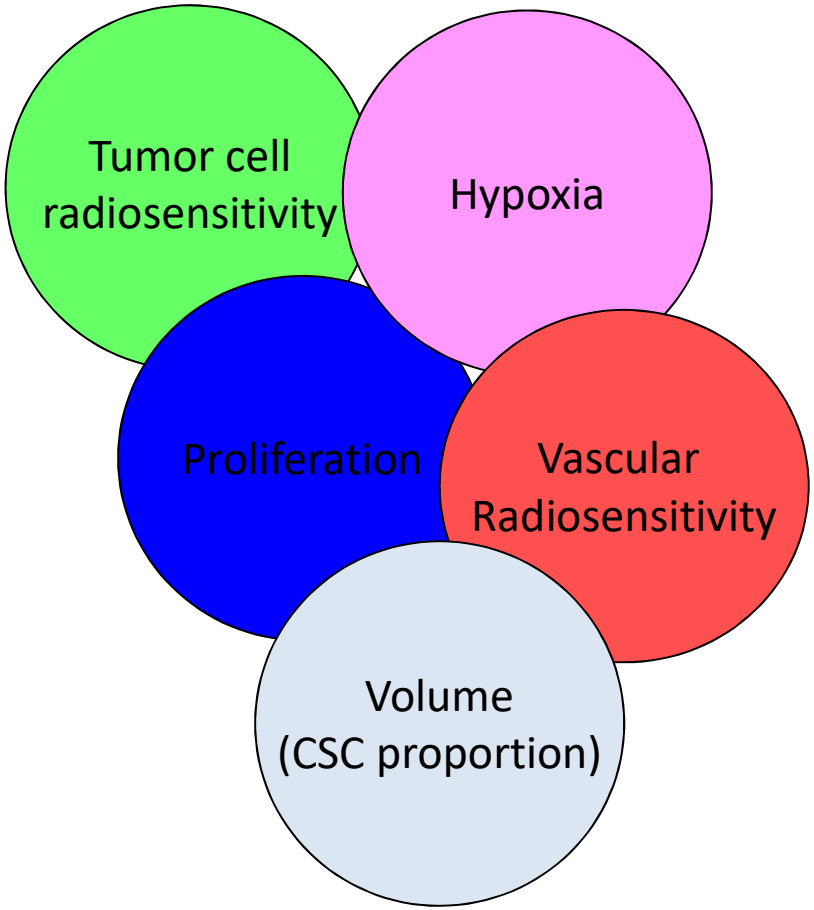
Summary TCD50 assay

- Best assay available for experimental radiotherapy
- Most relevant for clinical practice
- Tumour cells remain in situ
- Dependent only on clonogenic cells
- All clonogenic cells are assayed, not only some logs
  - Thus also survival of small resistant subgroups of clonogens can be assayed
- Good for radiobiological modelling



Factors influencing local tumor control

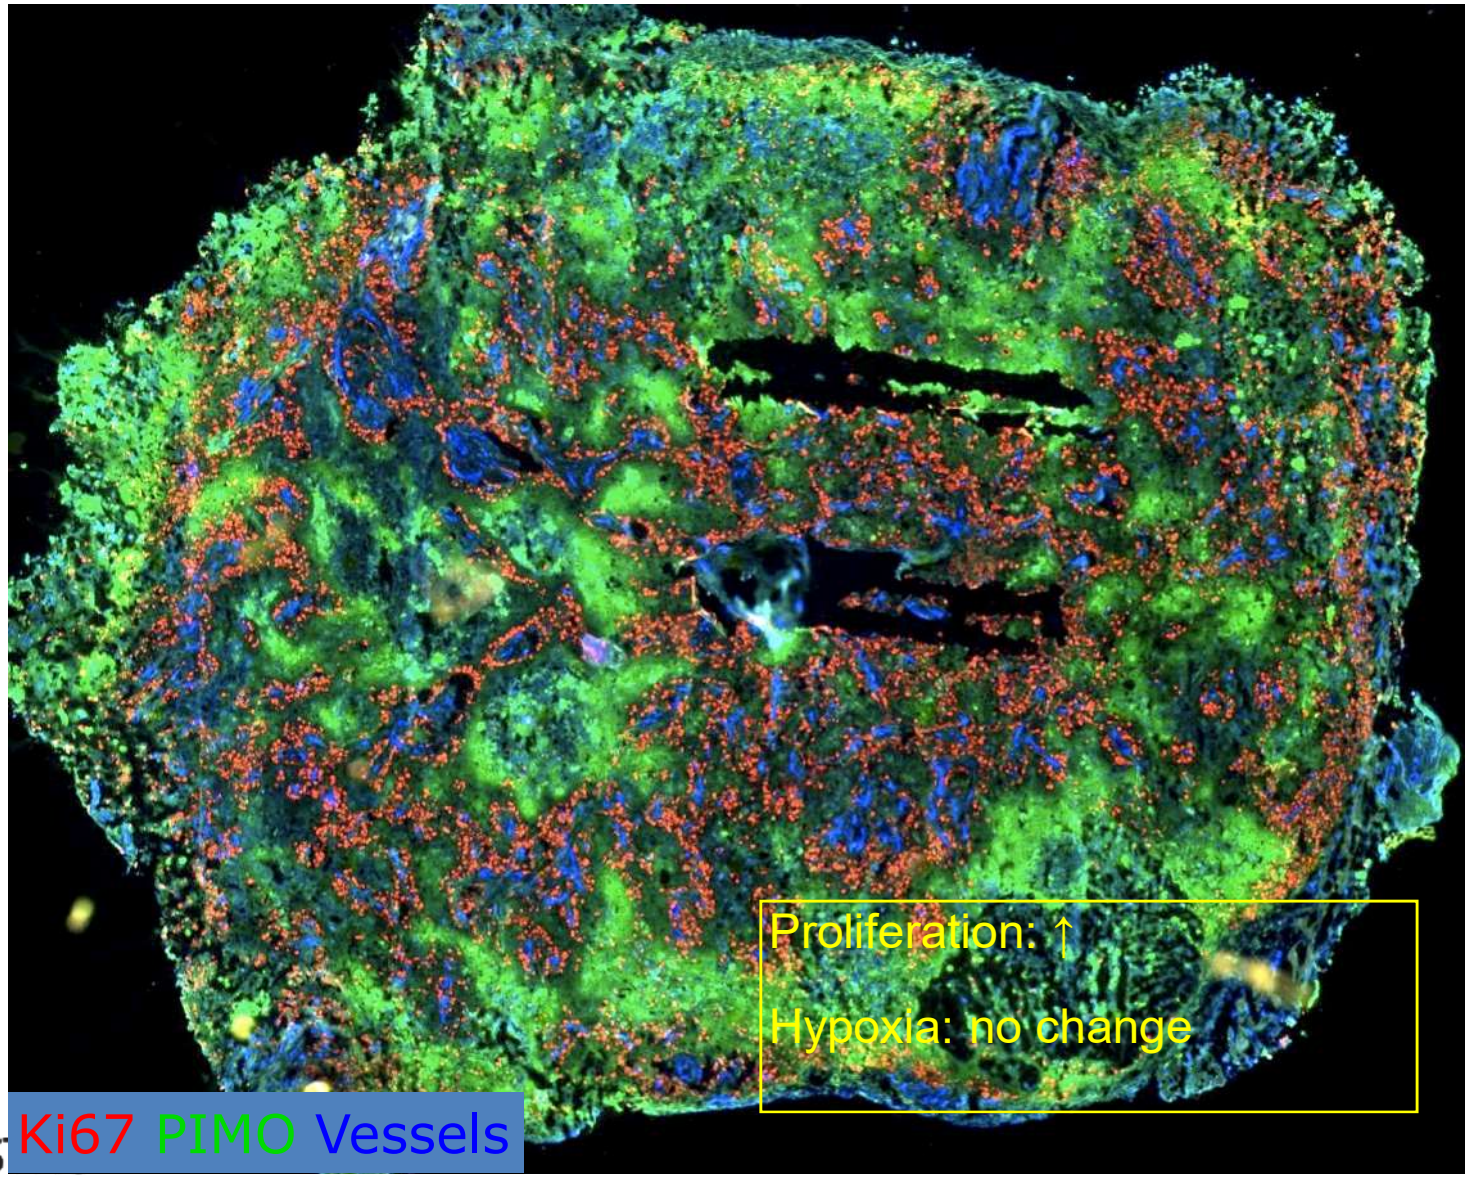
Proliferation & hypoxia in s.c.c. xenograft after 8 X 3 Gy/4 weeks + VEGFR-inhibitor



ES School

Repopulation of clonogenic tumor cells

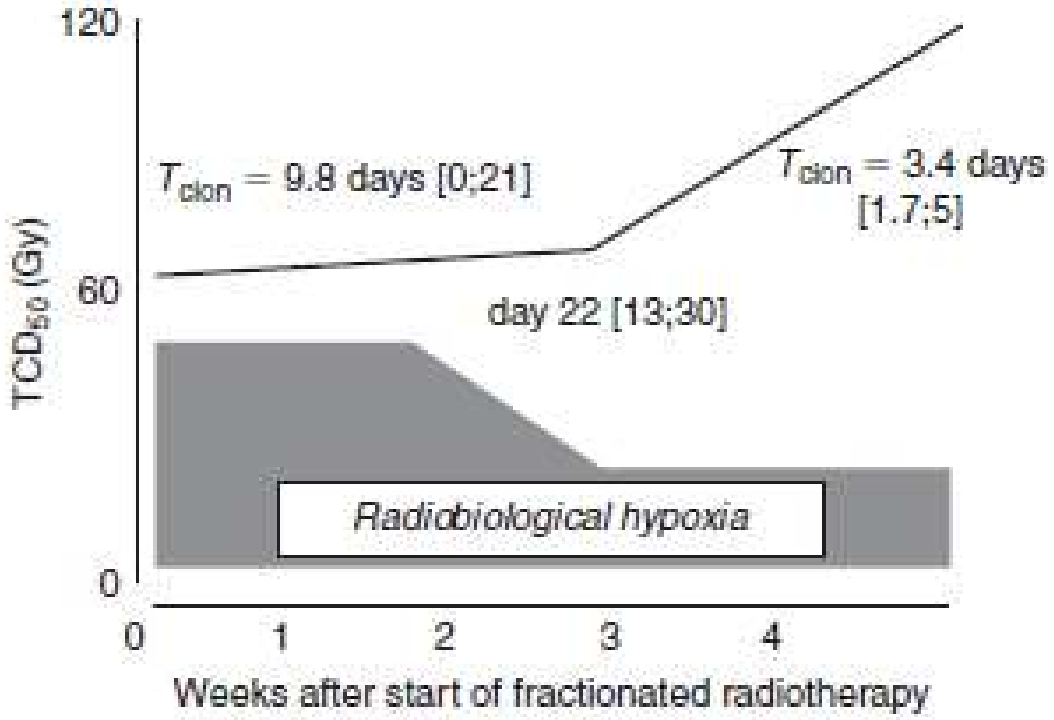


Figure 7.13 Rate, kinetics and underlying mechanism of repopulation of clonogenic tumour cells in FaDu squamous cell carcinoma growing in nude mice

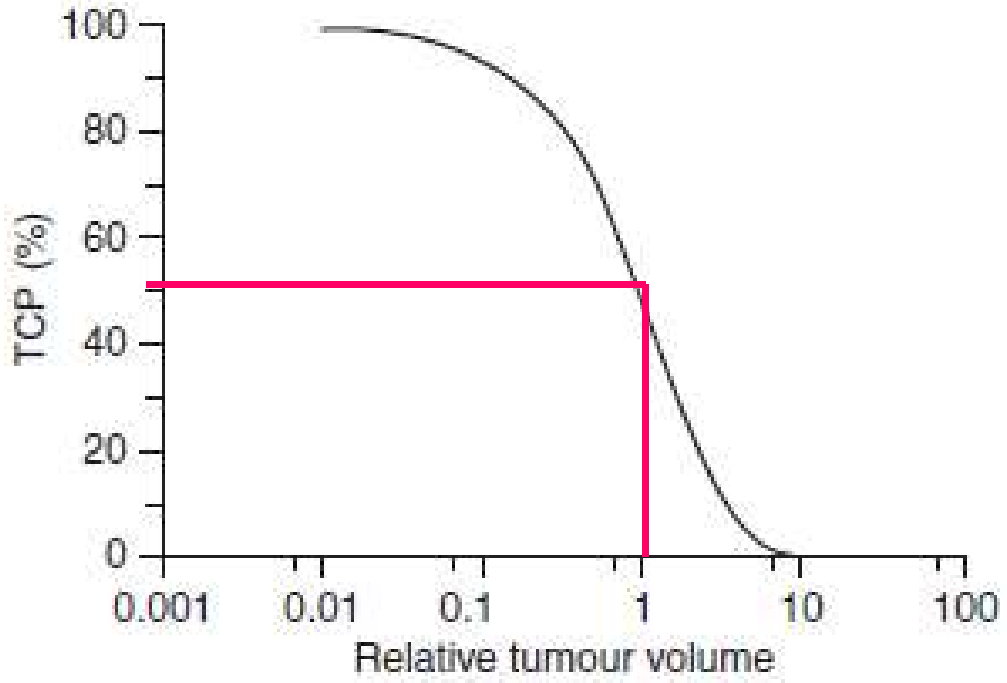
Tumor volume

- Important determinant of local tumor control!



Summary

- Tumor response to radiation depends on
  - Intrinsic cellular radiosensitivity
  - Stromal interactions (vasculature)
  - Microenvironment (hypoxia)
  - Tumour volume (stem cell number)
  - Cellular proliferation (repopulation)

Take home messages

- Tumor models can be used to explore
  - Different treatment regimes
  - Importance of biological pathways
- Volume response:
  - Measure time to regrowth, not regression.
  - Correct for doubling time when comparing tumors
- Tumor cure: gold standard
  - Not possible with drugs alone (insufficient kill)
  - Many animals and long time, so only use as confirmation

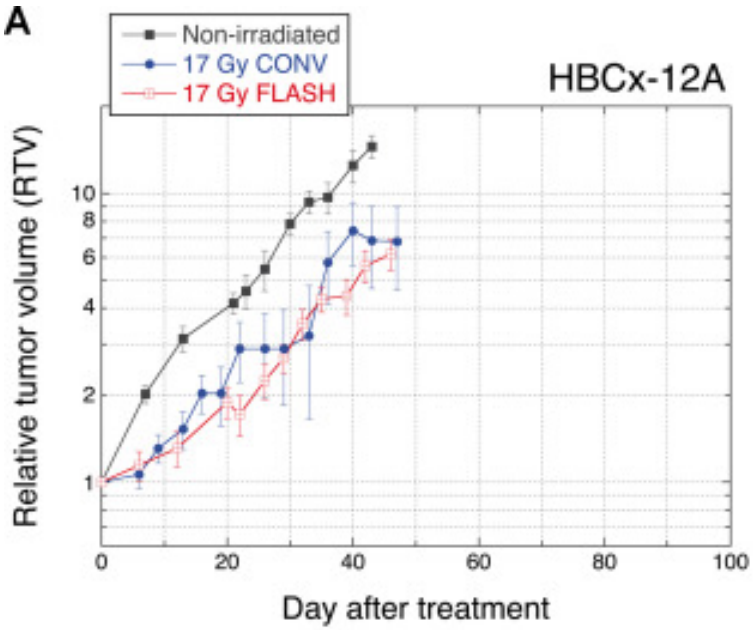
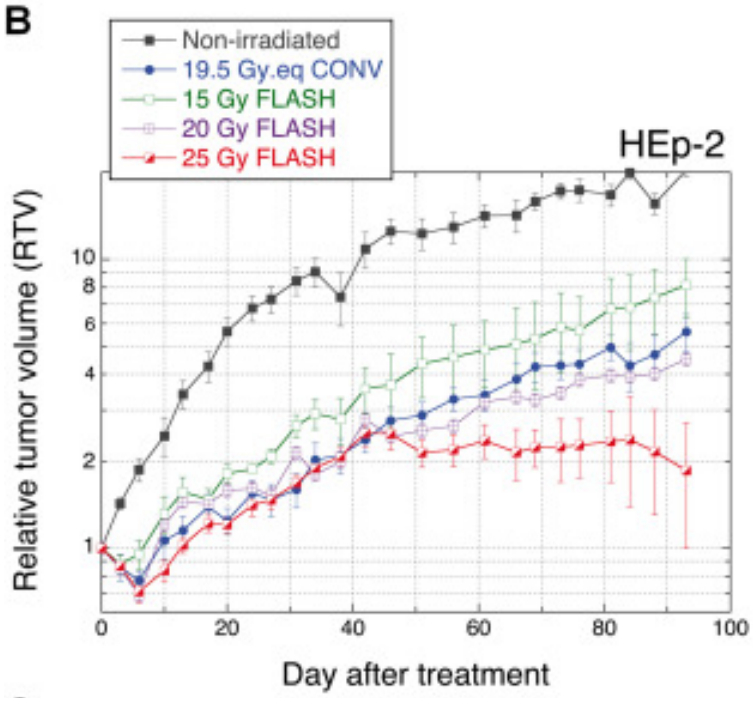
Effectiveness of very high dose rate

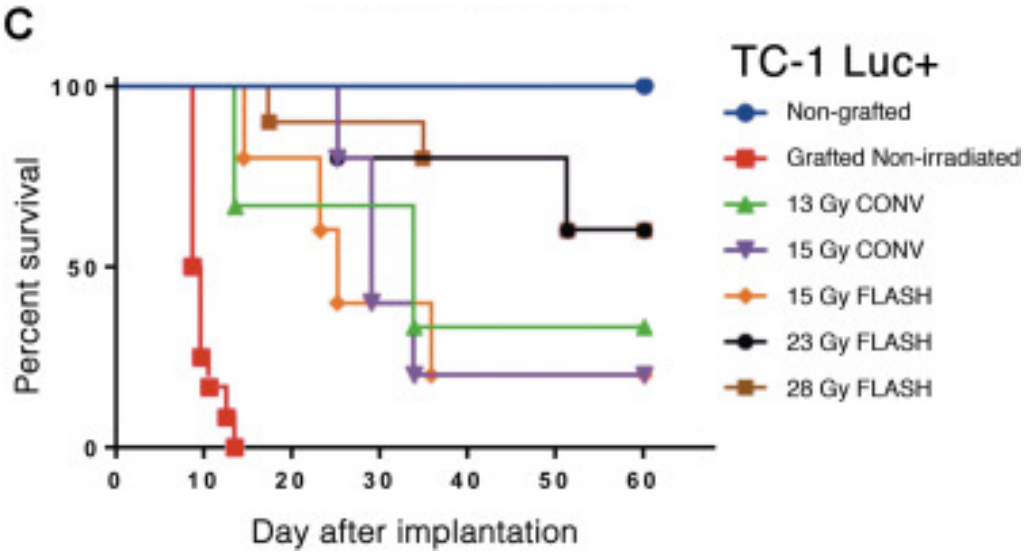
With the development of flattening filter-free linear accelerators for radiotherapy, the instantaneous dose rate has increased by approximately a factor 4.
The present study investigates the radiobiological effect of this high instantaneous dose rate on two cell lines

B.S. Sørensen et al. Radiother & Oncol 101 (2011) 223–225

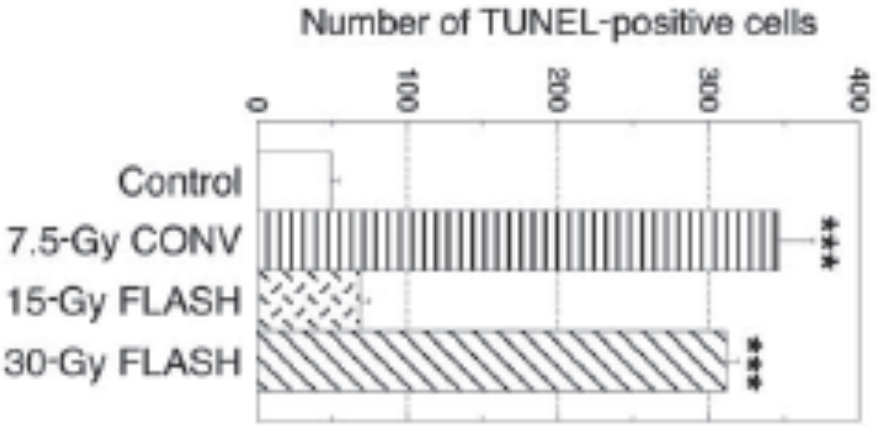
Effectiveness of very high dose rate Flash: 40 Gy/s

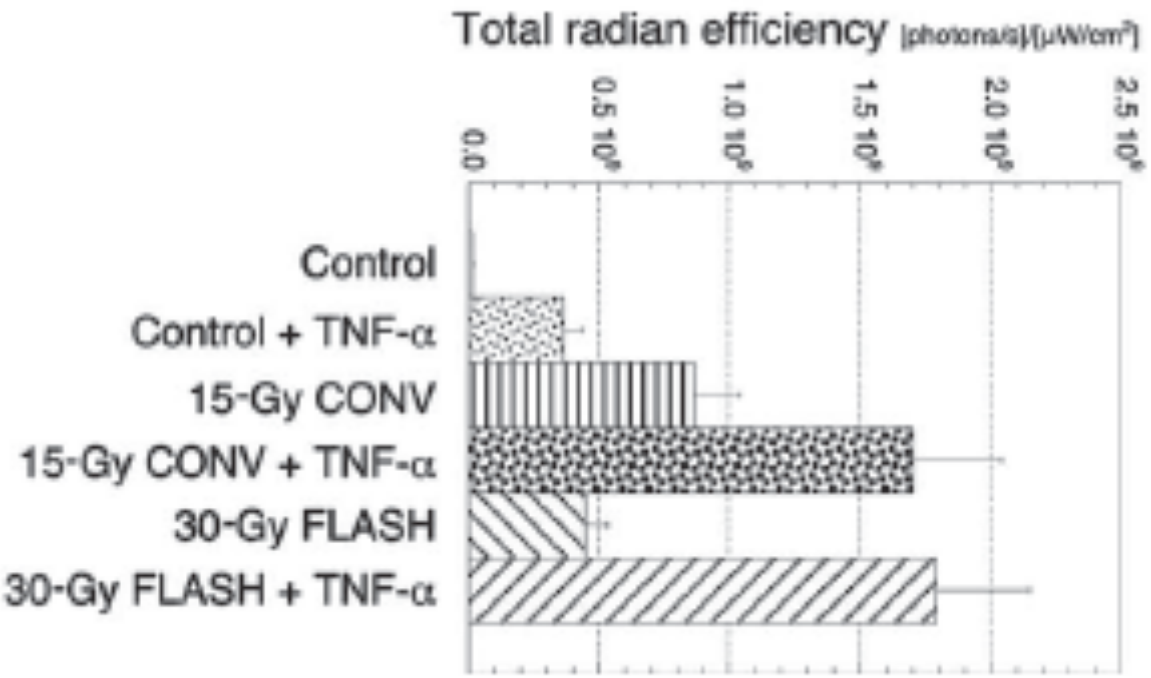






Fauvodon et al. Sci Transl Med. 2014





Fauvodon et al. Sci Transl Med. 2014

Summary

- Continuous low dose rate irradiation
  - Irradiation times (hours - days) are long as compared to the half time of repair (0.5 - 1.5 hour). Effect dominated by repair capacity (α/β value)
- High dose rate irradiation
  - Irradiation time is too short for repair during the irradiation, unless repair is very fast (in the order of minutes).
- IMRT
  - For complex treatments lasting ≥20-30 min, loss of effective dose may be 5-10%, but depends on α/β and $T_{1/2.}$
  - Possibly compensated by reoxygenation in vivo
  - High instantaneous dose rate (flattening filter-free): no change in effect

Promise and Pitfalls of Heavy-Particle Therapy

Timur Mitin and Anthony L. Zietman

A B S T R A C T

Proton beam therapy, the most common form of heavy-particle radiation therapy, is not a new invention, but it has gained considerable public attention because of the high cost of installing and operating the rapidly increasing number of treatment centers. This article reviews the physical properties of proton beam therapy and focuses on the up-to-date clinical evidence comparing proton beam therapy with the more standard and widely available radiation therapy treatment alternatives. In a cost-conscious era of health care, the hypothetical benefits of proton beam therapy will have to be supported by demonstrable clinical gains. Proton beam therapy represents, through its scale and its cost, a battleground for the policy debate around managing expensive technology in modern medicine.

- Suspension containing particles of thorium dioxide
- Contrast medium in X-ray diagnostics in 1930s and 40s
- Excellent images:
  thorium has high absorption cross section
- The naturally abundant nuclide ^{232}Th is slightly unstable, decays through emission of an alpha particle
- Drug is distributed to
  liver, spleen, lymph nodes, bone
- Biological half-life is 22 years,
  physical half life $>10^{10}$ years!

Thorotrast cancers

Relative risk is preferred to ***Absolute risk***

- ***Relative risk (RR)***
  expression of excess risk relative to the underlying (baseline) risk.
  If excess risk is zero, RR is 1 (100%).
  If excess risk equals the baseline risk, RR is 2 (200%)

- ***Absolute risk***
  expression of excess risk based on the assumption that the excess risk from radiation exposure adds to the underlying risk by an increment dependent on dose but
  independent of the underlying natural risk

Ipsilateral and contralateral second lung cancers in patients treated with post-operative radiotherapy of breast cancer, 1973-2001

Darby SC et al. *Lancet Oncol* 2005;6:557-65

Summary: Radiation 1

- Radiation carcinogenesis is a stochastic effect
- Human experience includes early workers exposed occupationally, patients exposed to medical irradiation, survivors of A-bomb attacks on Hiroshima and Nagasaki, and Chernobyl
- Shortest latency is for leukemia, which peaks at 5 to 7 years. For solid tumours, latency may extend to > 60 years
- Radiation-induced cancer risks are usually based on a time-related Relative Risk (RR) model
- A dose and dose-rate effectiveness factor (DDREF) converts risk estimates from acute exposures (*e.g.* A-bomb data) to the low dose and low dose rates encountered in radiation protection. ICRP conservatively assumes DDREF = 2

Summary: Radiation 2

- For working populations, ICRP risk estimates of excess cancer mortality:
  8.2×10^{-2} per sievert for high doses and high dose rates
  4.1×10^{-2} per sievert for low doses and low dose rates
- For the general population, ICRP risk estimates are:
  11.0×10^{-2} per sievert for high doses and high dose rates
  5.5×10^{-2} per sievert for low doses and low dose rates
- Workers in the nuclear industry are not more likely to develop cancer than non-nuclear workers
- Irradiation *in utero* by diagnostic X rays gives RR = 1.4 for leukemia and childhood cancers. This is high because malignancies in children are rare, but absolute risk is about 6% per gray, similar to risk in adult A-bomb survivors

Summary: Radiotherapy 1

- In radical radiotherapy, radiation exposure to non-involved organs and tissues may cause 2nd cancers several decades later
- In adult cancer patients, the risk of radiation-induced 2nd cancers is much smaller than the risk of recurrent primary cancer
- In adults, >90% of 2nd cancers after radiotherapy are due simply to increased life expectancy after cure of primary
- Risk of radiation-induced 2nd cancers is much greater in younger cancer patients; these increased cancer rates may persist lifelong
- Most radiation-induced 2nd cancers occur in the high-dose volume but also appear in the low dose (<2 Gy) volume

Summary: Radiotherapy 2

- Pronounced differences in types of radiation-induced 2nd cancers exist between children, young adults and elderly patients treated with radiotherapy
- Types of 2nd cancers after radiotherapy are different from those induced by low-dose total body irradiation, *e.g.* in the A-bomb survivors
- Different biological mechanisms can lead to 2nd cancers after radiotherapy, depending on dose distribution and age of the irradiated patient. Dose risk relationships, therefore, can be complex
- Risk of radiotherapy-induced 2nd cancers should *not* be estimated using the effective dose method proposed by ICRP for radiation protection purposes
