

Imaging for physicists

Welcome and introduction

Tufve Nyholm

Evaluation - Certificates

Evaluation

Very important for us to be able to continuously improve and adapt the course to the needs

Evaluation forms: Sent to you from Survey Monkey (If any problem contact Miika)

Certificates

Will be handed out by Miika at the last day

Case assignments

A list of topics has been distributed

Group size: Ideal: 4-5 people

Study the topic and give a short presentation (x min) on Thursday

Use the suggested literature as a starting point – much more information can be found on the web

Presentation: Not only a literature review - the focus should be on own reflections.

Social program

Course dinner: Today (Sunday). We leave from Lobby at 19.00

Dinner starts at 20.00 - El Pimpi

Free afternoon: Tuesday

ESTRO School

Imaging for physicists

Goals

- Improve the understanding of the physics principles of MRI, PET and CT
- Explore potential applications of these imaging modalities in clinical practice.

Learning outcomes

- Understand the basic concepts of MRI, PET and CT physics
- Understand the key technical challenges and solutions unique to the application of MRI, PET and advanced CT in radiotherapy
- Understand the potential and challenges of biological imaging methods in radiotherapy treatment planning and follow-up.

ESTRO School

Imaging for physicists

Rational

- Imaging is a fundamental part of radiotherapy today
- The importance will likely increase further

MRI physics - basic principles

Eirik Malinen

Background

- All clinical applications of MRI today are based on magnetic properties of the hydrogen nucleus
- Body tissues contains lots of water and fat, and hence hydrogen

Nuclear magnetic moment

- Stern-Gerlach experiment:

Otto Stern

Walter Gerlach

→ Atomic nuclei has a quantized magnetic moment

Magnetic moment and spin

- Consider charge q in circular motion:

Current:

$$i = \frac{\Delta q}{\Delta t} = \frac{qv}{2\pi r}$$

Magnetic moment:

$$\mu = iA = \frac{q}{2m} L, \quad L = mvr$$

- Rotating charged sphere with uniform charge:

$$\mu = \frac{q}{2m} \mathbf{S}$$

Spin!

Quantized nuclear spin

- Nuclear spin is a form of angular momentum
- Nuclear spin, \mathbf{I} , is quantized in units of \hbar
- Nuclear quantum number depends on nuclear configuration; $I=1/2, 1, \dots$
- Hydrogen has spin $I=1/2$, with spin projection numbers $m_I=+1/2, -1/2$; spin 'up' or 'down'
- Magnetic moment is $\boldsymbol{\mu}=\gamma\mathbf{I}$

↑
Gyromagnetic ratio

Unpaired nucleons, spin and γ

Nucleus	Unpaired Protons	Unpaired Neutrons	Spin	γ (MHz/T)
^1H	1	0	1/2	42.58
^2H	1	1	1	6.54
^{31}P	1	0	1/2	17.25
^{23}Na	1	2	3/2	11.27
^{14}N	1	1	1	3.08
^{13}C	0	1	1/2	10.71
^{19}F	1	0	1/2	40.08

Potential energy in magnetic field

- In an external magnetic field, the potential energy is:

$$E_{pot} = -\boldsymbol{\mu} \cdot \mathbf{B}$$

$$= -\gamma\hbar m_I \mathbf{B} = \mp \frac{1}{2} \gamma\hbar B$$

→ Two energy states are possible

- *Zeeman effect*

Pieter Zeeman

Magnetic resonance

- Spin system under an external magnetic field exposed to electromagnetic radiation

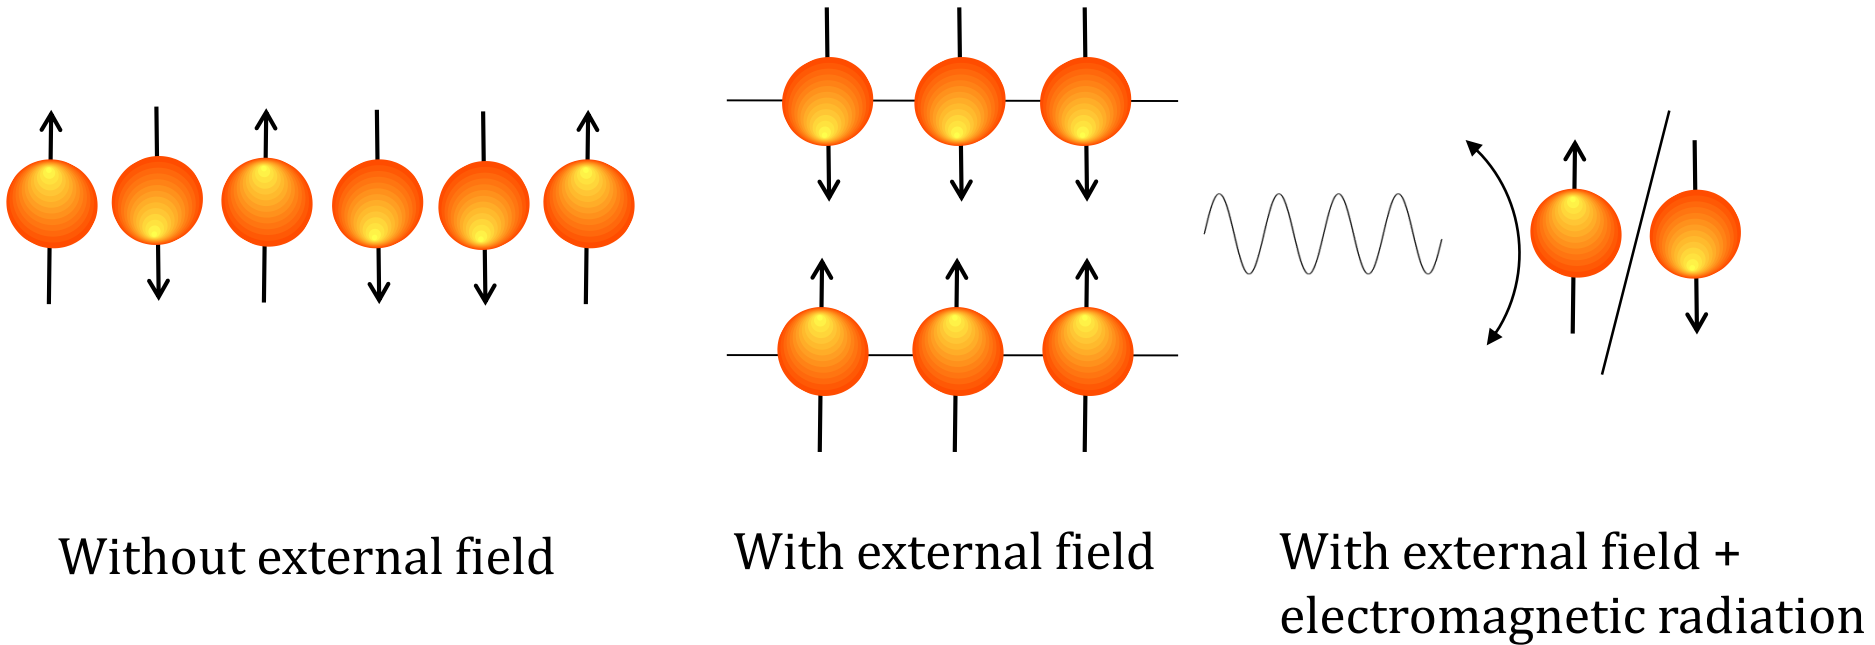

Isidor Isaac Rabi

- Transitions from spin down to spin up or vice versa may occur if $\hbar\omega = \Delta E_{\text{pot}} = \gamma\hbar B$

Magnetic resonance

- $\hbar\omega = \gamma\hbar B \rightarrow \omega = \gamma B$; *resonance condition*

- Resonance frequency, ^1H , $B=1\text{T}$: $\omega \approx 43 \text{ MHz}$
→ radiofrequency !

Macroscopic considerations

- Spin transition probability is equal for *up* → *down* and *down* → *up*
- How can a net energy absorption be observed?
- Distribution of spins follows Boltzmann:

$$\frac{N_{\downarrow}}{N_{\uparrow}} = e^{-\Delta E_{pot} / kT} = e^{-\hbar\gamma B / kT}$$

- Difference increases with B and decreases with T

Macroscopic magnetization

- Population difference generates a net magnetization

- The more spins, the stronger the magnetization
- Torque exerted on a magnet by a magnetic field:

$$\boldsymbol{\tau} = \frac{d\mathbf{M}}{dt} = \gamma \mathbf{M} \times \mathbf{B}$$

Bloch equations

$$\boldsymbol{\tau} = \frac{d\mathbf{M}}{dt} = \gamma \mathbf{M} \times \mathbf{B}$$

$$\Rightarrow \frac{dM_x}{dt} = \gamma B M_y, \quad \frac{dM_y}{dt} = -\gamma B M_x, \quad \frac{dM_z}{dt} = 0$$

\Rightarrow

$$M_x(t) = M_x^0 \cos(\omega_L t), \quad M_y(t) = M_y^0 \sin(\omega_L t)$$

$$M_z(t) = M_0$$

- $\omega_L = \gamma B$; *Larmor frequency*
- Set of equations describing a *precession* around the axis defined by \mathbf{B} (z-axis)

Felix Bloch

Joseph Larmor

Spin precession

Spin precession

Spins out of phase

All spins in phase with same Larmor frequency

Introducing the RF field

- How can the magnetization be altered?
- Introduce oscillating (RF) magnetic field in the xy-plane

Flip angle

- The degree of which the magnetization is tipped relative to B_0 due to an excitation pulse
- From Bloch's considerations:

$$\theta = 2\pi\gamma\tau B_1$$

- t : duration of pulse
- B_1 : \sim RF power

T1 relaxation

- Fluctuating magnetic fields from the molecular environment may have Larmor frequency → stimulated transitions may occur
- After an RF-pulse, the z-component of M relaxes back to equilibrium via such stimulated transitions
- Longitudinal relaxation, Spin lattice relaxation, T1 relaxation
- Rate of relaxation: $R1 = 1/T1$

Varies between tissues

T2 relaxation

- The *transverse* component of the magnetization also decays
- Local, microscopic field inhomogeneities causes each spin to precess with a frequency slightly different from ω_L
- An excitation pulse initially causes all spins to precess in phase, but a dephasing then occurs
- transverse- or spin-spin relaxation; T2
- $T2 < T1$

T2 relaxation cont'd

- However, transverse relaxation is also caused by B_0 inhomogeneities and tissue magnetic susceptibility
- Actual T2 time is denoted $T2^*$:

$$\frac{1}{T2^*} = \frac{1}{T2} + \gamma\Delta B_0$$

- $T2^* < T2$

Relaxation

Relaxation – 90° pulse and T1

Relaxation - 90° pulse and T2

Relaxation dynamics

- Bloch's equations expanded with relaxation components; $M_{xy}/T2^*$ and $(M_z - M_0)/T1$
- May be shown that:

$$M_z(t) = M_0(1 - e^{-t/T1}) \quad \longrightarrow$$

$$t = T1 \Rightarrow M_z = 0.63M_{z,\infty}$$

$$M_{xy}(t) = M_{xy,0}e^{-t/T2^*} \quad \longrightarrow$$

$$t = T2^* \Rightarrow M_{xy} = 0.37M_{xy,0}$$

Relaxation times

Tissue	T1 (msec)	T2 (msec)
Water/CSF	4000	2000
Gray matter	900	90
Muscle	900	50
Liver	500	40
Fat	250	70
Tendon	400	5
Proteins	250	0.1- 1.0
Ice	5000	0.001

Relaxation dynamics and contrast

— Brain

— CSF

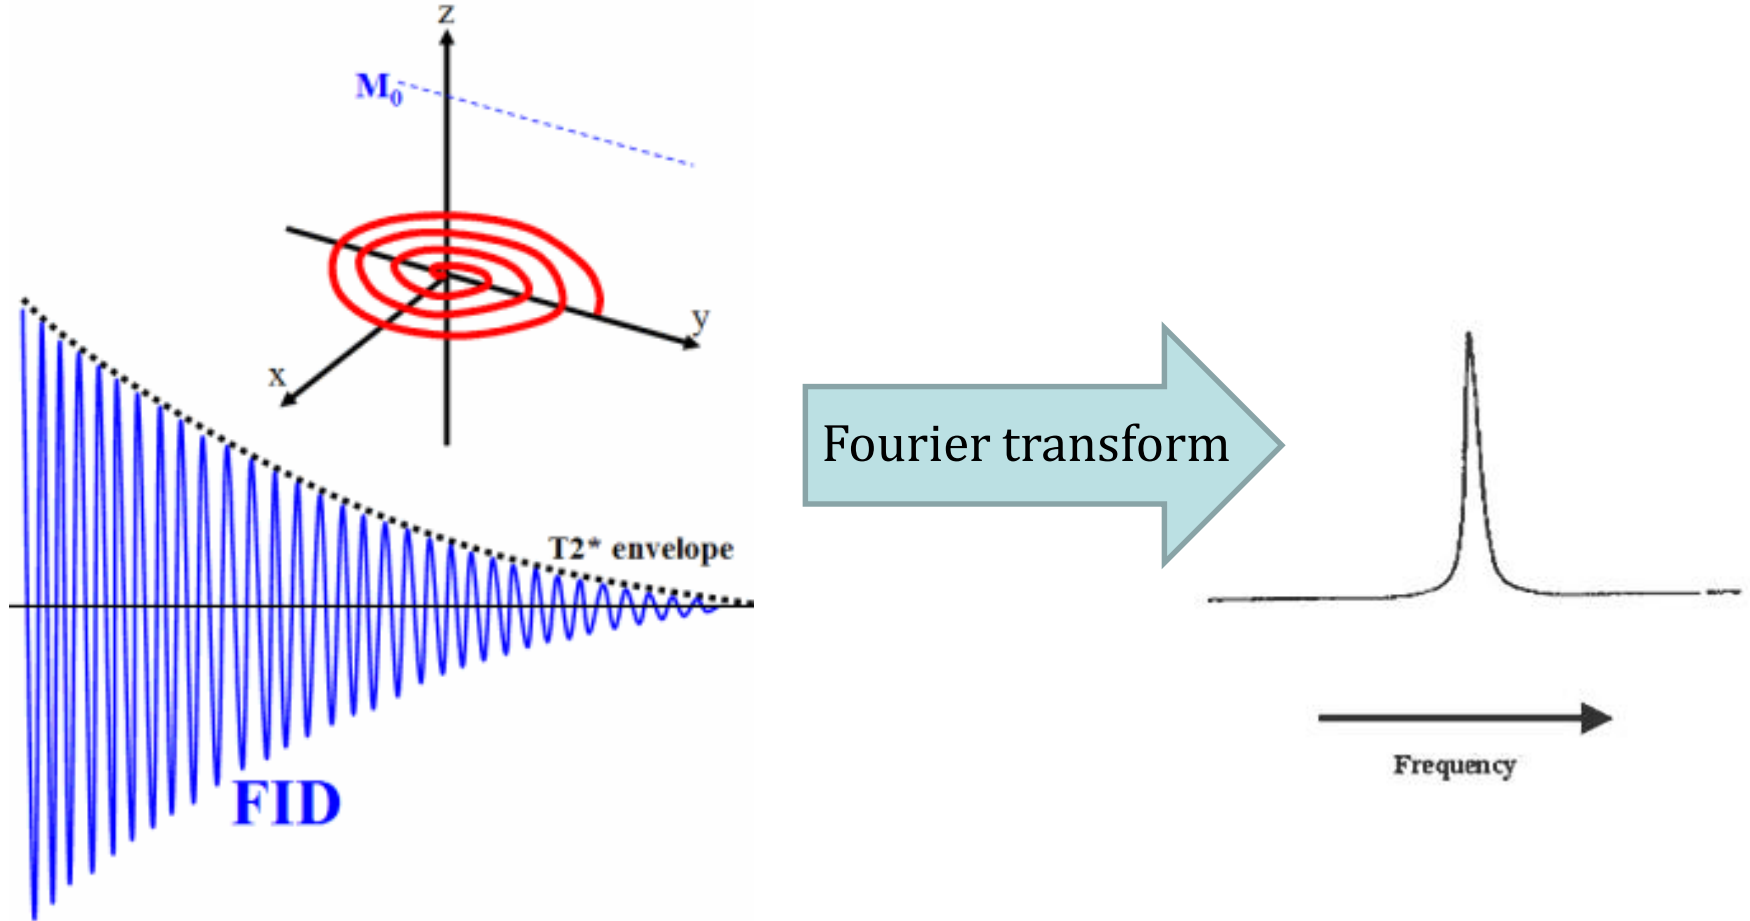

Detection

- Changes in magnetization give rise to a current in a wire loop (Faraday's law of induction)
- Receiver coil perpendicular to B_0 :

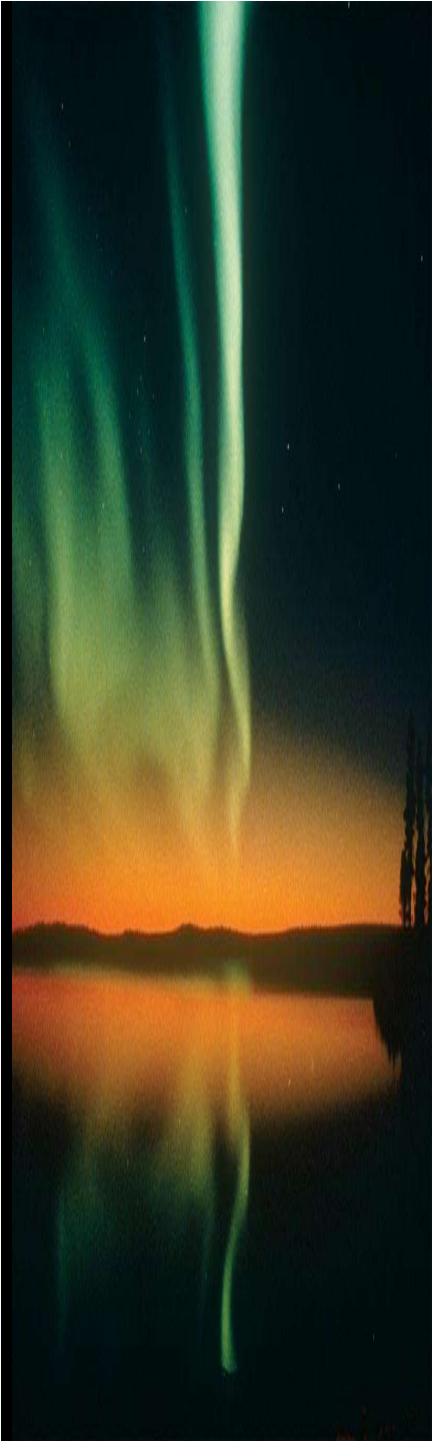

Free induction decay

- Envelope of FID describes the T_2^* -decay:

Relaxation

T1 relaxation
Parallel plane

Rotating coordinate system

T2 relaxation
Transversal plane

B_0

The transversal component gives signal

T1 relaxation

- Spin-lattice or longitudinal relaxation
- Restoring longitudinal magnetization after RF excitation
- T1 – Time until 63% of the initial magnetization M_0 is restored

Adipose tissue – 240ms

Spinal fluid – 4300ms

Gray matter – 980ms

White matter – 780ms

Muscles – 880ms

$$M(t)_z = M_0 \left[1 - e^{-t/T_1} \right]$$

T2 relaxation

- Spin-spin or transversal relaxation
- Loss of transversal magnetization after RF excitation
- T2 – time until 63% of the transversal magnetization is lost

Adipose tissue – 70ms

Spinal fluid – 2200ms

Gray matter – 100ms

White matter – 90ms

Muscles – 50ms

$$M(t)_r = M_{r,t=0} e^{-t/T_2}$$

T2

T2* relaxation

$$M(t)_r = M_{r,t=0} e^{-t/T2^*}$$

Spin-Echo sequence

- 180 degree pulse refocus the spins
- Signal independent of T_2^*

Spin-Echo sequence

- Parallel component
- Transversal component

Spin-Echo sequence

T1 relaxation

$$M(t)_z = M_0 \left[1 - e^{-t/T_1} \right]$$

T2 relaxation

$$M(t)_r = M_{r,t=0} e^{-t/T_2}$$

Signal equation

$$S = k\rho \left(1 - e^{-TR/T_1} \right) e^{-TE/T_2}$$

Turbo spin echo Fast spin echo

Gradient echo sequences

- No refocusing pulse → sensitive to $T2^*$
- Gradients used to generate an echo
- Main benefit: Faster than Spin-Echo

Gradient echo (T2*)

Gradient echo (T2*)

— Parallel component
— Transversal component

Spooling

Without spooling

With spooling

— Parallel component

— Transversal component

Spooling

- Gradient spooling: Apply a strong gradient to dephase the spins
- RF spooling: Make the flip in different directions every time

— Parallel component

— Transversal component

Gradient echo

$$S \sim \rho \left(\sin(\theta) e^{-TE/T2^*} \right) \frac{1 - e^{-TR/T1}}{1 - \cos(\theta) e^{-TR/T1}}$$

Small angle - reduces T1 weighting and yielding proton density weighting

Large flip - yields T1 weighting

Short TR - increases T2* weighting (residual transverse magnetization is dominant)

Long TR - enhances T1 weighting

Short TE - reduces T2* weighting and increases T1 or PD weighting

Long TE - enhances T2* weighting

$$\theta_{Ernst} = \cos^{-1} \left(e^{-TR/T1} \right)$$

Optimal flip angle

— Parallel component
— Transversal component

Very small angle

Small angle

Large angle

Very large angle

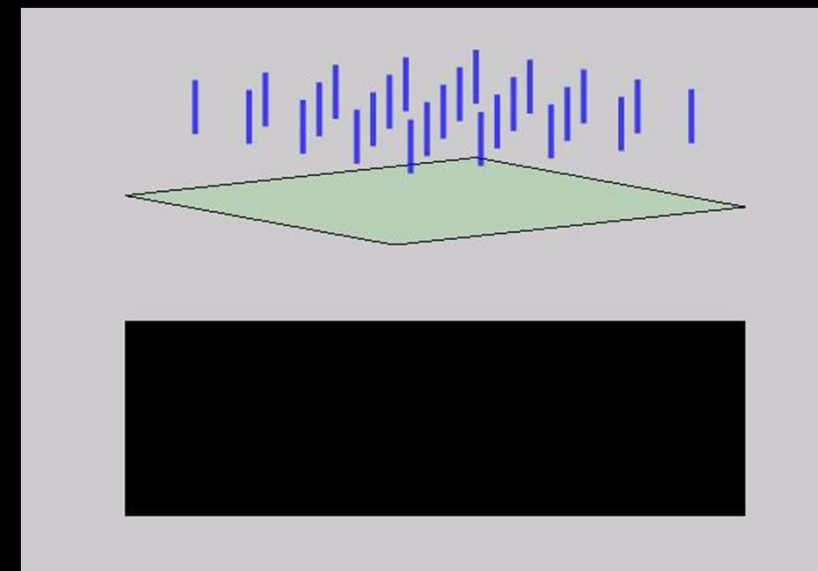

Phase contrast

$$\text{Phase} \sim TE * \Delta B$$

A little bit more about phase in the DCE lecture

Summary again (Spin-echo)

- **T1 Weighting**
 - Maximizing T1 \rightarrow short TR
 - Minimizing T2 \rightarrow short TE
- **T2 Weighting**
 - Maximizing T2 \rightarrow long TE
 - Minimizing T1 \rightarrow long TR
- **Proton weighting**
 - Minimizing T2 \rightarrow short TE
 - Minimizing T1 \rightarrow long TR

MRI Physics: Space Encoding

A/Prof Gary Liney

5th November 2017

ESTRO Imaging for Physicists

- MRI extremely flexible spatial localisation
Orientation easily altered
- Gradients used to modulate phase and frequency
In-plane directions always 'phase' and 'frequency'
- Signal is reconstructed with 2D or 3D
Fourier Transformation

Spin Echo Sequence

Spin Echo Sequence

An axial image..

Fourier Transform (FT)

- Time signal can be decomposed into sum of sinusoids of different frequencies, phases and amplitudes

$$s(t) = a_0 + a_1 \sin(\omega_1 t + \varphi_1) + a_2 \sin(\omega_2 t + \varphi_2) + \dots$$

- Fourier series may be represented by frequency spectrum
- Time and frequency domain data can be thought of as FT pairs

Fourier Transform (FT)

- S1 has amplitude a and frequency f
- S2 has $a/2$ and $3f$
- S3 = S1 + S2
- S3 is two sine waves of different *frequency* and *amplitude*

The FT is shown

FT Pairs

Sinusoid

Delta

Sinc

'Top Hat'

Time

Frequency

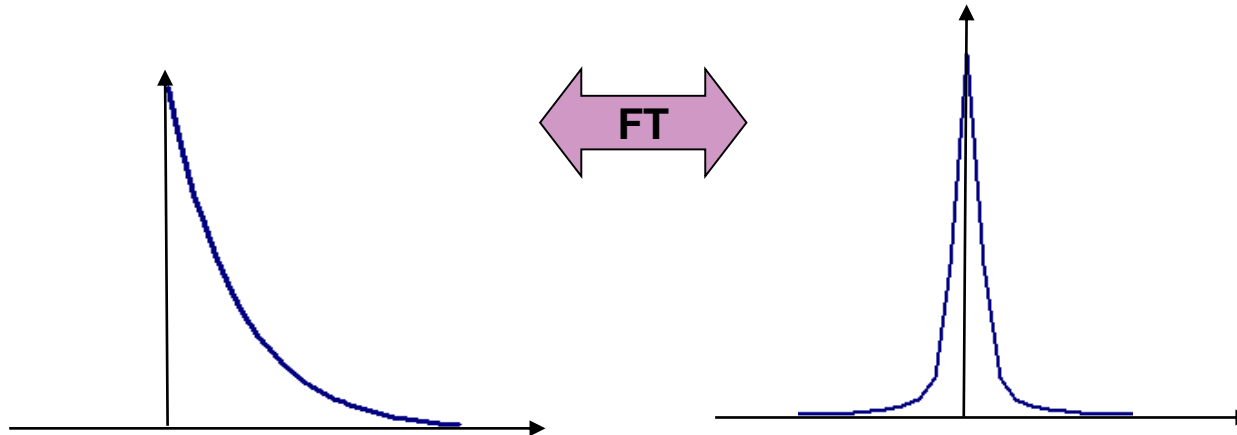

FT Pairs

Gaussian

Gaussian

Exponential

Lorentzian

Time

Frequency

Gradients

- Recall that the resonant frequency is proportional to field strength

$$\omega_0 = \gamma B_0$$

- Magnetic gradient changes B_0 field strength over distance
- In MRI a linear gradient changes the resonant frequency in a given direction

$$\omega = \gamma(B_0 + xG_x)$$

$$G_x = \frac{dB_0}{dx}$$

$$G_y = \frac{dB_0}{dy}$$

$$G_z = \frac{dB_0}{dz}$$

Slice Selection

Slice Selection

Slice Selection

Only this section can be 'seen' by the RF coil

Slice Selection

- Gradient used to change resonant frequency in slice direction
- Excite spins using (*sinc-shaped*) 90° RF pulse containing a bandwidth of frequencies
- Only a particular section of spins are excited into transverse plane
- Signal has been discriminated in one dimension
- Can change orientation, slice thickness and position

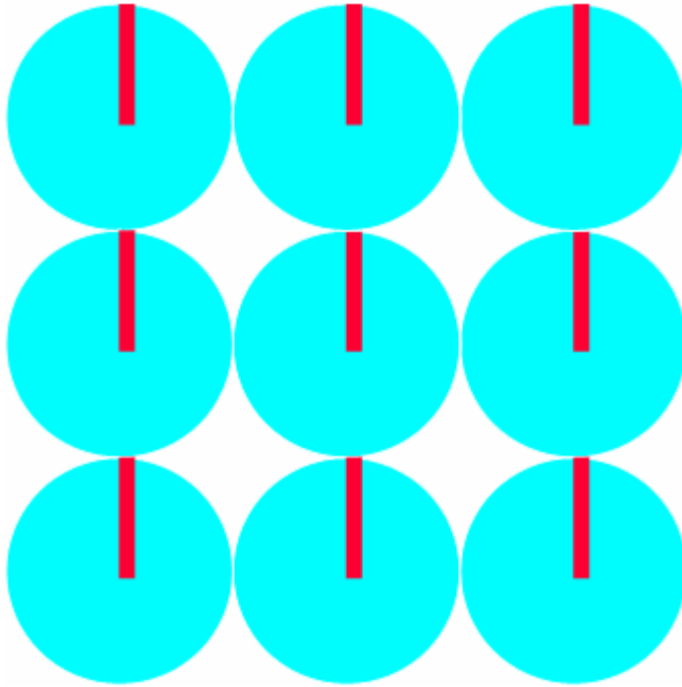

Slice Selection

Phase & Frequency Encoding

- Need to still encode signal in remaining directions (x & y)
 - Use changes of frequency & phase
- When a gradient is applied the spins will be at different phases once the gradient has been turned off
- This is the role of the phase encoding gradient
- Used in combination with frequency encoding gradient in the 2nd direction...

In-plane Encoding

Initially, all spins
have
same frequency

In-plane Encoding

- Apply a **gradient** left to right
- Linear change in B_0

In-plane Encoding

- After gradient is removed
- Spins revert to same frequency
- Phase is different between columns
- This gradient is applied n times with different amplitudes

In-plane Encoding

- Apply a further **gradient** bottom to top
- This gradient is applied once
- Sample the data m times
- Create $m \times n$ pixel image

Phase Encoding

- Each pixel is assigned a unique phase and frequency
- FT decodes unique frequency but only measures summation of phase
- Individual phase contributions cannot be detected
- Need multiple increments of PE gradient to provide enough information about phase changes
- Number of PE increments depends on image matrix

Spin Echo Sequence

Resonance condition

$$\omega = \gamma (B_0 + zG_z)$$

Spin Echo Sequence

Increment gradient after RF pulse and before read-out

Spin Echo Sequence

Apply gradient during read-out

Multi-Slice Imaging

- Period between the echo and the next RF pulse is called *dead time*
- Used to excite a separate slice
- Multiple slices are acquired in each TR
- Slice profiles are not rectangular leading to cross-excitation
- Slices are acquired with gaps or interleaved

Scan Time

- Frequency encoding done at time of echo
- Phase encoding done over many TRs
- Time between TR-TE is dead time

$$\text{Scan time} = \text{TR} \times N_{\text{av}} \times N_{\text{PE}}$$

'3D' Sequences

- True 3D volume rather than multiple 2D slices
- A slab or multiple-slabs are selected
- Phase encoding also in the 'slice' dimension
 - Through-plane resolution can be comparable to in-plane
 - Phase wrap in 'slice' direction
- SNR is improved, scan time longer:

$$N_{PE} \times TR \times NEX \times N_s$$

Volumetric Imaging

$$\text{Scan time} = TR \times N_{av} \times N_{PE}$$

$$\text{Scan time} = TR \times N_{av} \times N_{PE1} \times N_{PE2}$$

Typical gradient resolution parameters (45 mT/m):
(2D) in-plane 0.012 mm; slice thickness 0.1 mm
(3D) partition 0.05 mm

What is k-space?

- 'k' is wave-number: number of cycles per unit distance
 - Spatial analogue to 'cycles per second' (frequency)
- k-space is the raw data
 - An array of numbers whose FT is the MR image
- Each row in k-space corresponds to the echo data obtained from a single application of the PE gradient
 - Rows near centre correspond to low-order PE steps (small gradients)
 - Rows at edges correspond to high-order steps

What is k-space?

k-space and image-space of the brain

What is k-space?

- All of k-space needs to be filled to create an image
 - ✓ Centre: bulk signal/contrast information
 - ✓ Edge: image detail
- Individual cells do not correspond one-to-one with individual pixels in image
- Each cell has information about every image pixel: *explains why motion artefacts propagate through whole image*

k-space

$$\text{FOV} = 1/\Delta k$$
$$\Delta x = 1/\text{FOV}_k$$

k-space

$$\text{FOV} = 1/\Delta k$$
$$\Delta x = 1/\text{FOV}_k$$

ESTRO Imaging for Physicists

Historical Perspective

(short video)

The MRI Controlled Area

Control Room

Pressure release hatch

RF Cage

- MRI inherently low (RF) signal technique
- Faraday cage
 - All 6 sides enclosed in copper
 - Electromagnetic shielding
 - Examples microwave oven, coax cable
- Integrity must be maintained
 - Penetration panel
 - Mesh window, waveguide
 - Closed scan room door, no fluorescent lights

RF Cage Construction

Waveguides

Mesh Window

Door surround

Penetration Panel

The Scanner

...plus shielding coils, shim coils and cryostat!

Equipment & Safety

Three magnetic field interactions to consider

Main Magnet

Magnet Field (B_0)

- Low sensitivity requires very high field
- 1 Tesla = 10,000 Gauss
cf. 0.3-0.7 G earth's field
- Mostly superconductors
Niobium-titanium (9.5 K)
field decay: 5-10 G y^{-1}
field stability: <0.1 ppm h^{-1}

1987: Elscint's Gyrex System

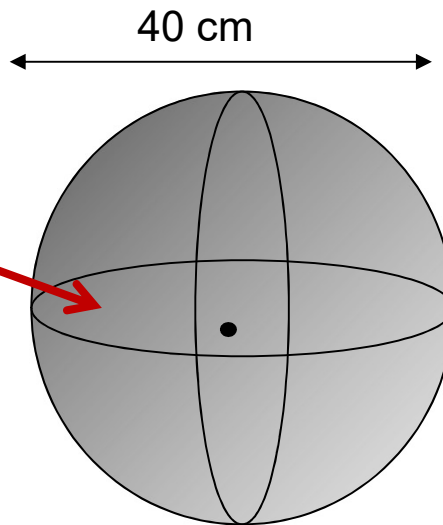

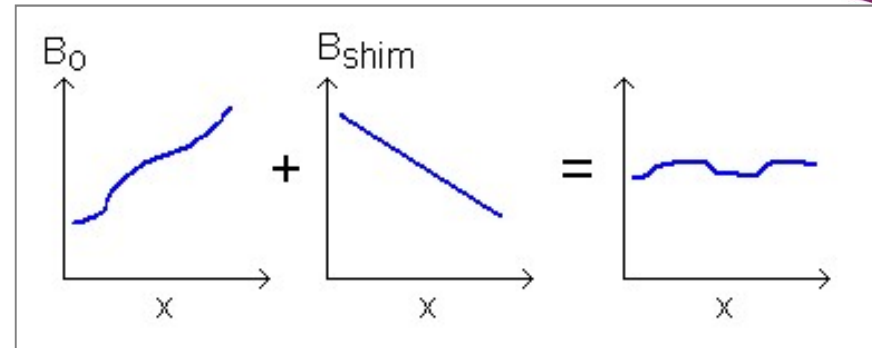

Philips' vertical HFO System

Homogeneity (Inside the Magnet)

Uniform imaging volume at isocentre

e.g. $DSV_{40\text{cm}} = 0.2 \text{ ppm}$

(at 1.5 T):

$0.2 \times 63.87 \text{ MHz} = \underline{12.8 \text{ Hz}}$

- Magnet is shimmed at installation- additional (dynamic) shimming may be required

Outside the Magnet: Fringe Field

- Magnet is shielded to reduce extent of fringe field
5 G line for an unshielded 7 T is 23m away!
- Active & passive shielding is use
- Active shielding causes a sharp field gradient
Magnitude and variation of field need to be understood

Note: 'Magnetic Shielding' is also sometimes used to describe RF shielding (Faraday cage)

Proximity Limits

- Each scanner has its 'footprint'
- '5 Gauss line' (0.5 mT) should be confined to scan room
- Radial & axial components
Typically axial 1.6 times larger
- May be measured with handheld gaussmeter

> 30 G	Stainless steel, non-ferromagnetic objects
< 30 G	ECG monitors, unrestrained ferromagnetic objects
< 10 G	Credit cards, x-ray tubes
< 5 G	Pacemakers, general public
< 3 G	Moving cars etc
< 1 G	TVs, CT & PET scanners
< 0.5 G	Railways, gamma cameras

0.5 mT

0.5 mT

The Inner Controlled Area

30 Gauss (3 mT)

Static Field (B_0) Effects

- **Translational Force (Projectiles)**
Force product ($B_0 \times dB_0/dz$)
Ferromagnetic objects
- **Torque**
Proportional to B_0^2
- **Bioeffects?**
Some transient effects (magnetophosphenes, metallic taste, vertigo) at 4.0 Tesla
No known long term effects

STATIC Field Gradient

$$F_z = \frac{V\chi}{\mu_0} B_0 \frac{\partial B_0}{\partial z}$$

- Peak areas around the bore ends (field, spatial gradient)
- Field can be as high as 1.7-2.4 Tesla on a 1.5 T scanner

The Projectile Effect

Field Gradient Map

Boy, 6, killed in MRI accident

By MELISSA KLEIN AND OLIVER W. PRICHARD

THE JOURNAL NEWS

(Original publication: July 31, 2001)

VALHALLA — A 6-year-old boy died two days after he was smashed in the head by a metal oxygen canister that was pulled by magnetic force into the MRI machine where he was being examined, Westchester Medical Center officials said yesterday.

An unidentified hospital employee brought the oxygen tank within reach of the 10-ton magnet's field, and it shot through the air to the center of the machine, the hospital said.

The boy, Michael Colombini of Croton-on-Hudson, died Sunday at the hospital, where he had undergone surgery before the MRI. An autopsy revealed that he died of a blunt force trauma to the head with a fractured skull and brain hemorrhage, the Westchester County Medical Examiner's Office said.

Implants & Devices

- 1 April, 2000 Australia: Patient with pacemaker scanned and died as a result of malfunction
- Another accident left a patient blinded from a minute metal fragment in his eye
- Ex-vivo testing of devices required at *appropriate field strength*
- Deflection Angle Test (see next)

Is it 'Magnetic'?

ASTM Labels

MR Unsafe

MR Conditional

MR Safe

2005: Replaced terms *MR Compatible* and *MR Unsafe*

MR Conditional Pacemakers

- Up to 75% pacemaker patients will need MRI
- Main concerns are function & heating
- MR conditional types exist
 - *Reduced ferromagnetic components*
 - *MR specific mode*
 - *Radiopaque marking*
 - *Replaced read switch*
 - *Power supply protection*

Patient Screening

- ✓ Operate controlled area
- ✓ Screen patients/helpers
- ✓ Orbit x-ray if required
- ✓ Check compatibility of device (all 3 fields!)

If in doubt DO NOT scan

Quench

Cryostat

Vent Pipe

**Liquid helium (boiling point 4.2 K)
cryogen**

Gradient Coils

Imaging Gradients

- 3 orthogonal or in combination
 - ✓ Spatially encode image
- Higher amplitudes mean:
 - ✓ Better resolution
 - ✓ greater diffusion weighting
- Faster switching rates mean:
 - ✓ Faster scans

$$\omega_x = \gamma(B_0 + xG_x)$$

$$\omega_y = \gamma(B_0 + yG_y)$$

$$\omega_z = \gamma(B_0 + zG_z)$$

Gradient Linearity

No system distortion on RT Planning

'db by dt'

- Gradient waveform trapezoidal
- Amplitude, Rise time, Slew rate
e.g. 40 mT/m & 200 μs = 200 T/m/s
- Rapid changes ('db/dt') potential safety aspects

$$\text{Slew Rate (T/m/s)} = \frac{\text{Amplitude (mT/m)}}{\text{Rise Time (\mu\text{s})}}$$

Acoustic Noise

Lorentz force causes
gradient coils to vibrate
Sequence dependent
Increases with B_0

Manufacturer	Field Strength (T)	SPL (dB(A))
Philips	1.5	112
Siemens	1.5	106
GE	1.5	110
Varian	3.0	118
Bruker	3.0	113

Painful at 134 dB
Permanent damage at 120 dB

$$\vec{F}_L = I d\vec{l} \times \vec{B}_0$$

Peripheral Nerve Stimulation (PNS)

Depolarisation of nerve cells from electrical field stimulation
Empirically measured; Cardiac stimulation should not occur
PNS threshold used as basis of scanner limit

Common to set limit at 20 cm radius
 More useful to consider ΔB & ΔG : linear
 with rise time

	N	Axis	db/dt (T/s)	ΔB (mT)	SR (T/m/s)	ΔG (mT/m)	τ (μ s)
Reilly (1989)	-			54	7.5		138
Bourland (1999)	84	y	14.9	5.4			365

		xy	18.6	8.7			467
		xyz	20.1	10.2			507
Zhang (2003)	20	xy	25.1	13.2	77.0	40.5	526

Literature PNS thresholds (Adapted from Zhang et al MRM 50:50-58; 2003)

Solutions

- Noise

- ✓ Bore liner, gradients mounted to floor & inside vacuum
- ✓ Ear plugs or ear defenders

- PNS

- ✓ Dual gradients
- ✓ Parallel imaging (RF coil encoding)

RF Coils

RF Coil Designs

Coils used as Rx or Tx/Rx

solenoid

surface

B_1

birdcage

saddle

Signal Characteristics

$$B = \frac{\mu_0 I 2 \pi a^2}{r^{3/2}}$$

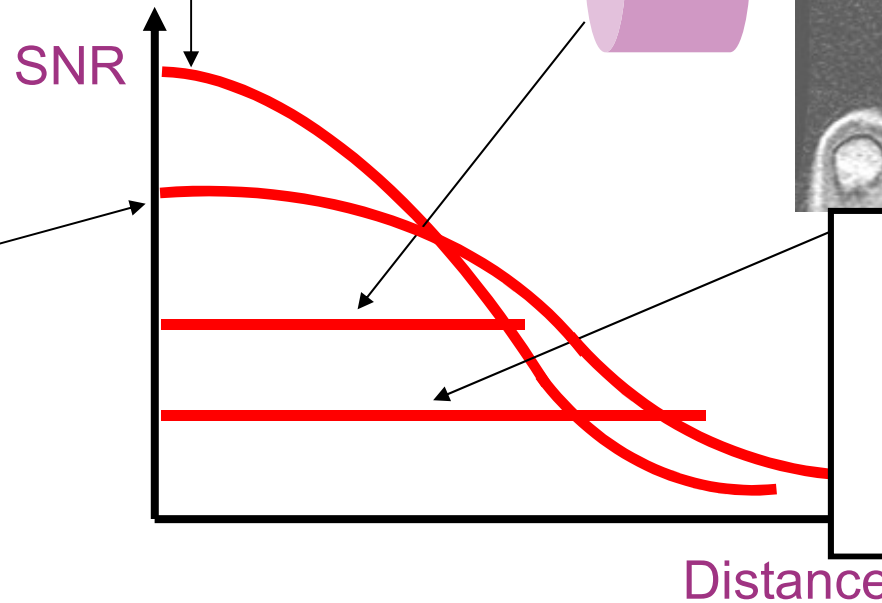

Surface Coil:
Excellent SNR
close to coil
Poor uniformity

Theoretical cylinder coils

Body Coil:
Poor SNR
Excellent
uniformity

Finite Element Modelling used for
complicated designs

B₁ Uniformity

- Surface coils require intensity correction
- At 3T $\lambda \approx 26$ cm, leads to dielectric artefacts
- Dual transmit body coil used to remedy signal variation

original

corrected

Coil Arrays

- Extend surface coil coverage
Small coil excellent SNR
- Overlap to prevent mutual inductance
- Separate Rx channels
Noise not correlated, further increase SNR
- Can be used in parallel imaging*

18 channel body coil

64 channel H&N coil

**covered in 'Speed-up & specialised sequences'*

RF Heating

- RF power deposition expressed as **Specific Absorption Rate** or **SAR** (in W/Kg)
- Up to 3.0 T, $SAR \propto B^2$
- heat stress (Testis, Foetus etc), implants/devices
- At higher field the body is more conductive and leads to weaker penetration
- SAR depends on RF pulses per unit time, patient weight, flip angle, RF wave form, field strength, transmit coil design (quadrature or linear)
- Scanner calculates SAR and also performs real time monitoring (time average and peak)

RF Heating Effect

hotspots and in extreme cases **RF burns**

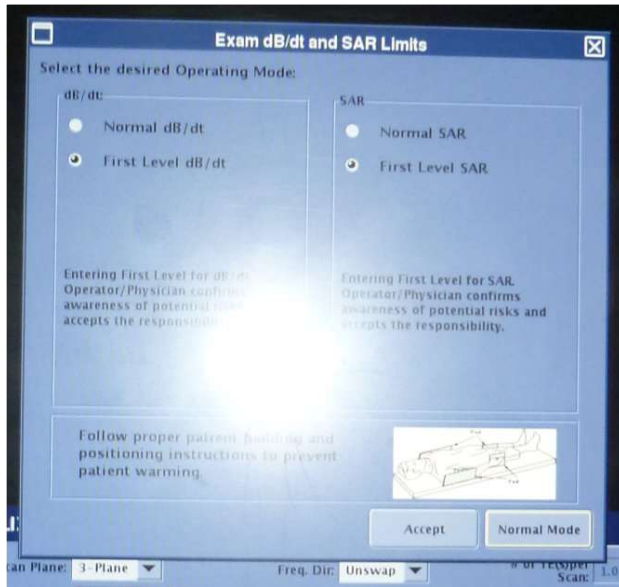

Avoid crossed cables, patient loops

Quadrature Coils

- Linear polarisation- only half RF power effective
- Circularly polarised
Signal has 90° phase
- Efficient transmission
Power halved, reduced SAR
- Receiver coils
SNR increases $\sqrt{2}$

Exposure Limits*

Stratify operation (and safe limits) into 3 modes

- (1) Normal: No effects
- (2) Controlled or First Level: Transient/mild effects
- (3) Research/Experimental: Unrestricted & requires monitoring

**Detailed exposure limits at the end of this talk*

Pregnancy

No harmful effects- better than ionising radiation.
Pregnant women normally excluded in first trimester.

Foetus expected to be more susceptible to MRI.
Contrast agents can pass placenta- no breast feeding for 24hrs

Figure 3. Distributions of SAR_{10g} at 64 MHz in sections $x = 0.008$ m (left) and $y = 0.008$ m (right). The origin of coordinates, located in the foetal brain, is shown. The dB scale is relative to the maximum SAR_{10g} which occurs in the left wrist. The relatively low SAR in the foetus (F), foetal brain (FB) and placenta (P), and high SAR in the amniotic fluid (AF) are evident.

Molecular Imaging with Positron Emission Tomography (PET)

PET imaging adds molecular information to morphology and function imaged with CT and/or MRI.

T2w MRI and PET (BrainPET) show small satellite in dorsal area of frontal sinus (detected on PET).

Boss et al, JNM 2010; 51.

Basic principle of PET

- ▶ Positron emitters (β^+) used as biomarkers
- ▶ Positron-electron annihilation
⇒ Two γ -quanta with 511 keV each are emitted under approx. 180°
- ▶ Coincidence detection in a detector ring

Today: Combined PET/CT

**PET/CT:
combination of
structure and
function**

*First clinical PET/CT
prototype (mid 1990s) [3]*

State-of-the-art PET/CT Designs

(a) Gemini series, Philips Healthcare Systems

(b) Biograph series, Siemens Healthcare Solutions

(d) Aquiduo series, Toshiba Medical Systems

(e) Sceptre series, Hitachi Medical Systems

(f) Anyscan series, Mediso

! All PET/CT tomographs combine diagnostic PET and CT components and a dedicated patient support system. !

PET/CT

CT

+

PET

=

PET/CT

Raw data stored in sinograms

Sinograms:

Measurement of the activity distribution of a radioactive tracer.

$x = \text{offset}$

Radial Sampling

Mapping from sampling projections to sinograms [2].

Transaxial field of view of a PET tomograph is defined by the acceptance angle in the plane.

2D-/3D-PET

2D-PET

- Geometric collimation with septa
- Data sampling only with $\theta=0^\circ$
- Lower overall sensitivity
- Lower fraction of scattered photons

3D-PET

- Projections at polar angles $\theta > 0^\circ$ measured
- Increased sensitivity
- Higher scatter fraction
- Special reconstruction algorithms are necessary

2D/3D-PET acquisition

2D acquisition: the entire FOV is sampled.

3D acquisition: truncation of projections occurs for $\theta > 0^\circ$.

This results in loss of data corresponding the ends of the tomograph [2].

Axial Sensitivity

2D axial sensitivity profile for a line source in air in a 16-ring tomograph [2].

Axial sensitivity variation for 3D acquisition in a 16-ring tomograph [2].

Image Formation

- (1) Emission scan
- (2) Normalization scans (one per plane in 2D) to correct for differential detector efficiencies and geometric effects related to the detector ring
- (3) Set of sinograms of attenuation correction factors to correct of photon attenuation (self-absorption or scattering) by the object

Desired for PET:

1. High stopping efficiency
2. Good energy resolution

Scintillation detectors

- Inorganic crystal that emits visible light photons after interaction of photons with detector.
- # of scintillation photons is proportional to the energy deposited in the crystal.
- Important properties for application in PET:
 - Stopping power for 511 keV photons
 - Signal decay time
 - Light output
 - Intrinsic energy resolution

Properties of scintillation detectors applied in PET

Property	NaI(Tl)	BGO	LSO	YSO	GSO

NaI(Tl): sodium iodide doped with thallium

BGO: bismuth germanate (Bi₄Ge₃O₁₂)

LSO: lutetium oxyorthosilicate doped with cerium(Lu₂SiO₅:Ce)

YSO: yttrium oxyorthosilicate doped with cerium(Y₂SiO₅:Ce)

GSO: gadolinium oxyorthosilicate doped with cerium(Gd₂SiO₅:Ce)

New: LYSO

Photo-multiplier tubes (PMTs)

PMTs: photo-detectors used in scintillation detectors for PET

- (1) Incoming photon deposits its energy at the photocathode, release of a photo-electron
- (2) Applied electric field accelerates the electron to the first dynode
- (3) Emission of multiple secondary electrons due to increased electron energy
- (4) ...

😊 Good signal-to-noise ratio (SNR)

😞 Low quantum efficiency (QE) ~ 25%

Detector Designs used in PET

One-to-one coupling:

- Single crystals glued to individual photo-detector
- Spatial resolution limited by discr crystal size

Block detector design:

- Rectangular scintillator block sectioned by partial saw cuts of different depth into discrete elements
- Usually 4 attached PMTs
- Anger positioning

Detector Designs used in PET

Anger detector:

- Large scintillator crystal glued to array of PMTs
- Weighted centroid positioning algorithm used to estimate interaction position within the detector

Block detector system + Anger logic [3]

*Block detector Siemens-CTI ECAT 951,
8x8 block BGO with 4 PMTs (from [2])*

Timing Resolution and Coincidence Detection

Coincidence time window: 2τ

Time-of-flight (TOF) PET

- In addition to the coincidence information, the difference in flight time is registered

$$\Delta t = \frac{2\Delta x}{c}$$

- Better SNR

(a) Localization without TOF,
(b) with TOF. Townsend, PMB 2008 [3]

Detected Events in PET

- ▶ Detection event is valid (= **prompt** event) if
 - Two photons are detected in coincidence window
 - LOR is within valid acceptance angle
 - Energy of both photons within selected energy window

True coincidence (A), scattered coincidence (B), random coincidence (C)

Prompt Events

- ▶ **Single event**
 - single photon is counted by detector (1-10%)
- ▶ **True coincidence**
 - event derives from single positron-electron annihilation
 - both photons reach tomograph without interaction
- ▶ **Random coincidence**
 - two nuclei decay at approximately the same time
 - random event count rate (R_{ab}) between two detectors a and b :

$$R_{ab} = 2\tau \cdot N_a N_b \propto N^2$$

Prompt Events (II)

▶ Scattered events

- One or both photons detected have undergone a Compton interaction
- Loss in energy and change in direction
- Due to poor energy resolution, many scattered photons cannot be discriminated
- Wrong LOR assigned

▶ Multiple (triple) events

- Three events from two annihilations detected
- Event is disregarded
- Proportional to count rate

Performance of PET Systems

- ▶ Sensitivity

$$S = \frac{c}{t \cdot A} = \left[\frac{\text{counts}}{\text{sec kBq}} \right]$$

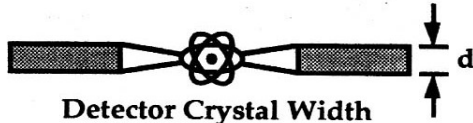

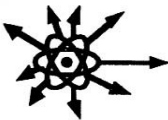

- Good systems reach $S=7-9 \text{ counts}/(\text{sec.kBq})$

- ▶ Spatial Resolution
- ▶ Energy Resolution
- ▶ Count Rate Performance
- ▶ Scatter Fraction

Performance of PET Systems: Spatial Resolution

➔ Determined by *full width half maximum* (FWHM) of *point spread function* (PSF): $FWHM = \sqrt{8 \ln(2\sigma)}$

Resolution Factors

Factor	Shape	FWHM
 <p>Detector Crystal Width</p>		$d/2$
 <p>Anger Logic</p>		0 (individual coupling) 2.2 mm (Anger logic)* *empirically determined from published data
 <p>Photon Noncolinearity</p>		1.3 mm (head) 2.1 mm (heart)
 <p>Positron Range</p>		0.5 mm (^{18}F) 4.5 mm (^{82}Rb)
Reconstruction Algorithm	multiplicative factor	1.25 (in-plane) 1.0 (axial)

Performance of PET Systems: Energy Resolution

- ▶ Statistical uncertainty of energy determination due to limited light yield of scintillator crystal
- ▶ Two methods for determination of energy resolution:
 - *Single event* energy resolution
 - *Coincidence* (i.e. both events) energy resolution

Energy spectra for single photons for a BGO PET system [2].

Performance of PET Systems: Count Rate Performance

- ▶ Ratio Trues/Randoms unbalanced for high Activities
- ▶ Processing of detected photons takes finite time
- ▶ Noise Equivalent Count Rate:

$$NECR = \frac{T^2}{T + S + 2fR}$$

T: trues
S: scattered
R: randoms
f: rel. area of object on proj. surface

Count rate curves for true, random and multiple coincidences. Derived curves for expected and noise equivalent count rate [2]. Data recorded on a CTI ECAT 953B PET using a ^{11}C -filled cylinder in water.

Performance of PET Systems: Scatter Fraction

- ▶ Fraction of the total coincidences recorded in the photopeak window that have been scattered
- ▶ Sources of scattering
 - Scattering within the object containing the radionuclide
 - Scattering off the gantry components (lead septa/side shields)
 - Scattering within the detectors

Log-lin count rate profiles of line source in air/water show additive scatter component outside of central peak [2].

Performance of PET Systems: Scatter Fraction

- ▶ Fraction of the total coincidences recorded in the photopeak window that have been scattered
- ▶ Sources of scattering
 - Scattering within the object containing the radionuclide
 - Scattering off the gantry components (lead septa/side shields)
 - Scattering within the detectors
- ▶ Scatter fraction can be reduced by
 - TOF
 - Usage of a powerful iterative reconstruction method
 - Shielding of scattered photons by septa and endshields
 - Small coincidence window
 - Good energy resolution

Summary

- Positron emitter used as radioactive tracer in the patient
- Use of collimators to generate 'image slices'
- Detection of γ -quanta in scintillation crystal
- Better resolution due to Anger logic
- Signal amplification using PMTs
- Image reconstruction

Imaging for Physicists

Artifacts 1

Uulke van der Heide

Artifacts in MRI

Artifacts in MRI

- An image artifact is any property or effect observed in an image that does not appear in the original object
- Images can be distorted in many ways
 - Signal loss
 - Deformations
 - Poor resolution
 - Ghosting
 - Aliasing
 -
- Consequences for use
 - Interpretation is difficult
 - Geometrical accuracy may be compromised

Outline

- Origin of geometrical artifacts
 - Fold-over artifacts
 - Ringing
 - Impact of field distortions

Origin of various artifacts

- Sampling of k-space
 - Sample k-space in too large steps
 - Don't sample high k-values
- Magnetic field errors
 - Inhomogeneous B_0 field
 - non-linear gradients
 - Susceptibility
 - Chemical shift
- Motion

Imaging artifact

- T_1 -weighted SE image of a brain
- What is wrong?

Sampling the MR signal

- Nyquist criterium: signal must be sampled at at least twice the rate of the highest frequency component

Sampling the MR signal

- Nyquist criterium: signal must be sampled at at least twice the rate of the highest frequency component

- If the signal contains higher frequency components, aliasing occurs

Resolve aliasing by increasing sampling frequency

- Nyquist criterium: signal must be sampled at at least twice the rate of the highest frequency component

- By increasing the sample frequency, the higher frequency components can be resolved and aliasing is avoided

Field Of View covers entire object: no fold-over

What happens with the distance between lines in k-space, if you reduce the field of view by a factor of 2?

- ★ 1. The distance between k-lines is increased by a factor of 2
- 2. The distance between k-lines is reduced by a factor of 2
- 3. The distance between k-lines remains the same (but the extent of k-space is reduced by a factor of 2)

Field Of View covers entire object: no fold-over

FOV too small: fold-over

FOV

How to suppress fold-over artifacts?

- If $\text{NSA} > 1$: Measure all k-lines (full FOV), but reconstruct only half of the image

How to suppress fold-over artifacts?

FOV

- If $\text{NSA} > 1$: Measure all k-lines (full FOV), but reconstruct only half of the image

How to suppress fold-over artifacts?

- If NSA=1: Saturate the signal from outside the field-of-view with REST slabs

Imaging artifact

- T_1 -weighted SE image of a brain
- What is the difference between the left and right image?

Imaging artifact

- T_1 -weighted SE image of a brain
- What is the difference between the left and right image?

Truncation errors (ringing)

- Imaging sharp edges requires high frequency components in k-space
- Cutting off the high-frequency k-lines causes oscillations in the image

How to avoid truncation errors (Ringing)

- sample k-space up to sufficiently high frequencies (use sufficiently small voxels during acquisition)
- filtering; the ringing may disappear, but the spatial resolution of the image, and sharpness of edges tends to be compromised

Sampling of k-space

Aliasing/Fold-over artifact:

- Fold-over of signal from outside field-of-view into the image
- Appears in phase-encoding direction

What to do about it:

- Increase FOV in phase-encoding direction
 - (decrease the distance between k-lines)
- Suppress signal from outside FOV

Sampling of k-space

Ring artifact:

- Oscillating pattern next to sharp edges in an image

What to do about it:

- Decrease voxel size
 - (sample higher k-values)
- Filter the image

Sampling k-space in practice

- Let's assume we sample k-space well. Do we really sample, what we thought we sampled?
- Spatial encoding occurs by switching gradients to modulate frequency and phase
- How can this process lead to artifacts?

$$\omega = \gamma \mathbf{B}_0$$

Linear magnetic gradient fields (x, y, z) create spatial differentiation of the signals

→ 3D images

Position encoding in a spin-echo sequence

RF pulse

Slice selection gradient

Phase encoding gradient

Frequency encoding gradient

Signal detection

Slice selection: transversal

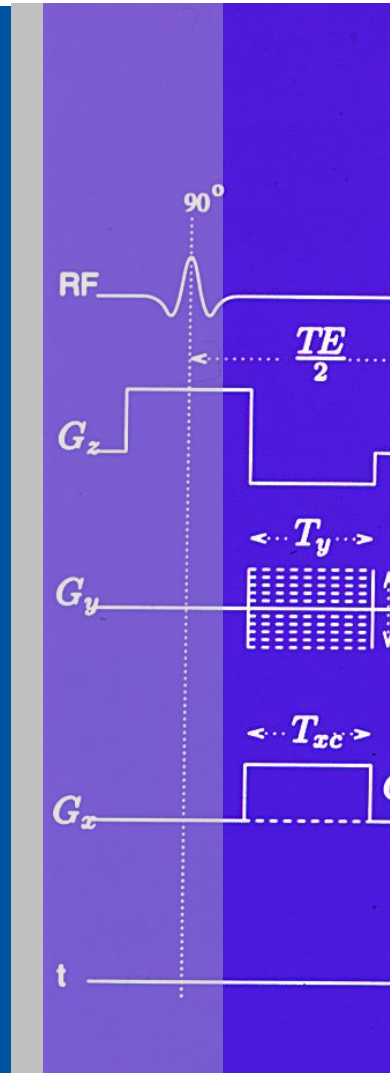

Resonance condition

$$\omega = \gamma (B_0 + zG_z)$$

Phase encoding

Apply gradient after RF pulse and before read-out

Phase encoding

$$\omega = \gamma B_0$$

G_{phase} _____

Phase encoding

$$\omega = \gamma (B_0 + yG_y)$$

Phase encoding

$$\omega = \gamma B_0$$

G_{phase} _____

Frequency encoding (read-out)

Apply gradient during read-out

Frequency encoding (read-out)

$$\omega = \gamma (B_0 + xG_x)$$

Position encoding in a spin-echo sequence

2D Fourier transform imaging

n^{th} time sample of the signal after the m^{th} phase encoding step:

$$S(n, m) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} A(x, y, z) e^{i\Phi(x, y, z, n, m)} dx dy dz,$$

Discrete 2D inverse Fourier transformation:

$$A'(u, v) = \sum_{n=-\frac{N_s}{2}}^{\frac{N_s}{2}-1} \sum_{m=-\frac{N_p}{2}}^{\frac{N_p}{2}-1} S(n, m) e^{-i\Phi(u, v, n, m)},$$

with

$$n \in \left[-\frac{N_s}{2}, \frac{N_s}{2} - 1\right] \text{ and } m \in \left[-\frac{N_p}{2}, \frac{N_p}{2} - 1\right].$$

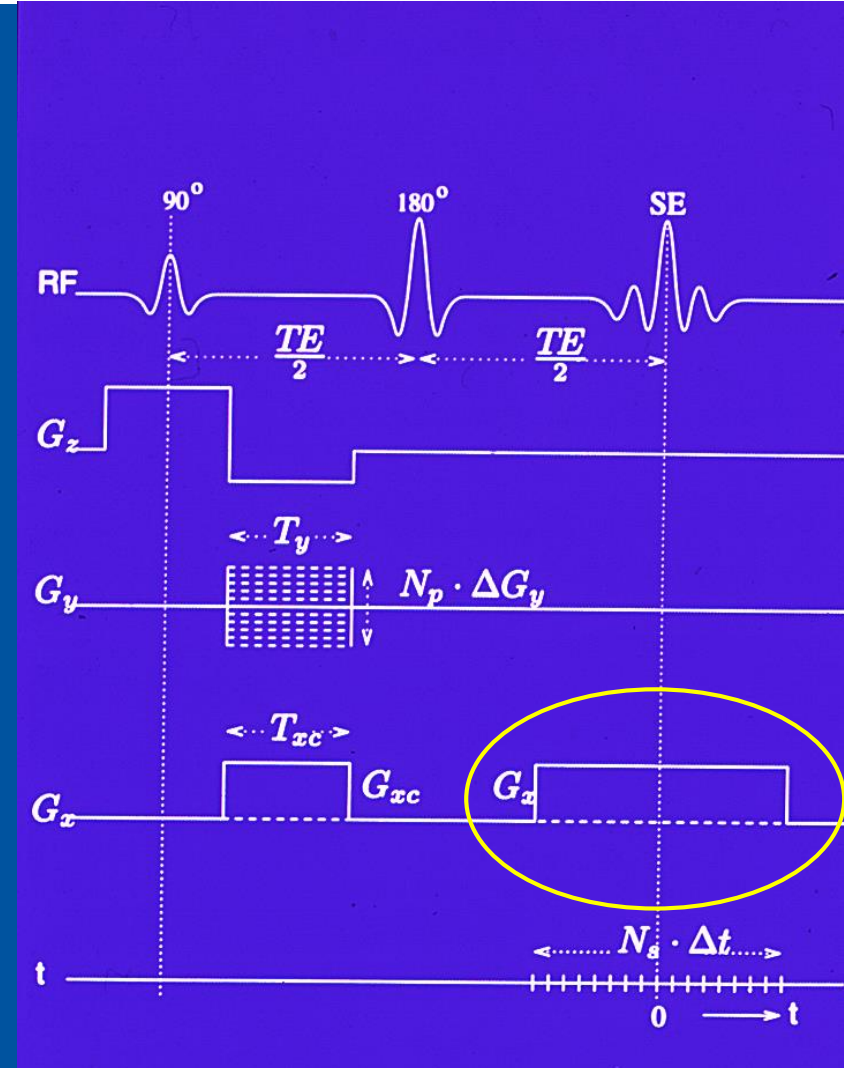

gives complex image $A'(u, v)$.

A spin-echo sequence in k-space

A spin-echo sequence in k-space

Phase evolution

$$\Phi_0(t) = \omega_0 t$$

- The phase shift depends on the strength and duration of the gradient applied;

$$\Delta\Phi(T) = \Delta\omega T = \gamma\Delta B T$$

- For the phase-encoding (y) and read-out (x) gradients, this means:

$$\Delta\Phi_m = \gamma y m \Delta G_y T_y$$

and

$$\Delta\Phi_n = \gamma x G_x n \Delta T_x$$

- In a spin-echo sequence, the spins flip 180° during the 180° pulse. Thus, a phase difference created before the 180° pulse has the opposite effect during read-out

Phase evolution

$$\Phi(x, y, z, n, m) = -\gamma x G_{xc} T_{xc} + \gamma x G_x \left(n + \frac{N_s}{2} \right) \Delta t - \gamma y m \Delta G_y T_y.$$

With a balanced read-out gradient:

$$-G_{xc} T_{xc} + G_x \Delta t \frac{N_s}{2} = 0,$$

And in the absence of field inhomogeneities:

$$\Phi(x, y, z, n, m) = \gamma x G_x n \Delta t - \gamma y m \Delta G_y T_y.$$

with

$$n \in \left[-\frac{N_s}{2}, \frac{N_s}{2} - 1 \right] \text{ and } m \in \left[-\frac{N_p}{2}, \frac{N_p}{2} - 1 \right].$$

echo centered in the acquisition window at $t=0$ ($n=0, m=0$)

A spin-echo sequence in k-space

$$k_y = \gamma y m \Delta G_y T_y$$

$$k_x = \gamma x G_x n \Delta T_x$$

Do we really sample k-space the way we think we do?

Many reasons why the phase evolution can be distorted

- Hardware
 - non-linear gradients
- Patient
 - chemical shift
 - Susceptibility

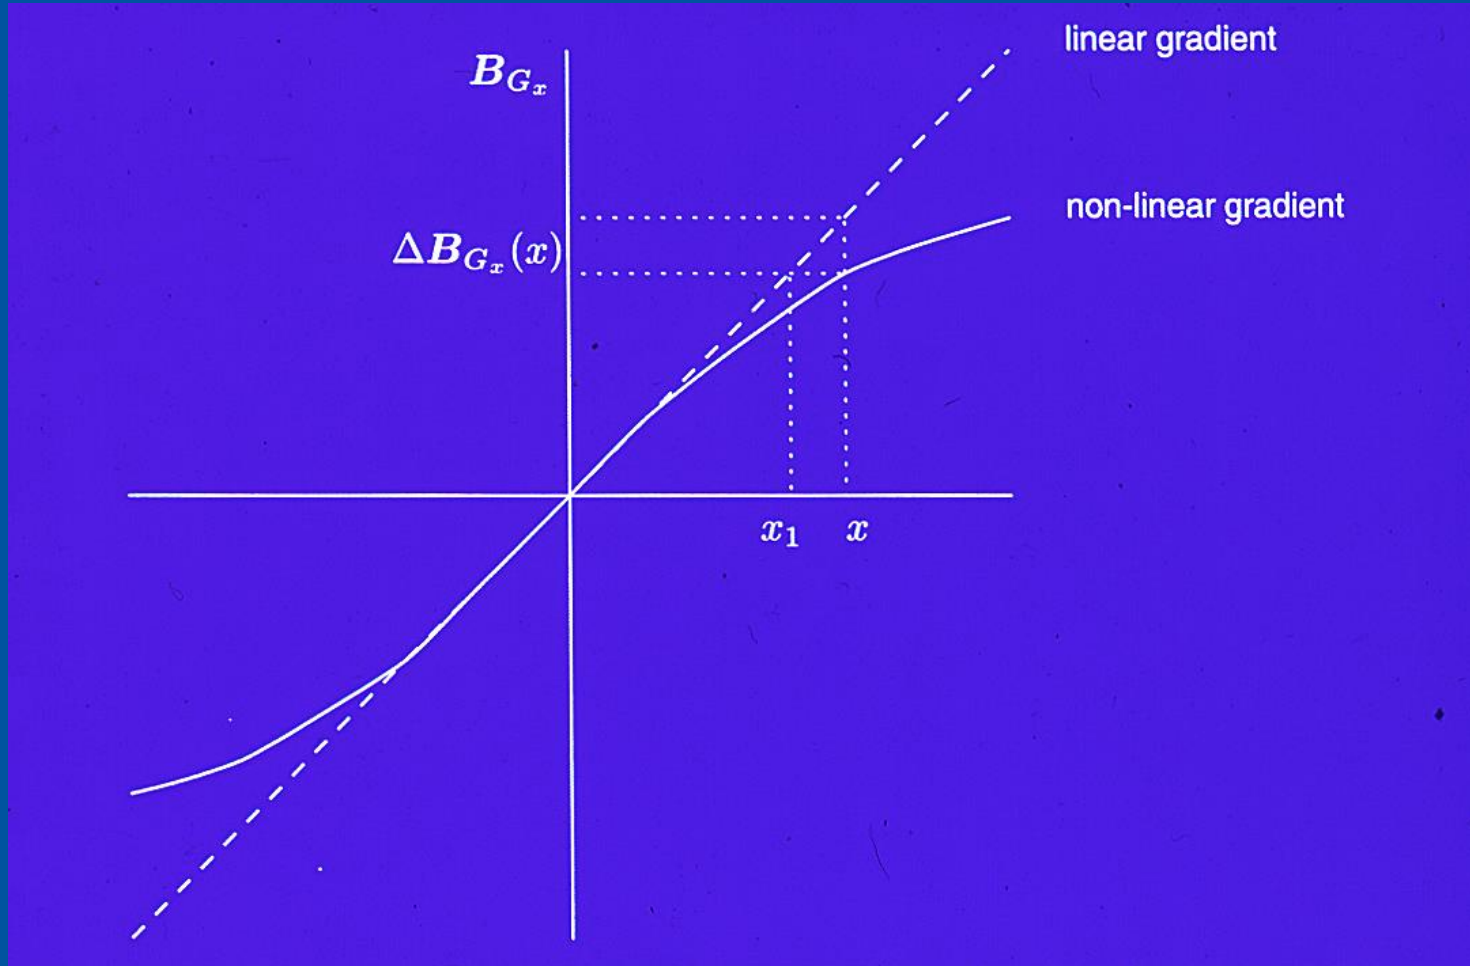

Imperfections of B_0 and gradient fields

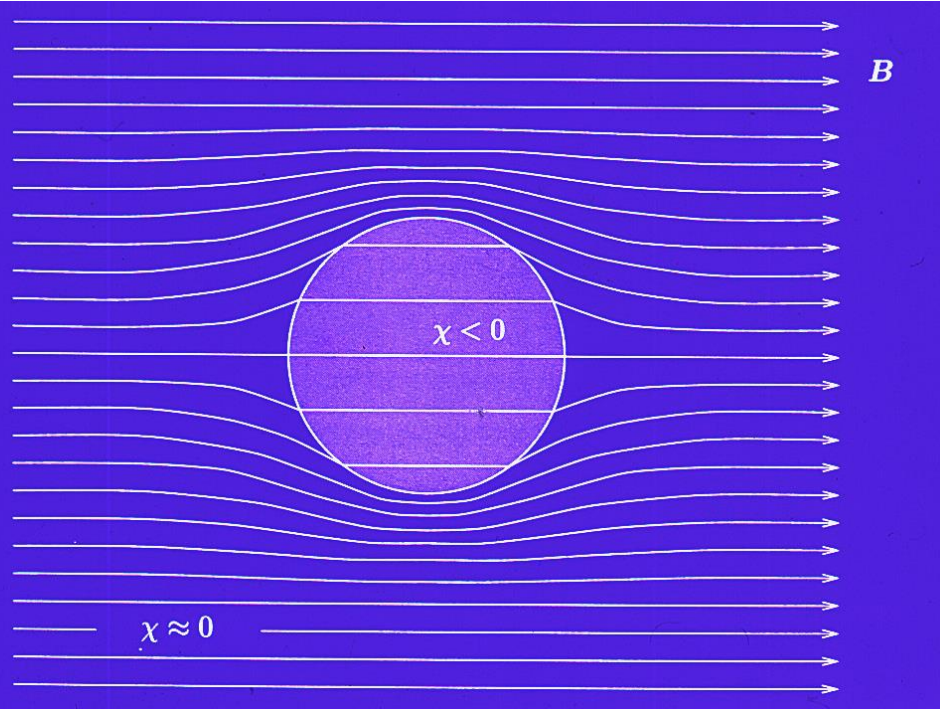

Imperfect magnetic field homogeneity:

- divergence of the magnetic field lines at the end of the coil
- imperfect winding the superconducting wire
- variations of current densities in the wire
- Distortion of the magnetic field by metal close to the scanner

Non-linear gradients cause position distortions

Magnetic susceptibility

Magnetic susceptibility χ : $M = \chi H$

M = magnetization, H = magnetic field

- diamagnetic materials: $\chi < 0$ (tissues ca. $-9 \cdot 10^{-6}$)
- paramagnetic materials: $\chi > 0$
- ferromagnetic materials: very large susceptibility
- air: $\chi = 0$

Water-fat shift

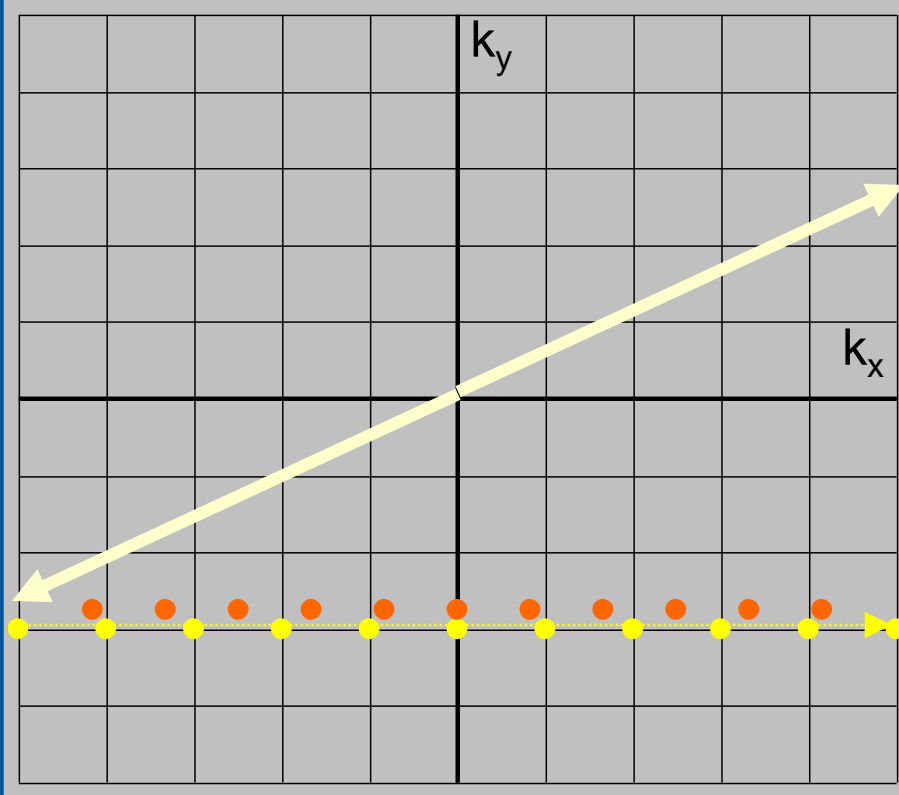

Magnetic field at the nucleus depends on magnetic shielding of surrounding electron clouds, depends on molecular environment

example:

resonant frequencies of protons in fat and water differ by 3.4 ppm

Erroneous sampling of k-space

Position errors: slice selection

A deviation of the magnetic field during the 90° pulse results in a shift in the selected slice:

$$z_1 = z - \frac{\Delta B_0}{G_z} - \frac{\Delta B_{G_z}}{G_z}$$

Distortion of phase evolution

$$\begin{aligned} \Phi^{distorted}(x, y, z, n, m) &= \Phi(x, y, z, n, m) \\ &+ \gamma \Delta B_0(x, y, z) n \Delta t \\ &+ \gamma \Delta B_{G_x}(x, y, z) n \Delta t \\ &- \gamma m \Delta B_{\Delta G_y}(x, y, z) T_y \end{aligned}$$

With:

$\Phi^{distorted}$ the distorted phase evolution

Φ the ideal phase evolution:

$$\Phi(x, y, z, n, m) = \gamma x G_x n \Delta t - \gamma y m \Delta G_y T_y$$

Impact on geometrical accuracy

Interpretation of the effect of disturbances:

$$\Phi^{distorted}(x, y, z, n, m) = \Phi(x_1, y_1, z_1, n, m)$$

Group x-terms for distortions in read-out direction:

$$\gamma x G_x n \Delta t + \gamma \Delta B_0(x, y, z) n \Delta t + \gamma \Delta B_{G_x}(x, y, z) n \Delta t = \gamma x_1 G_x n \Delta t$$

and solve for x_1

$$x_1 = x + \frac{\Delta B_0(x, y, z)}{G_x} + \frac{\Delta B_{G_x}(x, y, z)}{G_x}$$

Impact on geometrical accuracy

Group y-terms for distortions in fase-encoding direction:

$$-\gamma y m \Delta G_y T_y - \gamma m \Delta B_{\Delta G_y}(x, y, z) T_y = -\gamma y_1 m \Delta G_y T_y$$

and solve for y_1

$$y_1 = y + \frac{\Delta B_{\Delta G_y}}{\Delta G_y}$$

Assuming that the errors in the gradient are independent of the gradient step, this is equal to

$$y_1 = y + \frac{\Delta B_{G_y}}{G_y}$$

Result: geometrical distortion in spin-echo imaging

$$x_1 = x + \frac{\Delta B_0(x, y, z)}{G_x} + \frac{\Delta B_{G_x}(x, y, z)}{G_x}$$

In the frequency-encoding direction, both the non-linearity of the frequency-encoding gradient and static field inhomogeneity cause geometric distortions

$$y_1 = y + \frac{\Delta B_{G_y}}{G_y}$$

In the phase-encoding direction, distortions are solely caused by the non-linearity of the phase-encoding gradient

Water and fat have a slightly different resonance frequency. This results in a shift between the water and the fat in an image, called 'water-fat shift'

In what direction does this shift occur?

1. Slice direction
2. Phase-encoding direction
- ★ 3. Read-out direction

Result: geometrical distortion in spin-echo imaging

$$x_1 = x + \frac{\Delta B_0(x, y, z)}{G_x} + \frac{\Delta B_{G_x}(x, y, z)}{G_x}$$

frequency-encoding (read-out) direction:

- non-linearity of the gradient
- static field inhomogeneity
(= static difference in resonance frequency)

$$y_1 = y + \frac{\Delta B_{G_y}}{G_y}$$

phase-encoding direction:

- non-linearity of the gradient

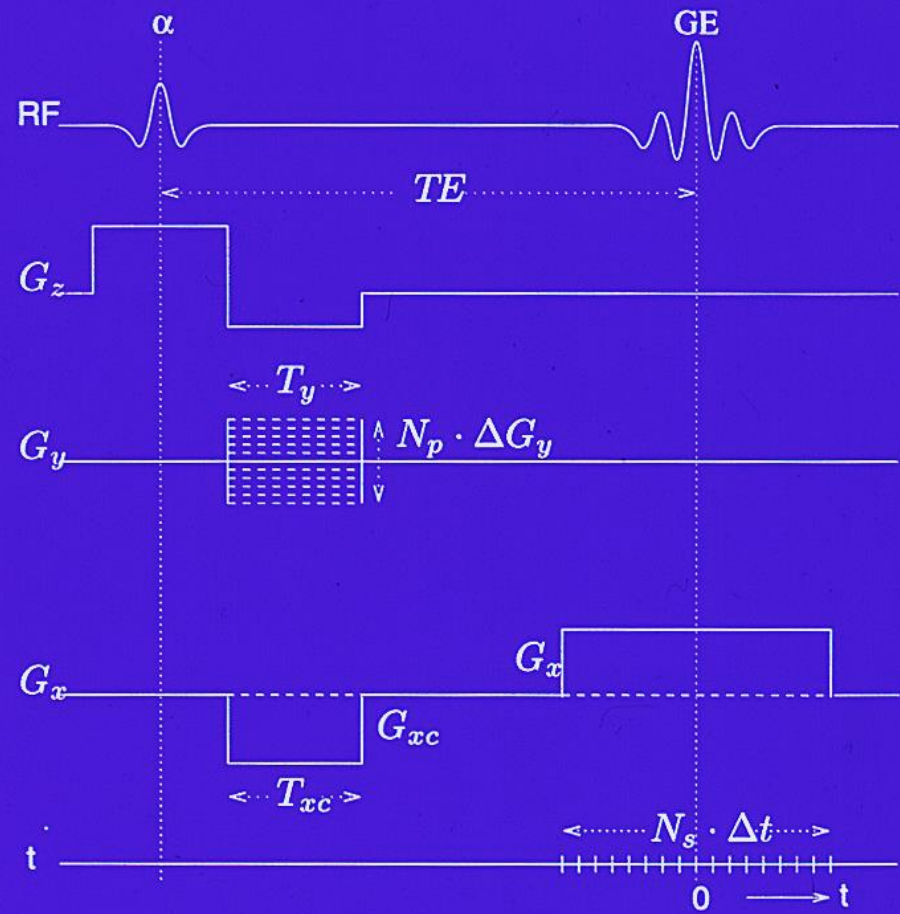

Distortions in a Gradient Echo sequence

In Gradient Echo imaging, the same distortions occur.

However, in the frequency-encoding direction also dephasing occurs, resulting in signal loss:

$$\Delta\Phi(x, y, z) = \gamma TE \Delta B_0(x, y, z)$$

Dephasing due to static field inhomogeneities

Rephasing in a Spin Echo sequence

Continued dephasing in a Gradient Echo sequence

Phantom experiments

Some qualitative experiments with coaxial cylinder
(water air susceptibility difference):

air: $\chi \approx 0$
water: $\chi \approx -9 \cdot 10^{-6}$

Dephasing effects increase with TE in gradient echo imaging

- Dephasing artifacts increase with Echo Time

Dephasing effects increase with TE in gradient echo imaging

- 3T scanner
- FFE sequence; TR = 100 ms, FA 45°

Summary 1

- Many reasons exist for artifacts in images
 - Erroneous sampling of k-space
 - Aliasing
 - Ringing
 - Magnetic field errors
 - Gradient artifacts
 - Susceptibility artifacts
 - Water-fat shift
- Geometrical artifacts show up in a particular direction
 - Phase encoding direction: aliasing
 - Read-out direction: susceptibility, water-fat shift
- Dephasing results in signal loss in gradient echo sequences

MRI Physics: Speed-up and Specialised Sequences

A/Prof Gary Liney

6th November 2017

ESTRO Imaging for Physicists

Introduction

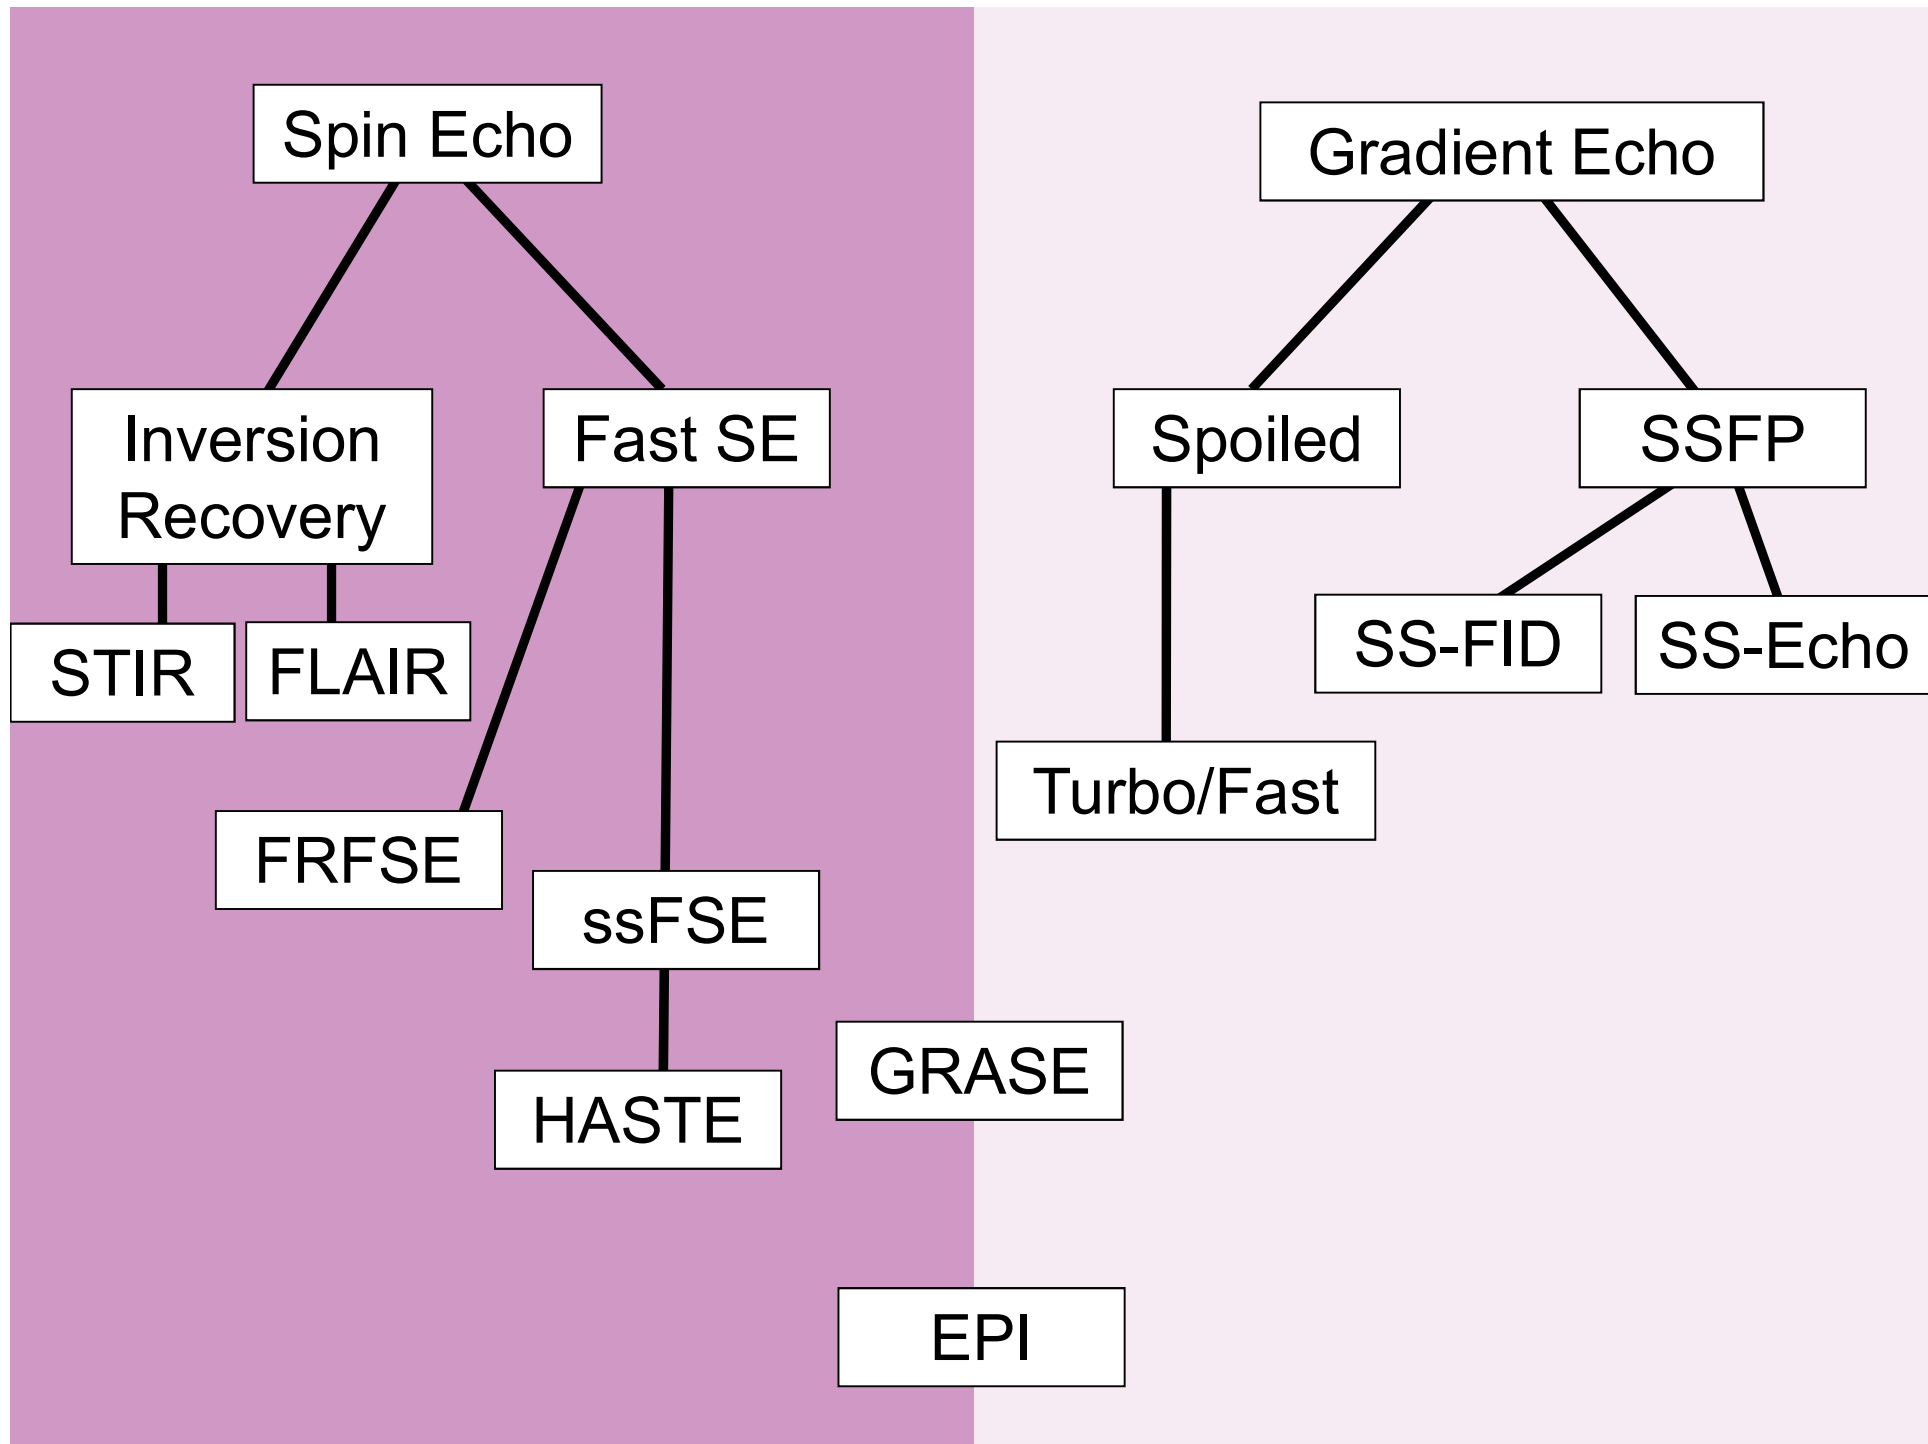

- MRI slow technique (compared to CT)
- Desirable to cover anatomy quickly
 - ✓ Patient comfort
 - ✓ Reduce artefacts
 - ✓ Image physiological
- Some sequences specific for RT

0.5 T (c1993)
32 x 4 mm in 5 min

3.0 T (2010)
148 x 1 mm in 3.5 min

Spin-echoes...

- T_2 -weighted essentially limited by long TR
- Increase speed by:
 - Segmented k-space
Acquire more than one line of k-space per TR
 - Partial k-space
Acquire less than full k-space

k-space: Acquisition strategies

Spin-echo

Single-Shot

Partial Data

Segmented

Radial

Parallel imaging

k-space: Scan Time

$$TR \times N_{AV} \times N_{PE}$$

$$TR \times N_{AV}$$

$$TR \times N_{AV} \times (N_{PE}/2)$$

$$(TR \times N_{AV} \times N_{PE}) / ETL$$

$$TR \times N_{AV} \times N_{PE} \times 2\pi$$

$$(TR \times N_{AV} \times N_{PE}) / R$$

Fast (Turbo) Spin Echo

- Multiple SEs but individually phase encoded
- Scan time reduced by ETL ('Turbo factor')
- Effective TE
- Image quality trade-off
 - If ETL or ESP too large blurring
- Characteristic bright fat
 - J-coupling breakdown caused by use of echo trains

Aka:
FSE
TSE
RARE

$$\text{Scan time} = (\text{TR} \times N_{\text{AV}} \times N_{\text{PE}}) / \text{ETL}$$

FSE (TSE)

Example: FSE

FSE extensively used in prostate: axial and coronal planes at 3.0 Tesla without ER coil and excellent T2-weighting

Partial k-Space

Partial Fourier/ Fractional NEX

- Half of phase encoding
- **Reduced scan time**
- Other reduction fractions possible

Partial Echo

- Half of echo
- Reduced minimum TE
- No effect on scan time

ssFSE and HASTE

Single shot FSE (ssFSE)

- All k-space in one TR
- Good for high contrast and volume coverage
- MRCP exam right

MIP from ssFSE
(TE/TR = 260 ms/12 s)

HASTE

- Single shot AND partial k-space
- Just over half k-space acquired
- Reasonable temporal & spatial resolution (prostate right)

HASTE

Echo Planar Imaging (EPI)

- Implemented by Peter Mansfield (1977)
- Single-shot (can be run multi-shot)
 - Scan time = TR
- Blipped, spiral and constant versions
- Inherently noisy
- Limited resolution (e.g. 64 or 128 matrix)
- Can be SE or GRE based
- Widespread use in fMRI & DWI

EPI

Prone to artefacts:

- N/2 ghosting (switching between lines)
- Distortions (eddy currents)
- Large chemical shift requires fat suppression
- Huge susceptibility effects along PE

EPI with B_0 Correction

Non corrected

Corrected

Susceptibility effects are particularly noticeable in frontal and occipital lobes.

Roberto Garcia-Alvarez,
GE Healthcare*

Robust DWI

Conventional single shot EPI

RESOLVE

EPI

RESOLVE

GRASE

- Hybrid sequence
- Gradient And Spin Echo
- Also known as TurboGSE
- Multiple spin-echoes and gradient echoes at each spin-echo
 - 'Gradient' AND 'Turbo' factors to consider
- Each echo phase encoded

$$\text{Scan time} = (\text{TR} \times N_{\text{AV}} \times N_{\text{PE}}) / (N_{\text{GRE}} \times N_{\text{SE}})$$

GRASE (TGSE)

Example: TGSE

TGSE

GE

- TGSE in prostate with gold seeds compared to GE
- T_2 -w contrast and seed visualisation in one sequence

Gradient-echoes...

- Inherently fast due to lack of 180° and short TR
- Partially excite using reduced flip (Ernst) angle
 - Not restricted by relaxation
- If we further reduce TR...
 - Steady-state magnetisation when $TR \ll T_2$

- Rapid successive RF pulses
- Refocus residual transverse magnetisation into 'Hahn' echoes
- Using or destroying these alters contrast

Steady State Sequences

- Spoiling (or 'incoherent steady state')
 - Removes residual transverse signal
 - Use RF (or gradient) spoiling
 - RF phase angle increased to produce net cancellation of transverse magnetization
 - Incomplete spoiling leads to 'FLASH-bands'

FLASH (Turbo-FLASH)
SPGR (FSPGR)
RF-FAST

$$S \propto \frac{\sin \alpha [1 - \exp(-TR / T_1)] \exp(-TE / T_2^*)}{1 - \cos \alpha \exp(-TR / T_1)}$$

Steady State Sequences

- Rewinding (SS-FID)

- Maintains coherent transverse magnetisation
- FISP, GRASS rewind phase encoding only
- ‘True’ FISP or bFFE rewind all 3 gradient directions

Have to additionally phase cycle RF (ROAST)

- Time Reversed sequences (SS-Echo)

- PSIF
- Use (Hahn) echo -essentially T_2 -weighted

FAST
FISP
GRASS
bFFE/bSSFP
FIESTA

CE-FAST
PSIF
SSFP

Signals depend on:
flip angle, T_1/T_2

Steady-State Sequences

RF spoiled:
phase (ϕ) is
increased

Example: TrueFISP

Reduced artefacts with cardiac shim

Real time free
breathing lung
scans using
TrueFISP

Gradient-Speed Limit

$$G \cdot t \times \text{pixel width} = \text{constant}$$

Gradients can
be made to run
faster

but

Physiological
limit = PNS

Parallel Imaging

- Acquire fewer k-space lines
 - ✓ Speed up scanning
- Use Coil Arrays to:

Unwrap aliased images (image space) 'SENSE' -like

OR

Generate missing lines (k-space) 'SMASH' -like

$$\text{Scan time} = (\text{TR} \times N_{\text{AV}} \times N_{\text{PE}}) / R$$

'Coil Encoding'

Multi-channel RF coils:
Signal strength from one coil
with respect to another
provides
alternative localisation method

Parallel Imaging

Full k-space
(takes time!)

Whole image

Parallel Imaging

Parallel Imaging

Image space methods

SMASH

AutoSMASH

GRAPPA

ARC

SENSE
ASSET

mSENSE

k-space methods

iPAT

SENSE

- SENSitivity Encoding
- Commercially implemented by Philips
- Other Implementations:
 - ASSET (GE), SPEEDER (Toshiba), RAPID (Hitachi)
- Apply knowledge of coil sensitivity profiles to calculate aliased signal component
- Can be applied in through-plane phase encoding (3D)
- Reduction Factor = 1 to number of coils (+non integers)
- Cannot handle inherent aliasing (FOV must encompass object)

Where $\Delta y = \text{FOV}_{\text{rec}}/R$

Acquired FOV

Reconstructed FOV

$$I(y)_1 = C_1(y)S(y) + C_1(y + \text{FOV}_{\text{rec}}/R)S(y + \text{FOV}_{\text{rec}}/R)$$

$$I(y)_2 = C_2(y)S(y) + C_2(y + \text{FOV}_{\text{rec}}/R)S(y + \text{FOV}_{\text{rec}}/R)$$

$$I_j(x, y) = \sum_{n=0}^{n_A-1} C_j(x, y + n\Delta Y) S(x, y + n\Delta Y)$$

$$I_j(y) = C_j(y) S(y) + C_j(y + \Delta Y) S(y + \Delta Y) + \dots + C_j(y + (n_A - 1)\Delta Y) S(y + (n_A - 1)\Delta Y)$$

$$\begin{pmatrix} I_1(x, y) \\ I_2(x, y) \\ \vdots \\ I_L(x, y) \end{pmatrix}_{L \times 1} = \begin{pmatrix} C_1(x, y) & C_1(x, y + \Delta Y) & \cdot & \cdot & \cdot & C_1(x, y + (n_A - 1)\Delta Y) \\ C_2(x, y) & C_2(x, y + \Delta Y) & \cdot & \cdot & \cdot & C_2(x, y + (n_A - 1)\Delta Y) \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ C_L(x, y) & C_L(x, y + \Delta Y) & \cdot & \cdot & \cdot & C_L(x, y + (n_A - 1)\Delta Y) \end{pmatrix}_{L \times n_A} \begin{pmatrix} S(x, y) \\ S(x, y + \Delta Y) \\ \cdot \\ \cdot \\ S(x, y + (n_A - 1)\Delta Y) \end{pmatrix}_{n_A \times 1}$$

$$I = C S$$

SENSE

- Calibration scan (sensitivity maps) required
- Typically 20 s
- single scan only
- Relies on no patient motion between calibration and speed-up scans
- Modified SENSE uses calibration from oversample k-space

$$SNR' = \frac{SNR}{g\sqrt{R}}$$

SMASH

- SiMultaneous Acquisition of Spatial Harmonics
- Re-create sinusoidal signal variation from 'missing' phase encoding

Empirical self calibration:

AutoSMASH

GRAPPA

ARC

Example: iPAT

iPAT (4): 5 min 17 s

5 min 42 s

DIXON Imaging

- Fat and water have different resonance frequencies (220 Hz at 1.5 T)
- At specific echo times (TE) fat and water are either in phase ($=1/220$ Hz or every 4.6 ms) or out of phase
- Total of 4 Image contrasts are obtained (useful in MR-only)

k-space: Acquisition strategies

Spin-echo

Single-Shot

Partial Data

Segmented

Radial

Parallel imaging

Radial Acquisition

Ultra-short TE

- Radial (and spiral) trajectory very fast and efficient
- TE can be further minimised with non-selective or half RF pulses and ramp sampling
- TE can be limited to switching capability of Tx/Rx
- $TE \leq 0.1 \text{ ms}$ ($100 \mu\text{s}$) said to be 'ultrashort'
- In some methods (ZTE and PETRA) gradients ramped up prior to sampling

Ultra-short TE

T2 values

Water: 4000 ms
Soft-tissue: 90 ms
Achilles tendon: 5 ms
Cortical bone: 0.5 ms
Ice: 0.015 ms

Solid material becomes visible if we can encode signal rapidly

UTE Examples

Lung

H&N

High SNR in cortical bone

Bone segmentation

0.07 ms - 2.3 ms = subtraction

PET Image Formation

Random Correction

- ▶ Randoms: $R_{ab} = 2\tau \cdot N_a N_b \propto N^2$

Correction Methods:

- ▶ Tail Fitting
 - Estimate random distribution in the object by fitting the tails outside the object
- ▶ Estimation from Single Rates
 - Direct determination from single rates N_a and N_b
- ▶ Delayed Coincidence Channel Estimation
 - Data stream containing signals from one channel is delayed for several times the coincidence window
 - Removal of all annihilation events
 - Any coincidences detected are random
 - Subtraction from coincidences in the prompt channel

Normalization

- ▶ LORs have different sensitivities
- ▶ Individual correction factor for each LOR

Correction Methods:

- ▶ Direct Normalization
 - Illumination of all possible LORs with planar or rot. line source
 - Long scan times necessary
 - Sources must have very uniform activity distribution

Mean radial geometric profiles for three block-detectors. Asymmetry due to the fact that centre of rotation of sources not coincident with center of detector ring (from [2]).

- ▶ Component-based Model for Normalization

Dead Time Correction

- ▶ Measurement of dead time with ‘decaying source’
 - Uniform source (^{18}F , ^{11}C) of known activity
 - Measurements of singles, prompt and random coincidence rates

- ▶ Construction of look-up tables for dead time correction factors

(a) Effect of dead time on count rate linearity.

(b) Effect of shortening the signal integration time (from [2]).

Scatter Correction

- ▶ Most likely: Compton scattering

- ▶ Compton equation
$$E_{sc} = \frac{E}{1 + \frac{E}{m_0 c^2} (1 - \cos \Omega)}$$

- Relates photon energy before (E) and after scattering (E_{sc}) to scattering angle Ω
- $m_0 c^2$: resting energy of electron before scattering

Correction strategies:

- Fitting scatter tails
- Direct measurement
- Dual energy window methods
- Multiple energy window methods
- Simulation-based methods

Spectral distribution of scattered 511 keV photons [2].

Improved image quality due to random and scatter correction

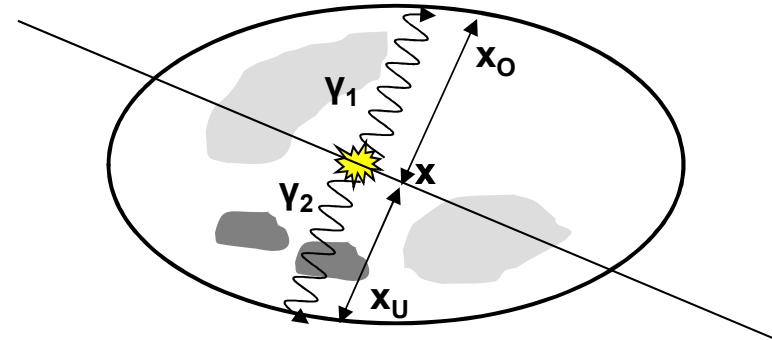

Attenuation Correction

Probability P_1 for quant γ_1 to reach a detector:

$$P_1 = k_1 \cdot e^{-\int_x^{x_0} \mu(x) dx}$$

Accordingly P_2 for quant γ_2 :

$$P_2 = k_2 \cdot e^{-\int_{x_u}^x \mu(x) dx}$$

Probability for a coincidence event:

$$P_{tot} = P_1 \cdot P_2 = k_1 \cdot k_2 \cdot e^{-\int_{x_u}^{x_0} \mu(x) dx}$$

Accurate attenuation correction is possible if the line integral $\int_{x_u}^{x_0} \mu(x) dx$ can be obtained from a transmission measurement.

 **CT is used for attenuation correction!**

CT-based attenuation correction

4D-PET/CT vs. 3D-PET/CT

Aristophanous et al, IJROBP 2012; 82(1): e99-105.

- Comparison of PET-based GTV contouring on 3D- vs. 4D PET (different phases: 20%, 60%)
- RT volumes contoured on 4D-PET (orange) were larger than 3D-PET volumes (pink)

Image Reconstruction

sinogram

Reconstructed image

1. Filtered Backprojection
2. Iterative Reconstruction Methods

Analogue to CT reconstruction: Filtered Backprojection

- ▶ Works well for lower noise environment of brain
- ▶ Not optimal for whole-body imaging

Schematic representation of FBP [1].

Fourier Slice Theorem

The Fourier transform of the projection equals the Fourier transform of the density distribution along a line in polar coordinates.

Filtered Backprojection (FBP)

Filtered Backprojection FBP

- ▶ Backprojection of all projections yields a blurred image.
- ▶ Unblurring Operation = convolution with an edge enhancing filter
- ▶ 1D-convolution of the sinogram with a ramp filter that enhances high frequencies (Linearity of projection operation allows to convolve projection data with a filter!)

Filtered Backprojection

To increase edge definition, the projections are convolved with an edge enhancement filter:

filtered Sinogram

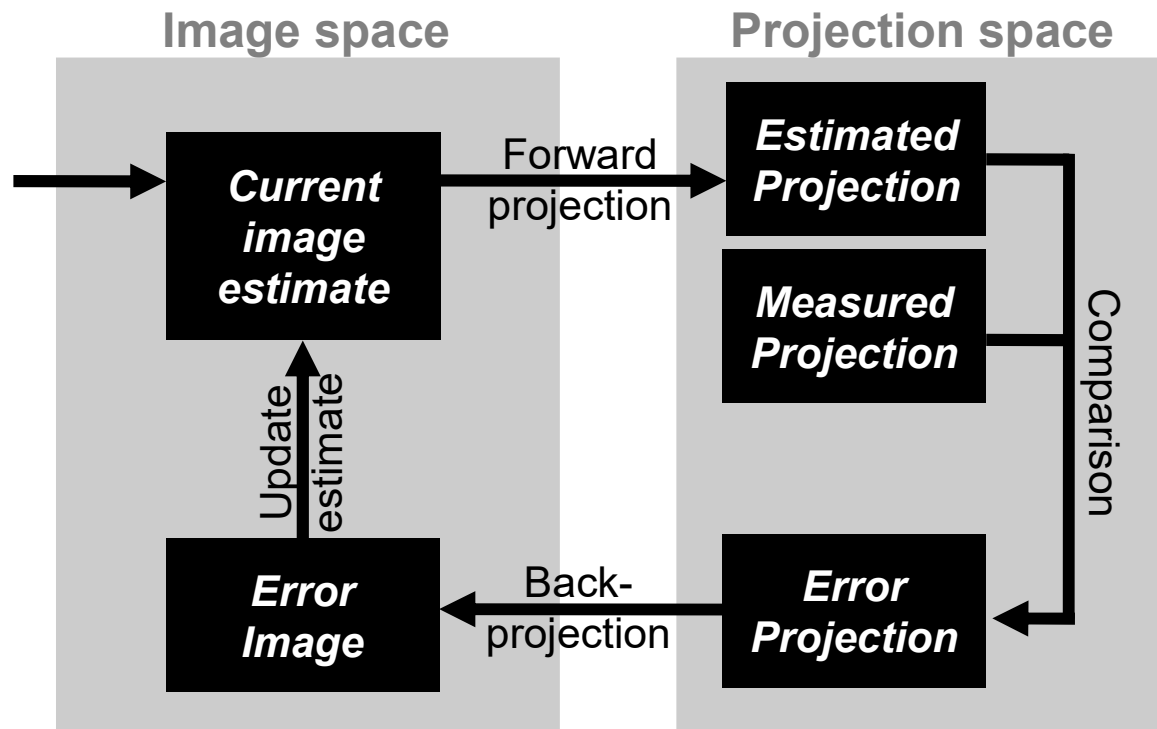

filtered Backprojection

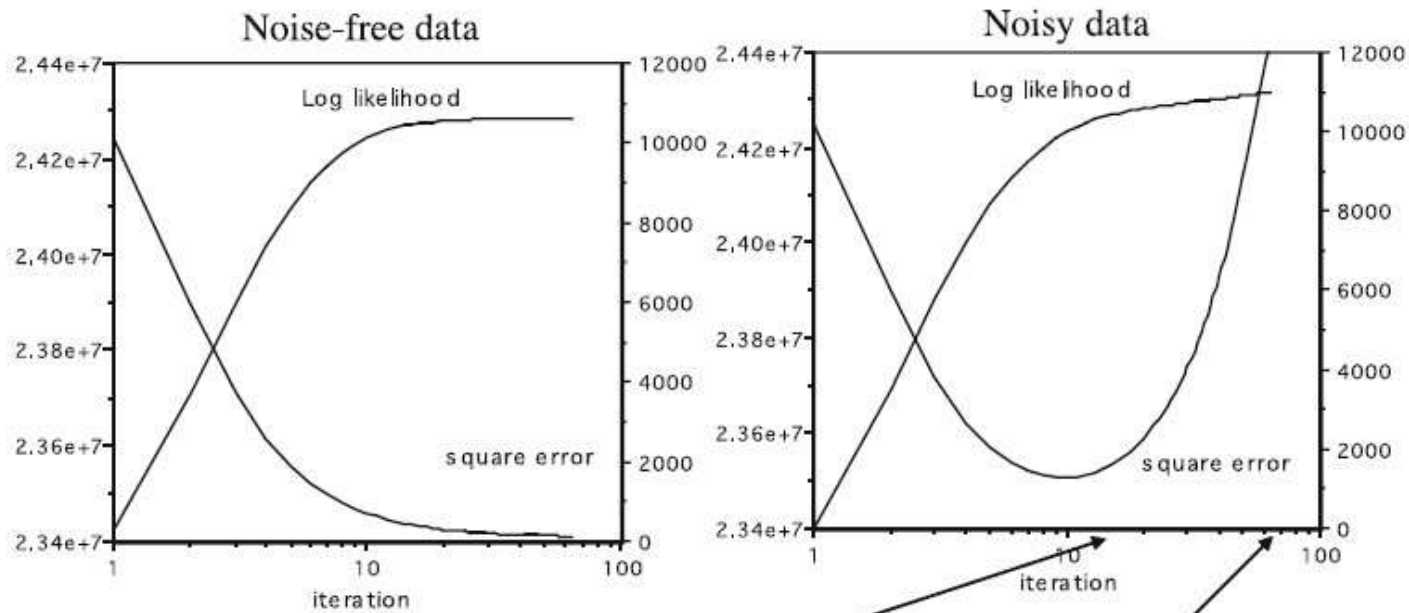

Iterative reconstruction: ML-EM

- ▶ Iterative reconstruction
 - Discrete representation of data and image
- ▶ **Expectation maximization (EM)** algorithm offers determination of **maximum likelihood (ML)** estimate of the image

ML-EM: noisy data introduce instabilities

2D reconstruction of math. phantom with ML-EM. Poisson log-likelihood and square reconstruction error with regard to reference image versus number of iterations [1].

OSEM (ordered subset EM)

- ▶ Accelerated version of ML-EM
- ▶ LOR data are partitioned in S disjoint subsets
$$J_1, \dots, J_S \subset [1, \dots, N_{LOR}]$$
- ▶ Commonly, projections are divided into subsets with different views, or azimuthal angles
- ▶ ML-EM algorithm for data from one subset only
- ▶ Each subset processed in well-defined order
- ▶ Convergence accelerated by factor $\approx S$

OSEM (ordered subset EM)

3D Iterative Reconstruction

- ▶ Fully 3D PET measurements and reconstruction
- ▶ Increasing computational demands
- ▶ Rebinning 3D data into 2D transaxial slices

Time-of-Flight (TOF) PET

- ▶ Difference in flight time of photons is registered

$$\Delta t = \frac{2\Delta x}{c}$$

- ▶ Probability of event occurrence is limited to a certain area along the LOR
- ▶ Better SNR
 - Especially in the abdomen / heavy patients

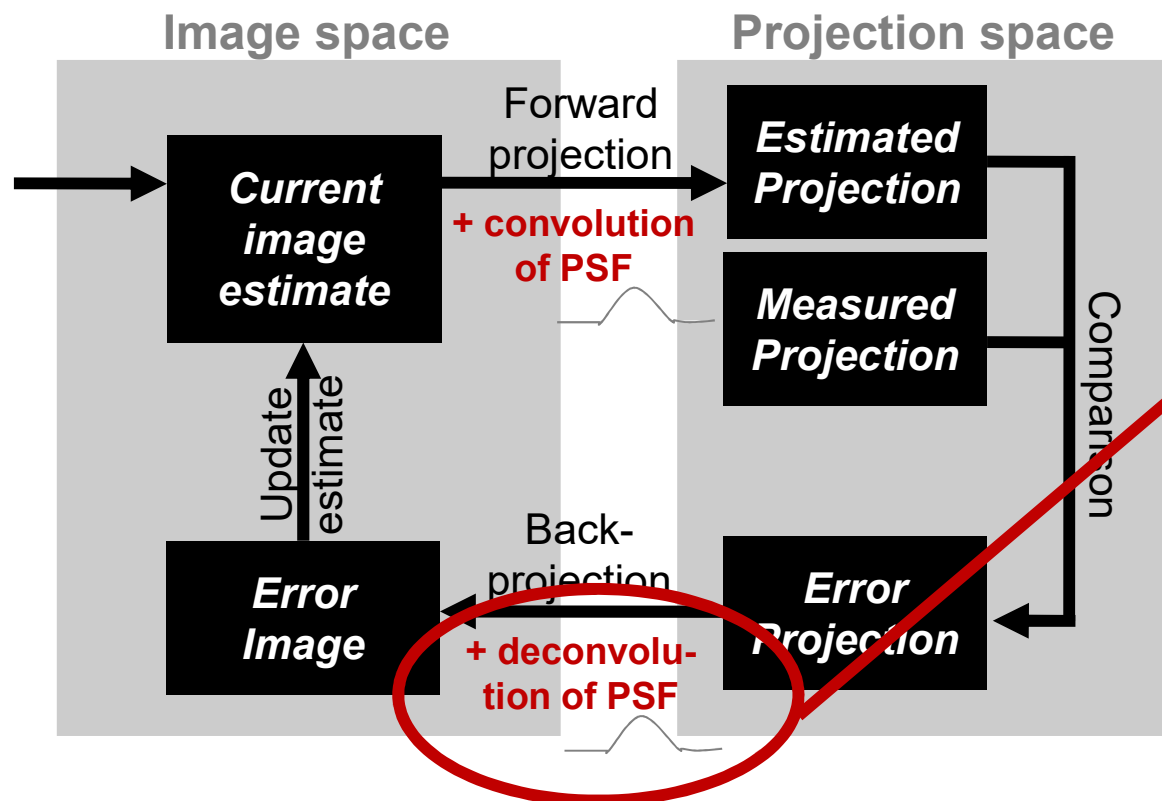

Resolution Modeling - PSF

- ▶ Deconvolution of local **point-spread functions (PSF)** during iterative reconstruction
- ▶ Enhanced resolution
- ▶ Reduction of blurring and distortions

Iterative reconstruction with resolution modeling

- May introduce Gibbs-artifacts
- Not necessarily activity conservation

Improvement of PET/CT Image Quality

Iterative

Reconstruction

(D)

TOF+PSF

Iterative

Reconstruction

Courtesy R. Boellaard, Amsterdam

Summary: Reconstruction

- ▶ Today, iterative reconstruction (IR) algorithms are standard on all PET/CT systems
- ▶ Superior image quality when compared to filtered back projection
- ▶ Iteratively reconstructed images are characterized by
 - number of iterations and subsets
 - matrix and voxel size
 - image zoom
 - image smoothing, smoothing filter size or kernel (FWHM).
- ▶ IR methods employing a sufficient number of iterations and subsets to ensure sufficient amount of convergence are preferred.
- ▶ Reconstructed with and without AC recommended to allow inspection of AC artifacts.

Quantitative analysis of PET images

Tracer uptake is frequently quantified by the

Standardized uptake value (SUV)

$$SUV = \frac{C}{A} w$$

with C : tumor/voxel activity concentration [Bq/ml]

A : injected activity [Bq]

w : body weight [g]

!!! *SUV=1 means that the tracer is equally distributed in the whole body*

Radiotherapy target volume delineation (TVD) based on PET

Floor of mouth carcinoma, 45 y, w

- ▶ Most commonly used for TVD: [^{18}F]FDG
- ▶ Image Registration / Patient Positioning very important issue
- ▶ **Which is the correct threshold to use?**

Absolute Thresholding

PET image

Line profile

- ▶ Fix SUV-threshold of 2.0/2.5
- ▶ Easy to implement
- ▶ Often fails when the physiologic background activity lies above the threshold
- ▶ Absolute SUVs are strongly influenced by various technical factors (scan protocol, image acquisition, reconstruction, scanner calibration, etc.)

Relative Thresholding

PET image

Line profile

- ▶ Relative Threshold T , depending on the max. intensity
- ▶ Commonly used: $x=42\%$ (40-50%)
- ▶ Easy to implement
- ▶ Calibration with phantom measurements possible
- ▶ Frequently used in clinical routine

Iterative Thresholding

PET image

Line profile

- ▶ Background-subtracted relative threshold level
- ▶ Adjustable threshold x
- ▶ Iterative approach based on phantom measurements

Source-to-Background Algorithms

PET image

Line profile

- ▶ Constant C determined from phantom measurements
- ▶ Works very well for quasi-spherical lesions
- ▶ *Value of C depending of different factors:*
 - *Lesion size and shape*
 - *Scanner type and calibration*
 - *Reconstruction protocol*
 - *Image analysis software*

**Schaefer et al, EJNMMI 2008;
35(11): 1989-99.**

Comparison of different contouring approaches

Contours created with different segmentation algorithms: **manual delineation** (21.8 ccm), **absolute threshold SUV=2.5** (35.0 ccm), **relative threshold 42% of maximum PET intensity** (11.5 ccm), **adaptive thresholding** (10.6 ccm), **source-to-background based algorithm of Schaefer et al** (13.0 ccm)

Gradient-based auto-contouring

1. Image processing

- ▶ **Denoising** by bilateral edge-preserving filter

Fig. 2 Axial PET images from a patient with a hypopharyngeal tumour. On the *left panel*, the PET image corresponds to the raw image reconstructed with 3D OSEM algorithm. The application of the bilateral filter and the deconvolution algorithm restored the intensity gradient (*right panel*) in comparison with the classical 4-mm Gaussian filter (*middle panel*)

Geets et al, EJNMMI 2007; 34: 1427-1438.

Gradient-based auto-segmentation

2. Gradient-based segmentation

- ▶ Derive a gradient-intensity image:
Plains & Plateaus → Mountain chains & Valleys
- ▶ Crest detection by applying Watershed Transformation
- ▶ Cluster analysis

PET image

Line profile

Gradient-based segmentation improves target volume definition in NSCLC

Wanet M et al. *Radiother Oncol* 2011;98:117-25.

- N=10 NSCLC patients
- GTV delineation on CT±PET
- Comparison with surgical specimen
- PET yields more robust delineation in poorly defined tumors
- Gradient based seg. outper-formed threshold method in terms of accuracy and robustness

Activity Recovery, Partial Volume Effect: The Smaller the Volume, the Darker it Appears

Effect of reconstruction on PET-based contouring

Comparison of auto-contouring methods with „intelligent“ manual delineation

Bayne M et al. Int J Radiother Oncol Biol Phys 2010; 77: 1151-7.

- GTVs contoured by 6 experts using a **highly standardized protocol**
- Autocontouring with SUV=2.5, 3.5, 4.0, and 40% SUV_{max}
- Automatic delineations differed widely
- Visual contouring protocol gave reproducible results

EARL: Standardization of clinical PET scanners

Guideline of the EANM (European Assoc. of Nuclear Medicine):

“FDG PET and PET/CT: EANM procedure guideline for tumour PET imaging: version 1.0.” (Boellaard R et al, EJNMMI 2010; 37(1):181-200)

Objectives of EARL:

- to provide a minimum standard of PET/CT scanner performance in order to harmonise the acquisition and interpretation of PET scans
- ensure similar performance of PET/CT systems within a multicentre setting
- characterisation of imaging site by continuing quality control, making it highly eligible as a participant in multicentre studies
- high quality of routine patient examinations

EARL: Multicenter QC and calibration

- Calibration
 - Minimum allowable deviation: +/- 10%
- SUV recovery
 - For SUV_{max}
 - For SUV_{mean}

<http://www.earl.eanm.org>

Summary / Conclusion

- ▶ For quantitative PET imaging, raw data correction is necessary
 - Random, scatter and dead time correction
 - Normalization
 - Attenuation correction with CT!
- ▶ Image reconstruction
 - FBP, ML-EM, OSEM, 3D-reconstruction protocols
- ▶ Automatic contouring algorithms for RT
 - Absolute / relative thresholding
 - Iterative thresholding
 - Source-to-background
 - Gradient-based algorithm

Applications: MRI in Brain

Cynthia Ménard, M.D.

Goal – MRI Simulation

- Build ideal patient model for radiotherapy planning
 - Accurate and precise depiction of target and organ boundaries (reduce observer uncertainty, enable autosegmentation)
 - Representative of therapy conditions (+ motion)
 - Geometrically accurate
 - Inform on tissue composition / dose attenuation
 - Bridge to online guidance tools
 - Predictive of response (guide dose prescriptions)

Brain Applications

- High precision
 - SRT / SRS
 - Brain metastasis
 - Base of skull benign lesions
- Poor prognosis
 - Glioblastoma(GBM)

Pyramidal Tract / Speech

Figure 2. Treatment plans developed without (left side) and with (right side) the introduction of the pyramidal tracts in the optimization process for the meningioma case, plotted in axial and sagittal planes. This patient received 21 Gy units of radiation in 7 Gy fractions. The radiation dose to pyramidal tract is lowered from 2396.7 to 1441.96 cGy after the optimized process with pyramidal tract.

Figure 3. Treatment plans developed without (left side) and with (right side) the introduction of the language area in the optimization process for the AVM case, plotted in axial and sagittal planes. This patient received 16 Gy in single fraction. The maximum radiation dose to the language area is lowered from 1587.55 to 1273.88 cGy after the optimized process with language area. AVM indicates arteriovenous malformation.

DTI Map

ative JHU ICBM-DTI-81 white-matter atlas labels overlaid on our cohort's mean FA image and mean FA skeleton. GeCC, genu of corpus callosum; AIC, anterior limb of internal capsule; PIC, posterior limb of internal capsule; RIC, retrolenticular part of internal capsule; PTR, splenium of corpus callosum; Tp, tapetum; FcSt, fornix (cres)/stria terminalis; EC, external capsule; SLF, superior longitudinal fasciculus and body of fornix; SS, sagittal stratum; Cp, cingulum (parahippocampal); PCR, posterior corona radiata; SFOF, superior fronto-occipital fasciculus; SCR, superior corona radiata. Note: uncinate fasciculus and corticospinal tracts not shown.

Atlas-based Segmentation

Eloquent Cortex

Fig. 1. (A) Cortical regions from the Desikan-Killiany atlas available in the FreeSurfer neuroimaging software suite. Regions are displayed on the FreeSurfer average brain for illustration, but statistical analyses were carried out using the corresponding regions delineated in the native magnetic resonance imaging space of each patient. Average radiation dose and average cortical thickness change were calculated for each region. (B) Cortical regions with significant radiation dose-dependent cortical atrophy in linear mixed-effects model. FreeSurfer average brain surface shown in gray (light gray for gyrus, dark gray for sulcus). Regions statistically significant after correction for multiple comparisons are colored. Only the left hemisphere is shown for convenience, but statistical tests included bilateral observations.

- Occurs in high-dose region

SWI after WBRT

Conclusions

- MRI is central to radiotherapy planning and response assessment.
- Geometric fidelity relevant in high-precision treatments (SRS) and base of skull.
- Emphasis on image quality
- Consider expanding planning protocol (diffusion) to assist response assessment.

Why do we measure Diffusion MRI?

micro
resolution, nm

meso
resolution, μm

macro
resolution, mm

Meso scale:

Enormous complexity, making tissues diverse & functionally distinct

Macro – meso gap:

~3 orders of magnitude (1000x!)

Scaling of resolution

What we measure:
mm

What we want:
 μm

Diffusion MRI: the *in vivo* microscope?

Michiel Kleinnijhuis, PhD thesis

Diffusion probes length scales on the order of 1 – 50 μm

Diffusion basics

Robert
Brown
1827

Louis
Bachelier
1900

Albert
Einstein
1905

Marian
Schmoluchowski
1906

Diffusion basics

Einstein's Diffusion formula:

$$\langle (r - r_0)^2 \rangle = 2Dt$$

Brownian motion

random walk: $(r - r_0)^2 = \frac{t}{\delta t} \varepsilon^2$

PDF of displacements

Gaussian PDF

$$P(r|r_0, t) = \frac{1}{\sqrt{4\pi Dt}} \exp\left(-\frac{(r - r_0)^2}{4\pi Dt}\right)$$

What do we probe with Diffusion MRI?

$$D(t) = \frac{\langle (r - r_0)^2 \rangle}{2dt}$$

Free diffusion
true Brownian motion

Unrestricted *in vivo* diffusion
low cellularity & defective membranes

Restricted *in vivo* diffusion
high cellularity & intact membranes

$$D_{\text{pure water}} = 3 \mu\text{m}^2/\text{ms} @ 37^\circ$$

$$D_{\text{in-vivo}} \approx 1 \mu\text{m}^2/\text{ms} @ 37^\circ \text{ (depending on restrictions)}$$

Cellularity in lung tumors

Apparent Diffusion Coefficient
ADC = 1 [$\mu\text{m}^2/\text{ms}$]
= 1000 [$10^{-6}\text{mm}^2/\text{s}$]

What is Diffusion: Summary

- The motion of water molecules *in vivo*
- In biological tissues the observed or “apparent” diffusion of water with tissues typically \lll pure water
- Interactions with intracellular elements, membranes, and macromolecules restrict water diffusion
- The DWI signal is derived from the motion of water molecules in the extracellular space, the intracellular space and the intravascular space

How do we measure DWI?

Quick MR physics refresher

How to create Diffusion Weighting?

Echo Planar Imaging

A typical DWI acquisition

How do we measure DWI?

Quick MR physics refresher

How to create Diffusion Weighting?

Echo Planar Imaging

A typical DWI acquisition

A simple MRI pulse sequence

TE = echo time

Determines how much T2 decay before signal is acquired

TR = repetition time

Determines how much T1 relaxation occurs before next RF pulse

MRI Pulse Sequence = Sheet Music

EPI

TSE

Sebastian Bach sequence

MR Signal

$$S = M_0 \cdot (1 - e^{-TR/T1}) \cdot (e^{-TE/T2})$$

Gradient Echo vs. Spin Echo

GRE

SE

Spin Echo Diffusion-weighted imaging

Stejskal & Tanner 1965

Without diffusion:
all spins have fixed position

1. All spins accrue phase depending on their (static) position
2. 180° pulse flips magnetization
3. All spins realign

Without diffusion:
all spins have fixed position

1. All spins accrue phase depending on their (static) position
2. 180° pulse flips magnetization
3. All spins realign

With diffusion:
spins undergo
continuous motion

1. All spins accrue phase (with varying speed) according to changing position
2. 180° pulse flips magnetization
3. No complete realignment

In the presence of diffusion, the resulting signal will be lower.

More diffusion
=
Less signal

Diffusion parameters (the options you have)

By adjusting the *time spacing* and *strength* of the gradients we can change the amount of Diffusion Weighting (i.e., “making the sequence more or less sensitive to molecular motion”)

The amount DW is expressed as the b-value: $b \propto q^2 * \Delta$

$$b = (\gamma G \delta)^2 \cdot \left(\Delta - \delta/3 \right)$$

low b-value = bright image

high b-value = dark image

MR physics refresher: contrast

$$S = M_0 \cdot (1 - e^{-TR/T1}) \cdot (e^{-TE/T2}) \cdot e^{-bD}$$

b = diffusion gradient

D = diffusion coefficient

MR physics refresher: contrast

$$S = \frac{M_0 \cdot (1 - e^{-TR/T1}) \cdot (e^{-TE/T2})}{e^{-bD}}$$

$$S = \frac{S_0}{e^{-bD}}$$

b = diffusion gradient
 D = diffusion coefficient

Diffusion weighted contrast

Gaussian distribution of diffusion

If DW signal comes from free diffusion, gradient magnetic pulse would decay DW signal mono-exponentially with b-value

Diffusivity ($-bD$) decreases linearly across b-value

Diffusion coefficient is constant

Effect of b-values on DWI: free diffusion

Water phantom

'Perfusion'

Slow diffusing component;
@ b-values > ~150 s/mm²
'Diffusion'

Figure 4. Model of biologic tissue. A tissue can be described by a volume fraction f of water flowing (f) and diffusing (a) in capillaries. This fraction involves only perfused capillaries, which are a part of total capillaries, depending on the current physiologic or pathologic situations. The rest of the voxel water, occupying a volume fraction $1 - f$, is involved in diffusion only. This volume fraction corresponds to extracellular (b) and intracellular (c) spaces. There are exchanges between those two compartments (c). In a simple approach, exchanges between water inside capillaries and outside capillaries (d) during the measurement time (100 msec) are neglected. Another assumption is that the diffusion coefficient in sectors a , b , and c is nearly the same.

The effect of b-values on DWI: perfusion at low b-val

How will the choice of b-values influence the calculated b-value?

- A. only low b-values will results in a lower ADC
- B. only high b-values will result in a lower ADC
- C. the calculated ADC is independent of the b-value

Summary: DWI contrast

- Diffusion is not free / Gaussian distributed in biological tissues.
 - ADC value dependent on chosen b-values
- Low b-values ($< 150 \text{ s/mm}^2$) probe for perfusion effects
- Intermediate b-values (up to 1000 s/mm^2 , or $1/\text{ADC}$) best for evaluating diffusion metrics (ADC, FA, etc.) Jones & Basser, 2004
- Higher b-values (e.g., 2500 s/mm^2) may be more beneficial for tractography, likely as a result of greater sensitivity in detecting smaller fibers Rane, Nair & Duong, 2010

Echo Planar Imaging (EPI)

Invented by Sir Peter Mansfield, 1977
Nottingham, UK

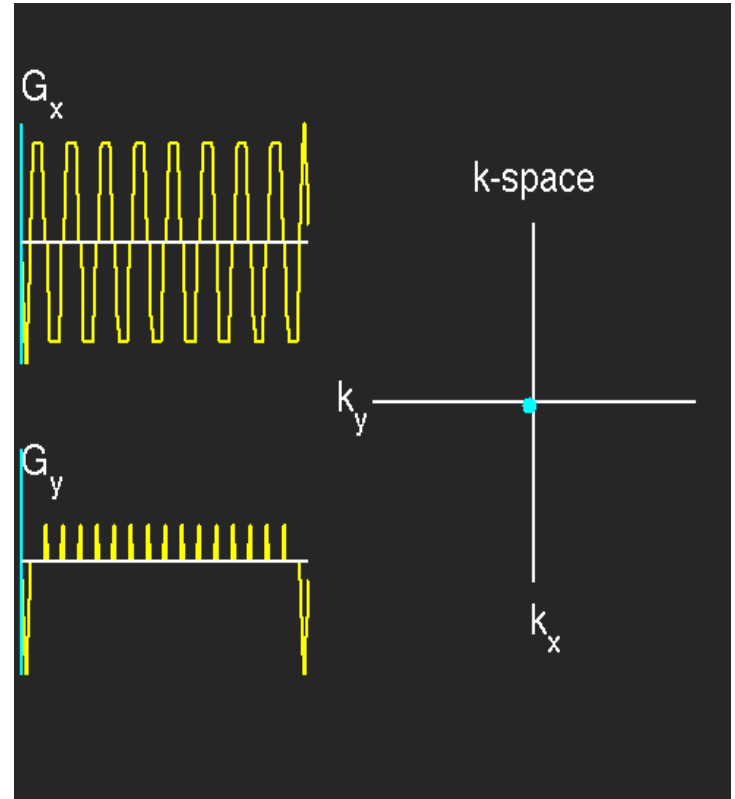

Many gradient echoes after single excitation

- High SNR/time
- Low SAR
- Ideal for quantitative MRI
- “snapshot MRI”

Many applications:

Perfusion MRI (ASL)
fMRI (BOLD)
Diffusion MRI
Real-time imaging

..

Gradient-Echo EPI

- Entire k-space acquired in one shot
- Fastest Cartesian readout available (~50 ms)
- No 180 pulses => gradient echo instead of spin echo (BOLD, ASL, RT-MRI)

Spin-Echo EPI

- Entire k-space acquired in one shot
- Fastest Cartesian readout available (~ 50 ms)
- **DWI:** Append 180 refocussing pulse & DW gradients

The Pitfalls of EPI: Distortion

- Geometric displacements along EPI phase encode direction
- Caused by field inhomogeneities (susceptibility artefacts)
- Can be partly corrected as a post processing step

Calculate amount of displacement

No distortion

$$\omega = \gamma(B_0 + G_x x)$$

$$G_x x = \frac{\omega}{\gamma} - B_0$$

$$x = \frac{\frac{\omega}{\gamma} - B_0}{G_x}$$

With susceptibility offset

$$\omega = \gamma(B_0 + G_x x + \Delta B(x, y))$$

$$G_x x = \frac{\omega}{\gamma} - B_0 - \Delta B(x, y)$$

$$x = \frac{\frac{\omega}{\gamma} - B_0}{G_x} - \frac{\Delta B(x, y)}{G_x}$$

$$\Delta x = \frac{\Delta B(x, y)}{G_x}$$

small gradient gives
large displacement!

EPI Distortion

Simplified EPI readout to understand appearance of image distortions in EPI...

field

fast gradient

slow gradient

net (fast)

net (slow)

Distortion correction

Processing steps

1. Acquire fieldmap
2. Convert to displacement map
3. Calculate inverse transform
4. Warp original image

Corrections in Head & Neck

Corrections in Head & Neck

Summary: EPI

- Many benefits
 - Single-shot EPI prevents motion corrupted images
 - Very efficient acquisition scheme (fast!)
- Longer readout = more image artifacts
 - Image distortions occur along the slow (Phase Encode) direction, because the effective gradient strength is low
- Dealing with distortions
 - Shimming (homogenize the magnetic field)
 - Acquire a field-map (measure the field to correct distortions)
 - Reduce readout length (high BW, parallel imaging)

How do we measure DWI?

sensitive to microstructural changes

DTI post-processing

$$\begin{bmatrix} ADC_1 \\ ADC_2 \\ \vdots \\ ADC_N \end{bmatrix} = \begin{bmatrix} g_{x1}^2 & g_{y1}^2 & g_{z1}^2 & 2g_{x1}g_{y1} & 2g_{x1}g_{z1} & 2g_{y1}g_{z1} \\ g_{x2}^2 & g_{y2}^2 & g_{z2}^2 & 2g_{x2}g_{y2} & 2g_{x2}g_{z2} & 2g_{y2}g_{z2} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ g_{xN}^2 & g_{yN}^2 & g_{zN}^2 & 2g_{xN}g_{yN} & 2g_{xN}g_{zN} & 2g_{yN}g_{zN} \end{bmatrix} \begin{bmatrix} D_{xx} \\ D_{yy} \\ D_{zz} \\ D_{xy} \\ D_{xz} \\ D_{yz} \end{bmatrix}$$

$$D = \begin{bmatrix} D_{xx} & D_{xy} & D_{xz} \\ D_{yx} & D_{yy} & D_{yz} \\ D_{zx} & D_{zy} & D_{zz} \end{bmatrix} = E^T \begin{bmatrix} \lambda_1 & 0 & 0 \\ 0 & \lambda_1 & 0 \\ 0 & 0 & \lambda_1 \end{bmatrix} E$$

Measuring diffusion

- Diffusion dataset
 - Multiple diffusion directions
 - Oncology application: 3 orthogonal directions (isotropic diffusion)
 - Diffusion Tensor Imaging (DTI): up to 128+ directions
 - Multiple b-values
 - At least 2: $b=0$ & $b>0$
 - Calculate ADC
 - IVIM: up to 10 b-values
- Lots of data to acquire

Some body DWI examples

APPLICATIONS: MRI IN CERVICAL CANCER

Piet Dirix MD, PhD

Dpt. of Radiation Oncology, Iridium Cancer Network

Associate Professor, University of Antwerp

www.iridiumkankernetwerk.be

Cervical cancer

Age-standardised death rates from cervical cancer by country (per 100,000 inhabitants).

Incidence & mortality dependent on screening & vaccination:

+/- 75% decrease in developed countries

+/- 80% of all cases of cervical cancers now occur in developing countries

Vaccination

- Persistent viral infection with carcinogenic HPV types causes virtually all cancer of the cervix and most cases of anal cancer. The carcinogenic types, HPV 16 and HPV 18 cause approximately 70 percent of all cervical cancers worldwide and 72 percent of anal cancers. HPV types 31, 33, 45, 52, and 58 are estimated to cause an additional 19 percent of invasive cervical cancers. HPV 6 and HPV 11 cause approximately 90 percent of genital warts.
- Available vaccines:
 - Gardasil, a quadrivalent HPV vaccine, targets HPV types 6, 11, 16, and 18.
 - Gardasil 9, a 9-valent vaccine, targets the same HPV types as the quadrivalent vaccine (6, 11, 16, and 18) as well as types 31, 33, 45, 52, and 58.
 - Cervarix, a bivalent vaccine, targets HPV types 16 and 18.
- HPV immunization is most effective among individuals who have not yet been infected with HPV (i.e. before sexual debut).
- Routine immunization should be offered to girls 11 to 12 years of age, but can be administered as early as nine years. Catch-up vaccination should be offered for females aged 13 to 26 years who have not been previously vaccinated. If cost and availability are not issues, the 9-valent vaccine should be used for females in whom HPV vaccination is indicated.

MRI in radiotherapy for cervical cancer

1. Cervical cancer
- 2. MRI & FDG-PET/CT for pre-treatment assessment of cervical cancer:**
 - 1. Parametrial invasion (PMI)**
 - 2. Nodal staging**
3. MRI for external beam radiotherapy (EBRT) planning
4. MRI for brachytherapy planning
5. MRI for response assessment

Question 1: PMI?

Especially in small tumors (< 4 cm), confined to the cervix:

Determine the right patients for surgery vs. CRT

To avoid tri-modality treatment with its known complications

ACRIN 6651 – GOG 183

Fig 1. Patient flowchart. Of 208 patients enrolled in the study, nine were subsequently deemed ineligible; of the remaining 199 patients, 172 (86%) had complete data sets for inclusion in the data analysis. CT, computed tomography; MRI, magnetic resonance imaging; FIGO, International Federation of Gynecology and Obstetrics.

ACRIN 6651 – GOG 183

Fig 2. Plots of receiver operating characteristic (ROC) curves for the assessment of cervical involvement by magnetic resonance imaging (MRI) and computed tomography (CT). For each modality, the estimated area under the ROC curve is reported. MRI was significantly better than CT for detecting cervical tumor, as measured by the respective areas under the ROC curves (AUC).

Fig 4. Positive and negative predictive values of computed tomography (CT) and magnetic resonance imaging (MRI) for different stage thresholds. When the threshold was set at stage IA, CT and MRI had high positive predictive value (PPV; 0.95; 0.90 to 0.98 for both modalities) and low negative predictive value (NPV; 0.19; 0.08 to 0.35; and 0.27; 0.11 to 0.50; respectively). PPV decreased and NPV increased as the stage threshold increased.

MRI correlated more closely with surgicopathological findings than CT or clinical examination

Table 2

AUC Values for Retrospective Interpretation of CT and MR Imaging Studies

Parameter	Mean AUC*		Difference in AUC between Studies [†]	P Value
	CT	MR Imaging		
Tumor visualization	0.58 (0.52–0.63)	0.77 (0.67–0.86)	0.20 (0.12, 0.27)	<.001
Parametrial invasion [‡]	0.62 (0.54–0.68)	0.68 (0.64–0.75)	0.07 (0.001, 0.15)	.047

* Data in parentheses are ranges over the readers.

[†] Comparisons between MR imaging and CT were performed for the patients common to the MR imaging and CT analysis sets. Data in parentheses are 95% confidence intervals (CIs).

[‡] The left and right sides of the parametrium were treated as clusters within the same subject.

MRI is better than CT for tumor visualization and depiction of parametrial invasion.

MRI has 94% accuracy and 95% NPV for determining PMI.

PMI: need for multiplanar FSE-T2

a.
Figure 13. The value of orthogonal multiplanar high-resolution T2-weighted FRFSE sequences for evaluating cervical cancer. **(a)** Sagittal T2-weighted MR image shows a hyperintense mass (arrow), a finding indicative of high-grade cervical adenocarcinoma. **(b)** Axial T2-weighted MR image obtained coronal to the plane of the tumor poorly depicts the cervical stroma and parametrial invasion. The fibrous stroma on the right has an irregular contour (arrow), and minute interruptions of the fibrous stroma are seen at left (arrowheads), a finding indicative of deep cervical stromal invasion and possible parametrial extension. **(c)** Axial oblique high-resolution T2-weighted MR image, obtained perpendicular to the axis of the cervix at the level of possible deep cervical stromal and parametrial extension, shows an intact thin layer of preserved fibrous stroma bilaterally (arrows), indicating that the tumor is confined to the cervix.

DWI to predict PMI

Park J.J. et al. Eur Radiol 2014.

Question 2: LNI?

Pelvic nodal involvement is noted in 30–50% of patients.

Para-aortic nodes are involved in 10–25% of patients.

Nodal staging: PET-CT

Table 2: Pooled and single estimates for index test prediction of lymph node status in patients

Index test	No. of studies	No. of women	Sensitivity (95% CI), %	Specificity (95% CI), %
Sentinel node biopsy	31	1140	91.4 (87.1-94.6)	100 (99.6-100)
Positron emission tomography	8	445	74.7 (63.3-84.0)	97.6 (95.4-98.9)
Magnetic resonance imaging	24	1206	55.5 (49.2-61.7)	93.2 (91.4-94.0)
Computed tomography	32	2640	57.5 (53.5-61.4)	92.3 (91.1-93.5)

Note: CI = confidence interval, LR = likelihood ratio.

Meta-analysis of 72 studies including 5042 women:

PET: sens 75% and spec 98%

MRI: sens 56% and spec 93%

CT: sens 58% and spec 92%

Pelvic LN staging: added value of DWI

ADC showed superior correlation with PET-CT compared with conventional size-based criteria on T2-TSE.

Meta-analysis on DWI for nodal staging

The pooled sensitivity and specificity of DWI were 0.86 and 0.84, respectively.

Meta-analysis on DWI for nodal staging

0,85 (95% CI 0,84 – 0,87)

1,04 (95% CI 1,04 – 1,05)

The heterogeneity was relatively high between studies.
Large-scale, high-quality trials with standard protocols are required.

p < 0,05

Para-aortic nodes

	FDG-PET or PET/CT*	MRI	CT
Sensitivity (95% CI)			
Havrilesky (2005) ^{14†}	84% (68–94)	67% (9–99)	..
Choi (2010) ^{7†‡}	82% (75–87)	56% (51–62)	50% (43–57)
Choi (2010) ^{7†§}	54% (46–61)	38% (32–43)	52% (42–62)
Chou (2010) ^{15§}	66.7% (35–89.9)	25% (5.8–57.2)	..
Kitajima (2011) ¹⁶	52.3% vs 61.4%¶	..	40.9%
Specificity (95% CI)			
Havrilesky (2005) ^{14†}	95% (89–98)	100%	..
Choi (2010) ^{7†‡}	95% (93–97)	91% (90–93)	92% (90–94)
Choi (2010) ^{7†§}	97% (96–98)	97% (97–98)	92% (90–94)
Chou (2010) ¹⁵	100% (79.2–100)	93.8% (69.7–99.0)	..
Kitajima (2011) ¹⁶	96.8% vs 98.1%¶	..	97.8%

The prevalence of para-aortic nodal metastasis locally-advanced disease is 10–25%. The true-positive rate of PET is high, suggesting that surgical staging is not necessary if uptake takes place in the para-aortic region. However, false-negative results (in the para-aortic region) have been recorded in 12% of patients, rising to 22% in those with uptake during PET of the pelvic nodes.

Pre-treatment assessment: conclusions

- Local staging: MRI
 - If suspect for bladder invasion: cystoscopy
 - If suspect for rectal invasion: rectoscopy
- Nodal and distant staging: PET-CT
 - If pelvic LN+, consider surgical para-aortic staging

MRI in radiotherapy for cervical cancer

1. Cervical cancer
2. MRI & FDG-PET/CT for pre-treatment assessment of cervical cancer
3. **MRI for external beam radiotherapy (EBRT) planning:**
 1. **Target volume delineation**
 2. **Image-guidance**
4. MRI for brachytherapy planning
5. MRI for response assessment

Question 1: target volume delineation

The most clinically relevant benefit of MRI for cervical cancer planning lies in the clear visualization of the cervical tumor in multiple planes allowing for a reliable volumetric definition of the target volume.

GTV delineation

GTV = high SI zones in cervix & surroundings on T2

PET/MRI for GTV

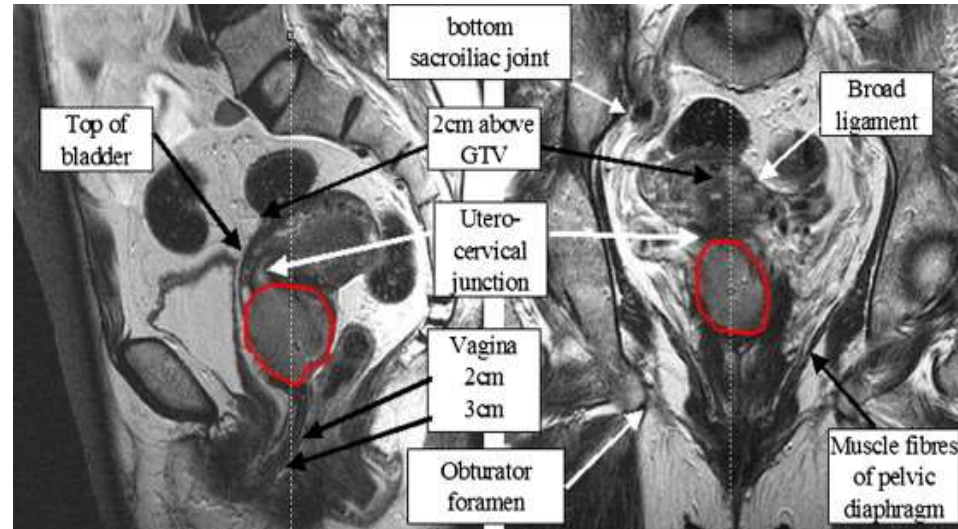

Correlation between SUV_{max} & ADC_{min}

Grueneisen J. et al. Plos One 2014.

CTV delineation

GTV + margin of at least 10 mm, unless safe barriers (bone, muscle).

Parametria, uterus & (part of) vagina (at least 20 mm below GTV).

Pelvic LN: parametrial, pararectal, internal iliac, external iliac, presacral & common iliac.

Inguinal LN if stage IIIA. Para-Aortic LN only if involved?

Nodal volumes should follow the relevant vessels with a margin of 7 mm in the loose connective tissue.

CTV consensus guidelines (1)

Tumoral CTV:

Table 2. CTV components

GTV	Entire GTV; intermediate/high signal seen on T ₂ -weighted MR images
Cervix	Entire cervix; if not already included within GTV contour
Uterus	Entire uterus
Parametrium	Entire parametrium, including ovaries; include entire mesorectum if uterosacral ligament involved
Vagina	Minimal or no vaginal extension: upper half of the vagina Upper vaginal involvement: upper two-thirds of the vagina Extensive vaginal involvement: entire vagina

CTV consensus guidelines (2)

Nodal CTV:

PTV delineation

The combination of 2 problems:

- unpredictable organ motion
- substantial tumor regression

resulted in conservative margin recommendations by the Consortium.

PTV margins of 1.5 to 2 cm around the CTV were recommended if good quality daily soft tissue verification was available during treatment.

A PTV margin of 7 mm around the nodal CTV was agreed upon in line with previous recommendations in the postoperative cervix cancer setting (e.g., RTOG 0418).

Question 2: inter- and intrafraction mobility

MRI is particularly useful to measure motion variability due to its excellent soft tissue visualization, the absence of radiation, the availability of multiplanar imaging and fast 4D imaging. Using serial MRIs during external beam radiation for cervical cancer demonstrates that the uterus, cervix, vagina and even pelvic lymph nodes have considerable motion between treatments due to changes in bladder filling, rectal filling and other internal motion.

— GTV

— CTV

— PTV

MRI-guided IMRT: organ motion (1)

Large interscan motion was found for all 3 POI, only partially explained by variations in bladder and rectal filling. The margins required to encompass 90% of the interscan motion were 4 cm at the fundus and 1.5 cm at the external cervical os.

MRI-guided IMRT: organ motion (2)

The CTV required margins of 24, 17, 12, 16, 11 and 8 mm. The shift of the GTV and CTV in the AP directions correlated weakly with the change in rectal volume. For the bladder, the correlations were even weaker.

MRI-guided IMRT: organ motion (3)

- Twenty-two patients underwent 2–3 offline MRI exams before and during their radiation treatment.
- Each MRI exam included four sagittal and four axial MRI scans alternately within 16 min.
- The maximum (residual) motions within 16 min for all points on the CTV contour for 90% of the MRI exams without registration, with rigid bony anatomy registration, and with rigid soft tissue registration were 10.6, 9.9, and 4.0 mm.
- A significant but weak correlation was found between intrafraction bladder filling and CTV motion.

Online MRI guidance

Fig. 5. Dose volume histograms of the bladder, rectum, bowel, and sigmoid for patient 3 for both pre-IMRT and online-IMRT.

Online-IMRT compared to pre-IMRT significantly reduced the volume of healthy tissue irradiated to all dose levels, except V_{10Gy} .

UCLA

GYN: Endometrial

GYN- Endometrial

Planning MRI: Note Rectal Fill

Daily MRI: Note Rectal Fill Change

Fraction #7

PTV coverage affected up to 25% of Beam-on time

GYN- Endometrial

MRI-guided IMRT: what about LN?

Fig. 1. Pre-treatment transversal (a) and sagittal (b) T2-weighted MR image of a patient with an enlarged lymph node in the left obturator region. The delineations of the node on the pre-treatment scan (yellow line), scan in week 1 (green line), week 2 (orange line), week 3 (purple line) and week 4 (blue line) are all overlaid on the pre-treatment MR image. The red line represents the manually derived margin to encompass the node in all weeks.

Nodal volume regression from the pre-treatment situation to week 4 was 58% on average. Nodal volumes partly increased between the pre-treatment scans and the scans in weeks 1–3, but in week 4 all nodes except one had regressed. Around the nodal volumes ITV margins accounting for volume changes and position shifts of 7.0, 4.0, 7.0, 8.0, 7.0 and 9.0 mm to the medial, lateral, anterior, posterior, superior and inferior directions were needed to cover 95% of all nodes.

MRI-guided IMRT: tumor shrinkage

After 30 Gy, the GTVs decreased an average of 46% (6.1–100%). The TVs on the intratreatment MRI remained sufficiently covered by the 95% isodose. Repeated IMRT planning can improve the sparing of the bowel and rectum in patients with substantial tumor regression.

MRI in radiotherapy for cervical cancer

1. Cervical cancer
2. MRI & FDG-PET/CT for pre-treatment assessment of cervical cancer
3. MRI for external beam radiotherapy (EBRT) planning
- 4. MRI for brachytherapy planning**
5. MRI for response assessment

Brachytherapy is not optional

Fig. 2. Kaplan-Meier overall survival estimate stratified by boost modality. IMRT = intensity modulated radiation therapy; SBRT = stereotactic body radiation therapy.

MRI-guided, adaptive brachytherapy

Left panel shows transverse MRI at time of diagnosis with PMI (left and right). At the time of BT, there was still residual PMI. A combined intracavitary- interstitial applicator (5 needles) was used. Middle and right panel show paratransverse and coronal MRI at the time of BT. The volumes are as follows: residual GTV (magenta), CTV HR (red), CTV IR (pink), bladder (yellow), and sigmoid (orange). Isodoses 15 Gy (cyan) and 7.5 Gy (green) correspond to 84 Gy and 60 Gy in terms of total EQD2.

GEC-ESTRO target definitions (1)

GTV_B: macroscopic tumor at BT

Clinical examination

MRI: high SI zones in cervix and surroundings

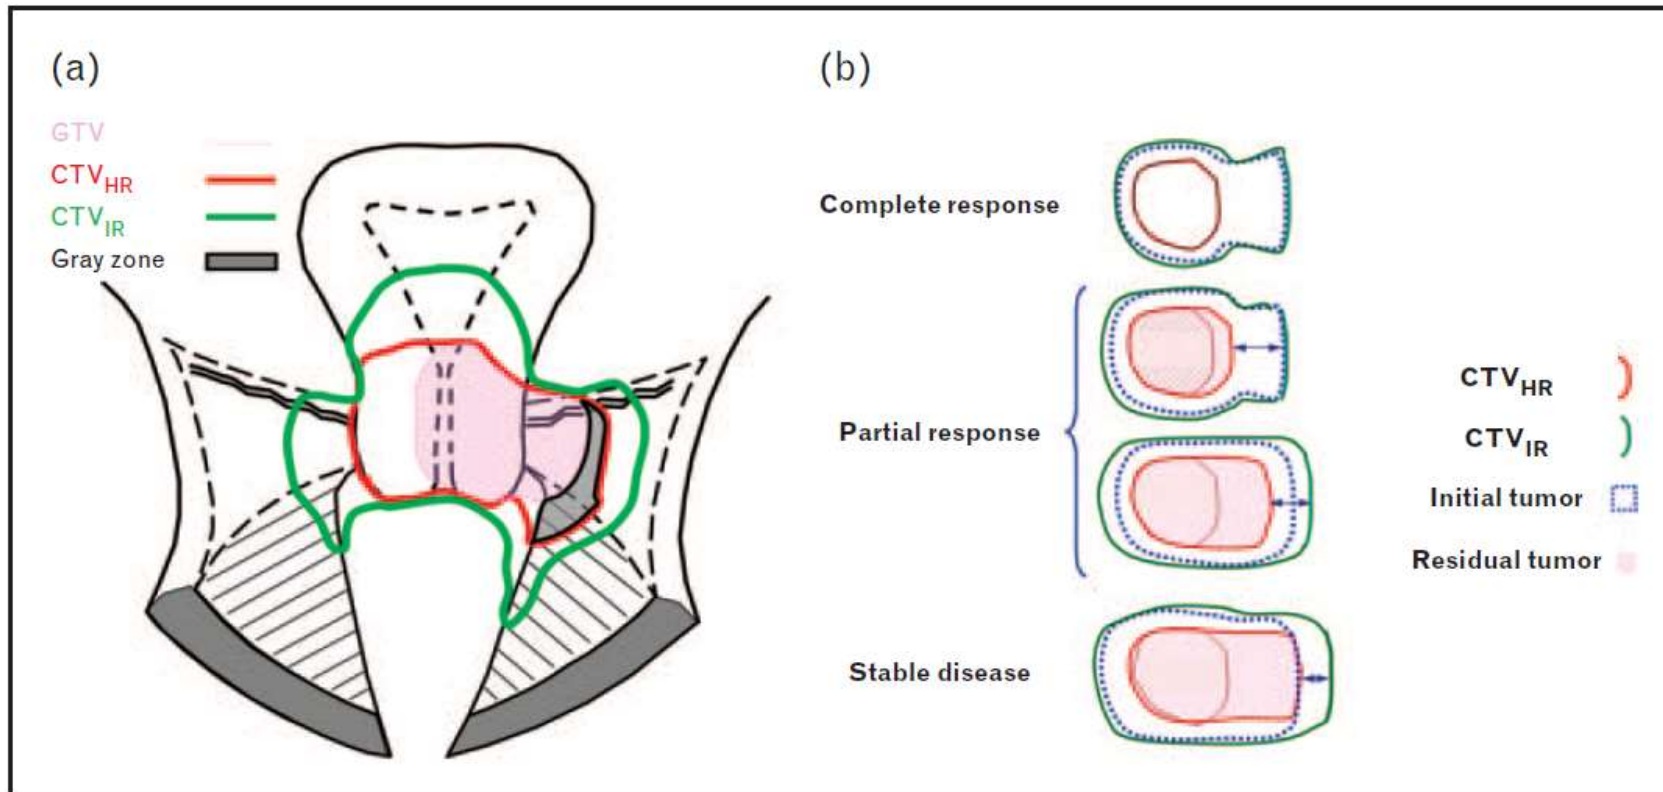

GEC-ESTRO target definitions (2)

- **HR CTV:** whole cervix (assumed residual tumor)
 - Persistent GTV
 - Always whole cervix
 - Presumed extracervical tumor extension:
 - Residual clinically edematous zones
 - Residual grey zones on MRI
 - No safety margins are added
 - Dose high enough to sterilize macroscopic tumor
- **IR CTV:** significant microscopic disease at BT
 - Encompasses HR CTV
 - Safety margins (5 – 15 mm) depending on tumor spread
- **LR CTV:** presumed treated with EBRT, not treated with BT

GEC-ESTRO target definitions (3)

Allows for an “adaptive” boost

IODV in IGABT

Due to lower delineation uncertainties when compared to GTV and IR CTV, HR CTV may be considered most robust volume

Dosimetric impact of IODV

For the target volumes the dosimetric impact of IODV was smallest for the GTV and HR-CTV, while IODV had an even smaller impact on the bladder and rectum.

DWI/DCE/FDG-PET decreases IODV

Han K. et al. Radiother Oncol 2016.

GEC-ESTRO treatment planning

Table 1. Recommendations for recording and reporting 3D gynaecological brachytherapy

Complete description of clinical situation including anatomy and pathology and imaging examination
 dimensions and volume of GTV at diagnosis and at time of brachytherapy
 dimensions and volumes of HR CTV and IR CTV, respectively
 Complete description of 3D sectional imaging technique and contouring procedure
 Complete description of brachytherapy technique
 radionuclide; source type (wire, stepping source); source strength; applicator type; type of afterloading (manual or remote); description of additional interstitial needles if any
 Treatment prescription and treatment planning
 applicator reconstruction technique, standard loading pattern, dose specification method; optimisation method, if applied
 Prescribed dose
 Total Reference Air Kerma (TRAK)
 Dose at point A (right, left, mean)
 D100, D90 for GTV and HR CTV and IR CTV, respectively
 Dose to bladder and rectum for ICRU reference points
 $D_{0.100}$, D_{100} , D_{200} for organs at risk (e.g. rectum, sigmoid, bladder) (vagina³)
 D_{500} , D_{1000} for organs at risk if contouring of organ walls is performed
 Complete description of time-dose pattern: physical and biologically weighted doses ($\alpha/\beta=10$ Gy for GTV and CTV; $\alpha/\beta=3$ Gy for OAR; $T_{1/2}=1.5$ h for GTV, CTV and OAR)

³ For vagina dose volume parameters still need to be defined.

GEC-ESTRO MRI recommendations

Image acquisition protocols for pre-RT MRI scan and BT MRI scan. This table summarises the important information regarding sequence, plane orientation, coverage/borders for each of the different MRI sequences.

Protocol	Number	Mandatory (M)/optional (O)	Sequence	Plane orientation	Coverage/borders
Pre-RT MRI scan	1	M	T2 FSE	Para-axial (according to cervix uteri)	Above uterine corpus – inferior border of symphysis pubis/entire vagina if distal vaginal involvement
	2	M	T2 FSE	Sagittal	Pelvic side wall (obturator muscle)
	3	M	T2 FSE	Para-coronal (according to cervix uteri)	Uterine corpus – cervix – vagina – tumour
	4	M	T2 FSE	Axial	Discus L4–L5 – inferior border of symphysis pubis/entire vagina and inguinal regions if distal vaginal involvement
	5	O	T1 FSE or 3D GRE without contrast ^a	Axial	Discus L4–L5 – inferior border of symphysis pubis/entire vagina and inguinal regions if distal vaginal involvement
	6	O	T1 FSE with contrast ^a	Sagittal	Pelvic side wall (obturator muscle)
	7	O	T1 FSE or 3D GRE with contrast ^a	Axial (isotropic 3D GRE)	Uterine corpus – cervix – vagina – tumour
BT MRI scan	8	M	T2 FSE	Para-axial (according to cervix uteri)	Above uterine corpus – 3 cm below lower surface of vaginal applicator/entire vagina if distal vaginal involvement
	9	M	T2 FSE	Para-sagittal (according to cervix uteri)	Pelvic side wall (obturator muscle)
	10	M	T2 FSE	Para-coronal (according to cervix uteri)	Uterine corpus – cervix – vagina – tumour
	11	O	T2 FSE	Axial	Above uterine corpus – 3 cm below lower surface of vaginal applicator/entire vagina if distal vaginal involvement
	12	O	3D T2 FSE isotropic	Coronal or axial with reconstructions	Large coverage inherent in this sequence
	13	O	T1 FSE, FLASH, T1 GRE 3D	As appropriate	At least entire applicator

^aWhen contrast series are applied (6 and/or 7): use same T1 sequence for pre-contrast and lymph node evaluation.

MRI-guided BT: manual optimization

= Individual shaping of isodose lines to spare OAR without lowering target dose.

MRI-guided BT: when things go wrong...

09-2000: stage IIIB cervical ca.
EBRT + 3D BT boost with
insufficient optimization (D90 < 70
Gy HR CTV)

08-2001: parametrial/pelvic wall recurrence

Results

Group	Year	N	Dose rate	Interstitial BT (%)	LC	OS	Grade 3-4 tox
Vienna	2011	156	HDR	44%	95% at 3 yrs	68% at 3 yrs	6%
Aarhus	2013	140	PDR	43%	91% at 3 yrs	79% at 3 yrs	7%
Pittsburg	2014	128	HDR	0%	92% at 2 yrs	88% at 2 yrs	1%
Paris	2015	225	PDR	2%	86% at 3 yrs	76% at 3 yrs	7%
Leuven	2016	154	PDR	16%	96% at 3 yrs	65% at 5 yrs	11%
Retro-EMBRACE	2016	731	mixed	23%	91% at 3 yrs	74% at 3 yrs	11%

Conclusion: 86 – 96% local control at 2 – 3 years, with severe late toxicity \leq 10%.

2D vs. IGABT (1)

2D vs. IGABT (2)

Group	Year	Type	Arms	N	OS	Grade 3-4 tox
Vienna	2007	Retrospective	IGABT 2D	72 73	64% at 3 yrs, p = 0,03 53%	10%, p = NS 22%
STIC trial	2012	Prospective	IGABT 2D	117 118	74% at 2 yrs, p = NS 55%	3%, p = 0,004 23%
Aarhus	2013	Retrospective	IGABT 2D	140 99	79% at 3 yrs, p = 0,005 63%	7%, p = 0,02 15%
Leiden	2014	Retrospective	IGABT 2D	83 43	86% at 3 yrs, p < 0,01 43%	3%, p < 0,01 21%

IGABT provides higher LC and lower toxicity rates compared to classical radiographs-based BT.

EMBRACE trial (1)

International study on MRI-guided Brachytherapy in locally Advanced Cervical cancer.

European study on MRI-guided brachytherapy in locally advanced cervical cancer (GEC-ESTRO) started in 2008.

Accrual ended in December 2015, with > 1400 patients included.

Prospective observational multicenter setting

Primary endpoints: LC and morbidity.

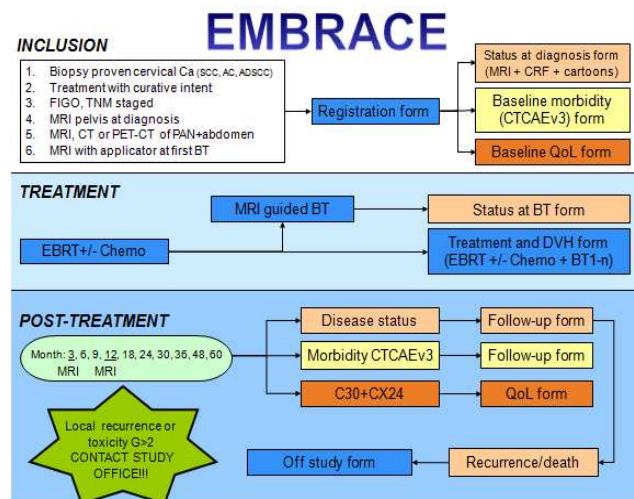

Secondary endpoints: RC, DFS, OS and QoL.

Correlation between image-based DVH and outcome.

FIGO IB to IVA

Dose-volume effect for OAR

Dose-volume effect for tumor response

Fig. 2. Local control as depending on CTV_{HR} dose and volume according to the multivariate Cox regression model. The figure shows predicted 3-year actuarial local control as a function of CTV_{HR} volume for three different dose levels: 75 Gy, 85 Gy and 95 Gy and for the median OTT of 49 days.

MRI in radiotherapy for cervical cancer

1. Cervical cancer
2. MRI & FDG-PET/CT for pre-treatment assessment of cervical cancer
3. MRI for external beam radiotherapy (EBRT) planning
4. MRI for brachytherapy planning
5. **MRI for response assessment:**
 1. **Volume measurements**
 2. **Functional imaging**

Response assessment: T2w MRI

Response assessment: functional imaging

Table 1 The functional imaging biomarkers in cervical cancer at the baseline, early during therapy, and 3 months after chemoradiation therapy (CRT)

Time point	FDG-PET/CT	Functional MRI
Baseline	Baseline tumor SUV_{max} predicts local tumor response to therapy and survival [20–23]. Baseline MTV predicts PFS and OS [24, 25]. Lymph node status on PET is more predictive of outcome than FIGO stage [27, 28••, 29, 30]	Absolute ADC values at the baseline do not predict outcome [56, 57]
Early during CRT	A CMR on PET as early as 4 weeks during therapy carries a good prognosis. The PPV of a PMR at this stage is less reliable [43, 44•, 45]	The change in ADC_{min} between the baseline and at 2 weeks during CRT rather than absolute values may predict outcome [56, 57, 75••]
3 months after completion of CRT	Visual response criteria (CMR, PMR, PD) is highly predictive of PFS at 3 months post CRT [34, 35]. Metabolic response 3 months after completion of CRT predicts the pattern of treatment failure [36•]	

ADC apparent diffusion coefficient, *CMR* complete metabolic response, *CT* computed tomography, *FDG* F-18 2-deoxy-2-fluorodeoxyglucose, *FIGO* International Federation of Gynecology and Obstetrics, *MRI* magnetic resonance imaging, *MTV* metabolic tumor volume, *OS* overall survival, *PD* progressive disease, *PET* positron emission tomography, *PFS* progression-free survival, *PMR* partial metabolic response, *PPV* positive predictive value, *SUV* standardized uptake value

- Partial responders
- Non responders

Response assessment: PET/MRI

Micco M. et al. Eur J Radiol 2014.

Take home messages

- Using MRI, patients can be more accurately staged and guided towards the correct management options.
- For patients that require radiation therapy, MRI shows excellent soft tissue delineation and should be incorporated into both external beam and brachytherapy treatment planning.
- Image-based BT allows for individualization of the applicator with possible incorporation of interstitial needles, leading to adapted treatment planning, optimized prescription dose and limitation of dose to OAR.
- In the future, MRI will likely become even more prevalent as deformable dose registration, adaptive imaging for external beam and functional imaging become more established.

MRI throughout cervical cancer treatment

Dominant Tumors

- Need to further improve *radio-therapeutic* ratio in prostate cancer
- Cancer outcomes related to gross tumor-bearing sub-regions
- Approach → Tumor-targeting
- Need → Accurate technique

Local Failure

Figure 5 A 75-year-old male presented with a small nodule at the left base of the gland (ie, clinical T2a), PSA of 6 ng/mL, and Gleason Score (GS) of 7 (3 + 4) and was treated with a prostate brachytherapy implant alone to 144 Gy with ^{125}I . Postimplant dosimetry demonstrated a V100 = 97% and a D90 = 177 Gy; however, the left midgland was not covered with the 100% isodose line (A). The patient's PSA reached a nadir of 0.3 ng/mL 18 months after the implant. At 6 years after treatment, he had a PSA of 2.3 ng/mL with a PSA doubling time greater than 12 months (D). Multiparametric 1.5T MRI including T2W (B), DWI (C), DCE (E), and ADC maps (F) localized the recurrence at the left midgland. Metastatic workup showed negative result. Biopsy of the left midgland confirmed adenocarcinoma with a GS of 7 (4 + 3). ADC, apparent diffusion coefficient. (Color version of figure is available online.)

Figure 4: Data from 66-year-old patient with prostate cancer: presurgical PSA, 5.52 ng/mL (5.52 $\mu\text{g/L}$); clinical stage, T1c; surgical Gleason score, 3 + 4; and pathologic tumor volume, 4.77 cm^3 . Whole-mount step-section histopathologic map shows prostate gland. (a) Only one (of 12) slices shown; tumor was present on seven slices. (b) Closest transverse T2-weighted image corresponding to matching pathologic slice. (c) ADC map of slice in b. (d) Mask generated from voxels that satisfy cluster requirements (ADC cutoff, 0.0016 mm^2/sec). (e) ROI containing the voxel cluster that satisfies all criteria (ADC cutoff, 0.0016 mm^2/sec). Tumor volume was 5.11 cm^3 measured on T2-weighted images and 4.81 cm^3 on combined T2-weighted and DW MR images.

Scatterplots of tumor volume measurements made on basis of MR images (T2-weighted and combined T2-weighted and DW MR images) versus histopathologic measurements

PTV(CTV)

Systematic Review – Tumor Boost

Systematic Review

- Thirteen papers describing 11 unique patient series and 833 patients in total were identified.
- Methods and details of GTV definition and treatment varied substantially between series.
- GTV boosts were on average 8 Gy (range 3–35 Gy) for external beam, or 150% for brachytherapy (range 130–155%) and GTV volumes were small (<10 ml).
- Reported toxicity rates were low and may reflect the modest boost doses, small volumes and conservative DVH constraints employed in most studies.

FT?

Ultra-Focal Therapy

Focal Therapy

Focused Therapy

Modalities for FT

b

Types of Ablative Energy used for FT

Goal for FT

Alternative to whole-gland therapy
vs.
Complement to active surveillance

FDA-AUA-SUO workshop 2015

- Criteria for patient selection remain debatable
- Long term cancer control remains to be established in properly designed and well-performed prospective clinical trials
- Concerns
 - excessive, unnecessary use, and
 - inadequate treatment

Location and Toxicity

Innadequate Treatment ?

- Yes - prostate cancer us usually multifocal
- BUT - Not treating indolent, microscopic, Gleason 6 disease is a legitimate proposal

Consensus - Selection

- mpMRI guided biopsy
- Low+ Int Risk planned for whole-gland therapy
- PSA < 10
- GTV 1.5ml or 20% of gland volume (3ml and 25% if lateralized to one hemigland)
- One core of G6 (<1mm) can be ignored

Back-up Plan in 25%

Table 1: Focal therapy eligibility criteria, based on the NCCN intermediate-risk definition⁹ and recent consensus guidelines⁷.

Eligibility criteria:
Clinical stage \leq T2c
Serum PSA \leq 20 ng/mL
ROI on mpMRI grade \geq 3
csCaP within mpMRI-derived ROI, defined as GS \leq 4+3 in any core, or GS 3+3 with maximum cancer core length (MCCL) \geq 4mm
At least 10 template and 2 targeted cores obtained, demonstrating unilateral csCaP
Ineligible:
Clinical stage \geq T3a
Serum PSA $>$ 20 ng/mL
GS $>$ 4+3 CaP in any core
Bilateral csCaP (GS 3+3 and MCCL \geq 4 mm OR any GS \geq 3+4)
Absence of csCaP

Salvage FT (brachytherapy)

Table 2
Selected series of outcomes for partial gland salvage brachytherapy

Series	N	Primary therapy	Rescuing MRI (Y/N)	Clinical characteristics at salvage	Salvage therapy volume	ADT (Y/N)	Followup post-salvage	FFF	DMFS	GU toxicity	GI toxicity
LDR											
Hsu et al., 2013 (17)	15	BT = 12 BT + EBRT = 2	Y	Gleason ≥8: 13.3% Median PSA: 3.5	2.8 cc (1.5–14.5 cc)	N	23.3 mo	3 y: 71.4% (gleason)	100%	G1/G2: 93% G3: 0	
Peters et al., 2014 (23)	20	BT = 7 EBRT = 12	Y	Gleason ≥8: 0 Median PSA: 4.7	23% (6–50)	Y (n = 5)	36 mo	3 y: 60%	80%	Late GU: G2: 0.05% G3: 0.05%	Late GI: G2: 1%
Kanogi et al., 2016 (28)	12	BT = 12	Y (n = 5)	Gleason ≥8: 17% Median PSA: 4.1	NR	Y (n = 3)	56 mo	4 y: 78%	100%	Acute: G2: 25%	Late: G2: 8%

Y = yes; N = no; ADT = androgen deprivation therapy; FFF = freedom from failure; DMFS = distant metastases-free survival; GU = genitourinary; GI = gastrointestinal; LDR = low dose rate; BT = brachytherapy; EBRT = external beam radiation therapy; PSA = prostate-specific antigen; NR = not reported; HDR = high dose rate; RP = radical prostatectomy.

Indications for Prostate MRI Sim

Quality Indicator	Importance Rating (9,essential)
When CT image quality is compromised (e.g. prosthetic hip implants) or absent from workflow	7,8
When PTV margins are small (≤ 5 mm).	7
In post-planning for LDR prostate brachytherapy to improve dosimetric accuracy.	7.3
When delineating a distinct GTV (MRI-visible tumor volume) and CTV volumes	9

Preparation and Set-Up

Quality Indicator	Importance Rating (9,essential)
Endorectal coil acquisitions should be avoided in the absence of robust deformable image registration tools.	8
Administration of anti-peristaltic agents should be strongly considered to improve image quality, unless contraindicated	7.3
Bladder filling state should be comfortable in order to reduce motion-related artifacts.	7.1
Patient positioning should approximate treatment conditions (bowel prep, bladder prep, +/- immobilization devices), while maximizing SNR (i.e. surface coils should be applied as close as possible to the patient surface).	8

MRI Acquisition

Quality Indicator	Importance Rating (9,essential)
MRI acquisition protocols should generally follow PIRADSv2 guidelines (acr.org) in order to facilitate diagnostic reporting.	7,7
Replacing coronal and sagittal T2w images with an isotropic T2w 3D axial acquisition is justified in radiotherapy planning, especially at 1.5T.	6
When implanted fiducial markers (FMs) or brachytherapy seeds must be resolved, strategies to augment the FM signature on above images may suffice (eg. Increase voxel resolution, PD via dual echo acquisition, intermediate TE).	7
A separate image may be acquired to more clearly highlight FMs (e.g. GRE, PD, SSFP, UTE)	7

MRI Acquisition

Quality Indicator	Importance Rating (9,essential)
DWI is recommended to assist in depiction of tumours if needed.	9
DCE is considered optional except for salvage of recurrence.	7
Activation of vendor-provided gradient distortion correction and optimization of bandwidth (fat/water pixel shift <1mm) is recommended to maintain geometric fidelity.	8
DWI should follow the QIBA profile (qibawiki.rsna.org). Distortion can be minimized using i) R-L phase-encode direction, ii) volume shimming over the gland, iii) minimizing effective echo-spacing, and iv) considering segmented or other non-EPI techniques.	8.5
Motion-related artefacts should be mitigated by limiting acquisition time to < 5 minutes when possible. Sequences should be repeated if motion-related artifacts.	7.8

Image Registration

Quality Indicator	Importance Rating (9,essential)
MRI registration to CT consists of a prostate-to-prostate local registration. Bone-to-bone registration of the pelvis is discouraged.	8,7
The quality of image registration must be evaluated by a physicist and/or physician prior to treatment planning. Rotations should be carefully scrutinized. Errors in registration translate to systematic errors that propagate through the treatment course, and must be minimized.	7,8
In salvage after prostatectomy, users should use great care to consider and mitigate variation in bladder and bowel filling between CT and MRI, and to reproduce treatment conditions. The potential for registration error is considered large in this setting. Accurate registration at the level of the external urethral sphincter and gross recurrent tumour (if present) is prioritised.	7.7
Inter-sequence motion of the prostate gland during an MRI examination may occur. Such displacements must be evaluated and corrected if present. DWI may require registration to T2w when distortions are observed.	7.2

CHUM Workflow

* manual point-based registration (PD to CT) using 4 implanted markers (sup and inf) for a total of 8 points.

** if required (due to motion) anatomic automated registration prostate-to-prostate using mutual information algorithm.

Sievers K. W. et al. Eur J Radiol 2000.
Dirix P. et al. Int J Radiat Oncol Biol Phys 2010.

MRI for all base of skull tumors!

Fig. 2. The axial CT scan of patient 1 (ethmoid tumor). In red, the four contours as outlined on this scan by the four observers; in green, the contours outlined on axial MRI. Note the difference in the posterior border; on the CT either the clivus is entirely included in the Gross Tumor Volume or not at all.

Fig. 3. The axial MRI scan of patient 1 (ethmoid tumor), resampled to fit the CT scan of Fig. 2. The contours outlined in the CT scan are red; the contours drawn on this axial MRI are green. On the CT scan, the observers outlined either the whole clivus as tumor or did not include the clivus at all in their Gross Tumor Volume. On the MRI, half of the clivus was included in the GTV.

MRI for oropharyngeal cancer (OPC)

Table 1

MRI and CT volumes for GTV, CTV and PTV and OAR. A difference between CT GTV and MRI GTV was detected. This difference was confirmed to be significant following the assessment of volumes delineated by other clinicians ($p = 0.003$).

Mean volume units in cm ³ (SEM)	Mean volume on MR (cm ³) ± SE	Mean volume on CT (cm ³) ± SE	VOI	p value
GTV primary	22.2 (11.1)	9.5 (5.9)	0.34	0.05
GTV primary for all clinicians	24.6 (5.7)	14.4 (3.1)	N/A	0.003
GTV primary and lymph nodes	30.2	16.2	0.5	0.05
GTV primary and lymph nodes for all clinicians	30.8 (8)	18.5 (4)	N/A	0.01
GTV nodes only	5.8 (1.3)	5.8 (1.1)	N/A	0.9
CTV	301.2 (28.9)	309.5 (27.7)	0.9	0.23
PTV	448	452	0.9	0.6
Nodal CTV	53.8	53.9	0.6	1
Nodal PTV	131	125	0.8	0.5
Parotid volumes (n = 16)	26.1 ± 1.9	22.9 ± 2.2	0.7	0.01
Brainstem (n = 8)	24.8 ± 1.2	30.2 ± 2.2	0.8	0.002
Spinal cord (n = 8)	7.3 ± 0.5	11.9 ± 1.1	0.7	0.002

MRI for hypopharyngo-laryngeal cancer (1)

Table 1. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) values of MR images of the larynx for various receiver coils

Receiver coil	SNR (vocal cord)	CNR (cord/thyroid)
Integrated transmit/receiver body coil	3.4	5.9
Four-channel phased-array coil	4.6	5.9
Quadrature head coil	6.2	12.3
Multi-element head-and-neck coil with neck coverage	15.4	27.2
Two-element flexible surface coil (11-cm diameter)	19.8	43.4
Two-element flexible surface coil at 3.0 T (11-cm diameter)*	16.9	42.7

* CNR and SNR for magnetic field strength of 3.0 T. All other values are determined for a field strength of 1.5 T.

MRI for hypopharyngo-laryngeal cancer (2)

Table 3

Inter-observer and inter-modality (i.e. CT-based against MRI-based GTVs for every single observer) variability for laryngeal/hypopharyngeal tumors ($n=10$)

	CT		MRI		Inter-modality variability*
	Volume (ml)	SEM	Volume (ml)	SEM	
Observer 1	18.1	5.8	19.3	4.9	***
Observer 2	20.7	6.1	21.5	5.7	$P=0.76$
Observer 3	20.9	5.8	20.0	4.7	$P=0.75$
Observer 4	19.3	5.9	22.1	5.6	$P=0.44$
Observer 5	21.9	6.1	21.8	5.3	$P=0.99$
Inter-observer variability**	$P=0.29$		$P=0.16$		

* P -values assessed by paired t -test or Wilcoxon rank test. ** P -values assessed by ANOVA. ***Not assessed as CT-based and MR-based volume delineation was performed by two different radiologists (see Materials and Methods for explanation).

Table 4

Inter-observer and inter-modality (i.e. CT-based against MRI-based volume for every single observer) variability for parotid glands ($n=20$)

	CT		MR		Inter-modality variability*
	Volume (ml)	SD	Volume (ml)	SD	
Observer 1	34.8	9.6	30.6	12.3	$P < 0.001$
Observer 2	29.4	8.7	27.9	9.5	$P=0.11$
Observer 3	26.8	9.3	20.4	8.0	$P < 0.001$
Inter-observer variability**	$P < 0.001$		$P < 0.001$		

* P -values assessed by paired t -test or Wilcoxon rank test. ** P -values assessed by ANOVA.

MR sequences for RT target delineation

Table 1 Proposal of Preferred MRI Sequences for Radiotherapy Target Delineation

Tumor Site	Subsite	Sequence	References
Brain	–	Postgadolinium T1-TSE or SPGR	13,14
		T2-TSE	13-15
		FLAIR-TSE	15
		DTI for anisotropic margins	16,17
		DTI for OAR delineation	16,18,19
Head and neck	Base of skull	Postgadolinium T1-TSE	20-22,25
		T2-TSE with fat suppression	20-22,25
	Pharyngolaryngeal	Postgadolinium T1-TSE	25-28
		T2-TSE with fat suppression	25-28
		DWI for nodal staging	31-39 (Table 2)
Breast cancer	–	T1-TSE	51
		3D T1-GRE	52-54
Rectal cancer	–	T2-TSE	55,57-61
		STIR T1- and T2-TSE	58
Prostate cancer	–	T2-TSE	68-73
		DWI, MRSI, and DCE-MRI	75-79

Abbreviation: MRSI, MR spectroscopy imaging.

PET/MRI for hypopharyngo-laryngeal cancer

- In 9 laryngectomy patients: PET was most accurate modality.
- However, no modality depicted superficial tumor extension.

Caution with FDG-PET for GTV delineation

- **Local in-field recurrences can occur outside the PET-GTV.**
- **FDG-PET is not suitable as an exclusive modality for GTV delineation.**
- **Inherently low spatial resolution functional imaging such as FDG-PET should not be used as a surrogate for anatomical imaging.**
- **Functional imaging indicates tumor biology (proliferation, hypoxia,...), rather than the exact tumor extension.**

Belgian prospective trial on PET delineation

Table 3
Volume comparison.

Volumes	PET (mean cm ³)	CT (mean cm ³)	p
<i>GTV</i>

<i>PTV T 50</i>			
All patients	189.7	202.6	0.02
Larynx and hypopharynx	113.7	100.4	0.1
Oropharynx and oral cavity	207.9	227.1	<0.01
Lille	286.2	286.4	0.7
Brussels	142.8	163.6	0.02
Namur	217.6	221.7	0.5

No marginal recurrences (in the CTV-CT but outside the CTV-PET) were observed.

2. Highly conformal RT: LN staging is crucial

avoid geographic miss
& regional recurrence

optimize organ-sparing
e.g. salivary glands,
swallowing structures

Comparison Between CT and FDG-PET for Nodal Staging

Site	Sensitivity		Specificity	
	CT (%)	FDG-PET (%)	CT (%)	FDG-PET (%)
Head and neck cancer	36-86	50-96	56-100	88-100

Sensitivity: FN because limited spatial resolution (0.5 cm)

Specificity: FP due to inflammation

Very promising, especially PET/CT, but not yet standard.

Materials and Methods

- 33 patients with advanced HNSCC planned for surgery with neck dissection:

- Radiotherapy planning study:

Results (1)

198 LN could be evaluated:

153 benign LN:

ADC = 0.00119 ± 0.00022 mm²/sec

45 malignant LN:

ADC = 0.00085 ± 0.00027 mm²/sec

p < 0.0001

Cut-off ADC value: 0.00094 mm²/sec

Results (2)

Nodal staging agreement between imaging results & pathology findings			
Modality	Kappa	95% CI	McNemar's test
CT/TSE	0.56	0.16 - 0.96	P = 0.019
DWI	0.97	0.84 - 1.00	

Sensitivity of 89% & specificity of 97% per LN.

DWI allows the radiation oncologist to very closely approach the true nodal target volume:

Dose-escalation (~ PPV of 91%)?

Organ-sparing (~ NPV of 97%)?

Preliminary results, require confirmation in a larger group...

4. Towards a biological target volume (BTV)?

- **BTV derived from functional/biological imaging guides customized dose delivery to various parts of the treatment volume.**
- = “dose-painting” or “dose-sculpting”.

FDG-PET

UZ Gent Phase I trial

Prescription-dose levels to the PTVs

PTV	Dose per fraction (Gy)		Total dose (Gy)	NID ₂ Gy (Gy)
	Fractions 1–10	Fractions 11–32		
PTV _{PET} = level I of dose escalation	2.5	2.16	72.5	78.2
PTV _{PET} = level II of dose escalation	3.0*	2.16	77.5	86.7
PTV ₆₉ = macroscopic tumor + enlarged lymph nodes	2.16	2.16	69.1	72.5
PTV ₆₆ = resected lymph nodes with capsule rupture	2.06	2.06	65.9	67.2
PTV ₆₂ = resected lymph nodes without capsule rupture	1.94	1.94	62.1	60.9
PTV ₅₆ = elective lymph nodes	1.75	1.75	56.0	51.1

- 23 pts dose level I (5.7 Gy), 18 pts dose level II (14.2 Gy) in first 10 fractions.
- 2 cases of DLT at dose level I (grade 4 dermatitis & dysphagia).
- 1 toxic death at dose level II (not RT-related?).
- In 4 of 9 relapsed patients, the site of relapse was in the PTV-PET.
- PET-guided dose escalation appears to be well-tolerated?

Pretreatment ADC of the primary lesion

Pre-treatment ADC correlates with outcome?

Five studies failed to distinguish patients with unfavourable disease based on pretreatment ADC.

Six studies found high pre-treatment tumour ADC to be predictive of poor outcome following CRT.

The pre-treatment ADC thresholds appear to be fairly concordant with primary $ADC < 0.79-0.88 \times 10^{-3} \text{ mm}^2/\text{s}$ and nodal $ADC < 1.11-1.14 \times 10^{-3} \text{ mm}^2/\text{s}$ to be predictive of favourable outcome.

Association between ADC and pathology (2)

Figure 5

Figure 5: Digitized whole-mount H-E section (original magnification, $\times 10$) of a T3 hypopharyngeal carcinoma. The tumor shows an intermediate CD of 6188 cells per square millimeter, 38% nuclear area, 38% stromal area, NC ratio of 1.59, and intermediate ADC of $1.19 \times 10^{-3} \text{ mm}^2/\text{sec}$.

Figure 6

Figure 6: Digitized whole-mount H-E section (original magnification, $\times 10$) of a T4a laryngeal carcinoma. The tumor shows a high CD of 8050 cells per square millimeter, 65% nuclear area, 18% stromal area, NC ratio of 4.14, and low ADC of $0.96 \times 10^{-3} \text{ mm}^2/\text{sec}$.

All reported results for DWI & response assessment

Study	n	During CRT	After CRT	Correlation	Results
Kim et al. <i>Clin Cancer Res 2009</i>	33	1w	2w	Response after CRT	Baseline ADC of responders was significantly lower. A significant increase in ADC was observed in responders within 1 week of CRT which remained until after CRT.
Galban et al. <i>Transl Oncol 2009</i>	15	3w	-	6-month LC	Significant differences in ADC were observed between patients with different outcomes.
Vandecaveye et al. <i>Eur Radiol 2010</i>	30	2w & 4w	-	2-year LRC	The Δ ADC 2 and 4 weeks after the start of CRT was significantly lower in lesions with recurrence.
King et al. <i>Eur Radiol 2010</i>	50	2w	6w	2-year LRC	A significant correlation was found between local failure and post-treatment ADC but not pre- or intra-treatment ADC.
Hatakenaka et al. <i>IJROBP 2011</i>	38	-	-	2-year LC	Baseline ADC of responders was significantly lower.
Vandecaveye et al. <i>IJROBP 2012</i>	29	-	3w	2-year LRC	The Δ ADC of lesions with later recurrence was significantly lower.
Srinivasan et al. <i>JCAT 2012</i>	17	-	-	2-year outcome	Baseline ADC of responders was significantly lower.
King et al. <i>Radiology 2013</i>	30	2w	-	2-year LC	Baseline ADC showed no correlation with local failure. During treatment, primary tumors showed a significantly lower Δ ADC for local failure.

Initial K^{trans} predicts outcome

Shukla-Dave A. et al. Int J Radiat Oncol Biol Phys 2012.

Repeated imaging during RT

First results confirm good prognosis of HPV+

18F-FDG MTV or TLG as early predictors of response

Large variations in pre-CT ADT due to HPV+ patients

A Left tonsil, primary ADC = $1.54 \times 10^{-3} \text{ mm}^2/\text{s}$ (3,933 voxels)

B Right tonsil/soft palate, primary ADC = $0.91 \times 10^{-3} \text{ mm}^2/\text{s}$ (10,007 voxels)

Ideally on an MRI-RT machine?

DWI: non-invasive evaluation of salivary gland function

Response to stimulation of the parotid glands of all patients before and after RT.

DWI: non-invasive evaluation of salivary gland function

7. Pitfalls of DWI

Rapid evolution of body imaging protocols

Divergence among and between vendors on data measurements/analysis and lack of transparency on how measurements are made

No accepted standards for measurements and analysis

Multiple data acquisition protocols depending on body part and usage of data

Qualitative to quantitative assessments

Lack of understanding of DW-MRI at a microscopic level

Multiexponential decay components which affect the calculated ADC values

Incomplete validation and documentation of reproducibility

Divergent nomenclature and symbols

Lack of multicenter working methodologies, accepted quality assurance (QA) standards, and physiologically realistic phantoms

Registration (1)

Non-rigid registration needed for distortion

Registration (2)

	Mean error	SD	Median error	Maximal error
Original SSD	7.78 mm	4.15 mm	7.10 mm	20.26 mm
Final SSD	2.10 mm	1.39 mm	1.83 mm	6.53 mm

Registration (3)

Conclusions

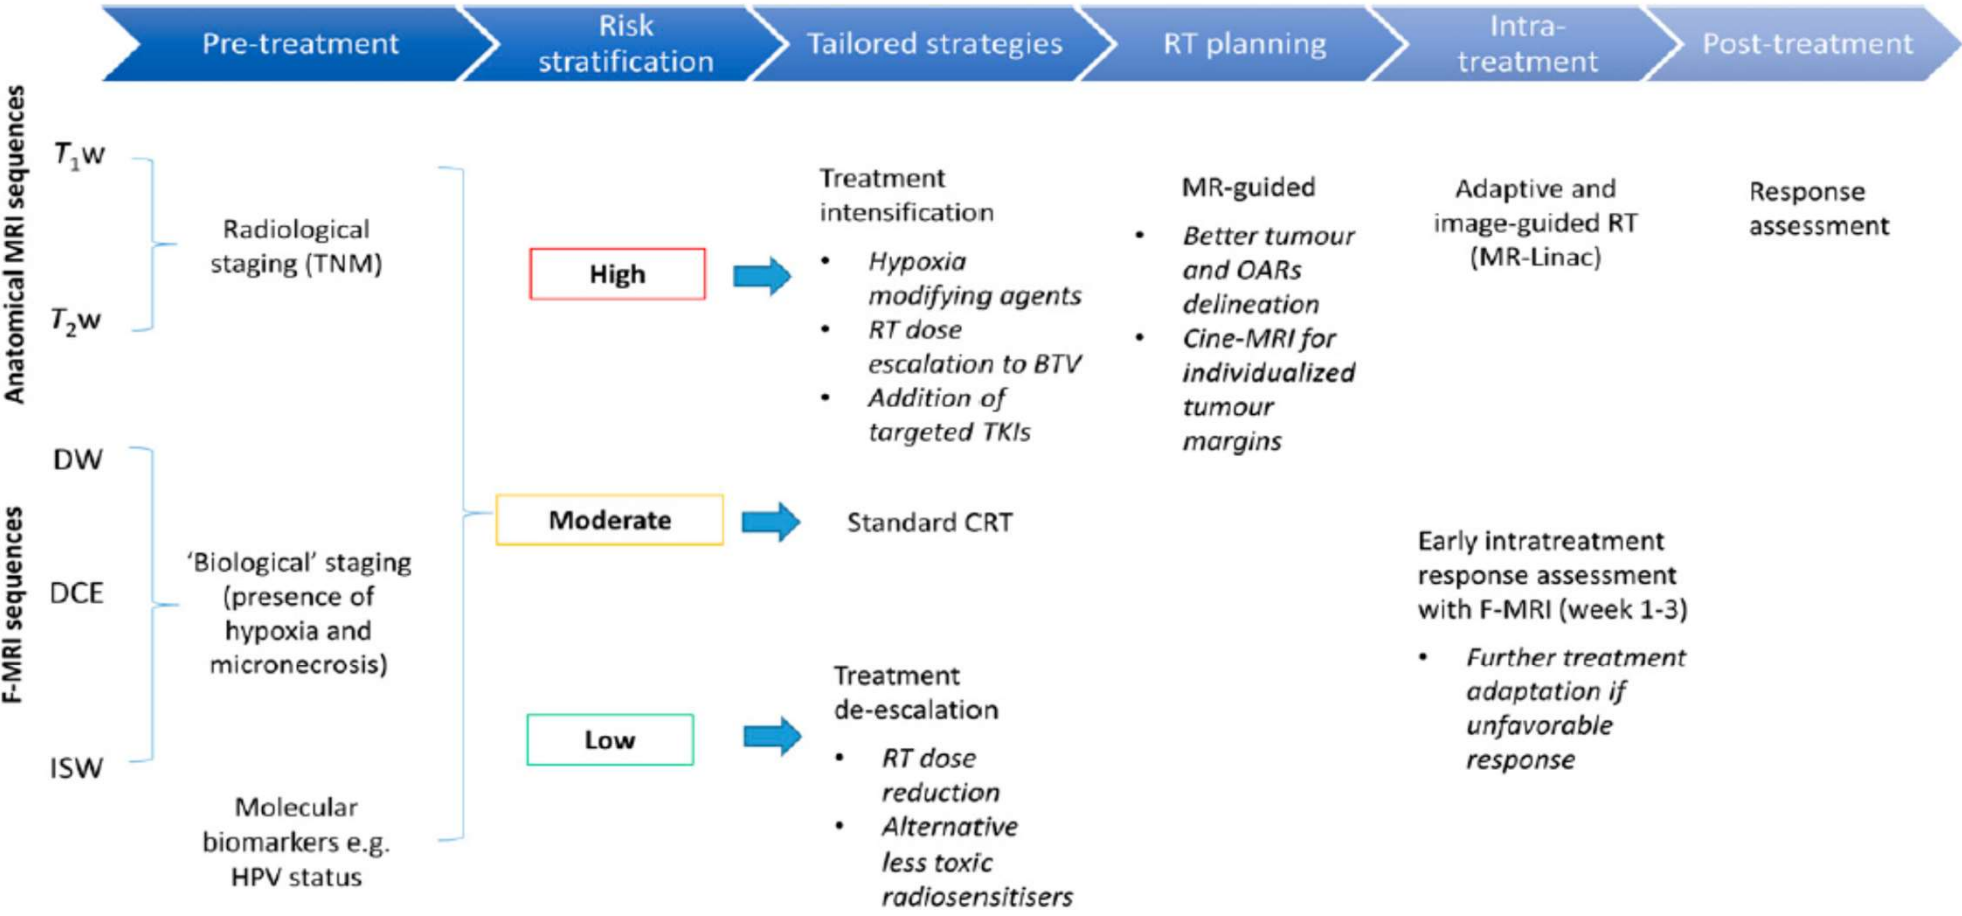

- Important role for anatomical MRI, especially in base of skull and oropharyngeal cancer.
- DWI and DCE-MRI could guide dose-painting and early response assessment.
- Standardisation of technique (b-values), interpretation, and registration.

Table 1 Key themes emerging from preclinical and clinical data on diffusion MRI in cancer.

Key themes	Strength of evidence*
Apparent diffusion coefficient (ADC) maps generated with low b-values are dominated by diffusion-related flow information	3
ADC maps provide information on the cellularity of tissues that can be used for lesion characterization	3
Pretherapy ADC maps may indicate the outcome of therapy	2
There is a transient decrease in ADC at the start of therapy that probably represents cellular swelling	1
Therapy-induced increases in ADC coincide with the onset of cell lysis and necrosis, and changes in ADC values predict clinical outcome for some tumors	4/2
Apoptotic cell removal and/or repopulation by resistant cells may cause decreases in ADC at the end of therapy	3

*Strength of evidence scale (1–5): weak–moderate–substantial–firm–definite (scale based on authors' perceptions of the literature used for this Review).

X-ray Attenuation

- Beer's law:

$$I = I_0 e^{-\int_0^L \mu(x, E) dx} \int_0^{\text{keV}_p} dE$$

Used for filtered back-projection: $I = I_0 e^{-\int_0^L \mu(x) dx}$

- Attenuation coefficient:

$$\mu_x(E) = x_R f_R(E) + x_P f_P(E) + x_C f_C(E) + x_{PP} f_{PP}(E)$$

X-ray Detection

X-ray Detection

Scintillator-based detector:

- Detector divided up into small blocks (pixelated)
- Conversion of the x-ray photon into the visible light
- Isotropic emission of the light collected by reflection at the septa and then detected by the photodiode

Semiconductor-based detector:

- Continuous crystal with a pixelated anode
- Conversion of the x-ray photons into free charge carriers
- Drift of the charge cloud towards the pixelated anode by a bias voltage

X-ray Detection

X-ray Detection

X-ray Detection

- Indirect conversion
- Pulse overlap (only pile-up)
- Energy integrating (EI)

- Direct conversion
- Photon counting (PC)
- Energy-selective

Sinogram Creation

Rebinning:

All projections from different angles are re-sorted in such a way to be parallel.

This means only the central projection is considered for each view angle theta, while all the others are parallel to it and comes from different rotation steps.

Sinogram Creation

Rebinning:

All projections from different angles are re-sorted in such a way to be parallel.

This means only the central projection is considered for each view angle θ , while all the others are parallel to it and comes from different rotation steps.

Sinogram Creation

- Lambert-Beer law is considered with some simplifications:
 - No dependency on the energy.
 - No detector response is modeled.
 - Focal spot is assumed dimensionless.
 - No scatter or other artifacts are considered.
- Each detector ξ measures the attenuated intensity along the direction θ .
- The attenuation follows a negative exponential behavior and depends on the line integral of the attenuation coefficients met along that way.

$$I(\theta, \xi) = I_0(\theta, \xi) e^{-\int_0^L \mu(\xi, \eta) d\eta}$$

- Since for each angle and detector only the structures along that path are responsible for the attenuation, the coordinates x and y can be expressed as:

$$\xi = x \cos(\theta) + y \sin(\theta)$$

$$\eta = -x \sin(\theta) + y \cos(\theta)$$

Sinogram Creation

From the intensity domain, it is convenient to move to projections domain, via division and negative log operation:

$$I(\theta, \xi) = I_0(\theta, \xi) e^{-\int_0^L \mu(\xi, \eta) d\eta}$$

$$\frac{I(\theta, \xi)}{I_0(\theta, \xi)} = e^{-\int_0^L \mu(\xi, \eta) d\eta}$$

$$-\ln \left(\frac{I(\theta, \xi)}{I_0(\theta, \xi)} \right) = \int_0^L \mu(\xi, \eta) d\eta = p(\theta, \xi) = p_\theta(\xi)$$

Sinogram Creation

The sinogram is the collection of projections for each detector, for each angle (from 0 to π).

Sinogram Creation

Detector index ξ

The sinogram is the collection of projections for each detector, for each angle (from 0 to π).

Sinogram Creation

The sinogram is the collection of projections for each detector, for each angle (from 0 to π).

Slice Theorem

Detector index ξ

Sinogram

θ

Rotation angle θ

The 1D Fourier transform of a sinogram line, is equal to the the extrapolation of the 1D line from the 2D Fourier transform of the original image along the respective angle:

$$p_{\theta}(\xi) = \int_0^L \mu(\xi, \eta) d\eta$$

$$P_{\theta}(q) = \mathcal{F}(p_{\theta}(\xi)) = \int_{-\infty}^{\infty} \left(\int_0^L \mu(\xi, \eta) d\eta \right) e^{-2\pi i q \xi} d\xi$$

$$P_{\theta}(q) = \mathcal{F}(p_{\theta}(\xi)) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \mu(\xi(x, y), \eta(x, y)) e^{-2\pi i q (x \cos(\theta) + y \sin(\theta))} dx dy$$

$$P_{\theta}(q) = \mathcal{F}(p_{\theta}(\xi)) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x, y) e^{-2\pi i (x q \cos(\theta) + y q \sin(\theta))} dx dy$$

$$F(u, v) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x, y) e^{-2\pi i (xu + yv)} dx dy$$

$$P_{\theta}(q) = F(u, v) \quad \text{for } u = q \cos(\theta), \quad v = q \sin(\theta)$$

Slice Theorem

Backprojection

The back-projection operation consists in smearing back each sinogram line along the projection angle.

Doing this operation for each angle, for at least 180 degrees, should allow to obtain again the original image, via super imposition of all the projections profiles.

Backprojection

Developing the mathematics behind, one can see that via simple back-projection a different image is obtained, which does not correspond to the initial one (for example positive values are assigned also to pixels outside of the object).

It turns out that a simple back-projection results in:

$$g(x, y) = f(x, y) * h(x, y)$$

which means the original image is convolved with a point spread function $h(x,y)$.

Backprojection

Simple backprojection

Filtered Backprojection

For inverse Fourier transform we have:

$$f(x, y) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} F(u, v) e^{2\pi i(xu + yv)} du dv$$

We saw from slice theorem, that for $u = q \cos(\theta)$ and $v = q \sin(\theta)$, we have that $F(u, v)$ equals $P_{\theta}(q)$.

We can move to polar coordinates and re-write

$$f(x, y) = \int_0^{2\pi} \int_{-\infty}^{\infty} F(q \cos(\theta), q \sin(\theta)) e^{2\pi i(xq \cos(\theta) + yq \sin(\theta))} q dq d\theta$$

which can be re-written after some passages as:

$$f(x, y) = \int_0^{2\pi} \int_{-\infty}^{\infty} P_{\theta}(q) e^{2\pi i q \xi} |q| dq d\theta$$

Filtered Backprojection

$$f(x, y) = \int_0^{\pi} \int_{-\infty}^{\infty} P_{\theta}(q) e^{2\pi i q \xi} |q| dq d\theta = f(x, y) = \int_0^{\pi} \int_{-\infty}^{\infty} P_{\theta}(q) e^{2\pi i q \xi} |q| dq d\theta$$

We can recognize that the integral in dq (marked in yellow) is nothing but the sinogram high-pass filtered in Fourier domain, where the filter is $|q|$.

With some approximation, the inverse Fourier transform of the filter is a sinc function, which means that, to obtain the original image, we have to convolve the sinogram with a „edge enhancing“ filter.

Filtered Backprojection

Simple backprojection

Filtered backprojection

Filtered Backprojection

With FBP, not so much can be optimized, except for the reconstruction kernel, which can be chosen to control the Modulation Transfer Function (i.e. the spatial frequency response of the algorithm).

Smooth kernels reduce noise and spatial frequency.

Sharp kernels allow to see more fine structures, but introduce more noise in the image.

Furthermore:

- all approximation done to solve the inverse problem might generate artifacts,
- to reconstruct an image, the rotation must be at least 180° plus fan angle.

Algebraic Reconstructions

Algebraic reconstructions are much more flexible, but significantly slower. They approach the problem as a set of linear equations to be solved.

$$\begin{cases} w_{1,1}f(1) + w_{1,2}f(2) + \cdots + w_{1,N}f(N) = p_1 \\ \vdots \\ w_{M,1}f(1) + w_{M,2}f(2) + \cdots + w_{M,N}f(N) = p_M \end{cases}$$

Where:

- $f(i)$ are the unknowns, i.e. the values of the image for each voxel $1 \leq i \leq N$
- $w(i, j)$ are the coefficients which are known and derived from system's geometry. They indicate how much each voxel i „falls“ into the path of that specific projection $1 \leq j \leq M$
- p_j are the measured projections.

Algebraic Reconstructions

$$\begin{cases} w_{1,1}f(1) + w_{1,2}f(2) + \cdots + w_{1,N}f(N) = p_1 \\ \vdots \\ w_{M,1}f(1) + w_{M,2}f(2) + \cdots + w_{M,N}f(N) = p_M \end{cases}$$

In a matrix form we can write:

$$\mathbf{A} \cdot \mathbf{f} = \mathbf{p}$$

Where

$$\mathbf{A} = \begin{pmatrix} w(1,1) & \cdots & w(N,1) \\ \vdots & \vdots & \vdots \\ w(1,M) & \cdots & w(N,M) \end{pmatrix} \quad \mathbf{f} = \begin{pmatrix} f(1) \\ \vdots \\ f(N) \end{pmatrix} \quad \mathbf{p} = \begin{pmatrix} p_1 \\ \vdots \\ p_M \end{pmatrix}$$

The system cannot be exactly solved because of the presence of noise and artifacts, and also because the system matrix \mathbf{A} is difficult to invert, since it is very sparse and big.

Normally the pseudo-solution is found as:

$$\mathbf{f}^* = \arg \min_{\mathbf{f}} \|\mathbf{A} \cdot \mathbf{f} - \mathbf{p}\|_2^2$$

Algebraic Reconstructions

The algorithm is very flexible and allows, for example, to weight each projection according to how reliable it is, remembering that when very few photons are measured, the signal to noise ratio of the projection decreases.

This variation of the algorithm is known as penalized weighted least square error (PWLS):

$$\mathbf{f}^* = \arg \min_{\mathbf{f}} ((\mathbf{A} \cdot \mathbf{f} - \mathbf{p})^T \mathbf{W}^{-1} (\mathbf{A} \cdot \mathbf{f} - \mathbf{p}))$$

Where the matrix \mathbf{W} is a diagonal matrix containing the weights for each projection.

Algebraic Reconstructions

Normally, a so-called „regularizer“ function is added to the cost function to be minimized, in such a way to incorporate noise and/or artifacts reduction and create an algebraic reconstruction algorithm optimized for a specific problem or scenario.

Here few examples:

- Total variation:

$$\mathbf{f}^* = \arg \min_{\mathbf{f}} \|\mathbf{A} \cdot \mathbf{f} - \mathbf{p}\|_2^2 + \lambda \|\nabla \mathbf{f}\|_1$$

- Nuclear norm (for correlated images):

$$\mathbf{f}^* = \arg \min_{\mathbf{f}} \|\mathbf{A} \cdot \mathbf{f} - \mathbf{p}\|_2^2 + \lambda \|\mathbf{f}\|_*$$

- Prior-induce similarity:

$$\mathbf{f}^* = \arg \min_{\mathbf{f}} \|\mathbf{A} \cdot \mathbf{f} - \mathbf{p}\|_2^2 + \lambda \|R(\mathbf{f} - \mathbf{g})\|_2$$

- Dictionary based:

$$\mathbf{f}^* = \arg \min_{\mathbf{f}} \|\mathbf{A} \cdot \mathbf{f} - \mathbf{p}\|_2^2 + \lambda \|\mathbf{f} - \mathbf{Dc}\|_2^2$$

Noise

Theoretically, the number of photons that reach the detectors can be described as a cascade of Bernoulli distribution, describing the probability that a photon is emitted or not, absorbed from the patient or not, detected or not etc. This cascade can be approximated with a Poisson distribution and hence we can write:

$$n \sim \mathcal{P}(N, N)$$

Meaning that the variance of the distribution is equivalent to the expected number of photons. This means that for a high number of photons also the noise is increasing, but the SNR will overall decrease since

$$\text{SNR} = \frac{N}{\sqrt{N}} = \sqrt{N}$$

The noise is theoretically uncorrelated, but the cross-talk between adjacent detectors, the logarithmic operation to obtain the sinogram, and especially the filtering of the sinogram and backprojection operations make such that the noise is spatially correlated in image domain.

Motion Artifacts

While noise has a stochastic nature, artifacts arise for specific reasons, and sometimes can be corrected or reduced.

All artifacts are due to some inconsistencies in the projections. For example motion artifacts are generated when an object moves during the acquisition.

Since the object is moving, only some projections are passing through it, while others that should have intersected the object do not intersect it anymore, and the other way around.

Some of the possible ways to solve this issue are:

- Improving scan speed
- Instructing the patient
- Acquiring data with less than 180° of rotation. This would generate other types of artifacts (namely truncation artifacts) since the data are incomplete, but these new artifacts might be easier to correct for.
- Reduce entropy in selected regions of the image

Beam Hardening Artifacts

Another type of inconsistency is the fact that the Beer Lambert law is simplified without taking into account the energy dependency.

$$I = I_0 e^{-\int_0^L \int_0^{keV_P} \mu(x, E) dx dE} \longrightarrow I = I_0 e^{-\int_0^L \mu(x) dx}$$

In particular lower energy photons are attenuated more respect to higher energy ones. But the formula used for the reconstruction assumes that the only reasons for different attenuations are the attenuation coefficients and the intersection lengths.

Beam Hardening Artifacts

Common ways to correct for these artifacts consist in:

- Segmenting the metal or high attenuating objects in the image (which are the main responsible of the artifacts, since the inhomogeneity in the absorption due to the energy is maximum when highly attenuating objects are met).
- Identifying all the affected projections, i.e. those projections that have passed through these objects.
- Replacing the affected projection with some sort of interpolation of the non-affected adjacent ones.

These types of algorithms are normally iterative: small improvements are done in each iteration, until a cost function is minimized.

 - Dose measurements

CTDI

CTDI measures the dose absorbed by the phantom in one tube rotation, without any table movement.

CTDI

Absorbed dose:

$$1 \text{ Gy} = 1 \text{ J/Kg}$$

CTDI

CTDI definition:

$$\text{CTDI} = \frac{1}{NT} \int_{-\infty}^{\infty} D(z) dz$$

CTDI measures the entire dose along z-axis (integral along z), accumulated in the phantom in one tube rotation, without any table movement. The result is normalized by the beam nominal width, (i.e. detectors coverage: NT)

N = number of detectors

T = single detector's width

CTDI

CTDI measurement:

We cannot measure an integral from $-\infty$ to $+\infty$.

Plus, we need a reference standardized value.

10 cm sensors are used.
So the dose accumulated in the phantom in a distance from -50 mm to +50 mm from the center is measured

CTDI

CTDI₁₀₀

Using sensors of 100 mm, we define CTDI₁₀₀ like:

$$\text{CTDI}_{100} = \frac{1}{NT} \int_{-50}^{50} D(z) dz$$

CTDI

CTDI_w

The dose accumulated will be different in the center and in the periphery of the phantom. Sensors are positioned both in the center and in the periphery.

The absorbed dose, will be calculated as a weighted average of central and peripheral measured values:

$$\text{CTDI}_w = \frac{1}{3}\text{CTDI}_{100}^{\text{central}} + \frac{2}{3}\text{CTDI}_{100}^{\text{peripheral}}$$

CTDI

CTDI_{vol}

Now we have to take into account the fact that the table (for spiral examinations) is actually moving. We define CTDI_{vol} as:

$$\text{CTDI}_{\text{vol}} = \frac{\text{CTDI}_w}{\text{pitch}}$$

CTDI_{vol} reflects the dose that a 32 cm or 16 cm water phantom would absorb with the specific scan settings.

Patient size plays an important role in estimating the effectively absorbed dose and should be taken into account.

One way of doing it is to calculate the effective diameter of the patient and estimate the absorbed dose via a proportion with the diameter of the phantom.

Effective dose is calculated as DLP*w, where the weight w depends on the body region and the DLP is the CTDI multiplied by the scan length.

Form DLP to Effective Dose

Normalised values of effective dose per dose-length product (DLP) over various body regions and (standard) patient age¹:

Region of body	Effective dose per DLP (mSv (mGy cm) ⁻¹) by age				
	0 ^a	1y ^a	5y ^a	10y ^a	Adult ^b
Head & neck	0.013	0.0085	0.0057	0.0042	0.0031

Material Quantification

Liver VNC

Material Quantification

Liver VNC

Material Quantification

Liver VNC

Material Quantification

Liver VNC

Iodine overlay is obtained via subtraction of the mixed image and the VNC image.
Fat fraction is obtained for each voxel via relative distance of VNC point to the calibration points (fat and tissue).

Material Quantification

Problem in Presence of a 4th Material (i.e. Calcium)

Material Quantification

Liver VNC

Other quantification applications are possible, changing:

- Calibration materials (for example air and soft tissue for lung iodine enhancement)
- Material to be quantified (for example calcium instead of iodine, VNCa)

Mixed image

Virtual non-contrast and iodine image

Material Quantification

Other Applications

Material Quantification

Other Applications

Material Quantification

Other Applications

MR

DE mixed CT
(equivalent to SE 120 kV)

VNCa

Calcium has weak DE properties. VNCa works fine for small body regions.

Material Quantification

Spectral Separation

Fat	-95	Fat	-90
Rel. CM	1.46		

120 kV (Split Filter Au+Sn)

Material Quantification

Protocols Considerations

- Post-processing:
 - Do not change calibration parameters.
- Dedicated kernels.
- Pitch should be low (<1).
- Slow rotation time (0.5 s)
- If possible, narrow collimation should be employed (e.g. to minimize scatter), at the expenses of examination time.
- Reconstructed slice thickness S_{eff} .
- Noise and false iodine overlay values.
- The main assumption fails in presence of:
 - Noise
 - Physical artifacts (beam hardening)
 - Motion
 - Contrast media flow

Photon Counting Principle

Scintillator-based detector:

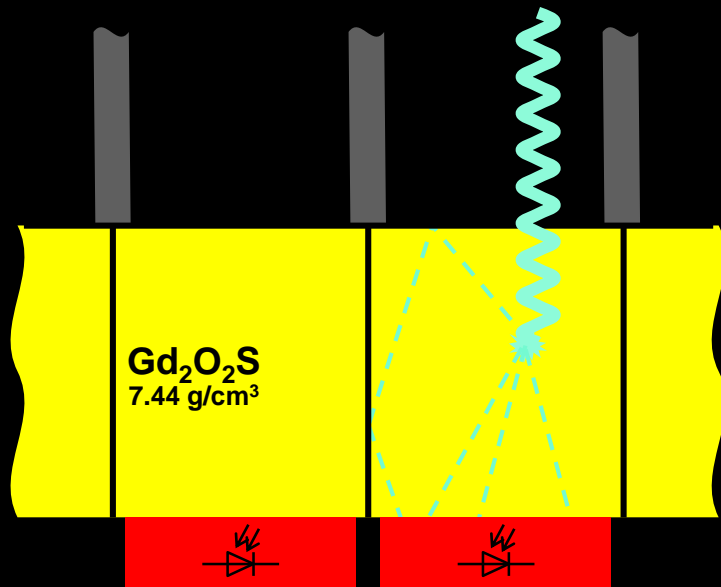

- Detector divided up into small blocks (pixelated)
- Conversion of the x-ray photon into the visible light
- Isotropic emission of the light collected by reflection at the septa and then detected by the photodiode

Semiconductor-based detector:

- Continuous crystal with a pixelated anode
- Conversion of the x-ray photons into free charge carriers
- Drift of the charge cloud towards the pixelated anode by a bias voltage

Photon Counting Principle

Photon Counting Benefits

Up to 4 energy bins images.

- Multiple contrast material
- Separation of calcium and Iodine

Better spatial resolution.

- Lung structures
- Inner ear, bones

No electronic noise.

Photon Counting Limitations

charge-sharing and pile-up

Charge-sharing

Ideal case

Low energy bin

High energy bin

Realistic case

Low energy bin

High energy bin

Index of Contents

- **Introduction:**
 - X-ray attenuation
 - DE principles and technical solutions
- **Clinical applications and protocol optimization:**
 - Material classification
 - Material quantification (decomposition)
 - **Pseudo-monoenergetic images**
 - Electron density and effective atomic number images

Pseudo-Monoenergetic Images

Attenuation coefficient for a material x:

$$\mu_x(E) = x_P f_P(E) + x_C f_C(E)$$

Attenuation coefficient for materials y and z:

$$\mu_y(E) = y_P f_P(E) + y_C f_C(E)$$

y and z are called “basis material”. They have to be chosen in such a way that their photoelectric and Compton cross-sections (y_P, z_P and y_C, z_C respectively) are known.

$$\mu_z(E) = z_P f_P(E) + z_C f_C(E)$$

Pseudo-Monoenergetic Images

Direct Method

$$\mu_x(E) = x_P f_P(E) + x_C f_C(E)$$

$$\left\{ \begin{array}{l} \mu_x(E_{\text{low}}) = x_P f_P(E_{\text{low}}) + x_C f_C(E_{\text{low}}) \\ \mu_x(E_{\text{high}}) = x_P f_P(E_{\text{high}}) + x_C f_C(E_{\text{high}}) \end{array} \right.$$

Unknown: x_P, x_C

Known: $f_P(E), f_C(E) \quad \forall E$

Measured: $\mu_x(E_{\text{low}}), \mu_x(E_{\text{high}})$

Pseudo-Monoenergetic Images

Material Basis Method (more robust)

$$\mu_x(E) = x_P f_P(E) + x_C f_C(E)$$

$$\begin{cases} \mu_y(E) = y_P f_P(E) + y_C f_C(E) \\ \mu_z(E) = z_P f_P(E) + z_C f_C(E) \end{cases}$$

$$\begin{aligned} f_P(E) &= g_1(\mu_y(E), \mu_z(E)) \\ f_C(E) &= g_2(\mu_y(E), \mu_z(E)) \end{aligned}$$

Pseudo-Monoenergetic Images

Material Basis Method (more robust)

$$\mu_x(E) = x_P f_P(E) + x_C f_C(E)$$

$$f_P(E) = g_1(\mu_y(E), \mu_z(E))$$

$$f_C(E) = g_2(\mu_y(E), \mu_z(E))$$

$$\begin{cases} \mu_x(E_{\text{low}}) = a_y \mu_y(E_{\text{low}}) + a_z \mu_z(E_{\text{low}}) \\ \mu_x(E_{\text{high}}) = a_y \mu_y(E_{\text{high}}) + a_z \mu_z(E_{\text{high}}) \end{cases}$$

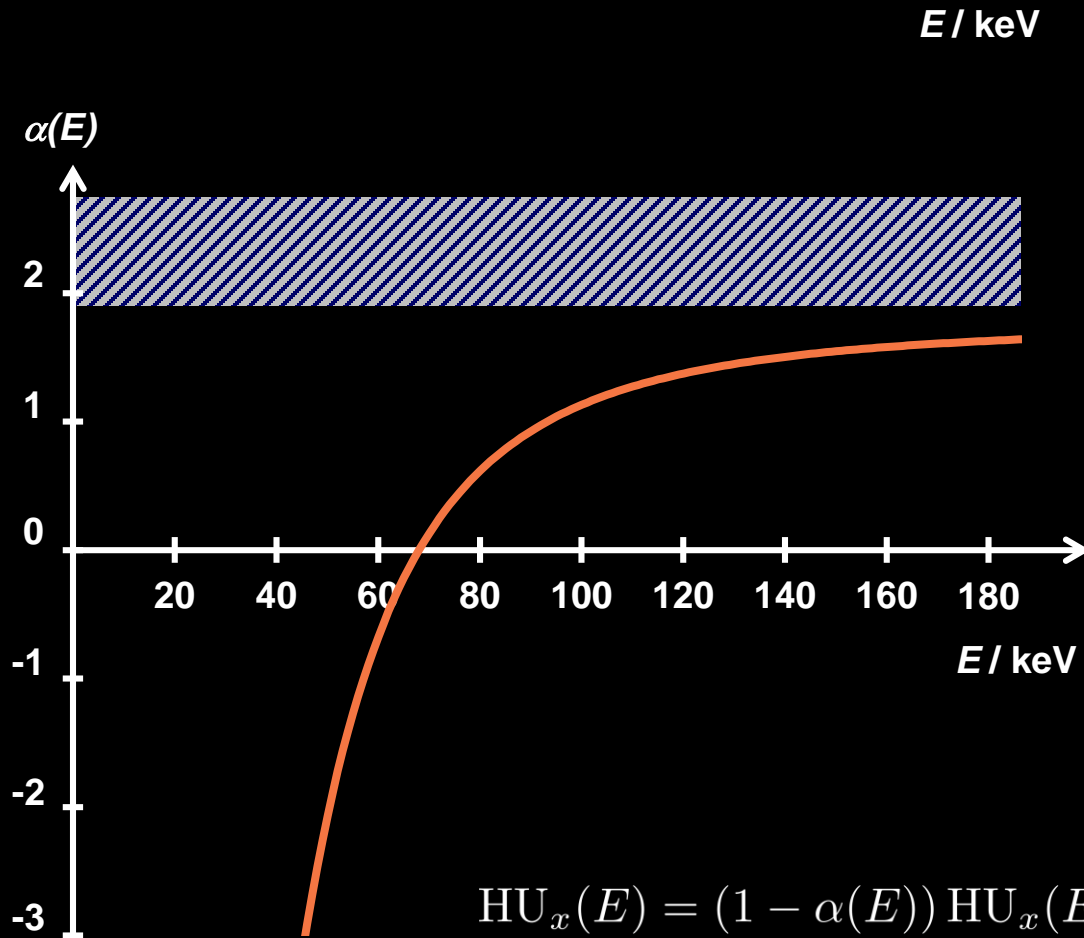

$$\mu_x(E) = a_y \mu_y(E) + a_z \mu_z(E)$$

Pseudo-Monoenergetic Images

Solving the system and expressing everything in CT values, if one of the two basis material is water, we obtain:

$$\text{HU}_x(E) = (1 - \alpha(E)) \text{HU}_x(E_{\text{low}}) + \alpha(E) \text{HU}_x(E_{\text{high}})$$

Pseudo-Monoenergetic Images

Pseudo-Monoenergetic Images

Considerations

- The two basis materials are iodine and water. All calibration values are stored and cannot be changed.
- The acquisition protocol is straight forward. In vendors' softwares, pseudo-monoenergetic images can be calculated in rawdata domain directly.
- Pseudo-monoenergetic can be used for spectroscopic analysis, plotting CT values of an ROI for different energies.
- It can be used also to optimize CNR.
- Again, spectral separation and low noise would lead to better and more robust results.

Index of Contents

- **Introduction:**
 - X-ray attenuation
 - DE principles and technical solutions
- **Clinical applications and protocol optimization:**
 - Material classification
 - Material quantification (decomposition)
 - Pseudo-monoenergetic images
 - **Electron density and effective atomic number images**

Electron Density and Effective Atomic Number Images

Direct Method

$$\mu_x(E) \sim \rho_x \frac{N_A}{A_x} Z_x \left(Z_x^3 \frac{1}{E^3} + f_{\text{KN}}(E) \right)$$

- ρ_x , density of the element $\left[\frac{g}{m^3} \right] \rightarrow$ unknown
- N_A , Avogadro number: number of atoms needed to have A grams of an element of atomic mass A \rightarrow known
- A_x , atomic mass of the element [a.m.u.] ($\sim g$) \rightarrow unknown
- Z_x , average atomic number of the voxel (i.e. number of electrons of the element) \rightarrow unknown

Electron Density and Effective Atomic Number Images

Direct Method

Electron density is defined as the number of electrons in one unit of volume:

$$\rho_e = \frac{n}{m^3} = \frac{g}{m^3} \frac{n}{g} = \frac{g}{m^3} \left(n_e \frac{n_a}{g} \right) = \rho Z \frac{N_A}{A}$$

$$\mu_x(E) \sim \rho_x \frac{N_A}{A_x} Z_x \left(Z_x^3 \frac{1}{E^3} + f_{\text{KN}}(E) \right)$$

$$\mu_x(E) \sim \rho_{e_x} \left(Z_x^3 \frac{1}{E^3} + f_{\text{KN}}(E) \right)$$

Electron Density and Effective Atomic Number Images

Material Basis Method (more robust)

Same principles and derivation employed for pseudo-monoenergetic images.

Once the contribution of each basis material are calculated for one voxel, a weighted average of their electron densities (instead of the attenuation values) is performed.

$$\mu_x(E) = a_y \mu_y(E) + a_z \mu_z(E) \quad \text{Pseudo-monoenergetic formula}$$

$$\rho_{e_x} = a_y \rho_{e_y} + a_z \rho_{e_z} \quad \text{Electron density formula (does not depend on energy)}$$

Electron Density and Effective Atomic Number Images

Material Basis Method (more robust)

Since electron density is usually normalized by the electron density of water, if water is also one of the basis materials (y=water and z=iodine, for example), then the formula becomes:

$$\hat{\rho}_{e_x} = \frac{\rho_{e_x}}{\rho_{e_w}} = a_w \frac{\rho_{e_w}}{\rho_{e_w}} + a_i \frac{\rho_{e_i}}{\rho_{e_w}} = a_w + a_i \hat{\rho}_{e_i}$$

The effective atomic number is a weighted average of the atomic numbers of basis materials:

$$Z_x = \left[\left(\frac{a_w}{a_w + a_i \hat{\rho}_{e_i}} Z_w \right)^n + \left(\frac{a_i \hat{\rho}_{e_i}}{a_w + a_i \hat{\rho}_{e_i}} Z_i \right)^n \right]^{\frac{1}{n}}$$

Electron Density and Effective Atomic Number Images

Considerations

Since the principles are so similar to pseudo-monoenergetic applications, the same considerations hold.

Clinical application is different: electron density is useful for radiotherapy treatment planning, since it is linear with stopping power, while CT values are not.

Metal Artifacts Reduction

Metal artifacts generation:

- Beam hardening
- Photon starvation
- Scattering

Metal Artifact Reduction DE MAR

$$D = W + \alpha_1 \delta$$

$$D = W + \alpha_1 \delta + \alpha_2 \delta^2 + \alpha_3 \delta^3$$

$$D = W + \alpha_1 \delta + \alpha_2 \delta^2$$

Metal Artifact Reduction DE MAR

$$D^L = W + \alpha_1^L \delta + \alpha_2^L \delta^2 + \alpha_3^L \delta^3$$

$$D^H = W + \alpha_1^H \delta + \alpha_2^H \delta^2 + \alpha_3^H \delta^3$$

Metal Artifact Reduction DE MAR

$$a_0^E I_0 + a_1^E I_1$$

$$a_2^E I_2 + a_3^E I_3$$

I_L

I_H

$$I_M = \alpha I_H + (1 - \alpha) I_L$$

$$\alpha > 1$$

Metal Artifact Reduction DE MAR

Limitations:

- Loss of quantitative HU information
- Loss of contrast

Improvement:

Frequency split approach (Mono+):

- Low spatial frequencies from a positive combination of I_L and I_H
- High spatial frequencies from the negative combination of I_L and I_H

Metal Artifact Reduction IMAR

General inpainting methods

Metal Artifact Reduction IMAR

PET tracers and applications

Eirik Malinen

Why PET

- Cancer has upregulated cellular pathways that can be exploited in molecular imaging
- Localize and define the tumor and nodes
- Assess disease aggressiveness
- Evaluate treatment

Uptake reflects cellular processes

Tracer production - cyclotron

- Cyclotron provides e.g. accelerated protons
- Target undergoes nuclear reactions

Tracer production - generator

- Long lived parent nuclei decays to short-lived positron emitting daughter, e.g. $^{68}\text{Ge} \rightarrow ^{68}\text{Ga}$

- No need for cyclotron onsite

Isotopes and disintegration

Radionuclide	Half-life	E_{max} (Mev)	β^+ Branching Fraction
^{11}C	20.4 min	0.96	1.00
^{13}N	9.97 min	1.20	1.00
^{15}O	122 s	1.73	1.00
^{18}F	109.8 min	0.63	0.97
^{22}Na	2.60 y	0.55	0.90
^{62}Cu	9.74 min	2.93	0.97
^{64}Cu	12.7 h	0.65	0.29
^{68}Ga	67.6 min	1.89	0.89
^{76}Br	16.2 h	Various	0.56
^{82}Rb	1.27 min	2.60, 3.38	0.96
^{124}I	4.17 d	1.53, 2.14	0.23

Tracer production – ^{18}F -FDG

- ^{18}O irradiated with protons

- ^{18}F added to mannose triflate →
- Several steps involving labelling, purification and hydrolysis

^{18}F -FDG

Glucose

Flourodeoxyglucose

PET workflow

<http://www.vandamlab.org/research>

^{18}F -FDG – a biomarker

Extract maximum uptake

Conventional vs dynamic PET

Conventional PET:

- Patient rests for 1 hour after injection
- Produces a "static" PET image series (3D)

Dynamic PET

- PET-acquisition starts at the time of injection
- May give a dynamic image series (4D)

Dynamic FDG-PET

- Time stamp for each coincidence in the listmode file → reconstruct in time intervals

Dynamic FDG-PET

Kinetic modelling

$K_1 = 0.20$
 $k_2 = 0.40$
 $k_3 = 0.037$
 $v_p = 0.16$
 $MR_{FDG} = 0.016$
 $r^2 = 0.89$

FDG

PET/CT in RT

Table 1 PET-CT integration for imaging of tumor metabolism with [¹⁸ F]-FDG				
Reference	Site of tumor	n	Conclusion of study	Potential applicability
Krengli <i>et al.</i> (2010) ⁹⁰	Anal cancer	27	Addition of [¹⁸ F]-FDG-PET-CT resulted in significant stage variation with change of treatment in a subgroup. The GTV and the CTV changed in shape and in size	Staging and target volume delineation
Ford <i>et al.</i> (2008) ⁹³	Breast	12	The targets using PET-CT were significantly larger than with CT alone	Target volume delineation
Kidd <i>et al.</i> (2010) ⁴¹	Cervix uteri	83	Predicting response, pelvic recurrence risk, and disease-specific survival	Prognostic
Weber <i>et al.</i> (2001) ⁴⁴ Schmidt <i>et al.</i> (2009) ⁴⁵ Lordick <i>et al.</i> (2007) ⁴⁹	Esophagus	40 5 1,195	PET imaging may differentiate responding and nonresponding tumors early in the course of therapy, but this result has not been confirmed by other studies	Early response measurement with conflicting results
Madani <i>et al.</i> (2007) ⁴⁸ Schinagl <i>et al.</i> (2009) ⁹² Geets <i>et al.</i> (2007) ⁹⁵	Head and neck	41 78 10	Adaptive IMRT with [¹⁸ F]-FDG-PET images has a significant impact on the delineation of GTV; however, the results depend on the PET segmentation tool used, and validation is, therefore, necessary	Target volume delineation and target boosting
Pommier <i>et al.</i> (2010) ⁸⁸	Hodgkin lymphoma	137	[¹⁸ F]-FDG-PET for treatment planning in Hodgkin lymphoma leads to modification of treatment and radiotherapy planning	Target volume delineation
Sasaki <i>et al.</i> (2005) ⁴² Hoekstra <i>et al.</i> (2005) ⁵⁰ Vinod <i>et al.</i> (2010) ⁸⁷ Petit <i>et al.</i> (2009) ⁹¹ Aerts <i>et al.</i> (2009) ⁹⁹	NSCLC	1,624 7 5 39 55	[¹⁸ F]-FDG-PET helps in the delineation of GTV [¹⁸ F]-FDG-PET has additional value over CT alone in monitoring response and may predict survival early during induction chemotherapy. Probability that a voxel is metabolically controlled decreased with increasing [¹⁸ F]-FDG uptake and tumor volume; pretreatment [¹⁸ F]-FDG-PET-CT identifies residual metabolically active areas	Early response measurement Prognostic/predictive target volume delineation
Jingu <i>et al.</i> (2010) ⁴⁶ Janssen <i>et al.</i> (2010) ⁵¹	Rectum	12 46	[¹⁸ F]-FDG-PET-guided IMRT can facilitate dose escalation and can be used to detect early metabolic responses during chemoradiotherapy	Target boosting Early response measurement
van Loon <i>et al.</i> (2008) ⁹⁴	SCLC	21	[¹⁸ F]-FDG-PET in limited disease SCLC changed the treatment plan in 24% of patients compared with CT	Target volume delineation
Benz <i>et al.</i> (2009) ⁴³	Sarcoma	50	Reduction in [¹⁸ F]-FDG uptake at early follow-up is a sensitive predictor of histopathological tumor response	Prognostic, early response measurement

Tumor delineation

- Where is the tumor tissue in a blurred image?

Not perfect correspondence

Blurring due to PET limitations

- One specific tracer reflect one tumor property

Tumor delineation

PET was most accurate. No modality (PET/MRI/CT) managed to depict superficial tumor extension.

Tumor delineation

PET/CT

MRI

$$DSC = \frac{A \cap B}{\frac{1}{2} \cdot (|A| + |B|)}$$

Treatment monitoring

Resistant sarcoma

Sensitive lymphoma

Treatment monitoring

- Repeated imaging to assess changes in disease
- RECIST - Response Evaluation Criteria In Solid Tumors

Tumor shrinkage in different cervical tumors

- Tumor volume may not reflect clonogens
- Shrinkage depends on cell kill, inter-fraction proliferation *and* cell clearance

PET quantification issues

- Intra-patient variation

- SUV is 'semi-quantitative'

Treatment monitoring

- Early decline better than evaluation later (?)
- When to image?

PERCIST

- ^{18}F -FDG PET response criteria
- Complete metabolic response; disappearance of signal
- Partial metabolic response; $> 30\%$ reduction in uptake
- Progressive metabolic disease; $> 30\%$ increase
- Liver normalization recommended to minimize variability
- Still, few applications in RT

Response evaluation

- ^{18}F -FDG PET of liver mets after stereotactic RT

IJROBP, Vol. 83, No. 5, pp. e613ee618, 2012

Radiobiological interpretation

- Use images to estimate tumor radioresistance

Multi-tracer assessment

Monitoring normal tissues

- Parotid gland function as measured by ^{11}C -methionine-PET

Problem

Patient 1

Patient 2

Same max.
image value!

How to *quantify* differences in tumor appearance?

→ look for e.g. *texture* in images

PET/CT hardware for RT

- Laser bridge
- Flat table top
- Positioning aids
- Fixation devices

Quality control – RT components

- As with regular CT simulators:
 - Check for table motion constancy, also with varying load
 - Immobilization devices; check e.g. landmarks relative to table top
 - Assess laser geometry and accuracy by alignment tools

Quality control – CT scanner

- CT numbers (HU)
- Noise, uniformity
- Slice thickness
- Spatial resolution
- Table accuracy

Eur J Nucl Med Mol Imaging (2010) 37:662–671
Med Phys 2003; 30: 2762–2792
IAEA HUMAN HEALTH SERIES 27

Quality control – PET scanner

- Uniformity, coincid. sensitivity
- Activity calibr., normalization
- Correctional measures
 - randoms, scatter, atten.

Cylindrical ^{68}Ge phantom

QC sinogram

Image quality tests - PET

NEMA phantom

6-min scan (8:1 ratio;
sphere-to-background)

PET/CT alignment

- Offset between PET and CT image measured during acceptance
- Maintenance/upgrades/repairs may change offset

PET image reconstruction

- Affects detection and delineation
- Standardized protocols and procedures are required

Regular iterative
reconstruction

TOF+PSF
reconstruction

PET image reconstruction

- Iterative methods are standard, and characterized by
 - Number of iterations and subsets
 - Matrix and voxel size
 - Smoothing kernel
- Number of iterations \times subsets > 40
- Full 3D reconstruction *without* acceleration (e.g. Fourier rebinning)
- PET image reconstruction with and without attenuation correction

PET reconstruction and quantification

PET reconstruction and quantification

- Affects e.g. SUVs and autosegmented volumes

OSEM2i image

OSEM

PSF

~15% difference in thresholded TVs

Example PET protocol

NARLAL-trial: Heterogeneous FDG-guided dose escalation (with concomitant Navelbine®)

- SUV_{peak} more robust than SUV_{max}
- NEMA phantom at participating centers:

Contouring

- Different automated approaches such as thresholding and gradient-based methods

Contouring

3 observers' delineations

Thresholded volume

Median inter-observer
DICE: 0.68

$$DSC = \frac{A \cap B}{\frac{1}{2} \cdot (|A| + |B|)}$$

Contouring

- Segmentation may not result in useful tumor definitions because of
 - Noise
 - Tracer uptake inhomogeneities (tumour+ backgr.)
 - Sometimes low tumour-to-background ratios
- This also causes inter-method variability
- Segmented VOIs must be checked visually

Eur J Nucl Med Mol Imaging (2015) 42:328–354

DOI 10.1007/s00259-014-2961-x

**FDG PET/CT: EANM procedure guidelines for tumour imaging:
version 2.0**

Image registration

- Misregistration in PET/CT can occur:

Axial fused FDG PET–CT image of axilla incl. lymph node

- CT-series of PET/CT represents reference frame
- Image registration may be required:
 - In multimodal delineation applications (e.g. +MRI)
 - If PET/CT is not acquired in RT setting (then coreg. with planning CT)
 - For IGRT with e.g. CBCT

Image registration

- Linear, rigid methods
 - Landmark – based
 - Mutual information
- Non-linear ‘deformable’ methods
 - Volume / feature-based algorithms
 - Optical flow methods
 - Demons algorithm
- Deformable methods difficult to validate

DICOM transfer

- Comply with DICOM (RT) standard

- RT planning system is not NM viewer

Respiratory motion

Motion management

- Respiratory gating
 - synchronization of the acquisition systems (CT and PET) to the patient's respiration
- Breath-hold techniques
 - patient is asked to hold his/her breath
- Tidal breathing
 - patient instructed to breathe shallowly
- Slow CT scan
 - Both PET and CT image motion blurred

Breath hold vs free breathing

Respiratory gated 4D PET/CT

Blue contour:
ITV from CT-MIP

Staff training

- Adequate training is important
- Include personnel from nuclear medicine and radiotherapy
- Patient instructions pivotal

“Whoa! *That* was a good one! Try it, Hobbs—just poke his brain right where my finger is!”

PET/CT use

- TVs should be delineated by an oncologist together with an experienced nuclear medicine physician
- Automated delineation techniques may be appropriate, subject to manual editing and visual confirmation
- Registration algorithms used should be validated; non-rigid algorithms should be used with caution.
- Ensure that there is a common understanding of QC requirements
- Transfer of DICOM data to TPS should be validated

PET/CT suggestions

- Design for use in RT at the department
- Set up team of nuclear medicine physician, oncologist, PET physicist, RT physicist, RTT
- Determine protocols (may vary with cancer diagnosis), e.g. use of CE-CT
- PET/CT-only ('direct') or PET-supplemented ('indirect') workflow
- If PET/CT at external department, more crosstalk and bilateral decisions

PET/CT suggestions

- Torso scan for staging
 - ‘Low-dose’ CT possible
- Limited longitudinal scan for TV delination
 - Particular attention to CE-CT / ‘high-dose’ CT, fixation
- Standardize set of image acquisition parameters and injected activity

PET/MR for RT

Deformable Image Registration (DIR)

- DIR still not in clinical use
- Small study in 5 H&N patients (Speight et al, Leeds, UK)
- Using MIRADA RTx (Oxford, UK) software
- Propagation of spheres & points to quantify plus visual assessment
- Qualitative evaluation sufficient following quantitative commissioning of DIR tool
- Inaccuracy in spine, register ROI in that region
- DIR improves use of diagnostic MRI

Diagnostic MRI in RT

2 stage process: Rigid & Deformable

Deformable Image Registration (DIR)

DTA and Clinician assessment for patient 1 out of shell

(left) Visual assessment of 'plausibility'
(right) results in one patient

Dedicated MR-Simulator

Positioning lasers

Wide bore

Flat table top
32 ch RF coil in bed

- 3.0 Tesla
- 45 mT/m, 200 T/m/s gradients
- Digital RF
- Dual transmitters
- 64 channel system
- Full suite of functional imaging

MR-Simulator

Requirement	Recommendation/Comment
System	1.5 T or 3.0 T wide bore (70 cm) scanner
Set-up	Flat table & immobilisation; utilise high channel RF coil arrays & intensity correction
Distortion	3D gradient correction; measure residual. High BW; Optimise shim where needed; B0 mapping still not widely available
Protocol	2D TSE & DIXON (\pm C) primary planning sequences; 3D important in specific cases (e.g. T2 MR-only, T1 SRS) Functional & motion assessment not standard
Resolution/ coverage	maximum 1mm or 1 pixel fat-water shift 2-3/0 mm slices (2D) standard; 4 mm functional (e.g. DWI) Single concatenation 3D isotropic as required 30 cm scan coverage

MRI in RT Position: H&N

Courtesy GE Healthcare Research

Extended SI coverage

- Combination of head, anterior and posterior (table) coils

MRI in RT Position: Body

Coil support vs compression
Preservation of skin contour vs
maximise SNR
PET-MR (right)-rigid set-up permits
attenuation correction

Rigid Registration

- Registration based on bones/markers/soft-tissue?
- Variability between scans/anatomy
- Variability between fusion
- Errors of 2-5 mm reported

Interest in MR-Only

Increase due to MR-PET (from 2010) and MRg (from 2013)

Edmund, J. M., & Nyholm, T. (2017). A review of substitute CT generation for MRI-only radiation therapy. *Radiation Oncology*, 12(1), 28.

Can we get rid of CT? ED Accuracy

2010 Jonsson

- Adequate bulk density sufficient $<1.6\%$ accuracy
looked at prostate head & even in lung with air cavity
- Large (15%) change in assigned density \Rightarrow modest 1-2% dose change

2016 Juha

- Dual bulk (water, bone) vs homogenous vs full conversion for brain & prostate
- Homogenous unacceptable errors in certain cases; bone and soft tissue essential; further heterogeneity improves accuracy
- Dual $<2\%$; heterogeneous model $<0.5\%$

- Reduce errors associated with MR-CT
- Simplify workflow & cost
- Remove CT scan- synthetic or substitute CT (sCT)
- Move towards MRg delivery systems and MR-PET
- Three main methods:
 - Bulk density (tissue class/segmentation)
 - Voxel based ('model learning')
 - Atlas based
- Hybrid approaches also exist
- Commercial solutions now available from several vendors

Typical MR-only Sequences

Generic name	Use/Comment
T2/T1	Conventional image contrasts. Has been used extensively in prostate Atlas methods.
DIXON	Images at specific echo times to generate 4 contrasts (in, out-phase, fat & water) in one scan.
UTE	With TE < 0.1 ms to generate positive signal in bone. Separates air & bone. Sometimes used as dual echo sequence.
TOF	Angiography scan to generate high blood signal. Distinguish vessels from bone in certain cases

2D or 3D?

Contiguous thin 2D T2-w FSE showing good contrast for RT planning

3D T2-w FSE showing better resolution and no motion issue

1. Bulk Density

Assign bulk density to tissue class(es)

- Advantages
 - No registration
 - Robust wrt abnormal anatomy
- Disadvantages
 - Accuracy depends on increasing classes
 - Manual contouring required
 - sDRR not realistic

Kim J, Garbarino K., et al. . Radiat Oncol (2015)

2. Voxel Based

Use a model or statistical learning to identify tissue components.

- Advantages

Fast, robust

- Disadvantages

Multiple sequences (or echoes) required

Generalisability

May require manual bone contours

Kapanen M. et al (2013)

Johansson et al Med Phys (2011)

Example: Dual calibration model (prostate)

Korhonen et al. 2014

- 1.5 T wide bore GE scanner
- MRI signal from Dixon in-phase MRI scan mapped to HU value
- Requires separate mapping models for bone and soft tissue regions (requires bone contouring)
- Method has been used clinically on prostate patients for MRI-only workflow
- n=200; 16 (8%) requiring additional CT

Korhonen, et al. 2014. *Med Phys* 41(1)

Results

Measure	Sequence(s)	Mask Air	Result
Bone Surface Distance between CT and sCT	PETRA	N/A	1.34 mm
	UTE (4ms & 40 μ s)	N/A	1.89 mm
Mean HU error between CT and sCT	PETRA	Not Masked	-0.01 \pm 22.84
	UTE (4ms & 40 μ s)		1.52 \pm 39.13
	T2 and PETRA		-0.26 \pm 18.86
	PETRA	Masked	15.59 \pm 180.71
	UTE (4ms & 40 μ s)		102.35 \pm 332.48
	T2 and PETRA		-12.63 \pm 101.77

HU generation from a single 3-class sequence (bone, air, soft-tissue) versus 4-class (bone, air, fat, muscle)

3. Atlas Based

Use image registration to map previous MR-CT scans to a new MRI

- Advantages

Robust to image variation

Can be used to generate autocontours

- Disadvantages

Can be slow

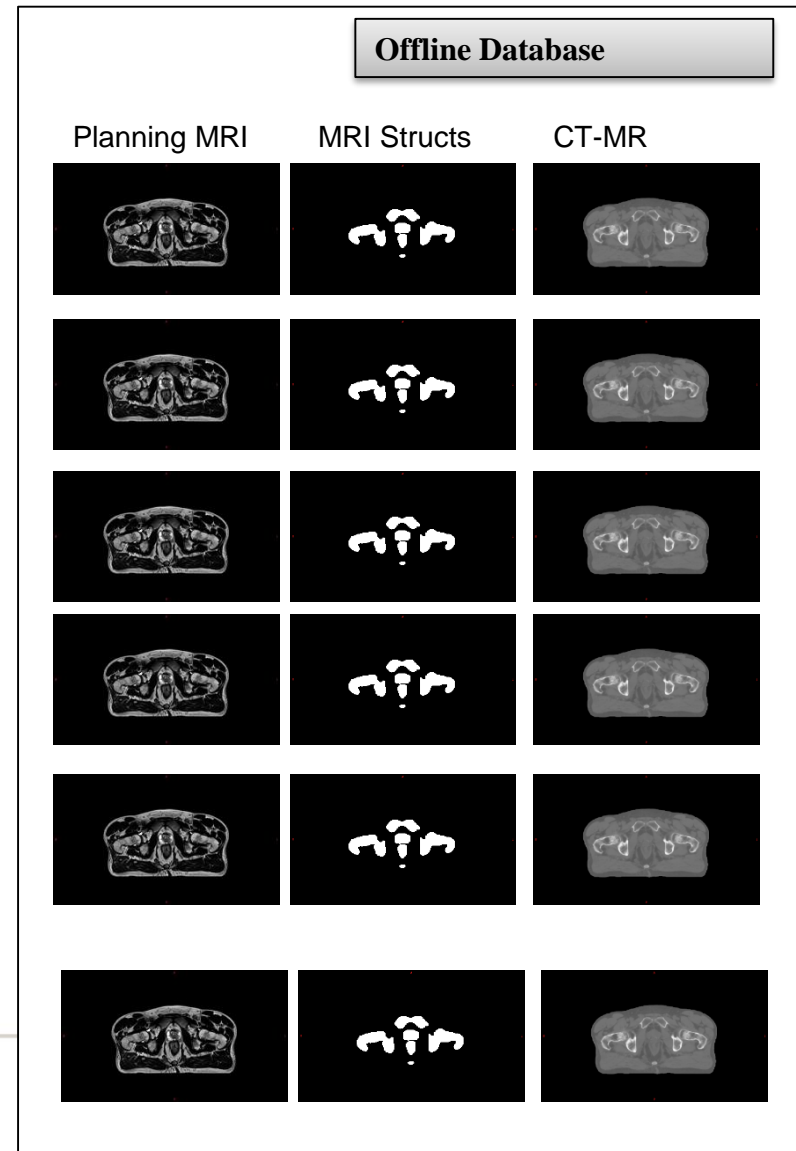

Anatomy specific & abnormalities cause problems

sCT: Multi-Patient Atlas approach

Construct offline database

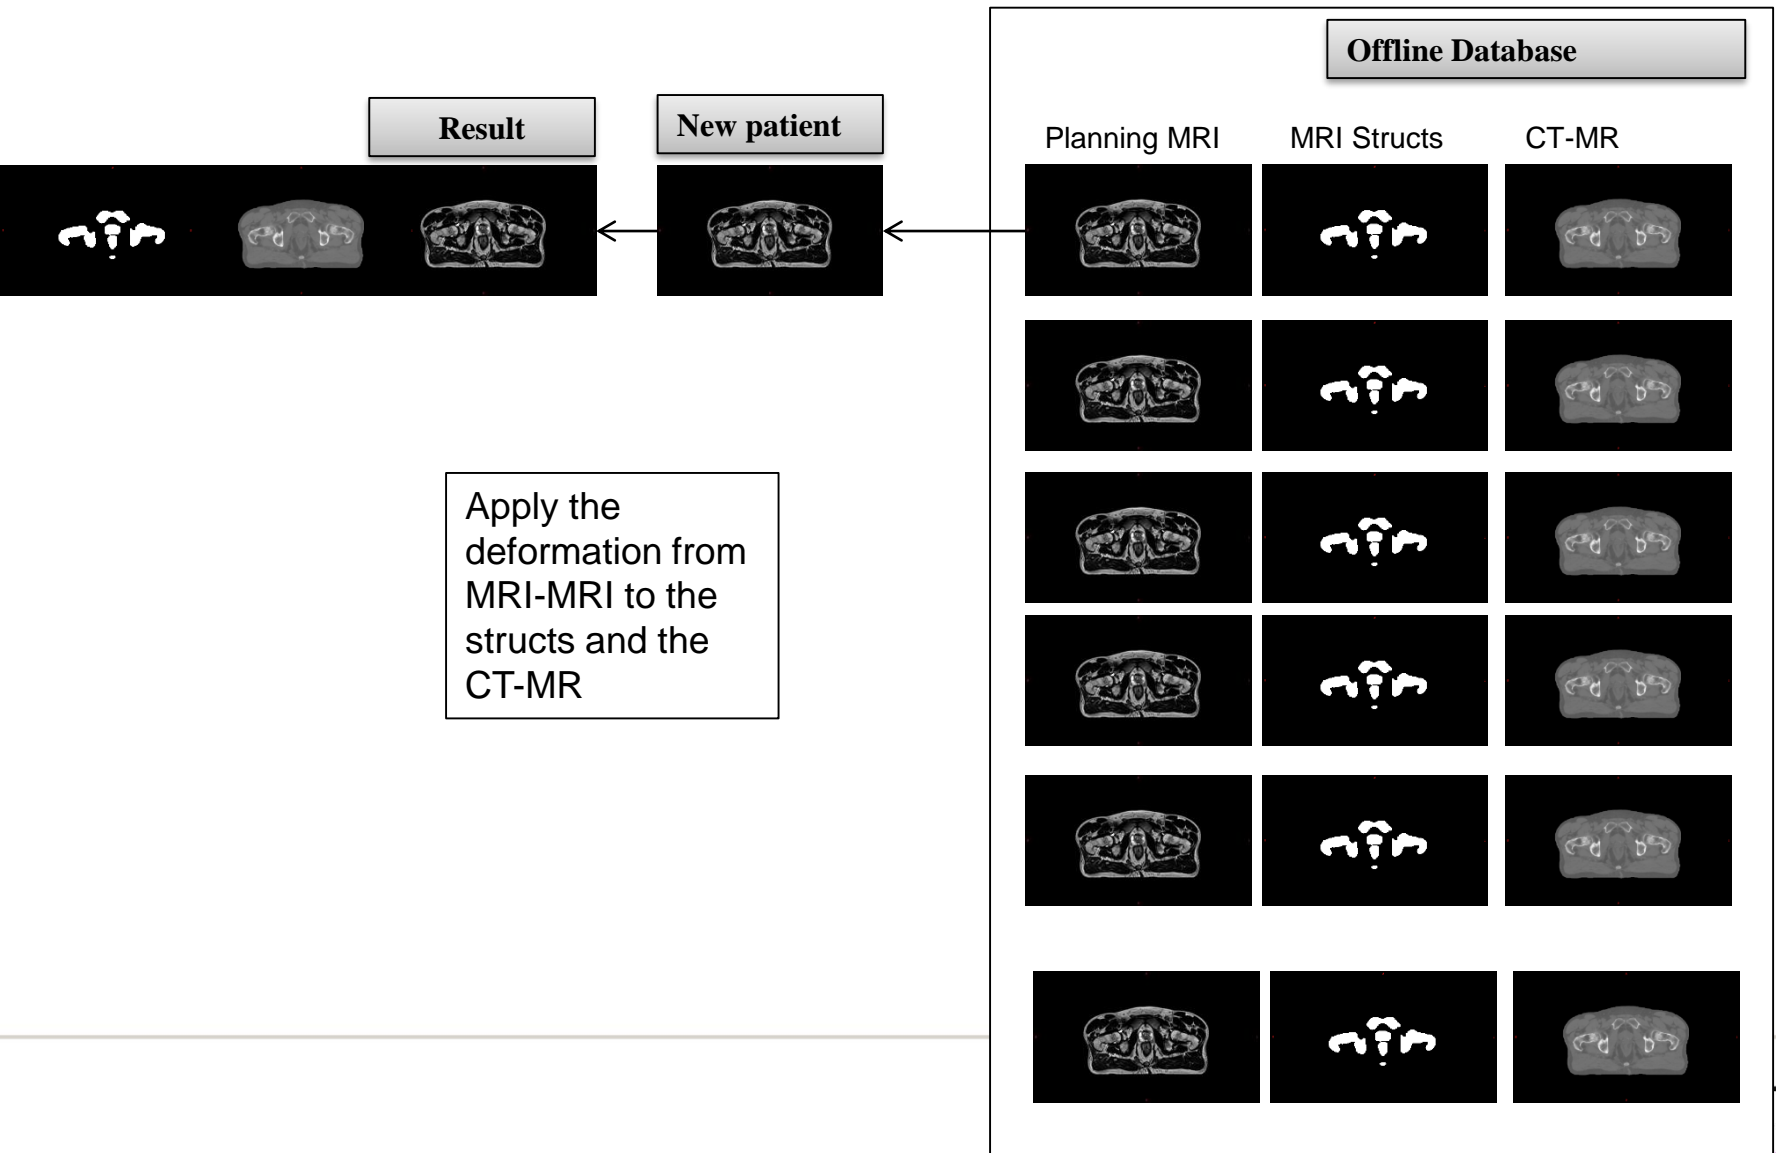

Rigid and
structure guided
NR MR-CT
database

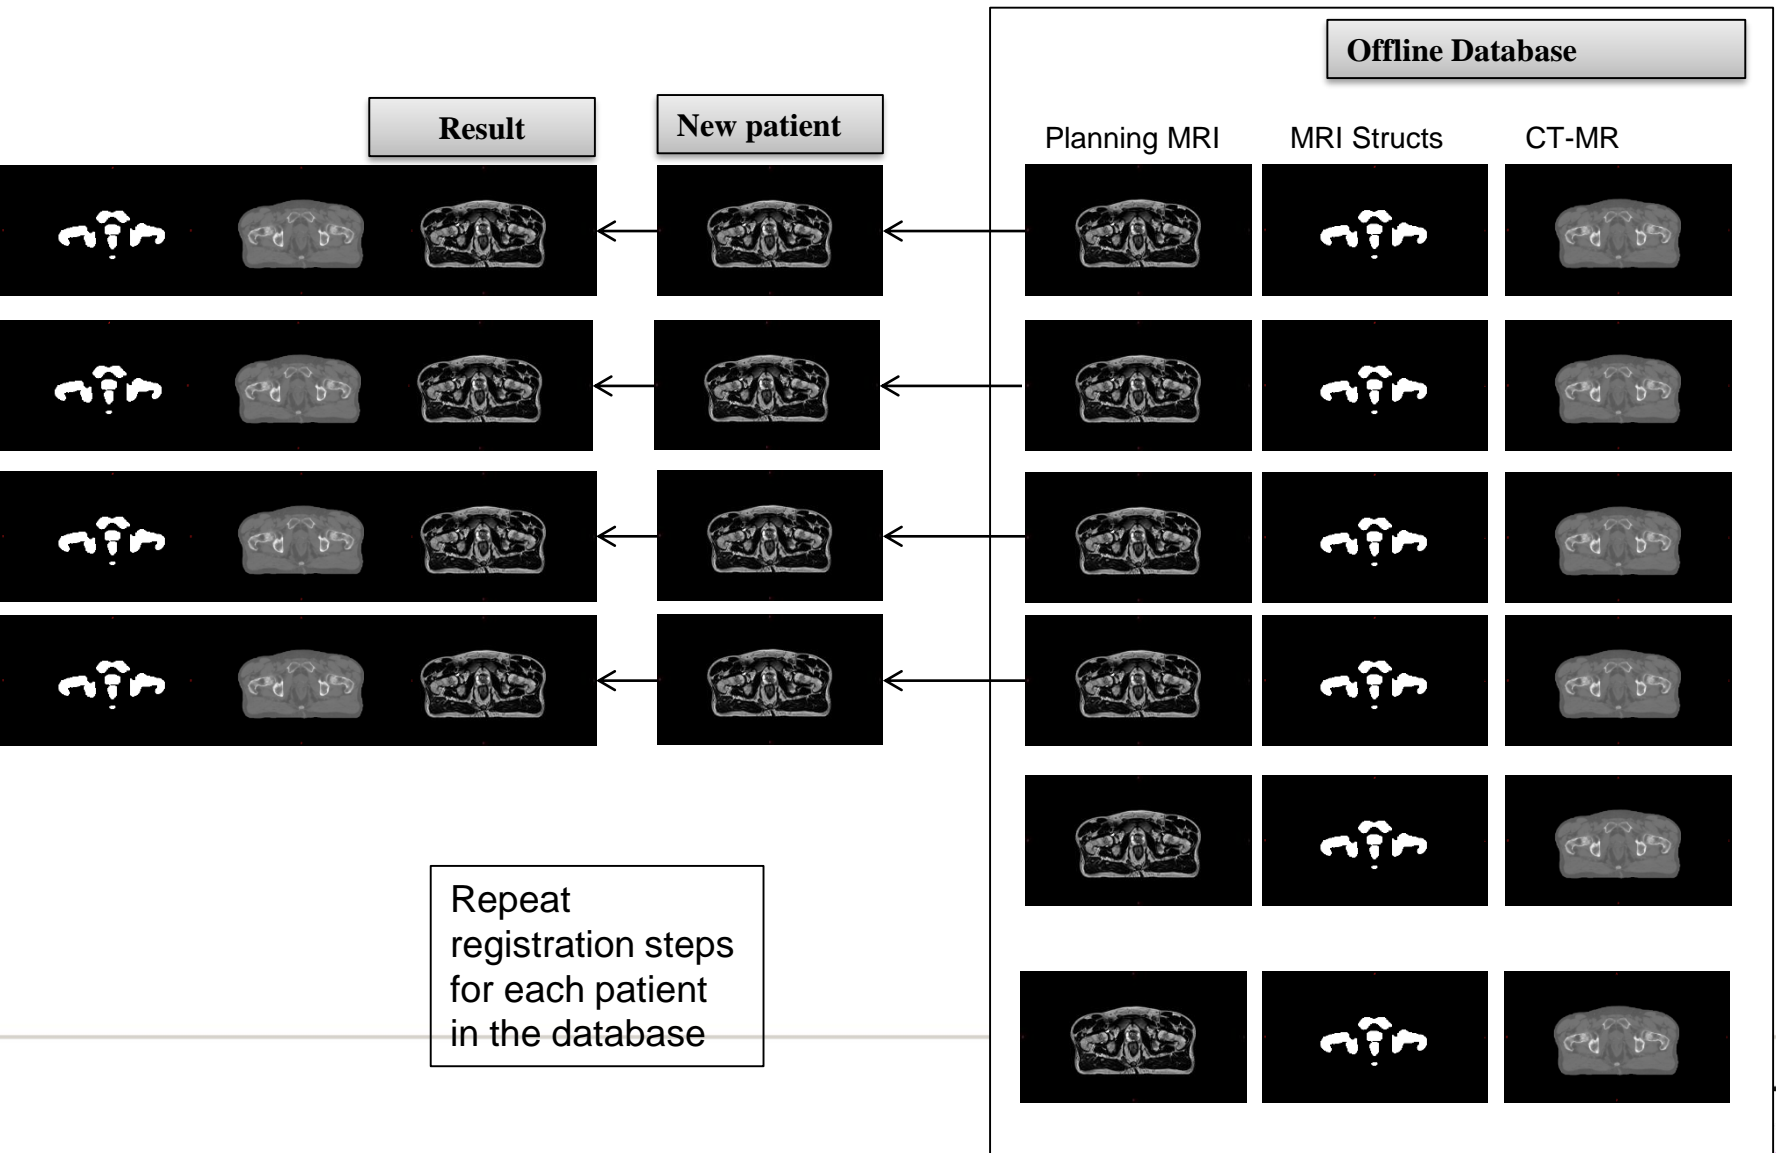

sCT: Multi-Patient Atlas approach

sCT: Multi-Patient Atlas approach

sCT: Multi-Patient Atlas approach

sCT: Multi-Patient Atlas approach

The CT images are then combined to generate a sCT for the current patient

Robustness

Variations in MRI protocol did not produce significant dosimetric changes in sCT.

Commercial Solutions (I)

MRCAT (Philips)

- Prostate
- Uses DIXON in-phase SI and bone atlas for bone shape/HU
- Uses DIXON (water and fat) to assign HU to soft-tissues

N Tyagi et al 2017 Phys. Med. Biol. 62 2961.

MRIPlanner (Spectronic Medical, Sweden)

- See *Siversson et al Med. Phys 2015*
- Prostate
- Uses Statistical Decomposition Algorithm along with template Atlas
- Atlas of 15 patients
- T2-w SPACE or multislice 2D FSE was used similar results
- Possible slight worse with 3T (patient distortion lower BW)
- Speight et al showed similar results in other male pelvic sites

T₂-w MRI to the left, sCT generated using MRIPlanner (top right) & original CT (bottom right)

Commercial Solutions (III)

Siemens Healthcare (WIP)

- See *Hsu et al Phys Med Biol 2013*
- Brain
- Probabilistic approach using fuzzy c-means clustering with spatial constraint
- Requires input of 5 separate image series (6 contrasts)
- UTE & TOF used as masks

T_1 , T_2 , Dixon used in soft-tissue classifiers
 UTE1 & TOF used as pre-processing masks

Multi-Centre Trials

MR-Only Prostate External Radiotherapy (OPERA) trial

Persson et al 2017

4 Centres different scanners/field strength

170 prostate patients; whole FOV T2-w scan high BW

Commercial software (Spectronic Medical)

Dose 0.3%, gamma 99.97% PTV 2/2

Slight contour differences between CT & MR- density correction improves this (air/water etc)

High precision Prostate Substitute CT External beam Radiotherapy (HIPSTER)

2 Australian Centres (Newcastle & Liverpool)

Phase I roll-out & QA stage

3D SPACE sequence & in-house (Atlas based) software

Trial currently in progress

Validation of sCT

A number of performance metrics are used:

Dose difference

- Percentage difference at prescription points, isocentre or DVH points

MAE

- Voxel-wise mean difference in HU; Values sensitive to inclusion of more soft-tissue or air

Overlap (DSC or MASD) in bone

- Dice similarity coefficient or Mean Hausendorf Distance

Gamma index

- Displayed as a map; combined distance to agreement and dose difference

Validation of sCT

*Typical values observed.

Dose difference

- Percentage difference at prescription points, isocentre or DVH points

0.3-2.5%

MAE

- Voxel-wise mean difference in HU; Values sensitive to inclusion of more soft-tissue or air

80-200 HU (brain) & 40 HU (prostate)

Overlap (DSC or MASD) in bone

- Dice similarity coefficient or Mean Hausendorf Distance

$0.5 < DSC < 0.95$

Gamma index

- Displayed as a map; combined distance to agreement and dose difference

2% & 2mm > 98%

*Edmund, J. M., & Nyholm, T. (2017).

MRg-RT: Current Status

System	Radiation type	Field strength	Magnet type	Orientation	1 st Patient Tx
Elekta Unity	6 MV	1.5 T	Closed supercon	Perpendicular	May 2017
Australian	4 & 6 MV	1.0 T	Split supercon	Inline (and perp.)	Early 2018
Alberta	6 MV	0.5 T	High temp supercon with steel yoke	Inline	Not known
Viewray	⁶⁰ Co or 6 MV	0.35 T	Split resistive	Perpendicular	July 2017 (Linac) February 2014 (Co)

MRg-RT

- 0.35 T MRI integrated with 3 Co-60 heads
- Integrated planning system Monte Carlo dose calculation
- Still use CT initially
- Use of manual bulk density override
- Whole exam typical 1 hour

Summary

- MR-CT planning requires treatment position scans
- Diagnostic MRI possible with DIR
- Three main methods for sCT: tissue class, learning and atlas with some overlap
 - Most sCT papers focus on brain with MAE ~130 HU
 - Prostate MAE ~40 HU
- Commercial solutions for prostate include: MRCAT (Phillips), MRIPlanner (Spectronic) & research prototype (Siemens)
- Need for standardisation in approach, validation & implementation
- Further clinical trials

Derived Parameters

Blood flow (BF): volume of contrast media entering the voxel in one unit of time (in mL/min), normalized by one unit of volume (typically 100 mL). The unit of measure is

$$\frac{\text{mL}}{\text{min} \cdot 100 \text{ mL}}$$

Derived Parameters

Blood volume (BV): volume of contrast media allowable in the voxel (mL), normalized by one unit of volume (typically 100 mL).

Unit of measure: $\frac{\text{mL}}{100 \text{ mL}}$

Derived Parameters

Permeability-surface area product (PS): volume of contrast media exiting the intravascular space and entering the extravascular-extracellular space (EES) in one unit of time, normalized by one unit of volume.

Unit of measure:

$$\frac{\text{mL}}{\text{min} \cdot 100 \text{ mL}}$$

Derived Parameters

Other parameters:

- Extraction fraction (E): average volume of contrast media allowable in the extravascular-extracellular space (EES):

$$E = 1 - e^{-\frac{PS}{BF}} \quad \text{if } BF \gg PS \text{ (like for tumors) we can write:}$$

$$E \simeq \frac{PS}{BF}, \quad \text{dimensionless.}$$

- k^{trans} : constant of transfer from intravascular space to EES. It is closely related to PS, and often given instead of it, under the assumption $BF \gg PS$.

$$k^{\text{trans}} = E \cdot BF \simeq PS$$

$$\text{Unit of measure} \quad \frac{\text{mL}}{\text{min} \cdot 100 \text{ mL}}$$

Derived Parameters

- Mean transit time (MTT): average time needed from one single molecule of contrast media to transit through the voxel.
- Time to peak (TTP): time of maximum concentration in the voxel.
- Time to start (TTS): time of contrast media arrival.

Perfusion Models Introduction

At the basis of each model there is a simple and intuitive formulation made by Fick:

$$c_t(t) = \text{BF}_{\text{in}} \int_0^t c_a(t) dt - \text{BF}_{\text{out}} \int_0^t c_v(t) dt$$

Since the outflow from tissue to the venous system is of less clinical interest, it is normally not investigated. It is relatively safe to assume $\text{BF}_{\text{in}} = \text{BF}_{\text{out}} = \text{BF}$

Perfusion Models Introduction

Fick's principle becomes:

$$c_t(t) = \text{BF} \int_0^t (c_a(t) - c_v(t)) dt$$

- Same AIF for each voxel.
- Different assumptions on vein.

One Compartment Models

Maximum Slope

$$c_t(t) = \text{BF} \int_0^t (c_a(t) - c_v(t)) dt$$

Maximum slope model simply assumes

$$c_v(t) = 0$$

$$c_t(t) = \text{BF} \int_0^t c_a(t) dt \quad \Rightarrow \quad \frac{d}{dt} c_t(t) = \text{BF} c_a(t) \quad \Rightarrow \quad \left. \frac{d}{dt} c_t(t) \right|_{\max} = \text{BF} c_a(t) \Big|_{\max}$$

According to this model, the maximum slope of tissue TAC occur at the same time of arterial peak, and their ratio gives the blood flow.

$$\text{BF} = \frac{\left. \frac{d}{dt} c_t(t) \right|_{\max}}{c_a(t) \Big|_{\max}}$$

One Compartment Models

Maximum Slope

Correct acquisition

- Few points used.
- Empty vein assumption.
- Robust to noise and artifacts.
- Short times.
- High sampling time.
- Not all parameters are calculated.

One Compartment Models

Maximum Slope

Incorrect acquisition

- Few points used.
- Empty vein assumption.
- Robust to noise and artifacts.
- Short times.
- High sampling time.
- Not all parameters are calculated.

Two Compartments Models Deconvolution

$$c_t(t) = \text{BF} \int_0^t (c_a(t) - c_v(t)) dt$$

The deconvolution model assumes $c_v(t) = p(t) * c_a(t)$ where

$p(t)$ is the probability that a molecule of contrast takes time t to transit through the tissue voxel.

Now we can write:

$$c_t(t) = \text{BF} \int_0^t (c_a(t) - c_v(t)) dt = \text{BF} \int_0^t (c_a(t) - p(t) * c_a(t)) dt = \text{BF} c_a(t) * \left(1 - \int_0^t p(t) dt\right)$$

$\int_0^t p(t) dt$ is the probability that a molecule of contrast is already in the vein at time t .

$1 - \int_0^t p(t) dt$ is the probability that a molecule of contrast is still in the tissue voxel at time t . This quantity is also called IRF (impulse response function).

Two Compartments Models Deconvolution

$$c_t(t) = \text{BF} \int_0^t (c_a(t) - c_v(t)) dt = \text{BF} c_a(t) * \text{IRF}(t)$$

Two Compartments Models Deconvolution

$$c_t(t) = \text{BF} \int_0^t (c_a(t) - c_v(t)) dt = \text{BF} c_a(t) * \text{IRF}(t)$$

Deconvolving the tissue TAC with the arterial input function, would result in a BF-scaled IRF:

There are different ways to perform the deconvolution step, and different assumptions that can be made to model the obtained IRF and to calculate different parameters.

Two Compartments Models Deconvolution

In matrix form, we can write:

$$\begin{pmatrix} c_v(t_1) \\ c_v(t_2) \\ \vdots \\ c_v(t_T) \end{pmatrix} = \text{BF} \cdot \begin{pmatrix} c_a(t_1) & 0 & 0 & 0 \\ c_a(t_2) & c_a(t_1) & \cdots & 0 \\ \vdots & \vdots & \ddots & 0 \\ c_a(t_T) & c_a(t_{T-1}) & \cdots & c_a(t_1) \end{pmatrix} \cdot \begin{pmatrix} \text{IRF}(t_1) \\ \text{IRF}(t_2) \\ \vdots \\ \text{IRF}(T) \end{pmatrix}$$

The matrix of the AIF must be inverted to calculate the BF-scaled IRF. Normally, deconvolution is performed via singular values decomposition (SVD).

Two Compartments Models Deconvolution

- Different assumptions on IRF shape.

- Parametric deconvolution.
- scan times are too long, E is not constant.

Two Compartments Models Deconvolution

Important considerations on the deconvolution model:

- More robust to suboptimal injection.
- Different assumptions and different guidelines for each vendor.
- High sampling time.
- Dose, coverage, sampling time tradeoff.
- Entire TAC is used for each voxel.
- Dose reduction strategies.
- All the most important parameters are calculated.

Maximum Slope vs. Deconvolution

Fick principle:

$$c_t(t) = \text{BF} \int_0^t (c_a(t) - c_v(t)) dt$$

Maximum slope model:

$$c_t(t) = \text{BF} \int_0^t c_a(t) dt$$

Deconvolution model:

$$c_t(t) = \text{BF} c_a(t) * \text{IRF}$$

Two Compartments Models

Tofts model.

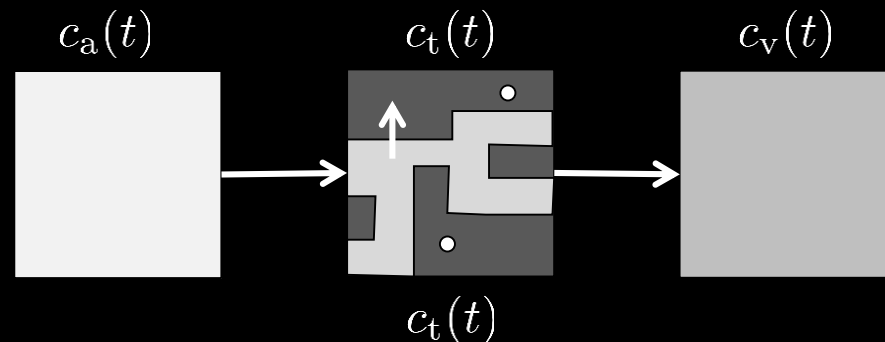

Patlak model.

Two Compartments Models

Tofts Model

Capillaries concentration is assumed to be equal to artery concentration, which means we are in an equilibrium phase. For these models late data are used, and the exchange of contrast from arteries to capillaries (BF) cannot be calculated.

Deconvolution model:

Tofts model:

Two Compartments Models

Tofts Model

$$c_t(t) = v_i c_a(t) + k^{\text{trans}} \int_0^t c_a(t) e^{-k^{\text{ep}}(t-t_0)} dt$$

The Tofts model considers the concentration in one voxel as a weighted sum of the intravascular component and the extravascular-extracellular component. The three open parameters are:

- v_e, v_i Extra- and intravascular volume
- k^{trans} Transfer function from capillaries to EES
- k^{ep} Transfer function from EES to capillaries

Where it holds

$$k^{\text{ep}} = \frac{k^{\text{trans}}}{v_e}$$

Two Compartments Models

Patlak Model

Patlak model is a simplification of Tofts model.

It assumes no backflow is occurring:

$$c_t(t) = v_i c_a(t) + k^{\text{trans}} \int_0^t c_a(t) dt$$

If we normalize by the arterial input function:

$$\frac{c_t(t)}{c_a(t)} = v_i + k^{\text{trans}} \frac{\int_0^t c_a(t) dt}{c_a(t)}$$

it becomes a linear fitting, the slope being k^{trans} and the intercept v_i .

Two Compartments Models

Patlak Model

Some considerations on the Patlak model:

- Late data.
- Few data.
- Limits of the “no-backflow” assumption.
- Sometimes used in combination with other models.

Index of Contents

- **Introduction:**

 - One compartment models – maximum slope
 - Two compartments models – deconvolution, Toft, Patlak
- **Clinical applications and optimization:**
 - **Oncology: liver, lung, other organs**
 - Neurology: brain perfusion for stroke
 - Myocardial perfusion

General Workflow

- Topogram.
- Planning.
- Test bolus. For example: 10 mL contrast @ 5 or 6 mL/s + 50 mL saline @ same flow.
- Set perfusion scan parameters. For example: 45 mL contrast @ 5 or 6 mL/s + 50 mL saline @ same flow
- **Set delay of perfusion scan.**
- Set injection parameters.

Oncology: Liver

Liver model:

dual maximum lobe model.

Liver – Example

Oncology: Liver

Some useful parameters that can be obtained are:

- ALP (arterial liver perfusion): arterial BF
- PLP (portal liver perfusion): portal BF
- HPI (hepatic index) = $ALP / (ALP + PLP)$

So far no dual input deconvolution models have been included in vendors solution.

Liver – Example (Unfiltered)

Liver – Example (Filtered)

Oncology: Liver

Practical important considerations:

- Breath hold.
- High flow injection, short injection time.
- Pre-warm contrast media.
- Spleen or kidney scanned (if hepatic index is needed).

Oncology: Liver

- One example on Siemens machine (Somatom Force):
 - 80 kV
 - 110 mAs
 - 176 mm coverage
 - 20x1.5 s + 5x3 s
 - Injection 50 mL contrast @ 5 mL/s + 40 mL saline @ 5 mL/s

 - 54.62 mGy
 - 1031.4 mGy·cm
 - 15.4 mSv

Oncology: Lung

- Two inputs. Decide upfront.
- Limit motion.

 - One compartment models – maximum slope
 - Two compartments models – deconvolution, Toft, Patlak
- **Clinical applications and optimization:**
 - Oncology: liver, lung, other organs
 - **Neurology: brain perfusion for stroke**
 - Myocardial perfusion

Neurology: Brain Perfusion for Stroke

- Small signal enhancement.
- Small and rigid motion.
- High sampling time.
- Injection time should be not longer than 8 s.
- Patlak model does not really apply in this case (unless there is a tumor) for two main reasons:
 - The presence of blood-brain barrier prevents the blood from going to the EES.
 - Permeability is BF-limited.

Brain – Example (Unfiltered)

Brain – Example (Filtered)

Index of Contents

 - Two compartments models – deconvolution, Toft, Patlak
- **Clinical applications and optimization:**
 - Oncology: liver, lung, other organs
 - Neurology: brain perfusion for stroke
 - **Myocardial perfusion**

Myocardial Perfusion

- Many limitations:
 - Motion. Synchronization with ECG. Breath-hold.
 - Must be done in stress conditions. High HR. Increase of motion. need to increase acquisition time. Systolic phase.
 - Synchronization with ECG seriously limits sampling time.
 - If a big coverage (16 cm) is not available, the shuttle mode must be used: sampling time further reduced by half.
 - BF is really fast in the myocardium ($\sim 300 \text{ mL} / \text{min} \cdot 100 \text{ mL}$). Normally such values cannot easily be obtained with such low temporal sampling (~ 3 to 4 s), thus some models derived from Tofts are normally employed to calculate PS and backflow, capillaries volume etc. BF is then calculated with MS models.
 - Backflow occurs very quickly, so models assuming no backflow (like Patlak) are not suitable to this application.
 - Beam hardening artifacts in myocardium (limitation on how low the kV can be set).

General Principle

Both in DE and CTP, the software will provide numbers. There is no way to know if these numbers are correct or not, the only possible thing to do is knowing upfront what to do in order to have reliable results, by combining:

- Clinical knowledge of physiological principles.
- Background knowledge of algorithms assumptions.
- Physical knowledge of CT and of the algorithms.
- Experience.

Imaging For Physicists

Artifacts 2

Uulke van der Heide

Many reasons for artifacts

Erroneous sampling of k-space

- Aliasing
- Ringing

Many reasons for artifacts

- Magnetic field errors
 - Gradient artifacts
 - Susceptibility artifacts
 - Water-fat shift
- Geometrical artifacts show up in a particular direction

$$x_1 = x + \frac{\Delta B_0(x, y, z)}{G_x} + \frac{\Delta B_{G_x}(x, y, z)}{G_x}$$

$$y_1 = y + \frac{\Delta B_{G_y}}{G_y}$$

Many reasons for artifacts

- Field distortions lead to signal loss in gradient echo sequences due to dephasing
- Dephasing is proportional to echo time

Outline lecture 2

- Measurements for characterizing geometrical accuracy
 - Phantom design
 - Characterizing gradient errors
- Examples
- Practical consequences
- Summary

Homogeneity of the main magnetic field

e.g. uniformity in diameter of spherical volume $DSV_{40\text{cm}} = 0.2$ ppm

(at 1.5 T):
 $0.2 \times 63.87 \text{ MHz} = \underline{12.8 \text{ Hz}}$

- Magnet is shimmed at installation- additional (dynamic) shimming may be required

Gradient fields

Linear changes in B_0 in each orthogonal direction

Correction of imperfect B_0 and gradient fields

Image distortion and correction on a 0.23 T open MRI scanner

Mah et al. 2002 Int. J. Radiat. Oncol. Biol. Phys. 53 (3), 757-765

Phantoms

Vermandel 2014

Commercial: Quasar, Modus

Torfeh 2015

Walker 2015

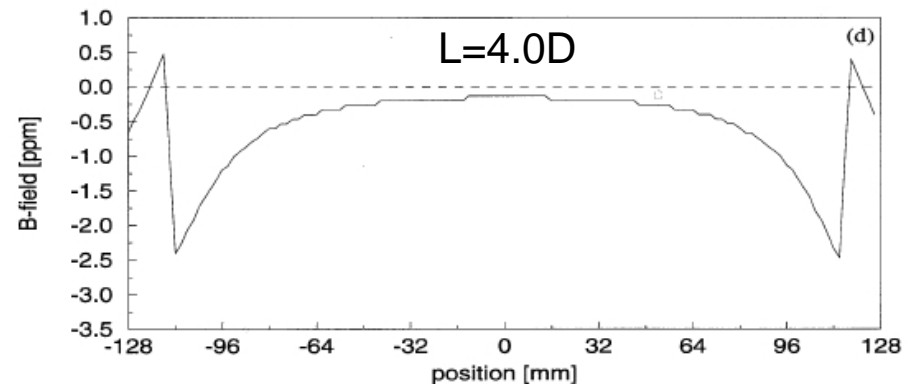

Vendor: GE

Design of a phantom for field-error measurements

A schematic overview of the cylinder with respect to B_0 (D is the diameter and L the length).

- Use tubes that are long relative to their diameter

Cross-section of calculated B-field in ppm along the cylinder axis

Setup of experiments to characterize magnetic field inhomogeneity and gradient non-linearity

Experiment 1:

- phase encoding along y
- Frequency encoding along x

$$x_1 = x + \frac{\Delta B_0(x, y, z)}{G_x} + \frac{\Delta B_{G_x}(x, y, z)}{G_x}$$
$$y_1 = y + \frac{\Delta B_{G_y}}{G_y}$$

Experiment 2:

- phase encoding along x
- Frequency encoding along y

$$x_2 = x + \frac{\Delta B_{G_x}}{G_x}$$
$$y_2 = y + \frac{\Delta B_0(x, y, z)}{G_y} + \frac{\Delta B_{G_y}(x, y, z)}{G_y}$$

Distortion mapping

Gradient reversal and subtraction

Frequency encoding:

$$x' = x + \frac{\Delta B_0}{G_x} + \frac{\Delta B_{G_x}}{G_x}$$

Phase encoding:

$$y' = y + \frac{\Delta B_{G_y}}{G_y}$$

Residual gradient

B₀ component

Continuous or stepped table measurement

Restrict volume

Move table through isocentre

Gradient corrections

- 3D correction introduced circa 2006 and adopted by vendors

System measurements

Paper	Year	Phantom size	System	Error
Vermandel	2014	(Head) 24 cm	Various 3.0T & 1.5T	Mean 1 mm uncorrected, 0.5 mm corrected
Glide-Hurst	2014	2500 points, 40 x 40 x 40 cm	1.0T Panorama	24% > 3mm at 150-200 mm radius
Balter	2014	4689 points, 46 x 35 x 17 cm	3.0T Skyra	<1 mm at 17 cm radius (60 mm z)
Walker	2015	5830 points, 50 x 38 x 51 cm	3.0T Skyra	250 mm radial, 200 mm z 29-87% of phantom <2mm
Torfeh	2015	357 rods, 40 x 40 x 19 cm	1.5T GE 450w	95% <1mm at 200 mm radial

Characterizing geometrical distortions

- Currently no standard phantom/QA
- Good resolution of points
- Large coverage (x,y,z)
- Flexible design (weight)
- CT compatible
- Rods v points (susceptibility)
- Positive/negative signal material
- Semi-automated measurements

Magnetic susceptibility

Paramagnetic
 $\chi > 0$

ΔB_0

Diamagnetic
 $\chi < 0$

Local field
variation ΔB_0
superimposes
linear gradient

- Off-resonance effects: distortion and signal variations (voids & hyperintensity)
- Ferromagnetic material ($\chi \gg 0$) has severe effect

Susceptibility artifacts

- Markers around head

Susceptibility artifacts

- Markers without head

Susceptibility artifacts

- Overlay of images

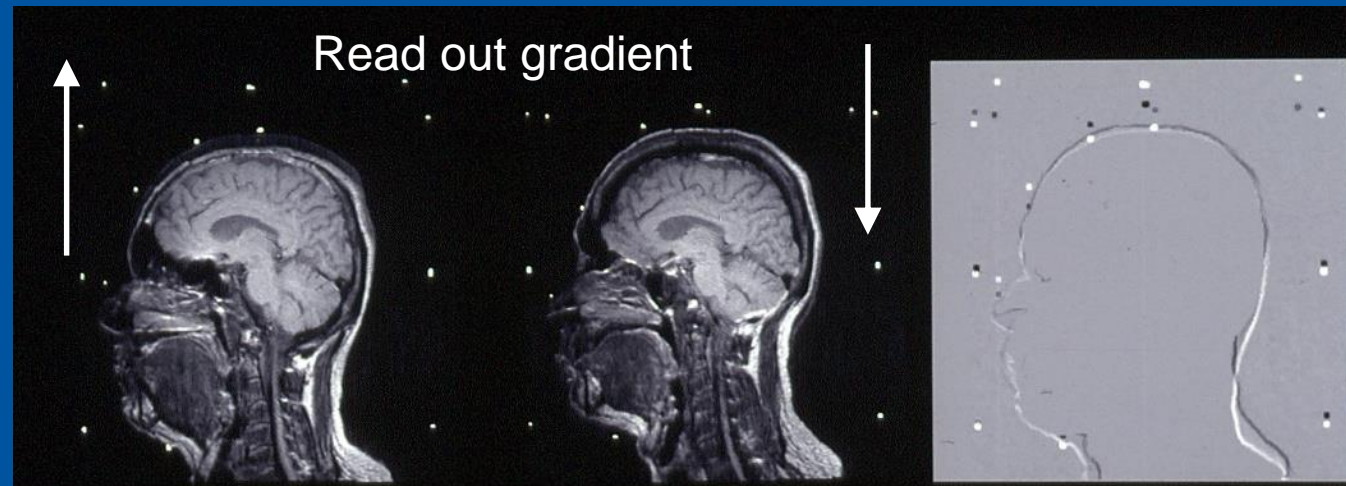

Calculation of field distortions

Susceptibility artifact in read-out direction

$$x_1 = x + \frac{\Delta B_0(x, y, z)}{G_x} + \frac{\Delta B_{G_x}(x, y, z)}{G_x}$$

B0 mapping

Magnitude

Phase (TE1)

Phase (TE2)

Difference

$$\Delta B_0 = \frac{\Delta\phi}{\gamma\Delta TE}$$

Maximum 34 Hz (0.3 ppm)

Maximum
203 Hz (1.6
ppm @ 3T)

- Air/tissue interfaces problematic
- Dynamic & HO shimming
- May be measured/corrected:
 - Image at two different TEs
 - Reconstruct phase difference
- Bhagwandien measured -5 to +6ppm i.e. nearly twice WFS

B0 mapping

Male volunteer. Notice B_0 variations near the rectum due to susceptibility effects of rectal gas

Such a map can be used to calculate the distortion of the image, and in some cases correct for it

Examples of artifacts

- Susceptibility artifacts
- Water-fat shift
- Motion
- bSSFP artifacts (bTFE, bFFE, trueFISP)
- EPI artifacts

Example from clinical practice. What is wrong?

- MRI exam of patient with cervical cancer
- T2-SE sequences shows large area with signal loss
- T1w-THRIVE sequence shows dark ring

CT scan of same patient

- No obvious metal
- However: a small ferro-magnetic button in her clothes
- Solution: remove metal

Patient with hip prosthesis

- A metal hip prosthesis (titanium)
- Verified that it is safe for the patient
- Big artifact on bSSFP sequence

Patient with hip prosthesis

- The T_1 -SE sequence and T_2 -TSE sequence show a void at the location of the hip, but minimal distortions

Susceptibility artifact

Artifact:

- Geometrical distortions
- Signal loss

What to do about it:

- Avoid metal, as much as you can
- Minimize pockets of air if possible
- maximize band-width (maximize gradient strength)
- Avoid GE sequences, use SE
- Use short echo times

Electron shielding different between molecules

$$B' = B \times (1 - \sigma)$$

Water-fat shift (WFS) = 220 Hz at 1.5 T

- Produces characteristic signal misregistration
- Assign enough 'Hz' across each pixel..increase BW

Water-fat shift

Magnetic field at the nucleus depends on magnetic shielding of surrounding electron clouds, depends on molecular environment

example:

resonant frequencies of protons in fat and water differ by 220 Hz

220 Hz = 3.4 ppm at 1.5 T

$3.4 \cdot 10^{-6} \cdot 1.5\text{T} = 5.1 \mu\text{T}$ at 1.5 T

$= 5.1 \mu\text{T} / 3 \text{ mT/m} = 1.7 \text{ mm}$ at 1.5 T and read out gradient 3 mT/m

- artifact
 - increases with B_0
 - decreases with gradient strength

Impact of band width in read-out direction (water-fat shift)

Spin echo

Water-fat shift:

5 pixels

4 pixels

2 pixel

1 pixel

- Susceptibility artifact occurs in read-out direction
- Gradient echo shows additional dephasing

Water-fat shift

Water-fat shift ≈ 9 mm
Contour distortions
marker position error

Distortions due to ΔB_0 (water fat shift, susceptibility) can be reduced to < 1 mm by increasing gradient strength, However: gradient errors remain!

Water-fat shift

Artifact:

- Geometrical distortions
- Signal loss

What to do about it:

- Maximize band-width (maximize gradient strength)
- Fat suppression

Question: motion artifacts

- Motion of a patient in the MRI scanner results in an artifact. What is the appearance of this artifact?
 1. Blurring of the image in each slice
 2. Ghost images in each slice, overlaying the 'true' image
 3. Shifts between the slices

Motion of a patient in the MRI scanner results in an artifact. What is the appearance of this artifact?

1. Blurring of the image in each slice
2. Ghost images in each slice, overlaying the 'true' image
3. Shifts between the slices

Motion artifacts

Ghost images

- Interference at periodical intervals along phase encoding axis
- A small motion may result in large offsets

Motion artifacts

- Motion artifacts propagate mainly in the phase-encoding direction. Motion between phase encoding steps will corrupt the phase-encoding, resulting in ghosts
- Signal sampling in the read-out direction is usually faster than physiological motion and may produce only some spatial blurring

What to do about it?

- Fixation
 - Breath hold
- Fast imaging, cine MRI
- Respiratory gating, cardiac gating etc.
- Navigators, Propeller/MultiVane

Motion correction with a Propeller sequence

- Sample a set of lines in k-space repeatedly at a different orientation
 - The central part is sampled each time, allowing for a phase correction of the signal
 - The outer part of k-space is sampled only by one of the vanes

Propeller sequence: Eye movement

- The MultiVane sequence in a Philips 3T achieva scanner reduces the ghosting artifact around the eyes
- Near blood vessels 'streak' artifacts show up, due to undersampling of the outer part of k-space

bSSFP artifact

- Balanced Steady State Free Precession

also known as:

- bTFE, bFFE (Philips)
 - trueFISP (Siemens)
 - FIESTA (GE)
- Steady state depends on T_1 and T_2
 - Spins from many excitations create a steady state of precessing spins
 - B0 distortions (susceptibility) result in spins that are off-resonance and don't see the RF pulses. Thus they don't produce a signal

bSSFP artifacts at rectum prostate interface

bSSFP artifact

Artifact:

- A periodic pattern of dark bands in the image

What to do about it:

- Avoid metal, as much as you can
- Minimize pockets of air if possible
- Optimize shimming
- Change the center frequency f_0 (multiple series with shifted f_0)

EPI artifacts

- Very fast switching of gradients because all phase-encoding is done within one read-out
- A very narrow band width is used to collect the data rapidly (example BW = 42 Hz per pixel)
- Therefore very sensitive to B_0 distortions

EPI artifact

Artifact:

- Geometrical distortion

What to do about it:

- Optimize shimming
- Use multi-shot EPI, rather than single shot

Geometrical artifacts

Artifact	axis	remedy
Fold-over (aliasing)	phase encoding	increase FOV
Ringling (truncation)	both	reduce voxel size
Susceptibility	read-out	increase BW
Water-fat shift	read-out	increase BW
Motion (ghosting)	phase encoding	reduce motion gating fast scanning

Practical consequences

- The geometrical accuracy of MR images tends to be worse towards the edges of the field of view
- Field distortions due to susceptibility differences are large near interfaces (body contour, air pockets)
- Devices used during interventions (brachytherapy) make cause artifacts

Practical consequences

(a)

(b)

Largest distortions at the edges of the MR bore

Markers on the skin not reliable as reference for beam setup

Distortions depend on material, shape and orientation

Summary 1

- Many reasons exist for artifacts in images
 - Erroneous sampling of k-space
 - Aliasing
 - Ringing
 - Magnetic field errors
 - Gradient artifacts
 - Susceptibility artifacts
 - Water-fat shift
- Geometrical artifacts show up in a particular direction
 - Phase encoding direction: aliasing
 - Read-out direction: susceptibility, water-fat shift
- Dephasing results in signal loss in gradient echo sequences

Summary 2

- Characterizing geometrical distortions can be done with a phantom
 - Avoid inducing additional susceptibility artifacts
 - Distortions depend on specific sequence
- Geometrical accuracy tends to deteriorate towards the body contour and tends to be good in the center of the body
 - Localization of external markers may be inaccurate
- Many possibilities exist to avoid artifacts or to minimize their impact. It is important to be aware of possible artifacts

‘Elk nadeel heb z’n voordeel’

‘Every drawback has a benefit’

Artifacts are often exploited to create new contrast mechanisms

Artifact	MRI technique
Susceptibility	Dynamic Susceptibility Contrast MRI Blood Oxygen Level Dependent (BOLD) MRI
Water-fat shift	DIXON (separation of water and fat imaging) MRI spectroscopy
In-flow artifacts	MR angiography

IMAGE GUIDED AND ADAPTIVE RADIOTHERAPY IN CLINICAL PRACTICE

11-15 February, 2018

Budapest, Hungary

Fan beam vs Cone beam

Fan beam CT (traditional CT)

- Just a slice of the sample is irradiated (2D)
- Detector row (1D)

Fan beam CT (traditional CT)

- A larger 3D volume is irradiated
- Planar detector (2D)

Cone beam CT

For 4-slice CT scanners an ideal fan beam geometry can be assumed during the reconstruction. For cone angles above around 2-4 degrees reconstruction adapted to the cone beam should be used (Feldkamp algorithm, 1984).

Flat-detector computed tomography (FD-CT)
Kalender et al. Eur Radiol (2007)

Cone beam CT

The cone-beam problem in CT: a single off-center detector row does not yield data representing details of solely one object slice. The larger the cone beam angle, the greater are potential inconsistencies in the data.

Increased irradiated volume
→
Increased scatter

Scattered photons

Scatter artifacts in CBCT

- Reduction of image contrast
- Increased image noise
- Non-uniformity artifacts (Cupping)

Dealing with scatter

FIG. 4. Scatter dependency on material succession along the ray. Monte Carlo simulation. Phantom: two slabs, 5 cm bone and 20 cm water. Acquisition: X-ray spectrum at 70 kV, field-size $40 \times 30 \text{ cm}^2$, no antiscatter grid. Plots show scatter and primary fluence in central line at the detector. (a) *SPR* in center is 25% higher than in (b).

Scatter reduction with grid

(a) No Grid
 $FOV_z = 22 \text{ cm}$
 $a_{vox} = 0.5 \text{ mm}$

(b) 10:1 Grid
 $FOV_z = 22 \text{ cm}$
 $a_{vox} = 0.5 \text{ mm}$

Encyclopaedia of Medical
Imaging; Petterson ed.

Other artifacts

- Ghosting – Detector after-glow from previous exposure
- Aliasing – Undersampling of voxels far from the source due to the cone shape of the beam
 - Cause the commonly seen lines from the center to the peripheral part of the image
- Patient motion
- Non-ideal gantry rotation
 - Variation in gantry rotation speed
 - Sag of detector and/or X-ray source

Schulze et al. 2011

Not corrected

Corrected

Rit et al. 2008

QA of CBCT

- Alignment of kV and MV lines
 - verify isocenter 3D agreement
 - verify registration and alignment process
- Image quality
 - monitor image quality parameters
 - watch for degradation
- Patient dose
 - measure base value (surrogates: air dose, HVL)
 - monitor changes

Prostate

Evaluation of semi-quantitative dynamic contrast-enhanced MRI parameters for prostate cancer in correlation to whole-mount histopathology

Sofie Isebaert et al.

European Journal of Radiology 2012

Qualitative methods

Quantitative methods

Qualitative methods

The initial area under curve (IAUC) is one of the most frequently used parameters. But time to peak (TTP), maximum signal (S_{\max}), initial and washout slope, relative signal enhancement (RSI), and peak enhancement ratio (PER) are also popular.

Prostate

Evaluation of semi-quantitative dynamic contrast-enhanced MRI parameters for prostate cancer in correlation to whole-mount histopathology

Sofie Isebaert et al.

European Journal of Radiology 2012

The area under the ROC curve for all DCE-MRI parameters and the resulting sensitivity and specificity (95% CI) based on the chosen threshold values.

Parameter	AUC	Chosen threshold	Sensitivity (%)	Specificity (%)
C_{peak}^a (au)	0.68	> 1.456	68 (54–80)	66 (52–79)
TTP^b (s)	0.71	≤ 56.25	40 (27–54)	94 (84–99)
Wash-in ^c (s^{-1})	0.82	> 7.940	72 (58–83)	81 (68–91)
Wash-out ^d (s^{-1})	0.65	≤ 0.202	49 (35–63)	79 (66–89)
Wash-in + Wash-out	0.86	≤ -0.402	68 (54–80)	87 (75–95)

^a C_{peak} , maximal contrast enhancement.

^b TTP, time to peak.

^c Wash-in, speed of contrast uptake.

^d Wash-out, clearance rate of contrast agent; au, arbitrary units.

Qualitative methods

Slope dependent on blood flow, permability, and propeties of surrounding tissue

Slope dependent on blood flow, permability, and propeties of surrounding tissue

The DCE-MRI experiment

$$\frac{1}{T_i} = \frac{1}{T_{i,0}} + r_i C$$

T_i – Relaxation time with contrast agent
 $T_{i,0}$ – Relaxation time without contrast agent
 R_i – proportionality constant
 C – concentration of contrast agent

The DCE-MRI experiment Sequence

3D - Spoiled Gradient Echo

- Short TE \rightarrow small effect from T_2^*
- Short TR \rightarrow fast sequence

The DCE-MRI experiment

Initial T1 relaxation

$$\frac{1}{T_1} = \frac{1}{T_{1,0}} + r_1 C$$

T_1 – Relaxation time with contrast agent
 $T_{1,0}$ – Relaxation time without contrast agent
 R_1 – proportionality constant (Relaxivity)
 C – concentration of contrast agent

Signal dependence on flip angle and T1

$$S \propto M_0 \sin(\theta) e^{-TE/T_2^*} \left(\frac{1 - e^{-TR/T_1}}{1 - \cos(\theta) e^{-TR/T_1}} \right)$$

Make repeated measurements with different flip angles

Fit the equation and determine T1

The DCE-MRI experiment

Signal equation

Combining $\frac{1}{T_1} = \frac{1}{T_{1,0}} + r_1 C$

With $S \propto M_0 \sin(\theta) e^{-TE/T_2^*} \left(\frac{1 - e^{-TR/T_1}}{1 - \cos(\theta) e^{-TR/T_1}} \right)$.

We get
$$\Delta(t) = \frac{S(t)}{S_0} = \frac{\left(1 - \cos(\theta) e^{-TR \cdot T_{10}^{-1}}\right) \left(1 - e^{-TR(T_{10}^{-1} + r_1 C(t))}\right)}{\left(1 - e^{-TR \cdot T_{10}^{-1}}\right) \left(1 - \cos(\theta) e^{-TR(T_{10}^{-1} + r_1 C(t))}\right)}$$

For low concentrations: $C(t) = (r_1 T_{10})^{-1} (\Delta(t) - 1)$.

Summary so far

Dynamic series gives clinically relevant information

Problem: without quantitative methods the results will be:

1. Dependent on scanner
2. Dependent on sequence
3. Dependent on coils
4. Etc.

Quantitative methods rely on determination of the contrast agent concentration

Problem: This is not easy to determine

1. Unknown relaxivity
2. Complicated relation between concentration and signal
3. Inflow effects
4. Water exchange
5. Spoiling
6. Etc.

Next step

Baseline T_{10} data

Injection of contrast agent

- Intravenous administration followed by saline flush
- Infusion or bolus (preferred)
- Manual injection or power injector
- Tight reproducible bolus
- Delivered in ~10 s to reduce errors in modeling
- Image before, during and after

Image acquisition

Imaging Procedure

- Localizer
- Anatomic sequences T1, T2 weighted imaging
- Variable Flip angle (VFA) T1 weighted imaging (T1 fitting) (a)
- 3D Gradient echo volumetric imaging (dynamic imaging) (b)

(a) A variable flip angle series, for pre-contrast agent native tissue $T_{1,0}$ mapping.

- Ensure TR and TE values stay constant for all flip angles,
- Flip angles: The range of # of flip angles supported in the literature varies from 2-7.
- Number of signal averages (NSA or NEX) > 2.

(b). DCE-MRI Protocol: Pulse Sequence:

- **Pulse Sequence:** 3D fast spoiled gradient recalled echo or equivalent
- **Coils:** Transmit: Body coil; Receive: Body coil or phased array receive coil

No parallel imaging options??????

No magnetization preparation schemes

http://www.rsna.org/QIBA_.aspx

Parameter	Compliance Levels
TE	
Acceptable	2.0-2.5ms
Target	1.5-2.0ms
Ideal	<1.5ms

Dynamic series

Parameter	Compliance Levels
TR	
Acceptable	5-7ms
Target	3-5ms
Ideal	< 3ms

Temporal resolution: The temporal resolution should be less than 10 sec.

Flip angles: Smaller flip angles will lead to potential saturation of the signal intensity vs. gadolinium concentration, particularly in vessels. Note should be made that SAR limits may affect the maximum allowable flip angle. Operators should use the maximal allowed flip angle when SAR limitations occur. Flip angles ranging from 25-35 degrees are recommended in order to minimize saturation effects and to avoid specific absorption rate (SAR) problems.

Receiver Bandwidth: Greater or equal to ± 31.25 kHz (or ~ 250 Hz/pixel)

Field of View (FOV) and Partial Fourier (“fractional echo” and/or reduced phase-encoding FOV) as needed to meet temporal resolution requirements

Number of Slices: Acceptable: ≥ 10 prior to zero fill. Ideal: as many as possible while maintaining ideal temporal resolution.

Slice thickness: *Ideal:* <5 mm, *Target:* 5.1-6 mm, *Acceptable:* 6.1-8 mm

Matrix: 256 x 160 (before applying rectangular FOV) – in order to meet 1-2mm in-plane spatial resolution

Number of acquisitions (phases): Sufficient to allow acquisition of at least 5 minutes of post injection data plus at least 5 phases acquired before contrast agent injection (baseline images).

Digitized bit depth: The maximum dynamic range should be utilized, e.g., “extended dynamic range” or equivalent.

Temporal resolution < 10sec.

Summary

- Potential
 - Provides information about physiological properties of the tissue on a voxel by voxel level
 - Selection of treatment modality
 - Design of radiotherapy
 - Follow-up and adoption of therapy
- Problems
 - Not fully quantitative
 - Depends on models
 - Standardization

Magnetic resonance spectroscopy (MRS)

- With strong magnetic field
 - Nuclei spins are oriented and rotate with a well defined frequency

Larmor frequency

$$\omega = -\gamma B$$

42.576 MHz/T

Magnetic field

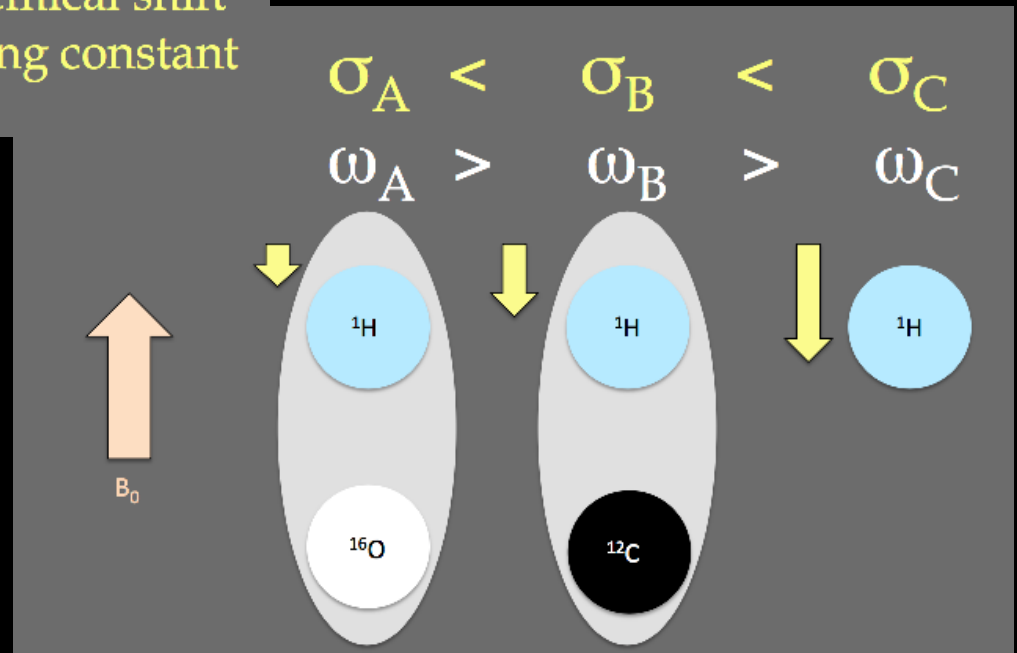

Shielding

$$B_{\text{local}} = -\sigma B_0$$

$$\omega = \gamma B_0 (1 - \sigma)$$

σ = chemical shift
shielding constant

MRI vs MRS

- Magnetic resonance imaging (MRI) is almost always based on measurement of water signal
 - A lot of signal
- Magnetic resonance spectroscopy (MRS) measures protons in other molecules
 - Low concentrations → Low SNR → Many averages, large voxels, limited FOV

Spectra

Example Lactate

Commonly reported metabolites (Brain)

Metabolite	Cellular meanings of metabolites
NAA – N-acetyl-aspartate	Marker of number and viability of neurons
Cr – creatine	Markers of systems of energy of encephalic cells
Co – choline	Membrane markers It is related to cell membrane production and destruction High concentrations indicate hypercellularity and myelin destruction
Lac – lactate	Absence in normal tissue High concentrations indicate fault of cellular oxidative respiration
Lip – lipids	Necrosis marker (high grade tumors)
GLX – glutamine-glutamate	Neurotransmitter, neuroexcitator, detoxificator and regulator of neurotransmission activity
mi – mio-inositol	Osmolite (osmolar regulator of cell volume) Glial marker

Spectra

Example brain

Invited Review

Combined Magnetic Resonance Imaging and Spectroscopic Imaging Approach to Molecular Imaging of Prostate Cancer

John Kurhanewicz, PhD,* Mark G. Swanson, PhD, Sarah J. Nelson, PhD, and Daniel B. Vigneron, PhD

Technical issues in MRS

- Water suppression
 - Water concentration is approx 1000 times higher than metabolites
- Shimming
 - Underlying B0 needs to very well defined in volume
- Outer volume suppression
 - Signal from outside the volume (typically lipids) disturb the measurement

Water suppression

- Apply frequency selective pulse (for water: 4.7 ppm) prior to excitation pulse
- This tips only water spins into transverse plane (all others left along z)
- Apply crusher gradient to dephase water spins, then begin MRS acquisition

Shimming

Poor Shim

Better Shim

Lipid suppression

- Lipids are found throughout body:

- – Extracranial lipids
- – Periprostatic lipids
- – Breast
- – Axilla
- – etc.

- Lipids can distort baseline of spectra so that metabolites cannot be detected
- Lipids resonate at 1.3 ppm
- Lipids can be suppressed using outer volume suppression techniques

Lipid suppression

Poor suppression

Adequate suppression

Outline

- Why online MRI guided RT?
- Hardware & technical developments
- Commissioning & QA
- Clinical results
- Towards real-time adaptive radiotherapy

More than just swapping out image modality

Radiotherapy is: dealing with uncertainties

Uncertainty requires a homogeneous dose over a large volume
'invisibility' of the target limits dose escalation

Reducing Margins

- Better visualization of target (here: lymph nodes) using MRI
- Reduce motion margins by MLC tracking

Current treatment

Target ind. lymph nodes

Improved imaging

Real-time tracking of liver

Adaptive treatments

Rectal tumor boost

- 50 Gy to the rectum
- **+ 10 Gy extra to the tumor**
- 5x daily on MR-Linac

This will allow:

- adapt to local changes in anatomy
- spare surrounding healthy tissue..
- increase dose to tumor..
- reduce number of boost fractions..
-

Conventional treatment process

Conventional Linac

move patient
to suit treatment plan

MRI Linac

Magnet design parameters

- **Field strength**
- Openness (bore length & diameter)
- Linac compatibility
- Helium boil off
- Energy consumption
- Homogeneity
- FOV
- Stability

The Effect of Field strength

[1] Hoult DI, JMRI 2000; 12:46-67

[2] Pohman, MRM 2016; 75:801-809

Goal: Spin polarization

Higher B_0 = more polarization
=> higher signal to work with

$$\text{SNR} \sim B_0 \quad [1]$$

$$\text{More recently:} \\ \text{SNR} \sim B_0^{1.65} \quad [2]$$

Based on Hanson, Concepts in Magn Res, 2006; 32A:329-240

The Effect of Field strength

0.35T

1.5T

3T

7T

SNR scales with

- field strength
- voxel size
- 1/receiver bandwidth (=speed)

Higher field strength also gives:

- better functional contrast (BOLD, DWI, DCE)

but also,

- Longer T_1 relaxation rates
- higher SAR
- higher susceptibility effects
- different ERE/EFE effects

distortions

DSV (mm)	Maximum error
300	0.9 mm
350	1.8 mm
400	2.3 mm

The circles describe a 400 mm DSV.

Distortion increases with distance to isoc

- Important to characterize distortions for MRI-only planning and MR-guided systems
- Size of the distortions spatially varying and varies per tumor site!

The Effect of Radiation

Radiation induced current in the RF coils of integrated linac-MR systems: The effect of buildup and magnetic field

Ben Burke, Andrei Ghila, B. G. Fallone, and Satyapal Rathee

“Radiation induced currents in the coil”

VI. CONCLUSIONS

This investigation demonstrates that the RIC can be reduced with the appropriate combination of coil conductor and buildup. Our results indicate that about 1 cm of teflon wrapped around an aluminum RF coil would essentially eliminate radiation induced currents in the coil. This method of RIC removal can effectively be applied to practical RF coil geometries and the presence of magnetic fields. In cylindrical coil geometries, the air gap is more important than the presence of the magnetic field. In planar geometries, the amount of buildup material required to achieve adequate RIC reduction is similar to that required with no field present. The RIC simulation is a useful tool for practical coil design where radiation effects must be considered. Preliminary experiment using nonideal buildup around the solenoid demonstrated the reduction in SNR lost due to RIC.

Conclusion

- MRI for IGRT enables **seeing what you treat**
- Given the specific imaging/reconstruction constraints, we have to **adopt MRI techniques** from radiology to the regime of MR-guided radiotherapy
- New MR imaging methods will enable fast, on-line, and real-time **motion characterization**
- Response monitoring by quantitative functional MRI *may* even allow us to adapt our treatment before anatomical change is visible

Questions?

Advanced Imaging for Physicists

Application of CT and PET for radiotherapy of lung cancer

Uulke van der Heide

Imaging for radiotherapy of lung cancer

- Staging and target definition
- Imaging for treatment monitoring and follow-up
- Imaging during treatment

CT imaging for radiotherapy of lung cancer

- Many imaging modalities are possible for lung cancer
- CT is the basic imaging modality in radiotherapy of lung
- Soft tissue contrast is good in lung, densities for RT are important

CT imaging for radiotherapy of lung cancer

- Many imaging modalities are possible for lung cancer
- CT is the basic imaging modality in radiotherapy of lung
- Soft tissue contrast is good in lung, densities for RT are important
- A 3D CT scan shows substantial breathing artifacts

CT imaging for radiotherapy of lung cancer

- Many imaging modalities are possible for lung cancer
- CT is the basic imaging modality in radiotherapy of lung
- Soft tissue contrast is good in lung, densities for RT are important
- A 3D CT scan shows substantial breathing artifacts
- A 'slow scan' reveals the extent of the motion, but shows a blurred image
- A 4D CT scan is preferable

PET and SPECT for radiotherapy of lung cancer

- FDG-PET is commonly used for staging
- Ventilation/Perfusion SPECT shows functional lung tissue

FDG-PET

MRI is not commonly used for lung cancer

- The soft-tissue contrast of MRI is not an advantage in lung cancer, compared to CT
- Susceptibility differences between lung and surrounding tissue may compromise geometrical accuracy
- Is useful to monitor unusual breathing patterns

cine-MRI

Dinkel et al. 2009; Int. J. Radiat. Oncol. Biol. Phys. 91:449-454

FDG-PET improves accuracy of staging in non-small cell lung cancer

- Addition of PET changes the TNM clinical stage of patients with non-small-cell lung cancer
- patient with diagnosis of T1N0M0 stage I adenocarcinoma.
- PET shows a pre-tracheal lymph node.
- Stage changes to T1N2M0

Fig. 3. This patient was enrolled in the study with a diagnosis of a T1N0M0, Stage I adenocarcinoma of the lung. The positron emission tomography (PET) scan demonstrated an FDG-avid pretracheal lymph node, changing the clinical stage to T1N2M0, IIIA disease. One can see the fiducial markers containing FDG on the posterior aspect of the patient's contour.

Bradley et al. 2004; Int. J. Radiat. Oncol. Biol. Phys. 59:78-86

FDG-PET improves accuracy of staging in non-small cell lung cancer

A Tabulated Summary of the FDG PET Literature

Sanjiv S. Gambhir, Johannes Czernin, Judy Schwimmer, Daniel H. S. Silverman, R. Edward Coleman, and Michael E. Phelps

Monitoring volume changes during treatment

- Analyze volume changes during treatment with daily MVCT
- Mean volume decrease is 73 +/-18% in 42 days
- Non-responders show slower regression

Bral et al. 2009; Int. J. Radiat. Oncol. Biol. Phys. 91:438-442

Imaging of recurrences, follow-up

- Compare FDG uptake pre-radiotherapy with post-radiotherapy (49-184 days after end of treatment)
- Residual FDG uptake is associated with worse overall survival after treatment

Aerts et al. 2009. Radiother Oncol. 91:386-392

Imaging of recurrences, follow-up

- Residual FDG uptake correlated with location of high uptake pre-radiotherapy

Aerts et al. 2009. Radiother Oncol. 91:386-392

Limitations of PET for staging of lung cancer

- uptake of FDG in inflammatory sites
- false negative PET after chemotherapy
- small lesions (< 1 cm³) may not be seen
- Respiratory motion causes blurring of image in 3D PET

Nehmeh et al. 2004; Med. Phys. 31:3179-3186

PET(-CT) for staging of lung cancer

- PET improves accuracy of staging
 - High negative predictive value of PET for mediastinal lymph nodes
- Improved staging has impact on treatment strategy
 - Selective irradiation of mediastinum based on PET results in low rates of nodal failure
- Residual FDG uptake after treatment correlates with location of high uptake pre-treatment and is associated with worse outcome
- What is the impact of PET on delineation?

Improved consistency of GTV delineation

Caldwell et al. 2001; *Int. J. Radiat. Oncol. Biol. Phys.* 51:923-931

Improved consistency of GTV delineation

- With CT-only, in 12 of 30 patients, all 3 observers' volumes lie within 28% (the standard deviation of the variation in the group)

Improved consistency of GTV delineation

- With CT and PET, in 23 of 30 patients, all 3 observers' volumes lie within 28% (the standard deviation of the variation in the group)

Different methods for tumor delineation on PET produce very different results

- **GTV₄₀**: take 40% of SUV_{max} as threshold
- **GTV_{bg}**: threshold based on mean within GTV_{70} and background
- **GTV_{CT}**: delineation on CT
- GTV_{40} is inadequate, but GTV_{bg} also differs significantly from GTV_{CT}

Auto-contouring algorithms improve consistency

- Source to Background ratio (SBR) determines a threshold level, determined from phantom experiments (FDG-filled spheres in background)
- 5 observers delineated the tumor manually (a) and edited an SBR-based contour if they deemed necessary (b)
- The SBR-based and edited contours show much less variability

Baardwijk et al. 2007; Int J Radiat Oncol Biol Phys. 68:771-778

Impact of FDG-PET on definition of PTV

- ↑ High sensitivity to positive lymph nodes
- ↓ High negative predictive value for lymph nodes
- ↓ Tumor can be differentiated from atelectasis
- ↓ Reduced inter-observer variability

MacManus et al. 2009;
Radiother. Oncol. 91:85-94

Validation of PET contouring algorithms with pathology is essential

- Maximal diameter of SBR-based GTV compared with the maximal diameter of the primary tumor, after surgical resection

Baardwijk et al. 2007; Int J Radiat Oncol Biol Phys. 68:771-778

3D validation of contouring with pathology

- Large deformations of resection specimen make 3D correlation with pre-operative imaging is very difficult
- Lung lobes were inflated with formalin to approximate the CT volume
- Registration in two steps:
 1. find correct orientation of CT with sliced specimen; resample CT in the same plane
 2. match macroscopic slices to CT volume
- Verify GTV volume and shape
- Identify the extent of the CTV

(b)

(c)

Stroom et al. 2007; Int J Radiat Oncol Biol Phys. 69:267-275

PET and CT registration: planning CT and CT of the PET-CT

- Is a specific planning PET-CT scan required? or can a PET-CT scan made for diagnostic purposes be used for delineation?

Table 1

Differences between diagnostic and planning positron emission tomography/computed tomography (PET/CT) scans

	Diagnostic PET/CT	Planning PET/CT
Anatomical and functional image	Yes	Yes
Able to be fused to radiotherapy planning CT	Yes	Yes
Flat bed insert on machine bed	No	Yes
Patient set up in treatment position	No	Yes
Same day as planning CT, contemporaneous image	No	Yes

Yap et al. 2010; Clin Oncol. 22:554-560

PET and CT registration: planning CT and CT of the PET-CT

- An average of 4 mm registration error between PET-CT to planning CT
- A diagnostic PET-CT has no larger registration errors than a planning PET-CT (if arms are positioned above the head)

how well are the PET and CT in a PET-CT registered?

- 19 lung cancer patients with 26 lesions
- 3D PET-CT exam
- Distance between center of lesions defined on PET and CT was 7.55 ± 4.73 mm
- Baseline shift during the exam

Cohade et al. 2002; Eur J Nucl Med Molec Imaging 30:721-726

Tumor motion during regular breathing

- Variety in observed behavior
- Large motion close to diaphragm
- Smaller motion towards top of lung
- hysteresis

Sonke et al., 2008. *Int J Radiat Oncol Biol Phys.* 70:590-598

4D PET-CT

- Acquire CT and PET signal with a signal reflecting the respiratory motion
- PET signal is sampled in 10 bins of ~ 0.5 s
- Reduced motion-induced blurring decreased the observed tumor volume by as much as 43%
- SUV values inside the tumor increase

Nehmeh et al. 2004; Med. Phys. 31:3179-3186

4D PET-CT

4D CT

4D PET

overlay

Attenuation correction for 4D PET

- A baseline shift between CT and PET results in an erroneous attenuation correction of the PET
- 4D PET attenuation correction with CT
 - standard 3D
 - average
 - mid-ventilation
 - 4D
- A baseline shift between CT and PET results in an erroneous attenuation correction of the PET

Attenuation correction for 4D PET

- in a 4D PET-CT scan, the phases of the 4D CT and 4D PET may not match
- What is a good strategy for attenuation correction?

Attenuation correction for 4D PET

two methods for attenuation correction:

1. each individual phase of CT
 2. 50% expiration CT (mid-ventilation)
- Differences in SUV and volume are small

Making a PET-CT for radiotherapy

- Registration of bony anatomy of a diagnostic PET-CT to planning CT is accurate
- baseline shift of tumor (shift relative to bony anatomy) frequently occurs
- gated (4D) PET-CT scan
 - SUV values higher than on blurred 3D scan
 - More precise imaging of tumor
- Attenuation correction on a single phase (mid-ventilation) of a 4D CT scan provides reliable SUV values

Target definition on a 4D CT scan

- How to define a target on a 4D CT scan

Target definition on a 4D CT scan

- Average of 10 phases ('slow scan')
- Maximum intensity projection of all phases

Internal Target Volume (ITV)

ITV is the combination of all volumes of all phases
= volume as shown on MIP

Internal Target Volume (ITV)

MIP

ITV is the combination of all volumes of all phases
= volume as shown on MIP

Internal Target Volume (ITV)

MIP

ITV is the combination of all volumes of all phases
= volume as shown on MIP

- Radiation treatment is possible during free breathing
- A PTV margin surrounds the ITV for delivery uncertainties

Maximum exhale phase

50

- GTV is the tumor as shown in a single phase; maximum exhale is most reproducible

Maximum exhale phase

50

- GTV is the tumor as shown in a single phase; maximum exhale is most reproducible
- ITV is added to account for residual motion

Maximum exhale phase

50

- GTV is the tumor as shown in a single phase; maximum exhale is most reproducible
- ITV is added to account for residual motion
- Gating is required: radiation treatment must be done during breath hold at maximum exhale; A PTV margin surrounds the ITV for delivery uncertainties

Mid-Ventilation scan

Identify the phase in the breathing cycle that is the best approximation of the mean position M

Mid-Ventilation scan

Mid-ventilation

- GTV is defined on the mid-ventilation phase (phase closest to the mean position of the tumor)

Mid-Ventilation scan

Mid-ventilation

- GTV is defined on the mid-ventilation phase (phase closest to the mean position of the tumor)
- Radiation treatment is possible during free breathing
- A PTV margin surrounds the GTV for delivery uncertainties and breathing

Wolthaus et al. 2006. Int J Radiat Oncol Biol Phys. 65:1560-1571

Different PTV STRATEGIES

	Conv-CT		ITV		Gating		MidP	
	Σ	σ	Σ	σ	Σ	σ	Σ	σ
Off-line correction protocol								
Respiration contribution								
Periodic motion (mm)	5.0	5.0	—	—	—	—	0.5	5.0
Baseline variation (mm)	3.9	2.4	3.9	2.4	3.9	2.4	3.9	2.4
Setup contribution	1.7	4.0	1.7	4.0	1.7	4.0	1.7	4.0
Total	6.6	6.8	4.3	4.7	4.3	4.7	4.3	6.8
ITV motion expansion (mm)	—		7.5		2.3		—	
Total margin (mm)	20.6		20.2		15.0		14.9	
Perfect on-line correction protocol								
Respiration contribution								
Periodic motion (mm)	0.0	5.0	—	—	—	—	0.0	5.0
Baseline variation (mm)	0.0	2.4	0.0	2.4	0.0	2.4	0.0	2.4
Setup contribution	0.0	4.0	0.0	4.0	0.0	4.0	0.0	4.0
Total	6.6	6.8	4.3	4.7	4.3	4.7	4.3	6.8
ITV motion expansion (mm)	—		7.5		2.3		—	
Total margin (mm)	4.2		9.6		4.4		4.2	

- Off-line correction: based on bony anatomy
 - large margins required to account for baseline variation
- On-line correction: based on image of tumor

Different PTV STRATEGIES

	Conv-CT		ITV		Gating		MidP	
	Σ	σ	Σ	σ	Σ	σ	Σ	σ
Off-line correction protocol								
Respiration contribution								
Periodic motion (mm)	5.0	5.0	—	—	—	—	0.5	5.0
Baseline variation (mm)	3.9	2.4	3.9	2.4	3.9	2.4	3.9	2.4
Setup contribution	1.7	4.0	1.7	4.0	1.7	4.0	1.7	4.0
Total	6.6	6.8	4.3	4.7	4.3	4.7	4.3	6.8
ITV motion expansion (mm)	—			7.5		2.3		—
Total margin (mm)		20.6		20.2		15.0		14.9
Perfect on-line correction protocol								
Respiration contribution								
Periodic motion (mm)	0.0	5.0	—	—	—	—	0.0	5.0
Baseline variation (mm)	0.0	2.4	0.0	2.4	0.0	2.4	0.0	2.4
Setup contribution	0.0	4.0	0.0	4.0	0.0	4.0	0.0	4.0
Total	6.6	6.8	4.3	4.7	4.3	4.7	4.3	6.8
ITV motion expansion (mm)	—			7.5		2.3		—
Total margin (mm)		4.2		9.6		4.4		4.2

- Off-line correction: based on bony anatomy
 - large margins required to account for baseline variation
- On-line correction: based on image of tumor
 - ITV motion expansion is much larger than the respiratory contribution in the margin for MidVentilation and gating

Impact of motion on dose

- Dose deposition in lung tumors is influenced by variations in electron density
- What happens to the dose if a tumor moves?
- Is a dose calculation per breathing phase necessary?

Impact of tumor motion on dose distribution

Dose moves with tumor

Plans based on ITV, with
0 mm margin

Impact of tumor motion on accumulated dose is very small

- Planned dose to 99% of the PTV
- Accumulated dose to 99% of the CTV, considering tumor motion

X-ray tube

kV imager

Baseline shifts

Two subsequent CBCT scans

- Good registration of bony anatomy
- Large displacement of average tumor position, close to diaphragm

Intra-fraction displacement of bone and tumor

- Displacement of tumor during treatment (40 minutes) can be up to 6 mm
- Part of this is due to motion of the patient's bony anatomy
- Part is due to base-line shift
- Correlation is high in L-R direction, poorer in other directions

Sonke et al. 2008. Int J Radiat Oncol Biol Phys. 74:567-574

SBRT Lung protocol at NKI-AVL

- Acquire 4D CT scan
- Select mid-ventilation phase:
Element of 4D scan closest to mid-position
- Optimize treatment plan on mid-ventilation

- Acquire 4D CBCT
- Bone match → Tumor match
- Apply correction
- Validate correction with 2nd scan
- Contact physician if
 - Shift > 1 cm
 - Anatomical changes

Margins versus amplitude

$$M = 2.5\Sigma + 0.84\sqrt{(\sigma_p^2 + \sigma^2)} - 0.84\sigma_p^2 \neq 2.5\Sigma + 0.7\sigma \quad \sigma_p \approx 6.4 \text{ mm}$$

Assures 80% isodose encompasses GTV 90% of time in lung

Summary

- FDG-PET and CT are the prime imaging modalities in lung cancer
- PET improves the accuracy of staging
 - high negative predictive value for mediastinal lymph nodes
- More consistent contouring is possible with PET-CT
 - volume may increase (include lymph nodes) and decrease (avoid atelectasis)
 - systematic approach to thresholding (e.g. source-to-background ratio)
 - validation with pathology is essential
- 4D imaging CT is required for precise delineation of the tumor and characterizing the extent of motion
 - Tumor motion is not detected directly; surrogates are used

Summary

- Target definition
 - ITV, free breathing
 - Exhale – gating
 - Mid-ventilation, free breathing
- Dose calculation
 - Accurate dose model, also during IMRT/RapidArc optimization
 - In older studies: prescribed dose \neq actual dose (deviations of up to 30%!)
- Position verification with cone-beam CT allows accurate targeting of the tumor (stereotactic body radiotherapy)
